Abstract

Emotion is considered to be a core element in performances [1]. In computer animation, both body motions and facial expressions are two popular mediums for a character to express the emotion. However, there has been limited research in studying how to effectively synthesize these two types of character movements using different levels of emotion strength with intuitive control, which is difficult to be modelled effectively. In this work, we explore a common model that can be used to represent the emotion for the applications of body motions and facial expressions synthesis. Unlike previous work which encode emotions into discrete motion style descriptors, we propose a continuous control indicator called *emotion strength*, by controlling which a data-driven approach is presented to synthesize motions with fine control over emotions. Rather than interpolating motion features to synthesize new motion as in existing work, our method explicitly learns a model mapping low-level motion features to the emotion strength. Since the motion synthesis model is learned in the training stage, the computation time required for synthesizing motions at run-time is very low. We further demonstrate the generality of our proposed framework by editing 2D face images using relative emotion strength. As a result, our method can be applied to interactive applications such as computer games, image editing tools and virtual reality applications, as well as offline applications such as animation and movie production.

Keywords: motion capture, data-driven, motion synthesis, emotion motion, image editing, facial expression, relative attribute

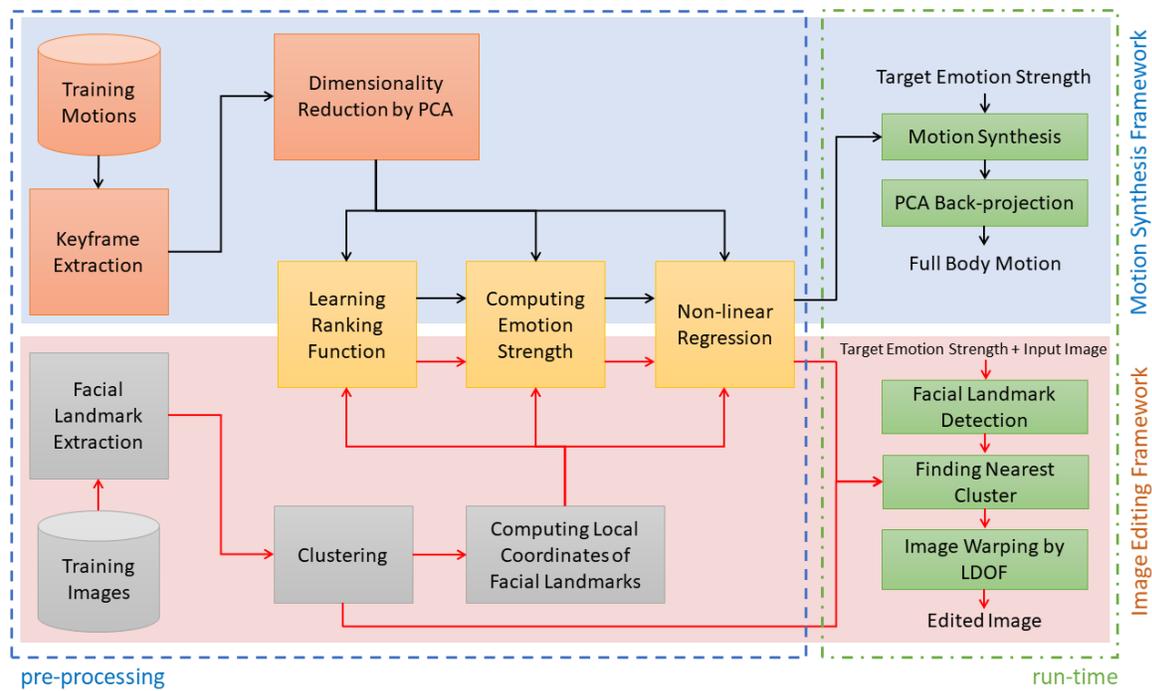

Figure 1: Overview of the proposed methodology. Both of the motion synthesizing framework (upper) and the face image editing framework are sharing the same set of core algorithms.

1 Introduction

Editing and synthesizing multimedia data such as 3D human motions and 2D images is a challenging task due to the high dimensionality of the data representation as well as the subjective aesthetic judgment. As a result, most of the tasks in human motion and image editing are still completed manually nowadays in the entertainment industry. With the advancement of machine learning algorithms and technologies, *learning how to edit and synthesize multimedia data* becomes an appealing direction.

6
7 Synthesizing realistic human motion from existing motion data, either acquired by mo-
8 tion capture (MOCAP) devices or hand-crafted, has been an active research area in the
9 past two decades. In graphics applications such as movies, animation, interactive computer
10 games and virtual reality (VR), realism of human motion plays an important role in enhanc-
11 ing the user's experience. In the past, motion naturalness and the ease of control have been
12 intensively studied. While they make the character animation tasks easier, we argue that
13 naturalness and control alone are not enough to generate realistic and diversified motions.

23

24 Emotion is considered to be a core element in performances [1], which is an indispens-
25 able piece in motion realism. In computer animation, both body motions and facial expres-
26 sions are two popular mediums for a character to express the emotion. To understand and
27 represent the emotion, there is an increasing focus on analyzing how motion emotion are
28 perceived by users [2, 3, 4, 5]. While it is possible to identify emotion automatically from
29 motion, synthesizing motion with controllable emotion intensity is much more challenging
30 due to the high-dimensionality in the control parameters as well as the complex relationship
31 between such control parameters and the emotional expressions.

43 The most relevant stream of work is style transfer from example motions to a new one
44 [6, 7]. However, the existing work solves this problem by interpolating sample motions. We
45 argue that a drawback of such an approach is *interpolating the motion but not necessarily*
46 *interpolating the emotion*. In other words, existing methods mainly learn low-level motions
47 features in the way that the control of interpolation only happens at the motion level, not
48 at the emotion level. This is because the learning methods ignore the relations between
49

6
7 low-level motion features and high-level emotions. In this work, we tackle this problem by
8
9 learning the relationship between low-level motion features (such as joint positions, veloci-
10
11 ties) and high-level emotion attributes with different levels of strengths.
12
13

14 Learning the relationship between low-level motion features and mid-/high-level seman-
15
16 tic representation has been explored in the computer vision community. *Attributes* [8] have
17
18 been widely used in visual recognition tasks. In particular, relative attributes [9] that indicate
19
20 the relative strength of an attribute between two samples can naturally be used to describe
21
22 the differences in high-level semantics such as styles and emotions among different motions.
23
24 The relationship between motion features and the attribute can be learned from the training
25
26 data to facilitate motion synthesis.
27
28
29
30

31 In this paper, we propose a new data-driven method to synthesize motion with controlled
32
33 emotion expressions. The goal is to synthesize motions with emotions intuitively, such as
34
35 directly specifying the level of *happiness* (i.e a scalar scale) of the motion to be edited. Our
36
37 method treats the emotion of each motion as a high-level representation (i.e. attribute) and
38
39 learns the relative strength of the emotion by pairwise relative attribute. A scoring function
40
41 that evaluates the attribute strength will be learned and used to guide the motion synthesis
42
43 process. To our knowledge, our method is the first attempt to learn the relationship between
44
45 low-level motion features and human nameable attributes for motion synthesis instead of
46
47 interpolating motion directly. Since the learning process is done in the pre-processing stage,
48
49 the run time computational cost is very low. Our proposed methods are general which do
50
51 not make any assumptions on the features computed from the data. We further demonstrate

2.1 Style-based motion synthesis and editing

An early work by [10] proposed to synthesize styled motion sequences by interpolating and extrapolating the styles from the training motion data using a learned statistical model called *style machine*. [11] proposed an approach to project input motion to lower dimensional space by Principal Component Analysis (PCA) and compare the difference with other example motions in the database. The differences are then to be used as the style of the input motion and transferred to other motions. [12] proposed to learn the difference in the styles in motion pairs (e.g. a neutral and a styled motion as input and output styles). The relationship between the input and output motions in training can then be described by a linear time-invariant (LTI) model. Using such a model, the learned style can be transferred to a new input motion. [13] proposed a method for editing motion using Gaussian process models of dynamics and kinematics. Such an approach can be used for motion style transfer. [6] proposed a real-time approach for style transfer for human motion. Their method represents the style difference between the input and output motions by a time-varying mixture of autoregressive models. Their method learns such models automatically from unlabeled heterogeneous motion data.

While many style editing and transferring approaches have been proposed, most of the work focuses on finding the differences between motions with different styles and creating new motion by interpolation. We argue that such an approach does not necessarily interpolate the underlying emotion of the motion. In this work, we learn the relationship between

1
2
3
4
5
6
7 motion features and emotion strength such that the motion synthesis process can be directly
8 controlled using the target emotion strength.
9
10

11 **2.2 Attribute-based representations**

12
13
14 Visual attributes are human-nameable semantic concepts of things in the world and are pop-
15 ular in the computer vision community for image recognition [8]. [9] further proposed the
16 concept of the relative attribute to capture the relative attribute strength between data. The
17 aforementioned approaches mainly focused on handling visual recognition tasks (e.g. image
18 classification). A recent work showed that images (e.g. 2D outdoor scenes) can be edited
19 by applying the relative attribute concepts [14]. Another recent work learns the mapping
20 between high-level descriptors (e.g. softness, silkiness) and simulation parameters for cloth
21 simulation [15]. A perceptual control space is then created and the cloth simulation can be
22 controlled by adjusting the degrees in selected high-level descriptors. These recent studies
23 motivated us to learn such a relative attribute strength for motion synthesis.

37
38
39
40

41 To sum up, most of the existing work focuses on learning the attribute strength from
42 input data for recognition tasks. While some recent work applied the concept of attribute-
43 based editing in the computer graphics community, our work is the first to make use of the
44 attribute strength for human motion editing.

2.3 Facial image editing

Editing facial image attracts a lot of interests in the Computer Vision community in recent years. Kaneko et al. [16] proposed a new deep learning framework for editing face image by attributes. A Generative Adversarial Network (GAN) is used for learning the distribution of the face image with emotion expression in the space. Since then, a wide range of GAN-based face image editing approaches are presented. Expression Generative Adversarial Network (ExprGAN) [17] encodes the "expressive code" to improve the expressiveness of the image representation and results in higher image quality based on a GAN network. In Computer Graphics, a recent work proposed by Averbuch-Elor et al. [18] animates a single portrait by an input video. The driving video is captured from another subject and the proposed method extracts the facial deformation pattern from the video. The deformation pattern is then applied to the target image by 2D image warping. Additional details such as creases and wrinkles are added to the target image to further improve the quality of the resultant image. Portenier et al. [19] proposed a deep learning framework based on deep Convolution Neural Networks (CNN) and GAN for sketch-based face image editing.

While we share some similar interests in editing face image with intuitive controls as in the aforementioned work, the existing work is either 1) require additional guidance for control (such as driving video), or 2) solely focusing on editing face images. In contrast, the framework proposed in this paper is generic and can be applied to both human skeletal motion and face image editing.

3 Overview

For the sake of clarity in presenting the proposed methods, the motion synthesis framework will be explained first in Section 4. Then, the proposed face image editing framework will be presented in Section 5.

The overview of our proposed motion synthesis framework is illustrated in Figure 1. There are two stages in the proposed framework: pre-processing and run-time stages. The pre-processing stage learns models for analyzing and synthesizing motions with different emotion strength. Firstly, we collect motions with emotion labels as the input of our framework. Next, the motions are represented compactly by keyframing and dimensionality reduction. Then, the relative emotion strength of the training motion data is computed by a ranking function. Finally, the relative emotion strength and compact motion representation will be used for training a motion synthesis model.

During run-time, the target emotion strength (i.e. a scalar value) will be used as input to control how the motion will be synthesized using the model trained in the pre-processing stage. Full body motion can be obtained by back-projecting the synthesized compact motion representation to full body motion space.

4 Learning Attribute Strength

In this section, we present the core methodology of the new data-driven motion synthesis approach that learns the relationship between low-level motion features and the emotion

1
2
3
4
5
6
7 strength. Firstly, the motion data being used in our approach for learning will be explained
8
9 in Section 4.1. Next, we propose to use a compact motion representation that removes the
10
11 temporal redundancy of the motion in Section 4.2. Thirdly, the dimensionality of the frame-
12
13 based (i.e. pose) representation (Section 4.2.3) is further reduced to facilitate the learning
14
15 process in a later stage. Finally, the learning process of the ranking function that computes
16
17 the emotion strength will be explained in Section 4.3.
18

20
21
22

23 **4.1 Motions with Emotions**

24
25
26 In order to analyze and learn the relationship between low-level motion features and the
27
28 strength of emotion expressions, a significant amount of human motion data has to be col-
29
30 lected. In this work, the MOCAP data from the Body Movement Library [20] was used.
31
32 This dataset contains 4080 human motion sequences captured using a commercial optical
33
34 motion capture system. The motions were captured from 30 (15 male and 15 female, ranging
35
36 from 17 to 29 years old and with a mean age of 22 years old) *non-professional participants*
37
38 in order to capture natural emotion expressions rather than capturing staged/exaggerated
39
40 motions from professional performers. There are three motion types: *knocking*, *lifting*, and
41
42 *throwing*.
43
44
45
46
47

48 Each motion contains a sequence of poses captured from a single subject and represented
49
50 by the joint positions in Cartesian coordinates in each frame. From the raw motion data, we
51
52 extracted 33 joint positions in each frame. The duration of each motion sequence ranges
53
54
55
56
57

1
2
3
4
5
6
7 from 65 to 457 frames at 60 Hz. The dataset was designed for recognizing identity, gender
8 and emotion from the motion data. As a result, each subject performed each motion type
9
10 with 4 different emotion expressions: *Neutral*, *Angry*, *Happy*, and *Sad* .
11
12

13
14 In this work, we focus on using two emotion models, namely *Happiness* and *Anger*,
15 because a continuous emotion parameterization can be achieved. Specifically, for the *Hap-*
16 *piness* model, we define *Happy* and *Sad* to be opposite to each other and *Neutral* to be at the
17 middle. For the *Anger* model, we define *Anger* and *Neutral* as two extremes. As a result,
18
19 we can simplify the parameterization as a single scalar value to control the emotion level
20 continuously in *Happiness* (*Happy* \leftrightarrow *Neutral* \leftrightarrow *Sad*) and *Anger* (*Angry* \leftrightarrow *Neutral*). This
21
22 allows us to control the emotion strength continuously.

28
29
30
31
32

33 **4.2 Motion Representation**

34
35
36 Having presented the details of the motion data for training, we now explain the compact
37 motion representation used in our proposed framework. Each motion M contains a sequence
38 of poses p , i.e. $M = \{p_1, \dots, p_n\}$, where n is the total number of frames (or poses) of M .
39
40 Each pose p_i is represented by the 3D joint positions in Cartesian coordinates. As there are
41
42 33 joints extracted from the raw motion data, each pose is represented by a 99-dimensional
43
44 vector. In order to facilitate the learning process, we normalize all data by removing the
45
46 translation and the vertical rotation (i.e. y -axis) of the root joint in the first frame as in
47
48 other data-driven approaches (e.g. [21], [22]). By normalizing the pose in this way, the
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 differences of the postures can be compared directly in the Euclidean distance of the 3D
8 joint positions. This has been widely used in data-driven motion synthesis approaches such
9 as Motion Graphs [22].
10
11
12
13

14 15 16 **4.2.1 Keyframe Extraction** 17

18 Human motions are naturally temporally redundant and removing such redundancy can fa-
19 cilitate the the learning process in later stages. In addition, the motion sequences we col-
20 lected have different durations. As a result, As a result, it is difficult to carry out machine
21 learning from the training motion without preprocessing the data [23]. To tackle the afore-
22 mentioned problems, keyframes of each motion are extracted by Curve Simplification algo-
23 rithm [24]. Given a motion M , a set of q keyframes $K = \{k_1, \dots, k_q\}$ will be extracted, which
24 minimizes the reconstruction error when interpolating the in-between motion using spline
25 interpolation. In this study, we tested the reconstruction error with 10-15 keyframes and
26 empirically found that using 13 keyframes can balance the trade-off between reconstruction
27 error and compactness of the motion representation.
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43

44 45 **4.2.2 Joint Velocity** 46

47 We observed that some of the subjects expressed different emotions by using different speed
48 and rhythm when performing the motion. Using the *knocking door* motion as an example.
49 The subjects tended to move faster when they were *happy*, and moved slower when they
50
51
52
53
54
55
56
57
58
59
60

were *sad*. For this reason, the velocity of the joints between adjacent keyframes is computed:

$$v_{i+1} = \frac{k_{i+1} - k_i}{\Delta t} \quad (1)$$

where Δt is the duration between the two adjacent keyframes. Here, we compute the joint velocity from adjacent keyframes instead of adjacent frames in the original motion because we want to reconstruct the full motion into different durations by editing the velocity. Specifically, given the adjacent keyframes and the joint velocity, the duration between two adjacent keyframes can be approximated by:

$$\Delta t = \frac{k_{i+1} - k_i}{v_{i+1}} \quad (2)$$

By this, the speed of the motion can be adjusted easily using this compact representation. Finally, each keyframe contains the pose features k_i and velocity features v_i and results in a $99 + 99 = 198$ -dimensional feature vector.

4.2.3 Manifold Learning

It has been argued that natural motions form a motion manifold and can be embedded in a lower dimensional space [25], which gives a compact representation of motions. To further reduce the dimensionality of the pre-frame (i.e. pose) feature to facilitate the learning process (will be explained in Section 4.3), the pose features and velocity features are concatenated and projected to a low-dimensional space. While many dimensionality reduction approaches are available, Principal Component Analysis (PCA) has been used for analyzing

1
2
3
4
5
6
7 the style difference for motion synthesis [11]. This leads us to use such a simple, low-
8 computational cost and widely used dimensionality reduction techniques in the proposed
9 method.
10
11
12

13
14 One of the issues is to select an appropriate dimensionality in the latent space such that
15 the essential information in the original motion is retained. We empirically calculate the
16 reconstruction error (i.e. back-projecting the latent representation and compare the result
17 with the keyframe features) using different numbers of dimension in the latent space. We
18 found that projecting the keyframe features (for each keyframe) from 198-d to 40-d achieved
19 low reconstruction error and we use this setting in all experiments.

25
26
27
28
29

30 **4.3 Learning the Ranking Function**

31
32 In this section, we will explain how to learn the relationship between the latent representa-
33 tion and the strength of the attribute from two sets of inputs: i) the compact motion features
34 explained in Section 4.2.3 and ii) the emotion label associated with each motion. One sim-
35 ple way to learn such a function is to train a regression function on the ground truth emotion
36 strength and the corresponding motion features. However, the ground truth attribute strength
37 may not be available in the database. In the Body Movement Library database we used,
38 only a single label (i.e. the emotion) is associated with each motion. The relative emotion
39 strength between motions with the same class label is not available.
40
41
42
43
44
45
46
47
48
49
50
51

52
53 Inspired by [9], a ranking function can be learned from a small set of pairwise training
54
55
56
57

1
2
3
4
5
6
7 samples with relative ranking on an attribute (i.e. emotion in our framework). Such a
8
9 ranking function can then be used for computing the attribute strength of unseen data. The
10
11 learning process can be formulated as a max-margin optimization problem. Specifically, we
12
13 learn a ranking function $r(x_i)$ in which :

$$14 \quad r(x_i) = wx_i \quad (3)$$

15
16
17
18
19
20
21 to weight each input feature and return the weighted sum as the attribute score that indicates
22
23 the attribute strength. When solving for the ranking function, a set of *relative constraints*
24
25 have to be satisfied. Using the notation in [9]:

$$26 \quad \forall (i, j) \in O : wx_i > wx_j \quad (4)$$

$$27 \quad \forall (i, j) \in S : wx_i = wx_j \quad (5)$$

28
29
30
31
32
33
34
35 where O and S are sets that contain *ordered* and *similar* paired samples, and x_i and x_j are
36
37 the feature vectors of the i -th and j -th samples (motions in our approach).

38
39
40 More specifically, the ordered set O contains motions with differences in ground truth
41
42 attribute strength in each pair as in Eq. 4. In the dataset we used, we setup the ordered
43
44 pairwise relative constraints according to the emotion labels of the training motions: *Happy*
45
46 $> Neutral > Sad$ and *Angry > Neutral* when training the *Happiness* and *Anger* ranking
47
48 functions, respectively. On the other hand, the similar set S contains motions with similar
49
50 ground truth attribute strength in each pair as in Eq. 5. The similar set contains the pairwise
51
52 motions with the same emotion label in our proposed framework. The attribute strength of
53
54
55
56
57
58
59
60

each sample can be computed by multiplying the learned weights w with the feature vector (e.g. x_i or x_j) and our task is to learn w by:

$$\begin{aligned}
 \min_w \quad & \frac{1}{2} \|w\|_2^2 + C \left(\sum \xi_{ij}^2 + \sum \gamma_{ij}^2 \right) \\
 \text{s.t.} \quad & w(x_i - x_j) \geq 1 - \xi_{ij}; \forall (i, j) \in O \\
 & |w(x_i - x_j)| \leq \gamma_{ij}; \forall (i, j) \in S \\
 & \xi_{ij} \geq 0; \gamma_{ij} \geq 0,
 \end{aligned} \tag{6}$$

where C is the trade-off parameter to control the softness of the pairwise relative constraints to be satisfied, and ξ_{ij} and γ_{ij} are slack variables. Introducing the slack variables are serving the purpose of relaxing the constraints on classifying all training samples perfectly as in conventional SVMs. Since there are two groups of samples, namely ordered and similar, ξ_{ij} and γ_{ij} are introduced to relax the constraints for solving for w to satisfy all of the ordered and similar samples, respectively. This primal problem can be solved efficiently by Newton's method [26].

4.4 Motion Synthesis by Attribute Strength

Having learned the ranking function as explained in Section 4.3, the emotion strength (a scalar) of each training motion can be computed. Since our ultimate goal is to synthesize new motion by specifying the emotion strength, here we propose to learn a regression model on the emotion strength and the corresponding motion features from the training data. Specifically, we learn a regression function $f(s)$ that takes the target emotion strength s as

input and returns the dimensionality reduced motion feature x :

$$x = f(s) \quad (7)$$

In the implementation of the proposed framework, we train the regression function using the Neural Network regression model in Matlab [27]. The implementation details will be explained in Section 6.1.

5 Editing Facial Expression on 2D Images by Attribute

Strength

Having presented the method to learn the mapping between high-level attribute strength and low-level motion features for motion editing tasks in previous sections, we further show the generality of our proposed method by editing facial expressions on 2D images. In particular, the process to the ranking function is exactly the same as in the proposed motion editing framework (Section 4.3). The main difference is the features used in the training. The details will be explained below.

5.1 Face Images and Pre-processing

The 2D images used in the training process and experiments are obtained from the Labeled Faces in the Wild (LFW) [28] dataset. The dataset contains 13233 images captured from 5749 subjects. The attributes of each image are calculated using the method proposed by

1
2
3
4
5
6
7 Kumar et al. [29] and those values are available to the public on the author's website.
8

9
10 Since the face images are obtained from different sources (so-called 'in the wild'), im-
11 age pre-processing is required to facilitate the learning process in the later stages in the
12 framework. In particular, the illumination variations in 2D images will make the learning
13 process more challenging. To tackle this problem, 2D facial landmark positions are used
14 in our proposed framework as there will be no color and image appearance information
15 will be included in the training process. Using 2D locations can keep the facial expression
16 representation abstract to facilitate the attribute strength learning process as well.
17
18
19
20
21
22
23
24
25

26 In the pre-processing stage, the facial landmarks on each image are detected using the
27 method proposed by Zhu and Ramanan [30]. The source code provided by the authors [30]
28 were used in our experiments and 66 facial landmarks are extracted from each image. The
29 facial landmarks detected from two examples in the LFW dataset are illustrated in Figure 2.
30
31
32
33
34
35
36 The facial landmark positions are represented by a set of 2D coordinates.
37
38
39

40 **5.2 Handling Pose Variation**

41

42
43 In addition to the illumination variations, pose variations is another problem which af-
44 fects the performance of the learning process when images collected/captured from different
45 sources. To alleviate this problem, we cluster the images based on the contour of the face.
46 Specifically, the 2D facial landmarks coordinates are converted into local coordinates using
47 the average position of all extracted landmarks as the origin. Then, all images are clustered
48
49
50
51
52
53
54
55
56
57
58
59
60

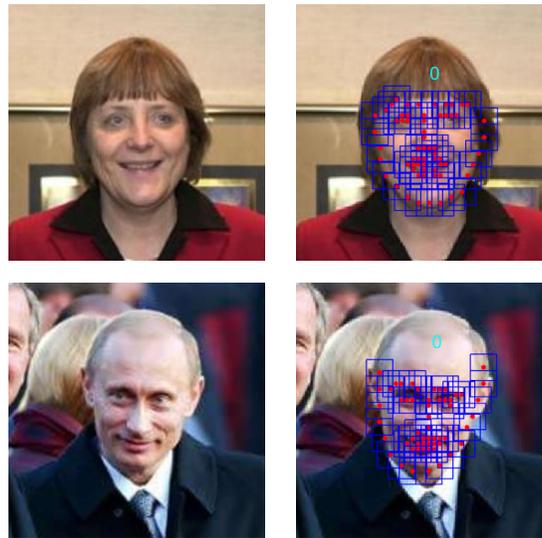

Figure 2: 68 facial landmarks (red dots) are detected using the method proposed by Zhu and Ramanan [30].

by the local coordinates of the landmarks located on the contour. In our experiment, we found that using k-means clustering with $k = 12$ to cluster the faces can lead to reasonable cluster sizes for the learning tasks while containing faces with similar poses within each cluster. An example is shown in Figure 3 and the centroids clearly show the pose variations in the dataset we used.

5.3 Facial Expression Representation

While human faces have the same structure, the distances between different regions (i.e. eyes, nose and mouth) vary on different faces. Directly using the absolute 2D facial landmark positions extracted using [30] will produce sub-optimal results. To tackle this problem, the absolute facial landmark coordinates are converted into the local coordinates within each

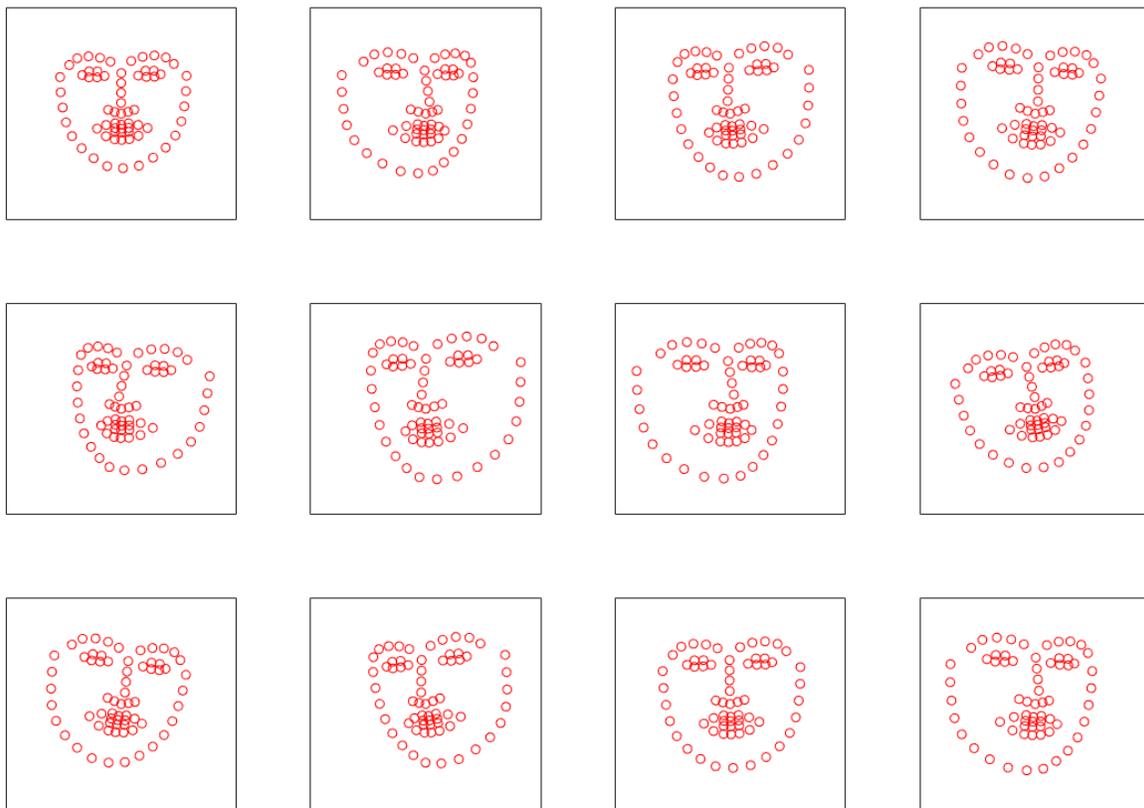

Figure 3: An example of the facial landmark positions of the 12 centroids computed from the clustering process.

1
2
3
4
5
6
7 region. The origin of each region is defined by the average position of all the landmarks be-
8
9
10 longing to that region. Finally, we concatenate the local 2D coordinates from 4 regions
11
12 (two eyes, nose and mouth) into a single vector as the input in the attribute strength learn-
13
14 ing process. Each face is represented by 49 landmarks and the 98-d vector contains the
15
16 corresponding local coordinates.
17
18
19
20

21 **5.4 Learning Attribute Strength on Facial Features**

22
23
24 The same ranking function learning process explained in Section 4.3 is used for learning the
25
26 attribute strength from 2D images. To handle the pose variations, the ranking function is
27
28 learned in each of the 12 face image clusters. The ‘smile’ attribute values computed by the
29
30 attribute prediction method [29] are used to construct O and S (the sets that contain *ordered*
31
32 and *similar* paired samples, explained in Section 4.3) for the training process. In particular,
33
34 we define the happiness attribute strength as *the higher the smile attribute value, the more*
35
36 *happy the subject is.*
37
38
39
40
41
42

43 **5.5 2D Image Editing by Attribute Strength**

44
45
46 Having learned the ranking function as explained in Section 5.4, the emotion strength, which
47
48 is a scalar, of each training facial landmark feature can be computed. Again, we learn a
49
50 regression model on the emotion strength and the corresponding facial landmark features
51
52 from the training data as in the motion synthesis framework explained in Section 4.4.
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7 Specifically, the input of the learned regression model is the desired emotion strength
8 and the output will be a set of facial landmark positions. To edit the 2D image, we first
9 compute the difference between the facial landmark positions on the original input image
10 and the output of the regression model. Then, the differences of the landmark positions
11 will be used for warping the 2D image by Large Displacement Optical Flow (LDOF) [31].
12 Samples of edited images will be presented in Section 6.6.

23

24 **6 Experimental Results**

25
26
27 In this section, we present the results obtained using the proposed method. Firstly, we visu-
28 alize the motions projected to a low-dimensional space when training our motion synthesis
29 models in Section 6.2. Next, we evaluate the performance of the learned ranking functions
30 that contain the relationship between low-level motion features and emotion strength numer-
31 ically in Section 6.3. Thirdly, we present the computational cost for the training process in
32 Section 6.4. Then, new motions are synthesized using the learned motion synthesis models
33 in Section 6.5. We further demonstrate the generality of our proposed framework by editing
34 2D face images in Section 6.6.

49 **6.1 Implementation Details**

50
51 We used the Toolbox for Dimensionality Reduction library [32] to reduce the feature dimen-
52 sion from 198-d to 40-d. For the relative attribute ranking, we used the Matlab implemen-
53 tion from 198-d to 40-d. For the relative attribute ranking, we used the Matlab implemen-

6
7 tation provided by the authors of [9]. The proposed framework was implemented in Matlab
8
9 R2015a [27] and all the experiments were conducted on a 64-bit machine with Intel Xeon
10
11 2.4GHz (E5-2620) and 64GB memory. The experiments ran on a single thread without any
12
13 performance boost.
14
15
16
17

18 **6.2 Visualization of the Low-dimensional Space**

19
20
21
22 In order to learn the ranking function efficiently and effectively, the motion features are
23
24 projected into latent space with a much lower dimensionality. In the experiments, each pose
25
26 (frame) is represented by a 40-d in the latent space (198-d in the original motion). The
27
28 dimensionality in the latent representation is selected empirically to balance the trade-off
29
30 between training time and reconstruction error rate. We use 10 as the hidden layer size
31
32 in the Neural-Network regression for training the motion synthesis model. We selected 10
33
34 empirically. We visually inspected the visual quality of the synthesized motions and the
35
36 ranking accuracy quantitatively. We found that the performance does not improve with
37
38 bigger hidden layer size and we selected 10 when implementing the framework. The latent
39
40 representation of the motions with different emotions are illustrated in Figure 4 and 5 (left
41
42 columns). Notice that only the first 3 principal components are displayed.
43
44
45
46
47

48
49 However, due to the style differences and variations between the subjects, the motions,
50
51 which are represented as curves, with different emotion labels are mixed together. This
52
53 shows that directly interpolating motions in the low dimensional space may result in signifi-
54
55
56
57

1
2
3
4
5
6
7 cant change in the emotion strength as the motions (i.e. trajectories) with different emotions
8
9 (i.e. colors) are tangled.

10
11 To facilitate motion synthesis by controlling the emotion strength, our proposed frame-
12 work must be able to learn the important motions features that affect the emotion strength.
13
14 The relationship can be learned by training a ranking function as explained in Section 4.3.
15
16 The ranking function will be used for calculating the motion strength (a scalar value) of
17 each motion. Then, the motions are ranked by the motion strength as shown in Figure 4
18 and 5 (right columns). The results indicate that the learned ranking function can effectively
19 evaluate the emotion strength of each motion and is able to separate motions from different
20 emotion strength. This facilitates the motion synthesis process as the ranking function con-
21 tains the weights of each motion feature that reflects how much each feature contributes to
22 the change in the emotion strength.

38 **6.3 Evaluating the Learned Ranking Function**

39
40
41 In addition to visualizing the effectiveness of the learned ranking functions on evaluating the
42 emotion strength, we further evaluate the performance of the ranking function numerically.
43
44 Specifically, we split the collected motions into 2 sets with equal numbers of motions - one
45 set for training and the other set for testing such that the testing motions are 'unseen' data
46 to the ranking function. Next, we use the labels of the training motions to setup the relative
47 constraints as explained in Section 4.3. We vary the percentage of training data to train

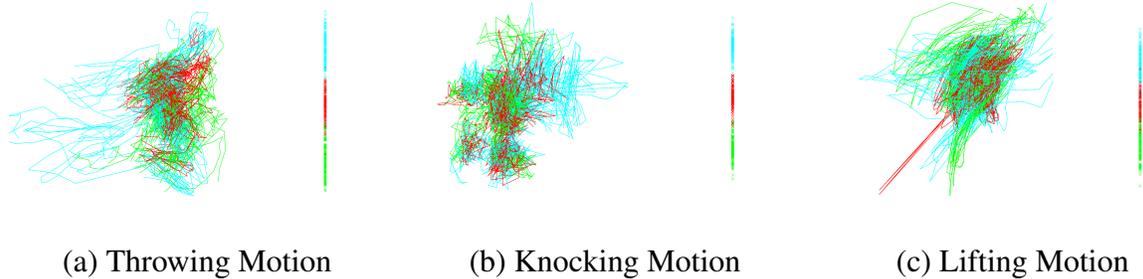

Figure 4: Visualizing the closeness of the training motions in (left column in each motion type) latent space (projected by PCA) and (right column) sequential order based on the emotion strength computed using the learned **happiness** ranking function on different motion types. Each keyframe is projected to the latent space using PCA and each of the polygon line in the figure is representing a motion sequence. Motions are colored according to the ground truth emotion labels: Happy (cyan), Neutral (red) and Sad (green).

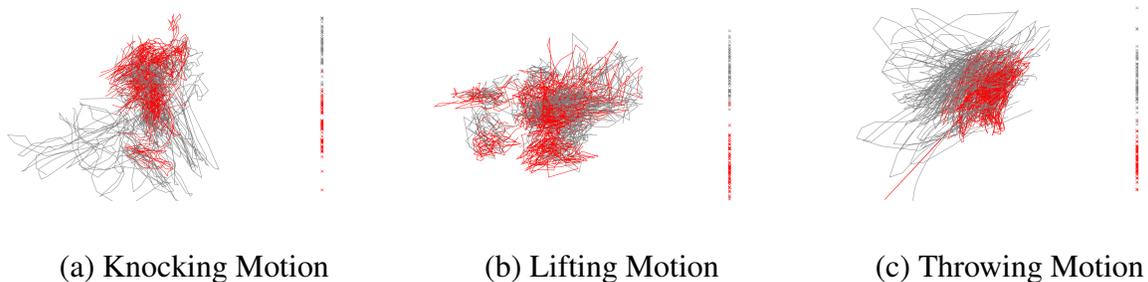

Figure 5: Visualizing the closeness of the training motions in (left column in each motion type) latent space (projected by PCA) and (right column) sequential order based on the emotion strength computed using the learned **anger** ranking function on different motion types. Motions are colored according to the ground truth emotion labels: Angry (grey) and Neutral (red).

1
2
3
4
5
6
7 the ranking function by randomly selecting the samples without considering the emotion
8 strength. Then, the learned ranking function is used for computing the emotion strength of
9 the testing motions. Finally, we compare the computed relative emotions strength to the
10 labels of the testing motions and obtain the accuracy in ranking the testing motions. The
11 same process is conducted on 3 different types of features, namely *PCA 80-d*, *PCA 40-*
12 *d* and *no PCA*. The experiment is repeated 3 times and the average accuracy is reported.
13 The results are shown in Table 1 and 2. They indicate that high ranking accuracy can be
14 achieved in which the learned ranking function can be generalized to unseen data. This
15 highlights the robustness of the ranking function. Moreover, the results also show that using
16 PCA to reduce the dimensionality of the frame-based features does not have a significant
17 impact on the ranking accuracy while improving the efficiency of the training process. We
18 also vary the number of relative constraints used to train the ranking function as in [33] to
19 reflect the model generality and the results show that there are no significant differences in
20 the ranking accuracy. This further highlights the advantage of using our system as only a
21 relatively small amount is needed to train the ranking function.

feature setup (i.e. no PCA). This further highlights the performance gain using the proposed dimensionality reduction approach.

Table 4 shows the computation time required for training the non-linear regression function explained in Section 4.4. The training time varies from 10 to 15.5 minutes. Nevertheless, this training process is performed in the pre-processing stage and thus the training time is acceptable. A perform gain is expected when a parallel implementation of non-linear regression is used.

motion type	emotion	computation time (s)

	Happiness	647.27

Table 4: Computational cost (in seconds) for training the non-linear regression function using different motion features.

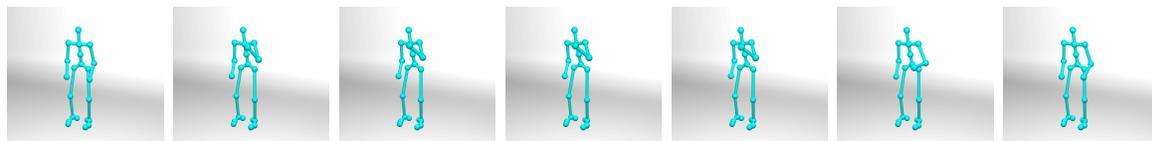

6.5 Synthesizing Motions with Different Emotion Strength

In this section, we show a number of motions with different emotion strength synthesized by our proposed framework. As explained in Section 4.4, a regression function is trained using the emotion strength and features obtained from the training data. At run-time, new motions can be created by specifying target emotion strength. We compared the synthesized motions with the training data at different emotion strength. Screen shots of training data and synthesized motions are shown in Figures 6, 7 and 8. The results show that our proposed method can synthesize motions with emotions that are comparable to the training data. More results can be found in the video demo accompanying with this paper.

We further visualize the trajectory of the left hand in all of the synthesized motions in

6
7 Figures 9-11 by showing a sphere on the 3D positions of the hand at every frame. The
8 spheres are coloured according to the speed in that frame (red refers to a higher speed while
9 blue refers to a lower speed). The spheres are the hand joint positions sampled evenly on
10 the time domain, and the difference in the speed between different synthesized motions over
11 time can further be highlighted by the sparsity of the spheres on the hand trajectory (the
12 more sparse the spheres are, the faster the motion is).
13
14
15
16
17
18
19
20

21 Figure 9 illustrates the hand trajectories of throwing motions synthesized by adjusting
22 the emotion strength. In Figure 9 (a), the hand trajectory becomes sparser and more spheres
23 are colours in red when increasing the anger level (from left to right). It implies the hand
24 is moving faster when the anger level increases. Also, the strongest anger level shows the
25 motion exaggerated more. These observations align with our observations in real-life. The
26 relationship between the speed of the hand and emotion strength also applies to happiness
27 as shown in Figure 9 (b). However, we can see the difference in the hand trajectories in the
28 motions synthesized by anger and happiness. All motions synthesized by adjusting the hap-
29 piness level are having similar hand trajectories. This result highlights the effectiveness in
30 synthesizing a wide variety of motion by adjusting the emotion strength using our proposed
31 method.

3
4
5
6
7 showed a consistent trend in increasing the speed of the motion when the emotion strength
8
9 increases.

10
11
12 Figure 11 illustrates the hand trajectories of knocking motions synthesized by adjusting
13
14 the emotion strength. In general, the knocking motions synthesized by adjusting the happi-
15
16 ness level (Figure 11 (a)) are having a more similar hand trajectory than those synthesized
17
18 by adjusting the anger level (Figure 11 (b)). The knocking motions synthesized by adjusting
19
20 the anger level showed an interesting pattern in which the character is a bit hesitant in the
21
22 motions with lower anger level. The difference in the hand trajectories again highlights the
23
24 effectiveness of our proposed method.

30 31 **6.6 Editing 2D Images using Attribute Strength**

32
33
34 In this section, we present the results on editing 2D face images using the proposed frame-
35
36 work. We used the Labeled Faces in the Wild (LFW) [28] dataset in our experiment. The
37
38 dataset contains 13233 images captured from 5749 subjects. We divided the dataset into
39
40 two halves as training and testing sets by randomly assigning images to the image sets. The
41
42 attributes of each image are calculated using the method proposed by Kumar et al. [29] and
43
44 train the ranking function and regression model using the methods explained in Section 5.
45
46

47
48 At run-time, given an input image and the desired change in attribute strength value,
49
50 the facial landmarks are extracted using [30]. Next, the facial landmarks are converted
51
52 into local coordinates by using the average positions of the facial landmarks and the local

3
4
5
6
7 coordinates are compared to those 12 centroids computed in Section 5.2. The model trained
8
9 with the cluster which is closest to the input face image will be selected to alleviate the pose
10
11 variations problem. Since the models are learned offline, the face image can be edited at
12
13 interactive rate at run-time.
14
15

16
17 Examples of the edited images are shown in Figure 12 and 13. The results show that
18
19 our proposed framework is general and able to edit images by simply specifying the desired
20
21 change in attribute strength.

25

26 **7 Conclusion and Discussions**

27
28
29

30 In summary, this paper presents a new data-driven approach to learn the underlying rela-
31
32 tionship between low-level features and high-level emotion expressions at different level of
33
34 strength. Our method takes the advantages of using relative attribute [9] to learn a ranking
35
36 function that evaluates the attributes strength from low-level motion features. Since only
37
38 weak relative constraints are used in the training process, the training data is not necessarily
39
40 labeled with ground truth attribute strength as in the data set we used. Our method further
41
42 makes use of the computed attribute strength for motion and facial expression synthesis.
43
44
45 Once the model is learned in the pre-processing stage, synthesis can be done by specifying
46
47 the target attribute strength at run-time. Our method can be applied to a wide variety of ap-
48
49 plications such as animation and movie production, as well as interactive applications such
50
51 as computer games and virtual reality applications.

5
6
7 As the first attempt and a preliminary study on analyzing and utilizing learned attribute
8 strength for motion and facial expression synthesis, we only focused on learning a single
9 attribute from the data. However, as shown in previous studies in recognition tasks [33],
10 taking into account the correlations between multiple attributes can improve the attribute
11 learning performance. In our application, such an approach could enable the synthesis with
12 multiple types of emotion expression, which is an interesting future research direction. An-
13 other future direction is conducting a user study to evaluate the emotion strength level of the
14 synthesized results for validating the ranking function learned by our method. We are also
15 planning to explore other possible low-level motion and facial features to be included in the
16 learning process.

CAVW-18-0022.R1 - A Generic Framework for Editing and Synthesizing Multimodal Data with Relative Emotion Strength

We would like to thank the reviewers for the constructive comments and suggestions. In this response letter, we will address the questions raised by the reviewers as highlight the revision as follows:

Reviewing: 1

Comments to the Author

The paper proposes a new technique to generate new motions and images by relative emotion strength. The idea is interesting. After the the revision, the paper is in good form. A few minor things that can be quickly resolved:

Re: Thanks for the suggestions and highlighting the typos in the paper. All of the minor editing issues are fixed in the revised paper.

Page 32: hand positions => joint positions?

Re: We are referring to the hand joint position. The spheres are showing the trajectory of the hand joint. We updated the paper by using the term "hand joint position" to avoid confusion.

"we cannot carry out machine learning from the training motion data directly." please provide a ref to justify the claim.

Re: Sorry for the confusion as we were explaining we cannot use the training (time-series) data with different lengths as the input of simple machine learning algorithms such as SVM. A reference paper related to preprocessing time-series data is cited and we rephrased the sentence on P. 14 to:

"As a result, it is difficult to carry out machine learning from the training motion without preprocessing the data [cite]".

Figure 4: It is unclear what Figure 4 want to illustrate. The visualisation does not convey useful information without understanding the underlying type of data, and the subtle differences. Authors can remove the figure, or provide further clarification. Is it one motion of knocking? Or all motions in knocking? or it means Closeness?

Re: Figure 4 contains 3 sets of 'sub-figures) (a, b and c) and each of them contains a single type of motion in the training data. Each keyframe is projected to the latent space using PCA and each of the polygon line in the figure is representing a motion sequence. By visualizing all motion sequences in latent space can demonstrate the closeness of the motions in different emotion strength levels.

We revised the caption of Figure 4 accordingly:

"Visualizing the closeness of the training motions in (left column in each motion type) latent space (projected by PCA) and (right column) sequential order based on the emotion strength computed using the learned happiness ranking function on different motion types. Each keyframe is projected to the latent space using PCA and each of the polygon line in the figure is representing a motion sequence. Motions are colored according to the ground truth emotion labels: Happy (cyan), Neutral (red) and Sad (green)."

Reviewing: 2

Comments to the Author

The revised manuscript is mostly satisfactory now. There are two minor comments:

CAVW-18-0022.R1 - A Generic Framework for Editing and Synthesizing Multimodal Data with Relative Emotion Strength

1
2
3 1. p.10: "The driving video is capture form another subject and ..." is not properly written. Do you
4 mean "... is captured from ..." instead?
5

6 [Re: Thanks for the suggestion and we fixed this in the revised paper.](#)
7

8 2. Section 6.3: The elaboration of results and the training/testing process are still not clear. First, as
9 mentioned in the last review, results table 1 and 2 show that in some occasions, using small
10 percentage of data as training set produced results of higher accuracy. Also, some result accuracy even
11 deteriorates when more training data were used. Could this be an over-fitting problem due to a
12 specific portion of training data was chosen? The authors did not mention whether cross-validation
13 was conducted. The authors should elaborate further what mechanism they have employed to ensure
14 the result robustness.
15
16

17 [Re: As mentioned in the last review, the training/testing process is done by dividing the data into 2
18 halves in the pre-processing stage and the number of motions used for testing the system is fixed.
19 When testing each % level of training pairs, we randomly pick the training samples without considering
20 the label \(i.e. the emotion strength level\). We also used the same set of selected motion samples for
21 all 3 types of features \(i.e. PCA 80-d, PCA 40-d and no PCA\). We did not conduct any cross-validation
22 in the training process. The noise in sampling and lack of cross-validation may result in the drop in
23 accuracy with more training data in the knocking dataset.
24
25](#)

26 [Nevertheless, the main purpose of this experiment is to show that there are no significant differences
27 in the ranking accuracy across different % of training data used, which reduces the requirement on
28 the volume of training data. When extending this research in the future, we will take into account the
29 suggestions and improve the results by incorporating all these techniques to avoid potential
30 overfitting.
31
32](#)

33 [We revised Section 6.3 as follows:](#)
34

35 ["In addition to visualizing the effectiveness of the learned ranking functions on evaluating the emotion
36 strength, we further evaluate the performance of the ranking function numerically. Specifically, we
37 split the collected motions into 2 sets with equal numbers of motions - one set for training and the
38 other set for testing such that the testing motions are 'unseen' data to the ranking function. Next, we
39 use the labels of the training motions to setup the relative constraints as explained in Section
40 \ref{sec:learnW}. We vary the percentage of training data to train the ranking function by randomly
41 selecting the samples without considering the emotion strength. Then, the learned ranking function
42 is used for computing the emotion strength of the testing motions. Finally, we compare the computed
43 relative emotions strength to the labels of the testing motions and obtain the accuracy in ranking the
44 testing motions. The same process is conducted on 3 different types of features, namely PCA 80-d,
45 PCA 40-d and no PCA. The experiment is repeated 3 times and the average accuracy is reported."
46
47
48
49
50](#)

51 **Reviewing: 3**

52 Comments to the Author
53

54 I see that the authors have addressed all my comments. They have provided a video to show the
55 results to complement the paper. I think the current paper looks good to me.
