Preface

Recent years have witnessed a dramatic resurgence of interest in channel coding within the optical communications community, as evidenced by the increase of the number of publications, and many eye-catching implementations and experimental demonstrations presented at major conferences. The main drivers behind the emergence of channel coding in optical communications are: (1) high demands in bandwidth thanks to the recent growth of Internet usage, IPTV, VoIP, and YouTube; and (2) rapid advance of silicon signal processing capability. In recent years, with the rapid growth of data-centric services and the general deployment of broadband access networks, there has been a strong demand driving the dense wavelength division multiplexing (DWDM) network upgrade from 10 Gb/s per channel to more spectrally efficient 40 Gb/s or 100 Gb/s per channel, and beyond. The 100 Gb/s Ethernet (100 GbE) is currently under standardization for both local area networks (LANs) and wide area networks (WANs). The 400 Gb/s and 1 Tb/s are regarded to be the next steps after 100 Gb/s and have started already attracting research community interests. Migrating to higher transmission rates comes along with numerous challenges such as degradation in the signal quality due to different linear and nonlinear channel impairments and increased installation costs. To deal with those channel impairments novel advanced techniques in modulation and detection, coding, and signal processing should be developed. Such topics will be described in detail in this book.

The introduction of sophisticated electronic digital signal processing (DSP), coherent detection, and coding could fundamentally alter the optical networks as we see them today. DSP has played a vital role in wireless communication and has enabled so-called software-defined radio (SDR). Thanks to the recent resurgence of coherent detection and the recent drive toward dynamically reconfigurable optical networks with transmission speeds beyond 100 Gb/s, DSP and forward error correction (FEC) are becoming increasingly important. Regardless of the data destination, an optical transport system (OTS) must provide the predefined bit-error rate (BER) performance. To achieve a target BER regardless of the data destination, the future OTS should be able to adjust the FEC strength according to the optical channel conditions. Such an approach leads us toward the *software-defined optical transmission* (SDOT) in which the transponder can be adapted or reconfigured to multiple standards, multiple modulation formats, or code rates, a concept very similar to SDR.

Although channel coding for optical channels has gained prominence and emerged as the leading ultra-high-speed optical transmission enabling technology, FEC seems to be rather alien to many optical engineers. The optical engineers are aware that FEC potentially hold the keys to solving many major problems for today's "fragile" and "rigid" optical networks, but feel intimidated by sophisticated coding terminology. This book is intended to give a coherent, self-contained, and comprehensive introduction to the fundamentals of channel coding and DSP for optical communications. It is designed for three diverse groups of researchers: (1) optical communication engineers who are proficient in the optical science and are interested in applying coding theory and DSP, but not familiar with basic coding concepts, (2) wireless communication engineers who are very much adequate with their DSP and coding skill sets, but are disoriented by the perceived huge gap between optical and RF communications worlds, and (3) coding experts interested in entering the world of optical communications. An attempt has been made to make the individual chapters self-contained as much as possible while maintaining the flow and connection between them.

This book is organized into 11 chapters, and treats topics related to modulation, DSP and coding for optical channels starting from the fundamentals of optical communication and major channel impairments and noise sources, through DSP and coding, to various applications, such as single-mode fiber transmission, multimode fiber transmission, free space-optical systems, and optical access networks. This book presents interesting research problems in the emerging field of channel coding, constrained coding, coded-modulation, and turbo equalization and touches on the intriguing issue related to future research topics in coding for optical channels. The main purpose of this book is: (1) to describe the FEC schemes currently in use in optical communications, (2) to describe different classes of codes on graphs of high interest for next-generation high-speed optical transport, (3) to describe how to combine multilevel modulation and channel coding optimally, and (4) to describe how to perform equalization and soft decoding jointly, in a so-called turbo equalization fashion.

The authors would like to thank their colleagues and students, in particular, H. G. Batshon, L. L. Minkov, M. Arabaci, A. R. Krishnan, S. K. Planjery, L. Xu, T. Wang, M. Cvijetic, F. Kueppers, S. Denic, M. Ivkovic, M. A. Neifeld, J. Anguita, T. Mizuochi, X. Liu, I. Gabitov, N. Alic, G. T. Djordjevic, and S. K. Turitsyn, whose collaboration or support on the subject of coding for optical channels contributed directly and indirectly to the completion of this book. The authors would like to acknowledge National Science Foundation (NSF), NEC Laboratories America, and Opnext for their support of coding theory and coding for optical channels research activities.

Finally, special thanks are extended to Charles Glaser and Amanda Davis of Springer US for their tremendous effort in organizing the logistics of this book including editing and promotion, which is indispensable to make this book happen.

Contents

1	Introduction	1
1.1	Historical Perspective of Optical Communications	2
1.2	Optical Transmission and Optical Networking	4
1.3	Optical Communications Trends	9
1.3.1	Migration to 100 Gb/s Ethernet and Beyond	9
1.3.2	Dynamically Reconfigurable Optical Networks	10
1.3.3	Software-Defined Optical Transmission	11
1.3.4	Digital Signal Processing and Coherent Detection	13
1.3.5	OFDM for Optical Communications	14
1.4	Forward Error Correction for Optical Communications and Networks	16
1.5	Organization of the Book	20
	References	22
2	Fundamentals of Optical Communication	25
2.1	Introduction	25
2.2	Key Optical Components	26
2.2.1	Optical Transmitters	30
2.2.2	Optical Receivers	35
2.2.3	Optical Fibers	37
2.2.4	Optical Amplifiers	40
2.2.5	Other Optical Components	44
2.3	Direct Detection Modulation Schemes	49
2.3.1	Non-Return-to-Zero	49
2.3.2	Return-to-Zero	50
2.3.3	Alternate Mark Inversion	50
2.3.4	Duobinary Modulation Format	51
2.3.5	Carrier-Suppressed Return-to-Zero	52
2.3.6	NRZ-DPSK	54
2.3.7	RZ-DPSK	54
2.4	Coherent Detection Modulation Schemes	55
2.4.1	Optical Hybrids and Balanced Receivers	61
2.4.2	Dominant Coherent Detector Noise Sources	63

2.4.3	Homodyne Coherent Detection	67
2.4.4	Phase Diversity Receivers	68
2.4.5	Polarization Control and Polarization Diversity	69
2.4.6	Polarization Multiplexing and Coded Modulation	70
2.5	Summary	72

About the Authors

Ivan B. Djordjevic is an Assistant Professor in the Department of Electrical and Computer Engineering at the University of Arizona, Tucson, where he is directing the Optical Communications Systems Laboratory (OCSL). He is the author or coauthor of more than 100 journal publications and more than 100 conference papers. Dr. Djordjevic is also the author, together with Dr. William Shieh, of the book *OFDM for Optical Communications*, Elsevier, 2009. His current research interests include optical networks, error control coding, constrained coding, coded modulation, turbo equalization, OFDM applications, and quantum error correction. He is an Associate Editor for the *Research Letters in Optics* and the *International Journal of Optics*.

William E. Ryan is a Professor in the Department of Electrical and Computer Engineering at the University of Arizona. He has published numerous papers in the leading conferences and journals in the area of communication theory and channel coding. He is also the author (with Shu Lin) of the graduate textbook *Channel Codes: Classical and Modern*, Cambridge University Press, 2009. His research interests are in coding and signal processing with applications to magnetic data storage and data communications.

Dr. Bane Vasic received his B.Sc., M.Sc., and Ph.D. from the University of Nis, Serbia. He is currently a Professor of Electrical and Computer Engineering and Mathematics at the University of Arizona, Tucson. Prior to this appointment, he was at Bell Laboratories. He is a Member of the Editorial Board of the IEEE Transactions on Magnetics, and was a chair or technical program chair for several workshops and conferences including: IEEE CTW 2003 and 2007, DIMACS Workgroup and Workshop on Theoretical Advances in Information Recording, 2004, LANL Workshop on Applications of Statistical Physics to Coding Theory, 2004, Communication Theory Symposium within ICC 2006. He has authored a number of journal and conference articles, book chapters and edited three books, and his patents are implemented in Bell Labs chips. His research interests include coding theory, communication theory, constrained systems, and digital communications and recording.
