# Preface

The theory of computing provides computer science with concepts, models, and formalisms for reasoning about both the resources needed to carry out computations and the efficiency of the computations that use these resources. It provides tools to measure the difficulty of combinatorial problems both absolutely and in comparison with other problems. Courses in this subject help students gain analytic skills and enable them to recognize the limits of computation. For these reasons, a course in the theory of computing is usually required in the graduate computer science curriculum.

The harder question to address is which topics such a course should cover. We believe that students should learn the fundamental models of computation, the limitations of computation, and the distinctions between feasible and intractable. In particular, the phenomena of NP-completeness and NP-hardness have pervaded much of science and transformed computer science. One option is to survey a large number of theoretical subjects, typically focusing on automata and formal languages. However, these subjects are less important to theoretical computer science, and to computer science as a whole, now than in the past. Many students have taken such a course as part of their undergraduate education. We chose not to take that route because computability and complexity theory are the subjects that we feel deeply about and that we believe are important for students to learn. Furthermore, a graduate course should be scholarly. It is better to treat important topics thoroughly than to survey the field.

This textbook is intended for use in an introductory graduate course in theoretical computer science. It contains material that should be core knowledge in the theory of computation for all graduate students in computer science. It is self-contained and is best suited for a one-semester course. Most of the text can be covered in one semester by moving expeditiously through the core material of

Chapters 2 through 6 and then covering parts of Chapter 7. We will give more details about this below.

As a graduate course, students should have some prerequisite preparation. The ideal preparation would be the kind of course that we mentioned above: an undergraduate course that introduced topics such as automata theory, formal languages, computability theory, or complexity theory. We stress, however, that there is nothing in such a course that a student needs to know before studying this text. Our personal experience suggests that we cannot presume that all of our students have taken such an undergraduate course. For those students who have not, we advise that they need at least some prior exposure that will have developed mathematical skills. Prior courses in mathematical logic, algebra (at the level of groups, rings, or fields), or number theory, for example, would all serve this purpose.

Despite the diverse backgrounds of our students, we have found that graduate students are capable of learning sophisticated material when it is explained clearly and precisely. That has been our goal in writing this book.

This book also is suitable for advanced undergraduate students who have satisfied the prerequisites. It is an appropriate first course in complexity theory for students who will continue to study and work in this subject area.

The text begins with a preliminary chapter that gives a brief description of several topics in mathematics. We included this in order to keep the book self-contained and to ensure that all students have a common notation. Some of these sections simply enable students to understand some of the important examples that arise later. For example, we include a section on number theory and algebra that includes all that is necessary for students to understand that primality belongs to NP.

The text starts properly with classical computability theory. We build complexity theory on top of that. Doing so has the pedagogical advantage that students learn a qualitative subject before advancing to a quantitative one. Also, the concepts build from one to the other. For example, although we give a complete proof that the satisfiability problem is NP-complete, it is easy for students to understand that the bounded halting problem is NP-complete, because they already know that the classical halting problem is c.e.-complete.

We use the terms *partial computable* and *computably enumerable (c.e.)* instead of the traditional terminology, *partial recursive* and *recursively enumerable (r.e.)*, respectively. We do so simply to eliminate confusion. Students of computer science know of “recursion” as a programming paradigm. We do not prove here that Turing-computable partial functions are equivalent to partial recursive functions, so by not using that notation, we avoid the matter altogether. Although the notation we are using has been commonplace in the computability theory and mathematical logic community for several years, instructors might want to advise their students that the older terminology seems commonplace within the theoretical computer science community. Computable functions are defined on the set of words over a finite alphabet, which we identify with the set of natural numbers in a straightforward manner. We use the term *effective*, in the nontechnical, intu-

itive sense, to denote computational processes on other data types. For example, we will say that a set of Turing machines is “effectively enumerable” if its set of indices is computably enumerable.

Chapter 4 concludes with a short list of topics that students should know from the chapters on computability theory before proceeding to study complexity theory. We advise instructors who wish to minimize coverage of computability theory to refer to this list. Typically, we do not cover the second section on the recursion theorem (Section 3.10) in a one-semester course. Although we do not recommend it, it is possible to begin the study of complexity theory after learning the first five sections of Chapter 3 and at least part of Section 3.9 on oracle Turing machines, Turing reductions, and the arithmetical hierarchy.

In Chapter 5 we treat general properties of complexity classes and relationships between complexity classes. These include important older results such as the space and time hierarchy theorems, as well as the more recent result of Immerman and Szelepcsényi that space-bounded classes are closed under complements. Instructors might be anxious to get to NP-complete problems (Chapter 6) and NP-hard problems (Chapter 7) but students need to learn the basic results of complexity theory and it is instructive for them to understand the relationships between P, NP, and other deterministic and nondeterministic, low-level complexity classes. Students should learn that nondeterminism is not well understood in general, that  $P = ? NP$  is not an isolated question, and that other classes have complete problems as well (which we take up in Chapter 7). Nevertheless, Chapter 5 is a long chapter. Many of the results in this chapter are proved by complicated Turing-machine simulations and counting arguments, which give students great insight, but can be time-consuming to cover. For this reason, instructors might be advised to survey some of this material if the alternative would mean not having sufficient time for the later chapters.

Homework exercises are an important part of this book. They are embedded in the text where they naturally arise, and students should not proceed without working on them. Many are simple exercises, whereas others are challenging. Often we leave important but easy-to-prove propositions as exercises. We provide additional problems at the end of chapters, which extend and apply the material covered there.

Once again, our intent has been to write a text that is suitable for all graduate students, that provides the right background for those who will continue to study complexity theory, and that can be taught in one semester. There are several important topics in complexity theory that cannot be treated properly in a one-semester course. Currently we are writing a second part to this text, which will be suitable for an optional second semester course, covering nonuniform complexity (Boolean circuits), parallelism, probabilistic classes, and interactive protocols.

# Contents

<b>Preface</b>	<b>vii</b>
<b>1 Preliminaries</b>	<b>1</b>
1.1 Words and Languages . . . . .	1
1.2 $K$ -adic Representation . . . . .	2
1.3 Partial Functions . . . . .	3
1.4 Graphs . . . . .	4
1.5 Propositional Logic . . . . .	6
1.5.1 Boolean Functions . . . . .	8
1.6 Cardinality . . . . .	8
1.6.1 Ordered Sets . . . . .	10
1.7 Elementary Algebra . . . . .	11
1.7.1 Rings and Fields . . . . .	11
1.7.2 Groups . . . . .	15
1.7.3 Number Theory . . . . .	17
<b>2 Introduction to Computability</b>	<b>22</b>
2.1 Turing Machines . . . . .	23
2.2 Turing-Machine Concepts . . . . .	26
2.3 Variations of Turing Machines . . . . .	28
2.3.1 Multitape Turing Machines . . . . .	29
2.3.2 Nondeterministic Turing Machines . . . . .	31
2.4 Church's Thesis . . . . .	34
2.5 RAMs . . . . .	36
2.5.1 Turing Machines for RAMS . . . . .	39

<b>3</b>	<b>Undecidability</b>	<b>41</b>
3.1	Decision Problems . . . . .	41
3.2	Undecidable Problems . . . . .	43
3.3	Pairing Functions . . . . .	46
3.4	Computably Enumerable Sets . . . . .	47
3.5	Halting Problem, Reductions, and Complete Sets . . . . .	50
3.5.1	Complete Problems . . . . .	52
3.6	$S$ - $m$ - $n$ Theorem . . . . .	53
3.7	Recursion Theorem . . . . .	55
3.8	Rice's Theorem . . . . .	57
3.9	Turing Reductions and Oracle Turing Machines . . . . .	59
3.10	Recursion Theorem, Continued . . . . .	66
3.11	References . . . . .	69
3.12	Additional Homework Problems . . . . .	70
<b>4</b>	<b>Introduction to Complexity Theory</b>	<b>72</b>
4.1	Complexity Classes and Complexity Measures . . . . .	74
4.1.1	Computing Functions . . . . .	76
4.2	Prerequisites . . . . .	77
<b>5</b>	<b>Basic Results of Complexity Theory</b>	<b>78</b>
5.1	Linear Compression and Speedup . . . . .	80
5.2	Constructible Functions . . . . .	86
5.2.1	Simultaneous Simulation . . . . .	87
5.3	Tape Reduction . . . . .	90
5.4	Inclusion Relationships . . . . .	97
5.4.1	Relations between the Standard Classes . . . . .	105
5.5	Separation Results . . . . .	107
5.6	Translation Techniques and Padding . . . . .	111
5.6.1	Tally Languages . . . . .	113
5.7	Relations between the Standard Classes—Continued . . . . .	115
5.7.1	Complements of Complexity Classes: The Immerman–Szelepcsényi Theorem . . . . .	116
5.8	Additional Homework Problems . . . . .	120
<b>6</b>	<b>Nondeterminism and NP-Completeness</b>	<b>122</b>
6.1	Characterizing NP . . . . .	123
6.2	The Class P . . . . .	124
6.3	Enumerations . . . . .	126
6.4	NP-Completeness . . . . .	128
6.5	The Cook–Levin Theorem . . . . .	130
6.6	More NP-Complete Problems . . . . .	136
6.6.1	The Diagonal Set Is NP-Complete . . . . .	137
6.6.2	Some Natural NP-Complete Problems . . . . .	138

6.7	Additional Homework Problems . . . . .	142
<b>7</b>	<b>Relative Computability</b>	<b>145</b>
7.1	NP-Hardness . . . . .	147
7.2	Search Problems . . . . .	151
