Preface

This book contains the papers of the 16th Advances in Computer Games Conference (ACG 2019) held in Macau, China. The conference took place during August 11–13, 2019, in conjunction with the IJCAI conference, the Computer Olympiad, and the World Computer-Chess Championship.

The ACG conference series is a major international forum for researchers and developers interested in all aspects of artificial intelligence and computer game playing. Earlier conferences took place in London, UK (1975), Edinburgh, UK (1978), London, UK (1981, 1984), Noordwijkerhout, The Netherlands (1987), London, UK (1990), Maastricht, The Netherlands (1993, 1996), Paderborn, Germany (1999), Graz, Austria (2003), Taipei, Taiwan (2005), Pamplona, Spain (2009), Tilburg, The Netherlands (2011), and Leiden, The Netherlands (2015, 2017).

In this conference 19 papers were submitted. Each paper was sent to three reviewers. The Program Committee accepted 12 papers for presentation at the conference and publication in these proceedings. As per usual, we informed the authors that they submitted their contribution to a post-conference editing process. The two-step process is meant (a) to give authors the opportunity to include the results of the fruitful discussion after the lecture in their paper, and (b) to maintain the high-quality threshold of the ACG series.

Moreover three invited talks were given by Jonathan Schaeffer, Nathan Sturtevant and Cameron Browne, Eric Piette, and Matthew Stephenson.

We now give a brief introduction to the papers included in this book regrouped by topics.

Cooperation

The first paper is "Advice are Useful for Game AI: Experiments with Alpha-Beta Search Players in Shogi" by Shogo Takeuchi. It presents methods to strengthen a game AI using advice from other game AIs during game play. Advice are moves selected by an adviser and propose a mechanism that makes a player search again when the player's move is different from advice. Experiment are made for the game of Shogi.

The second paper by Eisuke Sato and Hirotaka Osawa is "Reducing Partner's Cognitive Load by Estimating the Level of Understanding in the Cooperative Game Hanabi." Hanabi is a cooperative game for ordering cards through information exchange. Cooperation is achieved in terms of not only increased scores, but also reduced cognitive load for the players. The thinking time is used as an indicator of cognitive load, and the results showed that it is inversely proportional to the confidence of choice. When the agent uses the thinking time of the player the mean thinking time of the human player is shortened. It suggests that it could reduce the cognitive load of the players without influencing performance.

The third paper by Gregory Schmidt and Philip Shoptaugh is "Making a Better Game: The History of Cluster." The authors present a case study of the initial inspiration and design process that led to successfully optimized versions of the game Cluster.

Single Player Games

The fourth paper by Taishi Oikawa, Chu-Hsuan Hsueh, and Kokolo Ikeda is "Enhancing Human Players' T-Spin Technique in Tetris with Procedural Problem Generation." They are interested in programs that can entertain or teach human players. They automatically generate puzzles so that human players improve at playing the game of Tetris. A technique hard to learn for beginners is T-spin. Automatically generated two-step T-spin problems are given to human players to solve and they enable to improve their skills at Tetris.

The fifth paper by Kiminori Matsuzaki is "A Further Investigation of Neural Network Players for Game 2048." Game 2048 is a stochastic single-player game. Strong 2048 computer players use N-tuple networks trained by reinforcement learning. The paper investigates neural-network players for Game 2048 and improve their layers and their inputs and outputs. The best neural-network player achieved an average score of 215 803 without search techniques, which is comparable to N-tuple-network players.

Mathematical Approaches

The sixth paper by Michael Hartisch and Ulf Lorenz is "A Novel Application for Game Tree Search - Exploiting Pruning Mechanisms for Quantified Integer Programs." They investigate pruning in search trees of so-called quantified integer (linear) programs (QIPs). QIPs consist of a set of linear inequalities and a minimax objective function, where some variables are existentially and others are universally quantified. They develop and theoretically substantiate tree pruning techniques based upon algebraic properties. The implementation of their findings can massively speed up the search process.

The seventh paper by Nicolas Fabiano and Ryan Hayward is "New Hex Patterns for Fill and Prune." A fill pattern in the game of Hex is a subposition with one or more empty cells that can be filled without changing the position's minimax value. Some cells can be pruned and ignored when searching for a winning move. They introduce two new kinds of Hex fill – mutual and near-dead – and some resulting fill patterns. They show four new permanently-inferior fill patterns and present three new prune results, based on strong-reversing, reversing, and game-history respectively.

The eighth paper by Jos Uiterwijk is "Solving Cram Using Combinatorial Game Theory." He investigates the board game Cram, which is an impartial combinatorial game, using an $\alpha\beta$ solver. He uses knowledge obtained from Combinatorial Game Theory (CGT) for his solver. Using endgame databases pre-filled with CGT values (nimbers) for all positions fitting on boards with at most 30 squares and also using two efficient move-ordering heuristics gives a large improvement of solving power. He also defines five more heuristics based on CGT that further reduce the sizes of the solution trees considerably. He was able to solve all odd by odd Cram boards for which results were available from the literature (even by even and odd by even boards are trivially

solved). He proves new results for the 3 \times 21 board, a first-player win, and the 5 \times 11 board, a second-player win.

Nonogram: General and Specific Approaches

The ninth paper by Aline Hufschmitt, Jean-Noel Vittaut, and Nicolas Jouandeau is "Exploiting Game Decompositions in Monte Carlo Tree Search." They propose the Multiple Tree MCTS (MT-MCTS) approach to simultaneously build multiple MCTS trees corresponding to different sub-games. They apply it to single player games from General Game Playing. Complex compound games are solved from 2 times faster (Incredible) up to 25 times faster (Nonogram).

The tenth paper by Yan-Rong Guo, Wei-Chiao Huang, Jia-Jun Yeh, Hsi-Ya Chang, Lung-Pin Chen, and Kuo-Chan, Huang is "On Efficiency of Fully Probing Mechanisms in Nonogram Solving Algorithm." Fully probing plays is important for Nonogram. The authors address several critical factors influencing fully probing efficiency: re-probing policy, probing sequence, and computational overhead. Taking into account these factors improves the speed of solving Nonogram puzzles significantly.

Deep Learning

The eleventh paper by Hsiao-Chung Hsieh, Ti-Rong Wu, Ting Han Wei, and I-Chen Wu is "Net2Net Extension for the AlphaGo Zero Algorithm." The number of residual blocks of a neural network that learns to play the game of Go following the AlphaGo Zero approach is important for the strength of the program but also takes more time for self-play. The authors propose a method to deepen the residual network without reducing performance. The deepening process is performed by inserting new layers into the original network. They present three insertion schemes. For 9×9 Go, they obtain a 61.69% win rate against the unextended player while greatly saving the time for self-play.

The twelfth paper by Tomihiro Kimura and Kokolo Ikeda is "Designing Policy Network with Deep Learning in Turn-Based Strategy Games." They apply deep learning to turn-based strategy games. A recurrent policy network is developed learning from game records. The game data are generated using Monte Carlo Tree Search. The resulting policy network outperforms MCTS.

Invited Papers

The first invited paper by Nathan Sturtevant is "Steps towards Strongly Solving 7x7 Chinese Checkers." Chinese Checkers is a game for 2–6 players that has been used as a testbed for game AI in the past. He provides an overview of what is required to strongly solve versions of the game, including a complete set of rules needed to solve the game. We provide results on smaller boards with result showing that these games are all a first-player win.

The second invited paper by Cameron Browne, Matthew Stephenson, Éric Piette, and Dennis J.N.J. Soemers is "The Ludii General Game System: Interactive Demonstration." Ludii is a new general game system, currently under development, which aims to support a wider range of games than existing systems and approaches. It is

viii Preface

being developed primarily for the task of game design, but offers a number of other potential benefits for game and AI researchers, professionals, and hobbyists. The paper describes the approach behind Ludii, how it works, how it is used, and what it can potentially do.

Acknowledgment

This book would not have been produced without the help of many persons. In particular, we would like to mention the authors and reviewers for their help. Moreover, the organizers of IJCAI, the Computer Olympiad, and the World Computer-Chess Championship have contributed substantially by bringing the researchers together.
