HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# Finite state transducers for modular Möbius number systems 

Martin Delacourt ${ }^{1}$ and Petr Kůrka ${ }^{2}$<br>${ }^{1}$ Laboratoire d'Informatique Fondamentale de Marseille, 39 rue Joliot Curie, F-13453 Marseille Cedex, France.<br>${ }^{2}$ Center for Theoretical Study, Academy of Sciences and Charles University in Prague, Jilská 1, CZ-11000 Praha 1, Czechia.

#### Abstract

Modular Möbius number systems consist of Möbius transformations with integer coefficients and unit determinant. We show that in any modular Möbius number system, the computation of a Möbius transformation with integer coefficients can be performed by a finite state transducer and has linear time complexity. As a byproduct we show that every modular Möbius number system has the expansion subshift of finite type.

Keywords: exact real algorithms, expansion subshift, absorptions, emissions.

## 1 Introduction

In an unpublished but influential manuscript, Gosper [1] shows that continued fractions can be used for arithmetical algorithms, provided they are redundant. Based on these ideas, exact real arithmetical algorithms have been developed in Vuillemin [15], Kornerup and Matula [4] or Potts [13]. These algorithms perform a sequence of input absorptions and output emissions and update their inner state, which may be a $(2 \times 2)$-matrix in the case of a Möbius transformation or a $(2 \times 4)$-matrix in the case of binary operations like addition or multiplication.

Using the concepts and methods of symbolic dynamics, exact real arithmetic has been generalized in the theory of Möbius number systems (MNS) introduced in Kůrka [6] and developed in Kůrka and Kazda [10]. Möbius number systems represent real numbers by infinite words from a one-sided expansion subshift. The letters of the alphabet stand for real orientation-preserving Möbius transformations and the concatenation of letters corresponds to the composition of transformations. In Kůrka [7] we have investigated MNS in which rational numbers have periodic or preperiodic expansions and in Kůrka [9] we have characterized MNS whose expansion subshifts are of finite type or sofic.

The time complexity of the unary exact real algorithm which computes a Möbius transformation depends on the growth of its inner state matrices during the computation. Heckmann [2] analyzes this process in positional number systems and proves the Law of big numbers (not to be confused with the Law of
large numbers), saying that the norm of the state matrix after $n$ absorptions or emissions is at least of the order $r^{n / 2}$ for $r$-ary positional systems. This implies that the bit size of the state matrices grows at least linearly, and arithmetical operations have quadratic time complexity. In Kůrka [8] we have shown that in a general MNS the growth of the state matrices can be slower and we conjectured that the state matrices can even remain bounded. In the present paper we show that this is the case for modular MNS, i.e., MNS whose transformations have integer coefficients and unit determinant. It follows that the unary algorithm can be realized by a finite state transducer and has linear time complexity. This generalizes the results of Raney [14] and complements the results of Konečný [3], who proves (in a slightly different context), that the only differentiable functions computable by finite state transducers are Möbius transformations.

## 2 Möbius transformations

The extended real line $\overline{\mathbb{R}}=\mathbb{R} \cup\{\infty\}$ can be regarded as a projective space, i.e., the space of one-dimensional subspaces of the two-dimensional vector space. On $\overline{\mathbb{R}}$ we have homogeneous coordinates $x=\left(x_{0}, x_{1}\right) \in \mathbb{R}^{2} \backslash\{(0,0)\}$ with equality $x=y$ iff $\operatorname{det}(x, y)=x_{0} y_{1}-x_{1} y_{0}=0$. We regard $x \in \overline{\mathbb{R}}$ as a column vector, and write it usually as $x=\frac{x_{0}}{x_{1}}=x_{0} / x_{1}$, for example $\infty=1 / 0$. The stereographic projection $\mathbf{h}(z)=(i z+1) /(z+i)$ maps $\overline{\mathbb{R}}$ to the unit circle $\partial \mathbb{D}=\{z \in \mathbb{C}:|z|=1\}$ in the complex plane, and the upper half-plane $\mathbb{U}=\{z \in \mathbb{C}: \Im(z)>0\}$ conformally to the unit disc $\mathbb{D}=\{z \in \mathbb{C}:|z|<1\}$.

A real orientation-preserving Möbius transformation (MT) is a selfmap of $\overline{\mathbb{R}}$ of the form

$$
M_{(a, b, c, d)}(x)=\frac{a x+b}{c x+d}=\frac{a x_{0}+b x_{1}}{c x_{0}+d x_{1}}
$$

where $a, b, c, d \in \mathbb{R}$ and $\operatorname{det}\left(M_{(a, b, c, d)}\right)=a d-b c>0$. Möbius transformations form a group and act also on the upper half-plane $\mathbb{U}$ : If $z \in \mathbb{U}$ then $M(z) \in \mathbb{U}$ as well. On $\overline{\mathbb{D}}:=\mathbb{D} \cup \partial \mathbb{D}$ we get disc Möbius transformations defined by $\widehat{M}_{(a, b, c, d)}(z)=\mathbf{h} \circ M_{(a, b, c, d)} \circ \mathbf{h}^{-1}(z)=(\alpha z+\beta) /(\bar{\beta} z+\bar{\alpha})$, where $\alpha=(a+d)+$ $(b-c) i, \beta=(b+c)+(a-d) i$. The circle derivation of $M=M_{(a, b, c, d)}$ at $x \in \overline{\mathbb{R}}$ is defined by

$$
M^{\bullet}(x)=\left|\widehat{M}^{\prime}(\mathbf{h}(x))\right|=\frac{(a d-b c) \cdot\left(x_{0}^{2}+x_{1}^{2}\right)}{\left(a x_{0}+b x_{1}\right)^{2}+\left(c x_{0}+d x_{1}\right)^{2}}=\frac{\operatorname{det}(M) \cdot\|x\|^{2}}{\|M(x)\|^{2}} .
$$

The expansion interval of an MT is $\mathbf{V}(M)=\left\{x \in \overline{\mathbb{R}}:\left(M^{-1}\right)^{\bullet}(x)>1\right\}$. If $M=R_{\alpha}=M_{\left(\cos \frac{\alpha}{2}, \sin \frac{\alpha}{2},-\sin \frac{\alpha}{2}, \cos \frac{\alpha}{2}\right)}$ is a rotation, then $M^{\bullet}(x)=1$ and $\mathbf{V}(M)$ is empty. Otherwise $\mathbf{V}(M)$ is a proper set interval.

## 3 Intervals

A set interval is an open connected subset of $\overline{\mathbb{R}}$. A proper set interval is a nonempty set interval properly included in $\overline{\mathbb{R}}$. We represent proper set intervals
by $(2 \times 2)$-matrices whose columns are their left and right endpoints. The stereographic projection applied to $x=\frac{r \sin \alpha}{r \cos \alpha} \in \overline{\mathbb{R}}$ gives $\mathbf{h}(x)=\sin 2 \alpha-i \cos 2 \alpha=$ $e^{i\left(2 \alpha-\frac{\pi}{2}\right)}$, so it doubles the angles. Matrices with columns $x=\frac{r \sin \alpha}{r \cos \alpha}, y=\frac{s \sin \beta}{s \cos \beta}$ where $0 \leq \alpha<2 \pi, \alpha<\beta<\alpha+\pi$ therefore represent all proper intervals. Since $\operatorname{det}(x, y)=r s \sin (\alpha-\beta)<0$, we define matrix intervals as $(2 \times 2)$-matrices with negative determinant and write them as pairs $I=\left(\frac{x_{0}}{x_{1}}, \frac{y_{0}}{y_{1}}\right)$ of their left and right endpoints $\boldsymbol{l}(I)=\frac{x_{0}}{x_{1}}, \mathbf{r}(I)=\frac{y_{0}}{y_{1}}$. The set of matrix intervals is therefore

$$
\mathbb{I}(\mathbb{R})=\left\{\left(\frac{x_{0}}{x_{1}}, \frac{y_{0}}{y_{1}}\right) \in \mathrm{GL}(\mathbb{R}, 2): x_{0} y_{1}-x_{1} y_{0}<0\right\}
$$

We define the size and the length of an interval $(x, y)$ by

$$
\begin{aligned}
\mathrm{sz}(x, y) & =\frac{x_{0} y_{0}+x_{1} y_{1}}{x_{0} y_{1}-x_{1} y_{0}}=\frac{x \cdot y}{\operatorname{det}(x, y)}, \\
|(x, y)| & =\frac{1}{2}+\frac{1}{\pi} \arctan \mathrm{sz}(x, y)
\end{aligned}
$$

For $x=\frac{r \sin \alpha}{r \cos \alpha}, y=\frac{s \sin \beta}{s \cos \beta}$ we get $\mathrm{sz}(x, y)=-\cot (\beta-\alpha)=\tan \left(\beta-\alpha-\frac{\pi}{2}\right)$, so $|(x, y)|=(\beta-\alpha) / \pi$, provided $0<\beta-\alpha<\pi$. The length $|I| \in(0,1)$ of $I$ is an increasing function of the size $\mathrm{sz}(I) \in(-\infty,+\infty)$ of $I$. A matrix interval $I=(x, y)$ defines an open set interval by $z \in I \Leftrightarrow \operatorname{det}(x, z) \cdot \operatorname{det}(z, y)>0$, and a closed set interval $z \in \bar{I} \Leftrightarrow \operatorname{det}(x, z) \cdot \operatorname{det}(z, y) \geq 0$. If $I=\left(\frac{r \sin \alpha}{r \cos \alpha}, \frac{s \sin \beta}{s \cos \beta}\right)$, then $z=\frac{t \sin \gamma}{t \cos \gamma} \in I$ iff either $\alpha<\gamma<\beta$ or $\alpha+\pi<\gamma<\beta+\pi$. If $I, J$ are intervals, then $I \subseteq J$ iff $\mathbf{l}(I) \in \bar{J}$ and $\mathbf{r}(I) \in \bar{J}$. In this case $\mathrm{sz}(I) \leq \mathrm{sz}(J)$. When we transform intervals, we work with the matrix representations of MT rather than with the transformations themselves. Möbius transformations are represented by matrices

$$
\mathbb{M}(\mathbb{R})=\left\{M_{(a, b, c, d)} \in \mathrm{GL}(\mathbb{R}, 2): a d-b c>0\right\}
$$

which act on vectors $x \in \mathbb{R}^{2}$ by $x \mapsto M x$. Two matrices represent the same MT if one is a nonzero multiple of the other and the matrix multiplication corresponds to the composition of MT. If $M \in \mathbb{M}(\mathbb{R})$ and $I \in \mathbb{I}(\mathbb{R})$, then $M I$ is the interval which represents the $M$-image of the set interval of $I$.

## 4 Rational intervals

Denote by $\mathbb{Z}$ the set of integers and by $\overline{\mathbb{Q}}=\left\{x \in \mathbb{Z}^{2} \backslash\left\{\frac{0}{0}\right\}: \operatorname{gcd}(x)=1\right\}$ the set of (homogeneous coordinates of) rational numbers which we understand as a subset of $\overline{\mathbb{R}}$. Here $\operatorname{gcd}(x)$ is the greatest common divisor of $x_{0}$ and $x_{1}$. The norm of a vector $x \in \overline{\mathbb{Q}}$ is $\|x\|=\sqrt{x_{0}^{2}+x_{1}^{2}}$. Denote by

$$
\begin{aligned}
\mathbb{M}(\mathbb{Z}) & =\{M \in \mathrm{GL}(\mathbb{Z}, 2): \operatorname{gcd}(M)=1, \operatorname{det}(M)>0\}, \\
\mathbb{I}(\mathbb{Z}) & =\{I \in \mathrm{GL}(\mathbb{Z}, 2): \operatorname{gcd}(I)=1, \operatorname{det}(I)<0\} .
\end{aligned}
$$

The norm of a matrix $M_{(a, b, c, d)} \in \mathrm{GL}(\mathbb{Z}, 2)$ is $\|M\|=\sqrt{a^{2}+b^{2}+c^{2}+d^{2}}$. We have $\|M N\| \leq\|M\| \cdot\|N\|$ for $M, N \in \mathbb{M}(\mathbb{Z})$.

Lemma 1 If $I \in \mathbb{I}(\mathbb{Z})$ is an interval, then

$$
\sqrt{2 \cdot|\operatorname{det}(I) \cdot \mathrm{sz}(I)|} \leq\|I\| \leq 2 \cdot|\operatorname{det}(I)| \cdot \max \{|\mathrm{sz}(I)|, 1\} .
$$

Proof. Let $I=\left(\frac{a}{c}, \frac{b}{d}\right)$. Then $2 \cdot|\operatorname{det}(I) \cdot \mathrm{sz}(I)|=2|a b+c d| \leq\|I\|^{2}$, and we get the first inequality. To prove the second inequality, we show that in all cases $\max \{|a|,|b|,|c|,|d|\} \leq|\operatorname{det}(I)| \cdot \max \{|\operatorname{sz}(I)|, 1\}$. If $a=0$ or $d=0$ then $0 \neq|b c|=|\operatorname{det}(I)|$ and $|\operatorname{det}(I) \cdot \mathrm{sz}(I)|$ is either $|c d|$ or $|a b|$ and the claim is satisfied. If $b=0$ or $c=0$ then $0 \neq|a d|=|\operatorname{det}(I)|$ and $|\operatorname{det}(I) \cdot \mathrm{sz}(I)|$ is either $|c d|$ or $|a b|$ and the claim is satisfied. If $\operatorname{sgn}(a b) \cdot \operatorname{sgn}(c d)>0$ then

$$
|a| \cdot|b|+|c| \cdot|d|=|a b+c d|=|\operatorname{sz}(I) \cdot \operatorname{det}(I)|
$$

and the claim is satisfied. If $\operatorname{sgn}(a b) \cdot \operatorname{sgn}(c d)<0$ then $\operatorname{sgn}(a d) \cdot \operatorname{sgn}(b c)=$ $\operatorname{sgn}(a b c d)=\operatorname{sgn}(a b) \cdot \operatorname{sgn}(c d)<0$ and $|a| \cdot|d|+|b| \cdot|c|=|a d-b c|=|\operatorname{det}(I)|$, so the claim is satisfied.

Lemma 2 If $I \in \mathbb{I}(\mathbb{Z}), \mathrm{sz}(I)<0$ and $x \in I \cap \overline{\mathbb{Q}}$, then $\|I\| \leq \sqrt{5} \cdot\|x\| \cdot|\operatorname{det}(I)|$ and $|\operatorname{sz}(I)| \leq \frac{5}{2} \|\left. x\right|^{2} \cdot|\operatorname{det}(I)|$.

Proof. Let $x=\frac{p}{q} \in I=\left(\frac{a}{c}, \frac{b}{d}\right)$, and set $\alpha=-\operatorname{det}\left(\frac{a}{c}, \frac{p}{q}\right)=p c-a q, \beta=$ $-\operatorname{det}\left(\frac{p}{q}, \frac{b}{d}\right)=q b-p d$, so $\operatorname{sgn}(\alpha \cdot \beta)>0$. Replacing $x$ by $\frac{-p}{-q}$ if necessary, we can assume that $\alpha>0$ and $\beta>0$. Since $\operatorname{sz}(I)<0$ and $\operatorname{sz}\left(\frac{0}{1}, \frac{1}{0}\right)=0$, either $0 \notin I$ or $\infty \notin I$. Assume first $\infty \notin I$, so $c d=-\operatorname{det}\left(\frac{a}{c}, \frac{1}{0}\right) \cdot \operatorname{det}\left(\frac{1}{0}, \frac{b}{d}\right) \geq 0$. Since $q \neq 0$, $a=(p c-\alpha) / q, b=(p d+\beta) / q$, and $-\operatorname{det}(I)=(\alpha d+\beta c) / q=(\alpha|d|+\beta|c|) /|q|$, so $\alpha, \beta,|d|,|c|$ are bounded by $|q| \cdot|\operatorname{det}(I)|$. It follows that $|a|$ and $|b|$ are bounded by $(|p|+1) \cdot|\operatorname{det}(I)|$, so $\|I\|^{2} \leq 2\left(q^{2}+p^{2}+2|p|+1\right) \cdot \operatorname{det}(I)^{2}$. Similarly if $0 \notin I$, then $a b=-\operatorname{det}\left(\frac{a}{c}, \frac{0}{1}\right) \cdot \operatorname{det}\left(\frac{0}{1}, \frac{b}{d}\right) \geq 0$. Since $p \neq 0, c=(a q+\alpha) / p, d=(q b-\beta) / p$, and $-\operatorname{det}(I)=(\alpha b+\beta a) / p=(\alpha|b|+\beta|a|) /|p|$, so $\alpha, \beta,|a|,|b|$ are bounded by $|p| \cdot|\operatorname{det}(I)|$. It follows that $|c|$ and $|d|$ are bounded by $(|q|+1) \cdot|\operatorname{det}(I)|$, so $\|I\|^{2} \leq 2\left(p^{2}+q^{2}+2|q|+1\right) \cdot \operatorname{det}(I)^{2}$. In both cases $\|I\|^{2} \leq 5 \cdot\|x\|^{2} \cdot \operatorname{det}(I)^{2}$. Similarly we show that $|\mathrm{sz}(I)| \leq \frac{5}{2}| | x \|^{2} \cdot|\operatorname{det}(I)|$.

## 5 Subshifts

For a finite alphabet $\mathbb{A}$ denote by $\mathbb{A}^{*}:=\bigcup_{m \geq 0} \mathbb{A}^{m}$ the set of finite words. Denote $\lambda$ the empty word : $\mathbb{A}^{0}=\{\lambda\}$. The length of a word $u=u_{0} \ldots u_{m-1} \in \mathbb{A}^{m}$ is $|u|=m$. We denote by $\mathbb{A}^{\mathbb{N}}$ the Cantor space of infinite words with the metric $d(u, v)=2^{-k}$, where $k=\min \left\{i \geq 0: u_{i} \neq v_{i}\right\}$. We say that $v \in \mathbb{A}^{*}$ is a subword of $u \in \mathbb{A}^{*} \cup \mathbb{A}^{\mathbb{N}}$ and write $v \sqsubseteq u$, if $v=u_{[i, j)}=u_{i} \ldots u_{j-1}$ for some $0 \leq i \leq j \leq|u|$. The cylinder of $u \in \mathbb{A}^{n}$ is the set $[u]=\left\{v \in \mathbb{A}^{\mathbb{N}}: v_{[0, n)}=u\right\}$. The shift map $\sigma: \mathbb{A}^{\mathbb{N}} \rightarrow \mathbb{A}^{\mathbb{N}}$ is defined by $\sigma(u)_{i}=u_{i+1}$. A subshift is a nonempty set $\Sigma \subseteq \mathbb{A}^{\mathbb{N}}$ which is closed and $\sigma$-invariant, i.e., $\sigma(\Sigma) \subseteq \Sigma$. If $D \subseteq \mathbb{A}^{*}$ then $\Sigma_{D}=\left\{x \in \mathbb{A}^{\mathbb{N}}: \forall u \sqsubseteq x, u \notin D\right\}$ is the subshift (provided it is nonempty) with forbidden words $D$. Any subshift can be obtained in this way. A subshift
is uniquely determined by its language $\mathcal{L}(\Sigma)=\left\{u \in \mathbb{A}^{*}: \exists x \in \Sigma, u \sqsubseteq x\right\}$. Denote by $\mathcal{L}^{n}(\Sigma)=\mathcal{L}(\Sigma) \cap \mathbb{A}^{n}$.

A labelled graph over an alphabet $\mathbb{A}$ is a structure $\mathcal{G}=(V, E, s, t, \ell)$, where $V=|\mathcal{G}|$ is the set of vertices, $E$ is the set of edges, $s, t: E \rightarrow V$ are the source and target maps, and $\ell: E \rightarrow \mathbb{A}$ is a labeling function. The subshift of $\mathcal{G}$ consists of all labels of all paths of $\mathcal{G}$. A subshift is sofic, if it is the subshift of a finite labelled graph. A subshift $\Sigma$ is of finite type (SFT) of order $p$, if its forbidden words have length at most $p$, i.e., if $\Sigma=\Sigma_{D}$ for some set $D \subset \mathbb{A}^{p}$. In this case $u \in \mathbb{A}^{\mathbb{N}}$ belongs to $\Sigma$ iff all subwords of $u$ of length $p$ belong to $\mathcal{L}(\Sigma)$ (see Lind and Marcus [11] or Kůrka [5]).

A finite state transducer is a finite state automaton with a read only input tape in an alphabet $\mathbb{A}$ and a write only output tape in an alphabet $\mathbb{B}$. It is given by a finite labelled graph $\mathcal{G}$ with edges $q \xrightarrow{a / b} r$, where $a \in \mathbb{A} \cup\{\lambda\}$ is an input letter and $b \in \mathbb{B} \cup\{\lambda\}$ is an output letter. We say that the transducer is deterministic on a subshift $\Sigma \subseteq \mathbb{A}^{\mathbb{N}}$ if for each $q \in V$ and $u \in \Sigma$ there exists a unique $v=F_{\mathcal{G}}(u) \in \mathbb{B}^{\mathbb{N}}$ such that $u / v$ is the label of an infinite path with source $q$. Such a transducer determines a continuous mapping $F_{\mathcal{G}}: \Sigma \rightarrow \mathbb{B}^{\mathbb{N}}$. For any finite state transducer, the computation of $F_{\mathcal{G}}$ has linear time complexity.

## 6 Möbius number systems

A Möbius iterative system over an alphabet $\mathbb{A}$ is a map $F: \mathbb{A}^{*} \times \overline{\mathbb{R}} \rightarrow \overline{\mathbb{R}}$ or a family of orientation-preserving Möbius transformations $\left(F_{u}: \overline{\mathbb{R}} \rightarrow \overline{\mathbb{R}}\right)_{u \in \mathbb{A}^{*}}$ satisfying $F_{u v}=F_{u} \circ F_{v}$ and $F_{\lambda}=$ Id. An open almost-cover is a system of open intervals $\mathcal{W}=\left\{W_{a}: a \in \mathbb{A}\right\}$ indexed by the alphabet $\mathbb{A}$, such that $\bigcup_{a \in \mathbb{A}} \overline{W_{a}}=\overline{\mathbb{R}}$. If $W_{a} \cap W_{b}=\emptyset$ for $a \neq b$, then we say that $\mathcal{W}$ is an open partition. We denote by $\mathcal{E}(\mathcal{W})=\left\{\mathbf{l}\left(W_{a}\right), \mathbf{r}\left(W_{a}\right): a \in \mathbb{A}\right\}$ the set of endpoints of $\mathcal{W}$.

Definition 1 A Möbius number system over an alphabet $\mathbb{A}$ is a pair $(F, \mathcal{W})$ where $F: \mathbb{A}^{*} \times \overline{\mathbb{R}} \rightarrow \overline{\mathbb{R}}$ is a Möbius iterative system and $\mathcal{W}=\left\{W_{a}: a \in \mathbb{A}\right\}$ is an almost-cover, such that $W_{a} \subseteq \mathbf{V}\left(F_{a}\right)$ for each $a \in \mathbb{A}$. The interval cylinder of $u \in \mathbb{A}^{n+1}$ is $W_{u}=W_{u_{0}} \cap F_{u_{0}} W_{u_{1}} \cap \cdots \cap F_{u_{[0, n)}} W_{u_{n}}$. The expansion subshift $\mathcal{S}_{\mathcal{W}}$ is defined by $\mathcal{S}_{\mathcal{W}}=\left\{u \in \mathbb{A}^{\mathbb{N}}: \forall k>0, W_{u_{[0, k)}} \neq \emptyset\right\}$. We denote by $\mathcal{L}_{\mathcal{W}}=\mathcal{L}\left(\mathcal{S}_{\mathcal{W}}\right)$ the language of $\mathcal{S}_{\mathcal{W}}$ and by $\mathcal{L}_{\mathcal{W}}^{n}=\mathcal{L}^{n}\left(\mathcal{S}_{\mathcal{W}}\right)$.

For $u v \in \mathcal{L}_{\mathcal{W}}$ we have $W_{u v}=W_{u} \cap F_{u} W_{v}$. Given a $\operatorname{MNS}(F, \mathcal{W})$, we construct nondeterministically the expansion $u \in \mathcal{S}_{\mathcal{W}}$ of $x=x_{0} \in \overline{\mathbb{R}}$ as follows: Choose $u_{0}$ with $x \in W_{u_{0}}$, choose $u_{1}$ with $x_{1}=F_{u_{0}}^{-1}\left(x_{0}\right) \in W_{u_{1}}$, choose $u_{2}$ with $x_{2}=$ $F_{u_{1}}^{-1}\left(x_{1}\right) \in W_{u_{2}}$, etc. Then $x \in W_{u_{[0, n)}}$ for each $n$, so $W_{u}$ is the set of points which have expansion $u$.

Theorem 2 (Kůrka and Kazda [10]) If $(F, \mathcal{W})$ is a $M N S$ over $\mathbb{A}$, then there exists a continuous map $\Phi: \mathcal{S}_{\mathcal{W}} \rightarrow \overline{\mathbb{R}}$ such that for each $u \in \mathcal{S}_{\mathcal{W}}$ and $v \in \mathcal{L}_{\mathcal{W}}$,

$$
\lim _{n \rightarrow \infty} F_{u_{[0, n)}}(i)=\Phi(u),\{\Phi(u)\}=\bigcap_{n \geq 0} \overline{W_{u_{[0, n)}}}, \Phi\left([v] \cap \mathcal{S}_{\mathcal{W}}\right)=\overline{W_{v}}
$$

Here $i$ is the imaginary unit. In fact we have $\Phi(u)=\lim _{n \rightarrow \infty} F_{u_{[0, n)}}(z)$ for each $z \in \mathbb{U}$, and $\mathbf{h}(\Phi(u))=\lim _{n \rightarrow \infty} \widehat{F}_{u_{[0, n)}}(z)$ for each $z \in \mathbb{D}$. If $(F, \mathcal{W})$ is an MNS then $\lim _{n \rightarrow \infty} \max \left\{\left|W_{u}\right|: u \in \mathcal{L}_{\mathcal{W}}^{n}\right\}=0$. This is an immediate consequence of the uniform continuity of $\Phi: \mathcal{S}_{\mathcal{W}} \rightarrow \overline{\mathbb{R}}$.

Definition 3 We say that a $M N S(F, \mathcal{W})$ over $\mathbb{A}$ is an integer MNS if its transformations have integer entries and its intervals have rational endpoints, i.e., if $F_{a} \in \mathbb{M}(\mathbb{Z})$ and $W_{a} \in \mathbb{I}(\mathbb{Z})$ for each $a \in \mathbb{A}$. We say that an integer $M N S$ is modular, if all its transformations have unit determinant $\operatorname{det}\left(F_{a}\right)=1$.

## 7 Sofic Möbius number systems

Definition 4 Let $(F, \mathcal{W})$ be an $M N S$ over an alphabet $\mathbb{A}$. An open partition $\mathcal{V}=\left\{V_{p}: p \in \mathbb{B}\right\}$ is an $\mathbf{S F T}$ refinement of $\mathcal{W}$, if the following two conditions are satisfied for each $a \in \mathbb{A}, p, q \in \mathbb{B}$ :

1. If $V_{p} \cap W_{a} \neq \emptyset$ then $V_{p} \subseteq W_{a}$,
2. If $V_{p} \subseteq W_{a}$ and $V_{q} \cap F_{a}^{-1} V_{p} \neq \emptyset$ then $V_{q} \subseteq F_{a}^{-1} V_{p}$.

In this case we say that ( $F, \mathcal{W}, \mathcal{V}$ ) is a sofic Möbius number system. The base graph $\mathcal{G}_{(\mathcal{W}, \mathcal{V})}$ of $(F, \mathcal{W}, \mathcal{V})$ is an $\mathbb{A}$-labelled graph whose set of vertices are letters of $\mathbb{B}$ and whose labelled edges are $p \xrightarrow{a} q$ if $F_{a} V_{q} \subseteq V_{p} \subseteq W_{a}$. Denote by $\mathbb{C}=\left\{(p, a) \in \mathbb{B} \times \mathbb{A}: V_{p} \subseteq W_{a}\right\}$ and $\mathcal{S}_{(\mathcal{W}, \mathcal{V})} \subseteq \mathbb{C}^{\mathbb{N}}$ the SFT of order two with transitions $(p, a) \rightarrow(q, b)$ iff $p \xrightarrow{a} q$.

Theorem 5 (Kůrka [9]) If $(F, \mathcal{W})$ is an $M N S$, then $\mathcal{S}_{\mathcal{W}}$ is a sofic subshift iff there exists an SFT refinement $\mathcal{V}$ of $\mathcal{W}$. In this case $\mathcal{S}_{\mathcal{W}}$ is the subshift of the base graph $\mathcal{G}_{(\mathcal{W}, \mathcal{V})}$ and we have a factor map $\pi: \mathcal{S}_{(\mathcal{W}, \mathcal{V})} \rightarrow \mathcal{S}_{\mathcal{W}}$ given by $\pi(p, a)=a$.

Theorem 6 (Kůrka [9], Theorem 16) Each modular MNS has a sofic expansion subshift.

An example of a modular MNS has been studied by Raney [14], Niqui [12] and Kůrka [9]. Its alphabet is $\mathbb{A}=\{0,1,2,3\}$, the transformations are

$$
F_{0}(x)=\frac{x}{1+x}, F_{1}(x)=x+1, F_{2}(x)=x-1, F_{3}(x)=\frac{x}{1-x}
$$

and the intervals are $W_{0}=(0,1), W_{1}=(1, \infty), W_{2}=(\infty,-1), W_{3}=(-1,0)$. Since $F_{a}(0, \infty)=W_{a}$ for $a=0,1$ and $F_{a}(\infty, 0)=W_{a}$ for $a=2,3$, the expansion subshift is a union of two full subshifts which code respectively nonnegative and nonpositive real numbers: $\mathcal{S}_{\mathcal{W}}=\{0,1\}^{\mathbb{N}} \cup\{2,3\}^{\mathbb{N}}$. The system is closely related to continued fractions. Each $u \in\{0,1\}^{\mathbb{N}}$ can be written as $u=1^{a_{0}} 0^{a_{1}} 1^{a_{2}} \ldots$, where $a_{0} \geq 0$ and $a_{n}>0$ for $n>0$. Then $u$ is the expansion of the continued fraction $\left[a_{0}, a_{1}, a_{2}, \ldots\right]$, i.e.,

$$
\Phi(u)=\left[a_{0}, a_{1}, a_{2}, \ldots\right]=a_{0}+1 /\left(a_{1}+1 /\left(a_{2}+\cdots .\right.\right.
$$

If $a_{n}=\infty$ for some $n>0$, then $\Phi(u)=\left[a_{0}, \ldots, a_{n-1}\right]$ is a finite continued fraction.

| $a$ | $F_{a}$ | $W_{a}$ | $F_{a}^{-1} W_{a}$ |
| :---: | :---: | :---: | :---: |
| 0 | $[1,0,1,1]$ | $\left(\frac{0}{1}, \frac{2}{1}\right)$ | $\left(\frac{0}{1}, \frac{2}{-1}\right)$ |
| 1 | $[1,1,0,1]$ | $\left(\frac{1}{2}, \frac{1}{0}\right)$ | $\left(\frac{-1}{2}, \frac{1}{0}\right)$ |

Fig. 1. A modular MNS.

In Figure 1 we show a variant of this system with larger cylinder intervals $W_{a}=\mathbf{V}\left(F_{a}\right)$. Figure 1 bottom left shows the graphs of the circle derivations $\left(F_{a}^{-1}\right)^{\bullet}(x)$ together with the cylinder intervals $W_{a}$. In Figure 1 right we can see the values $\widehat{F}_{u}(0)$ of the disc MT $\widehat{F}_{u}$ at zero. The curves between $\widehat{F}_{u}(0)$ are constructed as follows. For each MT $M$ there exists a family $\left(M^{r}\right)_{r \in \mathbb{R}}$ of MT such that $M^{0}=\mathrm{Id}, M^{1}=M$, and $M^{r+s}=M^{r} M^{s}$. Each value $\widehat{F}_{u}(0)$ is joined to $\widehat{F}_{u a}(0)$ by the curve $\left(\widehat{F}_{u} \widehat{F}_{a}^{r}(0)\right)_{0 \leq r \leq 1}$. The labels $u \in \mathbb{A}^{*}$ at $\widehat{F}_{u}(0)$ are written in the direction of the tangent vectors $\widehat{F}_{u}^{\prime}(0)$. The SFT partition of the system has 8 intervals shown in Figure 2 left. The base graph can be seen in Figure 2 right. The expansion subshift $\mathcal{S}_{\mathcal{W}}$ is a SFT of order 4. with 20 forbidden words $03,12,21,30,020,131,202,313,0220,0232,0233,1322,1323,1331,2002,2010$, 2011, 3100, 3101, 3113.

Theorem 7 If $(F, \mathcal{W}, \mathcal{V})$ is a modular system, then $\pi: \mathcal{S}_{(\mathcal{W}, \mathcal{V})} \rightarrow \mathcal{S}_{\mathcal{W}}$ is an isomorphism, so $\mathcal{S}_{\mathcal{W}}$ is an SFT.

Proof. We show that if $(p, u) \in \mathcal{S}_{(\mathcal{W}, \mathcal{V})}$, then $p \in \mathbb{B}^{\mathbb{N}}$ is determined by $u \in \mathbb{A}^{\mathbb{N}}$. For $0 \leq n<m$ we have $V_{p_{n}} \subseteq W_{u_{n}}$ and $F_{u_{n}} V_{p_{n+1}} \subseteq V_{p_{n}}$, so

$$
\begin{aligned}
& F_{u_{[n, m)}} V_{p_{m}} \subseteq F_{u_{[n, m-1)}} V_{p_{m-1}} \subseteq \cdots \subseteq F_{u_{n}} V_{p_{n+1}} \subseteq V_{p_{n}} \\
& F_{u_{[n, m)}} V_{p_{m}} \subseteq F_{u_{[n, m-1)}} W_{u_{m-1}} \cap \cdots \cap F_{u_{n}} W_{u_{n+1}} \cap W_{u_{n}} \subseteq W_{u_{[n, m)}} .
\end{aligned}
$$

It follows that $\emptyset \neq F_{u_{[n, m)}} V_{p_{m}} \subseteq V_{p_{n}} \cap W_{u_{[n, m)}}$ is nonempty. Denote by $x_{n}=$ $\Phi\left(\sigma^{n}(u)\right)$, so $\left\{x_{n}\right\}=\bigcap_{m>n} \overline{W_{u_{[n, m)}}}$. If $x_{n}$ is irrational, then there exists $m>n$ such that $W_{u_{[n, m)}} \cap \mathcal{E}(\mathcal{V})=\emptyset$, so there exists exactly one $p_{n} \in \mathbb{B}$ with $V_{p_{n}} \cap$

| $p a$ | $V_{p}$ | $F_{a}$ | $F_{a}^{-1} V_{p}$ | followers |
| :---: | :---: | :---: | :---: | :---: |

Fig. 2. The SFT partition and the base graph of a modular system from Figure 1.
$W_{u_{[n, m)}} \neq \emptyset$. Assume that $x_{n}$ is rational. For each $m>n$ we have

$$
x_{m}=\Phi\left(\sigma^{m}(u)\right)=F_{u_{[n, m)}}^{-1}\left(x_{n}\right) \in \overline{W_{u_{m}}} \subseteq \overline{\mathbf{V}\left(F_{u_{m}}\right)},
$$

and $\left\|x_{m}\right\|^{2} /\left\|x_{m+1}\right\|^{2}=\left\|x_{m}\right\|^{2} /\left\|F_{u_{m}}^{-1}\left(x_{m}\right)\right\|^{2}=\left(F_{u_{m}}^{-1}\right) \bullet\left(x_{m}\right) \geq 1$, so $\left\|x_{m+1}\right\| \leq$ $\left\|x_{m}\right\|$. Moreover, if $x_{m} \in W_{u_{m}}$, then $\left\|x_{m+1}\right\|<\left\|x_{m}\right\|$. Since $\left\|x_{m}\right\|^{2} \in \mathbb{N}$, the set $\left\{m \geq n: x_{m} \in W_{u_{m}}\right\}$ is finite and there exists $m>n$ such that either $x_{k}=$ $\mathbf{l}\left(W_{u_{k}}\right)$ for all $k \geq m$, or $x_{k}=\mathbf{r}\left(W_{u_{k}}\right)$ for all $k \geq m$. Since $x_{n}=F_{u_{[n, k)}}\left(x_{k}\right) \in$ $\overline{W_{u_{[n, k)}}} \subseteq F_{u_{[n, k)}} \overline{W_{u_{k}}}$, we get $x_{n}=\mathbf{l}\left(W_{u_{[n, k)}}\right)$ for all $k \geq m$ in the former case and $x_{n}=\mathbf{r}\left(W_{u_{[n, k)}}\right)$ for all $k \geq m$ in the latter case. It follows that there exists $k>m$ such that $W_{u_{[n, k)}} \cap \mathcal{E}(\mathcal{V})=\emptyset$, so there exists a unique $p_{n}$ with $V_{p_{n}} \cap W_{u_{[n, k)}} \neq \emptyset$. This means that $p_{n}$ is uniquely determined by $u$. Since $F_{u_{n-1}} V_{p_{n}} \subseteq V_{p_{n-1}}$, the letter $p_{n-1}$ is uniquely determined by $p_{n}$ and the prefix $p_{[0, n)}$ of $p$ is uniquely determined by $p_{n}$.

Theorem 8 Assume that $(F, \mathcal{W}, \mathcal{V})$ is a modular $M N S$ and for $u \in \mathcal{L}_{\mathcal{W}}$ denote by $\mathcal{P}(u) \subseteq \mathbb{B}^{*}$ the set of paths with label $u$.

1. There exists $r>0$ such that the set $\left\{p_{[0, n-r]}: p \in \mathcal{P}(u)\right\}$ is a singleton for each $n>r$ and each finite word $u \in \mathcal{L}_{\mathcal{W}}^{n}$.
2. There exists $s>0$ such that $\mathcal{P}(u)$ has at most $s$ elements for each $u \in \mathcal{L}_{\mathcal{W}}$.
3. The map $\pi^{-1}: \mathcal{S}_{\mathcal{W}} \rightarrow \mathcal{S}_{(\mathcal{W}, \mathcal{V})}$ can be computed by a finite state transducer.

Proof. The existence of constants $r, s$ follows from Theorem 7 by a compactness argument. We define a finite state transducer for $\pi^{-1}$ as follows. Its vertices are sets $X \subseteq \mathbb{B}^{n}$, where $0<n \leq r$. The labelled edges are

$$
\begin{array}{ll}
X \xrightarrow{a / \lambda}\left\{p \in \mathbb{B}^{n+1}: p_{[0, n-1]} \in X, p_{n-1} \xrightarrow{a} p_{n}\right\} & \text { if } X \subseteq \mathbb{B}^{n}, n<r, \\
X \xrightarrow{a / b}\left\{p \in \mathbb{B}^{r}: b p_{[0, r-2]} \in X, p_{r-2} \xrightarrow{a} p_{r-1}\right\} & \text { if } X \subseteq \mathbb{B}^{r} .
\end{array}
$$

Then $u / p$ is the label of a path with the source $\mathbb{B}$ iff $p$ is a prefix of a path whose label is $u$.

In Table 2 left we show the computation of $\pi^{-1}(u)$ on input word $u=00133$. For each $n>0$ we give the set $\mathcal{P}\left(u_{[0, n)}\right)$ of all paths $p \in \mathbb{B}^{n+1}$ with label $u_{[0, n)}$.

## 8 Arithmetical algorithms

Definition 9 The unary graph for an integer sofic $M N S(F, \mathcal{W}, \mathcal{V})$ is a labelled graph whose vertices are $(X, p)$, where $X \in \mathbb{M}(\mathbb{Z})$ and $p \in \mathbb{B}$. Its labelled edges are

$$
\begin{aligned}
& \text { absorption: }(X, p) \xrightarrow{a / \lambda}\left(X F_{a}, q\right) \quad \text { if } F_{a} V_{q} \subseteq V_{p} \subseteq W_{a} \text {, } \\
& \text { emission: }(X, p) \xrightarrow{\lambda / b}\left(F_{b}^{-1} X, p\right) \text { if } X V_{p} \subseteq W_{b} \text {. }
\end{aligned}
$$

The labels of paths are concatenations of the labels of their edges. They have the form $u / v$ where $u \in \mathcal{L}_{\mathcal{W}}$ is an input word and $v \in \mathcal{L}_{\mathcal{W}}$ is an output word.

Proposition 10 If $(X, p) \xrightarrow{u / v}(Y, q)$ is a path in the unary graph, then

$$
Y=F_{v}^{-1} X F_{u}, F_{u} V_{q} \subseteq V_{p} \cap W_{u}, X F_{u} V_{q} \subseteq W_{v}
$$

Proof. Since $W_{\lambda}=\overline{\mathbb{R}}$ and $F_{\lambda}=\mathrm{Id}$, the statement holds for the absorption and emission edges. Assume by induction that the statement holds for a path with label $u / v$. If $(X, p) \xrightarrow{u / v}(Y, q) \xrightarrow{a / \lambda}(Z, r)$ then $Z=Y F_{a}=F_{v}^{-1} X F_{u a}, F_{a} V_{r} \subseteq V_{q} \subseteq$ $W_{a}$, so $F_{u a} V_{r} \subseteq F_{u} V_{q} \subseteq V_{p} \cap W_{u} \cap F_{u} W_{a}=V_{p} \cap W_{u a}$, and $X F_{u a} V_{r} \subseteq X F_{u} V_{q} \subseteq$ $W_{v}$, so the statement holds for $(X, p) \xrightarrow{u a / v}(Z, r)$. If $(X, p) \xrightarrow{u / v}(Y, q) \xrightarrow{\lambda / b}(Z, q)$ then $Z=F_{b}^{-1} Y=F_{v b}^{-1} X F_{u}$. From $F_{v}^{-1} X F_{u} V_{q}=Y V_{q} \subseteq W_{b}$ we get $X F_{u} V_{q} \subseteq$ $F_{v} W_{b}$, and therefore $X F_{u} V_{q} \subseteq W_{v} \cap F_{v} W_{b}=W_{v b}$. Moreover, $F_{u} V_{q} \subseteq V_{p} \cap W_{u}$, so the statement holds for $(X, p) \xrightarrow{u / v b}(Z, q)$.

Table 2. The computation of a path $p=0017=\pi^{-1}(001333)=\pi^{-1}(u)$ (left) and the computation of $v=010222=\Theta_{M}(p, u)$ on the input matrix $M(x)=(2 x+1) /(x+2)$ and the input path $0 \xrightarrow{0} 0 \xrightarrow{0} 1 \xrightarrow{1} 7 \xrightarrow{3} 7$ by the unary algorithm (right). The third column gives the values $v_{m}$ on emission steps and the empty word on absorption steps. The last column gives the vertex $p_{n}$ on emission steps and the edge $p_{n} \xrightarrow{u_{n}} p_{n+1}$ on absorption steps.

We consider a deterministic unary algorithm given in Table 1, which computes a path in the unary graph. Its input is a matrix $M \in \mathbb{M}(\mathbb{Z})$ and either a finite path $(p, u) \in \mathcal{L}_{(\mathcal{W}, \mathcal{V})}$ or an infinite path $(p, u) \in \mathcal{S}_{(\mathcal{W}, \mathcal{V})}$. We assume that the alphabet $\mathbb{A}$ is linearly ordered. At each step, the algorithm performs the first possible emission if there is one, and an absorption if there is no emission applicable. For an infinite input path, the algorithm computes an output word $v \in \mathcal{S}_{\mathcal{W}}$ such that $u / v$ is the label of a path in the unary graph with source $\left(M, p_{0}\right)$. An example of the computation of the unary algorithm is given in Table 2 right. We are going to prove that for a modular system $(F, \mathcal{W}, \mathcal{V})$, the norm of the state matrix $X$ remains bounded during the computation of the unary algorithm. To do so, we define some constants and prove several lemmas. Set

$$
\begin{aligned}
B_{0} & =\max \{\sqrt{5} \cdot\|x\|: x \in \mathcal{E}(\mathcal{W})\}, & & B_{1}=\max \left\{1,\left|\operatorname{sz}\left(F_{b}^{-1} W_{b}\right)\right|: b \in \mathbb{A}\right\} \\
D_{0} & =\min \left\{\left|\operatorname{det}\left(V_{p}\right)\right|: p \in \mathbb{B}\right\}, & & D_{1}=\max \left\{\left|\operatorname{det}\left(V_{p}\right)\right|: p \in \mathbb{B}\right\}, \\
G & =\max \left\{1,\left\|V_{p}^{-1} F_{a} V_{q}\right\|: p \xrightarrow{\rightarrow} q\right\}, & & H=\max \left\{\sqrt{D_{0}},\left\|V_{p}\right\|: p \in \mathbb{B}\right\}, \\
B & =\max \left\{B_{0}, 2 B_{1}\right\}, & & C_{0}=\max \left\{B^{2} D_{1}^{2} G^{2} / 2 D_{0}, B_{1}\right\}
\end{aligned}
$$

Lemma 3 1. If $(X, p) \xrightarrow{a / \lambda}\left(X F_{a}, q\right)$, then $\operatorname{sz}\left(X F_{a} V_{q}\right)<\mathrm{sz}\left(X V_{p}\right)$.
2. If $(X, p) \xrightarrow{\lambda / b}\left(F_{b}^{-1} X, p\right)$, then $0>\mathrm{sz}\left(X V_{p}\right)<\mathrm{sz}\left(F_{b}^{-1} X V_{p}\right)<B_{1}$.

Proof. The first claim follows from $X F_{a} V_{q} \subseteq X V_{p}$. To prove the second claim, note that for each $M \in \mathbb{M}(\mathbb{Z})$ we have $\operatorname{sz}(\mathbf{V}(M))<0$, so $\mathrm{sz}\left(W_{b}\right)<0$ for each $b \in$ $\mathbb{A}$. If $(X, p) \xrightarrow{\lambda / b}\left(F_{b}^{-1} X, p\right)$ is an emission edge, then $X V_{p} \subseteq W_{b}, \operatorname{sosz}\left(X V_{p}\right)<0$. Since $F_{b}^{-1} X V_{p} \subseteq F_{b}^{-1} W_{b}$, we get $\operatorname{sz}\left(F_{b}^{-1} X V_{p}\right)<B_{1}$. Since $F_{b}^{-1}$ is an expansion on $W_{b}$, we get $\mathrm{sz}\left(X V_{p}\right)<\mathrm{sz}\left(F_{b}^{-1} X V_{p}\right)$.

Lemma 4 If $(X, p) \xrightarrow{a / \lambda}\left(X F_{a}, q\right)$ is an absorption performed by the unary algorithm and $\mathrm{sz}\left(X V_{p}\right)<B_{1}$, then $\left\|X V_{p}\right\|<B D_{1} \operatorname{det}(X),\left|\mathrm{sz}\left(X V_{p}\right)\right|<C_{0} \operatorname{det}(X)$ and $\left|\operatorname{sz}\left(X F_{a} V_{q}\right)\right|<C_{0} \operatorname{det}(X)$.
Proof. We distinguish two cases. If $0 \leq \operatorname{sz}\left(X V_{p}\right)<B_{1}$, then by Lemma 1 we have $\left\|X V_{p}\right\|<2\left|\operatorname{det}\left(X V_{p}\right)\right| \cdot \max \left\{1,\left|\mathrm{sz}\left(X V_{p}\right)\right|\right\} \leq 2 B_{1} D_{1} \operatorname{det}(X)$. If $\operatorname{sz}\left(X V_{p}\right)<0$, then we use the fact that $X V_{p}$ is not contained in any $W_{a}$, so it must contain a point from $\mathcal{E}(\mathcal{W})$. By Lemma $2,\left\|X V_{p}\right\| \leq B_{0} \cdot\left|\operatorname{det}\left(X V_{p}\right)\right| \leq B_{0} D_{1} \operatorname{det}(X)$. Thus in both cases we have $\left\|X V_{p}\right\| \leq B D_{1} \operatorname{det}(X)$. It follows $\left\|X F_{a} V_{q}\right\| \leq\left\|X V_{p}\right\|$. $\left\|V_{p}^{-1} F_{a} V_{q}\right\| \leq B D_{1} G \cdot \operatorname{det}(X)$. By Lemma 1 we get
$\left|\mathrm{sz}\left(X V_{p}\right)\right| \leq\left\|X V_{p}\right\|^{2} / 2\left|\operatorname{det}\left(X V_{p}\right)\right| \leq \frac{B^{2} D_{1}^{2}}{2 D_{0}} \operatorname{det}(X) \leq C_{0} \operatorname{det}(X)$, and similarly $\left|\mathrm{sz}\left(X F_{a} V_{q}\right)\right| \leq \frac{B^{2} D_{1}^{2} G^{2}}{2 D_{0}} \operatorname{det}(X) \leq C_{0} \operatorname{det}(X)$.
Lemma 5 Every infinite path computed by the unary algorithm contains an infinite number of emissions.

Proof. Assume by contradiction that there exists an infinite path of absorptions with vertices $\left(X_{n}, p_{n}\right)$ and label $u / \lambda$, where $u \in \mathcal{S}_{\mathcal{W}}$. Since $F_{u_{[0, n)}} V_{p_{n}} \subseteq W_{u_{[0, n)}}$ and $\lim _{n \rightarrow \infty}\left|W_{u_{[0, n)}}\right|=0$, we get $\lim _{n \rightarrow \infty}\left|X_{0} F_{u_{[0, n)}} V_{p_{n}}\right|=0$ by the continuity of $X_{0}$, and therefore $\lim _{n \rightarrow \infty} \mathrm{sz}\left(X_{0} F_{u_{[0, n)}} V_{p_{n}}\right)=-\infty$. This is in a contradiction with Lemma 4.

Theorem 11 For a modular $M N S(F, \mathcal{W}, \mathcal{V})$ there exists a constant $C>0$ such that for every input matrix $M \in \mathbb{M}(\mathbb{Z})$, the unary algorithm computes a continuous function $\Theta_{M}: \mathcal{S}_{(\mathcal{W}, \mathcal{V})} \rightarrow \mathcal{S}_{\mathcal{W}}$ with $\Phi \Theta_{M}(p, u)=M \Phi(u)$, and the state matrix $X$ satisfies $\|X\|<C \cdot \max \left\{\|M\|^{2}, \operatorname{det}(M)^{2}\right\}$ during the computation.

Proof. Let $\left(X_{n}, p_{n}\right)$ be the vertices of the infinite path with source $\left(X_{0}, p_{0}\right)=$ $\left(M, p_{0}\right)$. If $\mathrm{sz}\left(X_{n} V_{p_{n}}\right)>C_{0} \operatorname{det}(M)$, then $\left(X_{n}, p_{n}\right)$ is an absorption vertex by Lemma 3 and $\mathrm{sz}\left(X_{n+1} V_{p_{n+1}}\right)<\mathrm{sz}\left(X_{n} V_{p_{n}}\right)$. If $\mathrm{sz}\left(X_{n} V_{p_{n}}\right)<-C_{0} \operatorname{det}(M)$, then $\left(X_{n}, p_{n}\right)$ is an emission vertex by Lemma 4 , and $\mathrm{sz}\left(X_{n+1} V_{p_{n+1}}\right)>\mathrm{sz}\left(X_{n} V_{p_{n}}\right)$. Thus there exists $m$, such that for all $n \geq m$ we have $\left|\operatorname{sz}\left(X_{n} V_{p_{n}}\right)\right|<C_{0} \operatorname{det}(M)$ while for $n<m$ we have $\left|\operatorname{sz}\left(X_{n} V_{p_{n}}\right)\right| \leq\left|\operatorname{sz}\left(M V_{p_{0}}\right)\right| \leq \frac{H^{2} \cdot\|M\|^{2}}{2 D_{0} \operatorname{det}(M)}$. By Lemma 1 we get either $\left\|X_{n} V_{p_{n}}\right\| \leq 2 D_{1} C_{0} \operatorname{det}(M)^{2}$ in the former case and $\left\|X_{n} V_{p_{n}}\right\| \leq$ $\frac{H^{2} D_{1}}{D_{0}}\|M\|^{2}$ in the latter case. Taking $C=\max \left\{2 H D_{1} C_{0}, H^{3} D_{1} / D_{0}\right\}$ we get

$$
\left\|X_{n}\right\| \leq\left\|X_{n} V_{p_{n}}\right\| \cdot\left\|V_{p_{n}}^{-1}\right\| \leq C \cdot \max \left\{\|M\|^{2}, \operatorname{det}(M)^{2}\right\}
$$

for all $n$, so the algorithm can be realized by a finite state transducer. By Lemma 5, for each $(p, u) \in \mathcal{S}_{(\mathcal{W}, \mathcal{V})}$ there exists a unique $v=\Theta_{M}(p, u)$ such that $u / v$ is the label of an infinite path with source $\left(M, p_{0}\right)$. For each $m$ there exists $n$ such that $u_{[0, n)} / v_{[0, m)}$ is the label of a finite path with source $\left(M, p_{0}\right)$, $\emptyset \neq F_{u_{[0, n)}} V_{p_{n}} \subseteq W_{u_{[0, n)}}$, and $\emptyset \neq M F_{u_{[0, n)}} V_{p_{n}} \subseteq W_{v_{[0, m)}}$. The intersection $\bigcap_{n} F_{u_{[0, n)}} \overline{V_{p_{n}}} \subseteq \bigcap_{n} \overline{W_{u_{[0, n)}}}$ is nonempty by compactness and has zero diameter, so it contains the unique point $\Phi(u)$. The intersection $\bigcap_{n} M F_{\left.u_{[0, n}\right)} \overline{V_{p_{n}}} \subseteq$ $\bigcap_{m} \overline{W_{v_{[0, m)}}}$ is a nonempty singleton which contains both $M(\Phi(u))$ and $\Phi(v)$, so $M(\Phi(u))=\Phi(v)$.

Corollary 12 If $(F, \mathcal{W}, \mathcal{V})$ is a modular $M N S$, then for each $M \in \mathbb{M}(\mathbb{Z})$ there exists a finite state transducer which computes a continuous function $\Psi_{M}: \mathcal{S}_{\mathcal{W}} \rightarrow$ $\mathcal{S}_{\mathcal{W}}$ which satisfies $\Phi \Psi_{M}=M \Phi$.

Proof. Using Theorems 8 and 11 we get $\Psi_{M}=\Theta_{M} \circ \pi^{-1}$.
A disadvantage of modular systems is that they are not redundant. As shown in Kůrka [7], the cylinder intervals of a modular system contain neither 0 nor $\infty$, so they cannot form a cover but only an almost-cover. In Kůrka [8] we argue that in some redundant MNS, the unary algorithm has asymtotically linear time complexity. The norm of the state matrix remains small most of the time, although fluctuations to larger values occur sporadically.
