# **Preference Elicitation in Prioritized Skyline Queries**

Denis Mindolin · Jan Chomicki

Received: date / Accepted: date

**Abstract** *Preference queries* incorporate the notion of binary *preference relation* into relational database querying. Instead of returning *all* the answers, such queries return only the *best* answers, according to a given preference relation.

Preference queries are a fast growing area of database research. *Skyline* queries constitute one of the most thoroughly studied classes of preference queries. A well known limitation of skyline queries is that skyline preference relations assign the same importance to all attributes. In this work, we study *p-skyline* queries that generalize skyline queries by allowing varying attribute importance in preference relations.

We perform an in-depth study of the properties of pskyline preference relations. In particular, we study the problems of containment and minimal extension. We apply the obtained results to the central problem of the paper: *eliciting relative importance of attributes*. Relative importance is implicit in the constructed p-skyline preference relation. The elicitation is based on user-selected sets of *superior* (positive) and *inferior* (negative) examples. We show that the computational complexity of elicitation depends on whether inferior examples are involved. If they are not, elicitation can be achieved in polynomial time. Otherwise, it is NPcomplete. Our experiments show that the proposed elicitation algorithm has high accuracy and good scalability.

# **1** Introduction

Effective and efficient *user preference management* is a crucial part of any successful sales-oriented business. Knowing *what* customers like and more importantly *why* they like that and what they *will* like in the future is an essential part of the modern risk management process. The essential components of preference management include preference specification, preference elicitation, and querying using preferences. Many preference handling frameworks have been developed [Börzsönyi et al(2001),Kießling and Köstler(2002), Brafman and Domshlak (2002),Chomicki(2003),P. Pu and Torrens(2003), Hansson(1995),Fishburn(1970)].

Our starting point here is the *skyline framework* [Börzsönyi et al(2001)]. The skyline preference relation is defined on top of a set of preferences over individual attributes. It represents the *Pareto improvement* principle: a tuple  $o_1$  is preferred to a tuple  $o_2$  iff  $o_1$  is as good as  $o_2$  according to all the attribute preferences, and  $o_1$  is strictly better than  $o_2$  according to at least one attribute preference. Now given a set of tuples, the set of the best tuples according to this principle is called a *skyline*.

*Example 1* Assume the following cars are available for sale.

	make	price	year
$t_1$	ford	30k	2007
<i>t</i> <sub>2</sub>	bmw	45k	2008
<i>t</i> <sub>3</sub>	kia	20k	2007
$t_4$	ford	40k	2008
$t_5$	bmw	50k	2006

Also, assume that Mary wants to buy a car and her attribute preferences are as follows:

 $\begin{array}{c|c} >_{make} \\ >_{year} \\ >_{price} \end{array} \quad BMW is better than Ford, Ford is better than Kia the car should be as new as possible the car should be as cheap as possible. \end{array}$ 

Then the skyline is

	make	price	year
$t_1$	ford	30k	2007
<i>t</i> <sub>2</sub>	bmw	45k	2008
<i>t</i> <sub>3</sub>	kia	20k	2007
$t_4$	ford	40k	2008

A large number of algorithms for computing skyline queries have been developed [Börzsönyi et al(2001), Chomicki et al(2003) comparable tuples. Godfrey et al(2005), Lin et al(2005)]. Elicitation of skyline preference relations based on user-provided feedback has also been studied [Jiang et al(2008)].

One of the reasons of the popularity of the skyline framework is the simplicity and intuitiveness of skyline semantics. Indeed, in order to define a skyline preference relation, one needs to provide only two parameters: the set  $\mathcal{A}$ of relevant attributes and the set  $\mathcal{H}$  of corresponding preferences over each individual attribute in  $\mathcal{A}$ . (In Example 1,  $\mathcal{A} = \{make, price, year\} \text{ and } \mathcal{H} = \{>_{make}, >_{price}, >_{year}\}.$ 

At the same time, the simplicity of skyline semantics comes with a number of well known limitations. One of them is the inability of skyline preference relations to capture the important notion of difference in attribute importance. The Pareto improvement principle implies that all relevant attributes have the same importance. However, in real life, it is often the case that benefits in one attribute may outweigh losses in one or more attributes. For instance, given two cars that differ in age and price, for some people the age is crucial while the price is secondary. Hence, in that case, the price has to be considered only when the benefits in age cannot be obtained, i.e., when the age of the two cars is the same.

Example 2 Assume that Mary decides that year is more important for her than make and price, which in turn are equally important. Thus, regardless of the values of make and price, a newer car is always better than an old one. At the same time, given two cars of the same age, one needs to compare their *make* and *price* to determine the better one. The set of the best tuples according to this preference relation is

	make	price	year
$t_2$	bmw	45k	2008
t4	ford	40k	2008

Namely,  $t_2$  and  $t_4$  are better than all other tuples in year, but  $t_2$  is better than  $t_4$  in make, and  $t_4$  is better than  $t_2$  in price.

Another drawback of the skyline framework is that the size of a skyline may be exponential in the number of attribute preferences [Godfrey(2004)]. A query result of that size is likely to overwhelm the user. In interactive preference elicitation scenarios [Balke et al(2007)], user preferences are elicited in a stepwise manner. A user is assumed to analyze the set of the best tuples according to the intermediate preference relation and criticize it in some way. Clearly, if such a tuple set is too large, it is hard to a expect high quality feedback from the user. The large size of a skyline is caused by the looseness of the Pareto improvement principle. Pareto improvement implies that if a tuple o is better than o' in one attribute, then the existence of some attribute in which o' is better than o makes the tuples *incomparable*. Thus, every additional attribute increases the number of in-

Here we develop the *p-skyline* framework which generalizes the skyline framework and addresses its limitations listed above: the inability to capture differences in attribute importance and large query results. The skyline semantics is enriched with the notion of attribute importance in a natural way. Assuming two relevant attributes A and B such that A is more important than B, a tuple with a better value of Ais unconditionally preferred to all tuples with worse values of A, regardless of their values of B. However, given a tuple with the same value of A, the one with a better value of Bis preferred (assuming no other attributes are involved). For equally important attributes, the Pareto improvement principle applies. Therefore, skyline queries are also representable in our framework.

Relative attribute importance implicit in a p-skyline preference relation is represented explicitly as a *p*-graph: a graph whose nodes are attributes, and edges go from more to less important attributes. Such graphs satisfy the properties quite natural for importance relationships: transitivity and irreflexivity. We show that, in addition to representing attribute importance, p-graphs play another important role in the pskyline framework: they can be used to determine equivalence and containment of p-skyline relations, and tuple dominance.

We notice that two p-skyline relations may differ in the following aspects:

- the set  $\mathcal{A}$  of relevant attributes,
- the set  $\mathcal{H}$  of preferences over those attributes, and
- the relative importance of the corresponding attributes, represented by a p-graph.

In this work, we are particularly interested in the class  $\mathcal{F}_{\mathcal{H}}$  of full p-skyline relations for which the set of relevant attributes  $\mathcal{A}$  consists of all the attributes and the set of corresponding attribute preferences is  $\mathcal{H}$ . Hence, two different p-skyline relations from  $\mathcal{F}_{\mathcal{H}}$  are different only in the corresponding pgraphs. We show the following properties of such relations:

- the containment and equivalence of p-skyline relations are equivalent to the containment and equivalence of their p-graphs;
- four transformation rules are enough to generate all minimal extensions of a p-skyline relation;
- the number of all minimal extensions of a p-skyline relation is *polynomial* in |A|;
- every  $\subset$ -chain in  $\mathcal{F}_{\mathcal{H}}$  is of *polynomial* length, although  $\mathcal{F}_{\mathcal{H}}$  contains at least  $|\mathcal{A}|!$  relations.

The properties listed above are used to develop the elicitation algorithm and prove its correctness. Incorporating attribute importance into skyline relations allows not only to model user preferences more accurately but also to make the size of the corresponding query results more manageable.

At the same time, enriching the skyline framework with attribute importance comes at a cost. To construct a p-skyline preference relation from a skyline relation, one needs to provide a p-graph describing relative attribute importance. However, requiring users to describe attribute importance explicitly seems impractical for several reasons. First, the number of pairwise attribute comparisons required may be large. Second, users themselves may be not fully aware of their own preferences.

To address this problem, we develop a method of *elicitation* of p-skyline relations based on simple *user-provided feedback*. The type of feedback used in the method consists of two sets of tuples belonging to a given set: *superior examples* [Jiang et al(2008)], i.e., the *desirable* tuples, and *inferior examples* [Jiang et al(2008)] i.e., the *undesirable* tuples. This type of feedback is quite natural in real life: given a set of tuples, a user needs to examine them and identify some tuples she likes and dislikes most. Moreover, it is advantageous from the point of view of user interface design – a user is required to perform a number of simple "check off" actions to identify such tuples. Finally, such feedback can be elicited automatically [Holland et al(2003)].

We consider the problems related to the construction of p-skyline relations covering the given superior and inferior examples. Specifically, we need to guarantee that the superior examples are among the best tuples and that the inferior examples are dominated by at least one other tuple. Also, to guarantee an optimal fit we postulate that the constructed relation be maximal. We show that determining the existence of a p-skyline relation covering the given examples is NPcomplete and constructing a maximal such relation FNPcomplete.

In real-life scenarios of preference elicitation using superior and inferior examples, users may only be indirectly involved in the process of identifying such examples. For instance, the click-through rate may be used to measure the popularity of products. Using this metric, it is easy to find the superior examples – the tuples with the highest clickthrough rate. However, the problem of identifying inferior examples – those which the user confidently dislikes – is harder. Namely, low click-through rate may mean that a tuple is inferior, the user does not know about it, or it simply does not satisfy the search criteria. Thus, there is a need for eliciting p-skyline relations based on superior examples only. We address that problem here. We show a polynomialtime algorithm for checking the existence of a p-skyline relation covering a given set of superior examples, and a polynomial-time algorithm for constructing a maximal p-skyline relation of that kind. The latter algorithm is based on checking the satisfaction of a *system of negative constraints*, each of which captures the fact that one tuple does not dominate another according to the p-skyline relation being constructed.

We provide two effective methods for *reducing* the size of systems of negative constraints and hence improving the performance of the elicitation algorithm. At the same time, we show that the problem of *minimizing* the size of such a system is unlikely to be efficiently solvable. The experimental evaluation of the algorithms on real life and synthetic data sets demonstrates high accuracy and scalability of the elicitation algorithm, as well as the efficacy of the proposed optimization methods.

The paper is organized as follows. In section 2, we introduce the concepts used throughout the paper. In section 3, we describe p-skylines – skylines enriched with relative attribute importance information. We also discuss the fundamental properties of such relations. In section 4, we study the problem of eliciting p-skyline relations based on superior and inferior examples. In Section 5, we show the results of the experimental evaluation of the proposed algorithms. Section 6 concludes the paper with a discussion of related and future work. The proofs of all the results presented in the paper are provided in the Appendix.

#### 2 Basic notations

#### 2.1 Binary relations

A *binary relation* R over a (finite of infinite) set S is a subset of  $S \times S$ . Binary relations may be *finite* or *infinite*. To denote  $(x, y) \in R$ , we may write R(x, y) or x R y. Here we list some typical properties of binary relations. A binary relation R is

- *irreflexive* iff  $\forall x . \neg R(x, x)$ ,
- *transitive* iff  $\forall x, y, z : R(x, y) \land R(y, z) \rightarrow R(x, z)$ ,
- connected iff  $\forall x, y, z : R(x, y) \lor R(y, x) \lor x = y$ ,
- a strict partial order (SPO) if it is irreflexive and transitive,
- a weak order iff it is an SPO such that

$$\forall x, y, z : R(x, y) \to R(x, z) \lor R(z, y),$$

- a total order if it is a connected SPO.

The *transitive closure* TC(R) of a binary relation R is defined as

$$(x, y) \in TC(R)$$
 iff  $R^m(x, y)$  for some  $m > 0$ ,

where

$$R^{1}(x,y) \equiv R(x,y)$$
$$R^{m+1}(x,y) \equiv \exists z . R(x,z) \land R^{m}(z,y)$$

A binary relation  $R \subseteq S \times S$  may be viewed as a directed graph. The set *S* is called *the set of nodes of R* and denoted as N(R). We say that the tuple *xy* is an *R*-edge from *x* to *y* if  $(x,y) \in R$ . A path in *R* (or an *R*-path) from *x* to *y* for an *R*-edge *xy* is a sequence of *R*-edges such that the start node of the first edge is *x*, the end node of the last edge is *y*, and the end node of every edge (except the last one) is the start node of the next edge in the sequence. The *length of an R*path is the number of *R*-edges in the path. An *R*-sequence is the sequence of nodes participating in an *R*-path. The *length* of an *R*-sequence is the number of nodes in it.

Given a directed graph *R* and its node *x*,

- $Ch_R(x) = \{y \mid (x, y) \in R\}$  is the set of *children of x in R*,
- $Pa_R(x) = \{y \mid (y,x) \in R\}$  is the set of *parents of x in R*,
- $Pa_R^*(x) = Pa_R(x) Pa_R(Pa_R(x))$  is the set of *immediate* parents of x in R,
- $Desc_R(x) = \{y \mid (x, y) \in TC(R)\}$  is the set of *descendents* of x in R,
- $Anc_R(x) = \{y \mid (y,x) \in TC(R)\}$  is the set of *ancestors of* x in R,
- $Sibl_R(x) = N(R) (Desc_R(x) \cup Anc_R(x) \cup \{x\})$  is the set of siblings of x in R

We also write  $Desc-self_R(x)$  and  $Anc-self_R(x)$  as shorthands of  $(Desc_R(x) \cup \{x\})$  and  $(Anc_R(x) \cup \{x\})$ , respectively. Similarly, we define set versions of the above definitions, e.g.,  $Ch_R(X) = \{y \mid \exists x \in X.(x,y) \in R\}.$ 

Given two nodes *x* and *y* of *R* and two sets of nodes *X* and *Y* of *R*, we write

- $R \models x \sim y \text{ iff } (x, y) \notin R \text{ and } (y, x) \notin R;$  $- R \models X \sim Y \text{ iff } \forall x \in X, y \in Y . R \models x \sim y;$
- $(X,Y) \in R$  iff  $\forall x \in X, y \in Y . (x,y) \in R$ .

## 2.2 Preference relations

Below we describe some concepts of a variant of the preference framework [Chomicki(2003)], which we adopt here.

Let  $\mathcal{A} = \{A_1, ..., A_n\}$  be a finite set of attributes (a relation schema). Every attribute  $A_i \in \mathcal{A}$  is associated with an *infinite domain*  $\mathcal{D}_{A_i}$ . The domains considered here are rationals and uninterpreted constants (numerical or categorical).

We work with the *universe of tuples*  $\mathcal{U} = \prod_{A_i \in \mathcal{A}} \mathcal{D}_{A_i}$ . Given a tuple  $o \in \mathcal{U}$ , we denote the value of its attribute  $A_i$  as  $o.A_i$ .

Preference relations we consider in this paper are of two types: *attribute* and *tuple*.

**Definition 1** (Attribute preference relation) An *attribute* preference relation  $>_{A_i}$  for an attribute  $A_i \in \mathcal{A}$  is a subset of  $\mathcal{D}_{A_i} \times \mathcal{D}_{A_i}$ , which is a *total order* over  $\mathcal{D}_{A_i}$ .

An attribute preference relation describes a preference over the values of a single attribute e.g., the *red* color is preferred to the *blue* color, or the make *BMW* is preferred to the make *Kia*.

**Definition 2 (Tuple preference relation)** A *tuple preference relation*  $\succ$  is a subset of  $\mathcal{U} \times \mathcal{U}$ , which is a strict partial order over  $\mathcal{U}$ .

In contrast to an attribute preference relation, a tuple preference relation describes a preference over *tuples*, e.g., a *red BMW* is preferred to a *blue Kia*. We say that

- a tuple o<sub>1</sub> dominates (is preferred to, is better than) a tuple o<sub>2</sub>, and
- $o_2$  is dominated by (is worse than)  $o_1$ ,

according to a preference relation  $\succ$ , iff  $t_1 \succ t_2$ . In the remaining part of the paper, tuple preference relations are simply referred to as preference relations.

We assume that both attribute and tuple preferences are defined as quantifier-free formulas over some appropriate signature. In this way both finite and infinite preference relations can be captured. For instance, the following formula defines an *infinite* tuple preference relation over the domains of the attributes *make*, *year*, and *price*.

$$o_1 \succ_1 o_2 = o_1.$$
year  $\ge o_2.$ year  $\land o_1.$ price  $\le o_2.$ price $\land$   
 $(o_1.$ make  $= BMW \land o_2.$ make  $= Ford \lor$   
 $o_1.$ make  $= Ford \land o_2.$ make  $= Kia\lor$   
 $o_1.$ make  $= BMW \land o_2.$ make  $= Kia\lor$   
 $o_1.$ make  $= o_2.$ make)  $\land (o_1.$ year  $\neq o_2.$ year  $\lor$   
 $o_1.$ price  $\neq o_2.$ price  $\lor o_1.$ make  $\neq o_2.$ make)

Given a tuple preference relation, the two most common tasks are:

- 1. *dominance testing*: checking if a tuple is preferred to another one, and
- 2. *computing the best (most preferred) tuples* in a given finite set of tuples.

The first problem is easily solved by checking if the formula representing the preference relation evaluates to true for the given pair of tuples. (Nevertheless, we will revisit this problem in section 3.) To deal with the second problem, a new *winnow* relational algebra operator was proposed [Chomicki(2003), Kießling(2002)]. **Definition 3 (Winnow)** If  $\succ$  is a tuple preference relation over  $\mathcal{U}$ , then the *winnow* operator  $\omega_{\succ}(\mathcal{A})$  is defined as

 $\omega_{\succ}(r) = \{t \in r \mid \neg \exists t' \in r \, : \, t' \succ t\}.$ 

for every finite subset r of  $\mathcal{U}$ .

# 3 p-skylines

Let  $\mathcal{A} = \{A_1, ..., A_n\}$  be a finite set of attributes and  $\mathcal{H} = \{>_{A_1}, ..., >_{A_n}\}$  be a set of the corresponding attribute preference relations. Below we define the syntax and the semantics of p-skyline relations.

**Notation:** We use "=" for syntactic identity of expressions and " $\equiv$ " for equality of relations viewed as sets of tuples.

**Definition 4** (**p-expression**) An expression  $\pi$  is a *p-expression* if

 $-\pi$  is  $>_{A_i}$  for  $A_i \in \mathcal{A}$ , or

- $-\pi = \pi_1 \otimes \pi_2$  for two p-expressions  $\pi_1$  and  $\pi_2$ , or
- $-\pi = \pi_1 \& \pi_2$ , for two p-expressions  $\pi_1$  and  $\pi_2$ .

**Definition 5** (**Relevant attributes**) Given a p-expression  $\pi$ , the corresponding *set of relevant attributes*  $Var(\pi)$  is:

- $\{A_i\}, \text{ if } \pi \text{ is } >_{A_i};$
- $Var(\pi_1) \cup Var(\pi_2)$  for  $\pi = \pi_1 \& \pi_2$  or  $\pi = \pi_1 \otimes \pi_2$ , where  $\pi_1$  and  $\pi_2$  are p-expressions.

Given a set of attributes X

 $o_1 \approx_X o_2$  iff  $\forall A \in X.o_1.A = o_2.A$ .

## Definition 6 (Preference relation induced by p-expression)

The preference relation  $\succ_{\pi}$  induced by a *p*-expression  $\pi$  is defined as

1. if  $\pi$  is  $>_{A_i}$  and  $A_i \in \mathcal{A}$ ,

$$\succ_{\pi} \equiv \{(o,o') \mid o,o' \in \mathcal{U} : o.A >_{A_i} o'.A\},\$$

and  $\succ_{\pi}$  is also written as  $\succ_{A_i}$ , and called an *atomic* preference relation,

2. for  $\pi = \pi_1 \& \pi_2$ ,

$$\succ_{\pi} \equiv \succ_{\pi_1} \cup (\approx_{Var(\pi_1)} \cap \succ_{\pi_2}),$$

3. for 
$$\pi = \pi_1 \otimes \pi_2$$
,

$$\succ_{\pi} \equiv (\succ_{\pi_1} \cap \approx_{Var(\pi_2)}) \cup (\succ_{\pi_2} \cap \approx_{Var(\pi_1)}) \cup (\succ_{\pi_1} \cap \succ_{\pi_2}),$$

where  $\succ_{\pi_1}$  and  $\succ_{\pi_2}$  are preference relations induced by the p-expressions  $\pi_1$  and  $\pi_2$ .

In the second case, we say that  $\succ_{\pi} \equiv \succ_{\pi_1} \& \succ_{\pi_2}$  and in the third case, that  $\succ_{\pi} \equiv \succ_{\pi_1} \otimes \succ_{\pi_2}$ . We also refer to the set of relevant attributes  $Var(\pi)$  of  $\pi$  as  $Var(\succ_{\pi})$ . When the context in clear, we may omit the subscript  $\pi$  and refer to p-skyline relations as  $\succ, \succ_1, \succ_2, \ldots$ . Note the difference between the *attribute* preference relation  $>_A$  and the *tuple* preference relation  $\succ_A$ . However, the correspondence between those two relations is straightforward.

The intuition behind Definition 6 is as follows. In the first case,  $\succ_{A_i}$  is the tuple preference relation corresponding to the attribute preference relation  $>_{A_i}$ . In the second case,  $\succ_{\pi}$  is composed of  $\succ_{\pi_1}$  and  $\succ_{\pi_2}$  in such a way that  $\succ_{\pi_1}$  has *higher importance* than  $\succ_{\pi_2}$ : a tuple *o* is preferred to *o'* according to  $\succ_{\pi}$  iff *o* is preferred to *o'* according to  $\succ_{\pi_1}$  and *o* is preferred to *o'* according to  $\succ_{\pi_1}$  and *o* is preferred to *o'* according to the preferred to *o'* according to  $\succ_{\pi_2}$ , or *o* and *o'* are *equal* in all the relevant attributes of  $\succ_{\pi_1}$  and *o* is preferred to *o'* according to  $\succ_{\pi_2}$ . The operator & is called *prioritized accumulation* [Kießling(2002)]. Similarly, if  $\pi = \pi_1 \otimes \pi_2$ , then  $\succ_{\pi_1}$  and  $\succ_{\pi_2}$  are considered to be *equally important* in  $\succ_{\pi}$ . The operator  $\otimes$  is called *Pareto accumulation* [Kießling(2002)]. Some known properties of these operators are summarized below.

**Proposition 1** [Kießling(2002)] *The operators*  $\otimes$  *and* & *are associative. The operator*  $\otimes$  *is commutative.* 

Since accumulation operators are associative, we extend them from binary to n-ary operators.

**Proposition 2** [Kießling(2002)] *A relation induced by a p*-*expression is an SPO, i.e., a tuple preference relation.* 

**Definition 7 (p-skyline relation)** A *p-skyline relation*  $\succ_{\pi}$  is the relation induced by a p-expression  $\pi$  such that for all subexpressions of  $\pi$  of the form  $\pi_1 \& \pi_2$  or  $\pi_1 \otimes \pi_2$ :

-  $Var(\pi_1) \cap Var(\pi_2) = \emptyset;$ 

– the relations induced by  $\pi_1$  and  $\pi_2$  are p-skyline relations.

A p-skyline relation  $\succ_{\pi}$  induced by  $\pi$  is *full* iff  $Var(\pi) = \mathcal{A}$ .

Essentially, p-skyline relations are induced by those pexpressions in which every member of  $\mathcal{H}$  is used at most once (exactly once in the case of full p-skyline relations). The set of *all full p-skyline relations* for  $\mathcal{H}$  is denoted by  $\mathcal{F}_{\mathcal{H}}$ . Further we consider only full p-skyline relations.

A key property of p-skyline relations is that the *skyline* preference relation  $sky_{\mathcal{H}}$  is the p-skyline relation induced by the p-expression  $>_{A_1} \otimes \ldots \otimes >_{A_n}$ . That is, the p-skyline framework is an *extension* of the skyline framework.

# 3.1 Syntax trees

Dealing with p-skyline relations, it is natural to represent the corresponding p-expressions as *syntax trees*. This representation is used in Section 3.4 for constructing minimal extensions of a p-skyline relation. Every *non-leaf node* of the syntax tree is labeled with an accumulation operator and corresponds to the result of applying the operator to the p-skyline relations represented by its children, from left to right. Every *leaf* node of the syntax tree is labeled with an attribute  $A \in \mathcal{A}$  and corresponds to the attribute preference relation  $>_A \in \mathcal{H}$  (and the atomic preference relation  $\succ_A$ ).

**Definition 9** (Normalized syntax tree) A syntax tree is *normalized* iff each of its non-leaf nodes is labeled differently from its parent.

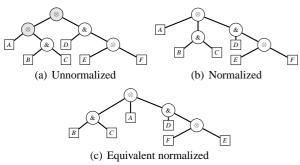

Clearly, for every p-skyline relation, there is a normalized syntax tree which may be constructed in polynomial time in the size of the original tree. To do that, one needs to find all occurrences of syntax tree nodes  $C_1$  and their children  $C_2$  such that  $C_1$  and  $C_2$  have the same label. After that,  $C_2$  has to be removed from the list of children of  $C_1$ , and the list of children of  $C_2$  has to be added to the list of children of  $C_1$  in place of  $C_2$ . The correctness of this procedure follows from Proposition 1.

We note that a normalized syntax tree is not unique for a p-skyline relation. That is due to the commutativity of  $\otimes$  (Proposition 1).

*Example 3* Let a p-skyline relation  $\succ^{1}$  be defined as

$$\succ = (\succ_A \otimes (\succ_B \& \succ_C)) \otimes (\succ_D \& (\succ_E \otimes \succ_F))$$

An unnormalized syntax tree of  $\succ$  is shown in Figure 1(a). Two normalized syntax trees of  $\succ$  are shown in Figures 1(b) and 1(c).

Every node of a syntax tree is itself a root of another syntax tree. Let us associate with every node C of a syntax

Fig. 2 P-graphs from Example 4

tree the set Var(C) of attributes which are descendants of *C* in the syntax tree or *C* itself (if it is a leaf). Essentially, Var(C) corresponds to  $Var(\pi_C)$  where  $\pi_C$  is the p-expression represented by the subtree with the root node *C*.

# 3.2 Attribute importance in p-skyline relations

Recall that the p-skyline relations composed using & (resp.  $\otimes$ ) have different (resp. equal) importance in the resulting relation. However, the composed p-skyline relations do not have to be *atomic* and may themselves be composed using & or  $\otimes$ . The problem we discuss in this section is *how to represent relative importance of attributes in different subtrees*. For this purpose, we define another graphical representation of a p-skyline relation – the *p*-graph.

**Definition 10** (**p-graph**) The *p-graph*  $\Gamma_{\succ}$  of a p-skyline relation  $\succ$  has the set of nodes  $N(\Gamma_{\succ}) = Var(\succ)$  and the set of edges  $E(\Gamma_{\succ})$ :

-  $E(\Gamma_{\succ}) = \emptyset$ , if  $\succ$  is an atomic preference relation; -  $E(\Gamma_{\succ}) = E(\Gamma_{\succ_1}) \cup E(\Gamma_{\succ_2})$ , if  $\succ = \succ_1 \otimes \succ_2$ ; -  $E(\Gamma_{\succ}) = E(\Gamma_{\succ_1}) \cup E(\Gamma_{\succ_2}) \cup (Var(\succ_1) \times Var(\succ_2))$ , if  $\succ = \succ_1 \& \succ_2$ ,

for two p-skyline relations  $\succ_1$  and  $\succ_2$ .

A p-graph represents the attribute importance relationships implicit in a p-skyline relation  $\succ$  in the following way: an edge in  $E(\Gamma_{\succ})$  goes from a *more important* attribute to a *less important* attribute. This follows from Definition 10: if  $\succ = \succ_1 \otimes \succ_2$  (i.e.,  $\succ_1$  and  $\succ_2$  are equally important in  $\succ$ ), then no new attribute importance relationships are added to  $E(\Gamma_{\succ})$ , and those which exist in  $E(\Gamma_{\succ_1})$  and  $E(\Gamma_{\succ_2})$  are preserved in  $E(\Gamma_{\succ})$ . Similarly, if  $\succ = \succ_1 \& \succ_2$ , then the attribute importance relationships in  $E(\Gamma_{\succ_1})$  and  $E(\Gamma_{\succ_2})$  are preserved in  $E(\Gamma_{\succ})$ , but new importance relationships are added: every attribute relevant to  $\succ_1$  is more important than every attribute relevant to  $\succ_2$ .

*Example 4* Take the p-skyline relations  $\succ_1$  and  $\succ_2$  as below. Their p-graphs are shown in Figure 2.

$$\succ_1 \equiv (\succ_A \otimes \succ_B) \& \succ_C$$
$$\succ_2 \equiv \succ_A \otimes \succ_B \otimes \succ_C$$

In the previous section, we showed that the skyline relation  $sky_{\mathcal{H}}$  is constructed as the Pareto accumulation of all the members of  $\mathcal{H}$ . Hence, the following holds.

<sup>&</sup>lt;sup>1</sup> Strictly speaking, we should use attribute preference relations from  $\mathcal{H}$ , instead of atomic preference relations. However, due to the close correspondence of the two kinds of relations, we abuse the notation a bit.

**Proposition 3** The p-graph  $\Gamma_{\text{sky}_{\mathcal{H}}}$  of the skyline relation  $\text{sky}_{\mathcal{H}}$  has the set of nodes  $N(\Gamma_{\text{sky}_{\mathcal{H}}}) = \mathcal{A}$  and the set of edges  $E(\Gamma_{\text{sky}_{\mathcal{H}}}) = \emptyset$ .

Theorem 1 shows that p-graphs indeed represent attribute importance. According to the theorem, a p-skyline relation can be decomposed into "dimensions" which are attribute preference relations. This decomposition shows which attribute preferences (resp. the corresponding attributes) are *less important* than a given attribute preference (resp. the corresponding attribute) in a preference relation.

**Theorem 1** Every *p*-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  is equal to

$$\succ \equiv TC\left(\bigcup_{A\in\mathcal{A}}q_A\right),$$

where

$$q_A \equiv \{(o_1, o_2) \mid o_1 A >_A o_2 A\} \cap \approx_{\mathcal{A} - (Ch_{\Gamma_{\succ}}(A) \cup \{A\})}.$$

The relation  $q_A$  may be viewed as a "projection" of the pskyline relation  $\succ$  to a "dimension" which is a preference relation over A. Comparing tuples on the attribute A one needs to consider only the attributes  $\mathcal{A} - (Ch_{\Gamma_{\succ}}(A) \cup \{A\})$  The values of the remaining attributes  $Ch_{\Gamma_{\succ}}(A)$  do not matter: those attributes are *less important* than A. The relation  $\succ'$  above can also be viewed as a relaxed *ceteris paribus preference relation* [Boutilier et al(2004)], for which attribute preferences are unconditioned on each other, and "*everything else being equal*" is replaced with " $\mathcal{A} - (Ch_{\Gamma_{\succ}}(A) \cup \{A\})$  being *equal*".

Now let us take a closer look at the properties of pgraphs. Since p-graphs represent attribute importance implicit in p-skyline relations, there are some properties of importance relationships that p-graphs are expected to have, for example *SPO*. In particular:

- no attribute should be more important than itself (irreflexivity), and
- if an attribute A is more important than an attribute B which is more important than an attribute C, A is expected to be more important than C too (transitivity).

As Theorem 2 shows, a p-graph is indeed an SPO<sup>2</sup>.

However, a graph needs to satisfy some additional properties in order to be a p-graph of some p-skyline relation. In particular, there is a requirement that the p-expression inducing the p-skyline relation contain exactly one occurrence of each member of  $\mathcal{H}$ . This requirement is captured by the Envelope property visualized in Figure 3: if a graph  $\Gamma$  has the three bold edges, then it must have at least one dashed edge.

# Theorem 2 (SPO+Envelope)

A directed graph  $\Gamma$  with the set of nodes A is a p-graph of some p-skyline relation iff

- 1.  $\Gamma$  is an SPO, and
- 2. Γ satisfies the Envelope property:

$$\begin{array}{l} \forall A, B, C, D \in \mathcal{A}, all \ different \\ (A, B) \in \Gamma \land \ (C, D) \in \Gamma \land (C, B) \in \Gamma \Rightarrow \\ (C, A) \in \Gamma \lor (A, D) \in \Gamma \lor (D, B) \in \Gamma \end{array}$$

Fig. 3 The Envelope property

We note that so far we have introduced two graph notations for p-skyline relations: syntax trees and p-graphs. Although these notations represent different concepts, there is a correspondence between them shown in the next proposition.

**Proposition 4 (Syntax tree and p-graph correspondence)** Let A and B be leaf nodes in a normalized syntax tree  $T_{\succ}$  of a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$ . Then  $(A,B) \in \Gamma_{\succ}$  iff the least common ancestor C of A and B in  $T_{\succ}$  is labeled by &, and A precedes B in the left-to-right tree traversal.

## 3.3 Properties of p-skyline relations

In this section, we show several fundamental properties of p-skyline relations. These properties are used later to efficiently perform essential operations on p-skyline relations: checking equivalence and containment of relations and (tuple) dominance testing. Before going further, we note that p-skyline relations are representable as formulas constructed from the corresponding p-expressions. So one can use such formulas to perform the operations mentioned above. For example, relation containment corresponds to formula implication. However, we show below more direct ways of performing the operations on p-skyline relations. The results presented in this section are used in sections 3.4 and 4.

Recall Example 3, where we showed that a p-skyline relation may have more than one syntax tree (and hence pexpression) defining it. In contrast, as shown in the next theorem, the p-graph corresponding to a p-skyline relation is *unique*.

**Theorem 3 (p-graph uniqueness)** Two p-skyline relations  $\succ_1, \succ_2 \in \mathcal{F}_{\mathcal{H}}$  are equal iff their p-graphs are identical.

<sup>&</sup>lt;sup>2</sup> The SPO properties of p-graphs should not be confused with the SPO properties of the p-skyline relations. In the former case, we are talking about ordering *attributes*; in the latter, about ordering *tuples*.

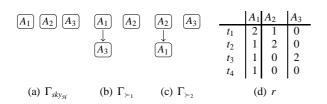

Fig. 4 Containment of p-skyline relations

According to Theorem 3, to check equality of p-skyline relations, one only needs to compare their p-graphs. As the next theorem shows, containment of p-skyline relations may be also checked using p-graphs.

**Theorem 4** (p-skyline relation containment) For *p*-skyline relations  $\succ_1, \succ_2 \in \mathcal{F}_{\mathcal{H}}, \succ_1 \subset \succ_2 \Leftrightarrow E(\Gamma_{\succ_1}) \subset E(\Gamma_{\succ_2}).$ 

Theorem 4 implies an important result. Recall that in Corollary 3 we showed that the edge set of the p-graph  $\Gamma_{sky_{\mathcal{H}}}$  of the skyline preference relation  $sky_{\mathcal{H}}$  is empty. Hence, the following facts are implied by Theorem 4.

**Corollary 1** For every relation instance r and p-skyline relations  $\succ_1$ ,  $\succ_2 \in \mathcal{F}_{\mathcal{H}}$ , s.t.  $\Gamma_{\succ_2} \subset \Gamma_{\succ_1}$ , we have  $\omega_{\succ_1}(r) \subseteq \omega_{\succ_2}(r) \subseteq \omega_{\text{sky}_{\mathcal{H}}}(r)$ 

The importance of Corollary 1 is that for every p-skyline relation, the winnow query result will always be contained in the corresponding skyline. In real life, that means that if user preferences are modeled as a p-skyline relation instead of a skyline relation, the size of the query result will not be larger than the size of the skyline, and may be smaller.

*Example 5* Let  $\mathcal{A} = \{A_1, A_2, A_3\}$ , and for every attribute, larger values are preferred. Consider the relations

$$sky_{\mathcal{H}} = \succ_{A_1} \otimes \succ_{A_2} \otimes \succ_{A_3} \\ \succ_1 = (\succ_{A_1} \& \succ_{A_3}) \otimes \succ_{A_2} \\ \succ_2 = (\succ_{A_2} \& \succ_{A_1}) \otimes \succ_{A_3}$$

whose p-graphs are shown in Figures 4(a), 4(b), and 4(c), respectively. Theorems 4 and 3 imply that  $sky_{\mathcal{H}} \subset \succ_1$ ,  $sky_{\mathcal{H}} \subset \succ_2$ ,  $\succ_1 \not\subseteq \succ_2$ , and  $\succ_2 \not\subseteq \succ_1$ . Take the relation instance r shown in Figure 4(d). Then  $\omega_{sky_{\mathcal{H}}}(r) = \{t_1, t_2, t_3\}, \omega_{\succ_1}(r) = \{t_1, t_2\}, \text{ and } \omega_{\succ_2}(r) = \{t_2, t_3\}.$ 

In Theorem 5, we show how one can directly test tuple dominance. The dominance is expressed in terms of *containment constraints* on attribute sets. This formulation is essential for our approach to preference elicitation (section 4).

Given two tuples  $o, o' \in \mathcal{U}$ , a p-skyline relation  $\succ$  and its p-graph  $\Gamma_{\succ}$ , let

- Diff(o, o') be the attributes in which o differs from o':

$$Diff(o,o') = \{A \in \mathcal{A} \mid o_1.A \neq o_2.A\},\$$

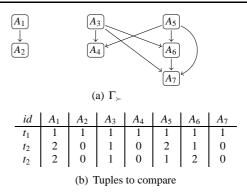

Fig. 5 Theorem 5 for dominance testing

-  $Top_{\succ}(o, o')$  be the topmost members of Diff(o, o'):

$$Top_{\succ}(o,o') = \{A \mid A \in Diff(o,o') \land \\ \neg \exists B \in Diff(o,o'). \ B \in Pa_{\Gamma_{\succ}}(A)\},\$$

- BetIn(o, o') be the attributes in which o is better than o':

 $BetIn(o_1, o_2) = \{A \in \mathcal{A} \mid o_1.A >_A o_2.A\}.$ 

**Theorem 5** (p-skyline dominance testing) Let  $o, o' \in \mathcal{U}$ s.t.  $o \neq o'$  and  $\succ \in \mathcal{F}_{\mathcal{H}}$ . Then the following conditions are equivalent:

1.  $o \succ o'$ ; 2.  $BetIn(o,o') \supseteq Top_{\succ}(o,o')$ ; 3.  $Ch_{\Gamma_{\succ}}(BetIn(o,o')) \supseteq BetIn(o',o)$ .

*Example* 6 Let  $\mathcal{A} = \{A_1, \dots, A_7\}$ , and for every attribute, larger values are preferred. Let a p-skyline relation  $\succ$  be represented by the p-graph shown in Figure 5(a). Consider the tuples  $t_1$ ,  $t_2$ ,  $t_3$  shown in Figure 5(b).  $BetIn(t_1, t_2) =$  $\{A_2, A_4, A_7\}$ ,  $BetIn(t_2, t_1) = \{A_1, A_5\}$ ,  $Diff(t_1, t_2) = \{A_1, A_2, A_4, A_5, A_7\}$ , and  $Top_{\succ}(t_1, t_2) = \{A_1, A_5\}$ . Thus,  $t_2 \succ t_1$ ,  $t_1 \not\succ t_2$ ,  $BetIn(t_1, t_3) = \{A_2, A_4, A_7\}$ ,  $BetIn(t_3, t_1) = \{A_1, A_6\}$ ,  $Diff(t_1, t_3) = \{A_1, A_2, A_4, A_6, A_7\}$ , and  $Top_{\succ}(t_1, t_3) = \{A_1, A_6\}$ .  $A_4, A_6\}$ . So  $t_3 \not\succ t_1$  and  $t_1 \not\succ t_3$ .

In Theorem 2, we showed that p-graphs satisfy SPO+ Envelope, where the property Envelope was formulated in terms of single p-graph nodes. However, it is often necessary to deal with *sets* of nodes. The next theorem generalizes the Envelope property to disjoint sets of nodes.

**Theorem 6** (GeneralEnvelope) Let  $\succ$  be a p-skyline relation with the p-graph  $\Gamma_{\succ}$ , and  $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}$ , disjoint node sets of  $\Gamma_{\succ}$ . Let the subgraphs of  $\Gamma_{\succ}$  induced by those node sets be singletons or unions of at least two disjoint subgraphs. Then

$$\begin{aligned} (\mathbf{A},\mathbf{B}) \in \Gamma_{\succ} \land (\mathbf{C},\mathbf{D}) \in \Gamma_{\succ} \land (\mathbf{C},\mathbf{B}) \in \Gamma_{\succ} \Rightarrow \\ (\mathbf{C},\mathbf{A}) \in \Gamma_{\succ} \lor (\mathbf{A},\mathbf{D}) \in \Gamma_{\succ} \lor (\mathbf{D},\mathbf{B}) \in \Gamma_{\succ} \end{aligned}$$

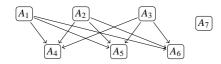

Fig. 6 The GeneralEnvelope property

Unlike Envelope which holds for every combination of four different nodes, the property of GeneralEnvelope holds for node subsets of a special form. That form is quite general. For instance,  $Var(\succ)$  induces disjoint subgraphs if  $\succ$  is defined as Pareto accumulation of p-skyline relations. Theorem 6 is used in the following section.

*Example* 7 Let  $\mathcal{A} = \{A_1, \dots, A_7\}$ . Consider the p-graph  $\Gamma_{\succ}$  (Figure 6) of

 $\succ = ((\succ_{A_1} \otimes \succ_{A_2} \otimes \succ_{A_3}) \& (\succ_{A_4} \otimes \succ_{A_5} \otimes \succ_{A_6})) \otimes \succ_{A_7}$ Let  $\mathbf{A} = \{A_1\}, \mathbf{B} = \{A_4\}, \mathbf{C} = \{A_2, A_3\}, \mathbf{D} = \{A_5, A_6\}$ . Then the p-graph satisfies GeneralEnvelope because

$$(\mathbf{A},\mathbf{B})\in\Gamma_{\succ}\wedge(\mathbf{C},\mathbf{D})\in\Gamma_{\succ}\wedge(\mathbf{C},\mathbf{B})\in\Gamma_{\succ}\wedge(\mathbf{A},\mathbf{D})\in\Gamma_{\succ}$$

## 3.4 Minimal extensions

We conclude this section by studying the notion of *minimal extension* of a p-skyline relation. This notion is central for our approach to preference elicitation (section 4). Intuitively, we will construct a p-skyline relation that incorporates user feedback using an iterative process that starts from the skyline relation and extends it repeatedly in a minimal way.

**Definition 11 (p-extension)** For a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$ , a p-skyline relation  $\succ_{ext} \in \mathcal{F}_{\mathcal{H}}$  is a *p-extension of*  $\succ$  if  $\succ \subset \succ_{ext}$ . The p-extension  $\succ_{ext}$  is *minimal* if there exists no  $\succ' \in \mathcal{F}_{\mathcal{H}}$  such that  $\succ \subset \succ' \subset \succ_{ext}$ .

Theorem 4 implies that for every p-skyline relation  $\succ$ , a p-extension  $\succ_{ext}$  of  $\succ$ , if it exists, may be obtained by constructing an extension  $\Gamma_{\succ_{ext}}$  of the p-graph  $\Gamma_{\succ}$ . Hence, the problem of constructing a minimal p-extension of a pskyline relation can be reduced to the problem of finding a minimal set of edges that when added to  $\Gamma_{\succ}$  form a graph satisfying SPO+Envelope. However, it is not clear how to find such a minimal set of edges efficiently: adding a single edge to a graph may not be enough due to violation of SPO+Envelope, as shown in the following example.

*Example* 8 Take the relation  $\succ$  from Example 7 (Figure 6), and add the edge  $(A_6, A_7)$  to its p-graph. Then to preserve SPO, we need to add the edges  $(A_1, A_7)$ ,  $(A_2, A_7)$ , and  $(A_3, A_7)$ . The resulting graph satisfies SPO+Envelope. However, if instead of the edge  $(A_6, A_7)$ , we add the edge  $(A_3, A_7)$ , then for preserving Envelope, it is enough to add  $(A_1, A_7)$  and  $(A_2, A_7)$  (other extension possibilities exist too). The resulting graph satisfies SPO+Envelope.

The method of constructing all minimal p-extensions we propose in this paper operates directly on normalized p-expressions represented as syntax trees. In particular, we show a set of transformation rules of syntax trees such that every unique application of a rule from this set results in a unique minimal p-extension of the original p-skyline relation. If *all* minimal p-extensions of a p-skyline relation are needed, then one needs to apply to the syntax tree *every* rule in every possible way.

The transformation rules are shown in Figure 8. On the left hand side, we show a part of the syntax tree of an original p-skyline relation. On the right hand side, we show how this part is modified in the resulting relation. We assume that the rest of the syntax tree is left unchanged. All the transformation rules operate on two children  $C_i$  and  $C_{i+1}$  of a  $\otimes$  -node of the syntax tree. For simplicity, these nodes are shown as consecutive children. However, in general  $C_i$  and  $C_{i+1}$  may be any pair of children nodes of the same  $\otimes$ -node. Their order is unimportant due to the associativity of  $\otimes$ .

Let us denote the original relation as  $\succ$  and the relation obtained as the result of applying one of the transformation rules as  $\succ_{ext}$ . Observation 1 shows that all the rules only *add* edges to the p-graph of the original preference relation and hence extend the p-skyline relation.

**Observation 1** If  $T_{\succ_{ext}}$  is obtained from  $T_{\succ}$  using some of  $Rule_1, \ldots, Rule_4$ , then  $E(\Gamma_{\succ}) \subset E(\Gamma_{\succ_{ext}})$ . Moreover,

 $\begin{aligned} &- if T_{\succ_{ext}} \text{ is a result of } Rule_1(T_{\succ}, C_i, C_{i+1}), \text{ then} \\ &E(\Gamma_{\succ_{ext}}) = E(\Gamma_{\succ}) \cup \{(X,Y) \mid X \in Var(N_1), Y \in Var(C_{i+1})\} \\ &- if T_{\succ_{ext}} \text{ is a result of } Rule_2(T_{\succ}, C_i, C_{i+1}), \text{ then} \\ &E(\Gamma_{\succ_{ext}}) = E(\Gamma_{\succ}) \cup \{(X,Y) \mid X \in Var(C_{i+1}), Y \in Var(N_m)\} \\ &- if T_{\succ_{ext}} \text{ is a result of } Rule_3(T_{\succ}, C_i, C_{i+1}), \text{ then} \\ &E(\Gamma_{\succ_{ext}}) = E(\Gamma_{\succ}) \cup (C_i, C_{i+1}) \\ &- if T_{\succ_{ext}} \text{ is a result of } Rule_4(T_{\succ}, C_i, C_{i+1}, s, t) \text{ for } s \in [1, n-1], t \in [1, m-1], \text{ then } E(\Gamma_{\succ_{ext}}) = E(\Gamma_{\succ}) \cup \end{aligned}$ 

$$\{(X,Y) \mid X \in \bigcup_{p \in 1...s} Var(N_p), Y \in \bigcup_{q \in t+1...n} Var(M_q)\} \cup \\ \{(X,Y) \mid X \in \bigcup_{p \in 1...t} Var(M_p), Y \in \bigcup_{q \in s+1...m} Var(N_q)\}$$

We note that every & - and  $\otimes$  -node in a syntax tree has to have at least two children nodes. This is because the operators & and  $\otimes$  must have at least two arguments. However, as a result of a transformation rule application, some & - and  $\otimes$  -nodes may end up with only one child node. These nodes are:

- 1. R' if k = 2 for  $Rule_1, Rule_2, Rule_3, Rule_4$ ;
- 2.  $R'_2$  if m = 2 for  $Rule_1, Rule_2$ ;
- 3.  $R'_3$  or  $R'_5$  if s = 1 or s = m 1, respectively, for  $Rule_4$ ;

Fig. 7 Single-child node elimination ( $\delta \in \{ \ \& \ , \ \otimes \ \})$ 

4.  $R'_4$  or  $R'_6$  if t = 1 or t = n - 1, respectively, for  $Rule_4$ .

In such cases, we remove the nodes with a single child and connect the child directly to the parent (Figure 7).

**Theorem 7 (minimal p-extension)** Let  $\succ \in \mathcal{F}_{\mathcal{H}}$ , and  $T_{\succ}$  be a normalized syntax tree of  $\succ$ . Then  $\succ_{ext}$  is a minimal p-extension of  $\succ$  iff the syntax tree  $T_{\succ_{ext}}$  of  $\succ_{ext}$  is obtained from  $T_{\succ}$  by a single application of a rule from Rule<sub>1</sub>,..., Rule<sub>4</sub>, followed by a single-child node elimination if necessary.

Theorem 7 has two important corollaries describing properties of minimal p-extensions.

**Corollary 2** For a p-skyline relation  $\succ$  with a normalized syntax tree  $T_{\succ}$ , a syntax tree  $T_{\succ_{ext}}$  of each of its minimal p-extensions  $\succ_{ext}$  may be constructed in time  $O(|\mathcal{A}|)$ .

In Corollary 2, we assume the adjacency-list representation of syntax trees. The total number of nodes in a tree is linear in the number of its leaf nodes [Cormen et al(2001)], which is  $|\mathcal{A}|$ . Thus the number of edges in  $T_{\succ}$  is  $O(|\mathcal{A}|)$ . The transformation of  $T_{\succ}$  using every rule requires removing  $O(|\mathcal{A}|)$  and adding  $O(|\mathcal{A}|)$  edges.

**Corollary 3** For a p-skyline relation  $\succ$ , the number of its minimal p-extensions is  $O(|\mathcal{A}|^4)$ .

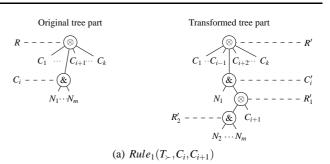

The justification for Corollary 3 is as follows. The set of minimal-extension rules is complete due to Theorem 7. Every rule operates on two nodes  $C_i$  and  $C_{i+1}$  of the syntax tree. Hence, the number of such node pairs is  $O(|\mathcal{A}|^2)$ . *Rule4* also relies on some partitioning of the sequence of child nodes of  $C_i$  and  $C_{i+1}$ . The total number of such partitionings is  $O(|\mathcal{A}|^2)$ . Thus, the total number of different rule applications is  $O(|\mathcal{A}|^2)$ . Consequently, the number of minimal pextensions is *polynomial* in the number of attributes. This differs from the number of *all* p-extensions of a p-skyline relation, which is  $\Omega(|\mathcal{A}|!)$ .

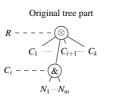

The last property related to p-extensions that we consider here is as follows. By Theorem 4, a p-extension of a p-skyline relation is obtained by adding edges to its p-graph. However, the total number of edges in a p-graph is at most  $O(|\mathcal{A}|^2)$ . Hence, the next Corollary holds.

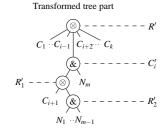

Corollary 4 Let S be a sequence of p-skyline relations

 $\succ_1,\ldots,\succ_k \in \mathcal{F}_{\mathcal{H}}$ 

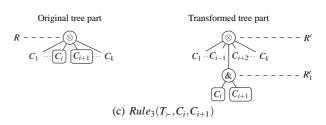

such that for every  $i \in [1, k-1]$ ,  $\succ_{i+1}$  is a p-extension of  $\succ_i$ . Then  $|S| = O(|\mathcal{A}|^2)$ .

 $\begin{array}{c} \hline C_i \\ C_i \end{array} - \text{leaf node} \\ \hline C_i \\ - \text{leaf or non-leaf node} \end{array}$ 

## 4 Elicitation of p-skyline relations

In Section 3, we proposed a class of preference relations called *p-skyline relations*. In this section, we introduce a method of constructing p-skyline relations based on user-provided feedback.

#### 4.1 Feedback-based elicitation

As we showed in the previous section, the p-skyline framework is a generalization of the skyline framework. The main difference between those frameworks is that in the p-skyline framework one can express varying attribute importance. On the other hand, one of the main distinguishing properties of the skyline framework is the simplicity of representing preferences. Namely, the user needs to provide only a set of attribute preferences to specify a preference relation. For pskylines, an additional piece of information, the relative importance of the attributes (in the form of, e.g., a p-graph or a p-expression), has to be also provided by the user. But how can relative attribute importance be specified? It seems impractical to ask the user to compare distinct attributes pairwise for importance: even though some relationships can be deduced by transitivity, the number of comparisons may still be too large. Another issue is even more serious: the users themselves may be not fully aware of their own preferences.

In this section, we propose an alternative approach to elicitation of attribute importance relationships, based on user feedback. We use the following scenario. A fixed, finite set of tuples is stored in a database relation  $O \subseteq U$ . All the tuples have the same set of attributes  $\mathcal{A}$ . We assume that, in addition to  $\mathcal{A}$ , a corresponding set of attribute preference relations  $\mathcal{H}$  is given. The user partitions  $\mathcal{O}$  into three disjoint subsets: the set G of tuples she confidently likes (superior examples), the set W of tuples she confidently dislikes (inferior examples), and the set of remaining tuples about which she is not sure. The output of our method is a p-skyline relation  $\succ$  (with the set of relevant attributes  $\mathcal{A}$ ), according to which all tuples in G are superior and all tuples in W are inferior. A tuple  $o \in O$  is *superior* if O does not contain any tuples preferred to o, according to  $\succ$ . A tuple  $o \in O$  is *infe*rior if there is at least one superior example in O, which is preferred to o. The last assumption is justified by a general principle that the user considers something bad because she knows of a better alternative.

Formally: given  $\mathcal{A}$ ,  $\mathcal{H}$ ,  $\mathcal{O}$ , G, and W, we want to construct a p-expression inducing a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  such that

- 1.  $G \subseteq \omega_{\succ}(\mathcal{O})$ , i.e., the tuples in *G* are among the most preferred tuples in *O*, according to  $\succ$ , and
- 2. for every tuple o' in W, there is a tuple o in G such that  $o \succ o'$ , i.e., o' is an inferior example.

Such a p-skyline relation  $\succ$  is called *favoring G and disfavoring W in O*. We may also skip "in *O*" when the context is clear.

The first problem we consider is the existence of a pskyline relation favoring *G* and disfavoring *W* in *O*.

**Problem DF–PSKYLINE.** Given a set of attributes  $\mathcal{A}$ , a set of attribute preference relations  $\mathcal{H}$ , a set of superior examples G and a set of inferior examples W in a set O, determine if there exists a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring G and disfavoring W in O.

In most real life scenarios, knowing that a favoring/disfavoring p-skyline relation *exists* is not sufficient. One needs to know the *contents* of such a relation.

**Problem FDF–PSKYLINE.** Given a set of attributes  $\mathcal{A}$ , a set of attribute preference relations  $\mathcal{H}$ , a set of superior examples G and a set of inferior examples W in a set O, construct a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring G and disfavoring W in O.

We notice that FDF-PSKYLINE is the *functional version* [Papadimitriou(1994)] of DF-PSKYLINE. Namely, given subsets *G* and *W* of *O*, an instance of FDF-PSKYLINE outputs "no" if there is no  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring *G* and disfavoring *W* in *O*. Otherwise, it outputs *some* p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring *G* and disfavoring *W* in *O*.

*Example 9* Let the set *O* consist of the following tuples describing cars for sale:

	make	price	year
$t_1$	ford	30k	2007
<i>t</i> <sub>2</sub>	bmw	45k	2008
$t_3$	kia	20k	2007
$t_4$	ford	40k	2008
$t_5$	bmw	50k	2006

Assume also Mary wants to buy a car and her preferences over automobile attributes are as follows.

 $>_{make}$ : *BMW* is better than *Ford*, *Ford* is better than *Kia*.  $>_{year}$ : higher values of *year* (i.e., newer cars) are preferred.  $>_{price}$ : lower values of *price* (i.e., cheaper cars) are preferred.

Let  $G = \{t_4\}$ ,  $W = \{t_3\}$ . We elicit a p-skyline relation  $\succ$  favoring G and disfavoring W. First,  $>_{make}$  cannot be more important than all other attribute preferences, since then  $t_2$  and  $t_5$  dominate  $t_4$  and thus  $t_4$  is not superior. Moreover,  $>_{price}$  cannot be more important than the other attribute preferences, because then  $t_3$  and  $t_1$  dominate  $t_4$ . However, if  $>_{year}$  is more important than the other attribute preferences, then  $t_4$  dominates  $t_1, t_3, t_5$  and  $t_2$  does not dominate  $t_4$  in  $>_{year}$ . At the same time, both  $t_2$  and  $t_4$  are the best according to  $>_{year}$ , but  $t_2$  dominates  $t_4$  in  $>_{make}$ . Therefore,  $>_{make}$  should not be more important than  $>_{price}$ . Thus, for example, the following p-skyline relation <sup>3</sup> favors G and disfavors W in O

 $\succ_1 = \succ_{year} \& (\succ_{price} \otimes \succ_{make})$ 

The set of the best tuples in *O* according to  $\succ_1$  is  $\{t_2, t_4\}$ .

<sup>&</sup>lt;sup>3</sup> Here we again replace attribute preference relations by atomic preference relations.

Generally, there may be zero, one or more p-skyline relations favoring *G* and disfavoring *W* in *O*. When more than one such relation exists, we pick a *maximal* one (in the settheoretic sense). Larger preference relations imply more dominated tuples and fewer most preferred ones. Consequently, the result of  $\omega_{\succ}(O)$  is likely to get more manageable due to its decreasing size. Moreover, maximizing  $\succ$  corresponds to minimizing  $\omega_{\succ}(O) - G$ , which implies more precise correspondence of  $\succ$  to the real user preferences. Thus, the next problem considered here is constructing maximal p-skyline relations favoring *G* and disfavoring *W*.

**Problem OPT-FDF-PSKYLINE.** Given a set of attributes  $\mathcal{A}$ , a set of attribute preference relations  $\mathcal{H}$ , a sets of superior examples G and a set of inferior examples W in a set O, construct a maximal p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring G and disfavoring W in O.

*Example 10* Take *G*, *W*, and  $\succ_1$  from Example 9. Note that to make  $t_4$  dominate  $t_2$ , we need to make *price* more important than *year*. As a result, the relation

$$\succ_2 = \succ_{year} \& \succ_{price} \& \succ_{make}$$

also favors *G* and disfavors *W* in *O* but the set of best tuples in *O* according to  $\succ_2$  is  $\{t_4\}$ . Moreover,  $\succ_2$  is *maximal*. The justification is that no other p-skyline relation favoring *G* and disfavoring *W* contains  $\succ_2$  since the p-graph of  $\succ_2$  is a total order of the attributes  $\{year, price, make\}$  and thus  $\succ_2$ is a maximal SPO.

Even though the notion of maximal favoring/disfavoring reduces the space of alternative p-skyline relations, there may still be more than one maximal favoring/disfavoring p-skyline relation, given  $\mathcal{A}$ ,  $\mathcal{H}$ , G, W, and O.

#### 4.2 Negative and positive constraints

We formalize now the kind of reasoning from Examples 9 and 10 using *constraints on attribute sets*. The constraints guarantee that the constructed p-skyline relation favors G and disfavors W in O.

Consider the notion of *favoring* G in O first. For a tuple  $o' \in G$  to be in the set of the most preferred tuples of O, o' must not be dominated by any tuple in O. That is,

$$\forall o \in \mathcal{O}, o' \in G . o \not\succ o' \tag{1}$$

Using Theorem 5, we can rewrite (1) as

$$\forall o \in \mathcal{O}, o' \in G . Ch_{\Gamma_{\succ}}(BetIn(o, o')) \not\supseteq BetIn(o', o),$$
(2)

where  $BetIn(o_1, o_2) = \{A \in \mathcal{A} \mid o_1.A >_A o_2.A\}$ . Note that no tuple can be preferred to itself by irreflexivity of  $\succ$ . Thus, a

p-skyline relation favoring *G* in *O* should satisfy  $(|O| - 1) \cdot |G|$  *negative* constraints  $\tau$  in the form:

 $\tau: Ch_{\Gamma_{\succ}}(\mathcal{L}_{\tau}) \not\supseteq \mathcal{R}_{\tau}$ 

where  $\mathcal{L}_{\tau} = BetIn(o, o'), \mathcal{R}_{\tau} = BetIn(o', o)$ . We denote this set of constraints as  $\mathcal{N}(G, O)$ .

*Example 11* Take Example 9. Then some p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring  $G = \{t_3\}$  in *O* has to satisfy each negative constraint below

$t_1 \not\succ t_3$	$Ch_{\Gamma_{\succ}}(\{make\}) \not\supseteq \{price\}$
$t_2 \not\succ t_3$	$Ch_{\Gamma_{\succ}}(\{make, year\}) \not\supseteq \{price\}$
$t_4 \not\succ t_3$	$Ch_{\Gamma_{\succ}}(\{make, year\}) \not\supseteq \{price\}$
$t_5 \not\succ t_3$	$Ch_{\Gamma_{\succ}}(\{make\}) \not\supseteq \{price, year\}$

Now consider the notion of *disfavoring* W in O. According to the definition, a p-skyline relation  $\succ$  favoring G disfavors W in O iff the following holds

$$\forall o' \in W \; \exists o \in G \; . \; o \succ o'. \tag{3}$$

Following Theorem 5, it can be rewritten as a set of *positive* constraints  $\mathcal{P}(W, G)$ 

$$\forall o' \in W \ \bigvee_{o_i \in G} Ch_{\Gamma_{\succ}}(BetIn(o_i, o')) \supseteq BetIn(o', o_i).$$

$$\tag{4}$$

Therefore, in order for  $\succ$  to disfavor W in O, it has to satisfy |W| positive constraints.

*Example 12* Take Example 9. Then every p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  favoring  $G = \{t_1, t_3\}$  and disfavoring  $W = \{t_4\}$  in O has to satisfy the constraint

$$t_1 \succ t_4 \lor t_3 \succ t_4$$

which is equivalent to the following positive constraint

$$Ch_{\Gamma_{\succ}}(\{price\}) \supseteq \{year\} \lor Ch_{\Gamma_{\succ}}(\{price\}) \supseteq \{year, make\},$$
  
which in turn is equivalent to

 $Ch_{\Gamma_{\succ}}(\{price\}) \supseteq \{year, make\}.$ 

Notice that positive and negative constraints are formulated in terms of relative importance of the attributes captured by the p-graph of the constructed p-skyline relation. Since p-skyline relations are uniquely identified by p-graphs (Theorem 3), we may refer to *a p-skyline relation satisfying/not satisfying a system of positive/negative constraints*. Formally, a p-skyline relation *satisfies* a system of (positive or negative) constraints iff it satisfies *every constraint* in the system.

Let us summarize the kinds of constraints we have considered so far. To construct a p-skyline relation  $\succ$  favoring G and disfavoring W in O, we need to construct a p-graph  $\Gamma_{\succ}$  that satisfies SPO+Envelope to guarantee that  $\succ$  be a p-skyline relation,  $\mathcal{N}(G, O)$  to guarantee favoring G in O, and  $\mathcal{P}(W, G)$  to guarantee disfavoring W in O. By Theorem 4, the p-graph of a maximal  $\succ$  is maximal among all graphs satisfying SPO+Envelope,  $\mathcal{N}(G, O)$ , and  $\mathcal{P}(W, G)$ .

# 4.3 Using superior and inferior examples

In this section, we study the computational complexity of the problems of existence of a favoring/disfavoring p-skyline relation and of constructing a favoring/disfavoring p-skyline relation.

# **Theorem 8** DF-PSKYLINE is NP-complete.

Now consider the problems of constructing favoring/disfavoring p-skyline relations. First, we consider the problem of constructing *some* p-skyline relation favoring G and disfavoring W in O. Afterwards we address the problem of constructing a *maximal* p-skyline relation. The results shown below are based on the following proposition.

**Proposition 5** Let  $\succ$  be a p-skyline relation, O a finite set of tuples, and G and W disjoint subsets of O. Then the next two operations can be done in polynomial time:

- verifying if ≻ is maximal favoring G and disfavoring W in O;
- constructing a maximal p-skyline relation ≻<sub>ext</sub> that favors G and disfavors W in O, and is a p-extension of ≻ favoring G and disfavoring W in O.

**Theorem 9** FDF–PSKYLINE is FNP-complete

Surprisingly, the problem of constructing a maximal favoring/disfavoring p-skyline relation is not harder then the problem of constructing some favoring/disfavoring p-skyline relation.

**Theorem 10** OPT-FDF-PSKYLINE is FNP-complete

#### 4.4 Using only superior examples

In view of Theorems 8, 9, and 10, we consider now restricted versions of the favoring/disfavoring p-skyline relation problems, where we assume no inferior examples ( $W = \emptyset$ ). Denote as DF<sup>+</sup>-PSKYLINE, FDF<sup>+</sup>-PSKYLINE, and OPT-FDF<sup>+</sup>-PSKYLINE the subclasses of DF-PSKYLINE, FDF-PSKYLINE, and OPT-FDF-PSKYLINE in which the sets of inferior examples W are empty. We show now that these problems are easier than their general counterparts: they can all be solved in polynomial time.

Consider DF<sup>+</sup>-PSKYLINE first. We showed in Corollary 1 that the set of the best objects according to the skyline preference relation is the largest among all p-skyline relations. Hence, the next proposition holds.

**Proposition 6** *There exists a p-skyline relation*  $\succ \in \mathcal{F}_{\mathcal{H}}$  *favoring G in O iff* 

Proposition 6 implies that to solve  $DF^+$ -PSKYLINE, one needs to run a skyline algorithm over O and check if the result contains G. This clearly can be done in polynomial time.

FDF<sup>+</sup>–PSKYLINE can also be solved in polynomial time: if  $G \subseteq \omega_{sky_{\mathcal{H}}}(O)$ , then  $sky_{\mathcal{H}}$  is a relation favoring *G* and disfavoring *W* in *O*. Otherwise, there is no such a relation.

Now consider OPT-FDF<sup>+</sup>-PSKYLINE. To specify a pskyline relation  $\succ$  favoring G in O, we need to construct the corresponding graph  $\Gamma_{\succ}$  which satisfies  $\mathcal{N}(G, O)$  and SPO+Envelope. Furthermore, to make the relation  $\succ$  maximal favoring G in O,  $\Gamma_{\succ}$  has to be a *maximal* graph satisfying these constraints. In the next section, we present an algorithm for constructing maximal p-skyline relations.

#### 4.4.1 Syntax tree transformation

Our approach to constructing maximal favoring p-skyline relations favoring G is based on iterative transformations of normalized syntax trees. We assume that the provided set of superior examples G satisfies Proposition 6, i.e.,  $G \subseteq$  $\omega_{sky_{a\ell}}(O)$ . The idea beyond our approach is as follows. First, we generate the set of negative constraints  $\mathcal{N}(G, \mathcal{O})$ . The pskyline relation we start with is  $sky_{\mathcal{H}}$  since it is the least p-skyline relation favoring G in O. In every iteration of the algorithm, we pick an attribute preference relation in  $\mathcal{H}$  and apply a fixed set of transformation rules to the syntax tree of the current p-skyline relation. As a result, we obtain a "locally maximal" p-skyline relation satisfying the given set  $\mathcal{N}(G, O)$  of negative constraints. Recall that a negative constraint in  $\mathcal{N}(G, \mathcal{O})$  represents the requirement that no tuple in G is dominated by a tuple in O. Eventually, this technique produces a maximal p-skyline relation satisfying  $\mathcal{N}(G, \mathcal{O})$ .

Let us describe now what we mean by "locally maximal".

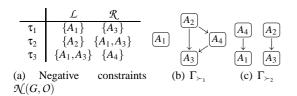

**Definition 12** Let *M* be a nonempty subset of  $\mathcal{A}$ . A p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  that favors *G* in *O* such that  $E(\Gamma_{\succ}) \subseteq M \times M$  is *M*-favoring *G* in *O*.

We note that, similarly to a maximal favoring p-skyline relation, a maximal M-favoring p-skyline relation is often not unique for given G, O, and M.

$id A_1 A_2 A_3 A_4$	Ĺ	R	$A_2$
$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$egin{array}{ccc}  au_1 & \{A_1\} \  au_2 & \{A_2\} \  au_3 & \{A_1,A_3\} \end{array}$	$\{A_3\}$	
$t_2  1  0  -1  0$	$\tau_2  \{A_2\}$	$\{A_1, A_3\}$	$[A_1] \downarrow [A_4]$
$\begin{array}{c ccccccccccccccccccccccccccccccccccc$	$\tau_3 \{A_1, A_3\}$	$\{A_4\}$	$\left(A_{3}\right)$
$t_4 \mid 1  0  1  -1$			
(a) Set of tuples $O$	(b) Negative $\mathcal{N}(G, O)$	constraint	s (c) maximal <i>M</i> -favoring

			p-skyline
			relation

Fig. 9 Example 13

 $G \subseteq \omega_{\mathrm{sky}_{\mathscr{H}}}(\mathcal{O}).$ 

#### Fig. 10 Example 14

*Example 13* Let  $\mathcal{A} = \{A_1, A_2, A_3, A_4\}$  and  $\mathcal{H} = \{>_{A_1}, >_{A_2}, >_{A_3}, >_{A_4}\}$ , where a greater value of the corresponding attribute is preferred, according to every  $>_{A_i}$ . Let the set of objects O be as shown in Figure 9(a) and  $G = \{t_1\}$ . Then the set of negative constraints  $\mathcal{N}(G, O)$  is shown in Figure 9(b). Consider the p-skyline relation  $\succ$  represented by the p-graph  $\Gamma_{\succ}$  shown in Figure 9(c). It is a maximal  $\{A_1, A_2, A_3\}$ -favoring relation because  $\Gamma_{\succ}$  satisfies all the constraints in  $\mathcal{N}(G, O)$  and every additional edge from one attribute to another attribute in  $\{A_1, A_2, A_3\}$  violates  $\mathcal{N}(G, O)$ . In particular, the edge  $(A_1, A_3)$  violates  $\tau_1$  and the edge  $(A_2, A_1)$  violates  $\tau_2$ . Every other edge between  $A_1, A_2$  and  $A_3$  induces one of the two edges above.

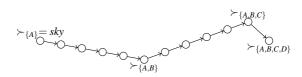

At the same time,  $\succ$  is not a maximal  $\mathcal{A}$ -favoring relation because, for example, the edge  $(A_4, A_1)$  may be added to  $\Gamma_{\succ}$ without violating  $\mathcal{N}(G, O)$ .

By Definition 12, the edge set of the p-graph of every maximal *M*-favoring relation is maximal among all the pgraphs of *M*-favoring relations. Note that if *M* is a singleton, the edge set of a p-graph  $\Gamma_{\succ}$  of a maximal *M*-favoring relation  $\succ$  is empty, i.e.,  $\succ = sky_{\mathcal{H}}$ . If  $M = \mathcal{A}$ , then a maximal p-skyline relation *M*-favoring *G* in *O* is also a maximal pskyline relation favoring *G* in *O*. Thus, if we had a method of transforming a maximal *M*-favoring p-skyline relation to a maximal  $(M \cup \{A\})$ -favoring p-skyline relation for each attribute *A*, we could construct a maximal favoring p-skyline relation iteratively. A useful property of such a transformation process is shown in the next proposition.

**Proposition 7** Let a relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  be a maximal *M*-favoring relation, and a p-extension  $\succ_{ext}$  of  $\succ$  be  $(M \cup \{A\})$ -favoring. Then every edge in  $E(\Gamma_{\succ_{ext}}) - E(\Gamma_{\succ})$  starts or ends in *A*.

*Example 14* Consider  $\mathcal{N}(G, O)$  from Example 13 (also depicted in Figure 10(a)), and the maximal  $\{A_1, A_2, A_3\}$ -favoring relation  $\succ$ . Several different maximal  $\mathcal{A}$ -favoring p-skyline relations containing  $\succ$  exist. Two of them are  $\succ_1$  and  $\succ_2$  whose p-graphs are shown in Figures 10(b) and 10(c).

In section 3.4, we showed four syntax tree transformation rules ,  $Rule_1 - Rule_4$ , for extending p-skyline relations in a minimal way. Although a maximal  $(M \cup \{A\})$ -favoring p-skyline relation is a p-extension of a maximal *M*-favoring p-skyline relation, it is not necessary a minimal p-extension

**Fig. 11** A path to a maximal  $\mathcal{A}$ -favoring p-skyline relation. The path starts from the maximal singleton-favoring p-skyline relation: the skyline relation. Every step is a minimal p-extension. The path goes through maximal *M*-favoring p-skyline relations ( $\succ_{\{A\}}, \succ_{\{A,B\}}, \ldots$ ) for incrementally increasing *M*. The path ends with a maximal *M*-favoring p-skyline relation for  $M = \mathcal{A}$ .

in general. However, an important property of that set of rules is its completeness, i.e., every minimal p-extension can be constructed using them. Hence, a maximal  $(M \cup \{A\})$ -favoring p-skyline relation can be produced from a maximal *M*-favoring p-skyline relation by *iterative application of the minimal extension rules*. This process is illustrated by Figure 11.

We use the following idea for constructing maximal  $(M \cup \{A\})$ -favoring relations. We start with a maximal *M*-favoring p-skyline relation  $\succ_0$  and apply the transformation rules to  $T_{\succ_0}$  in every possible way guaranteeing that the new edges in the p-graph go only from or to *A*. In other words, we construct all minimal  $(M \cup \{A\})$ -favoring p-extensions of  $\succ_0$ . We construct such p-extensions until we find the first one which does not violate  $\mathcal{N}(G, O)$ . When we find it (denote it as  $\succ_1$ ), we repeat all the steps above but for  $\succ_1$ . This process continues until for some  $\succ_m$ , every of its constructed minimal p-extension violates  $\mathcal{N}(G, O)$ . Since in every iteration we construct all minimal  $(M \cup \{A\})$ -favoring p-extensions,  $\succ_m$  is a maximal  $(M \cup \{A\})$ -favoring p-extension of  $\succ_0$ .

There is subtle point here. We can limit ourselves to *minimal* p-extensions because if a minimal p-extension violates  $\mathcal{N}(G, O)$ , so do all non-minimal p-extensions containing it. Also, if there exists a p-extension satisfying  $\mathcal{N}(G, O)$ , so does some minimal one. In fact, each p-extension of a p-skyline relation can be obtained through a finite sequence of minimal p-extensions. Those properties are characteristic of *negative* constraints. The properties do not hold for *positive* constraints and thus our approach cannot be directly generalized to such constraints.

An important condition to apply Theorem 7 is that the input syntax tree for every transformation rule be normalized. At the same time, syntax trees returned by the transformation rules are not guaranteed to be normalized. Therefore, we need to normalize a tree before applying transformation rules to it.

Consider the rules  $Rule_1 - Rule_4$  which can be used to construct an  $(M \cup \{A\})$ -favoring p-skyline relation from an *M*-favoring one. By Proposition 7, such rules may *only* add to the p-graph the edges that go to *A* or from *A*. According to Observation 1,  $Rule_1$  adds edges going to the node *A* if  $C_{i+1} = A$  or  $N_1 = A$ . Similarly,  $Rule_2$  adds edges going from *A* if  $C_{i+1} = A$  or  $N_m = A$ .  $Rule_3$  adds edges going from or to *A* if  $C_i = A$  or  $C_{i+1} = A$  correspondingly. However, *Rule*<sub>4</sub> can only be applied to a pair of & -nodes. Hence, as we showed in section 3.4, *Rule*<sub>4</sub> adds edges going from at least two nodes to at least two different nodes of a p-graph. Hence, every application of *Rule*<sub>4</sub> violates Proposition 7. We conclude that *Rule*<sub>1</sub>, *Rule*<sub>2</sub>, and *Rule*<sub>3</sub> are sufficient to construct every maximal ( $M \cup \{A\}$ )-favoring p-skyline relation.

## 4.4.2 Efficient constraint checking

Before going into the details of the algorithm of p-skyline relation elicitation, we consider an important step of the algorithm: testing if a p-extension of a p-skyline relation satisfies a set of negative constraints. We propose now an efficient method for this task.

Recall that a negative constraint is of the form

$$\tau: Ch_{\Gamma_{\succ}}(\mathcal{L}_{\tau}) \not\supseteq \mathcal{R}_{\tau}$$

It can be visualized as two layers of nodes  $\mathcal{L}_{\tau}$  and  $\mathcal{R}_{\tau}$ . For a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfying  $\tau$ , its p-graph  $\Gamma_{\succ}$  may contain edges going between the nodes of the layers  $\mathcal{L}_{\tau}$  and  $\mathcal{R}_{\tau}$ . However, in order for  $\succ$  to satisfy  $\tau$ , there should be at least one member of  $\mathcal{R}_{\tau}$  with no incoming edges from  $\mathcal{L}_{\tau}$ .

The method of efficient checking of negative constraints against a p-graph that we propose here is based on the fact that the edge set of the p-graph of a transformed p-skyline relation monotonically increases. Therefore, while we transform a p-skyline relation  $\succ$ , we can simply drop the elements of  $\mathcal{R}_{\tau}$  which already have incoming edges from  $\mathcal{L}_{\tau}$ . If we do so after every transformation of the p-skyline relation  $\succ$ , the negative constraint  $\tau$  will be violated by  $\Gamma_{\succ}$  only if  $\mathcal{R}_{\tau}$  is empty. The next proposition says that such a modification of negative constraints is valid.

**Proposition 8** Let a relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfy a system of negative constraints  $\mathcal{N}$ . Construct the system of negative constraints  $\mathcal{N}'$  from  $\mathcal{N}$  in which every constraint  $\tau' \in \mathcal{N}'$  is created from a constraint  $\tau$  of  $\mathcal{N}$  in the following way:

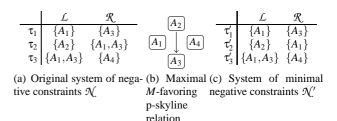

$$\begin{array}{l} - \ \mathcal{L}_{\tau'} = \mathcal{L}_{\tau} \\ - \ \mathcal{R}_{\tau'} = \mathcal{R}_{\tau} - \{ B \in \mathcal{R}_{\tau} \mid \exists A \in \mathcal{L}_{\tau} \ . \ (A, B) \in \Gamma_{\succ} \} \end{array}$$

Then every p-extension  $\succ'$  of  $\succ$  satisfies  $\mathcal{N}$  iff  $\succ'$  satisfies  $\mathcal{N}'$ .

A constraint  $\tau'$  constructed from  $\tau$  as shown in Proposition 8 is called a *minimal negative constraint w.r.t.*  $\succ$ . The corresponding system of negative constraints  $\mathcal{N}'$  is called a *system of minimal negative constraints w.r.t.*  $\succ$ .

Minimization of a system of negative constraints is illustrated in the next example.

*Example 15* Consider the system of negative constraints  $\mathcal{N}$  and the p-skyline relation  $\succ$  from Example 13 (they are

shown in Figures 12(a) and 12(b) correspondingly). The result  $\mathcal{N}'$  of minimization of  $\mathcal{N}$  w.r.t  $\succ$  is shown in Figure 12(c). Only the constraint  $\tau'_2$  is different from  $\tau_2$  because  $(A_2, A_3) \in \Gamma_{\succ}$  and  $A_2 \in \mathcal{L}_{\tau_2}, A_3 \in \mathcal{R}_{\tau_2}$ .

The next proposition summarizes the constraint checking rules over a system of minimal negative constraints.

**Proposition 9** Let a relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfy a system of negative constraints  $\mathcal{N}$ , and  $\mathcal{N}$  be minimal w.r.t.  $\succ$ . Let  $\succ'$  be a p-extension of  $\succ$  such that every edge in  $E(\Gamma_{\succ'}) - E(\Gamma_{\succ})$  starts or ends in A. Denote the new parents and children of A in  $\Gamma_{\succ'}$  as  $P_A$  and  $C_A$  correspondingly. Then  $\succ'$  violates  $\mathcal{N}$  iff there is a constraint  $\tau \in \mathcal{N}$  such that

1.  $\mathcal{R}_{\tau} = \{A\} \land P_A \cap \mathcal{L}_{\tau} \neq \emptyset$ , or 2.  $A \in \mathcal{L}_{\tau} \land \mathcal{R}_{\tau} \subseteq C_A$ 

Proposition 9 is illustrated in the next example.

*Example 16* Take the system of minimal negative constraints  $\mathcal{N}'$  w.r.t.  $\succ$  from Example 15. Construct a p-extension  $\succ'$  of  $\succ$  such that every edge in  $E(\Gamma_{\succ'}) - E(\Gamma_{\succ})$  starts or ends in  $A_4$ . Consider possible edges going to  $A_4$ . Use Proposition 9 to check if a new edge violates  $\mathcal{N}'$ . The edge  $(A_1, A_4)$  is not allowed in  $\Gamma_{\succ'}$  because then  $A_1 \in \mathcal{L}_{\tau'_3}$  and  $\{A_4\} = \mathcal{R}_{\tau'_3}$  (and thus the constraint  $\tau'_3$  is violated). The edge  $(A_3, A_4)$  is not allowed in  $\Gamma_{\succ'}$  because  $A_3 \in \mathcal{L}_{\tau'_3}$  and  $\{A_4\} = \mathcal{R}_{\tau'_3}$ . However, the edge  $(A_2, A_4)$  is allowed in  $\Gamma_{\succ'}$ . The p-graph of the resulting  $\succ'$  is shown in Figure 13. One can analyze the edges going from  $A_4$  in a similar fashion.

**Fig. 13**  $\Gamma_{\succ'}$  from Example 16

### 4.4.3 p-skyline elicitation

In this section, we show an algorithm for p-skyline relation elicitation which exploits the ideas developed in the previous sections.

The function elicit (Algorithm 1) is the main function of the algorithm. It takes four arguments: the set of superior examples G, the entire set of tuples O, the set of attribute preferences  $\mathcal{H}$ , and the set of all relevant attributes  $\mathcal{A}$ . It returns a normalized syntax tree of a maximal p-skyline relation favoring G in O. Following Proposition 6, we require G to be a subset of  $\omega_{sky_{\mathcal{H}}}(O)$ . First, we construct the set of negative constraints  $\mathcal{N}$  for the superior tuples G. We start with  $sky_{\mathcal{H}}$  as the initial p-skyline relation favoring G in O. After that, we take the set M consisting of a single attribute. In every iteration, we enlarge it and construct a maximal *M*-favoring p-skyline relation. As a result, the function returns a maximal p-skyline relation favoring G in O. The construction of a maximal  $(M \cup \{A\})$ -favoring relation from a maximal *M*-favoring relation is performed in the repeat/ until loop (lines 5-8). Here we use the function push which constructs a minimal  $(M \cup \{A\})$ -favoring p-extension of the relation represented by the syntax tree T. It returns true if T has been (minimally) extended to a relation not violating  $\mathcal{N}$ , and further p-extensions are feasible (though they may still violate  $\mathcal{N}$ ). Otherwise, it returns *false*. The syntax tree T passed to push has to be normalized. Hence, after extending the relation, we normalize its syntax tree (line 7) using the normalization procedure sketched in Section 3.1. The repeat/until loop terminates when all minimal extensions of T violate  $\mathcal{N}$ .

Algorithm 1 $elicit(G, O, \mathcal{H}, \mathcal{A})$
<b>Require:</b> $G \subseteq \omega_{sky_{g_f}}(O)$
1: $\mathcal{N} = \mathcal{N}(G, O)$
2: $T = a$ normalized syntax tree of $sky_{\mathcal{H}}$
3: $M =$ set containing an arbitrary attribute from $\mathcal{A}$
4: for each attribute A in $\mathcal{A} - M$ do
5: repeat
6: $r = \operatorname{push}(T, M, A, \mathcal{N});$
7: normalizeTree(root of T);
8: <b>until</b> <i>r</i> is false
9: $M = M \cup \{A\}$
10: end for
11: return $T$

Let us now take a closer look at the function push (Algorithm 2). It takes four arguments: a set M of attributes, a normalized syntax tree T of an M-favoring p-skyline relation  $\succ$ , the current attribute A, and a system of negative constraints  $\mathcal{N}$  minimal w.r.t.  $\succ$ . It returns *true* if a transformation rule  $q \in \{Rule_1, Rule_2, Rule_3\}$  has been applied to T without violating  $\mathcal{N}$ , and *false* if no transformation rule can be applied to T without violating  $\mathcal{N}$ . When push returns true,  $\mathcal{N}$  and T have been changed. Now  $\mathcal{N}$  is minimal w.r.t. the p-skyline relation represented by the modified syntax tree, and T has been modified by the rule q and is normalized.

The goal of push is to find an appropriate transformation rule which adds to the current p-graph edges going from M to A or vice versa. The function has two branches: the first for the parent of the node A in the syntax tree T being a & node (i.e., we may apply  $Rule_1$  where  $N_1$  is A or  $Rule_2$  where  $N_m$  is A), and the second for it being  $\otimes$  -node (i.e., we may apply  $Rule_1$  or  $Rule_2$  where  $C_{i+1}$  is A, or  $Rule_3$  where  $C_i$  or  $C_{i+1}$  is A). In the first branch (line 2-14), we distinguish between applying  $Rule_1$  (line 3-8) and  $Rule_2$  (line 9-14). It is easy to notice that, with the parameters specified above, the rules are exclusive, but the application patterns are similar. First, we find an appropriate child  $C_{i+1}$  of R (lines 4 and 10). (It is important for  $Var(C_{i+1})$  to be a subset of *M* because we want to add edges going from M to A or from A to M.) Then we check if the corresponding rule application does not violate  $\mathcal{N}$  using the function checkConstr (lines 5 and 11), as per Proposition 9. If the rule application does not violate  $\mathcal{N}$ , we apply the corresponding rule to T (lines 6 and 12) and minimize  $\mathcal{N}$  w.r.t. the p-skyline relation which is the result of the transformation (Proposition 8) using the function minimize.

The second branch of push is similar to the first one and different only in the transformation rules applied. So it is easy to notice that push checks every possible rule application not violating  $\mathcal{N}$ , and adds to the p-graph only edges going from A to the elements of M or vice versa.

In our implementation of the algorithm, all sets of attributes are represented as bitmaps of fixed size  $|\mathcal{A}|$ . Similarly, every negative constraint  $\tau$  is represented as a pair of bitmaps corresponding to  $\mathcal{L}_{\tau}$  and  $\mathcal{R}_{\tau}$ . With every node  $C_i$  of the syntax tree, we associate a variable storing  $Var(C_i)$ . Its value is updated whenever the children list of  $C_i$  is changed.

**Theorem 11** The function elicit returns a syntax tree of a maximal p-skyline relation favoring G in O. Its running time is  $O(|\mathcal{N}| \cdot |\mathcal{A}|^3)$ .

The order in which the attributes are selected and added to M in elicit is arbitrary. Moreover, the order of rule application in push may be also changed. That is, we currently try to apply *Rule*<sub>1</sub> (line 21) first and *Rule*<sub>2</sub> (line 25) afterwards. However, one can apply the rules in the opposite order. The same observation applies to  $Rule_3(T, A, C_i)$  and  $Rule_3(T, C_i, A)$  (lines 30 and 34, respectively). If the algorithm is changed along those lines, the generated p-skyline relation may be different. However, even if the p-skyline relation is different, it will still be a maximal p-skyline relation favoring G in O. Note also that due to the symmetry of  $\otimes$ , the order of children nodes of a  $\otimes$  -node may be different in normalized p-skyline trees of equivalent p-skyline relations. Hence, the order in which the leaf nodes are stored in the normalized syntax tree of  $sky_{\mathcal{H}}$  (line 2 of elicit) also affects the resulting p-skyline relation.

*Example 17* Take *O* and  $\mathcal{H}$  from Example 9, and *G* from Example 11. Then the corresponding system of negative constraints  $\mathcal{N} = \mathcal{N}(G, O)$  (Example 11) is shown in Figure 14(a). Consider the attributes in the following order: *make*, *price*, *year*. Run elicit. The tree *T* (line 2) is shown

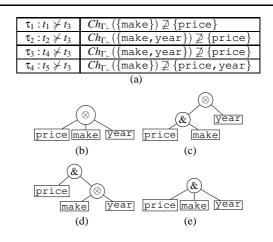

Fig. 14 Example 17

in Figure 14(b). The initial value of M is {make}. First, call  $push(T, \{make\}, price, \mathcal{N})$ . The parent of price is a  $\otimes$ node (Figure 14(b)), so we go to line 16 of push, where *R* is set to the  $\otimes$ -node (Figure 14(b)). After  $C_i$  is set to the node *make* in line 17, we go to line 29 because it is a leaf node. The checkConstr test in line 29 fails because  $\mathcal{N}$  prohibits the edge (*make*, *price*). Hence, we go to line 33 where the checkConstr test succeeds. We apply  $Rule_3(T, price, C_i)$ , push returns *true*, and the resulting syntax tree T is shown in Figure 14(c). Next time we call  $push(T, \{make\}, price, \mathcal{N})$  in the line 6 of elicit, we get to the line 4 of push. Since *year*  $\notin M$ , we immediately go to line 37 and return *false*. In elicit M is set to {*make*, *price*} and push(T, {*make*, *price*}, *year*,  $\mathcal{N}$ ) is called. There we go to line 16 (R is set to the  $\otimes$ -node in Figure 14(c)),  $C_i$  is set to the &-node (Figure 14(c)), we apply  $Rule_1(T, C_i, year)$  (the resulting tree T is shown in Figure 14(d)), and *true* is returned. When  $push(T, \{make, \})$ *price*}, *year*,  $\mathcal{N}$ ) is called the next time, we first go to line 16, *R* is set to the  $\otimes$ -node (Figure 14(d)), and *C<sub>i</sub>* to the node *make*. Then  $Rule_3(T, C_i, year)$  is applied (line 30) resulting in the tree T shown in Figure 14(e), and *true* is returned. Now  $push(T, \{make, price\}, year, \mathcal{N})$  gets called once again from elicit and returns *false*; and thus the tree in Figure 14(e) is the final one. According to the corresponding p-skyline relation,  $t_3$  dominates all other tuples in O.

The final p-skyline relation constructed in Example 17 is a prioritized accumulation of all the attribute preference relations. This is because  $\mathcal{N}$  effectively contained only one constraint (all constraints are implied by  $\tau_2$ , as shown below). When more constraints are involved, an elicited p-skyline relation may also have occurrences of Pareto accumulation.

## 4.5 Reducing the size of systems of negative constraints

As we showed in Theorem 11, the running time of the function elicit linearly depends on the size of the system of negative constraints  $\mathcal{N}$ . If  $\mathcal{N} = \mathcal{N}(G, O)$ , then  $\mathcal{N}$  contains  $(|O| - 1) \cdot |G|$  constraints. A natural question which arises here is whether we really need all the constraints in  $\mathcal{N}$  to elicit a maximal p-skyline relation satisfying  $\mathcal{N}$ . In particular, *can we replace*  $\mathcal{N}$  *with an equivalent subset of*  $\mathcal{N}$ ?

We define equivalence of systems of negative constraints in a natural way.

**Definition 13** Given two systems of negative constraints  $\mathcal{N}_1$  and  $\mathcal{N}_2$ , and two negative constraints  $\tau_1$ ,  $\tau_2$ :

- N<sub>1</sub> (resp. τ<sub>1</sub>) *implies* N<sub>2</sub> (resp. τ<sub>2</sub>) iff every ≻∈ F<sub>H</sub> satisfying N<sub>1</sub> (resp. τ<sub>1</sub>) also satisfies N<sub>2</sub> (resp. τ<sub>2</sub>);
- $\mathcal{N}_1$  (resp.  $\tau_1$ ) strictly implies  $\mathcal{N}_2$  (resp.  $\tau_2$ ) iff every  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfying  $\mathcal{N}_1$  (resp.  $\tau_1$ ) also satisfies  $\mathcal{N}_2$  (resp.  $\tau_2$ ), but  $\mathcal{N}_2$  (resp.  $\tau_2$ ) does not imply  $\mathcal{N}_1$  (resp.  $\tau_1$ );
- $\mathcal{N}_1$  (resp.  $\tau_1$ ) *is equivalent* to  $\mathcal{N}_2$  (resp.  $\tau_2$ ) iff  $\mathcal{N}_1$  (resp.  $\tau_1$ ) implies  $\mathcal{N}_2$  (resp.  $\tau_2$ ) and vice versa.

In particular, a subset of  $\mathcal{N}(G, O)$  from Example 17 that is equivalent to  $\mathcal{N}(G, O)$  is  $\mathcal{N}' = \{\tau_2\}$ : first,  $\mathcal{N}'$  clearly implies  $\mathcal{N}(G, O)$ ; second,  $\{\tau_3\}$  is trivially implied by  $\{\tau_2\}$ ,  $\{\tau_1\}$  is implied by  $\{\tau_2\}$  (if *price* is not a child of either *make* or *year*, it is not a child of *make*), and  $\{\tau_4\}$  is implied by  $\{\tau_2\}$ (if *price* is a child of neither *make* nor *year*, then both *price* and *year* cannot be children of *make*).

Below we propose a number of methods for computing an equivalent subset of a system of negative constraints.

# 4.5.1 Using $sky_{\mathcal{H}}(O)$ instead of O

The first method of reducing the size of a system of negative constraints is based on the following observation. Recall that each negative constraint is used to show that a tuple should not be preferred to a superior example. We also know that the relation  $sky_{\mathcal{H}}$  is the least p-skyline relation. By definition of the winnow operator, for every  $o' \in (O - \omega_{sky_{\mathcal{H}}}(O))$  there is a tuple  $o \in \omega_{sky_{\mathcal{H}}}(O)$  s.t. o is preferred to o' according to  $sky_{\mathcal{H}}$ . Since  $sky_{\mathcal{H}}$  is the least p-skyline relation, the same o is preferred to o' according to every p-skyline relation. Thus, to guarantee favoring G in O, the system of negative constraints needs to contain only the constraints showing that the tuples in  $\omega_{sky_{\mathcal{H}}}(O)$  are not preferred to the superior examples. Hence, the following proposition holds.

**Proposition 10** Given  $G \subseteq \omega_{\text{sky}_{\mathcal{H}}}(\mathcal{O})$ ,  $\mathcal{N}(G, \mathcal{O})$  is equivalent to  $\mathcal{N}(G, \omega_{\text{sky}_{\mathcal{H}}}(\mathcal{O}))$ .

Notice that  $\mathcal{N}(G, \omega_{sky_{\mathcal{H}}}(O))$  contains  $(|\omega_{sky_{\mathcal{H}}}(O)| - 1) \cdot |G|$  negative constraints. Proposition 10 also imply an important result: *if a user considers a tuple t superior based on the comparison with*  $\omega_{sky_{\mathcal{H}}}(O)$ , *comparing t with the tuples in*  $(O - \omega_{sky_{\mathcal{H}}}(O))$  *does not add any new information*.

# 4.5.2 Removing redundant constraints

The second method of reducing the size of a negative constraint system is based on determining the implication of distinct negative constraints in a system. Let two  $\tau_1, \tau_2 \in \mathcal{N}$  be such that  $\mathcal{L}_{\tau_2} \subseteq \mathcal{L}_{\tau_1}$ ,  $\mathcal{R}_{\tau_1} \subseteq \mathcal{R}_{\tau_2}$ . It is easy to check that  $\tau_1$ implies  $\tau_2$ . Thus, the constraint  $\tau_2$  is *redundant* and may be deleted from  $\mathcal{N}$ . This idea can also be expressed as follows:

 $\tau$  implies  $\tau'$  iff  $\mathcal{L}_{\tau'} \subseteq \mathcal{L}_{\tau} \land (\mathcal{A} - \mathcal{R}_{\tau'}) \subseteq (\mathcal{A} - \mathcal{R}_{\tau}).$ 

Let us represent  $\tau$  as a bitmap representing  $(\mathcal{A} - \mathcal{R}_{\tau})$  appended to a bitmap representing  $\mathcal{L}_{\tau}$ . We assume that a bit is set to 1 iff the corresponding attribute is in the corresponding set. Denote such a representation as  $bitmap(\tau)$ .

*Example 18* Let  $\mathcal{L}_{\tau} = \{A_1, A_3, A_5\}, \mathcal{R}_{\tau} = \{A_2\}, \mathcal{L}_{\tau'} = \{A_1, A_5\}, \mathcal{R}_{\tau'} = \{A_2, A_4\}.$  Let  $\mathcal{A} = \{A_1, \dots, A_5\}.$  As a result, *bitmap*( $\tau$ ) = 10101 10111 and *bitmap*( $\tau'$ ) = 10001 10101.

Consider  $bitmap(\tau)$  as a vector with  $2 \cdot |\mathcal{A}|$  dimensions. From the negative constraint implication rule, it follows that  $\tau$  strictly implies  $\tau'$  iff  $bitmap(\tau)$  and  $bitmap(\tau')$  satisfy the *Pareto improvement principle*, i.e., the value of every dimension of  $bitmap(\tau)$  is greater or equal to the corresponding value in  $bitmap(\tau)$ , and there is at least one dimension whose value in  $bitmap(\tau)$  is greater than in  $bitmap(\tau')$ . Therefore, the set of all non-redundant constraints in  $\mathcal{N}$  corresponds to the *skyline* of the set of bitmap representations of all constraints in  $\mathcal{N}$ . Moreover,  $bitmap(\tau)$  can have only two values in every dimension: 0 or 1. Thus, algorithms for computing skylines over low-cardinality domains (e.g. [Morse et al(2007)]) can be used to compute the set of nonredundant constraints.

# 4.5.3 Removing redundant sets of constraints

The method of determining redundant constraints in the previous section is based on distinct constraint implication. A more powerful version of this method would compute and discard *redundant subsets of*  $\mathcal{N}$  rather then redundant distinct constraints. However, as we show in this section, that problem appears to be significantly harder.

**Problem SUBSET-EQUIV.** Given systems of negative constraints  $\mathcal{N}_1$  and  $\mathcal{N}_2$  s.t.  $\mathcal{N}_2 \subseteq \mathcal{N}_1$ , check if  $\mathcal{N}_2$  is equivalent to  $\mathcal{N}_1$ .

To determine the complexity of SUBSET-EQUIV, we use a helper problem.

**Problem NEG-SYST-IMPL.** Given two systems of negative constraints  $\mathcal{N}_1$  and  $\mathcal{N}_2$ , check if  $\mathcal{N}_1$  implies  $\mathcal{N}_2$ .

It turns out that the problems NEG-SYST-IMPL and SUBSET-EQUIV are intractable in general.

**Theorem 12** NEG-SYST-IMPL is co-NP complete

# Theorem 13 SUBSET-EQUIV is co-NP complete

We notice that even though the problem of minimizing the size of a system of negative constraints is intractable in general, the methods of reducing its size we proposed in sections 4.5.2 and 4.5.1 result in a significant decrease in the size of the system. This is illustrated in Section 5.

# **5** Experiments

We have performed extensive experimental study of the proposed framework. The algorithms were implemented in Java. The experiments were run on Intel Core 2 Duo CPU 2.1 GHz with 2.0GB RAM under Windows XP. We used four data sets: one real-life and three synthetic.

# 5.1 Experiments with real-life data

In this subsection, we focus on experimenting with the accuracy of the elicit algorithm and the reduction of winnow result size, achieved by modeling user preferences using p-skyline relations. We use a data set *NHL* which stores statistics of NHL players [nhl(2008)], containing 9395 tuples. We consider three sets of relevant attributes  $\mathcal{A}$  containing 12, 9, and 6 attributes. The size of the corresponding skylines is 568, 114, and 33, respectively.

#### 5.1.1 Precision and recall

The aim of the first experiment is to demonstrate that the elicit algorithm has high accuracy. We use the following scenario. We assume that the real, hidden preferences of the user are modeled as a p-skyline relation  $\succ_{hid}$ . We also assume that the user provides the set of relevant attributes  $\mathcal{A}$ , the set of corresponding attribute preferences  $\mathcal{H}$ , and a set  $G_{hid}$  of tuples which she likes most in *NHL* (i.e.,  $G_{hid}$  are superior examples and  $G_{hid} \subseteq \omega_{\succ_{hid}}(NHL)$ ). We use  $G_{hid}$  to construct a maximal p-skyline relation  $\succ$  favoring  $G_{hid}$  in *NHL*. To measure the accuracy of elicit, we compare the set of the best tuples  $\omega_{\succ_{hid}}(NHL)$  with the set of the best tuples  $\omega_{\succ_{hid}}(NHL)$ . The latter is supposed to correctly reflect user preferences.

To model user preferences, we randomly generate 100 pskyline relations  $\succ_{hid}$ . For each  $\omega_{\succ_{hid}}(NHL)$ , we randomly pick 5 tuples from it, and use the tuples as superior examples  $G_{hid}$  to elicit three different maximal p-skyline relations  $\succ$ favoring  $G_{hid}$  in *NHL*. Out of those three relations, we pick the one resulting in  $\omega_{\succ}(NHL)$  of the smallest size. Then we add 5 more tuples from  $\omega_{\succ_{hid}}(NHL)$  to  $G_{hid}$  and repeat the same procedure. We keep adding tuples to  $G_{hid}$  from  $\omega_{\succ_{hid}}(NHL)$  until  $G_{hid}$  reaches  $\omega_{\succ_{hid}}(NHL)$ .

To measure the accuracy of the elicit algorithm, we compute the following three values:

1. precision of the p-skyline elicitation method:

$$precision = \frac{|\omega_{\succ}(NHL) \cap \omega_{\succ_{hid}}(NHL)|}{|\omega_{\succ}(NHL)|},$$

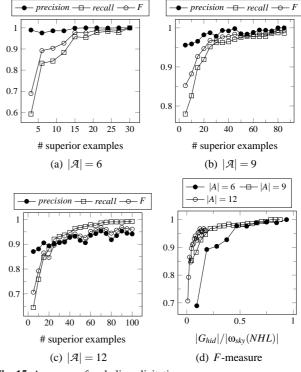

2. *recall* of the p-skyline elicitation method:

$$recall = \frac{|\omega_{\succ}(NHL) \cap \omega_{\succ_{hid}}(NHL)|}{|\omega_{\succ_{hid}}(NHL)|}$$

3. F-measure which combines precision and recall:

$$F = 2 \cdot \frac{precision \cdot recall}{precision + recall}$$

We plot the average values of those measures in Figures 15(a), 15(b), and 15(c). As can be observed, *precision* of the elicit algorithm is high in all experiments. In particular, it is greater than 0.9 in most cases, regardless of the number of superior examples and the number of relevant attributes. At the same time, *recall* starts from a low value when the number of superior examples is low. This is justified by the fact that elicit constructs a *maximal* relation favoring  $G_{hid}$  in *NHL*. Thus, when  $G_{hid}$  contains few tuples, it is not sufficient to capture the preference relation  $\succ_{hid}$ , and thus the ratio of false negatives is rather high. However, when we increase the number of superior examples, *recall* consistently grows.

In Figure 15(d), we plot the values of the *F*-measure with respect to the share of the skyline used as superior examples. As one can observe, the value of *F* starts from a comparatively low value of 0.7 but quickly reaches 0.9 via a small increase of the size of  $G_{hid}$ . Another important observation is that the value of *F* is generally inversely dependent on the number of relevant attributes (given the same ratio of

superior examples used). This is justified by the following observation. To construct a p-skyline relation favoring  $G_{hid}$  in *NHL*, the algorithm uses a set of negative constraints  $\mathcal{N}$ . Intuitively, the constructed p-skyline relation  $\succ$  will match the original relation  $\succ_{hid}$  better if the set  $\mathcal{N}$  captures  $\succ_{hid}$  sufficiently well. The number of constraints in  $\mathcal{N}$  depends not only on the number of superior examples but also on the skyline size. Since skyline sizes are generally smaller for smaller sets of  $\mathcal{A}$ , more superior examples are needed for smaller  $\mathcal{A}$  to capture  $\succ_{hid}$ .

## 5.1.2 Winnow result size

In Section 1, we discussed a well known deficiency of the skyline framework: skylines are generally of large size for large sets of relevant attributes  $\mathcal{A}$ . The goal of the experiments in this section is twofold. First, we demonstrate that using p-skyline relations to model user preferences results in *smaller winnow query results* in comparison to skyline relations. Second, we show that the reduction of query result size is significant if the *hidden* user preference relation is a p-skyline relation. In particular, we show that it is generally hard to find a p-skyline relation favoring *an arbitrary* subset of the skyline.

In this experiment, sets of superior examples are generated using two methods. First, they are drawn randomly from the set of the best objects  $\omega_{\succ hid}(NHL)$  according to a hidden p-skyline relation  $\succ_{hid}$ , as in the previous experiment and denoted  $G_{hid}$ . Second, they are drawn randomly from the skyline  $\omega_{sky}(NHL)$  and denoted  $G_{rand}$ . Notice that  $G_{rand}$ may not be favored by any p-skyline relation (besides  $sky_{\mathcal{H}}$ , of course). We use these sets to elicit p-skyline relations  $\succ$ that favor them. In Figure 16, we plot

winnow-size-ratio = 
$$\frac{|\omega_{\succ}(NHL)|}{|\omega_{sky_{af}}(NHL)|}$$
,

which shows the difference in the size of the results of pskyline and skyline queries.

Consider the graphs for  $G_{hid}$ . As the figures suggest, using p-skyline relations to model user preferences results in a significant reduction in the size of winnow query result, in comparison to skyline relations. It can be observed that using larger sets of relevant attributes  $\mathcal{A}$  generally results in smaller values of winnow-size-ratio. Moreover, for larger relevant attribute sets, winnow-size-ratio grows slowly. That is due to larger skyline size for such sets.

Another important observation is that *winnow-size-ratio* is always smaller for superior examples which correspond to p-skyline relations ( $G_{hid}$ ), in comparison to superior examples drawn randomly ( $G_{rand}$ ) from the skyline. The fact that superior examples correspond to a real p-skyline relation implies that they share some similarity expressed using the attribute importance relationships. For a set of random skyline tuples  $G_{rand}$ , such similarity exists when it contains

only a few tuples. Increasing the size of such a set decreases the similarity of the tuples, which results in a quick growth of *winnow-size-ratio*.

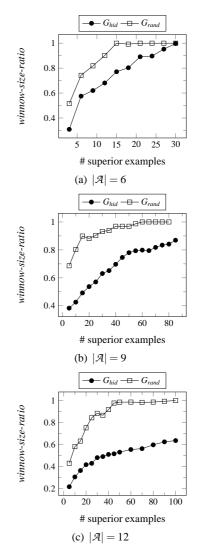

Fig. 16 p-skyline size reduction

#### 5.2 Experiments with synthetic data

Here we present experiments with synthetic data. The main goals of the experiments is to demonstrate that the proposed p-skyline relation elicitation approach is scalable and allows effective optimizations. We use three synthetic data sets here: correlated  $S_1$ , anti-correlated  $S_2$ , and uniform  $S_3$ . Each of them contains 50000 tuples. We use three different sets  $\mathcal{A}$  of 10, 15, and 20 relevant attributes. For each of those sets, we pick a different set of superior examples G. Sets G are constructed of *similar* tuples, similarity being measured as Euclidean distance. As before, given a set G, we use elicit to construct maximal p-skyline relations  $\succ$  favoring G. This setup is supposed to model an automated process of iden-

tifying superior objects G, in which a user is involved only indirectly.

# 5.2.1 Scalability

In this section, we show that the elicit algorithm is scalable with respect to various parameters. In Figure 17, we plot the dependence of the average running time of discover on the number of superior examples |G| used to elicit a p-skyline relation (Figure 17(a),  $|S_i| = 50000$ ,  $|\mathcal{A}| = 20$ ), the size of  $S_i$  for i = 1, ..., 3 (Figure 17(b), |G| = 50,  $|\mathcal{A}| =$ 20), and the number  $|\mathcal{A}|$  of relevant attributes (Figure 17(c),  $|S_i| = 50000$ , |G| = 50). The measured time does not include the time to construct the system of negative constraints and find the non-redundant constraints in it. According to our experiments, the preprocessing time predominantly depends on the performance of the skyline computation algorithm.

According to Figure 17(a), the running time of the algorithm increases until the size of G reaches 30. After that, it does not vary much. This is due to the fact that the algorithm performance depends on the number of negative constraints used. We use only *non-redundant* constraints for elicitation. As we show further (Figure 18(a)), the dependence of the size of a system of non-redundant constraints on the number of superior examples has a pattern similar to Figure 17(a).

The growth of the running time with the increase in the data set size (Figure 17(b)) is justified by the fact that the number of negative constraints depends on skyline size (Section 4.5). For the data sets used in the experiment, the skyline size grows with the size of the data set. Similarly, the running time of the algorithm grows with the number of relevant attributes (Figure 17(c)), due to the increase in the skyline size.

We conclude that the elicit algorithm is efficient and its running time scales well with respect to the number of superior examples, the size of the data set, and the number of relevant attributes used.

#### 5.2.2 Reduction in the number of negative constraints

In this section, we demonstrate that the algorithm elicit allows effective optimizations. Recall that the running time of elicit depends linearly (Theorem 11) on the number of negative constraints in the system  $\mathcal{N}$ . Here we show that the techniques proposed in Section 4.5 result in a significant reduction in the size of  $\mathcal{N}$ .

In Figure 18(a), we show how the number of negative constraints depends on the number of superior examples used to construct them. For every data set, we plot two values: the number of *unique* negative constraints in  $\mathcal{N}(G, \omega_{sky_{\mathcal{H}}}(S_i))$  for i = 1, ..., 3, and the number of *unique non-redundant* constraints in the corresponding system. We note that the reduction in the number of constraints achieved using the methods we proposed in Section 4.5 is significant. In particular, for the anti-correlated data set and G of size 150,

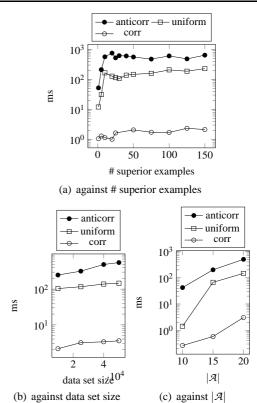

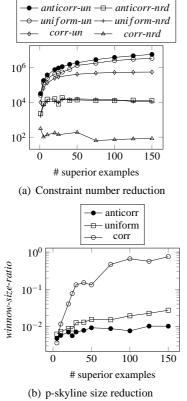

Fig. 17 Performance of p-skyline elicitation

the total number of constraints in  $\mathcal{N}(G, S_i)$  is approximately  $7.5 \cdot 10^6$ . Among them, about  $5.5 \cdot 10^6$  are unique in  $\mathcal{N}(G, \omega_{sky_{\mathcal{H}}}(S_i))$ . However, less than 1% of them (about  $12 \cdot 10^3$ ) are non-redundant.

#### 5.2.3 Winnow result size

In Section 5.1, we showed how the size of p-skyline query result depends on the number of relevant attributes and the size of the skyline. In this section, we show that another parameter which affects the size of winnow query result is data distribution. In Figure 18(b), we demonstrate how the size of the p-skyline query result varies with the number of superior examples. We compare this size with the size of the corresponding skyline and plot the value of winnow-size-ratio defined in the previous section. Here we use anti-correlated, uniform, and correlated data sets of 50000 tuples each. The number of relevant attributes is 20. The size of the corresponding skylines is: 41716 (anti-correlated), 37019 (uniform), and 33888 (correlated). For anti-correlated and uniform data sets, the values of winnow-size-ratio quickly reach a certain bound and then grow slowly with the number of superior examples. This bound is approximately 1% of the skyline size (i.e., about 350 tuples) for both data sets. At the same time, the growth of winnow-size-ratio for correlated data set is faster. Note that the values of winnow-size- ratio are generally lower for synthetic data sets, in comparison to the real-life data set NHL. This is due to the larger set

of relevant attributes and larger skyline sizes in the current experiment.

Fig. 18 Synthetic data experiments

We conclude that the experiments that we have carried out show that incorporating relative attribute importance into skyline relations in the form of p-skyline relations results in a significant reduction in query result size. The proposed algorithm elicit for eliciting a maximal p-skyline relation favoring a given set of superior examples has good scalability in terms of the data set size and the number of relevant attributes. The algorithm has high accuracy even for small sets of superior examples.

# 6 Related work

In this section, we discuss related work that has been done in the areas covered in the paper: modeling preferences as skyline relations and preference elicitation.

# 6.1 Modeling preferences as skyline relations

The p-skyline framework is based on the preference constructor approach proposed in [Kießling(2002)]. That approach was extended in [Kießling (2005)] by relaxing definitions of the accumulation operators and by using SV-relations, instead of equality, as indifference relations. [Kießling (2005)] Another direction of research using the skyline frameshowed that such an extension preserves the SPO properties of the resulting preference relations. The resulting relations were shown to be *larger* (in the set theoretic sense)

than the relations composed using the equality-based accumulational operators. However, relative importance of attributes implicit in such relations was addressed neither in [Kießling(2002)] nor [Kießling (2005)]. Containment of preference relations and minimal extensions were also not considered in these works.

[Börzsönyi et al(2001)] proposed the original skyline framework. That paper introduced an extension of SQL in which the skyline queries can be formulated. The paper also proposed a number of algorithms for computing skylines. Since then, many algorithms for that task have been developed ([Tan et al(2001),Kossmann et al(2002),Chomicki et al(2003), Lee et al(2007), Godfrey et al(2007)] and others).

[Godfrey et al(2005)] showed that the number of skyline points in a dataset may be exponential in the number of attributes. Since then, a number of approaches have been developed for reducing the size of skylines by computing only the most representative skyline objects.

[Chan et al(2006)] proposed to compute the set of kdominant skyline points instead of the entire skyline. Another variant of the skyline operator was presented in [Lin et al(2007)]. That operator computes k most representative tuples of a skyline. [Lin et al(2007)] showed that when the number of attributes involved is greater than two, the problem is NPhard in general. For such cases, [Lin et al(2007)] proposed a polynomial time approximation algorithm.

More recently, [Tao et al(2009)] proposed the distancebased representative skyline operator. This approach is based on the observation that if a skyline of a dataset consists of clusters, then in many cases, a user is interested in seeing only good representatives from each skyline cluster rather than the entire skyline (which may be quite large). If interested, the user may drill down to each cluster further on. The representativeness here is measured as the maximum of the distance from the cluster center to each object of the cluster. The authors studied the problem of computing k most representative skyline objects and proposed an efficient approximation algorithm for datasets with arbitrary dimensionality.

Another recent work in the area of skyline-size reduction is [Zhao et al(2010)]. There, the authors proposed the order-based representative skyline operator. The approach is based on a well-known fact that an object is in a skyline iff it maximizes some monotone utility function. As a measure of skyline object similarity, the authors used the similarity between (possibly infinite) sets of orders which favor the corresponding objects. The authors developed an algorithm for computing representatives of clusters of similar objects. They also proposed a method of eliciting user preferences which allows to drill down to clusters in an iterative manner. work concerns subspace skyline computation [Pei et al(2005), Yuan et al(2005)]. An interesting problem in this framework is how to identify the subspaces to whose skylines a given

tuple belongs. [Pei et al(2005)] showed an approach to that problem, which uses the notion of decisive subspace. A subspace skyline can be computed using every skyline algorithm. However, to compute k subspace skylines (for k different attribute sets), an algorithm for efficient computing of all subspace skylines at once [Pei et al(2005), Yuan et al(2005)] may be more efficient. [Yuan et al(2005)] introduced the related notion of skyline cube. The skyline cube approach was used in [Lee et al(2009)] to find the most interesting subspaces given an upper bound on the size of the corresponding skyline and a total order of attributes, the latter representing the importance of the attributes to the user.

We notice that the framework based on subspace skylines is, in a sense, orthogonal to the p-skyline framework proposed here. Both of them extend the skyline framework. In the subspace skyline framework, the relative importance of attributes is fixed (i.e., all considered attributes are of equal importance) while the sets of the relevant attributes may vary. In the p-skyline approach, the set of relevant attributes is fixed while the relative importance of them may vary. However, given a set of attribute preference relations, all subspace skylines and the results of all full p-skyline relations are subsets of the (full-space) skyline (assuming the distinct value property for subspace skylines).

[Zhang et al(2010)] studied the properties of skyline preference relations and showed that they are the only relations satisfying the introduced properties of rationality, transitivity, scaling robustness, and shifted robustness. The authors analyzed these properties and the outcome of their relaxation in skyline preference relations. They also showed how to adapt existing skyline computation algorithms to relaxed skylines. This work is particular interesting in the context of the current paper, since it gives some insights to possible approaches for computing *p*-skyline winnow queries.

#### 6.2 Preference elicitation

An approach to elicit preferences aggregated using the accumulation operators was proposed in [Holland et al(2003)]. Web server logs were used there to elicit preference relations. The approach was based on statistical properties of log data - more preferable tuples appear more frequently. The mining process was split into two parts: eliciting attribute preferences and eliciting accumulation operators which aggregate the attribute preferences. Attribute preferences to be elicited were in the form of predefined preference construcused a heuristic approach to elicit the way attribute preferences are aggregated (using Pareto and prioritized accumulation operators). The case when more than one different combination of accumulation operators may be elicited in the same data was not addressed. Moreover, no criteria of optimality of elicited preference relations were defined.

A framework for preference elicitation which is complementary to the approach we have developed here was presented in [Jiang et al(2008)]. In that work, preferences are modeled as skyline relations. Given a set of relevant attributes and a set of attribute preferences over some of them, the objective is to determine attribute preferences over the remaining attributes. The elicitation process is based on user feedback in terms of a set of superior and a set of inferior examples. The work is focused on eliciting minimal (in terms of relation size) attribute preference relations. [Jiang et al(2008)] showed that the problem of existence of such relations is NP-complete, and the computation problem is NP-hard. Two greedy heuristic algorithms were provided. The algorithms are not sound, i.e., for some inputs, the computed preferences may fail to be minimal. That approach and the approach we presented here are different in the following sense. First, [Jiang et al(2008)] dealt with skyline relations, and thus all attribute preferences are considered to be equally important. In contrast, the focus of our work is to elicit differences in attribute importance. Second, [Jiang et al(2008)] focused on eliciting minimal attribute preferences. In contrast, we are interested in constructing maximal tuple preference relations, since such relations guarantee a better fit to the provided set of superior examples. At the same time, our work and [Jiang et al(2008)] complement each other. Namely, when attribute preferences are not provided explicitly by the user, the approach of [Jiang et al(2008)] may be used to elicit them.

Another approach to preference relation elicitation in the skyline framework was introduced in [Lee et al(2008)]. It proposed to reduce skyline sizes by revising skyline preference relations by supplying additional tuple relationships: preference and equivalence. Such relationships are obtained from user answers to simple questions.

In quantitative preference frameworks [Fishburn(1970)], preferences are represented as *utility functions*: a tuple t is preferred to another tuple t' iff f(t) > f(t') for a utility function f. Attribute priorities are often represented here as weight coefficients in polynomial utility functions. A number of methods have been proposed to elicit utility functions - some of them are [Chajewska et al(2000),Boutilier(2002)]. Utility functions were shown to be effective for reasoning with preferences and querying databases with preferences (Top-K queries) [Fagin et al(2001), Das et al(2006), Bacchus and Grove(199 Some work has been performed on eliciting utility functions for preferences represented in other models [McGeachie and Doyle(2002)]. tors such as LOWEST, HIGHEST, POS, NEG etc. [Holland et al(2003)] omshlak and Joachims(2007)] described another model of preference elicitation in the form of utility functions. The authors proposed a framework for constructing a utility function consistent with a set of comparative statements about preferences (e.g., "A is better than B" or "A is as

good as B"). That approach does not rely on any structure of preference relations. [Vu Ha(1999)] proposed an approach to composing binary preference relations and *multi-linear* utility functions. A quantitative framework for eliciting binary preference relations based on knowledge based artificial neural network (KBANN) was presented in [Haddawy et al [Viappiani et al(2006)] studied the problems of incremental elicitation of user preference based on user provided *example critiques*.

# 7 Conclusion and future work

In this work, we explored the p-skyline framework which extends skylines with the notion of attribute importance captured by p-graphs. We studied the properties of p-skyline relations – checking dominance, containment and equality of such relations – and showed efficient methods for performing the checks using p-graphs. We proposed a complete set of transformation rules for efficient computation of minimal extensions of p-skyline relations.

The main problem studied here was the elicitation of p-skyline relations based on user-provided feedback in the form of superior and inferior examples. We showed that the problems of existence and construction of a maximal p-skyline relation favoring and disfavoring given sets of superior and inferior examples are intractable in general. For restricted versions of these problems - when the provided inferior example sets are empty - we designed polynomial time algorithms. We also identified some bottlenecks of constructing maximal p-skyline relations: the system of negative constraints used may be quite large in general, which directly affects the algorithm performance. To tackle that problem, we proposed several optimization techniques for reducing the size of such systems. We also showed that the problem of minimization of such systems is unlikely to be solvable in polynomial time in general. We conducted experimental studies of the proposed elicitation algorithm and optimization techniques. The study shows that the algorithm has good scalability in terms of the data set size and the number of relevant attributes, and high accuracy even for small sets of superior examples.

At the same time, we note that the our framework has a number of limitations that can be addressed in future work. First, we focused on *full* p-skyline relations. An interesting direction of future work would be to study the properties of *partial* p-skyline relations (i.e., defined on top of sets  $\mathcal{A}$  and  $\mathcal{H}$  of variable size).

Second, attribute preference relations considered in this work are limited to *total orders*. There are several reasons for this limitation:

- the limitation is natural in many contexts;
- attribute preferences in skyline relations are also typically total orders (although there are several papers, e.g., [Chan et al(2005), Balke et al(2006)], in which this limitation is lifted);

 some of our results require the assumption that attribute preferences are total orders, e.g., Theorem 5.

(2003)]. (2003)]. ized if the restriction of attribute preferences to total orders is relaxed. (To avoid any possible confusion, we emphasize that tuple preference relation considered in our work are *not* limited to total orders.)

Third, the DIFF attributes, discussed in the original skyline paper [Börzsönyi et al(2001)], were also not considered in this paper. This is another possible generalization.

Fourth, the type of user feedback for p-skyline relation elicitation – superior and inferior examples – may not fit some real-life scenarios. So a potentially promising direction is to adapt the p-skyline elicitation approach to other types of feedback. For that, one should study appropriate classes of attribute set constraints.

Finally, the problem of computing winnow queries with p-skyline relations is left for future work.

# **Appendix: Proofs**

Before going into the proofs, we introduce  $(\mathcal{W}^0, \mathcal{A}^0)$ -structures. A  $(\mathcal{W}^0, \mathcal{A}^0)$ -structure is based on the set of attributes  $\mathcal{A}^0$  and a function  $\mathcal{W}^0 = \{W_A : A \in \mathcal{A}^0\}$  mapping  $\mathcal{A}^0$  to subsets of  $\mathcal{A}^0$ .

**Definition 14** ( $(\mathcal{W}^0, \mathcal{A}^0)$ -structure) Let  $\mathcal{W}^0$  and  $\mathcal{A}^0$  be as discussed above and such that for every  $A \in \mathcal{A}^0, A \notin W_A$ . Then the  $(\mathcal{W}^0, \mathcal{A}^0)$ -structure is a tuple  $(\mathcal{W}^0, \mathcal{A}^0)$ , and the *relation generated by*  $(\mathcal{W}^0, \mathcal{A}^0)$  is

$$\succ_{(\mathcal{W}^0,\mathcal{A}^0)} \equiv TC\left(igcup_{A\in\mathcal{A}^0}q_A
ight),$$

where

$$q_A \equiv \{(o_1, o_2) \mid o_1.A >_A o_2.A\} \cap \approx_{\mathcal{A} - (W_A \cup \{A\})},$$

and  $>_A$  is the attribute preference relation for A in  $\mathcal{H}$ .

Let a tuple *o* dominate a tuple *o'* according to the relation  $\succ_{(\mathcal{W}^0,\mathcal{A}^0)}$  generated by  $(\mathcal{W}^0,\mathcal{A}^0)$ . By Definition 14, this is possible iff there exist a sequence of tuples  $\Sigma_{o,o'} = (o_1, o_2, \ldots, o_m, o_{m+1})$  such that  $o_1 = o, o_{m+1} = o'$ , and a sequence of attributes  $\Psi_{o,o'} = (A_{i_1}, \ldots, A_{i_m})$ , all in  $\mathcal{A}^0$ , such that

$$q_{A_{i_1}}(o_1, o_2), \ldots, q_{A_{i_m}}(o_m, o_{m+1})$$

Then the pair  $(\Sigma_{o,o'}, \Psi_{o,o'})$  is called a *derivation sequence* for  $o \succ_{(\mathcal{W}^0, \mathcal{A}^0)} o'$ . Given a pair of tuples, the corresponding derivation sequence is not unique in general.

We notice that the  $(\mathcal{W}^0, \mathcal{A}^0)$ -structures are an efficient tool used here to prove some theorems describing properties of p-skyline relations. Now, Theorem 1 can be reformulated as follows:

**Theorem 1'** Every p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  can be represented as a relation  $\succ_{(\mathcal{W},\mathcal{A})}$  generated by a  $(\mathcal{W},\mathcal{A})$ -structure such that for every  $A \in \mathcal{A}$ ,  $W_A = Ch_{\Gamma_{\succ}}(A)$ .

**Proof of Theorem 1'.** We show here that for every  $\succ \in \mathcal{F}_{\mathcal{H}}$ ,

$$\succ \equiv \succ_{(\mathcal{W},\mathcal{A})} \equiv TC\left(\bigcup_{A \in Var(\succ)} q_A\right)$$
$$q_A \equiv \{(o_1, o_2) \mid o_1.A \succ_A o_2.A\} \cap \approx_{\mathcal{A}-(W_A \cup \{A\})}$$

where  $\mathcal{W}_A = Ch_{\Gamma_{\succ}}(A)$  for  $A \in Var(\succ)$ . We prove the theorem by induction on the sizes of  $\mathcal{H}$  (and  $\mathcal{A}$ ).

*Base step.* Let  $\mathcal{H} = \{>_A\}$  and  $\mathcal{A} = \{A\}$ . Then  $\mathcal{F}_{\mathcal{H}}$  consists of a single atomic p-skyline relation  $\succ$  induced by  $>_A$ . Let  $W_A = Ch_{\Gamma \succ}(A) = \emptyset$ . Then

$$\succ = \succ_{(\mathcal{W},\mathcal{A})} \equiv TC(q_A)$$
$$q_A \equiv \{(o_1, o_2) \mid o_1.A >_A o_2.A\} \cap \approx_{\mathcal{A}-(W_A \cup \{A\})}.$$

*Inductive step.* Now assume that the theorem holds for  $\mathcal{H}$  and  $\mathcal{A}$  of size up to *n*. Prove that it holds for  $\mathcal{H}$  and  $\mathcal{A}$  of size n + 1. Let  $\succ = \succ_1 \otimes \succ_2$  (the case of  $\succ = \succ_1 \& \succ_2$  is similar). By the definition of induced p-skyline relations,

$$\succ \equiv (\succ_1 \cap \approx_{Var(\succ_2)}) \cup (\succ_2 \cap \approx_{Var(\succ_1)}) \cup (\succ_1 \cap \succ_2).$$

Thus, for two p-skyline relations  $\succ_1$  and  $\succ_2$  the inductive assumption implies that  $\succ_1$  and  $\succ_2$  can be represented by the structures  $(\mathcal{W}^1, \mathcal{A}^1)$  and  $(\mathcal{W}^2, \mathcal{A}^2)$ , for  $\mathcal{A}^1 = Var(\succ_1)$  and  $\mathcal{A}^2 = Var(\succ_2)$ . That is,

$$\succ_1 \equiv \succ_{(\mathcal{W}^1, \mathcal{A}^1)} \equiv TC(\bigcup_{A \in Var(\succ_1)} q_A^1)$$
(5)

$$-_{2} \equiv \succ_{(\mathcal{W}^{2},\mathcal{A}^{2})} \equiv TC(\bigcup_{A \in Var(\succ_{2})} q_{A}^{2})$$
(6)

where

×

$$q_{A}^{1} \equiv \{(o_{1}, o_{2}) \mid o_{1}.A >_{A} o_{2}.A\} \cap \approx_{Var(\succ_{1}) - (W_{A}^{1} \cup \{A\})}$$
(7)

$$I_{A}^{2} \equiv \{(o_{1}, o_{2}) \mid o_{1}.A >_{A} o_{2}.A\} \cap \approx_{Var(\succ_{2}) - (W_{A}^{2} \cup \{A\}).}$$
(8)

Since  $\succ$  is a p-skyline relation,

$$Var(\succ_1) \cap Var(\succ_2) = \emptyset.$$
(9)

$$\succ \equiv TC \left( \bigcup_{A \in Var(\succ_1)} q_A^1 \right) \cap \approx_{Var(\succ_2)} \cup \\ TC \left( \bigcup_{A \in Var(\succ_2)} q_A^2 \right) \cap \approx_{Var(\succ_1)} \cup \\ TC \left( \bigcup_{A \in Var(\succ_1)} q_A^1 \right) \cap TC \left( \bigcup_{A \in Var(\succ_2)} q_A^2 \right)$$
(10)

or equivalently

$$\succ \equiv TC \left( \bigcup_{A \in Var(\succ_1)} q_A^1 \cap \approx_{Var(\succ_2)} \right) \cup$$

$$TC \left( \bigcup_{A \in Var(\succ_2)} q_A^2 \cap \approx_{Var(\succ_1)} \right) \cup$$

$$TC \left( \bigcup_{A \in Var(\succ_1)} q_A^1 \right) \cap TC \left( \bigcup_{A \in Var(\succ_2)} q_A^2 \right).$$

$$(11)$$

Construct the function W as follows

$$W_A = \begin{cases} W_A^1, \text{ if } A \in Var(\succ_1) \\ W_A^2, \text{ if } A \in Var(\succ_2). \end{cases}$$

Let  $\mathcal{A} = Var(\succ_1) \cup Var(\succ_2) = Var(\succ)$  and  $\succ_{(\mathcal{W},\mathcal{A})}$  be generated by such  $(\mathcal{W},\mathcal{A})$ 

$$\succ_{(\mathcal{W},\mathcal{A})} \equiv TC(\bigcup_{A \in \mathcal{A}} q_A^*)$$
(12)

$$q_A^* \equiv \{ (o_1, o_2) \mid o_1 A >_A o_2 A \} \cap \approx_{\mathcal{A} - (W_A \cup \{A\})}.$$
(13)

for

We prove that  $\succ_{(\mathcal{W},\mathcal{A})}$  is equal to  $\succ$ . Before going into the proof, notice that (11) can be rewritten as

$$\succ \equiv TC \left( \bigcup_{A \in Var(\succ_1)} q_A^* \right) \cup TC \left( \bigcup_{A \in Var(\succ_2)} q_A^* \right) \cup TC \left( \bigcup_{A \in Var(\succ_2)} q_A^* \right) \cup TC \left( \bigcup_{A \in Var(\succ_1)} q_A^1 \right) \cap TC \left( \bigcup_{A \in Var(\succ_2)} q_A^2 \right).$$
(14)

1. Let  $o \succ_{(\mathcal{W},\mathcal{A})} o'$ . Let  $(\Sigma_{o,o'}, \Psi_{o,o'})$  be some derivation sequence for  $o \succ_{(\mathcal{W},\mathcal{A})} o'$ . W.l.o.g. let  $\Psi_{o,o'} = (A_1, \ldots, A_m), \Sigma_{o,o'} = (o = o_1, o_2, \ldots, o_m, o_{m+1} = o')$ , and

$$q_{A_1}^*(o_1, o_2), q_{A_2}^*(o_2, o_3), \dots, q_{A_m}^*(o_m, o_{m+1}).$$
(15)

By construction, each attribute  $A_i \in \Psi_{o,o'}$  is either in  $Var(\succ_1)$  or  $Var(\succ_2)$ . For every such  $A_i$ ,  $q_{A_i}^*(o_i, o_{i+1})$  implies  $o_i \succ o_{i+1}$  by (14). Therefore, (15) implies

$$o_1 \succ o_2, o_2 \succ o_3, \dots, o_m \succ o_{m+1}.$$
 (16)

Transitivity of p-skyline relations implies  $o_1 \succ o_{m+1}$ , i.e.  $o \succ o'$ .

- 2. Let  $o \succ o'$ . Then (14) leads to three cases
  - (a)  $(o,o') \in TC\left(\bigcup_{A \in Var(\succ_1)} q_A^*\right)$ . Then  $o \succ_{(\mathcal{W},\mathcal{A})} o'$  by (12).
  - (b)  $(o,o') \in TC\left(\bigcup_{A \in Var(\succ_2)} q_A^*\right)$ . Then  $o \succ_{(\mathcal{W},\mathcal{A})} o'$  by the same reasoning.
  - (c)  $(o, o') \in TC\left(\bigcup_{A \in Var(\succ_1)} q_A^1\right) \cap TC\left(\bigcup_{A \in Var(\succ_2)} q_A^2\right)$ . In this case, (9) implies that there is an object o'' whose values of  $Var(\succ_2)$  are equal to those of o, and the values of  $Var(\succ_1)$  are equal to those of o'. Then we have

$$(o, o'') \in TC\left(\bigcup_{A \in Var(\succ_1)} q_A^1\right) \cap \approx_{Var(\succ_2)} (o'', o') \in TC\left(\bigcup_{A \in Var(\succ_2)} q_A^1\right) \cap \approx_{Var(\succ_1)} q_A^1$$

or equivalently

$$(o, o'') \in TC \left(\bigcup_{A \in Var(\succ_1)} q_A^1 \cap \approx_{Var(\succ_2)}\right)$$
$$(o'', o') \in TC \left(\bigcup_{A \in Var(\succ_2)} q_A^1 \cap \approx_{Var(\succ_1)}\right)$$

which implies by (13) and (12)

$$o \succ_{(\mathcal{W},\mathcal{A})} o'', o'' \succ_{(\mathcal{W},\mathcal{A})} o'.$$

The transitivity of  $\succ_{(\mathcal{W},\mathcal{A})}$  implies  $o \succ_{(\mathcal{W},\mathcal{A})} o'$ .

Fig. 19 Forks of A and B

Recall that by Definition 10,

$$Ch_{\Gamma_{\succ}}(A) = \begin{cases} Ch_{\Gamma_{\succ_1}}, \text{ if } A \in Var(\succ_1) \\ Ch_{\Gamma_{\succ_2}} \text{ if } A \in Var(\succ_2). \end{cases}$$

Hence, given the inductive hypothesis, we proved that

$$W_A = Ch_{\Gamma_{\succ}}(A) = \begin{cases} W_A^1 = Ch_{\Gamma_{\succ_1}}, \text{ if } A \in Var(\succ_1) \\ W_A^2 = Ch_{\Gamma_{\succ_2}} & \text{ if } A \in Var(\succ_2). \end{cases}$$

**Theorem 2.** A directed graph  $\Gamma$  with the set of nodes A is a *p*-graph of some *p*-skyline relation iff

- 1.  $\Gamma$  is an SPO, and
- 2. Γ satisfies the Envelope property:

$$\begin{array}{l} \forall A, B, C, D \in \mathcal{A}, all \ different \\ (A, B) \in \Gamma \land \ (C, D) \in \Gamma \land (C, B) \in \Gamma \Rightarrow \\ (C, A) \in \Gamma \lor (A, D) \in \Gamma \lor (D, B) \in \Gamma \end{array}$$

To prove the theorem, we introduce the notion of the *typed partition* of a directed graph.

**Definition 15** Let  $\Gamma$  be a directed graph, and  $\Gamma_1$ ,  $\Gamma_2$  be two nonempty subgraphs of  $\Gamma$  such that  $N(\Gamma_1) \cap N(\Gamma_2) = \emptyset$  and  $N(\Gamma_1) \cup N(\Gamma_2) = N(\Gamma)$ . Then the pair  $\langle \Gamma_1, \Gamma_2 \rangle$  is a  $\sim$ -partition (respectively  $\rightarrow$ -partition) of  $\Gamma$  if  $\Gamma \models N(\Gamma_1) \sim N(\Gamma_2)$ , respectively  $(N(\Gamma_1), N(\Gamma_2)) \in \Gamma$ .

The proof of Theorem 2 is based on Lemmas 1 and 2. Lemma 1 establishes relationships between nodes in an SPO+ Envelope graph, while Lemma 2 establishes relationships between typed partitions in such a graph.

**Definition 16** Two nodes *A* and *B* of a directed graph  $\Gamma$  form a *fork* if *A* is different from *B*, and they conform to one of the patterns in Figure 19. The node *C* of  $\Gamma$  has to be different from *A* and *B*.

**Lemma 1** Let a directed graph  $\Gamma$  with at least two nodes satisfy SPO+Envelope. Then  $\Gamma$  has a  $\sim$ -partition, or every pair of nodes of  $\Gamma$  forms a fork.

**Proof.** For the sake of contradiction, assume  $\Gamma$  has no  $\sim$ -partition, and some pair of different nodes *A* and *B* of  $\Gamma$  does not form a fork, i.e.,

$$\begin{aligned} (A,B) \not\in \Gamma \land (B,A) \not\in \Gamma \land \neg \exists C \in N(\Gamma) \\ (A,C) \in \Gamma \land (B,C) \in \Gamma \lor (C,A) \in \Gamma \land (C,B) \in \Gamma. \end{aligned}$$

Let a subgraph  $\Gamma_1$  of  $\Gamma$  have the following set of nodes

$$N(\Gamma_1) = \{A\} \cup Pa_{\Gamma}(\{A\} \cup Ch_{\Gamma}(A)) \cup Ch_{\Gamma}(\{A\} \cup Pa_{\Gamma}(A))$$

and the subgraph  $\Gamma_2$  of  $\Gamma$  have the nodes  $N(\Gamma_2) = N(\Gamma) - N(\Gamma_1)$ . Assuming that  $B \in N(\Gamma_1)$  leads to contradiction by case analysis. So  $B \in N(\Gamma_2)$ . We conclude that both  $\Gamma_1$  and  $\Gamma_2$  are nonempty. Also, by case analysis we show that  $\Gamma \models N(\Gamma_1) \sim N(\Gamma_2)$ .

**Lemma 2** A directed graph  $\Gamma$  satisfying SPO+Envelope with at least two nodes has a  $\rightarrow$ -partition or a  $\sim$ -partition  $\langle \Gamma_{\succ_1}, \Gamma_{\succ_2} \rangle$  such that  $\Gamma_{\succ_1}$  and  $\Gamma_{\succ_2}$  satisfy SPO+Envelope.

**Proof.** We assume that no  $\sim$ -partition of  $\Gamma$  exists and show that there exists a  $\rightarrow$ -partition. Since  $\Gamma$  is a finite SPO, there exists a nonempty set  $Top \subseteq N(\Gamma)$  of all the nodes which have no incoming edges. If Top is a singleton, then Top dominates every node in  $N(\Gamma) - Top$ , and we get the  $\rightarrow$ partition  $\langle Top, N(\Gamma) - Top \rangle$ . Assume Top is not singleton. Pick two nodes  $T_1, T_2 \in Top$ .  $T_1$  and  $T_2$  have no incoming edges, and Lemma 1 implies that there exists a node  $Z_1$  such that  $(T_1, Z_1) \in \Gamma \land (T_2, Z_1) \in \Gamma$ . If |Top| > 2, pick some node  $T_k$  ( $T_k \neq T_1, T_k \neq T_2$ ) from *Top*. Since  $T_k$  has no incoming edges either, Lemma 1 implies that either  $T_k$  is a parent of  $Z_1$  or they have a common child (which is also a child of  $T_1$ and  $T_2$  by the transitivity of  $\Gamma$ ). Therefore, by picking every node of Top, we can show that there exists at least one node Z which is a child of all nodes in Top. Denote as M the set of all the nodes dominated by every node in Top. Above we showed that *M* contains at least one node.

Now let us show that if a node X is not in M then  $(X, M) \in \Gamma$ . Clearly, if  $X \in Top$ , then  $(X, M) \in \Gamma$ . So let  $X \notin Top$ . By definition of Top, there is a node  $T_1 \in Top$  such that  $(T_1, X) \in \Gamma$ . Assume there is a node  $Z \in M$  such that  $(X, Z) \notin \Gamma$ . By definition of M,  $(T_1, Z) \in \Gamma$ . Now pick some node T $(T \neq T_1)$  of Top. By definition of M,  $(T, Z) \in \Gamma$ . Let us apply Envelope:

$$\begin{aligned} (T,Z) \in \Gamma \land (T_1,Z) \in \Gamma \land (T_1,X) \in \Gamma \Rightarrow \\ (T_1,T) \in \Gamma \lor (T,X) \in \Gamma \lor (X,Z) \in \Gamma. \end{aligned}$$

The first and the last disjuncts in the right-hand-side of the expression contradict the assumptions  $(X,Z) \notin \Gamma$  and  $T \in Top$ . Therefore, the only choice is  $(T,X) \in \Gamma$ . However, *T* is an arbitrary node in *Top*. Therefore,  $(Top, X) \in \Gamma$  and thus  $X \in M$  by definition of *M*. We conclude that  $\langle N(\Gamma) - M, M \rangle$  is a  $\rightarrow$ -partition of  $\Gamma$ 

Finally, it is easy to check that every subgraph of an SPO+Envelope graph satisfies SPO+Envelope. □

**Proof of Theorem 2.** By induction on the the structure of the p-expression inducing a given p-skyline relation, it is easy to show that SPO+Envelope is satisfied by p-graphs. Now we show that every directed graph satisfying SPO+

Envelope is a p-graph of some p-skyline relation. Given such a graph  $\Gamma$ , we construct the corresponding p-skyline relation recursively. If  $\Gamma$  contains a single node, then the corresponding p-skyline relation is the atomic preference relation induced by the attribute preference relation of the corresponding attribute. If  $\Gamma$  has more than one node, then by Lemma 2,  $\Gamma$  has either a  $\rightarrow$ -partition or a  $\sim$ -partition  $\langle \Gamma_1, \Gamma_2 \rangle$  into nonempty subgraphs satisfying SPO+Envelope. If  $\langle \Gamma_1, \Gamma_2 \rangle$  is a  $\rightarrow$ -partition ( $\sim$ -partition), then the corresponding p-skyline relation is a prioritized (Pareto, respectively) accumulation of the p-skyline relations corresponding to  $\Gamma_1$  and  $\Gamma_2$ . This recursive construction exactly corresponds to the construction of W shown in Theorem 1.

**Proposition 4.** Let A and B be leaf nodes in a normalized syntax tree  $T_{\succ}$  of a p-skyline relation  $\succ \in \mathcal{F}_{\mathcal{H}}$ . Then  $(A, B) \in \Gamma_{\succ}$  iff the least common ancestor C of A and B in  $T_{\succ}$  is labeled by &, and A precedes B in the left-to-right tree traversal.

#### **Proof of Proposition 4.**

(⇐) Let  $\succ_C$  be a p-skyline relation represented by the syntax tree with the root node *C*. Definition 10 implies  $(A, B) \in \Gamma_{\succ_C}$ and  $E(\Gamma_{\succ_C}) \subseteq E(\Gamma_{\succ})$ .

⇒ Let  $(A,B) \in \Gamma_{\succ}$ . If *C* is of type & but *B* precedes *A* in left-to-right tree traversal, then Definition 10 implies  $(B,A) \in \Gamma_{\succ C}$  and hence  $(B,A) \in \Gamma_{\succ}$ , which is a contradiction to SPO of  $\Gamma_{\succ}$ . If *C* is of type  $\otimes$ , then by Definition 10,  $\Gamma_{\succ C} \models A \sim B$  and hence  $\Gamma_{\succ} \models A \sim B$ , which contradicts the initial assumption. □

**Theorem 3.** Two *p*-skyline relations  $\succ_1, \succ_2 \in \mathcal{F}_{\mathcal{H}}$  are equal iff their *p*-graphs are identical.

To prove the theorem, we use the next lemma.

**Lemma 3** Assume that  $\succ_1$  (resp.  $\succ_2$ ) are p-skyline relations in  $\mathcal{F}_{\mathcal{H}}$ , generated by  $(\mathcal{W}^1, \mathcal{A})$  and  $(\mathcal{W}^2, \mathcal{A})$ , respectively. If for some  $A \in \mathcal{A}$ ,  $W_A^1 - W_A^2 \neq \emptyset$ , then there is a pair  $o, o' \in \mathcal{U}$ such that

 $o \succ_1 o'$  and  $o \not\succ_2 o'$ .

**Proof.** We construct two tuples *o* and *o'* such that  $o \succ_{(\mathcal{W}^1,\mathcal{A})}$ *o'* (and thus  $o \succ_1 o'$ ), and  $o \not\succ_{(\mathcal{W}^2,\mathcal{A})} o'$  (and thus  $o \not\succ_2 o'$ ).

For every attribute  $A_i \in \mathcal{A}$ , pick two values  $v_{A_i}, v'_{A_i} \in \mathcal{D}_{A_i}$ such that  $v_{A_i} >_{A_i} v'_{A_i}$ . Construct the tuples *o* and *o'* as follows:

$$o.A_i = \begin{cases} v_{A_i}, \text{ if } A_i = A, \\ v_{A_i}, \text{ if } A_i \in \mathcal{A} - (\{A\} \cup W_A^1), \\ v'_{A_i}, \text{ otherwise } (A_i \in W_A^1) \end{cases}$$

$$o'.A_i = \begin{cases} v'_{A_i}, \text{ if } A_i = A, \\ v_{A_i}, \text{ if } A_i \in \mathcal{A} - (\{A\} \cup W_A^1), \\ v_{A_i}, \text{ otherwise } (A_i \in W_A^1) \end{cases}$$

By construction, it is clear that

$$(o,o') \in \{(o_1,o_2) \mid o_1 \succ_A o_2\} \cap \approx_{\mathcal{A}-(\{A\} \cup W_A^1)}$$

and thus  $o \succ_{(\mathcal{W}^1,\mathcal{A})} o'$  and  $o \succ_1 o'$ . Now assume  $o \succ_{(\mathcal{W}^2,\mathcal{A})} o'$  (and thus  $o \succ_2 o'$ ), i.e.

$$(o,o') \in TC\left(\bigcup_{A_i \in \mathcal{A}} q_{A_i}\right)$$
 (17)

where

$$q_{A_i} \equiv \{(o_1, o_2) \mid o_1 \succ_{A_i} o_2\} \cap \approx_{\mathcal{A} - (\{A_i\} \cup W_{A_i}^2)}.$$
(18)

(17) implies that there should exist a derivation sequence  $(\Sigma_{o,o'}, \Psi_{o,o'})$  for  $o \succ_{(\mathcal{W}^2,\mathcal{A})} o'$ . That is,  $\Sigma_{o,o'} = (o_1 = o, o_2, ..., o_m, o_{m+1} = o')$  is a sequence of tuples, and  $\Psi_{o,o'} = (A_{i_1}, ..., A_{i_m})$  is a sequence of attributes such that

$$q_{A_{i_1}}(o_1, o_2), \dots, q_{A_{i_m}}(o_m, o_{m+1}).$$
 (19)

Note that by (18),  $o_{i_k}$  may be worse than  $o_{i_{k+1}}$  in the values of  $W_{A_{i_i}^2}$  only.

First, we prove that  $\Psi_{o,o'} \subseteq W_A^2 \cup \{A\}$ . For the sake of contradiction, assume  $M = \Psi_{o,o'} - (W_A^2 \cup \{A\})$  is nonempty. Pick an element  $A_{top} \in M$  which has no ancestors from M in  $\Gamma_{\succ_2}$  (such an element exists due to acyclicity of  $\Gamma_{\succ_2}$ ). Since  $q_{A_{top}}$  is in the chain (19), we get

 $o.A_{top} >_{A_{top}} o'.A_{top}.$ 

By construction of o, o' that implies  $A_{top} = A$ , which is a contradiction. Thus,  $\Psi_{o,o'} \subseteq W_A^2 \cup \{A\}$ .

Second, we prove  $o \neq_{(W^2,\mathcal{A})} o'$ . For that, pick  $B \in W_A^1 - W_A^2$ . By construction of o and o',  $o'.B >_B o.B$ . That implies that there is a pair of tuples  $o_k, o_{k+1}$  in  $\Sigma_{o,o'}$  in which the value of B is changed from a less preferred to a more preferred one. That is possible only if  $B \in W_C^2$  for some attribute  $C \in \Psi_{o,o'} \subseteq W_A^2 \cup \{A\}$ . By Theorem 1,  $B \in Ch_{\Gamma_{\succ_2}}(C)$  and  $C \in Ch_{\Gamma_{\succ_2}}(A) \cup \{A\}$ . By transitivity of  $\Gamma_{\succ_2}$  (Theorem 2),  $B \in Ch_{\Gamma_{\succ_2}}(A) \cup \{A\}$ . By transitivity of  $\Gamma_{\succ_2}$  (Theorem 2),  $B \in Ch_{\Gamma_{\succ_2}}(A)$  (i.e.,  $B \in W_A^2$ ), which contradicts the definition of B. Hence,  $o \neq_{(W^2,\mathcal{A})} o'$ .

Now we go back to the proof of Theorem 3. Proof of

## Theorem 3.

 $(\Rightarrow)$  Every two p-skyline relations which have the same pgraph are represented by the same structure  $(\mathcal{W}, \mathcal{A})$ , by the definition of p-graph. Therefore, the p-skyline relations are equal.

E Pick two equal p-skyline relations  $\succ_1$  and  $\succ_2$ . Let the structures  $(\mathcal{W}^1, \mathcal{A}), (\mathcal{W}^2, \mathcal{A})$  and the p-graphs  $\Gamma_{\succ_1}, \Gamma_{\succ_2}$  represent  $\succ_1$  and  $\succ_2$ , respectively. Clearly, the node sets of  $\Gamma_{\succ_1}$  and  $\Gamma_{\succ_2}$  are equal to  $\mathcal{A}$ . If their edge sets are different, then the functions  $W^1$  and  $W^2$  are different. Pick  $A \in \mathcal{A}$  such that  $W_A^1 \neq W_A^2$ . Without loss of generality, we can assume  $W_A^1 - W_A^2 \neq 0$ . Lemma 3 implies that  $\succ_1$  and  $\succ_2$  are not equal, which is a contradiction.

**Theorem 4.** For *p*-skyline relations  $\succ_1, \succ_2 \in \mathcal{F}_{\mathcal{H}}, \succ_1 \subset \succ_2 \Leftrightarrow E(\Gamma_{\succ_1}) \subset E(\Gamma_{\succ_2}).$ 

# Proof.

 $\stackrel{(=)}{=} Let the structures <math>(\mathcal{W}^1, \mathcal{A})$  and  $(\mathcal{W}^2, \mathcal{A})$  generate relations  $\succ_{(\mathcal{W}^1, \mathcal{A})}$  and  $\succ_{(\mathcal{W}^2, \mathcal{A})}$  equal to  $\succ_1$  and  $\succ_2$ , correspondingly.  $E(\Gamma_{\succ_1}) \subset E(\Gamma_{\succ_2})$  implies that for all  $A \in \mathcal{A}$ ,  $W_A^1 \subseteq W_A^2$ . Hence,  $\succ_{(\mathcal{W}^1, \mathcal{A})} \subseteq \succ_{(\mathcal{W}^2, \mathcal{A})}$  and  $\succ_1 \subseteq \succ_2$ . Theorem 3 implies  $\succ_1 \subset \succ_2$ .  $\implies$  Let  $E(\Gamma_{\succ_1}) \not\subset E(\Gamma_{\succ_2})$ . If  $E(\Gamma_{\succ_1}) = E(\Gamma_{\succ_2})$ , then by Theorem 3,  $\succ_1 \equiv \succ_2$ , which is a contradiction. Therefore,  $E(\Gamma_{\succ_1}) \neq E(\Gamma_{\succ_2})$ , and for some A we have  $W_A^2 - W_A^1 \neq \emptyset$ . Lemma 3 implies  $\succ_1 \not\subset \succ_2$ , which is a contradiction.  $\Box$ 

**Theorem 5.** Let  $o, o' \in U$  s.t.  $o \neq o'$  and  $\succ \in \mathcal{F}_{\mathcal{H}}$ . Then the following conditions are equivalent:

1. 
$$o \succ o'$$
;  
2.  $BetIn(o,o') \supseteq Top_{\succ}(o,o')$ 

2. BetIn(o, o')  $\supseteq$  Iop $\succ$ (o, o'); 3. Ch<sub> $\Gamma \succ$ </sub> (BetIn(o, o'))  $\supseteq$  BetIn(o', o).

**Proof.** Let the structure  $(\mathcal{W}, \mathcal{A})$  generate a relation equal to  $\succ$ , i.e.

$$\succ \equiv \succ_{(\mathcal{W},\mathcal{A})} \equiv TC\left(\bigcup_{A\in\mathcal{A}}q_A\right)$$

where

$$q_A \equiv \{(o_1, o_2) \mid o_1.A >_A o_2.A\} \cap \approx_{\mathcal{A} - (W_A \cup \{A\})}$$

 $[1 \Leftrightarrow 3]$  Let  $Ch_{\Gamma_{\succ}}(BetIn(o, o')) \supseteq BetIn(o', o)$ . W.l.o.g., take  $BetIn(o, o') = \{A_1, \dots, A_k\}$ . It is easy to check that the sequence  $(\Sigma_{o,o'}, \Psi_{o,o'})$  constructed as follows is a derivation sequence for  $o \succ_{(\mathcal{W},\mathcal{A})} o'$ . Let  $\Psi_{o,o'} = BetIn(o,o') = \{A_1, \dots, A_k\}$ . Let the values of all the attributes  $\mathcal{A} - (BetIn(o,o') \cup BetIn(o', o))$  in  $\Sigma_{o,o'}$  be equal to those in o which are also equal to those in o'. Set  $o_1$  to o. Now pick i from 2 to k consecutively and set the values of  $\{A_i\} \cup (W_{A_i} \cap BetIn(o', o))$ in  $o_i$  to those in o'. Since  $W_{A_i} = Ch_{\Gamma_{\succ}}(A_i)$  (Theorem 1), the value of every attribute in  $o_k$  will be equal to the corresponding value in o'.

Now assume  $Ch_{\Gamma_{\succ}}(BetIn(o,o')) \not\supseteq BetIn(o',o)$ . Thus, the set  $BetIn(o',o) - Ch_{\Gamma_{\succ}}(BetIn(o,o'))$  is nonempty. Similarly to the proof of Lemma 3, it can be shown that no derivation sequence exists for  $o \succ_{(\mathcal{W},\mathcal{A})} o'$ .

[2 ⇔ 3] 2 implies 3 by definition of  $Top_{\succ}(o, o')$ . Prove that 3 implies 2. Assume that 3 holds but  $\exists A \in Top_{\succ}(o, o') - BetIn(o, o')$ . Since  $>_A$  is a total order,  $A \in BetIn(o', o)$ . Then 3 implies that  $A \notin Top_{\succ}(o, o')$ , which is a contradiction. **Theorem 6.** Let  $\succ$  be a *p*-skyline relation with the *p*-graph  $\Gamma_{\succ}$ , and **A**, **B**, **C**, and **D**, disjoint node sets of  $\Gamma_{\succ}$ . Let the subgraphs of  $\Gamma_{\succ}$  induced by those node sets be singletons or unions of at least two disjoint subgraphs. Then

$$\begin{aligned} (\mathbf{A},\mathbf{B}) \in \Gamma_{\succ} \land (\mathbf{C},\mathbf{D}) \in \Gamma_{\succ} \land (\mathbf{C},\mathbf{B}) \in \Gamma_{\succ} \Rightarrow \\ (\mathbf{C},\mathbf{A}) \in \Gamma_{\succ} \lor (\mathbf{A},\mathbf{D}) \in \Gamma_{\succ} \lor (\mathbf{D},\mathbf{B}) \in \Gamma_{\succ}. \end{aligned}$$

**Proof.** We prove the theorem by contradiction. Let

$$\begin{aligned} (\mathbf{A},\mathbf{B}) \in \Gamma_{\succ} \land (\mathbf{C},\mathbf{D}) \in \Gamma_{\succ} \land (\mathbf{C},\mathbf{B}) \in \Gamma_{\succ} \land \\ (\mathbf{C},\mathbf{A}) \not\in \Gamma_{\succ} \land (\mathbf{A},\mathbf{D}) \notin \Gamma_{\succ} \land (\mathbf{D},\mathbf{B}) \notin \Gamma_{\succ}. \end{aligned}$$

The second part is equivalent to the following:

$\exists C \in \mathbf{C}, A_1, A_2 \in \mathbf{A}, D_1, D_2 \in \mathbf{D}, B \in \mathbf{B}$	
$((C,A_2)  ot\in \Gamma_\succ \land$	(C-A2)
$(A_1,D_1)\not\in \Gamma_\succ\wedge$	(A1-D1)
$(D_2,B) ot\in\Gamma_\succ)$	(D2-B)

and from the first part

$$\begin{array}{ll} (A_1,B)\in\Gamma_{\succ} & (A1\text{-}B)\\ (A_2,B)\in\Gamma_{\succ} & (A2\text{-}B)\\ (C,D_1)\in\Gamma_{\succ} & (C\text{-}D1)\\ (C,D_2)\in\Gamma_{\succ} & (C\text{-}D2) \end{array}$$

Note that the fact that the subgraphs of  $\Gamma_{\succ}$  induced by **A**, **B**, **C**, **D** are singletons or unions of at least two disjoint subgraphs implies the following four cases for  $A_1$  and  $A_2$ :

$$\Gamma_{\succ} \models A_1 \sim A_2$$
(Case A1)  

$$(A_1, A_2) \in \Gamma_{\succ} \land \exists A_3 \in \mathbf{A} . \ \Gamma_{\succ} \models A_1 \sim A_3 \land \Gamma_{\succ} \models A_2 \sim A_3$$
(Case A2)  

$$(A_2, A_1) \in \Gamma_{\succ} \land \exists A_3 \in \mathbf{A} . \ \Gamma_{\succ} \models A_1 \sim A_3 \land \Gamma_{\succ} \models A_2 \sim A_3$$
(Case A3)  

$$A_1 \equiv A_2$$

Similarly, we have four cases for  $D_1, D_2$ :

$$\begin{split} \Gamma_{\succ} &\models D_1 \sim D_2 \\ (\text{Case D1}) \\ (D_1, D_2) \in \Gamma_{\succ} \land \exists D_3 \in \mathbf{D} \ . \ \Gamma_{\succ} &\models D_1 \sim D_3 \land \Gamma_{\succ} \models D_2 \sim D_3 \\ (\text{Case D2}) \\ (D_2, D_1) \in \Gamma_{\succ} \land \exists D_3 \in \mathbf{D} \ . \ \Gamma_{\succ} &\models D_1 \sim D_3 \land \Gamma_{\succ} \models D_2 \sim D_3 \\ (\text{Case D3}) \\ D_1 &\equiv D_2 \\ (\text{Case D4}) \end{split}$$

Notice that by our initial assumption, there exist two attributes  $A_1, A_2 \in \mathbf{A}$  and two attributes  $D_1, D_2 \in \mathbf{D}$ . Case A4 and D4 are due to the fact that  $A_1, A_2$  and  $D_1, D_2$  may corresponding to the same attributes in **A** and **D**, respectively.

Totally we have sixteen different cases, and we need to show that all of them lead to contradictions. One can show that all of them contradict the Envelope property. We demonstrate it for the case (A3-D2), while the other cases are handled similarly. In Figure 20, we show instances of the Envelope property. Recall that the Envelope property says that if a graph has certain three edges, it must have at least one of the other three edges. The instances we show below lead to only one possible edge while the other two violate some conditions above. The violated condition is shown below each corresponding edge. Finally, we show that there is an unsatisfiable instance of the Envelope property.

We have exhaustively tested the other fifteen cases and showed that similar contradictions can be derived for them, too.  $\hfill \Box$

Fig. 20 Case A3-D2

(Case A4)

**Theorem 7.** Let  $\succ \in \mathcal{F}_{\mathcal{H}}$ , and  $T_{\succ}$  be a normalized syntax tree of  $\succ$ . Then  $\succ_{ext}$  is a minimal p-extension of  $\succ$  iff the syntax tree  $T_{\succ_{ext}}$  of  $\succ_{ext}$  is obtained from  $T_{\succ}$  by a single application of a rule from  $Rule_1, \ldots, Rule_4$ , followed by a single-child node elimination if necessary.

To prove Theorem 7 we introduce the notions of *frontier nodes*, and *top* and *bottom* components in a syntax tree.

**Definition 17** The *top* and *bottom* components of a p-skyline relation  $\succ$  are defined as follows:

- 1. if  $\succ$  is the atomic preference relation induced by an attribute preference relation, then top = bottom =  $\succ$ ;
- 2. if  $\succ = \succ_1 \& \ldots \& \succ_m$ , then top =  $\succ_1$  and bottom =  $\succ_m$ .

Note that the notions of top and bottom components are undefined for p-skyline relations defined as Pareto accumulations of p-skyline relations.

**Definition 18** Let  $T_{\succ}$  be a normalized syntax tree of a pskyline relation  $\succ$ . Let also  $C_1$  and  $C_2$  be two different children nodes of a  $\otimes$ -node C in  $T_{\succ}$ . Let  $\succ_{ext}$  be a p-extension of  $\succ$ . Moreover, let the subgraphs of  $\Gamma_{\succ}$  and  $\Gamma_{\succ ext}$  induced by  $Var(C_1)$  be equal, as well as those induced by  $Var(C_2)$ . Let  $X \in Var(C_1)$ ,  $Y \in Var(C_2)$  be such that

 $(X,Y) \in \Gamma_{\succ_{ext}}.$ 

Then  $(C_1, C_2)$  is a frontier pair of  $T_{\succ}$  w.r.t.  $T_{\succ_{ext}}$ .

Given a frontier pair  $(C_1, C_2)$  of  $T_{\succ}$  w.r.t.  $T_{\succ_{ext}}$ , note that  $\Gamma_{\succ} \models Var(X) \sim Var(Y)$  by Proposition 4. By definition, a pskyline relation is constructed in a recursive way: a higherlevel relation is defined in terms of lower-level relations. Hence, the intuition behind the frontier pair is as follows. When  $\succ$  and  $\succ_{ext}$  are constructed, the lower-level relations  $\succ_{C_1}$  and  $\succ_{C_2}$  are present in both  $\succ$  and  $\succ_{ext}$ . However, the next-level relations defined using  $\succ_{C_1}$  and  $\succ_{C_2}$  in  $\succ$  and  $\succ_{ext}$  are different since  $\Gamma_{\succ_{ext}}$  has an edge from a member of  $Var(\succ_{C_1})$  to a member of  $Var(\succ_{C_2})$ , which is not present in  $\Gamma_{\succ}$ . The next lemma shows some properties of frontier pairs.

**Lemma 4** Let  $\succ_{ext}$  be a *p*-extension of  $\succ \in \mathcal{F}_{\mathcal{H}}$ , and  $T_{\succ}$  be a normalized syntax tree of  $\succ$ . Let also  $(C_1, C_2)$  (or  $(C_2, C_1)$ ) be a frontier pair of  $T_{\succ}$  w.r.t.  $T_{\succ_{ext}}$ . Denote the top and the bottom components of  $C_1$  as  $A_1, B_1$ , and the top and the bottom components of  $C_2$  as  $A_2, B_2$ . Then

 $(Var(A_1), Var(B_2)) \in \Gamma_{\succ_{ext}} \lor (Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}$ 

**Proof.** We consider the case of  $(C_1, C_2)$  being a frontier pair of  $T_{\succ}$  w.r.t.  $T_{\succ_{ext}}$ . The case of  $(C_2, C_1)$  is symmetric. Since  $(C_1, C_2)$  is a frontier pair of  $T_{\succ}$  w.r.t.  $T_{\succ_{ext}}$ , there are  $X \in Var(C_1)$  and  $Y \in Var(C_2)$  such that

 $(X,Y) \in \Gamma_{\succ_{ext}}$ 

Note that we have the following cases for  $X \in Var(C_1)$ 

<b>\$</b> 1	$Var(C_1) = \{X\}$ , i.e. $(C_1 = A_1 = B_1)$
<b>\$</b> 2	$C_1 = (A_1 \& \dots \& B_1), X \notin Var(A_1)$
<b>\$</b> 3	$C_1 = (A_1 \& \dots \& B_1), Var(A_1) = \{X\}$
<b>\$</b> 4	$C_1 = (A_1 \& \dots \& B_1), A_1 = A_1^1 \otimes A_1^2 \dots, X \in Var(A_1^1)$
	$A_1 = A_1^1 \otimes A_1^2 \dots, X \in Var(A_1^1)$

and for  $Y \in Var(C_2)$ 

$\lambda_1$	$Var(C_2) = \{Y\}$ , i.e. $(C_2 = A_2 = B_2)$
$\lambda_2$	$C_2 = (A_2 \& \dots \& B_2), Y \notin Var(B_2)$
$\lambda_3$	$C_2 = (A_2 \& \dots \& B_2), Var(B_2) = \{Y\}$
$\lambda_4$	$C_2 = (A_2 \& \dots \& B_2) B_2 = B_2^1 \otimes B_2^2 \dots, Y \in Var(B_2^1).$
	$B_2 = B_2^1 \otimes B_2^2 \dots, Y \in Var(B_2^1).$

The cases  $\phi_1, \phi_2$ , and  $\phi_3$  imply either  $(Var(A_1), X) \in \Gamma_{\succ_{ext}}$  or  $Var(A_1) = \{X\}$  and as a result  $(Var(A_1), Y) \in \Gamma_{\succ_{ext}}$  by transitivity of  $\Gamma_{\succ_{ext}}$ . Similarly, the cases  $\lambda_1, \lambda_2$ , and  $\lambda_3$  imply either  $Var(B_2) = \{Y\}$  or  $(Y, Var(B_2)) \in \Gamma_{\succ_{ext}}$ . Thus

every combination of these cases implies  $(Var(A_1), Var(B_2)) \in \Gamma_{\succ_{ext}}$ . Now consider the other combinations of the cases. All of them are handled similar to the case  $(\phi_4, \lambda_4)$ , so we consider it in detail.

Take the case  $\lambda_4$ . Take  $Y' \in Var(B_2) - Var(B_2^1)$  and apply GeneralEnvelope to  $\Gamma_{\succ_{ev}}$ :

$$(Var(A_2), Y') \in \Gamma_{\succ_{ext}} \land (Var(A_2), Y) \in \Gamma_{\succ_{ext}} \land (X, Y) \in \Gamma_{\succ_{ext}}$$

which implies

$$(Var(A_2), X) \in \Gamma_{\succ_{ext}} \lor (X, Y') \in \Gamma_{\succ_{ext}} \lor (Y', Y) \in \Gamma_{\succ_{ext}}.$$

 $(Y',Y) \notin \Gamma_{\succ_{ext}}$  follows from Proposition 4 and the fact that the subgraphs of  $\Gamma_{\succ_{ext}}$  and  $\Gamma_{\succ}$  that are induced by  $Var(C_2)$ are the same.  $(Var(A_2), X) \in \Gamma_{\succ_{ext}}$  and  $(X, Var(B_1)) \in \Gamma_{\succ_{ext}}$ (following from  $\phi_4$ ) imply  $(Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}$ , which is what we need. Hence,  $(Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}$  or (X, $Y') \in \Gamma_{\succ_{ext}}$  for all  $Y' \in Var(B_2) - Var(B_2^1)$ . Consider  $(X, Y') \in$  $\Gamma_{\succ_{ext}}$  and pick  $Y'' \in Var(B_2^1)$ . For such Y'' we have  $(Y', Y'') \notin$  $\Gamma_{\succ_{ext}}$  by Proposition 4. Therefore, we get a condition for GeneralEnvelope similar to the one above:

$$(Var(A_2), Y'') \in \Gamma_{\succ_{ext}} \land (Var(A_2), Y') \in \Gamma_{\succ_{ext}} \land (X, Y') \in \Gamma_{\succ_{ext}}$$

implying

$$(Var(A_2), X) \in \Gamma_{\succ_{ext}} \lor (X, Y'') \in \Gamma_{\succ_{ext}} \lor (Y'', Y') \in \Gamma_{\succ_{ext}}.$$

 $(Y'',Y') \notin \Gamma_{\succ_{ext}}$  by the same argument as above. Similarly to the above,  $(Var(A_2),X) \in \Gamma_{\succ_{ext}}$  and  $(X, Var(B_1)) \in \Gamma_{\succ_{ext}}$  imply  $(Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}$ , which is what we need. As a result, we have  $(Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}$  or  $(X, Y') \in \Gamma_{\succ_{ext}} \land (X, Y'') \in \Gamma_{\succ_{ext}}$  for all  $Y' \in Var(B_2) - Var(B_2^1), Y'' \in Var(B_2^1)$ , that is equivalent to

$$(Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}} \lor (X, Var(B_2)) \in \Gamma_{\succ_{ext}}$$

Elaborating the case  $\phi_4$  as above gives that

$$(Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}} \lor (Var(A_1), Y) \in \Gamma_{\succ_{ext}}$$

After combining these two results and applying General-Envelope to members of  $A_1$  and  $B_2$ , we get

$$(Var(A_1), Var(B_2)) \in \Gamma_{\succ_{ext}} \lor (Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}.$$

Now we go back to the proof of Theorem 7.

## **Proof of Theorem 7**

 $\stackrel{[\Rightarrow]}{\rightarrow}$  Let  $\succ_{ext}$  be a minimal p-extension of  $\succ$ . We show here that there is  $\succ' \in \mathcal{F}_{\mathcal{H}}$  obtained using a transformation rule  $Rule_1, \ldots, Rule_4$  such that

$$\succ \subset \succ' \subseteq \succ_{ext} . \tag{20}$$

By the minimal p-extension property of  $\succ_{ext}$  that implies  $\succ' = \succ_{ext}$ .

Theorem 4 implies that there are *X* and *Y* such that  $(X, Y) \in E(\Gamma_{\succ_{ext}}) - E(\Gamma_{\succ})$ . Let  $(C_1, C_2)$  be a frontier pair of  $T_{\succ}$  w.r.t.  $T_{\succ_{ext}}$  such that  $X \in Var(C_1)$  and  $Y \in Var(C_2)$ . Lemma 4 implies that

$$(Var(A_1), Var(B_2)) \in \Gamma_{\succ_{ext}} \lor (Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}}$$
(21)

for the top  $A_1, A_2$  and the bottom  $B_1, B_2$  components of  $C_1$ and  $C_2$ , correspondingly. Consider all possible types of  $C_1$ and  $C_2$ . (i) Let  $C_1, C_2$  be leaf nodes. Then  $\succ'$  for which (20) holds may be obtained by applying  $Rule_3(T_{\succ}, C_1, C_2)$ (if the first disjunct of (21) holds) or  $Rule_3(T_{\succ}, C_2, C_1)$  (if the second disjunct of (21) holds). (ii) Let  $C_1$  be a & -node and  $C_2$  be a leaf node. Then  $\succ'$  may be obtained by applying  $Rule_1(T_{\succ}, C_1, C_2)$  (if the first disjunct of (21) holds) or  $Rule_2(T_{\succ}, C_1, C_2)$  (if the second disjunct of (21) holds). Case (iii) when  $C_1$  is a leaf node and  $C_2$  is a & -node is similar to the previous case. Consider case (iv) when  $C_1$ and  $C_2$  are & -nodes. Let the first disjunct of (21) hold. The case of the second disjunct is analogous. We note that  $(Var(A_1), Var(B_1)) \in \Gamma_{\succ ext}$  and  $(Var(A_2), Var(B_2)) \in \Gamma_{\succ ext}$ . This with (21) is a condition for GeneralEnvelope:

$$(Var(A_1), Var(A_2)) \in \Gamma_{\succ_{ext}} \lor (Var(A_2), Var(B_1)) \in \Gamma_{\succ_{ext}} \lor (Var(B_1), Var(B_2)) \in \Gamma_{\succ_{ext}}$$

$$(22)$$

If the first disjunct of (22) holds, then  $\succ'$  can be obtained by applying  $Rule_1(T_{\succ}, C_1, C_2)$ . If the last disjunct of (22) holds, then  $\succ'$  can be obtained by applying  $Rule_2(T_{\succ}, C_2, C_1)$ . Let the second disjunct of (22) hold, i.e.  $(Var(A_2), Var(B_1)) \in$  $\Gamma_{\succ_{ext}}$ . Let the child nodes of  $C_1$  and  $C_2$  be the sequences  $(A_1 = N_1, \dots, N_m = B_1)$  and  $(A_2 = M_1, \dots, M_n = B_2)$  correspondingly. The fact that  $C_1$  and  $C_2$  are & -nodes implies  $(Var(N_i), Var(N_j)) \in \Gamma_{\succ}$  and  $(Var(M_i), Var(M_j)) \in \Gamma_{\succ}$  for all i < j. Since  $\succ \subseteq \succ_{ext}$ , the same edges are present in  $\Gamma_{\succ_{ext}}$ . Note that  $(M_1, N_m) \in \Gamma_{\succ_{ext}}$ . Pick every child of  $C_2$  in its list of children from right to left and find the first index t such that  $(Var(N_1), Var(M_t)) \notin \Gamma_{\succ_{ext}}$  but  $(Var(N_1), Var(M_{t+1})) \in$  $\Gamma_{\succ_{ext}}$ . If no such t exists, then  $(Var(N_1), Var(M_1)) \in \Gamma_{\succ_{ext}}$ and  $\succ'$  may be obtained by applying  $Rule_1(T_{\succ}, C_1, C_2)$ . Assume  $t \in [1, n]$ . Similarly, let *s* be the first index such that  $(Var(M_1), Var(N_s)) \notin \Gamma_{\succ_{ext}}$  but  $(Var(M_1), Var(N_{s+1})) \in \Gamma_{\succ_{ext}}$ . If s does not exist, then  $\succ'$  may be obtained by applying  $Rule_2(T_{\succ}, C_2, C_1)$ . So assume  $s \in [1, m]$ . If both *s* and *t* are equal to 1, then  $\succ'$  may be obtained using  $Rule_4(T_{\succ}, C_1, C_2, s, s)$ t). In all other cases, GeneralEnvelope can be used to show that for all  $i \in [1,s], j \in [t+1,n]$  ( $Var(N_i), Var(M_i)$ )  $\in$  $\Gamma_{\succ_{ext}}$  and for all  $i \in [1,t], j \in [s+1,m]$   $(Var(M_i), Var(N_j)) \in [s+1,m]$  $\Gamma_{\succ_{ext}}$ . Hence  $Rule_4(T_{\succ}, C_1, C_2, s, t)$  may be used to construct  $\succeq'_{ext}$ .

Show that every valid application of  $Rule_1, \ldots, Rule_4$  results in a minimal extension. We do it by case analysis.

Take *Rule*<sub>3</sub>, which results in adding the edge from  $C_i$  to  $C_{i+1}$  to the p-graph. This is clearly a minimal extension of the p-graph and hence the resulting p-skyline relation is a minimal extension of  $\succ$ . The analysis pattern for the remaining rules is as follows. We assume that some p-extension  $\succ_{ext}$  obtained by an application of *Rule*<sub>1</sub>, *Rule*<sub>2</sub>, or *Rule*<sub>4</sub> to  $\succ$  is not minimal, i.e., there is  $\succ'$  s.t.  $\succ \subset \succ' \subset \succ_{ext}$ . After that, we derive a contradiction that  $\Gamma_{\succ'} = \Gamma_{\succ_{ext}}$ . Take *Rule*<sub>1</sub>. Since  $\succ'$  is an extension of  $\succ$  contained in  $\succ_{ext}$ , there must be an edge from some  $A \in Var(N_1)$  to some B in the bottom component of  $C_{i+1}$ . Clearly, if  $Var(N_1) = \{A\}$  and  $Var(C_{i+1}) = \{B\}$ , then  $\Gamma_{\succ'} = \Gamma_{\succ_{ext}}$  and we get the contradiction we want. So assume  $Var(C_{i+1}) \neq \{B\}$ . Then applying GeneralEnvelope to

$$(A, Var(N_2)) \in \Gamma_{\succ'} \land (A, Var(B)) \in \Gamma_{\succ'} \land$$
  
 $(Var(T_{i+1}), B) \in \Gamma_{\succ'}$ 

(where  $T_{i+1}$  is the top component of  $C_{i+1}$ ) results in  $(A, Var(T_{i+1})) \in \Gamma_{\succ'}$  (and hence  $(A, Var(C_{i+1})) \in \Gamma_{\succ'}$  by transitivity of  $\Gamma_{\succ'}$ ). The other alternatives are impossible: the corresponding edges are missing in  $\Gamma_{\succ_{ext}}$  (and hence in  $\Gamma_{\succ'}$ , too). Clearly, if  $Var(N_1) = \{A\}$ , then we get the contradiction we need:  $\Gamma_{\succ'} = \Gamma_{\succ_{ext}}$ . So assume  $Var(N_1) \neq \{A\}$ . Denote  $S = Var(N_1) - \{A\}$ . Then applying GeneralEnvelope to

$$(S, Var(N_2)) \in \Gamma_{\succ'} \land (A, Var(N_2)) \in \Gamma_{\succ'} \land (A, Var(C_{i+1})) \in \Gamma_{\succ'}$$

results in  $(S, Var(C_{i+1})) \in \Gamma_{\succ'}$ . The other alternatives are prohibited because the corresponding p-graph edges are not in  $\Gamma_{\succ_{ext}}$  (and hence not in  $\Gamma_{\succ'}$ ). That results in  $(Var(N_1), Var(C_{i+1})) \in \Gamma_{\succ'}$  and the contradiction that  $\Gamma_{\succ_{ext}} = \Gamma_{\succ'}$ . The case analysis for  $Rule_2$  is similar.

Now let  $\succ_{ext}$  be obtained from  $\succ$  by applying  $Rule_4$ , and consider a p-extension  $\succ'$  of  $\succ$  s.t.  $\succ' \subset \succ_{ext}$ . Because of this assumption,  $\Gamma_{\succ'}$  has an edge from some  $A \in Var(N_1)$ to some  $B \in Var(M_n)$  or from some  $C \in Var(M_1)$  to some  $D \in Var(N_m)$ . Since these cases are completely symmetric, take  $(A, B) \in \Gamma_{\succ'}$ . Applying GeneralEnvelope to

$$(A, Var(N_{s+1})) \in \Gamma_{\succ'} \land (A, B) \in \Gamma_{\succ'} \land$$
$$(Var(M_t), Var(M_n)) \in \Gamma_{\succ'}$$

results in

$$(Var(M_t), Var(N_{s+1})) \in \Gamma_{\succ'}$$
(23)

since all the other alternatives are impossible – the corresponding p-graph edges are not in  $\Gamma_{\succ_{ext}}$  – and hence not in  $\Gamma_{\succ'}$ . Now apply GeneralEnvelope to

$$(Var(M_t), Var(M_{t+1})) \in \Gamma_{\succ'} \land (Var(M_t), Var(N_{s+1})) \in \Gamma_{\succ'} \land (Var(N_s), Var(N_{s+1})) \in \Gamma_{\succ'} \land$$

which results in

$$(Var(N_s), Var(M_{t+1})) \in \Gamma_{\succ'}$$
(24)

since all the other alternatives are impossible – the corresponding p-graph edges are not in  $\Gamma_{\succ ext}$  and hence not in  $\Gamma_{\succ'}$ . (23), (24), and the transitivity of  $\Gamma_{\succ'}$  implies that  $\Gamma_{\succ'} = \Gamma_{\succ ext}$ , which is a contradiction.

# **Theorem 8.** *DF*-*PSKYLINE is NP-complete.*

**Proof.** The favoring/disfavoring p-skyline existence problem is in NP since checking if a p-skyline relation  $\succ$  favors *G* and disfavors *W* in *O* can be done in polynomial time by evaluating  $\omega_{\succ}(O)$ , checking  $G \subseteq \omega_{\succ}(O)$ , and checking if for every member of *W* there is a member of *W* dominating it.

To show the hardness result, we do a polynomial-time reduction from SAT. This is a two-step reduction. First, we show that for every instance  $\phi$  of SAT there are corresponding instances of positive  $\mathcal{P}$  and negative  $\mathcal{N}$  constraints, and  $\phi$  has a solution iff  $\mathcal{P}$  and  $\mathcal{N}$  are satisfiable. Second, we show that for every such  $\mathcal{P}$  and  $\mathcal{N}$  there are corresponding instances of *G*, *W*, and *O*.

Consider instances of SAT in the following form

$$\phi(x_1,\ldots,x_n)=\psi_1(x_1,\ldots,x_n)\wedge\ldots\wedge\psi_m(x_1,\ldots,x_n)$$

where

$$\Psi_t(x_1,\ldots,x_n)=\widehat{x_{i_t}}\vee\ldots\vee\widehat{x_{j_t}}$$

For every instance of  $\phi$ , construct  $\mathcal{A} = \{c, y_1, \overline{y_1}, y'_1, \dots, y_n, \overline{y_n}, y'_n\}$ . The sets of positive and negative constraints are constructed as follows. Let  $\Gamma$  be a graph. For every variable  $x_i$ ,

1. Create positive constraints

$$\chi_i : (y_i, c) \in \Gamma \lor (\overline{y_i}, c) \in \Gamma$$
  
 $\pi_i : (\overline{y_i}, y'_i) \in \Gamma$ 

2. Create negative constraints

 $\lambda_{i}^{1} : (\overline{y_{i}}, y_{i}) \notin \Gamma$  $\lambda_{i}^{2} : (y_{i}, y_{i}') \notin \Gamma$  $\lambda_{i}^{3} : (y_{i}', c) \notin \Gamma$ 

Now, for every  $\psi_t(x_1, ..., x_n) = \widehat{x_{i_t}} \lor ... \lor \widehat{x_{j_t}}$  of  $\phi$  construct the following positive constraint

$$\mu_t: (\widehat{y_{i_t}}, c) \in \Gamma \lor \ldots \lor (\widehat{y_{i_t}}, c) \in \Gamma$$

where  $\widehat{y_i} = \begin{cases} y_i \text{ if } \widehat{x_i} = x_i \\ \overline{y_i} \text{ if } \widehat{x_i} = \overline{x_i}. \end{cases}$ 

We claim that there is a satisfying assignment  $(v_1, \ldots, v_n)$  for  $\phi$  iff there is a p-graph satisfying all the constraints above.

First, assume there is a p-graph  $\Gamma$  satisfying all the constraints above. Construct the assignment  $v = (v_1, \ldots, v_n)$  as follows:

$$v_i = \begin{cases} 0 \text{ if } (\overline{y_i}, c) \in \Gamma \\ 1 \text{ if } (y_i, c) \in \Gamma \end{cases}$$

Since  $\Gamma$  satisfies all  $\chi_i$ , for every *i* we have  $(y_i, c) \in \Gamma$ or  $(\overline{y_i}, c) \in \Gamma$ . Thus, every  $v_i$  will be assigned to some value according to the rule above. Now prove that  $v_i$  is assigned to only one value, i.e., we cannot have both  $(y_i, c) \in \Gamma$  and  $(\overline{y_i}, c) \in \Gamma$ . Since  $\Gamma$  satisfies  $\pi_i$ , we have  $(\overline{y_i}, y'_i) \in \Gamma$ . Thus having both  $(y_i, c) \in \Gamma$  and  $(\overline{y_i}, c) \in \Gamma$  and Envelope implies

$$(\overline{y_i}, y_i) \in \Gamma \lor (y_i, y'_i) \in \Gamma \lor (y'_i, c) \in \Gamma.$$

However, the expression above violates the constraints  $\lambda_i^1$ ,  $\lambda_i^2$ ,  $\lambda_i^3$ . Therefore, exactly one of  $(y_i, c) \in \Gamma$ ,  $(\overline{y_i}, c) \in \Gamma$  holds.

Take every  $\mu_t$ . Since it is satisfied by  $\Gamma$ , the corresponding  $\psi_i$  must be also satisfied by the construction of  $\mu_t$ . Therefore,  $\phi$  is also satisfied.

Now assume that there is an assignment  $(v_1, \ldots, v_n)$  satisfying  $\phi$ . Show that there is a p-graph  $\Gamma_{\succ}$  satisfying all the constraints above. Here we construct such a graph.

For every  $i \in [1, n]$ , draw the edge

$$(y_i, c) \in \Gamma_{\succ}$$
 if  $v_i = 1$ , and (P1)

$$(\overline{y_i}, c) \in \Gamma_{\succ}, \quad \text{otherwise}$$
 (P2)

This satisfies the constraint  $\chi_i$ . Moreover, all the constraints  $\mu_t$  are satisfied by the construction. Now, for every  $i \in [1, n]$ , draw the edge

$$(\overline{y_i}, y_i') \in \Gamma_{\succ} \tag{P3}$$

which satisfies the constraint  $\pi_i$ . As a result, all positive constraints are satisfied. Moreover, none of the edges above violates any negative constraints. Thus, all the constraints above are satisfied.

In addition to the edges above, let us draw the following edges

1. for every  $i, j \ (i \neq j)$  such that  $v_i = 0, v_j = 0$ , draw the edge

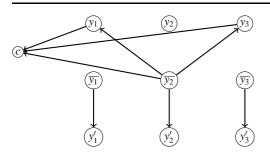

$$(\overline{y_i}, y_i') \in \Gamma_{\succ} \tag{P4}$$

It is clear that these edges do not violate any negative constraints above.

2. for every *i*, *j* such that  $v_i = 0, v_j = 1$ , draw the edge

$$(\overline{y_i}, y_j) \in \Gamma_{\succ} \tag{P5}$$

Since  $i \neq j$ , this edge does not violate any negative constraints above.

It is easy to verify that the constructed graph  $\Gamma_{\succ}$  satisfies SPO+Envelope and all the negative and positive constraints above.

Now let us show that there exist sets of objects O, G and W which can be used to obtain the constraints  $\chi_i$ ,  $\pi_i$ ,  $\lambda_i^1$ ,  $\lambda_i^2$ ,  $\lambda_i^3$ ,  $\mu_t$ . Assume that for every attribute in  $A \in \mathcal{A}$ , its domain contains at least three numbers  $\{-1,0,1\}$ , and greater values are to be preferred in the attribute preference relation  $>_A$ . Here we construct the sets G, W, M, and  $O = G \cup W \cup M$  that generate the positive and negative constraints above.

- 1. Let *G* consist of a single object *g* with all attributes values equal to 0.
- 2. Let  $W = \{b_1, \dots, b_n, u_1, \dots, u_n, w_1, \dots, w_m\}$  be constructed as follows:
  - for every  $i \in [1, ..., n]$ , let all the attributes of  $b_i$  be equal to 0, except for the value of  $\overline{y_i}$ , which is -1, and the value of  $y'_i$ , which is 1.
  - for every  $i \in [1, ..., n]$ , let all the attributes of  $u_i$  be equal to 0, except for the value of  $y_i, \overline{y_i}$ , which is -1, and the value of c, which is 1.
  - for every  $t \in [1, ..., m]$ , let  $\mu_t : (\widehat{y}_{i_t}, c) \in \Gamma \lor ... \lor (\widehat{y}_{j_t}, c) \in \Gamma$ , where  $\widehat{y}_i \in \{y_i, \overline{y}_i\}$ . Let all attributes of  $w_t$  be equal to 0, except for the value of *c*, which is 1, and the values of  $\widehat{y}_{i_t}, ..., \widehat{y}_{j_t}$  (whatever they are), which are -1.
- 3. Let  $M = \{m_1^1, m_1^2, m_1^3, ..., m_n^1, m_n^2, m_n^3\}$  be constructed as follows. For all  $i \in [1, ..., n]$ ,
  - Let all attributes of  $m_i^1$  be 0, except for the value  $y_i$ , which is -1, and the value of  $\overline{y_i}$  which is 1.
  - Let all attributes of  $m_i^2$  be 0, except for the value of  $y_i$ , which is 1, and the value of  $y'_i$ , which is -1.
  - Let all attributes of  $m_i^3$  are 0, except for the value of  $y'_i$ , which is 1, and the value of *c*, which is -1.

It can be easily shown that these sets of objects induce the set of constructed constraints (see Example 19).  $\Box$ 

*Example 19* Take n = 3 and

 $\phi(x_1, x_2, x_3) = (x_1 \lor x_2 \lor \overline{x_3}) \land (\overline{x_1} \lor x_2 \lor x_3).$ 

Then  $\mathcal{A} = \{c, y_1, \overline{y_1}, y'_1, y_2, \overline{y_2}, y'_2, y_3, \overline{y_3}, y'_3\}$ . The constraints  $\mu_1, \mu_2$  are

$$\mu_{1}: (y_{1}, c) \in \Gamma \lor (y_{2}, c) \in \Gamma \lor (\overline{y_{3}}, c) \in \Gamma$$
$$\mu_{2}: (\overline{y_{1}}, c) \in \Gamma \lor (y_{2}, c) \in \Gamma \lor (y_{3}, c) \in \Gamma$$

Take the assignment v = (1,0,1) satisfying  $\phi$ . By construction above, we get the graph  $\Gamma$  as in Figure 21.Now let us construct the sets *G*, *W* and *M* as above.

	<i>y</i> 1	$\overline{y_1}$	$y'_1$	<i>y</i> <sub>2</sub>	$\overline{y_2}$	$y'_2$	<i>y</i> 3	<u>y</u> 3	$y'_3$	С
g	0	0	0	0	0	0	0	0	0	0
$b_1$	0	-1	1	0	0	0	0	0	0	0
$b_2$	0	0	0	0	-1	1	0	0	0	0
$b_3$	0	0	0	0	0	0	0	-1	1	0
$u_1$	-1	-1	0	0	0	0	0	0	0	1
$u_2$	0	0	0	-1	-1	0	0	0	0	1
<i>u</i> <sub>3</sub>	0	0	0	0	0	0	-1	1	0	1
$w_1$	-1	0	0	-1	0	0	0	-1	0	1
$w_2$	0	-1	0	-1	0	0	-1	0	0	1
$m_1^1$	-1	1	0	0	0	0	0	0	0	0
$m_1^2$	1	0	-1	0	0	0	0	0	0	0
$m_1^{\tilde{3}}$	0	0	1	0	0	0	0	0	0	1
$m_2^{\hat{1}}$	0	0	0	-1	1	0	0	0	0	0
$m_2^{\overline{2}}$	0	0	0	1	0	-1	0	0	0	0
$m_{2}^{3}$	0	0	0	0	0	1	0	0	0	1
$m_3^{\overline{1}}$	0	0	0	0	0	0	-1	1	0	0
$m_3^{\tilde{2}}$	0	0	0	0	0	0	1	0	-1	0
$m_{1}^{3} \\ m_{2}^{1} \\ m_{2}^{2} \\ m_{2}^{3} \\ m_{3}^{3} \\ m_{3$	0	0	0	0	0	0	0	0	1	1

Then  $G = \{g\}$ ,  $W = \{b_1, b_2, b_3, u_1, u_2, u_3, w_1, w_2\}$ ,  $M = \{m_1^1, \ldots, m_3^3\}$ . For W to be a set of inferior examples, g must be preferred to each member of W. Take for instance,  $g \succ b_1$ . By Theorem 5, that is equivalent to  $(\overline{y_1}, y'_1) \in \Gamma_{\succ}$ , which corresponds to  $\pi_1$ . Similarly,  $g \succ u_1$  results in  $(y_1, c) \in \Gamma_{\succ} \lor (\overline{y_1}, c) \in \Gamma_{\succ}, \forall (\overline{y_2}, c) \in \Gamma_{\succ} \lor (\overline{y_3}, c) \in \Gamma_{\succ}$ , which corresponds to  $\mu_1$ . The other members of W are handled similarly (resulting in the remaining positive constraints).

For *G* to be superior, no member of  $M \cup W$  must be preferred to *g* according to  $\succ$ . Clearly, for a p-skyline relation  $\succ$ (which is an SPO), this is equivalent to saying that no member of only *M* must be preferred to *g*: above we already have constraints that *g* is preferred to every member of *W*, and  $\succ$  is irreflexive.  $m_1^1 \not\succ g$  results in  $(\overline{y_i}, y_1) \notin \Gamma_{\succ}$ , which corresponds to  $\lambda_1^1$ . The other members of *M* are handled similarly, resulting in the remaining negative constraints.

**Proposition 5.** Let  $\succ$  be a p-skyline relation, O a finite set of tuples, and G and W, disjoint subsets of O. Then the next two operations can be done in polynomial time:

- verifying if ≻ is maximal favoring G and disfavoring W in O;
- 2. constructing a maximal p-skyline relation  $\succ_{ext}$  that favors G, disfavors W in O and is a p-extension of  $\succ$  (un-

*der the assumption that*  $\succ$  *favors G and disfavors W in O*).

**Proof.** To check if  $\succ$  favors *G* and disfavors *W* in *O*, we need to compute  $\omega_{\succ}(O)$ , check  $G \subseteq \omega_{\succ}(O)$ , and verify that for every  $o \in W$ , there is  $o' \in G$  such that  $o' \succ o$ . All those tasks can clearly be performed in polynomial time. If some of these conditions fails,  $\succ$  is obviously not maximal. Otherwise, we need to check if each of its minimal p-extensions favors *G* and disfavors *W*. Note that since  $\succ$  disfavors *W* in *O*, each of its p-extensions also disfavors *W* in *O*. Hence,  $\succ$  is not maximal if at least one minimal p-extension favors *G* in *O*, and it is maximal otherwise. Corollaries 2 and 3 imply that all minimal p-extensions of  $\succ$  can be constructed in polynomial time.

To construct a maximal p-extension  $\succ'$  of  $\succ$ , we take  $\succ$ , construct all of its minimal p-extensions and verify if at least one of them favors *G* in *O*. If some of them does, we select it and repeat for it the same procedure. We do it until for some  $\succ'$  none of its minimal p-extensions favors *G* in *O*. This implies that  $\succ'$  is a maximal p-extension favoring *G* and disfavoring *W* in *O*. Moreover,  $\succ'$  is a superset of  $\succ$  by construction. Corollaries 2, 3, and 4 imply that such a computation can be done in polynomial time.

## **Theorem 9.** FDF-PSKYLINE is FNP-complete

**Proof.** Given two disjoint subsets *G* and *W* of *O* and  $\succ \in \mathcal{F}_{\mathcal{H}}$ , checking if  $\succ$  favors *G* and disfavors *W* in *O* can be done in polynomial time (Lemma 5). Hence, FDF-PSKYLINE is in FNP.

Now show that FDF-PSKYLINE is FNP-hard. To do that, we use a reduction from FSAT. In particular, we find functions R and S, both computable in logarithmic space, such that 1) for each instance x of FSAT, R(x) is an instance of FDF-PSKYLINE, and 2) for each correct output z of R(x), S(z) is a correct output of x. For such a reduction, we use the construction from the proof of Theorem 8. There we showed how a relation (denote it as  $\succ$ ) satisfying all the constraints (and thus favoring/disfavoring the constructed G and W) may be obtained. In the current reduction, if there is a p-skyline relation favoring G and disfavoring W in O, then the relation  $\succ$  itself is returned. Otherwise, "no" is returned.

The function R mentioned above has to convert an instance of FSAT to an instance of FDF-PSKYLINE (i.e., G, W, and O). In the reduction shown in the proof of Theorem 8, such a transformation is done via a set of constraints. However, it is easy to observe that such a construction can be performed using the corresponding instance of FSAT. By the construction, the sets G, M, and the subset  $\{b_1, \ldots, b_n, u_1, \ldots, u_n\}$  of W are common for every instance of FSAT with n variables. To construct the subset  $\{w_1, \ldots, w_m\}$  of W, one can use the expression  $\psi_t$  instead of the corresponding constraint  $\mu_t$ . It is clear that the function R performing such a transformation can be evaluated in logarithmic space. We construct the function *S* as follows. If the instance of FDF-PSKYLINE returns "no", *S* returns "no". Otherwise, it constructs the satisfying assignment  $(v_1, \ldots, v_n)$  in the following way: for every *i*,  $v_i$  is set to 1 if the p-graph contains the edge  $(y_i, c) \in \Gamma_{\succ}$ , and 0 otherwise. It is clear that such a computation may be done in logarithmic space.

**Theorem 10.** OPT-FDF-PSKYLINE is FNP-complete

**Proof.** Given  $\succ \in \mathcal{F}_{\mathcal{H}}$ , checking if it is maximal favoring *G* and disfavoring *W* can be done in polynomial time (Proposition 5). Hence, OPT-FDF-PSKYLINE is in FNP.

We reduce from FDF-PSKYLINE to show that it is FNPhard. Here we construct the function F that takes a p-skyline relation or "no" and returns a p-skyline relation or "no". Freturns "no" if its input is "no". If its input is a p-skyline relation  $\succ$ , it returns a maximal p-extension of  $\succ$  as shown in Proposition 5. As a result, F returns a maximal favoring/disfavoring p-skyline relation iff the corresponding favoring/disfavoring p-skyline relation exists. The functions R and Stransforming inputs of FDF-PSKYLINE to inputs of OPT-FDF-PSKYLINE and outputs of OPT-FDF-PSKYLINE to outputs of FDF-PSKYLINE correspondingly are trivial and hence are computable in logspace. Therefore, the problem OPT-FDF-PSKYLINE is FNP-complete.

**Proposition 7.** Let a relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  be a maximal *M*-favoring relation, and a *p*-extension  $\succ_{ext}$  of  $\succ$  be  $(M \cup \{A\})$ -favoring. Then every edge in  $E(\Gamma_{\succ_{ext}}) - E(\Gamma_{\succ})$  starts or ends in *A*.

**Proof.** Take  $\Gamma_{\succ_{ext}}$  and construct  $\Gamma'$  from it by removing all edges going from or to A. Clearly,  $\Gamma'$  is an SPO. Now consider the Envelope property. Pick four nodes of  $\Gamma_{\succ}$  different from A. Since  $\Gamma_{\succ_{ext}}$  is a p-graph, the Envelope property holds for the graph induced by these four nodes in  $\Gamma_{\succ_{ext}}$ . Envelope also holds for the corresponding subgraph of  $\Gamma'$ . Thus,  $\Gamma'$  satisfies the Envelope property as well, i.e., it's a p-graph of a p-skyline relation  $\succ'$ . Moreover,  $E(\Gamma_{\succ}) \subseteq$  $E(\Gamma_{\succ'})$  since  $\Gamma_{\succ}$  has no edges from/to A and  $E(\Gamma_{\succ}) \subseteq E(\Gamma_{\succ ext})$ . Since  $\succ$  is maximal *M*-favoring,  $E(\Gamma_{\succ}) = E(\Gamma')$ . Therefore, all edges in  $E(\Gamma_{\succ ext}) - E(\Gamma_{\succ})$  go from or to A. **Proposition 8.** Let a relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfy a system of negative constraints N. Construct the system of negative constraints  $\mathcal{N}'$  from  $\mathcal{N}$  in which every constraint  $\tau' \in \mathcal{N}'$ is created from a constraint  $\tau$  of  $\mathcal{N}$  in the following way:

$$\begin{array}{l} - \ \mathcal{L}_{\tau'} = \mathcal{L}_{\tau} \\ - \ \mathcal{R}_{\tau'} = \mathcal{R}_{\tau} - \{ B \in \mathcal{R}_{\tau} \mid \exists A \in \mathcal{L}_{\tau} \ . \ (A, B) \in \Gamma_{\succ} \}. \end{array}$$

Then every p-extension  $\succ'$  of  $\succ$  satisfies  $\mathcal{N}$  iff  $\succ'$  satisfies  $\mathcal{N}'$ .

# Proof.

Take  $\tau'$  from  $\mathcal{N}'$  with the corresponding  $\tau \in \mathcal{N}$ . By construction,  $\mathcal{L}_{\tau} = \mathcal{L}_{\tau}, \mathcal{R}_{\tau'} \subseteq \mathcal{R}_{\tau}$ . Now assume  $\succ'$  satisfies  $\tau'$ . This means that

$$\exists B \in \mathcal{R}_{\tau'} \,\,\forall A \in \mathcal{L}_{\tau'} \,\,:\, (A,B) \notin \Gamma_{\succ'} \tag{25}$$

Now recall that  $\mathcal{R}_{\mathfrak{r}'} \subseteq \mathcal{R}_{\mathfrak{r}}$ . Thus  $B \in \mathcal{R}_{\mathfrak{r}}$ . This together with  $\mathcal{L}_{\mathfrak{r}} = \mathcal{L}_{\mathfrak{r}'}$  and (25) gives

$$\exists B \in \mathcal{R}_{\tau} \; \forall A \in \mathcal{L}_{\tau} \; . \; (A,B) \notin \Gamma_{\succ'},$$

i.e.,  $\Gamma_{\succ'}$  satisfies  $\tau$ . rightarrow Now let  $\succ'$  satisfy  $\tau$ . This means

$$\exists B \in \mathcal{R}_{\mathfrak{T}} \,\forall A \in \mathcal{L}_{\mathfrak{T}} \,.\, (A, B) \notin \Gamma_{\succ'} \tag{26}$$

Since  $\succ \subseteq \succ', E(\Gamma_{\succ}) \subseteq E(\Gamma_{\succ'})$ . Thus, if there is no edge from  $\mathcal{L}_{\tau}$  to *B* in  $\Gamma_{\succ'}$ , then there is no such edge in its subset  $\Gamma_{\succ}$ . Recall that  $\tau'$  is a *minimized* version of  $\tau$  w.r.t.  $\succ$ . Thus, the lack of edge from  $\mathcal{L}_{\tau}$  to *B* in  $\Gamma_{\succ}$  implies  $B \in \mathcal{R}_{\tau'}$ . This together with  $\mathcal{L}_{\tau} = \mathcal{L}_{\tau'}$  and (26) gives

$$\exists B \in \mathcal{R}_{\mathfrak{T}'} \ \forall A \in \mathcal{L}_{\mathfrak{T}'} \ . \ (A,B) \notin \Gamma_{\succ'},$$

i.e.,  $\Gamma_{\succ'}$  satisfies  $\tau'$ .

**Proposition 9.** Let a relation  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfy a system of negative constraints  $\mathcal{N}$ , and  $\mathcal{N}$  be minimal w.r.t.  $\succ$ . Let  $\succ'$  be a *p*-extension of  $\succ$  such that every edge in  $E(\Gamma_{\succ'}) - E(\Gamma_{\succ})$  starts or ends in *A*. Denote the new parents and children of *A* in  $\Gamma_{\succ'}$  as  $P_A$  and  $C_A$  correspondingly. Then  $\succ'$  violates  $\mathcal{N}$  iff there is a constraint  $\tau \in \mathcal{N}$  such that

*1.*  $\mathcal{R}_{\mathfrak{T}} = \{A\} \land P_A \cap \mathcal{L}_{\mathfrak{T}} \neq \emptyset, or$ *2.*  $A \in \mathcal{L}_{\mathfrak{T}} \land \mathcal{R}_{\mathfrak{T}} \subseteq C_A$ 

#### Proof.

Trivial since the two conditions above imply violation of  $\mathcal{N}'_{i}$  by  $\succ$ .

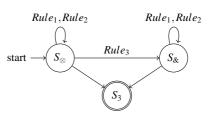

⇒ Assume that there is no constraint  $\tau$  for which the two conditions hold, but some  $\tau' \in \mathcal{N}$  is violated, i.e.,

$$Ch_{\Gamma_{\succ}}(\mathcal{L}_{\tau'}) \supseteq \mathcal{R}_{\tau'}$$

By Theorem 4,  $E(\Gamma_{\succ}) \subset E(\Gamma_{\succ'})$ . We also know that all the new edges in  $\Gamma_{\succ'}$  start or end in A. Since  $\Gamma_{\succ}$  satisfies  $\tau'$  but  $\Gamma_{\succ'}$  does not, we get that either  $A \in \mathcal{L}_{\tau'}$  or  $A \in \mathcal{R}_{\tau'}$ . If A is in  $\mathcal{R}_{\tau'}$  then the fact that  $\tau'$  is violated by  $\Gamma_{\succ'}$  implies that  $\mathcal{R}_{\tau'} =$  $\{A\}$ . Moreover, the fact that  $\tau'$  is minimal w.r.t.  $\succ$  implies  $P_A \cap \mathcal{L}_{\tau'} \neq \emptyset$ . If  $A \in \mathcal{L}_{\tau'}$ , then the minimality of  $\tau'$  implies that  $\tau'$  is violated because of  $\mathcal{R}_{\tau'} \subseteq C_A$ .

**Theorem 11.** The function elicit returns a syntax tree of a maximal p-skyline relation favoring G in O. Its running time is  $O(|\mathcal{N}| \cdot |\mathcal{A}|^3)$ .

**Proof.** First, we prove that elicit always returns a maximal p-skyline relation satisfying  $\mathcal{N}$ . By construction, the p-skyline relation returned by elicit satisfies the constructed system of negative constraints  $\mathcal{N}$ . Now prove that  $\succ$  returned by elicit is a maximal p-skyline relation satisfying  $\mathcal{N}$ . A simple case analysis shows that push picks every p-skyline relation

**Fig. 22** Using push for computation of a maximal  $(M \cup \{A\})$ -favoring p-skyline relation

- 1. which is a minimal p-extension of  $\succ$  represented by the parameter *T*, and
- 2. whose p-graph has only edges going between the nodes  $M \cup \{A\}$ ,

until it finds one not violating  $\mathcal N$  (of course, given the fact that the p-skyline relation, whose p-graph is obtained from  $\Gamma_{\succ}$  by removing edges going to/from A, is maximal M-favoring). Recall that T constructed in line 2 of elicit represents a maximal *M*-favoring p-skyline relation satisfying  $\mathcal{N}$ , for a singleton *M*. Now assume that  $T_{\succ}$  at the end of some iteration of the for-loop of elicit represents a nonmaximal  $M_1$ -favoring p-skyline relation  $\succ$ . Take the first such an iteration of the for-loop. It implies that there is an  $M_1$ -favoring p-skyline relation  $\succ^*$  which strictly contains  $\succ$ and satisfies  $\mathcal{N}$ . By Theorem 4,  $E(\Gamma_{\succ^*})$  also strictly contains  $E(\Gamma_{\succ})$ . Take an edge  $(X, Y) \in \Gamma_{\succ^*}$  which is not in  $E(\Gamma_{\succ})$ . Let  $\succ'$  be the relation constructed in the **for**-loop in elicit when A was equal to X or Y, whatever was the last one. Take the corresponding set of attributes  $M_2$ . According to the argument above,  $\succ'$  is maximal  $M_2$ -favoring. Since  $\succ' \subseteq \succ$ ,  $\Gamma_{\succ'}$  does not contain the edge (X, Y). At the same time, if we take  $\Gamma_{\succ^*}$  and leave in it only the edges going to and from the elements of  $M_2$ , it will strictly contain  $\Gamma_{\succ'}$  and not violate  $\mathcal{N}$ . Hence,  $\succ'$  is not maximal  $M_2$ -favoring, which is a contradiction. That implies that elicit returns a maximal A-favoring (or simply favoring) p-skyline relation satisfying N.

Now let us show that the running time of the algorithm is  $O(|\mathcal{N}| \cdot |\mathcal{A}|^3)$ . First, let us consider the running time of the sub-procedures. The running time of minimize and checkConstr is  $O(|\mathcal{N}| \cdot |\mathcal{A}|)$ . The time needed to modify the syntax tree using a transformation rule is  $O(|\mathcal{A}|)$ : every rule creates, deletes, and modifies a constant number of nodes of a syntax tree, but updating their *Var*-variables is done in  $O(|\mathcal{A}|)$ . Similarly, syntax tree normalization runs in time  $T_{normalizeTree} = O(|\mathcal{A}|)$  for such modified syntax trees. As a result, the time needed to execute the bodies of the loops (lines 5-8, 11-14, 18-36) of push is  $T_{rule} = O(|\mathcal{N}| \cdot |\mathcal{A}|)$ .

Now let *T* be a syntax tree of a maximal *M*-favoring p-skyline relation. Consider the way push is used in elicit to construct a maximal  $(M \cup \{A\})$ -favoring p-skyline relation. The state diagram of this process is shown in Figure

22. It has three states:  $S_{\otimes}$  and  $S_{\&}$  which correspond to *T* in which *A* is a child of a  $\otimes$ - and &-node, respectively; and  $S_3$  which corresponds to the case when no transformation rule can be applied to *T*, or every rule application violates  $\mathcal{N}$ .

The starting state is  $S_{\otimes}$ , because in the starting *T*, *A* is a child of the topmost  $\otimes$ -node. After applying the transformation rules  $Rule_1$  and  $Rule_2$  in lines 21 and 25 respectively, *A* becomes a child node of another  $\otimes$ -node of the modified *T*. After applying  $Rule_3$  (lines 30 and 34), *A* becomes a child of a &-node in the modified *T*, and we go to the state  $S_{\&}$ . When in  $S_{\&}$ , we can only apply  $Rule_1$  or  $Rule_2$  from lines 6 and 12 respectively. Note that after applying these rules, *A* is still a child of the same &-node in the modified *T*. When no rule can be applied to *T* at some state, we go to the accepting state  $S_3$  and return *false*.

Consider the total number of nodes of T enumerated in the loops (lines 4-8, 10-14, and 17-36) of push to construct a maximal  $(M \cup \{A\})$ -favoring p-skyline relation. Note that when we go from  $S_{\otimes}$  to  $S_{\otimes}$  by applying  $Rule_1$  or  $Rule_2$ , A becomes a descendent of the  $\otimes$ -node whose child it was originally. Hence, when in  $S_{\otimes}$  we enumerate the nodes  $C_i$  to apply  $Rule_1$  or  $Rule_2$  to, we never pick any  $C_i$  which we picked in the previous calls of push. In the process of going from  $S_{\&}$ to itself via an application of  $Rule_1$  or  $Rule_2$ , we may enumerate the same node  $C_{i+1}$  more than once because A does not change its parent &-node as a result of these applications. To avoid checking these rules against the same nodes  $C_{i+1}$  more than once, one can keep track of the nodes which have already been picked and tested.

The total number of nodes in a syntax tree is  $O(|\mathcal{A}|)$ , hence the tests  $Var(C_{i+1}) \subseteq M$  (lines 4, 10) and  $Var(C_i) \subseteq M$ (line 17) are performed  $O(|\mathcal{A}|)$  times and the rules are applied to the tree  $O(|\mathcal{A}|)$  times. Each of the containment tests above requires time  $O(|\mathcal{A}|)$ , given the bitmap representation of sets. Hence, to compute the syntax tree of a maximal  $(M \cup \{A\})$ -favoring from the syntax tree of a maximal M-favoring p-skyline relation, we need time  $O(|\mathcal{N}| \cdot |\mathcal{A}|^2)$ . Finally, the running time of elicit is  $O(|\mathcal{N}| \cdot |\mathcal{A}|^3)$ .  $\Box$ 

# **Theorem 12.** *NEG-SYST-IMPL is co-NP complete*

**Proof.** We show that checking the existence of  $\succ \in \mathcal{F}_{\mathcal{H}}$  satisfying  $\mathcal{N}_1$  but not satisfying  $\mathcal{N}_2$  is NP-complete. Clearly, this problem is in NP: we can guess  $\succ \in \mathcal{F}_{\mathcal{H}}$  and in polynomial time check if it satisfies every  $\tau \in \mathcal{N}_1$  (i.e., if there is a member of  $\mathcal{R}_{\tau}$  which has no parent in  $\mathcal{L}_{\tau}$ ) but violates some  $\tau' \in \mathcal{N}_2$ . Now prove that checking if there's  $\succ$  satisfying  $\mathcal{N}_1$ but violating  $\mathcal{N}_2$  is NP-hard.

Here we show the reduction from SAT. Consider instances of SAT in the following form

$$\varphi(x_1,\ldots,x_n)=\phi_1(x_1,\ldots,x_n)\wedge\ldots\wedge\phi_m(x_1,\ldots,x_n)$$

where

 $\phi_t(x_1,\ldots,x_n)=\widetilde{x_{i_t}}\vee\ldots\vee\widetilde{x_{j_t}}$ 

and  $\widetilde{x_i} \in \{x_i, \overline{x_i}\}$ . For every instance  $\varphi$ , we construct

$$\mathcal{A} = \{x_1, \overline{x_1}, \dots, x_n, \overline{x_n}, T, F\}$$

Construct  $\mathcal{N}_1$  as follows:

1. for every  $\phi_t(x_1, \dots, x_n) = \widetilde{x_{i_t}} \vee \dots \vee \widetilde{x_{j_t}}$ , create a constraint  $\tau_t^1$  as follows:

$$\mathcal{L}_{\tau_t^1} = \{F\}$$
$$\mathcal{R}_{\tau_t^1} = \{\widetilde{x_{i_t}}, \dots, \widetilde{x_{j_t}}\}$$

2. for every variable  $x_i$  of  $\varphi$ , create two constraints  $\tau_i^2$  and  $\tau_i^3$ :

$$\mathcal{L}_{\mathbf{\tau}_{i}^{2}} = \{T\}$$
  
 $\mathcal{R}_{\mathbf{\tau}_{i}^{2}} = \{x_{i}, \overline{x_{i}}\}$   
and

$$\mathcal{L}_{\tau_i^3} = \{F\}$$
$$\mathcal{R}_{\tau_i^3} = \{x_i, \overline{x_i}\}$$

Now we construct  $\mathcal{N}_2$  consisting of a single constraint  $\kappa$  as follows.

$$\mathcal{L}_{\kappa} = \{T, F\}$$
  
$$\mathcal{R}_{\kappa} = \{x_i, \overline{x_i}, \dots, x_n, \overline{x_n}\}$$

We prove that there is a satisfying assignment to  $\varphi$  iff there is a p-graph  $\Gamma$  satisfying  $\mathcal{N}_1$  and not satisfying  $\mathcal{N}_2$ . First, assume that there is a satisfying assignment  $y = (y_1, \dots, y_n)$  to  $\varphi$ . We construct the graph  $\Gamma$  as follows. For every  $i \in [1, n]$ ,

- 1. if  $y_i = 1$ , then  $(T, x_i) \in \Gamma$  and  $(F, \overline{x_i}) \in \Gamma$ ;
- 2. if  $y_i = 0$ , then  $(F, x_i) \in \Gamma$  and  $(T, \overline{x_i}) \in \Gamma$ ;
- 3.  $\Gamma$  has no other edges.

Clearly,  $\Gamma$  satisfies SPO (every node has either an incoming or outgoing edge, but not both) and Envelope (every node has at most one incoming edge) and hence is a p-graph. We show that  $\Gamma$  satisfies  $\mathcal{N}_1$ .

- 1. Consider every constraint  $\tau_t^1$  for every  $\phi_t(x_1, \ldots, x_n) = \widetilde{x_{i_t}} \vee \ldots \vee \widetilde{x_{j_t}}$ . Since *y* satisfies  $\phi_t$ , at least one of the conjuncts of  $\phi_t$  (say,  $\widetilde{x_{i_t}}$ ) is 1. If  $\widetilde{x_{i_t}} = x_{i_t}$ , then  $y_{i_t} = 1$ , and  $(F, x_{i_t}) \notin \Gamma$  by construction. If  $\widetilde{x_{i_t}} = \overline{x_{i_t}}$ , then  $y_{i_t} = 0$  and  $(F, \overline{x_{i_t}}) \notin \Gamma$ . Hence,  $\tau_t^1$  is satisfied.
- 2. Consider  $\tau_i^2$  and  $\tau_i^3$  for every  $x_i$ . By construction of  $\Gamma$ , they are satisfied because it cannot be the case that  $(T, x_i) \in \Gamma$  and  $(T, \overline{x_i}) \in \Gamma$  or  $(F, x_i) \in \Gamma$  and  $(F, \overline{x_i}) \in \Gamma$ . Hence,  $\tau_i^2$  and  $\tau_i^3$  are satisfied.

Now consider  $\mathcal{N}_2$  and the constraint  $\kappa$ . By construction, for every  $i \in [1, n]$ , the component  $y_i$  of y is set to 0 or 1. Hence,  $(T, x_i) \in \Gamma$  and  $(F, \overline{x_i}) \in \Gamma$  or  $(T, \overline{x_i}) \in \Gamma$  and  $(F, x_i) \in \Gamma$ . Therefore,  $\kappa$  is violated by  $\Gamma$ .

Now we show that if  $\mathcal{N}_1$  is satisfied by a p-graph  $\Gamma$  and  $\mathcal{N}_2$  is not, then there is a satisfying assignment *y* to  $\varphi$ . Take such a p-graph  $\Gamma$ . We construct *y* as follows:

$$y_i = \begin{cases} 1 \text{ if } (T, x_i) \in \Gamma \\ 0 \text{ if } (F, x_i) \in \Gamma, \end{cases}$$

First, we show that  $y_i$  is well defined, i.e., exactly one of the following holds for every  $i \in [1,n]$ :  $(T,x_i) \in \Gamma$  and  $(F,x_i) \in \Gamma$ . Since  $\kappa \in \mathcal{N}_2$  is violated by  $\Gamma$ , for every  $i \in [1,n]$ 

$$\forall i \in [1,n] . ((T,x_i) \in \Gamma \lor (F,x_i) \in \Gamma) \land ((T,\overline{x_i}) \in \Gamma \lor (F,\overline{x_i}) \in \Gamma)$$

$$(27)$$

Since  $\mathcal{N}_1$  is satisfied,

$$\forall i \in [1,n] . (T,x_i) \notin \Gamma \lor (T,\overline{x_i}) \notin \Gamma,$$
(28)

which follows from the satisfaction of  $\tau_i^2$ , and

$$\forall i \in [1,n] . (F,x_i) \notin \Gamma \lor (F,\overline{x_i}) \notin \Gamma,$$
(29)

which follows from the satisfaction of  $\tau_i^3$ . Therefore, (27), (28), and (29) imply

$$\forall i \in [1,n] . (T,x_i) \in \Gamma \land (F,x_i) \notin \Gamma \land (F,\overline{x_i}) \in \Gamma \land (T,\overline{x_i}) \notin \Gamma \lor (F,x_i) \in \Gamma \land (T,x_i) \notin \Gamma \land (T,\overline{x_i}) \in \Gamma \land (F,\overline{x_i}) \notin \Gamma$$
 (30)

Now we show that y satisfies  $\varphi$ . Since every  $\tau_t^1$  is satisfied, at least one of conjuncts of  $\phi_t$  (say,  $\widetilde{x_{i_t}}$ ) does not have an incoming edge from *F*. If  $\widetilde{x_{i_t}} = x_{i_t}$  (i.e.,  $(F, x_{i_t}) \notin \Gamma$ ) then by (30)  $(T, x_{i_t}) \in \Gamma$  and hence  $y_{i_t} = 1$ . Thus  $\phi_t$  is satisfied. Similarly, if  $\widetilde{x_{i_t}} = \overline{x_{i_t}}$  then  $(F, x_i) \in \Gamma$  and hence  $y_{i_t} = 0$ . Thus  $\phi_t$  is satisfied. Finally,  $\varphi$  is satisfied. Hence, we proved coNP-completeness of NEG-SYST-IMPL.

# Theorem 13. SUBSET-EQUIV is co-NP complete

**Proof.** The co-NP-completeness of SUBSET-EQUIV follows from the co-NP-completeness of NEG-SYST-IMPL. Namely, the membership test is the same as in NEG-SYST-IMPL. To show co-NP-hardness of SUBSET-EQUIV, we reduce from NEG-SYST-IMPL. We use the observation that  $\mathcal{N}_1$  implies  $\mathcal{N}_2$  iff  $\mathcal{N}_1 \cup \mathcal{N}_2$  is equivalent to  $\mathcal{N}_1$ .
