# Domination in Graphs of Minimum Degree at least Two and large Girth 

Christian Löwenstein ${ }^{1}$ and Dieter Rautenbach ${ }^{2}$<br>${ }^{1}$ Dr.-Arnoldi-Str. 6, D-56333 Winningen, Germany, email: christian@winningen.de<br>${ }^{2}$ Institut für Mathematik, TU Ilmenau, Postfach 100565, D-98684 Ilmenau, Germany, email: dieter.rautenbach@tu-ilmenau.de

#### Abstract

We prove that for graphs of order $n$, minimum degree $\delta \geq 2$ and girth $g \geq$ 5 the domination number $\gamma$ satisfies $\gamma \leq\left(\frac{1}{3}+\frac{2}{3 g}\right) n$. As a corollary this implies that for cubic graphs of order $n$ and girth $g \geq 5$ the domination number $\gamma$ satisfies $\gamma \leq$ $\left(\frac{44}{135}+\frac{82}{135 g}\right) n$ which improves recent results due to Kostochka and Stodolsky (An upper bound on the domination number of $n$-vertex connected cubic graphs, manuscript (2005)) and Kawarabayashi, Plummer and Saito (Domination in a graph with a 2-factor, J. Graph Theory 52 (2006), 1-6) for large enough girth. Furthermore, it confirms a conjecture due to Reed about connected cubic graphs (Paths, stars and the number three, Combin. Prob. Comput. 5 (1996), 267-276) for girth at least 83.

Keywords domination number; minimum degree; girth; cubic graph

## 1 Introduction

The domination number $\gamma(G)$ of a (finite, undirected and simple) graph $G=(V, E)$ is the minimum cardinality of a set $D \subseteq V$ of vertices such that every vertex in $V \backslash D$ has a neighbour in $D$. This parameter is one of the most well-studied in graph theory and the two volume monograph [4,5] provides an impressive account of the research related to this concept.

Fundamental results about the domination number $\gamma(G)$ are upper bounds in terms of the order $n$ and the minimum degree $\delta$ of the graph $G$. Ore [10] proved that $\gamma(G) \leq \frac{n}{2}$ provided $\delta \geq 1$. For $\delta \geq 2$ and all but 7 exceptional graphs Blank [1] and McCuaig and Shepherd [9] proved $\gamma(G) \leq \frac{2 n}{5}$. Equality in these two bounds is attained for infinitely many graphs which were characterized in $[9,11,16]$.

In [13] Reed proved that $\gamma(G) \leq \frac{3}{8} n$ for every graph $G$ of order $n$ and minimum degree at least 3 and he conjectured that this bound could be improved to $\left\lceil\frac{n}{3}\right\rceil$ for connected cubic graphs. While Reed's conjecture was disproved by Kostochka and Stodolsky [7] who constructed a sequence $\left(G_{k}\right)_{k \in \mathbb{N}}$ of connected cubic graphs with

$$
\lim _{k \rightarrow \infty} \frac{\gamma\left(G_{k}\right)}{\left|V\left(G_{k}\right)\right|} \geq \frac{1}{3}+\frac{1}{69}
$$

Kostochka and Stodolsky [8] proved $\gamma(G) \leq \frac{4}{11} n$ for every connected cubic graph $G$ of order $n>8$ and

$$
\begin{equation*}
\gamma(G) \leq\left(\frac{1}{3}+\frac{8}{3 g^{2}}\right) n \tag{1}
\end{equation*}
$$

for every connected cubic graph $G$ of order $n>8$ and girth $g$ where the girth is the length of a shortest cycle in $G$. The last result improved a recent result due to Kawarabayashi, Plummer and Saito [6] who proved that

$$
\begin{equation*}
\gamma(G) \leq\left(\frac{1}{3}+\frac{1}{9 k+3}\right) n \tag{2}
\end{equation*}
$$

for every 2-edge connected cubic graph $G$ of order $n$ and girth at least $3 k$ for some $k \in \mathbb{N}$.
The first to use the girth $g$ of a graph $G$ next to its order $n$ and minimum degree $\delta$ to bound the domination number $\gamma$ were probably Brigham and Dutton [2] who proved

$$
\gamma \leq\left\lceil\frac{n}{2}-\frac{g}{6}\right\rceil
$$

provided that $\delta \geq 2$ and $g \geq 5$. In [14, 15] Volkmann determined finite set of graphs $\mathcal{G}_{i}$ for $i \in\{1,2\}$ such that

$$
\gamma \leq\left\lceil\frac{n}{2}-\frac{g}{6}-\frac{3 i+3}{6}\right\rceil
$$

unless $G$ is a cycle or $G \in \mathcal{G}_{i}$. Motivated by these results Rautenbach [12] proved that for every $k \in \mathbb{N}$ there is a finite set $\mathcal{G}_{k}$ of graphs such that if $G$ is a graph of order $n$, minimum degree $\delta \geq 2$, girth $g \geq 5$ and domination number $\gamma$ that is not a cycle and does not belong to $\mathcal{G}_{k}$, then

$$
\gamma \leq \frac{n}{2}-\frac{g}{6}-k .
$$

In the present paper we prove a best-possible upper bound on the domination number of graphs of minimum degree at least 2 and girth at least 5 which allows to improve (1) and (2) for large enough girth. Furthermore, it confirms Reed's conjecture [13] for cubic graphs with girth at least 83 .

## 2 Results

We immediately proceed to our main result.
Theorem 1 If $G=(V, E)$ is a graph of order $n$, minimum degree $\delta \geq 2$, girth $g \geq 5$ and domination number $\gamma$, then

$$
\gamma \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right) n .
$$

Proof: For contradiction, we assume that $G=(V, E)$ is a counterexample of minimum sum of order and size. Let $n, g$ and $\gamma$ be as in the statement of the theorem. Since $n$ and $\gamma$ are linear with respect to the components of $G$ and $\frac{2}{3\left(3\left\lfloor\frac{q+1}{3}\right\rfloor+1\right)}$ is non-decreasing in $g$, the graph $G$ is connected. Furthermore, the set of vertices of degree at least 3 is independent. We prove several claims restricting the structure of $G$.

Claim 1. $G$ has a vertex of degree at least 3 .
Proof of Claim 1: For contradiction, we assume that $G$ has no vertex of degree at least 3 . In this case $G$ is a cycle of order at least $g$ and $\gamma=\left\lceil\frac{n}{3}\right\rceil$. If $n=g$, then

$$
\left\lceil\frac{n}{3}\right\rceil= \begin{cases}\frac{n}{3}<\left(\frac{1}{3}+\frac{2}{3(g+1)}\right) n & , \text { if } g \equiv 0(\bmod 3), \\ \frac{n+2}{3}=\left(\frac{1}{3}+\frac{2}{3 g}\right) n & , \text { if } g \equiv 1(\bmod 3) \text { and } \\ \frac{n+1}{3}<\left(\frac{1}{3}+\frac{2}{3(g+2)}\right) n & , \text { if } g \equiv 2(\bmod 3) .\end{cases}
$$

If $n=g+1$, then

Finally, if $n \geq g+2$, then

$$
\left\lceil\frac{n}{3}\right\rceil \leq \frac{n+2}{3} \leq\left(\frac{1}{3}+\frac{2}{3(g+2)}\right) n
$$

Since

$$
3\left\lfloor\frac{g+1}{3}\right\rfloor+1= \begin{cases}g+1 & , \text { if } g \equiv 0(\bmod 3), \\ g & , \text { if } g \equiv 1(\bmod 3) \text { and } \\ g+2, & \text { if } g \equiv 2(\bmod 3),\end{cases}
$$

we obtain in all cases the contradiction $\gamma \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right) n$ and the proof of the claim is complete.

A path $P$ in $G$ between vertices $x$ and $y$ of degree at least 3 whose internal vertices are all of degree 2 will be called 2-path and we set $p_{P}(x):=y$ and $p_{P}(y):=x$.

Claim 2. $G$ has no two vertices $u$ and $v$ of degree at least 3 that are joined by a 2-path $P$ of length 1 (mod 3).

Proof of Claim 2: For contradiction, we assume that such vertices $u$ and $v$ and such a path $P$ exist.

If $V^{\prime}$ denotes the set of internal vertices of the path, then $G\left[V^{\prime}\right]$ is a path of order $0(\bmod 3)$ which has a dominating set $D^{\prime}$ of cardinality $\frac{\left|V^{\prime}\right|}{3}$. Since the graph $G\left[V \backslash V^{\prime}\right]$ satisfies the assumptions of the theorem, we obtain, by the choice of $G$, that $G\left[V \backslash V^{\prime}\right]$ has a dominating set $D^{\prime \prime}$ of cardinality at most $\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right)$. Now, $D^{\prime} \cup D^{\prime \prime}$ is a dominating set of $G$ and we obtain

$$
\begin{aligned}
\gamma & \leq\left|D^{\prime}\right|+\left|D^{\prime \prime}\right| \\
& \leq \frac{\left|V^{\prime}\right|}{3}+\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right) \\
& <\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right) n,
\end{aligned}
$$

which implies a contradiction and the proof of the claim is complete.
Claim 3. $G$ has no vertex $u$ of degree at least 3 that lies on a cycle $C$ of length 1 (mod 3) whose vertices different from $u$ are all of degree 2 .

Proof of Claim 3: For contradiction, we assume that such a vertex $u$ and such a cycle $C$ exist.

Let $V^{\prime}$ denote a minimal set of vertices containing a neighbour of $u$ on the cycle $C$ such that $G\left[V \backslash V^{\prime}\right]$ has no vertex of degree less than 2 .

If $u$ is of degree at least 4 , then the graph $G\left[V^{\prime}\right]$ is a path of order $0(\bmod 3)$ and we obtain the same contradiction as in Claim 2.

Hence we can assume that $u$ is of degree 3. In this case the graph $G\left[V^{\prime}\right]$ arises from $C$ by attaching a path to $u$. Since $G\left[V^{\prime}\right]$ has a spanning subgraph which is a path, it has a dominating set $D^{\prime}$ of cardinality at most $\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$.

As before, $G\left[V \backslash V^{\prime}\right]$ has a dominating set $D^{\prime \prime}$ with $\left|D^{\prime \prime}\right| \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right)$. Now $D^{\prime} \cup D^{\prime \prime}$ is a dominating set of $G$ and using $\left|V^{\prime}\right| \geq g$ we obtain

$$
\begin{aligned}
\gamma & \leq\left|D^{\prime}\right|+\left|D^{\prime \prime}\right| \\
& \leq\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil+\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right) \\
& =\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right) n+\left(\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil-\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left|V^{\prime}\right|\right) .
\end{aligned}
$$

Considering the three cases $\left|V^{\prime}\right|=g,\left|V^{\prime}\right|=g+1$ and $\left|V^{\prime}\right|=g+2$ as in the proof of Claim 1 implies the contradiction $\gamma \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right) n$ and the proof of the claim is complete.

Claim 4. $G$ has no vertex u of degree at least 3 that lies on two cycles $C_{1}$ and $C_{2}$ of lengths $2(\bmod 3)$ whose vertices different from $u$ are all of degree 2 .

Proof of Claim 4: For contradiction, we assume that such a vertex $u$ and such cycles $C_{1}$ and $C_{2}$ exist.

Let $V^{\prime}$ denote a minimal set of vertices containing a neighbour of $u$ on the cycle $C_{1}$ and a neighbour of $u$ on the cycle $C_{2}$ such that $G\left[V \backslash V^{\prime}\right]$ has no vertex of degree less than 2 .

If $u$ is of degree at least 6 , then the graph $G\left[V^{\prime}\right]$ consists of two disjoint paths of order $1(\bmod 3)$ whose endvertices are adjacent to $u$. This easily implies that there is a set $D^{\prime} \subseteq\{u\} \cup V^{\prime}$ containing $u$ such that every vertex in $V^{\prime} \backslash D^{\prime}$ has a neighbour in $D^{\prime}$ and $\left|D^{\prime}\right|=\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$. Since $\left|V^{\prime}\right| \geq g$, we obtain a similar contradiction as in the proof of Claim 3.

Hence we can assume that $u$ is of degree at most 5 . In this case the graph $G\left[V^{\prime}\right]$ consists of $C_{1}$ and $C_{2}$ and possibly a path attached to $u$. Again, it is easy to see that $G\left[V^{\prime}\right]$ has a dominating set $D^{\prime}$ of cardinality at most $\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$. Since $\left|V^{\prime}\right| \geq g$, we obtain a similar contradiction as in the proof of Claim 3 and the proof of the claim is complete.

Claim 5. G has no two distinct vertices $u$ and $v$ of degree at least 3 such that $u$ lies on a cycle $C$ of length $2(\bmod 3)$ whose vertices different from $u$ are all of degree 2 , and $u$ and $v$ are joined by a 2-path $P$ of length 2 (mod 3).

Proof of Claim 5: For contradiction, we assume that such vertices $u$ and $v$, such a cycle $C$ and such a path $P$ exist.

Let $V^{\prime}$ denote a minimal set of vertices containing a neighbour of $u$ on the cycle $C$ and a neighbour of $u$ on the path $P$ such that $G\left[V \backslash V^{\prime}\right]$ has no vertex of degree less than 2 .

If $u$ is of degree at least 5 , then the graph $G\left[V^{\prime}\right]$ is the union of two paths of order $1(\bmod 3)$ which both have an endvertex that is adjacent to $u$. Again, there is a set $D^{\prime} \subseteq\{u\} \cup V^{\prime}$ containing $u$ such that every vertex in $V^{\prime} \backslash D^{\prime}$ has a neighbour in $D^{\prime}$ and $\left|D^{\prime}\right|=\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$. Since $\left|V^{\prime}\right| \geq g$, we obtain a similar contradiction as in the proof of Claim 3.

Hence we can assume that $u$ is of degree at most 4. Let $P^{\prime}$ denote the 2-path starting at $u$ that is internally disjoint from $C$ and $P$. Let $w$ denote the endvertex of $P^{\prime}$ different from $u$, i.e. $w=p_{P^{\prime}}(u)$. If $v \neq w$ or $v=w$ and $v$ is of degree at least 4 , then the graph $G\left[V^{\prime}\right]$ arises from $C, P$ and $P^{\prime}$ by deleting $v$ and $w$. If $v=w$ and $v$ is of degree 3 , then let $P^{\prime \prime}$ denote the 2 -path starting at $v$ that is internally disjoint from $P$ and $P^{\prime}$. Now the graph $G\left[V^{\prime}\right]$ arises from $C, P, P^{\prime}$ and $P^{\prime \prime}$ by deleting the endvertex of $P^{\prime \prime}$ different from $v$. In both cases, by the parity conditions, the graph $G\left[V^{\prime}\right]$ has a dominating set $D^{\prime}$ of cardinality at most $\left[\frac{\left|V^{\prime}\right|}{3}\right\rceil$. Since $\left|V^{\prime}\right| \geq g$, we obtain a similar contradiction as in the proof of Claim 3 and the proof of the claim is complete.

Claim 6. $G$ has no vertex $u$ that is joined to three vertices $v_{1}, v_{2}$ and $v_{3}$ of degree at least 3 by three distinct 2-paths of lengths $2(\bmod 3)$.

Proof of Claim 6: For contradiction, we assume that such vertices $u, v_{1}, v_{2}$ and $v_{3}$ and such paths exist. Let $P_{1}, P_{2}$ and $P_{3}$ denote the three 2-paths joining $u$ to $v_{1}, v_{2}$ and $v_{3}$,
respectively. Let $V_{0}^{\prime}$ denote the set of internal vertices of the three paths and let $V^{\prime}$ denote a minimal set of vertices containing $V_{0}^{\prime}$ such that $G\left[V \backslash V^{\prime}\right]$ has no vertex of degree less than 2. In order to complete the proof of Claim 6, we insert another claim about the structure of $G\left[V^{\prime}\right]$.

Claim 7. If $u, v_{1}, v_{2}, v_{3}, P_{1}, P_{2}, P_{3}, V_{0}^{\prime}$ and $V^{\prime}$ are as above, then
(i) either $u \notin V^{\prime}$ and $G\left[V^{\prime}\right]$ is the union of three paths of order $1(\bmod 3)$ each of which has an endvertex that is adjacent to $u$,
(ii) or $G\left[V^{\prime}\right]$ has a spanning subgraph which arises by identifying an endvertex in each of three or four paths of which three are of order $2(\bmod 3)$,
(iii) or $\left|V^{\prime}\right| \geq g$ and $G\left[V^{\prime}\right]$ has a spanning subgraph which arises by identifying an endvertex in each of three or four paths of which two are of order $2(\bmod 3)$,
(iv) or $u \notin V^{\prime},\left|V^{\prime}\right| \geq g$ and $G\left[V^{\prime}\right]$ has a spanning subgraph which is the union of three paths each of which has an endvertex that is adjacent to $u$ and two of these three paths are of order $1(\bmod 3)$.

Proof of Claim 7: If $w$ is a vertex of degree at most 1 in $G\left[V \backslash V_{0}^{\prime}\right]$, then let $P(w)$ denote the 2-path starting in $w$ that is internally disjoint from $V_{0}^{\prime}$. Note that $P(w)$ has length 0 if $w$ is an isolated vertex in $G\left[V \backslash V_{0}^{\prime}\right]$.

First, we assume that $\left|\left\{v_{1}, v_{2}, v_{3}\right\}\right|=3$, i.e. the vertices $v_{1}, v_{2}$ and $v_{3}$ are all distinct.
If $u$ is of degree 3 , then $V^{\prime}=\{u\} \cup V_{0}^{\prime}$ and (ii) holds.
If $u$ is of degree at least 5 , then $V^{\prime}=V_{0}^{\prime}$ and (i) holds.
Hence we can assume that $u$ is of degree 4 .
If either $p_{P(u)}(u) \notin\left\{v_{1}, v_{2}, v_{3}\right\}$ or $p_{P(u)}(u) \in\left\{v_{1}, v_{2}, v_{3}\right\}$, say $p(u)=v_{1}$, and $v_{1}$ is not of degree 3 , then (ii) holds.

Hence we can assume that $p(u)=v_{1}$ is of degree 3. Let $P^{\prime}$ denote the 2-path starting in $v_{1}$ that is internally disjoint from $V_{0}^{\prime}$ and $P(u)$.

If either $p_{P^{\prime}}\left(v_{1}\right) \notin\left\{v_{2}, v_{3}\right\}$ or $p_{P^{\prime}}\left(v_{1}\right) \in\left\{v_{2}, v_{3}\right\}$, say $p_{P^{\prime}}\left(v_{1}\right)=v_{2}$, and $v_{2}$ is not of degree 3 , then (ii) holds.

Hence we can assume that $p_{P^{\prime}}\left(v_{1}\right)=v_{2}$ is of degree 3. Let $P^{\prime \prime}$ denote the 2-path starting in $v_{2}$ that is internally disjoint from $V_{0}^{\prime}$ and $P^{\prime}$.

If either $p_{P^{\prime \prime}}\left(v_{2}\right) \neq v_{3}$ or $p_{P^{\prime \prime}}\left(v_{2}\right)=v_{3}$ and $v_{3}$ is not of degree 3 , then (ii) holds.
Hence we can assume that $p_{P^{\prime \prime}}\left(v_{2}\right)=v_{3}$ is of degree 3. Let $P^{\prime \prime \prime}$ denote the 2-path starting in $v_{3}$ that is internally disjoint from $V_{0}^{\prime}$ and $P^{\prime \prime}$. Clearly, $p_{P^{\prime \prime \prime}}\left(v_{3}\right) \notin\left\{u, v_{1}, v_{2}\right\}$ and (ii) holds. (Note that we can delete the edges incident to $v_{i}$ in $P_{i}$ for $1 \leq i \leq 3$ in order to obtain the spanning subgraph mentioned in (ii).)

Next, we assume that $\left|\left\{v_{1}, v_{2}, v_{3}\right\}\right|=1$. Note that the 2-paths between $u$ and $v_{1}=v_{2}=v_{3}$ form cycles of length at least $g$.

If $u$ and $v_{1}$ are both of degree at least 5 , then $V^{\prime}=V_{0}^{\prime}$ and (i) holds.
If $u$ is of degree at most 4 and $v_{1}$ is of degree at least 5, then (ii) holds. (Note that if $v_{1} \in V^{\prime}$, then we can delete the edges incident to $v_{1}$ in $P_{i}$ for $1 \leq i \leq 3$ in order to obtain the spanning subgraph mentioned in (ii).)

If $u$ is of degree at least 5 and $v_{1}$ is of degree at most 4, then (ii) holds. (Note that if $u \in V^{\prime}$, then we can delete the edges incident to $u$ in $P_{i}$ for $1 \leq i \leq 3$ in order to obtain the spanning subgraph mentioned in (ii).)

If $u$ and $v_{1}$ are both of degree at most 4, then either $P(u)=P\left(v_{1}\right)$ and (ii) holds or $P(u) \neq P\left(v_{1}\right)$ and (iii) holds. (Note that in the last case we can delete the edges incident to $v_{1}$ in $P_{1}$ and $P_{2}$ in order to obtain the spanning subgraph mentioned in (iii)).

Finally, we assume that $\left|\left\{v_{1}, v_{2}, v_{3}\right\}\right|=2$, say $v_{1}=v_{3} \neq v_{2}$. Note that the 2-paths $P_{1}$ and $P_{3}$ between $u$ and $v_{1}=v_{3}$ form a cycle of length at least $g$.

If $v_{1}$ is of degree at least 4 , then we can argue similarly as in the case $\left|\left\{v_{1}, v_{2}, v_{3}\right\}\right|=3$. Hence we can assume that $v_{1}$ is of degree 3 .
If $u$ and $v_{1}$ are joined by a 2-path $Q$ different from $P_{1}$ and $P_{3}$, then (iii) or (iv) hold depending on the degree of $u$. (Note that, if $u$ is of degree four for instance, then we can delete the edge incident to $u$ in $Q$ and the edge incident to $v_{1}$ in $P_{1}$ in order to obtain the spanning subgraph mentioned in (iii)).

Hence we can assume that $u$ and $v_{1}$ are not joined by a 2-path different from $P_{1}$ and $P_{3}$.

If $u$ is of degree 4 and $u$ and $v_{2}$ are joined by a 2-path different from $P_{2}$, then (iii) holds.
Hence we can assume that either $u$ is of degree at least 5 or $u$ and $v_{2}$ are not joined by a 2-path different from $P_{2}$.

In the remaining cases (iii) or (iv) hold which completes the proof of the claim.
We return to the proof of Claim 6.
Note that in Cases (i) or (iv) of the Claim 7 there is a set $D^{\prime} \subseteq\{u\} \cup V^{\prime}$ containing $u$ such that every vertex in $V^{\prime} \backslash D^{\prime}$ has a neighbour in $D^{\prime}$ and either $\left|D^{\prime}\right| \leq \frac{\left|V^{\prime}\right|}{3}$ (Case (i)) or $\left|D^{\prime}\right| \leq\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$ and $\left|V^{\prime}\right| \geq g$ (Case (iv)). Furthermore, by the parity conditions, in Cases (ii) and (iii) of Claim 7, the graph $G\left[V^{\prime}\right]$ has a dominating set $D^{\prime}$ such that either $\left|D^{\prime}\right| \leq \frac{\left|V^{\prime}\right|}{3}$ (Case (ii)) or $\left|D^{\prime}\right| \leq\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$ and $\left|V^{\prime}\right| \geq g$ (Case (iii)).

As before, $G\left[V \backslash V^{\prime}\right]$ has a dominating set $D^{\prime \prime}$ with $\left|D^{\prime \prime}\right| \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left[\frac{q+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right)$ and $D^{\prime} \cup D^{\prime \prime}$ is a dominating set of $G$. If $\left|D^{\prime}\right| \leq \frac{\left|V^{\prime}\right|}{3}$, then we obtain a similar contradiction as in Claim 2 and if $\left|D^{\prime}\right| \leq\left\lceil\frac{\left|V^{\prime}\right|}{3}\right\rceil$ and $\left|V^{\prime}\right| \geq g$, then we obtain a similar contradiction as in Claim 3. This completes the proof of the claim.

We have by now analysed the structure of $G$ far enough in order to describe a sufficiently small dominating set leading to the final contradiction. Let $V_{\geq 3}$ denote the set of vertices of degree at least 3 and let $n_{\geq 3}=\left|V_{\geq 3}\right|$. The graph $G\left[V \backslash V_{\geq 3}\right]$ is a collection of paths of order either $1(\bmod 3)$ or $2(\bmod 3)$.

Let $P_{1}, P_{2}, \ldots, P_{s}$ denote the set of vertices of the paths of order $1(\bmod 3)$ and let $Q_{1}, Q_{2}, \ldots, Q_{t}$ denote the set of vertices of the paths of order $2(\bmod 3)$.

By the above claims,

$$
s+t \geq \frac{3 n_{\geq 3}}{2} \text { and } s \leq n_{\geq 3}
$$

which implies

$$
t \geq \frac{n_{\geq 3}}{2} \quad \text { and } \quad\left(n_{\geq 3}-\frac{s}{3}-\frac{2 t}{3}\right) \leq \frac{n_{\geq 3}}{3}
$$

For $1 \leq i \leq s$, the path $G\left[P_{i}\right]$ without its one or two endvertices has a dominating set $D_{i}^{P}$ of cardinality $\frac{\left|P_{i}\right|-1}{3}$. For $1 \leq j \leq t$, the path $G\left[Q_{j}\right]$ without its two endvertices has a dominating set $D_{j}^{Q}$ of cardinality $\frac{\left|Q_{j}\right|-2}{3}$.

Now the set

$$
V_{\geq 3} \cup \bigcup_{i=1}^{s} D_{i}^{P} \cup \bigcup_{j=1}^{t} D_{j}^{Q}
$$

is a dominating set of $G$ and we obtain,

$$
\begin{aligned}
\gamma & \leq n_{\geq 3}+\sum_{i=1}^{s}\left|D_{i}^{P}\right|+\sum_{j=1}^{t}\left|D_{j}^{Q}\right| \\
& =n_{\geq 3}+\sum_{i=1}^{s} \frac{\left|P_{i}\right|-1}{3}+\sum_{j=1}^{t} \frac{\left|Q_{j}\right|-2}{3} \\
& =\left(n_{\geq 3}-\frac{s}{3}-\frac{2 t}{3}\right)+\sum_{i=1}^{s} \frac{\left|P_{i}\right|}{3}+\sum_{j=1}^{t} \frac{\left|Q_{j}\right|}{3} \\
& \leq \frac{n_{\geq 3}}{3}+\sum_{i=1}^{s} \frac{\left|P_{i}\right|}{3}+\sum_{j=1}^{t} \frac{\left|Q_{j}\right|}{3} \\
& \leq \frac{n}{3}
\end{aligned}
$$

This final contradiction completes the proof.
Note that Theorem 1 is best possible for the union of cycles $C_{3\left\lfloor\frac{q+1}{3}\right\rfloor+1}$. We derive some consequences of Theorem 1 for graphs of minimum degree at least 3 .
Corollary 2 If $G=(V, E)$ is a graph of order n, minimum degree $\delta \geq 3$, girth $g \geq 5$ and domination number $\gamma$, then

$$
\gamma \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-4 \alpha\left(G^{4}\right)\right)+\alpha\left(G^{4}\right)
$$

where $\alpha\left(G^{4}\right)$ denotes the independence number of $G^{4}$, i.e. the maximum cardinality of a set $I \subseteq V$ of vertices such that every two vertices in $I$ are at distance at least 5 .

Proof: Let $I \subseteq V$ be a set of vertices such that every two vertices in $I$ are at distance at least 5 and $|I|=\alpha\left(G^{4}\right)$. If $V^{\prime}=I \cup N_{G}(I)$, then $\left|V^{\prime}\right| \geq 4|I|$.

We will prove that $G\left[V \backslash V^{\prime}\right]$ has minimum degree at least 2. Therefore, for contradiction, we assume that there is a vertex $u \in V \backslash V^{\prime}$ which has 2 neighbours $v_{1}$ and $v_{2}$ in $V^{\prime}$. Clearly, $v_{1} \in N_{G}\left(w_{1}\right)$ and $v_{2} \in N_{G}\left(w_{2}\right)$ for some $w_{1}, w_{2} \in I$. If $w_{1}=w_{2}$, then $u v_{1} w_{1} v_{2} u$ is a cycle of length 4 which is a contradiction. If $w_{1} \neq w_{2}$, then $w_{1} v_{1} u v_{2} w_{2}$ is a path of length 4 between two vertices of $I$ which is a contradiction to the choice of $I$.

Therefore, $G\left[V \backslash V^{\prime}\right]$ has minimum degree at least 2 and, by Theorem 1, it has a dominating set $D^{\prime \prime}$ with $\left|D^{\prime \prime}\right| \leq\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right)$. Now $I \cup D^{\prime \prime}$ is a dominating set of $G$ and we obtain

$$
\begin{aligned}
\gamma(G) & \leq|I|+\left|D^{\prime \prime}\right| \\
& \leq \frac{1}{4}\left|V^{\prime}\right|+\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-\left|V^{\prime}\right|\right) \\
& \leq \alpha\left(G^{4}\right)+\left(\frac{1}{3}+\frac{2}{3\left(3\left\lfloor\frac{g+1}{3}\right\rfloor+1\right)}\right)\left(n-4 \alpha\left(G^{4}\right)\right)
\end{aligned}
$$

which completes the proof.
Since $\alpha(G) \geq \frac{n}{\Delta+1}$ for every graph $G$ of order $n$ and maximum degree $\Delta$ and the maximum degree of $G^{4}$ is at most $\Delta^{2}\left(\Delta^{2}-2 \Delta+2\right)$, we obtain the following immediate corollaries.

Corollary 3 If $G=(V, E)$ is a cubic graph of order $n$, girth $g \geq 5$ and domination number $\gamma$, then

$$
\gamma \leq\left(\frac{44}{135}+\frac{82}{135 g}\right) n
$$

Proof: If $g \leq 12$, then $\frac{44}{135}+\frac{82}{135 g} \geq \frac{3}{8}$ and Reed's bound [13] implies the desired result. If $g \geq 13$, then $G^{4}$ is neither complete nor an odd cycle and Brooks' theorem [3] implies that $\alpha\left(G^{4}\right) \geq \frac{n}{\Delta\left(G^{4}\right)} \geq \frac{n}{45}$ and the result follows from Corollary 2.

Note that $\frac{44}{135}+\frac{82}{135 g}<\frac{1}{3}$ for $g \geq 83$ and hence Corollary 3 improves the bounds (1) and (2) due to Kostochka and Stodolsky [8] and Kawarabayashi, Plummer and Saito [6] and also confirms Reed's conjecture [13] for large enough girth.

Corollary 4 For every $\Delta \geq \delta \geq 3$ there are constants $\alpha_{\delta, \Delta}<\frac{1}{3}$ and $\beta_{\delta, \Delta}$ such that if $G=(V, E)$ is a graph of order $n$, minimum degree $\delta$, maximum degree $\Delta$, girth $g \geq 5$ and domination number $\gamma$, then

$$
\gamma \leq\left(\alpha_{\delta, \Delta}+\frac{\beta_{\delta, \Delta}}{g}\right) n .
$$

Instead of giving exact expressions for $\alpha_{\delta, \Delta}$ and $\beta_{\delta, \Delta}$ in Corollary 4, we pose it as an open problem to determine the best-possible values for these coefficients.
