#### Abstract

An identifying code in a graph is a dominating set that also has the property that the closed neighborhood of each vertex in the graph has a distinct intersection with the set. The minimum cardinality of an identifying code, or ID code, in a graph $G$ is called the ID code number of $G$ and is denoted $\gamma^{\mathrm{ID}}(G)$. In this paper, we give upper and lower bounds for the ID code number of the prism of a graph, or $G \square K_{2}$. In particular, we show that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \geq \gamma^{\mathrm{ID}}(G)$ and we show that this bound is sharp. We also give upper and lower bounds for the ID code number of grid graphs and a general upper bound for $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)$.

Keywords: Identifying code, dominating set, Cartesian product, prism, grid graphs

## 1 Introduction

An identifying code, or ID code, in a graph is a dominating set that also has the property that the closed neighborhood of each vertex in the graph has a distinct intersection with the set. Thus every vertex of the graph can be uniquely located by using this intersection. Analogous to the domination number, the ID code number of a graph $G$ is the minimum cardinality of an ID code of $G$ and is denoted $\gamma^{\mathrm{ID}}(G)$. ID codes were first introduced in 1998 by Karpovsky, Chakrabarty and Levitin [15] who used them to analyze fault-detection problems in multi-processor systems. Since 1998 ID codes have been studied in many classes of graphs and an excellent, detailed list of references on ID codes can be found on Antoine Lobstein's webpage [17].

We shall focus on ID codes in a specific graph product, the Cartesian product. The Cartesian product of graphs $G$ and $H$, denoted $G \square H$, is the graph whose vertex set is $V(G) \times V(H)$. Two vertices $\left(u_{1}, u_{2}\right)$ and $\left(v_{1}, v_{2}\right)$ in $G \square H$ are adjacent if either $u_{1} v_{1} \in E(G)$ and $u_{2}=v_{2}$, or $u_{1}=v_{1}$ and $u_{2} v_{2} \in E(H)$. When $H=K_{2}$, we refer to $G \square K_{2}$ as the prism
of $G$. Cartesian products have been studied for some time, and extensive information on their structural properties can be found in [13] and [8].

With respect to graph products, ID codes have been studied in the direct product of cliques [18], hypercubes [2, 12, 14, 16, 19], and infinite grids [1, 3, 11]. As we will be focusing on Cartesian products, some of the more recent results regarding ID codes have been in the study of the Cartesian product of cliques [7, 5], and the Cartesian product of a path and a clique [10. In light of these results, we first focus on the prism of a graph. When studying any parameter in a Cartesian product, an important question is whether there exists some formula relating the value of the parameter in the product to the value of the parameter in the underlying factor graphs. In 9 the authors prove the following result that relates the domination number of the prism of a graph $G$ to the domination number of $G$.

Theorem 1 (9). If $G$ is any graph, then $\gamma(G) \leq \gamma\left(G \square K_{2}\right) \leq 2 \gamma(G)$.
Since identifying codes are in the first place dominating sets, it seems natural to suspect that if $G$ has an identifying code then a similar relationship would hold between $\gamma^{\mathrm{ID}}(G)$ and $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)$. Namely, it would be natural to suspect that $\gamma^{\mathrm{ID}}(G) \leq \gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq 2 \gamma^{\mathrm{ID}}(G)$. Indeed, we will prove that the lower bound in this inequality is correct and will show that the upper bound need not be true unless we make some additional assumptions on the minimum ID codes of $G$. It is known that for any graph $G$ of order $n, \gamma^{\text {ID }}(G) \leq n-1$. In [4] Foucaud et al. identify the class of all graphs which attain this bound, and interestingly enough, a subset of this class achieves the lower bound $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. We also demonstrate an infinite family of graphs with identifying codes that show the upper bound is sharp.

Finally, we concentrate on the ID code number of grid graphs, i.e. the Cartesian product of two paths. The problem of finding the exact value for the domination number of grid graphs was quite difficult and finally settled in [6. We expect finding the exact value for the ID code number of grid graphs to be just as difficult. In this paper, we give both upper and lower bounds for the ID code number of grid graphs, and we also give a general upper bound for the ID code number of the Cartesian product of a graph $G$ and a path.

The remainder of the paper is organized as follows. In Section 2 we give some useful definitions and terminology as well as prove some basic facts about minimum ID codes. In Section 3 we prove the natural upper bound for the ID code number of the prism of a graph $G$ when an additional assumption is imposed on $G$ and show this bound is sharp. Section 4 is devoted to giving a lower bound for $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)$ for any graph $G$. We also prove that the bound is sharp in this section. In Section [5, we give upper and lower bounds for $\gamma^{\mathrm{ID}}\left(P_{m} \square P_{n}\right)$ for any positive integers $2 \leq m \leq n$ and we give a general upper bound for $\gamma^{\mathrm{ID}}\left(G \square P_{m}\right)$.

## 2 Definitions and Preliminary Results

Given a simple undirected graph $G$ and a vertex $x$ of $G$, we let $N(x)$ denote the open neighborhood of $x$, that is, the set of vertices adjacent to $x$. The closed neighborhood of $x$
is $N[x]=N(x) \cup\{x\}$. By a code in $G$ we mean any nonempty subset of vertices in $G$. The vertices in a code are called codewords. A code $D$ in $G$ is a dominating set of $G$ if $D$ has a nonempty intersection with the closed neighborhood of every vertex of $G$. The domination number of $G$ is the cardinality of a smallest dominating set of $G$; it is denoted by $\gamma(G)$. A code having the property that the distance between any two codewords is at least 3 is called a 2-packing of $G$, and $\rho_{2}(G)$ is the smallest cardinality of a 2-packing in $G$. For compact writing we denote $N[x] \cap D$ by $I_{D}(x)$. A code $D$ separates two distinct vertices $x$ and $y$ if $I_{D}(x) \neq I_{D}(y)$. When $D=\{u\}$ we say that $u$ separates $x$ and $y$. As mentioned above, an identifying code (ID code for short) of $G$ is a code $C$ that is a dominating set of $G$ with the additional property that $C$ separates every pair of distinct vertices of $G$. The minimum cardinality of an ID code of $G$ is denoted $\gamma^{\mathrm{ID}}(G)$. Note that any graph having two vertices with the same closed neighborhood (so-called twins) does not have an ID code. If a graph has no twins, then we say it is twin-free.

If $h \in V(H)$, then the subgraph of $G \square H$ induced by $V(G) \times\{h\}$ is called a $G$-fiber and is denoted by $G^{h}$. In the special case of the prism of $G$ we will assume that $\{1,2\}$ is the vertex set of $K_{2}$, and these two $G$-fibers are then $G^{1}$ and $G^{2}$. When dealing with the prism we will simplify the notation and denote the vertex $(g, i)$ by $g^{i}$ for $i \in[2]$. Here [n] denotes the set of positive integers less than or equal to $n$. The map $p_{G}: V(G \square H) \rightarrow V(G)$ defined by $p_{G}(a, b)=a$ is the projection onto $G$.

While our main emphasis is on minimum ID codes in prisms of graphs, we will also need some basic facts about ID codes in more general Cartesian products. The proof of the following is straightforward and is omitted.

Proposition 2. If $G$ and $H$ both have minimum degree at least 1, then $G \square H$ is twin-free.
If $C$ is any ID code in a twin-free graph $G$ of order $n$, then $\left\{I_{C}(x)\right\}_{x \in V(G)}$ is a collection of $n$, pairwise distinct, nonempty subsets of $C$. This fact immediately implies the following result, which was first given in [15.
Proposition 3 ([15]). Let $G$ be any twin-free graph of order $n$. If $\gamma^{\mathrm{ID}}(G)=k$, then $n \leq 2^{k}-1$. Equivalently, $\gamma^{\mathrm{ID}}(G) \geq\left\lceil\log _{2}(n+1)\right\rceil$.

In particular, an easy application of Proposition 3 to prisms yields the following corollary.
Corollary 4. If $H$ is any graph of order $m$ with no isolated vertices, then

$$
\gamma^{\mathrm{ID}}\left(H \square K_{2}\right) \geq\left\lceil\log _{2}(2 m+1)\right\rceil .
$$

It also follows directly from Corollary 4 that if the prism of a graph $G$ has ID code number 3, then $G$ has order at most 3. Thus, we have the following result.

Corollary 5. If $G$ is a twin-free graph with no isolated vertices such that $\gamma^{\operatorname{ID}}(G)=3$, then $\gamma^{\text {ID }}\left(G \square K_{2}\right)>3$.

By more closely analyzing how an identifying code separates vertices in a prism we can deduce some restrictions on ID codes in prisms.

Lemma 6. Let $G$ be a nontrivial, connected graph of order $n$. If $C$ is an identifying code of $G \square K_{2}$ that has $m_{i}$ codewords in the $G$-layer $G^{i}$, for $i \in[2]$, then

$$
n \leq \min \left\{2^{m_{1}}-1+m_{2}, 2^{m_{2}}-1+m_{1}\right\} .
$$

Proof. Let $C$ be any ID code of $G \square K_{2}$ and for $i \in[2]$ and let $m_{i}=\left|C_{i}\right|$ where $C_{i}=C \cap V\left(G^{i}\right)$. Note that $\left\{a^{1}: a^{2} \notin C_{2}\right\},\left\{a^{1}: a^{2} \in C_{2}\right\}$ is a partition of $V\left(G^{1}\right)$. Any two vertices in the former subset are separated by $C_{1}$, and it follows that $\left|\left\{a^{1}: a^{2} \notin C_{2}\right\}\right| \leq 2^{m_{1}}-1$. Clearly the second of these parts of the partition has cardinality $m_{2}$. Combining these we get that $n=\left|V\left(G^{1}\right)\right| \leq 2^{m_{1}}-1+m_{2}$. The result follows by applying a similar argument to $G^{2}$.

Proposition 7. If the graph $G$ has no isolated vertices, then $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)>\gamma(G)$.
Proof. Suppose to the contrary that $G \square K_{2}$ has a minimum ID code $C$ such that $|C| \leq \gamma(G)$. Since $C$ dominates $G \square K_{2}$, it follows from [9] that $\gamma(G) \geq|C| \geq \gamma\left(G \square K_{2}\right) \geq \gamma(G)$, and hence $|C|=\gamma(G)$. As shown in [9], it follows that $C=\left(D_{1} \times\{1\}\right) \cup\left(D_{2} \times\{2\}\right)$ where $D=D_{1} \cup D_{2}$ and $D$ is a minimum dominating set of $G$ such that $V(G)-N\left[D_{1}\right]=D_{2}$ and $V(G)-N\left[D_{2}\right]=D_{1}$. Let $X=V(G)-D$. Every vertex of $X$ has exactly one neighbor in $D_{1}$ and exactly one neighbor in $D_{2}$. Let $x \in X$ and suppose $\{d\}=N(x) \cap D_{1}$. It now follows that $I_{C}(d, 2)=\{(d, 1)\}=I_{C}(x, 1)$, which contradicts the assumption that $C$ is an ID code for $G \square K_{2}$.

## 3 Upper Bound

In this section we prove that under a certain condition on the minimum ID codes of a graph the natural upper bound holds for the ID code number of its prism.

Theorem 8. If $G$ has a minimum ID code $I$ such that $G[I]$ has no isolated vertices, then $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq 2 \gamma^{\mathrm{ID}}(G)$.

Proof. Let $D=I \times\{1,2\}$, let $D_{1}=I \times\{1\}$, and let $D_{2}=I \times\{2\}$. It is clear that $D$ dominates $G \square K_{2}$ since $I$ dominates $G$. Let $x$ and $y$ be distinct vertices of $G \square K_{2}$. We show that $D$ separates $x$ and $y$. Suppose first that at least one of $x$ and $y$ belongs to $D$. Without loss of generality we assume that $x \in D_{1}$. If $y \in D_{1}$, then $x$ and $y$ have distinct neighbors in $D_{2}$. If $y \in G^{1}-D_{1}$, then $x$ has a neighbor in $D_{2}$ but $y$ does not. If $y \in G^{2}-D_{2}$, then since $G[I]$ has no isolated vertices it follows that $x$ has a neighbor in $D_{1}$, but $y$ does not. Finally, suppose that $y \in D_{2}$. If $p_{G}(x)=p_{G}(y)$, then $\left(N[x] \cap D_{1}\right)-N[y] \neq \emptyset$ since $G[I]$ has no isolated vertices. If $p_{G}(x) \neq p_{G}(y)$, then $x \in N[x]-N[y]$. Thus $D$ separates $x$ and $y$ if at least one of them belongs to $D$. Now suppose that $x \in V\left(G^{1}\right)-D_{1}$. If $y$ also belongs to $V\left(G^{1}\right)-D_{1}$, then $D$ separates $x$ and $y$ because $I$ separates $p_{G}(x)$ and $p_{g}(y)$. On the other hand, if $y \in V\left(G^{2}\right)-D_{2}$, then $N[y] \cap D \subseteq D_{2}$ while $N[x] \cap D \subseteq D_{1}$ and thus $D$ separates $x$ and $y$.

If we do not require that the subgraph of $G$ induced by a minimum ID code has no isolated vertices, then the conclusion may not hold. As an example, let $X=\{1,2,3,4\}$
and let $Y=\{A: A \subset\{1,2,3,4\}$ and $|A| \geq 2\}$. Construct a bipartite graph $G$ where $V(G)=X \cup Y$. In $G$ the vertex $j \in X$ is adjacent to the vertex $A \in Y$ exactly when $j \in A$. It is clear that $X$ is an identifying code in $G$ and it then follows by Proposition 3 that $\gamma^{\mathrm{ID}}(G) \geq \log _{2}(|V(G)|+1)=4$. It can be easily verified that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=9$, which shows that the conclusion of Theorem 8 does not hold for this graph.

The upper bound given in Theorem 8 is sharp. To see this we consider the infinite class of so-called corona graphs. For a given graph $H$ the corona of $H$ is the graph constructed from $H$ by adding a single (new) vertex of degree 1 adjacent to each vertex of $H$. The corona of $H$ is denoted by $H \circ K_{1}$. Suppose that $H$ is twin-free and connected. The set of vertices in the original graph $H$ is a minimum dominating set of $H \circ K_{1}$ and also separates all pairs of vertices in this corona since $H$ is twin-free. Consequently, $\gamma^{\mathrm{ID}}\left(H \circ K_{1}\right)=|V(H)|$. As the following proposition shows, we can also determine the identifying code number of the prisms of a more general class of graphs that includes these coronas. This result will also then yield an infinite family of graphs that achieve the upper bound given in Theorem 8 ,

Let $n$ be any positive integer larger than 1 . The class of graphs $\mathcal{H}_{n}$ consists of all the finite graphs that can be obtained from any connected graph of order $n$ by adding at least one new vertex of degree 1 adjacent to each of these $n$ vertices. (Note that $\mathcal{H}_{n}$ contains the corona of each connected graph of order n.)

Proposition 9. If $H \in \mathcal{H}_{n}$, then $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right)=|V(H)|$.
Proof. Suppose $H \in \mathcal{H}$, let $u_{1}, \ldots, u_{n}$ represent the vertices of the underlying graph of order $n$, and for each $i \in[n]$ let $x_{i, 1}, \ldots, x_{i, k_{i}}$ represent the vertices of degree 1 adjacent to $u_{i}$. One can easily verify that $V\left(H^{1}\right)$ is an ID code for $H \square K_{2}$. Hence $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right) \leq|V(H)|$. Suppose that $C$ is an ID code for $H \square K_{2}$. For each $i \in[n]$, let

$$
A_{i}=\left(\bigcup_{j=1}^{k_{i}}\left\{\left(x_{i, j}, 1\right),\left(x_{i, j}, 2\right)\right\}\right) \cup\left\{\left(u_{i}, 1\right),\left(u_{i}, 2\right)\right\}
$$

We claim that $\left|A_{i} \cap C\right| \geq k_{i}+1$ for each $i \in[n]$. Note first that if $\left\{\left(x_{i, j}, 1\right),\left(x_{i, j}, 2\right)\right\} \cap C=\emptyset$ for some $1 \leq j \leq k_{i}$, then $\left\{\left(u_{i}, 1\right),\left(u_{i}, 2\right)\right\} \subseteq C$ since $C$ dominates $H \square K_{2}$. If $k_{i}=1$, then we are done. So assume that $k_{i}>1$. If there exists $\ell \neq j$ such that

$$
\left\{\left(x_{i, j}, 1\right),\left(x_{i, j}, 2\right),\left(x_{i, \ell}, 1\right),\left(x_{i, \ell}, 2\right)\right\} \cap C=\emptyset,
$$

then $C$ does not separate $\left(x_{i, j}, 1\right)$ and $\left(x_{i, \ell}, 1\right)$. So in this case, $\left|A_{i} \cap C\right| \geq k_{i}+1$.
Next, suppose $\left|\left\{\left(x_{i, j}, 1\right),\left(x_{i, j}, 2\right)\right\} \cap C\right| \geq 1$ for each $1 \leq j \leq k_{i}$. If some $j$ satisfies $\left\{\left(x_{i, j}, 1\right),\left(x_{i, j}, 2\right)\right\} \subseteq C$, then we are done. So we may assume $\left|\left\{\left(x_{i, j}, 1\right),\left(x_{i, j}, 2\right)\right\} \cap C\right|=1$ for each $1 \leq j \leq k_{i}$. However, in this case one of $\left(u_{i}, 1\right)$ or $\left(u_{i}, 2\right)$ is in $C$ for otherwise $\left(x_{i, j}, 1\right)$ and $\left(x_{i, j}, 2\right)$ are not separated. Thus, $\left|A_{i} \cap C\right| \geq k_{i}+1$ in each case. This shows that $|C| \geq \sum_{i=1}^{n}\left|A_{i} \cap C\right| \geq \sum_{i=1}^{n}\left(k_{i}+1\right)=|V(H)|$.

If $H$ is connected and twin-free, then by Proposition 9 we see that the corona $H \circ K_{1}$ is a graph that achieves the upper bound in Theorem 8. Hence this bound is achieved for infinitely many graphs.

## 4 Lower Bound

As mentioned in Section [1. Hartnell and Rall show in [9] that $\gamma\left(G \square K_{2}\right) \geq \gamma(G)$ and we would naturally expect that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \geq \gamma^{\mathrm{ID}}(G)$ to be true as well. However, the same projection argument that was used in [9] creates complications when applied to an ID code. In particular, given an ID code $C$ of $G \square K_{2}, p_{G}[C]$ need not be an ID code of $G$ since $p_{G}[C]$ may induce isolated edges. However, we show in the following result that we can construct an ID code of $G$ from $p_{G}[C]$.
Theorem 10. For any twin-free graph $G$, $\gamma^{\mathrm{ID}}(G \square H) \geq \gamma^{\mathrm{ID}}(G) \rho_{2}(H)$.
Proof. Let $C$ be a minimum ID code of $G \square H$ and fix a vertex $h \in V(H)$. Let $C^{\prime}=$ $p_{G}\left[C \cap V\left(G^{h}\right)\right]$. If $C^{\prime}$ is an ID code of $G$, then we are done. So assume there exists at least one pair of vertices $x, y \in V(G)$ such that $I_{C^{\prime}}(x)=I_{C^{\prime}}(y)$. For any pair $x, y$ where $I_{C^{\prime}}(x)=I_{C^{\prime}}(y)$, we shall say that $x$ and $y$ are restricted twins with respect to $C^{\prime}$. Note that $x \sim y$ if $x$ and $y$ are restricted twins is an equivalence relation. It is clear that $x \sim x$ and if $x \sim y$ and $y \sim z$ then $I_{C^{\prime}}(x)=I_{C^{\prime}}(y)=I_{C^{\prime}}(z)$. Thus, $y \sim x$ and $x \sim z$. We let $R(x)$ represent the equivalence class of $x$, i.e. the set of restricted twins of $x$. It follows that $R(x) \cap R(y)=\emptyset$ or $R(x)=R(y)$ for all $x, y \in V(G)$.

Let $R\left(a_{1}\right), \ldots, R\left(a_{m}\right)$ be a complete set of distinct equivalence classes of $\sim$ restricted to $N\left[C^{\prime}\right]$, and let $R\left(a_{0}\right)=V(G)-N\left[C^{\prime}\right]$. Note that $N\left[C^{\prime}\right]=\cup_{i=1}^{m} R\left(a_{i}\right)$. If $R\left(a_{0}\right) \neq \emptyset$, then we assume $a_{0} \in R\left(a_{0}\right)$. Furthermore, we may assume that there exists some $m_{1} \in[m]$ and we can reindex the $a_{i}$ s if necessary so that $\left|R\left(a_{i}\right)\right|>1$ for each $i \in\left[m_{1}\right]$ and $\left|R\left(a_{i}\right)\right|=1$ for all $i>m_{1}$.
Claim 1 If $R\left(a_{0}\right) \neq \emptyset$, then we can choose a set of $\left|R\left(a_{0}\right)\right|$ vertices from $V(G)-C^{\prime}$ that dominates and separates each pair of vertices of $R\left(a_{0}\right)$.

Proof We proceed by induction on the cardinality of $R\left(a_{0}\right)$. Suppose first that $R\left(a_{0}\right)=$ $\left\{a_{0}\right\}$. It is clear that $\left\{a_{0}\right\}$ dominates and separates $R\left(a_{0}\right)$. Next, assume that $R\left(a_{0}\right)=$ $\left\{a_{0}, v\right\}$. If $a_{0}$ is not adjacent to $v$, then $\left\{a_{0}, v\right\}$ dominates and separates $R\left(a_{0}\right)$. So assume that $a_{0}$ is adjacent to $v$. If $\left(V(G)-C^{\prime}\right) \cap N\left[a_{0}\right]=\left(V(G)-C^{\prime}\right) \cap N[v]$, then $a_{0}$ and $v$ are twins in $G$ since $I_{C^{\prime}}\left(a_{0}\right)=I_{C^{\prime}}(v)$. So either there exists $w \in\left(V(G)-C^{\prime}\right) \cap\left(N\left[a_{0}\right]-N[v]\right)$ or there exists $w \in\left(V(G)-C^{\prime}\right) \cap\left(N[v]-N\left[a_{0}\right]\right)$. In either case, $\left\{a_{0}, w\right\}$ separates $R\left(a_{0}\right)$.

Assume that when $\left|R\left(a_{0}\right)\right|=k$, we can choose a set of $k$ vertices to dominate and separate each pair of vertices of $R\left(a_{0}\right)$. Suppose that $\left|R\left(a_{0}\right)\right|=\left\{u_{1}, \ldots, u_{k}, u_{k+1}\right\}$. By the inductive hypothesis, there exists a set $W \subseteq V(G)-C^{\prime}$ that dominates and separates each pair of vertices of $R\left(a_{0}\right)-\left\{u_{k+1}\right\}$ and $|W|=k$. If $W$ dominates and separates each pair of vertices in $R\left(a_{0}\right)$, then we are done. So first assume that $W$ does not dominate $u_{k+1}$. Note that since $W$ dominates $R\left(a_{0}\right)-\left\{u_{k+1}\right\}$, then $W \cap N\left[u_{k+1}\right] \neq W \cap N\left[u_{j}\right]$ for all $1 \leq j \leq k$. Thus, $W^{\prime}=W \cup\left\{u_{k+1}\right\}$ is a set of $k+1$ vertices that both dominates and separates each pair of vertices of $R\left(a_{0}\right)$.

Next, suppose that $W$ dominates $u_{k+1}$ but there exists some $j \in[k]$ such that $W \cap$ $N\left[u_{k+1}\right]=W \cap N\left[u_{j}\right]$. Note that if there exists $i \neq j$ such that $W \cap\left[u_{i}\right]=W \cap N\left[u_{k+1}\right]$, then $W$ does not separate $u_{i}$ and $u_{j}$, which is a contradiction. Thus, $u_{j}$ is the only vertex of $R\left(a_{0}\right)-\left\{u_{k+1}\right\}$ that satisfies $W \cap N\left[u_{k+1}\right]=W \cap N\left[u_{j}\right]$. There exists a vertex in
$V(G)-\left(W \cup C^{\prime}\right)$ that is adjacent to exactly one of $u_{k+1}$ or $u_{j}$ for otherwise $u_{k+1}$ and $u_{j}$ are twins in $G$. Assume first that there exists $z \in\left(N\left[u_{j}\right]-N\left[u_{k+1}\right]\right)-\left(W \cup C^{\prime}\right)$. It follows that $W^{\prime}=W \cup\{z\}$ separates every pair of vertices of $R\left(a_{0}\right)$. Otherwise, there exists $z \in\left(N\left[u_{k+1}\right]-N\left[u_{j}\right]\right)-\left(W \cup C^{\prime}\right)$ and $W^{\prime}=W \cup\{z\}$ separates every pair of vertices in $R\left(a_{0}\right)$. In either case, we have found a set of $\left|R\left(a_{0}\right)\right|$ vertices in $V(G)-C^{\prime}$ that dominates and separates each pair of vertices in $R\left(a_{0}\right)$.(व)

Claim 2 We can choose a set of $\left|R\left(a_{i}\right)\right|-1$ vertices from $V(G)-C^{\prime}$ that separates each pair of vertices of $R\left(a_{i}\right)$ for $i \in[m]$.

Proof First, let $m_{1}<i \leq m$. Note that $R\left(a_{i}\right)=\left\{a_{i}\right\}$ in which case there is no need to choose any vertices to separate $a_{i}$ from itself. Now suppose $i \in\left[m_{1}\right]$. As in the proof of Claim 2 , we proceed by induction on the cardinality of $R\left(a_{i}\right)$. Suppose first that $R\left(a_{i}\right)=\left\{a_{i}, v\right\}$. If $a_{i}$ is not adjacent to $v$, then it follows that $a_{i}$ and $v$ are not vertices of $C^{\prime}$. Moreover, $a_{i}$ separates $a_{i}$ and $v$. On the other hand, If $a_{i}$ is adjacent to $v$, then either there exists $w \in\left(V(G)-C^{\prime}\right) \cap\left(N\left[a_{i}\right]-N[v]\right)$ or there exists $w \in\left(V(G)-C^{\prime}\right) \cap\left(N[v]-N\left[a_{i}\right]\right)$ for otherwise $a_{i}$ and $v$ are twins in $G$. In either case, $w$ separates $a_{i}$ and $v$. So we shall assume that when $\left|R\left(a_{i}\right)\right|=k$, there exists a set of $k-1$ vertices in $V(G)-C^{\prime}$ that separates each pair of vertices of $R\left(a_{i}\right)$.

Suppose that $R\left(a_{i}\right)=\left\{u_{1}, \ldots u_{k+1}\right\}$. By the inductive hypothesis, there exists a set $W \subseteq V(G)-C^{\prime}$ of cardinality $k-1$ that separates each pair of vertices in $R\left(a_{i}\right)-\left\{u_{k+1}\right\}$. If $W$ separates $u_{k+1}$ and $u_{j}$ for all $j \in[k]$, then we are done. So assume that for some $j \in[k]$ that $W \cap N\left[u_{j}\right]=W \cap N\left[u_{k+1}\right]$. If there exists $1 \leq i \leq k, i \neq j$ such that $W \cap N\left[u_{i}\right]=W \cap N\left[u_{k+1}\right]$, then $W$ does not separate $u_{i}$ and $u_{j}$, which is a contradiction. Therefore, $u_{j}$ is the only vertex of $R\left(a_{i}\right)-\left\{u_{k+1}\right\}$ that satisfies $W \cap N\left[u_{j}\right]=W \cap N\left[u_{k+1}\right]$. Since $u_{j}$ and $u_{k+1}$ are not twins in $G$, then there exists $z \in V(G)-\left(W \cup C^{\prime}\right)$ that is adjacent to exactly one of $u_{j}$ or $u_{k+1}$. Thus, $W \cup\{z\}$ separates every pair of vertices of $R\left(a_{i}\right)$ and $|W \cup\{z\}|=k$. (ㅁ)

Finally, choose a minimal set $W$ of vertices from $V(G)-C^{\prime}$ that separates every pair of vertices from $R\left(a_{i}\right)$ for all $0 \leq i \leq m$ and dominates $R\left(a_{0}\right)$, which we know exists from Claim 1 and Claim 2. Note that $W \cup C^{\prime}$ dominates every vertex of $V(G)$ since every vertex $v$ not dominated by $C^{\prime}$ satisfies $v \in R\left(a_{0}\right)$ and $W$ dominates $R\left(a_{0}\right)$. Next, note that if $C^{\prime}$ does not separate a pair of vertices, say $x, y \in V(G)$, then there exists $a_{i}$ such that $\{x, y\} \subseteq R\left(a_{i}\right)$ for some $0 \leq i \leq m$. In this case, some vertex of $W$ separates $x$ and $y$. Thus, $W \cup C^{\prime}$ is an ID code of $G$ and $\gamma^{\text {ID }}(G) \leq\left|W \cup C^{\prime}\right|$. We claim that $\left|W \cup C^{\prime}\right| \leq\left|C \cap\left(V(G) \times N_{H}[h]\right)\right|$. Indeed, if $(u, h) \in V\left(G^{h}\right)$ where $u \in R\left(a_{0}\right)$, then there exists $h^{\prime} \in V(H)$ such that $h h^{\prime} \in E(H)$ and $\left(u, h^{\prime}\right) \in C$ since $C$ is an ID code of $G \square H$. Moreover, for each $1 \leq i \leq m$, consider the set $S_{i}=\left\{(u, h) \in V\left(G^{h}\right): u \in R\left(a_{i}\right)\right\}$. Since $C$ is an ID code of $G \square H,\left|C \cap\left(V(G) \times N_{H}(h)\right)\right| \geq\left|S_{i}\right|-1$. Thus, $|W| \leq\left|C \cap\left(V(G) \times N_{H}(h)\right)\right|$, which implies that

$$
\begin{aligned}
\left|W \cup C^{\prime}\right| & =|W|+\left|C^{\prime}\right| \\
& \leq\left|C \cap\left(V(G) \times N_{H}(h)\right)\right|+\left|C \cap V\left(G^{h}\right)\right| \\
& =\left|C \cap\left(V(G) \times N_{H}[h]\right)\right| .
\end{aligned}
$$

Notice that the above argument shows that there exist at least $\gamma^{\text {ID }}(G)$ codewords of $C$
in $V(G) \times N_{H}[h]$. Therefore, if we choose a maximum 2-packing, $T$, of $H$ and apply the same argument to each vertex of $T$, then the desired result follows.

We call the reader's attention to the fact that Theorem 10 does not require that $H$ be twin-free. Thus, an immediate consequence of Theorem 10 is the following.

Corollary 11. For any twin-free graphs $G$ and $H$,

$$
\gamma^{\mathrm{ID}}(G \square H) \geq \max \left\{\gamma^{\mathrm{ID}}(G) \rho_{2}(H), \rho_{2}(G) \gamma^{\mathrm{ID}}(H)\right\}
$$

Next, we show that the bound given in Theorem 10 is indeed sharp. For the remainder of this section, we consider only Cartesian products of the form $G \square K_{2}$. Note that by Corollary 4, $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)>\gamma^{\mathrm{ID}}(G)$ when $\gamma^{\mathrm{ID}}(G) \leq 3$ as $\gamma^{\mathrm{ID}}(G) \leq|V(G)|-1$ for all graphs. So the first case we consider is when $\gamma^{\mathrm{ID}}(G)=4$.

Surprisingly, the class of graphs for which $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)=4$ is a subclass of the graphs which satisfy $\gamma^{\mathrm{ID}}(G)=|V(G)|-1$. Foucaud et al. classified all such graphs that satisfy $\gamma^{\mathrm{ID}}(G)=|V(G)|-1$ in [4]. For ease of reference, we include the description of this class of graphs here along with their result.

For any integer $k \geq 1$, let $A_{k}=\left(V_{k}, E_{k}\right)$ be the graph with vertex set $V_{k}=\left\{x_{1}, \ldots, x_{2 k}\right\}$ and edge set $E_{k}=\left\{x_{i} x_{j}:|i-j| \leq k-1\right\}$. So for $k \geq 2, A_{k}=P_{2 k}^{k-1}$ and $A_{1}=\overline{K_{2}}$. Let $\mathcal{A}$ be the closure of $\left\{A_{i}: i \in \mathbb{N}\right\}$ with respect to the join operation $\bowtie$. Figure 1 depicts several graphs in $\mathcal{A}$.

Figure 1: Examples of graphs in $\mathcal{A}$

Theorem 12 (4). Given a connected graph $G$, we have $\gamma^{\mathrm{ID}}(G)=|V(G)|-1$ if and only if $G \in\left\{K_{1, t} \mid t \geq 2\right\} \cup \mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)$ and $G \nsubseteq A_{1}$.

We now show that a subclass of $\mathcal{A}$ contains precisely those graphs for which $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=$ $\gamma^{\mathrm{ID}}(G)=4$.

Theorem 13. For any connected twin-free graph $G$ such that $\gamma^{\mathrm{ID}}(G)=4, \gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=$ $\gamma^{\mathrm{ID}}(G)$ if and only if $G \in \mathcal{A} \bowtie K_{1}$.

Proof. Notice that if $G \in \mathcal{A} \bowtie K_{1}$ with $\gamma^{\mathrm{ID}}(G)=4$, then $G=A_{1} \bowtie A_{1} \bowtie K_{1}$ or $G=A_{2} \bowtie K_{1}$. In either case, we represent the vertices of $A_{1} \bowtie A_{1}$ or $A_{2}$ by $x_{1}, x_{2}, x_{3}, x_{4}$. If $G=A_{1} \bowtie A_{1} \bowtie K_{1}$, then $C=\left\{x_{1}^{1}, x_{2}^{1}, x_{3}^{2}, x_{4}^{2}\right\}$ is an ID code of $G \square K_{2}$. If $G=A_{2} \bowtie K_{2}$, then $C=\left\{x_{1}^{1}, x_{3}^{1}, x_{2}^{2}, x_{4}^{2}\right\}$ is an ID code of $G \square K_{2}$. Thus, $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq 4$. An application of Theorem 10 yields $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \geq \gamma^{\mathrm{ID}}(G)=4$. Therefore, $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=4$.

We now show the other direction. That is, let $G$ be a connected twin-free graph such that $\gamma^{\mathrm{ID}}(G)=4=\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)$. Let $C$ be a minimum ID code of $G \square K_{2}$ and partition the projection of $C$ onto $V(G), p_{G}[C]$, as

$$
\begin{aligned}
C_{1} & =\left\{v \in V(G): v^{1} \in C \text { and } v^{2} \notin C\right\} \\
C_{2} & =\left\{v \in V(G): v^{1} \notin C \text { and } v^{2} \in C\right\} \\
D & =\left\{v \in V(G): v^{1} \in C \text { and } v^{2} \in C\right\} .
\end{aligned}
$$

Suppose first that $\left|C_{1}\right|=1,|D|=0$, and let $C_{1}=\{v\}$. Thus, $I_{C}\left(v^{1}\right)=\left\{v^{1}\right\}$, which implies for every $u \in V(G)-\{v\}, u^{2} \in C$. It follows that $|V(G)|=4$, which contradicts the assumption that $\gamma^{\mathrm{ID}}(G)=4$. On the other hand, suppose $\left|C_{1}\right|=0,|D|=1$ and $D=\{v\}$. There exist precisely two vertices, say $x$ and $y$ in $G$ such that $x^{2} \in I_{C}\left(x^{1}\right)$ and $y^{2} \in I_{C}\left(y^{1}\right)$ as $\left|C_{2}\right|=2$. Every $w^{1} \in V\left(G^{1}\right)-\left\{v^{1}, x^{1}, y^{1}\right\}$ is dominated only by $v^{1}$ and this implies that $|V(G)|=4$, which is another contradiction. Thus, $\left|C_{1} \cup D\right|=2$ and similarly $\left|C_{2} \cup D\right|=2$.
(1) Suppose that $|D|=2$ and let $D=\{u, v\}$. It follows that the order of $G$ is at most 5, and since $\gamma^{\mathrm{ID}}(G)=4$, we have $|V(G)|=5$. Theorem 12 guarantees that $G \in\left\{K_{1,4}, A_{1} \bowtie A_{1} \bowtie K_{1}, A_{2} \bowtie K_{1}\right\}$, pictured below in Figure 2. Note that $u v \in$ $E(G)$ since the subgraph induced by $C$ contains no isolated edge. Furthermore, since $|V(G)|=5$, there exists $w \in V(G)$ such that $w$ is adjacent to both $u$ and $v$. Therefore, $G$ contains a triangle and it follows that $G \in\left\{A_{1} \bowtie A_{1} \bowtie K_{1}, A_{2} \bowtie K_{1}\right\}$.
(2) Suppose that $|D|=1$, meaning $\left|C_{1}\right|=1=\left|C_{2}\right|$, and let $C_{1}=\{u\}, D=\{v\}$, and $C_{2}=\{w\}$. Since the subgraph induced by $C$ contains no isolated edges, we may assume without loss of generality that $u v \in E(G)$. This immediately implies that $|V(G)|=5$ and there exist vertices $x$ and $y$ in $G$ such that $I_{C}\left(x^{1}\right)=\left\{u^{1}\right\}$ and $I_{C}\left(y^{1}\right)=\left\{v^{1}\right\}$. Therefore, $G \in\left\{A_{1} \bowtie A_{1} \bowtie K_{1}, A_{2} \bowtie K_{1}\right\}$ since the subgraph induced by $x, y, u$, and $v$ is a path.
(3) Suppose that $|D|=0,\left|C_{1}\right|=2=\left|C_{2}\right|$, and let $C_{1}=\{u, v\}$ and $C_{2}=\{x, y\}$. Note that $u v \notin E(G)$ and $x y \notin E(G)$ since the subgraph induced by $C$ contains no isolated edge. Thus, for any $w \in V(G)-\left(C_{1} \cup C_{2}\right), I_{C}\left(w^{1}\right)=\left\{u^{1}, v^{1}\right\}$ and $I_{C}\left(w^{2}\right)=\left\{x^{2}, y^{2}\right\}$. So $|V(G)|=5, N[w]=V(G)$, and $G \in\left\{K_{1,4}, A_{1} \bowtie A_{1} \bowtie K_{1}, A_{2} \bowtie K_{1}\right\}$. Also, $I_{C}\left(x^{1}\right) \neq\left\{x^{2}\right\}$ so $x$ has a neighbor in $C_{1}$. Therefore, we may conclude that $G \in$ $\left\{A_{1} \bowtie A_{1} \bowtie K_{1}, A_{2} \bowtie K_{1}\right\}$.

Based on the above result, we next show that for any integer $k \geq 4$, there exists a graph $G$ such that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)=k$.

Figure 2: Graphs of order 5 with ID code number 4
Theorem 14. If $G \in \mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)$ has order at least 5 , then $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. Moreover, if $G=G_{1} \bowtie G_{2}$ where $G_{1}, G_{2} \in \mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)-\left\{A_{1}, A_{2}\right\}$, then
$\gamma^{\mathrm{ID}}\left(\left(G_{1} \bowtie G_{2}\right) \square K_{2}\right)=\gamma^{\mathrm{ID}}\left(G_{1} \square K_{2}\right)+\gamma^{\mathrm{ID}}\left(G_{2} \square K_{2}\right)+1$.
Proof. For the time being, assume that $G \in \mathcal{A}$. We proceed by induction. Write $G=G_{1} \bowtie$ $\cdots \bowtie G_{m}$ where each $G_{i} \in\left\{A_{j}: j \in \mathbb{N}\right\}$. Suppose first that $G=A_{k}$ where $k>2$. That is, $G=P_{2 k}^{k-1}$ for some $k \geq 3$. We show that

$$
C=\left\{x_{1}^{1}, \ldots, x_{k-1}^{1}, x_{k+1}^{1}, \ldots, x_{2 k-2}^{1}, x_{k}^{2}, x_{2 k}^{2}\right\}
$$

is an ID code for $G \square K_{2}$ of order $2 k-1$. Figure 3 (a) depicts $C$ for $A_{5} \square K_{2}$. Let $u$ and $v$ be any pair of vertices in $G \square K_{2}$. One can easily verify that $C$ is a dominating set for $G \square K_{2}$ and if $u \in V\left(G^{1}\right)$ and $v \in V\left(G^{2}\right)$, then $C$ separates $u$ and $v$. We check all remaining cases.

Figure 3: Examples of ID codes of $A_{k} \square K_{2}$ or $\left(A_{k} \bowtie A_{\ell}\right) \square K_{2}$

Figure 4: Example of ID code of $\left(A_{2} \bowtie A_{4}\right) \square K_{2}$

Suppose first that $u=x_{i}^{1}$ and $v=x_{j}^{1}$ where $1 \leq i<j \leq 2 k$. If $1 \leq i<j \leq k-1$, then $x_{j+(k-1)}^{1}$ separates $u$ and $v$. If $1 \leq i \leq k-1$ and $j=k$, then $x_{k}^{2}$ separates $u$ and $v$. If $1 \leq i \leq k$ and $k+1 \leq j \leq 2 k$, then $x_{1}^{1}$ separates $u$ and $v$. If $k \leq i<j \leq 2 k-1$, then $x_{i-(k-1)}^{1}$ separates $u$ and $v$. If $k \leq i \leq 2 k-1$ and $j=2 k$, then $x_{2 k}^{2}$ separates $u$ and $v$.

Next, suppose that $u=x_{i}^{2}$ and $v=x_{j}^{2}$ where $1 \leq i<j \leq 2 k$. If $i \notin\{k, 2 k-1\}$, then $x_{i}^{1}$ separates $u$ and $v$. If $i=k$ and $j=2 k-1$, then $x_{2 k}^{2}$ separates $u$ and $v$. If $i=k$ and $j=2 k$, then $u$ separates $u$ and $v$. Finally, if $i=2 k-1$ and $j=2 k$, then $x_{k}^{2}$ separates $u$ and $v$. Thus, $C$ is an ID code of $G$, and we have shown that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq 2 k-1$.

On the other hand, $G \in \mathcal{A}$ so $\gamma^{\mathrm{ID}}(G)=2 k-1$ by Theorem 12. Thus, by Theorem 10 $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \geq \gamma^{\mathrm{ID}}(G)=2 k-1$, which implies that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$.

Next, suppose $G=A_{k} \bowtie A_{\ell}$ where $k \in[\ell]$. Since $G$ has order at least $5, \ell \geq 2$. Let $x_{1}, \ldots, x_{2 k}$ represent the vertices of $A_{k}$ and $y_{1}, \ldots, y_{2 \ell}$ represent the vertices of $A_{\ell}$. We construct an ID code of $G \square K_{2}$ based on the following three cases, where in each case $A=\left\{y_{i}^{1}: i=2 j+1\right.$ for $\left.0 \leq j \leq \ell-1\right\}$ and $B=\left\{y_{i}^{2}: i=2 j\right.$ for $\left.1 \leq j \leq \ell\right\}$.

1. Suppose $k=1$. Note that $\ell \geq 2$ since the order of $G$ is at least 6 . We show that $C=A \cup B \cup\left\{x_{1}^{1}\right\}$ is an ID code for $G \square K_{2}$. Figure 3 (b) depicts $C$ for $\left(A_{1} \bowtie A_{4}\right) \square K_{2}$. For $i \in[2]$ and each $v^{i} \in V\left(G^{i}\right),\left|N_{G^{i}}\left[v^{i}\right] \cap C\right| \geq 2$, and it follows that $C$ separates any vertex in $G^{1}$ from any vertex in $G^{2}$. Note that $x_{1}^{1}$ separates $x_{1}^{1}$ and $x_{2}^{1}$, and $x_{1}^{1}$ separates $x_{1}^{2}$ from any other vertex of $G^{2}$. Next, for $j \in[\ell], y_{2 j-1}^{1}$ separates $y_{2 j-1}^{2}$ from every other vertex of $G^{2}$. By definition of $A_{\ell}, N\left[y_{2 i}^{2}\right] \cap B \neq N\left[y_{2 j}^{2}\right] \cap B$ for $1 \leq i<j \leq \ell$. Since $N\left[x_{2}^{2}\right] \cap B=B, C$ separates $x_{2}^{2}$ from $y_{2 i}^{2}$ for $i \in[\ell]$. Similarly, $C$ separates any two vertices in $G^{1}$. Therefore, $C$ is an ID code of $G \square K_{2}$, which implies $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq \gamma^{\mathrm{ID}}(G)$.
2. Suppose $k \geq 2$. Let $T=\left\{x_{i}^{1}: 1 \leq i \leq 2 k-1\right\}$. We show that $C=A \cup B \cup T$ is an ID code of $G \square K_{2}$. Figure 4 depicts $C$ for $\left(A_{2} \bowtie A_{4}\right) \square K_{2}$. As in Case 1, $C$ separates any vertex in $G^{1}$ from any vertex in $G^{2}$. Note that for $i \in[2 k-1], x_{i}^{1}$ separates $x_{i}^{2}$ from any other vertex of $G^{2}$. Next, for $j \in[\ell], y_{2 j-1}^{1}$ separates $y_{2 j-1}^{2}$ from every other vertex of $G^{2}$. By definition of $A_{\ell}, N\left[y_{2 i}^{2}\right] \cap B \neq N\left[y_{2 j}^{2}\right] \cap B$ for $1 \leq i<j \leq \ell$. Since $N\left[x_{2 k}^{2}\right] \cap B=B, C$ separates $x_{2 k}^{2}$ from $y_{2 i}^{2}$ for $i \in[\ell]$. Similarly, $C$ separates any two vertices. Moreover, $C$ is an ID code of the subgraph induced by $\left\{x_{i}^{1}: 1 \leq i \leq 2 k\right\}$. For each $j \in[\ell], y_{2 j}^{2}$ separates $y_{2 j}^{1}$ from every other vertex in $G^{1}$. By definition $A_{\ell}$, $N\left[y_{2 i-1}^{1}\right] \cap A \neq N\left[y_{2 j-1}^{1}\right] \cap A$ for $1 \leq i<j \leq \ell$. Furthermore, this shows that $C$ separates $y_{2 i-1}^{1}$ from $x_{j}^{1}$ where $i \in[\ell]$ and $j \in[2 k]$ since $N\left[x_{j}^{1}\right] \cap A=A$. Therefore, $C$ is an ID code of $G \square K_{2}$, which implies $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq \gamma^{\mathrm{ID}}(G)$.

Finally, note that by Theorem 10, we know $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \geq \gamma^{\mathrm{ID}}(G)$, which implies $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=$ $\gamma^{\mathrm{ID}}(G)$. This concludes the base cases.

Suppose now that $r \geq 2$ and that if $G=G_{1} \bowtie \cdots \bowtie G_{r}$ where each $G_{j} \in\left\{A_{i}: i \in \mathbb{N}\right\}$, then $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. Now consider $H=A_{s} \bowtie G_{1} \bowtie \cdots \bowtie G_{r}$ where $s \geq 1$. Let $G=G_{1} \bowtie \cdots \bowtie G_{r}$. We can assume with no loss of generality that in the expansion $G=G_{1} \bowtie \cdots \bowtie G_{r}$ that $\left|V\left(G_{a}\right)\right| \leq\left|V\left(G_{b}\right)\right|$ when $a<b$. Thus, if $\left|V\left(A_{s}\right)\right|>\left|V\left(G_{1}\right)\right|$, we can let $H=G_{1} \bowtie\left(A_{s} \bowtie G_{2} \bowtie \cdots \bowtie G_{s}\right)$.

Suppose first that $H=A_{1} \bowtie G$. Let $C$ be a minimum ID code for $G \square K_{2}$ and let $x_{1}, x_{2}$ represent the vertices of $A_{1}$. We claim that $C^{\prime}=C \cup\left\{x_{1}^{1}, x_{2}^{1}\right\}$ is an ID code for $H \square K_{2}$. Clearly $C^{\prime}$ dominates $H \square K_{2}$, and any pair of vertices in $V\left(G \square K_{2}\right)$ are separated by $C$, and therefore by $C^{\prime}$. Suppose that $u, v \in\left\{x_{1}^{1}, x_{2}^{1}, x_{1}^{2}, x_{2}^{2}\right\}$. Note that if $u \in\left\{x_{1}^{1}, x_{2}^{1}\right\}$, then $I_{C^{\prime}}(u) \cap G^{1} \neq \emptyset$. Similarly, if $u \in\left\{x_{1}^{2}, x_{2}^{2}\right\}$, then $I_{C^{\prime}}(u) \cap G^{2} \neq \emptyset$. Thus, if $u \in\left\{x_{1}^{1}, x_{2}^{1}\right\}$ and $v \in\left\{x_{1}^{2}, x_{2}^{2}\right\}$, then $I_{C^{\prime}}(u) \neq I_{C^{\prime}}(v)$. If $u=x_{1}^{1}$ and $v=x_{2}^{1}$, then $u \in I_{C^{\prime}}(u)$ but $u \notin I_{C^{\prime}}(v)$. Similarly, if $u=x_{1}^{2}$ and $v=x_{2}^{2}$, then $x_{1}^{1} \in I_{C^{\prime}}(u)$ but $x_{1}^{1} \notin I_{C^{\prime}}(v)$. Finally, if $u \in\left\{x_{1}^{1}, x_{2}^{1}, x_{1}^{2}, x_{2}^{2}\right\}$ and $v \notin\left\{x_{1}^{1}, x_{2}^{1}, x_{1}^{2}, x_{2}^{2}\right\}$, then one of $x_{1}^{1}$ or $x_{2}^{1}$ separates $u$ and $v$. Thus,
$C^{\prime}$ is an ID code of $H \square K_{2}$ and by the inductive assumption and Theorem 12

$$
\left|C^{\prime}\right|=2+|C|=2+\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=2+\gamma^{\mathrm{ID}}(G)=|V(H)|-1=\gamma^{\mathrm{ID}}(H)
$$

This implies that $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right) \leq \gamma^{\mathrm{ID}}(H)$. An application of Theorem10 gives $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right)=$ $\gamma^{\mathrm{ID}}(H)$ 。

Next, suppose that $H=A_{i} \bowtie G$ where $i \geq 2$. Let $C$ be a minimum ID code of $G \square K_{2}$. We claim that $C^{\prime}=C \cup A_{i}^{1}$ is an ID code of $H \square K_{2}$. Clearly $C^{\prime}$ dominates $H \square K_{2}$, and any pair of vertices in $V\left(G \square K_{2}\right)$ are separated by $C$, and therefore by $C^{\prime}$. Next, note that $A_{i}^{1}$ is an ID code of $A_{i} \square K_{2}$. Thus, $C^{\prime}$ separates every pair of vertices in $A_{i}^{1} \cup A_{i}^{2}$. Finally, suppose that $u \in A_{i}^{1} \cup A_{i}^{2}$ and $v \in G^{1} \cup G^{2}$. If $u \in A_{i}^{1}$ and $v \in G^{2}$, then $u$ separates $u$ and $v$. Similarly, if $u \in A_{i}^{2}$ and $v \in G^{2}$, then some vertex of $A_{i}^{1}$ separates $u$ and $v$. So assume that $v \in G^{1}$. No vertex of $A_{i}^{1} \cup A_{i}^{2}$ is adjacent to every vertex of $A_{i}^{1}$, but $A_{i}^{1} \subset I_{C^{\prime}}(v)$. Hence $C^{\prime}$ separates every pair of vertices in $H \square K_{2}$, and consequently $C^{\prime}$ is an ID code of $H \square K_{2}$. In a manner similar to that in the previous case, by using our induction assumption together with Theorems 10 and 12 we get that $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right)=\gamma^{\mathrm{ID}}(H)$.

Next, suppose that $G \in \mathcal{A} \bowtie K_{1}$. As above, we proceed by induction with base case $G=A_{k} \bowtie K_{1}$ where $k \in \mathbb{N}$. Note that $k \geq 2$ since the order of $G$ is at least 5 . If $k=2$, then we are done by Theorem [13. If $k>2$, then one can easily verify that $C=A \cup B$ where $A=\left\{x_{2 j-1}^{1}: j \in[k]\right\}$ and $B=\left\{x_{2 j}^{2}: j \in[k]\right\}$ is an ID code for $G \square K_{2}$. Thus, $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \leq|V(G)|-1$ and by Theorem 10, we have $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. We now assume that for some $m \geq 2, \gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$ if $G=G_{1} \bowtie G_{2} \bowtie \cdots \bowtie G_{m-1} \bowtie K_{1}$ where each $G_{j} \in\left\{A_{i}: i \in \mathbb{N}\right\}$.

Suppose $H=G_{1} \bowtie \cdots \bowtie G_{m} \bowtie K_{1}$ where $G_{j} \in\left\{A_{i}: i \in \mathbb{N}\right\}$. Label the vertices of $G_{j}=A_{t_{j}}, t_{j} \geq 1$, as $x_{j, 1}, \ldots, x_{j, 2 t_{j}}$ and let $y$ be the vertex of $K_{1}$. For each $j$ where $G_{j}=A_{1}$, let $C_{j}=\left\{x_{j, 1}^{1}, x_{j, 2}^{1}\right\}$ if $j$ is odd and let $C_{j}=\left\{x_{j, 1}^{2}, x_{j, 2}^{2}\right\}$ if $j$ is even. For each $G_{j}=A_{t_{j}}$ where $t_{j}>1$, let

$$
C_{j, 1}=\left\{x_{j, 2 k-1}^{1}: k \in\left[t_{j}\right]\right\}
$$

and

$$
C_{j, 2}=\left\{x_{j, 2 k}^{2}: k \in\left[t_{j}\right]\right\}
$$

Finally, let $C_{j}=C_{j, 1} \cup C_{j, 2}$. We show that $C=\cup_{j=1}^{m} C_{j}$ is an ID code for $G \square K_{2}$. Let $u$ and $v$ be any two vertices in $V\left(G \square K_{2}\right)$. If $u \in G^{1}$ and $v \in G^{2}$, then $\left|I_{C}(u) \cap V\left(G^{1}\right)\right| \geq 2$ and $\left|I_{C}(v) \cap V\left(G^{2}\right)\right| \geq 2$, which implies that $C$ separates $u$ and $v$. Now suppose that $u$ and $v$ belong to $G^{1}$. If $u=y^{1}$, then $I_{C}(u)=C \cap V\left(G^{1}\right) \neq I_{C}(v)$, which shows that $C$ separates $u$ and $v$. If $u \notin C$, then $u$ is adjacent to a codeword in $G^{2}$, and this implies that $C$ separates $u$ and $v$. If $u \in\left\{x_{j, 1}^{1}, x_{j, 2}^{1}\right\}$ for some $j$ such that $G_{j}=A_{1}$, say $u=x_{j, 1}^{1}$, then $x_{j, 2}^{1}$ separates $u$ and $v$. If $u=x_{j, 2 k-1}^{1}$ for $k \in\left[t_{j}\right]$, then there exists a codeword $d$ such that $d \in G_{j}^{1}$ but $d \notin I_{C}(u)$. If $v$ does not belong to $G_{j}^{1}$, then $d$ separates $u$ and $v$. If $v$ is in $G_{j}^{1}$, the structure of $A_{t_{j}}$ shows that $C$ separates $u$ and $v$. A similar argument shows that $C$ separates $u$ and $v$ when both belong to $G^{2}$. Hence $C$ is and ID code for $H \square K_{2}$, and it follows that $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right) \leq|V(H)|-1=\gamma^{\mathrm{ID}}(H)$. By Theorem 10 we now conclude that $\gamma^{\mathrm{ID}}\left(H \square K_{2}\right)=\gamma^{\mathrm{ID}}(H)$. By induction we have shown that if $G \in \mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)$ has order at least 5 , then $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$.

Finally, notice that if we have $G \in \mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)$ where $G=G_{1} \bowtie G_{2}$ and $G_{1}, G_{2} \notin$ $\left\{A_{1}, A_{2}\right\}$, then

$$
\gamma^{\mathrm{ID}}\left(\left(G_{1} \bowtie G_{2}\right) \square K_{2}\right)=\left|V\left(G_{1}\right)\right|+\left|V\left(G_{2}\right)\right|-1=\gamma^{\mathrm{ID}}\left(G_{1} \square K_{2}\right)+\gamma^{\mathrm{ID}}\left(G_{2} \square K_{2}\right)+1
$$

The next immediate question is whether or not the graphs given in the statement of Theorem 14 are the only graphs which satisfy $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. Unfortunately, there are an infinite number of graphs that are not contained in the class $\mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)$ which satisfy $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. For example, consider the graph $G$ obtained from $A_{2} \bowtie A_{2} \bowtie$ $A_{2}$ as follows. Label the vertices of $A_{2}=P_{4}$ as $u, v, x, y$ and let $u_{i}, v_{i}, x_{i}, y_{i}$ represent the vertices of the $i^{t h}$ copy of $A_{2}$ for $i \in[3]$. To obtain $G$, let $w$ represent an additional vertex and add an edge between $w$ and $x_{3}$ and an edge between $w$ and $y_{3}$. Figure 5 depicts the graph $G$ without the edges between vertices of $A_{i}$ and $A_{j}$ when $i \neq j,\{i, j\} \subset\{1,2,3\}$.

Figure 5: $G$ obtained from $A_{2} \bowtie A_{2} \bowtie A_{2}$

We claim that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=11=\gamma^{\mathrm{ID}}(G)$. First, note that $V(G)-\left\{u_{3}, w\right\}$ is an ID code of $G$. Next, we show that $\gamma^{\mathrm{ID}}(G) \geq 11$. Let $C$ be a minimum ID code of $G$. If $w \notin C$, then it is clear that $|C| \geq 11$ since $G\left[\cup_{i=1}^{3}\left\{u_{i}, v_{i}, x_{i}, y_{i}\right\}\right]$ is isomorphic to $A_{2} \bowtie A_{2} \bowtie A_{2}$. So assume that $w \in C$. For each $i \in[3], x_{i} \in C$ in order to separate $u_{i}$ and $v_{i}$. Similarly, $v_{i} \in C$ in order to separate $x_{i}$ and $y_{i}$. For $i \in[2]$, either $u_{i} \in C$ or $y_{i} \in C$ in order to separate $v_{i}$ and $x_{i}$ and, with no loss of generality, we may assume $u_{i} \in C$ for $i \in[2]$. Finally, notice that in order to separate $v_{1}, v_{2}$, and $v_{3}$, at least two vertices of $\left\{y_{1}, y_{2}, y_{3}\right\}$ are in $C$. In any case, we have shown, $\gamma^{\mathrm{ID}}(G) \geq 11$. Furthermore, Theorem 10 guarantees that $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right) \geq 11$. On the other hand, notice that $G \square K_{2}$ is illustrated in Figure 6 and the black vertices form an ID code of $G \square K_{2}$. Thus, we have constructed a graph $G \notin \mathcal{A} \cup\left(\mathcal{A} \bowtie K_{1}\right)$ where $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$. Moreover, any graph $G$ obtained from the join of $k$ copies of $A_{2}$ by appending an additional vertex $w$ in the same way as above will satisfy $\gamma^{\mathrm{ID}}\left(G \square K_{2}\right)=\gamma^{\mathrm{ID}}(G)$.

Figure 6: ID code of $G \square K_{2}$

## 5 Grid graphs and general upper bounds

We now give upper bounds for the ID code number of $G \square P_{m}$ where $G$ is any graph and $m \geq 2$. First, we consider when $G$ is a path.

Theorem 15. For any positive integers $m$ and $k$ where $m \leq 3 k$,

$$
\begin{gathered}
\gamma^{\mathrm{ID}}\left(P_{m} \square P_{3 k}\right) \leq m k+k\left\lceil\frac{m}{3}\right\rceil, \\
\gamma^{\mathrm{ID}}\left(P_{m} \square P_{3 k+1}\right) \leq m k+k\left\lceil\frac{m}{3}\right\rceil+\left\lceil\frac{m}{2}\right\rceil, \\
\gamma^{\mathrm{ID}}\left(P_{m} \square P_{3 k+2}\right) \leq m(k+1)+(k-1)\left\lceil\frac{m}{3}\right\rceil .
\end{gathered}
$$

Proof. First, suppose $m \not \equiv 1(\bmod 3)$. We construct ID codes for each of the above cases. Let $\{0,1, \ldots, m-1\}$ represent the vertices of $P_{m}$ and let $\{0,1, \ldots, y\}$ represent the vertices of $P_{3 k+a}$ for $a \in\{0,1,2\}$. Define

$$
A=\{(i, j): 0 \leq i \leq m-1, j \equiv 1 \quad(\bmod 3)\}
$$

and

$$
B=\{(i, j): i \equiv 1 \quad(\bmod 3), j \equiv 2 \quad(\bmod 3)\} .
$$

Figure 7 (a) depicts the set $A \cup B$ for $k=2$ and $a=0$. One can easily verify that $A \cup B$ is an ID code for $P_{m} \square P_{3 k}$. Next, consider $P_{m} \square P_{3 k+1}$. Let

$$
C=\{(i, j): i \equiv 1 \quad(\bmod 2), j=y\} .
$$

Figure 7 (b) depicts the set $A \cup B \cup C$ for $k=2$ and $a=1$. Again, it is straightforward to verify that $A \cup B \cup C$ is an ID code for $P_{m} \square P_{3 k+1}$. Finally, consider $P_{m} \square P_{3 k+2}$. Define

$$
\begin{gathered}
X=\{(i, j): 0 \leq i \leq m-1, j \equiv 1 \quad(\bmod 3), j \neq y\}, \\
Y=\{(i, j): i \equiv 1 \quad(\bmod 3), j \equiv 2 \quad(\bmod 3), j \neq y-2\},
\end{gathered}
$$

and

$$
Z=\{(i, j): 0 \leq i \leq m-1, j=y-1\} .
$$

The set $X \cup Y \cup Z$ is an ID code for $P_{m} \square P_{3 k+2}$.
Now, suppose that $m \equiv 1(\bmod 3)$ and let

$$
B^{\prime}=B \cup\{(i, j): i=m-1, j \equiv 2 \quad(\bmod 3)\}
$$

and

$$
Y^{\prime}=Y \cup\{(i, j): i=m-1, j \equiv 2 \quad(\bmod 3), j \neq y-2\} .
$$

One can easily verify that $A \cup B^{\prime}$ is an ID code for $P_{m} \square P_{3 k}, A \cup B^{\prime} \cup C$ is an ID code of $P_{m} \square P_{3 k+1}$, and $X \cup Y^{\prime} \cup Z$ is an ID code of $P_{m} \square P_{3 k+2}$.

Figure 7: Examples of ID codes when $m \not \equiv 1(\bmod 3)$

Theorem 16. For positive integers $m$ and $n$ where $2 \leq m \leq n, \gamma^{\mathrm{ID}}\left(P_{m} \square P_{n}\right) \geq m n / 3$.
Proof. Let $C$ be a minimum ID code of $G=P_{m} \square P_{n}$. Partition $V(G)$ as follows. Let

$$
\begin{gathered}
C_{1}=\{v \in V(G): v \in C, v \text { isolated in } G[C]\}, \\
C_{2}=C-C_{1},
\end{gathered}
$$

and for each $i \in[4]$,

$$
N_{i}=\{v \in V(G)-C: v \text { is adjacent to } i \text { vertices in } C\} .
$$

We further partition $C_{1}$ and $C_{2}$ as follows. For $i \in[3]$, let $A_{i}=\left\{v \in C_{1}: \operatorname{deg}(v)=i+1\right\}$ and let $B_{i}=\left\{v \in C_{2}: \operatorname{deg}(v)=i+1\right\}$. Note that the number of edges between $C$ and $V(G)-C$ is at most $2\left|A_{1}\right|+3\left|A_{2}\right|+4\left|A_{3}\right|+\left|B_{1}\right|+2\left|B_{2}\right|+3\left|B_{3}\right|$. On the other hand, the number of edges between $C$ and $V(G)-C$ is precisely $\left|N_{1}\right|+2\left|N_{2}\right|+3\left|N_{3}\right|+4\left|N_{4}\right|$. Thus,

$$
\begin{aligned}
|C|+\left|A_{1}\right|+2\left|A_{2}\right|+3\left|A_{3}\right|+\left|B_{2}\right|+2\left|B_{3}\right| & =2\left|A_{1}\right|+3\left|A_{2}\right|+4\left|A_{3}\right|+\left|B_{1}\right|+2\left|B_{2}\right|+3\left|B_{3}\right| \\
& \geq\left|N_{1}\right|+2\left|N_{2}\right|+3\left|N_{3}\right|+4\left|N_{4}\right| \\
& =m n-|C|+\left|N_{2}\right|+2\left|N_{3}\right|+3\left|N_{4}\right| .
\end{aligned}
$$

Therefore,

$$
2|C|+\left|A_{1}\right|+2\left|A_{2}\right|+3\left|A_{3}\right|+\left|B_{2}\right|+2\left|B_{3}\right| \geq m n+\left|N_{2}\right|+2\left|N_{3}\right|+3\left|N_{4}\right| .
$$

Next, notice that

$$
\left|A_{1}\right|+2\left|A_{2}\right|+3\left|A_{3}\right|+\left|B_{2}\right|+2\left|B_{3}\right| \leq 3\left|C_{1}\right|+2\left|C_{2}\right|=3|C|-\left|C_{2}\right|,
$$

which implies that

$$
2|C|+3|C|-\left|C_{2}\right| \geq m n+\left|N_{2}\right|+2\left|N_{3}\right|+3\left|N_{4}\right| .
$$

On the other hand, no vertex of $N_{1}$ is adjacent to a vertex of $C_{1}$ for otherwise $C$ would not separate such a pair of vertices. Thus, each vertex of $N_{1}$ is adjacent to precisely one
vertex of $C_{2}$. Moreover, there can exist no more than $\left|C_{2}\right|$ vertices in $N_{1}$. Therefore, we may conclude that

$$
\begin{aligned}
5|C| & \geq m n+\left|N_{2}\right|+2\left|N_{3}\right|+3\left|N_{4}\right|+\left|C_{2}\right| \\
& \geq m n+\left|N_{2}\right|+2\left|N_{3}\right|+3\left|N_{4}\right|+\left|N_{1}\right| \\
& \geq m n+m n-|C|+\left|N_{3}\right|+2\left|N_{4}\right| \\
& \geq 2 m n-|C| .
\end{aligned}
$$

It follows that $|C| \geq m n / 3$.
Note that when $n=3 k$ for some $k \in \mathbb{N}$, it follows from Theorem 16 that $\gamma^{\mathrm{ID}}\left(P_{m} \square P_{3 k}\right) \geq$ $m k$. Thus the gap between Theorem 15 and Theorem 16 is $m k / 3$. Now we provide a general upper bound for $\gamma^{\mathrm{ID}}\left(G \square P_{m}\right)$ whenever $m \geq 3$ and $G$ is twin-free.

Theorem 17. For any twin-free graph $G$ of order $n$ and any positive integer $m \geq 3$,

$$
\gamma^{\mathrm{ID}}\left(G \square P_{m}\right) \leq \min \left\{m \gamma^{\mathrm{ID}}(G), m \gamma(G)+\left\lceil\frac{m}{3}\right\rceil(n-\gamma(G))\right\} .
$$

Proof. Let $D$ be an ID code of $G$. Certainly $C=\left\{(u, v) \mid u \in D, v \in P_{m}\right\}$ is an ID code of $G \square P_{m}$. Next, let $A$ be a minimum dominating set of $G$. Let $\{0,1, \ldots, m-1\}$ represent the vertices of $P_{m}$. Let $X=\left\{(u, v) \mid u \in A, v \in P_{m}\right\}$ and $Y=\{(u, v) \mid u \in V(G)-A, v \equiv 1$ $(\bmod 3)\}$. If $m \not \equiv 1(\bmod 3)$, then $X \cup Y$ is an ID-code of $G \square P_{m}$. If $m \equiv 1(\bmod 3)$, then let $Y^{\prime}=\{(u, v) \mid u \in V(G)-A, v \equiv 1(\bmod 3)$ or $v=m-1\}$. The set $X \cup Y^{\prime}$ is an ID code of $G \square P_{m}$. In either case, we have constructed an ID code of cardinality $m \gamma(G)+\left\lceil\frac{m}{3}\right\rceil(n-\gamma(G))$.
