#### Abstract

The standard theory of quantum computation relies on the idea that the basic information quantity is represented by a superposition of elements of the canonical basis and the notion of probability naturally follows from the Born rule. In this work we consider three valued quantum computational logics. More specifically, we will focus on the Hilbert space $\mathbb{C}^{3}$, we discuss extensions of several gates to this space and, using the notion of effect probability, we provide a characterization of its states.

Keywords Quantum Computational Logics • Qutrits

## 1 Introduction

The usual notion of uncertainty seems to be tightly related to an epistemic condition [26]. A typical case: a coin was flipped, but a specified knower couldn't see which side of the coin faced up when it landed. It seems to be generally accepted that uncertainty deals with ignorance: a certain predicate is uncertain, with respect to a specific knower, if the information available is not sufficient to determine its applicability.

On the other hand, vagueness seems to be unrelated with ignorance. Instead, this notion often refers to concepts whose extensions are lacking in clarity [25], [17], [34]. Natural examples of vague concepts are predicates admitting "border-line cases", in which it is hard to sharply determine whether an object falls completely in the extension of the predicate or not. Rather, an object may possess specific properties to some extent. A successful framework for dealing with vagueness is provided by many-valued logics [21], [24].

[^0]In the microscopic domain, appreciable overlaps between the concepts of uncertainty and vagueness are to mention. A remarkable example is the "Stern-Gerlach experiment" that shows how particles possess an intrinsic angular momentum that can assume certain discrete values only. The experiment is normally conducted using atoms or electrically neutral particles, that are treated as classical spinning dipoles; they will precess in a magnetic field because of the torque that the field exerts on the dipoles. If the magnetic field where the particles move through is not homogeneous, then the force on one end of the dipole of each particle will be slightly greater than the opposing force on the other end, so that there is a net force which deflects the trajectory of the particles. If the particles were classical spinning objects, one would expect that the distribution of their spin angular momentum vectors will be random and the spectrum will be continuous, because each particle will be deflected by a different amount, producing a density distribution on the detector screen. Instead, the particles passing through the Stern-Gerlach apparatus are deflected either up (say $|0\rangle$ ) or down (say $|1\rangle$ ) by a specific amount, because - how is well know nowadays - the spectrum of quantum angular momentum is discrete.

Formally speaking and by using the common Dirac notation, we describe the state of a particle that is passing through a Stern-Gerlach apparatus as the following superposition
$|\psi\rangle=a|0\rangle+b|1\rangle$, where $|a|^{2}$ and $|b|^{2}$ are the probabilities to detect the particle with spin up or down, respectively. The state $|\psi\rangle$ is a pure state, that represents a maximal piece of information that cannot be increased by any further observation. However, once a state $|\psi\rangle$ is fixed, by its very nature, it involves an amount of uncertainty, which in this case is a property of the state not related to the observer's knowledge. A state may also be mixed and it can represent a non-maximal piece of information, mathematically represented by a density operator.

We will see that, at the microscopic level, uncertainty and vagueness can be captured under several degrees of freedom rendering the two notions amenable of interactions not available in the classical world.

Useful tools for inquiring into possible interplays of vagueness and uncertainty in the quantum realm are provided by quantum computational logics. These logics, investigated by Maria Luisa Dalla Chiara, Roberto Giuntini and other authors, including, for example, the present papers [2], [5], [6], [9], [11], [20], differ from the well known Birkhoff-von Neumann approach to quantum logic, where propositions ascribing properties are represented by projection operators - or, equivalently, by closed subspaces of a Hilbert space. In quantum computational logics meanings of sentences are no longer represented by projector operators on a Hilbert space, but by means of quantum information quantities: qubits, qutrits, density operators. In this framework fuzzy-like structures appear at different levels, and with different status. The aim of this paper is to discuss this further bridge between many-valued and quantum logics.

The paper is organized as follows: in Section 2 we provide all the basic notions necessary to render the article self-contained; in Section 3 we focus on the concepts of uncertainty, mixedness and degrees of truth as a foundational motivation in the context of many-valued quantum computational logics; in Section 4 we discuss some unary quantum gates in the context of standard and manyvalued quantum computational logics; in Section 5 we introduce the notion of effect probability. This notion will be expedient in showing a characterization of mixed states in $\mathbb{C}^{3}$. Finally, we close the paper with some comments.

## 2 Basic Notions

For the reader's convenience, we recall in this section all the basic notions required for a complete understanding of the paper.

Consider the $n$-fold tensor product Hilbert space $\otimes^{n} \mathbb{C}^{d}$, with $n \geq 1$ and $d \geq 2$.
The canonical orthonormal basis $\mathcal{B}^{\left(d^{n}\right)}$ of $\otimes^{n} \mathbb{C}^{d}$ is defined as follows:

$$
\mathcal{B}^{\left(d^{n}\right)}=\left\{\left|x_{1}, \ldots, x_{n}\right\rangle: x_{i} \in\left\{0, \frac{1}{d-1}, \frac{2}{d-1}, \ldots, 1\right\}, \forall i \in\{1, \ldots, n\}\right\}
$$

where
$-\left|x_{1}, \ldots, x_{n}\right\rangle$ is an abbreviation for the tensor product $\left|x_{1}\right\rangle \otimes \ldots \otimes\left|x_{n}\right\rangle ;$

- the vector $\left|\frac{i}{d-1}\right\rangle \in \mathbb{C}^{d}$ (with $0 \leq i \leq d-1$ ) is a $d$-dimensional column vector with 1 in the $(i+1)^{t h}$-entry and 0 in all the other $d-1$ entries.

## Definition 1 Qudit

A unit vector in the Hilbert space $\mathbb{C}^{d}($ with $d \geq 2)$ is a qudit. As a special case, if $d=2$ the unit vector is the so called qubit, whose extensive expression $|\psi\rangle=a|0\rangle+b|1\rangle$ (where $|a|^{2}+|b|^{2}=1$ ) was already mentioned in the previous Section.

Definition 2 Quregister and Qumix
A quregister is a unit vector in $\otimes^{n} \mathbb{C}^{d}$ and a qumix (or mixed state) is a density operator in $\otimes^{n} \mathbb{C}^{d}$.

So, a vector in $\otimes^{n} \mathbb{C}^{d}$ is a $n$-fold tensor product of $d$-dimensional vectors. Trivially, qudits are special cases of quregisters.

Definition 3 Truth-values of a quregister
We say that the truth-value of a quregister $\left|x_{1}, \ldots, x_{n-1}, \frac{i}{d-1}\right\rangle \in \otimes^{n} \mathbb{C}^{d}$ is $\frac{i}{d-1}$, with $0 \leq i \leq d-1$.
For, the truth-value of a quregister only depends on its last component. In particular, if $i=0$ we say that the register is false and if $i=d-1$ we say that the register is true.

Let us remark that the number of different truth-values over the Hilbert space $\otimes^{n} \mathbb{C}^{d}$ is $d$, for any value of $n$.

Definition 4 The truth-value projectors
A truth-value projection on $\otimes^{n} \mathbb{C}^{d}$ is a projector $P_{\frac{i}{\left(d^{n}\right)}}^{d-1}$ whose range is the closed subspace spanned by the set of all quregisters whose $n^{t h}$ component is $\left|\frac{i}{d-1}\right\rangle$, where $P_{\frac{i}{d-1}}^{\left(d^{n}\right)}=I^{(n-1)} \otimes P_{\frac{i}{d-1}}^{(d)}$ and $0 \leq i \leq d-1$.

In particular, the truth-projection of $\otimes^{n} \mathbb{C}^{d}$ is the projection operator $P_{1}^{\left(d^{n}\right)}$ whose range is the closed subspace spanned by the set of all true quregisters of $\otimes^{n} \mathbb{C}^{d}$.

As an example, let us note that the projector operators $P_{1}^{\left(2^{2}\right)} \in \otimes^{2} \mathbb{C}^{2}$ and $P_{1}^{(4)} \in \mathbb{C}^{4}$, take, respectively, the form:

$$
P_{1}^{\left(2^{2}\right)}=I \otimes P_{1}^{(2)}=\left(\begin{array}{llll}
0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1
\end{array}\right) \text { and } P_{1}^{(4)}=\left(\begin{array}{llll}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1
\end{array}\right)
$$

For any qumix $\rho \in \otimes^{n} \mathbb{C}^{d}$ it is possible to introduce a notion of probability, according with the Born rule, as follows:

Definition $5 \frac{i}{d-1}$-probability Let $\rho$ be a qumix in $\otimes^{n} \mathbb{C}^{d}$. The probability [14] that $\rho$ has the truth-value $\frac{i}{d-1}$ (with $0 \leq i \leq d-1)$ is defined by as:

$$
\operatorname{Pr}_{\frac{i}{d-1}}^{(d)}=\operatorname{tr}\left(P_{\frac{i}{d-1}}^{\left(d^{n}\right)} \rho\right),
$$

where $t r$ is the trace functional.
From an intuitive point of view, $\operatorname{Pr}_{\frac{i}{d-1}}^{(d)}$ represents the probability that the information stored by the qumix $\rho$ is the truth-value $\frac{i}{d-1}$.

The unitary evolution of quregisters and qumixes is dictated by quantum logical gates. Quantum logical gates (and the quantum operations they naturally induce) are unitary transformations that map quregisters (qumixes) in $\otimes^{n} \mathbb{C}^{d}$ into quregisters (qumixes) in $\otimes^{n} \mathbb{C}^{d}$. From a foundational perspective, it could be useful to distinguish between

- semiclassical quantum gates: unitary operators that transform basis elements into basis elements;
- genuinely quantum gates: unitary operators that transform basis elements into superposition states.
In the rest of the paper, we will mostly be interested in the Hilbert space $\mathbb{C}^{3}$. We say that a unit vector in $\mathbb{C}^{3}$ is a qutrit, a density operator (qumix) in $\mathbb{C}^{3}$ is a qutrit-density operator and a quantum logical gate on $\mathbb{C}^{3}$ is a qutrit-gate.

## 3 Uncertainty and degrees of truth

### 3.1 Uncertainty

The concept of uncertainty has been a major topic of discussion for engineers, philosophers and mathematicians working on statistical theories. In particular, in the context of risk analysis [8], many scholars categorize uncertainties into two main families: aleatoric and epistemic uncertainty [15], [27]. The first family groups those deriving from randomness in samples while the second those that stem from a lack of knowledge. Examples of aleatoric uncertainty are the occurrence of an hurricane in the Gulf of Mexico, or the hight of an arbitrary individual in a certain population. On the other hand examples of epistemic uncertainty include, for instance, the global effect clouds formation have on the temperature of earth, or the nature of certain earthquake mechanisms [29]. Aleatoric uncertainty comprises unknowns that vary each time the same experiment is performed. According with [15], aleatoric uncertainty is related to the intrinsic randomness of a phenomenon, and epistemic uncertainty is caused by a lack of knowledge.

In both cases, however, the notion of uncertainty is tightly related to a condition of the modeler. It is a concept that has to deal with ignorance: a given predicate is uncertain, relative to a specific modeler, when the available information is not sufficient to determine its applicability [26]. However, once we enter the quantum domain, the concept of uncertainty assumes a different status, and new degrees of freedom will be available for this concept. Let us recall for a moment the classical two-slits experiment. A coherent light source is placed in front of a screen that contains two parallel slits. The wave nature of light causes the light waves passing through the two slits interfere, producing bright
and dark bands on the screen placed behind the slits. The interference phenomenon is formally expressed by a superposition state $|\psi\rangle=a|0\rangle+b|1\rangle$ where $|\psi\rangle$ represents the state of a photon before coming up against one of the two slits, $|0\rangle$ and $|1\rangle$ represent the states of a photon after it passed through either the first or the second slits, respectively, and $|a|^{2}$ and $|b|^{2}$ are the respective probabilities. Differently from the classical case, the state $|\psi\rangle$ is ontologically superposed: before a measurement occurs, the photon is neither in the state $|0\rangle$ nor in $|1\rangle$ but in a mere superposition between both. This feature of $|\psi\rangle$ is unrelated to the ignorance of the modeler and this fact is formally expressed by the unitarity of the state $|\psi\rangle$, in fact $|\psi\rangle$ is said to be a pure state. The concepts of complete knowledge (or maximal information), unit vector and pure state are, in this context, one and the same notion.

From a quantum logical point of view also, once we agree on a logical basis, uncertainty is related to proper features of the state only, without any reference to any knowledge of a possible observer [10]. Upon setting $|0\rangle$ and $|1\rangle$ to be our choices for the truth values "false" and "true" respectively, the superposed state $|\psi\rangle=a|0\rangle+b|1\rangle$ expresses a logical uncertainty (from now on simply uncertainty) between the possible truth values: $|0\rangle$ and $|1\rangle$, with the respective truth-probabilities $|a|^{2}$ and $|b|^{2}$ (with $|a|^{2}+|b|^{2}=1$ ), in accord with the Born rule.

However, it is not the case that, in general, any superposition state has non-zero truth-probability. Indeed, consider the state $\left|\psi^{\prime}\right\rangle \in \otimes^{2} \mathbb{C}^{2}$ :

$$
\begin{equation*}
\left|\psi^{\prime}\right\rangle=\frac{1}{\sqrt{2}}|00\rangle+\frac{1}{\sqrt{2}}|10\rangle=\left(\frac{1}{\sqrt{2}}|0\rangle+\frac{1}{\sqrt{2}}|1\rangle\right) \otimes|0\rangle . \tag{1}
\end{equation*}
$$

It can be easily verified that $\left|\psi^{\prime}\right\rangle$ is a superposition state whose truth-probability is 0 . On the other hand (due to the non-commutativity of the tensor product), the state $\left|\psi^{\prime \prime}\right\rangle=|0\rangle \otimes\left(\frac{1}{\sqrt{2}}|0\rangle+\frac{1}{\sqrt{2}}|1\rangle\right)$ is both an uncertain and superposed state in $\otimes^{2} \mathbb{C}^{2}$.

### 3.2 Mixedness

The information a given system provides can be considered along an alternative degree of freedom: its mixedness.

In general, a quantum system may not be in a pure state, and the information quantity it describes may not be maximal. This could be due to, e.g., a non-complete efficiency of a preparation procedure, or, in general, to the interaction of the system with the environment, so that decoherence phenomena may arise corrupting the experimenter's knowledge on the system. On the other hand, there are interesting processes that cannot be represented by unitary evolutions. For instance, consider the case when, at the end of a computational process, a non-unitary operation - a measurement - is applied, and the state of the system collapses into a probability distribution over pure states, namely a proper mixed state (mixed state for short) [33]. A mixed state represents a non-maximal information on the system, that could be increased by further observations. In this case an evident epistemic feature comes into play. However, even if the concept of mixed state patently involves an observer, the property of "being mixed" should not be regarded as an exclusively epistemic condition devoid of any ontological commitment. In the microscopic context, indeed, any observation substantially modifies a state; and the property of "needing further observation to be completely known" should be considered an ontological feature of a system. As an example, quantum decoherence phenomena [35] consist in the loss of the coherence of the phase angles between the components of a system in a quantum superposition: an amount of information
from the system vanishes into the environment (in accord with a sort of for all practical purposes pragmatic approach). This loss of the coherence induces a decreasing of the information on the physical system. For this reason, mixed states represent a crucial tool in quantum decoherence theory [31], [35].

As a generalization of the unitary case, it is possible for mixed states also to resort a notion of uncertainty that coherently generalizes the concept considered in the case of pure states. We say that a mixed state $\rho$ represents an uncertain piece of information if its probability value is in the interval $(0,1)$. Let us remark that, differently from the unitary case, for an arbitrary density operator $\rho$ the property of being mixed is formally equivalent to the fact that

$$
\begin{equation*}
\operatorname{Tr}\left(\rho^{2}\right)<1 . \tag{2}
\end{equation*}
$$

This corresponds to the non-unitarity of $\rho$ : in fact, $\operatorname{Tr}\left(\rho^{2}\right)=1$ if and only if $\rho$ is a pure state. For any density operator $\rho$ on $\otimes^{n} \mathbb{C}^{d}$, its (normalized) linear entropy $S L$, defined as $\frac{d^{n}}{d^{n}-1}\left(1-\operatorname{Tr}\left(\rho^{2}\right)\right)$, provides a measure of its degree of mixedness, or impurity. Clearly, only when $S L(\rho)=0, \rho$ represents a maximal piece of information. In this case $\rho$ is a pure state.

Although uncertainty and mixedness are proper features of a state, they are independent of each other. The following table exemplifies a few simple cases in which they can be told apart.

## Table 1

|  | Uncertain | Not Uncertain |
| :---: | :---: | :---: |
| Mixed | $\left(\begin{array}{cc}1-\lambda & 0 \\ 0 & \lambda\end{array}\right)$ with $\lambda \in(0,1)$ | $\left(\begin{array}{cccc}0 & 0 & 0 & 0 \\ 0 & 1 / 2 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 / 2\end{array}\right)$ |
| Not Mixed | $\frac{1}{2}\left(\begin{array}{ll}1 & 1 \\ 1 & 1\end{array}\right)$ | $\left(\begin{array}{ll}0 & 0 \\ 0 & 1\end{array}\right)$ |

### 3.3 Degrees of truth

Quantum computational logics, in the interpretation of Maria Luisa Dalla Chiara, Giampiero Cattaneo and other authors, including the present writers [5], [6], [9], [10], [11], depart from the usual Birkhoff-von Neumann approach, where meanings of sentences are projection operators, or, equivalently, closed subspaces of a Hilbert space.
In this other approach, what really matters are quantum information units: qubits, quregisters, and, more generally, density operators on a given Hilbert space $\otimes^{n} \mathbb{C}^{2}$ [20]. Fuzzy-like structures have appeared in this context which have been extensively studied [12,13,18]. However, as noted in [16], this fuzzy behavior is mainly due to probabilistic features concerning uncertainty aspects of a state. Namely, the probabilities of a state to be detected either in the "false" state $P_{0}^{\left(2^{n}\right)}$, or in the "true" state $P_{1}^{\left(2^{n}\right)}$. In fact, the backdrop is an Hilbert space which is a tensor power of the space $\mathbb{C}^{2}$, where only two possible "truth-values" are available: $|0\rangle$ and $|1\rangle$. Within this approach, no other truth values are allowed. A state may be uncertain, of course; but it would be uncertain with respect to the true and to the false projector.
Under several aspects, this standpoint may be considered unduly restrictive. For, as mentioned in
[2,28], it is absolutely conceivable to encounter cases in which a physical system may collapse into several states. A definite case in point are qutrits [22,32], where a state $|\psi\rangle$ may have probabilities $a_{0}, a_{\frac{1}{2}}, a_{1}$ to be detected in the basis states $|0\rangle,\left|\frac{1}{2}\right\rangle,|1\rangle$, respectively. Consider, for instance, the states:

$$
\begin{aligned}
|\psi\rangle & =\frac{1}{\sqrt{2}}(|0\rangle+|1\rangle) \\
\left|\psi^{\prime}\right\rangle & =\quad\left|\frac{1}{2}\right\rangle
\end{aligned}
$$

in $\mathbb{C}^{2}$ and $\mathbb{C}^{3}$, respectively. On the one hand, $|\psi\rangle$ in the first equation above is an uncertain and pure state. However, only truth and false probabilities can be associated to $|\psi\rangle$, since $|\psi\rangle$ is a state in $\mathbb{C}^{2}$.
On the other hand, the state $\left|\psi^{\prime}\right\rangle$ is neither uncertain, nor mixed: it is the state $\left|\frac{1}{2}\right\rangle$. This other value should not be considered as a superposition of basis elements, because it is on its own another basis element. Indeed, for any $n$, in the tensor power $\otimes^{n} \mathbb{C}^{2}$, the only possible truth values are classical; in $\mathbb{C}^{3}$ a new truth-value appears: $\left|\frac{1}{2}\right\rangle$.
The Hilbert space $\mathbb{C}^{4}$ provides a neat example. The spaces $\otimes^{2} \mathbb{C}^{2}$ and $\mathbb{C}^{4}$ are clearly isomorphic. Actually they are the same mathematical object. However, from the perspective of quantum computational logics they provide distinct logical semantics.
For instance, the vector

$$
|\psi\rangle=|01\rangle=\left(\begin{array}{l}
0 \\
1 \\
0 \\
0
\end{array}\right)
$$

is a true register in $\otimes^{2} \mathbb{C}^{2}$, because the last component of the tensor product is $|1\rangle$.
On the other hand, this can be easily seen to be not the case in $\mathbb{C}^{4}$, since

$$
P_{1}^{(4)}=|1\rangle\langle 1|=\left(\begin{array}{llll}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1
\end{array}\right)
$$

where $|1\rangle \in \mathbb{C}^{4}$.
This fact is a consequence of the assumptions we made for the notions of true and false state. According with Definition 3, it is evident that the outcome of a measurement in $\otimes^{2} \mathbb{C}^{2}$ is, in terms of truth and false probabilities, necessarily two-valued, since it is committed to a classical backdrop. This won't be longer the case if a different notion of truth comes into play. For, in $\mathbb{C}^{4}$, up to the choice of the basis, there are four possible available values: $|0\rangle,\left|\frac{1}{3}\right\rangle,\left|\frac{2}{3}\right\rangle,|1\rangle$.

According with this idea, if we agree on the computational basis, the state

$$
|\psi\rangle=\left(\begin{array}{l}
0 \\
1 \\
0 \\
0
\end{array}\right)
$$

would correspond to the state $\left|\frac{1}{3}\right\rangle$.
This brief observation is expedient to emphasize that the choice of the quantum information units determines the context in which quantum computational logics operate. If we start with a
quantum information unit in $\mathbb{C}^{2}$, then every possible quantum computational logic would rely on a classical two-valued setting. On the other hand, if our choice is $\mathbb{C}^{n}, n>2$, new truth-values come into play.

From now on, let us focus on the Hilbert space $\mathbb{C}^{3}$. A concrete physical system that should be

Table 2
necessarily represented by a state in $\mathbb{C}^{3}$ is depicted in Table 2 . Consider a 3 -levels energy system in an excited state $\left|\psi_{1}\right\rangle$, whose energy is $\varepsilon_{0}+\Delta \varepsilon_{2}$. Three events - with respective probabilities $\left|a_{1}\right|^{2}$, $\left|a_{2}\right|^{2}$ and $\left|a_{3}\right|^{2}$ (related to the respective gap of energy) - are possible:

1. the system remains in the same state $\left|\psi_{1}\right\rangle$;
2. the system decays in the state $\left|\psi_{\frac{1}{2}}\right\rangle$, whose respective energy is $\varepsilon_{0}+\Delta \varepsilon_{1}$;
3. the system collapses to the ground state $\left|\psi_{0}\right\rangle$, whose respective energy is $\varepsilon_{0}$.

The 3-levels energy system described above can be formally expressed as a qutrit - a unit vector in $\mathbb{C}^{3}$ :

$$
|\psi\rangle=a_{0}\left|\psi_{0}\right\rangle+a_{\frac{1}{2}}\left|\psi_{\frac{1}{2}}\right\rangle+a_{1}\left|\psi_{1}\right\rangle .
$$

A natural example comes from the 3-levels laser in quantum optics [3], that is a special case of the population inversion phenomenon that occurs when a system of atoms exists in a non-equilibrium state such that more atoms are in an excited state than in the ground energy level. In this case, the evolution of the state should consider different possible decays from a state to another (different possible energy transactions). The probability of each decay is related with the respective gap of energy. During the dacay process, a laser is emitted and its wavelength depends on the corresponding gap of energy.

As we will see in the next section, the observations above induce effective consequences in the extension of the definitions of some standard unary quantum logical gates on the Hilbert space $\mathbb{C}^{3}$.

## 4 Extending the quantum gates

In this section we discuss extensions of several well known quantum gates to the case of qutrits. These constructions exploit the fact that in $\mathbb{C}^{3}$ - as well as in $\otimes^{n} \mathbb{C}^{3}$ - the new truth value widens the usual behavior of gates in $\mathbb{C}^{2}$ - as well as in $\otimes^{n} \mathbb{C}^{2}$ - along distinct degrees of freedom. In fact, we will see that single gates in $\mathbb{C}^{2}$ may admit several extensions in the case of qutrits.

### 4.1 The negation

Qubit case: For any $n \geq 1$, the negation on $\otimes^{n} \mathbb{C}^{2}$ is the unitary operator $N o t^{\left(2^{n}\right)}$ such that, for every element $\left|x_{1}, \ldots, x_{n}\right\rangle$ of the computational basis $\mathcal{B}^{\left(2^{n}\right)}$,

$$
\operatorname{Not}^{\left(2^{n}\right)}\left(\left|x_{1}, \ldots, x_{n}\right\rangle\right)=\left|x_{1}, \ldots, x_{n-1}\right\rangle \otimes\left|1-x_{n}\right\rangle
$$

We have that:

$$
N o t^{\left(2^{n}\right)}= \begin{cases}\sigma_{x} & \text { if } n=1 \\ I^{(n-1)} \otimes \sigma_{x}, & \text { otherwise }\end{cases}
$$

where $\sigma_{x}:=\left(\begin{array}{ll}0 & 1 \\ 1 & 0\end{array}\right)$ is the "first" Pauli matrix.
Qutrit case: Given the usual basis $\mathcal{B}^{(3)}=\left\{|0\rangle,\left|\frac{1}{2}\right\rangle,|1\rangle\right\}$ of $\mathbb{C}^{3}$, it is possible to define a negation $N o t_{\left|\frac{1}{2}\right\rangle}^{(3)}$ as expected by

$$
N o t_{\left|\frac{1}{2}\right\rangle}^{(3)}|x\rangle=|1-x\rangle,
$$

where $x \in\left\{0, \frac{1}{2}, 1\right\}$. We use the subscript $\left|\frac{1}{2}\right\rangle$ to emphasize the fact that $\left|\frac{1}{2}\right\rangle$ is a fixpoint of $N o t_{\left|\frac{1}{2}\right\rangle}^{(3)}$, i.e. $N o t_{\left|\frac{1}{2}\right\rangle}^{(3)}\left|\frac{1}{2}\right\rangle=\left|\frac{1}{2}\right\rangle$.

We can easily obtain the matrix form $\operatorname{Not}^{(3)}{ }_{\left|\frac{1}{2}\right\rangle}=\left(\begin{array}{lll}0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0\end{array}\right)$ such that:

$$
\operatorname{Not}_{\left|\frac{1}{2}\right\rangle}^{(3)}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{l}
c \\
b \\
a
\end{array}\right) .
$$

This idea can be easily generalized to the other basis states as follows:

$$
N o t{ }^{(3)}{ }_{|0\rangle}=\left(\begin{array}{lll}
1 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{array}\right) \text { and } N o t^{(3)}{ }_{|1\rangle}=\left(\begin{array}{lll}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 1
\end{array}\right) .
$$

Let us remark that, for any $i \in\left\{0, \frac{1}{2}, 1\right\}, N o t_{|i\rangle}^{(3)} \cdot N o t_{|i\rangle}^{(3)}=I^{(3)}$.

Remark 1 Note that, given the computational basis $\mathcal{B}^{(4)}=\left\{|0\rangle,\left|\frac{1}{3}\right\rangle,\left|\frac{2}{3}\right\rangle,|1\rangle\right\}$, and $\mathcal{B}^{\left(2^{2}\right)}=\{|00\rangle,|01\rangle,|10\rangle,|11\rangle\}$ the Not-like gates they induce are essentially different. Namely,

$$
N o t_{\left|\frac{1}{2}\right\rangle}^{(4)}=\left(\begin{array}{llll}
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0
\end{array}\right)
$$

but

$$
N o t^{\left(2^{2}\right)}=I^{(2)} \otimes \operatorname{Not}^{(2)}\left(\begin{array}{llll}
0 & 1 & 0 & 0 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
0 & 0 & 1 & 0
\end{array}\right)
$$

### 4.2 The Hadamard gate

Qubit case: For any $n \geq 1$, the Hadamard gate on $\otimes^{n} \mathbb{C}^{2}$ is the linear operator $H^{\left(2^{n}\right)}$ such that for every element $\left|x_{1}, \ldots, \bar{x}_{n}\right\rangle$ of the computational basis $\mathcal{B}^{\left(2^{n}\right)}$ :

$$
H^{\left(2^{n}\right)}\left(\left|x_{1}, \ldots, x_{n}\right\rangle\right)=\left|x_{1}, \ldots, x_{n-1}\right\rangle \otimes \frac{1}{\sqrt{2}}\left((-1)^{x_{n}}\left|x_{n}\right\rangle+\left|1-x_{n}\right\rangle\right)
$$

We have that

$$
H^{\left(2^{n}\right)}=\left\{\begin{array}{lc}
H & \text { if } n=1 \\
I^{n-1} \otimes H, & \text { otherwise }
\end{array}\right.
$$

where $H$ is the Hadamard matrix:

$$
H=\frac{1}{\sqrt{2}}\left(\begin{array}{cc}
1 & 1 \\
1 & -1
\end{array}\right)
$$

The basic property of $H^{\left(2^{n}\right)}$ is that, for any $|\psi\rangle \in \otimes^{n} \mathbb{C}^{2}$ :

$$
H^{\left(2^{n}\right)}\left(H^{\left(2^{n}\right)}(|\psi\rangle)\right)=|\psi\rangle
$$

Qutrit case: In [1], the following extension of the Hadamard gate for qutrits is considered

$$
H^{(3)}=\frac{1}{\sqrt{3}}\left(\begin{array}{ccc}
1 & 1 & 1 \\
1 & \frac{1}{6}(-1+i \sqrt{3}) & -\frac{1}{6}(1+i \sqrt{3}) \\
1-\frac{1}{6}(1+i \sqrt{3}) & \frac{1}{6}(-1+i \sqrt{3})
\end{array}\right)
$$

as a tool in the framework of distillation protocols for fault tolerant quantum computationprecisely Magic State Distillation.

We state without proof the main properties of $H^{(3)}$ :

## Lemma 1

1. For any $|\psi\rangle \in \mathcal{B}^{(3)}, H^{(3)}|\psi\rangle=a|0\rangle+b\left|\frac{1}{2}\right\rangle+c|1\rangle$ s.t $|a|^{2}=|b|^{2}=|c|^{2}=\frac{1}{3}$;
2. $H^{(3)}$ is a genuinely quantum gate;
3. $H^{(3)} \cdot H^{(3)}=N o t_{|0\rangle}^{(3)} \neq I$;
4. for any density operator ${ }^{1} \rho$ on $\mathbb{C}^{3}, S L(\rho) \neq S L\left(H^{(3)}(\rho)\right)$.

As shown in the previous lemma, $H^{(3)}$ preserves several desirable features of $H$ : it is a genuinely quantum gate that transforms states in the logical base $\mathcal{B}^{(3)}$ into superposition states with uniformly distributed probabilities.

Along different lines, other possible extensions of the Hadamard gate are the square root of the identity gates [20]:

$$
\begin{aligned}
& \sqrt{I}_{|0\rangle}^{(3)}=1 \oplus H_{\left(\mathbb{C}^{2}\right)}=\frac{\sqrt{2}}{2}\left(\begin{array}{ccc}
\sqrt{2} & 0 & 0 \\
0 & 1 & 1 \\
0 & 1 & -1
\end{array}\right) ; \sqrt{I}_{\left|\frac{1}{2}\right\rangle}^{(3)}=\frac{\sqrt{2}}{2}\left(\begin{array}{ccc}
1 & 0 & 1 \\
0 & \sqrt{2} & 0 \\
1 & 0 & -1
\end{array}\right) \\
& \sqrt{I}_{|1\rangle}^{(3)}=H_{\left(\mathbb{C}^{2}\right)} \oplus 1=\frac{\sqrt{2}}{2}\left(\begin{array}{ccc}
1 & 1 & 0 \\
1 & -1 & 0 \\
0 & 0 & \sqrt{2}
\end{array}\right)
\end{aligned}
$$

where $\oplus$ indicates the matrix direct sum.
Some properties of the gates above follow:
Lemma 2 For any $i \in\left\{0, \frac{1}{2}, 1\right\}$ :

1. $\sqrt{I}_{|i\rangle}^{(3)}$ is a genuinely quantum qutrit-gate;
2. $\sqrt{I}_{|i\rangle}^{(3)} \cdot \sqrt{I}_{|i\rangle}^{(3)}=I$;

3. 

$$
\sqrt{I}_{|0\rangle}^{(3)}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{c}
a \\
\frac{1}{\sqrt{2}}(b+c) \\
\frac{1}{\sqrt{2}}(b-c)
\end{array}\right) ; \sqrt{I}_{\left|\frac{1}{2}\right\rangle}^{(3)}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{c}
\frac{1}{\sqrt{2}}(a+c) \\
b \\
\frac{1}{\sqrt{2}}(a-c)
\end{array}\right) ; \quad \sqrt{I_{|1\rangle}^{(3)}}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{c}
\frac{1}{\sqrt{2}}(a+b) \\
\frac{1}{\sqrt{2}}(a-b) \\
c
\end{array}\right)
$$

Let us remark that, in the Hilbert space $\mathbb{C}^{3}$ the Hadamard gate $H^{(3)}$ does not behave as a square

### 4.3 The Square-Root of the Negation

Qubit case: For any $n \geq 1$, the square root of the negation [7] on $\otimes^{n} \mathbb{C}^{2}$ is the unitary operator $\sqrt{N o t}{ }^{\left(2^{n}\right)}$ such that, for every element $\left|x_{1}, \ldots, x_{n}\right\rangle$ of the computational basis $\mathcal{B}^{\left(2^{n}\right)}$,

$$
\sqrt{N o t}^{\left(2^{n}\right)}\left(\left|x_{1}, \ldots, x_{n}\right\rangle\right)=\left|x_{1}, \ldots, x_{n-1}\right\rangle \otimes \frac{1}{2}\left((1+i)\left|x_{n}\right\rangle+(1-i)\left|1-x_{n}\right\rangle\right) .
$$

The basic property of $\sqrt{N o t}^{\left(2^{n}\right)}$ is the following: for any $|\psi\rangle \in \otimes^{n} \mathbb{C}^{2}$,

$$
\sqrt{N o t}^{\left(2^{n}\right)}\left(\sqrt{N o t}^{\left(2^{n}\right)}(|\psi\rangle)\right)=\operatorname{Not}^{\left(2^{n}\right)}(|\psi\rangle)
$$

[^1]From a logical point of view, therefore, the square root of the negation can be regarded as a kind of "tentative partial negation" that transforms precise pieces of information into maximally uncertain ones. For, we have

$$
\operatorname{Pr}_{1}^{(2)}\left(\sqrt{N o t}^{(2)}(|0\rangle)\right)=\frac{1}{2}=\operatorname{Pr}_{1}^{(2)}\left(\sqrt{\operatorname{Not}}^{(1)}(|1\rangle)\right)
$$

As noticed in [9, Lemma 17.1.11], this gate possesses no Boolean counterpart.
Qutrit case: As in the case of the gate $N o t_{|i\rangle}^{(3)}, i \in\left\{0, \frac{1}{2}, 1\right\}$, once we enter in the qutrit world, several possible widening of $\sqrt{N o t}^{(2)}$ are available. Namely, given the usual basis $\mathcal{B}^{(3)}$ of $\mathbb{C}^{3}$, it is possible to define the gates $\sqrt{N o t}_{|0\rangle}^{(3)}, \sqrt{N o t}_{\left|\frac{1}{2}\right\rangle}^{(3)}$, and $\sqrt{N o t}_{|1\rangle}^{(3)}$ as follows:

$$
\begin{aligned}
& \sqrt{N o t}_{|0\rangle}^{(3)}=1 \oplus \sqrt{N o t}^{(2)}=\frac{1}{2}\left(\begin{array}{ccc}
2 & 0 & 0 \\
0 & 1+i & 1-i \\
0 & 1-i & 1+i
\end{array}\right) ; \\
& \sqrt{N o t}_{\left|\frac{1}{2}\right\rangle}^{(3)}=\frac{1}{2}\left(\begin{array}{ccc}
1+i & 0 & 1-i \\
0 & 2 & 0 \\
1-i & 0 & 1+i
\end{array}\right) ; \\
& \sqrt{N o t}_{|1\rangle}^{(3)}=\sqrt{N o t}^{(3)} \oplus 1=\frac{1}{2}\left(\begin{array}{ccc}
1+i & 1-i & 0 \\
1-i & 1+i & 0 \\
0 & 0 & 2
\end{array}\right) .
\end{aligned}
$$

Similarly to $\sqrt{I}_{|i\rangle}^{(3)}$, it can be seen that the gates $\sqrt{N o t}_{|i\rangle}^{(3)}$ also, act "locally" as genuinely quantum gates on two of the base vectors, leaving unchanged $|0\rangle,\left|\frac{1}{2}\right\rangle,|1\rangle$, respectively:

$$
\begin{aligned}
& \sqrt{N o t}_{|0\rangle}^{(3)}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{c}
a \\
\frac{1}{2}[(1+i) b+(1-i) c] \\
\frac{1}{2}[(1-i) b+(1+i) c]
\end{array}\right) ; \\
& \sqrt{N o t}_{\left|\frac{1}{2}\right\rangle}^{(3)}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{c}
\frac{1}{2}[(1+i) a+(1-i) c] \\
b \\
\frac{1}{2}[(1-i) a+(1+i) c]
\end{array}\right) ; \\
& \sqrt{N o t}_{|1\rangle}^{(3)}\left(\begin{array}{l}
a \\
b \\
c
\end{array}\right)=\left(\begin{array}{c}
\frac{1}{2}[(1+i) a+(1-i) b] \\
\frac{1}{2}[(1-i) a+(1+i) b] \\
c
\end{array}\right) .
\end{aligned}
$$

Some interesting properties of the gates above are summarized in the following:
Lemma 3 For any $i \in\left\{0, \frac{1}{2}, 1\right\}$,

1. $\sqrt{N o t}_{|i\rangle}^{(3)}$ is a genuinely quantum qutrit-gate;
2. $\sqrt{N o t}_{|i\rangle}^{(3)} \cdot \sqrt{N o t}_{|i\rangle}^{(3)}=N o t_{|i\rangle}^{(3)}$;
3. for any density operator $\rho$ on $\mathbb{C}^{3}, S L(\rho)=S L\left(\sqrt{N o t}_{|i\rangle}^{(3)}(\rho)\right)$ (as in the qubit case).

## 5 Effect caracterization of density operators on $\mathbb{C}^{3}$

As mentioned in 3.2, when an interaction between a system and the environment comes into play, the state of the system is represented by a qumix. It is well known that Pauli matrices $\sigma_{1}, \sigma_{2}, \sigma_{3}$ and $I$ form a basis for the set of density operators on $\mathbb{C}^{2}$, so that an arbitrary density operator $\rho$ in $\mathbb{C}^{2}$ may be represented as

$$
\rho=\frac{1}{2}\left(I+r_{1} \sigma_{1}+r_{2} \sigma_{2}+r_{3} \sigma_{3}\right)
$$

where $r_{1}, r_{2}$ and $r_{3}$ are real numbers such that $r_{1}^{2}+r_{2}^{2}+r_{3}^{2} \leq 1$. The vector $\left(r_{1}, r_{2}, r_{3}\right)$ represents the uniquely determined point in the Bloch sphere associated to $\rho$ : the Bloch-vector of $\rho$. There is a one-to-one correspondence between the space of the lenght- 1 vectors in $\mathbb{R}^{3}$ and the space of the density operators in $\mathbb{C}^{2}$.

A representation of this sort can be obtained for any $n$-dimensional Hilbert space through generalized Pauli-matrices. In particular, in $\mathbb{C}^{3}$, Pauli matrices are generalized by Gell-Mann matrices [30].

It can be seen that any density operator $\rho$ in $\mathbb{C}^{3}$ [22] can be written as

$$
\begin{equation*}
\rho=\frac{1}{3}\left(I+\sqrt{3} \sum_{i=1}^{8} r_{i} \lambda_{i}\right) \tag{3}
\end{equation*}
$$

where $r_{i}$ are real numbers such that $\sum_{i=1}^{8}\left|r_{i}\right|^{2}=1$.
Let us observe that lenght-1 vectors in $\mathbb{R}^{8}$ and the space of the density operators in $\mathbb{C}^{3}$ are not in one-to-one correspondence. Indeed, if $r_{i}=1$ for $i=8$ and $r_{i}=0$ otherwise, then the eigenvalues of the corresponding operator $\rho$ in Equation (3) would be $\left\{\frac{2}{3}, \frac{2}{3},-\frac{1}{3}\right\}$, against the positivity requirement.

In this section, we propose an alternative characterization of density operators in $\mathbb{C}^{3}$ through the notion of effect probability.

Definition 6 Let $\mathbb{H}$ be a complex Hilbert space that represents the state space of a quantum system S . The set of effects $E(\mathbb{H})$ for $S$ is the set of operators

$$
\{A: \forall|\psi\rangle \in \mathbb{H}, 0 \leq\langle\psi \mid A \psi\rangle \leq 1\}
$$

Following [23], an effect represents a yes-no measurements (for example a measurement on a SternGerlach apparatus, whose outputs can only be spin up or spin down [4, I.1.2]) that may be unsharp [19]: sharp measurements are mere idealization, impossible in practice, where measurements are always imprecise to some degree. This unsharpness arises from the interaction between the system and the environment. For example, consider a geiger or a photon counter performing a position measurement on a one-particle quantum system. If the system is completely isolated from the environment and the detector is perfectly accurate, then it clicks if and only if the particle is detected within a certain sensitivity domain $B \subset R^{3}$. However, this situation is a limit condition, not encompassing real situations, where the system interacts with the environment and the measurement device is not perfectly accurate. In this case, an adequate calibration experiment classifies the confidence that the apparatus clicks when the particle is in $B$ as a real value in $(0,1)$. According to [23], this can be considered an example of a yes-not measurement quantum event (the particle is/is not in a certain sensitivity domain $B$ ) to whose outcomes a probability value can be assigned.

Phenomena of this sort motivated the development of POVM (positive operator valued measure) theory, that generalises standard PVM (positive valued measure) theory [4, §1.3]. POVM relies on the fact that the physical reality is described as it emerges when investigated by measuring processes, which are to be considered, themselves, as physical processes. Perhaps, the striking difference between PVM and POVM is that, while PVM considers only sharp observables, represented by hermitian operators, and projective measurements, POVM widens this setting to unsharp observables, represented by effects, to which effect-valued measurements, that generalize within this context projective measurements, are associated [4, p.6]. Indeed, to any effect valued measurement a probability measurement (effect probability) is naturally associated by the Born rule [4, (1.21)]:

$$
\begin{equation*}
\operatorname{Pr}_{(E)}(\rho)=\operatorname{tr}(E \rho), \tag{4}
\end{equation*}
$$

where $E$ and $\rho$ are an effect and a density operator on an Hilbert space $\mathbb{H}$, respectively.
In the case of $\mathbb{C}^{3}$, the notion of effect probability turns out to be particularly expedient for our purposes if $E$ in (4) is the effect:

$$
E=\left(\begin{array}{ccc}
0 & 0 & 0 \\
0 & \frac{1}{2} & 0 \\
0 & 0 & 1
\end{array}\right)
$$

In fact, using this particular effect probability we can define a three-valued quantum computational logic on $\mathbb{C}^{3}$ that consistently generalizes two-valued quantum computational logic on $\mathbb{C}^{3}$. Indeed, for any $|i\rangle$ in the computational basis, $\operatorname{Pr}_{(E)}(|i\rangle)=i$. Moreover, $\operatorname{Pr}_{(E)}$ is crucial in proving the following:
Proposition 1 Let $\rho$ be a density operator in $\mathbb{C}^{3}$ and consider the following set of gates: $A=$ $\left\{I, N o t_{|0\rangle}^{(3)}, \sqrt{I}_{|i\rangle}^{(3)}, \sqrt{N o t^{(3)}}{ }_{|i\rangle}\right\}_{i \in\left\{0, \frac{1}{2}, 1\right\}}$. Then $\rho$ is uniquely characterized by the following equations:

1. $\operatorname{Pr}_{(E)}(\rho)=\frac{1}{6}\left(3-\sqrt{3} r_{3}-3 r_{8}\right)$
2. $\operatorname{Pr}_{(E)}\left(N o t_{|0\rangle}^{(3)} \rho\right)=\frac{1}{2}-\frac{r_{3}}{\sqrt{3}}$
3. $\operatorname{Pr}_{(E)}\left(\sqrt{I}_{|0\rangle}^{(3)} \rho\right)=\frac{1}{12}\left(6-3 \sqrt{3} r_{3}-2 \sqrt{3} r_{6}-3 r_{8}\right)$
4. $\operatorname{Pr}_{(E)}\left(\sqrt{I}_{\left|\frac{1}{2}\right\rangle}^{(3)} \rho\right)=\frac{1}{2}-\frac{r_{4}}{\sqrt{3}}$
5. $\left.\operatorname{Pr}_{(E)}(\sqrt{I}(1\rangle\rangle\right)=\frac{1}{6}\left(3-\sqrt{3} r_{1}-3 r_{8}\right)$
6. $\operatorname{Pr}_{(E)}\left(\sqrt{N o t}{ }_{|0\rangle}^{(3)} \rho\right)=\frac{1}{12}\left(6-3 \sqrt{3} r_{3}-2 \sqrt{3} r_{7}-3 r_{8}\right)$
7. $\operatorname{Pr}_{(E)}\left(\sqrt{N o t}_{\left|\frac{1}{2}\right\rangle}^{(3)} \rho\right)=\frac{1}{2}-\frac{r_{5}}{\sqrt{3}}$
8. $\operatorname{Pr}_{(E)}\left(\sqrt{N o t}_{|1\rangle}^{(3)} \rho\right)=\frac{1}{6}\left(3-\sqrt{3} r_{2}-3 r_{8}\right)$

Proof Simply notice that the linearly independent Equations (1)-(8) uniquely characterize the Bloch vector associated to $\rho$.

## 6 Conclusions

The aim of this paper was foundational. In particular, we tried to spell out how the concepts of uncertainty and truth-degree meet new degrees of freedom in the framework of quantum computational logics. A natural future development of the ideas in this paper would include:

- a study of binary qutrit-gates;
- a generalization of Proposition 1 to an arbitrary Hilbert space.

[^1]:    1 The extensive definition of a density operator $\rho$ on $\mathbb{C}^{3}$ is provided in the next Section. When a qutrit quantum gate $A$ is applied to a density operator $\rho$ on $\mathbb{C}^{3}$, the evolution of $\rho$ is given by: $A \rho A^{\dagger}$. Since no danger of confusion will be impending, for the sake of notational simplicity, from now on we write $A(\rho)$.
