14 **Abstract**

15 In sprinkler irrigation the water distribution uniformity in field conditions is not  
16 always a known factor, mainly due to the many variables involved, especially the wind.  
17 The main objective of this study was to design, install and test an automatic sprinkler  
18 bench to measure the irrigation uniformity of solid set systems for multiple wind  
19 conditions in real time. The system developed measures the different wind speeds and  
20 directions while simultaneously recording the rainfall distribution automatically.  
21 Consequently, the system requires little manual intervention, thus reducing the  
22 operating costs. All the information generated is stored in a database, obtaining multiple  
23 results of irrigation uniformity for each stable wind regime. As a second step,  
24 uniformities in different situations (layouts and wind directions) were studied. In  
25 addition, this study shows the potential for assessing the influence of different variables

26 on irrigation uniformity for several sets of sprinklers. As an example of possible  
27 applications, 12150 results of uniformity coefficients for conventional impact rotary  
28 head sprinklers with hexagonal nozzles in windy conditions were generated. These data  
29 were used to establish comparisons between different sprinklers. To do this, a multiple  
30 linear regression methodology was applied in order to analyse the influence of the  
31 different contour variables on the irrigation uniformity. The test bench presented along  
32 with the methodology to simulate and generate multiple scenarios constitutes a powerful  
33 tool for designers, farmers and technicians both for the improvement of existing  
34 installations and for future designs. The generation of a large amount of irrigation  
35 uniformity results for sprinkler irrigation in different wind conditions will lead to a large  
36 database with the potential to be able to determine the irrigation uniformity in all  
37 common scenarios.

38 *Keywords:* Solid set sprinkler systems; irrigation evaluation; automation

39

## 40 **1. Introduction**

41 The modernization processes carried out in the irrigated areas have led to the  
42 installation of pressurized networks. This fact has induced a change from surface  
43 irrigation to sprinkler or trickle irrigation, which are purported to have higher water  
44 application efficiencies, better control of the water depth applied and enable automation.  
45 However, sprinkler systems have certain disadvantages with respect to trickle irrigation.  
46 The most important is the poor uniformity of irrigation in wind conditions and the  
47 means to determine it. Water application uniformity is the main indicator of irrigation  
48 quality. It can be expressed through different parameters or coefficients, such as the  
49 Distribution Uniformity (DU) (Merriam and Keller, 1978) or the Christiansen's

50 Uniformity coefficient (CU) (Christiansen, 1942). Irrigation management with sprinkler  
51 irrigation systems would benefit from site-specific, comprehensive and accurate  
52 information about irrigation uniformity, especially in windy conditions. With one study  
53 using a well-executed irrigation schedule based on crop requirements, yield increased  
54 with a higher irrigation uniformity (Li., 1998). According to Keller and Bliesner (1990),  
55 most irrigation sprinkler systems require a minimum CU value greater than 80%. Bralts  
56 et al. (1994) indicated that a 5-12% increase in CU could lead to 3-17% more yield in  
57 wheat grain. Moreover, according to Tarjuelo et al. (1999b), low CU values generally  
58 indicate a faulty combination of the number and size of nozzles, pressure and spacing of  
59 sprinklers.

60 Many factors affect the performance of sprinkler irrigation. However, the wind  
61 is an uncontrollable variable and has a decisive influence on sprinkler irrigation  
62 efficiency and uniformity (Tarjuelo et al., 1999b). Therefore, knowing the DU for each  
63 irrigation scenario and possible wind regime is desirable. This allows for determining  
64 the optimal timing for irrigation in order to minimize the effects due to wind (Sánchez  
65 et al., 2011). .

66 Wind speed and direction are the main parameters that have a greater impact on  
67 the water distribution model (Tarjuelo et al., 1999b) and play an important role in drift  
68 and evaporation losses (Tarjuelo et al., 2000; Keller and Bliesner, 1990). Many authors  
69 indicate that the influence of the wind depends greatly on system design parameters,  
70 such as working pressure, spacing, nozzle size or type of sprinkler (Keller and Bliesner,  
71 1990).

72 Different methods can be used to determine sprinkler irrigation uniformity. Each  
73 procedure is adapted to information requirements, with a more or less limited scope of

74 results. In a Radial model (Vories and Von Bernuth, 1986), an isolated and windless  
75 evaluation of the sprinkler is performed, using a certain nozzle and a specific operating  
76 pressure. It is basically an evaluation with a row of rain gauges along the radius of the  
77 wet area of the sprinkler. The results obtained are used to measure the irrigation  
78 uniformity that the entire wet area in the field would have. It is mainly used to  
79 characterize the sprinklers and nozzles in ideal conditions without wind (Tarjuelo et al.,  
80 1999a). It is required information for sprinkler manufacturers which offer basic data for  
81 the irrigation design.

82         The Matrix model (ISO 15886-3:2012, 2012) is also an evaluation of an isolated  
83 sprinkler, but having the advantage of knowing the complete water distribution pattern  
84 of the sprinkler in the whole wet area. It is mainly used to characterize the sprinkler and  
85 the nozzles in windy conditions. It consists in setting a network of rain gauges covering  
86 the wetted surface of an isolated sprinkler. This will allow for overlapping data  
87 according to the operation layout. This procedure has three disadvantages: (1) the  
88 variability of the climatic conditions during the test, (2) the different evaporation rate in  
89 the peripheral collectors with respect to the central ones and (3) the high manpower  
90 requirements for each test. It is mainly used in research centres dedicated to the study of  
91 sprinkle irrigation.

92         Lastly, the evaluation of the system (Merriam and Keller, 1978; Merriam et al.,  
93 1980) consists of the actual field evaluation of an existing irrigation facility. It is  
94 performed in a sample area of the installation and by the provision of a network of  
95 collectors. It is ideal to determine the quality of irrigation in specific conditions (wind,  
96 pressure, etc.) in which the evaluation is done.

97

98           However, in recent decades, many simulation models for irrigation have been  
99 developed with different theories, in order to avoid the problems of experimental field  
100 tests. Ballistic models are based on simulating the trajectory of drops of water in the air  
101 when they come out of the sprinkler and are distorted by the action of wind (Seginer et  
102 al., 1991; Carrion et al., 2001; Montero et al., 2001; Playan et al., 2006; Li et al, 2015  
103 and Yongchong et al., 2015). Semi-empirical models simulate the shape of water  
104 distribution distorted by the wind, starting from results in windless conditions (Richards  
105 and Weatherhead, 1993; Han et al., 1994; Molle and Le Gat, 2000; Granier et al., 2003  
106 and Oliveira et al., 2013). Other models use mathematical techniques of artificial neural  
107 networks, simulating the effect of the wind on the sprinkler water distribution pattern  
108 (Lazarovitch et al., 2009; Hinnell et al., 2010; Sayyadi et al., 2012). In each case, the  
109 simulation models should be calibrated and validated through experimental tests.

110           Depending on the chosen method, the quantity and quality of information will  
111 vary. In ballistic models, a large database that characterizes all the sprinklers can be  
112 obtained but only for the conditions of operation without wind. Semi-empirical models  
113 can be considered the most accurate and their results can be easily extrapolated.  
114 However, this evaluation is costly both in time and resources, and requires a specific  
115 infrastructure. In the third case, many field evaluations can be performed but in such  
116 specific conditions that they will not readily adapt to other circumstances.

117           For obtaining water distribution data from isolated sprinklers, radial or matrix  
118 models can be used. Both can be automated to avoid labour costs, while they have the  
119 advantage of reducing the error due to evaporation from the collectors during the test.  
120 Hodges et al. (1990) used the matrix system in an automated test facility programmed to  
121 operate unattended when wind speed exceeded  $2.2 \text{ m}\cdot\text{s}^{-1}$ . Although, as has been stated,  
122 previous attempts have been made, it is necessary to consolidate a system in order to

123 have an operational tool that addresses the lack of knowledge about irrigation  
124 uniformity under multiple real operating conditions.

125 The main objective of this work is the design of an automatic test bench for the  
126 study of uniformity in solid set sprinklers systems in different wind conditions. The  
127 main differences with respect to the bench developed by Hodges et al. (1990) are:

- 128 - Increasing the surface area of the bench so as to permit rain collection with  
129 winds greater than  $2.2 \text{ m}\cdot\text{s}^{-1}$ .
- 130 - Improving measurement precision by increasing collector size.
- 131 - Having a more accurate and efficient data acquisition system which permits  
132 real-time data analysis. This allows for instantaneous extraction of data  
133 concerning water distribution and wind speed and direction, therefore  
134 permitting the execution of more trials per working day thus increasing  
135 bench performance.

136 The development of this equipment involves a complex data acquisition and  
137 processing system which allows further analysis. This tool will not only generate a large  
138 amount of experimental data, but coupled with the simulation method proposed by Han  
139 et al. (1994) will be able to recreate solutions for any real situation that may occur in the  
140 field.

141

## 142 **2. Materials and methods**

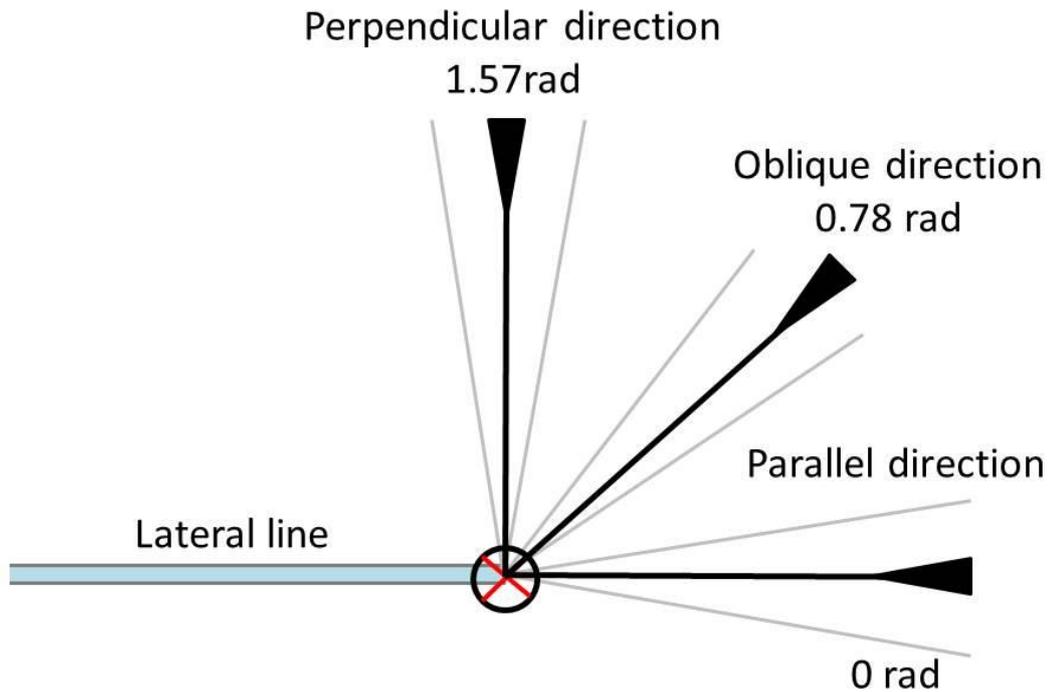

### 143 **2.1. Design requirements**

144           The test bench was located at the Agrarian Research and Training Centre of  
145 Chipiona in Cadiz, Spain (Geographical coordinates: 36.751351,-6.4003860). The  
146 following requirements were contemplated:

147 1.       Isolated sprinkler test following the method proposed in ISO 15886-3:2012  
148           (2012).

149 2.       Instant and continuous measurement of the temporal and spatial water  
150           distribution, using automatic rain gauges with a tipping bucket, that register the  
151           amount and the time in which water is collected at each sampling point. The  
152           sprinkler is located in the centre of the grid of rain gauges, which are  
153           electronically interconnected, with a spacing of 2 by 2 meters.

154 3.       Instantaneous measurement of the wind speed and direction at all times with an  
155           automatic wind sensor. The relative wind directions are standardized in a later  
156           simulation, with respect to the irrigation lateral (Norenberg et al., 2017), in three  
157           directions: parallel, oblique and perpendicular, independent of the wind direction  
158           (Figure 1). This allows for the organization and simplification of the substantial  
159           amount of results obtained.

160

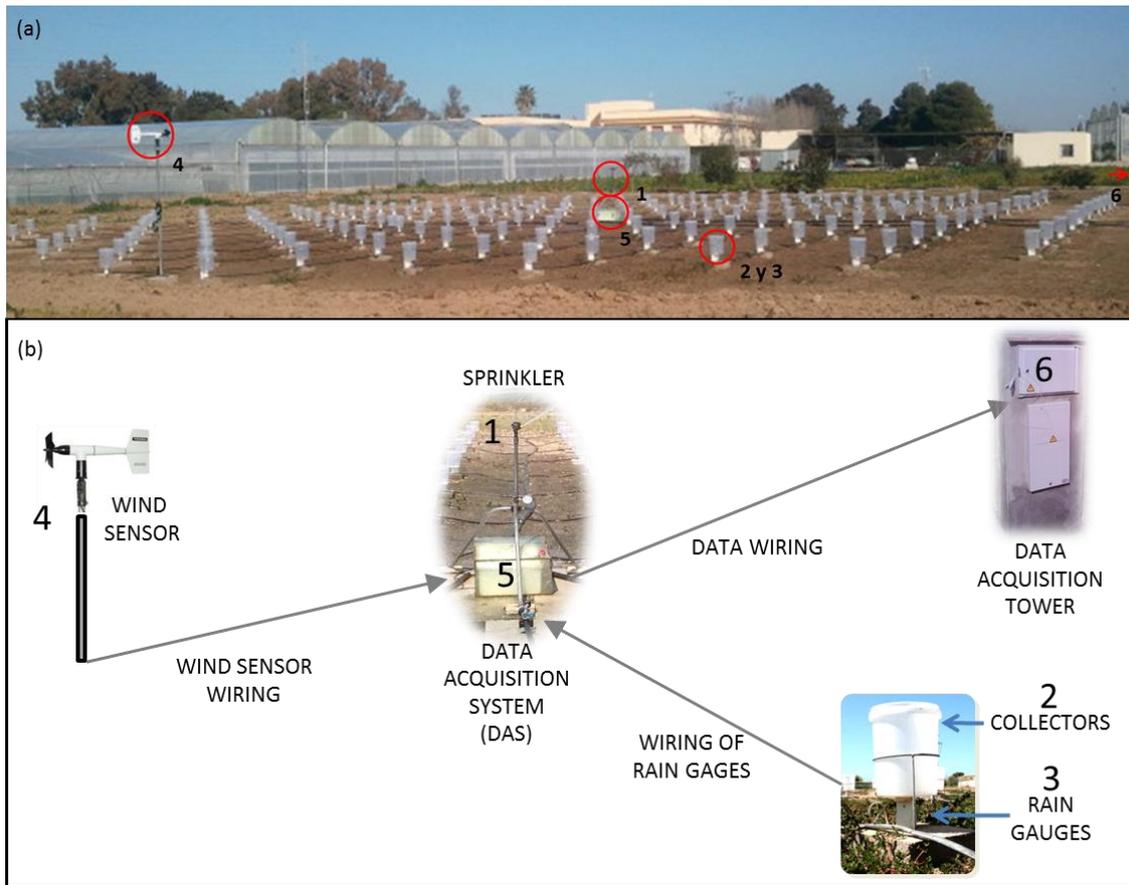

161 **Figure 1.** Standardization of relative wind directions with respect to the lateral line.

162 4. Obtaining and processing of data: All values of instant rainfall at each sampling  
 163 point and wind speed and direction were stored in a data acquisition and storage  
 164 system. They were processed for all results of irrigation uniformity with respect  
 165 to the recorded wind in the different situations.

166 The equipment was prepared to keep working non-stop, in order to acquire data  
 167 from different wind regimes throughout the trial period.

## 168 2.2. System Architecture

169 The bench consists of six functional units (Figure 2) each of which is described  
 170 below.

171

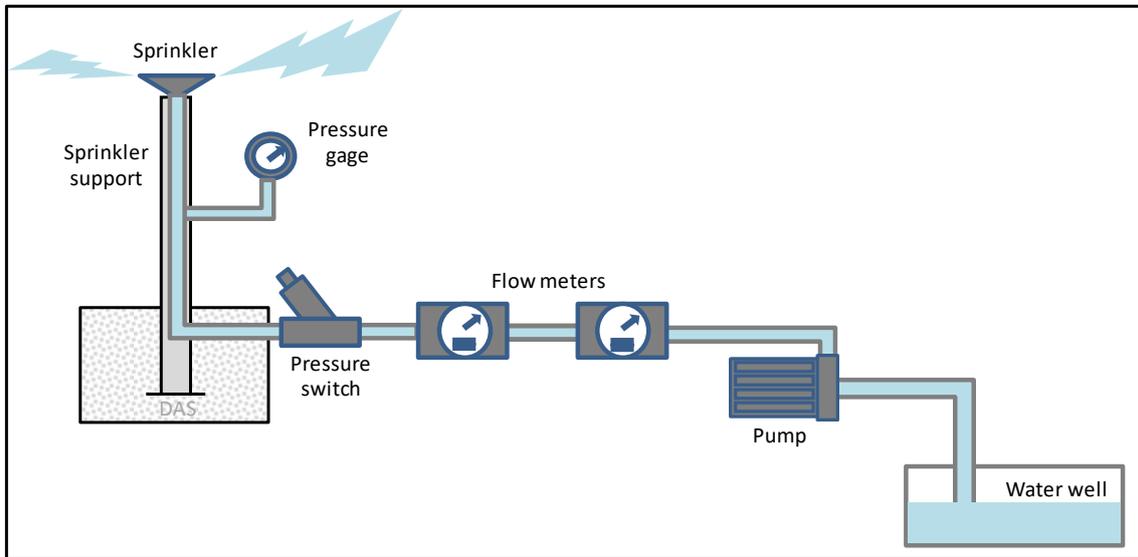

172 **Figure 2.** (a) In-field test and (b) components of test bench. (1) sprinkler, (2) catch can,  
 173 (3) automated rain gauges, (4) wind sensor, (5) Data Acquisition System (DAS), and (6)  
 174 data acquisition tower.

175 2.2.1. Hydraulic system

176 Water was supplied from a well by means of a 2.2 kW pump Prisma 35 N  
 177 (ESPA 2025 S.L., Banyoles, Spain). A polyethylene 90 mm pipe carries water from the  
 178 pump to the sprinkler (Figure 3).

179 According to the standard ISO 15886-3:2012 (2012), changes of pressure must  
 180 not be over 2% throughout the trial. Therefore, a pressure regulator is placed  
 181 downstream of the pump in order to ensure the exact required pressure at all times. Two  
 182 flowmeters (ARAD, model M25, one inch in diameter) were installed to register the

183 flow (with an accuracy of  $5 \cdot 10^{-5} \text{ m}^3$ ). Both were located before the pressure regulator  
184 with a series arrangement for detecting measurement errors. A tripod supported the trial  
185 sprinkler, where the pressure data was collected with a glycerine manometer with a  
186 range of up to 600 kPa.

187

188 **Figure 3.** Hydraulic design of test bench.

189 2.2.2. Catch cans and rain gauges

190 The catch cans (also called collectors) were cylindrical plastic containers (Figure  
191 4) with 7.5 L of capacity, with an inner diameter of 0.21 m and a height of 0.265 m.  
192 Their dimensions are compatible with the requirements of the standard ISO 15886-  
193 3:2012 (2012).

194

195

196 **Figure 4.** Collector attached to each automatic rain gauge

197

198 They were placed on the top of the rain gauges (Figure 4) and their main  
199 function is to increase the surface of water collection to improve accuracy. In order to  
200 measure the water received at each point of the evaluation zone, automatic cup rain  
201 gauges Rain-O-Matic® Small (Pronamic, Ringkøbing, Denmark) were used. They are  
202 individual prismatic collectors (0.1 x 0.1 x 0.05 m) with a pyramidal trunk water inlet  
203 where the collected water empties into small holes that allow their passage to a  
204 calibrated tilting bucket that emits an electric pulse each 5 mL of water. The time in  
205 which the pulse is generated and the identification number of the corresponding rain  
206 gauge are recorded by the Data Acquisition System.

207

### 2.2.3. Wind sensor

208

209 A wind sensor model 05106 (Campbell Scientific Spain, S.L.) with a range of 0  
210 to 100 m·s<sup>-1</sup> of wind speed (accuracy of 0.3 m·s<sup>-1</sup>) is employed. It measures wind  
211 direction from 0 to 6.28319 rad with a margin of error of 0.0523599 rad.

211

### 2.2.4. Data Acquisition System (DAS)

212 The Data Acquisition System (DAS) is designed to obtain data from 178  
213 sensors, two of which correspond to wind speed and direction and the rest to 176 rain  
214 gauges. The DAS is mounted inside a weatherproof box located under the sprinkler  
215 (Figure 2).

#### 216 2.2.5. Data acquisition tower

217 Outside the trial area a tower has been placed with a double function: (1)  
218 regulation and power supply, and (2) laptop connection point to access the DAS. The  
219 tower was connected to the DAS by means of two wires, one for power and one for  
220 communication (RS232). It enables both online data connecting for maintenance and  
221 checking the system operation.

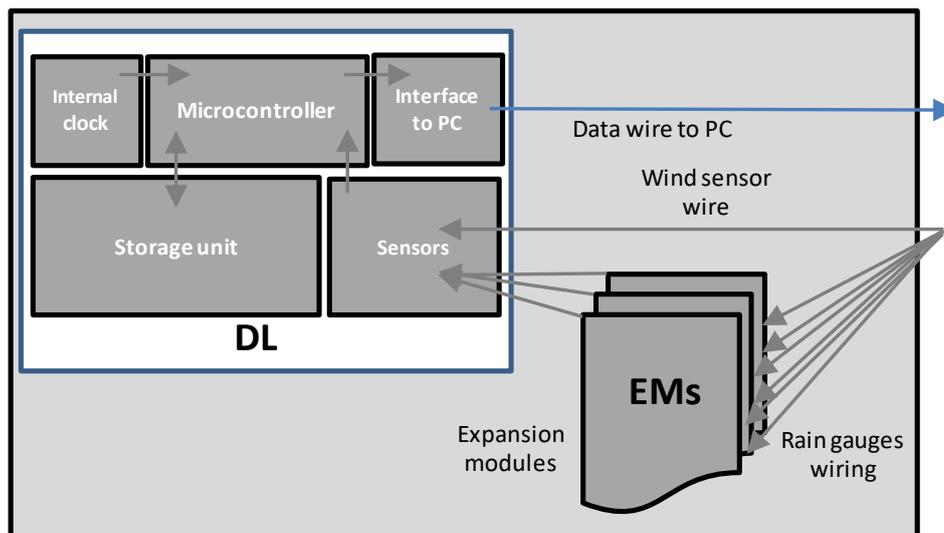

### 222 **2.3 Electronic control subsystem**

223 This is the most complex subsystem of the bench and is closely associated with  
224 the DAS. Its components are:

- 225 - Data Logger (DL) model CR1000 (Campbell Scientific), with 8 inputs for  
226 sensor data. They are connected to the wind sensor and the expansion modules  
227 collecting data from each of the 176 rain gauges. It includes a microcontroller,  
228 an internal clock, a data storage unit, an interface for communication with the  
229 laptop that will collect the data and a console to connect the sensors.
- 230 - 13 data Expansion Modules (EM) SDM-IO16 16 Channel Input/Output  
231 (Campbell Scientific), with 16 inputs each, allowing data acquisition of 176  
232 entries of automatic rain gauges. The expansion modules will be connected in  
233 parallel via 3 inputs to the DL.
- 234 - Weather protection box LE129GX (Campbell Scientific), which isolates the  
235 entire DAS from outdoor humidity conditions. In order to avoid the direct action

236 of the water, this outdoor enclosure is covered by a custom-built rigid outer  
237 casing.

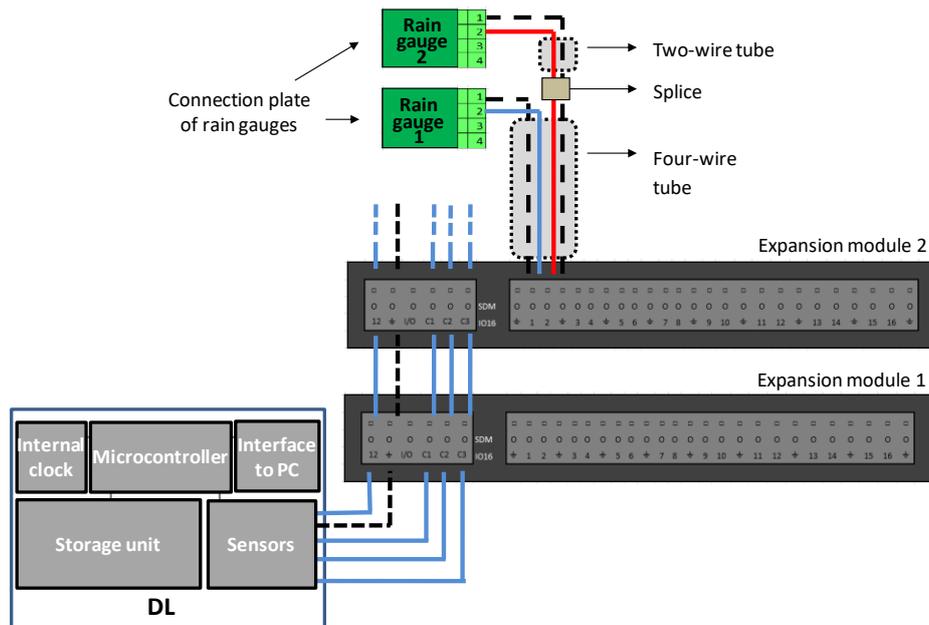

238 The EM collects the pulses of each rain gauge, which are identified, registered  
239 and ordered in time in the DL (Figure5). Each EM previously references the signal  
240 coming from each rain gauge. Each measurement is recorded in the DL and organized  
241 by date and time thanks to the internal clock. The connection to a laptop allows for the  
242 transfer of data in addition to a control in real time of the system when required. The  
243 connection between the EM and the rain gauges is performed by pairs of rain gauges (a  
244 primary rain gauge and a satellite) to optimize the cost of wiring between the DAS and  
245 the rain gauges. Subsequently, the first EM will be directly connected to the DL and the  
246 remaining will be connected among them in cascade and in parallel (Figure 6).

247

248 **Figure 5.** Scheme of the Data Acquisition System (DAS).

249

250

251 **Figure 6.** Scheme of connection among the expansion modules and one pair of rain  
 252 gauges.

253 **2.4 Software and data processing**

254 Treatment and analysis of the data is completely computerised. Several  
 255 concatenated software programs have been used in the development of the methodology  
 256 for the collection and processing of data, from the programming of the DL internal  
 257 software, to the results of DU for the different configurations of sprinklers.

258 **2.4.1 DL data management**

259 Two software programs from Campbell Scientific have been used for the  
 260 programming of the DL and downloading data. *LoggerNet 4.4* allows the data to be  
 261 communicated and downloaded from the DL to the laptop. *Short Cut 3.2.2* is the  
 262 program editor for the DL.

263 **2.4.2 Data processing**

264 A worksheet (Microsoft Excel 2010) was used for the data selection, the  
265 generation of tables and graphics of the results as well as the processing of data to adapt  
266 them to the requirements of the sprinkler irrigation simulation program. This  
267 worksheet's main function is to extract multiple groups of data with the same conditions  
268 from the main dataset. Due to the fact that in each trial day the conditions are variable  
269 over time, intervals with small variations in wind direction and speed values are chosen  
270 according to a criterion of restricted variability.

#### 271 2.4.3. Overlapping of the results to different layouts

272 SpacePro 3.0 (Center for Irrigation Technology, 2010) was used to overlap the  
273 isolated sprinkler test results obtained by the test bench to simulate different layouts of  
274 multiple sprinklers. It allows a wide range of configurations and combinations of  
275 distances between sprinklers and different wind directions. This software is used to  
276 calculate uniformity of distribution, DU (Merriam and Keller, 1978); the Christiansen  
277 uniformity coefficient, CU (Christiansen, 1942); rainfall ( $\text{mm}\cdot\text{h}^{-1}$ ); and the Scheduling  
278 Coefficient (SC) over 5% of the surface (Butter, 1990) from a given pluviometer  
279 distribution in the form of a data matrix.

#### 280 **2.5. Maintenance and calibration.**

281 Although each rain gauge was factory calibrated and certified, they all have to  
282 be periodically recalibrated. Routine maintenance and calibration tasks are necessary  
283 especially when the information from a certain rain gauge is not being received in the  
284 DAS. This usually means that there is some problem such as deposition and formation  
285 of mud in the bowl of the automatic rain gauge, obstruction of the rain gauges produced  
286 by spontaneous fauna like snails, poor electrical contacts, etc. Therefore, the

287 maintenance plan included two fundamental tasks: cleaning the rain gauges and its  
288 subsequent calibration.

289 The cleaning operations consisted of removing the collector and the rain gauge  
290 cover and washing with a pressure hose. When the presence of weeds or snails was  
291 detected, herbicides and helicides were applied to keep the mechanism of the rain gauge  
292 free of obstacles.

293 A recalibration of the rain gauges was carried out in each maintenance task. In it,  
294 the value measured by each rain gauge is corrected with respect to a known rainfall  
295 value. This generated a correction coefficient for each rain gauge.

296 The calibration consisted of the following steps: activation of the bench without  
297 sprinkler, pouring 0.25 L of water into each rain gauge during 2.5 minutes (3 s per  
298 pulse), simulating the maximum flow rate that a sprinkler can give and not exceeding  
299 the range of measuring capability provided by the manufacturer of the rain gauge. Once  
300 provided the correct amount of water in all gauges, data from the DAS is downloaded  
301 and the correction coefficient is calculated for each rain gauge to be subsequently  
302 applied to all measurements.

## 303 **2.6. Example of use.**

304 As an example of how the test bench can be used, multiple tests were performed  
305 with different sprinklers in diverse conditions taking into account eight variables (Table  
306 1).

307 Table 1. Summary of the number of values defined for each test variable.

| Variable | Number of values |
|----------|------------------|
|----------|------------------|

|   |     |
|---|-----|
| Manufacturer                            | 5   |
| Sprinkler models per manufacturer       | 2   |
| Number of nozzle combinations per model | 1-4 |
| Working pressures per combination       | 3   |
| Wind speeds per combination             | 2   |
| Wind directions per wind speed          | 3   |
| Layouts per combination                 | 81  |
| Layout shapes per combination           | 2   |

308

309           The first three variables (manufacturer, sprinkler model and nozzle combination)  
310 refer to the most common sprinklers used in Spain (Table 2). The following (pressure,  
311 wind speed and direction of the wind and layout) correspond to the following values:

- 312           - Tested pressures: 200, 250, and 350 kPa.
- 313           - Wind speeds: 2 values preferably were processed only for each sprinkler  
314 model, one with slight wind (less than  $2 \text{ m}\cdot\text{s}^{-1}$ ) and the other with  
315 moderate wind (between 2 and  $4 \text{ m}\cdot\text{s}^{-1}$ ).
- 316           - Wind directions: parallel, oblique and perpendicular with respect to the  
317 lateral, categorising the multiple results that could be obtained in those  
318 three.
- 319           - The layouts studied correspond to all the combinations ranging from 10 x  
320 10 m to 18 x 18 m in all possible configurations with an interval of 1 m  
321 between each layout variation.
- 322           - The two shapes studied are rectangular and triangular.

323 Table 2. Manufacturer, sprinkler models and nozzle combinations considered.

| Manufacturer | Sprinkler model | Nozzle combination           |                                    |                                   |     |
|--------------|-----------------|------------------------------|------------------------------------|-----------------------------------|-----|
|              |                 | Main nozzle (diameter in mm) | Jet-straightening vane (Yes or No) | Secondary nozzle (diameter in mm) |     |
| Unirain      | F46             | 2.6                          | Y                                  |                                   |     |
|              |                 | 3.6                          | Y                                  |                                   |     |
|              |                 | 3.2                          | Y                                  |                                   |     |

|              |                 | 3.2                          | N                                  |                                   |     |

324

325           Afterwards, the data obtained for an isolated sprinkler was used to simulate  
326 multiple scenarios, calculating irrigation uniformity for different layouts. For the  
327 analysis, three sets of sprinklers have been considered:

- 328       - Set 1: Conventional impact sprinklers with hexagonal nozzles.
- 329       - Set 2: Non-conventional impact rotary head sprinklers with bayonet nozzles
- 330       - Set 3: Rotary sprinklers.

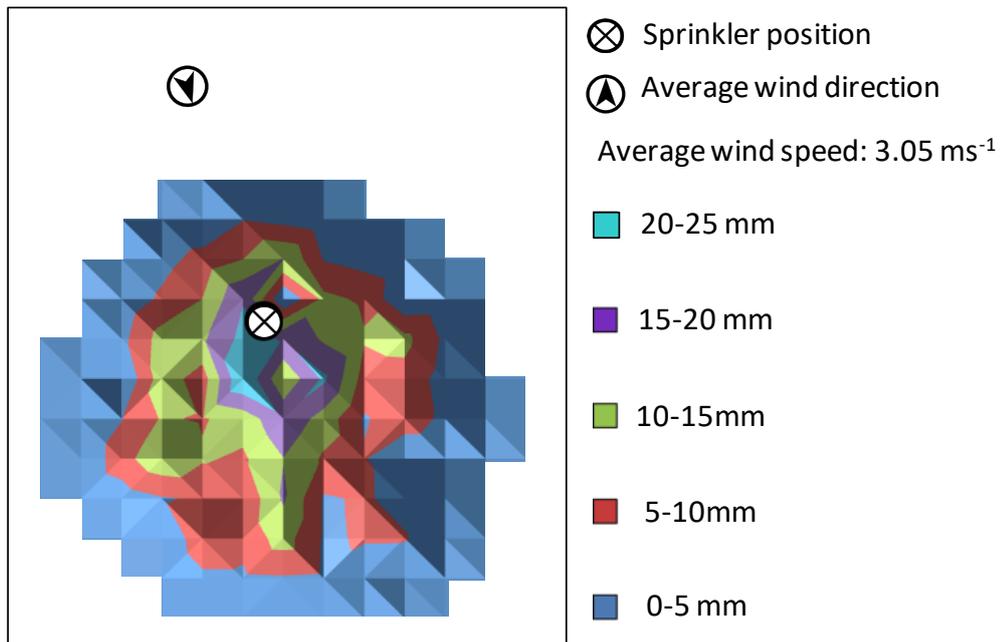

331

### 332   **3. Results and discussion**

333 The test bench developed enables the performance analysis of sprinklers with  
334 different operating characteristics and wind conditions. In order to show the potential of  
335 the information generated, an example of application of the equipment was described.  
336 Furthermore, analysis of the results and the potential to determine the influence of  
337 different variables on the water uniformity distribution were presented.

### 338 3.1. Example of data extracted in a field test.

339 The results presented correspond to one in-field irrigation test extracted from the  
340 total dataset, and are always characterized by a constant wind speed and direction (wind  
341 speed standard deviation not exceeding  $1 \text{ m}\cdot\text{s}^{-1}$  and  $20^\circ$  in direction). Figure 7 represents  
342 an example of the data obtained from the DAS with the boundary conditions displayed  
343 in Table 4.

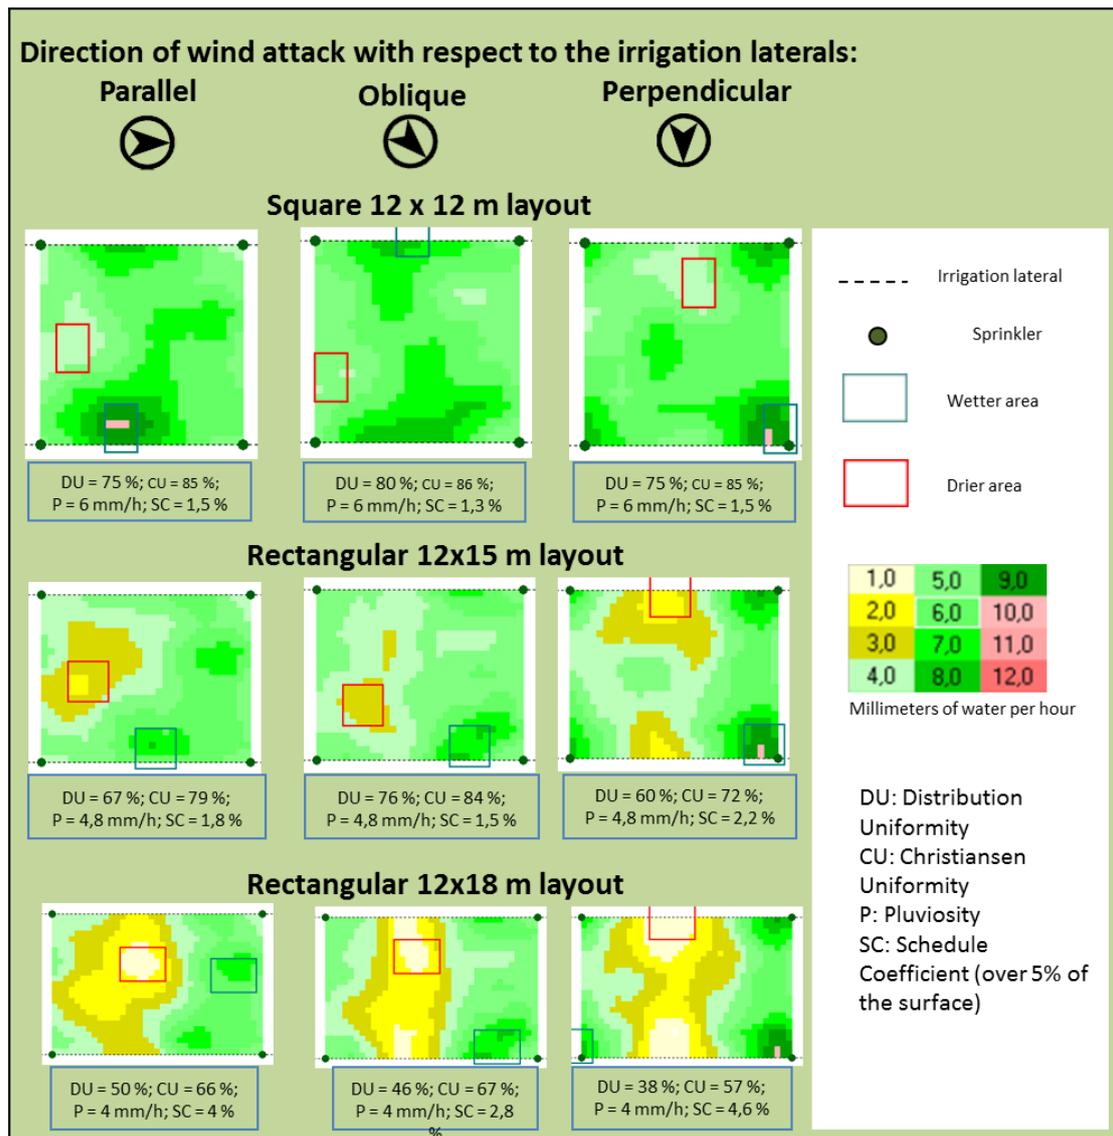

345 **Figure 7.** Unirain F46 sprinkler water distribution pattern during one in-field test

346 Table 4. Variables involved in the test

| <b>Variable</b>        | <b>Description</b>                                  |
|------------------------|---|
| Tested sprinkler       | Unirain F46 sprinkler (Unirain S.A., Spain)         |
| Nozzles diameter       | 3.17 mm (primary) and 2.38 mm with vane (secondary) |
| Working pressure       | 300 kPa   |
| Test duration          | 60 min  |
| Sprinkler height       | 1.30 m  |
| Average wind speed     | 3.05 m·s <sup>-1</sup>                              |
| Average wind direction | 5.99 rad with respect to geographic North           |
| Sprinkler flow rate    | 954 L·h <sup>-1</sup>                               |

347

348           Afterwards, the numerical data of these results was introduced in the Space Pro  
349 program to calculate CU and DU with different irrigation layouts and wind directions.  
350 In this way, the water distribution for different irrigation layout configurations is  
351 calculated for the three already defined wind directions. Figures 8 and 9 show the  
352 results for the most common irrigation layouts in Spain. These results are only a sample  
353 of the capacity for analysis of sprinkler irrigation uniformity. In addition, any other  
354 layouts and wind direction can also be simulated.

355

356 **Figure 8.** Results of the trial for an example with three irrigation layouts and three wind  
357 directions.

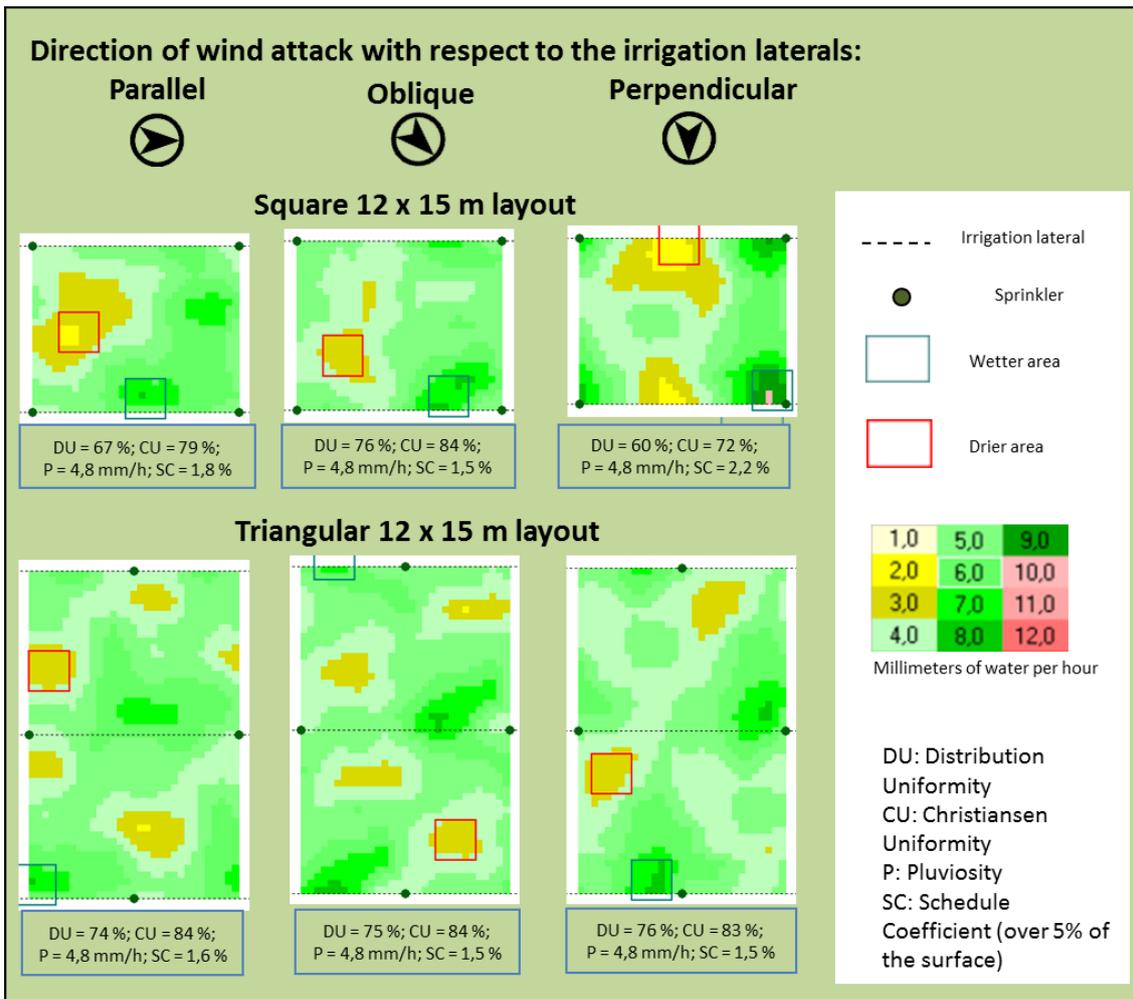

358 Figure 8 shows the results for 12 x 12, 12 x 15 and 12 x 18 m layouts in three  
359 wind directions (parallel, oblique and perpendicular to the irrigation lateral). The best  
360 values of uniformity indicators are obtained for the 12 x 12 m layout, which differ  
361 depending on the wind direction. For all the layouts, a small improvement in DU is  
362 observed with an oblique wind, compared to other conditions, while the perpendicular  
363 wind direction offers the worst results. For the 12 x 15 m and 12 x 18 m layouts, the  
364 coefficients obtained present lower values (the worst being the latter) and the

365 differences between the three types of wind direction are more pronounced. In the third  
366 case, the differences between parallel and oblique types are attenuated, being the  
367 perpendicular wind which leads to the worst coefficients.

368         On the other hand, the option of using similar layouts with different shapes has  
369 been studied. Figure 9 shows a comparison between the 12 x 15 m rectangular  
370 configuration analysed in the previous case with a triangular staggered 15 x 12 m  
371 sprinkler layout. Similar values of the coefficients are observed with an oblique wind.  
372 However, if the wind is parallel or perpendicular to the laterals, a considerable  
373 improvement using a triangular layout is obtained. Therefore, in a situation where the  
374 wind direction is not oblique or often changes, a triangular configuration would be  
375 recommended for this layout. Thus, thanks to this type of analysis, an improvement in  
376 uniformity can be achieved by simply changing the configuration without any additional  
377 investment cost.

378

379

381

382 **Figure 9.** Results of the trial comparing the rectangular layout with the triangular 12 x  
383 15 m layout.

384            Taking into account all the combinations, there were 29160 results generated  
385 with the automatic bench. Therefore, the irrigation uniformity in most common  
386 situations occurring in the field was analysed. In addition to this number of results, any  
387 wind scenario could be extrapolated from existing experimental data using the  
388 methodology proposed by Han et al. (1994).

389            With the design of this prototype of automatic test bench, and thanks to the  
390 combination of methodologies for data treatment, overlapping layouts and simulation of

391 multiple wind directions, a vast amount of information is available for each one of the  
392 tested sprinklers. Therefore, by means of a query tool in the results database, any  
393 scenario can be assessed as desired.

### 394 **3.2. Example study of the influence of several variables on the irrigation** 395 **uniformity for different types of sprinklers.**

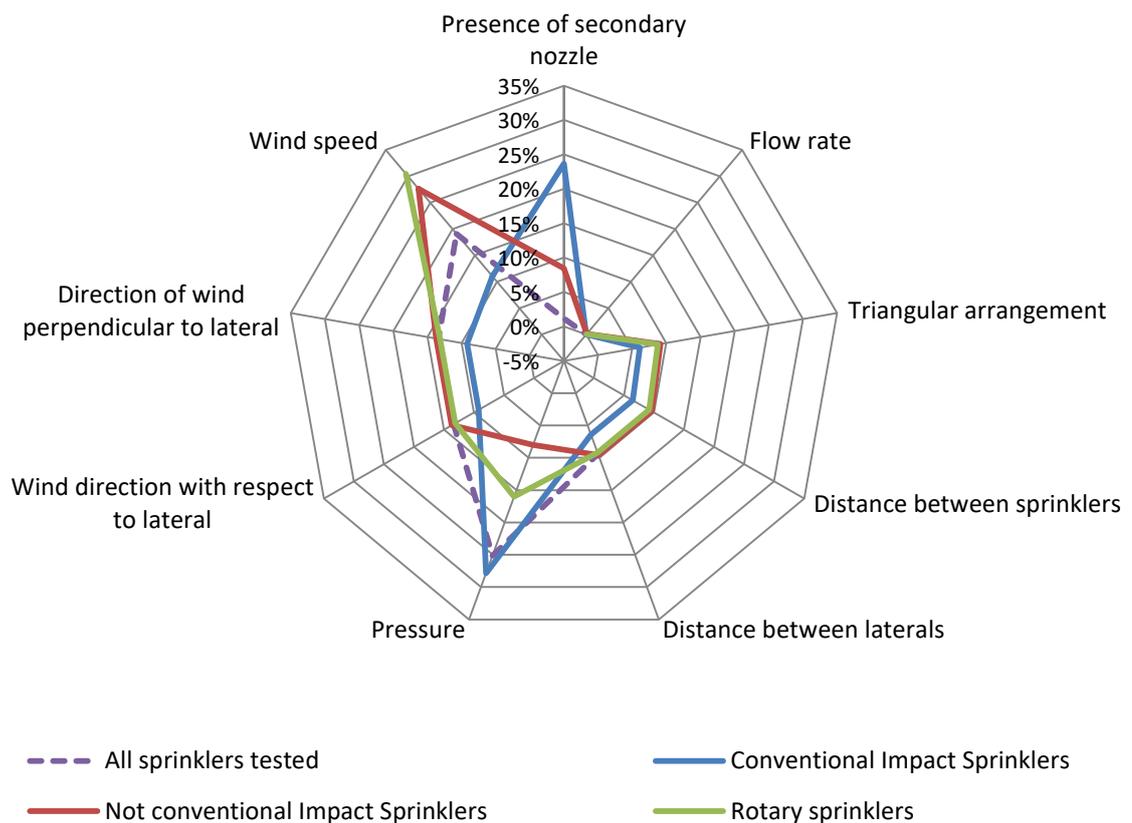

396 The set of results obtained with the test bench can be used for multiple  
397 objectives with a strategic purpose. This section presents an example of use for the  
398 generated results. In this case, a mathematical model for a global data analysis with both  
399 dependent and independent variables is used. This technique allows researchers to  
400 establish relationships among dataset variables. The results have been classified  
401 according to the sprinkler type as determined in the Materials and methods section:

- 402 - Set 1: 12150 results of uniformity coefficients for conventional impact rotary  
403 head sprinklers with hexagonal nozzles.
- 404 - Set 2: 10206 results of uniformity coefficients for non-conventional impact  
405 rotary head sprinklers with bayonet nozzles.
- 406 - Set 3: 6804 results of uniformity coefficients for rotary sprinklers.

407 Figure 10 shows the result of applying a multiple linear regression to the three  
408 sets of sprinklers. The  $R^2$  values are: 0.5801 for all analysed sprinklers, 0.7392 for the  
409 conventional impact sprinklers, 0.6017 for not conventional impact sprinklers, and  
410 0.581 for rotary sprinklers. All are acceptable values for a multiple linear regression.  
411 The influence of each variable on the irrigation uniformity for the different groups of  
412 sprinklers considered is estimated in the graphic.

413 This analysis produces ample information for irrigation management and system  
414 design decisions. For example, when using conventional impact sprinklers, the layout or

415 wind conditions had less influence. However, the working pressure and the existence of  
 416 a secondary nozzle were key factors. On the other hand, for non-conventional impact or  
 417 rotary sprinklers, the layout and the wind were the most important variables, based on a  
 418 large dataset.

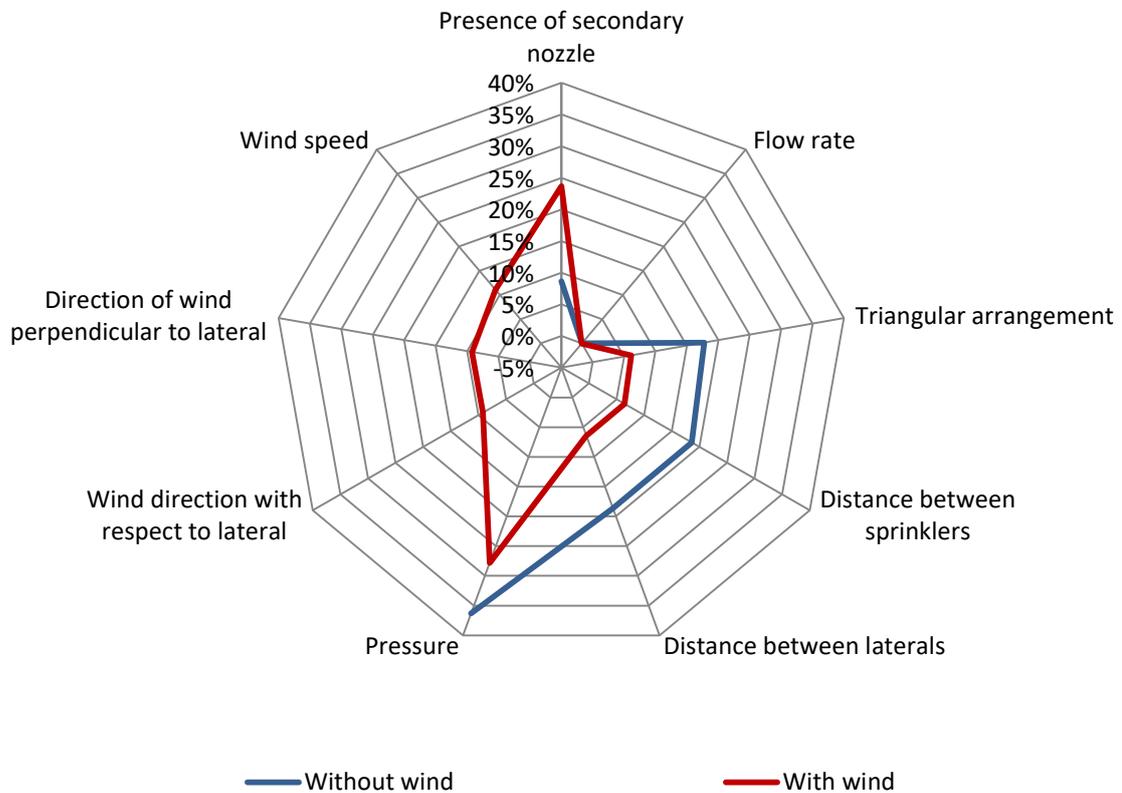

419

420 **Figure 10.** Influence of each variable on the irrigation uniformity of in each set of  
 421 sprinklers tested with wind.

422 The scale of analysis can be reduced as shown in Figure 11, which compares the  
 423 set of conventional impact sprinklers with and without wind (7128 results obtained from  
 424 a conventional radial bench). The  $R^2$  values are: 0.6345 with no wind and 0.7392 in  
 425 windy conditions. In this case the number of results is lower and the objective of the  
 426 analysis is different. In this example, pressure and layout of the sprinklers are less

427 important in wind conditions than with no wind, but the presence of a secondary nozzle  
 428 has a greater effect when there is wind.

429

430 **Figure 11.** Influence of each variable on the irrigation uniformity of conventional  
 431 impact sprinklers with and without wind.

432 Other authors like Faria et al. (2013) have also pointed out the potential of using  
 433 computational simulation as an aid to determine the water distribution uniformity of  
 434 sprinklers working under different conditions. Thanks to the large amount of data  
 435 generated, the most impactful variables in play for each situation can be determined.

436

#### 437 **4. Conclusions**

438           The automatic sprinkler test bench developed is a useful tool that allows  
439 generating a vast amount of experimental data regarding irrigation uniformity for  
440 sprinklers. With the application of semiempirical models of wind simulation, it will be  
441 possible to predict any irrigation situation that might occur in reality. It can be used for  
442 in-field tests of different models of sprinklers and wind conditions, speeding up the  
443 information gathering time required to simulate the uniformity of sprinkler irrigation  
444 systems.

445           By performing multiple tests for different sprinklers, a database will be obtained,  
446 serving as support for an expert system for characterizing any scenario that can occur in  
447 the field. This constitutes an unprecedented tool for advising both on the design of the  
448 sprinkler irrigation systems and on optimal operation. It will also serve to optimize  
449 existing facilities by introducing small changes in their management, not involving  
450 large investments.

451

#### 452 **Acknowledgements**

453 We would like to thank the ‘Instituto de Investigación y Formación Agraria y Pesquera  
454 de Andalucía’ for the financing of the project through the ‘Sistema de Asesoramiento al  
455 Regante’ program.
