Dead-zone

In this paper, a fuzzy adaptive variable-structure controller is investigated for a class of uncertain multi-input multi-output (MIMO) chaotic systems with both sector nonlinearities and dead-zones. A suitable adaptive fuzzy system is used to reasonably approximate the uncertain functions. A Lyapunov approach is employed to derive the parameter adaptation laws and prove the boundedness of all signals of the closed-loop system as well as the exponential convergence of the closed-loop errors to an adjustable region. The proposed controller can be applied to the systems with or without sector nonlinearities and/or dead-zones in the input. The effectiveness of the proposed fuzzy adaptive controller is illustrated throughout simulation results.

1. Introduction

Chaotic system is a very complex dynamical nonlinear system and its response exhibits some specific features such as excessive sensitivity to initial conditions, broad Fourier transform spectrums, and irregular identities of the motion in phase plane (Chen & Ueta, 1999; Vanecek & Celikovsky, 1996). Chaos control problem was firstly considered by Ott, Grebogi, and Yorke (1990). Since then, it has been extensively investigated in the past two decades (Chen & Dong, 1998). Several (linear and nonlinear) control techniques have been successfully applied for the control of chaotic systems (for synchronisation, tracking, or stabilisation purposes) such that: PID control (Ghezi & Peccardi, 1997), adaptive feedback control (Feki, 2003; Hua, Guan, & Shi, 2005), observer-based control (Boulkroune, Chekireb, Tadjine, & Bouatmane, 2006; Boulkroune, Chekireb, Tadjine, & M'Saad, 2006; Boulkroune, Chekireb, Tadjine, & Bouatmane, 2007), sliding-mode control (Ablay, 2009; Nazzal & Natsheh, 2007; Yau, Chen, & Chen, 2000), adaptive backstepping control (Ge & Wang, 2000; Wang & Ge, 2001), adaptive fuzzy control (Boulkroune et al., 2006; Chang, 2001; Liu & Zheng, 2009; Poursamad & Markazi, 2009; Roopaei & Jahromi, 2008; Roopaei, Jahromi, & Jafari, 2009), adaptive neural control (Ge & Wang, 2002), etc. A key assumption in all previous control schemes (Ablay, 2009; Boulkroune, Chekireb, Tadjine, & Bouatmane, 2006; Boulkroune, Chekireb, Tadjine, & M'Saad, 2006; Boulkroune et al., 2007; Chang, 2001; Feki, 2003; Ghezi and Peccardi, 1997; Ge and

Wang, 2000, 2002; Hua et al., 2005; Liu and Zheng, 2009; Nazzal and Natsheh, 2007; Poursamad and Markazi, 2009; Roopaei and Jahromi, 2008; Roopaei et al., 2009; Wang and Ge, 2001; Yau et al., 2000) is that the chaotic system *has linear inputs*.

The control problem of uncertain nonlinear (chaotic or non-chaotic) systems *with nonlinear inputs* has received a great interest because of the input nonlinearities, such as saturation, backlash, dead-zones, and so on, naturally originate from physical limitations in system realization (Boulkroune, M'Saad, Tadjine, & Farza, 2008; Hsu, Wang, & Lin, 2004). It is worth mentioning that the existence of input nonlinearities may leads to notable performance degradations or even instability of the control system. It is thereby more advisable to take into account the effects of the input nonlinearities in the control design as well as the stability analysis. Recently, some control schemes have been proposed (Chang, 2007; Chiang, Hung, Yan, Yang, & Chang, 2007; Hung, Yan, & Liao, 2008; Yan, Shyu, & Lin, 2005) for a class of chaotic systems *with input sector nonlinearities and/or dead-zones*. However, these underlying results suffer from some fundamental limitations. Firstly, the class considered of the chaotic systems is relatively simple (i.e. the chaotic systems considered in these works is not of type MIMO). Secondly, the so-called *gain reduction tolerances* of the input nonlinearities and upper bounds of the model uncertainties are required to be known or partially known.

Motivated by works in Yan et al. (2005), Chiang et al. (2007), Chang (2007) and Hung et al. (2008), one aims at designing a fuzzy adaptive variable-structure controller for a class of uncertain chaotic MIMO systems containing both sector nonlinearities and dead-zones. Bearing in mind the available results (Chang, 2007; Chiang et al., 2007; Hung et al., 2008; Yan et al., 2005), the main contributions of this paper are:

- The class considered of the chaotic systems is MIMO.
- The knowledge of gain reduction tolerances of the nonlinear dead-zones is not necessary in the controller design.
- The upper bounds of the uncertainties (i.e. nonlinear functions) are assumed to be unknown and estimated by using adaptive fuzzy systems.

2. Notation, problem statement and preliminaries

Consider the following class of uncertain chaotic MIMO systems described by:

$$\begin{aligned} y_1^{(r_1)} &= f_1(x) + \sum_{j=1}^p (g_{1j} \Phi_j(u_j)) + d_1(t), \\ &\vdots \\ y_p^{(r_p)} &= f_p(x) + \sum_{j=1}^p (g_{pj} \Phi_j(u_j)) + d_p(t), \end{aligned} \quad (1)$$

where $x = [y_1, \dot{y}_1, \dots, y_1^{(r_1-1)}, \dots, y_p, \dot{y}_p, \dots, y_p^{(r_p-1)}]^T \in R^r$ is the overall state vector which is assumed to be available for measurement and $u = [u_1, \dots, u_p]^T \in R^p$ is the control input vector, $y = [y_1, \dots, y_p]^T \in R^p$ is the output vector, and $f_i(x)$, $i = 1, \dots, p$ are unknown continuous nonlinear functions, g_{ij} , $i, j = 1, \dots, p$ are unknown constant control-gains, $\Phi(u) = [\Phi_1(u_1), \Phi_2(u_2), \dots, \Phi_p(u_p)]^T$ is a nonlinear input function vector satisfying some properties which will be given later, and $d_i(t)$ are unknown external disturbances.

Let us denote

$$y^{(r)} = [y_1^{(r_1)} \dots y_p^{(r_p)}]^T, \quad F(x) = [f_1(x) \dots f_p(x)]^T, \\ D(t) = [d_1(t) \dots d_p(t)]^T, \quad G = \begin{bmatrix} g_{11} & \dots & g_{1p} \\ \vdots & \ddots & \vdots \\ g_{p1} & \dots & g_{pp} \end{bmatrix}.$$

Then, the system (1) can be rewritten in the following compact form:

$$y^{(r)} = F(x) + G\Phi(u) + D(t), \quad (2)$$

where $F(\cdot)$, $\Phi(\cdot)$, $D(\cdot) \in R^p$ and $G(\cdot) \in R^{p \times p}$.

Now, we make the following reasonable assumptions.

Assumption 1 The desired trajectory vector $x_d = [x_{d1}^T, \dots, x_{dp}^T, y_{d1}^{(r_1)}, \dots, y_{dp}^{(r_p)}]^T$, where $x_{di} = [y_{di}, \dot{y}_{di}, \dots, y_{di}^{(r_i-1)}]^T$, $\forall i = 1, \dots, p$, is supposed to be continuous, bounded and available for measurement. Then, $x_d \in \Omega_{x_d} \subset R^{r+p}$, with Ω_{x_d} is a known compact set.

Assumption 2

- (a) Without loss of generality, we assume that the unknown control-gains matrix G is symmetric and positive-definite. As a result, there exists an unknown positive constant σ_{g0} , such that: $G \geq \sigma_{g0} I_p$, with I_p is the $p \times p$ identity matrix.
- (b) The disturbance $d_i(t)$ is bounded as follows: $|d_i(t)| \leq \bar{d}_i$, $\forall i = 1, \dots, p$, with \bar{d}_i is unknown positive constant.

Remark 1

- (a) The model (2) can be used to describe a large class of MIMO or SISO (chaotic or non chaotic) nonlinear dynamical systems namely:
- Robotic systems: e.g. single-link robot, two-link robotic manipulator used in Kar and Behera (2009),

- Induction motors (Youcef & Wahba, 2009),
- Some mechanical systems: e.g. mass-spring-damper system in Chen, Lin, and Chen (2008),
- Chaotic systems: e.g. Chua's circuit (Chang, 2001), Unified chaotic system (Lü, Chen, Cheng, & Celikovskyy, 2002; Ablay, 2009), Arneodo chaotic system (Hua et al., 2005), gyro system (Roopaei et al., 2009), Genesio chaotic system, Rössler system, Duffing and Holmes system, and many others.

(b) Assumption 2a is not restrictive, as it is satisfied by many physical systems. Note that this assumption is frequent in the literature devoted to adaptive (fuzzy or neural) control of MIMO systems. Also, it guarantees the controllability of the system (1).

(c) Note that the fundamental results of this paper can be adapted, with few modifications, to the case where G is symmetric and negative-definite.

The objective of this paper is to design a control law u such as the output vector y follows the specified desired trajectory $y_d = [y_{d1}, \dots, y_{dp}]^T \in R^p$, with all involved signals in the closed-loop system remain bounded.

Let us define the tracking error by

$$\begin{aligned} e_1 &= y_1 - y_{d1}, \\ &\vdots \\ e_p &= y_p - y_{dp} \end{aligned} \quad (3)$$

and the filtered tracking error as

$$S = [S_1, \dots, S_p]^T \quad (4)$$

with

$$S_i = \left[\frac{d}{dt} + \lambda_i \right]^{r_i-1} e_i, \quad \text{for } \lambda_i > 0, \quad \forall i = 1, \dots, p. \quad (5)$$

Then, we can write (5) as follows

$$S_i = \lambda_i^{r_i-1} e_i + (r_i - 1) \lambda_i^{r_i-2} \dot{e}_i + \dots + (r_i - 1) \lambda_i e_i^{(r_i-2)} + e_i^{(r_i-1)}, \quad (6)$$

with $i = 1, \dots, p$.

Notice that if we choose $\lambda_i > 0$, with $i = 1, \dots, p$, then the roots of the polynomial $H_i(s) = \lambda_i^{r_i-1} + (r_i - 1) \lambda_i^{r_i-2} s + \dots + (r_i - 1) \lambda_i s^{r_i-2} + s^{r_i-1}$ related to the characteristic equation of $S_i = 0$ are all in the open left-half plane.

The relation (6) can be rewritten in the following compact form

$$S_i = C_i^T E_i \quad (7)$$

with

$$E_i = \begin{bmatrix} e_i & \dot{e}_i & \dots & e_i^{(r_i-2)} & e_i^{(r_i-1)} \end{bmatrix}^T, \quad (8)$$

$$C_i^T = \begin{bmatrix} \lambda_i^{r_i-1} & (r_i - 1) \lambda_i^{r_i-2} & \dots & (r_i - 1) \lambda_i & 1 \end{bmatrix}. \quad (9)$$

Consequently, the vector S takes the form:

$$S = C^T E, \quad (10)$$

where

$$C^T = \text{diag} \left[C_1^T \ C_2^T \ \dots \ C_p^T \right]_{(p \times r)}, \quad (11)$$

$$E = \begin{bmatrix} E_1^T & E_2^T & \dots & E_p^T \end{bmatrix}_{(r \times 1)}^T. \quad (12)$$

And the dynamic of S_i is described by:

$$\dot{S}_i = C_i^T \dot{E}_i + e_i^{(r_i)}, \quad \text{and } i = 1, \dots, p, \quad (13)$$

where C_{ri} is given by

$$C_{ri}^T = [0 \lambda_i^{r_i-1} (r_i - 1) \lambda_i^{r_i-2} \dots 0.5(r_i - 1)(r_i - 2) \lambda_i^2 (r_i - 1) \lambda_i]. \quad (14)$$

The dynamic of S can be written in the following compact form

$$\dot{S} = C_r^T E + e^{(r)}, \quad (15)$$

where

$$C_r^T = \text{diag} [C_{r1}^T \ C_{r2}^T \ \dots \ C_{rp}^T]_{(p \times r)}, \quad (16)$$

$$e^{(r)} = [e_1^{(r_1)} \ e_2^{(r_2)} \ \dots \ e_p^{(r_p)}]^T \quad (17)$$

with

$$e^{(r)} = y^{(r)} - y_d^{(r)}, \quad (18)$$

where $y^{(r)} = [y_1^{(r_1)} \ y_2^{(r_2)} \ \dots \ y_p^{(r_p)}]^T$ is previously defined, and

$$y_d^{(r)} = [y_{d1}^{(r_1)} \ y_{d2}^{(r_2)} \ \dots \ y_{dp}^{(r_p)}]^T, \quad (19)$$

From (18), we can write (15) as follows

$$\dot{S} = C_r^T E + y^{(r)} - y_d^{(r)}. \quad (20)$$

Thereafter, (20) will be used in the development of the proposed controller and the stability analysis.

2.1. Description of the fuzzy logic system

The basic configuration of a fuzzy logic system consists of a fuzzifier, some fuzzy IF-THEN rules, a fuzzy inference engine and a defuzzifier, as shown in Fig. 1. The fuzzy inference engine uses the fuzzy IF-THEN rules to perform a mapping from an input vector $\underline{x}^T = [x_1, x_2, \dots, x_n] \in R^n$ to an output $\hat{f} \in R$.

The i th fuzzy rule is written as

$$R^{(i)}: \text{ if } x_1 \text{ is } A_1^i \text{ and } \dots \text{ and } x_n \text{ is } A_n^i \text{ then } \hat{f} \text{ is } f^i, \quad (21)$$

where A_1^i, A_2^i, \dots , and A_n^i are fuzzy sets and f^i is the fuzzy singleton for the output in the i th rule. By using the singleton fuzzifier, product inference, and center-average defuzzifier, the output of the fuzzy system can be expressed as follows:

$$\hat{f}(\underline{x}) = \frac{\sum_{i=1}^m f^i \left(\prod_{j=1}^n \mu_{A_j^i}(x_j) \right)}{\sum_{i=1}^m \left(\prod_{j=1}^n \mu_{A_j^i}(x_j) \right)} = \theta^T \psi(\underline{x}), \quad (22)$$

where $\mu_{A_j^i}(x_j)$ is the degree of membership of x_j to A_j^i , m is the number of fuzzy rules, $\theta^T = [f^1, f^2, \dots, f^m]$ is the adjustable parameter vector (composed of consequent parameters), and $\psi^T = [\psi^1, \psi^2, \dots, \psi^m]$, with

$$\psi^i(\underline{x}) = \frac{\left(\prod_{j=1}^n \mu_{A_j^i}(x_j) \right)}{\sum_{i=1}^m \left(\prod_{j=1}^n \mu_{A_j^i}(x_j) \right)} \quad (23)$$

is the fuzzy basis function (FBF). Throughout the paper, it is assumed that the FBFs are selected so that there is always at least one active rule (Wang, 1994), i.e. $\sum_{i=1}^m \left(\prod_{j=1}^n \mu_{A_j^i}(x_j) \right) > 0$.

It is worth noting that the fuzzy system (22) is commonly used in control applications. Following the universal approximation results (Wang, 1994), the fuzzy system (22) is able to approximate any nonlinear smooth function $f(\underline{x})$ on a compact operating space to an arbitrary degree of accuracy. Of particular importance, it is assumed that the structure of the fuzzy system (i.e. the pertinent inputs, the number of membership functions for each input and the number of rules) and the membership function parameters are properly specified beforehand. The consequent parameters, i.e. θ , are determined by adaptation algorithms.

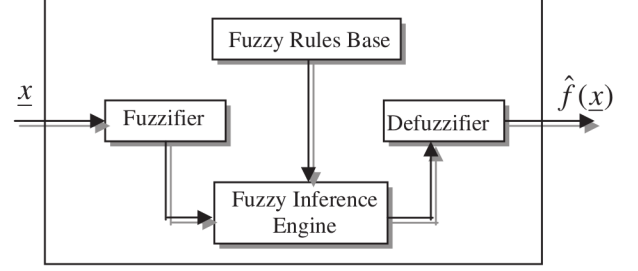

Fig. 1. The basic configuration of a fuzzy logic system.

2.2. Input nonlinearity

The mathematical model of the input nonlinearity $\Phi_i(u_i)$ is described by

$$\Phi_i(u_i) = \begin{cases} \phi_{i+}(u_i)(u_i - u_{i+}), & u_i > u_{i+}, \\ 0, & -u_{i-} \leq u_i \leq u_{i+}, \\ \phi_{i-}(u_i)(u_i + u_{i-}), & u_i < -u_{i-}, \end{cases} \quad (24)$$

where $\phi_{i+}(u_i) > 0$ and $\phi_{i-}(u_i) > 0$ are nonlinear functions of u_i , and $u_{i+} > 0$, $u_{i-} > 0$ are constants.

The input nonlinearity $\Phi_i(u_i)$ satisfies the following important properties:

$$\begin{aligned} (u_i - u_{i+})\Phi_i(u_i) &\geq m_{i+}^*(u_i - u_{i+})^2, & u_i > u_{i+}, \\ (u_i + u_{i-})\Phi_i(u_i) &\geq m_{i-}^*(u_i + u_{i-})^2, & u_i < -u_{i-}, \end{aligned} \quad (25)$$

where m_{i+}^* and m_{i-}^* are constants called “gain reduction tolerances”. Let us denote $\eta_i = \min \{m_{i+}^*, m_{i-}^*\}$.

In order to study the characteristics of this input nonlinearity in the control problems, the following assumptions are made:

Assumption 3

- The gain reduction tolerances, m_{i+}^* and m_{i-}^* , are unknown. Therefore, η_i is also unknown.
- The explicit mathematical expression of $\Phi_i(u_i)$ is uncertain, except the properties (25) and constants u_{i+} and u_{i-} (which are assumed to be known).

Remark 2

- It is clear from (24) and (25) that for $u_{i+} = u_{i-} = 0$, the input nonlinearity $\Phi_i(u_i)$ is reduced to the special sector nonlinear function. Hence, the considered MIMO system with the input nonlinearities (24) is a more general form.
- Note that the model (24) has also been used in Yan et al. (2005), Chiang et al. (2007), Chang (2007) and Hung et al. (2008). Compared to our contribution, these papers have the following limitations:

- The considered class of chaotic systems is a simple SISO system with sector nonlinearities and/or dead-zones.
- The gain reduction tolerances m_{i+}^* and m_{i-}^* or their minimum $\eta_i = \min \{m_{i+}^*, m_{i-}^*\}$ are assumed to be known.
- The upper bounds of uncertainties are required to be known.

3. Design of the fuzzy adaptive controller

In this section, a fuzzy adaptive variable-structure control scheme is developed for the class of unknown chaotic MIMO systems described by (2).

By substituting (2) into (20), the dynamics of S become

$$\dot{S} = C_r^T E + F(x) + G\Phi(u) + D(t) - y_d^{(r)}. \quad (26)$$

Posing $G_1 = G^{-1}$ and $D_g(t) = G^{-1}D(t)$, we have

$$G_1 \dot{S} = G_1 [C_r^T E - y_d^{(r)} + F(x)] + \Phi(u) + D_g(t). \quad (27)$$

To facilitate the stability analysis and control design, we rewrite the dynamics of S as follows

$$\begin{aligned} G_1 \dot{S} &= G_1 [C_r^T E - y_d^{(r)} + F(x)] + \Phi(u) + D_g(t) \\ &= \alpha(x, v) + \Phi(u) + D_g(t), \end{aligned} \quad (28)$$

where $\alpha(x, v) = [\alpha_1(x, v), \alpha_2(x, v), \dots, \alpha_p(x, v)]^T = G_1[v + F(x)]$ and $v = C_r^T E - y_d^{(r)}$.

Assumption 4. There exists an unknown continuous positive function $\bar{\alpha}_i(x)$ such that:

$$|\alpha_i(x, v)| \leq \eta \bar{\alpha}_i(x), \quad \forall x \in \Omega_x \subset R^r.$$

where $\eta = \min_i \{\eta_i\}$.

Remark 3. Assumption 4 is not restrictive for the following reasons:

- The upper bound $\eta \bar{\alpha}_i(x)$ is assumed to be unknown.
- Since v is a function of (x, x_d) , $x_d \in L_\infty$ and $\alpha_i(x, v)$ is a continuous function, therefore such a function (i.e. $\bar{\alpha}_i(x)$) always exists.

The unknown continuous nonlinear function $\bar{\alpha}_i(x)$ can be approximated, on a compact set Ω_x , by the fuzzy systems (22) as follows:

$$\hat{\alpha}_i(x, \theta) = \theta_i^T \psi_i(x), \quad (29)$$

where $\psi_i(x)$ is the FBF vector, which is fixed a priori by the designer, and θ_i is the adjustable parameter vector of the fuzzy system.

Let us define

$$\theta_i^* = \arg \min_{\theta_i} \left[\sup_{x \in \Omega_x} |\bar{\alpha}_i(x) - \hat{\alpha}_i(x, \theta_i)| \right] \quad (30)$$

as the optimal values of θ_i .

Note that the optimal values of θ_i are *artificial constant quantities* introduced only for analysis purposes, and their values are not needed when implementing the controller.

Define

$$\tilde{\theta}_i = \theta_i - \theta_i^*$$

as the parameter estimation error, and

$$\varepsilon_i(x) = \bar{\alpha}_i(x) - \hat{\alpha}_i(x, \theta_i^*) \quad (31)$$

is the fuzzy approximation error, where $\hat{\alpha}_i(x, \theta_i^*) = \theta_i^{*T} \psi_i(x)$.

As in the literature (Boukroune et al., 2006; Boukroune et al., 2008; Boukroune, Tadjine, M'saad, & Farza, 2008; Boukroune, M'Saad, Tadjine, & Farza, 2010; Chang, 2001; Liu & Zheng, 2009; Roopaei & Jahromi, 2008; Roopaei et al., 2009; Poursamad & Markazi, 2009; Wang, 1994; Youcef & Wahba, 2009), we assume that the used fuzzy systems do not violate the universal approximator property on the compact set Ω_x , which is assumed large enough so that the input vector of the fuzzy system remains in Ω_x under closed-loop control system. So it is reasonable to assume that the fuzzy approximation error is bounded for all $x \in \Omega_x$, i.e.

$$|\varepsilon_i(x)| \leq \bar{\varepsilon}_i, \quad \forall x \in \Omega_x,$$

where $\bar{\varepsilon}_i$ is an unknown constant.

From the above analysis, we have

$$\begin{aligned} \hat{\alpha}_i(x, \theta_i) - \bar{\alpha}_i(x) &= \hat{\alpha}_i(x, \theta_i) - \hat{\alpha}_i(x, \theta_i^*) + \hat{\alpha}_i(x, \theta_i^*) - \bar{\alpha}_i(x), \\ &= \hat{\alpha}_i(x, \theta_i) - \hat{\alpha}_i(x, \theta_i^*) - \varepsilon_i(x), \\ &= \tilde{\theta}_i^T \psi_i(x) - \varepsilon_i(x). \end{aligned} \quad (32)$$

To meet the control objective, a suitable fuzzy adaptive variable-structure controller is proposed as follows:

$$u_i = \begin{cases} -\rho_i(t) \text{sign}(S_i) - u_{i-}, & S_i > 0, \\ 0, & S_i = 0, \\ -\rho_i(t) \text{sign}(S_i) + u_{i+}, & S_i < 0, \end{cases} \quad (33)$$

with $\rho_i(t) = k_{0i} + k_{1i}|S_i| + \theta_i^T \psi_i(x)$, $\forall i = 1, \dots, p$ and

$$\dot{k}_{0i} = -\gamma_{0i} \sigma_{0i} k_{0i} + \gamma_{0i} |S_i|, \quad k_{0i}(0) \geq 0, \quad (34)$$

$$\dot{\theta}_i = -\gamma_{1i} \sigma_{1i} \theta_i + \gamma_{1i} |S_i| \psi_i(x), \quad \theta_{i0}(0) \geq 0, \quad (35)$$

where γ_{0i} , γ_{1i} , σ_{0i} , σ_{1i} , $k_{1i} > 0$ are design constants, and k_{0i} and θ_i are the online estimates of the uncertain terms $k_{0i}^* = \bar{\varepsilon}_i + \bar{d}_{gi}$ and θ_i^* , respectively. Note that \bar{d}_{gi} are unknown positive constants which satisfy: $\sum_{i=1}^p \bar{d}_{gi} |S_i| \geq |S^T D_g(t) / \eta|$.

Remark 4. With $k_{0i}(0) \geq 0$ and $\theta_i(0) \geq 0$, it follows from adaptive laws (34) and (35) that their respective solutions satisfy $k_{0i}(t) \geq 0$ and $\theta_i(t) \geq 0$, for $t > 0$.

Multiplying (28) by S^T and using Assumption 4, we have

$$\begin{aligned} \frac{1}{\eta} S^T G_1 \dot{S} &= \frac{1}{\eta} S^T \alpha(x, v) + \frac{1}{\eta} S^T \Phi(u) + \frac{1}{\eta} S^T D_g(t) \\ &\leq \sum_{i=1}^p |S_i| \bar{\alpha}_i(x) + \frac{1}{\eta} S^T \Phi(u) + \frac{1}{\eta} S^T D_g(t). \end{aligned} \quad (36)$$

From (32) and (36), we get

$$\begin{aligned} \frac{1}{\eta} S^T G_1 \dot{S} &\leq \sum_{i=1}^p |S_i| \bar{\alpha}_i(x) + \frac{1}{\eta} S^T \Phi(u) + \frac{1}{\eta} S^T D_g(t) \\ &\leq -\sum_{i=1}^p |S_i| \tilde{k}_{0i} - \sum_{i=1}^p |S_i| \tilde{\theta}_i^T \psi_i(x) + \sum_{i=1}^p |S_i| k_{0i} \\ &\quad + \sum_{i=1}^p |S_i| \theta_i^T \psi_i(x) + \frac{1}{\eta} S^T \Phi(u), \end{aligned} \quad (37)$$

where $\tilde{\theta}_i = \theta_i - \theta_i^*$ and $\tilde{k}_{0i} = k_{0i} - k_{0i}^* = k_{0i} - \bar{\varepsilon}_i - \bar{d}_{gi}$.

Theorem 1. Consider the system (2) and suppose that Assumptions 1–4 are satisfied. Then, the control law defined by (33)–(35) guarantees the following properties:

- All signals in the closed loop system are uniformly ultimately bounded.
- The solution of the closed-loop error system exponentially converges to an adjustable region.

Proof of Theorem 1. Let us consider the following Lyapunov function candidate:

$$V = \frac{1}{2\eta} S^T G_1 S + \frac{1}{2} \sum_{i=1}^p \frac{1}{\gamma_{0i}} \tilde{k}_{0i}^2 + \frac{1}{2} \sum_{i=1}^p \frac{1}{\gamma_{1i}} \tilde{\theta}_i^T \tilde{\theta}_i. \quad (38)$$

Its time derivative is given by

$$\dot{V} = \frac{1}{\eta} S^T G_1 \dot{S} + \sum_{i=1}^p \frac{1}{\gamma_{0i}} \tilde{k}_{0i} \dot{\tilde{k}}_{0i} + \sum_{i=1}^p \frac{1}{\gamma_{1i}} \tilde{\theta}_i^T \dot{\tilde{\theta}}_i \quad (39)$$

with $\dot{\tilde{G}}_1 = 0$.

We can easily show from (33) that $u_i < -u_{i-}$ for $S_i > 0$ and $u_i > u_{i+}$ for $S_i < 0$. Thus, we get from (25) and (33), that for $S_i > 0$

$$(u_i + u_{i-})\Phi_i(u_i) = -\rho_i(t)\text{sign}(S_i)\Phi_i(u_i) \geq m_{i-}^*\rho_i^2(t) \geq \eta\rho_i^2(t) \quad (40)$$

and for $S_i < 0$

$$(u_i - u_{i+})\Phi_i(u_i) = -\rho_i(t)\text{sign}(S_i)\Phi_i(u_i) \geq m_{i+}^*\rho_i^2(t) \geq \eta\rho_i^2(t). \quad (41)$$

Then, for $S_i < 0$ and $S_i > 0$, we have

$$-\rho_i(t)\text{sign}(S_i)\Phi_i(u_i) \geq \eta\rho_i^2(t). \quad (42)$$

From (42) and using the facts $S_i^2 > 0$ and $S_i\text{sign}(S_i) = |S_i|$, we have

$$-\rho_i(t)S_i^2\text{sign}(S_i)\Phi_i(u_i) \geq \eta\rho_i^2(t)S_i^2 = \eta\rho_i^2(t)|S_i|^2. \quad (43)$$

Finally for all S_i (i.e. for $S_i < 0$, $S_i = 0$ and $S_i > 0$), we have

$$S_i\Phi_i(u_i) \leq -\eta\rho_i(t)|S_i|. \quad (44)$$

Using the expressions (34), (35), (44) and (37), (39) becomes

$$\begin{aligned} \dot{V} &\leq \sum_{i=1}^p |S_i|k_{0i} + \sum_{i=1}^p |S_i|\theta_i^T\psi_i(x) + \frac{1}{\eta} \sum_{i=1}^p S_i\Phi_i(u_i) - \sum_{i=1}^p \sigma_{0i}\tilde{k}_{0i}k_{0i} \\ &\quad - \sum_{i=1}^p \sigma_{1i}\tilde{\theta}_i^T\theta_i \leq \sum_{i=1}^p |S_i|k_{0i} + \sum_{i=1}^p |S_i|\theta_i^T\psi_i(x) + \sum_{i=1}^p -\rho_i(t)|S_i| \\ &\quad - \sum_{i=1}^p \sigma_{0i}\tilde{k}_{0i}k_{0i} - \sum_{i=1}^p \sigma_{1i}\tilde{\theta}_i^T\theta_i \\ &= -\sum_{i=1}^p k_{1i}S_i^2 - \sum_{i=1}^p \sigma_{0i}\tilde{k}_{0i}k_{0i} - \sum_{i=1}^p \sigma_{1i}\tilde{\theta}_i^T\theta_i. \end{aligned} \quad (45)$$

We can easily verify that

$$\begin{aligned} -\sigma_{0i}\tilde{k}_{0i}k_{0i} &\leq -\frac{\sigma_{0i}}{2}\tilde{k}_{0i}^2 + \frac{\sigma_{0i}}{2}k_{0i}^{*2} \\ -\sigma_{1i}\tilde{\theta}_i^T\theta_i &\leq -\frac{\sigma_{1i}}{2}\|\tilde{\theta}_i\|^2 + \frac{\sigma_{1i}}{2}\|\theta_i^*\|^2. \end{aligned}$$

Using the previous inequalities, (45) becomes

$$\dot{V} \leq -\sum_{i=1}^p k_{1i}S_i^2 - \sum_{i=1}^p \frac{\sigma_{0i}}{2}\tilde{k}_{0i}^2 - \sum_{i=1}^p \frac{\sigma_{1i}}{2}\|\tilde{\theta}_i\|^2 + \sum_{i=1}^p \frac{\sigma_{0i}}{2}k_{0i}^{*2} + \sum_{i=1}^p \frac{\sigma_{1i}}{2}\|\theta_i^*\|^2. \quad (46)$$

Since $G \geq \sigma_{g0}I_p$ (recall that the matrix G is symmetric and positive-definite), then

$$S^T G^{-1} S = S^T G_1 S \leq \frac{1}{\sigma_{g0}} \|S\|^2. \quad (47)$$

From (46) and (47), we have

$$\dot{V} \leq -\mu V + \pi, \quad (48)$$

$$\begin{aligned} \text{where } \pi &= \sum_{i=1}^p \frac{\sigma_{0i}}{2} k_{0i}^{*2} + \sum_{i=1}^p \frac{\sigma_{1i}}{2} \|\theta_i^*\|^2 \\ \mu &= \min\{\min_i\{2\eta\sigma_{g0}k_{1i}\}, \min_i\{\gamma_{0i}\sigma_{0i}\}, \min_i\{\gamma_{1i}\sigma_{1i}\}\}. \end{aligned}$$

Multiplying (48) by $e^{\mu t}$ yields

$$\frac{d}{dt}(Ve^{\mu t}) \leq \pi e^{\mu t}. \quad (49)$$

Integrating (49) over $[0, t]$, we have

$$0 \leq V(t) \leq \frac{\pi}{\mu} + \left(V(0) - \frac{\pi}{\mu}\right)e^{-\mu t}. \quad (50)$$

Therefore, all signals of the closed-loop system, i.e. k_{0i} , θ_i , S_i , E and x , are uniformly ultimately bounded. Then, u_i is also bounded.

From (38), $V(0)$ can be determined as follows

$$\begin{aligned} V(0) &= \frac{1}{2\eta} S(0)^T G_1 S(0) + \frac{1}{2} \sum_{i=1}^p \frac{1}{\gamma_{0i}} (k_{0i}(0) - k_{0i}^*)^2 + \frac{1}{2} \sum_{i=1}^p \\ &\quad \times \frac{1}{\gamma_{1i}} (\theta_i(0) - \theta_i^*)^T (\theta_i(0) - \theta_i^*). \end{aligned} \quad (51)$$

Since G_1 is symmetric and positive-definite (i.e. it exists an unknown positive constant σ_{g1} , such that: $G_1 \geq \sigma_{g1}I_p$), from (50) and (38), we have

$$|S_i| \leq \left(\frac{2\eta}{\sigma_{g1}} \left(\frac{\pi}{\mu} + \left(V(0) - \frac{\pi}{\mu} \right) e^{-\mu t} \right) \right)^{1/2}.$$

Then, the solution of S_i exponentially converges to a bounded region

$$\Omega_{S_i} = \left\{ S_i \mid |S_i| \leq \left(\frac{2\eta}{\sigma_{g1}} \frac{\pi}{\mu} \right)^{1/2} \right\}. \text{ This ends the proof of the theorem. } \square$$

Remark 5 If $\Phi_i(u_i) = u_i$ (or when $u_{i+} = u_{i-} = 0$, and $\phi_{i+}(u_i) = \phi_{i-}(u_i) = 1$), i.e. there are no both dead-zones and sector nonlinearities in the input function, we can show that the proposed controller remains still applicable to such MIMO chaotic systems.

Remark 6

- (1) In the case where $u_{i+} = u_{i-} = u_{i0}$, (33) is reduced to the following expression:

$$u_i = -(\rho_i(t) + u_{i0})\text{sign}(S_i), \quad (52)$$

where $\rho_i(t) = k_{0i} + k_{1i}|S_i| + \theta_i^T\psi_i(x)$.

- (2) To eliminate the chattering effect caused by the discontinuous control term in (33) and (52), the function $\text{sign}(\cdot)$ must be replaced by any equivalent smooth function such as: $\tanh(\cdot)$, $\arctan(\cdot)$, $\text{Sat}(\cdot)$...etc.

4. Simulation results

In this section, simulation studies are carried out to show the effectiveness of the proposed adaptive fuzzy controller. For this end, we consider the tracking control problem of the uncertain unified-chaotic system. This unified-chaotic system introduced by Lü et al. (2002) is described by the following dynamics (Ablay, 2009):

$$\begin{cases} \dot{x}_1 = (25\alpha + 10)(x_2 - x_1), \\ \dot{x}_2 = (28 - 35\alpha)x_1 + (29\alpha - 1)x_2 - x_1x_3, \\ \dot{x}_3 = x_1x_2 - (8 + \alpha)x_3/3, \end{cases} \quad (53)$$

where x_1, x_2, x_3 are state variables and $\alpha \in [0, 1]$ is the system parameter. When $\alpha \in [0, 0.8]$, system (53) is called the generalized Lorenz chaotic system (Lorenz, 1963). When $\alpha = 0.8$, system (53) is called the Lü chaotic system (Lü & Chen, 2002), and when $\alpha \in [0.8, 1]$, system (53) is called the generalized Chen chaotic system (Chen & Ueta, 1999). It is worth noting that the unified chaotic system can be seen in atmospheric sciences, laser devices, and other systems related to convection (Ablay, 2009).

The unified-chaotic system with control inputs and external-disturbances is described by:

$$\begin{cases} \dot{x}_1 = (25\alpha + 10)(x_2 - x_1) + \Phi_1(u_1) + d_1(t), \\ \dot{x}_2 = (28 - 35\alpha)x_1 + (29\alpha - 1)x_2 - x_1x_3 + \Phi_2(u_2) + d_2(t), \\ \dot{x}_3 = x_1x_2 - (8 + \alpha)x_3/3 + \Phi_3(u_3) + d_3(t), \end{cases} \quad (54)$$

where $\Phi_i(u_i)$, $i = 1, 2, 3$, are the models of the inevitable input nonlinearities.

Let $y = x = [x_1, x_2, x_3]^T$, $u = [u_1, u_2, u_3]^T$, $\Phi(u) = [\Phi_1(u_1), \Phi_2(u_2), \Phi_3(u_3)]^T$, and $D(t) = [d_1(t), d_2(t), d_3(t)]^T$. Then, the system (eq. (54)) can be expressed as follows:

$$\dot{y} = F(x) + G\Phi(u) + D(t), \quad (55)$$

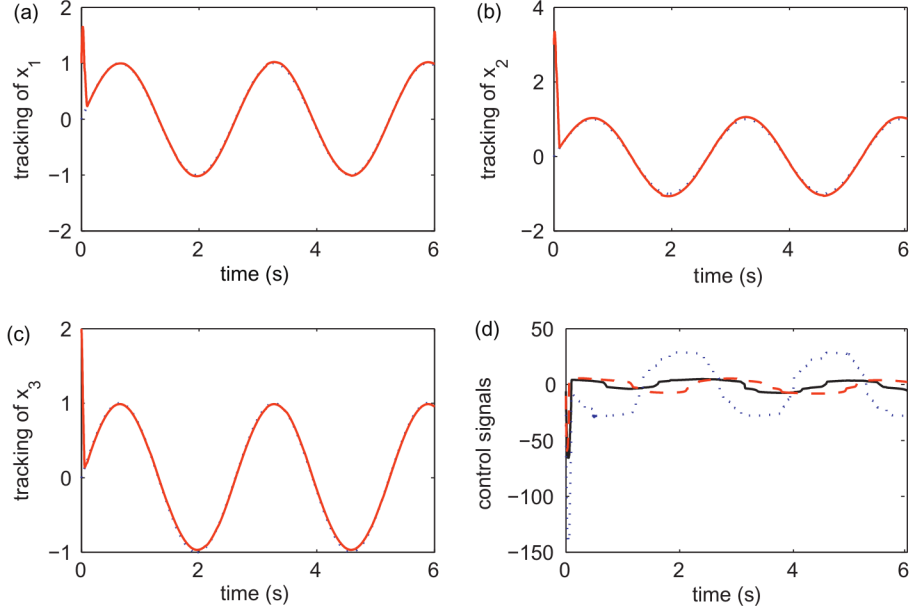

Fig. 2. Simulation results (with $\alpha = 0.8$). **(a)** Tracking of x_1 : x_1 (solid line) and x_{d1} (dotted line). **(b)** Tracking of x_2 : x_2 (solid line) and x_{d2} (dotted line). **(c)** Tracking of x_3 : x_3 (solid line) and x_{d3} (dotted line). **(d)** Control input signals applied at $t = 0$ s: u_1 (solid line), u_2 (dotted line) and u_3 (dashed line).

Fig. 3. Simulation results (with $\alpha = 1$). **(a)** Tracking of x_1 : x_1 (solid line) and x_{d1} (dotted line). **(b)** Tracking of x_2 : x_2 (solid line) and x_{d2} (dotted line). **(c)** Tracking of x_3 : x_3 (solid line) and x_{d3} (dotted line). **(d)** Control input signals applied at $t = 0$ s: u_1 (solid line), u_2 (dotted line) and u_3 (dashed line).

where

$$F(x) = \begin{pmatrix} (25\alpha + 10)(x_2 - x_1) \\ (28 - 35\alpha)x_1 + (29\alpha - 1)x_2 - x_1x_3 \\ x_1x_2 - (8 + \alpha)x_3/3 \end{pmatrix}, \quad G = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

The input nonlinearities, $\Phi_i(u_i)$, for $i = 1, 3$, are described by:

$$\Phi_i(u_i) = \begin{cases} (u_i - 2)(1 - 0.3 \sin(u_i)), & u_i > 2, \\ 0, & -2 \leq u_i \leq 2, \\ (u_i + 2)(0.8 - 0.3 \cos(u_i)), & u_i < -2, \end{cases}$$

But, the input nonlinearity $\Phi_2(u_2)$ is supposed to be:

$$\Phi_2(u_2) = \begin{cases} (u_2 - 5)(1 - 0.3 \sin(u_2)), & u_2 > 5, \\ 0, & -5 \leq u_2 \leq 5, \\ (u_2 + 5)(0.8 - 0.3 \cos(u_2)), & u_2 < -5, \end{cases}$$

It is worth noting that the system model (i.e. $F(x)$, G , $\Phi(u)$ and $D(t)$) is assumed to be unknown by the controller, except some structural properties such as:

- The symmetry and the sign of G ,
- The properties (25) of $\Phi_i(u_i)$ and the knowledge of u_{i+} and u_{i-} , with $i = 1, 2, 3$.

In fact, the model (54) is only required here for simulation purposes.

The initial conditions of the system are taken as $x(0) = [x_1(0), x_2(0), x_3(0)]^T = [1, 3, 2]^T$. The desired trajectories are selected as $x_{d1} = x_{d2} = x_{d3} = \sin(2.4t)$. The external disturbances are selected as follows: $d_1(t) = d_2(t) = d_3(t) = \sin(t)$.

The adaptive fuzzy systems, $\theta_i^T \psi_i(x)$, with $i = 1, 2, 3$, have the vector $x = [x_1, x_2, x_3]^T$ as input. For each entry variable of these fuzzy systems, as in Boulkroune et al. (2008), we define three triangular membership functions uniformly distributed on the intervals $[-2, 2]$. The design parameters are chosen as follows: $\gamma_{01} = \gamma_{03} = 30$, $\gamma_{02} = 80$, $\gamma_{11} = \gamma_{12} = \gamma_{13} = 4000$, $\sigma_{01} = \sigma_{02} = \sigma_{03} = 0.001$, $\sigma_{11} = \sigma_{12} = \sigma_{13} = 0.0005$, $\lambda_1 = \lambda_2 = \lambda_3 = 2$, $k_{11} = k_{12} = k_{13} = 2$. The initial conditions are selected as: $k_{01}(0) = k_{02}(0) = k_{03}(0) = 0$, $\theta_{1j}(0) = \theta_{2j}(0) = \theta_{3j}(0) = 0, j = 1, \dots, 27$.

Note that, in all simulations, the discontinuous function $\text{sign}(S_i)$ has been replaced by a smooth function $\tanh(k_{si}S_i)$, with $k_{si} = 20$, $i = 1, 2, 3$.

According to the value of α , we will consider two simulation cases:

- $\alpha = 0.8$, the proposed controller is applied to Lü chaotic system,
- $\alpha = 1$, the proposed controller is applied to the generalized Chen chaotic system.

(a) Case 1 (when $\alpha = 0.8$) The simulation results of the proposed controller applied at time $t = 0$ s are shown in Fig. 2. These simulation results clearly show that the tracking performance is nice. Consequently the effects due to system uncertainties, unavoidable input nonlinearities (dead-zone and sector nonlinearity) and bounded external disturbances in Lü chaotic system can be efficiently diminished by the proposed fuzzy adaptive control scheme. From this figure, we can also see the boundedness of the control signals.

(b) Case 2 (when $\alpha = 1$) The simulation results of this case are shown in Fig. 3. From these simulation results, we can see that the states (x_1, x_2, x_3) quickly converge to respective desired trajectories (x_{d1}, x_{d2}, x_{d3}) by activation of control signals at time $t = 0$ s.

5. Conclusion

In this paper, a fuzzy adaptive variable-structure controller for a class of MIMO unknown chaotic systems subject to actuator sector nonlinearities and dead-zones has been proposed. An adaptive fuzzy system has been used to reasonably approximate the upper bounds of the uncertainties. Of fundamental interest, it has been proven by using a Lyapunov approach that the proposed control system is stable and its underlying tracking error converges exponentially to an adjustable region. Simulation results have been given to emphasize the effectiveness of the proposed controller.
