30    **Abstract**

31    The production of anti-Zika virus (ZIKV) therapeutics has become increasingly important as the propagation of the  
32    devastating virus continues largely unchecked. Notably, a causal relationship between ZIKV infection and  
33    neurodevelopmental abnormalities has been widely reported, yet a specific mechanism underlying impaired  
34    neurological development has not been identified. Here, we report on the design of several synthetic competitive  
35    inhibitory peptides against key pathogenic ZIKV proteins through the prediction of protein-protein interactions (PPIs).  
36    Often, PPIs between host and viral proteins are crucial for infection and pathogenesis, making them attractive targets  
37    for therapeutics. Using two complementary sequence-based PPI prediction tools, we first produced a comprehensive  
38    map of predicted human-ZIKV PPIs (involving 209 human protein candidates). We then designed several peptides  
39    intended to disrupt the corresponding host-pathogen interactions thereby acting as anti-ZIKV therapeutics. The data  
40    generated in this study constitute a foundational resource to aid in the multi-disciplinary effort to combat ZIKV  
41    infection, including the design of additional synthetic proteins.

42    **Introduction**

43    The Zika virus (ZIKV) is currently causing an ongoing pandemic, incurring considerable human impact. The rapid  
44    spread of the virus throughout the Western hemisphere has driven a significant accumulation of knowledge on ZIKV  
45    infection [1–4]. The ZIKV is a positive-sense single stranded RNA (+ssRNA) arbovirus from the genus *Flavivirus*  
46    [5,6]. A mature ZIKV virion contains a monopartite segment of +ssRNA 10,800 nucleotides enclosed in a capsid  
47    comprised of C-proteins and surrounded by a 50 nm spherical envelope. The membrane is comprised of membrane  
48    (M) and envelope (E) proteins arranged around the icosahedral capsid. The entire genome is translated into a single  
49    polyprotein 3,419 amino acids in length, which is cleaved at ten locations to produce 11 individual proteins. Despite  
50    significant similarity to other *Flaviviridae*, the ZIKV results in some symptoms that are not associated with members  
51    of this viral family such as Dengue or Yellow Fever [7].

52    Host-virus protein-protein interactions (PPIs) are essential for viral infection and propagation as well as neuroinvasion  
53    [8]. The ZIKV appears to be highly neuroinvasive ( $6.5 \times 10^7$  viral RNA copies/mg of brain tissue [9]) and has been  
54    linked to numerous neurological complications including congenital brain abnormalities [10], infant microcephaly  
55    [11], Guillain-Barré syndrome [12], and meningoencephalitis [13]. Additionally, the ZIKV has been found to cause  
56    testicular atrophy [14], and may be spread as a sexually transmitted infection [15].

57 Investigating the host-virus interactome is an important step in identifying targets for novel anti-viral therapeutics  
58 [16]. Designing molecules, such as competitive peptides that interfere with these PPIs, can serve as efficient anti-viral  
59 therapies [17–19]. An early example of such anti-viral peptides is S6 — a 111 amino acid long fragment of human  
60 integrase interactor protein 1 which forms a PPI with HIV-1 integrase protein. S6 is shown to be an effective inhibitor  
61 of HIV-1 replication [20].

62 Global PPI prediction analysis is a robust method for probing the network of host-pathogen interactions that occur at  
63 various stages of the viral life cycle. Recognition of pertinent PPIs between host cell proteins and ZIKV components  
64 can guide the development of synthetic inhibitory peptides capable of disrupting such interactions. In the current study,  
65 we use this approach to generate a list of specific peptide sequences that might function in combating ZIKV infection.  
66 We believe that the overproduction of these synthetic peptides may interfere with several human-ZIKV PPIs, thus  
67 interrupting the ZIKV lifecycle. Considering that the World Health Organization has lifted the declaration of  
68 emergency for the ZIKV, shifting to threat management of the ZIKV is important as many mechanisms of  
69 pathogenesis are still unclear. The designed peptides provided here may therefore prove to be useful therapeutics  
70 against ZIKV infection, and could aid in overall ZIKV management.

71 **Materials and Methods**

72 **PIPE Prediction**

73 From the suite of available sequence-based methods, the Protein-Protein Interaction Prediction Engine (PIPE) excels  
74 in terms of specificity and execution time [21]. PIPE was developed to investigate short co-occurring polypeptide  
75 sequences between two proteins to determine their likelihood of interaction [22–24]. This likelihood of interaction is  
76 captured by two scores: PIPE-Score and Similarity-Weighted score (further described in Pitre *et al*, 2008) [24]. Two  
77 datasets were used to perform the PIPE analysis, the first using the entire set of known human-virus interactions  
78 (irrespective of virus type) and the second considering only interactions specific to the *Flaviviridae*, *Herpeviridae*,  
79 *Arteriviridae*, and *Coronaviridae* families. PIPE analysis was applied to all combinations of human-ZIKV (20,515  
80 human proteins, 11 ZIKV proteins). This resulted in a high confidence interaction network comprising the top-scoring  
81 0.02% of predicted PPIs including 45 human-ZIKV interactions corresponding to 23 unique human proteins. From  
82 these 23 candidates, we chose the top 17 to further investigate based on their apparent relevance to human health.

83 **DeNovo Prediction**

84 DeNovo is a host-virus PPI prediction tool tailored to predict cross-species protein interactions for newly identified  
85 viral organisms for which no interaction data are previously known [25]. Given the lack of known interactions for the  
86 ZIKV, DeNovo is well suited to this task. Similar to PIPE, DeNovo is a sequence-based method designed to leverage  
87 all currently known viral interaction data [25]. Unlike PIPE, however, DeNovo exploits the physiochemical properties  
88 of the human host's proteins to inform its predictions [25]. Learning these characteristics in the commonly shared  
89 human host, across all known host-viral interactions, enhances the discovery of interactions in the organism of interest.  
90 Determining the high confidence interactions as those with a probability of interaction greater than or equal to 80%  
91 resulted in 871 human-ZIKV interactions (0.38% of all putative PPIs) corresponding to 186 candidate human proteins  
92 (supplementary table 1). From these 186 candidates, we performed a literature search on eight due to their relevance  
93 to ZIKV infection to supplement the 17 from the PIPE analysis.

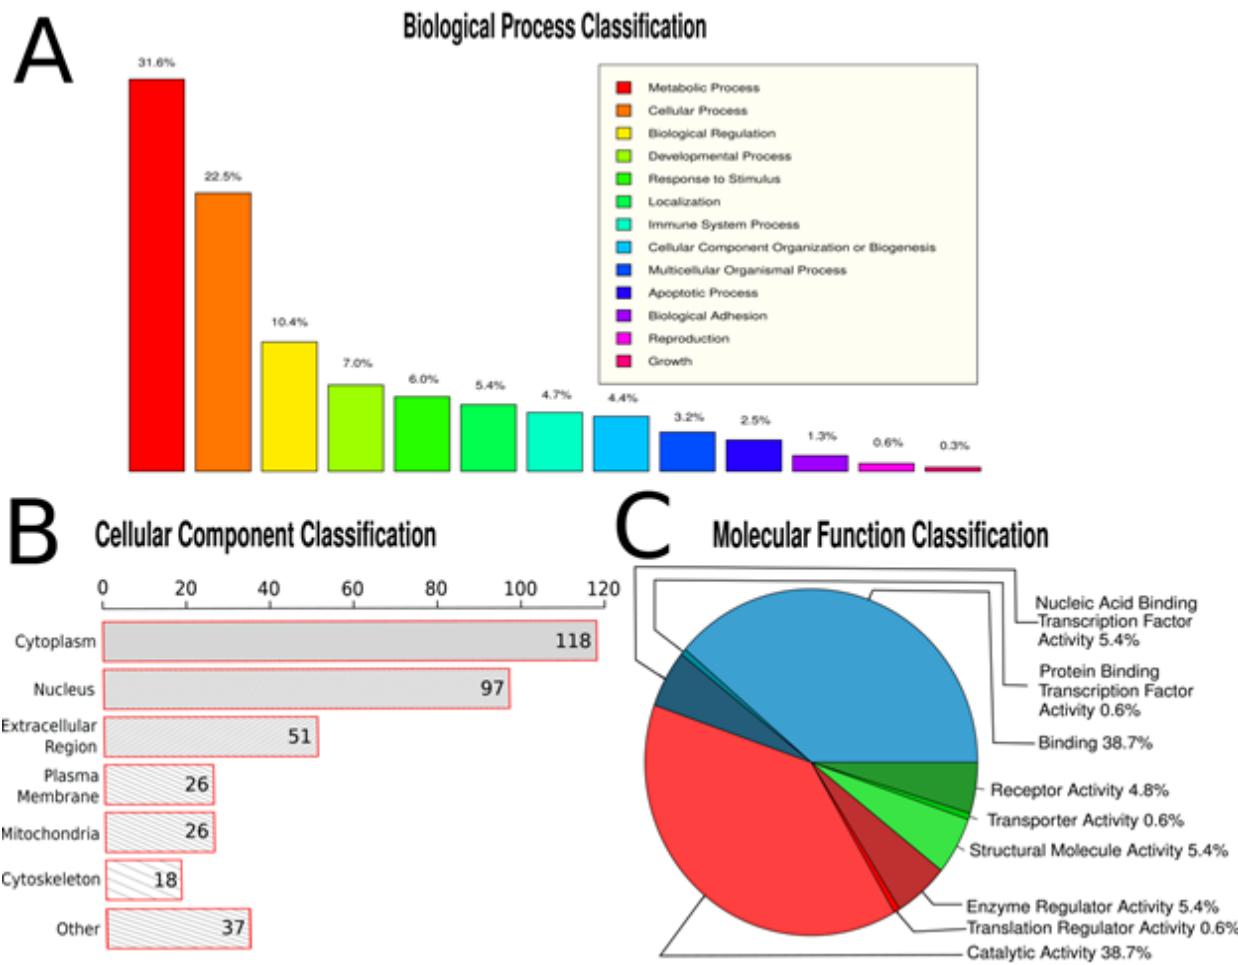

#### 94 **Prediction of PPI-Sites**

95 The list of PPIs generated from both methods can be used to inform the design of anti-ZIKV therapeutics by using  
96 peptide sequences from the predicted PPI site, which we refer to as the PPI-Site. We define the PPI-Site as the peptide  
97 sequence that is responsible for mediating the PPIs. When PIPE predicts an interaction between the two corresponding  
98 proteins, it will also report the predicted site of interaction using the amino acid sequences from both proteins. Using  
99 our previously reported PIPE output, we selected for PIPE's built-in peak height attribute, which we refer to as H.  
100 This is a measure of the number of times two corresponding sequence pairs co-occur within the annotated database of  
101 known PPI normalized to its expected occurrence. Selecting for H within our top 17 interactions produced 4 human-  
102 ZIKV PPI-Sites which we believe mediate the human-ZIKV PPIs.

#### 103 **Results**

104 To generate a list of anti-ZIKV peptides, we first predicted a network of PPIs between humans and the ZIKV. This  
105 was accomplished using two complementary computational modeling methods — each trained on currently known  
106 high-confidence human-viral interactions obtained from VirusMentha (incorporating the MINT, IntAct, DIP,  
107 MatrixDB, and BioGRID databases) [26]. The first method, PIPE, is proficient in host-virus interaction prediction and  
108 has successfully been used to predict novel interactions in humans, yeast, and most recently in viruses (Hepatitis C  
109 and HIV-1) [22,24,27,28]. The second method, DeNovo, is specifically designed for the prediction of interactions  
110 between proteins from a host and newly discovered viral organisms independent of prior known host-virus interactions  
111 [25]. Figure 1 highlights the ontology classification of the 209 human proteins believed to participate in human-ZIKV

112 PPIs based on their interaction profiles from both methods. In table 1, we report a total of 25 high priority human  
113 protein (and their associated ZIKV interactors) from our list of 209 candidates based on their correlation to known  
114 mechanisms of ZIKV infection, pathology, and symptomology. Of the eleven ZIKV proteins considered, the nine  
115 interacting proteins reported in our results correspond to the structural proteins: Envelope (E), Capsid (C),  
116 Premembrane (Pr), and Membrane (M), and the non-structural proteins: NS1, NS2A, NS3, NS4B, and the RNA-  
117 dependent RNA polymerase NS5 proteins. These proteins not only highlight protein candidates for PPI-based  
118 therapeutic design, but also they may provide potential mechanisms of ZIKV infection.

119  
120 **Fig. 1** Human Protein Geneontology (GO) Classification using PANTHER GO-Slim. The evaluation of GO term  
121 enrichment for 198 of the 209 high confidence human proteins (8 unmapped proteins were excluded) for biological  
122 process (a), cellular component (b) and molecular function (c). Our list of 209 predicted high confidence human  
123 proteins can be found in supplementary table 1

124

125 **Table 1: The 25 human protein candidates determined by PIPE (P) or DeNovo (N), respective ZIKV  
126 interactors, function (F), associated disease phenotype (D), and supporting literature.**

\* indicates interaction pairs also predicted for the Dengue virus.

127 From the list of 25 candidates, we here examine a subset of four proteins - RNASET2, ENO2, TRAF4, and CEP63 of  
128 particular interest for anti-ZIKV therapeutics. The first candidate, RNASET2, has been implicated in the occurrence  
129 of microcephaly [33] which is of special interest as no proposed mechanism exists linking the ZIKV to microcephaly.  
130 The second candidate, ENO2, has been linked to early brain development of humans [60], and may be useful in the  
131 study the pathogenesis of possible ZIKV-associated neurological disorders. TRAF4 is our third candidate and has  
132 been reported to be involved in TNF-receptor activity [46]. We believe that interfering with this receptor may affect  
133 ZIKV absorption and/or release. Finally, CEP63 has been previously implicated in p53 dependent microcephaly [52].  
134 Considering that microcephaly is a hallmark of ZIKV infection in infants [61], designing a therapeutic which interrupts  
135 a ZIKV interaction with CEP63 may prove useful. We identified the site of interactions (PPI-Site) between these  
136 proteins and their ZIKV interacting partners (table 2). Overproduction of these PPI-Sites via synthetic peptides can  
137 interfere with human-ZIKV PPIs, potentially acting as competitive inhibitors against the corresponding ZIKV protein.  
138 Consequently, PPI-Sites can provide the basis for effective anti-ZIKV therapeutics.

156 **Discussion**

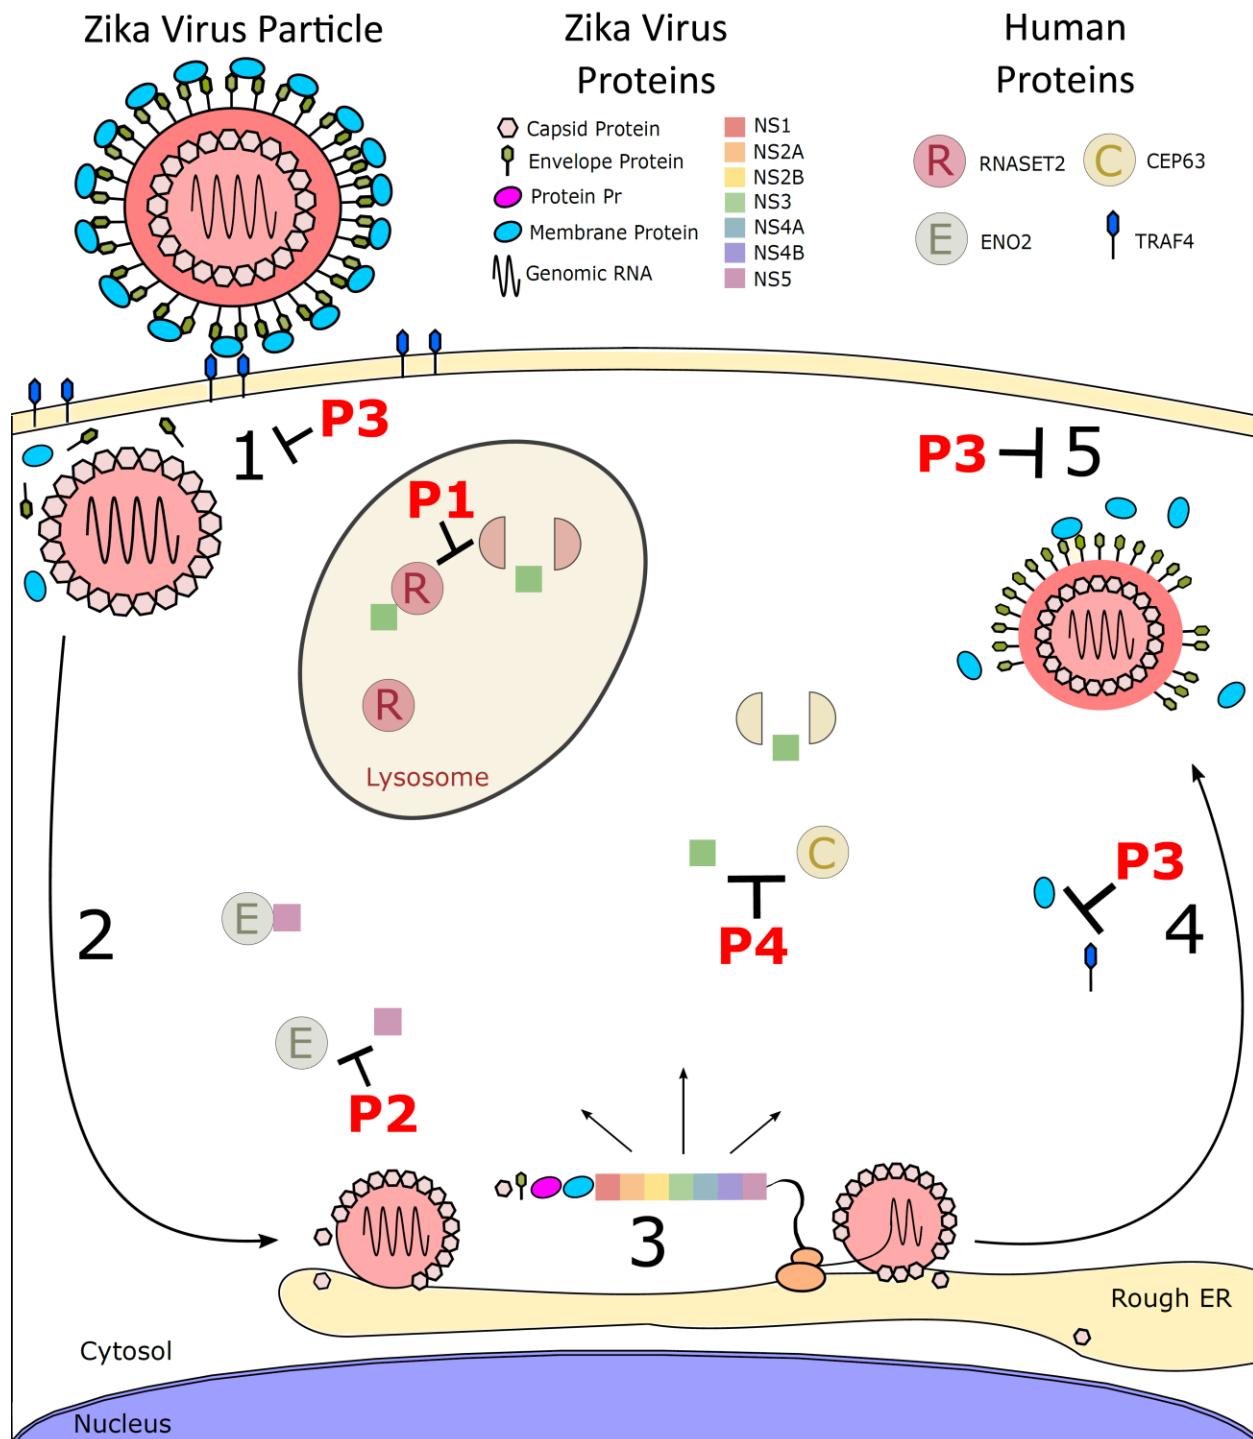

157 At the outset of this study, we sought to design anti-ZIKV therapeutics by identifying PPI-Sites from predicted human-  
158 ZIKV PPIs. By identifying these PPI-Sites on both the host and viral proteins, we provide a scaffold for the design of  
159 peptides which may inhibit ZIKV proteins or compete for binding to functionally-relevant targets. We employed two  
160 computational tools to predict PPIs, namely PIPE and DeNovo, and produced a priority list of testable protein  
161 interaction candidates which can be used as an important resource for multiple disciplines. In particular, the amino  
162 acid sequences identified here as being responsible for mediating interactions between human and ZIKV proteins can  
163 serve as the basis for engineering additional anti-ZIKV therapeutics.

164

165 One of the primary public health concerns of the ZIKV infection has been occurrence of microcephaly in newborn  
166 children who are infected with the virus, or whose mothers have been infected. It is therefore possible that the virus is  
167 acting on the fetus during pregnancy, and affecting development. Our candidate, RNASET2 has been causally linked  
168 to a range of neurologic impairments including microcephaly, multifocal white matter lesions, and anterior temporal  
169 lobe subcortical cysts [33]. RNASET2 has been shown to localize to the lysosome, where it may function in RNA  
170 catabolism [62]. Zebrafish models have established that the loss of function in RNASET2 results in neuronal  
171 lysosomal disorder [63] congruent with findings in humans that have linked lysosomal disorders to the development  
172 of microcephaly [34]. Moreover, a loss of function mutation at amino acid 184 in the RNASET2 protein has been  
173 found in infants with cystic leukoencephalopathy leading to microcephaly, white matter lesions, and other temporal  
174 lobe deficiencies [33].

175 We predicted an interaction between the human protein RNASET2 and the ZIKV serine protease NS3. Interestingly,  
176 two *Flaviviridae* (Hepatitis C and Dengue) have been found to interact with human RNASET2 protein via their NS3  
177 protein *in vitro* [64]. The proteolytic domain of the ZIKV NS3 serine protease occurs at residues 1-175 [65,66], and  
178 RNASET2 is a proteolytic target at residue 24-25, which when cleaved produces a signaling peptide and the functional

179 domain [67]. Within this functional domain exists a serine at residue 188, congruent with our predicted site of  
180 interaction (PPI-Site, residue 188-215) and four residues downstream of the leukoencephalopathy-associated  
181 mutation. Interestingly, we predict that this site interacts with the proteolytic domain of NS3 (PPI-Site, residue 1-178)  
182 which may impact the functionality of RNASET2, as the functional domain would theoretically be cleaved in two  
183 (Figure 2). Disrupting this interaction via introduction of the identified PPI-Sites (P1) in excess could disrupt the ZIKV  
184 lifecycle in the cell. Alternatively, the binding of the PPI-Site to the proteolytic domain of NS3 can interfere with the  
185 mode of action of NS3 by deactivating its proteolytic domain in a PPI independent manner. In both cases, excess of  
186 P1 may interfere with ZIKV infection and hence may function as an effective anti-ZIKV therapy.

187

188 **Fig. 2** The ZIKV lifecycle within a human cell, and the peptide drugs that may interfere with its different steps. 1: The  
189 ZIKV particle adsorbs into the human cell, possibly via TRAF4. P3 may interfere with this step. 2: The virion is  
190 uncoated in the cytoplasm. 3: ZIKV RNA undergoes translation to produce the ZIKV polypeptide. P1, P2 and P4 are  
191 designed to interfere with the activity of synthesized ZIKV polypeptides. 4: The immature virion is assembled and

192 moves to the cell membrane. 5: The ZIKV particle exits the host cell. P3 may also interfere with these last two steps.  
193 The ENO2 interaction with NS5 may impact neurodevelopment. This is the proposed site of P2 activity. The predicted  
194 interaction between RNASET2 and NS3, which we hypothesize to cleave the RNASET2 functional protein at amino  
195 acid 188 is the predicted site of P1 activity. The interaction between CEP63 and NS3 may result in a cleaved CEP63  
196 protein representing the proposed site of P4 activity. P1: SQDEEVQTIGIELCLTKQDQLQNCTEP, P2:  
197 ALISSGLSVVEQEKLNDNLMLELDGTENKSK, P3: MCALVSRQRQELQELRRELEELSVGSDGVL, and P4:  
198 QEQQQKEEKLRESEKLLEALQEEKRELKAALQSQENLIHE.

199  
200 Our additional peptide sequences come from the interactions between ENO2-NS5, TRAF4-M, and CEP63-NS3, as  
201 seen in Figure 2. These three additional human protein candidates are all involved in neurodevelopment. Specifically,  
202 ENO2 (neuron-specific enolase) is important for normal brain development in humans [30]. A member of the enolase  
203 family, ENO2 promotes cell maturation in the central nervous system [68]. During early development, neuronal cells  
204 switch from ENO1 (non-neuronal enolase) to ENO2 in order to promote brain development [29] (Figure 2).  
205 Interestingly, a similar interaction was reported by Munoz *et al.* where they describe an interaction between the *Aedes*  
206 *aegypti* enolase and Dengue virus NS5 protein [69]. The predicted P2 peptide could potentially act as competitive  
207 inhibitor for the NS5 binding site. In this way, we predict that P2 will interrupt the lifecycle of the ZIKV in the human  
208 cell, thus acting as an effective therapeutic.

209 A previous study identified AXL as a receptor candidate that is active in the ZIKV lifecycle [70]. Although not a  
210 receptor, TRAF4 is an essential element for normal TNF receptor function as TRAFs have been previously identified  
211 as adaptor proteins for membrane receptors [71]. Therefore, it is possible that the ZIKV M protein may be impacting  
212 functionality of the TNF receptor via TRAF4, possibly increasing the function of TNF. Pertaining to  
213 neurodevelopment, it has been shown that TRAF4 is required for normal neural crest formation [46]. If the ZIKV M  
214 protein is binding to TRAF4 in a inhibitory manner, it is possible that TNF receptor functionality may be impacted  
215 [71], and that neural crest formation may be negatively affected [46]. The corresponding PPI-Site derived peptide for  
216 this interaction is P3. Overproducing this peptide may interfere with ZIKV adsorption/penetration and thus act as a  
217 promising anti-ZIKV therapeutic. As well, if the ZIKV M protein is inhibiting TRAF4 leading to impaired neural crest  
218 formation, inhibiting the M protein via P3 would be ideal.

219 Finally, a short motif within centrosomal protein CEP63 was predicted to interact with the ZIKV serine protease NS3.  
220 This is an important interaction as the loss of CEP63 in mice results in microcephaly [52]. It is therefore possible that  
221 the NS3 serine protease could act on one of the two serines within the interaction site on CEP63, rendering the protein  
222 dysfunctional. Overproduction of P4 may be able to saturate NS3 activity and prevent detrimental proteolytic cleavage  
223 of the endogenous target.  
224 In this study, we have identified proteins and PPI-Sites of interest and designed a series of peptides that could be used  
225 to combat ZIKV infection. These peptides theoretically interfere with the activity of their corresponding ZIKV  
226 proteins by competing for their interacting partners. Additional manipulation and/or modification of the peptides  
227 designed in this study can lead to new anti-viral therapeutics with improved properties such as increased half-life or  
228 stronger binding properties. The information provided here can be used to develop and engineer viral therapeutics for  
229 the ZIKV, a process that has been achieved with other viruses and is proposed for the ZIKV [72,73].
