Abstract

We present version 2.1 of the *High Energy Jets* (HEJ) Monte Carlo event generator. With the new version, high-energy logarithms can now be summed to all orders in processes with final-state leptons originating from a charged or neutral vector boson together with multiple jets, in addition to processes available in earlier versions. Furthermore, the resummation is extended to include an additional gauge-invariant class of next-to-leading logarithmic corrections. HEJ 2.1 can be obtained from <https://hej.hepforge.org>.

1 Introduction

High Energy Jets (HEJ) is a Monte Carlo event generator for processes involving two or more jets. It implements the eponymous formalism for the all-order summation of high-energy logarithms in $\frac{\hat{s}}{p_T^2}$ developed in [1–3]. This summation is necessary to obtain a good description of events with large invariant masses or large rapidity separations between the outgoing particles. Extensive reviews of the formalism can be found in [4, 5].

HEJ has been validated against data in numerous studies on pure multijet production [6–9], production of a leptonically decaying W boson together with two or more jets [10–12], and the production of multiple jets together with two charged leptons, created from an intermediate photon or Z boson [13]. A further particularly interesting channel is the gluon-fusion production of a Higgs boson together with two or more jets. It constitutes the dominant background in measurements of Higgs boson production in weak boson fusion (VBF), and the application of typical VBF cuts projects out a region of phase space where the summation of high-energy logarithms yields significant corrections [14]. For this process, as well as for pure multijet production, the original leading-logarithmic (LL) summation was supplemented with a numerically important gauge-invariant subset of the next-to-leading-logarithmic (NLL) corrections to achieve a better description away from the asymptotic high-energy limit [4].

A complete redesign allowed to extend the matching between resummation and fixed-order predictions to the highest multiplicities [15], taking into account at the same time quark mass corrections in the gluon-fusion production of a Higgs boson together with jets [16]. This revised matching procedure, initially implemented for pure multijet and Higgs boson plus jets production, is the foundation of HEJ 2 [17].

Here, we present HEJ 2.1. This new version elevates the fixed-order matching for the aforementioned processes involving an intermediate W or Z boson or photon to the superior HEJ 2 procedure. Furthermore, it includes a new subset of NLL corrections for pure multijet production and the production of a W boson together with jets. With these additions, HEJ 2.1 supersedes all earlier HEJ versions. We briefly describe the addition of the processes involving intermediate vector bosons and the new NLL corrections associated with the emission of additional quark-antiquark pairs in section 2. In section 3, we give an explicit example demonstrating how HEJ 2.1 can be used to supplement leading-order descriptions of the production of two leptons with jets with high-energy resummation. We conclude in section 4.

2 Improvements over previous versions

The most significant improvements over previous versions of HEJ are the addition of high-energy resummation for the production of two leptons together with two or more jets and the inclusion of NLL corrections involving the production of an additional quark-antiquark pair. In the following, we briefly summarise how these new processes are described in the *High Energy Jets* formalism. A more detailed description of both the underlying formalism and the improvements discussed here is given in [5].

2.1 Leading-logarithmic resummation in HEJ 2

In HEJ 2, fixed-order predictions are supplemented with high-energy resummation in the following way. First, a number of leading-order events are generated. Then, for each event, it is determined whether the corresponding matrix element contributes at a logarithmic accuracy that is included in the current state-of-the-art HEJ resummation. While HEJ currently includes partial NLL resummation, we restrict the following discussion to LL resummation for the sake of clarity.

To identify event configurations contributing at LL accuracy, we order incoming and outgoing particles according to rapidity, see figure 1. We then draw a leading-order auxiliary diagram with as many t -channel gluons as possible. It should be stressed that this diagram only serves to determine the logarithmic order and is never used to compute the actual matrix element. A configuration contributes at LL accuracy iff the number of t -channel gluons is maximal, i.e. if no other rapidity ordering of an equivalent set of final-state particles allows a diagram with a larger number of t -channel gluon exchanges. By “equivalent” we mean that we do not distinguish between parton flavours, such that all final states shown in figure 1 are treated on the same footing.

Figure 1: Identification of configurations with leading-logarithmic contributions. The leftmost configuration allows the maximum of three t -channel gluon exchanges and therefore contributes at LL accuracy. The remaining configurations permit at most two t -channel gluons. They are suppressed in the high-energy limit.

If the matrix element of the currently considered event contributes at a logarithmic order that is covered by the resummation, we replace the original event with a number of newly generated events. These new events add further gluon emissions, while preserving the rapidities of the original jets and non-parton particles. Details of the procedure are given in [15]. In order to obtain an all-order resummed prediction, while at the same time retaining leading-order accuracy, the newly generated events are reweighted by a factor

$$w_{\text{res}} = \frac{|\overline{\mathcal{M}}^{\text{HEJ}}|^2}{|\overline{\mathcal{M}}_{\text{LO}}^{\text{HEJ}}|^2}, \quad (1)$$

where \mathcal{M}^{HEJ} is the all-order resummed matrix element in the high-energy limit and $\mathcal{M}_{\text{LO}}^{\text{HEJ}}$ its leading-order truncation. The bar denotes the sum (average) over outgoing (incoming) helicities and colours.

The HEJ matrix elements are the only process-specific ingredient in the resummation procedure. In the following, we recall their general structure and give results for the new processes included in HEJ 2.1.

2.2 Leading-logarithmic matrix elements

We are interested in the LL HEJ matrix elements for processes $f_a f_b \rightarrow X f_{a'} \cdot n g \cdot f_{b'}$, where X denotes any number of additional colourless outgoing particles. With the exception of X , particles are ordered according to rapidity. f_a is therefore the incoming parton in the backward direction, with flavour a , and f_b the parton in the forward direction. The most backward outgoing parton is $f_{a'}$ with rapidity y_1 , followed by n gluons with rapidities $y_2 < \dots < y_{n+1}$ and the most forward outgoing parton $f_{b'}$ with rapidity y_{n+2} .

In the absence of X , the outgoing flavours match the incoming ones, i.e. $a' = a, b' = b$. This is still the case if a charged lepton-antilepton pair $X = l\bar{l}$ is produced. However, for this process we require a virtual photon or Z boson, which implies that at least one of f_a and f_b has to be a quark or antiquark. When producing a pair of charged lepton and a neutrino, $X = l\bar{\nu}_l$ or $X = \bar{l}\nu_l$, a quark or antiquark couples to a virtual W boson. This means that the respective flavour is changed, so that either $a' \neq a$ or $b' \neq b$.

2.2.1 Matrix element without interference

The square of the LL HEJ matrix element in the absence of interference has the following structure, illustrated also in figure 2:

$$\begin{aligned} \overline{|\mathcal{M}_{f_a f_b \rightarrow X f_{a'} \cdot n g \cdot f_{b'}}^{\text{HEJ}}|} &= \mathcal{B}_{f_a, f_b, X}(p_a, p_b, p_1, p_{n+2}, \{p\}_X) \\ &\cdot \prod_{i=1}^n \mathcal{V}(p_a, p_b, p_1, p_{n+2}, q_i, q_{i+1}) \\ &\cdot \prod_{i=1}^{n+1} \mathcal{W}(q_j, y_j, y_{j+1}) \end{aligned} \quad (2)$$

p_a and p_b are the momenta of f_a and f_b , p_i with $1 \leq i \leq n+2$ the outgoing momenta ordered by ascending rapidity, and q_j the t -channel momenta related by $q_j = q_{j-1} - p_j$. The first t -channel momentum q_1 is process-dependent; if there are no additional particles X it is given by $q_1 = p_a - p_1$. $\{p\}_X$ represents the local momenta associated with the production of X .

Figure 2: Structure of the LL HEJ matrix element in the absence of X .

$\mathcal{B}_{f_a, f_b, X}$ is the square of the Born-level matrix element for the process without any additional gluon emissions, $n = 0$. \mathcal{V} describes the real gluon emission corrections to this process,

whereas \mathcal{W} accounts for the virtual corrections. Both are process-independent and given by

$$\mathcal{V}(p_a, p_b, p_1, p_{n+2}, q_i, q_{i+1}) = -\frac{C_A}{q_i^2 q_{i+1}^2} V^\mu(q_i, q_{i+1}) V_\mu(q_i, q_{i+1}), \quad (3)$$

$$\mathcal{W}(q_j, y_j, y_{j+1}) = \exp[\omega^0(q_{j\perp})(y_{j+1} - y_j)]. \quad (4)$$

Using a short-hand notation, we have suppressed the dependence of the Lipatov vertex function V^μ on the incoming and outgoing momenta:

$$V^\mu(q_i, q_{i+1}) = V^\mu(p_a, p_b, p_1, p_{n+2}, q_i, q_{i+1}). \quad (5)$$

Explicit expressions for V^μ and the regularised Regge trajectory ω^0 are derived in [1, 18].

The only process-dependent part is the Born function $\mathcal{B}_{f_a, f_b, X}$. It is derived via matching to full QCD, i.e. by requiring that \mathcal{B} is equivalent to the corresponding QCD amplitude in the high-energy limit. In the *High Energy Jets* formalism, exact gauge invariance and superior numerical agreement with full QCD over the whole phase space are achieved by only neglecting a gauge-invariant subset of the terms that are suppressed in the high-energy limit. Specifically, only those terms that would break the following t -channel factorised form are discarded.

$$\mathcal{B}_{f_a, f_b, X}(p_a, p_b, p_1, p_{n+2}, \{p\}_X) = (g_s^2)^2 \frac{K_{f_a} K_{f_b}}{4(N_C^2 - 1)} \|S_{f_a f_b \rightarrow X f_{a'} \dots f_{b'}}\|^2 \frac{1}{q_1^2 q_{n+1}^2}. \quad (6)$$

K_{f_a} and K_{f_b} are colour factors depending on the incoming partons. For an (anti-)quark i the corresponding factor is simply $K_{f_i} = C_F$. Gluons lead to more complex factors K_g involving also their kinematics [2]. Finally, $S_{f_a f_b \rightarrow X f_{a'} \dots f_{b'}}$ is the contraction of two (generalised) currents, with double bars indicating the sum over helicities. In pure QCD, X is absent and the current contraction is simply

$$\|S_{f_a f_b \rightarrow f_a \dots f_b}\|^2 \equiv \|j^a \cdot j^b\|^2 = \sum_{h_a, h_b} |j^{\mu, h_a}(p_1, p_a) j_\mu^{h_b}(p_{n+2}, p_b)|^2, \quad (7)$$

where j_μ^h is the current

$$j_\mu^h(p, q) = \bar{u}^h(p) \gamma_\mu u^h(q) \quad (8)$$

for helicity h .

A pair consisting of a lepton¹ with momentum p_ℓ and an antilepton with momentum $p_{\bar{\ell}}$ is produced via a virtual vector boson $V \in \{W^+, W^-, Z, \gamma\}$ coupling to either of the partons f_a or f_b . We can account for this process by modifying the corresponding current. Assuming without loss of generality a coupling to f_a , we obtain

$$\|S_{f_a f_b \rightarrow X f_{a'} \dots f_b}\|^2 \equiv \|j_V^a \cdot j^b\|^2 = \sum_{h_a, h_b, h_\ell} \left| j_V^{\mu, h_a h_\ell}(p_1, p_a, p_\ell, p_{\bar{\ell}}) j_\mu^{h_b}(p_{n+2}, p_b) \right|^2, \quad (9)$$

with the generalised current [5]

$$j_V^{\mu, h_a h_\ell}(p_a, p_\ell, p_{\bar{\ell}}, p_1) = \frac{g_V^2}{2} \frac{1}{p_V^2 - M_V^2 + i \Gamma_V M_V} \bar{u}^{h_\ell}(p_\ell) \gamma_\alpha v^{h_\ell}(p_{\bar{\ell}}) \cdot \left(\frac{\bar{u}^{h_a}(p_1) \gamma^\alpha (\not{p}_V + \not{p}_1) \gamma^\mu u^{h_a}(p_a)}{(p_V + p_1)^2} + \frac{\bar{u}^{h_a}(p_1) \gamma^\mu (\not{p}_a - \not{p}_V) \gamma^\alpha u^{h_a}(p_a)}{(p_a - p_V)^2} \right).$$

$p_V = p_\ell + p_{\bar{\ell}}$ is the vector boson momentum, g_V its coupling to the fermion f_a , M_V its mass and Γ_V the width. Note that the emission of a virtual vector boson off f_a implies that the first t -channel momentum is now given by $q_1 = p_a - p_1 - p_V$.

¹We do not distinguish between charged leptons and neutrinos here.

2.2.2 Interference

So far, we have not considered interference between different channels. For charged lepton plus neutrino production interference can arise between emission of the virtual W boson off parton f_a and emission off parton f_b if both are (anti-)quarks. This contribution is numerically small and neglected in HEJ 2.1. This kinematic suppression is absent in the production of a charged lepton-antilepton. What is more, there is an additional interference between production via a photon and production via a Z boson. Since both effects are non-negligible, we consider the squared LL matrix element with full interference for this process. Here, we have to distinguish between t -channel momenta q_{aj} for emission of the vector boson off parton f_a and q_{bj} for emission off f_b . They are given by

$$q_{a1} = p_a - p_1 - p_V, \quad q_{aj} = q_{a(j-1)} - p_j, \quad (10)$$

$$q_{b1} = p_a - p_1, \quad q_{bj} = q_{b(j-1)} - p_j. \quad (11)$$

The square of the matrix element then reads [13]

$$\begin{aligned} \left| \mathcal{M}_{\text{HEJ}}^{f_a f_b \rightarrow l \bar{l} f_a \cdot n g \cdot f_b} \right|^2 &= (g_s^2)^2 \frac{K_{f_a} K_{f_b}}{4(N_c^2 - 1)} (g_s^2 C_A)^n \\ &\times \left(\frac{\|j_{Z\gamma}^a \cdot j^b\|^2}{q_{a1}^2 q_{a(n+1)}^2} \prod_{i=1}^n \frac{-V^2(q_{ai}, q_{a(i+1)})}{q_{ai}^2 q_{a(i+1)}^2} \prod_{i=1}^{n+1} \exp(\omega^0(q_{ai\perp})(y_{i+1} - y_i)) \right. \\ &+ \frac{\|j^a \cdot j_{Z\gamma}^b\|^2}{q_{b1}^2 q_{b(n+1)}^2} \prod_{i=1}^n \frac{-V^2(q_{bi}, q_{b(i+1)})}{q_{bi}^2 q_{b(i+1)}^2} \prod_{i=1}^{n+1} \exp(\omega^0(q_{bi\perp})(y_{i+1} - y_i)) \\ &- \frac{2\Re\{(j_{Z\gamma}^a \cdot j^b)(j^a \cdot j_{Z\gamma}^b)\}}{\sqrt{q_{a1}^2 q_{b1}^2} \sqrt{q_{a(n+1)}^2 q_{b(n+1)}^2}} \\ &\left. \times \prod_{i=1}^n \frac{V(q_{ai}, q_{a(i+1)}) \cdot V(q_{bi}, q_{b(i+1)})}{\sqrt{q_{ai}^2 q_{bi}^2} \sqrt{q_{a(i+1)}^2 q_{b(i+1)}^2}} \prod_{i=1}^{n+1} \exp(\omega^0(\sqrt{q_{ai\perp} q_{bi\perp}})(y_{i+1} - y_i)) \right), \end{aligned} \quad (12)$$

where we have introduced the combined current $j_{Z\gamma} = j_Z + j_\gamma$ and the notation (cf. equation (9))

$$(j_V^a \cdot j^b)(j^a \cdot j_V^b) \equiv \sum_{h_a, h_b, h_\ell} j_V^{\mu, h_a h_\ell}(p_1, p_a, p_\ell, p_{\bar{\ell}}) j_\mu^{h_b}(p_{n+2}, p_b) \overline{j_\nu^{h_a}(p_1, p_a) j_V^{\nu, h_b h_\ell}(p_{n+2}, p_b, p_\ell, p_{\bar{\ell}})}. \quad (13)$$

The equation (12) for the square of the matrix element with interference assumes that both f_a and f_b are (anti-)quarks. If, for instance, f_b is a gluon instead, terms involving $j_{Z\gamma}^b$ do not contribute and the expression simplifies to equation (2) with the current contraction in equation (9) and $j_V^a \rightarrow j_{Z\gamma}^a$.

2.3 Next-to-leading logarithmic corrections

There are two sources of NLL contributions. First, the matrix elements for LL configurations, discussed in section 2.2, receive NLL corrections. These types of corrections will be considered in future HEJ versions. Second, configurations that do not allow the maximal number of gluonic t -channel exchanges according to the discussion in section 2.1 only contribute at higher logarithmic orders. For instance, this is the case for configurations where a gluon is produced outside the rapidity order mandated for LL configurations. Ordering all particles apart from X according to their rapidity, these processes are denoted by $f_a f_b \rightarrow X g f_{a'} \cdot n g \cdot f_{b'}$, where $f_{a'}$ is an (anti-)quark and $f_a f_b \rightarrow X f_{a'} \cdot n g \cdot f_{b'} g$ with an (anti-)quark $f_{b'}$. These “unordered gluon” NLL configurations were considered in [4] and are already accounted for in HEJ 2.0.

Studying the production of a W boson together with jets, it is found that further numerically important NLL configurations arise through the production of additional pairs of a quark q and an antiquark \bar{q}' . Note that in general the flavours q and q' can be different if there is a W boson coupling. We distinguish between “central” production,

$$f_a f_b \rightarrow X f_{a'} \cdot n_1 g \cdot q \bar{q}' \cdot (n - n_1) g \cdot f_{b'}, \quad (14)$$

and “extremal” production

$$g f_b \rightarrow X q \bar{q}' \cdot n g \cdot f_{b'}, \quad (15)$$

$$f_a g \rightarrow X f_{a'} \cdot n g \cdot q \bar{q}'. \quad (16)$$

In either case, the description is independent of the relative rapidity ordering between q and \bar{q} . In fact, the squares of the matrix elements for these configurations have the same structure as at LL accuracy, see equation (2). Differences only arise in the Born function \mathcal{B} and in the expressions for the t -channel momenta q_i . HEJ 2.1 supports resummation of these configurations for pure multijet production (X is absent) and the production of a leptonically decaying W boson together with multiple jets ($X = l\bar{\nu}$ or $X = \bar{l}\nu$).

2.3.1 Pure multijet production

We first consider multijet production with an extremal quark-antiquark pair. For this, we assume the (same-flavour) quark-antiquark pair to be emitted in the backward direction; forward emission is completely analogous. The configurations in question are of the form

$$g f_b \rightarrow q \bar{q} \cdot n g \cdot f_b, \quad (17)$$

In the *High Energy Jets* formalism the production of the $q\bar{q}$ pair from an incoming gluon is described by an effective current $j_{q\bar{q}}^{\mu,d,h_a h_q h_{\bar{q}}}(p_a, p_q, p_{\bar{q}})$, where d is a colour index in the adjoint representation, h_a the helicity of the incoming gluon, and p_q, h_q ($p_{\bar{q}}, h_{\bar{q}}$) the momentum and helicity of the outgoing (anti-)quark. An explicit expression for $j_{q\bar{q}}^{\mu,d,h_a h_q h_{\bar{q}}}$ is derived in [5]. The structure of the matrix element is illustrated in figure 3a. Note that due to the emission of the $q\bar{q}$ pair the first t -channel momentum is now given by $q_1 = p_a - p_q - p_{\bar{q}}$. In summary, the Born function contributing to the matrix element with extremal $q\bar{q}$ production reads

$$\mathcal{B}_{g,f_b}^{\text{ext}} = (g_s^2)^3 \frac{K_{f_b}}{4(N_C^2 - 1)} \|S_{g f_b \rightarrow q \bar{q} \cdots f_b}\|^2 \frac{1}{q_1^2 q_{n+1}^2}, \quad (18)$$

where

$$\|S_{g f_b \rightarrow q \bar{q} \cdots f_b}\|^2 \equiv \|j_{q\bar{q}} \cdot j^b\|^2 = \sum_{h_a, h_b, h_q, h_{\bar{q}}} \left| j_{q\bar{q}}^{\mu,d,h_a h_q h_{\bar{q}}}(p_a, p_q, p_{\bar{q}}) j_{\mu}^{h_b}(p_b, p_{n_2}) T_{b(n+2)}^d \right|^2. \quad (19)$$

Central $q\bar{q}$ production is depicted in figure 3b and corresponds to the configuration

$$f_a f_b \rightarrow f_a \cdot n_1 g \cdot q \bar{q} \cdot (n - n_1) g \cdot f_b. \quad (20)$$

The central production is described by an effective vertex $X_{\text{cen}}^{\mu\nu}$ that can be absorbed into the current contraction. The Born function then reads

$$\mathcal{B}_{f_a, f_b}^{\text{cen}} = (g_s^2)^4 \frac{K_{f_a} K_{f_b}}{4(N_C^2 - 1)} \|S_{f_a f_b \rightarrow f_a \cdots q \bar{q} \cdots f_b}\|^2 \frac{1}{q_1^2 q_{n+2}^2} \quad (21)$$

with the current contraction

$$\|S_{f_a f_b \rightarrow f_a \cdots q \bar{q} \cdots f_b}\|^2 \equiv \|j^a \cdot X_{\text{cen}} \cdot j^b\|^2 = \sum_{h_a, h_b} |j_{\mu}^{h_a}(p_1, p_a) X_{\text{cen}}^{\mu\nu} j_{\nu}^{h_b}(p_{n+2}, p_b)|^2, \quad (22)$$

where $X_{\text{cen}}^{\mu\nu}$ is derived in [5]. The t -channel momenta are given by

$$q_i = \begin{cases} p_a - \sum_{j=1}^i p_j & i \leq n_1 + 1 \\ p_a - p_q - p_{\bar{q}} - \sum_{j=1}^i p_j & i > n_1 + 1 \end{cases}. \quad (23)$$

Figure 3: Structure of the matrix element for multijet production involving an extremal (a) or central (b) quark-antiquark pair.

2.3.2 W + jets production

If an additional leptonically decaying W boson is produced we have to distinguish between two cases. Similarly to the LL configurations, the W boson may couple to a fermion line associated with an incoming quark or antiquark. This causes a flavour change $f_a \rightarrow f_{a'}$ or $f_b \rightarrow f_{b'}$. Assuming without loss of generality the latter possibility the corresponding configurations read

$$gf_b \rightarrow Xq\bar{q} \cdot ng \cdot f_{b'} \quad (\text{extremal } q\bar{q}), \quad (24)$$

$$f_a f_b \rightarrow Xf_a \cdot n_1 g \cdot q\bar{q} \cdot (n - n_1) g \cdot f_{b'} \quad (\text{central } q\bar{q}), \quad (25)$$

where $X = l\bar{\nu}_l$ or $X = \bar{l}\nu_l$.

The Born functions for both configurations are obtained from the corresponding pure-jets Born functions in equations (18) and (21) by replacing the standard current $j^\mu(p_b, p_{n+2})$ with the generalisation $j_V^\mu(p_b, p_\ell, p_{\bar{\ell}}, p_{n+2})$ for the emission of a vector boson $V = W$, see equation (10).

The second possibility is a coupling of the W boson to the fermion line of the produced $q\bar{q}'$, where now $q \neq q'$. For extremal $q\bar{q}'$ production, the Born function is obtained from equations (18) and (19) by replacing the current $j_{q\bar{q}}$ with a new effective current $j_{Wq\bar{q}'}$. In complete analogy the central production is described by replacing X_{cen} with a new effective vertex $X_{W\text{cen}}$ in equations (21), (22). Explicit results for $j_{Wq\bar{q}'}$ and $X_{W\text{cen}}$ were obtained in [5].

3 Application: W + jets production

In order to demonstrate the recent additions to HEJ we now show in detail how to obtain a prediction for the production of a W boson with multiple jets. Specifically, we consider the process $pp \rightarrow (W^- \rightarrow e\bar{\nu}_e) + \geq 2 \text{ jets}$. The parameters are listed in table 1.

3.1 Fixed-order input

In order to run HEJ, we have to generate leading-order input events. Any generator producing event files in the Les Houches Event File (LHEF) [20] format can be used to this end. Here,

Collider energy	$\sqrt{s} = 13 \text{ TeV}$
Scales	$\mu_r = \frac{H_T}{2}$ $\mu_f = \frac{H_T}{2}$
PDF set	CT18NLO
Electroweak input parameters	$G_F = 1.3663787 \cdot 10^{-5} \text{ GeV}^{-2}$ $m_W = 80.385 \text{ GeV}$ $\Gamma_W = 2.085 \text{ GeV}$ $m_Z = 91.187 \text{ GeV}$ $\Gamma_Z = 2.495 \text{ GeV}$
Jet definition	anti- k_t [19] $R = 0.7$ $p_\perp > 20 \text{ GeV}$

Table 1: Parameters used for the production of a leptonically decaying W boson with multiple jets.

we use Sherpa [21] with the following run card. The entries are explained in detail in the Sherpa documentation.

```

Note that we have chosen a minimum jet transverse momentum of 18 GeV instead of the 20 GeV listed in table 1. The reason for this is that the HEJ resummation can change the transverse momenta of the jets slightly compared to the input leading-order events. It is therefore recommended to choose a minimum transverse momentum that is at least 10% smaller in the fixed-order generation. It is also prudent to ensure that the final predictions do not change when choosing an even smaller value.

The contribution from events containing such “soft” jets with transverse momenta below the value required in the final analysis is numerically small. This means that a significant amount of computing time can be saved by generating and combining two separate input event samples: a sample with low statistics in which each event contains at least one soft jet, and a large sample without any soft sets. For simplicity, we do not consider this optimisation here.

With the above `Run.dat` run card, an event file `events_W2j.lhe` can be generated by running

```
Sherpa
```

in the same directory. The generated events will contain exactly two jets, but it is straightforward to generate higher-multiplicity samples by increasing the required number of jets in `FastjetFinder`, adding the corresponding number of 93 entries to the `Process` final state, and adjusting the name of the output file in the `EVENT_OUTPUT`. HEJ can then be used to merge samples with different multiplicities. Typically, the contribution of higher jet multiplicities in the analysis will be decreasing, and it is often enough to consider at most four or five jets. One can save computing time at the price of sacrificing leading-order accuracy by using the HEJ fixed-order generator (HEJFOG) for high multiplicities. An example is shown in

appendix A.

3.2 Resummation with HEJ

In addition to the fixed-order input, HEJ also requires a configuration file. A template `config.yml` is included in the HEJ source code. Adopting the current set of parameters from table 1 and enabling resummation for all supported NLL configurations we get

`config_Wjets.yml`

```
## Number of attempted resummation phase space points for each input event
trials: 10

resummation jets:      # resummation jet properties
  algorithm: antikt     # jet clustering algorithm
  R: 0.7               # jet R parameter
  min pt: 20          # minimum jet transverse momentum

fixed order jets:      # properties of input jets
  min pt: 18
  # by default, algorithm and R are like for resummation jets

## Treatment of the various event classes
## the supported settings are: reweight, keep, discard
## non-resummable events cannot be reweighted
event treatment:
  FKL: reweight
  # Enable resummation for NLL configurations
  unordered: reweight
  extremal qqbar: reweight
  central qqbar: reweight
  non-resummable: keep

## Central scale choice or choices
scales: H_T/2

## Selection of random number generator and seed
random generator:
  name: mixmax
  seed: 1

## Whether or not to include higher order logs
log correction: false

## Vacuum expectation value
vev: 246.2196508

## Properties of the weak gauge bosons
particle properties:
  W:
    mass: 80.385
    width: 2.085
  Z:
    mass: 91.187
    width: 2.495
  Higgs:
    mass: 125
    width: 0.004165
```

We can now generate HEJ events and calculate the total resummed cross section by running

```
HEJ config_Wjets.yml events_W2j.lhe
```

If HEJ was compiled with support for Rivet [22], the generated events can be forwarded directly to the MC_WJETS analysis by adding the following lines to `config_Wjets.yml` before running HEJ:

```
analyses:
  - rivet: MC_WJETS
    output: HEJ_W2j
```

Another possibility is to create an output event file for manual analysis. After compiling HEJ with support for the HepMC 2 [23] format, we can add the following entry to `config_Wjets.yml`:

```
event output:
  - HEJ_W2j.hepmc2
```

We can then run HEJ as before and feed the generated events into the MC_WJETS analysis with

```
rivet -a MC_WJETS -o HEJ_W2j.yoda HEJ_W2j.hepmc2
```

Results for higher jet multiplicities are obtained in the same way after adjusting the file names in the configuration files and run commands. To guarantee statistical independence it is also recommended to change the `seed` in `config_Wjets.yml`. To obtain a prediction that is inclusive in jet multiplicity, we combine the Rivet output with²

```
yodastack -o HEJ_Wjets.yoda HEJ_W*j.yoda
```

Finally,

```
rivet-mkhtml HEJ_Wjets.yoda
```

produces analysis plots. As examples, we show the inclusive N -jet cross sections and the invariant mass distribution of the two hardest jets obtained from fixed-order input events with up to four jets in figure 4.

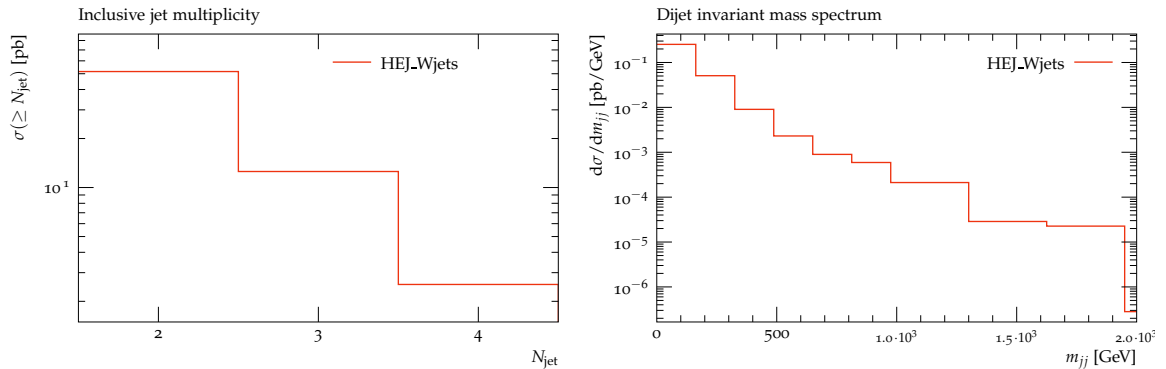

Figure 4: Inclusive N -jet cross sections (left) and dijet invariant mass spectrum (right) obtained with Sherpa and HEJ 2.1 for the production of a W boson with at least two jets.

²In older Rivet versions `yodamerge --add` can be used instead of `yodastack`.

4 Conclusions

This article accompanies the release of the event generator, HEJ 2.1 which provides predictions for hadronic colliders which contain contributions at all orders in α_s to achieve leading-logarithmic accuracy in \hat{s}/p_\perp^2 . The output is given as exclusive events meaning that predictions can be obtained for arbitrary experimental cuts and analyses.

Here, after a brief outline of the general HEJ formalism, we have described the new extensions which have broadened the scope of the all-order predictions. Specifically, new matrix elements which allow for interference between channels with *different* assignments of effective t -channel momenta have been developed to give an accurate description of $pp \rightarrow (Z/\gamma^* \rightarrow \ell\bar{\ell}) + \geq 2$ jets (section 2.2.2). Secondly, the full set of NLL contributions corresponding to processes which have no LL component have been incorporated through the derivation of necessary additional Born processes (section 2.3). These form a well-defined, gauge-invariant subset of the full NLL corrections.

Finally, we have provided a worked example explicitly showing all the steps necessary to generate predictions for $pp \rightarrow (W^- \rightarrow e\bar{\nu}_e) + \geq 2$ jets.

Acknowledgements

HEJ uses FastJet [24], LHAPDF [25], and FORM [26].

We are pleased to acknowledge funding from the UK Science and Technology Facilities Council, the Royal Society, the ERC Starting Grant 715049 “QCDforfuture”, the Marie Skłodowska-Curie Innovative Training Network MCnetITN3 (grant agreement no. 722104), and the EU TMR network SAGEX agreement No. 764850 (Marie Skłodowska-Curie).

A $W +$ jets production with the HEJ fixed-order generator

The generation of fixed-order events with high jet multiplicities can become prohibitively expensive in computing time. In such cases the HEJ fixed-order generator (HEJFOG) can be used to quickly obtain results in the high-energy approximation. A typical use case is to produce HEJ input files with exact leading-order accuracy up to a given jet multiplicity as discussed in section 3.1 and supplement them with high-multiplicity event files produced with the HEJFOG.

As an example, we slightly modify the configuration file `configF0.yml` included in the HEJ source code to produce events for the process $pp \rightarrow (W^- \rightarrow e\bar{\nu}_e) + 5$ jets.

`config_HEJFOG.yml`

```
## Number of generated events
events: 10000

jets:
  min pt: 18          # minimal jet pt, should be slightly below analysis cut
  peak pt: 20         # peak pt of jets, should be at analysis cut
  algorithm: antikt    # jet clustering algorithm
  R: 0.7              # jet R parameter
  max rapidity: 5     # maximum jet rapidity
