#### Abstract

We study the complexity of two-person constraint satisfaction games. An instance of such a game is given by a collection of constraints on overlapping sets of variables, and the two players alternately make moves assigning values from a finite domain to the variables, in a specified order. The first player tries to satisfy all constraints, while the other tries to break at least one constraint; the goal is to decide whether the first player has a winning strategy. We show that such games can be conveniently represented by a logical form of quantified constraint satisfaction, where an instance is given by a first-order sentence in which quantifiers alternate and the quantifier-free part is a conjunction of (positive) atomic formulas; the goal is to decide whether the sentence is true. While the problem of deciding such a game is PSPACE-complete in general, by restricting the set of allowed constraint predicates, one can obtain infinite classes of constraint satisfaction games of lower complexity. We use the quantified constraint satisfaction framework to study how the complexity of deciding such a game depends on the parameter set of allowed predicates. With every predicate, one can associate certain predicate-preserving operations, called polymorphisms. We show that the complexity of our games is determined by the surjective polymorphisms of the constraint predicates. We illustrate how this result can be used by identifying the complexity of a wide variety of constraint satisfaction games.

## 1. Introduction

The constraint satisfaction problem (CSP) provides a general framework in which a wide variety of combinatorial search problems can be expressed in a natural way $[19,24]$. An instance of the CSP can be viewed as a collection of predicates on overlapping sets of variables; the aim is to determine whether there exist values for all of the variables such that all of the specified predicates hold simultaneously. Although the CSP, in its general formulation, is NP-complete and hence likely to be intractable, it can be parameterized by restricting the set of allowed predicates which can be used as constraints. The problem of classifying the complexity of the CSP (and its many variants) for all possible parameter sets has attracted much attention, because constraint satisfaction problems play an important role in many areas of computer science and

[^0]artificial intelligence [24]. An important outcome of research in this direction has been the design of sophisticated new polynomial-time algorithms for solving a wide variety of problems (see, for example, [7,22]). In addition, classification results for the CSP are significant from a complexity-theoretic standpoint, as they provide large subclasses of complexity classes that avoid intermediate complexity. For example, in the case of the class NP, a number of dichotomy results have been obtained [6,7,19,27].

The complexity of combinatorial games is also a major line of research (see [28,29,43,51]). In this paper, we study the complexity of two-person constraint satisfaction games, in which, given a CSP instance, two players (call them $\exists$ and $\forall$ ) alternately assign values to the variables in a specified order. Player $\exists$ tries to satisfy all constraints, while player $\forall$ (the adversary) tries to break at least one constraint; the goal is to decide whether player $\exists$ has a winning strategy. Note that the order of variables is specified in every instance, since otherwise (if the players were allowed to choose the variable ordering) the adversary would be able to break constraints too easily. The complexity of some related games was studied in $[2,49]$. A different kind of game has already been studied in the context of constraint satisfaction [39] where it was used to prove tractability of certain CSPs.

The CSP can be expressed as the problem of deciding the truth of a given first-order sentence consisting of a conjunction of predicates, where all of the variables are existentially quantified. Hence the CSP generalises the standard propositional satisfiability problem, by allowing the possible values for the variables to be chosen from an arbitrary finite set, and allowing the constraints to be arbitrary predicates rather than just clauses. Satisfiability games of the form described above can be conveniently cast as (and are equivalent to) quantified satisfiability problems, known as QSAT. Similarly, games of this form on CSP instances are equivalent to quantified constraint satisfaction problems (QCSP), in which universal quantifiers are allowed in the sentence, in addition to existential quantifiers [19,20]. The existentially quantified variables correspond to the moves of $\exists$, and the universally quantified ones to the moves of $\forall$; the (specified) order of moves corresponds to the order of quantifiers in the formula. Note that if the quantifiers do not alternate in a formula then the standard trick is to insert into the prefix appropriately quantified "dummy" variables that do not appear in the quantifier-free part; obviously, this does not affect validity of the formula, and the size of the formula increases by an at most constant factor.

The QCSP framework is actively studied in artificial intelligence, where it is used to model problems, for example, in nonmonotonic reasoning [25] and in planning [48]. One motivating example for the study of the QCSP arises in the development of automated systems with certain integrity constraints; such a system should be able to respond to any action of the user (who may be thought of as an adversary) in such a way that the integrity constraints are satisfied. Checking whether or not such a system is safe amounts to solving a QCSP. Several general (superpolynomial or incomplete) algorithms for the Boolean QCSP (that is, QSAT) have been suggested [13,32,37,53], and recently researchers have begun to look for ways to solve non-Boolean QCSP problems [3,31,41,53].

It is not hard to see that QCSP is PSPACE-complete in general. However, with certain restrictions on the type of predicates allowed in instances, the constraint satisfaction game may be easier to decide. Our ultimate goal is to determine how the complexity of deciding a constraint satisfaction game depends on the parameter set (of predicates allowed in instances).

The Boolean QCSP and some of its restrictions, such as Quantified 3-SAT, have always been standard examples of PSPACE-complete problems [30,43,50]. However, for some parameter sets, Boolean QCSP has been shown to be tractable: for all binary predicates in [1], and for Horn predicates in [37]. Indeed, a complete classification for the Boolean QCSP was obtained in [19,20] (see Theorem 3.8, below).

However, the general non-Boolean QCSP has not yet been systematically studied from the viewpoint of complexity classification. This paper initiates a systematic approach to the complexity classification of the QCSP over arbitrary finite domains. Between the announcement of (some of) the results of this paper $[4,5,15]$ and publication of this extended version, several further papers following this line of research have appeared, e.g., [14,16-18,26,42].

Obtaining complexity classifications for non-Boolean CSPs is significantly more difficult than for Boolean CSPs: the direct combinatorial approach used in the Boolean case is infeasible, so more involved techniques are required. A far-reaching approach for tackling this general case via graph theory, logic and games has been developed in $[21,27,38]$. However, the most successful approach to date has been the algebraic approach developed in [12,34,36] (see also [40]). This approach has led to many new tractability and classification results for non-Boolean CSPs (see for example, [8-11,21,22,40]) and, thus far, has culminated in a complete classification of the complexity of CSPs for the three-valued case [6], and the case when all unary predicates are available [7].

In this paper, we extend the algebraic framework that has been used to study the CSP, and we show that certain algebraic objects (surjective polymorphisms) determine the complexity of the QCSP for any given choice of parameter set. We then use this approach to identify several classes of parameter sets yielding a tractable QCSP. The CSP for each of these classes is already known to be tractable [36,40], but establishing the tractability of the QCSP for these classes requires considerable further effort. Moreover, we show that some surjective polymorphisms that are known to guarantee the tractability of the CSP fail to do so for the QCSP. We also apply the results to classify the complexity of a range of constraint satisfaction games.

The paper is organised as follows. In Section 2, we give the basic definitions, explain the connection between the QCSP and constraint satisfaction games, and provide some examples. Then, in Section 3.1, we outline the algebraic approach to the CSP and, in Section 3.2, we cite known complexity results on the QCSP. An algebraic approach to the QCSP is developed in Section 3.3. Then, in Sections 4.1 and 4.2, we prove the tractability of QCSPs corresponding to Mal'tsev and near-unanimity polymorphisms. Section 5 is devoted to the main intractability result. In Section 6, we show that certain semilattice polymorphisms guarantee tractability of the corresponding QCSPs, while all other semilattice polymorphisms do not. Finally, in

Section 7 we obtain a complete classification for QCSPs in which the graphs of all the permutations of the values are available; the result is a 'trichotomy', that is, every problem either belongs to PTIME, or is NP-complete, or is PSPACE-complete.

## 2. Definitions and Examples

Throughout this paper, we use the standard correspondence between predicates and relations: a relation consists of all tuples of values for which the corresponding predicate holds. We will use the same symbol for a predicate and its corresponding relation, since the meaning will always be clear from the context. We will use $R_{D}^{(m)}$ to denote the set of all $m$-ary relations (or predicates) over a set $D$, and $R_{D}$ to denote the set of all relations over a set $D$, that is, $R_{D}=\bigcup_{m=1}^{\infty} R_{D}^{(m)}$.

The constraint satisfaction problem can be defined as follows.
Definition 2.1. An instance of the CSP on $D$ is a formula $\psi=\psi_{1} \wedge \ldots \wedge \psi_{q}$ where each $\psi_{i}$ is a (positive) atomic formula involving a predicate from $R_{D}$. The question is whether $\psi$ is satisfiable.

An instance of the QCSP is a first-order sentence $\exists v_{1} \forall v_{2} \ldots \mathcal{Q}_{l} v_{l} \psi$, where $\psi$ is an instance of the CSP whose variables are chosen from $v_{1}, \ldots, v_{l}$ and the quantifiers alternate; the question is whether the sentence is true.

The predicates appearing in an instance will be referred to as constraints, since each of them restricts the possible models for $\psi$ in some way.

As explained in the introduction, the version of the QCSP where the quantifiers are not required to alternate is the same from a complexity point of view, since the alternation can always be achieved by using dummy variables. This more general version will often be used in our technical results. Note that by using dummy variables we can also change whether the first (and/or last) quantifier is existential or universal.

Note that the CSP decision problem is the particular case of the QCSP problem where all of the universally quantified variables are dummy variables.

Since the QCSP is our model for constraint satisfaction games, we will also use the following game-theoretic characterization of QCSP instances.

Definition 2.2. Let $\phi=\forall y_{1} \exists x_{1} \ldots \forall y_{n} \exists x_{n} \psi$ be a QCSP instance over a domain $D$. A strategy for $\exists$ in $\phi$ is a sequence of mappings $\left\{\tau_{i}: D^{i} \rightarrow D\right\}_{i=1, \ldots, n}$; it is said to be a winning strategy if, for any mapping $\sigma:\left\{y_{1}, \ldots, y_{n}\right\} \rightarrow D$ defined on the universally quantified variables of $\phi$, the formula $\psi$ is true under the mapping taking each $y_{i}$ to $\sigma\left(y_{i}\right)$ and each $x_{i}$ to $\tau_{i}\left(\sigma\left(y_{1}\right), \ldots, \sigma\left(y_{i}\right)\right)$.

The following proposition is straightforward.
Proposition 2.3. A QCSP instance $\phi$ is true if and only if $\exists$ has a winning strategy in $\phi$.
It is well-known that the QCSP and CSP decision problems, in the general formulations given above, are PSPACE-complete and NP-complete, respectively. The broad research problem we focus on in this paper is to classify the complexity of the following parameterized version of the QCSP, for all possible parameterizations.

Definition 2.4. Let $\Gamma \subseteq R_{D}$. The decision problems $\operatorname{CSP}(\Gamma)$ and $\operatorname{QCSP}(\Gamma)$ are restrictions of CSP and QCSP, respectively, to instances in which all predicates belong to $\Gamma$.

We will now describe several combinatorial games that can be cast as $\operatorname{QCSP}(\Gamma)$ for a suitable set $\Gamma$.
Example 2.5 (not-all-equal 2-colouring game). An instance of this game is given by a linearly ordered set $A$ and a collection $C$ of (at most) three-element subsets of $A$. The players colour, in turn, elements of $A$ with two colours, black and white, according to the ordering of $A$. Player $\exists$ wins if and only if, after all elements in $A$ are coloured, each set in $C$ has elements of both colours.

This game exactly corresponds to the problem $\operatorname{QCSP}\left(\left\{\varrho_{\text {nae }}\right\}\right)$ where $\varrho_{\text {nae }}$ is the ternary relation on $\{0,1\}$ defined by $\varrho_{\text {nae }}=\{0,1\}^{3} \backslash\{(0,0,0),(1,1,1)\}$.

Example 2.6 (one-in-three 2-colouring game). An instance of this game is the same as in the preceding example. Player $\exists$ wins if and only if, after all elements in $A$ are coloured, each set in $C$ has exactly one black element.

This game exactly corresponds to the problem $\operatorname{QCSP}\left(\left\{\varrho_{1 i n 3}\right\}\right)$ where $\varrho_{1 i n 3}$ is the ternary relation on $\{0,1\}$ defined by $\varrho_{1 i n 3}=\{(0,0,1),(0,1,0),(1,0,0)\}$.

Example 2.7 (graph $k$-colouring game). In this game, an instance is a graph whose vertices are linearly ordered. In each move, a player colours one of the vertices in one of $k$ colours. The order of moves is specified by the ordering on the vertices. Player $\exists$ wins if and only if, after all vertices are coloured, no adjacent vertices are of the same colour.

This game precisely corresponds to $\operatorname{QCSP}\left(\left\{\neq k_{k}\right\}\right)$ where $\neq k$ is the disequality predicate on a set $D$ such that $|D|=k$. To see this, consider the vertices of an input graph as variables, then the constraints are of the form $\neq_{k}(x, y)$ where $(x, y)$ runs through the set of edges of the graph.

Note that the game described in Example 2.7 is different from the graph colouring games of Bodlaender [2], where both players must satisfy all constraints by their moves, and the loser is the one who cannot make a move.

Example 2.8 (one-or-both colour matching game). In this game, an instance is a directed graph $G$ whose nodes are linearly ordered, together with a set $D$ (of colours). In addition, every arc ( $x, y$ ) of $G$ has a label which is a (suggested) pair $a, b$ of colours from $D$ for $x$ and $y$, respectively. In each move, a player colours one of the nodes of $G$ with some colour from $D$. The order of moves is specified by the ordering on the vertices. Player $\exists$ wins if and only if, after all vertices are coloured, the suggested pair of colours on every arc $(x, y)$ matches at least one of the actual colours given to $x, y$.

This game precisely corresponds to $\operatorname{QCSP}\left(\Gamma_{c m}\right)$ where $\Gamma_{c m} \subseteq R_{D}$ consists of all binary relations of the form $\varrho_{a, b}=\{(u, v) \mid$ $u=a \vee v=b\}$, for $a, b \in D$.

Example 2.9 (colour implication game). In this game, an instance is a directed graph $G$ whose nodes are linearly ordered, together with a set $D$ (of colours) containing two distinguished colours, black and white. In addition, every arc ( $x, y$ ) of $G$ has a label which is a (suggested) pair $a, b$ of non-distinguished colours from $D$ for $x$ and $y$, respectively. In each move, a player assigns a colour $c_{x}$ to a vertex $x$ of $G$. The order of moves is specified by the ordering on the vertices. Player $\exists$ wins if and only if, after all nodes are coloured, every arc $e=(x, y)$ satisfies the following condition: if $c_{x}$ is black or matches its suggested colour, then $c_{y}$ is also black or matches its suggested colour.

This game precisely corresponds to $\operatorname{QCSP}\left(\Gamma_{c i}\right)$ where $\Gamma_{c i} \subseteq R_{D}$ consists of all binary relations of the form $\varrho_{a, b}=\{(u, v) \mid$ $u \in\{a$, black $\} \Rightarrow v \in\{b$, black $\}\}$, for $a, b \in D \backslash\{$ black, white $\}$.

Example 2.10 (linear equations game). In this game, an instance consists of a system of linear equations over a finite field $K$ where the variables in the system are linearly ordered. The players alternately assign elements of $K$ to the variables in the specified order. Player $\exists$ wins if and only if the obtained assignment is a solution to the system.

This game precisely corresponds to $\operatorname{QCSP}\left(\Gamma_{\text {lin }}\right)$ where $\Gamma_{\text {lin }} \subseteq R_{K}$ consists of all relations expressible by a linear equation over $K$.

The results obtained in this paper will be sufficient to determine the complexity of deciding each of the six games described in Examples 2.5 to 2.10 (see Corollaries 3.9 and 8.1).

Finally, we observe that problems of the form $\operatorname{CSP}(\Gamma)$ with finite $\Gamma$ can be expressed as homomorphism problems (see, for example, $[27,34]$ ): in this formulation the question is to decide whether a given relational structure admits a homomorphism to a fixed relational structure. Hence all constraint satisfaction games can be viewed as particular examples of the following very general game.

Example 2.11 (homomorphism construction game). Fix an arbitrary relational structure $\mathcal{B}=\left(D ; \varrho_{1}^{\mathcal{B}}, \ldots, \varrho_{k}^{\mathcal{B}}\right)$ where $\varrho_{i}^{\mathcal{B}} \in R_{D}$ for all $i$. An instance of the game is another relational structure $\mathcal{A}=\left(V ; \varrho_{1}^{\mathcal{A}}, \ldots, \varrho_{k}^{\mathcal{A}}\right)$ such that the set $V$ is linearly ordered and, for all $1 \leq i \leq k, \varrho_{i}^{\mathcal{A}} \in R_{V}$ and the relations $\varrho_{i}^{\mathcal{B}}$ and $\varrho_{i}^{\mathcal{A}}$ are of the same arity.

The players construct a mapping $h: V \rightarrow D$ by choosing, in turn and according to the order on $V$, images for elements of $V$. Player $\exists$ wins if and only if $h$ is a homomorphism from $\mathcal{A}$ to $\mathcal{B}$, that is, for all $1 \leq i \leq k, h(\vec{x}) \in \varrho_{i}^{\mathcal{B}}$ whenever $\vec{x} \in \varrho_{i}^{\mathcal{A}}$.

This game precisely corresponds to $\operatorname{QCSP}(\Gamma)$ where $\Gamma=\left\{\varrho_{1}^{\mathcal{B}}, \ldots, \varrho_{k}^{\mathcal{B}}\right\}$. To see this, think of elements of $V$ as variables, and, for every $i$ and for every tuple $\vec{x} \in \varrho_{i}^{\mathcal{A}}$, introduce a constraint $\varrho_{i}^{\mathcal{B}}(\vec{x})$. As always, the order of moves corresponds to the order of quantifiers.

## 3. Classifying complexity

### 3.1. An algebraic approach

In earlier papers [12,34,36], an algebraic approach to studying the complexity of constraint satisfaction problems $\operatorname{CSP}(\Gamma)$ was developed (see also survey [40]). This approach is briefly reviewed in this section. We will use $O_{D}^{(n)}$ to denote the set of all $n$-ary operations on a set $D$ (that is, the set of mappings $f: D^{n} \rightarrow D$ ), and $O_{D}$ to denote the set $\bigcup_{n=1}^{\infty} O_{D}^{(n)}$. Any operation on $D$ can be extended in a standard way to an operation on tuples over $D$, as follows. For any operation $f \in O_{D}^{(n)}$, and any collection of $m$-tuples $\vec{a}_{1}, \vec{a}_{2}, \ldots, \vec{a}_{n} \in D^{m}$, where $\vec{a}_{i}=\left(\vec{a}_{i}(1), \ldots, \vec{a}_{i}(m)\right)$ (for $\left.i=1, \ldots, n\right)$, define $f\left(\vec{a}_{1}, \ldots, \vec{a}_{n}\right)$ to be the $m$-tuple $\left(f\left(\vec{a}_{1}(1), \ldots, \vec{a}_{n}(1)\right), \ldots, f\left(\vec{a}_{1}(m), \ldots, \vec{a}_{n}(m)\right)\right)$.

Definition 3.1. For any relation $\varrho \in R_{D}^{(m)}$, and any operation $f \in O_{D}^{(n)}$, if $f\left(\vec{a}_{1}, \ldots, \vec{a}_{n}\right) \in \varrho$ for all choices of $\vec{a}_{1}, \ldots, \vec{a}_{n} \in \varrho$, then $\varrho$ is said to be invariant under $f$, and $f$ is called a polymorphism of $\varrho$.

The set of all relations that are invariant under each operation from some set $C \subseteq O_{D}$ will be denoted $\operatorname{lnv}(C)$. The set of all operations that are polymorphisms of every relation from some set $\Gamma \subseteq R_{D}$ will be denoted $\operatorname{Pol}(\Gamma)$.

The following result provides a link between polymorphisms and the complexity of a CSP.
Theorem $3.2([34])$. Let $\Gamma_{1}$ and $\Gamma_{2}$ be sets of predicates over a finite set, such that $\Gamma_{1}$ is finite. If $\operatorname{Pol}\left(\Gamma_{2}\right) \subseteq \operatorname{Pol}\left(\Gamma_{1}\right)$ then $\operatorname{CSP}\left(\Gamma_{1}\right)$ is logarithmic-space reducible to $\operatorname{CSP}\left(\Gamma_{2}\right)$.

This result shows that, when the set of values is finite, finite sets of predicates with the same polymorphisms give rise to constraint satisfaction problems which are mutually reducible to one another. In other words, the complexity of $\operatorname{CSP}(\Gamma)$ is determined by the polymorphisms of $\Gamma$. Note that Theorem 3.2 was originally stated in [34] with polynomial-time reducibility, but, by using the result of [47], can easily be strengthened to logarithmic-space reduction.

The proof of Theorem 3.2 is made up of three crucial ingredients. The first is the fact that $\operatorname{Inv}(\cdot)$ and Pol $(\cdot)$ form a Galois correspondence between $R_{D}$ and $O_{D}$ (see Proposition 1.1.14 of [45]). A basic introduction to this correspondence can be found in [44], and a comprehensive study in [45].

Proposition 3.3. Let $D$ be a finite set, $\Gamma, \Gamma^{\prime} \subseteq R_{D}, C, C^{\prime} \subseteq O_{D}$. Then

$$
\begin{array}{ll}
\Gamma \subseteq \Gamma^{\prime} \Longrightarrow \operatorname{Pol}(\Gamma) \supseteq \operatorname{Pol}\left(\Gamma^{\prime}\right) & C \subseteq C^{\prime} \Longrightarrow \operatorname{lnv}(C) \supseteq \operatorname{lnv}\left(C^{\prime}\right) \\
\Gamma \subseteq \operatorname{Inv}(\operatorname{Pol}(\Gamma)) & C \subseteq \operatorname{Pol}(\operatorname{Inv}(C)) \\
\operatorname{Pol}(\Gamma)=\operatorname{Pol}(\operatorname{lnv}(\operatorname{Pol}(\Gamma))) & \operatorname{lnv}(C)=\operatorname{Inv}(\operatorname{Pol}(\operatorname{lnv}(C)))
\end{array}
$$

The second ingredient involves the set of predicates $\langle\Gamma\rangle$ defined below (see [34] for more information).
Definition 3.4. For any set $\Gamma \subseteq R_{D}$ the set $\langle\Gamma\rangle$ consists of all predicates that can be expressed using

1. predicates from $\Gamma$, together with the binary equality predicate $=_{D}$ on $D$,
2. conjunction,
3. existential quantification.

As the next proposition shows, the complexity of $\operatorname{CSP}(\Gamma)$ is, in effect, determined by $\langle\Gamma\rangle$; in particular, the problems $\operatorname{CSP}\left(\Gamma_{1}\right)$ and $\operatorname{CSP}\left(\Gamma_{2}\right)$ are of the same complexity if $\left\langle\Gamma_{1}\right\rangle=\left\langle\Gamma_{2}\right\rangle$.

Proposition 3.5 ([34,12]). Let $\Gamma_{1}$ and $\Gamma_{2}$ be sets of predicates over a finite set, such that $\Gamma_{1}$ is finite. If $\left\langle\Gamma_{1}\right\rangle \subseteq\left\langle\Gamma_{2}\right\rangle$, then $\operatorname{CSP}\left(\Gamma_{1}\right)$ is logarithmic-space reducible to $\operatorname{CSP}\left(\Gamma_{2}\right)$.

As with Theorem 3.2, this proposition was originally stated with polynomial-time reducibility, but it can be changed to logarithmic-space reducibility by using results of [47].

Finally, the third ingredient in the proof of Theorem 3.2 is the observation that the set $\langle\Gamma\rangle$ has an alternative characterization, which allows us to jump back to the polymorphisms of $\Gamma$.

Proposition 3.6 ([45]). For any set of predicates $\Gamma$ over a finite set, $\langle\Gamma\rangle=\operatorname{lnv}(\operatorname{Pol}(\Gamma))$.
In Section 3.3 below, we will show that each of these three ingredients has an analog in the analysis of the QCSP.

### 3.2. Known classification results

A number of results on the complexity of constraint satisfaction problems have been obtained via the viewpoint of polymorphisms (see survey [40]). Indeed, we can re-state the classic dichotomy theorem of Schaefer [50] using the notion of polymorphism.

Theorem 3.7 ([50]). For any $\Gamma \subseteq R_{\{0,1\}}, \operatorname{CSP}(\Gamma)$ is in PTIME when $\operatorname{Pol}(\Gamma)$ contains one of the following:

- the constant 0 or constant 1 operations,
- the conjunction $(\wedge)$ or disjunction $(\vee)$ operations,
- the affine operation $x-y+z(\bmod 2)$,
- the majority operation $(x \vee y) \wedge(x \vee z) \wedge(y \vee z)$.

In all other cases, $\operatorname{CSP}(\Gamma)$ is NP-complete.

This reformulation of Schaefer's theorem can be demonstrated to follow from Theorem 3.2 and well-known algebraic results of Post [46]; see [34].

The complexity of $\operatorname{QCSP}(\Gamma)$ has also been completely classified in the Boolean case, giving an analog of Theorem 3.7 for quantified constraints.

Theorem 3.8 ([19,20]). For any $\Gamma \subseteq R_{\{0,1\}}, \operatorname{QCSP}(\Gamma)$ is in PTIME when Pol( $\Gamma$ ) contains one of the following:

- the conjunction $(\wedge)$ or disjunction $(\vee)$ operations,
- the affine operation $x-y+z(\bmod 2)$,
- the majority operation $(x \vee y) \wedge(x \vee z) \wedge(y \vee z)$.

In all other cases, $\operatorname{QCSP}(\Gamma)$ is PSPACE-complete.
Using this theorem, it is not difficult to determine the complexity of the games described in Examples 2.5-2.10 in the special case of a two-valued domain.

Corollary 3.9. In the special case when $D=\{0,1\}$ :
(1) The games not-all-EQUAL 2-COLOURING and ONE-IN-THREE 2-COLOURING are PSPACE-complete.
(2) The games Graph 2-COLOURING, ONE-OR-BOTH COLOUR MATCHING, COLOUR IMPLICATION and LINEAR EQUATIONS can be decided in polynomial time.

Proof. It is easy to verify that if $\Gamma$ is $\left\{\varrho_{\text {nae }}\right\}$ or $\left\{\varrho_{1 i n}\right\}$ then none of the four operations from Theorem 3.8 is a polymorphism of $\Gamma$. By Theorem 3.8, this proves part (1).

It is also straightforward to check that the majority operation is a polymorphism of every binary predicate on $\{0,1\}$. Hence, by Theorem 3.8, the first three games listed in part (2) are polynomial-time decidable, since these games correspond to QCSPs with binary predicates. (Note that in the colour implication game we interpret black as 1 and white as 0 .) Finally, the affine operation is a polymorphism of any Boolean predicate given by a linear equation over GF(2), which shows that the fourth game listed in part (2) can also be decided in polynomial time.

Theorem 3.8 was originally proved using combinatorial methods which do not easily generalize to larger sets of values. However, this theorem is most concisely stated using polymorphisms. In the next section we will show that, as with the complexity of $\operatorname{CSP}(\Gamma)$, for all finite sets of values the complexity of $\operatorname{QCSP}(\Gamma)$ depends only on the polymorphisms of $\Gamma$. In particular, we will show that a suitably modified version of Theorem 3.2 holds with $\operatorname{QCSP}(\Gamma)$ in place of $\operatorname{CSP}(\Gamma)$ (see Theorem 3.16). Thus, the algebraic approach of using polymorphisms to study complexity can also be applied to quantified constraints.

### 3.3. Surjective polymorphisms and the QCSP

As we noted in Section 3.1, the successful use of the algebraic approach to the CSP is possible due to three statements: Propositions 3.3, 3.5 and 3.6.

We now establish that in the case of the QCSP three similar properties hold for surjective polymorphisms. We thereby introduce a new Galois connection that involves surjective polymorphisms in place of arbitrary polymorphisms. We show that surjective polymorphisms play a similar role in the analysis of the QCSP to that played by arbitrary polymorphisms for the ordinary CSP (cf. Theorem 3.2). Let s-Pol $(\Gamma)$ denote the set of all surjective operations contained in $\mathrm{Pol}(\Gamma)$. First, it is not hard to verify that the operators $\operatorname{Inv}(\cdot)$ and $s-\operatorname{Pol}(\cdot)$ form a Galois correspondence.

Proposition 3.10. Let $\Gamma, \Gamma^{\prime}$ be sets of predicates on a finite set $A$ and let $C, C^{\prime}$ be sets of surjective operations on $A$. Then

$$
\begin{array}{ll}
\Gamma \subseteq \Gamma^{\prime} \Longrightarrow \mathrm{s}-\operatorname{Pol}(\Gamma) \supseteq \mathrm{s}-\operatorname{Pol}\left(\Gamma^{\prime}\right) & C \subseteq C^{\prime} \Longrightarrow \operatorname{Inv}(C) \supseteq \operatorname{Inv}\left(C^{\prime}\right) \\
\Gamma \subseteq \operatorname{lnv}(\mathrm{s}-\operatorname{Pol}(\Gamma)) & C \subseteq \mathrm{~s}-\operatorname{Pol}(\operatorname{Inv}(C)) \\
\mathrm{s}-\operatorname{Pol}(\Gamma)=\mathrm{s}-\operatorname{Pol}(\operatorname{Inv}(\mathrm{s}-\operatorname{Pol}(\Gamma))) & \operatorname{Inv}(C)=\operatorname{Inv}(\mathrm{s}-\operatorname{Pol}(\operatorname{Inv}(C)))
\end{array}
$$

Next, we show that the complexity of $\operatorname{QCSP}(\Gamma)$ depends only on the set of predicates [ $\Gamma$ ], defined as follows.
Definition 3.11. For any set $\Gamma \subseteq R_{D}$, the set [ $\Gamma$ ] consists of all predicates that can be expressed using

1. predicates from $\Gamma$, together with the binary equality predicate $=_{D}$ on $D$,
2. conjunction,
3. existential quantification,
4. universal quantification.

We have the following parallel to Proposition 3.5.

Proposition 3.12. Let $\Gamma_{1}$ and $\Gamma_{2}$ be sets of predicates over a finite set, such that $\Gamma_{1}$ is finite. If $\left[\Gamma_{1}\right] \subseteq\left[\Gamma_{2}\right]$, then $\operatorname{QCSP}\left(\Gamma_{1}\right)$ is logarithmic-space reducible to $\operatorname{QCSP}\left(\Gamma_{2}\right)$.

Proof. Let $D$ be a finite set, and let $\Gamma_{1}, \Gamma_{2} \subseteq R_{D}$. By Definition 3.11, for any $n$-ary relation $\varrho$ in $\left[\Gamma_{1}\right]$, the predicate $\varrho\left(x_{1}, \ldots, x_{n}\right)$ is equivalent to a formula $\Phi_{\varrho}$ of the form $\mathcal{Q}_{1} y_{1} \ldots \mathcal{Q}_{m} y_{m} \mathcal{C}$, where the $\mathcal{Q}_{i}, 1 \leq i \leq m$ are quantifiers, and $\mathcal{C}$ is a conjunction of (positive) atomic formulas involving only predicates from $\Gamma_{2} \cup\left\{=_{D}\right\}$ and variables $x_{1}, \ldots, x_{n}, y_{1}, \ldots, y_{m}$.

Let sentence $\mathcal{P}_{0}$ be an instance of $\operatorname{QCSP}\left(\Gamma_{1}\right)$. Replace each predicate $\varrho$ in $\mathcal{P}_{0}$ by the corresponding formula $\Phi_{\varrho}$, to obtain an equivalent formula $\mathcal{P}_{1}$. Since $\Gamma_{1}$ is finite, this can be done in logarithmic space. Transform $\mathcal{P}_{1}$ into prenex normal form by moving all quantifiers (in order) to the front of the formula (renaming variables as needed to avoid name clashes). This transformation can also be carried out in logarithmic space. The resulting sentence, $\mathcal{P}_{2}$, is an instance of $\operatorname{QCSP}\left(\Gamma_{2} \cup\left\{={ }_{D}\right\}\right)$, and $\mathcal{P}_{2}$ is clearly equivalent to $\mathcal{P}_{0}$.

It now only remains to remove any occurrences of the equality relation from $\mathcal{P}_{2}$. We shall assume that $|D| \geq 2$ (the case $|D|=1$ is trivial). Consider the graph $G=(V, E)$ whose vertices are the variables appearing in $\mathcal{P}_{2}$ and

$$
E=\left\{(x, y) \in V^{2} \mid(x=y) \text { is a subformula in } \mathcal{P}_{2}\right\}
$$

For each connected component $K$, order the variables by the order in which they are quantified in $\mathcal{P}_{2}$. If $K$ contains two variables, $x$ and $y$, such that $x$ is before $y$ in this ordering and $y$ is universally quantified, then $\mathcal{P}_{2}$ (and hence $\mathcal{P}_{0}$ ) is obviously false. Note that, by the result of [47], the existence of a path between two given vertices in an undirected graph can be decided in logarithmic space. In the remaining cases, all of the variables in $K$ after the first must be existentially quantified, and because of the equality constraints they must all take the same value as the first variable. Hence, they can all be replaced with the first variable, removing the corresponding quantifiers, and removing the equality constraints. This can also be achieved in logarithmic space because we only need to check the existence of paths in $G$ when transforming $\mathcal{P}_{2}$ as described above. After this procedure, we obtain a sentence $\mathcal{P}_{3}$ that is equivalent to $\mathcal{P}_{0}$ and is an instance of $\operatorname{QCSP}\left(\Gamma_{2}\right)$. Moreover, the whole transformation can be carried out in logarithmic space.

The next example shows that Proposition 3.12 is stronger than Proposition 3.5 (reformulated for the QCSP in place of the CSP), as [ $\Gamma$ ] may be strictly larger than $\langle\Gamma\rangle$.

Example 3.13. Let $\varrho$ be the relation $\{0,1\}^{4} \backslash\{(0,0,0,1),(1,1,1,0)\}$, and let $\varrho_{\text {nae }}$ be the relation $\{0,1\}^{3} \backslash\{(0,0,0),(1,1,1)\}$ (as in Example 2.5). By "universally quantifying away" the last coordinate of $\varrho$, we obtain $\varrho_{\text {nae }} \in[\{\varrho\}]$. On the other hand, because the constant 0 and constant 1 operations are both polymorphisms of $\varrho$, every relation in $\langle\{\varrho\}\rangle$ contains both the "all-zeroes" tuple $(0, \ldots, 0)$ and the "all-ones" tuple $(1, \ldots, 1)$ by Theorem 3.6. It follows immediately that $\varrho_{\text {nae }} \notin\langle\{\varrho\}\rangle$. Setting $\Gamma_{1}=\left\{\varrho_{\text {nae }}\right\}$ and $\Gamma_{2}=\{\varrho\}$, we observe that $\Gamma_{1} \nsubseteq\left\langle\Gamma_{2}\right\rangle$, and $\Gamma_{1} \subseteq\left[\Gamma_{2}\right]$, giving examples of predicate sets $\Gamma_{1}, \Gamma_{2}$ such that the hypothesis of Proposition 3.12 holds, but the hypothesis of Proposition 3.5 does not. (Note that $\Gamma_{1} \subseteq\left\langle\Gamma_{2}\right\rangle$ if and only if $\left\langle\Gamma_{1}\right\rangle \subseteq\left\langle\Gamma_{2}\right\rangle$; likewise, $\Gamma_{1} \subseteq\left[\Gamma_{2}\right]$ if and only if $\left[\Gamma_{1}\right] \subseteq\left[\Gamma_{2}\right]$.)

In fact, we can use Proposition 3.12 to exhibit an example of a predicate giving rise to trivial CSPs, but also giving rise to intractable QCSPs.

Example 3.14. Let the relations $\varrho$ and $\varrho_{\text {nae }}$ be defined as in Example 3.13. Since $\varrho_{\text {nae }} \in[\{\varrho\}]$, Proposition 3.12 implies that $\operatorname{QCSP}\left(\left\{\varrho_{n a e}\right\}\right)$ reduces to $\operatorname{QCSP}(\{\varrho\})$, so by Corollary 3.9, $\operatorname{QCSP}(\{\varrho\})$ is PSPACE-complete. On the other hand, $\operatorname{CSP}(\{\varrho\})$ is trivial, as any instance is satisfiable by the "all-zeroes" or "all-ones" assignment.

Proposition 3.12 demonstrates the importance of the set $[\Gamma]$ with respect to the complexity of $\operatorname{QCSP}(\Gamma)$. By analogy to Theorem 3.6, $[\Gamma]$ can also be characterized in terms of polymorphisms.

Proposition 3.15. For any set of predicates $\Gamma$ over a finite set, we have $[\Gamma]=\operatorname{Inv}(\mathrm{s}-\mathrm{Pol}(\Gamma))$.
Proof. Let $D$ be a finite set, and let $\Gamma \subseteq R_{D}$. The equality relation, $=_{D}$, is invariant under every operation on $D$, so $\Gamma \cup\left\{==_{D}\right\} \subseteq$ $\operatorname{Inv}(s-\operatorname{Pol}(\Gamma))$. Let $f$ be a surjective operation on $D$. It is straightforward to verify that applying conjunction or any quantification to predicates invariant under $f$ gives another predicate which is also invariant under $f$. Hence, $[\Gamma] \subseteq \operatorname{lnv}(s-\operatorname{Pol}(\Gamma))$. Moreover, it follows that $\mathrm{s}-\mathrm{Pol}(\Gamma)=\mathrm{s}-\mathrm{Pol}([\Gamma])$.

To establish that $[\Gamma] \supseteq \operatorname{lnv}(\mathrm{s}-\mathrm{Pol}(\Gamma)$ ), we will show that for any $m$-ary relation $\varrho \in \operatorname{Inv}(\mathrm{s}-\mathrm{Pol}(\Gamma))$, the relation $\sigma$ is a member of $[\Gamma]$, where $\sigma$ is defined by

$$
\sigma=\left\{\left(a_{1}, a_{2}, \ldots, a_{m}, d_{1}, d_{2}, \ldots, d_{|D|}\right) \mid\left(a_{1}, \ldots, a_{m}\right) \in \varrho,\left(d_{1}, \ldots, d_{|D|}\right) \in D^{|D|}\right\}
$$

From this it follows that $\varrho \in[\Gamma]$, by existentially quantifying over the last $|D|$ variables in $\sigma$.
To show that $\sigma \in[\Gamma]$, we first define $\sigma^{\prime}=\bigcap\{\gamma \in[\Gamma] \mid \sigma \subseteq \gamma\}$. (Note that the intersection is finite.) Since [ $\Gamma$ ] contains the total relation $D^{m+|D|}$, and is closed under conjunction, $\sigma^{\prime}$ is a member of $[\Gamma]$ and $\sigma \subseteq \sigma^{\prime}$. In fact, $\sigma^{\prime}$ is the minimal relation of arity $m+|D|$ in [ $\Gamma$ ] with this property (when ordered by inclusion).

Now choose any tuple $\vec{c}=\left(b_{1}, \ldots, b_{m}, d_{1}, d_{2}, d_{3}, \ldots, d_{|D|}\right) \in \sigma^{\prime}$. Note that $\sigma^{\prime}$ must also contain all tuples of the form $\left(b_{1}, \ldots, b_{m}, d_{1}^{\prime}, d_{2}^{\prime}, d_{3}^{\prime}, \ldots, d_{|D|}^{\prime}\right)$, for each possible choice of $d_{1}^{\prime}, d_{2}^{\prime}, d_{3}^{\prime}, \ldots, d_{|D|}^{\prime}$, since otherwise we could obtain a smaller relation $\sigma^{\prime \prime}$ containing $\sigma$, by applying a sequence of universal quantifications, followed by a conjunction with the total relation $D^{m+|D|}$. Hence we may choose $\vec{c}$ so that the values of the $d_{i}$ are all distinct, that is, $\left\{d_{1}, d_{2}, \ldots, d_{|D|}\right\}=D$.

By Definition 3.11, $[\Gamma]$ is closed under conjunction and existential quantification, and contains the equality relation, $=_{D}$. It is well-known (see Theorems 1.2.3 and 2.1.3 in [45]), that such sets satisfy the condition $[\Gamma]=\operatorname{Inv}(\operatorname{Pol}([\Gamma])$ ). Furthermore, it is well-known (see Proposition 1.1.19 of [45]) and straightforward to verify that

$$
\sigma^{\prime}=\left\{f\left(\vec{a}_{1}, \ldots, \vec{a}_{n}\right) \mid n \geq 1, \vec{a}_{1}, \ldots, \vec{a}_{n} \in \sigma, f \in \operatorname{Pol}([\Gamma])\right\} .
$$

Therefore, there exist $n \geq 1, \vec{a}_{1}, \ldots, \vec{a}_{n} \in \sigma$ and an $n$-ary function $f \in \operatorname{Pol}([\Gamma])$ such that $\vec{c}=f\left(\vec{a}_{1}, \ldots, \vec{a}_{n}\right)$.
By the choice of $\vec{c}$, the function $f$ must be surjective. Therefore $f$ is in s- $\operatorname{Pol}([\Gamma])$, and so $f \in \mathrm{~s}-\operatorname{Pol}(\Gamma)$, by the observation above. By the choice of $\varrho$, this implies that $\varrho$ is invariant under $f$, and so $\left(b_{1}, \ldots, b_{m}\right) \in \varrho$. It follows that $\sigma^{\prime}=\sigma$, so $\sigma \in[\Gamma]$, as required.

We can now conclude that the complexity of $\operatorname{QCSP}(\Gamma)$ depends only on s-Pol $(\Gamma)$, the surjective polymorphisms of $\Gamma$. The following theorem follows immediately from Propositions 3.10, 3.12 and 3.15.

Theorem 3.16. Let $\Gamma_{1}$ and $\Gamma_{2}$ be sets of predicates over a finite set, such that $\Gamma_{1}$ is finite. Ifs-Pol $\left(\Gamma_{2}\right) \subseteq$ s-Pol $\left(\Gamma_{1}\right)$, then $\operatorname{QCSP}\left(\Gamma_{1}\right)$ is logarithmic-space reducible to $\operatorname{QCSP}\left(\Gamma_{2}\right)$.

This theorem offers a dual perspective on the phenomenon displayed by Example 3.14, whereby a predicate set $\Gamma$ can simultaneously give rise to a trivial CSP and give rise to an intractable QCSP. What is occurring is that the operations in POI( $\Gamma$ ) that guarantee tractability of $\operatorname{CSP}(\Gamma)$ are non-surjective, and hence are not present in s-Pol $(\Gamma)$.

## 4. Tractability

Comparing the statements of Theorems 3.7 and 3.8, we observe that, in two-valued domains, surjective polymorphisms which ensure the tractability of the CSP also ensure the tractability of the QCSP. However, it certainly cannot be taken for granted that a similar statement holds for non-Boolean domains. In this section, we show that it does hold for two broad classes of surjective polymorphisms.

### 4.1. Mal'tsev operations

An operation $m(x, y, z)$ on $D$ is said to be Mal'tsev if it satisfies the identities $m(x, y, y)=m(y, y, x)=x$ for all $x, y$. For example, for an Abelian group $G$, the operation $f(x, y, z)=x-y+z$, called the affine operation of $G$, is a Mal'tsev operation. Relations invariant under the affine operation of a finite Abelian group play a significant role in the study of the complexity of the standard constraint satisfaction problem [27,34,36].

Let $\Gamma=\operatorname{Inv}(\{m\})$, where $m$ is some fixed Mal'tsev operation. A polynomial-time algorithm for solving $\operatorname{CSP}(\Gamma)$ was given in [10]. Moreover, this algorithm also finds a satisfying assignment for any satisfiable instance of $\operatorname{CSP}(\Gamma)$. We will show now that $\operatorname{QCSP}(\Gamma)$ can also be solved in polynomial time by making repeated use of this algorithm.

Lemma 4.1. Let $m$ be a Mal'tsev operation on a finite set $D$, let $\mathcal{P}$ be an instance of $\operatorname{CCSP}(\operatorname{Inv}(\{m\})), \mathcal{P}=\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{n} x_{n} \psi\left(x_{1}, \ldots\right.$, $x_{n}$ ), and let $j$ be the maximal index such that $\mathcal{Q}_{j}$ is the universal quantifier.
(1) If $\psi^{\prime}\left(x_{1}, \ldots, x_{j-1}\right)=\forall x_{j} \exists x_{j+1} \ldots \exists x_{n} \psi\left(x_{1}, \ldots, x_{n}\right)$ is satisfiable then,forany model $\left(c_{1}, \ldots, c_{n}\right)$ of $\psi$, the tuple $\left(c_{1}, \ldots\right.$, $\left.c_{j-1}\right)$ is a model of $\psi^{\prime}$.
(2) $\mathcal{P}$ is true if and only if $\mathcal{P}^{\prime}=\mathcal{P}_{1} \wedge \mathcal{P}_{2}$ is true, where

$$
\begin{aligned}
& \mathcal{P}_{1}=\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{j-1} x_{j-1} \exists x_{j} \exists x_{j+1} \ldots \exists x_{n} \psi\left(x_{1}, \ldots, x_{n}\right), \\
& \mathcal{P}_{2}=\exists x_{1} \ldots \exists x_{j-1} \forall x_{j} \exists x_{j+1} \ldots \exists x_{n} \psi\left(x_{1}, \ldots, x_{n}\right) .
\end{aligned}
$$

## Proof

(1) Let $\left(a_{1}, \ldots, a_{j-1}\right)$ be a model for $\psi^{\prime}$, and for each $b \in D$, let $\left(a_{j}^{b}, \ldots, a_{n}^{b}\right)$ be an extension such that $\vec{a}^{b}=\left(a_{1}, \ldots, a_{j-1}, a_{j}^{b}\right.$, $\ldots, a_{n}^{b}$ ) is a model for $\psi$ and $a_{j}^{b}=b$.

Take an arbitrary model $\vec{c}=\left(c_{1}, \ldots, c_{j-1}, c_{j}, \ldots, c_{n}\right)$ of $\psi$. We need to show that $\left(c_{1}, \ldots, c_{j-1}\right)$ is a model of $\psi^{\prime}$. Fix an arbitrary $b \in D$ and let $\vec{d}=\left(d_{1}, \ldots, d_{n}\right)$ be equal to $m\left(\vec{a}^{b}, \vec{a}^{c_{j}}, \vec{c}\right)$. Proposition 3.15 implies that the predicate defined by $\psi$ is invariant under $m$, so $\vec{d}$ is a model of $\psi$, too. Moreover, we have $d_{i}=m\left(a_{i}, a_{i}, c_{i}\right)=c_{i}$ for $i \in\{1, \ldots, j-1\}$ and $d_{j}=m\left(a_{j}^{b}, a_{j}^{c_{j}}, c_{j}\right)=m\left(b, c_{j}, c_{j}\right)=b$. Thus, $\left(c_{1}, \ldots, c_{j-1}\right)$ is a model of $\psi^{\prime}$.

```
Input \(\mathcal{P}=\mathscr{2}_{1} x_{1} \ldots \mathscr{2}_{n} x_{n} \psi\left(x_{1}, \ldots, x_{n}\right)\) where \(\psi=\varrho_{1} \wedge \ldots \wedge \varrho_{q}\), and all \(\varrho_{i} \in \Gamma\).
Output 'YES' if \(\mathcal{P}\) is true, 'NO' otherwise.
    Step 1 solve the instance \(\exists x_{1} \ldots \exists x_{n} \psi\)
    Step 2 if \(\psi\) has a model then find one, \(\left(c_{1}, \ldots, c_{n}\right)\)
                            else output('NO') and stop
Step 3 for \(l=n, \ldots, 1\) do
Step 3.1 if \(\mathscr{Q}_{l}\) is the universal quantifier then
Step 3.2 for each \(b \in D\) do
Step 3.2.1 solve the instance \(\exists x_{l+1} \ldots \exists x_{n} \psi\left(c_{1}, \ldots, c_{l-1}, b, x_{l+1}, \ldots, x_{n}\right)\)
Step 3.2.2 If this instance has no solution then output('NO')
        and stop
            enddo
        enddo
Step 4 output('YES')
```

Fig. 1. Algorithm for deciding $\operatorname{QCSP}(\Gamma)$ when $\Gamma$ has a Mal'tsev polymorphism.
(2) Obviously, if $\mathcal{P}$ is true then $\mathcal{P}^{\prime}$ is also true. The inverse implication easily follows from part (1). Indeed, since $\mathcal{P}_{2}$ is true, we can apply (1); then, (1) implies that every tuple ( $c_{1}, \ldots, c_{j-1}$ ) that can be extended to a model of $\psi$ can be extended so with $c_{j}$ being any given element. Thus, since $\mathcal{P}_{1}$ is true, so is $\mathcal{P}$.

Theorem 4.2. Let $m$ be an arbitrary Mal'tsev operation on a finite set $D$. The problem class $\operatorname{QCSP}(\operatorname{Inv}(\{m\}))$ is in PTIME.
Proof. Let $\mathcal{P}=\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{n} x_{n} \psi\left(x_{1}, \ldots, x_{n}\right)$ be an instance of the problem class QCSP( $\left.\operatorname{Inv}(\{m\})\right)$. By repeatedly applying Lemma 4.1(2), one can show that $\mathcal{P}$ can be decomposed into a conjunction of instances which have the same quantifier-free part and each contain at most one universal quantifier. Moreover, if we can find a model of $\psi$ then Lemma 4.1(1) implies that initial segments of this model can be used in deciding whether each of the instances is true. It remains to notice that, as is easy to check, fixing a value for any variable in a predicate from $\operatorname{Inv}(\{m\})$ gives another predicate invariant under $m$, which implies that $\exists x_{l+1} \ldots \exists x_{n} \psi\left(c_{1}, \ldots, c_{l-1}, b, x_{l+1}, \ldots, x_{n}\right)$ is also an instance of $\operatorname{CSP}(\operatorname{Inv}(\{m\}))$. Now it follows that the algorithm shown in Fig. 1 is correct.

This algorithm uses $k|D|+1$ applications of an algorithm for solving the $\operatorname{problem} \operatorname{CSP}(\operatorname{Inv}(\{m\}))$, where $k$ is the number of universal quantifiers in an instance, and one application of an algorithm finding a model. Now we can use the polynomial-time algorithm for $\operatorname{CSP}(\operatorname{Inv}(\{m\}))$ developed in [10]. This completes the proof of Theorem 4.2.

Note that if the operation $m$ has a special form then the method described above can be used to derive more specialised, and more efficient, algorithms. For example, let $G$ be a finite Abelian group, with affine operation $f$, and unit element 0 , and let $\Gamma$ be a finite set of relations over $G$ which are invariant under $f$. Note that, by straightforward algebraic manipulation, it can be shown that any ( $n$-ary) relation invariant under $f$ is a coset of a subgroup of the group $G^{n}$.

In the simplest case, when the order of $G$ is prime, $G$ can be considered as a prime field, and hence $G^{n}$ can be considered as a vector space over $G$. In this case, each coset of a subgroup of $G^{n}$ is a linear variety, and it is well-known that such varieties can be defined by systems of linear equations, whose coefficients are elements of the field G. Therefore, in this case, QCSP (Г) can be considered as the problem of solving quantified linear systems over $G$, which can be done by applying standard techniques from linear algebra, or by using them in the above algorithm.

In the case when $G$ is an arbitrary Abelian group, $\operatorname{QCSP}(\Gamma)$ requires a similar but slightly more involved algorithm, see [5].

### 4.2. Near-unanimity operations

Our second example of surjective polymorphisms which give rise to tractable quantified constraint satisfaction problems concerns operations known as near-unanimity operations. An operation $f: D^{k} \rightarrow D$ is said to be near-unanimity if $k \geq 3$ and $f$ returns the value $a$ whenever at least $k-1$ of its arguments are equal to $a$; that is, for all $a, b \in D$, it holds that $a=f(b, a, a, \ldots, a, a, a)=f(a, b, a, \ldots, a, a, a)=\ldots=f(a, a, a, \ldots, a, b, a)=f(a, a, a, \ldots, a, a, b)$.

Before giving the tractability result for the QCSP associated with such polymorphisms, we introduce some notions of consistency.

Definition 4.3 ([35]). Let $\psi$ be an instance of the CSP with variable set $V=\left\{x_{1}, \ldots, x_{n}\right\}$. For a subset $V^{\prime}$ of $V$, a mapping $g^{\prime}: V^{\prime} \rightarrow D$ is a partial solution to $\psi$ if, for every atomic formula $\varrho(\vec{v})$ from $\psi$, there is an extension $g: V \rightarrow D$ of $g^{\prime}$ satisfying $\varrho(\vec{v})$. For any $j \geq 2$, the formula $\psi$ is said to be $j$-consistent if, for every subset $V^{\prime}$ of $V$ with $\left|V^{\prime}\right|=j-1$ and for every variable $v \in V \backslash V^{\prime}$, any partial solution $g^{\prime}: V^{\prime} \rightarrow D$ of $\psi$ can be extended to a partial solution $g^{\prime}: V^{\prime} \cup\{v\} \rightarrow D$ of $\psi$. The instance $\psi$ is strongly $k$-consistent if it is $j$-consistent for $j=2, \ldots, k$. The formula $\psi$ is said to be globally consistent if it is strongly $|V|$-consistent.

The following theorem shows that when a constraint language is invariant under a near-unanimity operation, ensuring a sufficiently high (but constant) degree of "local" consistency implies global consistency.

Theorem 4.4 ([35]). Let $f$ be an arbitrary near-unanimity operation of arity $r$ on a finite set D. Any instance of $\operatorname{CSP}(\operatorname{lnv}(\{f\}))$ which is strongly r-consistent is globally consistent.

Theorem 4.4 implies that invariance under a near-unanimity operation implies CSP tractability, as any CSP instance $\psi$ can be transformed into one that is strongly $r$-consistent in polynomial time, as follows. For each subset of variables $U=\left\{u_{1}, \ldots, u_{s}\right\}$, with $2 \leq s \leq r$, compute the relation $\varrho_{U}=\left\{\left(g\left(u_{1}\right), \ldots, g\left(u_{s}\right)\right) \mid g: U \rightarrow D\right.$ is a partial solution to $\left.\psi\right\}$. Then for each subset of $U$ containing $s-1$ variables, add a constraint whose relation allows precisely those assignments that can be extended to some element of $\varrho_{U}$. Note that these new constraints can be obtained from the original constraints (and the complete relation) by conjunction and existential quantification. Since $r$ is a constant, the new constraints can be obtained in polynomial time, and it can be straightforwardly checked that the obtained CSP instance is strongly $r$-consistent and has the same set of satisfying assignments as $\psi$.

We now prove that invariance under a near-unanimity operation implies tractability for QCSP as well.
Theorem 4.5. Let $f$ be an arbitrary near-unanimity operation on a finite set $D$. The problem class $\operatorname{QCSP}(\operatorname{Inv}(\{f\}))$ is in PTIME.
Proof. Let $f$ be a near-unanimity operation of arity $r$, and let $\mathcal{P}$ be an instance of the $\operatorname{QCSP}(\operatorname{Inv}(\{f\}))$ problem, $\mathcal{P}=\mathcal{Q}_{1} x_{1}$ $\ldots \mathcal{Q}_{n} x_{n} \psi$. We show that a new instance $\mathcal{P}^{\prime}$ of the $\operatorname{QCSP}(\operatorname{lnv}(\{f\}))$ problem can be computed in polynomial time, where $\mathcal{P}^{\prime}$ has one fewer quantifier than $\mathcal{P}$. Moreover, the instance $\mathcal{P}^{\prime}$ will have the property that it is valid if and only if $\mathcal{P}$ is valid. This suffices to establish that $\operatorname{QCSP}(\Gamma)$ is in PTIME, since the procedure can be iteratively applied to decide the validity of an instance of QCSP $(\Gamma)$.

The new formula $\mathcal{P}^{\prime}$ is obtained from $\mathcal{P}$ by elimination of the innermost quantifier and associated quantified variable, $\mathcal{Q}_{n} x_{n}$. We split into two cases depending on the type of $\mathcal{Q}_{n}$.

Case $\mathcal{Q}_{n}=\exists$ : Obtain $\psi_{0}$ from $\psi$ by establishing strong $r$-consistency; this can be done in polynomial time, as described above. As the procedure for establishing strong $r$-consistency involves adding predicates that can be obtained from the original predicates by using conjunction and existential quantification, all predicates in $\psi_{0}$ are invariant under $f$. We next create a formula $\psi^{\prime}$ by including in it every constraint from $\psi_{0}$, but "projecting out" the variable $x_{n}$ from any constraints where it is present. More precisely, we create $\psi^{\prime}$ as follows: for every constraint $\varrho_{0}\left(\vec{v}_{0}\right)$ in $\psi_{0}$, if $\vec{v}_{0}$ does not contain $x_{n}$, then include the constraint $\varrho_{0}\left(\vec{v}_{0}\right)$ in $\psi^{\prime}$; otherwise, include in $\psi^{\prime}$ the atomic formula equivalent to $\exists x_{n} \varrho_{0}\left(\vec{v}_{0}\right)$.

By Theorem 4.4, any satisfying assignment for $\psi^{\prime}$ can be extended to a satisfying assignment for $\psi_{0}$. Moreover, any satisfying assignment for $\psi_{0}$ is straightforwardly verified to be a satisfying assignment for $\psi^{\prime}$, from the definition of $\psi^{\prime}$. We therefore have that $\psi^{\prime}=\exists x_{n} \psi_{0}$, and may define $\mathcal{P}^{\prime}$ to be $\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{n-1} x_{n-1} \psi^{\prime}$.

Case $\mathcal{Q}_{n}=\forall$ : Create a formula $\psi^{\prime}$ from the formula $\psi$ as follows: replace each constraint $\varrho(\vec{v})$ in $\psi$ by the atomic formula equivalent to $\forall x_{n} \varrho(\vec{v})$. Since $f$ is surjective, every predicate in the new formula is invariant under $f$. We may therefore define $\mathcal{P}^{\prime}=\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{n-1} x_{n-1} \psi^{\prime}$.

Note that Theorem 4.5 can be strengthened for a special ternary near-unanimity operation known as the dual discriminator, which is the operation $d$ such that $d(x, y, z)=y$ if $y=z$ and $d(x, y, z)=x$ otherwise. It was shown in [5] that $\operatorname{QCSP}(\operatorname{lnv}(\{d\}))$ belongs to the complexity class NL.

## 5. Intractability

In this section we will use Theorem 3.16 to give a sufficient condition, in terms of surjective polymorphisms, for PSPACEcompleteness of QCSP $(\Gamma)$. We first establish that a particular QCSP problem is PSPACE-complete. This problem corresponds to a generalized form of the standard GRAPH- $|D|$-COLOURABILITY problem [30,43] (see Example 2.7).

Proposition 5.1. $\operatorname{QCSP}\left(\left\{\neq D_{D}\right\}\right)$ is PSPACE-complete when $|D| \geq 3$.

Proof. We prove this by reduction from $\operatorname{QCSP}\left(\left\{\varrho_{n a e}\right\}\right)$, where $\varrho_{\text {nae }}$ is the ternary not-all-equal predicate on 2 -element set, as defined in Example 2.5. Let $\mathcal{P}$ be an instance of $\operatorname{QCSP}\left(\left\{\varrho_{n a e}\right\}\right)$, with variables $v_{1}, v_{2}, \ldots, v_{n}$. We construct a corresponding instance $\mathcal{P}^{\prime}$ of $\operatorname{QCSP}\left(\left\{\neq D_{D}\right\}\right)$ as follows.

First construct a graph, $G_{\mathcal{P}}$, as shown in Fig. 2, with 3 nodes for each variable $v_{i}$ of $\mathcal{P}$ (labelled $x_{i}, y_{i}$ and $z_{i}$ ), 3 nodes for each triple of variables constrained by $\varrho_{\text {nae }}$ in $\mathcal{P}$, and one additional node (labelled $w$ ). Connect these nodes as indicated in Fig. 2, so that each $z_{i}$ is connected to $y_{i}$, each $y_{i}$ is connected to $x_{i}$ and $w$, and each $x_{i}$ is connected to $w$. For each triple of nodes representing a constraint on $v_{i_{1}}, v_{i_{2}}, v_{i_{3}}$, connect these nodes to form a triangle and also add edges from these nodes to the corresponding nodes $x_{i_{1}}, x_{i_{2}}, x_{i_{3}}$.

The standard $|D|$-colouring problem for the graph $G_{\mathcal{P}}$ can be represented as the satisfiability problem for the formula built as follows: introduce a variable for each node of the graph, and form a conjunction which contains a binary disequality

Fig. 2. The construction used in the proof of Proposition 5.1 (adapted from Fig. 9.8 in [43]).
constraint $\left.\neq D^{( } u, v\right)$ for each edge $(u, v)$ of the graph. (If $D$ contains more than 3 values, then we add a clique $C$ containing $|D|-3$ nodes to the graph $G_{\mathcal{P}}$ and connect each node, except the nodes $z_{i}$, in the original graph to each node of this clique. This ensures that each node, except the nodes $z_{i}$, in the original graph $G_{\mathcal{P}}$ must be coloured with one of the 3 colours not used to colour C.)

Now add quantifiers to this conjunction of constraints as follows. First existentially quantify the variable $w$ (and all the variables corresponding to nodes of the clique $C$, if present). Note that once values have been assigned to these nodes there are just two remaining possible values for each node $x_{i}$ and $y_{i}$.

Next, for each consecutive quantifier of $\mathcal{P}$ (in order) introduce 3 consecutive quantifiers as follows:

- For each existential quantifier in $\mathcal{P}, \exists v_{i}$, introduce $\exists z_{i} \exists y_{i} \exists x_{i}$.
- For each universal quantifier in $\mathcal{P}, \forall v_{i}$, introduce $\forall z_{i} \exists y_{i} \exists x_{i}$.

Finally, add existential quantifiers for all remaining variables (corresponding to the constraints of $\mathcal{P}$ ). This completes the definition of $\mathcal{P}^{\prime}$.

It is straightforward to check that there is an assignment of Boolean values to the variables $v_{1}, v_{2}, \ldots, v_{n}$ satisfying all of the constraints of $\mathcal{P}$ if and only if there is an assignment of values from $D$ to the variables of $\mathcal{P}^{\prime}$ satisfying all the constraints of $\mathcal{P}^{\prime}$. This is because to satisfy the constraints of $\mathcal{P}^{\prime}$, the 3 nodes in each triangle in $G_{\mathcal{P}}$ corresponding to a constraint of $\mathcal{P}$ must all be assigned distinct values, which is possible if and only if the corresponding nodes $x_{i_{1}}, x_{i_{2}}$ and $x_{i_{3}}$ connected to them do not all take the same value (which mimics satisfying assignments for the constraint $\varrho_{\text {nae }}\left(v_{i_{1}}, v_{i_{2}}, v_{i_{3}}\right)$ ). Furthermore, the construction of the quantifiers in $\mathcal{P}^{\prime}$ ensures that the sentence $\mathcal{P}^{\prime}$ is true if and only if $\mathcal{P}$ is true. To see this, note that for any variable $v_{i}$ of $\mathcal{P}$ which is universally quantified, the universal quantification on the corresponding $z_{i}$ in $\mathcal{P}^{\prime}$ forces $y_{i}$ (and, hence, $x_{i}$ ) to take both remaining available values, which mimics the universal quantification on $v_{i}$.

Hence, we have established a reduction from $\operatorname{QCSP}\left(\left\{\varrho_{n a e}\right\}\right)$ to $\operatorname{QCSP}\left(\left\{\neq D_{D}\right\}\right)$, and it is clear that this reduction can be carried out in logarithmic space. Since $\operatorname{QCSP}\left(\left\{\varrho_{n a e}\right\}\right)$ is PSPACE-complete, by Corollary 3.9, the result follows.

Theorem 5.2. For any finite set $D$ with $|D| \geq 3$, and any $\Gamma \subseteq R_{D}$, if every $f \in \operatorname{s-Pol}(\Gamma)$ is of the form $f\left(x_{1}, \ldots, x_{n}\right)=\pi\left(x_{i}\right)$ for some $1 \leq i \leq n$ and some permutation $\pi$ on $D$, then $\operatorname{QCSP}(\Gamma)$ is PSPACE-complete.

Proof. By Lemma 1.3.1 (b) of [45], $\operatorname{Pol}(\{\neq D\})$, for $|D| \geq 3$, consists of all operations of the form described in the Theorem. Hence $\operatorname{Pol}\left(\left\{\neq D_{D}\right\}\right)=\mathrm{s}-\operatorname{Pol}\left(\left\{\neq D_{D}\right\}\right)$, and we can apply Theorem 3.16 and Proposition 5.1.

We now give an example of a relation which has all possible non-surjective polymorphisms, but whose surjective polymorphisms are precisely the operations described in Theorem 5.2.

Example 5.3. Let $\tau_{s}$ be the $s$-ary "not-all-distinct" predicate holding on a tuple ( $a_{1}, \ldots, a_{s}$ ) if and only if $\left|\left\{a_{1}, \ldots, a_{s}\right\}\right|<s$. Note that $\tau_{s} \supseteq\{(a, \ldots, a) \mid a \in D\}$, so every instance of $\operatorname{CSP}\left(\left\{\tau_{s}\right\}\right)$ is trivially satisfiable by assigning the same value to all variables.

However, by Lemma 2.2.4 of [45], the set $\operatorname{Pol}\left(\left\{\tau_{|D|}\right\}\right)$ consists of all possible non-surjective operations on $D$, together with all operations of the form given in Theorem 5.2. Hence, $\left\{\tau_{|D|}\right\}$ satisfies the conditions of Theorem 5.2, and $\operatorname{QCSP}\left(\left\{\tau_{|D|}\right\}\right)$ is PSPACE-complete (when $|D| \geq 3$ ).

Interestingly, the predicate $\tau_{|D|}$ has the property that, for every predicate $\varrho \in\left\langle\tau_{|D|}\right\rangle \backslash\left\langle=_{D}\right\rangle$, we have $\langle\varrho\rangle=\left\langle\tau_{|D|}\right\rangle$ (Lemma 2.2.4 of [45]).

## 6. Semilattice operations

A semilattice operation $*$ on a set $D$ is a binary operation that satisfies the following conditions for all $a, b, c \in D$ :
(1) $*(a, a)=a($ idempotency $)$;
(2) $*(a, b)=*(b, a)$ (commutativity);
(3) $*(*(a, b), c)=*(a, *(b, c))$ (associativity).

Normally we shall use infix notation for semilattice operations and write $a * b$ rather than $*(a, b)$. As is easily seen, the propositional conjunction and disjunction operations are semilattice operations on the set $\{0,1\}$.

It is well-known that every semilattice operation $*$ induces a partial order $\leq_{*}$ where $a \leq * b$ if and only if $a_{*} b=b$. For $a, b \in D$, the element $a * b$ is the least upper bound of $a, b$ with respect to this order, i.e., $a, b \leq * a_{*} b$ and, for any $d \in D$ such that $a, b \leq * d$, we have $a * b \leq * d$.

Every semilattice operation $*$ has a zero element 0 with the property that $a \leq * 0$, or equivalently $a_{*} 0=0 * a=0$, for all $a \in A$. If a semilattice operation also has a unit element - that is an element 1 such that $1 \leq * a$, or equivalently $1 * a=a * 1=a$, for all $a \in A$ - then we say that it is a semilattice operation with unit or a monoid operation; otherwise, we say that it is a semilattice operation without unit. Interestingly, if $*$ is a monoid operation then, for any $a, b \in D$, there is a unique greatest lower bound $c$ of $a, b$ with respect to this order, i.e., $c \leq * a, b$ and, for any $d \in D$ such that $d \leq * a, b$, we have $d \leq * c$ (in other words, the order $\leq$ sis a lattice order). The greatest lower bound of $a, b$ will be denoted by $a \circ b$. Operation $*$ can be extended to an operation on tuples of elements from $D$ in the usual way (by applying the operation componentwise).

All forms of semilattice operations were shown to guarantee CSP tractability in [36]. For the QCSP the situation is rather different. The following theorem completely classifies the complexity of the QCSP over a set of predicates invariant under a semilattice operation.

Theorem 6.1. Let $*$ be a semilattice operation on a finite set $D$. If $*$ is an operation with unit then, for any finite $\Gamma \subseteq \operatorname{lnv}(\{*\})$, the problem $\operatorname{QCSP}(\Gamma)$ is in PTIME. Otherwise, there exists a finite $\Gamma \subseteq \operatorname{Inv}(\{*\})$ such that $\operatorname{QCSP}(\Gamma)$ is PSPACE-complete.

Note that the first part of this theorem establishes only "local tractability", that is, tractability for any finite subset of $\operatorname{Inv}(\{*\})$.

The proof of Theorem 6.1 is given in Sections 6.1 and 6.2 below.

### 6.1. Semilattice operations with unit

In this section, we demonstrate that finite sets of predicate which are invariant under a semilattice operation with unit give rise to tractable subproblems of the QCSP.

Our first step is to demonstrate that constraints which are invariant under a semilattice operation are decomposable into what we call Horn-like clauses. We introduce the following definitions and notation. A downward literal is an expression of the form $v \leq{ }_{*} d$, where $v$ is a variable and $d \in D$; and, an upward literal is an expression of the form $v \not \mathbb{*}_{*} d$, where $v$ is a variable and $d \in D$. We will call literals of the form $v \leq * 0$ or $v \not \subset * 0$ trivial. A literal occurring in a QCSP instance is an $\exists$-literal ( $\forall$-literal) if its variable is an existentially (universally) quantified variable. A Horn-like clause is a set with downward and upward literals as elements which contains at most one downward literal. A Horn-like clause is interpreted as the disjunction of the literals that it contains; that is, it is considered to be true if at least one of its literals is true.

Lemma 6.2. A predicate $\varrho$ is invariant under a semilattice operation if and only if $\varrho$ can be represented as a conjunction of Horn-like clauses.

Proof. For any semilattice operation $*$, the element $v_{1} * v_{2}$ is the least upper bound of $v_{1}, v_{2}$ with respect to the order $\leq_{*}$ Hence, $v_{1 *} v_{2} \leq * a$ if and only if $v_{1} \leq * a$ and $v_{2} \leq * a$. Using this result it is straightforward to verify that any Horn-like clause is invariant under the corresponding semilattice operation.

For the converse, let $\varrho$ be invariant under a semilattice operation $*$. It suffices to show that for each $\vec{a} \notin \varrho$, there exists a Horn-like clause $H_{\vec{a}}$ such that any tuple from $\varrho$ satisfies $H_{\vec{a}}$, but $\vec{a}$ does not satisfy $H_{\vec{a}}$. Fix $\vec{a} \notin \varrho$, and define $\sigma_{\vec{a}}=\{\vec{b}: \vec{b} \in$ $\varrho, \vec{b} \leq * \vec{a}\}$ where $\leq$ sis extended to a partial ordering on tuples by defining $\vec{s} \leq \vec{t}$ if and only if at all coordinates $i, \vec{s}(i) \leq \vec{t}(i)$.

If $\sigma_{\vec{a}}$ is empty, then it can be verified that the Horn-like clause $H_{\vec{a}}=\bigcup_{i=1}^{r}\{\vec{v}(i) \not 又 * \vec{a}(i)\}$ has the desired properties, where $r$ denotes the length of the tuples $\vec{v}$ and $\vec{a}$. Otherwise, define $\vec{m}=\vec{b}_{1} * \vec{b}_{2} * \ldots * \vec{b}_{n}$, where $\sigma_{\vec{a}}=\left\{\vec{b}_{1}, \vec{b}_{2}, \ldots, \vec{b}_{n}\right\}$. It is straightforward to verify that $\sigma_{\vec{a}}$ is invariant under $*$, so $\vec{m} \in \sigma_{\vec{a}}$. Since $\sigma_{\vec{a}} \subseteq \varrho, \vec{m} \neq \vec{a}$, and $\vec{m}$ and $\vec{a}$ differ at some coordinate, say coordinate $j$ (that is, $\vec{m}(j) \neq \vec{a}(j)$, which implies that $\vec{m}(j)<_{*} \vec{a}(j)$ ). Hence, it can be verified that the Horn-like clause $H_{\vec{a}}=\left(\bigcup_{i=1}^{r}\left\{\vec{v}(i) \not{ }^{*} \vec{a}(i)\right\}\right) \cup\{\vec{v}(j) \leq * \vec{m}(j)\}$ has the desired properties.

Lemma 6.2 generalizes Horn's classic theorem that a constraint with relation invariant under logical AND ( $\wedge$ ) over the set $\{0,1\}$ is logically equivalent to a conjunction of Horn clauses [33]. To see this, we let $*=\wedge$; then we have $1 \leq * 0$ and the
only non-trivial downward literal is one of the form $v \leq * 1$, which is equivalent to the positive literal $v$. The only non-trivial upward literal is one of the form $v \not \leq * 1$, which is equivalent to the negative literal $\bar{v}$.

Our next step is to define a proof system, called QCSP-literal-resolution, and show that it is sound and complete for quantified formulas consisting of Horn-like clauses, with respect to a semilattice operation $*$ with unit. We define a Hornlike clause $H$ appearing in a QCSP $\mathcal{P}$ to be an existential unit clause if it contains only one $\exists$-literal, the single $\exists$-literal is downward, and for every $\forall$-variable $y$ in $H, y$ comes before the variable of the $\exists$-literal in the quantification order of the formula $\mathcal{P}$.

Definition 6.3. Let $\mathcal{P}$ be a QCSP instance with quantifier-free part $\psi$ where every predicate in $\psi$ is a Horn-like clause (with respect to a semilattice operation $*$ with unit). We say that a Horn-like clause $H$ is derivable by QCSP-literal-resolution from the formula $\psi$, denoted $\psi \vdash_{l} H$, if it can be obtained by applying the following rules.
0 . For every predicate $H$ in $\psi, \psi \vdash_{l} H$.

1. If $\psi \vdash_{l} H_{1}, \psi \vdash_{l} H_{2}$, and there exist elements $a, b \in D$ with $(x \leq * a) \in H_{1}$ and $(x \leq * b) \in H_{2}$, for some existentially quantified variable $x$, then

$$
\psi \vdash_{l}\left(H_{1} \backslash\{x \leq * a\}\right) \cup\left(H_{2} \backslash\{x \leq * b\}\right) \cup\{x \leq * a \circ b\}
$$

2. If $\psi \vdash_{l} H$ and $(x \leq * a) \in H$ for some $a \in D$ and some existentially quantified variable $x$, then for all $b \in D$ such that $a \leq * b$

$$
\psi \vdash_{l}\left(H \backslash\left\{x \leq_{*} a\right\}\right) \cup\left\{x \leq_{*} b\right\}
$$

3. If $\psi \vdash_{l} U$ and $\psi \vdash_{l} H$, where $U$ is an existential unit clause with downward literal $(x \leq * a)$, and $(x \not \leq * a) \in H$, then

$$
\psi \vdash_{l}(U \backslash\{x \leq * a\}) \cup(H \backslash\{x \nless * a\})
$$

4. If $\psi \vdash_{l} H, y$ is a universally quantified variable which is the last variable in the quantification order of $\psi$ occurring in $H$, and there exists a value $a \in D$ such that the assignment $y=a$ does not satisfy $H_{y}$ (the clause containing all $y$-literals in $H$ ), then

$$
\psi \vdash_{l} H \backslash H_{y} .
$$

Lemma 6.4. Let $\mathcal{P}$ be a QCSP instance with quantifier-free part $\psi$ such that every predicate in $\psi$ is a Horn-like clause (with respect to a semilattice operation $*$ with unit) without trivial literals. The sentence $\mathcal{P}$ is false if and only if $\psi \vdash_{l} \emptyset$.

Proof. Each of the rules listed in Definition 6.3 preserves satisfiability, so the "if" direction is straightforward, and we will focus on the "only if" direction. Assume without loss of generality that $\mathcal{P}$ has the form

$$
\forall y_{1} \exists x_{1} \ldots \forall y_{n} \exists x_{n} \psi\left(y_{1}, x_{1}, \ldots, y_{n}, x_{n}\right)
$$

and suppose that it is not the case that $\psi \vdash_{l} \emptyset$. Define (for $k=1, \ldots, n$ )

$$
\begin{aligned}
& \tau_{k}\left(a_{1}, \ldots, a_{k}\right)=*\left\{a \mid \text { the assignment } y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=a\right. \\
& \left.\quad \text { satisfies all existential unit clauses } C \text { containing } x_{k} \text { such that } \psi \vdash_{l} C\right\}
\end{aligned}
$$

Note that $\tau_{k}\left(a_{1}, \ldots, a_{k}\right)=0$ if there is no derivable existential unit clause containing $x_{k}$. We claim that the mappings $\tau_{k}$ form a winning strategy for $\exists$ in $\psi$. Let $f:\left\{y_{1}, \ldots, y_{n}\right\} \rightarrow D$ be an assignment to the $\forall$-variables of $\psi$; we wish to show that the assignment

$$
\tau_{f}(z)= \begin{cases}f\left(y_{k}\right) & \text { if } z=y_{k} \\ \tau_{k}\left(f\left(y_{1}\right), \ldots, f\left(y_{k}\right)\right) & \text { if } z=x_{k}\end{cases}
$$

satisfies all clauses of $\psi$. By rule 0 , it suffices to show that $\tau_{f}$ satisfies all clauses $H$ such that $\psi \vdash_{l} H$. Recall that a Horn-like clause potentially contains four types of literals: upward $\exists$-literals, upward $\forall$-literals, downward $\exists$-literals and downward $\forall$-literals, but has at most one downward literal of either kind. We shall prove that $\tau_{f}$ satisfies all clauses $H$ such that $\psi \vdash_{l} H$ by induction on the number, $u$, of upward $\exists$-literals contained in $H$.

We split the proof into three cases.
Case 1: $u=0$ and $H$ does not contain any downward $\exists$-literals either. In this case all literals of $H$ are $\forall$-literals, so if $\tau_{f}$ does not satisfy $H$, then the empty set can be derived from $H$ using rule 4, a contradiction.

Case 2: $u=0$ and $H$ contains a downward $\exists$-literal. By repeatedly applying rule 4 to eliminate $\forall$-literals in $H$ as many times as possible we obtain a new clause $H^{\prime}$. If the last variable in $H^{\prime}$ (relative to the quantification order of $\psi$ ) is a universally quantified variable $y$, then for all $a \in D$, every extension of the assignment $y=a$ satisfies $H^{\prime}$, and so in particular $H^{\prime}$ is satisfied by $f$. On the other hand, if the last variable in $H^{\prime}$ is an $\exists$-variable $x$, then $H^{\prime}$ is an existential unit clause and is satisfied by $\tau_{f}$ by the definition of the $\tau_{k}$.

Case 3 (Induction Step): Assume that $H$ contains at least one upward $\exists$-literal, $x_{k} \not \mathbb{Z}_{*} d$, and that all derivable clauses with a smaller number of upward $\exists$-literals are satisfied by $\tau_{f}$. Since clauses in $\psi$ contain only non-trivial literals, it can be easily verified that $H$ cannot contain the literal $x_{k} \not \approx * 0$, that is, we have $d<* 0$. Suppose (for contradiction) that $\tau_{f}$ does not satisfy $H$; then $\tau_{f}\left(x_{k}\right) \leq * d$.

For $i=1, \ldots, k$, denote $f\left(y_{i}\right)$ by $a_{i}$. Since $\tau_{f}\left(x_{k}\right)<* 0$, there exists an existential unit clause $C$ containing $x_{k}$ such that $\psi \vdash_{l} C$ and $C$ is not satisfied by the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=0$ (note that $C$ is clearly satisfied by the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=1$ ). Consider the existential unit clause $U$ obtained by applying rule 1 to all such clauses. Note that a further application of rule 1 to $C$ and $U$ would produce $U$ again. Clearly, we have that $\psi \vdash_{l} U$ and $U$ is not satisfied by the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=0$. Let $x_{k} \leq * t$ be the only downward $\exists$-literal in $U$. We argue that $t=\tau_{f}\left(x_{k}\right)$. If, for some $a$, the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=a$ satisfies all derivable existential unit clauses containing $x_{k}$, then, in particular, it satisfies $U$. Since $U$ is not satisfied by the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=0$, it follows that $a \leq * t$. Then, by the definition of $\tau_{f}$, we have $\tau_{f}\left(x_{k}\right) \leq * t$. On the other hand, the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=t$ satisfies all derivable existential unit clauses containing $x_{k}$. Clearly, it satisfies all such clauses that are satisfied already by the assignment $y_{1}=a_{1}, \ldots, y_{k}=a_{k}, x_{k}=0$. Furthermore, it satisfies the downward literal $x_{k} \leq * t^{\prime}$ in any other derivable existential unit clause $C^{\prime}$ containing $x_{k}$ because, as we mentioned above, the application of rule 1 to $C^{\prime}$ and $U$ gives $U$, implying that $t \circ t^{\prime}=t$, which is equivalent to $t \leq * t^{\prime}$. Hence, by the definition of $\tau_{f}$, we have $t \leq * \tau_{f}\left(x_{k}\right)$, and so $t=\tau_{f}\left(x_{k}\right)$. To summarize, the derivable existential unit clause $U$ contains the literal $x_{k} \leq * \tau_{f}\left(x_{k}\right)$ and has the property that $\tau_{f}$ does not satisfy $U \backslash\left\{x_{k} \leq * \tau_{f}\left(x_{k}\right)\right\}$.

Now by applying rule 2 we obtain $\psi \vdash_{l} U^{\prime}$, where $U^{\prime}=\left(U \backslash\left\{x_{k} \leq{ }_{*} \tau_{f}\left(x_{k}\right)\right\}\right) \cup\left\{x_{k} \leq * d\right\}$. Finally, by applying rule 3 we obtain $\psi \vdash_{l} H^{\prime}$, where $H^{\prime}=\left(U^{\prime} \backslash\left\{x_{k} \leq{ }_{*} d\right\}\right) \cup\left(H \backslash\left\{x_{k} \not{ }_{*} d\right\}\right)$. Notice that $H^{\prime}$ is not satisfied by $\tau_{f}$. Indeed, $\tau_{f}$ does not satisfy $U \backslash\left\{x_{k} \leq * \tau_{f}\left(x_{k}\right)\right\}$, and $U^{\prime} \backslash\left\{x_{k} \leq * d\right\}$ is just the same clause. Furthermore, $\tau_{f}$ does not satisfy $H \backslash\left\{x_{k} \not \mathbb{Z}_{*} d\right\}$ because, by our assumption, it does not satisfy $H$. The clause $H^{\prime}$ contains one less upward $\exists$-literal than $H$, but is not satisfied by $\tau_{f}$; this contradicts our inductive hypothesis.

Proposition 6.5. Let $*$ be an arbitrary semilattice operation with unit on a finite set $D$. For any finite $\Gamma \subseteq \operatorname{lnv}(\{*\})$, the problem class $\operatorname{QCSP}(\Gamma)$ is in PTIME.

Proof. Let $\mathcal{P}=\forall y_{1} \exists x_{1} \ldots \forall y_{n} \exists x_{n} \psi$ be an instance of $\operatorname{QCSP}(\Gamma)$, and let $*$ be a semilattice operation with unit element 1 and zero element 0 under which $\Gamma$ is invariant. By appeal to Lemma 6.2, every predicate invariant under $*$ can be represented as a conjunction of Horn-like clauses. In general, the size of this representation can grow exponentially (in the size of the predicate). However, for any fixed finite $\Gamma \subseteq \operatorname{lnv}(\{*\})$, this representation for all predicates in $\Gamma$ can be found in constant time. Hence, we can assume that $\psi$ contains only Horn-like clauses. We assume without loss of generality that no literals in $\psi$ are trivial.

Let $B^{\exists}$ denote the subset of $\psi$ containing all clauses with a downward $\exists$-literal. Let $B^{\forall}$ denote the subset of $\psi$ containing all clauses with a downward $\forall$-literal; and let $U$ denote the subset of $\psi$ containing all clauses having only upward literals. It can be straightforwardly verified that for every clause $C$ derivable from $\psi$ by QCSP-literal-resolution, there is a single $H \in B^{\forall} \cup U$ such that $C$ is derivable from $\mathcal{P}_{H} \stackrel{\text { def }}{=} \forall y_{1} \exists x_{1} \ldots \forall y_{n} \exists x_{n}\left(B^{\exists} \cup\{H\}\right)$. (This is because, by examination of the five rules, any derivable clause with a downward $\exists$-literal can be derived from $B^{\exists}$; the claim can then be proved by induction on the structure of a proof.) Hence, by Lemma 6.4, deciding whether or not $\mathcal{P}$ is true amounts to deciding whether or not $\mathcal{P}_{H}$ is true, for all $H \in B^{\forall} \cup U$. We will therefore show how to decide any such $\mathcal{P}_{H}$ in polynomial time. There are two cases to consider:

Case 1: $H \in U$. In this case we claim that the sentence $\mathcal{P}_{H}$ is true if and only if the CSP instance

$$
\exists x_{1} \ldots \exists x_{n}\left(\bigwedge\left\{C \backslash C^{\forall} \mid C \in B^{\exists} \cup\{H\}\right\}\right)
$$

is satisfiable (where $C^{\forall}$ denotes the set of all $\forall$-literals in the clause $C$ ). To establish this claim note that if this CSP instance is satisfiable, a satisfying assignment for it gives a winning strategy for $\mathcal{P}_{H}$ (which ignores the $\forall$-player); on the other hand, if this CSP instance is unsatisfiable, then $\mathcal{P}_{H}$ is unsatisfiable as the $\forall$-player can set all $\forall$-variables to 1 to falsify all $\forall$-literals, causing the $\exists$-player to lose. Satisfiability of this CSP instance can be decided in polynomial time by the results of [36], because all predicates in it are invariant under a semilattice operation.
Case 2: $H \in B^{\forall}$. In this case, let $y$ denote the variable in the downward literal of $H$ and remove all $\forall$-literals not over $y$ from the clauses of $B^{\exists} \cup\{H\}$ to obtain the set of clauses $\psi^{\prime}$. We claim that $\mathcal{P}_{H}$ is true if and only if $\mathcal{P}_{H}^{\prime}=\forall y_{1} \exists x_{1} \ldots \forall y_{n} \exists x_{n}\left(\psi^{\prime}\right)$ is true. We justify this as follows. First, from a QCSP-literal-resolution derivation of $\emptyset$ from $\mathcal{P}_{H}$, we may obtain a derivation of $\emptyset$ from $\mathcal{P}_{H}^{\prime}$ by removing, in the derivation, all $\forall$-literals not including $y$. Indeed, it is easy to check, by examining the
five rules, that every step in the obtained derivation remains valid. Second, a derivation of $\emptyset$ from $\mathcal{P}_{H}^{\prime}$ gives a derivation of $\emptyset$ from $\mathcal{P}_{H}$ by adding in $\forall$-literals as appropriate to derive (from $\mathcal{P}_{H}$ ) a clause consisting only of $\forall$-variables, from which $\emptyset$ can be derived by repeated applications of QCSP-literal-resolution rule 4 (with $a=1$ ). Notice that when the last variable in a clause in the quantification order is a $\forall$-variable $y$, all literals involving $y$ can be removed by using rule 4 with $a=1$.

We now show how to decide if $\mathcal{P}_{H}^{\prime}$ is true by reducing this question to an equivalent CSP instance. Let $y_{i}$ denote the single $\forall$-variable occurring in $\psi^{\prime}$. Clearly, $\mathcal{P}_{H}^{\prime}$ is equivalent to $\mathcal{P}_{H}^{\prime \prime}=\exists x_{1} \ldots \exists x_{i-1} \forall y_{i} \exists x_{i} \exists x_{i+1} \ldots \exists x_{n}\left(\psi^{\prime}\right)$. For all $a \in D$, define $\mathcal{P}_{a}^{\prime \prime}$ to be the formula $\mathcal{P}_{a}^{\prime \prime}=\exists x_{1}^{a} \ldots \exists x_{n}^{a}\left(\psi^{\prime}\left[y_{i} / a\right]\right)$ ), that is, the formula obtained from $\mathcal{P}_{H}^{\prime \prime}$ by eliminating $y_{i}$ from the quantifier prefix, instantiating $y_{i}$ with the value $a$ in $\psi^{\prime}$, and renaming each variable $x_{j}$ as $x_{j}^{a}$. We want to find assignments satisfying the predicates of the $\mathcal{P}_{a}^{\prime \prime}$ such that, for each $j=1, \ldots, i-1$, the values received by the variables $x_{j}^{a}$ are the same for all $a$. We can formulate the existence of such assignments as a CSP instance which has all the predicates of all the $\mathcal{P}_{a}^{\prime \prime}$ as constraints, as well as additional constraints $x_{j}^{a}=x_{j^{\prime}}^{a}$ for all $a \in D$ and all $1 \leq j<j^{\prime} \leq i-1$. This CSP instance is polynomial in the size of $\mathcal{P}_{H}$, and all predicates in it are invariant under the semilattice operation $*$. Hence, this instance can be decided in polynomial time by the results of [36].

### 6.2. Semilattice operations without unit

In this section, we show that if a semilattice operation $*$ on a set $D$ has no unit then $\operatorname{QCSP}(\operatorname{Inv}(\{*\}))$ is PSPACE-complete. First we note that if the semilattice operation $*$ has no unit then there are at least two different minimal elements with respect to $\leq_{*}$ We shall fix two such elements $a, b$ and denote the set $D \backslash\{a, b\}$ by $E$. Note that the minimality of $a, b$ implies that, for any $d \in D$, if $d \neq a$ then $a_{*} d \in E$, and if $d \neq b$ then $b * d \in E$.

To prove the PSPACE-completeness of $\operatorname{QCSP}(\operatorname{Inv}(\{*\}))$, we will make use of the following known combinatorial problem.
Definition 6.6 (succinct graph unreachability). A succinct representation of a digraph with $n$ vertices, where $n=2^{c}$ is a power of two, is a Boolean circuit $C$ with $2^{c}$ inputs. The digraph represented by $C$, denoted $G_{C}$, is defined as follows: the vertices of $G_{C}$ are $\{1,2, \ldots, n\}$; the pair $(i, j)$ is an edge of $G_{C}$ if and only if $C$ accepts the binary representations of the $c$-bit integers $i, j$ as inputs.

In the succinct graph unreachability problem we are given a succinct representation of a digraph $G$ and two vertices $s, t$ of the graph. The question is whether there is no path in $G$ that connects $s$ and $t$.

It is known (see, e.g., Exercise 20.2.9(b) of [43]) that the succinct Graph reachability problem is PSPACE-complete, and it follows that sUCCINCT GRAPH UNREACHABILITY is also PSPACE-complete.

Proposition 6.7 Let $*$ be a semilattice operation without unit. The SUCCINCT GRAPH UNREACHABILITY problem is polynomial-time reducible to $\operatorname{QCSP}(\Gamma)$ where $\Gamma$ is the set of all at most ternary relations from $\operatorname{Inv}(\{*\})$.

We remark that, in contrast to earlier results, the type of reduction employed here is polynomial-time reduction.
Proof. Let $C$ be a succinct representation of a directed graph $G_{C}$. Encodings of vertices of $G_{C}$, that is $c$-tuples, will be denoted by $\vec{x}, \vec{y}$ etc., where $\vec{x}=\left(x_{1}, \ldots, x_{c}\right)$.

Let $\varrho_{\vec{s}}(\vec{x})$ denote the formula $\varrho_{s_{1}}\left(x_{1}\right) \wedge \ldots \wedge \varrho_{s_{c}}\left(x_{c}\right)$, where each $\varrho_{d}$ is a constant relation, that is, a unary relation containing the single tuple (d). It is easily checked that each $\varrho_{d}$ is invariant under the operation * (here, the idempotency of * is used).

Now define a predicate $\varphi_{C}$ such that $\varphi_{C}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is true if and only if $\vec{x}, \vec{y} \in\{a, b\}^{c}$ and $\vec{x}=\vec{y}$, or there is a path in $G_{C}$ from the vertex encoded $\vec{x}$ to the vertex encoded $\vec{y}$ and $z_{1}=z_{2}$, or such a path does not exist, or one of $\vec{x}, \vec{y}$ does not belong to $\{a, b\}^{c}$. Note that $\varphi_{C}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is false precisely when $\vec{x}$ and $\vec{y}$ are encodings of distinct vertices in $G_{C}$ which are connected by a path, and $z_{1} \neq z_{2}$.

Using these predicates, an instance $C, \vec{s}, \vec{t}$ of the SUCCINCT GRAPH UNREACHABILITY problem can be reduced to the formula

$$
\mathcal{P}=\exists \vec{x}, \vec{y} \forall z_{1}, z_{2} \varrho_{\vec{s}}(\vec{x}) \wedge \varrho_{\vec{t}}(\vec{y}) \wedge \varphi_{C}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)
$$

Hence there exists a polynomial-time reduction from SUCCINCT GRAPH UNREACHABILITY to QCSP $(\Gamma)$ where $\Gamma$ is the set of all at most ternary relations from $\operatorname{Inv}(\{*\})$, provided that the predicate $\varphi_{C}$ can be transformed to an instance of $\operatorname{QCSP}(\Gamma)$ in polynomial time.

Step 1: Expressing the predicate $\varphi_{C}$ in simpler terms. We shall first show that the predicate $\varphi_{C}$ can be expressed using the predicate $\varphi\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ which is defined as follows. Predicate $\varphi\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is true if and only if $\vec{x}, \vec{y} \in\{a, b\}^{c}$ and $\vec{x}=\vec{y}$, or there is an edge in $G_{C}$ from the vertex encoding $\vec{x}$ to the vertex encoding $\vec{y}$ and $z_{1}=z_{2}$, or such an edge does not exist, or one of $\vec{x}, \vec{y}$ does not belong to $\{a, b\}^{c}$.

The most straightforward way to construct the predicate $\varphi_{C}$ is to define it inductively, as follows:

$$
\begin{aligned}
\varphi_{0}^{\prime}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right) & =\varphi\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right) \\
\varphi_{i}^{\prime}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right) & =\forall \vec{w}_{i} \exists r_{i} \varphi_{i-1}^{\prime}\left(\vec{x}, \vec{w}_{i}, z_{1}, r_{i}\right) \wedge \varphi_{i-1}^{\prime}\left(\vec{w}_{i}, \vec{y}, r_{i}, z_{2}\right)
\end{aligned}
$$

and $\varphi_{C}=\varphi_{c}^{\prime}$. Unfortunately, $\varphi_{c}^{\prime}$ is exponentially larger than $\varphi_{C}$, so we cannot use this technique directly. However, we can use a standard trick to obtain a shorter expression for $\varphi_{C}$ using universal quantifiers. To do this, we define the predicates $\varphi_{i}$ inductively, as follows:

$$
\begin{aligned}
& \varphi_{0}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)= \varphi\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right) \\
& \varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)= \forall \vec{w}_{i} \exists r_{i} \forall \vec{u}_{i}, \vec{v}_{i} \exists z_{i}^{\prime}, z_{i}^{\prime \prime} \\
& \qquad \varphi_{i-1}\left(\vec{u}_{i}, \vec{v}_{i}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right) \wedge \psi\left(\vec{x}, \vec{y}, \vec{u}_{i}, \vec{v}_{i}, \vec{w}_{i}, r_{i}, z_{1}, z_{2}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right) .
\end{aligned}
$$

In the above expression, the predicate $\psi\left(\vec{x}, \vec{y}, \vec{u}, \vec{v}, \vec{w}, z, z_{1}, z_{2}, z^{\prime}, z^{\prime \prime}\right)$ is defined by the following conditions:

- $\vec{x}, \vec{w}, \vec{u}, \vec{v} \in\{a, b\}^{c}$ and $\vec{u}=\vec{x}, \vec{v}=\vec{w}$ implies $z^{\prime}=z_{1}, z^{\prime \prime}=z$, and
$\bullet \vec{y}, \vec{w}, \vec{u}, \vec{v} \in\{a, b\}^{c}$ and $\vec{u}=\vec{w}, \vec{v}=\vec{y}$ implies $z^{\prime}=z, z^{\prime \prime}=z_{2}$.
In other words, $\psi$ is false only if the equalities on the left hold while the equalities on the right do not.
Finally, to obtain a QCSP instance we transform $\varphi_{c}$ to prenex normal form moving all the quantifiers to the beginning of the formula preserving their order. It is not hard to see that the obtained formula is equivalent to $\varphi_{c}$. We set $\varphi_{C}$ to be equal to this formula.

To show that this definition correctly captures $\varphi_{C}$, we prove by induction that $\varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is false precisely when $\vec{x}, \vec{y}$ are encodings of distinct vertices $s, t$ of $G_{C}$ which are connected by a path of length at most $2^{i}$, but $z_{1} \neq z_{2}$. The base case of induction follows from the definition of $\varphi$. Suppose that the result holds for $\varphi_{i-1}$.

Suppose first that $\vec{x}, \vec{y}$ are encodings of distinct vertices of $G_{C}$ that are connected by a path of length at most $2^{i}$. Choose some $z_{1}, z_{2}$. If $z_{1}=z_{2}$ then take $r_{i}=z_{i}^{\prime}=z_{i}^{\prime \prime}=z_{1}=z_{2}$. In this case $\varphi_{i-1}\left(\vec{u}_{i}, \vec{v}_{i}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ and $\psi\left(\vec{x}, \vec{y}, \vec{u}_{i}, \vec{v}_{i}, \vec{w}_{i}, r_{i}, z_{1}, z_{2}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ hold for any $\vec{u}_{i}, \vec{v}_{i}, \vec{w}_{i}$, so $\varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is true. If $z_{1} \neq z_{2}$ then, since $\vec{x}, \vec{y}$ are connected with a path of length at most $2^{i}$, there is a vertex $\vec{w}_{i}$ such that $\vec{x}, \vec{w}_{i}$ and $\vec{w}_{i}, \vec{y}$ are connected with paths of length at most $2^{i-1}$. Choose $\vec{u}_{i}=\vec{x}, \vec{v}_{i}=\vec{w}_{i}$. Then if $\varphi_{i-1}\left(\vec{u}_{i}, \vec{v}_{i}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ is true then we have $z_{i}^{\prime}=z_{i}^{\prime \prime}$, and if $\psi\left(\vec{x}, \vec{y}, \vec{u}_{i}, \vec{v}_{i}, \vec{w}_{i}, r_{i}, z_{1}, z_{2}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ is true then we have $r_{i}=z_{1}$. Similarly we can derive $r_{i}=z_{2}$, which means that $\varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is false.

Suppose now that $\vec{x}, \vec{y}$ are encodings of vertices of $G_{C}$ that are not connected by a path of length at most $2^{i}$. Choose some $z_{1}, z_{2}$. If $\vec{w}_{i} \notin\{a, b\}^{c}$ then set $r_{i}=z_{i}^{\prime}=z_{i}^{\prime \prime}=a$. Under this assignment we have that $\psi\left(\vec{x}, \vec{y}, \vec{u}_{i}, \vec{v}_{i}, \vec{w}_{i}, r_{i}, z_{1}, z_{2}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ and $\varphi_{i-1}\left(\vec{u}_{i}, \vec{v}_{i}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ hold for any $\vec{u}_{i}, \vec{v}_{i}$, so $\varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is true. Hence we may assume that $\vec{w}_{i} \in\{a, b\}^{c}$. In this case at least one of the pairs $\vec{x}, \vec{w}_{i}$ and $\vec{w}_{i}, \vec{y}$ are not connected by a path of length at most $2^{i-1}$. Without loss of generality suppose that there is no such path for $\vec{x}, \vec{w}_{i}$. Then set $r_{i}=z_{2}$. If neither $\vec{u}_{i}=\vec{x}, \vec{v}_{i}=\vec{w}_{i}$ nor $\vec{u}_{i}=\vec{w}_{i}, \vec{v}_{i}=\vec{y}$ then by setting $z_{i}^{\prime}=z_{i}^{\prime \prime}=a$ we make both predicates true, so $\varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is true. If $\vec{u}_{i}=\vec{x}, \vec{v}_{i}=\vec{w}_{i}$ then we set $z_{i}^{\prime}=z_{1}, z_{i}^{\prime \prime}=r_{i}$. Then $\psi\left(\vec{x}, \vec{y}, \vec{u}_{i}, \vec{v}_{i}, \vec{w}_{i}, r_{i}, z_{1}, z_{2}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ is true. Since $\vec{u}_{i}, \vec{v}_{i}$ are not connected with a path of length $2^{i-1}, \varphi_{i-1}\left(\vec{u}_{i}, \vec{v}_{i}, z_{i}^{\prime}, z_{i}^{\prime \prime}\right)$ is also true. Finally, if $\vec{u}_{i}=\vec{w}_{i}, \vec{v}_{i}=\vec{y}$ we set $z_{i}^{\prime}=r_{i}, z_{i}^{\prime \prime}=z_{2}$, and, as $r_{i}=z_{2}$, both predicates are true, so again $\varphi_{i}\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)$ is true.

Finally, suppose that one of $\vec{x}, \vec{y}$ does not belong to $\{a, b\}^{c}$, say, $\vec{x} \notin\{a, b\}^{c}$. If $\vec{w}_{i} \notin\{a, b\}^{c}$ then we proceed as above. Otherwise set $r_{i}=z_{2}$. If $\vec{u}_{i} \neq \vec{w}_{i}$ or $\vec{v}_{i} \neq \vec{y}$ then setting $z_{i}^{\prime}=z_{i}^{\prime \prime}=a$ we make both predicates true. If $\vec{u}_{i}=\vec{w}_{i}$ and $\vec{v}_{i}=\vec{y}$ then set $z_{i}^{\prime}=r_{i}, z_{i}^{\prime \prime}=z_{2}$.

This completes the proof by induction and establishes that the predicate $\varphi_{C}$ can be transformed in polynomial time into a QCSP instance containing only the predicates $\varphi$ and $\psi$. As is easily seen both predicates, $\varphi$ and $\psi$, are invariant under the semilattice operation, however, they do not fit our purpose, because the explicit representations of these predicates are exponential in the size of the original succinct graph unreachability instance. Thus, we need to show that these two predicates can be expressed by using at most ternary predicates from $\operatorname{Inv}(\{*\})$ in polynomial time.

Step 2: Expressing the predicates $\varphi$ and $\psi$. First, we introduce three relations corresponding to three types of logic gates. We will call these relations gate relations. The relations are partly given by their matrices (where columns correspond to tuples); the initial block of tuples contains the tuples that encode the gate, while the remaining tuples are needed for technical purposes and to obtain a relation invariant under the semilattice operation. Element $a$ will be interpreted as FALSE and $b$ as TRUE.

$$
\begin{aligned}
\varrho_{\mathrm{NOT}} & =\left(\begin{array}{ll}
a & b \\
b & a
\end{array}\right) \cup(E \times D) \\
\varrho_{\mathrm{OR}} & =\left(\begin{array}{llll}
a & a & b & b \\
a & b & a & b \\
a & b & b & b
\end{array}\right) \cup(E \times D \times D) \cup(D \times E \times D)
\end{aligned}
$$

$$
\varrho_{\mathrm{AND}}=\left(\begin{array}{llll}
a & a & b & b \\
a & b & a & b \\
a & a & a & b
\end{array}\right) \cup(E \times D \times D) \cup(D \times E \times D)
$$

It is straightforward to verify that each of these gate relations is invariant under the semilattice operation*.
The circuit $C$ representing the graph $G_{C}$ is a Boolean circuit with gates $\left\{g_{1}, \ldots, g_{k}\right\}$, inputs $u_{1}, \ldots, u_{\ell}$ and output $z$. For each gate $g_{i}$, we denote the inputs of $g_{i}$ by $x_{i}, y_{i}$ (to simplify the notation we shall assume that if $g_{i}$ is a NOT-gate then it still has the second input $y_{i}$, but it is void), and its output by $z_{i}$. Then $u_{1}, \ldots, u_{\ell} \in\left\{x_{1}, \ldots, x_{k}, y_{1}, \ldots, y_{k}\right\}, z \in\left\{z_{1}, \ldots, z_{k}\right\}$ and $z_{1}, \ldots, z_{k} \in\left\{x_{1}, \ldots, x_{k}, y_{1}, \ldots, y_{k}\right\} \cup\{z\}$. Without loss of generality we may assume that $z=z_{k}$. We will also assume that $C$ has no unused inputs, that is, in the graph representation of $C$ there is a path from every $u_{i}$ to $z$. The encoding of circuit $C$ will be the following existential conjunctive formula:

$$
\theta_{C}\left(u_{1}, \ldots, u_{\ell}, z\right)=\exists z_{1}, \ldots, z_{k-1} \bigwedge_{i=1}^{k} \varrho_{w_{i}}\left(x_{i}, y_{i}, z_{i}\right)
$$

where $w_{i}$ denotes the type of gate $g_{i}$ : NOT, AND, or OR.
We need three observations about the formula $\theta_{C}$.
(1) If $u_{1}, \ldots, u_{\ell} \in\{a, b\}$ and the quantifier free part of $\theta_{C}\left(u_{1}, \ldots, u_{\ell}, z\right)$ is satisfied, then $z_{1}, \ldots, z_{k} \in\{a, b\}$. This is easily verified using induction on the depth of circuit $C$, and the fact that, for any $w \in\{$ NOT,AND,OR $\}$, if $x, y \in\{a, b\}$ and $\varrho_{w}(x, y, z)$ holds then $z \in\{a, b\}$.
(2) If $u_{1}, \ldots, u_{\ell} \in\{a, b\}$ and $\theta_{C}\left(u_{1}, \ldots, u_{\ell}, z\right)$ holds, then $z=b$ if and only if $C\left(u_{1}, \ldots, u_{\ell}\right)$ is TRUE; otherwise $z=a$. Again this is easily verified using induction on the depth of the circuit and the structure of the relations.
(3) If $\left\{u_{1}, \ldots, u_{\ell}\right\} \cap E \neq \emptyset$ then $\theta_{C}\left(u_{1}, \ldots, u_{\ell}, z\right)$ holds for any $z \in D$.

To establish this, assume without loss of generality that $u_{j} \in E$. We proceed by induction on the depth of circuit $C$. Recall that $C$ is assumed to have no unused inputs. In the base case of induction, when $C$ contains only one gate, the result follows from the definitions of the gate relations. For the induction step, remove the output gate $g_{k}$ from $C$; the rest of $C$ then breaks into two circuits $C_{1}$ and $C_{2}$ (which may overlap). If $g_{k}$ is a NOT-gate $C_{2}$ can be assumed to be empty. At least one of them uses input $u_{j}$; without loss of generality we assume it is $C_{1}$. Let the output of $C_{1}$ be $z_{k-1}$. By the induction hypothesis, $\theta_{C_{1}}\left(u_{1}, \ldots, u_{\ell}, d\right)$ holds for any $d \in E$. Since $z_{k-1}$ is an input for $g_{k}$, the result follows from the definition of the gate relations.

Now let $\eta$ be the following ternary relation

$$
\eta=\left\{\left.\left(\begin{array}{l}
b \\
d \\
d
\end{array}\right) \right\rvert\, d \in D\right\} \cup((\{a\} \cup E) \times D \times D)
$$

It is straightforward to verify that $\eta$ is invariant under the semilattice operation $*$.
We claim that the predicate $\varphi$ can be expressed in terms of the predicates $\theta_{C}$ and $\eta$ in the following way:

$$
\varphi\left(\vec{x}, \vec{y}, z_{1}, z_{2}\right)=\exists z \theta_{C}(\vec{x}, \vec{y}, z) \wedge \eta\left(z, z_{1}, z_{2}\right)
$$

To establish this claim, note first that if either $\vec{x}$ or $\vec{y}$ contains a component from $E$, then choosing $z=a$ we satisfy both predicates on the right-hand side. The same is true if $C(\vec{x}, \vec{y})$ is FALSE. Finally, if $\vec{x}, \vec{y}$ correspond to vertices that are connected, that is, $C(\vec{x}, \vec{y})$ is TRUE, then the only value of $z$ satisfying $\theta_{C}$ is $b$, so to satisfy $\eta$ we have to have $z_{1}=z_{2}$.

We have shown that the predicate $\varphi$ can be expressed in polynomial time by using at most ternary predicates from $\operatorname{lnv}(\{*\})$. It only remains to show that the predicate $\psi$ defined earlier can also be expressed in polynomial time by using at most ternary predicates from $\operatorname{Inv}(\{*\})$.

Define the relation $\sigma$, as follows

$$
\sigma=\left(\begin{array}{ll}
a & b \\
a & b \\
b & b
\end{array}\right) \cup(E \times E \times\{b\}) \cup(((D \times D) \backslash\{(a, a),(b, b)\}) \times(\{a\} \cup E))
$$

It is straightforward to verify that $\sigma$ is invariant under the semilattice operation $*$. Let

$$
\begin{aligned}
\xi_{=}(\vec{x}, \vec{y}, z)=\exists s_{1}, \ldots, s_{c} \exists z_{1}, \ldots, z_{c-2} & \bigwedge_{i=1}^{c} \sigma\left(x_{i}, y_{i}, s_{i}\right) \wedge \varrho_{\mathrm{AND}}\left(s_{1}, s_{2}, z_{1}\right) \\
& \wedge \bigwedge_{i=2}^{c-2} \varrho_{\mathrm{AND}}\left(z_{i-1}, s_{i+1}, z_{i}\right) \wedge \varrho_{\mathrm{AND}}\left(z_{c-2}, s_{c}, z\right)
\end{aligned}
$$

Furthermore, let

$$
\begin{aligned}
& \xi_{\rightarrow}\left(\vec{x}, \vec{y}, \vec{u}, \vec{v}, z_{1}, z_{2}, z_{1}^{\prime}, z_{2}^{\prime}\right)=\exists s_{1}, s_{2} \exists t \\
& \quad \xi_{=}\left(\vec{x}, \vec{u}, s_{1}\right) \wedge \xi_{=}\left(\vec{y}, \vec{v}, s_{2}\right) \wedge \varrho_{\text {AND }}\left(s_{1}, s_{2}, t\right) \wedge \eta\left(t, z_{1}, z_{1}^{\prime}\right) \wedge \eta\left(t, z_{2}, z_{2}^{\prime}\right)
\end{aligned}
$$

We claim that

$$
\begin{aligned}
\psi\left(\vec{x}, \vec{y}, \vec{u}, \vec{v}, \vec{w}, z, z_{1}, z_{2}, z_{1}^{\prime}, z_{2}^{\prime}\right)=\xi_{\rightarrow} & \left(\vec{x}, \vec{w}, \vec{u}, \vec{v}, z_{1}, z, z_{1}^{\prime}, z_{2}^{\prime}\right) \wedge \\
& \xi_{\rightarrow}\left(\vec{w}, \vec{y}, \vec{u}, \vec{v}, z, z_{2}, z_{1}^{\prime}, z_{2}^{\prime}\right)
\end{aligned}
$$

To establish this claim, first consider the predicate $\xi_{=}(\vec{x}, \vec{y}, z)$. If this predicate holds and $\vec{x}=\vec{y}$ then all the $s_{i}$ equal $b$, and furthermore all the $z_{i}$ and $z$ equal $b$. If $\vec{x} \neq \vec{y}$ or one of them does not belong to $\{a, b\}^{c}$ then, for some $i$, we have $x_{i} \neq y_{i}$ or $\left\{x_{i}, y_{i}\right\} \cap E \neq \emptyset$, and since $\sigma\left(x_{i}, y_{i}, s_{i}\right)$ is true, $s_{i}$ can be chosen from $E$. Therefore, $z_{i-1}, \ldots, z_{c-2}, z$ can be chosen arbitrarily. Thus, $\xi_{=}(\vec{x}, \vec{y}, z)$ is true if and only if either $\vec{x}=\vec{y}$ and $\vec{x}, \vec{y} \in\{a, b\}^{c}$ and $z=b$, or else $\vec{x} \neq \vec{y}$ and $z$ is arbitrary, or $\vec{x}, \vec{y} \notin\{a, b\}^{c}$ and $z$ is arbitrary. Similarly, the predicate $\xi_{\rightarrow}\left(\vec{x}, \vec{y}, \vec{u}, \vec{v}, z_{1}, z_{2}, z_{1}^{\prime}, z_{2}^{\prime}\right)$ is true if and only if either one of $\vec{x}, \vec{y}, \vec{u}, \vec{v}$ is not a member of $\{a, b\}^{c}$, or $\vec{x} \neq \vec{u}$, or $\vec{y} \neq \vec{v}$, or $\vec{x}=\vec{u}, \vec{y}=\vec{v}$ and $z_{1}=z_{1}^{\prime}, z_{2}=z_{2}^{\prime}$.

Now consider $\psi\left(\vec{x}, \vec{y}, \vec{u}, \vec{v}, \vec{w}, z, z_{1}, z_{2}, z_{1}^{\prime}, z_{2}^{\prime}\right)$. Suppose that $\vec{x}, \vec{w}, \vec{u}, \vec{v} \in\{a, b\}^{c}, \vec{u}=\vec{x}, \vec{v}=\vec{w}$. Then, to ensure that $\xi_{\rightarrow}(\vec{x}, \vec{w}, \vec{u}$, $\left.\vec{v}, z_{1}, z, z_{1}^{\prime}, z_{2}^{\prime}\right)=1$, we must have $z_{1}^{\prime}=z_{1}, z_{2}^{\prime}=z$. Similarly, if $\vec{u}=\vec{w}, \vec{v}=\vec{y}$ then $z_{1}^{\prime}=z, z_{2}^{\prime}=z_{2}$. If these equalities do not hold, or one of $\vec{x}, \vec{w}$ and one of $\vec{w}, \vec{y}$ are not members of $\{a, b\}^{c}$, then both predicates $\xi_{\rightarrow}$ are true for any $z, z_{1}, z_{2}, z_{1}^{\prime}, z_{2}^{\prime}$ and so is $\psi$.

As easily seen, the number of predicates used to represent $\varphi, \psi$ and $\varphi_{C}$ is bounded by a linear polynomial in the number of gates in circuit $C$. Therefore, the construction described is a polynomial-time reduction from the succinct GRAPH UNREACHABILITY problem to $\operatorname{QCSP}(\Gamma)$ where $\Gamma$ is the set of at most ternary predicates invariant under the semilattice operation.

## 7. A trichotomy theorem

In this section, we apply results from the previous sections to obtain a complete classification of complexity of QCSP $(\Gamma)$ in those cases where $\Gamma$ contains the set $\Delta$ of all graphs of permutations. Recall that the graph of a permutation $\pi$ is the binary relation $\{(x, y) \mid y=\pi(x)\}$ (or the binary predicate $\pi(x)=y$ ). The complexity of $\operatorname{CSP}(\Gamma)$ for such sets $\Gamma$ is completely classified in [23].

We will need two new surjective operations:

- The $k$-ary near projection operation,

$$
l_{k}\left(x_{1}, \ldots, x_{k}\right)= \begin{cases}x_{1} & \text { if } x_{1}, \ldots, x_{k} \text { are all different, } \\ x_{k} & \text { otherwise }\end{cases}
$$

- The ternary switching operation,

$$
s(x, y, z)= \begin{cases}x & \text { if } y=z \\ y & \text { if } x=z \\ z & \text { otherwise }\end{cases}
$$

Recall that the dual discriminator operation is defined as follows:

$$
d(x, y, z)= \begin{cases}y & \text { if } y=z \\ x & \text { otherwise }\end{cases}
$$

Proposition 7.1 If $\Gamma \subseteq R_{D},|D| \geq 3$, and $l_{|D|} \in \mathrm{s}-\operatorname{Pol}(\Gamma)$ then $\operatorname{QCSP}(\Gamma)$ is polynomial-time reducible to $\operatorname{CSP}(\operatorname{lnv}(\operatorname{Pol}(\Gamma)))$. In particular, $\operatorname{QCSP}(\Gamma)$ is in $\mathbf{N P}$.

Proof. For any $\vec{a}=\left(a_{1}, \ldots, a_{n}\right) \in D^{n}$, and any subsequence $i_{1}, \ldots, i_{k}$ of the sequence $1, \ldots, n$, we define $\operatorname{pr}_{i_{1}, \ldots, i_{k}} \vec{a}$ to be the $k$-tuple ( $a_{i_{1}}, \ldots, a_{i_{k}}$ ). Moreover, for any $n$-ary relation $\varrho$, we define $\operatorname{pr}_{i_{1}, \ldots, i_{k}} \varrho$ to be the $k$-ary relation

$$
\operatorname{pr}_{i_{1}, \ldots, i_{k}} \varrho=\left\{\operatorname{pr}_{i_{1}, \ldots, i_{k}} \vec{a} \mid \vec{a}=\left(a_{1}, \ldots, a_{n}\right) \in \varrho\right\}
$$

For $I=\left\{i_{1}, \ldots, i_{k}\right\}$, we will sometimes write $\operatorname{pr}_{I} \varrho$ instead of $\operatorname{pr}_{i_{1}, \ldots, i_{k}} \varrho$. Note that $\operatorname{Pol}\left(\left\{\operatorname{pr}_{I} \varrho\right\}\right) \supseteq \operatorname{Pol}(\{\varrho\})$.
We first clarify the structure of relations over a set $D$ which are invariant under the near-projection operation $l_{|D|}$.
Let $\underline{n}$ denote the set $\{1, \ldots, n\}$. Suppose $I_{1}, \ldots, I_{k}$ is a partition of $\underline{n}$ and let $\varrho_{j}=\operatorname{pr}_{I_{j}} \varrho$ for $j=1, \ldots, k$. Then we write $\varrho=\varrho_{1} \times \ldots \times \varrho_{k}$ if $\varrho$ can be represented as $\varrho=\left\{\vec{a} \mid \operatorname{pr}_{I_{j}} \vec{a} \in \varrho_{j}\right.$ for every $\left.j=1, \ldots, k\right\}$.

Lemma 7.2 Let $\varrho \in R_{D}^{(n)}$, where $|D| \geq 3$.
If $\varrho \in \operatorname{lnv}\left(\left\{l_{|D|}\right\}\right)$ and $\operatorname{pr}_{i} \varrho=D$ for every $i \in \underline{n}$, then $\varrho$ is of the form

$$
\varrho=\varrho_{1} \times \ldots \times \varrho_{k}
$$

where each $\varrho_{j}=\left\{\left(a, \pi_{2 j}(a), \ldots, \pi_{m_{j}}(a)\right) \mid a \in D\right\}$, for some permutations $\pi_{2 j}, \ldots, \pi_{m_{j} j}$ of $D$.
Proof. We prove the lemma by induction on $n$. When $n=1$ the result holds trivially, so consider the case when $n=2$. Assume that $\varrho$ is not a graph of a permutation. Then there exist $b_{1}, b_{2}, b \in D$ such that $b_{1} \neq b_{2}$ and $\left(b_{1}, b\right),\left(b_{2}, b\right) \in \varrho$ (or $\left.\left(b, b_{1}\right),\left(b, b_{2}\right) \in \varrho\right)$. Since $\operatorname{pr}_{1} \varrho=D$, it is possible to choose $\vec{a}_{1}, \vec{a}_{2}, \ldots, \vec{a}_{|D|} \in \varrho$ so that $\operatorname{pr}_{1} \vec{a}_{1}, \ldots, \operatorname{pr}_{1} \vec{a}_{|D|}$ are all different, $\operatorname{pr}_{1} \vec{a}_{1}=(x)$, where $x$ is an arbitrary element from $D \backslash\left\{b_{1}, b_{2}\right\}, \vec{a}_{2}=\left(b_{1}, b\right)$, and $\vec{a}_{|D|}=\left(b_{2}, b\right)$. Since $\varrho$ is invariant under $l_{|D|}$, we have $l_{|D|}\left(\vec{a}_{1}, \ldots, \vec{a}_{k}\right)=\left(\operatorname{pr}_{1} \vec{a}_{1}, b\right) \in \varrho$, and hence $(x, b) \in \varrho$ for all $x \in D$.

It follows that, for any $(x, y) \in D^{2}$ we can choose $\vec{c}_{1}, \vec{c}_{2}, \ldots, \vec{c}_{|D|} \in \varrho$ such that $\operatorname{pr}_{1} \vec{c}_{1}, \ldots, \operatorname{pr}_{1} \vec{c}_{|D|}$ are all different, $\operatorname{pr}_{1} \vec{c}_{1}=$ $(x), \operatorname{pr}_{2} \vec{c}_{|D|}=(y)$, and $\operatorname{pr}_{2} \vec{c}_{1}=\ldots=\operatorname{pr}_{2} \vec{c}_{|D|-1}=(b)$. Since $\varrho$ is invariant under $l_{|D|}$, we have $l_{|D|}\left(\vec{c}_{1}, \ldots, \vec{c}_{|D|}\right)=(x, y) \in \varrho$, and hence $\varrho=D^{2}$.

We now prove the induction step. By the argument above, for any pair $i, j \in \underline{n}$ the projection $\operatorname{pr}_{i, j} \varrho$ is either $D^{2}$, or the graph of a permutation. Assume that there exist $i, j$ such that $\mathrm{pr}_{i, j} \varrho$ is the graph of a permutation $\pi$. By the inductive hypothesis $\operatorname{pr}_{\underline{n} \backslash\{j\}} \varrho$ can be represented in the form

$$
\operatorname{pr}_{\underline{n} \backslash j j\}} \varrho=\varrho_{1} \times \ldots \times \varrho_{k}
$$

and the $i$ th coordinate position occurs in one of $\varrho_{1}, \ldots, \varrho_{k}$. Suppose, for simplicity, that $i$ is the last coordinate position in $\varrho_{1}$, that is,

$$
\begin{array}{r}
\varrho_{1}=\left\{\left(a_{i_{1}}, \ldots, a_{i_{m_{1}-1}}, a_{i}\right) \mid a_{i_{1}} \in D, a_{i_{s}}=\pi_{s 1}\left(a_{i_{1}}\right)\right. \\
\text { for } \left.s \in\left\{2, \ldots, m_{1}-1\right\}, a_{i}=\pi_{i}\left(a_{i_{1}}\right)\right\} .
\end{array}
$$

Then, letting

$$
\begin{aligned}
& \varrho_{1}^{\prime}=\left\{\left(a_{i_{1}}, \ldots, a_{i_{m_{1}-1}}, a_{i}, a_{j}\right) \mid a_{i_{1}} \in D, a_{i_{s}}=\pi_{s 1}\left(a_{i_{1}}\right)\right. \\
& \left.\quad \text { for } s \in\left\{2, \ldots, m_{1}-1\right\}, a_{i}=\pi_{i}\left(a_{i_{1}}\right), a_{j}=\pi \pi_{i}\left(a_{i_{1}}\right)\right\}
\end{aligned}
$$

we have $\varrho=\varrho_{1}^{\prime} \times \varrho_{2} \times \ldots \times \varrho_{k}$, as required.
It remains to prove that if $\mathrm{pr}_{i, j} \varrho=D^{2}$ for every $i, j \in \underline{n}$, then $\varrho=D^{n}$.
For any $a \in D$, define

$$
\varrho_{a}=\left\{\left(a_{1}, \ldots, a_{n-1}\right) \mid\left(a_{1}, \ldots, a_{n-1}, a\right) \in \varrho\right\}
$$

Since the operation $l_{|D|}$ is idempotent, that is, it satisfies $l_{|D|}(x, \ldots, x)=x$ for all $x, \varrho_{a}$ also belongs to $\operatorname{lnv}\left(\left\{l_{|D|}\right\}\right)$.
Consider first the case $n=3$.
Suppose that, for some $a \in D$, the relation $\varrho_{a}$ is not the graph of a permutation. Then $\varrho_{a}=D^{2}$ by the argument above. Take any $c \in D$ such that $c \neq a$. Then there exists a tuple $\vec{c}=\left(c_{1}, c_{2}, c\right) \in \varrho$. For $1 \leq i \leq|D|-1$, choose $\vec{a}_{i}=\left(x_{i}, y_{i}, a\right) \in \varrho$, such that $\left\{x_{1}, \ldots, x_{|D|-1}, c_{1}\right\}=\left\{y_{1}, \ldots, y_{|D|-1}, c_{2}\right\}=D$. Then $l_{|D|}\left(\vec{a}_{1}, \ldots, \vec{a}_{|D|-1}, \vec{c}\right)=\left(x_{1}, y_{1}, c\right) \in \varrho$. Since we can change $y_{1}$ whilst keeping the same $x_{1}$, we conclude that $\varrho_{c}$ is not the graph of a permutation. Thus $\varrho_{c}=D^{2}$ for all $c \in D$, which implies that $\varrho=D^{3}$.

Now consider the remaining case, where $\varrho_{a}$ is the graph of a permutation for each $a \in D$. In this case $\left|\varrho_{a}\right|=|D|$ for each $a$, and since $\left|\operatorname{pr}_{1,2} \varrho\right|=\left|\bigcup_{a \in D} \varrho_{a}\right|=\left|D^{2}\right|$, we have $\varrho_{a} \cap \varrho_{b}=\emptyset$ for all $a, b \in D$ such that $a \neq b$. Assume that $D=$ $\left\{d_{1}, d_{2}, \ldots, d_{|D|}\right\}$. For $1 \leq i \leq|D|-1$, choose $\vec{a}_{i}=\left(a_{i}, d_{1}, d_{i}\right) \in \varrho$, and choose $\vec{a}_{|D|}=\left(a_{1}, b, d_{|D|}\right) \in \varrho$. Note that $a_{1}, \ldots$, $a_{|D|-1}$ are all different, and $b \neq d_{1}$, because $\varrho_{d_{i}} \cap \varrho_{d_{j}}=\emptyset$ if $i \neq j$. Now $l_{|D|}\left(\vec{a}_{1}, \ldots, \vec{a}_{|D|}\right)=\left(a_{1}, b, d_{1}\right) \in \varrho$, so $\left(a_{1}, b\right) \in$ $\varrho_{d_{1}} \cap \varrho_{d_{|| |}}$, a contradiction.

If $n>3$ then, by the inductive hypothesis, we have $\operatorname{pr}_{i, j, n} \varrho=D^{3}$ and, consequently, $\operatorname{pr}_{i, j} \varrho_{a}=D^{2}$ holds for all $1 \leq i, j \leq$ $n-1$. Applying the inductive hypothesis to $\varrho_{a}$, we obtain $\varrho_{a}=D^{n-1}$ for each $a \in D$, which implies that $\varrho=D^{n}$.

Lemma 7.3 Let $\varrho \in R_{D}^{(n)}$, where $|D| \geq 3$.
If $\varrho \in \operatorname{Inv}\left(\left\{l_{|D|}\right\}\right)$ and $I=\left\{i \in \underline{n}| | \operatorname{pr}_{i} \varrho|<|D|\}\right.$, then $\varrho=\operatorname{pr}_{I} \varrho \times \operatorname{pr}_{\underline{n} \backslash I} \varrho$.
Proof. By Lemma 7.2, $\operatorname{pr}_{\underline{n} \backslash I} \varrho=\varrho_{1} \times \ldots \times \varrho_{k}$ where $\varrho_{j}=\left\{\left(a, \pi_{2 j}(a), \ldots, \pi_{m_{j} j}(a)\right) \mid a \in D\right\}$ and $\pi_{2 j}, \ldots, \pi_{m_{j} j}$ are permutations of $D$. Denote the set of coordinate indices of $\varrho_{j}$ by $J_{j}$, and let $J$ be a system of representatives of $J_{1}, \ldots, J_{k}$. Then $\operatorname{pr}_{J} \varrho=D^{|J|}$.

Take an arbitrary $\vec{b} \in \operatorname{pr}_{I} \varrho$ and $\vec{c} \in \operatorname{pr}_{J} \varrho$. There exists $\vec{a}_{|D|} \in \operatorname{pr}_{I \cup J} \varrho$ such that $\operatorname{pr}_{I} \vec{a}_{|D|}=\vec{b}$. For $1 \leq i \leq|D|-1$, choose $\vec{a}_{i} \in \operatorname{pr}_{I \cup J} \varrho$ such that $\operatorname{pr}_{j} \vec{a}_{1}=\vec{c}$ and for each $j \in J,\left\{\operatorname{pr}_{j} \vec{a}_{i}|1 \leq i \leq|D|\}=D\right.$. (This is possible because $\operatorname{pr}_{j} \varrho=D^{|J|}$.)

Now let $\vec{d}=l_{|D|}\left(\vec{a}_{1}, \ldots, \vec{a}_{|D|}\right) \in \operatorname{pr}_{I \cup J} \varrho$. It is easy to check that $\operatorname{pr}_{I} \vec{d}=\vec{b}$ and $\operatorname{pr}_{J} \vec{d}=\vec{c}$. Hence, $\operatorname{pr}_{I \cup J} \varrho=\operatorname{pr}_{I} \varrho \times \operatorname{pr}_{J} \varrho$. Finally, by the choice of $J$, any element from $\operatorname{pr}_{I \cup J} \varrho$ has a unique extension to an element of $\varrho$, and the result follows.

Now we can complete the proof of Proposition 7.1 by constructing a polynomial-time reduction from $\operatorname{QCSP}(\Gamma)$ to $\operatorname{CSP}(\operatorname{lnv}(\operatorname{Pol}(\Gamma)))$ for any $\Gamma \subseteq R_{D}$, with $|D| \geq 3$, such that $l_{|D|} \in \mathrm{s}-\operatorname{Pol}(\Gamma)$.

Let $\mathcal{P}=\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{l} x_{l} \phi$ be an instance of $\operatorname{QCSP}(\Gamma)$ where $\phi=\varrho_{1}\left(\vec{v}_{1}\right) \wedge \ldots \wedge \varrho_{q}\left(\vec{v}_{q}\right)$. For any pair $\varrho_{s}\left(\vec{v}_{s}\right)$ and $\varrho_{t}\left(\vec{v}_{t}\right)$ of atomic formulas in $\phi$, we can replace $\varrho_{s}\left(\vec{v}_{s}\right)$ by the atomic formula $\varrho_{s}^{\prime}\left(\vec{v}_{s}\right)$ which is equivalent to $\left.\varrho_{s}\left(\vec{v}_{s}\right) \wedge \exists y_{1}, \ldots, y_{p} \varrho_{t}\left(\vec{v}_{t}\right)\right)$ where $y_{1}, \ldots, y_{p}$ are the variables that appear in $\vec{v}_{t}$ but not in $\vec{v}_{s}$. If we repeat this process until no further changes result, we obtain (in polynomial time) an instance $\mathcal{P}^{\prime}=\mathcal{Q}_{1} x_{1} \ldots \mathcal{Q}_{l} x_{l} \phi^{\prime}$ which is equivalent to the original instance $\mathcal{P}$. Moreover, all predicates in $\phi^{\prime}$ belong to $\langle\Gamma\rangle$, and hence, by Proposition 3.3, to $\operatorname{lnv}(\operatorname{Pol}(\Gamma))$.

Note that, if two constraints in $\phi^{\prime}$ share a variable then the projections of the corresponding predicates on the coordinates where this variable occurs are the same. If one of the predicates in $\phi^{\prime}$ is always false, or if some variable that cannot take all values is universally quantified in $\mathcal{P}^{\prime}$, then clearly $\mathcal{P}^{\prime}$ is false, and so is $\mathcal{P}$. Otherwise, by Lemmas 7.2 and $7.3, \phi^{\prime}$ can be represented as $\phi_{1} \wedge \phi_{2}$ so that $\phi_{1}$ and $\phi_{2}$ have no variable in common, $\phi_{1}$ is a conjunction of graphs of permutations, and no variable in $\phi_{2}$ can take all possible values. Hence $\mathcal{P}^{\prime}$ can be represented as a conjunction of two sentences: one (corresponding to $\left.\phi_{1}\right)$ is an instance of $\operatorname{QCSP}(\Delta)$, and the other (corresponding to $\left.\phi_{2}\right)$ is an instance of $\operatorname{CSP}(\operatorname{lnv}(\operatorname{Pol}(\Gamma)))$. It is easy to check that $\Delta \subseteq \operatorname{lnv}(\{d\})$. Hence, since the dual discriminator operation is a near-unanimity operation, by Theorem 4.5, we can solve any instance of $\operatorname{QCSP}(\Delta)$ in polynomial time, and so reduce $\operatorname{QCSP}(\Gamma)$ to $\operatorname{CSP}(\operatorname{Inv}(\operatorname{Pol}(\Gamma)))$ in polynomial time.

Theorem 7.4 Let $\Delta \subseteq \Gamma \subseteq R_{D}$, and $|D| \geq 3$.

- If s-Pol $(\Gamma)$ contains the dual discriminator d, or the switching operation s, or an affine operation, then $\mathrm{QCSP}(\Gamma)$ is in PTIME;
- else, if s-Pol $(\Gamma)$ contains $l_{|D|}$, then $\operatorname{QCSP}(\Gamma)$ is $\mathbf{N P}$-complete;
- else $\operatorname{QCSP}(\Gamma)$ is PSPACE-complete.

Proof. Chapter 5 of [52] shows that, either s-Pol $(\Gamma)$ consists of all projections (that is, all functions of the form $f\left(x_{1}, \ldots, x_{n}\right)$ $=x_{i}$ for some $1 \leq i \leq n$ ), or else s-Pol $(\Gamma)$ contains the dual discriminator operation, $d$, or the near-projection operation, $l_{|D|}$, or (when $|D| \in\{3,4\}$ ) an affine operation. If s-Pol $(\Gamma)$ consists of all projections then, by Theorem 5.2, QCSP $(\Gamma)$ is PSPACEcomplete. If s-Pol $(\Gamma)$ contains $d$ or an affine operation then, by Theorem 4.2 or Theorem $4.5, \mathrm{QCSP}(\Gamma)$ is in PTIME.

Suppose that $s-\operatorname{Pol}(\Gamma)$ contains $l_{|D|}$, but neither $d$ nor the affine operation. Then, by Proposition 7.1, QCSP $(\Gamma)$ is in NP. Note that $s$ is a Mal'tsev operation, and, hence, if s-Pol $(\Gamma)$ contains $s$ then $\operatorname{QCSP}(\Gamma)$ is solvable in polynomial time by Theorem 4.2. If $s-\operatorname{Pol}(\Gamma)$ contains none of $s, d$, and the affine operation then, by Theorem 12 of [23], CSP $(\Gamma)$ is NP-complete. Since, obviously, $\operatorname{CSP}(\Gamma)$ is polynomial-time reducible to $\operatorname{QCSP}(\Gamma)$, and $\operatorname{QCSP}(\Gamma)$ is in $\mathbf{N P}$, the result follows.

Note that, for finite $\Gamma$ over a fixed finite set $D$, the conditions in Theorem 7.4 can be efficiently checked.

## 8. Conclusions

We have shown that the algebraic theory relating complexity and polymorphisms, which was originally developed for the standard constraint satisfaction problem allowing only existential quantifiers, can be extended to deal with the more general framework of the quantified constraint satisfaction problem.

In this extension of the theory it turns out that it is the surjective polymorphisms of the predicates used in problem instances which determine the complexity of the corresponding problems. Using this information we have been able to identify subproblems of the quantified constraint satisfaction problem lying in (or complete for) some standard complexity classes.

As an example of using these results, we now classify the complexity of the constraint satisfaction games described in Examples 2.7-2.10.

## Corollary 8.1

(1) The graph $k$-colouring game described in Example 2.7 can be decided in polynomial time when $k \leq 2$ and is PSPACEcomplete when $k \geq 3$.
(2) The ONE-OR-BOTH COLOUR MATCHING GAME described in Example 2.8 can be decided in polynomial time.
(3) The COLOUR IMPLICATION GAME described in Example 2.9 can be decided in polynomial time.
(4) The LINEAR EQUATIONS GAME described in Example 2.10 can be decided in polynomial time.

## Proof

(1) Follows immediately from Corollary 3.9 and Proposition 5.1.
(2) It is straightforward to verify that each relation in $\Gamma_{c m}$ defined in Example 2.8 is invariant under the dual discriminator operation, which is a near unanimity operation. Hence, by Theorem 4.5, the ONE-OR-BOTH COLOUR MATCHING GAME can be decided in polynomial time.
(3) The COLOUR IMPLICATION GAME defined in Example 2.9 involves a set $D$ of colours containing two distinguished colours, black and white. Consider the binary operation $*$ on $D$ such that, for all $v \in D$, we have $v * v=v *$ black $=$ black $* v=v$, and, for any distinct $u, v \in D \backslash\{$ black $\}$, we have $u * v=$ white. It is easy to check that $*$ is a semilattice operation where the black colour is a unit element. The corresponding lattice order $\leq$ is a so-called "diamond" order: it has black as the least element, white as the greatest element, and all other colours incomparable with each other. It is straightforward to verify that each of the relations $\varrho_{a, b}$ defined in Example 2.9 is equal to the set $\left\{(u, v) \mid\left(u \not{ }_{*} a\right) \vee\left(v \leq{ }_{*} b\right)\right\}$. Hence, by Lemma 6.2, the set of relations $\Gamma_{c i}$ is invariant under the operation $*$. The result then follows from Theorem 6.1.
(4) It is easy to verify that each relation in $\Gamma_{\text {lin }}$ defined in Example 2.10 is invariant under the affine operation of the field $K$. Hence, by Theorem 4.2, the LINEAR EQUATIONS GAME can be decided in polynomial time.
