Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

ABSTRACT

Aldose reductase reduces glucose to sorbitol. It plays a key role in many of the complications arising from diabetes. Thus, Aldose reductase inhibitors (ARI) have been identified as promising therapeutic agents for treating such complications of diabetes, as neuropathy, nephropathy, retinopathy, and cataracts. In this paper, a virtual screening protocol applied to a library of compounds in house, has been utilized to discover novel ARIs. IC_{50} 's were determined for 15 hits that inhibited ALR2 to greater than 50% at 50 μ M, and ten of these have an IC_{50} of 10 μ M or less, corresponding to a rather substantial hit rate of 14% at this level. The specificity of these compounds relative to their cross-reactivity with human ALR1 was also assessed by inhibition assays. This resulted in identification of novel inhibitors with IC_{50} 's comparable to the commercially available drug, epalrestat and greater than an order of magnitude better selectivity.

INTRODUCTION

Diabetes patients suffer from long-term complications, such as neuropathy, nephropathy, retinopathy and cataracts.^{1, 2} Although the mechanisms of diabetic complications are not completely understood, many biochemical pathways associated with hyperglycemia have been identified.³ The sorbitol pathway is one of the most important pathways implicated in long-term complications.³ Aldose reductase enzyme (ALR2, EC1.1.1.21, AKR1B1) is a member of the aldo-ketoreductase (AKR) superfamily, and, together with sorbitol dehydrogenase forms the polyol pathway.⁴ ALR2 is the rate-limiting enzyme in this pathway. It reduces the aldehyde form of glucose to sorbitol by using NADPH as a cofactor. Then, sorbitol dehydrogenase converts the sorbitol to fructose by using NAD⁺ as a cofactor.⁵ Under normal circumstances, the affinity of ALR2 and glucose is low. While, under hyperglycemic circumstances, highly expressed ALR2 results in twofold to fourfold accelerated conversion of glucose to sorbitol. However, the rate of sorbitol dehydrogenase metabolism is not affected, which results in significant sorbitol accumulation under hyperglycemic circumstances. The sorbitol accumulation leads to osmotic swelling, changes in membrane permeability, and oxidative stress culminating in tissue injury associated with late-onset diabetic complications.⁶

According to recent reports, ALR2 is up-regulated not only under hyperglycemic conditions, but also in other pathological states including cardiac disorders (myocardial ischemia and ischemia-reperfusion injury, congestive heart failure, cardiac hypertrophy, and cardiomyopathy), inflammation, mood disorders, renal

1 insufficiency, ovarian abnormalities, and human cancers such as liver, breast, ovarian,
2 cervical, and rectal cancers.⁷⁻⁹ Those pathological processes have become major
3 threats to human health in the 21st century.

4 Because of these observations, aldose reductase has emerged as an attractive
5 therapeutic target for long-term diabetic complications, cardiac disorders, and
6 inflammatory diseases. Intense efforts have been directed toward the development of
7 effective aldose reductase inhibitors,¹⁰ however, only a few compounds have reached
8 clinical trials, such as, alrestatin,¹¹ tolrestat,¹² epalrestat,¹³ zopolrestat,¹⁴ zenarestat,¹⁵
9 ponalrestat,¹⁶ and lidorestat¹⁷. So far, epalrestat (Kinedak), marketed in Japan and
10 China, is the only commercially available ARI drug. Aside from epalrestat ALR2
11 inhibitors have failed in clinical trials because of poor pharmacokinetic properties and
12 side effects¹⁸ and even epalrestat has been withdrawn from the market in other
13 countries because of its side effects. Thus it is important to develop novel ARIs with
14 improved efficacy, pharmacodynamics, pharmacokinetic properties and safety profile.

15 X-ray studies reveal that there are at least three distinct binding pocket
16 conformations of ALR2, corresponding to three different ligand types.¹⁹ These
17 binding pockets were reported by Sandro and coworkers (PDB codes: 2PDK²⁰,
18 1US0,²¹ and 2FZD^{22,23}). Comparative structural analysis and molecular dynamic (MD)
19 simulations studies indicate that for ALR2, a single experimental structure is not
20 sufficient to predict all possible binding modes;¹⁹ and a higher virtual screening score
21 does not necessarily correspond to higher biological activity because of false
22 negatives from the docking procedure.^{10, 24} These deficiencies result in lower virtual

1 screening hit rates.

2 Therefore, we exploited a virtual screening protocol, combined with MD
3 simulations to overcome some of these issues. Starting with three experimental
4 structures (PDB entries: 2PDK, 1US0 and 2FZD), we use MD simulations to sample
5 accessible binding site conformers around each. The final binding site conformations
6 are then derived by averaging the conformers from the three MD simulation results,
7 respectively. The compound library is then virtually screened against these three
8 averaged structures, and the docked complexes were optimized by MD simulations to
9 assess their stability. As MD simulations are extremely computationally demanding
10 and in general intractable to apply to numerous ligand-protein systems ligands, we
11 exploited Graphics Processing Unit (GPU) technology, which significantly accelerates
12 the calculation relative to more conventional central processing units (CPUs).^{25, 26} The
13 compounds selected through this virtual screening protocol were tested for ALR2
14 inhibition in vitro, and highly active ARIs containing new chemotypes were identified.
15 In addition, the selectivity of compounds demonstrating potent ALR2 inhibition was
16 assessed by testing for ALR1 inhibition, and their toxicity was also tested by MTT
17 (3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyltetrazolium bromide) assays: they showed
18 considerable selectivity and no evidence of cell toxicity.

19 20 **RESULTS AND DISCUSSION**

21 ***In Silico* Screening Against ALR2.** Accounting for protein flexibility and induced
22 fit effects continues to be a challenge in virtual screening efforts.^{27, 28} This is

1 especially true for the human ALR2 binding pocket.^{19, 29, 30} The significant mutual
2 induced-fit effects upon binding different ligands to ALR2, provides a challenge for
3 standard structure-based virtual screening.³¹⁻³³ Virtual screening can be done via either
4 docking molecules into a single binding pocket conformation derived from an
5 experimental structure,^{10, 34, 35} or docking molecules into multiple binding pocket
6 conformations derived from multiple experimental structures simultaneously.³⁶ For
7 example in previous work, using a clustering approach of diverse binding site
8 volumetric shapes, we chose four representative structures as a compromise between
9 more extensive sampling and computational tractability.^{27,28} Cosconati and coworkers
10 reported that the multiple binding pocket strategy applied to ALR2 resulted in a
11 higher virtual screening hit rate.²³ Given the significant plasticity of this protein, the
12 question arises as to whether a more extensive sampling of ALR2 conformational
13 space could further improve either enrichment or diversity of ligands recovered.¹⁹ The
14 protocol we use here to further account for ligand-receptor flexibility is given in
15 Figure 1. The virtual screening protocol starts with the three ALR2-ligand complexes
16 (PDB codes: 2PDK, 1US0, and 2FZD) that represent three types of static binding
17 modes. MD simulations were applied to these structures for six nanoseconds (ns) to
18 refine the protein structure especially for regions that may be poorly resolved in the
19 X-ray. The time averaged structures over the last nanosecond of the trajectories (See
20 Supporting Information, Figure S1) were then, minimized by steepest descent
21 (Discovery Studio 2.1, Accelrys Inc., San Diego, CA.) to refine covalent geometry
22 and remove collisions. These refined structures were then employed for docking in

the first stage of the virtual screening campaign.

The GSMTL (Guangdong Small Molecule Tangible Library), a small molecule repository containing more than 7,200 compounds, was selected for screening against ALR2.³⁷ The compounds in the library were docked against the three refined binding pocket conformations with FlexX. In order to establish criteria for the virtual screening hits, we have: (1) docked 927 known ALR2 inhibitors³⁸ into the three binding pockets to calibrate the relation between activity and FlexX score, generating an averaged active compound FlexX docking score (ACFDS), and (2) computed active ALR2 inhibitor protein ligand interaction fingerprints (PLIF) from 76 co-crystal structures in MOE (Molecular Operating Environment³⁹, Figure 2).

The virtual screening hits then have to pass three filters:

(1) The FlexX docking score must be below the ACFDS. 1,238 compound hits passed this filter.

(2) Hits, which have acceptable scores, are retained only if their PLIFs match the active ALR2 inhibitor PLIF (at least two hydrogen bonds with Tyr48, His110, or Trp111, and hydrophobic interaction with the specificity hydrophobic pocket). 128 compound hits passed this filter.

(3) Each of the 128 hits was subjected to MD simulations. Only hits with RMSD (root-mean-square deviation) values less than 3 Å from the docked pose were retained. This is an “internal consistency” check to ensure that the docked conformation scored is indeed the stable conformation of the system. 71 compounds survived this criterion. These final hits were further tested by

bioassays. (Note each compound had three binding modes corresponding to the three ALR2 binding pocket conformations described above (Figure 1); if a compound passed through the first two filters bound to more than one of the structures the pose with the highest docking score was selected for this last MD refinement stage.)

We note that our primary goal is to reduce the number of compounds that need to be subjected to more expensive experimental screening while achieving a good “yield” of a reasonable number of hits i.e. remove false positives. The filters outlined above indubitably remove some true positives as well, as does the inherent virtual screening algorithm itself, but as long as we achieve the requisite number and quality (diversity, scaffolds etc.) we have achieved our goal. This is the basic assumption in any screening campaign. Any of these filters might be omitted if sufficient hits are not obtained. Questions naturally arise about the consequences of omitting any of the filters or adding others and also comparing with other algorithms. Some estimate of the utility of the procedure may be obtained by comparison with a simple similarity search. This is given below. A detailed study of the effect of all the variables/filters in the algorithm as well as comparison with other algorithms is the subject of further study. Here our goal was primarily to find new ARIs containing novel chemotypes.

Confirmation of the Hits from Virtual Screening. The 71 final hits were assayed for ALR2 inhibition as described in methods. The bioassays confirmed that

26 of the compounds showed a minimum of 30% inhibition of ALR2 at 50 μ M (Table 1). The 26 confirmed ALR2 inhibitors are depicted in Figure 3. IC_{50} 's were determined for the 15 hits which inhibited ALR2 to greater than 50% at 50 μ M. In order to ensure that the IC_{50} determinations are reliable, IC_{50} values of quercetin and epalrestat (Figure S2) were obtained and verified to reproduce previously reported values^{40, 41} (28 μ M and 0.28 μ M). The most active compounds are **14** and **25**; they demonstrate sub-micromolar IC_{50} concentrations (0.22 μ M and 0.89 μ M), values comparable to the commercially available drug, epalrestat. Other promising compounds were **1**, **18**, **22**, and **24**, which exhibited IC_{50} values < 10 μ M.

Comparison of Results with Simple Ligand Based Searches. We have carried out both a 2D similarity search as well as a substructure search in order to confirm that these simpler techniques^{42, 43} do not recover the novel actives resulting from the docking protocol discussed above. In the similarity search, a total of 22 ALR2 actives derived from the DUD (A Directory of Useful Decoys; <http://dud.docking.org/>), along with the reference compounds quercetin and epalrestat, shown in Figure S3 were chosen as the reference structures. The two dimensional structural similarities of the structures in the Guangdong Small Molecule Tangible Library (GSMTL) database, with the 24 queries were calculated based on an atom-center fragment approach.^{42, 43} Imposing a similarity threshold of 80%, we retrieved 67 hits from GSMTL database. Among these hits, 51 of them were flavone derivatives arising from similarity with quercetin, and 16 "non-flavones". The preponderance of flavones arises presumably due to their ubiquity in herbs and plants.⁴⁴ The non-flavanoid hits are shown in Table

1 S1 along with the reference compound they arose from.

2 For a second simple similarity search control we exploited a Markush search.⁴⁵

3 Six Markush search queries were prepared as shown in Figure S4. A total of 421 hits
4 were found. Of these the majority included either a flavone scaffold or benzoic
5 sulfonic groups, while 67 of the 421 represent other diverse scaffolds.⁴⁶

6 The most liberal, first order “atom center fragment”^{42, 43} cutoff was used in these
7 similarity studies in order to retrieve the maximum number of compounds, Despite
8 this none of the actives identified in the docking studies were found by even this
9 liberal definition of similarity.

10 **Structural Characteristics of the Confirmed Hits.** Like epalrestat, most of these
11 new ALR2 inhibitors contain carboxylic acid moieties. In particular, the two
12 sub-micromolar compounds, **14** and **25** as well as the four compounds with single
13 digit IC₅₀ values (**1**, **18**, **22**, and **24**), all contain the carboxylic acid moiety. The most
14 favorable docking score for **14** from the three binding pocket conformations was
15 -31.39 kcal/mol (Table S2). The predicted binding mode of compound **14** was stable
16 in MD simulations with a time averaged RMSD of ~1 Å over the 6 nanoseconds
17 trajectory (Figure S5 of Supporting Information).

18 As seen in Figure 4a, the ligand carboxyl inserts into the anion binding pocket,
19 H-bonding with Tyr48, His110, and Trp111 side chains and engages in an electrostatic
20 interaction with the nicotinamide moiety of the NADP⁺ cofactor. Additional hydrogen
21 bonds were formed between the acyl oxygen of **14** and Trp111. The naphthalene ring
22 of compound **14** occupies ALR2’s specificity pocket forming hydrophobic contacts

1 with Trp79, Trp111, Phe122, Phe115 and Leu300. Not surprisingly these interactions
2 are consistent with the PLIFs, which, based on the assays, correlate with the activity
3 against ALR2. Figure 5a shows the dose-response curve of compound **14** with an IC₅₀
4 value of 0.22 μM.

5 Compounds **17** and **18** contain the large fluorene hydrophobic group. This large
6 hydrophobic group is not well accommodated in the hydrophobic pocket of ALR2 and
7 extends into the solvent, perhaps accounting for the somewhat lower affinity of
8 compounds **17** and **18** (15.67 μM and 6.30 μM) relative to compound **14** (0.22 μM).
9 (Figure S6 of Supporting Information and Figure 4b).

10 On the other hand, compound **22** has a pyrazine group that is a smaller hydrophobic
11 group than either the naphthyl group in **14** (or the fluorene moiety found in compounds
12 **17** and **18**). The pyrazine group is well accommodated in the ALR2 hydrophobic
13 pocket. However, the pyrazine is too small to make hydrophobic contacts with Trp79,
14 Trp111, Phe122, Phe115 and Leu300 as compound **14** does. This may account for the
15 somewhat weaker activity compound **22** (3.65 μM, Figure 5c) than **14** (0.22 μM).

16 Compound **7** demonstrated moderate activity against ALR2 with an IC₅₀ value of
17 25.05 μM (Table 1). The predicted binding mode of compound **7** is shown in Figure
18 4d. In this binding mode, compound **7** forms hydrogen bonds with His110 and Trp111
19 via its ketone oxygen, and another hydrogen bond between its benzofuran-5-hydroxyl
20 and Trp20. In addition, π - π stacking interactions between the benzene ring of
21 compound **7** and Trp111 were observed, which may well contribute to the activity.²³
22 One of the reasons for the π - π stacking interactions is the orientation of the three

1 hydrogen bonds. MD simulations indicated the RMSD of compound **7** fluctuates
2 around 1 Å (Figure S5 of Supporting Information).

3 It has been reported that sulfonic or sulfonamide groups on an ALR2 inhibitor
4 form hydrogen bonds with Tyr48, His110, or Trp111 in the anion binding pocket.^{23, 35}
5 This moiety was found in active compounds from the TCM database as well.
6 Compounds **11** and **12**, containing this functional group displayed inhibition of ALR2,
7 with compound **11**, having an IC₅₀ of 11.14 μM. Docking studies demonstrated that
8 the binding modes of compounds **11** and **12** were similar and indeed reflected the
9 hydrogen bonds (Figure S6b and 6c of Supporting Information) reported in the
10 previous studies.^{23, 35} Interestingly, compound **12** has both carboxyl and sulfonamide
11 groups, and the sulfonamide is found to bind in the anion pocket in the docked
12 structure.

13 Compound **25** is a curcumin derivative, a natural product extracted from *Curcuma*
14 *longa* L. Curcumin has been shown to be effective in delaying streptozotocin
15 (STZ)-induced diabetic cataracts in rats mainly through its antioxidant properties and
16 inhibition of ALR2.⁴⁷ It inhibited human recombinant ALR2 with an IC₅₀ of 10.0
17 μM.⁴⁸ Compound **25** demonstrated 11-fold increased inhibition against ALR2 over
18 that of curcumin itself. The dose-response curve of compound **25**, with an IC₅₀ value
19 of 0.89 μM, is depicted in Figure 5c. It was predicted that the 3, 5-dione of compound
20 **25** binds in the anion binding pocket of ALR2, and forms three hydrogen bonds with
21 Tyr48, His110, and Trp111 (Figure 4e). An additional hydrogen bond was formed
22 between the ether and carboxyl groups of compound **25** and Val 299. Also, π-π

1 stacking interactions between one of the phenyl rings in compound **25** and Trp111 is
2
3
4
5
6 observed. Like compound **7**, the binding mode of compound **25** to ALR2 was similar
7
8
9 to that of the ligand IDD594 in the 1US0 structure.

10
11 Both the flexibility of ALR2 and the ability of the ligands to induce
12
13 conformational deformations to accommodate binding are reflected in the binding
14
15 modes of these new ALR2 inhibitors. As shown in Figure S9 of Supporting
16
17 Information, ligand induced-fit results in side-chain and even backbone changes in
18
19 Cys298, Ala299, Leu300, and Phe122.
20
21
22

23
24 **Selectivity Studies Against ALR1.** Many ALR2 inhibitors were potent in both in
25
26 vitro and in vivo studies, even in animal studies, but still failed in clinical trials due to
27
28 side effects or poor efficacy. The side effects may be due in part to the failures of
29
30 selective inhibition of ALR2 with respect to ALR1 (aldehyde reductase, EC 1.1.1.2)⁴⁹.
31
32
33 The sequence similarity of ALR1 and ALR2 is close to 65%.⁵⁰ To assess the
34
35 selectivity of the 26 confirmed ALR2 inhibitors given in Figure 3, the 15 most potent
36
37 compounds were tested for their ability to inhibit human recombinant ALR1 as well
38
39 (Table 2). The assays confirmed that 8 of the compounds showed a maximum
40
41 inhibition of ALR1 of less than ~ 25% at 50 μ M, with five of these less than 10%
42
43 (Table 2). Compound **14**, the most active compound, only exhibits inhibition of ALR1
44
45 by 24% at 50 μ M, which is somewhat better than epalrestat's selectivity (90%
46
47 inhibition of ALR1 at 50 μ M).
48
49
50
51
52

53
54 IC_{50} 's were determined for the 7 hits which inhibited ALR2 to greater than 40% at
55
56 50 μ M. The only compound among these ALR2 inhibitors which didn't show
57
58
59
60

selectivity was compound **7**, IC₅₀ values are 31.33 μM for ALR1 (Figure S8) and 25.05 μM for ALR2. As revealed by the IC₅₀, compound **25**, the second most active compound (IC₅₀=0.89 μM), exhibited 100-fold selectivity for ALR2 with respect to ALR1 (IC₅₀=94.65 μM, Table 2). The similar potency and superior selectivity of these compounds when compared to the drug epalrestat suggest that these new ALR2 inhibitors presented here are worthy of further development.

Structure Activity Relationship (SAR) for Compound **14** and Analogues.

Compound **14**, a β-amino-phenylpropanoic derivative, demonstrates excellent potency and selectivity for ALR2. Actually, compounds **14**, **22**, **23**, and **24** share the same β-amino-phenylpropanoic scaffold with consistent efficacy against ALR2. The latter three compounds show even greater selectivity for ALR2 than **14**, based on the percent inhibition at 50 μM data.

To further explore the SAR of β-amino-phenylpropanoic derivatives for ALR2 inhibition, 10 additional analogues were selected by a substructure search of the GSMTL database in house. The ALR2 inhibition activities were evaluated as listed in Table 3.

The β-amino-phenylpropanoic scaffold has three substituent positions, R₁₋₃. Substituents at R₁ include: naphthalene (**14**); 1,2,3,4-tetrahydronaphthalene (**15**, **29**), pyrazine (**22-24**); pyridine (**35**, **36**); and phenyl groups. The activities of these groups are in the following order:

Naphthalene > pyrazine > pyridine > phenyl > 1,2,3,4-tetrahydronaphthalene.

This indicates that a large aromatic hydrophobic group at R₁ is important for

1 inhibition, and that the size and orientation of R₁ plays a key role. Docking studies
2 showed that R₁ resides in the hydrophobic specificity pocket consisting of Trp79,
3 Trp111, Phe122, Phe115 and Leu300. Smaller hydrophobic groups for R₁ show lower
4 activity due to inadequate hydrophobic interactions in the binding pocket. Compound
5 **15** has a large hydrophobic group for R₁, however, the aliphatic portion of the
6 tetrahydronaphthalene group cannot be accommodated as well in the pocket, which
7 also results in the loss of a hydrogen bond between the acyl oxygen of compound **15**
8 with Trp111 of ALR2 accounting for its reduced affinity (Figure 6a and 6b). Similar
9 considerations apply to compound **29** (Table 3).

10 The R₂ group on the benzene ring in the β -amino-phenylpropanoic derivatives is
11 surrounded by hydrophobic residues, Trp20, Val47 and Tyr48 (Figure 6a). It was
12 expected that an additional hydrophobic group at R₂ would further favor activity. This
13 was investigated by assessing the activities of compounds **27**, **28**, **30** and **33** (Table 3).
14 These compounds share the same scaffold, and the only variation is at R₂ (**27**, F; **28**,
15 Cl; **30**, CH₃; **33**, H). The trend here is not so clear. Compounds **27**, **28**, and **30** are
16 more active than compound **33**, which has hydrogen at R₂, consistent with the
17 hypothesis, however compounds **27** and **28** are essentially equally active contrary to
18 what might be expected. The SAR of R₃ is unclear due to insufficient data. The
19 general SAR for β -amino-phenylpropanoic scaffold is summarized in Figure 6c.

20 **In Vitro Cytotoxicity Assay.** A necessity of any drug compound is that it has
21 negligible toxicity. As a preliminary assessment of toxicity we carried out cell
22 viability assays for the 15 hits which inhibited ALR2 to greater than 50% at 50 μ M.

1 The viability of human embryonic kidney cell lines 293 (HEK 293) with these
2 compounds was evaluated. The results are given in Table 4. With the exception of
3 compounds **11** and **13** the remaining compounds showed negligible cytotoxicity,
4 similar to that of epalrestat. The most active compounds **14** and **25** exhibited only
5 10.46% and 13.85% inhibition at 12.5 μ M, respectively. The similar potency, lack of
6 toxicity, and superior selectivity of these compounds when compared to the drug
7 Epalresta suggest that the new ALR2 inhibitors presented here are worthy of further
8 development.

9 **The Pharmacokinetic Properties of the Active Compounds.** ADME/T properties,
10 including the absorption, solubility, BBB, hepatotoxicity, CYP 2D6, alogP, and PSA
11 of the 26 ALR2 inhibitors, have been evaluated *in silico* through Discovery Studio 2.1
12 (Accelrys, Inc., San Diego, CA). Compared with Epalrestat (the only marketed ALR2
13 inhibitor), the ADME/T properties of most of our compounds are in the required
14 druggability ranges, especially for compound **14** (β -amino-phenylpropanoic scaffold).
15 The detailed results and comparisons can be found in Table S5 (Supporting
16 Information).

17 CONCLUSIONS

18 New selective human aldose reductase 2 (ALR2) inhibitors have been discovered
19 by a protocol of virtual screening in multiple binding pocket conformations followed
20 by binding assays as well as selectivity and toxicity assessments. Several of the
21 resulting potent ALR2 inhibitors contain a β -amino-phenylpropanoic scaffold.
22 Biological tests demonstrated that two of the ALR2 inhibitors demonstrate

1 sub-micromolar IC₅₀ values (0.22 μM and 0.89 μM), which are comparable to the
2 commercially available drug, epalrestat, while showing superior selectivity to
3 epalrestat relative to inhibition of ALR1. SAR studies on the
4 β-amino-phenylpropanoic compound **14** and its analogs provide insight for further
5 optimization of these leads.

6 These results also tend to validate the *in silico* methods used. While conventional
7 structure-based virtual screening often starts with single conformation, we have
8 exploited a conformational sampling process via MD simulations. The conformation
9 sampling process produces multiple consensus binding pockets, which represent the
10 dynamic conformation changes of a binding pocket interacting with a different ligand.
11 A series of three filters were then used on the hits to optimize the yields. Our
12 screening protocol applied to this system resulted in more active hits and a success
13 rate of 14% based on compounds retrieved with IC₅₀'s of 10 μM or less. Recently,
14 many tools and protocols have been developed in our labs for lead identification;⁵¹⁻⁵⁴
15 we will combine these tools and protocols to improve the quality of ALR2 inhibitors.

16 **EXPERIMENTAL SECTION**

17 **Receptor Preparation.** Three ALR2 protein-ligand complexes (PDB entries:
18 2PDK, 1US0, and 2FZD) were placed in a TIP3P octahedral water box such that the
19 box boundary is at least 10 Å from any protein atom, and MD simulations were
20 performed for 6 nanoseconds. The water molecules in the crystal data were kept.
21 Three average structures were calculated from the equilibrated stage of the MD
22 trajectories (from 5-6 nanoseconds) of 2PDK, 1US0 and 2FZD. The three averaged

1 structures were then optimized with the steepest descent method for 200 steps using

1 structures were then optimized with the steepest descent method for 200 steps using
2 Discovery Studio 2.1.⁵⁵

3 The FlexX module in Sybyl 7.3⁵⁶ was used to dock our compound library against
4 the three consensus structures. The active sites were defined as all residues within 6.5
5 Å radius of the reference molecule in each optimized structure and cofactors were
6 retained during the docking process. Other FlexX parameters were set to default
7 values.

8 **Compound Library Preparation.** The structures from the GSMTL database
9 (~7,249 compounds) were docked against the three consensus structures. All
10 inorganic atoms in the structures were removed prior to the virtual screening using the
11 MOE package (Molecular Operating Environment).³⁹ The remaining moieties were
12 preprocessed (eg, adding hydrogen atoms; setting ionization states to be appropriate
13 for a pH range of 6.5 to 8.5; and generating stereo isomers and valid single 3D
14 conformers) by means of the Ligand Preparation module of Discovery Studio 2.1.

15 The structures of the training compounds and their inhibition data ($IC_{50} < 50 \mu M$)
16 were downloaded from the Binding DB database,³⁸ and were preprocessed as
17 described above.

18 **Establishment of the Selection Criteria.** 927 compounds, which had IC_{50} 's lower
19 than 50 μM , were selected from the Binding DB database. The compounds were
20 individually docked against the three consensus structures with FlexX. This results in
21 three FlexX scores for each compound: Fscore1 (derived from 2PDK), Fscore2
22 (derived from 1US0), and Fscore3 (derived from 2FZD). Thus three sets of 927

FlexX scores were obtained for the 927 compounds docked to each of the three protein structures. One of the selection criteria was obtained by averaging each set of docking scores for a given structure, i.e. $FS_i = \langle Fscore_i \rangle_{927}$; $i=1-3$. Then criterion 1 was invoked.

Criterion 1. Each of the hit compound's three FlexX scores (generated from docking into 2PDK, 1US0, and 2FZD respectively) should be more favorable than the corresponding average scores obtained for training set for each system.

The second selection criterion was obtained by insisting that certain key protein-ligand interactions were satisfied in the docked structure. The key ligand binding residues were identified by means of MOE. Protein ligand interaction fingerprints (PLIF) were calculated from 76 ALR2 structures selected from the PDB. This corresponded to all ligand ALR2 structures excluding those containing mutations in the active site. From this analysis it was concluded that:

Criterion 2. A hit compound's docked conformation should have hydrogen bonds to at least two of the three key residues (i.e., Tyr48, His110, and Trp111) and hydrophobic interaction with the specificity hydrophobic pocket (Trp79, Trp111, Phe122, Phe115 and Leu300).

Finally the third criterion simply insures that the dynamic trajectory hasn't taken the ligand-protein to another conformational state or pose of the ligand.

Criterion 3: The RMSD of the ligand, from its docked pose, resulting from the MD simulation should be less than 3 Å.

A final virtual screening hit must satisfy all three criteria.

Virtual Screening. The FlexX docking program (Sybyl 7.3) was employed for the virtual screening. As a consistency check three native ligands were docked back into their host crystal structures to confirm the performance of FlexX for the human ALR2 system. The RMSD between the docking pose of native ligand and the experimental pose in the consensus structure complex was less than 1 Å.

The 927 training compounds derived from the Binding DB database were docked to the three consensus structures, respectively. Only the best pose per ligand, as described above, was recorded for each docking run.

Structures from the GSMTL database were then virtually screened against the three consensus structures simultaneously with the FlexX docking program. For each compound, the program recorded 20 structural poses per run. These poses were analyzed by a clustering algorithm, and the structure from the largest cluster with the best FlexX score was selected. If the docking score was more favorable than the average docking score of known hits to that structure, ie $FS_i \leq \langle Fscore_i \rangle_{927}$) as defined above, the corresponding compound was then assessed by the two final criteria.

MD Simulations. MD simulations were performed using the PMEMD module in AMBER 11⁵⁷ accelerated by running on a GPU system, the NVIDIA CUDA processor. The three initial co-crystal structures (2PDK, 1US0 and 2FZD) were solvated in a 10Å octahedral box with TIP3P water. Periodic boundary conditions were applied.

The AMBER ff99SB force field⁵⁸ was exploited for the protein, and the general AMBER force field (GAFF)⁵⁹ was applied to the three structures. The cofactor

parameters were obtained from the literature.⁶⁰ The partial charges of three substrates were computed using the HF/6-31 G* basis set from GAUSSIAN03,⁶¹ and refined by RESP calculation using the antechamber module of the AMBER 11 package. Sodium ions were added in order to neutralize the systems. To remove possible steric stresses, the systems were minimized for 1,000 steps with the steepest descent method, followed by application of conjugate gradients for another 1,000 steps. Each of the three systems was linearly heated from 0 to 300K using a Langevin thermostat, with a collision frequency of 5.0 ps⁻¹, and harmonic restraints of 4 kcal/mol/Å² on the backbone atoms over 20 ps and then equilibrated for 50 ps at 300 K using the NVT ensemble. Finally, dynamics simulations of 6 ns were carried out for the production step in an NPT ensemble at 1atm and 300 K. The coordinates of the system were saved at every picosecond.

The temperature was kept at 300 K by means of a weak coupling algorithm.⁶² Covalent bonds involving hydrogen were constrained using the SHAKE algorithm.⁶³ The Particle-Mesh-Ewald method⁶⁴ was applied to treat the long range electrostatic interactions with a 10 Å non-bonded cutoff. The three average structures were calculated from the equilibrated stage of the MD trajectories (from 5 ns to 6 ns), and subsequent optimized with steepest descents for 200 steps. The three minimized average structures were then used for the virtual screening campaign. 128 structural complexes, which satisfied the first two filters, were submitted for MD simulations as described. The RMSD between the docked pose and averaged MD simulated pose for a hit candidate was checked to make sure the ligand pose had not undergone a

1 conformational transition in the MD (criterion 3) to reduce the chances of false
2 positives from the docking procedure.

3 **Chemistry.** All compounds tested for ALR2 inhibitions were taken from the
4 GSMTL in our laboratory. Purity of the compounds was assessed by HPLC equipped
5 with a ZORBAX SB-C18 column (250 mm×4.6 mm, 5 μm particle size) and a
6 UV/VIS detector setting of $\lambda = 254$ nm. The compounds were eluted with the two
7 solvent systems (CH₃OH as the organic phase in method I and CH₃CN as the organic
8 phase in method II) at a flow rate of 0.5 mL/min. HPLC analysis of the compounds
9 assayed confirmed the purity at $\geq 95\%$ (Table S3). Sources information and ¹H NMR,
10 MS data were listed in Table S4.

11 **Expression and Purification of Recombinant Human ALR2.** Recombinant
12 human ALR2 was expressed and purified as described by Nishimura et al.⁶⁵ The
13 human ALR2 gene was cloned into pET15b vector (Novagen) and expressed in
14 *Escherichia coli* strain BL21 (+) (Novagen). The hexahistidine tagged protein was
15 induced by IPTG (Isopropyl β-D-1-thiogalactopyranoside) during a 20 h period at
16 25 °C and purified using a Ni-affinity column (Qiagen).

17 **Expression and Purification of Recombinant Human ALR1.** Expression and
18 purification of recombinant human ALR1 was carried out following the methods
19 described by Bohren et al.^{66,67} The recombinant human ALR1 expression plasmid in
20 pReceiver-B01 was expressed in *E. coli* using a T7-based expression system and
21 purified using a Ni-affinity column.

22 **In Vitro Recombinant Human ALR2 Inhibition Assay.** A spectrophotometric

assay⁶⁸ was employed for in vitro inhibitory tests via the detection of absorbance decreases from the oxidation of NADPH to NADP⁺ catalyzed by the ALR2 enzyme. The absorbance at 340 nm was monitored at 30°C with an ultraviolet spectrophotometer reader. The assay was performed using a 1 mL reaction cuvette with sodium phosphate buffer (0.1 M), NADPH cofactor (0.15 mM), Li₂SO₄ (0.4 M), human ALR2 (0.486 μM), and D-glyceraldehyde substrate (10 mM).

The predicted hits and reference compounds (quercetin and epalrestat) were dissolved in dimethyl sulfoxide (DMSO). The final concentration of DMSO was not more than 1%. The inhibitory activities of tested compounds were assayed by adding them to the reaction cuvettes at 50 μM. Those compounds found to be active were tested at additional concentration ranging from 0.1 to 10 μM. The IC₅₀ value for each compound was determined as the compound concentration that inhibited human ALR2 activity by 50%. The IC₅₀ values was curve-fitted as described by Alexiou et al.⁶⁹ Compounds were tested at a minimum of five concentrations and all experiments were performed in triplicate. To exclude any possible nonspecific/promiscuous inhibition of ALR2, we deepened our hit validation, repeating all the assays in the presence of 0.01% Triton X-100, as suggested by Shoichet.⁶³ None of the observed inhibitory activities was affected by the addition of the nonionic detergent, confirming the activity.

In Vitro Recombinant Human ALR1 Inhibition Assay. To study the selectivity of ALR2 inhibitors, an inhibition study of ALR1 was carried out by monitoring the oxidation of NADPH at 340 nm as a function of time using glyceraldehyde as

1 substrate. The assay mixture contained 0.1 M sodium phosphate buffer of pH 6.2, 10
2 mM DL-glyceraldehyde, 0.1 mM NADPH. The confirmed ALR2 inhibitors were
3 added to the ALR1 assay mixture and tested at 37°C. The IC₅₀ values of compounds
4 having > 40% inhibition at 50 µM were determined as previously described.⁶⁹
5 Compounds were tested at a minimum of five concentrations and the experiments
6 were performed in triplicate.

7 **In Vitro Cell Viability Assay.** Cell proliferation was measured in an MTT assay
8 protocol (Table 4). Five thousand HEK 293 (human embryonic kidney 293) cells were
9 inserted in a 96-well plate in 100 µL of indicated medium in the presence of
10 compounds at the indicated concentration. After incubation for 48 hours, the cells
11 were further incubated with 20 µL of 2.5 mg/mL MTT for 4 hours at 37 °C in a
12 humidified incubator with 5% CO₂. Then the formazan dye was dissolved in 100 µL
13 of DMSO, and the absorbance was measured at 570 nm by using PowerWaveTMXS
14 microplate spectrophotometer (BioTek). The inhibition rate (%) was calculated as:

$$\text{Inhibition (\%)} = [1 - (A_{570, \text{compd}}) / (A_{570, \text{control}})] \times 100\%$$

Figure 1. A flowchart of the protocol of virtual screening multiple binding pocket conformations supported by molecular dynamic simulations.

Figure 2. The protein ligand interaction fingerprints (PLIF) derived from 76 available co-crystal structures of ALR2 and inhibitors.

Figure 3. Structures of hits from the virtual screening scheme.

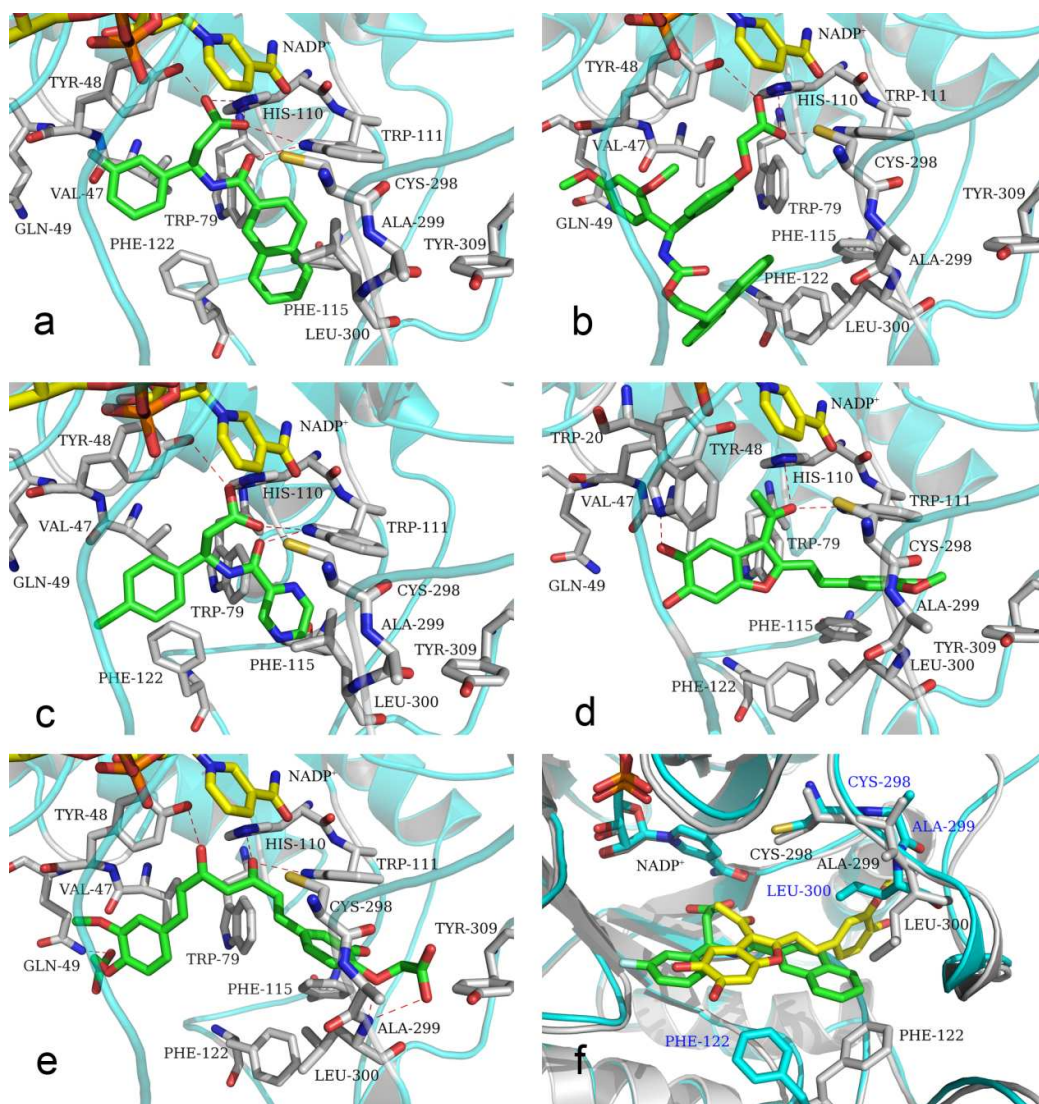

Figure 4. Binding modes for compounds **14** (a), **18** (b), **22** (c), **7** (d), and **25** (e).

Hydrogen bonds are depicted by red dotted lines. The induced-fit effect can be seen in (f), where one can see PHE-122, ALA-299 and LEU-300 undergoing significant displacements to accommodate the bound ligand. The bound structures of compounds **7** and **14** are derived by averaging the MD simulated structures from 1US0 and 2FZD, respectively.

Figure 5. ALR2 inhibition dose-response curves for compound **14** (a), **18** (b), and **25** (c). Values are generated using at least five concentrations of the inhibitors (μM), with triplicate determinations at each concentration. Percent inhibition is plotted on the ordinate, against the log of the concentration on the abscissa.

Figure 6. (a) Superimposition of the binding modes of compounds **14** (green), **15** (magenta), **22** (light blue), and **27** (orange). (b) Binding mode for compound **15**. (c) A summary of the SAR of β -amino-phenylpropanoic acid derivatives.

Table 1. Virtual screening hits and their in vitro assay results for ALR2 inhibitions.
