Abstract—Recently, low-cost dual constellation receivers with simultaneous tracking of GPS and GLONASS satellites and raw carrier phase output have become available. This enables a faster and more reliable ambiguity fixing especially in areas with limited satellite visibility, e.g. street canyons.

In this paper, we present a combined GPS/ GLONASS RTK positioning with code multipath estimation for low-cost receivers. We use double difference measurements and take the integer property of both the GPS and GLONASS ambiguities into account. For GLONASS, this requires a reparametrization of the double difference ambiguities and a subsequent parameter mapping.

The re-parameterized measurement models are used for ambiguity fixing with real measurements from two low-cost dual constellation GNSS receivers. We obtain residuals of a few centimeters for both GPS and GLONASS fixed carrier phases.

I. INTRODUCTION

Low-cost dual-constellation GNSS receivers with *carrier phase* measurement output have been developed recently. The increased number of simultaneously available satellites enables a faster and more reliable ambiguity fixing.

GLONASS uses a Frequency Division Multiple Access (FDMA) scheme, which results in a different carrier wavelength for every satellite. Consequently, the double difference combination of carrier phase integer ambiguities is no longer integer-valued. However, the double difference ambiguity combination can be represented as the linear combination of a double difference integer ambiguity and a single difference integer ambiguity. This representation has two consequences: The first one is a rank-defect due to the additional single difference ambiguity. The second consequence addresses the wavelength of the single difference ambiguity, which is in the order of only $65\mu\text{m}$. This small wavelength prevents any reliable fixing. Therefore, a parameter transformation is needed, which overcomes the rank-defect and still preserves the integer property.

We derive the transformation in section III. Section IV briefly describes the RTK positioning with combined GPS and GLONASS measurements. We estimate a code multipath parameter for every GPS and GLONASS satellite to exploit the time-correlation of multipath and to prevent a mapping of multipath to other state parameters. Finally, we present some measurement results in Section V and conclude this paper in Section VI.

II. MEASUREMENT MODEL

The undifferenced carrier phase measurement for the k -th GLONASS satellite of the r -th receiver is modeled as

$$\lambda_k \varphi_r^k = \| \vec{x}_r - \vec{x}^k \| + c(\delta\tau_r - \delta\tau^k) - I_r^k + T_r^k + \lambda_k N_r^k + \tilde{\beta}_r(n_k) + \beta^k + \varepsilon_r^k, \quad (1)$$

with the wavelength λ_k , the carrier phase measurement φ_r^k in units of cycles, the receiver position \vec{x}_r , the satellite position \vec{x}^k , the speed of light c in vacuum, the receiver clock offset $\delta\tau_r$, the satellite clock offset $\delta\tau^k$, the ionospheric delay I_r^k , the tropospheric delay T_r^k , the integer ambiguity N_r^k , the receiver phase bias $\tilde{\beta}_r(n_k)$ being a linear function of the GLONASS channel number n_k , the satellite phase bias β^k and the phase noise ε_r^k .

The receiver phase biases are generated by the receiver's digital signal processing chain (see Sleewaegen et al. [1][2]) and can be accurately modeled as the sum of a satellite-independent bias $\beta_{0,r}$ and a bias $n_k\beta_r$ that is proportional to the GLONASS channel number (see Wanninger [3]):

$$\tilde{\beta}_r(n_k) = \beta_{0,r} + n_k\beta_r \quad (2)$$

The GPS carrier phase measurements are modeled similarly and we refer to our earlier publication [4] for more details.

The single difference (SD) between the measurements of receivers r and u eliminates the satellite clock offset and phase bias, i.e.

$$\begin{aligned} \lambda_k \varphi_{ur}^k &= \vec{e}_u^k (\vec{x}_u - \vec{x}^k) - \vec{e}_r^k (\vec{x}_r - \vec{x}^k) \\ &\quad + c\delta\tau_{ur} - I_{ur}^k + T_{ur}^k + \lambda_k N_{ur}^k + \beta_{ur} + \varepsilon_{ur}^k \\ &= \vec{e}_u^k \vec{x}_{ur} + \vec{e}_u^k + c\delta\tau_{ur} - I_{ur}^k + T_{ur}^k \\ &\quad + \lambda_k N_{ur}^k + \beta_{0,ur} + n_k\beta_{ur} + \varepsilon_{ur}^k, \end{aligned} \quad (3)$$

with c_{ur}^k being the synchronization correction between receivers u and r as described in [5][6][7].

The double difference (DD) further eliminates the differential receiver clock offset and phase bias, i.e.

$$\begin{aligned} \lambda_k \varphi_{ur}^k - \lambda_l \varphi_{ur}^l &= \vec{e}_u^{kl} \vec{x}_{ur} + c_{ur}^{kl} - I_{ur}^{kl} + T_{ur}^{kl} \\ &\quad + \lambda_k N_{ur}^k - \lambda_l N_{ur}^l \\ &\quad + (n_k - n_l)\beta_{ur} + \varepsilon_{ur}^{kl} \end{aligned} \quad (4)$$

We subtract all available a priori information including the synchronization correction, and the differential ionospheric and tropospheric delay estimates \hat{I}_{ur}^{kl} and \hat{T}_{ur}^{kl} , i.e.

$$\begin{aligned}\lambda_k \tilde{\varphi}_{ur}^k - \lambda_l \tilde{\varphi}_{ur}^l &= \lambda_k \varphi_{ur}^k - \lambda_l \varphi_{ur}^l \\ &\quad - c_{ur}^{kl} + \hat{I}_{ur}^{kl} - \hat{T}_{ur}^{kl} \\ &= \vec{e}_u^k \vec{x}_{ur} - \Delta I_{ur}^{kl} + \Delta T_{ur}^{kl} \\ &\quad + \lambda_k N_{ur}^k - \lambda_l N_{ur}^l \\ &\quad + (n_k - n_l) \beta_{ur} + \varepsilon_{ur}^{kl},\end{aligned}\quad (5)$$

which leaves the relative position \vec{x}_{ur} , the residual atmospheric delays, the integer ambiguities N_{ur}^k and N_{ur}^l , and the differential receiver phase bias β_{ur} as unknowns.

The double difference ambiguity term can be rewritten as

$$\lambda_k N_{ur}^k - \lambda_l N_{ur}^l = \lambda_k N_{ur}^{kl} + (\lambda_k - \lambda_l) N_{ur}^l, \quad (6)$$

with N_{ur}^{kl} being the DD integer ambiguity and N_{ur}^l being the SD integer ambiguity.

The differences of wavelengths can be further developed with $f_k = f_0 + n_k \Delta f = (n_0 + n_k) \Delta f$ as

$$\begin{aligned}\lambda_k - \lambda_l &= \frac{c}{f_0 + n_k \Delta f} - \frac{c}{f_0 + n_l \Delta f} \\ &= c \cdot (n_l - n_k) \frac{\Delta f}{f_k \cdot f_l} = \lambda_k \cdot \frac{n_l - n_k}{n_0 + n_l},\end{aligned}\quad (7)$$

which is approximately $65 \mu\text{m}$ for $n_0 = f_0 / \Delta f = 2848$ and $n_l - n_k = 1$.

Eq. (6) can be written in matrix-vector notation as

$$\begin{bmatrix} \lambda_1 N_{ur}^1 - \lambda_l N_{ur}^l \\ \lambda_2 N_{ur}^2 - \lambda_l N_{ur}^l \\ \vdots \\ \lambda_K N_{ur}^K - \lambda_l N_{ur}^l \end{bmatrix} = \underbrace{\begin{bmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_K \end{bmatrix}}_{\Lambda} \cdot \begin{bmatrix} \lambda_1 - \lambda_l \\ \lambda_2 - \lambda_l \\ \vdots \\ \lambda_K - \lambda_l \end{bmatrix} \cdot \begin{bmatrix} N_{ur}^{1l} \\ N_{ur}^{2l} \\ \vdots \\ N_{ur}^{Kl} \end{bmatrix}. \quad (8)$$

III. PARAMETER TRANSFORMATION

The ambiguity coefficient matrix Λ has $K + 1$ columns but only K rows, which results in a rank-deficient system of equations. Therefore, we map one DD ambiguity (here: the first one N_{ur}^{1l}) to the SD ambiguity N_{ur}^l and introduce \bar{N}_{ur}^l as

$$\begin{aligned}\bar{N}_{ur}^l &:= N_{ur}^l + \frac{\lambda_1}{\lambda_1 - \lambda_l} N_{ur}^{1l} \\ &= N_{ur}^l + \frac{n_0 + n_l}{n_l - n_1} N_{ur}^{1l}.\end{aligned}\quad (9)$$

The other DD ambiguities have to be adjusted respectively, i.e.

$$\tilde{N}_{ur}^{kl} = N_{ur}^{kl} - \frac{n_l - n_k}{n_l - n_1} \cdot N_{ur}^{1l}. \quad (10)$$

Note that both \bar{N}_{ur}^l and \tilde{N}_{ur}^{kl} are integer valued for any N_{ur}^{1l} only if $n_l - n_1$ is 1.

Multiplying both the SD and DD ambiguities by $n_l - n_1$ ensures that the ambiguities are always integer valued, i.e.

$$\begin{aligned}\bar{N}_{ur}^l &= (n_l - n_1) \cdot \tilde{N}_{ur}^l \\ &= (n_l - n_1) \cdot N_{ur}^l + (n_0 + n_l) \cdot N_{ur}^{1l} \in \mathbb{Z} \\ \tilde{N}_{ur}^{kl} &= (n_l - n_1) \cdot \tilde{N}_{ur}^{kl} \\ &= (n_l - n_1) \cdot N_{ur}^{kl} - (n_l - n_k) \cdot N_{ur}^{1l} \in \mathbb{Z}.\end{aligned}\quad (11)$$

We rewrite Eq. (8) in terms of \bar{N}_{ur}^l and \tilde{N}_{ur}^{kl} to obtain the following *full-rank* ambiguity transformation:

$$\begin{bmatrix} \lambda_1 N_{ur}^1 - \lambda_l N_{ur}^l \\ \lambda_2 N_{ur}^2 - \lambda_l N_{ur}^l \\ \vdots \\ \lambda_K N_{ur}^K - \lambda_l N_{ur}^l \end{bmatrix} = \begin{bmatrix} 0 & \dots & 0 \\ \frac{\lambda_2}{n_l - n_1} & & \frac{\lambda_1 - \lambda_l}{n_l - n_1} \\ & \ddots & \vdots \\ & & \frac{\lambda_K - \lambda_l}{n_l - n_1} \end{bmatrix} \cdot \begin{bmatrix} \bar{N}_{ur}^l \\ \vdots \\ \tilde{N}_{ur}^{kl} \end{bmatrix}. \quad (12)$$

We recommend to choose n_l and n_1 such that $n_l - n_1 = 1$. In this case, the combined $K - 2$ DD ambiguities \tilde{N}_{ur}^{kl} can be considered as *integer*-valued with wavelengths λ_k , $k \in \{1, \dots, K\}$, while the SD ambiguity \bar{N}_{ur}^l is considered as *real*-valued due to the small differential wavelengths $\lambda_k - \lambda_l$.

The DD carrier phase measurements of Eq. (5) also include the unknown differential receiver phase bias β_{ur} , which can not be separated from the ambiguities. Therefore, we map the differential receiver phase bias β_{ur} to the SD ambiguity \bar{N}_{ur}^l , i.e.

$$\begin{aligned}&\frac{\lambda_k - \lambda_l}{n_l - n_1} \cdot \bar{N}_{ur}^l + (n_k - n_l) \cdot \beta_{ur} \\ &= \frac{\lambda_k - \lambda_l}{n_l - n_1} \cdot \left(\bar{N}_{ur}^l + \frac{(n_k - n_l)(n_l - n_1)}{\lambda_k - \lambda_l} \cdot \beta_{ur} \right) \\ &= \frac{\lambda_k - \lambda_l}{n_l - n_1} \cdot \left(\bar{N}_{ur}^l - \underbrace{\frac{(n_0 + n_l)(n_l - n_1)}{\lambda_k} \cdot \beta_{ur}}_{\gamma_k} \right),\end{aligned}\quad (13)$$

where the last identity was obtained with Eq. (7). The dependency of the joint SD ambiguity/bias term on λ_k is not desirable as only one SD parameter can be estimated. We replace λ_k by $\lambda_0 = c/f_0$ in γ_k introduce the error term ε :

$$\frac{\lambda_k - \lambda_l}{n_l - n_1} \cdot (\bar{N}_{ur}^l - \gamma_k \beta_{ur}) \stackrel{!}{=} \frac{\lambda_k - \lambda_l}{n_l - n_1} \cdot (\bar{N}_{ur}^l - \gamma_0 \beta_{ur}) + \varepsilon \quad (14)$$

Solving for ε yields

$$\begin{aligned}\varepsilon &= \frac{\lambda_k - \lambda_l}{n_l - n_1} \cdot (\gamma_0 - \gamma_k) \cdot \beta_{ur} \\ &= (\lambda_k - \lambda_l) \cdot (n_0 + n_l) \cdot \left(\frac{1}{\lambda_0} - \frac{1}{\lambda_k} \right) \cdot \beta_{ur} \\ &= (\lambda_k - \lambda_l) \cdot (n_0 + n_l) \cdot \left(\frac{n_k \Delta f}{c} \right) \cdot \beta_{ur}.\end{aligned}\quad (15)$$

Replacing Δf by $f_l/(n_0 + n_l)$ further simplifies ε to

$$\varepsilon = \frac{\lambda_k - \lambda_l}{\lambda_l} \cdot n_k \cdot \beta_{ur}, \quad (16)$$

which is far below the millimeter-level for any relevant phase bias β_{ur} . Thus, we can neglect ε and replace γ_k by γ_0 in Eq. (13).

The DD carrier phase measurements of Eq. (5) can be written with Eq. (12) in matrix-vector notation as

$$\begin{aligned} & \begin{bmatrix} \lambda_1 \tilde{\varphi}_{ur}^1 - \lambda_l \tilde{\varphi}_{ur}^l \\ \lambda_2 \tilde{\varphi}_{ur}^2 - \lambda_l \tilde{\varphi}_{ur}^l \\ \vdots \\ \lambda_K \tilde{\varphi}_{ur}^K - \lambda_l \tilde{\varphi}_{ur}^l \end{bmatrix} \\ &= \begin{bmatrix} \vec{e}_u^{1l} & \frac{\lambda_1 - \lambda_l}{n_l - n_1} \\ \vec{e}_u^{2l} & \frac{\lambda_2 - \lambda_l}{n_l - n_1} \\ \vdots & \\ \vec{e}_u^{Kl} & \frac{\lambda_K - \lambda_l}{n_l - n_1} \end{bmatrix} \begin{bmatrix} \vec{x}_{ur} \\ \bar{N}_{ur}^l - \gamma_0 \beta_{ur} \end{bmatrix} \\ &+ \begin{bmatrix} 0 & \dots & 0 \\ \frac{\lambda_2}{n_l - n_1} & \ddots & \frac{\lambda_K}{n_l - n_1} \end{bmatrix} \cdot \begin{bmatrix} \bar{N}_{ur}^{2l} \\ \vdots \\ \bar{N}_{ur}^{Kl} \end{bmatrix} + \begin{bmatrix} \varepsilon_{ur}^{1l} \\ \varepsilon_{ur}^{2l} \\ \vdots \\ \varepsilon_{ur}^{Kl} \end{bmatrix}, \end{aligned} \quad (17)$$

where we have assumed that the residual atmospheric errors are negligible.

The DD pseudorange measurements of GLONASS are also affected by inter-frequency biases. We extend the model of [9], and map the DD code bias b_{ur}^{kl} to the DD code multipath $\Delta\rho_{MP_{ur}^{kl}}$, i.e.

$$\begin{aligned} \begin{bmatrix} \tilde{\rho}_{ur}^{1l} \\ \vdots \\ \tilde{\rho}_{ur}^{Kl} \end{bmatrix} &= \begin{bmatrix} \tilde{\rho}_{ur}^{1l} - c_{ur}^{1l} \\ \vdots \\ \tilde{\rho}_{ur}^{Kl} - c_{ur}^{Kl} \end{bmatrix} \\ &= \begin{bmatrix} \vec{e}_u^{1l} & 1 & \\ \vdots & \ddots & \\ \vec{e}_u^{Kl} & & 1 \end{bmatrix} \begin{bmatrix} \vec{x}_{ur} \\ \Delta\rho_{MP_{ur}^{1l}} + b_{ur}^{1l} \\ \vdots \\ \Delta\rho_{MP_{ur}^{Kl}} + b_{ur}^{Kl} \end{bmatrix} + \begin{bmatrix} \eta_{ur}^{1l} \\ \vdots \\ \eta_{ur}^{Kl} \end{bmatrix} \end{aligned} \quad (18)$$

IV. RTK POSITIONING WITH GPS AND GLONASS

In this section, the measurements of GPS and GLONASS are considered jointly. Therefore, we extend the notation by introducing the superscript labels GPS and GLO as constellation identifiers. The combined measurement vector is written as

$$y = \begin{pmatrix} y_{\varphi}^{\text{GPS}} \\ y_{\varphi}^{\text{GLO}} \end{pmatrix} \quad (19)$$

with

$$y^{\text{GPS}} = \begin{pmatrix} y_{\varphi}^{\text{GPS}} \\ y_{\rho}^{\text{GPS}} \end{pmatrix} = \begin{pmatrix} \lambda \tilde{\varphi}_{ur}^{1l, \text{GPS}} \\ \vdots \\ \frac{\lambda \tilde{\varphi}_{ur}^{Kl, \text{GPS}}}{\tilde{\rho}_{ur}^{1l, \text{GPS}}} \end{pmatrix}, \quad (20)$$

and

$$y^{\text{GLO}} = \begin{pmatrix} y_{\varphi}^{\text{GLO}} \\ y_{\rho}^{\text{GLO}} \end{pmatrix} = \begin{pmatrix} \lambda_1^{\text{GLO}} \tilde{\varphi}_{ur}^{1l, \text{GLO}} - \lambda_l^{\text{GLO}} \tilde{\varphi}_{ur}^{l, \text{GLO}} \\ \vdots \\ \frac{\lambda_K^{\text{GLO}} \tilde{\varphi}_{ur}^{Kl, \text{GLO}} - \lambda_l^{\text{GLO}} \tilde{\varphi}_{ur}^{l, \text{GLO}}}{\tilde{\rho}_{ur}^{1l, \text{GLO}}} \\ \vdots \\ \tilde{\rho}_{ur}^{Kl, \text{GLO}} \end{pmatrix}. \quad (21)$$

The unknown parameters are stacked in the state vector

$$x = (\vec{x}_{ur}^T, \underbrace{\Delta\rho_{MP_{ur}^{1l}}, \dots, \Delta\rho_{MP_{ur}^{Kl}}}_{\in \mathbb{R}}, \underbrace{\bar{N}_{ur}^{l, \text{GLO}} - \gamma_0 \beta_{ur}^{\text{GLO}}}_{\in \mathbb{R}}, \underbrace{\Delta\rho_{MP_{ur}^{1l}} + b_{ur}^{1l, \text{GLO}}, \dots, \Delta\rho_{MP_{ur}^{Kl}} + b_{ur}^{Kl, \text{GLO}}}_{\in \mathbb{R}}, \underbrace{N_{ur}^{1l, \text{GPS}}, \dots, N_{ur}^{Kl, \text{GPS}}, \bar{N}_{ur}^{2l, \text{GLO}}, \dots, \bar{N}_{ur}^{Kl, \text{GLO}}}_{\in \mathbb{Z}})^T. \quad (22)$$

We use a standard Kalman filter [10] to determine the real-valued float solution \hat{x} from y , and subsequently apply the LAMBDA method of Teunissen [8] with the extensions of Henkel and Sperl [9] for fixing of the DD GPS and GLONASS ambiguities.

Once the ambiguities are fixed, it is sufficient to consider the fixed phase measurements given by

$$\check{y} = \left(y_{\varphi}^{\text{GPS}} - \lambda \check{N}_{ur}^{\text{GPS}}, \underbrace{\begin{pmatrix} 0 & \dots & 0 \\ \frac{\lambda_2}{n_l - n_1} & \ddots & \frac{\lambda_K}{n_l - n_1} \end{pmatrix} \cdot \begin{pmatrix} \check{N}_{ur}^{2l, \text{GLO}} \\ \vdots \\ \check{N}_{ur}^{Kl, \text{GLO}} \end{pmatrix}}_{\in \mathbb{Z}} \right). \quad (23)$$

The fixed least-squares estimates of the baseline and SD ambiguity are obtained from the measurement model of Eq. (17) and given by

$$\begin{bmatrix} \check{x}_{ur} \\ \check{N}_{ur}^{l, \text{GLO}} - \gamma_0 \check{\beta}_{ur}^{\text{GLO}} \end{bmatrix} = (H^T \Sigma^{-1} H)^{-1} H^T \Sigma^{-1} \check{y}, \quad (24)$$

with

$$H = \begin{pmatrix} H^{\text{GPS}} & 0 \\ H^{\text{GLO}} & a^{\text{GLO}} \end{pmatrix}, \quad (25)$$

with the sub-matrices

$$H^{\text{GPS}} = H^{\text{GLO}} = \begin{pmatrix} \vec{e}_u^{1l} \\ \vdots \\ \vec{e}_u^{Kl} \end{pmatrix} \quad \text{and} \quad a^{\text{GLO}} = \begin{pmatrix} \frac{\lambda_1 - \lambda_l}{n_l - n_1} \\ \vdots \\ \frac{\lambda_K - \lambda_l}{n_l - n_1} \end{pmatrix}, \quad (26)$$

and the measurement covariance matrix Σ .

The accuracy of the least-squares estimation can be analyzed with the measurement residuals given by

$$r_{\tilde{y}} = P_H^\perp \tilde{y} \quad \text{with} \quad P_H^\perp = 1 - H(H^T \Sigma^{-1} H)^{-1} H^T \Sigma^{-1}. \quad (27)$$

V. MEASUREMENT RESULTS

In this section, we analyze the performance of RTK positioning and attitude determination using two multi-sensor modules from ANavS and the measurements from a virtual reference station (VRS). Each multi-sensor module includes a low-cost LEA M8T multi-GNSS receiver from u-blox, a GNSS patch antenna, a low-cost inertial sensor from Invensense (MPU 9150) and a barometer from Bosch Sensortec. The multi-sensor modules were mounted on the roof of a car for joint RTK position and attitude determination as described in [7][9]. The VRS and the reference station network were operated by Axionet and the measurements were received with the NTRIP client. The length of the attitude baseline on the vehicle was 80 cm and the length of the RTK baseline between the vehicle and the VRS was 5 km.

Fig. 1 and 2 show the fixed DD phase residuals of the attitude baseline for both GPS and GLONASS. The residuals of all satellites are drift-free with a magnitude of clearly less than 1 cycle, which indicates a correct ambiguity fixing and a positioning accuracy of 2 cm. The residuals of GLONASS are almost unbiased whereas the GPS DD phase residuals show some biases of up to 2 cm over the considered time period of 13 minutes. Potential reasons for these small biases are phase multipath, wrong ambiguity fixings, the projection of GLONASS errors into GPS or unmodeled biases. We considered simultaneous measurements from multiple attitude baselines using receivers of the same type to get a better insight. We obtained different biases and believe that phase multipath is the primary source of these biases for low-cost receivers.

Fig. 3 and 4 show the fixed phase residuals of both GPS and GLONASS for the RTK baseline. The result is similar to the attitude baseline, i.e. the residuals of all satellites are again drift-free with a magnitude of clearly less than 1 cycle, which indicates a correct ambiguity fixing. The GPS residuals have again some small biases while the GLONASS residuals are almost unbiased. This can be explained to some extent by the real-valued scalar parameter $\bar{N}_{ur}^l - \gamma_0 \beta_{ur}$ of GLONASS, which can absorb some biases. Obviously, the residual atmospheric errors are negligible for the considered baseline length of 5 km as the GLONASS residuals remain unbiased.

VI. CONCLUSION

In this paper, a method for RTK positioning with GPS and GLONASS measurements from low-cost GNSS receivers was described. The GLONASS double difference ambiguities are decomposed into an *integer*-valued double difference ambiguity for *every* satellite and a *common single* difference ambiguity. The common ambiguity is treated as real-valued as the wavelength is too small for ambiguity resolution. We also estimate the interfrequency phase and code biases and pseudorange multipath.

The GPS/ GLONASS dual constellation RTK was verified with real measurements from low-cost ANavS multi-sensor modules and a Virtual Reference Station from Axionet. The residuals of the fixed GPS and GLONASS carrier phase measurements were less than 2 cm for most of the time, which indicates a correct ambiguity fixing and results in a millimeter-to centimeter-level positioning accuracy.
