Abstract—This paper addresses the problem of competition vs. cooperation in the downlink, between base stations (BSs), of a multiple input multiple output (MIMO) interference, heterogeneous wireless network (HetNet). This research presents a scenario where a macrocell base station (MBS) and a cochannel femtocell base station (FBS) each simultaneously serving their own user equipment (UE), has to choose to act as individual systems or to cooperate in coordinated multipoint transmission (CoMP). The paper employes both the theories of noncooperative and cooperative games in a unified procedure to analyze the decision making process. The BSs of the competing system are assumed to operate at the maximum expected sum rate (MESR) correlated equilibrium (CE), which is compared against the value of CoMP to establish the stability of the coalition. It is proven that there exists a threshold geographical separation, d_{th} , between the macrocell user equipment (MUE) and FBS, under which the region of coordination is non-empty. Theoretical results are verified through simulations.

I. INTRODUCTION

Small cells are an easily deployable solution to the increasing demand for capacity. Underlay small cells improve the capacity of the network through frequency reuse and higher link gains due to shorter distances to the user equipment (UE). On the downside the unplanned deployment of small cells in the larger cell structure creates unforeseen interference conditions. Such dynamic interference situations require novel solutions [1].

Coordinated multipoint transmission (CoMP) introduces dynamic interaction between multiple cells to increase network performance and reduce interference. In our research we consider the CoMP scheme of joint transmission (JT) [2]. We begin with the hypotheses that JT must be a rational decision, which is profitable for both macro- and femto-systems, since these systems may belong to independent operators/users. In human interactions, cooperation among a group is justifiable if all the members are better off in that group than if they were in any other group structure among themselves. This rational behavior is embedded in the solution concept of *core* in coalition formation games.

Past research of heterogeneous networks (HetNets) of macro-femtocells, has used both non-cooperative and cooperative games. In [3] a Stackelberg game is formulated where pricing is employed to move the equilibria towards a tolerable interference level for the *macrocell base station* (MBS). In [4] a potential game based analysis of *Nash equilibrium* (NE)

of power and subcarrier allocation, for a multicell interference environment is presented. In [5] power distribution over resource blocks of cognitive *femtocell base stations* (FBSs) is analyzed for their *correlated equilibrium* (CE). In [6], [7] ϵ -correlated equilibrium solution is presented for underlayed femtocells to minimize interference to the macro-system. CE is the form of equilibrium used in this paper as well.

In [8], [9] coalition formation games with externalities are used to group the femtocells to mitigate collisions and reduce interference. In [10] a coalition game together with the solution concept of *recursive core* is used to model the cooperative interaction between *macrocell user equipment* (MUE) and *femtocell user equipment* (FUE). They conclude that forming of disjoint coalitions increases the rates of both MUE and FUE. In [11] a coalition formation game is employed to partition a dense network of femtocells to minimize interference where they introduce a polynomial time algorithm for group formation. In [12] both *transferable utility* (TU) and *nontransferable utility* (NTU) coalition formation games are used for cooperation of receivers and transmitters in an interference environment.

This paper is set apart from the above related research, since it brings together both theories of non-cooperative and coalition formation games to model femto-maro interaction in CoMP. A similar analysis but, for non-CoMP case, is presented in [13]. The terms non-cooperative and cooperative are in accordance to their use in the game theory literature whereas the terms coordination, CoMP, and JT are used synonymously.

The rest of the paper consists of the system model in Section II, game-theoretic formulation and solution in Section III, simulation results in Section IV and conclusion with summary in Section V.

II. SYSTEM MODEL

The paper considers the downlink transmission of a two tier HetNet, which consists of a single MBS m and a single FBS f, separated by a distance d>0. Each base station (BS) has an active user equipment (UE). It is possible that the BSs serve more than one user but the assumption is that at any given instant each BS transmits to only one selected user. The two BSs each possesses T number of transmit antennas while each UE possesses R number of receive antennas. Fig. 1 depicts the system model. The origin of the plane is at MBS. We define two modes of operation, namely uncoordinated

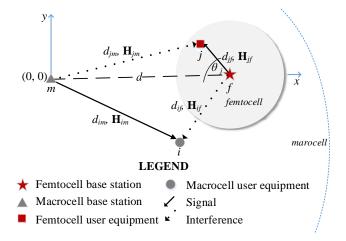

Figure 1. System model. The attributes on arrows indicate the effective distance between elements and their respective channel matrices.

and coordinated. In uncoordinated mode the two BSs act as separate transmitters where MBS serves MUE while FBS serves FUE. On the contrary if the two cells conform to the coordinated mode, then the two BSs cooperate through CoMP.

The channel model includes large scale signal attenuation as a function of distance. Channel gain matrix is multiplied by a magnitude, which is a path loss function of distance between BS and UE [14]. The received baseband equivalent signal \mathbf{y}_i (resp. \mathbf{y}_j) at MUE i (resp. FUE j) for uncoordinated transmission over Gaussian channel are

$$\mathbf{y}_{i} \triangleq d_{im}^{-\alpha} \mathbf{H}_{im} \mathbf{V}_{m} \mathbf{s}_{i} + d_{if}^{-\alpha} \mathbf{H}_{if} \mathbf{V}_{f} \mathbf{s}_{j} + \mathbf{n}_{i}, \tag{1}$$

$$\mathbf{y}_{j} \triangleq d_{jf}^{-\alpha} \mathbf{H}_{jf} \mathbf{V}_{f} \mathbf{s}_{j} + d_{jm}^{-\alpha} \mathbf{H}_{jm} \mathbf{V}_{m} \mathbf{s}_{i} + \mathbf{n}_{j},$$
 (2)

where d_{im} , d_{if} , d_{jf} , $d_{jm} \geq 0$ are the effective distances between the respective indexed elements, \mathbf{H}_{im} is the $R \times T$ complex valued channel gain matrix from MBS m to MUE i and \mathbf{H}_{if} , \mathbf{H}_{jf} , \mathbf{H}_{jm} are interpreted analogously. The matrix \mathbf{V}_m (resp. \mathbf{V}_f) is the precoder at MBS (resp. FBS). The independent symbol vector of unit variance at MBS m (resp. at FBS m) to MUE i (resp. to FUE j) is denoted by \mathbf{s}_i (resp. \mathbf{s}_j). The exponent $(-\alpha)$, where α is a positive real valued scalar, accounts for path loss, and \mathbf{n}_i , \mathbf{n}_j are circular symmetric, uncorrelated additive withe Gaussian noise (AWGN) vectors.

The achievable rate, treating interference as noise, of the macro system, $R_{\rm uc}^m$, is given by (3) [15].

$$R_{\text{uc}}^{m} \triangleq \log \det \left(\mathbf{I}_{R} + \frac{d_{im}^{-2\alpha} \mathbf{H}_{im} \mathbf{V}_{m} \mathbf{V}_{m}^{H} \mathbf{H}_{im}^{H}}{d_{if}^{-2\alpha} \mathbf{H}_{if} \mathbf{V}_{f} \mathbf{V}_{f}^{H} \mathbf{H}_{if}^{H} + \sigma^{2} \mathbf{I}_{R}} \right), \quad (3)$$

$$R_{\text{uc}}^{f} \triangleq \log \det \left(\mathbf{I}_{R} + \frac{d_{jf}^{-2\alpha} \mathbf{H}_{jf} \mathbf{V}_{f} \mathbf{V}_{f}^{H} \mathbf{H}_{jf}^{H}}{d_{jm}^{-2\alpha} \mathbf{H}_{jm} \mathbf{V}_{m} \mathbf{V}_{m}^{H} \mathbf{H}_{jm}^{H} + \sigma^{2} \mathbf{I}_{R}} \right).$$

$$(4)$$

Above σ^2 is variance of circular symmetric noise and \mathbf{I}_R is the $R \times R$ identity matrix. For a matrix \mathbf{X} in the complex field, \mathbf{X}^H denotes the Hermitian transpose. Analogously we define the achievable rate, R_{uc}^f , of the femto-system (4).

Now suppose that the two BSs coordinate through JT. The coordination is such that, FBS must transmit to both UE their respective symbols. It is possible to extend this model to include the case where both BSs transmit to both UE. The paper only consider MUE receiving JT since FUE are mostly home/office users who are less mobile and they have higher downlink gains whereas MUE may be highly mobile and operate under high signal fading and interference. The received signals at MUE and FUE in coordinated transmission are then given by (5) and (6) respectively. Note matrix augmentation in (5).

$$\mathbf{y}_{i} \triangleq d_{im}^{-\alpha} \mathbf{H}_{im} \mathbf{V}_{m} \mathbf{s}_{im} + d_{if}^{-\alpha} \mathbf{H}_{if} \mathbf{V}_{if} \mathbf{s}_{if} + \mathbf{n}_{i}, \tag{5}$$

$$\mathbf{y}_{j} \triangleq d_{if}^{-\alpha} \mathbf{H}_{jf} \mathbf{V}_{jf} \mathbf{s}_{j} + d_{jm}^{-\alpha} \mathbf{H}_{jm} \mathbf{V}_{m} \mathbf{s}_{im} + \mathbf{n}_{j}, \tag{6}$$

$$R_{c}^{f} \triangleq \log \det \left(\mathbf{I}_{R} + \frac{d_{jf}^{-2\alpha} \mathbf{H}_{jf} \mathbf{V}_{jf} \mathbf{V}_{jf}^{H} \mathbf{H}_{jf}^{H}}{d_{jm}^{-2\alpha} \mathbf{H}_{jm} \mathbf{V}_{m} \mathbf{V}_{m}^{H} \mathbf{H}_{jm}^{H} + \sigma^{2} \mathbf{I}_{R}} \right). (7)$$

Above V_{if} (resp. V_{jf}) is the precoder matrix at FBS for MUE (resp. FUE), V_m is the MBS precoder. The signal model assumes that the precoders V_{if} and V_{jf} are such that there is no interuser interference from FBS to the two UE. To that end block diagonalization (BD) can be employed at FBS [16]. The independent unit variance transmission streams from MBS and FBS to MUE are s_{im} and s_{if} . Then the achievable rates of FUE R_c^f , and MUE R_c^m , for the coordinated transmission scheme are given by (7) and (8) respectively [17]. This paper consider that the precoders at the two BSs are chosen from a finite predefined code-book. The finite code book model not only affords a finite action space game, but also reflects the systems in practical implementations such as LTE, which define a finite code-book.

III. CORE SOLUTION

Now the paper presents two non-cooperative games one for the uncoordinated system, G1 and one for the coordinated system, G2. The relation between G1 and G2 is established in the ensuing development. Both games have identical set of players $\mathcal{N} \triangleq \{MBS, FBS\}$, i.e., the two BSs. The action spaces of the players are their precoder code-books. In the uncoordinated case (resp. coordinated case) the sets of precoders of MBS and FBS are denoted by A_{muc} and A_{fuc} (resp. \mathcal{A}_{mc} and \mathcal{A}_{fc}) respectively. Let $\mathbf{0} \notin \mathcal{A}_{fc}$ (does not contain zero precoder), which avoids the trivial case of non-JT. The product sets of the action spaces are $A_{uc} \triangleq A_{muc} \times A_{fuc}$ and $A_c \triangleq A_{mc} \times A_{fc}$. The utility functions of the two players in the uncoordinated case (resp. coordinated case) are $R_{\rm uc}^m$ and $R_{\rm uc}^f$ (resp. $R_{\rm c}^m$ and $R_{\rm c}^f$). The joint action of G_1 is $\mathbf{V} \triangleq (\mathbf{V}_m, \mathbf{V}_f) \in \mathcal{A}_{ ext{uc}}$ where $\mathbf{V}_m \in \mathcal{A}_{m ext{uc}}$ and $\mathbf{V}_f \in \mathcal{A}_{f ext{uc}}$ and the joint action of G_2 is $\mathbf{V} \in \mathcal{A}_c$ such that $\mathbf{V} \triangleq (\mathbf{V}_m, \mathbf{V}_f)$ where $\mathbf{V}_m \in \mathcal{A}_{mc}$ and $\mathbf{V}_f \in \mathcal{A}_{fc}$. Note that FBS's action $\mathbf{V}_f \in \mathcal{A}_{fc}$, consists of two precoders $\mathbf{V}_f \triangleq (\mathbf{V}_{if}, \mathbf{V}_{jf})$. The MBS (resp. FBS) has identical maximum transmit power in both uncoordinated and coordinated cases, i.e., for

$$R_{c}^{m} \triangleq \log \det \left(\mathbf{I}_{R} + \frac{d_{im}^{-2\alpha}}{\sigma^{2}} \mathbf{H}_{im} \mathbf{V}_{m} \mathbf{V}_{m}^{H} \mathbf{H}_{im}^{H} + \frac{d_{if}^{-2\alpha}}{\sigma^{2}} \mathbf{H}_{if} \mathbf{V}_{if} \mathbf{V}_{if}^{H} \mathbf{H}_{if}^{H} \right),$$
(8)

$$0 \prec \mathbf{I}_{R} + d_{im}^{\prime - 2\alpha} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}} \mathbf{A} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}} \preceq \mathbf{I}_{R} + d_{im}^{-2\alpha} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}} \mathbf{A} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}}, \tag{9}$$

$$0 \prec \mathbf{I}_R + d_{im}^{-2\alpha} \mathbf{A}^{\frac{1}{2}} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{-1} \mathbf{A}^{\frac{1}{2}} \preceq \mathbf{I}_R + d_{im}^{-2\alpha} \mathbf{A}^{\frac{1}{2}} \left(d_{if}^{\prime -2\alpha} \mathbf{B} + \mathbf{C} \right)^{-1} \mathbf{A}^{\frac{1}{2}}. \tag{10}$$

$$\begin{split} & \text{FBS,} \ \max_{\mathbf{V} \in \mathcal{A}_{\text{fuc}}} \left\{ \text{Trace} \left(\mathbf{V}^H \mathbf{V} \right) \right\} = \max_{\mathbf{V}_f \in \mathcal{A}_{\text{fc}}} \left\{ \text{Trace} \left(\mathbf{V}_{if} \mathbf{V}_{if}^H \right) + \right. \\ & \left. \text{Trace} \left(\mathbf{V}_{jf} \mathbf{V}_{jf}^H \right) \right\} \ \text{and analogously for MBS.} \end{split}$$

Now one possesses all the ingredients necessary to define the non-cooperative games, G_1 and G_2 . The uncoordinated game is give by the tuple $G_1 \triangleq \left\langle \mathcal{N}, \mathcal{A}_{\text{uc}}, \left\{ R_{\text{uc}}^m, R_{\text{uc}}^f \right\} \right\rangle$. The game when the two systems are in coordination is $G_2 \triangleq \left\langle \mathcal{N}, \mathcal{A}_c, \left\{ R_c^m, R_c^f \right\} \right\rangle$. Let us set aside the above defined two games for a moment,

we come back to them shortly. To analyze the coordinated system one must utilize coalitional games from the cooperative game theory. The most widely used solution concept in coalitional games is the *core*. In order for the two BSs to coordinate the core of the coalition game must be nonempty. A nonempty core implies that the grand coalition, which includes all the players, has a value, which is divisible among the players so that no other partition of subsets of players can give a better value to any of the players. The analysis of the core requires that the cooperative game has TU, which means that the sum utility of the coalition (the two cells in this case) renders itself to be shared between the members. But one observes, from the system model, that the sum rate of the coordinated system is not arbitrarily transferable between the two players. Therefore we follow a usual trick employed in such situations, introduce a monitory transfer i.e., payment, between the macro and femto systems. It is imperative to understand that such a monitory transfer is not merely a tool to make the problem amenable to coalitional game analysis, but also has an important engineering and economic aspect: coordination between the systems require sharing power with external users and communication of symbol information and channel state information (CSI) between the BSs. Such transactions have to be compensated in any practical system in order to provide an incentive to take part in CoMP. After introducing the payment c, the utility of MBS, U_c^m , and FBS, $U_{\rm c}^f$, is given by (11). The payment is of units of rate, which can be interpreted in monitory terms as applicable.

$$U_{\rm c}^m \triangleq R_{\rm c}^m - c, \qquad U_{\rm c}^f \triangleq R_{\rm c}^f + c.$$
 (11)

A coalitional game in characteristic form requires a set of players and a value function [18]. In this paper the set of players is \mathcal{N} , which has three nonempty subsets.

To define the value function we revisit the games G_1 and G_2 . There are multiple definitions of equilibria for non-cooperative games. This research is interested in CE, which is

a generalization of NE [18].

Definition 1. CE of the game G_1 is a probability distribution $\tilde{p}_{uc}(\cdot)$ on the joint action space \mathcal{A}_{uc} such that $\forall \mathbf{V} \in \mathcal{A}_{uc}, \forall \mathbf{V}'_m \in \mathcal{A}_{muc}$, and $\forall \mathbf{V}'_f \in \mathcal{A}_{fuc}$

$$\sum_{\mathbf{V}:\mathbf{V}_{f}\in\mathcal{A}_{fuc}}\tilde{p}_{uc}\left(\mathbf{V}\right)R_{uc}^{m}\left(\mathbf{V}\right)\geq\sum_{\mathbf{V}:\mathbf{V}_{f}\in\mathcal{A}_{fuc}}\tilde{p}_{uc}\left(\mathbf{V}\right)R_{uc}^{m}\left(\mathbf{V}_{m}^{\prime},\mathbf{V}_{f}\right),$$
(12)

$$\sum_{\mathbf{V}:\mathbf{V}_{m}\in\mathcal{A}_{muc}}\tilde{p}_{uc}\left(\mathbf{V}\right)R_{uc}^{f}\left(\mathbf{V}\right)\geq\sum_{\mathbf{V}:\mathbf{V}_{m}\in\mathcal{A}_{muc}}\tilde{p}_{uc}\left(\mathbf{V}\right)R_{uc}^{f}\left(\mathbf{V}_{f}^{\prime},\mathbf{V}_{m}\right).$$
(13)

Similarly we define the CE of the game G_2 , the probability distribution $\tilde{p}_c(\cdot)$ on the action space \mathcal{A}_c , which satisfies \forall $\mathbf{V} \in \mathcal{A}_c$, \forall $\mathbf{V}'_m \in \mathcal{A}_{mc}$, and \forall $\mathbf{V}'_f \in \mathcal{A}_{fc}$

$$\sum_{\mathbf{V}:\mathbf{V}_{f}\in\mathcal{A}_{fc}}\tilde{p}_{c}\left(\mathbf{V}\right)R_{c}^{m}\left(\mathbf{V}\right)\geq\sum_{\mathbf{V}:\mathbf{V}_{f}\in\mathcal{A}_{fc}}\tilde{p}_{c}\left(\mathbf{V}\right)R_{c}^{m}\left(\mathbf{V}_{m}^{\prime},\mathbf{V}_{f}\right),$$
(14)

$$\sum_{\mathbf{V}:\mathbf{V}_{m}\in\mathcal{A}_{mc}}\tilde{p}_{c}\left(\mathbf{V}\right)R_{c}^{f}\left(\mathbf{V}\right)\geq\sum_{\mathbf{V}:\mathbf{V}_{m}\in\mathcal{A}_{mc}}\tilde{p}_{c}\left(\mathbf{V}\right)R_{c}^{f}\left(\mathbf{V}_{f}^{\prime},\mathbf{V}_{m}\right).$$
(15)

While a finite game is guaranteed to have at least one CE, in most cases there are an infinite set of CE [18]. Out of this set of CE this paper choose the equilibrium, which maximizes the expected sum rate. The *maximum expected sum rate correlated equilibrium* (MESR-CE) of game G₁ is the probability distribution obtained through solving the following linear system;

maximize
$$\sum_{\mathbf{V} \in \mathcal{A}_{uc}} p_{uc} \left(\mathbf{V} \right) \left(R_{uc}^{m} \left(\mathbf{V} \right) + R_{uc}^{f} \left(\mathbf{V} \right) \right),$$
subject to (12), (13), (16)
$$\sum_{\mathbf{V} \in \mathcal{A}_{uc}} p_{uc} \left(\mathbf{V} \right) = 1,$$

$$p_{uc} \left(\mathbf{V} \right) > 0, \forall \mathbf{V} \in \mathcal{A}_{uc},$$

where $p_{\mathrm{uc}}\left(\mathbf{V}\right)$ is the probability of joint action $\mathbf{V} \in \mathcal{A}_{\mathrm{uc}}$ and $\mathbf{p}_{\mathrm{uc}} \triangleq \left(p_{\mathrm{uc}}\left(\mathbf{V}\right)\right)_{\mathbf{V} \in \mathcal{A}_{\mathrm{uc}}}$. The expected rate of each player at CE of \mathbf{G}_{1} is

$$R_{\text{uc,cor}}^{m} \triangleq \sum_{\mathbf{V} \in \mathcal{A}_{\text{uc}}} \tilde{p}_{\text{uc}}(\mathbf{V}) R_{\text{uc}}^{m}(\mathbf{V}),$$
 (17)

$$R_{\text{uc,cor}}^{f} \triangleq \sum_{\mathbf{V} \in \mathcal{A}_{\text{uc}}} \tilde{p}_{\text{uc}}(\mathbf{V}) R_{\text{uc}}^{f}(\mathbf{V}),$$
 (18)

where $\tilde{p}_{uc}\left(\cdot\right)$ is the MESR-CE solution of the linear program (16).

Analogously one can obtain the MESR-CE of game G_2 as the solution to the following linear system;

$$R_{c, \text{ cor}} \triangleq \text{maximize } \sum_{\mathbf{V} \in \mathcal{A}_{c}} p_{c}\left(\mathbf{V}\right) \left(R_{c}^{m}\left(\mathbf{V}\right) + R_{c}^{f}\left(\mathbf{V}\right)\right),$$

$$\text{subject to } (14), (15),$$

$$\sum_{\mathbf{V} \in \mathcal{A}_{c}} p_{c}\left(\mathbf{V}\right) = 1,$$

$$p_{c}\left(\mathbf{V}\right) \geq 0, \forall \mathbf{V} \in \mathcal{A}_{c},$$

$$(19)$$

where $\mathbf{p}_{c} \triangleq (p_{c}(\mathbf{V}))_{\mathbf{V} \in \mathcal{A}_{c}}$. Let $\tilde{p}_{c}(\cdot)$ be the MESR-CE distribution of game G_{2} . The expected rate of each player at CE of G_{2} is

$$R_{\text{c,cor}}^{m} \triangleq \sum_{\mathbf{V} \in A} \tilde{p}_{\text{c}}(\mathbf{V}) R_{\text{c}}^{m}(\mathbf{V}),$$
 (20)

$$R_{\text{c,cor}}^{f} \triangleq \sum_{\mathbf{V} \in A_{c}} \tilde{p}_{c}(\mathbf{V}) R_{c}^{f}(\mathbf{V}).$$
 (21)

Now the value function $v(\cdot)$ of the coalition game is as follows;

$$v\left(\mathcal{S}\right) \triangleq \begin{cases} R_{\text{uc,cor}}^{m} & \mathcal{S} = \{\text{MBS}\}, \\ R_{\text{uc, cor}}^{f} & \mathcal{S} = \{\text{FBS}\}, \\ R_{\text{c, cor}} & \mathcal{S} = \mathcal{N}. \end{cases}$$
(22)

At this point let us recap the development of this section so far: in the above definition of the value function v(S), $R_{\text{uc,cor}}^m$ in (17) (resp. $R_{\text{uc,cor}}^f$ in (18)) is the expected rate obtained by the macro system (resp. femto system) while playing the MESR-CE in G_1 . On the other hand the value of the grand coalition, $R_{c, \text{cor}}$ in (19), is the MESR of the two BSs while playing the MESR-CE in G_2 . Then the coalitional game in characteristic form is defined by the tuple $G_3 \triangleq \langle \mathcal{N}, v(\cdot) \rangle$.

Definition 2. The core is the set of allocations such that no subgroup within the coalition can do better by leaving to form other coalitions [18].

In our game the set of allocations are U_c^m and U_c^f in (11), such that $U_c^m + U_c^f = R_{c, cor}$.

A. Region of Coordination

As MUE moves closer to FBS, signal level drops and interference level rises, hence one expects cooperation with FBS to be preferable to MBS. Since the sum rate can be apportioned between the two systems through the monitory transfer, one expects to find a c, at which the core is non empty. The region where the core is non empty is called, the *region of coordination* or identically *CoMP region*. In a single input single output (SISO) system a signal to interference plus noise ratio (SINR) based argument easily demonstrates the existence of a core but the argument for MIMO requires a bit more analysis.

Proposition 1. $v(\mathcal{N}) \geq v(\text{MBS}) + v(\text{FBS})$ if and only if there exists a payment c such that $U_c^m \geq R_{\text{uc,cor}}^m$ and $U_c^f \geq R_{\text{uc,cor}}^f$.

Proof: We provide a constructive proof. By (11) and while G2 system is in CE the utilities are $U_{\rm c}^m=R_{\rm c,cor}^m-c$ and $U_{\rm c}^f=R_{\rm c,cor}^m+c$. Let us consider the LHS of iff, which is equivalent to $R_{\rm c,cor}\geq R_{\rm uc,cor}^m+R_{\rm uc,cor}^f$, which implies either $R_{\rm c,cor}^m\geq R_{\rm uc,cor}^m$ or $R_{\rm c,cor}^f\geq R_{\rm uc,cor}^f$ or both. Let us take the case where $R_{\rm c,cor}^m\geq R_{\rm uc,cor}^m$ and $R_{\rm c,cor}^f\leq R_{\rm uc,cor}^f$, all other cases can be similarly proven. Then there exists a positive constant c such that $\left(R_{\rm c,cor}^m-c\right)=U_{\rm c}^m\geq R_{\rm uc,cor}^m$ and $\left(R_{\rm c,cor}^f+c\right)=U_{\rm c}^f\geq R_{\rm uc,cor}^f$ since $\left(R_{\rm c,cor}^m-c\right)+\left(R_{\rm c,cor}^f+c\right)\geq R_{\rm uc,cor}^m+R_{\rm uc,cor}^f$. Converse (RHS \Longrightarrow LHS) is proven simply by summing the two inequalities $U_c^m\geq R_{\rm uc,cor}^m$ and $U_c^f\geq R_{\rm uc,cor}^f$.

Proposition 1 claims that $R_{\rm c, \, cor} \geq R_{\rm uc, cor}^m + R_{\rm uc, cor}^m$ is a necessary and sufficient condition for the core of G_3 to be nonempty.

In order to establish the final result we need the following propositions.

Proposition 2. R_{uc}^m is monotonically decreasing in d_{im} and monotonically increasing in d_{if} .

Proof: The proof depends on Loewner ordering of positive semidefinite (PSD) matrices ([19] 7.7). For two PSD matrices \mathbf{A} , \mathbf{B} , we write $\mathbf{A} \succeq \mathbf{B}$ (resp. $\mathbf{A} \succ \mathbf{B}$) if $\mathbf{A} - \mathbf{B} \succeq 0$ is PSD (resp. $\mathbf{A} - \mathbf{B} \succ 0$ positive definite (PD)). Let $\mathbf{A} \triangleq \mathbf{H}_{im} \mathbf{V}_m \mathbf{V}_m^H \mathbf{H}_{im}^H$, $\mathbf{B} \triangleq \mathbf{H}_{if} \mathbf{V}_f \mathbf{V}_f^H \mathbf{H}_{if}^H$ and $\mathbf{C} \triangleq \sigma^2 \mathbf{I}_R$. \mathbf{A} , \mathbf{B} are PSD and \mathbf{C} is PD, also $d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C}$ is PD. Then the capacity of maro-system (3) can be reformulated as

$$R_{\mathrm{uc}}^{m} = \log \det \left(\mathbf{I}_{R} + d_{im}^{-2\alpha} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{-\frac{1}{2}} \mathbf{A} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}} \right).$$

Let $0 < d_{im} < d'_{im}$, so (9) (see page above) holds, therefore the determinant of (24) is no less than the determinant of (23), which implies that the determinant is monotonically decreasing in d_{im} .

$$\mathbf{I}_R + d_{im}^{\prime - 2\alpha} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}} \mathbf{A} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}}. \quad (23)$$

$$\mathbf{I}_R + d_{im}^{-2\alpha} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}} \mathbf{A} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{\frac{-1}{2}}. \quad (24)$$

Next we reformulate (3),

$$R_{\mathrm{uc}}^{m} = \log \det \left(\mathbf{I}_{R} + d_{im}^{-2\alpha} \mathbf{A}^{\frac{1}{2}} \left(d_{if}^{-2\alpha} \mathbf{B} + \mathbf{C} \right)^{-1} \mathbf{A}^{\frac{1}{2}} \right),$$

and let $0 < d_{if} < d'_{if}$. Then (10) holds and by a similar argument to above we have that the determinant is increasing in d_{if} . This completes the proof.

Now we consider the properties of R_c^m .

Proposition 3. $R_c^m(\cdot)$ is monotonically increasing in $d_{if}^{-2\alpha}$ and $d_{im}^{-2\alpha}$ and is bounded from below by

$$\gamma^{m}\left(d_{if}, \mathbf{V}_{if}\right) \triangleq \log \det \left(\mathbf{I}_{R} + \frac{1}{\sigma^{2}} d_{if}^{-\alpha} \mathbf{H}_{if} \mathbf{V}_{if} \mathbf{V}_{if}^{H} d_{if}^{-\alpha} \mathbf{H}_{if}^{H}\right).$$

Proof: The proof utilizes Weyl's inequality for Hermitian matrices [20]. Let us first consider $d_{if}^{-2\alpha}$. Suppose \mathbf{X} , \mathbf{Y} are two Hermitian matrices of size $n \times n$, then the Weyl's inequality states that

$$\lambda_i(\mathbf{X}) + \lambda_n(\mathbf{Y}) \le \lambda_i(\mathbf{X} + \mathbf{Y}) \le \lambda_i(\mathbf{X}) + \lambda_1(\mathbf{Y}), \quad i = 1, \dots, n,$$

where $\lambda_i(\mathbf{X})$ is the i^{th} largest eigenvalue of \mathbf{X} , i.e., largest eigenvalue is $\lambda_1(\mathbf{X})$ and smallest is $\lambda_n(\mathbf{X})$. If \mathbf{X} , \mathbf{Y} are positive semidefinite (PSD) note that the inequality reduces to

$$0 \le \lambda_i(\mathbf{X}) \le \lambda_i(\mathbf{X} + \mathbf{Y}) \le \lambda_i(\mathbf{X}) + \lambda_1(\mathbf{Y}), \quad i = 1, \dots, n.$$

Let $\mathbf{X} = \mathbf{I}_R + \frac{d_{im}^{-2\alpha}}{\sigma^2} \mathbf{H}_{im} \mathbf{V}_m \mathbf{V}_m^H \mathbf{H}_{im}^H + \frac{d_{if}^{-2\alpha}}{\sigma^2} \mathbf{H}_{if} \mathbf{V}_{if} \mathbf{V}_{if}^H \mathbf{H}_{if}^H$ and $\mathbf{Y} = \frac{\delta}{\sigma^2} \mathbf{H}_{if} \mathbf{V}_{if} \mathbf{V}_{if}^H \mathbf{H}_{if}^H$ where $\delta \in \mathbb{R}_+$. Then monotonicity in $d_{if}^{-2\alpha}$ follows from

$$0 < \det(\mathbf{X}) = \prod_{i} \lambda_i(\mathbf{X}) \le \det(\mathbf{X} + \mathbf{Y}) = \prod_{i} \lambda_i(\mathbf{X} + \mathbf{Y}).$$

Similarly the proof extends to $d_{im}^{-2\alpha}$. Then setting $d_{im}^{-2\alpha}=0$ the lower bound is achieved.

Theorem 1. For some d > 0 under Assumption 1, $\exists d_{th}$ such that for $d_{if} \leq d_{th}$, the region of cooperation is nonempty¹.

Proof: Let $\mathbf{V} = (\mathbf{V}_{if}, \mathbf{V}_{jf}) \in \mathcal{A}_{c}, \ \mathbf{V}' \in \mathcal{A}_{uc}$ be any two actions from the respective spaces and let the location of the FUE be fixed relative to the FBS at $(\bar{d}_{jf}, \bar{\theta}_{j})$. Then $R_{c}^{f}(\mathbf{V})$ and $R_{uc}^{f}(\mathbf{V}')$ are constants irrespective of location of MUE. Now consider that MUE moves along a trajectory with decreasing d_{if} and increasing d_{im} . By Proposition 2, $R_{uc}^{m}(\mathbf{V}')$ is decreasing. As $d_{if} \to 0$, by Proposition 3, $R_{c}^{m}(d_{if}, \cdot) \to \infty$. Therefore there must exist $d_{if} \leq d_{th}$, such that $R_{c}^{m}(d_{if}, \cdot) + R_{c}^{f}(\mathbf{V}) \geq R_{uc}^{m}(\mathbf{V}') + R_{uc}^{f}(\mathbf{V}')$. Since the action choice was arbitrary $\exists d_{th}$ such that, $\min_{\mathbf{V} \in \mathcal{A}_{c}} \left(R_{c}^{m}(\mathbf{V}) + R_{c}^{f}(\mathbf{V}) \right) \geq \max_{\mathbf{V} \in \mathcal{A}_{uc}} \left(R_{uc}^{m}(\mathbf{V}) + R_{uc}^{f}(\mathbf{V}) \right)$.

 $\max_{\mathbf{V} \in \mathcal{A}_{\mathrm{uc}}} \left(R_{\mathrm{uc}}^{m}\left(\mathbf{V}\right) + R_{\mathrm{uc}}^{f}\left(\mathbf{V}\right) \right).$ Therefore \forall probability distributions \tilde{p}_{uc} and \tilde{p}_{c} , we have $\sum_{\mathbf{V} \in \mathcal{A}_{\mathrm{c}}} \tilde{p}_{\mathrm{c}}\left(\mathbf{V}\right) \left(R_{\mathrm{c}}^{m}\left(\mathbf{V}\right) + R_{\mathrm{c}}^{f}\left(\mathbf{V}\right) \right) \geq \sum_{\mathbf{V} \in \mathcal{A}_{\mathrm{uc}}} \tilde{p}_{\mathrm{uc}}\left(\mathbf{V}\right) \left(R_{\mathrm{uc}}^{m}\left(\mathbf{V}\right) + R_{\mathrm{uc}}^{f}\left(\mathbf{V}\right) \right).$ This completes the proof.

Theorem 1 together with Proposition 1 suggests the existence of a region around the FBS where the core is nonempty. Thus we establish the rationality of CoMP scheme JT.

IV. NUMERICAL RESULTS

The distances are measured in meters (m), we locate MBS at (0,0), FBS at (1000,0), and FUE (990,0). Unless otherwise stated, the default maximum transmit power of MBS is 5 W and of FBS is 1 W. The two BSs each has 4 antennas and each UE has 2 antennas. In the coordinated mode of transmission, by default FBS distributes the power evenly among FUE and MUE. The AWGN power is set at 10^{-4} W. In the Fig. 2 MUE moves from far negative x region towards the FBS in linear trajectories. One such trajectory is shown in the figure.

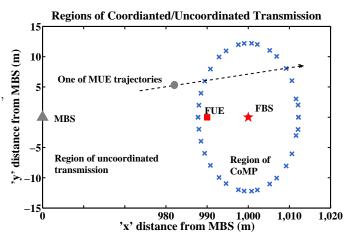

Figure 2. Region of coordination.

Difference in Coordinated and Uncoordinated MESR

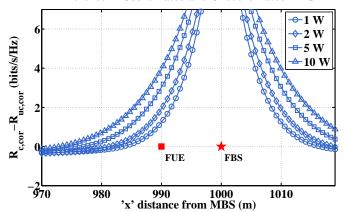

Figure 3. Dependence of CoMP region on FBS transmit power.

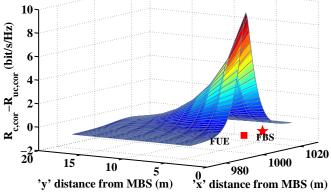

The region where coordination is preferred over uncoordinated transmission is marked. The symmetry in the region is due to the use of symmetric channel matrices on either side of the FBS.

In the rest of the figures the trajectory of the MUE is on the x axis (y coordinate is 0). Fig. 3 denotes the expansion of the CoMP region as the FBS transmit power increases. One also sees from the figure that $R_{\rm c,\ cor}$ far exceeds $R_{\rm uc,\ cor}$ as MUE approaches FBS. Fig. 4 shows, on the plan of (x,y), the excess value of the coalition over the value of uncoordinated system.

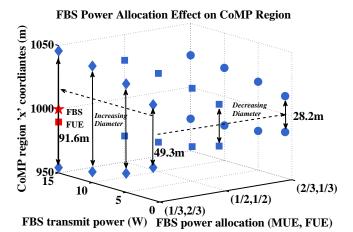

Fig. 5 demonstrates that as the amount of power allocated to MUE increases the *diameter* of the coordination region shrinks. The term diameter is loosely used to mean the distance between the entry point and exit point of CoMP region when the MUE's trajectory is on x axis (y coordinate 0). Consider the two MUE power ratios of a and c such that c > a. Then the explanation for the phenomenon seen in Fig. 5 is that while operating at ratio c if the FBS switches to CoMP at the coordination boundary of the ratio a then the reduction of FUE rate is higher than the increase in MUE rate as still MUE is further away from FBS than FUE, thus discouraging

¹Distances are absolute values. See Fig. 1, Section II for distance notation.

Excess MESR of the Coalition on the Plane

Geometric distribution of value of coalition, $v(\mathcal{N})$, over uncoordinated system.

The variation of the diameter of the CoMP region with FBS power allocation ratio (a, b). Here (a, b) implies a and b fractions of power are assigned to MUE and FUE respectively.

the formation of the coalition till MUE moves closer to FBS.

V. CONCLUSION

This paper considered the downlink of a HetNet consisting of a maro- and a femtocell. Two non-cooperative games were devised. The first game, G_1 , had the two cells in competition. In the second game, G_2 , the cells were in coordination (CoMP). In each game the cells operated in the respective maximum expected sum rate-correlated equilibria (MESR-CE). Then a third game, G3, was defined which is a coalition game in characteristic form with transferable utility. In G₃ the value of the coalition was allowed to be arbitrarily transferred between the two cells via a payment. The solution mechanism of core, was used in the coalitional games G3 with value function based on MESR-CE of G₁ and G₂. Then the paper proved the existence of a region where the core of the game G₃ is nonempty, which demonstrates that CoMP is a rational decision in some region and the CoMP decision making is reduced to identifying a threshold separation d_{th} . CoMP decision mechanisms for more complex channel models with more than two cells can be considered in future work.
