The work described in this presentation was funded by the Office of Electricity Delivery and Energy Reliability, Smart Grids Program, and also by the Energy Efficiency and Renewable Energy's Technology Commercialization Fund, both of the U.S.DOE under Contract No. DE-AC02-05CH11231. The authors are also very grateful to Merrill Smith for her continued support of the DER-CAM development.

Outline

- Our contribution to microgrids / global concept
- What is DER-CAM?
- Web-Opt: connecting clients to DER-CAM
- Example applications
 - AEP test-bed: Columbus, OH
 - Santa Rita Jail: Dublin, CA
 - University of New Mexico: Albuquerque, NM
- Further/Future Work

Our Contribution to Microgrids

Global Model Concept for Microgrids

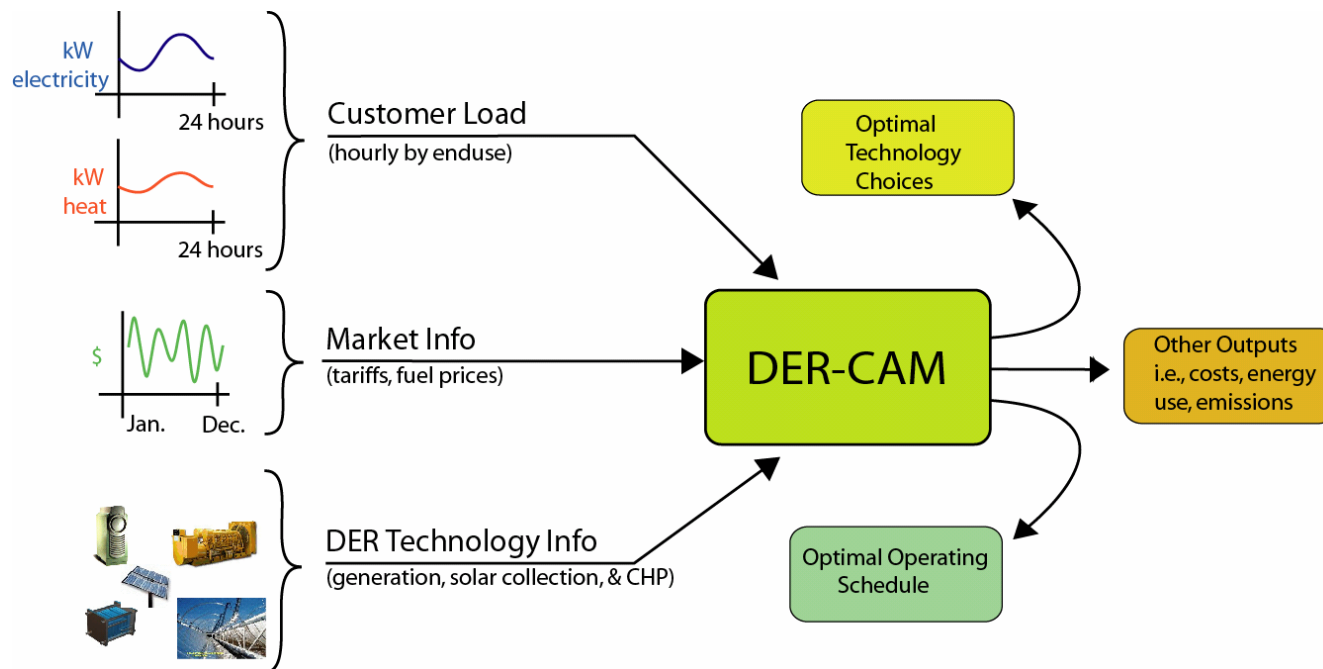

What is DER-CAM

Distributed Energy Resources Customer Adoption Model (DER-CAM)

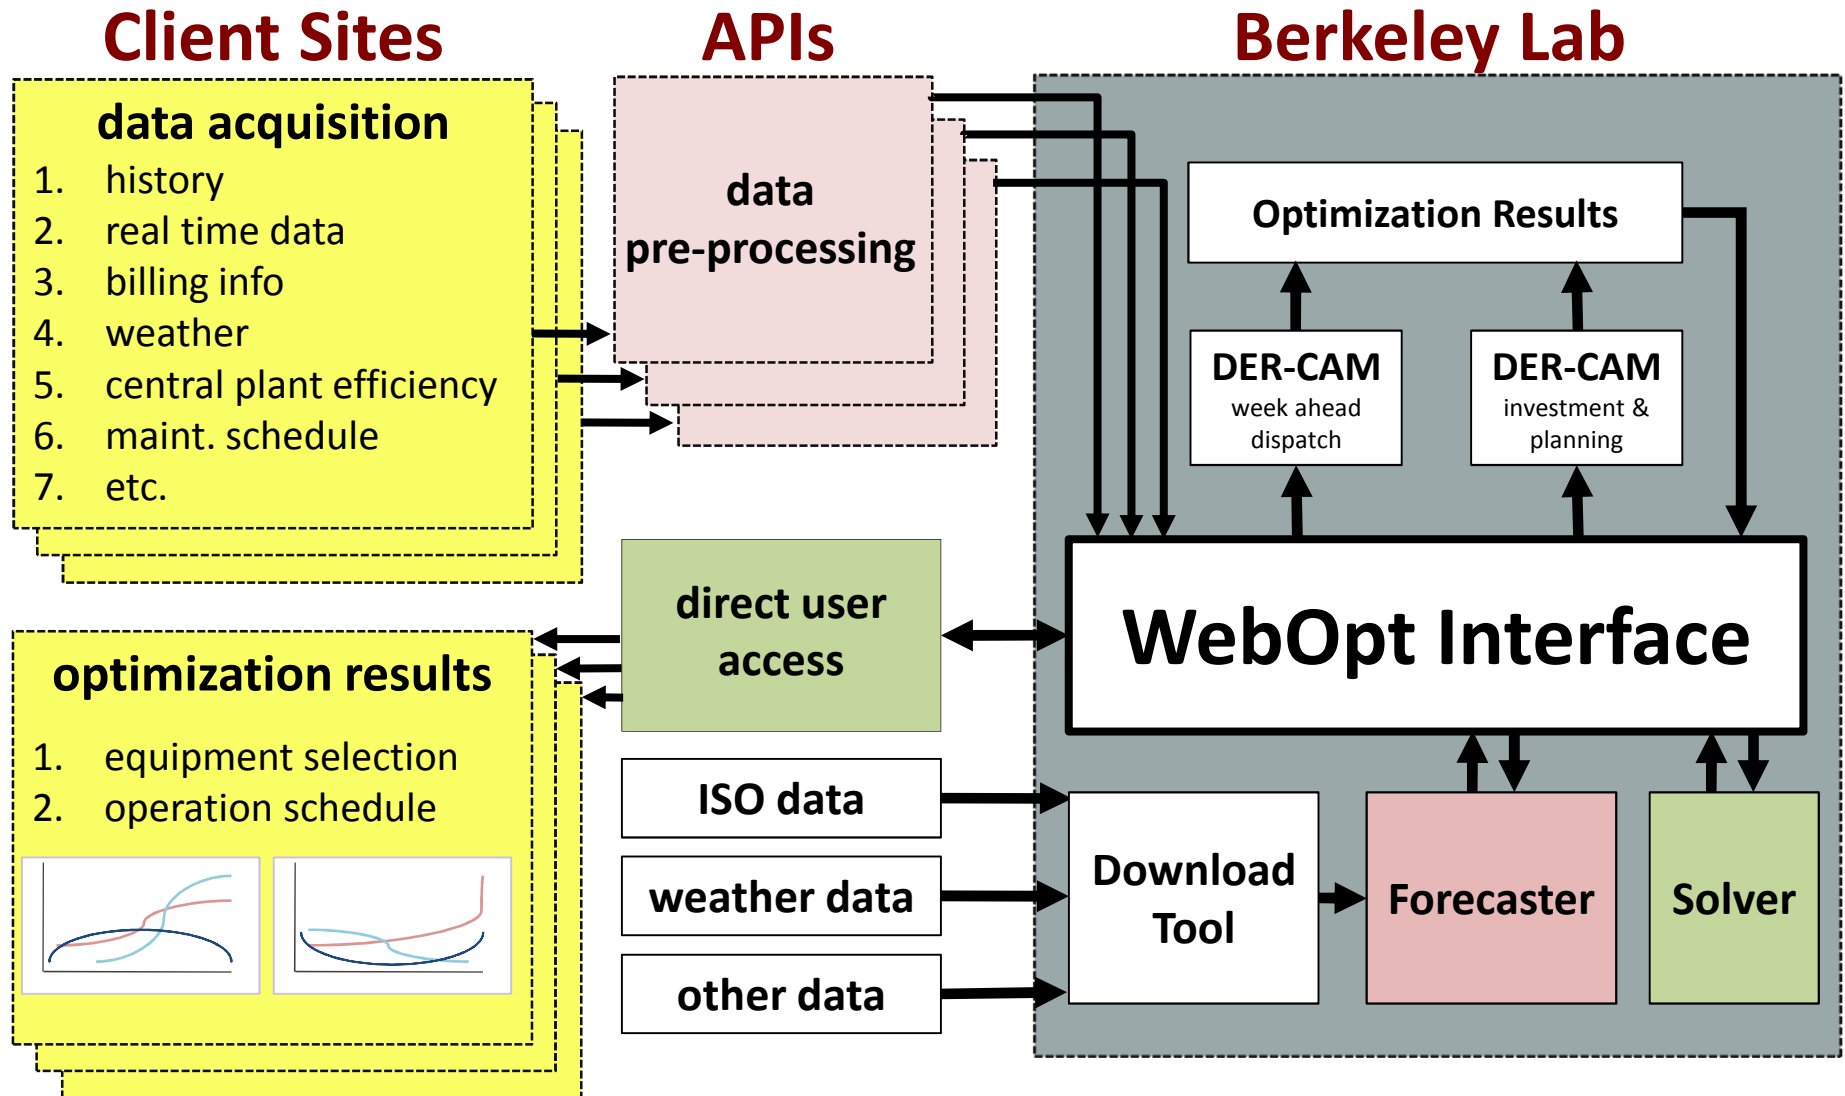

- is a deterministic Mixed Integer Linear Program (MILP), written in the General Algebraic Modeling System (GAMS®)
- minimizes annual energy costs, CO₂ emissions, or multiple objectives of providing services on the building level (typically buildings with 250-2000 kW peak)
- produces technology neutral pure optimal results with highly variable runtime
- has been designed for more than 10 years by Berkeley Lab and collaborations in the US, Germany, Spain, Belgium, Japan, and Australia → exchange visitors
- first commercialization (*web clients*) and real-time optimization steps
- 270 DER-CAM *web clients* to date

DER-CAM Versions

- **Investment & Planning:** determines optimal equipment combination and operation based on *historic* load data, weather, and tariffs
- **Operations:** determines optimal week-ahead scheduling for installed equipment and *forecasted* loads and weather, tariffs

Access to DER-CAM via WebOpt

Investment & Planning WebOpt: Web-Interface

Overview/Optimization Settings Load Profiles Utility Tariffs Technologies Demand Response Solar Radiation Marginal CO2 Macrogrid Results

Optimization Settings

☒ Investment in DER

☒ NG powered DER and CHP ☐ Absorption refrigeration

☒ Electric storage ☒ PV

☒ Heat storage ☒ Solar thermal

☒ Absorption chiller ☐ Demand response

☐ Do-nothing (no investments, all energy will be bought from the utility)

☐ Show pay-back period in result file

☒ Show advanced input options

Advanced Input Options

Interest rate for investments: 6 %

Max. available space for PV system at site: 3000 m2

Max. allowed annual energy costs (including annualized capital costs): 99 m\$

Max. pay-back period for investments: 12 years

Optimization Objective

☒ Cost minimization

☐ CO2 minimization

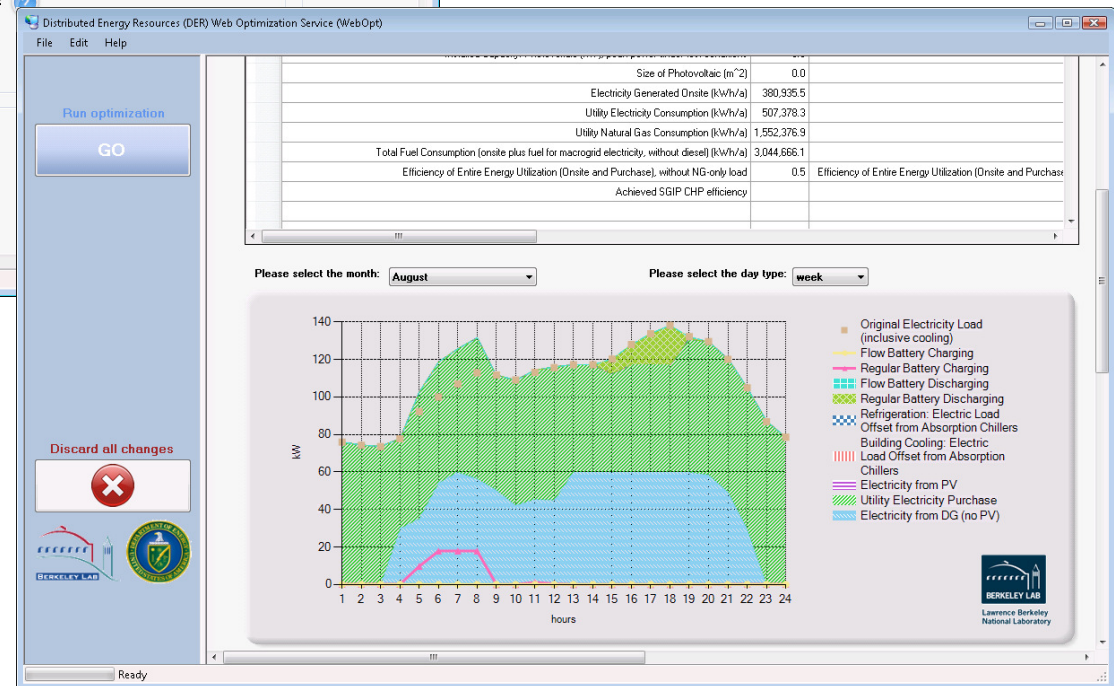

Please note that with a CO2 minimization strategy the maximum possible PV area at the site and the maximum annual energy bill are very frequently the binding constraints in the optimization. Please check "Show advanced input options" and change the advanced input options if needed.

Discard all changes

Ready

DER-CAM Web-Service for natural gas fired CHP, PV, solar thermal, electric storage, and absorption chillers

➤ no direct EMS coupling / feedback

<http://der.lbl.gov/der-cam/how-access-der-cam>

Application 1: AEP

CERTS Microgrid *Concept*

- seamless islanding and reconnection via single PCC
- peer-to-peer, autonomous coordination among micro-sources (w/o high bandwidth communications)
- plug-and-play - no custom engineering
- energy manager on arbitrary platform

CERTS Microgrid *Test Bed Demonstration at AEP*

our objectives:

- generate load profiles and optimal scheduling for testing of 3 CHP systems
 - TECOGEN PROTOTYPE 60kW CHP
 - OLYMPIAN 100kW CHP
 - TECOGEN INV 100KW CHP
- develop automated interface for schedule delivery to AEP

Application 2: Santa Rita Jail (SRJ)

objectives:

- deliver optimized week-ahead scheduling of onsite electric storage with Operations DER-CAM
- determine potential reduction in utility feeder peak demand through strategic battery dispatch

3 MW peak load facility
CERTS microgrid functionality

DER On-site:

- photovoltaic: 1.2 MW peak
- fuel cell: 1 MW molten carbonate
- electric storage: 2 MW 2MWh Li-ion

SRJ: Utility Feeder Demand

SRJ: Optimal Schedules*

Solution 1:
utility bill
minimization

Solution 2:
feeder peak
minimization
+\$3.8k demand charge
3.5% reduction

*Jail-Only Results
(note scale)

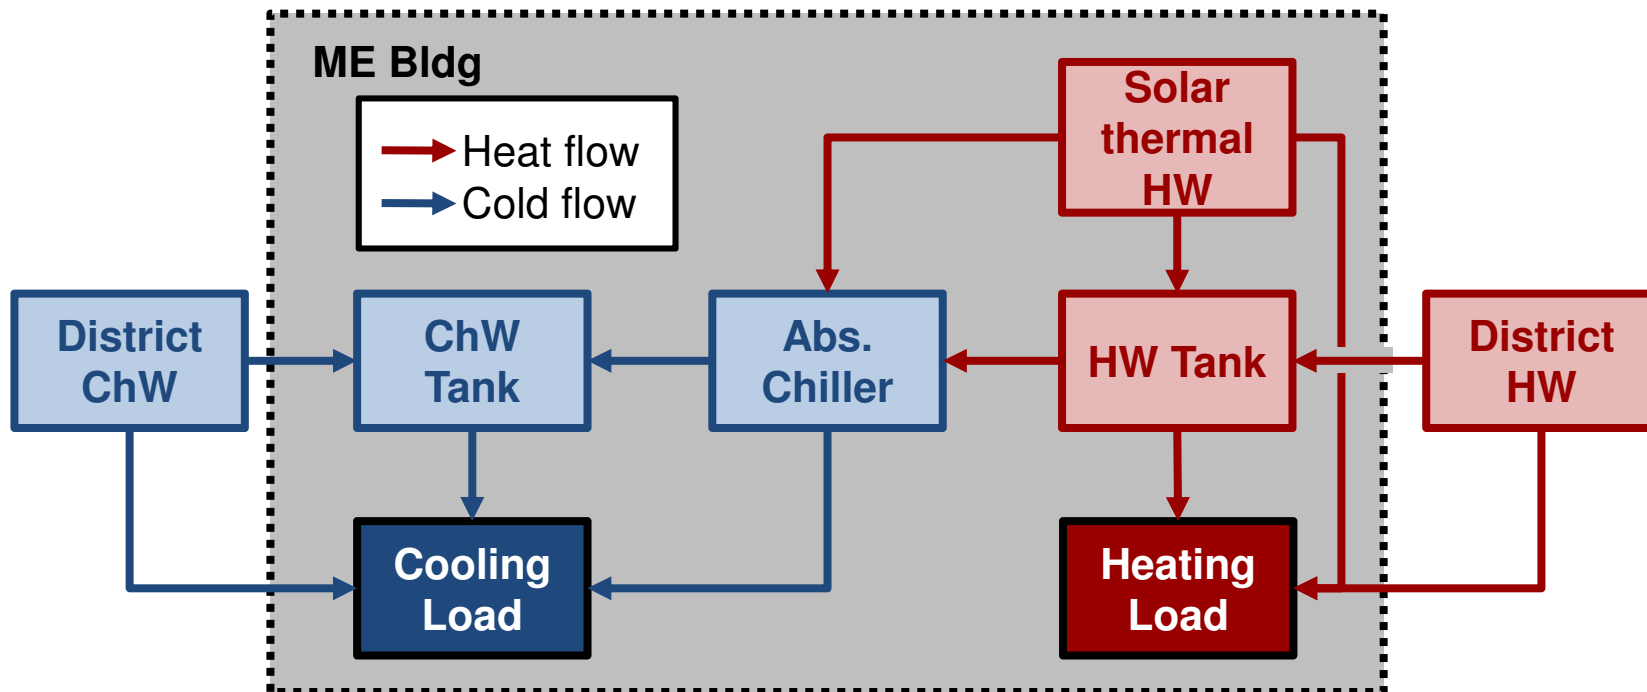

Application 3: UNM

objectives:

- generate optimized scheduling of cooling equipment
 - solar thermal collection
 - hot water storage
 - chilled water storage
 - absorption chiller
- deliver results daily via automated interface to UNM building control system (delta controller)

UNM Test Equipment/Configuration

equipment capacities:

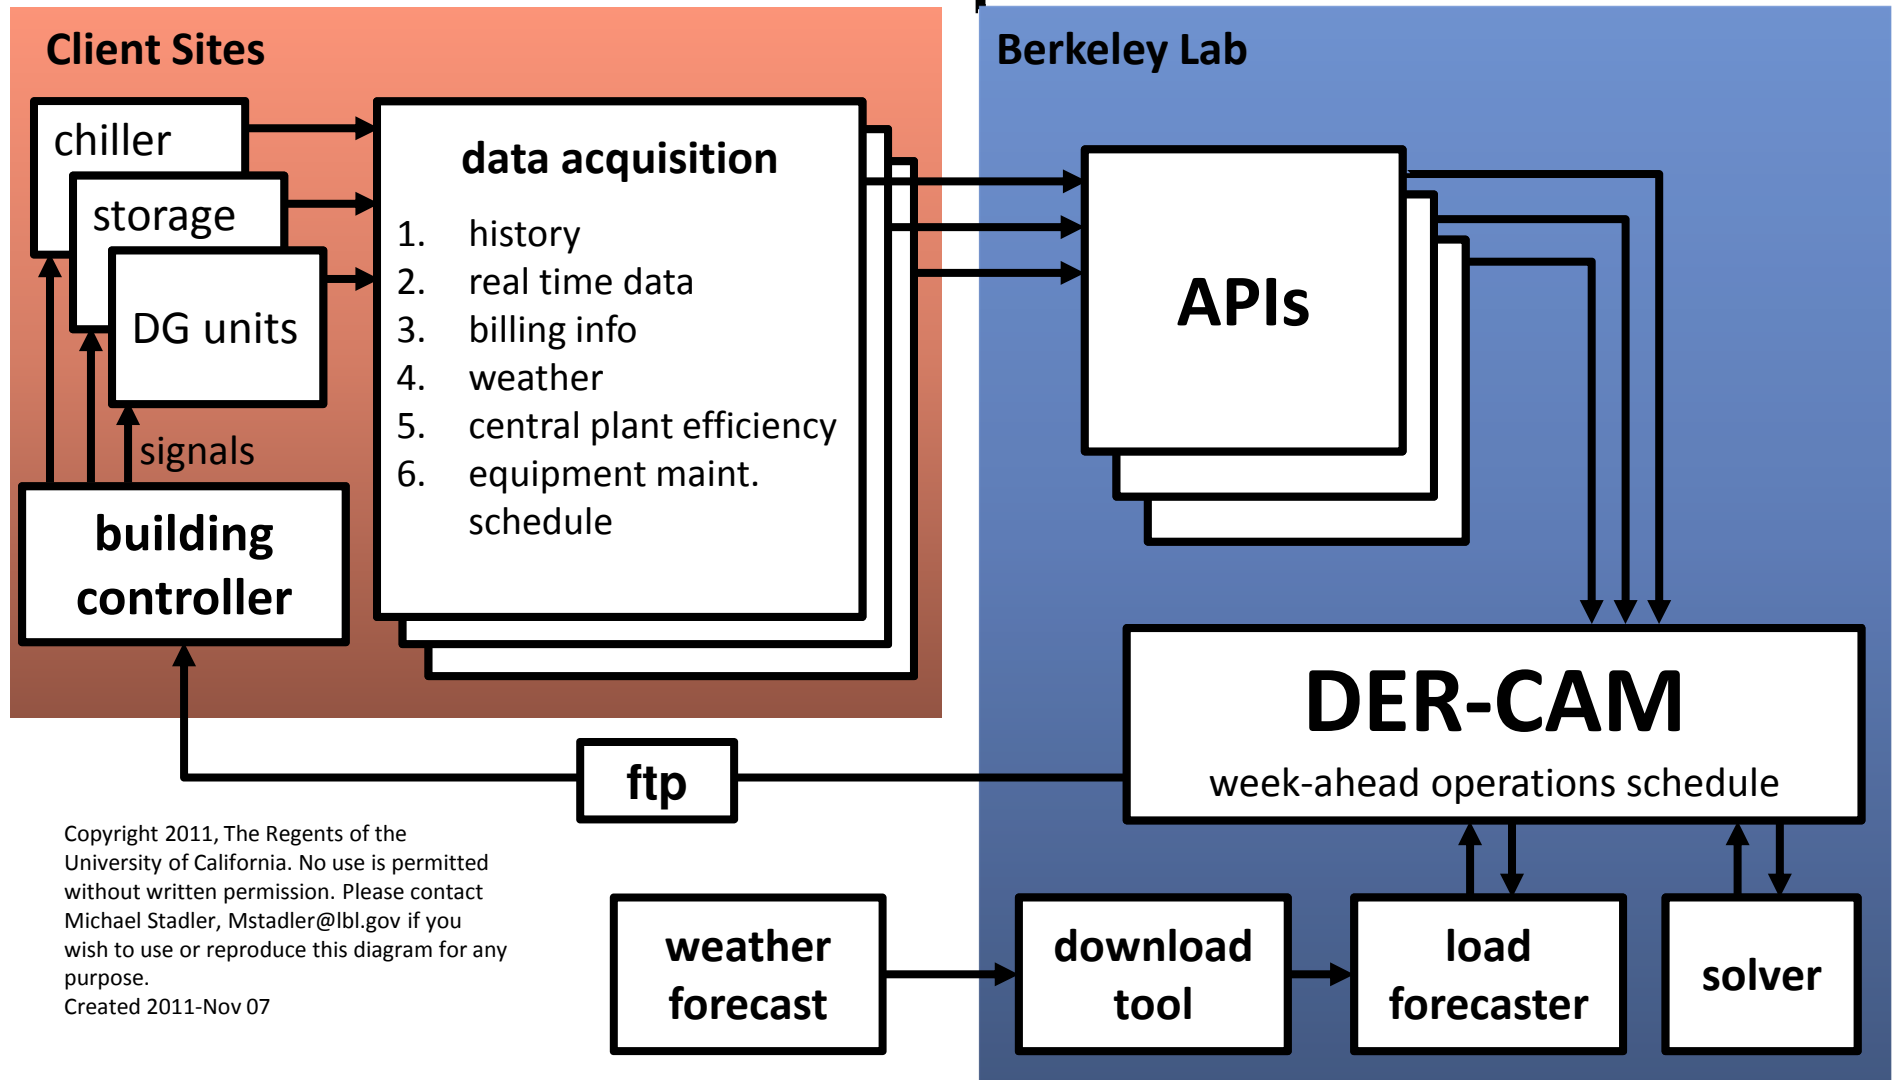

- solar thermal: 170 kW peak rating
 - absorption chiller: 70 kW
 - chilled water storage: 3800 kWh
 - hot water storage: 300 kWh (9000 gallons)
- (all values thermal)

UNM: Cooling Results

automated delivery of results through the duration of cooling season (mid October)

UNM WebOpt Structure

Created 2011-Nov 07

Further/Future Work

- sporadic fuel-cell outages complicate forecast of utility electricity demand → stochastic optimization
- microgrid multi-objective optimization framework
- plug-in electric vehicle demonstration at Los Angeles AFB
role: extend demonstration to a true microgrid, provide OpenADR instructions from CAISO AS & SCE DR markets, optimize all bidding and scheduling (esp. PEV charging & discharging), control loads while grid connected, balance generation and prioritize loads while islanded
- finish Web-Interface for operations DER-CAM
- add new technologies, e.g. wind, heat pumps
- convert linear DER-CAM to a non-linear optimization to be able to capture technical constraints more realistically, e.g. efficiency curves
- integration of building energy simulation, flexible temperature set points, demand-side control
- power flow constraints, voltage support

End

Thank you!

Questions and comments are very welcome.

Further Work/Uncertainty

- implementation of stochastic linear programming in Operations DER-CAM to model uncertainty
- possibility to explicitly account for uncertainty through user defined scenarios
- generic approach allows introducing uncertainty in multiple parameters, such as generation outages, fuel prices or weather conditions
- first application under design is the optimal battery scheduling at the SRJ under the uncertainty in fuel cell availability
- using the stochastic approach allows minimizing energy costs under any possible scenario realization

Further Work/Uncertainty, Draft Results

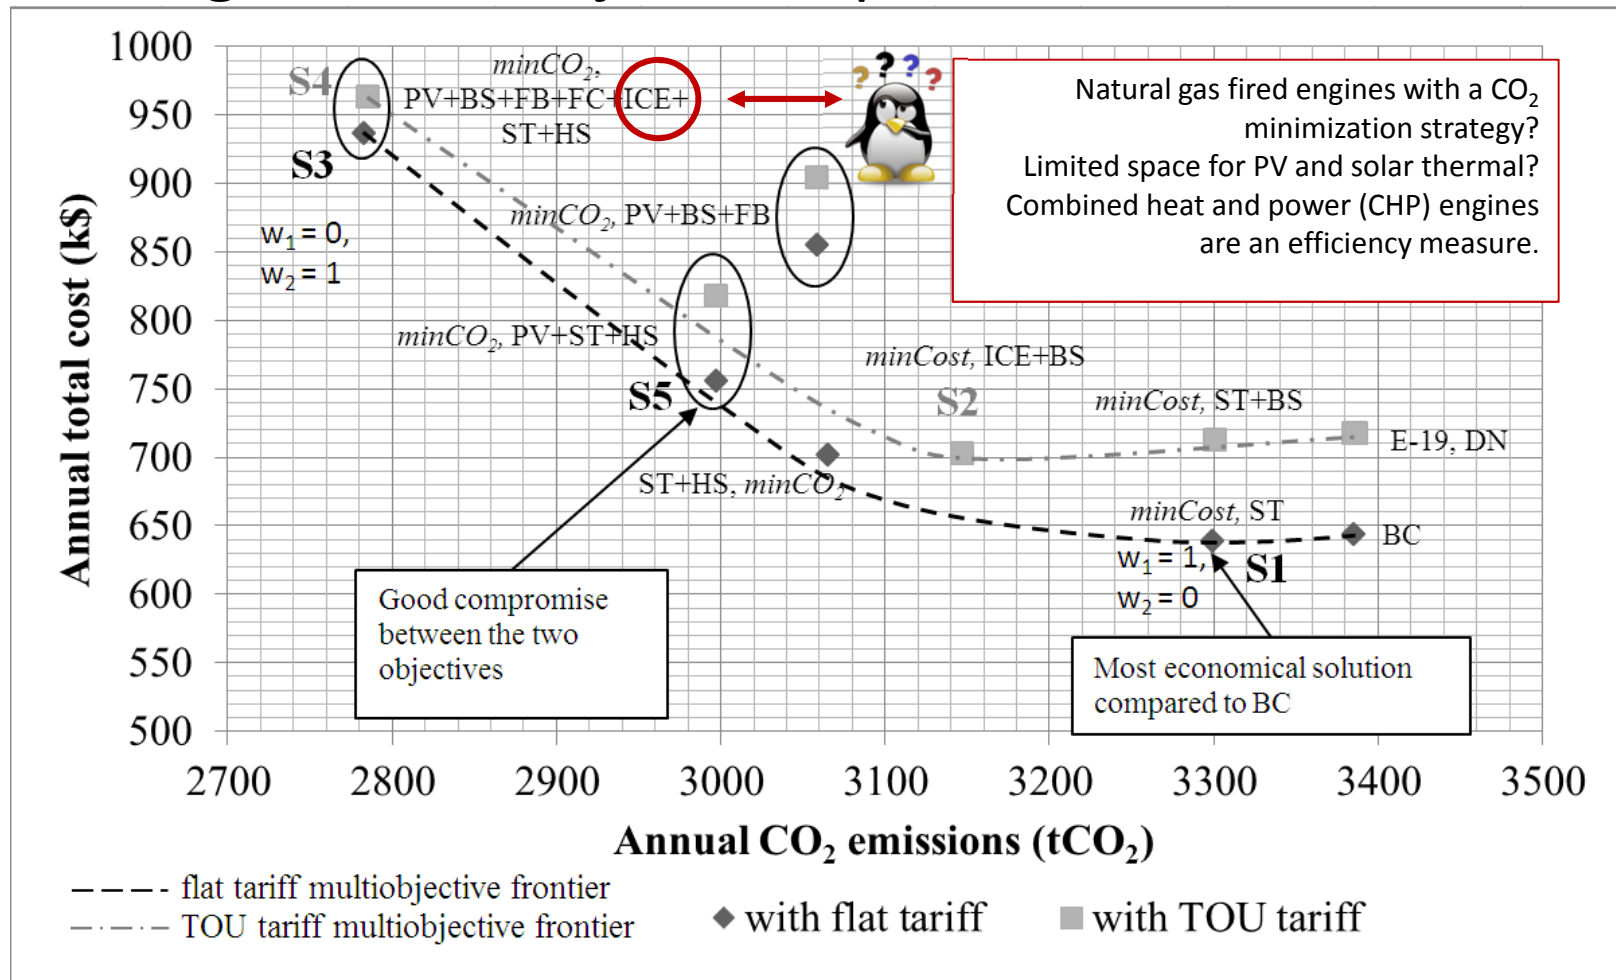

Avg. H1:H3 –
Average of optimal
battery schedules H1
to H3, obtained from
fuel cell availability
scenarios 1 to 3.

HS – Optimal battery
schedule obtained
by the stochastic
model, where all
scenarios are
considered
simultaneously.

Observed fuel cell scenario	1		2		3	
Battery schedule	Avg. H1:H3	HS	Avg. H1:H3	HS	Avg. H1:H3	HS
Total energy costs	\$ 70 296	\$ 69 126	\$ 59 017	\$ 57 560	\$ 64 213	\$ 60 431
TOU charges	\$ 26 807	\$ 26 837	\$ 21 245	\$ 21 351	\$ 23 232	\$ 21 821
Demand charges	\$ 42 705	\$ 41 567	\$ 29 596	\$ 28 160	\$ 35 661	\$ 30 968

- optimal battery schedules can be obtained assuming availability scenarios separately (deterministic approach) or simultaneously (stochastic approach)
- the stochastic approach yields lower energy costs in the realization of unexpected events and a more conservative scheduling

Microgrid multi-objective optimization framework

PV: photovoltaic, BS: conventional lead acid battery, FB: Zinc Bromine flow battery, FC: fuel cell with waste heat utilization, ICE: internal combustion engine with waste heat utilization, ST: solar thermal conventional collectors, HS: Heat storage, BC: Base case, and DN: "Do nothing" case
