# BOUNDS FOR CODES IN PRODUCTS OF SPACES, GRASSMANN AND STIEFEL MANIFOLDS 

CHRISTINE BACHOC, YAEL BEN-HAIM, AND SIMON LITSYN, SENIOR MEMBER, IEEE

#### Abstract

Upper bounds are derived for codes in Stiefel and Grassmann manifolds with given minimum chordal distance. They stem from upper bounds for codes in the product of unit spheres and projective spaces. The new bounds are asymptotically better than the previously known ones.

## 1. Introduction

Use of multiple transmit and receive antennas essentially increases the spectral efficiency of wireless systems (see [1 and references therein). Analysis of Rayleigh flat-fading multiple-input multiple-output (MIMO) scenarios with $m$ transmit antennas and $n$ transmitted symbols, reveals that relevant coding schemes can be designed as collections of elements (points) in the complex Grassmann manifold - the set of $m$-dimensional linear subspaces in $\mathbb{C}^{n}$, if the channel is unknown to the receiver, and in the complex Stiefel manifold - the set of $m$ orthonormal vectors in $\mathbb{C}^{n}$, if the channel is known to the receiver. An appropriately defined distance measure between the points characterizes diversity of the designed scheme. Following standard for coding theory considerations, we study the relation between the number of points (the size of a code) and the minimum distance between distinct code points. Our aim in this paper is to obtain new upper bounds for the size of codes in Grassmann and Stiefel manifolds.

The most powerful technique for this kind of problems is the linear programming method (called also the polynomial method), initiated by Delsarte [2]. The method is very well understood in the case of 2 -point homogeneous spaces (defined in the next section), where very explicit bounds, and also good asymptotic bounds on the rate of codes have been derived. Examples are the Hamming and Johnson schemes, treated in [3], the unit sphere of $\mathbb{R}^{n}$ 4], and the projective spaces [4, [5.

When the underlying space is homogeneous and symmetric but not 2point homogeneous, the situation is much more complicated, although the

[^0]principles of the linear programming method remain valid. The difficulties come from the fact that the zonal functions defined for these spaces are not functions of one variable, but afford several variables. The Grassmann spaces considered in this paper fall into this category. An attempt to overcome this problem was carried out in [6]. An asymptotic bound for the rate of Grassmannian codes was obtained, involving the asymptotics of the largest eigenvalue of some symmetric endomorphism. This bound however is not optimal since it was improved for $m>1$ by some volume-type arguments for a large range of values of the minimal distance [7].

There is one trivial case of symmetric spaces of rank $m>1$ for which the classical treatment of the linear programming method is easily extended: it is the direct product of 2-point homogeneous spaces, such as the direct product of $m$ copies of the unit sphere. An example of a similarly easy case is provided by the non-binary Johnson space [8, 9, 10, that is the product of the Hamming and the binary Johnson scheme.

The approach developed this paper is to relate Grassmann and Stiefel spaces and their associated codes to various products of 2-point homogeneous spaces, and hence to derive upper bounds for these codes in a rather easy way. The asymptotic versions of the new bounds provide the best currently known asymptotic bounds.

The paper is organized as follows. Definitions and known results are given in Section 2. Section 3 describes various relations between the spaces and their codes. The simplest one connects Grassmann and Stiefel spaces to the unit sphere of an asymptotically equal dimension; therefrom, for example, we obtain a bound for the asymptotic rate of Grassmannian codes that already improves upon the previous ones (Theorem 3.2). Section 4 develops the Delsarte polynomial method for the products of spaces under consideration, including the classical method that involves the ChristoffelDarboux formula, and derives upper bounds for the size of the associated codes. A bound for the asymptotic rate of these codes is obtained. Section 5 discusses the consequences for the Grassmannian and Stiefel codes. In particular, we show that the bound obtained on the asymptotic rate of Grassmannian codes from the product of projective spaces is sometimes better than the one obtained in Section 3. We conclude in Section 6

## 2. Definitions and known results

We shall use the following notations and definitions. We say that $f(n) \lesssim$ $g(n), f(n) \simeq g(n), f(n) \gtrsim g(n)$ if $\lim _{n \rightarrow \infty} \frac{f(n)}{g(n)} \leq 1, \lim _{n \rightarrow \infty} \frac{f(n)}{g(n)}=$ 1 , $\lim _{n \rightarrow \infty} \frac{f(n)}{g(n)} \geq 1$, respectively. A code in a metric space $(X, d)$ is a finite set contained in the space, and a codeword is an element of the code. The size of a code $C$ is its cardinality, and its rate is $R(C):=\frac{1}{n} \ln |C|$ where $\ln$ denotes the natural logarithm. The meaning of $n$ will be defined separately for each space. Indeed, a more consistent and general definition of the rate of a code in a manifold $X$ would be $\frac{1}{\operatorname{dim}(X)} \ln |C|$. The minimum distance of
a code is the minimum distance (induced by the relevant metric) between a pair of distinct codewords. A metric space $(X, d)$ is called 2-point homogeneous, if $X$ affords the transitive action of a group $G$, such that the orbits of the action of $G$ on $X \times X$ are characterized by the distance $d$. In other words, for all $(x, y) \in X$ and $g \in G, d(g(x), g(y))=d(x, y)$, and moreover, for all pairs $(x, y),\left(x^{\prime}, y^{\prime}\right) \in G$, there exists $g \in G$ such that $g(x)=x^{\prime}$ and $g(y)=y^{\prime}$ if and only if $d(x, y)=d\left(x^{\prime}, y^{\prime}\right)$. It is a well-known fact that the compact Riemannian manifolds that are two-point homogeneous are exactly: the unit sphere $S^{n-1}$, the projective spaces $\mathbb{P}^{n-1}(K)$ where $K=\mathbb{R}, \mathbb{C}, \mathbb{H}$ and the projective plane over the octonions $\mathbb{P}^{2}(\mathbb{O})$ (see 11 , and 12 for more about the octonions and $\mathbb{P}^{2}(\mathbb{O})$ ).
2.1. The real compact two-point homogeneous spaces. The unit sphere of the Euclidean space $\mathbb{R}^{n}$ is denoted $S^{n-1}$, namely,

$$
\begin{equation*}
S^{n-1}:=\left\{\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n} \mid \sum_{i=1}^{n} x_{i}^{2}=1\right\} \tag{1}
\end{equation*}
$$

The standard scalar product in $\mathbb{R}^{n}$, given by $(u \cdot v)=\sum_{i=1}^{n} u_{i} v_{i}$, defines the Euclidean distance between two points of $S^{n-1}$ :

$$
\begin{equation*}
\|u-v\|=\sqrt{\sum_{i=1}^{n}\left(u_{i}-v_{i}\right)^{2}}=\sqrt{2} \sqrt{1-(u \cdot v)} \tag{2}
\end{equation*}
$$

The angular distance between $u$ and $v$ is defined by the angle $\theta(u, v) \in[0, \pi]$, also denoted $\theta$ when the context is clear. We have of course

$$
\begin{equation*}
\|u-v\|=\sqrt{2} \sqrt{1-\cos \theta} \tag{3}
\end{equation*}
$$

The best known asymptotic bounds on the rate of spherical codes as a function of the minimum distance are given in the following theorems. Theorem 2.1 is the Chabauty-Shannon-Wyner, which is the analog of the Gilbert-Varshamov bound for codes over finite fields, Theorem 2.2 is the linear programming bound, and Theorem 2.3 is an Elias-Bassalygo type improvement due to Yaglom. See [13, 14] for details on these bounds.

Theorem 2.1 ([15, [16, [17]). There exists a sequence of codes $\left\{C_{n}\right\}_{n=1}^{\infty}$ such that $C_{n}$ is of length $n$, minimum angular distance $\theta \leq \pi / 2$, and rate $R\left(C_{n}\right):=\frac{1}{n} \ln \left|C_{n}\right|$ which satisfies

$$
\begin{equation*}
R\left(C_{n}\right) \gtrsim-\ln \sin \theta \tag{4}
\end{equation*}
$$

Theorem 2.2 ([4]). Let $C$ be a spherical code with minimum angular distance $\theta \leq \pi / 2$. Then, when $n \rightarrow \infty$,

$$
\begin{equation*}
R(C) \lesssim R_{L P}(\theta):=\frac{1+\sin \theta}{2 \sin \theta} H\left(\frac{1-\sin \theta}{1+\sin \theta}\right) \tag{5}
\end{equation*}
$$

where $H$ is the entropy function, $H(x):=-x \ln x-(1-x) \ln (1-x)$.

Theorem 2.3 ([4]). Let $C$ be a spherical code with minimum angular distance $\theta \leq \pi / 2$. Then, for any $\theta / 2 \leq \varphi \leq \pi / 2$, when $n \rightarrow \infty$,

$$
\begin{equation*}
R(C) \lesssim \tilde{R}(\alpha)-\ln \sin \varphi \tag{6}
\end{equation*}
$$

where $\sin (\alpha / 2)=\frac{\sin (\theta / 2)}{\sin \varphi}$, and $\tilde{R}(\alpha)$ is an upper bound on the asymptotic rate of spherical codes with minimum angular distance $\alpha$.

For $\tilde{R}=R_{L P}$, the optimal choice of $\varphi$ is discussed in [4]; it corresponds to $\alpha \sim 63^{\circ}$ and gives a better bound than $R_{L P}(\theta)$ when $\theta$ is smaller than $\alpha$ :

$$
\begin{equation*}
R(C) \lesssim R_{Y}(\theta):=-\ln \sqrt{1-\cos \theta}-0.0686 \tag{7}
\end{equation*}
$$

We denote by $R_{S}(\theta)$ the function that provides the best known bound for the asymptotic rate of spherical codes:

$$
R_{S}(\theta)= \begin{cases}R_{Y}(\theta) & \text { if } \theta<\alpha  \tag{8}\\ R_{L P}(\theta) & \text { if } \alpha \leq \theta \leq \pi / 2\end{cases}
$$

Remark 2.4. The asymptotic rate of spherical codes with minimum angular distance at least $\pi / 2$ is known to be equal to zero. This is a consequence of the Rankin bound (18], see also [13] or [14]).

The other real compact manifolds which are two-point homogeneous can be treated in a similar way. As was recalled before, these are the projective spaces $\mathbb{P}^{n-1}(K)$ where $K=\mathbb{R}, \mathbb{C}, \mathbb{H}$ (the field of real quaternions) and $n \geq 3$, and the projective plane over the octonions $\mathbb{P}^{2}(\mathbb{O})$. In order to treat the fields of coefficients in a uniform way, we extend the definition of $(x \cdot y)$ so that, for all $x, y \in K^{n},(x \cdot y)=\sum_{i=1}^{n} x_{i} \overline{y_{i}}$, where the conjugation $x \rightarrow \bar{x}$ is the standard one over $K=\mathbb{C}, \mathbb{H}, \mathbb{O}$ and is the identity over $\mathbb{R}$. Also we conventionally assume that $n=3$ when $K=\mathbb{O}$. The group $G$ under which these spaces are two-point homogeneous is respectively the orthogonal group $O\left(\mathbb{R}^{n}\right)$, the unitary groups $U\left(K^{n}\right)$ with $K=\mathbb{C}, \mathbb{H}$, and the Lie group $F_{4}$ (see [12] for this last case).

The angular distance between $p$ and $q$ in $\mathbb{P}^{n-1}(K)$ is defined by the angle $\theta=\theta(p, q) \in[0, \pi / 2]$ such that $\cos \theta(p, q)=|(e \cdot f)|$ where $e, f$ are arbitrary chosen unit vectors of the lines $p, q$. It is shown in [4] and [5] that the linear programming method applies to these spaces. The derived asymptotic bound for the rate can also be obtained from the bounds for spherical codes, because to a code $C$ in $\mathbb{P}^{n-1}(K)$ one can associate a code in $S^{c n-1}$ with the same size and a minimum angular distance at least equal to the one of $C$, selecting a unit vector in each element of $C$. One obtains:

Theorem 2.5 (4]). Let $C$ be a code in $\mathbb{P}^{n-1}(K)$ with minimum angular distance $\theta \leq \pi / 2$. Let $c:=1,2,4$ respectively when $K=\mathbb{R}, \mathbb{C}, \mathbb{H}$ (so that $c=[K: \mathbb{R}])$. Then, when $n \rightarrow \infty$,

$$
\begin{equation*}
R(C):=\frac{1}{n} \ln |C| \lesssim c R_{S}(\theta) \tag{9}
\end{equation*}
$$

2.2. The Grassmann space. Let $K$ be the real or the complex field. The Grassmann space $\mathcal{G}_{m, n}(K)$ is the set of all subspaces of dimension $m$ in $K^{n}$. It is a homogeneous space under the action of either the orthogonal group $O\left(\mathbb{R}^{n}\right)$ or the unitary group $U\left(\mathbb{C}^{n}\right)$. We will denote $\mathcal{G}_{m, n}$ when $K$ is arbitrary. It is worth noticing that when $m=1$ we recover the projective space. Several metrics have been defined in $\mathcal{G}_{m, n}$, see [19, 20]. In this paper we consider the chordal distance, which was introduced in [21] and studied in (19, 7, 6, 21, 20. The following two definitions for the chordal distance $d_{c}(p, q)$ are equivalent.

Definition 2.6. Given the planes $p, q \in \mathcal{G}_{m, n}$, apply the following procedure. Initialize the sets of unit vectors $A=\emptyset$ and $B=\emptyset$. In the ith step, choose the vectors $a_{i}, b_{i}$ such that:
(i) $a_{i}$ is contained in $p$ and $b_{i}$ is contained in $q$.
(ii) $a_{i}$ is orthogonal to all the vectors in $A$ and $b_{i}$ is orthogonal to all the vectors in $B$.
(iii) Among all the vectors satisfying the conditions in (i) and (ii), the angle between $a_{i}$ and $b_{i}$ is minimal (i.e., their inner / Hermitian product module is maximal).
Set $\theta_{i}$ to be the angle between $a_{i}$ and $b_{i}$, insert $a_{i}$ to $A$ and $b_{i}$ to $B$, and proceed to the next step, until $m$ angles $0 \leq \theta_{1} \leq \theta_{2} \leq \ldots \leq \theta_{m} \leq \pi / 2$, called the principal angles between $p$ and $q$, have been defined. Then the chordal distance is

$$
d_{c}(p, q):=\sqrt{\sum_{i=1}^{m} \sin ^{2} \theta_{i}}=\sqrt{m-\sum_{i=1}^{m} \cos ^{2} \theta_{i}} .
$$

Lemma 2.7 ([21). For a plane $p \in \mathcal{G}_{m, n}$, let $A_{p}$ be a $p \times n$ matrix whose rows form an orthonormal basis of $p$, and let $\pi_{p}:=A_{p}^{*} A_{p}$ be the matrix of the orthogonal projection on $p$ ( $A_{p}^{*}$ denotes the Hermitian conjugate of $A_{p}$ ). Then, the projection matrix $\pi_{p}$ does not depend on the choice of $A_{p}$, and, given two planes $p, q \in \mathcal{G}_{m, n}$, the chordal distance is

$$
\begin{equation*}
d_{c}(p, q):=\sqrt{m-\operatorname{trace}\left(\pi_{p} \circ \pi_{q}\right)} . \tag{10}
\end{equation*}
$$

We review some known bounds on the size of codes in Grassmann spaces. We recall that $c=1$ if $K=\mathbb{R}$ and $c=2$ if $K=\mathbb{C}$. The first work in the area is due to Conway et al. [21]. They found an isometric embedding from $\mathcal{G}_{m, n}(\mathbb{R})$ to the Euclidean sphere with radius $\sqrt{\frac{m(n-m)}{n}}$ in $\mathbb{R}^{\frac{1}{2}(n-1)(n+2)}$ (a similar embedding exists also for $\mathcal{G}_{m, n}(\mathbb{C})$, see [19]). This enabled them to use the Rankin bound on spherical codes [18] to derive the following non-asymptotic bound.

Theorem 2.8. Let $C$ be a code in $\mathcal{G}_{m, n}(\mathbb{R})$ with minimum chordal distance d. Then

$$
d \leq\left\{\begin{array}{cc}
\frac{m(n-m)}{n} \frac{|C|}{|C|-1}  \tag{11}\\
\frac{m(n-m)}{n} & \text { if }|C|>\frac{1}{2} n(n+1)
\end{array}\right.
$$

Later, an asymptotic expression to the volume of a ball in Grassmann spaces was derived by Barg and Nogin [19], yielding the analogue of GilbertVarshamov and the Hamming asymptotic bounds for the rate $R(C):=$ $\frac{1}{n} \ln |C|$ of Grassmannian codes.
Theorem 2.9 (19). For any pair of constants $d$, $m$, such that $d \leq \sqrt{m}$, there exists an infinite sequence of codes $\left\{C_{n}\right\}$ in $\mathcal{G}_{m, n}$ with minimum chordal distance $d$ and rate

$$
\begin{equation*}
R \gtrsim-c m \ln \frac{d}{\sqrt{m}} . \tag{12}
\end{equation*}
$$

Theorem 2.10 (19). Let $C$ be in $\mathcal{G}_{m, n}$ with minimum chordal distance $d$. Then, when $n \rightarrow \infty$,

$$
\begin{equation*}
R(C) \lesssim-c m \ln \left(\sqrt{1-\sqrt{1-d^{2} / 2 m}}\right) . \tag{13}
\end{equation*}
$$

A linear programming bound was derived by Bachoc [6].
Theorem 2.11 (6]). Let $C$ be a code in $\mathcal{G}_{m, n}(\mathbb{R})$ with minimum chordal distance $d$. Then, when $n \rightarrow \infty$,

$$
\begin{equation*}
R(C) \lesssim m[(1+\rho) \ln (1+\rho)-\rho \ln \rho], \tag{14}
\end{equation*}
$$

where

$$
\begin{equation*}
\rho=\frac{1}{2} m(\sqrt{m} / d-1) . \tag{15}
\end{equation*}
$$

We note that the derivation of the linear programming bound is not a straightforward analogy to the derivation of this bound in other metric spaces, since it involves a family of orthogonal generalized Jacobi polynomials with several variables, and that the bound (14) in the case $m=1$ coincides with the bound for the real projective space of Theorem [2.5. The case of the complex Grassmann space is not treated in [6] but could be treated in a similar way.

Finally, a new upper bound was introduced recently by Barg and Nogin [7], using Blichfeldt's density method.
Theorem 2.12. Let $C$ be a code over the Grassmann space $\mathcal{G}_{m, n}(\mathbb{R})$ with minimum chordal distance $d$. Then

$$
\begin{equation*}
R(C) \lesssim-m \ln \left(\sqrt{1-\sqrt{1-d^{2} / m}}\right) . \tag{16}
\end{equation*}
$$

It is immediate to see that this bound improves upon (13) and upon (14) for $m>1$ and for a large range of values of $d$. Hence, until this paper, Theorems 2.11 and 2.12 provide the best asymptotic known upper bounds on the rate of codes in $\mathcal{G}_{m, n}(\mathbb{R})$.
2.3. The Stiefel manifold. The Stiefel manifold $\mathcal{V}_{m, n}(K)$ is the set of $m$-tuples of orthonormal vectors in $K^{n}$, or equivalently

$$
\mathcal{V}_{m, n}(K)=\left\{X \in M^{m \times n}(K) \mid X X^{*}=\operatorname{Id}_{m}\right\}
$$

where $\operatorname{Id}_{m}$ is the $m \times m$ identity matrix. The orthogonal group $O\left(\mathbb{R}^{n}\right)$ if $K=\mathbb{R}$, respectively the unitary group $U\left(\mathbb{C}^{n}\right)$ if $K=\mathbb{C}$ acts transitively on $\mathcal{V}_{m, n}(K)$, and this space can be identified with the set of classes $O\left(\mathbb{R}^{n}\right) / O\left(\mathbb{R}^{n-m}\right)$, respectively $U\left(\mathbb{C}^{n}\right) / U\left(\mathbb{C}^{n-m}\right)$.

The distance considered in coding theory is

$$
d(X, Y):=\|X-Y\|=\sqrt{\operatorname{trace}\left((X-Y)\left(X^{*}-Y^{*}\right)\right)} .
$$

In other words, $d(X, Y)$ is the Euclidean distance between $X$ and $Y$, when $X$ and $Y$ are regarded as one-dimensional vectors of length $m n$. We refer the reader to [22] for a treatment of codes in Stiefel manifolds.

## 3. More spaces and their interconnections

The simplest of these connections relate Grassmann and Stiefel spaces to a single unit sphere, and allow to apply directly the known bounds for spherical codes to the Grassmannian and Stiefel codes. We start with them, then we introduce the products of spheres and projective spaces and their relations with Grassmann and Stiefel spaces.
3.1. $\mathcal{G}_{m, n}$ and $S^{c m n-1}$. We follow the notations and definitions of Section 2.2. For all $p, q \in \mathcal{G}_{m, n}(K)$, we set

$$
\sigma(p, q):=\sum_{i=1}^{m} \cos ^{2} \theta_{i}=\operatorname{trace}\left(\pi_{p} \circ \pi_{q}\right) .
$$

We define a mapping

$$
\beta: \mathcal{G}_{m, n}(K) \rightarrow S^{c m n-1}
$$

in the following way. We select for all $p \in \mathcal{G}_{m, n}(K)$, an orthonormal basis $\left(e_{1}, \ldots, e_{m}\right)$ of $p$ whose elements belong to $K^{n}$. With the usual identification of $\mathbb{C}$ and $\mathbb{R} \times \mathbb{R}$ through the mapping $z=x+i y \rightarrow(x, y)$, we consider these elements in $\mathbb{R}^{c n}$. Then $\beta(p)$ is chosen to be the element of $\mathbb{R}^{c m n}$ obtained by the concatenation of $e_{1}, \ldots, e_{m}$, divided by $\sqrt{m}$. Obviously, $\beta(p) \in S^{c m n-1}$.

The new bounds for Grassmann spaces rely on the following lemma.
Lemma 3.1. For all $p, q \in \mathcal{G}_{m, n}(K)$,

$$
\cos \theta(\beta(p), \beta(q)) \leq \sqrt{\frac{\sigma(p, q)}{m}} .
$$

Proof. Let $\beta(p)=e$, obtained from an orthonormal basis $\left(e_{1}, e_{2}, \ldots, e_{m}\right)$ of $p$ and $\beta(q)=e^{\prime}$, obtained from an orthonormal basis $\left(e_{1}^{\prime}, \ldots, e_{m}^{\prime}\right)$ of $q$. We compute $\sigma(p, q)=\operatorname{trace}\left(\pi_{p} \circ \pi_{q}\right)$. Let $A_{p}, A_{q}$ denote the $m \times n$ matrices whose rows are the basis elements $e_{i}, e_{i}^{\prime}$ respectively. Then

$$
\sigma(p, q)=\operatorname{trace}\left(\pi_{p} \circ \pi_{q}\right)=\operatorname{trace}\left(A_{p}^{*} A_{p} A_{q}^{*} A_{q}\right)=\operatorname{trace}\left(A_{p} A_{q}^{*} A_{q} A_{p}^{*}\right)
$$

The entries of the matrix $A_{p} A_{q}^{*}$ are the hermitian products $\left(e_{i} \cdot e_{j}^{\prime}\right)$. So we obtain:

$$
\begin{equation*}
\sigma(p, q)=\sum_{1 \leq i, j \leq m}\left|\left(e_{i} \cdot e_{j}^{\prime}\right)\right|^{2} \tag{17}
\end{equation*}
$$

If $K=\mathbb{R}$, we obtain from Cauchy-Schwartz inequality

$$
\begin{equation*}
\cos \theta\left(e, e^{\prime}\right)=\left(e \cdot e^{\prime}\right)=\frac{\sum_{i=1}^{m}\left(e_{i} \cdot e_{i}^{\prime}\right)}{m} \leq \sqrt{\frac{\sum_{i=1}^{m}\left(e_{i} \cdot e_{i}^{\prime}\right)^{2}}{m}} \leq \sqrt{\frac{\sigma(p, q)}{m}} \tag{18}
\end{equation*}
$$

If $K=\mathbb{C}$, let us denote by $\Re(z)$ the real part of a complex number $z$. In the identification $\mathbb{C}^{n}=\mathbb{R}^{2 n}$ recalled above, the standard scalar product on $\mathbb{R}^{2 n}$ is given by $\Re(h(x, y))$. With the obvious inequality $\Re(h(x, y))^{2} \leq$ $|h(x, y)|^{2}$, we obtain the same inequality $\cos \theta\left(e, e^{\prime}\right) \leq \sqrt{\frac{\sigma(p, q)}{m}}$ (where $e$ and $e^{\prime}$ are considered in the unit sphere of $R^{2 n}$.)

Let us recall Definition 2.6 of the chordal distance $d_{c}(p, q)$ in Grassmann spaces. The definition involves the construction of orthonormal basis $\left(a_{1}, \ldots, a_{m}\right)$ and $\left(b_{1}, \ldots, b_{m}\right)$ for $p$ and $q$ respectively, such that the principle angles $\theta_{i}$ satisfy $\cos \theta_{i}=\left|\left(a_{i} \cdot b_{i}\right)\right|$ and $\sigma(p, q)=\sum_{i=1}^{m} \cos ^{2} \theta_{i}$. Lemma 3.1 shows that if one chooses arbitrary orthonormal basis $\left(e_{1}, \ldots, e_{m}\right)$ of $p,\left(e_{1}^{\prime}, \ldots, e_{m}^{\prime}\right)$ of $q$, and defines an alternative set of "principal angles" $\theta_{1}^{\prime}, \ldots, \theta_{m}^{\prime}$ by $\theta_{i}^{\prime}=\arccos \left|\left(e_{i} \cdot e_{i}^{\prime}\right)\right|$, then $\sigma(p, q) \geq \sum_{i=1}^{m} \cos ^{2} \theta_{i}^{\prime}$. Thus, an upper bound on the chordal distance between $p$ and $q$ is obtained.

It follows from Lemma 3.1 that the bounds for spherical codes (of the sphere $S^{c m n-1}$ ) can be applied to codes in Grassmann spaces. We obtain for the asymptotic rate:

Theorem 3.2. Let $C$ be a code in $\mathcal{G}_{m, n}(K)$ with minimal chordal distance $d=\sqrt{m-s}$, and let $\theta=\arccos (\sqrt{s / m})$. Then, when $n \rightarrow+\infty$,

$$
\begin{equation*}
R(C) \lesssim c m R_{S}(\theta) \tag{19}
\end{equation*}
$$

where $R_{S}$ is defined in (8).
Figure 1 compares (19) with some of the existing bounds, given in Section 2.2. The bound (16) can also be obtained using the mapping $\beta$, joined with the Rankin-Blichfeldt bound [7]. It is well known that the Rankin-Blichfeldt bound [18] is improved by the bound $R_{S}(\theta)$ for all values of $\theta$.

Remark 3.3. In [21], the authors introduce an isometric embedding of $\mathcal{G}_{m, n}(\mathbb{R})$ into a unit sphere, but the dimension of this sphere is much larger than the one of the Grassmann space $((n-1)(n+2) / 2$ instead of $m(n-m))$. Instead, the dimension of $S^{c m n-1}$ is asymptotically equivalent to the one of $\mathcal{G}_{m, n}(K)$, but our embedding is not isometric.

Figure 1. Upper bound on the asymptotic rate of real Grassmannian codes with minimum chordal distance $d, m=$ 3. From top to bottom: a linear programming bound (14), a Blichfeldt-type bound (16), and the new bound (19)
3.2. $\mathcal{V}_{m, n}$ and $S^{c m n-1}$.

Lemma 3.4. Let $X, Y \in \mathcal{V}_{m, n}(K), K=\mathbb{R}, \mathbb{C}$. Let $\left(e_{1}, \ldots e_{m}\right)$ denote the rows of $X$, respectively $\left(e_{1}^{\prime}, \ldots e_{m}^{\prime}\right)$ for the rows of $Y$. Then

$$
d(X, Y)=\sqrt{2} \sqrt{m-\sum_{i=1}^{m} \Re\left(e_{i} \cdot e_{i}^{\prime}\right)} .
$$

Proof. We calculate

$$
\begin{aligned}
\|X-Y\|^{2} & =\operatorname{trace}\left((X-Y)\left(X^{*}-Y^{*}\right)\right) \\
& =\operatorname{trace}\left(X X^{*}-X Y^{*}-Y X^{*}+Y Y^{*}\right) \\
& =2 m-2 \Re\left(\operatorname{trace}\left(X Y^{*}\right)\right)
\end{aligned}
$$

since $X X^{*}=Y Y^{*}=\operatorname{Id}_{m}$ and $\overline{\operatorname{trace}\left(X Y^{*}\right)}=\operatorname{trace}\left(\overline{X Y^{*}}\right)=\operatorname{trace}\left(Y X^{*}\right)$. We conclude with

$$
\operatorname{trace}\left(X Y^{*}\right)=\sum_{i=1}^{m}\left(e_{i} \cdot e_{i}^{\prime}\right) .
$$

Again with the identification of $\mathbb{C}^{n}$ with $\mathbb{R}^{2 n}$, we view $\mathcal{V}_{m, n}(\mathbb{C})$ as a submanifold of $\mathcal{V}_{m, 2 n}(\mathbb{R})$ endowed with the distance

$$
d(X, Y)=\|X-Y\|=\sqrt{2} \sqrt{m-\sum_{i=1}^{m}\left(e_{i} \cdot e_{i}^{\prime}\right)} .
$$

We see that the obvious mapping:

$$
\begin{aligned}
\gamma: \mathcal{V}_{m, n}(K) & \rightarrow S^{c m n-1} \\
X & \mapsto \gamma(X)=\frac{1}{\sqrt{m}}\left(e_{1}, \ldots, e_{m}\right)
\end{aligned}
$$

is this time, up to a suitable scaling of the distances, an isometry. Hence the bounds for spherical codes also apply to $\mathcal{V}_{m, n}(K)$, probably in a quite efficient way. Still, one constraint is not encoded in it: the fact that the vectors $e_{i}$ are pairwise orthogonal and of norm 1. We resume these observations in the following theorem.
Theorem 3.5. Any upper bound on the size of codes in $S^{c m n-1}$ with minimum angular distance $\theta=\arccos (s / m)$ is also an upper bound for codes in the Stiefel space $\mathcal{V}_{m, n}(K)$ with minimum distance $\sqrt{2} \sqrt{m-s}$. In particular, we have for the asymptotic rate, when $n \rightarrow+\infty$,

$$
\begin{equation*}
R(C) \lesssim c m R_{S}(\theta) \tag{20}
\end{equation*}
$$

where $R_{S}$ is defined in (8).
3.3. $\mathcal{G}_{m, n}, \mathcal{V}_{m, n}$ and products of spaces. So far we have established a relation between codes in $\mathcal{G}_{m, n}$ and $\mathcal{V}_{m, n}$ and codes in $S^{c m n-1}$. It is worth noticing that the mappings $\beta$ and $\gamma$ defined above factor out by $\left(S^{c n-1}\right)^{m}$, since the elements $e_{i}$ are unit vectors. Hence bounds for codes in $\left(S^{c n-1}\right)^{m}$, will imply bounds for codes in $\mathcal{G}_{m, n}$ and $\mathcal{V}_{m, n}$. This is the motivation to the generalization of the linear programming method to the product of unit spheres, and more generally to the product of 2-point homogeneous spaces, which is proposed in the next section. As we shall see, the asymptotic bound for the rate of codes in $\left(S^{c n-1}\right)^{m}$ is not better than for $S^{c m n-1}$, hence doesn't improve on (19) and (20). A better result is obtained for Grassmann spaces with the product of projective spaces.

We now define more precisely the products of spaces and their associated distances that will be studied in the next section. We start with the product of $m$ copies of the unit sphere of $\mathbb{R}^{n}$ :

$$
\left(S^{n-1}\right)^{m}=\left\{e=\left(e_{1}, \ldots, e_{m}\right) \mid e_{i} \in S^{n-1}\right\} .
$$

We consider on $\left(S^{n-1}\right)^{m}$ the distance given by

$$
\begin{aligned}
d\left(e, e^{\prime}\right) & =\sqrt{\sum_{i=1}^{m}\left\|e_{i}-e_{i}^{\prime}\right\|^{2}} \\
& =\sqrt{2 m} \sqrt{1-\frac{\sum_{i=1}^{m} \cos \theta_{i}}{m}}
\end{aligned}
$$

where $\cos \theta_{i}=\left(e_{i} \cdot e_{i}^{\prime}\right)$. We attach to a pair $e, e^{\prime} \in\left(S^{n-1}\right)^{m}$ an angle $\theta=\theta\left(e, e^{\prime}\right) \in[0, \pi]$ such that

$$
\begin{equation*}
\cos \theta=\frac{\sum_{i=1}^{m} \cos \theta_{i}}{m} \tag{21}
\end{equation*}
$$

and we call $\theta$ the angular distance between $e$ and $e^{\prime}$. The angle $\theta$ is also the angle between the vectors $e / \sqrt{m}$ and $e^{\prime} / \sqrt{m}$, viewed as elements of $S^{m n-1}$.

We define, for the remaining 2-point homogeneous spaces recalled above, and without specifying the field $K$,

$$
\left(\mathbb{P}^{n-1}\right)^{m}=\left\{p=\left(p_{1}, \ldots, p_{m}\right) \mid p_{i} \in \mathbb{P}^{n-1}\right\}
$$

We attach to a pair $p, p^{\prime} \in\left(\mathbb{P}^{n-1}\right)^{m}$ an angle $\theta=\theta\left(p, p^{\prime}\right) \in[0, \pi / 2]$ such that

$$
\cos ^{2} \theta=\frac{\sum_{i=1}^{m} \cos ^{2} \theta_{i}}{m}
$$

where $\theta_{i}=\theta\left(p_{i}, q_{i}\right)$ and we call $\theta$ the angular distance between $p$ and $p^{\prime}$. We consider on $\left(\mathbb{P}^{n-1}\right)^{m}$ the "chordal" distance given by

$$
d\left(p, p^{\prime}\right)=\sqrt{m-\sum_{i=1}^{m} \cos ^{2} \theta_{i}}=\sqrt{m} \sin \theta
$$

In order to derive bounds for codes in Grassmann spaces $\mathcal{G}_{m, n}(K)$, we shall make use of the mapping:

$$
\nu: \mathcal{G}_{m, n}(K) \rightarrow\left(\mathbb{P}^{n-1}(K)\right)^{m}
$$

defined in the following way: for all $p \in \mathcal{G}_{m, n}(K)$, we choose a $m$-tuple $\left(p_{1}, \ldots, p_{m}\right)$ of pairwise orthogonal lines of $p$. We set $\nu(p)=\left(p_{1}, \ldots, p_{m}\right)$.

Because of the equation (17), we have similarly:

$$
\cos ^{2} \theta(\nu(p), \nu(q)) \leq \frac{\sigma(p, q)}{m}
$$

hence the bounds for codes in $\left(\mathbb{P}^{n-1}(K)\right)^{m}$ apply to codes in Grassmann spaces.

## 4. Bounds for codes in the product of 2-point homogeneous SPACES

In this section, $X$ denotes one of the spaces $S^{n-1}, \mathbb{P}^{n-1}(K)$ where $K=$ $\mathbb{R}, \mathbb{C}, \mathbb{H}$, or the projective plane over the octonions $\mathbb{P}^{2}(\mathbb{O})$. We derive bounds for codes in $X^{m}$ with a given minimum distance, following Delsarte's linear programming method as performed in 4. As a reference on orthogonal polynomials, we refer to [23].
4.1. Review of the necessary material on the harmonic analysis of the spaces $X$. We recall that, to each of these spaces is associated a family of orthogonal polynomials of one variable, which are the zonal polynomials relative to the action of the group $G$ (see [4], [5], [24]). For $X=S^{n-1}$, these polynomials are the Gegenbauer polynomials with parameter $n / 2-1$ and associated orthogonal measure $\left(1-x^{2}\right)^{(n-3) / 2}$ on the interval $[-1,1]$. For
$X=\mathbb{P}^{n-1}(K)$, these polynomials are Jacobi polynomials with parameters $(\alpha, \beta)$ defined by:

$$
\alpha=\frac{c}{2}(n-1)-1, \beta=\frac{c}{2}-1 .
$$

More precisely, the values of $(\alpha, \beta)$ are as follows:

|  | $c$ | $\alpha$ | $\beta$ |
| :---: | :---: | :---: | :---: |
| $\mathbb{R}$ | 1 | $(n-3) / 2$ | $-1 / 2$ |
| $\mathbb{C}$ | 2 | $n-2$ | 0 |
| $\mathbb{H}$ | 4 | $2 n-3$ | 1 |
| $\mathbb{O}$ | 8 | 7 | 3 |

The orthogonal measure associated to the parameters $(\alpha, \beta)$ is $x^{\beta}(1-x)^{\alpha}$ over the interval $[0,1]$. We generically denote by $P_{k}(x)$ these polynomials, with $\operatorname{deg}\left(P_{k}\right)=k$ and $P_{k}(1)=1$. We let $\mu(x)$ denote their normalized associated orthogonal measure and $[P, Q]$ the corresponding scalar product on $\mathbb{R}[x]$ (so that $[P, Q]=\int P(x) Q(x) \mu(x) d x$ and $[1,1]=1$ ). Moreover, we have $\left[P_{k}, P_{k}\right]=d_{k}^{-1}$ where $d_{k}$ denotes the dimension of the irreducible representation of $G$ associated to $P_{k}$ (e.g. when $X=S^{n-1}$, $\left.d_{k}=\operatorname{dim} \operatorname{Harm}_{k}=\binom{n+k-1}{k}-\binom{n+k-3}{k-2}\right)$.

The three-terms relation expresses $x P_{k}(x)$ as a linear combination of the polynomials $P_{i}$ :

$$
x P_{k}(x)=a_{k} P_{k+1}(x)+b_{k} P_{k}(x)+c_{k} P_{k-1}(x)
$$

for some sequences of rational numbers $\left(a_{k}\right),\left(b_{k}\right),\left(c_{k}\right)$. It is enough for our purpose to know that $\left(a_{k}\right)$ is bounded when $n$ and $k$ tend to $+\infty$ with $n / k$ tending to a finite limit. For example, when $X=S^{n-1}$,

$$
a_{k}=\frac{n-2+k}{n-2+2 k} .
$$

For all $(u, v) \in X$, we define

$$
t(u, v)= \begin{cases}(u \cdot v)=\cos \theta(u, v) & \text { if } X=S^{n-1} \\ \cos ^{2} \theta(u, v) & \text { if } X=\mathbb{P}^{n-1}(K) .\end{cases}
$$

The zonal function on $X$ associated to $P_{k}$ is given by:

$$
(u, v) \rightarrow P_{k}(t(u, v)) .
$$

The so-called 'positivity property' related to these polynomials, and underlying the linear programming method in $X$, is the following: for all code $C \subset X$, and for all $k \geq 0$,

$$
\sum_{u \in C} \sum_{v \in C} P_{k}(t(u, v)) \geq 0 .
$$

4.2. The linear programming method on $X^{m}$. Now we consider the product spaces $X^{m}$. The positivity property generalizes to the following:

Lemma 4.1. Let $C \subset X^{m}$. Let us denote elements of $C$ by $u=\left(u_{1}, \ldots, u_{m}\right)$ with $u_{i} \in X$. For all $\left(k_{1}, \ldots, k_{m}\right) \in \mathbb{N}^{m}$,

$$
\sum_{u \in C} \sum_{v \in C} \prod_{i=1}^{m} P_{k_{i}}\left(t\left(u_{i}, v_{i}\right)\right) \geq 0
$$

Proof. This is the positivity property in the product space $X^{m}$. The group $G^{m}$ acts transitively on $X^{m}$; the $G^{m}$-irreducible components of $L^{2}\left(X^{m}\right)$ are the tensor products of the $G$-irreducible components of each $L^{2}(X)$ and the associated zonal functions are given by the polynomials in the $m$ variables $x_{1}, \ldots, x_{m}$

$$
\prod_{i=1}^{m} P_{k_{i}}\left(x_{i}\right), \quad\left(k_{1}, \ldots, k_{m}\right) \in \mathbb{N}^{m}
$$

in the way:

$$
(u, v) \mapsto \prod_{i=1}^{m} P_{k_{i}}\left(t\left(u_{i}, v_{i}\right)\right)
$$

Remark 4.2. In a sense, the polynomials $\prod_{i=1}^{m} P_{k_{i}}\left(x_{i}\right)$ are fake multivariate polynomials since the $m$ variables are separated. As we shall see, for this reason it is much easier to deal with them, compared with the zonal polynomials for the Grassmann space (see [6]).

The polynomials $\prod_{i=1}^{m} P_{k_{i}}\left(x_{i}\right)$ generate the polynomial algebra $\mathbb{C}\left[x_{1}, \ldots, x_{m}\right]$, and are orthogonal for the product measure

$$
\lambda \prod_{i=1}^{m} \mu\left(x_{i}\right) d x_{i}
$$

with support $[-1,1]^{m}$ when $X=S^{n-1}$, respectively $[0,1]^{m}$ otherwise, and where $\lambda$ is chosen so that the total measure is equal to 1 . The associated scalar product on $\mathbb{R}\left[x_{1}, \ldots, x_{m}\right]$ is denoted by $[$,$] . We take the following$ notations: a multi-index in $\mathbb{N}^{m}$ is denoted by $\underline{k}=\left(k_{1}, \ldots, k_{m}\right)$ and we define for $x=\left(x_{1}, \ldots, x_{m}\right), P_{\underline{k}}(x)=P_{\underline{k}}\left(x_{1}, \ldots, x_{m}\right):=\prod_{i=1}^{m} P_{k_{i}}\left(x_{i}\right)$, and $d_{\underline{k}}:=\prod_{i=1}^{m} d_{k_{i}}$. Obviously we have, for all $\underline{k}$ and $\underline{l}$,

$$
\begin{equation*}
\left[P_{\underline{k}}, P_{\underline{l}}\right]=\delta_{\underline{k}, \underline{l}} d_{\underline{k}}^{-1} . \tag{22}
\end{equation*}
$$

Moreover, we define

$$
\sigma(x):=\sum_{i=1}^{m} x_{i} .
$$

For any angle $\theta$ we denote

$$
\begin{cases}t=\cos \theta & \text { if } X=S^{n-1} \\ t=\cos ^{2} \theta & \text { if } X=\mathbb{P}^{n-1}(K)\end{cases}
$$

Now we can formulate the usual associated linear programming bound:
Proposition 4.3. Assume $F \in \mathbb{R}\left[x_{1}, \ldots, x_{m}\right]$ satisfies the conditions:
(i) $F=\sum_{\underline{k}} f_{\underline{k}} P_{\underline{k}}$ with $f_{\underline{k}} \geq 0$ for all $\underline{k}$, and $f_{0}>0$
(ii) $\left\{\begin{array}{lll}\text { If } X=S^{n-1}, \quad F\left(x_{1}, \ldots, x_{m}\right) \leq 0 \quad \begin{array}{l}\text { for all }\left(x_{1}, \ldots, x_{m}\right) \in[-1,1]^{m} \\ \\ \text { such that } \sigma(x) \leq m \cos \theta=m t\end{array} \\ \text { If } X \neq S^{n-1}, \quad F\left(x_{1}, \ldots, x_{m}\right) \leq 0 \quad \begin{array}{l}\text { for all }\left(x_{1}, \ldots, x_{m}\right) \in[0,1]^{m} \\ \text { such that } \sigma(x) \leq m \cos ^{2} \theta=m t\end{array}\end{array}\right.$

Then, any code $C$ in $X^{m}$ with minimum angular distance $\theta$ satisfies

$$
|C| \leq \frac{F(1, \ldots, 1)}{f_{0}}
$$

Proof. We reproduce the standard argument. Let

$$
S:=\sum_{u \in C} \sum_{v \in C} F\left(t\left(u_{1}, v_{1}\right), \ldots, t\left(u_{m}, v_{m}\right)\right) .
$$

The pairs $(u, v)$ with $u=v$ contribute in this sum for $|C| F(1, \ldots, 1)$. From condition (ii) and the assumption that for $u \neq v \in C, \cos \theta(u, v) \leq \cos \theta$, the other terms are non positive. Hence, $S \leq|C| F(1, \ldots, 1)$.

On the other hand, we have

$$
S=\sum_{\underline{k}} f_{\underline{k}}\left(\sum_{u, v \in C} P_{\underline{k}}\left(t\left(u_{1}, v_{1}\right), \ldots, t\left(u_{m}, v_{m}\right)\right) .\right.
$$

The term corresponding to $\underline{k}=0=(0, \ldots, 0)$ gives $f_{0}|C|^{2}$ while the other terms are non-negative from the positivity property of the polynomials $P_{\underline{k}}$ (Lemma 4.11). Hence $S \geq f_{0}|C|^{2}$. The two inequalities lead to the announced bound.
4.3. Examples of small degree. Let us work out the case of polynomials of small degree.
(i) $X=S^{n-1}$
(a) Degree 1: we take $F=\left(x_{1}+\cdots+x_{m}\right)-m t$. Since $P_{1}(x)=x, F$ satisfies the hypothesis of Proposition 4.3 if and only if $t<0$. We obtain:

$$
\begin{equation*}
\text { If } \cos \theta=t<0, \quad|C| \leq 1-\frac{1}{t} \tag{23}
\end{equation*}
$$

(b) Degree 2: we take $F=\left(\left(x_{1}+\cdots+x_{m}\right)+m\right)\left(\left(x_{1}+\cdots+x_{m}\right)-\right.$ $m t$ ). We have

$$
\begin{aligned}
F & =\left(x_{1}+\cdots+x_{m}\right)^{2}+m(1-t)\left(x_{1}+\cdots+x_{m}\right)-m^{2} t \\
& =\sum x_{i}^{2}+2 \sum_{i<j} x_{i} x_{j}+m(1-t) \sum x_{i}-m^{2} t \\
& =\sum\left(x_{i}^{2}-\frac{1}{n}\right)+2 \sum_{i<j} x_{i} x_{j}+m(1-t) \sum x_{i}+\frac{m}{n}-m^{2} t
\end{aligned}
$$

Since $P_{2}(x)=\left(x^{2}-1 / n\right) /(1-1 / n), F$ satisfies the hypothesis of Proposition 4.3 if and only if $\frac{m}{n}-m^{2} t>0$. We obtain:

$$
\begin{equation*}
\text { If } \cos \theta=t<\frac{1}{m n}, \quad|C| \leq \frac{2 m n(1-t)}{1-m n t} . \tag{24}
\end{equation*}
$$

The two bounds take the value $1+m n$ at their crossing point, corresponding to $t=-1 / m n$. .
(ii) $X=\mathbb{P}^{n-1}(K)$, Degree 1: we have, up to a multiplicative factor, $P_{1}(x)=x-\frac{\beta+1}{\alpha+\beta+2}=x-\frac{1}{n}$. We take $F=\left(x_{1}+\cdots+x_{m}\right)-m t=$ $\left(x_{1}-\frac{1}{n}\right)+\cdots+\left(x_{m}-\frac{1}{n}\right)+\frac{m}{n}-m t$. $F$ satisfies the hypothesis of Proposition 4.3 if and only if $t<1 / n$. We obtain:

$$
\begin{equation*}
\text { If } \cos ^{2} \theta=t<\frac{1}{n}, \quad|C| \leq \frac{1-t}{1 / n-t} . \tag{25}
\end{equation*}
$$

4.4. Christoffel-Darboux formula and an explicit bound. It remains to apply the standard method with Christoffel-Darboux formula. For $\underline{k}=$ $\left(k_{1}, \ldots, k_{m}\right)$ and $\underline{l}=\left(l_{1}, \ldots, l_{m}\right)$, the notation $\underline{l} \leq \underline{k}$ stands for: $l_{i} \leq k_{i}$ for all $1 \leq i \leq m$.

Proposition 4.4. Let $y=\left(y_{1}, \ldots, y_{m}\right) \in \mathbb{R}^{m}$ and $\underline{k}=\left(k_{1}, \ldots, k_{m}\right) \in \mathbb{N}^{m}$, and define

$$
K_{\underline{k}}(x, y):=\sum_{\underline{l} \leq \underline{k}} d_{\underline{l}} P_{\underline{l}}(x) P_{\underline{l}}(y)=\prod_{j=1}^{m}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right)
$$

and

$$
N_{\underline{k}}(x, y):=\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}} Q_{k_{t}}\left(x_{t}, y_{t}\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right)
$$

where

$$
Q_{k_{t}}\left(x_{t}, y_{t}\right):=P_{k_{t}+1}\left(x_{t}\right) P_{k_{t}}\left(y_{t}\right)-P_{k_{t}}\left(x_{t}\right) P_{k_{t}+1}\left(y_{t}\right) .
$$

Then we have the Christoffel-Darboux type formula:

$$
K_{\underline{k}}(x, y)=\frac{N_{\underline{k}}(x, y)}{\sigma(x)-\sigma(y)} .
$$

Proof. Since $\sigma(x)-\sigma(y)=\sum_{t=1}^{m} x_{t}-\sum_{t=1}^{m} y_{t}=\sum_{t=1}^{m}\left(x_{t}-y_{t}\right)$,

$$
\begin{aligned}
(\sigma(x)-\sigma(y)) & K_{\underline{k}}(x, y)=\left(\sum_{t=1}^{m}\left(x_{t}-y_{t}\right)\right) \prod_{j=1}^{m}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right) \\
& =\sum_{t=1}^{m}\left(\left(x_{t}-y_{t}\right) \sum_{i=0}^{k_{t}} d_{i} P_{i}\left(x_{t}\right) P_{i}\left(y_{t}\right)\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right)
\end{aligned}
$$

The Christoffel-Darboux formula for the polynomials $P_{k}$ gives:

$$
\left(x_{t}-y_{t}\right) \sum_{i=0}^{k_{t}} d_{i} P_{i}\left(x_{t}\right) P_{i}\left(y_{t}\right)=d_{k_{t}} a_{k_{t}} Q_{k_{t}}\left(x_{t}, y_{t}\right)
$$

with the notations of the proposition, hence the result.

Following the standard method, we apply Proposition 4.3 to the function

$$
\frac{N_{\underline{\underline{k}}}(x, y)^{2}}{\sigma(x)-\sigma(y)} .
$$

Proposition 4.5. Let $y=\left(y_{1}, \ldots, y_{m}\right) \in \mathbb{R}^{m}$ and $\underline{k} \in \mathbb{N}^{m}$, and define

$$
F(x):=\frac{N_{\underline{k}}(x, y)^{2}}{\sigma(x)-\sigma(y)}=(\sigma(x)-\sigma(y)) K_{\underline{\underline{k}}}(x, y)^{2}=K_{\underline{k}}(x, y) N_{\underline{k}}(x, y) .
$$

If $y$ satisfies the conditions:
(i) $P_{i}\left(y_{t}\right) \geq 0$ for all $0 \leq i \leq k_{t}$ and for all $1 \leq t \leq m$
(ii) $P_{k_{t}+1}\left(y_{t}\right) \leq 0$ for all $1 \leq t \leq m$
then $F$ satisfies the hypothesis of Proposition 4.3 for all $\theta$ such that $m t \leq$ $\sigma(y)$. Consequently, for any code $C$ in $X^{m}$ with minimum angular distance $\theta$,

$$
\begin{equation*}
|C| \leq \frac{\left(\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}}\left(P_{k_{t}}\left(y_{t}\right)-P_{k_{t}+1}\left(y_{t}\right)\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(y_{j}\right)\right)\right)^{2}}{-(m-\sigma(y)) \sum_{t=1}^{m} d_{k_{t}} a_{k_{t}} P_{k_{t}}\left(y_{t}\right) P_{k_{t}+1}\left(y_{t}\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i}\left(P_{i}\left(y_{j}\right)\right)^{2}\right)} . \tag{26}
\end{equation*}
$$

Proof. Clearly, under the assumptions (i) and (ii), $K_{\underline{k}}(x, y)$ and $N_{\underline{k}}(x, y)$ have non-negative coefficients on the $P_{l}$. This is enough to ensure that it is also the case for the product $K_{\underline{k}}(x, y) N_{\underline{k}}(x, y)$ (recall that the product of two polynomials with non-negative coefficients on the $P_{k}$ also has non-negative coefficients on the $P_{k}$. This property transfers straightforwardly to the $P_{\underline{k}}$; it is anyway general to any family of zonal polynomials).

Obviously the sign of $F(x)$ is the sign of $\sigma(x)-\sigma(y)$ so the conditions of Proposition 4.3 are fulfilled.

It remains to compute $f_{0}=[F, 1]$ and $F(1, \ldots, 1)$.

$$
\begin{aligned}
& {[F, 1]=[K, N]} \\
& =\left[\prod_{j=1}^{m}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right), \sum_{t=1}^{m} d_{k_{t}} a_{k_{t}} Q_{k_{t}}\left(x_{t}, y_{t}\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right)\right] \\
& =\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}}\left[\prod_{j=1}^{m}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right), Q_{k_{t}}\left(x_{t}, y_{t}\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right)\right] \\
& =\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}}\left[\sum_{i=0}^{k_{t}} d_{i} P_{i}\left(x_{t}\right) P_{i}\left(y_{t}\right), Q_{k_{t}}\left(x_{t}, y_{t}\right)\right] \\
& \cdot \prod_{j \neq t}\left[\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right), \sum_{i=0}^{k_{j}} d_{i} P_{i}\left(x_{j}\right) P_{i}\left(y_{j}\right)\right] \\
& =\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}}\left(-P_{k_{t}}\left(y_{t}\right) P_{k_{t}+1}\left(y_{t}\right)\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i}\left(P_{i}\left(y_{j}\right)\right)^{2}\right)
\end{aligned}
$$

where the last equality follows from (22).
Let us now compute $F(1, \ldots, 1)$. We have:

$$
F(1, \ldots, 1)=\frac{N_{\underline{k}}(\underline{1}, y)^{2}}{m-\sigma(y)}
$$

and

$$
N_{\underline{k}}(\underline{1}, y)=\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}}\left(P_{k_{t}}\left(y_{t}\right)-P_{k_{t}+1}\left(y_{t}\right)\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(y_{j}\right)\right) .
$$

Applying the resulting bound of Proposition 4.3 leads to the announced bound.

We proceed to choose the parameters $y$ and $\underline{k}$ such that the conditions of Proposition 4.5 will be satisfied. We follow the standard method. We first choose the multi-index $\underline{k}$ such that $m t \leq \sum_{t=1}^{m} z_{k_{t}}$, where $z_{k_{t}}$ is the largest zero of $P_{k_{t}}$. The interlacing property of the zeros of the orthogonal polynomials $P_{\underline{k}}$ guarantees that there exists $y$ such that $z_{k_{t}} \leq y_{t} \leq z_{k_{t}+1}$ and

$$
P_{k_{t}}\left(y_{t}\right)+P_{k_{t}+1}\left(y_{t}\right)=0
$$

for all $1 \leq t \leq m$. Thus, $P_{i}\left(y_{t}\right)>0$ and $P_{k_{t}+1}\left(y_{t}\right)<0$ for all $0 \leq i \leq k_{t}$ and $1 \leq t \leq m$.

Now we have:

$$
\begin{aligned}
f_{0}=[F, 1] & =\sum_{t=1}^{m} d_{k_{t}} a_{k_{t}}\left(P_{k_{t}}\left(y_{t}\right)\right)^{2} \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i}\left(P_{i}\left(y_{i}\right)\right)^{2}\right) \\
& =\sum_{t=1}^{m} a_{k_{t}} \sum_{\substack{\underline{l} \leq k \\
l_{t}=k_{t}}} d_{\underline{l}}\left(P_{\underline{l}}(y)\right)^{2}
\end{aligned}
$$

and

$$
\begin{aligned}
N_{\underline{k}}(\underline{1}, y) & =2 \sum_{t=1}^{m} d_{k_{t}} a_{k_{t}} P_{k_{t}}\left(y_{t}\right) \prod_{j \neq t}\left(\sum_{i=0}^{k_{j}} d_{i} P_{i}\left(y_{j}\right)\right) \\
& =2 \sum_{t=1}^{m} a_{k_{t}} \sum_{\substack{\underline{l} \leq k \\
l_{t}=k_{t}}} d_{\underline{l}} P_{\underline{l}}(y) .
\end{aligned}
$$

With Cauchy-Schwartz inequality (applied twice),

$$
\begin{aligned}
F(1, \ldots, 1) & =\frac{4}{(m-\sigma(y))}\left(\sum_{t=1}^{m} a_{k_{t}} \sum_{\substack{\underline{l} \leq \underline{k} \\
l_{t}=k_{t}}} d_{\underline{l}} P_{\underline{l}}(y)\right)^{2} \\
& \leq \frac{4}{(m-\sigma(y))}\left(\sum_{t=1}^{m} a_{k_{t}}\right)\left(\sum_{t=1}^{m} a_{k_{t}}\left(\sum_{\substack{\underline{l} \leq \underline{k} \\
l_{t}=k_{t}}} d_{\underline{l}} P_{\underline{l}}(y)\right)^{2}\right) \\
& \leq \frac{4}{(m-\sigma(y))}\left(\sum_{t=1}^{m} a_{k_{t}}\right)\left(\sum_{t=1}^{m} a_{k_{t}}\left(\sum_{\substack{\underline{l} \leq \underline{k} \\
l_{t}=k_{t}}} d_{\underline{l}}\right)\left(\sum_{\substack{\underline{l} \leq \underline{k} \\
l_{t}=k_{t}}} d_{\underline{l}}\left(P_{\underline{l}}(y)\right)^{2}\right)\right) \\
& \leq \frac{4}{(m-\sigma(y))}\left(\sum_{t=1}^{m} a_{k_{t}}\right)\left(\sum_{\underline{l} \leq \underline{k}} d_{\underline{l}}\right)\left(\sum_{t=1}^{m} a_{k_{t}} \sum_{\substack{\underline{l} \leq \underline{k} \\
l_{t}=k_{t}}} d_{\underline{l}}\left(P_{\underline{l}}(y)\right)^{2}\right) \\
& =\frac{4}{(m-\sigma(y))}\left(\sum_{t=1}^{m} a_{k_{t}}\right) \prod_{t=1}^{m}\left(\sum_{i=0}^{k_{t}} d_{i}\right) f_{0}
\end{aligned}
$$

Denote $D_{k_{t}}:=\sum_{i=0}^{k_{t}} d_{i}$. We obtain

$$
|C| \leq \frac{4\left(\sum_{t=1}^{m} a_{k_{t}}\right) \prod_{t=1}^{m} D_{k_{t}}}{m-\sigma(y)} .
$$

We summarize the above result in the following statement:
Proposition 4.6. For any code $C$ in $X^{m}$ with minimum angular distance $\theta$, for any multi-index $\underline{k}$ such that $m t \leq \sum_{t=1}^{m} z_{k_{t}}$, let $y_{t}$ satisfy $z_{k_{t}} \leq y_{t} \leq z_{k_{t}+1}$ and

$$
P_{k_{t}}\left(y_{t}\right)+P_{k_{t}+1}\left(y_{t}\right)=0,
$$

then

$$
\begin{equation*}
|C| \leq \frac{4\left(\sum_{t=1}^{m} a_{k_{t}}\right) \prod_{t=1}^{m} D_{k_{t}}}{m-\sigma(y)} \tag{27}
\end{equation*}
$$

Remark 4.7. Using the so-called adjacent polynomials instead of the Gegenbauer polynomials, an enhancement of (27) was derived for $m=1$ [5, 13]. It seems that this can be generalized for all $m$.
4.5. A bound for the asymptotic rate. Now we consider the limit when $n \rightarrow+\infty$ of the rate $R(C):=\frac{1}{n} \ln |C|$ (of course the space $\mathbb{P}^{2}(\mathbb{O})$ is not concerned anymore) of the codes $C$ of $X^{m}$. We derive an upper bound for this limit from (27). The next theorem settles the result obtained that way only in the case $X=\mathbb{P}^{n-1}(K)$ because this bound, in the case of $X=S^{n-1}$, turns out to be the same as the one obtained from the trivial isometric embedding $\left(S^{n-1}\right)^{m} \rightarrow S^{m n-1}$ (see Remark 4.9).
Theorem 4.8. Let $C$ be a code in $X^{m}, X=\mathbb{P}^{n-1}(K)$, with minimum angular distance $\theta$, and let $\left(\theta_{1}, \ldots, \theta_{m}\right) \in[0, \pi / 2]^{m}$ satisfy $\sum_{t=1}^{m} \cos ^{2} \theta_{t}=$ $m \cos ^{2} \theta$. Then, when $n \rightarrow \infty$,

$$
\begin{equation*}
R(C) \lesssim c\left(R_{L P}\left(\theta_{1}\right)+\ldots+R_{L P}\left(\theta_{m}\right)\right) \tag{28}
\end{equation*}
$$

where $R_{L P}$ is defined in (2.2).
Proof. Same as in [4], involving the asymptotic estimate of $z_{k}$. We reproduce it here: Consider an infinite sequence $k(n)$ such that $2 k(n) / c n$ tends to a finite limit $\rho$ as $n$ tends to infinity. Then [4]

$$
\lim _{n \rightarrow \infty} z_{k(n)}=4 \frac{\rho^{-1}+1}{\left(\rho^{-1}+2\right)^{2}}
$$

and, since from [5],

$$
D_{k} \simeq\binom{\frac{c}{2} n+k-1}{k}^{2}
$$

we have
$\lim _{n \rightarrow \infty} \frac{1}{n} \ln D_{k(n)}=\lim _{n \rightarrow \infty} \frac{2}{n} \ln \binom{\frac{c}{2} n+k(n)-1}{k(n)}=c((1+\rho) \ln (1+\rho)-\rho \ln \rho)$.
Inverting the conditions

$$
\cos ^{2} \theta_{t}=4 \frac{\rho_{t}^{-1}+1}{\left(\rho_{t}^{-1}+2\right)^{2}}
$$

leads to

$$
\rho_{t}=\frac{1-\sin \theta_{t}}{2 \sin \theta_{t}}
$$

Let $k_{t}=\left\lfloor\rho_{t} n\right\rfloor$, and let $y_{t}$ satisfy $z_{k_{t}} \leq y_{t} \leq z_{k_{t}+1}$ and $P_{k_{t}}\left(y_{t}\right)+P_{k_{t}+1}\left(y_{t}\right)=$ 0 (the existence of $y_{t}$ is guaranteed by the interlacing property of the zeros of the Jacobi polynomials). Then from (27),

$$
|C| \leq \frac{4\left(\sum_{t=1}^{m} a_{k_{t}}\right) \prod_{t=1}^{m} D_{k_{t}}}{m-\sigma(y)}
$$

Since $\sigma(y) \simeq m \cos ^{2} \theta$ and the expression $\frac{4 \sum_{t=1}^{m} a_{k t}}{m-\sigma(y)}$ has a finite limit when $k_{t} / n$ tends to $\rho_{t}$, the rate $R(C)$ satisfies

$$
R(C) \lesssim \frac{1}{n} \sum_{t=1}^{m} \ln D_{k_{t}} \simeq \sum_{t=1}^{m} c\left(\left(1+\rho_{t}\right) \ln \left(1+\rho_{t}\right)-\rho_{t} \ln \left(\rho_{t}\right)\right)
$$

Remark 4.9. - It is worth noticing that the choice $\theta_{t}=\theta$ in (28) yields to the bound

$$
\begin{equation*}
R(C) \lesssim c m R_{L P}(\theta) \tag{29}
\end{equation*}
$$

This bound can be derived more easily, since every code in $X^{m}$ is also a code in the cmn-th dimensional unit sphere (combining the mapping $\beta$ for $m=1$ and the obvious mapping $\left.\left(S^{n-1}\right)^{m} \rightarrow S^{m n-1}\right)$. It turns out that, since the function $R_{L P}(\theta)$ as a function of $t=$ $\cos ^{2} \theta$ is not convex, the bound (28) slightly improves on (29). We discuss this in more details in the next subsection.

- The same method applied to $X=S^{n-1}$ would lead to:
$R(C) \lesssim R_{L P}\left(\theta_{1}\right)+\ldots+R_{L P}\left(\theta_{m}\right)$, for all $\theta_{t}$ such that $\sum_{t=1}^{m} \cos \theta_{t}=m \cos \theta$.
But the function $R_{L P}(\theta)$ as a function of $t=\cos \theta$ is convex, therefore the choice of $\left(\theta_{1}, \ldots, \theta_{m}\right)$ that minimizes the right hand side is $\theta_{1}=\cdots=\theta_{m}=\theta$, yielding (29).
4.6. Analysis of (28) versus (29). Let $C^{2}$ be the set of continuous, twice differentiable functions with continuous second derivative. For a function $f$ defined on $\left[0,1\left[\right.\right.$, of class $C^{2}$, we denote:

$$
f^{(m)}(t):=\min _{\substack{t_{1}, \ldots, t_{m} \in\left[0,1\left[ \\\sum_{i=1}^{m} t_{i}=m t\right.\right.}} \frac{f\left(t_{1}\right)+\cdots+f\left(t_{m}\right)}{m} .
$$

Clearly, if $f$ is convex on $\left[0,1\left[\right.\right.$, we have $f^{(m)}=f$, and, if $f \leq g, f^{(m)} \leq g^{(m)}$. It is also easy to see that $f^{\left(m^{\prime}\right)} \leq f^{(m)}$ when $m$ divides $m^{\prime}$.

The function we are interested in is $f(t)=R_{L P}(\theta)$ where $t=\cos ^{2} \theta$. We have

$$
f(t)=(1+\rho(t)) \ln (1+\rho(t))-\rho(t) \ln (\rho(t))
$$

where

$$
\rho(t)=\frac{1}{2}\left(-1+(1-t)^{-1 / 2}\right) .
$$

One can check that the second derivative of $f$ takes negative values on some interval $\left[0, t_{0}\right], t_{0} \simeq 0.208$, and then takes positive values on $\left[t_{0}, 1[\right.$. The function $f$ is an increasing function, with $f(0)=0$, first concave then convex. We consider the function $g$ on $\left[0,1\left[\right.\right.$, whose graph $\mathcal{C}_{g}$ determines the
convex hull of the portion of plane above the graph $\mathcal{C}_{f}$ of $f$. The function $g$ is uniquely determined by the conditions:

$$
\left\{\begin{array}{l}
g \leq f \\
g \text { is convex } \\
g \text { is maximal with these properties }
\end{array}\right.
$$

Let us denote by $t_{1}$ the unique value for which the tangent at $\left(t_{1}, f\left(t_{1}\right)\right)$ to $\mathcal{C}_{f}$ contains the origin $(0,0)$. The value $t_{1} \simeq 0.379$ is the unique solution to

$$
f(t)=f^{\prime}(t) t
$$

and the slope of the tangent to $\mathcal{C}_{f}$ at $t_{1}$ equals $f^{\prime}\left(t_{1}\right) \simeq 1.089$. Then the function $g$ is defined by:

$$
\begin{cases}g(t)=f^{\prime}\left(t_{1}\right) t \simeq 1.089 t & \text { for all } t \in\left[0, t_{1}\right] \\ g(t)=f(t) & \text { for all } t \in\left[t_{1}, 1[ \right.\end{cases}
$$

Since $g$ is convex, we have for all $m$ and all $t \in\left[0,1\left[, g^{(m)}(t)=g(t) \leq f^{(m)}(t)\right.\right.$. In other words, on $\left[0, t_{1}\right], f^{(m)}$ is somewhere between $g$ and $f$, and on $\left[t_{1}, 1[\right.$, $f^{(m)}=f$. Clearly, when $m \rightarrow+\infty, f^{(m)} \rightarrow g$. Also, the maximum $\delta$ of $f(t)-g(t)$ is an upper bound for the maximum of $f(t)-f^{(m)}(t)$. Numerical calculation gives $\delta \simeq 0.016$. Considering our primary goal, i.e., to compare (28) and (29), this means that the improvement of (29) upon (28) is upperbounded by 0.016 m .

It seems difficult to determine the optimal choice of $\left(t_{1}, \ldots, t_{m}\right)$ that minimizes the quotient $\frac{f\left(t_{1}\right)+\cdots+f\left(t_{m}\right)}{m}$. A natural choice is $\left(t_{1}, \ldots, t_{m}\right)=$ $(0,0, . ., m t / r, \ldots, m t / r)$ with $r$ non-zero and equal coordinates. In that case, $\frac{f\left(t_{1}\right)+\cdots+f\left(t_{m}\right)}{m}=\frac{r}{m} f\left(\frac{m t}{r}\right)$ and requires $t<r / m$. If $t=\frac{r t_{1}}{m}$, it is certainly the best choice since then the resulting point lies on $\mathcal{C}_{g}$. Numerical experiments seem to show that, for $m=2,3$, and $t<1 / m, r=1$ does minimize the quotient $\frac{f\left(t_{1}\right)+\cdots+f\left(t_{m}\right)}{m}$.

## 5. Bounds for codes in the Grassmann and Stiefel manifolds

In this section, we summarize the consequences of the above results for Grassmann and Stiefel codes. Following a standard notation in coding theory, we denote by $A(X, d)$, the maximal number of elements of a code $C$ of the space $X$ with minimum distance $d$.

We have proved in the section 3.3 that the size of Grassmannian codes with minimal chordal distance $d=\sqrt{m-s}$ is upper bounded by the size of codes in $\mathbb{P}^{n-1}(K)^{m}$ with minimal angular distance $\theta$, where $\cos ^{2} \theta=s / m$. Thus we have proved that:

$$
\begin{equation*}
A\left(\mathcal{G}_{m, n}(K), d\right) \leq A\left(\mathbb{P}^{n-1}(K)^{m}, \theta\right) \text { with } \theta=\arccos \sqrt{1-d^{2} / m} \tag{30}
\end{equation*}
$$

Linear programming bounds on $A\left(\mathbb{P}^{n-1}(K)^{m}, \theta\right)$ were derived in Section 4
We believe that these bounds are not good in general for finite values of the parameters, because we use only a rough estimate of $\sigma(p, q)=$ $\operatorname{trace}\left(\pi_{p} \circ \pi_{q}\right)$ in the inequality (18) (we replace $\sum_{1 \leq i, j \leq m}\left(e_{i} \cdot e_{j}^{\prime}\right)^{2}$ with
$\left.\sum_{1 \leq i \leq m}\left(e_{i} \cdot e_{i}^{\prime}\right)^{2}\right)$. If we compare the bounds obtained with the zonal polynomials of small degree, (25) is worse than the simplex bound, obtained from the zonal polynomial of degree 1 of $\mathcal{G}_{m, n}(\mathbb{R})$. Moreover, numerical experiments for small parameters $m$ and $n$ (with the package LRS, by David Avis, http://cgm.cs.mcgill.ca/~avis/C/lrs.html), confirms that the bounds obtained from the zonal polynomials of $\mathcal{G}_{m, n}(\mathbb{R})$ are sharper than the ones obtained from Proposition 4.3 for $X=\mathbb{P}^{n-1}(\mathbb{R})^{m}$.

Surprisingly, the consideration of $\mathbb{P}^{n-1}(K)^{m}$ allows us to obtain better bounds for the asymptotic rate than the ones obtained previously by either the isometric embedding given in [21] of $\mathcal{G}_{m, n}$ into a unit sphere of the dimension $(n-1)(n+2) / 2$ (see also Remark (3.3), or the spectral method developed in [6] with the zonal polynomials of $\mathcal{G}_{m, n}$. We summarize the new bound we have obtained in the next theorem:

Theorem 5.1. Let $C$ be a code in $\mathcal{G}_{m, n}(K)$ with minimal chordal distance $d=\sqrt{m-s}$, and let $\theta=\arccos (\sqrt{s / m})$. Then, when $n \rightarrow+\infty$,

$$
\begin{equation*}
R(C) \lesssim \min \left\{R_{1}(d), R_{2}(d)\right\}, \tag{31}
\end{equation*}
$$

where

$$
\begin{equation*}
R_{1}(d)=\min _{\substack{\left(\theta_{1}, \ldots, \theta_{m}\right) \in[0, \pi / 2]^{m} \\ \sum_{i=1}^{m} \cos ^{2} \theta_{i}=m \cos ^{2} \theta}} c\left(R_{L P}\left(\theta_{1}\right)+\cdots+R_{L P}\left(\theta_{m}\right)\right) \tag{32}
\end{equation*}
$$

and

$$
\begin{equation*}
R_{2}(d)=c m R_{S}(\theta) . \tag{33}
\end{equation*}
$$

The bounds $R_{1}(d)$ and $R_{2}(d)$ are depicted in Figure 2
We have proved in Section 3.3 that the size of Stiefel codes with minimal chordal distance $d=\sqrt{2} \sqrt{m-s}$ is upper-bounded by the size of codes in $\left(S^{c n-1}\right)^{m}$ with minimal angular distance $\theta$, where $\cos \theta=s / m$. In Section 4 we derived linear programming bounds for codes in $\left(S^{c n-1}\right)^{m}$, thus implying bounds for Stiefel codes. These bounds are, up to our knowledge, the first general bounds for Stiefel codes, and we believe that they are rather sharp. For the asymptotic rate, the best result is obtained in (20). We summarize these results in the following theorem:
Theorem 5.2. With the previous notations, and $\theta=\arccos \left(1-d^{2} / 2 m\right)$,
(i) $A\left(\mathcal{V}_{m, n}(K), d\right) \leq A\left(\left(S^{c n-1}\right)^{m}, \theta\right)$
(ii) When $n \rightarrow+\infty, R(C) \lesssim c m R_{S}(\theta)$

## 6. Conclusions

Using relations between Grassmann and Stiefel manifolds and other spaces, we derive new bounds on the size of Grassmannian codes (Theorem 5.1) and Stiefel codes (Theorem 5.2). These are the best known asymptotic bounds on the rate of Grassmannian and Stiefel codes.

Figure 2. Upper bounds on the asymptotic rate of real Grassmannian codes with minimum chordal distance $d, m=$ 3. The solid line is $R_{1}(d)$, and the dashed line is $R_{2}(d)$ (see Theorem (3.2)

## Acknowledgement

We thank Jean Creignou for helpful discussions about spherical and Grassmannian codes.
