# A uniform approach to constraint-solving for lists, multisets, compact lists, and sets 

Agostino Dovier* Carla Piazza* Gianfranco Rossi ${ }^{\dagger}$

June 1, 2018

#### Abstract

Lists, multisets, and sets are well-known data structures whose usefulness is widely recognized in various areas of Computer Science. These data structures have been analyzed from an axiomatic point of view with a parametric approach in [11] where the relevant unification algorithms have been developed. In this paper we extend these results considering more general constraints including not only equality but also membership constraints as well as their negative counterparts.

Keywords: Membership and Equality Constraints, Lists, Multisets, Compact Lists, Sets.

## 1 Introduction

Programming and specification languages usually allow the user to represent various forms of aggregates of data objects, characterized by the way elements are organized and accessed. In this paper we consider four different kinds of aggregates: lists, multisets, compact lists, and sets. The basic difference between them lies in the order and/or repetitions of their data objects.

Importance of these forms of aggregates is widely recognized in various areas of Computer Science. Lists are the classical example used to introduce dynamic data structures in imperative programming languages. They are the fundamental data structure in functional and logic languages. Sets are the main data structure used in specification languages (e.g., in Z [21) and in high-level declarative programming languages (4) 12, 16, 18; but also imperative programming languages may take advantage from the set data abstraction (e.g., SETL [22]). Multisets, often called bags in the literature, emerge as the most natural data structure in several interesting applications (3) (25). A compact list is a list in which contiguous occurrences of the same element are immaterial; some possible application examples are suggested in 11.

The lattice of the four aggregates

Lists, multisets, compact lists, and sets have been analyzed from an axiomatic point of view and studied in the context of (Constraint) Logic Programming (CLP) languages [11-see figure on the left for a lattice induced by their axiomatizations. In this context, these aggregates are conveniently represented as terms, using different constructors.
The theories studied deal with aggregate constructor symbols as well as with an arbitrary number of free constant and function symbols. (11 focuses on equality between terms in each of the four theories. This amounts to solve the unification problems in the equational theories describing the properties of the four considered aggregates. Unification algorithms for all of

[^0]them are provided in [11; NP-unification algorithms for sets and multisets are also presented in (1) 8]. In Section 3 and 5.1] we recall the main results of [11.

In this paper we extend the results of [11 to the case of more general constraints. The constraints we consider are conjunctions of literals based on both equality and membership predicate symbols. For the case of sets, the problem is studied in [13, 14]. In Section 4 we define the notion of constraints and we identify the privileged models for the axiomatic theories used to describe the considered aggregates. We show that satisfiability of constraints in those models is equivalent to satisfiability in any model. We then define the notion of solved form for constraints, and we prove that solved form constraints are satisfiable over the proposed privileged models. In Section 5e describe, for each kind of aggregate, the constraint rewriting procedures used to eliminate all atomic constraints not in solved form. We use these procedures in Section 6 to solve the general satisfiability problem for the considered constraints. Some conclusions are drawn in Section 7 Throughout the paper the word aggregate is used for denoting generically one of the four considered aggregates, namely lists, multisets, compact lists, and sets.

## 2 Preliminary Notions

Basic knowledge of first-order logic (e.g., [5, 15]) is assumed; in this section we recall some notions and we fix some notations that we will use throughout the paper.

A first-order language $\mathcal{L}=\langle\Sigma, \mathcal{V}\rangle$ is defined by a signature $\Sigma=\langle\mathcal{F}, \Pi\rangle$ composed by a set $\mathcal{F}$ of constant and function symbols, by a set $\Pi$ of predicate symbols, and by a denumerable set $\mathcal{V}$ of variables. A (first-order) theory $\mathcal{T}$ on a language $\mathcal{L}$ is a set of closed first-order formulas of $\mathcal{L}$ such that each closed formula of $\mathcal{L}$ which can be deduced from $\mathcal{T}$ is in $\mathcal{T}$. A (first-order) set of axioms $\Theta$ on $\mathcal{L}$ is a set of closed first-order formulas of $\mathcal{L}$. A set of axioms $\Theta$ is said to be an axiomatization of $\mathcal{T}$ if $\mathcal{T}$ is the smallest theory such that $\Theta \subseteq \mathcal{T}$. Sometimes we use the term theory also to refer to an axiomatization of the theory. When $\Theta=\left\{\varphi_{1}, \ldots, \varphi_{n}\right\}$, and $A_{1}, \ldots, A_{n}$ are the names of the formulas $\varphi_{1}, \ldots, \varphi_{n}$, we refer to that theory simply as: $A_{1} \cdots A_{n}$.

Capital letters $X, Y, Z$, etc. are used to represent variables, $f, g$, etc. to represent constant and function symbols, and $p, q$, etc. to represent predicate symbols. We also use $\bar{X}$ to denote a (possibly empty) sequence of variables. $T(\mathcal{F}, \mathcal{V})(T(\mathcal{F}))$ denotes the set of first-order terms (resp., ground terms) built from $\mathcal{F}$ and $\mathcal{V}$ (resp., $\mathcal{F}$ ). The function size $: T(\mathcal{F}, \mathcal{V}) \longrightarrow \mathbb{N}$ returns the number of occurrences of constant and function symbols in a term. Given a term $t$, with $F V(t)$ we denote the set of all variables which occur in the term $t$. Given a sequence of terms $t_{1}, \ldots, t_{n}, F V\left(t_{1}, \ldots, t_{n}\right)$ is the set $\bigcup_{i=1}^{n} F V\left(t_{i}\right)$. When the context is clear, we use $\bar{t}$ to denote a sequence $t_{1}, \ldots, t_{n}$ of terms. If $\varphi$ is a first-order formula, $F V(\varphi)$ denotes the set of free variables in $\varphi$. $\exists \varphi(\forall \varphi)$ is used to denote the existential (universal) closure of the formula $\varphi$, namely $\exists X_{1} \cdots \exists X_{n} \varphi\left(\forall X_{1} \cdots \forall X_{n} \varphi\right)$, where $\left\{X_{1}, \ldots, X_{n}\right\}=F V(\varphi)$. An equational axiom is a formula of the form $\forall X_{1} \cdots \forall X_{n}(\ell=r)$ where $F V(\ell=r)=\left\{X_{1}, \ldots, X_{n}\right\}$. An equational theory is an axiomatization whose axioms are equational axioms.

Given a first-order theory $\mathcal{L}=\langle\Sigma, \mathcal{V}\rangle$, a $\Sigma$-structure is a pair $\mathcal{A}=\langle A, I\rangle$ where $A$ is a non-empty set (the domain) and $I$ is the interpretation function of all constant, function, and predicate symbols of $\Sigma$ on $A$. A valuation $\sigma$ is a function from a subset of the set of variables $\mathcal{V}$ to $A$. $\sigma$ and $I$ determine uniquely a function $\sigma^{I}$ from the set of first-order terms over $\mathcal{L}$ to $A$ and a function from the set of formulas over $\mathcal{L}$ to the set $\{$ false, true $\}$. When the $\Sigma$-structure is fixed, $\sigma^{I}$ depends only by $\sigma$. Thus, with abuse of notation, $\sigma^{I}$ is simply written as $\sigma$. Given a $\Sigma$-structure $\mathcal{A}$, a valuation $\sigma$ is said a successful valuation of $\varphi$ if $\sigma(\varphi)=$ true. This fact is also denoted by: $\mathcal{A} \models \sigma^{I}(\varphi)$. A formula $\varphi$ is satisfiable in $\mathcal{A}$ if there is a valuation $\sigma: F V(\varphi) \longrightarrow A$ such that $\mathcal{A} \models \sigma(\varphi)$. In this case we say that $\mathcal{A} \models \exists \varphi$. We say that $\mathcal{A} \models \varphi$ if for every valuation $\sigma$ from $F V(\varphi) \longrightarrow A$ it holds that $\mathcal{A} \models \sigma(\varphi)$. A formula $\varphi$ is satisfiable in $\mathcal{A}$ if there is a valuation $\sigma: F V(\varphi) \longrightarrow A$ such that $\mathcal{A} \models \sigma(\varphi)$. In this case we say that $\mathcal{A} \vDash \exists \varphi$. We remind that a formula is satisfiable in a $\Sigma$-structure $\mathcal{A}$ if and only if its existential closure is satisfiable in $\mathcal{A}$. Two formulas $C_{1}$ and $C_{2}$ are equi-satisfiable in $\mathcal{A}$ if: $C_{1}$ is satisfiable in $\mathcal{A}$ if and only if
$C_{2}$ is satisfiable in $\mathcal{A}$. A structure $\mathcal{A}$ is a model of a theory $\mathcal{T}$ if $\mathcal{A} \models \varphi$ for all $\varphi$ in $\mathcal{T}$. We say that $\mathcal{T} \models \varphi$ if $\mathcal{A} \models \varphi$ for all models $\mathcal{A}$ of $\mathcal{T}$.

## 3 The Theories

For each aggregate considered, we assume that $\Pi$ is $\{=, \in\}$ and $\mathcal{F}$ contains the constant symbol nil and exactly one among the binary function symbols:

$$
\begin{array}{lll}
{[\cdot \mid \cdot]} & \text { for lists, } & \{\cdot \mid \cdot \rrbracket \\
\llbracket \cdot \mid \cdot \rrbracket & \text { for compact lists, multisets, } & \{\cdot \mid \cdot\}
\end{array} \text { for sets, }
$$

Moreover, each signature can contain an arbitrary number of other constant and function symbols. The four function symbols above are referred as the aggregate constructors. The empty list, multiset, compact list, and set are all denoted by the constant symbol nil. We use simple syntactic notations for terms built using these symbols. In particular, the list [ $s_{1} \mid\left[s_{2} \mid \cdots\left[s_{n} \mid t\right] \cdots\right]$ ] will be denoted by $\left[s_{1}, \ldots, s_{n} \mid t\right]$ or simply by $\left[s_{1}, \ldots, s_{n}\right]$ when $t$ is nil. The same conventions will be exploited also for the other aggregates.

### 3.1 Lists

The language $\mathcal{L}_{\text {List }}$ is defined as $\left\langle\Sigma_{\text {List }}, \mathcal{V}\right\rangle$, where $\Sigma_{\text {List }}=\left\langle\mathcal{F}_{\text {List }}, \Pi\right\rangle,[\cdot \mid \cdot]$ and nil are in $\mathcal{F}_{\text {List }}$, and $\Pi=\{=, \in\}$. We recall that $\mathcal{F}_{\text {List }}$ can contain other constant and function symbols. The first-order theory List for lists is shown in the figure below.

| $(K)$ | $\forall x y_{1} \cdots y_{n}$ | $\left(x \notin f\left(y_{1}, \ldots, y_{n}\right)\right)$ | $f \in \mathcal{F}_{\text {List }}, f$ is not $[\cdot \mid \cdot]$ |
| :---: | ---: | :---: | :---: |
| $(W)$ | $\forall y v x$ | $(x \in[y \mid v] \leftrightarrow x \in v \vee x=y)$ |  |
| $\left(F_{1}\right)$ | $\forall x_{1} \cdots x_{n} y_{1} \cdots y_{n}$ | $\binom{f\left(x_{1}, \ldots, x_{n}\right)=f\left(y_{1}, \ldots, y_{n}\right)}{\rightarrow x_{1}=y_{1} \wedge \cdots \wedge x_{n}=y_{n}}$ | $f \in \mathcal{F}_{\text {List }}$ |
| $\left(F_{2}\right)$ | $\forall x_{1} \cdots x_{m} y_{1} \cdots y_{n}$ | $f\left(x_{1}, \ldots, x_{m}\right) \neq g\left(y_{1}, \ldots, y_{m}\right)$ | $f, g \in \mathcal{F}_{\text {List }}, f$ is not $g$ |
| $\left(F_{3}\right)$ | $\forall x$ | $(x \neq t[x])$ |  |
|  | where $t[x]$ denotes a term $t$, having $x$ as proper subterm |  |  |

The three axiom schemata $\left(F_{1}\right),\left(F_{2}\right)$, and $\left(F_{3}\right)$ (called freeness axioms, or Clark's equality axioms - see [6]) have been originally introduced by Mal'cev in [20]. Observe that ( $F_{1}$ ) holds for $[\cdot \mid \cdot]$ as a particular case. $\left(F_{3}\right)$ states that there is no term which is also a subterm of itself. Note that $(K)$ implies that $\forall x(x \notin \mathrm{nil})$.

### 3.2 Multisets

The language $\mathcal{L}_{M S e t}$ is defined as $\left\langle\Sigma_{M S e t}, \mathcal{V}\right\rangle$, where $\Sigma_{M S e t}=\left\langle\mathcal{F}_{M S e t}, \Pi\right\rangle,\{[\cdot \mid \cdot\}$ and nil are in $\mathcal{F}_{M S e t}$, and $\Pi=\{=, \in\}$. A theory of multisets - called MSet - can be simply obtained from the theory of lists shown above. The constructor $[\cdot \mid \cdot]$ is replaced by the constructor $\{\cdot \mid \cdot]\}$ in axiom schema $(K)$ and axiom $(W)$. The behavior of this new symbol is regulated by the following equational axiom

$$
\begin{array}{|lll|}
\hline\left(E_{p}^{m}\right) \quad \forall x y z\{x, y \mid z\}=\{y, x \mid z\} & \text { (permutativity) } \\
\hline
\end{array}
$$

which, intuitively, states that the order of elements in a multiset is immaterial. Axiom schema $\left(F_{1}\right)$ does not hold for multisets, when $f$ is $\{\cdot \mid \cdot\}$. It is replaced by axiom schemata $\left(F_{1}^{m}\right)$ :

$$
\begin{gathered}
\left.\begin{array}{c}
\left.\forall F_{1}^{m}\right) \quad \forall x_{1} \cdots x_{n} y_{1} \cdots y_{n}
\end{array} \begin{array}{c}
f\left(x_{1}, \ldots, x_{n}\right)=f\left(y_{1}, \ldots, y_{n}\right) \\
\rightarrow x_{1}=y_{1} \wedge \cdots \wedge x_{n}=y_{n}
\end{array}\right) \\
\text { for any } f \in \mathcal{F}_{M S e t}, f \text { distinct from }\{\cdot \mid \cdot\}
\end{gathered}
$$

In the theory $K W E_{p}^{m} F_{1}^{m} F_{2} F_{3}$, however, we lack in a general criterion for establishing equality and disequality between multisets. To obtain it, the following multiset extensionality property is introduced: Two multisets are equal if and only if they have the same number of occurrences of each element, regardless of their order. The axiom proposed in [11] to force this property is the following:
$\left(E_{k}^{m}\right) \quad \forall y_{1} y_{2} v_{1} v_{2}\left(\begin{array}{r}\left.\left\{y_{1} \mid v_{1}\right\}\right\}=\left\{y_{2} \mid v_{2}\right\} \\ \left(y_{1}=y_{2} \wedge v_{1}=v_{2}\right) \vee \\ \exists z\left(v_{1}=\left\{y_{2} \mid z\right\} \wedge v_{2}=\left\{y_{1} \mid z\right\}\right)\end{array}\right)$.
$\left(E_{k}^{m}\right)$ implies $\left(E_{p}^{m}\right)$. Axiom schema $\left(F_{3}^{m}\right)$ is also introduced:

$$
\left(F_{3}^{m}\right) \quad \forall x_{1} \cdots x_{m} y_{1} \cdots y_{n} x \quad\binom{\left\{x_{1}, \ldots, x_{m} \mid x\right\}=\left\{y_{1}, \ldots, y_{n} \mid x\right\}}{\rightarrow\left\{x_{1}, \ldots, x_{m}\right\}=\left\{y_{1}, \ldots, y_{n}\right\}}
$$

Axiom schema $\left(F_{3}^{m}\right)$ reinforces the acyclicity condition imposed by standard axiom schema $\left(F_{3}\right)$. As a matter of fact, $X \neq\{a, b, b \mid X\}$ follows from $\left(F_{3}\right)$. Axiom schema $\left(F_{3}^{m}\right)$ states that, since $\{a, a, b\} \neq\{a, b, b\}$, then $\{a, a, b \mid X\} \neq\{a, b, b \mid X\}$. This property is not a consequence of the the remaining part of the theory.

### 3.3 Compact Lists

The language $\mathcal{L}_{\text {CList }}$ is defined as $\mathcal{L}_{\text {CList }}=\left\langle\Sigma_{\text {CList }}, \mathcal{V}\right\rangle$, where $\Sigma_{\text {CList }}=\left\langle\mathcal{F}_{\text {CList }}, \Pi\right\rangle, \llbracket \cdot \mid \cdot \rrbracket$ and nil are in $\mathcal{F}_{\text {CList }}$, and $\Pi=\{=, \in\}$. Similarly to multisets, the theory of compact lists-called CList - is obtained from the theory of lists with only a few changes. The list constructor symbol is replaced by the binary compact list constructor $\llbracket \cdot \mid \cdot \rrbracket$ in $(K)$ and $(W)$. The behavior of this symbol is regulated by the equational axiom

$$
\left(E_{a}^{c}\right) \quad \forall x y \llbracket x, x|y \rrbracket=\llbracket x| y \rrbracket \quad \text { (absorption) }
$$

which, intuitively, states that contiguous duplicates in a compact list are immaterial. As for multisets, we introduce a general criterion for establishing both equality and disequality between compact lists. This is obtained by introducing the following axiom:

$$
\left(E_{k}^{c}\right) \quad \forall y_{1} y_{2} v_{1} v_{2}\left(\begin{array}{rl}
\llbracket y_{1} \mid v_{1} \rrbracket & =\llbracket y_{2} \mid v_{2} \rrbracket \leftrightarrow \\
& \left(y_{1}=y_{2} \wedge v_{1}=v_{2}\right) \vee \\
& \left(y_{1}=y_{2} \wedge v_{1}=\llbracket y_{2} \mid v_{2} \rrbracket\right) \vee \\
& \left(y_{1}=y_{2} \wedge \llbracket y_{1} \mid v_{1} \rrbracket=v_{2}\right)
\end{array}\right)
$$

$\left(E_{a}^{c}\right)$ is implied by $\left(E_{k}^{c}\right)$. Axiom schema $\left(F_{1}\right)$ is replaced by axiom schema $\left(F_{1}^{c}\right)$ :

$$
\begin{array}{|c}
\left(F_{1}^{c}\right) \quad \forall x_{1} \cdots x_{n} y_{1} \cdots y_{n}
\end{array} \quad\binom{f\left(x_{1}, \ldots, x_{n}\right)=f\left(y_{1}, \ldots, y_{n}\right)}{\rightarrow x_{1}=y_{1} \wedge \cdots \wedge x_{n}=y_{n}}, ~\left(\begin{array}{l}
\text { for any } f \in \mathcal{F}_{\text {CList }}, f \text { distinct from } \llbracket \cdot \mid \cdot \rrbracket
\end{array}\right.
$$

The freeness axiom $\left(F_{3}\right)$ needs to be suitably modified. The introduction of $\left(F_{3}\right)$ is motivated by the requirement of finding solutions to equality constraints over $\Sigma$-structures with the domain built based on Herbrand Universe, where each term is modeled by a finite tree. As opposed to lists and multisets, an equation such as $X=\llbracket \mathrm{nil} \mid X \rrbracket$ admits a solution in these structures. Precisely, a solution that binds $X$ to the term $\llbracket n i l \mid t \rrbracket$, where $t$ is any term. Therefore, as explained in [11, axiom schema $\left(F_{3}\right)$ should be weakened and, thus, replaced by:

$$
\begin{aligned}
& \left(F_{3}^{c}\right) \quad \forall x \quad(x \neq t[x]) \\
& \text { unless: } t \text { is of the form } \llbracket t_{1}, \ldots, t_{n} \mid x \rrbracket \text {, with } n>0 \text {, } \\
& x \notin F V\left(t_{1}, \ldots, t_{n}\right) \text {, and } t_{1}=\cdots=t_{n}
\end{aligned}
$$

| Name | empty | with | Equality |  | Herbrand | Acycl. | Perm. | Abs. | Equational Name |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| List | $(K)$ | $(W)$ | $\left(F_{1}\right)$ |  | $\left(F_{2}\right)$ | $\left(F_{3}\right)$ |  |  | $E_{\text {List }}$ |
| MSet | $(K)$ | $(W)$ | $\left(E_{k}^{m}\right)$ | $\left(F_{1}^{m}\right)$ | $\left(F_{2}\right)$ | $\left(F_{3}\right)$ | $\left(E_{p}^{m}\right)$ |  | $E_{\text {MSet }}$ |
| CList | $(K)$ | $(W)$ | $\left(E_{k}^{c}\right)$ | $\left(F_{1}^{c}\right)$ | $\left(F_{2}\right)$ | $\left(F_{3}^{c}\right)$ |  | $\left(E_{a}^{c}\right)$ | $E_{\text {CList }}$ |
| Set | $(K)$ | $(W)$ | $\left(E_{k}^{s}\right)$ | $\left(F_{1}^{s}\right)$ | $\left(F_{2}\right)$ | $\left(F_{3}^{s}\right)$ | $\left(E_{p}^{s}\right)$ | $\left(E_{a}^{s}\right)$ | $E_{\text {Set }}$ |

Figure 1: Axioms for the four theories

### 3.4 Sets

The language $\mathcal{L}_{S e t}$ is defined as $\mathcal{L}_{\text {Set }}=\left\langle\Sigma_{S e t}, \mathcal{V}\right\rangle$, where $\Sigma_{S e t}=\left\langle\mathcal{F}_{S e t}, \Pi\right\rangle,\{\cdot \mid \cdot\}$ and nil are in $\mathcal{F}_{\text {Set }}$, and $\Pi=\{=, \in\}$. The last theory we consider is the simple theory of sets Set. Sets have both the permutativity and the absorption properties which, in the case of $\{\cdot \mid \cdot\}$, can be rewritten as follows:

$$
\begin{array}{|lrl|}
\hline\left(E_{p}^{s}\right) & \forall x y z\{x, y \mid z\} & =\{y, x \mid z\} \\
\left(E_{a}^{s}\right) & \forall x y\{x, x \mid y\} & =\{x \mid y\} \\
\hline
\end{array}
$$

A criterion for testing equality (and disequality) between sets is obtained by merging the multiset equality axiom $\left(E_{k}^{m}\right)$ and the compact list equality axiom $\left(E_{k}^{c}\right)$ :

$$
\left(E_{k}^{s}\right) \quad \forall y_{1} y_{2} v_{1} v_{2}\left(\begin{array}{r}
\left\{y_{1} \mid v_{1}\right\}=\left\{y_{2} \mid v_{2}\right\} \\
\left(y_{1}=y_{2} \wedge v_{1}=v_{2}\right) \vee \\
\left(y_{1}=y_{2} \wedge v_{1}=\left\{y_{2} \mid v_{2}\right\}\right) \vee \\
\left(y_{1}=y_{2} \wedge\left\{y_{1} \mid v_{1}\right\}=v_{2}\right) \vee \\
\exists k\left(v_{1}=\left\{y_{2} \mid k\right\} \wedge v_{2}=\left\{y_{1} \mid k\right\}\right)
\end{array}\right)
$$

According to $\left(E_{k}^{s}\right)$ duplicates and ordering of elements in sets are immaterial. Thus, $\left(E_{k}^{s}\right)$ implies the equational axioms $\left(E_{p}^{s}\right)$ and $\left(E_{a}^{s}\right)$. In 11] it is also proved that they are equivalent when domains are made by terms. The theory Set also contains axioms $(K),(W)$ with $[\cdot \mid \cdot]$ replaced by $\{\cdot \mid \cdot\}$, and axiom schemata $\left(F_{2}\right)$ Axiom schema $\left(F_{1}\right)$ is replaced by:

$$
\begin{gathered}
\left(F_{1}^{s}\right) \quad \forall x_{1} \cdots x_{n} y_{1} \cdots y_{n} \quad\binom{f\left(x_{1}, \ldots, x_{n}\right)=f\left(y_{1}, \ldots, y_{n}\right)}{\rightarrow x_{1}=y_{1} \wedge \cdots \wedge x_{n}=y_{n}} \\
\text { for any } f \in \mathcal{F}_{\text {Set }}, f \text { distinct from }\{\cdot \mid \cdot\}
\end{gathered}
$$

The modification of axiom schema $\left(F_{3}\right)$ for sets, instead, simplifies the one used for compact lists:

$$
\begin{array}{rc}
\hline\left(F_{3}^{s}\right) & \forall x \quad(x \neq t[x]) \\
& \text { unless: } t \text { is of the form }\left\{t_{1}, \ldots, t_{n} \mid x\right\} \text { and } x \in F V\left(t_{1}, \ldots, t_{n}\right) \\
\hline
\end{array}
$$

### 3.5 Equational theories

As we have seen in this section, each aggregate constructor is precisely characterized by zero, one or 2 equational axioms. We define the four corresponding equational theories as follows:

| $E_{\text {List }}$ | the empty theory for List, |
| ---: | :--- |
| $E_{M S e t}$ | consisting of the Permutativity axiom $\left(E_{p}^{m}\right)$ for MSet, |
| $E_{\text {CList }}$ | consisting of the Absorption axiom $\left(E_{a}^{c}\right)$ for CList, |
| $E_{\text {Set }}$ | consisting of both the Permutativity $\left(E_{p}^{s}\right)$ and Absorption $\left(E_{a}^{s}\right)$ axioms for Set. |

Relationships between these equational theories, $\Sigma$-structures, and the proposed first-order theories for aggregates are explained in the next section. Figure 1 summarizes the axiomatizations of the four theories.

## 4 Constraints, Privileged Models, and Solved Form

In this section we introduce the privileged models for the four theories introduced in the previous section. These models are used to testing satisfiability of the particular kind of formulas we are concerned with, namely, constraints. We then show that the models and the theories defined in the previous section correspond on the class of constraints considered. Moreover, we give a general notion of solved form for constraints, and we prove that a solved form constraint is satisfiable in the corresponding privileged model.

Definition 4.1 (Constraints) Let $\mathbb{T}$ be either List or MSet or CList or Set. A $\mathbb{T}$-constraint $C_{\mathbb{T}}$ is a conjunction of atomic $\mathcal{L}_{\mathbb{T}}$-formulas or negation of atomic $\mathcal{L}_{\mathbb{T}}$-formulas of the form $s \pi t$, where $\pi \in \Pi$, and $s, t \in T\left(\mathcal{F}_{\mathbb{T}}, \mathcal{V}\right)$.

Throughout the paper we will use the following terminology to refer to particular kinds of constraints: equality (resp., disequality) constraints are conjunctions of atomic formulas of the form $s=t$ (resp., $s \neq t$ ). Membership (resp., not-membership) constraints are conjunctions of membership atoms (resp., membership negative literals), i.e. formulas of the kind $s \in t$ (resp., $s \notin t)$.

### 4.1 Privileged Models

As discussed in Section 3.5, each aggregate constructor is precisely characterized by an equational theory, that we have named $E_{L i s t}, E_{M S e t}, E_{C L i s t}$, and $E_{S e t}$. Using the appropriate equational theory we can define a privileged model for the first-order theory List, MSet, CList, and Set for each aggregate. Each model is obtained as a partition of the Herbrand Universe.
Definition 4.2 Let $\mathbb{T}$ be List (resp., MSet, CList, or Set). A privileged $\Sigma$-structure for $\mathbb{T}$ is defined as follows.

1. The domain of the $\Sigma$-structure is the quotient $T\left(\mathcal{F}_{\mathbb{T}}\right) / \equiv_{\mathbb{T}}$ of the Herbrand Universe $T\left(\mathcal{F}_{\mathbb{T}}\right)$ over the smallest congruence relation $\equiv_{\mathbb{T}}$ induced by the equational theory $E_{\mathbb{T}}$ on $T\left(\mathcal{F}_{\mathbb{T}}\right)$.
2. The interpretation of a term $t$ is its equivalence class w.r.t. $\equiv_{\mathbb{T}}$, denoted by $(t)$.
3. $=$ is interpreted as the identity on the domain $T\left(\mathcal{F}_{\mathbb{T}}\right) / \equiv_{\mathbb{T}}$.
4. The interpretation of membership is: $(t) \in(S)$ is true if and only if there is a term in $(s)$ of the form $\left[t_{1}, \ldots, t_{n}, t \mid r\right]$ (resp., $\left\{t_{1}, \ldots, t_{n}, t \mid r\right\}, \llbracket t_{1}, \ldots, t_{n}, t \mid r \rrbracket$, or $\left\{t_{1}, \ldots, t_{n}, t \mid r\right\}$ ) for some terms $t_{1}, \ldots, t_{n}, r$.

It is easy to prove that the above defined $\Sigma$-structures are in fact models of the corresponding theories. In Lemma A. 2 we prove this property for multisets. ¿From now on, we will call the privileged $\Sigma$-structures above defined privileged models for List, MSet, CList, and Set. We refer to them as $\mathcal{L I S T}, \mathcal{M S E T}, \mathcal{C} \mathcal{L I S T}$, and $\mathcal{S E T}$, respectively.

Remark 4.3 When (s) is the class of a multiset (resp., a set), since the permutativity property holds, the requirement for $(t) \in(s)$ to be true can be simplified to: $\{t \mid r\}$ (resp., $\{t \mid r\}$ ) is in (S).

The following notion from [19] is crucial for characterizing the above privileged models.
Definition 4.4 Given a first-order language $\mathcal{L}=\langle\Sigma, \mathcal{V}\rangle$, a set of first-order formulas $\mathcal{C}$ on $\mathcal{L}$, a theory $\mathcal{T}$ on $\mathcal{L}$, and a $\Sigma$-structure $\mathcal{A}, \mathcal{T}$ and $\mathcal{A}$ correspond on the set $\mathcal{C}$ if, for each $\varphi \in \mathcal{C}$, we have that $\mathcal{T} \models \exists \varphi$ if and only if $\mathcal{A} \models \exists \varphi$.

This property means that if $\varphi$ is an element of $\mathcal{C}$ and $\varphi$ is satisfiable in $\mathcal{A}$, then it is satisfiable in all the models of $\mathcal{T}$. We prove the correspondence property for our theories and the privileged models, when the class $\mathcal{C}$ is the class of constraints defined in Definition 4.1 We show below the proof of this result in the case of the model $\mathcal{M S E T}$ and the theory MSet. The other cases are similar. In the proof we use some basic results which can be found in the Appendix $\AA$ (Lemmas A.1 A.3).

Theorem 4.5 The model $\mathcal{M S E T}$ (resp., $\mathcal{L I S T}, \mathcal{C} \mathcal{L I S T}, \mathcal{S E T}$ ) and the theory MSet (resp., List, CList, and Set) correspond on the class of MSet- (resp., List-, CList-, and Set-)constraints.

Proof. From Lemma A. 2 it follows that $\mathcal{M S E}$ T is a model of $M S e t$, namely that if $C$ is a first-order formula and MSet $\models C$, then $\mathcal{M S E T} \models C$.

On the other hand, if $\exists C$ is a formula with only existential quantifiers, then $\mathcal{M S E T} \models \exists C$ if and only if there exists $\sigma$ such that $\mathcal{M S E T} \models \sigma(C)$. Assume that $\mathcal{M} \models \sigma(C)$. From Lemmas A. 1 and A. 3 we have that $\mathcal{M} \models \exists C$ for all models $\mathcal{M}$ of MSet. This implies that MSet $\models \exists C$.

### 4.2 Solved Form

Solved form constraints play a fundamental rôle in establishing satisfiability of constraints in the corresponding privileged model. The solved form is obtained by defining first a weaker form, called the pre-solved form, and then by adding to this form two further conditions.

Definition 4.6 $A$ constraint $C=c_{1} \wedge \cdots \wedge c_{n}$ is in pre-solved form if for $i \in\{1, \ldots, n\}, c_{i}$ is in pre-solved form in $C$, i.e. in one of the following forms:

- $X=t$ and $X$ does not occur elsewhere in $C$
- $t \in X$ and $X$ does not occur in $t$
- $X \neq t$ and $X$ does not occur in $t$
- $t \notin X$ and $X$ does not occur in $t$.

A constraint in pre-solved form is not guaranteed to be satisfiable in the corresponding privileged model. For example, the constraint $X \in Y \wedge Y \in X$ is in pre-solved form but it is unsatisfiable in each of the privileged models $\mathcal{L I S T}, \mathcal{M S E T}, \mathcal{C} \mathcal{L I S T}$, and $\mathcal{S E T}$. The first condition we introduce below takes care of this situation.

Definition 4.7 (Acyclicity Condition) Let $C$ be a pre-solved form constraint and $C^{\in}$ be the part of $C$ containing only membership constraints. Let $\mathcal{G}_{C}^{\in}$ be the directed graph obtained as follows:
Nodes. Associate a distinct node to each variable $X$ in $C^{\epsilon}$.
Edges. If $t \in X$ is in $C^{\in}, \nu_{1}, \ldots, \nu_{n}$ are the nodes associated with the variables in $t$, and $\mu$ is the node associated with the variable $X$, then add the edges $\left\langle\nu_{1}, \mu\right\rangle, \ldots,\left\langle\nu_{n}, \mu\right\rangle$.
We say that a pre-solved form constraint $C$ is acyclic if $\mathcal{G}_{C}^{\in}$ is acyclic.
The acyclicity condition is not sufficient for satisfiability. Consider the constraint $\{A, B\} \in$ $X \wedge\{B, A\} \notin X$. It is in pre-solved form and acyclic but unsatisfiable in all the considered privileged models. Conversely, the constraint $\{A\} \in X \wedge\{a\} \notin X$ is satisfiable in $\mathcal{S E} \mathcal{T}$ (e.g., $A=b, X=\{\{b\}\})$. We observe that whenever there are two constraints $t \in X$ and $t^{\prime} \notin X$ in $C$ such that $t$ and $t^{\prime}$ are equivalent terms in the equational theory $E_{\mathbb{T}}$, the constraint $C$ is unsatisfiable.

This analysis, however, does not cover all the possible cases in which an acyclic constraint in pre-solved form is unsatisfiable, as it ensues from the following example:

$$
a \in X \wedge X \in Y \wedge\{a \mid X\} \notin Y
$$

Observe that there are no pairs of terms $t, t^{\prime}$ of the form singled out above. Nevertheless, since the satisfiability of $a \in X$ is equivalent in Set to that of $X=\{a \mid N\}$ ( $N$ is a new variable), we have that the constraint is equi-satisfiable to:

$$
X=\{a \mid N\} \wedge\{a \mid N\} \in Y \wedge\{a, a \mid N\} \notin Y
$$

Now, $\{a \mid N\}$ and $\{a, a \mid N\}$ are equivalent terms in $E_{S e t}$, and thus the constraint is unsatisfiable.
To formally define the second condition for solved form constraints, taking into account all the possible cases informally described above, we introduce the following definitions.

Definition 4.8 Let $\theta \equiv\left[X_{1} / t_{1}, \ldots, X_{n} / t_{n}\right]$ be a substitution and $m \in \mathbb{N}$. We recursively define the substitution $\theta^{m}$ as:

$$
\left\{\begin{aligned}
\theta^{1} & =\theta \\
\theta^{m+1} & =\left[X_{1} / \theta^{m}\left(t_{1}\right), \ldots, X_{n} / \theta^{m}\left(t_{n}\right)\right] \quad m>0
\end{aligned}\right.
$$

If there exists $m>0$ such that $\theta^{m+1} \equiv \theta^{m}$ we say that $\theta$ is stabilizing. Given a stabilizing substitution $\theta$, the closure $\theta^{*}$ of $\theta$ is the substitution $\theta^{m}$ such that $\forall k>m$ we have that $\theta^{k} \equiv \theta^{m}$.
Definition 4.9 Let $C$ be a constraint in pre-solved form over the language $\mathcal{L}_{\text {List }}\left(\mathcal{L}_{\text {MSet }}, \mathcal{L}_{\text {CList }}, \mathcal{L}_{\text {Set }}\right)$ and let $t_{1}^{1} \in X_{1}, \ldots, t_{1}^{k_{1}} \in X_{1}, \ldots, t_{q}^{1} \in X_{q}, \ldots, t_{q}^{k_{q}} \in X_{q}$ be all membership atoms of $C$. We define the member substitution $\sigma_{C}$ as follows:

$$
\sigma_{C} \equiv\left[X_{1} /\left[F_{1}, t_{1}^{1}, \ldots, t_{1}^{k_{1}} \mid M_{1}\right], \ldots, X_{q} /\left[F_{q}, t_{q}^{1}, \ldots, t_{q}^{k_{q}} \mid M_{q}\right]\right]
$$

(respectively, $\sigma_{C} \equiv\left[X_{1} /\left\{F_{1}, t_{1}^{1}, \ldots, t_{1}^{k_{1}} \mid M_{1}\right\}, \ldots\right], \sigma_{C} \equiv\left[X_{1} / \llbracket F_{1}, t_{1}^{1}, \ldots, t_{1}^{k_{1}} \mid M_{1} \rrbracket, \ldots\right]$, $\left.\sigma_{C} \equiv\left[X_{1} /\left\{F_{1}, t_{1}^{1}, \ldots, t_{1}^{k_{1}} \mid M_{1}\right\}, \ldots\right]\right)$ where $F_{i}$ and $M_{i}$ are new variables not occurring in $C$.

The member substitution $\sigma_{C}$ forces all the terms $t_{i}^{j}$ 's to be member of the aggregate represented by $X_{i}$. The variable $F_{i}$ in $X_{i}$ is necessary in the case of compact lists. As a matter of fact, in every valuation $\sigma$ satisfying the constraint:

$$
Y \in X_{1} \wedge \llbracket Y \mid X_{1} \rrbracket \in X_{2} \wedge X_{1} \notin X_{2}
$$

it must be $\sigma\left(X_{1}\right) \neq \sigma\left(\llbracket Y \mid X_{1} \rrbracket\right)$. Thus, in $\sigma_{C}$ we give the possibility to the first element of $\sigma\left(X_{1}\right)$ to be different from $\sigma(Y)$. We show in the Appendix that if $C$ is a constraint in pre-solved form and acyclic, then $\sigma_{C}$ is stabilizing (Lemma A.4).

We are now ready to state the second condition for the solved form.
Definition 4.10 (Membership Consistency Condition) Let $E_{\mathbb{T}}$ be one of the four equational theories for aggregates. A constraint $C$ in pre-solved form and acyclic is membership consistent if for each pair of literals of the form $t \notin X, t^{\prime} \in X$ in $C$ we have that:

$$
E_{\mathbb{T}} \not \models \forall\left(\sigma_{C}^{*}(t)=\sigma_{C}^{*}\left(t^{\prime}\right)\right) .
$$

The definition of solved form, therefore, can be given simply as follows:
Definition 4.11 (Solved Form) A constraint $C$ in pre-solved form is said to be in solved form if it satisfies the membership consistent condition.

Observe that the membership consistency condition implies the acyclicity condition. It is a semantic requirement of equivalence of two terms under a given equational theory. However, this test can be automatized in the following way. As well-known from unification theory (see, e.g., [2, 23]), given an equational theory $E$, knowing whether two terms are equivalent modulo $\equiv_{E}$ is the same as verifying whether the two terms $t$ and $t^{\prime}$ are $E$-unifiable with empty m.g.u. $(\varepsilon)$. Thus, the test is connected with the availability of a unification algorithm for the theory $E_{\mathbb{T}}$. In [11 it is proved that the four equational theories we are dealing with are finitary (i.e., they admit a finite set of mgu's that covers all possible unifiers) and, moreover, the unification algorithms for the four theories are presented. This give us a decision procedure for the above test.

As an example, let $C$ be the pre-solved form and acyclic Set-constraint: $a \in Y \wedge Y \in X \wedge X \in$ $Z \wedge\{\{a \mid Y\} \mid X\} \notin Z$. It holds that:

$$
\begin{aligned}
\sigma_{C}= & {\left[Y /\left\{F_{Y}, a \mid M_{Y}\right\}, X /\left\{F_{X}, Y \mid M_{X}\right\}, Z /\left\{F_{Z}, X \mid M_{Z}\right\}\right], } \\
\sigma_{C}^{*}= & {\left[Y /\left\{F_{Y}, a \mid M_{Y}\right\}, X /\left\{F_{X},\left\{F_{Y}, a \mid M_{Y}\right\} \mid M_{X}\right\},\right.} \\
& \left.Z /\left\{F_{Z},\left\{F_{X},\left\{F_{Y}, a \mid M_{Y}\right\} \mid M_{X}\right\} \mid M_{Z}\right\}\right] \\
\sigma_{C}^{*}(X)= & \left\{F_{X},\left\{F_{Y}, a \mid M_{Y}\right\} \mid M_{X}\right\} \\
\sigma_{C}^{*}(\{\{a \mid Y\} \mid X\})= & \left\{\left\{a, F_{Y}, a \mid M_{Y}\right\}, F_{X},\left\{F_{Y}, a \mid M_{Y}\right\} \mid M_{X}\right\}
\end{aligned}
$$

The constraint is not in solved form since $E_{\text {Set }} \models \forall\left(\sigma_{C}^{*}(X)=\sigma_{C}^{*}(\{\{a \mid Y\} \mid X\})\right)$.
We prove now that solved form constraints are satisfiable in the corresponding privileged models. We prove the property for Set-constraints. The proof is similar for the other cases.

Theorem 4.12 (Satisfiability of the Solved Form) Let $C$ be a constraint in solved form over the language $\mathcal{L}_{\text {Set }}$ (resp., $\left.\mathcal{L}_{\text {List }}, \mathcal{L}_{M S e t}, \mathcal{L}_{\text {CList }}\right)$. Then $\mathcal{S E T} \models \exists C$ (resp., $\mathcal{L I S T}, \mathcal{M S E T}$, and $\mathcal{C} \mathcal{L I S T})$.

Proof. We split $C$ into the four parts: $C^{=}, C^{\in}, C^{\notin}$, and $C^{\neq}$, containing $=, \in, \notin$, and $\neq$ literals, respectively. For all pairs of literals $p \in V, r \notin V$ in $C$ let $N E Q_{p r}$ be an auxiliary variable, that will be used as a 'constraint store', initialized to the empty set $\emptyset$. We will use the two auxiliary functions rank and find. The rank of a well-founded set is basically the maximum nesting of braces needed to write it. Precisely:

$$
\operatorname{rank}(s)= \begin{cases}0 & \text { if } s \text { is not of the form }\{u \mid v\} \\ \max \{1+\operatorname{rank}(u), \operatorname{rank}(v)\} & \text { if } s \text { is }\{u \mid v\}\end{cases}
$$

find $(X, t)$ is a function that produces for each pair $(X, t)$ a set of integer numbers indicating the 'depth' of the occurrences of the variable $X$ in $t$. It can be defined as:
$\operatorname{find}(X, t)=\left\{\begin{array}{l}\emptyset \\ \{0\} \\ \{1+n: n \in \operatorname{find}(X, y)\} \\ \left\{1+n: n \in \operatorname{find}\left(X, t_{1}\right) \cup \cdots \cup \operatorname{find}\left(X, t_{m}\right)\right\} \\ \{1+n: n \in \operatorname{find}(X, y)\} \cup \operatorname{find}(X, s)\end{array}\right.$

> if $t$ is a constant term if $t$ is a variable $X$
> if $t$ is $\left\{y \mid f\left(t_{1}, \ldots, t_{m}\right)\right\}, f$ is not $\{\cdot \mid \cdot\}$
> if $t$ is $f\left(t_{1}, \ldots, t_{m}\right), f$ is not $\{\cdot \mid \cdot\}$
> if $t$ is $\{y \mid s\}, s \neq$ nil

We build a successful valuation $\gamma$ of $C$, in various steps.
$C^{=}$is of the form $X_{1}=t_{1} \wedge \cdots \wedge X_{m}=t_{m}$. We define the mapping: $\theta_{1}=\left[X_{1} / t_{1}, \ldots, X_{m} / t_{m}\right]$.
$C^{\in}$ is of the form $p_{1}^{1} \in V_{1} \wedge \cdots \wedge p_{1}^{v 1} \in V_{1} \wedge \cdots \wedge p_{q}^{v q} \in V_{q}$. Consider the member substitution

$$
\sigma_{C}=\left[V_{1} /\left\{F_{1}, p_{1}^{1}, \ldots, p_{1}^{v 1} \mid M_{1}\right\}, \ldots, V_{q} /\left\{F_{q}, p_{q}^{1}, \ldots, p_{q}^{v q} \mid M_{q}\right\}\right] .
$$

Since, by hypothesis, $C$ is acyclic, then $\sigma_{C}^{*}$ can be computed (see Lemma A.4).
For each pair of literals $p \in V, r \notin V$ of $C$ consider the equality constraints in solved form $D_{1}, \ldots, D_{k}$ that are the solutions to the unification problem $\sigma_{C}^{*}(p)=\sigma_{C}^{*}(r)$ (since $C$ is in solved form they are all different from the empty substitution). By the results concerning unification (cf. [11]) we have that

$$
\sigma_{C}^{*}(p)=\sigma_{C}^{*}(r) \leftrightarrow \bigvee_{j=1}^{k}\left(\exists \bar{N}\left(D_{j}\right)\right)
$$

where $\bar{N}$ are new variables, and each $D_{j}$ is a conjunction of equations which contains at least one atom of the form $A=\left\{a_{1}, \ldots, a_{h} \mid B\right\}$ with $A \in F V\left(\sigma_{C}^{*}(p)\right) \cup F V\left(\sigma_{C}^{*}(r)\right)$ and $F V\left(a_{i}\right) \subseteq$ $F V\left(\sigma_{C}^{*}(p)\right) \cup F V\left(\sigma_{C}^{*}(r)\right)$, or one atom of the form $A=B$ with $A, B \in F V\left(\sigma_{C}^{*}(p)\right) \cup F V\left(\sigma_{C}^{*}(r)\right)$. Since we want to satisfy $\sigma_{C}^{*}(r) \notin \sigma_{C}^{*}(V)$ we are interested in satisfying $\sigma_{C}^{*}(r) \neq \sigma_{C}^{*}(p)$, which is in turn equivalent to:

$$
\bigwedge_{j=1}^{k}\left(\forall N \neg D_{j}\right)
$$

For doing that, for each $D_{j}$ we choose an atom of the form $A=\left\{a_{1}, \ldots, a_{h} \mid B\right\}$ or $A=B$ and we store it in the variable $N E Q_{p r}$. Points (5) and (6) below will take care of this constraint store.
$C^{\notin}$ is of the form $r_{1} \notin Y_{1} \wedge \cdots \wedge r_{n} \notin Y_{n}\left(Y_{i}\right.$ does not occur in $\left.r_{i}\right)$ and $C^{\neq}$is of the form $Z_{1} \neq$ $s_{1} \wedge \cdots \wedge Z_{o} \neq s_{o}\left(Z_{i}\right.$ does not occur in $\left.s_{i}\right)$. Let $W_{1}, \ldots, W_{h}$ be the variables occurring in $C$ other than $X_{1}, \ldots, X_{m}, V_{1}, \ldots, V_{q}, Y_{1}, \ldots, Y_{n}, Z_{1}, \ldots, Z_{o}$.
Let $\bar{s}=\max \left\{\operatorname{rank}(t): t\right.$ occurs in $\left.\sigma_{C}^{*}\left(\theta_{1}(C)\right)\right\}+1+h$.
Let $R_{1}, \ldots, R_{j}$ be the variables occurring in $\sigma_{C}^{*}\left(\theta_{1}\left(C^{\notin} \wedge C^{\neq}\right)\right.$) (actually, the variables $\bar{F}, \bar{M}$, and some of the $\bar{Y}$ and $\bar{Z})$ and $n_{1}, \ldots, n_{j}$ be auxiliary variables ranging over $\mathbb{N}$.
We build an integer disequation system $S$ in the following way:

1. $S=\left\{n_{i}>\bar{s}: \forall i \in\{1, \ldots, j\}\right\} \cup\left\{n_{i_{1}} \neq n_{i_{2}}: \forall i_{1}, i_{2} \in\{1, \ldots, j\}, i_{1} \neq i_{2}\right\}$.
2. For each literal $R_{i_{1}} \neq t$ in $\sigma_{C}^{*}\left(C^{\neq}\right)$

$$
S=S \cup\left\{n_{i_{1}} \neq n_{i_{2}}+c: \forall i_{2} \neq i_{1}, \forall c \in \operatorname{find}\left(R_{i_{2}}, t\right)\right\}
$$

3. For each literal $\left\{R_{i_{1}}, p_{j}^{1}, \ldots, p_{j}^{v j} \mid R_{h}\right\} \neq t$ in $\sigma_{C}^{*}\left(C^{\neq}\right)$

$$
S=S \cup\left\{n_{i_{1}} \neq n_{i_{2}}+c-1: \forall i_{2} \neq i_{1}, \forall c \in \operatorname{find}\left(R_{i_{2}}, t\right)\right\}
$$

4. For each literal $t \notin R_{i_{1}}$ in $\sigma_{C}^{*}\left(C^{\notin}\right)$

$$
S=S \cup\left\{n_{i_{1}} \neq n_{i_{2}}+c+1: \forall i_{2} \neq i_{1}, \forall c \in \operatorname{find}\left(R_{i_{2}}, t\right)\right\}
$$

5. For each literal $t \notin\left\{R_{h}, p_{j}^{1}, \ldots, p_{j}^{v j} \mid R_{i_{1}}\right\}$, for each $k \leq v j$, for all $R_{i_{2}}=\left\{a_{1}, \ldots, a_{h} \mid B\right\}$ in $N E Q_{p_{j}^{k} t}$

$$
S=S \cup\left\{n_{i_{2}} \neq n_{i_{3}}+c+1: \forall i_{3} \neq i_{2}, \forall c \in \operatorname{find}\left(R_{i_{3}}, a_{1}\right)\right\}
$$

6. For each literal $t \notin\left\{R_{h}, p_{j}^{1}, \ldots, p_{j}^{v j} \mid R_{i_{1}}\right\}$, for each $k \leq v j$, for all $R_{i_{2}}=R_{i_{3}}$ in $N E Q_{p_{j}^{k} t}$

$$
S=S \cup\left\{n_{i_{2}} \neq n_{i_{3}}\right\}
$$

7. For each literal $t \notin\left\{R_{i_{1}}, p_{j}^{1}, \ldots, p_{j}^{v j} \mid R_{h}\right\}$,

$$
S=S \cup\left\{n_{i_{1}} \neq n_{i_{2}}+c: \forall i_{2} \neq i_{1}, \forall c \in \operatorname{find}\left(R_{i_{2}}, t\right)\right\}
$$

8. For each literal $t \notin\left\{R_{h}, p_{j}^{1}, \ldots, p_{j}^{v j} \mid R_{i_{1}}\right\}$,

$$
S=S \cup\left\{n_{i_{1}} \neq n_{i_{2}}+c+1: \forall i_{2} \neq i_{1}, \forall c \in \operatorname{find}\left(R_{i_{2}}, t\right)\right\}
$$

An integer disequation is safe if, after expression evaluation, it is not of the form $u \neq u$. A safe disequation has always an infinite number of solutions. A finite set of safe disequations has always an infinite number of solutions. We show that all disequations of $S$ are safe. The disequations generated at point (1) are safe by definition; those introduced in points (2), (4), (5), (6), (7), and (8) are safe since $c$ is always a positive number. We prove that the disequations generated at point (3) are safe. If in $C$ there was a situation of the form $p_{1} \in Y \wedge \ldots \wedge p_{m} \in Y \wedge Y \neq t$ from which we have obtained $\left\{F_{Y}, \sigma_{C}^{*}\left(p_{1}\right), \ldots, \sigma_{C}^{*}\left(p_{m}\right) \mid M_{Y}\right\} \neq \sigma_{C}^{*}(t)$, then we had, from the definition of solved form, that $Y$ does not occur in $t$, hence $F_{Y}$ does not occur at depth 1 in $\sigma_{C}^{*}(t)$, hence we do not obtain a disequation of the form $n_{F_{Y}} \neq n_{F_{Y}}+1-1$.

From the safeness property, it is possible to find an integer solution to the system $S$ by choosing arbitrarily large values satisfying the constraints. Let $\left\{n_{1}=\bar{n}_{1}, \ldots, n_{j}=\bar{n}_{j}\right\}$ be a solution and define

$$
\theta_{2}=\left[R_{i} /\{\text { nil }\}^{\bar{n}_{i}}: \forall i \in\{1, \ldots, j\}\right]
$$

Let $\gamma=\theta_{1} \sigma_{C}^{*} \theta_{2}$ (where $s \mu \nu$ stands for $(s \mu) \nu$ ) and observe that $C \gamma$ is a conjunction of ground literals. We show that $K E_{k}^{s} F_{1}^{s} F_{2} F_{s}^{3} \models C \gamma$. We analyze each literal of $C$.
$X=t: \theta_{1}(X)$ coincides syntactically with $\theta_{1}(t)=t$. Hence, a literal of this form is true in any model of equality.
$t \in X: \theta_{2}\left(\sigma_{C}^{*}(X)\right)=\left\{\ldots, \theta_{2}\left(\sigma_{C}^{*}(t)\right), \ldots\right\}$, so the atom is satisfied.
$Z \neq u$ : two cases are possible:

1. if there are no atoms of the form $t \in Z$ in $C$, then the conditions in $S$ and over $\bar{s}$ ensure that $\operatorname{rank}(\gamma(Z)) \neq \operatorname{rank}(\gamma(u))$;
2. if there is at least one atom of the form $t \in Z$ in $C$, then $\sigma_{C}^{*}(Z)=\left\{F, t_{1}, \ldots, t_{k} \mid M\right\}$, the conditions in $S$ and over $\bar{s}$ ensure that $\operatorname{rank}(\gamma(F)) \neq \operatorname{rank}(\gamma(u))-1$, hence $\gamma(F)$ is not an element of $\gamma(u)$.
$r \notin Y:$ two cases are possible:
3. no atoms of the form $t \in Y$ occur in $C$ : if $r$ is ground, then it can not be an element of $Y$ since $\gamma(Y)=\{\text { nil }\}^{i}$, with $i \geq \bar{s}$; if $r$ is not ground, then the conditions in $S$ ensure that $\operatorname{rank}(\gamma(Y)) \neq \operatorname{rank}(\gamma(r))+1$;
4. at least one atom of the form $t \in Y$ occurs in $C$, hence $\sigma_{C}^{*}(Y)=\left\{F, t_{1}, \ldots, t_{k} \mid M\right\}$ : if $r$ is ground the result is trivial; if $r$ is not ground then the conditions in $S$ ensure that $\operatorname{rank}\left(\gamma\left(t_{j}\right)\right) \neq \operatorname{rank}(\gamma(r))$ for all $j \leq k, \operatorname{rank}(\gamma(F)) \neq \operatorname{rank}(\gamma(r))$, and $\operatorname{rank}(\gamma(M)) \neq$ $\operatorname{rank}(\gamma(r))+1$.

Remark 4.13 The task of testing whether a pre-solved form constraint $C$ is in solved form could be avoided in the cases of multisets and sets, where all membership atoms can be removed. As a matter of fact, in the privileged models considered for sets and multisets it holds that:

$$
s \in t \leftrightarrow \exists N(t=\{s \mid N\})
$$

We can therefore replace each membership atom $s \in t$ with an equi-satisfiable equality atom $t=\{s \mid N\}$ with $N$ a new variable. This implies that the additional conditions on the pre-solved form are not required at all, since membership atoms can be removed.

## 5 Constraint Rewriting Procedures

In this section we describe the procedures that can be used to rewrite a given constraint $C$ into a equi-satisfiable disjunction of constraints in pre-solved form. All the procedures have the same overall structure shown in Figure 2 they take a constraint $C$ as their input and repeatedly select an conjunct $c$ in $C$ not in pre-solved form (if any) and apply one of the rewriting rules to it. The procedure stops when the constraint $C$ is in pre-solved or false is a conjunct of the constraint. The procedure is non-deterministic. Some rewriting rules have two or more possible non-deterministic choices. Each non deterministic computation returns a constraint of the form above. However there is globally a finite set $C_{1}, \ldots, C_{k}$ of constraints non-deterministically returned. The input constraint $C$ and the disjunction $C_{1} \vee \cdots \vee C_{k}$ are equi-satisfiable.

Let $\mathbb{T}$ be one of the theories List, MSet, CList, Set, $\pi$ a symbol in $\{=, \neq, \in, \notin\}$, and $C$ a $\mathbb{T}$-constraint

```
while C contains an atomic constraint c of the form \ell\pir not in pre-solved form and c\not= false do 
    select c;
    if c=false then return false
    else if c= true then erase c
    else apply to c any rewriting rule for }\mathbb{T}\mathrm{ -constraints of the form }\cdot\pi\cdot\mathrm{ ;
return C
```

### 5.1 Equality Constraints

Unification algorithms for verifying the satisfiability and producing the solutions of equality constraints in the four aggregate's theories have been proposed in [11. The unification algorithms proposed in 11 fall in the general schema of Figure 2 Some determinism in the statement select $c$ is added to ensure termination. They are called:

| Unify_lists for lists | Unify_msets (Unify_bags in [11]) for multisets |
| :--- | :--- |
| Unify_clists for compact lists | Unify_sets for sets |

and they are used unaltered in the four global constraint solvers that we propose in this paper.
The output of the algorithms is either false, when the constraint is unsatisfiable, or a collection of solved form constraints (Def. 4.11) composed only by equality atoms. In Figure 3 we have reported the rewriting rules for the multisets unification used in algorithm Unify_msets.

The algorithm uses the auxiliary functions tail and untail defined as follows:

$$
\begin{array}{lll}
\operatorname{tail}\left(f\left(t_{1}, \ldots, t_{n}\right)\right) & =f\left(t_{1}, \ldots, t_{n}\right) & f \text { is not }\{\cdot \mid \cdot\}, n \geq 0 \\
\operatorname{tail}(X) & =X & X \text { is a variable } \\
\operatorname{tail}(\{t \mid s\}) & =\operatorname{tail}(s) & \\
\text { untail }(X) & =\operatorname{nil} & X \text { is a variable } \\
\operatorname{untail}(\{t \mid s\}) & =\{t \mid \text { untail }(s)\} &
\end{array}
$$

| Rules for Unify_msets |  |
| :---: | :---: |
| (1) | $X=X \quad \mapsto \quad$ true |
| (2) | $\left.\begin{array}{r}t=X \\ t \text { is not a variable }\end{array}\right\} \quad \mapsto \quad X=t$ |
| (3) | $X$ does not occur in $t, X$ occurs in $C\} \mapsto$ $X=t$ and apply the substitution $X / t$ to $C$ |
| (4) | $\left.\begin{array}{r}X=t \\ X \text { is not } t \text { and } X \text { occurs in } t\end{array}\right\} \quad \mapsto \quad$ false |
| (5) | $\left.\begin{array}{r} f\left(s_{1}, \ldots, s_{m}\right)=g\left(t_{1}, \ldots, t_{n}\right) \\ f \text { is not } g \end{array}\right\} \quad \mapsto \quad \text { false }$ |
| (6) | $\begin{array}{r} f\left(s_{1}, \ldots, s_{m}\right)=f\left(t_{1}, \ldots, t_{m}\right) \\ m \geq 0, f \text { is not }\{\cdot \mid \cdot\} \\ s_{1}=t_{1} \wedge \ldots \wedge s_{m}=t_{m} \end{array}$ |
| (7) | $\left.\begin{array}{r}\{t \mid s\}=\left\{t^{\prime} \mid s^{\prime}\right\} \\ \text { tail }(s) \text { and tail }\left(s^{\prime}\right) \text { are not the same variable }\end{array}\right\} \quad \mapsto \quad$(i) $\quad\left(t=t^{\prime} \wedge s=s^{\prime}\right) \vee$ <br> $\left(\right.$ ii) $\quad\left(s=\left\{t^{\prime} \mid N\right\} \wedge\{t \mid N\}=s^{\prime}\right)$ |

Figure 3: Rewriting rules for the Unification algorithm for multisets

### 5.2 Membership and not-Membership Constraints

The rewriting rules for membership and not-membership constraints are justified by axioms ( $K$ ) and $(W)$ that hold in all the four theories. Therefore, in Figure 4 we give a single definition of these rules. They are used within the main loop in Figure 2 to define the rewriting procedures for membership and not-membership constraints over the considered aggregate. When useful, we will refer to these procedures with the generic names in- $\mathbb{T}$ and nin- $\mathbb{T}$, where $\mathbb{T}$ is any of the aggregate theories.

Let $\operatorname{cons}_{\mathbb{T}}(\cdot, \cdot)$ be the aggregate constructor for the theory $\mathbb{T}$

| Rules for in-T |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| (1) | $\begin{array}{r} r \in f\left(t_{1}, \ldots, t_{n}\right) \\ f \text { is not } \operatorname{cons}_{\mathbb{T}}(\cdot, \cdot) \\ \hline \end{array}$ | $\mapsto$ false |  |  |
| (2) | $r \in \operatorname{cons}_{\mathbb{T}}(t, s)$ | $\mapsto$ | $\begin{aligned} & r=t \vee \\ & r \in s \end{aligned}$ |  |
| (3) | $\begin{array}{r} r \in X \\ X \in F V(r) \\ \hline \end{array}$ | $\mapsto$ | false |  |

| Rules for nin-T |  |  |  |
| :---: | :---: | :---: | :---: |
| (1) | $\begin{array}{r} r \notin f\left(t_{1}, \ldots, t_{n}\right) \\ f \text { is } \operatorname{not} \operatorname{cons}_{\mathbb{T}}(\cdot, \cdot \cdot) \end{array}$ | $\mapsto$ | true |
| (2) | $r \notin \mathrm{cons}_{\mathbb{T}}(t, s)$ | $\mapsto$ | $r \neq t \wedge r \notin s$ |
| (3) | $\begin{array}{r} r \notin X \\ X \in F V(r) \\ \hline \end{array}$ | $\mapsto$ | true |

Figure 4: Parametric rewriting rules for membership and not-membership constraints

Lemma 5.1 Let $\mathbb{T}$ be one of the theories List, MSet, CList, Set, and $\mathcal{A}_{\mathbb{T}}$ the privileged model for the theory $\mathbb{T}$. Let $C$ be a $\mathbb{T}$-constraint, $C_{1}, \ldots, C_{k}$ be the constraints non-deterministically returned by nin- $\mathbb{T}(\mathrm{in}-\mathbb{T}(C)))$, and $\bar{N}_{i}=F V\left(C_{i}\right) \backslash F V(C)$. Then $\mathcal{A}_{\mathbb{T}} \models \forall\left(C \leftrightarrow \bigvee_{i=1}^{k} \exists \bar{N}_{i} C_{i}\right)$.

Proof. We prove correctness and completeness for lists, thus with respect to the model $\mathcal{L I S T}$. Soundness and completeness for the other aggregates are proved in the very same way. Soundness and completeness is proved for each rewriting rule separately since the rules are mutually exclusive. When possible, we simply point out the axioms of the corresponding theory List involved in the proof (note that $\mathcal{L I S T}$ is a model of those axioms):
in-List, rule (1). $r \in f\left(t_{1}, \ldots, t_{n}\right)$, with $f$ different from $[\cdot \mid \cdot]$ is equivalent to true by axiom $(K)$.
in-List, rule (2). This is exactly axiom ( $W$ ).
in-List, rule (3). Assume that there is a valuation $\sigma$ such that $\mathcal{L I S T} \models \sigma(r \in X)$. This means that $\sigma(X)$ contains a term of the form: $\left[s_{1}, \ldots, s_{n}, r^{\prime} \mid t\right]$ for some terms $s_{1}, \ldots, s_{n}, t$, and some term $r^{\prime}$ in $\sigma(r)$. Axiom ( $F_{3}$ ) ensures that $X$ can not be a subterm of $r$.
nin-List, rules (1), (2), (3). Same proofs as for the corresponding in-List rules, using the same axioms.

In the above lemma it holds that the lists of variables $\bar{N}_{i}$ are all empty. However, for the sake of uniformity with respect to the other similar correctness results, we have made them explicit. Let us observe that the rewriting rules for procedure in-MSet and in-Set could safely be extended by the rule:

| (4) | $\begin{array}{r} r \in X \\ X \notin F V(r) \\ \hline \end{array}$ | $\mapsto \quad X=\{r \mid N\} \quad(X=\{r \mid N\})$ |
| :---: | :---: | :---: |

where $N$ is a new variable (see also Remark 4.13). In this way, we are sure to completely remove membership atoms from the constraints and that the pre-solved form constraints obtained are in solved form.

### 5.3 Disequality constraints

Rewriting rules for disequality constraints consist of a part which is the same for the four theories (although parametric with respect to the considered theory), and a part which is specific for each one of the four theories. Rules of the common part are shown in Figure 5 while specific rules are described in the next subsections.

Let $\operatorname{cons}_{\mathbb{T}}(\cdot, \cdot)$ be the aggregate constructor for the theory $\mathbb{T}$

| Rules for neq-T |  |  |
| :---: | :---: | :---: |
| (1) | $\left.\begin{array}{r} d \neq d \\ d \text { is a constant } \end{array}\right\}$ | $\mapsto$ false |
| (2) | $\left.\begin{array}{r} f\left(s_{1}, \ldots, s_{m}\right) \neq g\left(t_{1}, \ldots, t_{n}\right) \\ f \text { is not } g \end{array}\right\}$ | $\mapsto \quad$ true |
| (3) | $\left.\begin{array}{r}t \neq X \\ t \text { is not a variable }\end{array}\right\}$ | $\mapsto \quad X \neq t$ |
| (4) | $\left.\begin{array}{r} X \neq X \\ X \text { is a variable } \end{array}\right\}$ | $\mapsto$ false |
| (5) | $\left.\begin{array}{r} f\left(s_{1}, \ldots, s_{n}\right) \neq f\left(t_{1}, \ldots, t_{n}\right)  \tag{1}\\ n>0, f \text { is not } \operatorname{cons}_{\mathbb{T}}(\cdot, \cdot) \end{array}\right\}$ | $\begin{align*} \mapsto & s_{1} \neq t_{1} \vee \\ & \vdots \\ & s_{n} \neq t_{n} \tag{n} \end{align*}$ |

Figure 5: General rewriting rules for disequality constraints

### 5.3.1 Lists

Specific rules for the theory List are presented in Figure 6] These rules are inserted in the general schema of Figure 2 to generate the procedure neq-List.

| Rules for neq-List |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| (1)-(5) | see Figure 5 |  |  |  |
| (6) | $\left[s_{1} \mid s_{2}\right] \neq\left[t_{1} \mid t_{2}\right]$ | $\mapsto$ | $\begin{aligned} & s_{1} \neq t_{1} \\ & s_{2} \neq t_{2} \end{aligned}$ |  |
| (7) | $\begin{array}{r} X \neq f\left(t_{1}, \ldots, t_{n}\right) \\ X \in F V\left(t_{1}, \ldots, t_{n}\right) \\ \hline \end{array}$ |  | true |  |

Figure 6: Rewriting rules for disequality constraints over lists

Lemma 5.2 Let $C$ be a List-constraint, $C_{1}, \ldots, C_{k}$ be the constraints non-deterministically returned by neq-List $(C)$, and $\bar{N}_{i}=F V\left(C_{i}\right) \backslash F V(C)$. Then List $\models \forall\left(C \leftrightarrow \bigvee_{i=1}^{k} \exists \bar{N}_{i} C_{i}\right)$.

Proof. Soundness and completeness of the rewriting rules (and, hence, of the whole rewriting procedure neq-List) are immediate consequence of standard equality axioms and axiom schemata $\left(F_{1}\right),\left(F_{2}\right)$, and $\left(F_{3}\right)$.

### 5.3.2 Multisets

Disequality constraints over multisets are simplified using the rewriting rules presented in Figure 7 They make use of functions tail and untail defined in Section 5.1 Using these rules within the generic rewriting scheme of Figure 2 we get the rewriting procedure for disequality constraints over multisets, called neq-MSet.

| Rules for neq-MSet |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| (1)-(5) | see Figure 5 |  |  |  |
| (6.1) | $\left.\left\{t_{1} \mid s_{1}\right\}\right\} \neq\left\{t_{2} \mid s_{2}\right\}$ tail $\left(s_{1}\right)$ and tail $\left(s_{2}\right)$ are the same variable | $\mapsto$ | untail |  |
| (6.2) | $\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}$ tail $\left(s_{1}\right)$ and tail $\left(s_{2}\right)$ are not the same variable | $\mapsto$ | $\begin{aligned} & \left(t_{1} \neq\right. \\ & \left(\left\{t_{2}\right.\right. \\ & \hline \end{aligned}$ | $\begin{gathered} (a) \\ (b) \\ \hline \end{gathered}$ |
| (7) | $\begin{array}{r} X \neq f\left(t_{1}, \ldots, t_{n}\right) \\ X \in F V\left(t_{1}, \ldots, t_{n}\right) \\ \hline \end{array}$ |  | true |  |

Figure 7: Rewriting rules for disequality constraints over multisets

Some words are needed for explaining the rules related to the management of disequalities between multisets; in particular rule (6.2) of Figure 7 If we use directly axiom $\left(E_{k}^{m}\right)$, we have that:

$$
\begin{aligned}
\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\} \leftrightarrow & \left(t_{1} \neq t_{2} \vee s_{1} \neq s_{2}\right) \wedge \\
& \forall N\left(s_{2} \neq\left\{t_{2} \mid N\right\} \vee s_{1} \neq\left\{t_{1} \mid N\right\}\right)
\end{aligned}
$$

This way, an universal quantification is introduced: this is no longer a constraint according to Definition 4.1

Alternatively, we could use the intuitive notion of multi-membership: $x \in^{i} y$ if $x$ belongs at least $i$ times to the multiset $y$. This way, one can provide an alternative version of equality and disequality between multisets. In particular, we have:

$$
\begin{aligned}
\left.\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}\right\} \leftrightarrow \quad \exists X \exists n & (n \in \mathbb{N} \wedge \\
& \left.\left(X \in^{n}\left\{t_{1} \mid s_{1}\right\}\right\} \wedge X \nexists^{n}\left\{t_{2} \mid s_{2}\right\}\right) \vee \\
& \left.\left(X \in^{n}\left\{t_{2} \mid s_{2}\right\}\right\} \wedge X \notin \not^{n}\left\{t_{1} \mid s_{1}\right\}\left\{\left\{t_{2} \mid s_{2}\right\}\right)\right)
\end{aligned}
$$

In this case, however, we have a quantification on natural numbers: we are outside the language we are studying. The rewriting rule (6.2) adopted in Figure 7 avoids these difficulties introducing
only existential quantification. Its correctness and completeness are proved in the following lemma.

Lemma 5.3 Let $C$ be a MSet-constraint, $C_{1}, \ldots, C_{k}$ be the constraints non-deterministically returned by neq-MSet $(C)$, and $\bar{N}_{i}=F V\left(C_{i}\right) \backslash F V(C)$. Then $\mathcal{M S E T} \models \forall\left(C \leftrightarrow \bigvee_{i=1}^{k} \exists \bar{N}_{i} C_{i}\right)$.

Proof. From Lemma 5.2 we know that the result holds for rules (1)-(5) and (7) for the model $\mathcal{L I S T}$. Since permutativity has not been used for that result, and axiom $\left(F_{3}\right)$ holds for both the theories, the same holds for the model $\mathcal{M S E}$. We need to prove correctness and completeness of rewriting rules (6.1) and (6.2).
(6.1) It is immediately justified by axiom schema $\left(F_{3}^{m}\right)$.
(6.2) The constraint $\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}$ is equivalent to:

$$
\begin{align*}
& t_{1} \notin\left\{t_{2} \mid s_{2}\right\} \wedge \wedge\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\} \vee  \tag{1}\\
& t_{1} \in\left\{t_{2} \mid s_{2}\right\} \wedge\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\} \tag{2}
\end{align*}
$$

Since we are looking for successful valuations over $\mathcal{M S E \mathcal { T }}$ that deal with multisets of finite elements, axiom $\left(E_{k}^{m}\right)$ ensures that $t_{1} \notin\left\{t_{2} \mid s_{2}\right\}$ implies $\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}$. Thus, formula (11) is equivalent to $\left.t_{1} \in\left\{t_{2} \mid s_{2}\right\}\right\}$ which, in turn, is equivalent by ( $W$ ) to the disjunct ( $a$ ) of the rewriting rule.
Consider now formula (2). It is easy to see that

$$
\begin{equation*}
\mathcal{M S E \mathcal { T }} \models \forall\left(t_{1} \in\left\{t_{2} \mid s_{2}\right\} \leftrightarrow \exists M\left(\left\{t_{1} \mid M\right\}=\left\{t_{2} \mid s_{2}\right\}\right)\right) \tag{3}
\end{equation*}
$$

Thus, (2) is equivalent to

$$
\begin{equation*}
\exists M\left(\left\{t_{1} \mid M\right\}=\left\{t_{2} \mid s_{2}\right\} \wedge\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}\right) \tag{4}
\end{equation*}
$$

It remains to prove that (4) is equivalent to the disjunct (b), namely:

$$
\begin{equation*}
\left.\exists N\left(s_{1} \neq N \wedge\left\{t_{2} \mid s_{2}\right\}\right\}=\left\{t_{1} \mid N\right\}\right) \tag{5}
\end{equation*}
$$

(4) $\rightarrow$ (5) Assume there is $M$ so as to satisfy (4). $M=s_{1}$ will immediately lead to a contradiction. Thus, (5) is satisfied by $N=M$.
(5) $\rightarrow$ (4) Assume there is $N$ so as to satisfy (5). It follows immediately from the fact, true for finite multisets, that $s_{1} \neq N$ implies $\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{1} \mid N\right\}$. Thus, choose $M=N$.

### 5.3.3 Compact Lists

The rewriting rules for disequality constraints over compact lists are shown in Figure 8 These rules can be immediately exploited in conjunction with the generic scheme of Figure 2 to obtain a rewriting procedure for disequality constraints over multisets-called neq-CList. Soundness and completeness of neq-CList are stated by the following lemma.

Lemma 5.4 Let $C$ be a CList-constraint, $C_{1}, \ldots, C_{k}$ be the constraints non-deterministically returned by neq-CList $(C)$, and $\bar{N}_{i}=F V\left(C_{i}\right) \backslash F V(C)$. Then $\mathcal{C} \mathcal{L I S T} \models \forall\left(C \leftrightarrow \bigvee_{i=1}^{k} \exists \bar{N}_{i} C_{i}\right)$.

Proof. For rules (1)-(5) the result follows immediately from those for lists. Rules (7.1)-(7.3) follows from axiom $\left(F_{3}^{c}\right)$. Rule (6) is exactly axiom $\left(E_{k}^{c}\right)$.

Observe that, differently from multisets, the rewriting rule for disequality between compact lists follows immediately from axiom $\left(E_{k}^{c}\right)$. As a matter of fact, this axiom does not introduce any new variable.

| Rules for neq-CList |  |  |  |
| :---: | :---: | :---: | :---: |
| (1)-(5) | see Figure 5 |  |  |
| (6) | $\begin{array}{r} \left.\llbracket t_{1}\left\|s_{1} \rrbracket \neq \llbracket t_{2}\right\| s_{2} \rrbracket\right\} \\ \\ t_{1} \\ s_{1} \end{array}$ | $\begin{aligned} & \mapsto \\ = & t_{2} \vee \\ \hdashline & s_{2} \wedge \llbracket t_{1}\left\|s_{1} \rrbracket \neq s_{2} \wedge s_{1} \neq \llbracket t_{2}\right\| s_{2} \rrbracket \end{aligned}$ | (a) <br> (b) |
| (7.1) | $\left.\begin{array}{r} X \neq f\left(t_{1}, \ldots, t_{n}\right) \\ X \in F V\left(t_{1}, \ldots, t_{n}\right), f \text { is not } \llbracket \cdot \mid \cdot \rrbracket \end{array}\right\}$ | $\mapsto \quad$ true |  |
| (7.2) | $\left.\begin{array}{c} X \neq \llbracket t_{1}, \ldots, t_{n} \mid X \rrbracket \\ X \in F V\left(t_{1}, \ldots, t_{n}\right) \end{array}\right\}$ | $\mapsto \quad$ true |  |
| (7.3) | $\left.\begin{array}{r} X \neq \llbracket t_{1}, \ldots, t_{n} \mid X \rrbracket \\ X \notin F V\left(t_{1}, \ldots, t_{n}\right) \end{array}\right\}$ | $\begin{array}{ll} \mapsto \quad & t_{1} \neq t_{2} \vee \\ \vdots \\ & t_{1} \neq t_{n} \vee \\ X & =\operatorname{nil} \vee \\ X & =\llbracket N_{1} \mid N_{2} \rrbracket \wedge N_{1} \neq t_{1} \end{array}$ | $\begin{gathered} (a .1) \\ \vdots \\ (a . n) \\ (b) \\ (c) \\ \hline \end{gathered}$ |

Figure 8: Rewriting rules for disequality constraints over compact lists

| Rules for neq-Set |  |
| :---: | :---: |
| (1)-(5) | see Figure [5] |
| (6) | $\begin{array}{rlr} \left.\hline\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}\right\} & \mapsto & \\ Z \in\left\{t_{1} \mid s_{1}\right\} & \wedge Z \notin\left\{t_{2} \mid s_{2}\right\} \vee & (a) \\ Z \in\left\{t_{2} \mid s_{2}\right\} & \wedge Z \notin\left\{t_{1} \mid s_{1}\right\} & (b)  \tag{b}\\ \hline \end{array}$ |
| (7.1) | $\left.\begin{array}{r} X \neq f\left(t_{1}, \ldots, t_{n}\right) \\ X \in F V\left(t_{1}, \ldots, t_{n}\right), f \text { is not }\{\cdot \mid \cdot\} \end{array}\right\} \quad \mapsto \quad \text { true }$ |
| (7.2) | $\left.\begin{array}{r} X \neq\left\{t_{1}, \ldots, t_{n} \mid X\right\} \\ X \in F V\left(t_{1}, \ldots, t_{n}\right) \end{array}\right\} \quad \mapsto \quad \text { true }$ |
| (7.3) | $\left.\begin{array}{rl} \hline X \neq\left\{t_{1}, \ldots, t_{n} \mid X\right\} \\ X \notin F V\left(t_{1}, \ldots, t_{n}\right) \end{array}\right\} \quad \mapsto \quad t_{1} \notin X \vee \quad(i)$ |

Figure 9: Rewriting rules for disequality constraints over sets

### 5.3.4 Sets

Disequality constraints over sets are dealt with by the rewriting rules shown in Figure 9, and they constitute the procedure neq-Set.

Some remarks are needed regarding rule (6). As for multisets, axiom $\left(E_{k}^{s}\right)$ introduces an existentially quantified variable to state equality. Thus, its direct application for stating disequality requires universally quantified constraints that go outside the language. On the other hand, the rewriting rule (6.2) used for multisets can not be used in this context. In fact, the property that $s_{1} \neq N$ implies $\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{1} \mid N\right\}$, that holds for finite multisets, does not hold for sets. For instance, $\{a\} \neq\{a, b\}$ but $\{b, a\}=\{b, a, b\}$. Thus, this rewriting rule would be not correct for sets.

A rewriting rule for disequality constraints over sets can be obtained by taking the negation of the standard extensionality axiom

$$
\begin{array}{|llll}
\hline\left(E_{k}\right) & x=y \quad \leftrightarrow \quad \forall z(z \in x \leftrightarrow z \in y) \\
\hline
\end{array}
$$

Lemma 5.5 Let $C$ be a Set-constraint, $C_{1}, \ldots, C_{k}$ be the constraints non-deterministically returned by neq-Set $(C)$, and $\bar{N}_{i}=F V\left(C_{i}\right) \backslash F V(C)$. Then $\mathcal{S E} \mathcal{T} \models \forall\left(C \leftarrow \bigvee_{i=1}^{k} \exists \bar{N}_{i} C_{i}\right)$.

Proof. For rules (1)-(5) the result follows from those for lists. Rules (7.1) and (7.2) are exactly axiom $\left(F_{3}^{s}\right)$. Rule (6) is axiom $\left(E_{k}\right)$, implied by $\left(E_{k}^{s}\right)$ on $\mathcal{S E T}$.

Remark 5.6 In our theories an aggregate can be built by starting from any ground uninterpreted Herbrand term-called the kernel-and then adding to this term the elements that compose the aggregate. Thus, two aggregates can contain the same elements but nevertheless they can be different because of their different kernels. For example, the two terms $\{a \mid b\}$ and $\{a \mid c\}$ denote two different sets containing the same elements (a) but based on different kernels (b and c, respectively).

Rewriting rules for disequality constraints over aggregates other than sets are formulated in such a way to take care of the (possibly different) kernels in the two aggregates without having to explicitly resort to kernels. Conversely, the rewriting rule for disequality constraints over sets (rule (6)) is not able to "force" disequality between two sets when they have the same elements but different kernels. This the reason why the $(\rightarrow)$ direction of Lemma 5.5 does not hold.

A possible completion of the above procedures to take care of this case is presented in [14]; for doing that some technical complications are introduced. Basically, a new constraint (ker) is introduced and the rewriting rule (6) is endowed with a third non-deterministic case: $\operatorname{ker}\left(s_{1}\right) \neq$ $\operatorname{ker}\left(s_{2}\right)$. The advantage of this solution is completeness (the $(\rightarrow)$ direction of Lemma 5.5). However, for the sake of simplicity, we do not add here the details on the modifications of the rewriting rules for dealing with ker that are instead presented in [14.

## 6 Constraint solving

In this section we address the problem of establishing if a constraint $C$ is satisfiable or not in the corresponding privileged model. The correspondence result (Theorem4.5) ensures that the property is inherited by any model.

Constraint satisfiability for the theory $\mathbb{T}$ is checked by the non-deterministic rewriting procedure $S A T_{\mathbb{T}}$ shown in Figure 10 Its definition is completely parametric with respect to the theory involved. $\mathrm{SAT}_{\mathbb{T}}$ uses iteratively the various rewriting procedures presented in the previous section, until a fixed-point is reached-i.e., any new rewritings do not further simplify the constraint. This happens exactly when the constraint is in pre-solved form or it is false. The two conditions that guarantee that a constraint in pre-solved form is in solved form are tested by function is_solved $\mathbb{T}^{T}$ shown in Figure 11

By Theorem 4.12 a constraint in solved form is guaranteed to be satisfiable in the corresponding model. Moreover, it will be proved (see Theorem 6.2) that the disjunction of solved form constraints returned by $S A T_{\mathbb{T}}$ is equi-satisfiable in that model to the original constraint $C$. Therefore, $\mathrm{SAT}_{\mathbb{T}}$ can be used as a test procedure to check satisfiability of $C$ : if it is able to reduce $C$ to at least one solved form constraint $C^{\prime}$ then $C$ is satisfiable; otherwise, $C$ is unsatisfiable. Moreover, the generated constraint in solved form can be immediately exploited to compute all possible solutions for $C$.

```
function SAT }\mp@subsup{\mathbb{T}}{}{(}C
    repeat
        C':=C;
        C:= Unify_Tss(neq-T्T(nin-T(in-T(T}(C)))
    until C= C';
    return( is_solved
```

Figure 10: The satisfiability procedure, parametric with respect to $\mathbb{T}$

The rest of this section is devoted to prove the crucial result of termination for procedure $\mathrm{SAT}_{\mathbb{T}}(C)$ and, then, to prove its soundness and completeness.

```
function is_solved \({ }_{T}(C)\)
    build the directed graph \(\mathcal{G}_{C}^{\in}\);
    if \(\mathcal{G}_{C}^{\in}\) has a cycle
        then return false
        else
            compute \(\sigma_{C}^{*}\)
            if there is a pair \(t \in X, t^{\prime} \notin X\) in \(C\) s.t. \(\mathbb{T} \models \forall\left(\sigma_{C}^{*}(t)=\sigma_{C}^{*}\left(t^{\prime}\right)\right)\)
                then return false
                else return \(C\).
```

Figure 11: Final check for solved form constraints

Theorem 6.1 (Termination) Let $\mathbb{T}$ be one of the theories List, MSet, CList, Set, and $C$ be $a \mathbb{T}$-constraint. Each non-deterministic execution of $\mathrm{SAT}_{\mathbb{T}}(C)$ terminates in a finite number of steps. Moreover, the constraint returned is either false or a solved form constraint.

Proof. We give the proof for the case of MSet. The other proofs are in Appendix B
It is immediate to see, by the definition of the procedures, that if $C$ is different from false and not in pre-solved form, then some rewriting rule can be applied. The function is_solved ${ }_{M S e t}$, whose termination follows from termination of Unify_msets [11, needed for the solved form test $\mathbb{T} \models \forall\left(\sigma_{C}^{*}(t)=\sigma_{C}^{*}\left(t^{\prime}\right)\right)$, produces by definition solved form constraints or false.

We prove that the repeat cycle can not loop forever. For doing that, we define a complexity measure for constraints. Let us assume that constraints of the form $X=t$, with $X$ neither in $t$ nor elsewhere in $C$, are removed from $C$. Similarly, we assume that true constraints are not counted in the complexity measure. These two assumptions are safe since those constraints do not fire any new rule application. The complexity measure that we associate with a constraint is the following triple:

$$
\left.\begin{array}{rl}
\operatorname{compl}(C)=\left\langle\begin{array}{l}
\alpha(C)
\end{array}=\# \text { vars in } C,\right. \\
\beta(C)=\{\operatorname{size}(s)+\operatorname{size}(t): s \text { op } t \in C\} \\
\gamma(C) & =\sum_{\text {sop } t \in C} \operatorname{size}(s)
\end{array}\right\rangle
$$

The first and third element of the tuple are non-negative integers. The second is a multiset of non-negative integers. They are well-ordered [9] by the ordering obtained as the transitive closure of the rule:

$$
\left\{s_{1}, \ldots, s_{i-1}, t_{1}, \ldots, t_{n}, s_{i+1}, \ldots, s_{m}\right\} \prec\left\{s_{1}, \ldots, s_{m}\right\},
$$

for $i \in\{1, \ldots, m\}, n \geq 0, t_{1}<s_{i}, \ldots, t_{n}<s_{i}$. The ordering on triples is the (well-founded) lexicographical ordering.

We will prove that given a constraint $C$, in a finite number of non-failing successive rule applications, a constraint $C^{\prime}$ with lower complexity is reached. We show, by case analysis, this property. Most rule applications decreases the complexity in one step. When this does not happen, we enter in more detail.
Unify_msets(1) $\alpha$ does not increase, $\beta$ decreases.
Unify_msets(2) $\alpha$ and $\beta$ do not increase. $\gamma$ decreases, since $\operatorname{size}(X)=0$ and $\operatorname{size}(t)>0$.
Unify_msets(3) $\alpha$ decreases by 1 .
Unify_msets(6) $\alpha$ does not increase. $\beta$ decreases, since an equation of size $1+\sum_{i=1}^{m} \operatorname{size}\left(s_{i}\right)+\operatorname{size}\left(t_{i}\right)$ is replaced by $m$ smaller equations of size $\operatorname{size}\left(s_{i}\right)+\operatorname{size}\left(t_{i}\right)$.
Unify_msets(7) In this case the complexity may remain unchanged at the first step. However, the unification algorithm adopts a selection strategy that ensures that after a finite number of steps, we either reach a situation such that $\alpha$ decreases or a situation where $\alpha$ is unchanged and $\beta$ decreases (see 11 for details).
Unify_msets(8) After one rule application, we are in the case (7) with both the tails of the multisets non variables. After a finite number of steps, we enter the situation where $\alpha$ is unchanged and $\beta$ decreases.
in-MSet(2) $\alpha$ does not increase. $\beta$ decreases, since a constraint of size $1+\operatorname{size}(r)+\operatorname{size}(s)+\operatorname{size}(t)$ is non-deterministically replaced by one of smaller size $\operatorname{size}(r)+\operatorname{size}(s)$ or $\operatorname{size}(r)+\operatorname{size}(t)$.
nin-MSet(1), (3) Trivially, $\alpha$ does not increase and $\beta$ decreases.
nin-MSet(2) $\alpha$ does not increase. $\beta$ decreases, since a constraint of size $1+\operatorname{size}(r)+\operatorname{size}(s)+\operatorname{size}(t)$ is non-deterministically replaced by two of smaller size $\operatorname{size}(r)+\operatorname{size}(s)$ and $\operatorname{size}(r)+\operatorname{size}(t)$.
neq-MSet(2), (7) Trivially, $\alpha$ does not increase and $\beta$ decreases.
neq-MSet(3) $\alpha$ and $\beta$ do not increase. $\gamma$ decreases, since $\operatorname{size}(X)=0$ and $\operatorname{size}(t)>0$.
neq-MSet(5) $\alpha$ does not increase. $\beta$ decreases, since a constraint of size $1+\sum_{i=1}^{m} \operatorname{size}\left(s_{i}\right)+\operatorname{size}\left(t_{i}\right)$ is non-deterministically replaced by one of size $\operatorname{size}\left(s_{i}\right)+\operatorname{size}\left(t_{i}\right)$.
neq-MSet(6.2) A unique application of this rule may not decrease the constraint complexity. Thus, we enter in some detail. The rule removes $\left\{t_{1} \mid s_{1}\right\} \neq\left\{t_{2} \mid s_{2}\right\}$ and introduces

$$
\begin{align*}
& \left\{t_{2} \mid s_{2}\right\}=\left\{t_{1} \mid N\right\} \wedge  \tag{6}\\
& s_{1} \neq N \tag{7}
\end{align*}
$$

Consider now the two cases:

1. $\left\{t_{2} \mid s_{2}\right\}$ is $\left\{r_{1}, \ldots, r_{n}\right\}$
2. $\left\{t_{2} \mid s_{2}\right\}$ is $\left\{r_{1}, \ldots, r_{n} \mid A\right\}$, for some variable $A$ distinct from $N$ that has just been introduced.

In the first case the successive execution of Unify_bags replaces equation (6) by:

$$
t_{1}=r_{i}, N=\left\{r_{1}, \ldots, r_{i-1}, r_{i+1}, \ldots, r_{n}\right\}
$$

for some $i=1, \ldots, n$. We have that

$$
\left.\operatorname{size}\left(t_{1}\right)+\operatorname{size}\left(r_{i}\right)<\operatorname{size}\left(\left\{t_{1} \mid s_{1}\right\}\right\}\right)+\operatorname{size}\left(\left\{t_{2} \mid s_{2}\right\}\right) .
$$

The equation $N=\left\{r_{1}, \ldots, r_{i-1}, r_{i+1}, \ldots, r_{n}\right\}$ is eliminated by applying the substitution for $N$. $N$ occurs only in the constraint $s_{1} \neq N$, that becomes $s_{1} \neq\left\{r_{1}, \ldots, r_{i-1}, r_{i+1}, \ldots, r_{n}\right\}$. Again, its size is strictly smaller than that of the original disequality constraint. Thus, after some further steps, $\alpha$ remains unchanged while $\beta$ decreases. Strictly speaking, some other actions may occur during that sequence of actions. However, if no other rule (6.2) is executed, then all rules decrease the complexity tuples. Conversely, if other rules of this form are executed, then we need to wait for all the substitutions of this form to be applied. But they are all independent processes.
The second case is similar, but in this case a substitution also for $A$ is computed, ensuring that $\alpha$ decreases.
neq-MSet(6.1) After one step, we are in the above situation (6.2).

The soundness and completeness result of the global constraint solving procedure for List, MSet, and CList follows from the lemmas in the previous section and two lemmas in the Appendix A

Theorem 6.2 (Soundness - Completeness) Let $\mathbb{T}$ be one of the theories List, MSet, CList, and Set, $C$ be a $\mathbb{T}$-constraint, and $C_{1}, \ldots, C_{k}$ be the solved form constraints non-deterministically returned by $\mathrm{SAT}_{\mathbb{T}}(C)$, and $\bar{N}_{i}$ be $F V\left(C_{i}\right) \backslash F V(C)$. Then $\mathcal{A}_{\mathbb{T}} \models \forall\left(C \leftrightarrow \bigvee_{i=1}^{k} \exists \bar{N}_{i} C_{i}\right)$, where $\mathcal{A}_{\mathbb{T}}$ is the model which corresponds with $\mathbb{T}$.

Proof. Theorem 6.1 ensures the termination of each non-deterministic branch. At each branch point, the number of non-deterministic choices is finite. Thus, $C_{1}, \ldots, C_{k}$ can be effectively computed. Soundness and completeness follow from the results proved individually for the procedures involved: Lemma 5.1 for in- $\mathbb{T}$ and nin- $\mathbb{T}$; Lemma 5.2 Lemma 5.3 Lemma 5.4 and Lemma 5.5 for neq-MSet, neq-List, neq-CList, and neq-Set, respectively; Lemma A.6 for is_solved ${ }_{\mathbb{T}}(C)$; 11 for unification.

Corollary 6.3 (Decidability) Given a $\mathbb{T}$-constraint $C$, it is decidable whether $\mathcal{A} \models \exists C$, where $\mathcal{A}$ is one of the privileged models $\mathcal{L I S T}, \mathcal{M S E T}, \mathcal{C L I S T}, \mathcal{S E T}$.

Proof. From Theorem 6.2 we know that $C$ is equi-satisfiable to $C_{1} \vee \cdots \vee C_{k}$. If all the $C_{i}$ are false, then $C$ is unsatisfiable in $\mathcal{L I S T}(\mathcal{M S E} \mathcal{T}, \mathcal{C L I S T}, \mathcal{S E T})$. Otherwise, it is satisfiable, since solved form constraints are satisfiable (Theorem 4.12).

### 6.1 Complexity Issues

Complexity of the four unification problems is studied in [11: the decision problem for unification is proved to be solvable in linear time for lists, and it is NP-complete for the other cases.

In the case of lists, if the constraint is a conjunction of equality and disequality constraints, then the satisfiability problem for a constraint $C$ is solvable in $O\left(n^{2}\right)$ where $n=|C|$ [2, 7]. Instead, the satisfiability problem for conjunctions of membership and disequality constraints over lists is NP-hard. As a matter of fact, let us consider the following instance of 3-SAT:

$$
\left(X_{1} \vee X_{2} \vee \neg X_{3}\right) \wedge\left(\neg X_{1} \vee X_{2} \vee X_{3}\right) \wedge\left(X_{1} \vee \neg X_{2} \vee X_{3}\right)
$$

The above instance of 3-SAT can be re-written as the following constraint problem:

$$
\left.\begin{array}{cccc}
X_{1} \in[\underline{0}, \underline{1}] & \wedge & Y_{1} \in[\underline{0}, \underline{1}] & \wedge \\
{\left[X_{1}, Y_{1}\right] \neq[\underline{0}, \underline{0}]} & \wedge & {\left[X_{1}, Y_{1}\right] \neq[\underline{1}, \underline{1}]} & \wedge \\
X_{2} \in[\underline{0}, \underline{1}] & \wedge & Y_{2} \in[\underline{0}, \underline{1}] & \wedge \\
{\left[X_{2}, Y_{2}\right] \neq[\underline{0}, \underline{0}]} & \wedge & {\left[X_{2}, Y_{2}\right] \neq[\underline{1}, \underline{1}]} & \wedge \\
X_{3} \in[\underline{0}, \underline{1}] & \wedge & Y_{3} \in[\underline{0}, \underline{1}] & \wedge \\
{\left[X_{3}, Y_{3}\right] \neq[\underline{0}, \underline{0}]} & \wedge & {\left[X_{3}, Y_{3}\right] \neq[\underline{1}, \underline{1}]} & \wedge \\
{\left[X_{1}, X_{2}, Y_{3}\right] \neq[\underline{0}, \underline{0}, \underline{0}]} & \wedge & {\left[Y_{1}, X_{2}, X_{3}\right] \neq[\underline{0}, \underline{0}, \underline{0}]} & \wedge
\end{array}\right]\left[X_{1}, Y_{2}, X_{3}\right] \neq[\underline{0}, \underline{0}, \underline{0}]
$$

where $\underline{0}$ and $\underline{1}$ can be represented by nil and [nil], respectively, and $Y_{i}$ takes the place of $\neg X_{i}$ and vice versa. It is immediate to prove that any substitution satisfying the constraint problem is also a solution for the above formula, provided $\underline{0}$ is interpreted as false and $\underline{1}$ is interpreted as true, and vice versa.

## 7 Conclusions

In this paper we have extended the results of [11] studying the constraint solving problem for four different theories: the theories of lists, multisets, compact lists, and sets. The analyzed constraints are conjunctions of literals based on equality and membership predicate symbols. We have identified the privileged models for these theories by showing that they correspond with the theories on the class of considered constraints. We have developed a notion of solved form (proved to be satisfiable) and presented the rewriting algorithms which allow this notion to be used to decide the satisfiability problems in the four contexts.

In particular, we have shown how constraint solving can be developed parametrically for these theories and we have pointed out the differences and similarities between the four kinds of aggregates.

As further work it could be interesting to study the properties of the four aggregates in presence of append-like operators (append for lists, $\cup$ for sets, $\uplus$ for multisets). These operators can not be defined without using universal quantifiers (or recursion) with the languages analyzed in this paper 10.

## Acknowledgments

The authors wish to thank Alberto Policriti, Ashish Tiwari, and Silvia Monica for useful discussions on the topics of this paper. The anonymous referee greatly helped us in improving the presentation of the paper. This work is partially supported by MIUR project Ragionamento su aggregati e numeri a supporto della programmazione e relative verifiche.

## A Proofs of Model Properties

We recall some technical definitions. Given two $\Sigma$-structures $\mathcal{A}$ and $\mathcal{B}, \mathcal{B}=\left\langle B,(\cdot)^{\mathcal{B}}\right\rangle$ is a substructure of $\mathcal{A}=\left\langle A,(\cdot)^{\mathcal{A}}\right\rangle$ if $B \subseteq A$ and for all $x \in B$ it holds that $(x)^{\mathcal{A}}=(x)^{\mathcal{B}}$. Given two $\Sigma$-structures $\mathcal{A}$ and $\mathcal{B}$, a function $h: A \longrightarrow B$ is said to be an homomorphism from $\mathcal{A}$ to $\mathcal{B}$ if: $(i) \forall f \in \mathcal{F}, a_{1}, \ldots, a_{n} \in$ $A_{\mathcal{B}}\left(h\left(f^{\mathcal{A}}\left(a_{1}, \ldots, a_{n}\right)\right)=f^{\mathcal{B}}\left(h\left(a_{1}\right), \ldots, h\left(a_{n}\right)\right)\right)$ and (ii) $\forall p \in \Pi, a_{1}, \ldots, a_{m} \in A\left(p^{\mathcal{A}}\left(a_{1}, \ldots, a_{m}\right) \rightarrow\right.$ $\left.p^{\mathcal{B}}\left(h\left(a_{1}\right), \ldots, h\left(a_{m}\right)\right)\right) . h$ is said to be an isomorphism if $f$ is bijective and in the property (ii) also the $\leftarrow$ implication holds. Given two $\Sigma$-structures $\mathcal{A}$ and $\mathcal{B}$, an embedding of $\mathcal{A}$ in $\mathcal{B}$ is an isomorphism from $\mathcal{A}$ to a substructure of $\mathcal{B}$.

Lemma A. 1 ( $\mathbf{5 ]}$ ) Let $\mathcal{A}$ and $\mathcal{B}$ be two $\Sigma$-structures and let $h$ be an embedding of $\mathcal{A}$ in $\mathcal{B}$. If $\varphi$ is an open formula of $\mathcal{L}=\langle\Sigma, \mathcal{V}\rangle$, then for each valuation $\sigma$ on $A$ it holds that:

$$
\mathcal{A} \models \sigma(\varphi) \leftrightarrow \mathcal{B} \models h(\sigma(\varphi)) .
$$

Lemma A. $2 \mathcal{M S E T}$ is a model of the theory MSet.
Proof. For each axioms/axiom schemata ( $A$ ) of the theory $M$ Set we need to prove that $\mathcal{M S E} \mathcal{T}$ models $(A)$ (briefly, $\mathcal{M S E T} \models(A)$ ). We give only the sketch of the proof.
$(K),(W)$ : The fact that $\mathcal{M S E \mathcal { T }}$ is a model of $(K)$ and $(W)$ is a consequence of the interpretation of the membership predicate in $\mathcal{M S E \mathcal { T }}$ (cf. point (4) of Def. 4.2).
$\left(F_{1}^{m}\right)$ : This axiom holds in $\mathcal{M S E \mathcal { F }}$, since $f\left(t_{1}, \ldots, t_{n}\right)$ and $f\left(s_{1}, \ldots, s_{n}\right)$ can be in the same class in $\mathcal{M S E \mathcal { T }}$, only if for all $i=1, \ldots, n$ it holds that $t_{i}$ and $s_{i}$ belong to the same class.
$\left(F_{2}\right)$ : It holds trivially, by definition of $\mathcal{M S E \mathcal { S }}$, since terms beginning with different free symbols belong to different classes.
$\left(F_{3}\right),\left(F_{3}^{m}\right):$ The fact that $\mathcal{M S E \mathcal { T }} \models\left(F_{3}\right)$ and $\mathcal{M S E \mathcal { T }} \models\left(F_{3}^{m}\right)$ holds in virtue of the finite size of each ground term; it can be formally proved by induction on the complexity of the terms.
$\left(E_{p}^{m}\right): \mathcal{M S E} \mathcal{T}$ is a model of $\left(E_{p}^{m}\right)$, since for any equational theory $E, T(\mathcal{F}) / \equiv_{E}$ is a model of $E$ [23].
$\left(E_{k}^{m}\right): \mathcal{M S E T}$ is a model of $\left(E_{p}^{m}\right)$, as seen in the previous point, but it is also the initial model, namely two terms $s$ and $t$ are in the same class if and only if $\left(E_{p}^{m}\right)$ can prove that $s=t$. This is exactly the meaning of the axiom $\left(E_{k}^{m}\right)$.

Lemma A. 3 If $\mathcal{M}$ is a model of MSet, then the function $h: T\left(\mathcal{F}_{M S e t}\right) / \equiv_{E_{M S E t}} \longrightarrow M$, defined as $h(t)=t^{\mathcal{M}}$ is an embedding of $\mathcal{M S E T}$ in $\mathcal{M}$.

Proof. We will prove the following facts:

1. The definition of $h(t)$ does not depend on the choice of the representative of the class;
2. $h$ is an homomorphism;
3. $h$ is injective;
4. if $h(\circledast) \in^{\mathcal{M}} h(\Im)$, then $(t) \in^{\mathcal{M S E T}}$ (s).

These facts imply the thesis.

1. If $t_{1}$ and $t_{2}$ are two terms such that $\left(t_{1}\right)=\left(t_{2}\right.$, then by definition $\left(E_{p}^{m}\right) \models t_{1}=t_{2}$. Since $\mathcal{A} \models t_{1}=t_{2}$ holds in every model $\mathcal{A}$ of $\left(E_{p}^{m}\right)$, then in particular it holds in $\mathcal{M}$, i.e., $t_{1}^{\mathcal{M}}=t_{2}^{\mathcal{M}}$.
2. We need to prove that:
(a) for all $f \in \mathcal{F}_{M S e t}$ and for all terms $t_{1}, \ldots, t_{n} \in T\left(\mathcal{F}_{M S e t}\right)$ it holds that

$$
h\left(f^{\mathcal{M S E T}}\left(\underline{t_{1}}, \ldots, \underline{t_{n}}\right)\right)=f^{\mathcal{M}}\left(h\left(t_{1}\right), \ldots, h\left(t_{n}\right)\right)
$$

Now,

$$
\begin{aligned}
h\left(f^{\mathcal{M S E T}}\left(\underline{t_{1}}, \ldots, \underline{t_{n}}\right)\right) & =h\left(f\left(t_{1}, \ldots, t_{n}\right)\right) & & \text { By fact (1) above } \\
& =\left(f\left(t_{1}, \ldots, t_{n}\right)\right)^{\mathcal{M}} & & \text { By def. of } h \\
& =f^{\mathcal{M}}\left(t_{1}^{\mathcal{M}}, \ldots, t_{n}^{\mathcal{M}}\right) & & \text { By def. of structure } \\
& =f^{\mathcal{M}}\left(h\left(t_{1}\right), \ldots, h\left(t_{n}\right)\right) & & \text { By def. of } h
\end{aligned}
$$

(b) for all terms $t$ and $s$, if $(t) \in^{\mathcal{M S E T}}(S$, then $h(t)) \in^{\mathcal{M}} h\left((s)\right.$. From $(t) \in^{\mathcal{M S E T}}(s)$, using fact 1. above, we have that there is a term $s^{\prime}$ in (S) of the form $\{t \mid r\}$ and that $h(S)=s^{\prime \mathcal{M}}$. Hence, we have that $h(S)=\left\{t^{\mathcal{M}} \mid r^{\mathcal{M}}\right\}^{\mathcal{M}} ;(W)$ ensures that $h(t)=t^{\mathcal{M}}$ belongs to it.
3. We prove, by structural induction on $t_{1}$, that if $h\left(\widetilde{t_{1}}\right)=h\left(\widetilde{t_{2}}\right)$, then $\widehat{t_{1}}=\left(\overparen{t_{2}}\right.$.

Basis. Let $t_{1}$ be a constant $c$. Since $\mathcal{M}$ is a model of axiom schema $\left(F_{2}\right)$, it can not be that $t_{2}=f\left(s_{1}, \ldots, s_{n}\right)$, with $f$ different from $c$. Hence, it must be that $t_{2}=c$.
Step. Let $t_{1}$ be $f\left(s_{1}, \ldots, s_{n}\right)$, with $f \not \equiv\{|\cdot| \cdot\}$. It cannot be $t_{2} \equiv g\left(r_{1}, \ldots, r_{m}\right)$, with $g \not \equiv f$, since $\mathcal{M}$ is a model of $\left(F_{2}\right)$. So, it must be $t_{2} \equiv f\left(r_{1}, \ldots, r_{n}\right)$, and, by $\left(F_{1}\right), s_{i}^{\mathcal{M}}=r_{i}^{\mathcal{M}}$, for all $i \leq n$. Using the inductive hypothesis we have $\widehat{t_{1}}=\overline{t_{2}}$.
Let $t_{1}$ be $\left\{s_{1}, \ldots, s_{n} \mid r\right\}$, with $r$ not of the form $\left\{r_{1} \mid r_{2}\right\}$. Since it cannot be that $t_{2}$ is $f\left(v_{1}, \ldots, v_{n}\right)$ (from the previous case applied to $t_{2}$ ), then it must be $t_{2}$ is $\left\{u_{1}, \ldots, u_{m} \mid v\right\}$, for some $v$ not of the form $\left\{v_{1} \mid v_{2}\right\}$. Let us assume, by contradiction, that $\overline{t_{1}} \neq t_{2}$, and $t_{1}^{\mathcal{M}}=t_{2}^{\mathcal{M}}$, while the thesis holds for all terms of lower complexity. From $t_{1}^{\mathcal{M}}=t_{2}^{\mathcal{M}}$ we obtain that the two terms have in $\mathcal{M}$ the same elements. Since $\mathcal{M}$ is a model of $(W)$, the elements of $t_{1}^{\mathcal{M}}$ are exactly $s_{1}^{\mathcal{M}}, \ldots, s_{n}^{\mathcal{M}}$ and the elements of $t_{2}^{\mathcal{M}}$ are exactly $u_{1}^{\mathcal{M}}, \ldots, u_{m}^{\mathcal{M}}$. So, by inductive hypothesis, there is a bijection $b:\{1, \ldots, n\} \longrightarrow\{1, \ldots, m\}$ such that $\bar{s}_{i}=u_{b(i)}$. This means that $m=n$ and that there is a term $t_{2}^{\prime}$ in $\widehat{t_{2}}$ of the form $\left\{s_{1}, \ldots, s_{m} \mid v\right\}$. Applying $n$ times $\left(E_{k}^{m}\right)$, in all possible ways, we obtain that $r^{\mathcal{M}}=v^{\mathcal{M}}$, hence by inductive hypothesis $r($ (v). From this fact, we conclude that $\left(\underline{t_{2}}=\underline{t_{2}^{\prime}}=\left\{s_{1}, \ldots, s_{n} \mid r\right\}=\underline{t}_{1}\right.$, which is in contradiction with our assumption.
4. If $h(t)) \in^{\mathcal{M}} h\left((s)\right.$, then $t^{\mathcal{M}} \in^{\mathcal{M}} s^{\mathcal{M}}$ and hence $(K)$ implies that $s$ must be a term of the form $\left\{t_{1} \mid t_{2}\right\}$. By induction on $s$ using $(W)$, we can prove that in particular $s$ must be a term of the form $\left\{t_{1}, \ldots, t_{i}, \ldots, t_{n} \mid r\right\}$, with $t_{1}^{\mathcal{M}}=t^{\mathcal{M}}=h((t)$. We have already proved that $h$ is injective, hence it must be $t_{1} \in \notin$, and from this we obtain $(t) \in^{\mathcal{M S E I}}$ (s).

Lemma A. 4 If $C$ is a constraint in pre-solved form and acyclic, then $\sigma_{C}$ is stabilizing.
Proof. We prove that $\sigma_{C}^{*} \equiv \sigma_{C}^{q-1}$, where $q$ is the number of variables which occur in the right-hand side of membership atoms.

The acyclicity condition ensures that there are no loops in the graph $\mathcal{G}_{C}^{\in}$. Consider now the substitution $\sigma_{C}$ and let $B$ be the set of the nodes of the graph that belong to its domain (we identify variables and corresponding nodes). Each application of $\sigma_{C}$ on the terms of its codomain can be intuitively mimicked by a game that updates the value of $B$ with the nodes corresponding to the variables occurring in the terms $\sigma_{C}(B)$. These nodes can be computed by collecting the nodes that can be reached by crossing an edge from a node of $B$ (new variables $F_{i}, M_{i}$ are all different, and they are not in the domain of $\sigma_{C}$, so we can forget them). The process will terminate when either $B$ is empty or it contains only variables that are not in the domain of $\sigma_{C}$. Since $\mathcal{G}_{C}^{\in}$ is acyclic, this process must terminate, and since the longest path in the graph is shorter than $q$, it is plain o see that $q-1$ is an upper bound to the number of iterations.

Lemma A. 5 Let $\mathbb{T}$ be one of the theories List, MSet, CList, $\mathcal{A}_{\mathbb{T}}$ the model (structure) which corresponds with $\mathbb{T}$, and $E_{\mathbb{T}}$ the associated equational theory. Let $t, t^{\prime}$ be two terms and $C$ a solved form constraint over the language $\mathcal{L}_{\mathbb{T}}$, such that $F V(t) \cup F V\left(t^{\prime}\right) \subseteq F V(C)$. If $\mathcal{A}_{\mathbb{T}} \not \vDash \forall\left(t=t^{\prime}\right)$, then $E_{\mathbb{T}} \not \vDash \forall\left(\sigma_{C}^{*}(t)=\right.$ $\left.\sigma_{C}^{*}\left(t^{\prime}\right)\right)$.

Proof. Let $R=\left\{X_{1}, \ldots, X_{n}\right\}$ be the set of variables over which $\sigma_{C}$ is defined. By induction on the sum of the complexities of $t$ and $t^{\prime}$ we prove the following property that implies the thesis of the lemma.

$$
\begin{aligned}
& \text { If there exists } \theta \text { such that } \mathcal{A}_{\mathbb{T}} \models \theta(t) \neq \theta\left(t^{\prime}\right) \text {, then there exists } \theta^{\prime} \text { such that } \mathcal{A}_{\mathbb{T}} \models \theta^{\prime}\left(\sigma_{C}^{*}(t)\right) \neq \\
& \theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right) \text {. }
\end{aligned}
$$

Let us consider the valuation $\theta^{\prime \prime}$ defined as:

$$
\theta^{\prime \prime}(Y)= \begin{cases}\theta(Y) & \text { if } Y \notin R \\ \theta\left(X_{i}\right) & \text { if } Y \equiv M_{X_{i}}\end{cases}
$$

Observe that $\theta^{\prime \prime}$ is not defined over the variables $F_{X_{1}}, \ldots, F_{X_{n}}$.

Let $m=\max \left\{\operatorname{size}\left(\theta^{\prime \prime}\left(\sigma_{C}^{*}(t)\right)\right)\right.$, size $\left.\left(\theta^{\prime \prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)\right)\right\}+1$. We can now define the valuation $\theta^{\prime}$ in the following way:

$$
\theta^{\prime}(Y)= \begin{cases}{[\mathrm{nil}]^{m * i}\left(\{\mathrm{nil}\}^{m * i}, \llbracket \mathrm{nil} \rrbracket^{m * i}\right)} & \text { if } Y \equiv F_{X_{i}} \\ \theta^{\prime \prime}(Y) & \text { otherwise }\end{cases}
$$

If $t=Y_{1}$ and $t^{\prime}=Y_{2}$ are variables then:

- if $\sigma_{C}$ is not defined neither on $Y_{1}$ nor on $Y_{2}$, then $\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{1}\right)\right)=\theta^{\prime}\left(Y_{1}\right)=\theta\left(Y_{1}\right) \neq \theta\left(Y_{2}\right)=\theta^{\prime}\left(Y_{2}\right)=$ $\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{2}\right)\right)$;
- if $\sigma_{C}$ is defined on $Y_{1}$ and not on $Y_{2}$ (or viceversa), then $\operatorname{size}\left(\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{1}\right)\right)\right) \geq \operatorname{size}\left(\theta^{\prime}\left(F_{Y_{1}}\right)\right)>$ $\operatorname{size}\left(\theta^{\prime}\left(Y_{2}\right)\right)$;
- if $\sigma_{C}$ is defined both on $Y_{1}$ and on $Y_{2}$, then:

List and CList: $\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{1}\right)\right)$ and $\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{2}\right)\right)$ differ on their first element.
MSet: $\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{1}\right)\right)$ and $\theta^{\prime}\left(\sigma_{C}^{*}\left(Y_{2}\right)\right)$ differ on their elements $\theta^{\prime}\left(F_{Y_{1}}\right)$ and $\theta^{\prime}\left(F_{Y_{2}}\right)$.
If $t=Y$ is a variable and $t^{\prime}$ is $f\left(t_{1}^{\prime}, \ldots, t_{h}^{\prime}\right)$, also when $f$ is of the form $[\cdot \mid \cdot], \mathbb{\llbracket} \cdot \mid \cdot \rrbracket,\{[\mid \cdot \mathbb{\}}$, then:

- if $\sigma_{C}$ is not defined on $F V\left(t^{\prime}\right) \cup Y$, then we have immediately the thesis since $\theta^{\prime}\left(\sigma_{C}^{*}(Y)\right)=\theta(Y)$ and $\theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)=\theta\left(t^{\prime}\right)$;
- if $\sigma_{C}$ is defined on $Y$, but not on $F V\left(t^{\prime}\right)$, then we have the thesis since $\operatorname{size}\left(\theta^{\prime}\left(\sigma_{C}^{*}(Y)\right)\right)>$ $\operatorname{size}\left(\theta\left(t^{\prime}\right)\right)$;
- if $\sigma_{C}$ is defined on at least one variable of $t^{\prime}$ and not on $Y$, then as in the previous case we have the thesis;
- if $\sigma_{C}$ is defined on $Y$ and on at least one of the variables of $t^{\prime}$, then:

List and CList: it can never be the case that the first element of $\theta^{\prime}\left(\sigma_{C}^{*}(Y)\right)$-i.e. $\theta^{\prime}\left(F_{Y}\right)$-is equal to the first element of $\theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)$; this follows from the conditions we have imposed on all the $\theta^{\prime}\left(F_{X_{i}}\right)$.
MSet: two cases are possible: $\theta^{\prime}\left(F_{Y}\right)$ is not an element of $\theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)$, from which we have the thesis.
$\theta^{\prime}\left(F_{Y}\right)$ is an element of $\theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)$ : this means that tail $\left(t^{\prime}\right)=Y$, hence the thesis follows.
If $t$ is $f\left(t_{1}, \ldots, t_{h}\right)$ and $t^{\prime}=g\left(t_{1}^{\prime}, \ldots, t_{k}^{\prime}\right)$, with $f$ different from $g$, then it is trivial.
If $t$ is $f\left(t_{1}, \ldots, t_{h}\right)$ and $t^{\prime}$ is $f\left(t_{1}^{\prime}, \ldots, t_{h}^{\prime}\right)$, with $f$ different from $[\cdot \mid \cdot], \llbracket \cdot \mid \cdot \rrbracket,\{\cdot \mid \cdot \rrbracket\}$, then by inductive hypothesis we have the thesis.
If $t$ is $\left[t_{1} \mid t_{2}\right]$ and $t^{\prime}$ is $\left[t_{1}^{\prime} \mid t_{2}^{\prime}\right]$, then from $\mathcal{L I S T} \models \theta(t) \neq \theta\left(t^{\prime}\right)$ we have that it must be $\mathcal{L I S T} \models \theta\left(t_{1}\right) \neq$ $\theta\left(t_{1}^{\prime}\right)$ or $\mathcal{L I S T} \models \theta\left(t_{2}\right) \neq \theta\left(t_{2}^{\prime}\right)$, hence, in both cases, we obtain the thesis by inductive hypothesis.
If $t$ is $\llbracket t_{1} \mid t_{2} \rrbracket$ and $t^{\prime}$ is $\llbracket t_{1}^{\prime} \mid t_{2}^{\prime} \rrbracket$, then from $\mathcal{C L I S T} \models \theta(t) \neq \theta\left(t^{\prime}\right)$ we have that it must be $\mathcal{C L I S T} \models$ $\theta\left(t_{1}\right) \neq \theta\left(t_{1}^{\prime}\right)$ or $\mathcal{C} \mathcal{L I S T} \models \theta\left(t_{2}\right) \neq \theta\left(t_{2}^{\prime}\right) \wedge \theta\left(t_{2}\right) \neq \llbracket \theta\left(t_{1}^{\prime}\right)\left|\theta\left(t_{2}^{\prime}\right) \rrbracket \wedge \theta\left(t_{2}^{\prime}\right) \neq \llbracket \theta\left(t_{1}\right)\right| \theta\left(t_{2}\right) \rrbracket$, hence:

- in the first case we obtain the thesis by inductive hypothesis on $t_{1}$ and $t_{1}^{\prime}$.
- in the second case by inductive hypothesis on $t_{2}$ and $t_{2}^{\prime}$, on $t_{2}$ and $\llbracket t_{1}^{\prime} \mid t_{2}^{\prime} \rrbracket$, on $t_{2}^{\prime}$ and $\llbracket t_{1} \mid t_{2} \rrbracket$, we obtain that $\mathcal{C} \mathcal{L I S T} \models \theta^{\prime}\left(\sigma_{C}^{*}\left(t_{2}\right)\right) \neq \theta^{\prime}\left(\sigma_{C}^{*}\left(t_{2}^{\prime}\right)\right)$ and $\mathcal{C L I S T} \models \theta^{\prime}\left(\sigma_{C}^{*}\left(t_{2}\right)\right) \neq \theta^{\prime}\left(\sigma_{C}^{*}\left(\llbracket t_{1}^{\prime} \mid t_{2}^{\prime} \rrbracket\right)\right)$ and $\mathcal{C L I S T} \models \theta^{\prime}\left(\sigma_{C}^{*}\left(t_{2}^{\prime}\right)\right) \neq \theta^{\prime}\left(\sigma_{C}^{*}\left(\llbracket t_{1} \mid t_{2} \rrbracket\right)\right)$, which implies our thesis.
If $t$ is $\left\{t_{1} \mid t_{2}\right\}$ and $t^{\prime}$ is $\left\{t_{1}^{\prime} \mid t_{2}^{\prime}\right\}$, then:
- if tail $\left(t_{2}\right)$ and tail $\left(t_{2}^{\prime}\right)$ are the same variable, the we obtain the thesis by inductive hypothesis on untail $\left.\left(\left\{t_{1} \mid t_{2}\right\}\right\}\right)$ and untail $\left.\left(\left\{t_{1}^{\prime} \mid t_{2}^{\prime}\right\}\right\}\right)$;
- if tail $\left(t_{2}\right)=Y$ and $\operatorname{tail}\left(t_{2}^{\prime}\right)=Y^{\prime}$ are not the same variable and $\sigma_{C}$ is not defined on $Y$ or on $Y^{\prime}$, then $\theta^{\prime}\left(F_{Y}\right)$ or $\theta^{\prime}\left(F_{Y^{\prime}}\right.$ is not an element of both $\theta^{\prime}\left(\sigma_{C}^{*}(t)\right)$ and $\theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)$;
- if tail $\left(t_{2}\right)=Y$ and tail $\left(t_{2}^{\prime}\right)=Y^{\prime}$ are not the same variable and $\sigma_{C}$ is not defined on $Y$ and on $Y^{\prime}$, then we can restrict ourselves to the case in which there is an element $s$ of $\theta(t)$ which is not an element of $\theta\left(t^{\prime}\right)$ (in the general case we would have to consider that there exists $s$ such that there are $m$ occurrences of $s$ in $\theta(t)$ and $n$ occurrences in $\theta\left(t^{\prime}\right)$ with $\left.m \neq n\right)$ :
- if $s$ is an element of $\theta(Y)$, then, from the fact that $\sigma_{C}$ is not defined on $Y$, we have the thesis, since it cannot be the case that one of the elements of untail $\left(t^{\prime}\right)$ becomes equal to $\theta(s)$ (the new elements have a size which is greater);
- if $s$ is an element of untail $(t)$, then we have $t=\left\{u_{1}, \ldots, u_{h}, \ldots, u_{m} \mid Y\right\}$ and $s=\theta\left(u_{h}\right)$, hence, from the inductive hypothesis, we have that $\theta^{\prime}\left(\sigma_{C}^{*}\left(u_{h}\right)\right)$ is still different from all elements of $\theta^{\prime}\left(\sigma_{C}^{*}\left(\right.\right.$ untail $\left.\left.\left(t^{\prime}\right)\right)\right)$, and it is immediate that it is different from all the elements of $\theta^{\prime}\left(Y^{\prime}\right)$, hence $\theta^{\prime}\left(\sigma_{C}^{*}\left(u_{h}\right)\right)$ is an element of $\theta^{\prime}\left(\sigma_{C}^{*}(t)\right)$ which is not in $\theta^{\prime}\left(\sigma_{C}^{*}\left(t^{\prime}\right)\right)$.

Lemma A. 6 Let $\mathbb{T}$ be one of the theories List, CList, MSet and Set, and C a constraint in pre-solved form over the language of $\mathbb{T}$. If is_solved $\mathbb{T}_{\mathbb{T}}(\mathbb{C})$ returns false, then $C$ is not satisfiable in the model $\mathcal{A}_{\mathbb{T}}$ which corresponds with $\mathbb{T}$.

Proof. If is_solved ${ }_{\mathbb{T}}(\mathrm{C})$ returns false because $\mathcal{G}_{C}^{\in}$ has a cycle then the result is trivial, since all aggregates in $\mathcal{A}$ are well-founded. Otherwise:
For List, MSet, CList: From Lemma A.5 we know that $\mathbb{T} \models \forall\left(\sigma_{C}^{*}(t)=\sigma_{C}^{*}\left(t^{\prime}\right)\right)$ implies $\mathbb{T} \models \forall\left(t=t^{\prime}\right)$, hence, since $t \in X$ and $t^{\prime} \notin X$ are in $C, C$ is not satisfiable in the model $\mathcal{A}$ which corresponds with $\mathbb{T}$.
For Set: Let $\sigma_{C}^{*} \equiv\left[X_{1} /\left\{F_{1}, p_{1}^{1}, \ldots, p_{1}^{k_{1}} \mid M_{1}\right\}, \ldots, X_{q} /\left\{F_{q}, p_{q}^{1}, \ldots, p_{q}^{k_{q}} \mid M_{q}\right\}\right]$, we have that if $\mathcal{S E T} \models$ $C \gamma$, then $\mathcal{S E T} \models\left(C \sigma_{C}^{*}\right) \gamma^{\prime}$, where $\gamma^{\prime}$ is defined as follows

$$
\gamma^{\prime}(Y)= \begin{cases}\gamma\left(X_{i}\right) & \text { if } Y \equiv M_{i} \\ p_{i}^{1} & \text { if } Y \equiv F_{i} \\ \gamma(Y) & \text { otherwise }\end{cases}
$$

Hence, if is_solved ${ }_{S e t}$ returns false this means that $C \sigma_{C}^{*}$ is not satisfiable in $\mathcal{S E} \mathcal{T}$, which implies that $C$ is not satisfiable in $\mathcal{S E T}$.

## B Termination Proofs (Theorem 6.1)

## Termination of SAT List

Using the same measure as for SAT $_{M S e t}$ termination follows.

## Termination of SAT ${ }_{\text {CList }}$

Finding a global decreasing measure implies that this measure is decreased by each rule of each algorithm involved. The measure developed in [11 for proving termination of Unify_clists is rather complex. This is due to the fact that new variables are (apparently) freely introduced in the constraint by this procedure. Instead of extending such complex measure to the general case, we use here a different approach for proving termination. The proof is based:

- on the fact that each single rewriting procedure terminates (for Unify_clists it follows from [11]; for the other three procedures the result is trivial) and
- on the fact that it is possible to find a bound on the number of possible repeat cycles.

The remaining part of the proof is devoted to find this bound. First of all observe that:

- After the execution of in-CList there are only membership atoms of the form $t \in X$ with $X \notin$ $F V(t)$. New equations can be introduced.
- After the execution of in-CList there are only not-membership literals of the form $t \notin X$ with $X \notin$ $F V(t)$. New disequality constraints can be introduced. Membership atoms are not introduced.
- After the execution of neq-CList there are only disequality constraints of the form $X \neq t$ with $X \notin F V(t)$. New equations can be introduced. $\in$ and $\notin$-constraints are not introduced.
- Unify_clists eliminates all equality constraints producing a substitution. This substitution, when applied to membership, not-membership, and disequality literals in pre-solved form can force a new execution of the procedures in-CList, nin-CList, and neq-CList. However, new executions of Unify_clists are possible only if in-CList and neq-CList introduce new equations. In the following we will find a bound on the number of possible new equations inserted.
Let us analyze membership constraints. Each membership atom of the form $t \in \llbracket s^{\prime} \mid s^{\prime \prime} \rrbracket$ is rewritten to false or to $t=s^{\prime} \vee t \in s^{\prime \prime}$. This means that in each non-deterministic branch of the rewriting process at most one equation is introduced for each initial membership atom. Thus, if $k$ is the number of membership atoms in $C$ at the beginning of the computation, at most $k$ equality atoms (that can fire

Unify_clists) can be introduced. If we prove termination with $k=0$ then full termination easily follows, since it is the same as considering $k$ successive (terminating) executions.

Let us consider the procedure neq-CList. Action (7.2) can replace a disequality constraint of the form: $X \neq \llbracket t_{1}, \ldots, t_{n} \mid X \rrbracket$ with the following equations, identifying a substitution:

$$
\begin{align*}
X & =\text { nil }  \tag{8}\\
X & =\llbracket N_{1} \mid N_{2} \rrbracket \text { with } N_{1}, N_{2} \text { new variables. } \tag{9}
\end{align*}
$$

Let us analyze the various cases in which substitutions of this form have some effects on the constraint.

- there is $t \in X$ in $C$. This is not possible by hypothesis, since $k=0$.
- $t \notin X$ or $X \neq t$ and we know that $X$ does not occur in $t$. This implies a finite number of executions of rules of nin-CList or neq-CList. Since $X$ is not in $t$ and the variables $N_{1}$ and $N_{2}$ are newly introduced, it is impossible to generate a situation firing rule (7.2).
- Assume there are more than one equation introduced for the same variable $X$.
- If they are all of the form [8], then Unify_clists will apply the substitution and remove the redundant equations.
- If they are all of the form (9), then Unify_clists will perform a unification process between these new equations. The particular form of the equations allows us to see that the effect is to introduce new equations of the form $N_{1}=N_{1}^{\prime}$ between all the new variables used as elements and equations of the form $N_{2}=N_{2}^{\prime}$ or $N_{2}=\llbracket N_{1}^{\prime} \mid N_{2}^{\prime} \rrbracket$ between the new variables used as rests. The situation is similar to that in which a unique substitution is computed.
- If there are both equations of the form (8) and of the form (9), then a failing (thus, terminating) situation will be detected by Unify_clists.

## Termination of SAT ${ }_{\text {Set }}$

Finding a global decreasing measure implies that this measure is decreased by each rule of each algorithm involved. This is rather complex since it must subsume the measure developed in 11 for proving termination of Unify_sets. Thus, instead of extending such complex measure, we use here a different approach for proving termination. The proof is based:

- on the fact that each single rewriting procedure terminates (for Unify_sets it follows from [11; for the other three procedures the result is trivial) and
- on the fact that it is possible to control the number of new calls to unification.

In order to simplify the proof we assume a strategy for handling the non-determinism. The strategy will be pointed out during the discussion.

As observed in the proof of SAT ${ }_{\text {CList }}$, if $k$ is the number of membership atoms in $C$ at the beginning of the computation, at most $k$ equality atoms (that can fire Unify_sets) can be introduced. For this reason, we can safely forget this kind of constraints from the whole reasoning.

The only problem for termination is given by rules (6a) and (6b) of neq-CList. As a strategy, we can unfold the application of this rules (actually, adding a bit of determinism to the whole procedure). This means that rule ( $6 a$ ) (for ( $6 b$ ) the situation is symmetrical) is as follows: assume that $\left\{t_{1} \mid s_{1}\right\}$ is $\left\{v_{1}, \ldots, v_{m} \mid h\right\}$ and $\left\{t_{2} \mid s_{2}\right\}$ is $\left\{w_{1}, \ldots, w_{n} \mid k\right\}$, with $h, k$ variables or terms of the form $f(\ldots), g(\ldots)$, $f$ and $g$ different from $\{\cdot \mid \cdot\}$. The global effect of the subcomputation is that of returning a constraint of the form $(1 \leq i \leq m)$ :

$$
\begin{equation*}
N=v_{i}, v_{i} \neq w_{1}, \ldots, v_{i} \neq w_{n}, v_{i} \notin k \tag{10}
\end{equation*}
$$

or one constraint of the form

$$
\begin{equation*}
h=\left\{N \mid N^{\prime}\right\}, N \neq w_{1}, \ldots, N \neq w_{n}, N \notin k \tag{11}
\end{equation*}
$$

if $h$ is a variable. Notice that the application of this substitution is a sort of application of rule (4) of the procedure in-Set.

In the following discussion let us assume that termination by failure do not occur (but, in this case, termination follows trivially). Suppose to have already executed the first cycle of the repeat loop. Local termination ensures that this can be done in finite time. In the constraint there are no equations, while there can be negated membership and disequality literals not necessarily in pre-solved form.

Let us execute procedure nin-Set. No equations are introduced. In the constraint there are notmembership literals in pre-solved form and disequality constraints not necessarily in pre-solved form.

Let us execute the procedure neq-Set. We adopt a weak strategy to face the non-determinism: delay the constraints that fire action (6) as much as possible. This means that after a finite time the constraint is composed by a number of constraints of the form $X \neq t$ or $t \notin X$ with $X \notin F V(t)$ plus a (possibly empty) constraint $\tilde{C}$ of constraints all firing action (6) of neq-Set. Pick one constraint $c$ from $\tilde{C}$ and consider the possible non-deterministic executions.

- Assume that the situation of case (11) above does not occur in a non-deterministic branch. Then (see case (10) the constraint $c$ is replaced in $C$ by a number of constraints $v_{i} \neq w_{j}$ of fewer size. If they do not fire action (6) they can be directly processed to reach a pre-solved form. Otherwise, they are inserted in $\tilde{C}$, but since they are of fewer size, if the situation of case (11) never occur, this again implies termination.
- Assume now that the situation of case (11) occurs when processing the constraint $c$. Constraints

$$
N \neq w_{1}, \ldots, N \neq w_{n}, N \notin k
$$

are introduced. Constraints in pre-solved form of the form above, with $N$ a variable introduced as element of a set by action (6), are said passive constraints. Variables $N$ of this form are inserted in the constraint only by this step. We will see that passive disequality constraints remain in pre-solved form forever while negated membership passive literals have a controlled growth.
Assume to apply immediately the substitution $h /\left\{N \mid N^{\prime}\right\}$. Its effect can be the following, according to the position of $h$ in a constraint:
$-X \neq t[h]$ or $t[h] \notin X$ : the terms gets changed but the constraints remain in pre-solved form.
$-s[h] \neq t$ or $s \neq t[h]$ or $s[h] \neq t[h]$ : the terms change but the constraints remain in $\tilde{C}$ to be processed later.
$-t \notin h$ is transformed to $t \notin\left\{N \mid N^{\prime}\right\}$. One step of nin-Set is applied to obtain: $t \neq N \wedge t \notin N^{\prime}$. The first constraint is immediately transformed into $N \neq t$ (a passive constraint) while the second is in pre-solved form. Observe that if $t \notin h$ is passive (i.e., $t$ is a variable of type $N$ ), then only passive constraints are introduced.

- $h \neq t$ is transformed to $\left\{N \mid N^{\prime}\right\} \neq t$. Observe that $h \neq t$ can not be a passive constraint since $h$ is a 'rest' variable while the variables of passive constraints are 'element' variables, like $N$ here. A constraint in pre-solved form is no longer in pre-solved form. Let us apply the rewriting rules to it. It is immediately rewritten to true (e.g., when $t$ is $f(\cdots), f \neq\{\cdot \mid \cdot\}$ ) or it becomes in pre-solved form (when $t$ is a variable) or action (6) can be applied.
Both in cases (10) and in the case (11) we introduce a number of passive constraints and, in the last case, a substitution $N^{\prime} /\left\{N_{1} \mid N_{1}^{\prime}\right\}$ is applied. Notice that the global effect on the system it the fact that in the other constraints the original variable $h$ is replaced by $\left\{N, N_{1} \mid N_{1}^{\prime}\right\}$. This means that this situation can be performed at most once per each occurrence of $h$. And, the reasoning starting from substitutions of the form $\left\{N, N_{1}, \ldots, N_{\ell} \mid N_{\ell}^{\prime}\right\}$ is the same as that done here for $N^{\prime} /\left\{N_{1} \mid N_{1}^{\prime}\right\}$. At the end of the process, the number of constraints in $\tilde{C}$ is decreased and we have only introduced pre-solved form and passive constraints.
