#### Abstract

In this paper, we consider an extended concept of invariant for polynomial dynamical system (PDS) with domain and initial condition, and establish a sound and complete criterion for checking semi-algebraic invariants (SAI) for such PDSs. The main idea is encoding relevant dynamical properties as conditions on the high order Lie derivatives of polynomials occurring in the SAI. A direct consequence of this criterion is a relatively complete method of SAI generation based on template assumption and semi-algebraic constraint solving. Relative completeness means if there is an SAI in the form of a predefined template, then our method can indeed find one using this template.

## Keywords

Invariant, Semi-algebraic set, Polynomial dynamical system

## 1. INTRODUCTION

Hybrid systems are those systems involving both continuous evolutions and discrete transitions. How to design correct (desired) hybrid systems is a grand challenge in computer science and control theory. From a computer scientist's point of view, the main concern on hybrid systems up to now is to verify so-called safety properties. A safety property claims that some unsafe state is never reachable from any initial state along with any trajectory of the system.

### 1.1 Motivation

Directly computing the reachable set is a natural way to address this issue. As we know, there are two well-developed techniques for computing reachable set so far, that is, techniques based on model-checking [5, 22] and the decision procedure of Tarski algebra [28, respectively. However, the former technique requires the decidability and therefore can only be applied to some simple hybrid systems, e.g. timed automata [1], multirate automata [2], rectangular automata [21] 12, and so on. Comparably speaking, the latter technique has a wider scope of applications. For example, in

14 how to compute reachable sets for three classes of special linear hybrid systems are investigated. However, this technique heavily depends on whether the explicit solutions of the considered differential equations are or can be reduced to polynomials. So, this approach can not be applied to general linear hybrid systems, let alone nonlinear systems.

To deal with more complicated systems, recently, a deductive method has been established and successfully applied in practice [17, 18, which can be seen as a generalization of the so-called Floyd-Hoare-Naur inductive assertion method. Inductive assertion method is thought to be the dominant method for the verification of sequential programs. To generalize the inductive method to hybrid systems, a logic similar to Hoare logic which can deal with continuous dynamics is necessary. For example, differential-algebraic dynamic logic 16 due to Platzer was invented by extending dynamic logic with continuous statements. Recently, Liu et al 15 had another effort by extending Hoare logic to hybrid systems for the same purpose.

The most challenging part of the inductive method is how to discover invariants of hybrid systems. An invariant is a property that holds at all reachable states from any initial state that satisfies this property. If we can get invariants that are strong enough to imply the safety property to be verified, then we succeed in safety verification without solving differential equations, while differential equations have to be exactly solved or approximated in the methods via directly computing reachable sets. In particular, if the term expressions of a hybrid system are or can be reduced to polynomials, the so-called inductive invariants 25] can be effectively generated using the constraint-based approach 9 .

The key issue in generating inductive invariants of a hybrid system is to deal with continuous dynamics, i.e. to generate continuous invariant of the continuous evolution at each location (mode) of the hybrid system. A location (mode) of a hybrid system is usually represented by a continuous $d y$ namical system with domain and initial condition (CDSwDI for short) of the form $(H, \mathbf{f}, \Xi)$, where $\mathbf{f}$ is a vector field, $H$ is a domain restriction of continuous evolution, and $\Xi \subseteq H$ is a set of initial states. A property $\varphi$ is called a continuous invariant (CI for short) of ( $H, \mathbf{f}, \Xi$ ), if it is always satisfied along any trajectory whose starting point satisfies $\Xi$, as long as the trajectory still remains in domain $H$. For $\varphi$ to be a CI of $(H, \mathbf{f}, \Xi)$, the more complex the forms of $H, \mathbf{f}, \Xi$ and $\varphi$ are, the more intricate constraints should be induced
accordingly. A global (discrete) inductive invariant of a hybrid system consists of a set of CIs such that: the initial condition of the initial location (mode) entails the CI of the initial location, and if there is a discrete transition between two locations of the system, then the CI at the pre-location implies the CI at the post-location w.r.t. the discrete transition. There are many methods, e.g. 31, for certifying and generating global inductive invariants of a system by using the global inductiveness. Therefore in this paper we only focus on how to generate CI at a single location (mode), i.e. a CDSwDI.

### 1.2 Related Work

In the literature, lots of efforts have been made towards algebraic or semi-algebraic continuous invariants generation for polynomial dynamical systems, even though CI may have different synonyms.

The generation of algebraic invariants, i.e. sets defined by polynomial equations are usually based on the theory of ideals in polynomial ring. In 25], to handle continuous differential equations, two strong continuous consecution conditions are imposed on the predefined templates, and then the two conditions are encoded as ideal membership statements. The work in 23 showed that the set of algebraic invariants of a linear system, which forms a polynomial ideal, is computable. The above two approaches both use Gröbner bases computation. An efficient technique that computes algebraic invariants as the greatest fixed point of a monotone operator over pseudo ideals was presented in 24.

As for the polynomial inequality case, to guarantee that $p \geq 0$ is a CI of a $\operatorname{PDS}(H, \mathbf{f}, \Xi)$, it is useful to analyze the direction of $\mathbf{f}$ with regard to the set $p \geq 0$. In [19, 20, the authors proposed the notion barrier certificates for safety verification of hybrid systems. A polynomial $p$ could be a barrier certificate if the unsafe region is included in $p<0$, and at any point in $p=0$, $\mathbf{f}$ points (strictly) inwards the set $p \geq 0$. Such polynomial barrier certificates can be effectively computed using sum of squares decomposition and semi-definite programming. In 9 a similar idea is adopted and by reducing the conditions of CI to semi-algebraic constraints, invariants that are boolean combinations of polynomial equations and inequalities can be generated. Unfortunately, the approaches in [19, 9 were discovered in 27 [26. 16, to have certain problems with their soundness, if at the boundary of a CI, $\mathbf{f}$ is not strictly inward the invariant set. In 17 the authors proposed the notion of differential invariant and the principle of differential induction. Basically, $p \geq 0$ is a differential invariant of $(H, \mathbf{f}, \Xi)$ if at any point in $H$, the directional derivative of $p$ in the direction of $\mathbf{f}$ is nonnegative. Such requirement is strong, but provide a sound and effective way of generating complex semi-algebraic continuous invariants.

### 1.3 Our Contribution

The problem of checking inductiveness for continuous dynamical systems was considered in 27] and [26]. Therein various sound checking rules are presented, which are also complete for classes of continuous invariants, e.g. linear, quadratic, convex and smooth invariants. The authors even proposed a sound and relatively complete rule using higher order Lie derivatives, which is quite similar to ours. How-
ever, in their relatively complete rule there are infinitely many candidate tests and thus is computationally infeasible. Our work in this paper actually resolves this problem and completes the gap left open in 27, 26,

The relative completeness of our method means that for a given PDS, if there is an SAI of the predefined template, then our method can indeed discover one SAI using this template. Thus, there are two advantages with our approach comparing with the well-established approaches: firstly, more general SAIs can be generated; secondly, a by-product of the completeness of our approach is that whether a given semialgebraic set is really an SAI of a given PDS is decidable. This is quite useful in the interplay of discrete invariant generation (global) and CI generation (local).

### 1.4 Paper Organization

The rest of this paper is organized as follows. Section 2 presents some basic notions and fundamental theories on algebraic geometry and dynamical system. Section 3 gives a formal definition of the SAI generation problem. In Section 4 we prove the fundamental results based on which our method is developed. Section 5 illustrates the basic idea of our approach in simple cases. How to apply our approach to general cases is investigated in Section 6 Two case studies are given in Section 7 Section 8 concludes this paper with a discussion of future work.

## 2. PRELIMINARIES

In this section, we will recall some basic notions.

### 2.1 Polynomial Ideal Theory

Let $\mathbb{K}$ be an algebraic field and $\mathbb{K}\left[x_{1}, \ldots, x_{n}\right]$ denote the polynomial ring with coefficients in $\mathbb{K}$. In this paper, $\mathbb{K}$ will be taken as the rational number field $\mathbb{Q}$. Customarily, let $\mathbf{x}$ denote the $n$-tuple $\left(x_{1}, \cdots, x_{n}\right)$ with $\operatorname{dim}(\mathbf{x})=n$, and a polynomial in $\mathbb{Q}\left[x_{1}, \ldots, x_{n}\right](\mathbb{Q}[\mathbf{x}]$ for short) may be written as $p(\mathbf{x})$ or $p$ simply. A parametric polynomial

$$
p(\mathbf{u}, \mathbf{x}) \in \mathbb{Q}\left[u_{1}, u_{2}, \ldots, u_{t}, x_{1}, x_{2}, \ldots, x_{n}\right]
$$

is called a template, where $\mathbf{x}$ are variables taking values from $\mathbb{R}^{n}$ and $\mathbf{u}$ are coefficient parameters taking values from $\mathbb{R}^{t}$. Given $\mathbf{u}_{0} \in \mathbb{R}^{t}$, we call the polynomial $p_{\mathbf{u}_{0}}(\mathbf{x})$ resulted by substituting $\mathbf{u}_{0}$ for $\mathbf{u}$ in $p(\mathbf{u}, \mathbf{x})$ an instantiation of $p(\mathbf{u}, \mathbf{x})$.

In what follows, we recall the theory of polynomial ideal (refer to 6]).

Definition 1. A subset $I \subseteq \mathbb{K}[\mathbf{x}]$ is called an ideal if
i) $0 \in I$.
ii) If $p(\mathbf{x}), g(\mathbf{x}) \in I$, then $p(\mathbf{x})+g(\mathbf{x}) \in I$.
iii) If $p(\mathbf{x}) \in I$ and $h(\mathbf{x}) \in \mathbb{K}[\mathbf{x}]$, then $p(\mathbf{x}) h(\mathbf{x}) \in I$.

It is easy to check that if $p_{1}, \cdots, p_{k} \in \mathbb{K}[\mathbf{x}]$, then

$$
\left\langle p_{1}, \cdots, p_{k}\right\rangle=\left\{\sum_{i=1}^{k} p_{i} h_{i} \mid \forall i \in[1, k] . h_{i} \in \mathbb{K}[\mathbf{x}]\right\}
$$

is an ideal. In general, we say an ideal $I$ is generated by polynomials $g_{1}, \ldots, g_{k} \in \mathbb{K}[\mathbf{x}]$ if $I=\left\langle g_{1}, \ldots, g_{k}\right\rangle$, and $\left\{g_{1}, \ldots, g_{k}\right\}$ is called a set of generators of $I$.

Theorem 2 (Hilbert Basis Theorem). Every ideal $I \subseteq \mathbb{K}[\mathbf{x}]$ has a finite generating set. That is, $I=\left\langle g_{1}, \ldots, g_{k}\right\rangle$ for some $g_{1}, \ldots, g_{k} \in \mathbb{K}[\mathbf{x}]$.

For its proof, please refer to [6]. Based upon this result, it is easy to see that

Theorem 3 (Ascending Chain Condition). For any ascending chain

$$
I_{1} \subseteq I_{2} \subseteq \cdots \subseteq I_{\ell} \subseteq \cdots
$$

of ideals in polynomial ring $\mathbb{K}[\mathbf{x}]$, there must be $N$ such that for all $\ell \geq N, I_{\ell}=I_{N}$.

### 2.2 Semi-algebraic Set

An atomic polynomial formula over variables $x_{1}, x_{2}, \ldots, x_{n}$ is $p \triangleright 0$, where $p$ is a polynomial in $\mathbb{Q}[\mathbf{x}]$ and $\triangleright \in\{\geq,>, \leq,<$ $,=, \neq\}$. A quantifier free polynomial formula is a boolean combination of atomic polynomial formulas using connectives $\vee, \wedge, \neg, \rightarrow$, etc.

Definition 4 (Semi-algebraic Set). A subset $S$ of $\mathbb{R}^{n}$ is called a semi-algebraic set, if there is a quantifier free polynomial formula $\varphi$ s.t.

$$
S=\left\{\mathbf{x} \in \mathbb{R}^{n} \mid \varphi(\mathbf{x}) \text { is true }\right\} .
$$

We will use the $\mathcal{S}(\varphi)$ to denote the semi-algebraic set defined by a quantifier free polynomial formula $\varphi$. It is easy to check that any semi-algebraic set can be transformed into the form

$$
\mathcal{S}\left(\bigvee_{i=1}^{I} \bigwedge_{j=1}^{J_{i}} p_{i j} \triangleright 0\right), \text { where } \triangleright \in\{\geq,>\}
$$

Note that semi-algebraic sets are closed under basic set operations, since

- $\mathcal{S}\left(\varphi_{1}\right) \cap \mathcal{S}\left(\varphi_{2}\right)=\mathcal{S}\left(\varphi_{1} \wedge \varphi_{2}\right) ;$
- $\mathcal{S}\left(\varphi_{1}\right) \cup \mathcal{S}\left(\varphi_{2}\right)=\mathcal{S}\left(\varphi_{1} \vee \varphi_{2}\right) ;$
- $\mathcal{S}\left(\varphi_{1}\right)^{c}=\mathcal{S}\left(\neg \varphi_{1}\right) ;$
- $\mathcal{S}\left(\varphi_{1}\right) \backslash \mathcal{S}\left(\varphi_{2}\right)=\mathcal{S}\left(\varphi_{1}\right) \cap \mathcal{S}\left(\varphi_{2}\right)^{c}=\mathcal{S}\left(\varphi_{1} \wedge \neg \varphi_{2}\right)$,
where $A^{c}$ and $A \backslash B$ stand for the complement and subtraction operation of sets respectively.

### 2.3 Continuous Dynamical System

We recall the theory of continuous dynamical systems in the following. Please refer to 10 for details.

### 2.3.1 Trajectories of Continuous Dynamical System

 An autonomous continuous dynamical system (CDS) is modeled by first-order ordinary differential equations$$
\begin{equation*}
\dot{\mathbf{x}}=\mathbf{f}(\mathbf{x}) \tag{1}
\end{equation*}
$$

where $\mathbf{x} \in \mathbb{R}^{n}$ and $\mathbf{f}$ is a vector function from $\mathbb{R}^{n}$ to $\mathbb{R}^{n}$, which is also called a vector field in $\mathbb{R}^{n}$.

If $\mathbf{f}$ satisfies the local Lipschitz condition, then given $\mathbf{x}_{0} \in$ $\mathbb{R}^{n}$, there exists a unique solution $\mathbf{x}\left(\mathbf{x}_{0} ; t\right)$ of (1) defined on $(a, b)$ with $a<0<b$ s.t.

$$
\forall t \in(a, b) \cdot \frac{\mathrm{d} \mathbf{x}\left(\mathbf{x}_{0}, t\right)}{\mathrm{d} t}=\mathbf{f}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \quad \text { and } \quad \mathbf{x}\left(\mathbf{x}_{0} ; 0\right)=\mathbf{x}_{0} .
$$

When $\mathbf{x}_{0}$ is clear from the context, we just write $\mathbf{x}\left(\mathbf{x}_{0} ; t\right)$ as $\mathbf{x}(t)$. Based upon this, we shall use the following useful notions for our discussion in the sequel.

Definition 5 (Trajectory). Suppose $\mathbf{x}\left(\mathrm{x}_{0} ; t\right)$ is the solution to (1) defined on $(a, b)$ with $a<0<b$, as stated above. Then

- $\mathbf{x}\left(\mathbf{x}_{0} ; t\right)$ ( $\mathbf{x}(t)$ for short) defined on $[0, b)$ is called the trajectory of (1) starting from $\mathbf{x}_{0}$;
- $\mathbf{x}\left(\mathbf{x}_{0} ;-t\right)(\mathrm{x}(-t)$ for short) defined on $[0,-a)$, resulted by substituting -t for $t$ in $\mathbf{x}\left(\mathbf{x}_{0} ; t\right)$, is called the inverse trajectory of (1) starting from $\mathbf{x}_{0}$.

### 2.3.2 Polynomial Vector Field and Lie Derivatives

In this paper, we focus on vector fields defined by polynomials.

Definition 6 (Polynomial Vector Field). Suppose $\mathbf{f}=\left(f_{1}, f_{2}, \cdots, f_{n}\right)$ in (1). If for all $1 \leq i \leq n, f_{i}$ is a polynomial in $\mathbb{Q}\left[x_{1}, x_{2}, \ldots, x_{n}\right]$, then $\mathbf{f}$ is called a polynomial vector field, denoted by $\mathbf{f} \in \mathbb{Q}^{n}[\mathbf{x}]$.

Obviously polynomial vector fields satisfy the local Lipschitz condition. Let $p$ be a polynomial in ring $\mathbb{Q}[\mathbf{x}]$, which is a scalar function. Then the gradient of $p$ :

$$
\frac{\partial}{\partial \mathbf{x}} p \hat{=}\left(\frac{\partial p}{\partial x_{1}}, \frac{\partial p}{\partial x_{2}}, \cdots, \frac{\partial p}{\partial x_{n}}\right)
$$

is a vector of polynomials with dimension $\operatorname{dim}(\mathbf{x})$. Thus the inner product of a polynomial vector field $\mathbf{f}$ and the gradient of a polynomial $p$ is still a polynomial, if $\mathbf{f} \in \mathbb{Q}^{n}[\mathbf{x}]$ and $\operatorname{dim}(\mathbf{x})=n$ (in the rest of the paper, this will be assumed implicitly). Therefore we can inductively define the Lie derivatives of $p$ along $\mathbf{f}, L_{\mathbf{f}}^{k} p: \mathbb{R}^{n} \mapsto \mathbb{R}$, for $k \in \mathbb{N}$, as follows:

- $L_{\mathbf{f}}^{0} p(\mathbf{x})=p(\mathbf{x})$,
- $L_{\mathbf{f}}^{k} p(\mathbf{x})=\left(\frac{\partial}{\partial \mathbf{x}} L_{\mathbf{f}}^{k-1} p(\mathbf{x}), \mathbf{f}(\mathbf{x})\right)$, for $k>0$,
where $(\cdot, \cdot)$ is the inner product of two vectors, that is, $(\mathbf{a}, \mathbf{b})=\sum_{i=1}^{n} a_{i} b_{i}$ for $\mathbf{a}=\left(a_{1}, \ldots, a_{n}\right)$ and $\mathbf{b}=\left(b_{1}, \ldots, b_{n}\right)$.

Example 7. Suppose $\mathbf{f}=(-x, y)$ and $p(x, y)=x+y^{2}$, then

$$
\begin{aligned}
& L_{\mathbf{f}}^{0} p=x+y^{2} \\
& L_{\mathbf{f}}^{1} p=-x+2 y^{2} \\
& L_{\mathbf{f}}^{2} p=x+4 y^{2}
\end{aligned}
$$

For a parametric polynomial $p(\mathbf{u}, \mathbf{x})$, we can define the Lie derivatives of $p$ along $\mathbf{f}$ similarly if the gradient of $p(\mathbf{u}, \mathbf{x})$ is taken as $\frac{\partial}{\partial \mathbf{x}} p(\mathbf{u}, \mathbf{x})$, and all $L_{\mathrm{f}}^{i} p(\mathbf{u}, \mathbf{x})$ are still parametric polynomials.

Given a polynomial vector field, we can make use of Lie derivatives to investigate the tendency of its trajectory in terms of a polynomial $p$ (as an energy function). To capture this, look at Example 7 shown in I of Figure 1 .

In I of Figure 1 arrow $B$ denote the corresponding evolution direction according to the vector field $\mathbf{f}=(-x, y)$, and we could imagine the points on the parabola $p(x, y)=x+y^{2}$ with zero energy, and the points in white area have positive energy, i.e., $p(x, y)>0$. Arrow $A$ is the gradient $\left.\frac{\partial}{\partial \mathrm{x}} p\right|_{(-1,1)}$ of $p(x, y)$, which infers that the trajectory starting at $(-1,1)$ will enter white area immediately if the angle, between $\left.\frac{\partial}{\partial \mathrm{x}} p\right|_{(-1,1)}$ and the evolution direction at $(-1,1)$, is less than $\frac{\pi}{2}$, that is, the 1 -order Lie derivative is positive. Thus the 1 -order Lie derivative $\left.L_{\mathbf{f}}^{1} p\right|_{(-1,1)}=3$ of $p$ along $\mathbf{f}$ (the inner product of $\left.\frac{\partial}{\partial x} p\right|_{(-1,1)}$ and $\left.\left.\mathbf{f}(x, y)\right|_{(-1,1)}\right)$ predicts that there is some positive $d>0$ such that the trajectory starting at $(-1,1)$ (curve $C$ ) has the property $p(\mathbf{x}((-1,1), t))>0$ for all $t \in(0, d)$.

However, if the angle between gradient and evolution direction is $\frac{\pi}{2}$ or the gradient is zero-vector, then 1 -order Lie derivative is zero and it is impossible to predict trajectory tendency by means of 1 -order Lie derivative. In this case, we resort to nonzero higher order Lie derivatives. For this purpose, we introduce the pointwise rank of $p$ with respect to $\mathbf{f}$ as the function $\gamma_{p, \mathbf{f}}: \mathbb{R}^{n} \mapsto \mathbb{N} \cup\{\infty\}$ defined by

$$
\gamma_{p, \mathbf{f}}(\mathbf{x})=\min \left\{k \in \mathbb{N} \mid L_{\mathbf{f}}^{k} p(\mathbf{x}) \neq 0\right\}
$$

if such $k$ exists, otherwise $\gamma_{p, \mathbf{f}}(\mathbf{x})=\infty$.

Example 8. Let $\mathbf{f}(x, y)=\left(\dot{x}=-2 y, \dot{y}=x^{2}\right)$ and $h(x, y)=$ $x+y^{2}$, then

$$
\begin{aligned}
L_{\mathbf{f}}^{0} h(x, y) & =x+y^{2} \\
L_{\mathbf{f}}^{1} h(x, y) & =-2 y+2 x^{2} y \\
L_{\mathbf{f}}^{2} h(x, y) & =-8 y^{2} x-\left(2-2 x^{2}\right) x^{2}
\end{aligned}
$$

Here, $\gamma_{h, \mathbf{f}}(0,0)=\infty, \gamma_{h, \mathbf{f}}(-4,2)=1$, etc.
Look at II of Figure 1. At point $(-1,1)$ on curve $h(x, y)=$ 0 , the gradient of $h$ is $(1,2)$ (arrow $A$ ) and the evolution direction is $(-2,1)$ (arrow B), so their inner product is zero. Thus it is impossible to predict the tendency (in terms of curve $h(x, y)=0$ ) of trajectory starting from $(-1,1)$ via its 1-order Lie derivative. By a simple computation, its 2-order Lie derivative is 8 . Hence $\gamma_{h, \mathbf{f}}(-1,1)=2$. In the sequel,

I: 1-order Lie Derivative and Gradient

II: Demand for High Order Lie Derivative

Figure 1: Lie Derivatives
we shall show how to use such high order Lie derivatives to analyze the trajectory tendency.

For analyzing trajectory tendency by high order Lie derivatives, we need the following fact.

Proposition 9. Given polynomial functions $p$ and $\mathbf{f}$, then $\mathbf{x}_{0}$ is on the boundary $\mathcal{S}\left(p(\mathbf{x})=0\right.$ ) iff $\gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right) \neq 0$. Suppose $\mathrm{x}_{0}=\mathbf{x}(0)$, then it follows that
(a) if $\gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)<\infty$ and $L_{\mathbf{f}}^{\gamma_{p, f}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)>0$, then

$$
\exists \epsilon>0, \forall t \in(0, \epsilon) \cdot p(\mathbf{x}(t))>0
$$

(b) if $\gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)<\infty$ and $L_{\mathbf{f}}^{\gamma_{p, f}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)<0$, then

$$
\exists \epsilon>0, \forall t \in(0, \epsilon) \cdot p(\mathbf{x}(t))<0
$$

(c) if $\gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)=\infty$, then

$$
\exists \epsilon>0, \forall t \in(0, \epsilon) \cdot p(\mathbf{x}(t))=0
$$

Proof. Polynomial functions are analytic, so $\mathbf{f}$ is analytic and thus $\mathbf{x}(t)$ is analytic in a small interval $(a, b)$ containing zero [29. Besides, $p$ is analytic, so the Taylor expansion of $p(\mathbf{x}(t))$ at $t=0$

$$
\begin{align*}
p(\mathbf{x}(t)) & =p\left(\mathbf{x}_{0}\right)+\frac{\mathrm{d} p}{\mathrm{~d} t} \cdot t+\frac{\mathrm{d}^{2} p}{\mathrm{~d} t^{2}} \cdot \frac{t^{2}}{2!}+\cdots \\
& =L_{\mathbf{f}}^{0} p\left(\mathbf{x}_{0}\right)+L_{\mathbf{f}}^{1} p\left(\mathbf{x}_{0}\right) \cdot t+L_{\mathbf{f}}^{2} p\left(\mathbf{x}_{0}\right) \cdot \frac{t^{2}}{2!}+\cdots \tag{2}
\end{align*}
$$

converges in another small interval ( $a^{\prime}, b^{\prime}$ ) containing zero [13]. Then the conclusion of Proposition 9 follows immediately from formula (2) by case analysis on the sign of $L_{\mathbf{f}}^{\gamma_{p, f}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)$.

Based on this proposition, we introduce the notion of transverse set to indicate the tendency of the trajectories of a considered polynomial vector field in terms of the first nonzero Lie derivative of a underlying polynomial as follows.

Definition 10. Given a polynomial $p$ and a polynomial vector field $\dot{\mathbf{x}}=\mathbf{f}(\mathbf{x})$, the transverse set of $\mathbf{f}$ over the domain $\mathcal{S}(p(\mathbf{x}) \geq 0)$ is

$$
\operatorname{Tran}_{\mathbf{f} \uparrow p} \hat{=}\left\{\mathbf{x} \in \mathbb{R}^{n} \mid \gamma_{p, \mathbf{f}}(\mathbf{x})<\infty \wedge L_{\mathbf{f}}^{\gamma_{p, \mathbf{f}}(\mathbf{x})} p(\mathbf{x})<0\right\}
$$

Intuitively, if $\mathbf{x} \in \operatorname{Trans}_{\mathbf{f} \uparrow p}$, then either $\mathbf{x}$ is not in $\mathcal{S}(p(\mathbf{x}) \geq$ 0 ) or $\mathbf{x}$ is on the boundary of $\mathcal{S}(p(\mathbf{x}) \geq 0)$ such that the trajectory $\mathbf{x}(t)$ starting with $\mathbf{x}$ will exit $\mathcal{S}(p(\mathbf{x}) \geq 0)$ immediately.

## 3. SEMI-ALGEBRAIC INVARIANT

A hybrid system consists of a set of CDSs, a set of jumps between these CDSs, and a set of initial states. The CDSs in a hybrid system are a little different from the standard ones, as normally they are equipped with a domain and a set of initial states, in the form $(H, \mathbf{f}, \Xi)$, where $H$ is used to force some jumps outgoing the mode to happen, that is, a hybrid system can stay within a mode only if the domain of the current mode holds, and $\Xi$ is a subset of $H$, standing for the set of initial states. Obviously, a CDS can be seen as a special CDSwDI by letting $H=\mathbb{R}^{n}$. The goal of this paper is to present a complete method for automatically discovering SAIs of PDSs, based on which, as we discussed in the introduction, we can finally verify polynomial hybrid systems.

### 3.1 Continuous Invariants of CDSwDI

The notion of continuous invariant of CDSwDI is quite similar to the one of positive invariant set of CDS 3. Informally, a continuous invariant $P$ of a CDwDI $(H, \mathbf{f}, \Xi)$ is a superset of $\Xi$ such that all continuous evolutions starting from $\Xi$ keep within $P$ if they are within $H$. Here, we give a formal definition of CI adapted from [17] as follows:

Definition 11 (Continuous Invariant [17). Given a $C D S w D I(H, \mathbf{f}, \Xi)$ with $\Xi \subseteq H \subseteq \mathbb{R}^{n}$ and $\mathbf{f}: \mathbb{R}^{n} \mapsto \mathbb{R}^{n}$ that is local Lipschitz continuous, a set $P \subseteq \mathbb{R}^{n}$ is called a continuous invariant of ( $H, \mathbf{f}, \Xi$ ), iff

$$
\begin{aligned}
& \text { 1. } \Xi \rightarrow P ; \text { and } \\
& \text { 2. for all } \mathbf{x}_{0} \in P \text {, and for any } T \geq 0 \text {, } \\
& \left(\forall t \in[0, T] \cdot \mathbf{x}\left(\mathbf{x}_{0} ; t\right) \in H\right) \rightarrow\left(\forall t \in[0, T] \cdot \mathbf{x}\left(\mathbf{x}_{0} ; t\right) \in P\right)
\end{aligned}
$$

Regarding Definition (11) we would like to give the following remarks.

1. Continuous invariant in Definition 11 is more general than standard positive invariant set of continuous dynamical systems. However, if $H=\mathbb{R}^{n}$ and $\Xi=P$, then the two notions coincide.
2. One may have noticed that in Definition 11 a continuous invariant set $P$ is not necessarily a subset of domain $H$. In fact, any $P$ satisfying $H \subseteq P$ is continuous invariant of $(H, \mathbf{f}, \Xi)$. This seems weird at first sight, because such continuous invariant sets are useless if we only concern the CDSwDI in isolation. But it would be quite useful in the verification of the hybrid system if we assume that the continuous invariant of a mode always holds if the hybrid system does not stay within the mode.

### 3.2 PDS and SAI

Definition 12. A $C D S w D I(H, \mathbf{f}, \Xi)$ is called a polynomial dynamical system with semi-algebraic domain and initial states (PDS), if $H$ and $\Xi$ are semi-algebraic sets and $\mathbf{f}$ is a polynomial vector field in $\mathbb{Q}^{n}[\mathbf{x}]$.

A continuous invariant of a PDS is called a semi-algebraic invariant (SAI) if it is a semi-algebraic set.

In the subsequent sections, we will present a sound and complete method to automatically discover SAIs for a PDS.

## 4. FUNDAMENTAL RESULTS

The set $\operatorname{Trans}_{\mathbf{f} \uparrow p}$ in Definition 10 plays a crucial role in our theory. First of all, we have

Theorem 13. The set $\operatorname{Trans}_{\mathbf{f} \uparrow p}$ is a semi-algebraic set if $p$ is a polynomial and $\mathbf{f}$ is a polynomial vector field, and hence it is computable.

To prove this theorem, it suffices to show $\gamma_{p, \mathbf{f}}(\mathbf{x})$ is computable for each $\mathbf{x} \in \mathcal{S}(p(\mathbf{x}) \geq 0)$. However, $\gamma_{p, \mathbf{f}}(\mathbf{x})$ may be infinite for some $\mathbf{x} \in \mathcal{S}(p(\mathbf{x}) \geq 0)$. Thus, it seems that we have to compute $L_{\mathbf{f}}^{k} p(\mathbf{x})$ infinite times for such $\mathbf{x}$ to determine if $\mathbf{x} \in \operatorname{Trans}_{\mathbf{f} \uparrow p}$. Fortunately, we can find a uniform upper bound on $\gamma_{p, \mathbf{f}}(\mathbf{x})$ for all $\mathbf{x}$ with $\gamma_{p, \mathbf{f}}(\mathbf{x})$ being finite.

Theorem 14 (Rank Theorem). If $p$ and $\mathbf{f}$ are polynomial functions, then there is an integer $N$ such that for all $\mathbf{x} \in \mathbb{R}^{n}, \gamma_{p, \mathrm{f}}(\mathbf{x})<\infty$ implies $\gamma_{p, \mathbf{f}}(\mathbf{x}) \leq N$. Later on, such an $N$ is called the rank of $p$ and $\mathbf{f}$, denoted by $\gamma_{p, \mathbf{f}}$.

Proof. Let $D_{l}=\left\{\mathbf{x} \mid \forall m<l . L_{\mathrm{f}}^{m} p(\mathbf{x})=0\right\}$ for $l \geq 0$. Note that the sequence $\left\{D_{l}\right\}_{l \in \mathbb{N}}$ is decreasing. We will show that there is an $N$ such that $D_{l}=D_{N}$ for all $l \geq N$.

Since $p$ and $\mathbf{f}$ are polynomial functions, all $L_{\mathbf{f}}^{m} p(\mathbf{x})$ must be polynomials for any $m \in \mathbb{N}$. We consider the polynomial ideal $I$ generated by $\left\{L_{\mathbf{f}}^{m} p(\mathbf{x}) \mid m \in \mathbb{N}\right\}$. Let $I_{m}=$ $\left\langle L_{\mathbf{f}}^{0} p(\mathbf{x}), L_{\mathbf{f}}^{1} p(\mathbf{x}), \cdots, L_{\mathbf{f}}^{m} p(\mathbf{x})\right\rangle$. Then $I=\cup_{m} I_{n}$. By Theorem 3 there is $k$ such that $I=I_{k}$. Thus for all $l>k$, there are $g_{i} \in \mathbb{R}\left[x_{1}, \cdots, x_{n}\right]$ for $i \leq k$ such that $L_{\mathrm{f}}^{l} p(\mathbf{x})=$ $\sum_{i \leq k} g_{i} L_{\mathbf{f}}^{i} p(\mathbf{x})$ for all $\mathbf{x} \in \mathbb{R}^{n}$.

Fix $l>k$. If $\mathbf{x} \in D_{l}$, then $L_{\mathbf{f}}^{l} p(\mathbf{x})=\sum_{i \leq k} g_{i} L_{\mathbf{f}}^{i} p(\mathbf{x})=0$ since all $L_{\mathrm{f}}^{i} p(\mathbf{x})=0$ for $i \leq k$ as $\mathbf{x} \in D_{l}$. Let $N=k+1$. Then $D_{l}=D_{N}$ for all $l \geq N$. Thus, if $\mathrm{x} \in D_{N}$ then $\gamma_{p, \mathbf{f}}(\mathbf{x})=\infty$. Therefore, $\gamma_{p, \mathbf{f}}(\mathbf{x})<\infty$ implies $\gamma_{p, \mathbf{f}}(\mathbf{x}) \leq$ $N$.

Now, it suffices to compute the values

$$
L_{\mathbf{f}}^{0} p\left(\mathbf{x}_{0}\right), L_{\mathbf{f}}^{1} p\left(\mathbf{x}_{0}\right) \cdots, L_{\mathbf{f}}^{\gamma_{p, \mathbf{f}}} p\left(\mathbf{x}_{0}\right)
$$

to determine whether $\gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)$ is infinite. Therefore if $\gamma_{p, \mathbf{f}}$ is computable then $\operatorname{Trans}_{\mathbf{f} \uparrow p}$ is computable too. It is desirable to get an expression of $\gamma_{p, \mathbf{f}}$ for given $p$ and $\mathbf{f}$. However, we did not find it yet. Nevertheless, a computable upper bound for $\gamma_{p, \mathrm{f}}$ can indeed be found effectively according to the following theorem.

Theorem 15 (Fixed Point Theorem). If

$$
L_{\mathbf{f}}^{i+1} p \in\left\langle L_{\mathbf{f}}^{0} p, L_{\mathbf{f}}^{1} p, \cdots, L_{\mathbf{f}}^{i} p\right\rangle
$$

then $L_{\mathbf{f}}^{m} p \in\left\langle L_{\mathbf{f}}^{0} p, L_{\mathbf{f}}^{1} p, \cdots, L_{\mathbf{f}}^{i} p\right\rangle$, for all $m>i$.

Proof. We prove this theorem by induction. Assume this conclusion is true for all $l \leq k$ with $k>i$. Especially, $L_{\mathbf{f}}^{k} p \in\left\langle L_{\mathbf{f}}^{0} p, L_{\mathbf{f}}^{1} p, \cdots, L_{\mathbf{f}}^{i} p\right\rangle$. Then there are $g_{j} \in$ $\mathbb{R}\left[x_{1}, \cdots, x_{n}\right]$ for $j \leq i$ such that

$$
\begin{equation*}
L_{\mathbf{f}}^{k} p=\sum_{j \leq i} g_{j} L_{\mathbf{f}}^{j} p \tag{3}
\end{equation*}
$$

By the definition of Lie derivative and equation (3), it follows that

$$
\begin{aligned}
& L_{\mathbf{f}}^{k+1} p \\
& \quad=\left(\frac{\partial}{\partial \mathbf{x}} L_{\mathbf{f}}^{k} p, \mathbf{f}\right) \\
& =\left(\frac{\partial}{\partial \mathbf{x}}\left(\sum_{j \leq i} g_{j} L_{\mathbf{f}}^{j} p\right), \mathbf{f}\right) \\
& \quad=\sum_{j \leq i}\left(L_{\mathbf{f}}^{j} p \frac{\partial}{\partial \mathbf{x}} g_{j}, \mathbf{f}\right)+\sum_{j \leq i}\left(g_{j} \frac{\partial}{\partial \mathbf{x}} L_{\mathbf{f}}^{j} p, \mathbf{f}\right) \\
& \quad=\sum_{j \leq i}\left(\frac{\partial}{\partial \mathbf{x}} g_{j}, \mathbf{f}\right) L_{\mathbf{f}}^{j} p+\sum_{j \leq i} g_{j} L_{\mathbf{f}}^{j+1} p \\
& \quad=\sum_{j \leq i}\left(\frac{\partial}{\partial \mathbf{x}} g_{j}, \mathbf{f}\right) L_{\mathbf{f}}^{j} p+\sum_{j<i} g_{j} L_{\mathbf{f}}^{j+1} p+g_{i} L_{\mathbf{f}}^{i} p
\end{aligned}
$$

By induction hypothesis, $L_{\mathbf{f}}^{i} p$ is in $\left\langle L_{\mathbf{f}}^{0} p, L_{\mathbf{f}}^{1} p, \cdots, L_{\mathbf{f}}^{i} p\right\rangle$. So

$$
L_{\mathbf{f}}^{k+1} p \in\left\langle L_{\mathbf{f}}^{0} p, L_{\mathbf{f}}^{1} p, \cdots, L_{\mathbf{f}}^{i} p\right\rangle
$$

By induction, the theorem follows immediately.

Let $N_{p, \mathrm{f}}$ be the minimal $i$ satisfying the condition of Theorem 15 in the sequel. Then $\gamma_{p, \mathbf{f}} \leq N_{p, \mathbf{f}}$. Look at Example 8. where $N_{h, \mathbf{f}}=2$. Now, applying above two theorems we can prove Theorem 13

Proof of Theorem 13. Since $\gamma_{p, \mathbf{f}} \leq N_{p, \mathbf{f}}$,

$$
\mathbf{x} \in \operatorname{Trans}_{\mathbf{f} \uparrow p} \text { iff } \gamma_{p, \mathbf{f}}(\mathbf{x}) \leq N_{p, \mathbf{f}} \wedge L_{\mathbf{f}}^{\gamma_{p, \mathbf{f}}(\mathbf{x})} p(\mathbf{x})<0
$$

Therefore, $\operatorname{Trans}_{\mathbf{f} \uparrow p}$ is computable as $N_{p, \mathbf{f}}$ is computable according to Theorem 15 Given $p$ and $\mathbf{f}$, let

$$
\begin{equation*}
\pi^{(0)}(p, \mathbf{f}, \mathbf{x}) \widehat{=} p(\mathbf{x})<0 \tag{4}
\end{equation*}
$$

for $1 \leq i \in \mathbb{N}$,

$$
\begin{equation*}
\pi^{(i)}(p, \mathbf{f}, \mathbf{x}) \widehat{=}\left(\bigwedge_{0 \leq j<i} L_{\mathbf{f}}^{j} p(\mathbf{x})=0\right) \wedge L_{\mathbf{f}}^{i} p(\mathbf{x})<0 \tag{5}
\end{equation*}
$$

and

$$
\begin{equation*}
\pi(p, \mathbf{f}, \mathbf{x}) \widehat{ } \bigvee_{0 \leq i \leq N_{p, \mathbf{f}}} \pi^{(i)}(p, \mathbf{f}, \mathbf{x}) \tag{6}
\end{equation*}
$$

By Theorem 14 and $\gamma_{p, \mathrm{f}} \leq N_{p, \mathrm{f}}$, we have another equivalence

$$
\begin{equation*}
\mathbf{x} \in \operatorname{Trans}_{\mathbf{f} \uparrow p} \text { iff } \pi(p, \mathbf{f}, \mathbf{x}) \text { holds. } \tag{7}
\end{equation*}
$$

In fact, $\pi^{(i)}(p, \mathbf{f}, \mathbf{x})$ here is a particular semi-algebraic system, and so $\pi(p, \mathbf{f}, \mathbf{x})$ is a union of semi-algebraic systems. Thus $\operatorname{Trans}_{\mathbf{f} \uparrow p}$ is actually a semi-algebraic set.

In the SAI generation, it actually makes use of parametric polynomials $p(\mathbf{u}, \mathbf{x})$ with parameter $\mathbf{u}=\left(u_{1}, u_{2}, \ldots, u_{t}\right)$. The following theorem indicates Theorem 14 still holds after substituting $p(\mathbf{u}, \mathbf{x})$ for $p(\mathbf{x})$.

Theorem 16 (Parametric Rank Theorem). Given polynomial functions $p(\mathbf{u}, \mathbf{x})$ and $\mathbf{f}$, there is an integer $N$ such that $\gamma_{p_{\mathbf{u}_{0}}, \mathbf{f}}(\mathbf{x})<\infty$ implies $\gamma_{p_{\mathbf{u}_{0}}, \mathbf{f}}(\mathbf{x}) \leq N$ for all $\mathbf{x} \in \mathbb{R}^{n}$ and all $\mathbf{u}_{0} \in \mathbb{R}^{t}$.

This proof is quite close to the one of Theorem 14 The difference, between the proof of this theorem and the one of Theorem 14 lies in the settings of polynomials. Here, we consider polynomials $p$ and $\mathbf{f}$ in the polynomial ring $\mathbb{R}[\mathbf{u}, \mathbf{x}]$. Similarly, we also introduce the rank function on polynomials with parameters, still denoted by $\gamma_{p, \mathbf{f}}$. Accordingly, let $N_{p, \mathbf{f}}$ denote the upper bound computed by a similarity of Theorem 15.

## 5. GENERATING SAI IN SIMPLE CASE

Given a polynomial vector field $\dot{\mathbf{x}}=\mathbf{f}(\mathbf{x})$ with a semi-algebraic domain $H$ and initial condition $\Xi$, our task is to find a semialgebraic set $P$ such that $P$ is an SAI of $(H, \mathbf{f}, \Xi)$.

First of all, we illustrate our idea by showing how to compute an SAI of the simple form $P \widehat{=} p(\mathbf{x}) \geq 0$ for a simple domain $H \widehat{=} h(\mathbf{x}) \geq 0$. For convenience, we will simply write the dynamical system $(h(\mathbf{x}) \geq 0, \mathbf{f}, \Xi)$ as $(h, \mathbf{f}, \Xi)$. Notice that $P$ is an SAI of $(h, \mathbf{f}, \Xi)$ only if $\forall \mathbf{x}(\Xi(\mathbf{x}) \rightarrow P(\mathbf{x}))$. It is evident that if $\mathbf{x}(0)$ is in the interior of $\mathcal{S}(p(\mathbf{x}) \geq 0) \cap \mathcal{S}(h(\mathbf{x}) \geq 0)$, then the trajectory $\mathbf{x}(t)$ starting at $\mathbf{x}(0)$ will remain in the interior within adequately small $t>0$. Therefore, the condition of continuous invariant could be violated only at the points on the boundary $\mathcal{S}(p(\mathbf{x})=0)$ of $\mathcal{S}(p(\mathbf{x}) \geq 0)$. Thus by Definition 10 and Proposition $9, p \geq 0$ is an invariant of $(h, \mathbf{f}, \Xi)$ if and only if it meets $\forall \mathbf{x}(\Xi(\mathbf{x}) \rightarrow P(\mathbf{x}))$ and

$$
\mathbf{x} \in \mathcal{S}(p(\mathbf{x})=0) \rightarrow \mathbf{x} \notin \operatorname{Trans}_{\mathbf{f} \uparrow p} \backslash \operatorname{Trans}_{\mathbf{f} \uparrow h}
$$

i.e.

$$
\begin{equation*}
\mathbf{x} \in \mathcal{S}(p(\mathbf{x})=0) \rightarrow \mathbf{x} \in\left(\operatorname{Trans}_{\mathbf{f} \uparrow p}\right)^{c} \vee \operatorname{Trans}_{\mathbf{f} \uparrow h} \tag{8}
\end{equation*}
$$

By equivalences (7), the formula (8) is equivalent to

$$
p(\mathbf{x})=0 \rightarrow(\neg \pi(p, \mathbf{f}, \mathbf{x}) \vee \pi(h, \mathbf{f}, \mathbf{x}))
$$

i.e.

$$
\begin{equation*}
(p(\mathbf{x})=0 \wedge \pi(p, \mathbf{f}, \mathbf{x})) \rightarrow \pi(h, \mathbf{f}, \mathbf{x}) \tag{9}
\end{equation*}
$$

Let $\theta(h, p, \mathbf{f}, \mathbf{x})$ denote the formula (9). According to this equivalence, we obtain the sufficient and necessary condition for being SAI as follows.

Theorem 17 (Criterion Theorem). Given a polynomial $p, p(\mathbf{x}) \geq 0$ is an $S A I$ of system $(h, \mathbf{f}, \Xi)$ if and only if the formula $\theta(h, p, \mathbf{f}, \mathbf{x}) \wedge(\Xi(\mathbf{x}) \rightarrow p(\mathbf{x}) \geq 0)$ is true for all $\mathbf{x} \in \mathbb{R}^{n}$.

Now, we are ready to present a constraint based approach to generate polynomial continuous invariants. The basic idea is as follows:
I. First, set a parametric polynomial $p$ as

$$
\begin{equation*}
p(\mathbf{u}, \mathbf{x}) \widehat{=} \sum_{i_{1}+i_{2}+\cdots+i_{n}=k \leq d} u_{i_{1} i_{2} \cdots i_{n}} x_{1}^{i_{1}} x_{2}^{i_{2}} \cdots x_{n}^{i_{n}} . \tag{10}
\end{equation*}
$$

Such a parametric polynomial is called a template conventionally. There are $t=\binom{n+d}{d}$ many terms and accordingly $t$ many parameters $u_{i_{1} i_{2} \cdots i_{n}}$. For simplicity, let $\mathbf{u}$ denote such a $t$-tuple $\left\{u_{i_{1} i_{2} \cdots i_{n}}\right\}_{i_{1}+i_{2}+\cdots+i_{n}=k \leq d}$.
II. Then we appy the quantifier elimination ( $\mathrm{QE} \square$ for short) to the formula $\forall \mathbf{x} \cdot(\theta(h, p, \mathbf{f}, \mathbf{x}) \wedge(\Xi(\mathbf{x}) \rightarrow p(\mathbf{x}) \geq 0))$. If the output is false, then there is no polynomial continuous invariant of degree $\leq d$ for ( $h, \mathbf{f}, \Xi$ ). Otherwise, it will give us a constraint on $\mathbf{u}$, denoted by $R(\mathbf{u})$. In fact, $R(\mathbf{u})$ is a union of semi-algebraic systems (refer to (28]).
III. Let $S_{\text {Inv }}$ be the set of solutions to $R(\mathbf{u})$. Now, using a tool like DISCOVERER [30 to pick a $\mathbf{u}_{0} \in S_{\text {Inv }}$ and then $p_{\mathbf{u}_{0}}(\mathbf{x}) \geq 0$ is an invariant of $(h, \mathbf{f}, \Xi)$ by Theorem 17

## Remark

1) Note that in real applications, one usually picks up the specific terms with nonzero coefficients. A simplified template could make the resulted polynomial satisfy special conditions and also reduce the complexity of the searching process.
2) In the above Step III, if the dimension of $S_{\text {Inv }}$ equals $t$, then we can easily select a rational sample point $\mathbf{u}_{0}$ from $S_{\text {Inv }}$ and the obtained $p_{\mathbf{u}_{0}}(\mathbf{x}) \geq 0$ is an SAI in $\mathbb{R}^{n}$; otherwise when it is difficult (or impossible) to get a rational instantiation for $\mathbf{u}$, we can always compute an algebraic sample point $\mathbf{u}_{0} \in S_{\text {Inv }}$, that is, $\mathbf{u}_{0}$ is itself defined by polynomial equations. It is easy to show that in the latter case, $p_{\mathbf{u}_{0}}(\mathbf{x}) \geq 0$ is also an SAI in $\mathbb{R}^{n}$.

Example 18. Again, we make use of Example 8 to demonstrate above method. That is, $\mathbf{f}(x, y) \widehat{=}\left(\dot{x}=-2 y, \dot{y}=x^{2}\right)$. Here, we take $H \widehat{=}\left\{(x, y) \in \mathbb{R}^{2} \mid h(x, y)=-x-y^{2} \geq 0\right\}$ as the domain and $\Xi \widehat{=}\{(-1,0.5),(-0.5,-0.6)\}$ as the initial states. Apply procedure (I-III), we have:

1. Set a template $p(\mathbf{u}, \mathbf{x}):=a y(x-y) \geq 0$ where $\mathbf{u} \hat{=}\langle a\rangle$. Then we have $\gamma_{p, \mathrm{f}} \leq N_{p, \mathrm{f}}=2$.
2. Compute the corresponding formula

$$
\begin{aligned}
\theta(h, p, \mathbf{f}, \mathbf{x}) \widehat{ } \widehat{=} & p=0 \wedge\left(\pi_{p, \mathbf{f}, \mathbf{x}}^{(0)} \vee \pi_{p, \mathbf{f}, \mathbf{x}}^{(1)} \vee \pi_{p, \mathbf{f}, \mathbf{x}}^{(2)}\right) \rightarrow \\
& \left(\pi_{h, \mathbf{f}, \mathbf{x}}^{(0)} \vee \pi_{h, \mathbf{f}, \mathbf{x}}^{(1)} \vee \pi_{h, \mathbf{f}, \mathbf{x}}^{(2)}\right)
\end{aligned}
$$

[^0]

Figure 2: Semi-Algebraic Invariants

$$
\begin{aligned}
& \text { where } \\
& \pi_{h, \mathbf{f}, \mathbf{x}}^{(0)} \widehat{=}-x-y^{2}<0, \\
& \pi_{h, \mathbf{f}, \mathbf{x}}^{(1)} \widehat{=}-x-y^{2}=0 \wedge 2 y-2 x^{2} y<0, \\
& \pi_{h, \mathbf{f}, \mathbf{x}}^{(2)} \widehat{=}-x-y^{2}=0 \wedge 2 y-2 x^{2} y=0 \wedge \\
& 8 x y^{2}+2 x^{2}-2 x^{4}<0, \\
& \pi_{p, \mathbf{f}, \mathbf{x}}^{(0)} \widehat{=} a y(x-y)<0, \\
& \pi_{p, \mathbf{f}, \mathbf{x}}^{(1)} \widehat{=} a y(x-y)=0 \wedge-2 a y^{2}+a x^{3}-2 y a x^{2}<0, \\
& \pi_{p, \mathbf{f}, \mathbf{x}}^{(2)} \widehat{=} a y(x-y)=0 \wedge-2 a y^{2}+a x^{3}-2 y a x^{2}=0 \wedge \\
& 40 a x y^{2}-16 a y^{3}+32 a x^{3} y-10 a x^{4}<0 .
\end{aligned}
$$

Then we implement quantifier elimination on formula $\forall x, y(\theta(h, p, \mathbf{f}, \mathbf{x}) \wedge(0.5 a(-1-0.5) \geq 0 \wedge-0.6 a(-0.5+$ $0.6) \geq 0$ ). We get the constraint on $a$ is $a \leq 0$
3. Just pick $a=-1$, and then $-x y+y^{2} \geq 0$ is an invariant for $(H, \mathbf{f}, \Xi)$. The grey part of the picture III is the intersection of this invariant and domain $H$.

## 6. GENERAL CASE

Now, we consider how to automatically discover SAIs of a $\operatorname{PDS}$ in general case. Given a $\operatorname{PDS}(H, \mathbf{f}, \Xi)$ with

$$
\begin{equation*}
H=\mathcal{S}\left(\bigvee_{i=1}^{I} \bigwedge_{j=1}^{J_{i}} p_{i j}(\mathbf{x}) \triangleright 0\right), \Xi=\mathcal{S}\left(\bigvee_{i=1}^{N} \bigwedge_{j=1}^{M_{i}} q_{i j}(\mathbf{x}) \triangleright 0\right) \tag{11}
\end{equation*}
$$

and $\mathbf{f} \in \mathbb{Q}^{n}[\mathbf{x}]$, where $\Xi \subseteq H$ and $\triangleright \in\{\geq,>\}$. The procedure for automatically generating SAIs with a general template

$$
P=\mathcal{S}\left(\bigvee_{k=1}^{K} \bigwedge_{l=1}^{L_{k}} p_{k l}\left(\mathbf{u}_{k l}, \mathbf{x}\right) \triangleright 0\right), \text { where } \triangleright \in\{\geq,>\}
$$

for $(H, \mathbf{f}, \Xi)$, is essentially the same as the steps (I-III) depicted in the previous section. However, we must sophisticatedly handle the complex combination due to the complicated boundaries. In what follows, we will first establish the necessary and sufficient conditions for general CIs of a CDSwDI by some topological analysis. Then we show for SAIs of a PDS, these conditions can be encoded equivalently into first order polynomial formulas.

### 6.1 Necessary and Sufficient Condition for CI

First of all, we study a necessary and sufficient condition like formula (8) for $P$ being an invariant of ( $H, \mathbf{f}, \Xi$ ). To analyze the evolution tendency of trajectories dominated by
a locally Lipschitz continuous vector field $\mathbf{f}: \mathbb{R}^{n} \mapsto \mathbb{R}^{n}$ in terms of a subset $A$ of $\mathbb{R}^{n}$, we need the following notions and notations.

$$
\begin{gathered}
\operatorname{In}_{\mathbf{f}}(A) \widehat{=}\left\{\mathbf{x}_{0} \in \mathbb{R}^{n} \mid \exists \epsilon>0 \forall t \in(0, \epsilon) \cdot \mathbf{x}\left(\mathbf{x}_{0} ; t\right) \in A\right\} \\
\operatorname{IvIn}_{\mathbf{f}}(A) \widehat{=}\left\{\mathbf{x}_{0} \in \mathbb{R}^{n} \mid \exists \epsilon>0 \forall t \in(0, \epsilon) \cdot \mathbf{x}\left(\mathbf{x}_{0} ;-t\right) \in A\right\} .
\end{gathered}
$$

Intuitively, $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(A)$ means that the trajectory starting from $\mathbf{x}_{0}$ enters $A$ immediately and keeps inside $A$ for some time; $\mathbf{x}_{0} \in \operatorname{IvIn}_{\mathbf{f}}(A)$ means that the trajectory through $\mathbf{x}_{0}$ reaches $\mathbf{x}_{0}$ from the interior of $A$.

Analogous to $\operatorname{In}_{\mathbf{f}}(A)$ and $\operatorname{IvIn}_{\mathbf{f}}(A)$, we introduce another two notations $\operatorname{Out}_{\mathbf{f}}(A)$ and $\operatorname{IvOut}_{\mathbf{f}}(A)$.

$$
\begin{aligned}
\operatorname{Out}_{\mathbf{f}}(A) & \widehat{=}\left\{\mathbf{x}_{0} \in \mathbb{R}^{n} \mid \exists \epsilon>0 \forall t \in(0, \epsilon) \cdot \mathbf{x}\left(\mathbf{x}_{0} ; t\right) \in A^{c}\right\} ; \\
\operatorname{IvOut}_{\mathbf{f}}(A) & \widehat{=}\left\{\mathbf{x}_{0} \in \mathbb{R}^{n} \mid \exists \epsilon>0 \forall t \in(0, \epsilon) \cdot \mathbf{x}\left(\mathbf{x}_{0} ;-t\right) \in A^{c}\right\}
\end{aligned}
$$

where $A^{c}$ stands for the complement of $A$ in $\mathbb{R}^{n}$. Intuitively, $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(A)$ means that the trajectory starting at $\mathbf{x}_{0}$ leaves $A$ immediately and keep outside $A$ for some time in future; $\mathbf{x}_{0} \in \operatorname{IvOut}_{\mathbf{f}}(A)$ means that the trajectory passing through $\mathbf{x}_{0}$ reaches $\mathbf{x}_{0}$ from the outside of $A$.

Based on the above notations, we have

Theorem 19. Given a $C D S w D I(H, \mathbf{f}, \Xi)$ with $H \subseteq \mathbb{R}^{n}$, $\Xi \subseteq \mathbb{R}^{n}$ and locally Lipschitz continuous $\mathbf{f}: \mathbb{R}^{n} \mapsto \mathbb{R}^{n}$, a subset $P$ of $\mathbb{R}^{n}$ is a $C I$ of $(H, \mathbf{f}, \Xi)$ if and only if

$$
\begin{aligned}
& \text { 1. } \Xi \subseteq P \\
& \text { 2. } \forall \mathbf{x} \in P \cap H \cap \operatorname{In}_{\mathbf{f}}(H) \cdot \mathbf{x} \in \operatorname{In}_{\mathbf{f}}(P) \\
& \text { 3. } \forall \mathbf{x} \in P^{c} \cap H \cap \operatorname{IvIn}_{\mathbf{f}}(H) \cdot \mathbf{x} \in\left(\operatorname{IvIn}_{\mathbf{f}}(P)\right)^{c}
\end{aligned}
$$

Proof. First of all, the proof about condition 1 is trivial. In what follows, we focus on the proofs about conditions 2 and 3 .
$" \Leftarrow$ " Suppose $P$ is not a CI of $(H, \mathbf{f}, \Xi)$. According to Definition 11 there exists $\mathbf{x}_{0} \in P \cap H, T_{0}>0$ and $T_{1} \in\left(0, T_{0}\right]$ s.t.

$$
\forall t \in\left[0, T_{0}\right] \cdot \mathbf{x}(t) \in H \quad \text { and } \quad \mathbf{x}\left(T_{1}\right) \notin P .
$$

It is not difficult to check that the set

$$
\mathcal{T}_{P} \widehat{=}\{T \in \mathbb{R}, T \geq 0 \mid \forall t \in[0, T] \cdot \mathbf{x}(t) \in P\}
$$

is not empty, and is a right-open or right-closed interval $\left[0, T_{P}\right\rangle$ with $0 \leq T_{P} \leq T_{1}$. If $\left[0, T_{P}\right\rangle=\left[0, T_{P}\right]$, then $T_{P}<$ $T_{1}$. Thus $\mathbf{x}\left(T_{P}\right) \in P \cap H \cap \operatorname{In}_{\mathbf{f}}(H)$, but $\mathbf{x}\left(T_{P}\right) \notin \operatorname{In}_{\mathbf{f}}(P)$, otherwise $T_{P}$ could not be the right end point of $\mathcal{T}_{P}$. So 2 is violated.

If $\left[0, T_{P}\right\rangle=\left[0, T_{P}\right)$, then $T_{P}>0$ and $\mathbf{x}\left(T_{P}\right) \in P^{c} \cap H$. Furthermore, $\forall t \in\left[0, T_{P}\right) . \mathbf{x}(t) \in P \cap H$, i.e.

$$
\forall t \in\left[0, T_{P}\right) \cdot \mathbf{x}\left(\mathbf{x}_{0} ; t\right) \in P \cap H
$$

which is equivalent to

$$
\forall t \in\left[-T_{P}, 0\right) \cdot \mathbf{x}\left(\mathbf{x}_{0} ; t+T_{P}\right) \in P \cap H
$$

Let $\mathbf{x}_{0}^{\prime}=\mathbf{x}\left(\mathbf{x}_{0} ; T_{P}\right)$. Then $\mathbf{x}\left(\mathbf{x}_{0}^{\prime} ; t\right)=\mathbf{x}\left(\mathbf{x}_{0} ; t+T_{p}\right)$. Thus we get

$$
\forall t \in\left[-T_{P}, 0\right) \cdot \mathbf{x}\left(\mathbf{x}_{0}^{\prime} ; t\right) \in P \cap H
$$

i.e.

$$
\forall t \in\left(0, T_{P}\right] \cdot \mathbf{x}\left(\mathbf{x}_{0}^{\prime} ;-t\right) \in P \cap H
$$

This means $\mathbf{x}_{0}^{\prime} \in \operatorname{IvIn}_{\mathbf{f}}(H) \cap \operatorname{IvIn}_{\mathbf{f}}(P)$. Besides,

$$
\mathbf{x}_{0}^{\prime}=\mathbf{x}\left(\mathbf{x}_{0}^{\prime} ; 0\right)=\mathbf{x}\left(\mathbf{x}_{0} ; T_{P}\right)=\mathbf{x}\left(T_{P}\right) \in P^{c} \cap H
$$

So 3 is violated by $\mathbf{x}_{0}^{\prime}$.
" $\Rightarrow$ " If 2 does not hold, then there exists $\mathbf{x}_{1} \in P \cap H, \epsilon_{1}>0$ and $0<t_{1}<\epsilon_{1}$ such that $\forall t \in\left[0, \epsilon_{1}\right) \cdot \mathbf{x}\left(\mathbf{x}_{1} ; t\right) \in H$ and $\mathbf{x}\left(\mathbf{x}_{1} ; t_{1}\right) \notin P$. By Definition 11 $P$ could not be a CI.

If 3 does not hold, then there exists

$$
\mathbf{x}_{2} \in P^{c} \cap H \cap \operatorname{IvIn}_{\mathbf{f}}(H) \cap \operatorname{IvIn}_{\mathbf{f}}(P)
$$

This means there exists $\epsilon_{2}>0$ such that

$$
\forall t \in\left(0, \epsilon_{2}\right) \cdot \mathbf{x}\left(\mathbf{x}_{2} ;-t\right) \in P \cap H
$$

i.e.

$$
\forall t \in\left(-\epsilon_{2}, 0\right) \cdot \mathbf{x}\left(\mathbf{x}_{2} ; t\right) \in P \cap H
$$

Thus

$$
\forall t \in\left[-\epsilon_{2} / 2,0\right) \cdot \mathbf{x}\left(\mathbf{x}_{2} ; t\right) \in P \cap H
$$

i.e.

$$
\forall t \in\left[0, \epsilon_{2} / 2\right) . \mathbf{x}\left(\mathbf{x}_{2} ; t-\epsilon_{2} / 2\right) \in P \cap H
$$

Let $\mathbf{x}_{2}^{\prime}=\mathbf{x}\left(\mathbf{x}_{2} ;-\epsilon_{2} / 2\right)$. Then $\mathbf{x}\left(\mathbf{x}_{2}^{\prime} ; t\right)=\mathbf{x}\left(\mathbf{x}_{2} ; t-\epsilon_{2} / 2\right)$. Thus we get

$$
\forall t \in\left[0, \epsilon_{2} / 2\right) \cdot \mathbf{x}\left(\mathbf{x}_{2}^{\prime} ; t\right) \in P \cap H
$$

Furthermore,

$$
\mathbf{x}\left(\mathbf{x}_{2}^{\prime} ; \epsilon_{2} / 2\right)=\mathbf{x}\left(\mathbf{x}_{2} ; 0\right)=\mathbf{x}_{2} \in P^{c} \cap H
$$

Thus the trajectory starting from $\mathrm{x}_{2}^{\prime}$ violates the condition of Definition 11 so $P$ could not be a CI either.

### 6.2 Necessary and Sufficient Condition for SAI

Given a $\operatorname{PDS}(H, \mathbf{f}, \Xi)$ and an SAI $P$, to encode the conditions in Theorem 19 as polynomial formulas, it is sufficient to show that $\operatorname{In}_{\mathbf{f}}(H), \operatorname{In}_{\mathbf{f}}(P), \operatorname{IvIn}_{\mathbf{f}}(H)$ and $\operatorname{IvIn}_{\mathbf{f}}(P)$ are all semi-algebraic sets. By the structure of $H$, it is natural to consider the relation between $\operatorname{In}_{\mathbf{f}}(H)$ and $\operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{i j} \triangleright 0\right)\right)$. Through a careful analysis, we establish the following crucial equality:

Theorem 20. For a semi-algebraic set $H$ defined by formula (11) and a polynomial vector field $\mathbf{f}$, we have

$$
\operatorname{In}_{\mathbf{f}}(H)=\bigcup_{i=1}^{I} \bigcap_{j=1}^{J_{i}} \operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{i j} \triangleright 0\right)\right)
$$

To prove Theorem 20 we need the following two Lemmas, wherein $\triangleright \in\{\geq,>\}$.

Lemma 21. For any atomic polynomial formula $p \triangleright 0$ and polynomial vector field $\mathbf{f}$, and for any $\mathbf{x}_{0} \in \mathbb{R}^{n}$, we have either $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \triangleright 0))$ or $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(\mathcal{S}(p \triangleright 0))$.

Proof. Polynomial functions are analytic, so $\mathbf{f}$ is analytic and thus $\mathbf{x}\left(\mathbf{x}_{0} ; t\right)(\mathbf{x}(t)$ for short $)$ is analytic in a small interval $(a, b)$ containing 0 . Besides, $p$ is analytic, so the Taylor expansion of $p(\mathbf{x}(t))$ at $t=0$

$$
\begin{aligned}
p(\mathbf{x}(t)) & =p\left(\mathbf{x}_{0}\right)+\frac{\mathrm{d} p}{\mathrm{~d} t} \cdot t+\frac{\mathrm{d}^{2} p}{\mathrm{~d} t^{2}} \cdot \frac{t^{2}}{2!}+\cdots \\
& =L_{\mathbf{f}}^{0} p\left(\mathbf{x}_{0}\right)+L_{\mathbf{f}}^{1} p\left(\mathbf{x}_{0}\right) \cdot t+L_{\mathbf{f}}^{2} p\left(\mathbf{x}_{0}\right) \cdot \frac{t^{2}}{2!}+\cdots
\end{aligned}
$$

converges in $(a, b)$. Then the proof proceeds by case analysis on the sign of $L_{\mathbf{f}}^{\gamma_{p, f}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)$ :

- if $\gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)=\infty$, then $\exists \epsilon>0 \forall t \in(0, \epsilon) \cdot p(\mathbf{x}(t))=0$, so $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \geq 0))$ and $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(\mathcal{S}(p>0))$;
- if $L_{\mathbf{f}}^{\gamma_{p, \mathrm{f}}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)>0$, then $\exists \epsilon>0 \forall t \in(0, \epsilon) \cdot p(\mathbf{x}(t))>$ 0 , so $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \geq 0))$ and $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p>0))$;
- if $L_{\mathrm{f}}^{\gamma_{p, f}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)<0$, then $\exists \epsilon>0 \forall t \in(0, \epsilon) \cdot p(\mathbf{x}(t))<$ 0 , so $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(\mathcal{S}(p \geq 0))$ and $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(\mathcal{S}(p>0))$.

Then we can see that for all $\mathbf{x}_{0} \in \mathbb{R}^{n}$, either $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \triangleright$ $0)$ ) or $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(\mathcal{S}(p \triangleright 0))$.

Lemma 22. For any semi-algebraic set $B=\mathcal{S}\left(\bigwedge_{j=1}^{J} p_{j} \triangleright\right.$ 0 ), and polynomial vector field, we have

1. $\operatorname{In}_{\mathbf{f}}(B)=\bigcap_{j=1}^{J} \operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{j} \triangleright 0\right)\right)$;
2. for any $\mathbf{x}_{0} \in \mathbb{R}^{n}$, either $\mathbf{x}_{0} \in \operatorname{In}(B)$ or $\mathbf{x}_{0} \in \operatorname{Out}(B)$.

Proof. 1. " $\subseteq$ " Trivial.
$" \supseteq$ " For any $\mathbf{x}_{0} \in \bigcap_{j=1}^{J} \operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{j} \triangleright 0\right)\right)$, there exist positive $\epsilon_{1}, \epsilon_{2}, \ldots, \epsilon_{J}$ such that for all $1 \leq j \leq J$ and any $t \in\left(0, \epsilon_{j}\right), p_{j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0$. Let $\epsilon=\min \left\{\epsilon_{1}, \epsilon_{2}, \ldots, \epsilon_{J}\right\}$. Then for any $t \in(0, \epsilon), \bigwedge_{j=1}^{J} p_{j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0$. Thus $\mathbf{x}_{0} \in \operatorname{In}_{\mathbf{f}}(B)$.
2. By 1 if $\mathbf{x}_{0} \notin \operatorname{In}_{\mathbf{f}}(B)$, then there exists $j_{0} \in[1, J]$ such that $\mathbf{x}_{0} \notin \operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{j_{0}} \triangleright 0\right)\right)$. By Lemma $21 \mathbf{x}_{0} \in$ $\operatorname{Out}_{\mathbf{f}}\left(\mathcal{S}\left(p_{j_{0}} \triangleright 0\right)\right)$. Thus there exists $\epsilon>0$ s.t. for all $t \in(0, \epsilon), \neg\left(p_{j_{0}}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0\right)$. Then for all $t \in(0, \epsilon)$, $\bigvee_{j=1}^{J} \neg\left(p_{j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0\right)$, i.e. $\neg\left(\bigwedge_{j=1}^{J} p_{j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0\right)$. This means $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(B)$.
" $\subseteq$ " If $\mathbf{x}_{0} \notin \bigcup_{i=1}^{I} \bigcap_{j=1}^{J} \operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{i j} \triangleright 0\right)\right)$, then for all $i \in[1, I]$, $\mathbf{x}_{0} \notin \bigcap_{j=1}^{J} \operatorname{In}_{\mathbf{f}}\left(\mathcal{S}\left(p_{i j} \triangleright 0\right)\right)$. By Lemma 22 for all $i \in[1, I]$, $\mathbf{x}_{0} \in \operatorname{Out}_{\mathbf{f}}(B)$, where $B=\bigwedge_{j=1}^{J} p_{i j} \triangleright 0$. Thus there exist positive $\epsilon_{1}, \epsilon_{2}, \ldots, \epsilon_{I}$ s.t. for all $i \in[1, I]$ and any $t \in\left(0, \epsilon_{i}\right)$, $\neg\left(\bigwedge_{j=1}^{J} p_{i j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0\right)$. Let $\epsilon=\min \left\{\epsilon_{1}, \epsilon_{2}, \ldots, \epsilon_{I}\right\}$. Then for all $t \in(0, \epsilon), \bigwedge_{i=1}^{I} \neg\left(\bigwedge_{j=1}^{J} p_{i j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0\right)$, or equivalently, $\neg\left(\bigvee_{i=1}^{I} \bigwedge_{j=1}^{J} p_{i j}\left(\mathbf{x}\left(\mathbf{x}_{0} ; t\right)\right) \triangleright 0\right)$. This means $\mathbf{x}_{0} \in$ $\operatorname{Out}_{\mathbf{f}}(H)$ and $\mathbf{x}_{0} \notin \operatorname{In}_{\mathbf{f}}(H)$.

Based on Theorem 20 in order to show $\operatorname{In}_{\mathbf{f}}(H)$ is a semialgebraic set for any semi-algebraic set $H$, it is sufficient to show that $\operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \triangleright 0))$ is a semi-algebraic set for any polynomial $p$, where $\triangleright \in\{\geq,>\}$.

In fact, we have proved in Lemma 21 the following result.

Lemma 23. For any polynomial $p$ and polynomial vector field $\mathbf{f}$,

$$
\begin{aligned}
& \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p>0))=\Gamma_{+}(p, \mathbf{f}) \quad \text { and } \\
& \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \geq 0))=\Gamma_{0}(p, \mathbf{f}) \cup \Gamma_{+}(p, \mathbf{f}),
\end{aligned}
$$

where

$$
\begin{align*}
& \Gamma_{0}(p, \mathbf{f}) \xlongequal[=]{ }\left\{\mathbf{x}_{0} \in \mathbb{R}^{n} \mid \gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)=\infty\right\} \text { and }  \tag{12}\\
& \Gamma_{+}(p, \mathbf{f}) \widehat{=}\left\{\mathbf{x}_{0} \in \mathbb{R}^{n} \mid \gamma_{p, \mathbf{f}}\left(\mathbf{x}_{0}\right)<0 \wedge L_{f}^{\gamma_{p, f}\left(\mathbf{x}_{0}\right)} p\left(\mathbf{x}_{0}\right)>0\right\} \tag{13}
\end{align*}
$$

Next, we show $\Gamma_{0}$ and $\Gamma_{+}$are semi-algebraic sets. We will do so in a more general way for parametric polynomials $p(\mathbf{u}, \mathbf{x})$. In their proofs, we need the fundamental results about Lie derivatives shown in Section 4 In the sequel we adopt the convention that $\bigwedge_{i \in \emptyset} \phi_{i}=$ true, where $\phi_{i}$ is a polynomial formula.

Lemma 24. Given $p \widehat{=} p(\mathbf{u}, \mathbf{x})$ and polynomial vector field $\mathbf{f}$, for any $\mathbf{u}_{0} \in \mathbb{R}^{t}$ we have

$$
\Gamma_{0}\left(p_{\mathbf{u}_{0}}, \mathbf{f}\right)=\mathcal{S}\left(\left.\varphi_{0}(p, \mathbf{f})\right|_{\mathbf{u}=\mathbf{u}_{0}}\right)
$$

where

$$
\begin{equation*}
\varphi_{0}(p, \mathbf{f}) \widehat{=} \bigwedge_{i=0}^{N_{p, \mathbf{f}}} L_{\mathbf{f}}^{i} p=0 \tag{14}
\end{equation*}
$$

Proof. " $\subseteq$ " This is trivial by definition of pointwise rank in Section 2
" $\supseteq$ " If $\mathbf{x}_{0} \in \mathcal{S}\left(\left.\varphi_{0}(p, \mathbf{f})\right|_{\mathbf{u}=\mathbf{u}_{0}}\right)$, then by definition of pointwise rank we have $\gamma_{p_{u_{0}}, \mathbf{f}}\left(\mathbf{x}_{0}\right)>N_{p, \mathbf{f}}$. By the similarity of Theorem 14 with parameters in polynomial $p$, we get $\gamma_{p_{\mathbf{u}_{0}}, \mathbf{f}}\left(\mathbf{x}_{0}\right)=\infty$. Thus $\mathbf{x}_{0} \in \Gamma_{0}\left(p_{\mathbf{u}_{0}}, \mathbf{f}\right)$.

Lemma 25. Given $p \widehat{=} p(\mathbf{u}, \mathbf{x})$ and polynomial vector field $\mathbf{f}$, for any $\mathbf{u}_{0} \in \mathbb{R}^{t}$ we have

$$
\Gamma_{+}\left(p_{\mathbf{u}_{0}}, \mathbf{f}\right)=\mathcal{S}\left(\left.\psi_{+}(p, \mathbf{f})\right|_{\mathbf{u}=\mathbf{u}_{0}}\right),
$$

where

$$
\begin{equation*}
\psi_{+}(p, \mathbf{f}) \widehat{=} \bigvee_{i=0}^{N_{p, \mathbf{f}}} \psi^{(i)}(p, \mathbf{f}) \quad \text { with } \tag{15}
\end{equation*}
$$

$$
\psi^{(i)}(p, \mathbf{f}) \widehat{=}\left(\bigwedge_{j=0}^{i-1} L_{\mathbf{f}}^{j} p=0\right) \wedge L_{\mathbf{f}}^{i} p>0
$$

Proof. " $\supseteq$ " If $\mathbf{x}_{0} \in \mathcal{S}\left(\left.\varphi_{+}(p, \mathbf{f})\right|_{\mathbf{u}=\mathbf{u}_{0}}\right)$, then by definition of pointwise rank, we have

$$
\left(\gamma_{p_{\mathbf{u}_{0}}, \mathbf{f}}\left(\mathbf{x}_{0}\right) \leq N_{p, \mathbf{f}}<\infty\right) \wedge L_{\mathbf{f}}^{\gamma_{p_{\mathbf{u}_{0}}, \mathbf{f}}\left(\mathbf{x}_{0}\right)} p_{\mathbf{u}_{0}}\left(\mathbf{x}_{0}\right)>0 .
$$

Thus $\mathbf{x}_{0} \in \Gamma_{+}\left(p_{\mathbf{u}_{0}}, \mathbf{f}\right)$.
$" \subseteq$ " If $\mathbf{x}_{0} \in \Gamma_{+}\left(p_{\mathbf{u}_{0}}, \mathbf{f}\right)$, then by definition of pointwise rank we know $\mathbf{x}_{0}$ satisfies

$$
L_{\mathbf{f}}^{0} p_{\mathbf{u}_{0}}=0 \wedge \cdots \wedge L_{\mathbf{f}}^{\gamma_{\mathbf{u}_{0}}, \mathbf{f}^{\left(\mathbf{x}_{0}\right)-1}} p_{\mathbf{u}_{0}}=0 \wedge L_{\mathbf{f}}^{\gamma_{\mathbf{p}_{0}}, \mathbf{f}^{\left(\mathbf{x}_{0}\right)}} p_{\mathbf{u}_{0}}>0 .
$$

By the similarity of Theorem 14 with parameters in polynomial $p$, we have $\gamma_{p_{\mathbf{u}_{0}}, \mathbf{f}}\left(\mathbf{x}_{0}\right) \leq N_{p, \mathbf{f}}$. Thus $\mathbf{u}_{0}, \mathbf{x}_{0}$ satisfy $\phi^{\gamma_{\mathbf{u}_{0}, \mathfrak{f}}}(p, \mathbf{f})$. This means $\mathbf{x}_{0} \in \mathcal{S}\left(\left.\varphi_{+}(p, \mathbf{f})\right|_{\mathbf{u}=\mathbf{u}_{0}}\right)$.

Based on Lemma 23, 24 and 25 we have

Theorem 26. For any polynomial $p$ and vector field $\mathbf{f}$,

$$
\begin{aligned}
& \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p>0))=\mathcal{S}\left(\psi_{+}(p, \mathbf{f})\right), \text { and } \\
& \operatorname{In}_{\mathbf{f}}(\mathcal{S}(p \geq 0))=\mathcal{S}\left(\psi_{+}(p, \mathbf{f}) \vee \varphi_{0}(p, \mathbf{f})\right)
\end{aligned}
$$

where $\varphi_{0}(p, \mathbf{f})$ and $\psi_{+}(p, \mathbf{f})$ are defined in (14) and (15) respectively.

Therefore, $\operatorname{In}_{\mathbf{f}}(H)$ can be translated into a polynomial formula. By a similar argument, we are able to prove that

Theorem 27. For a semi-algebraic set $H$ defined by formula (11) and a polynomial vector field $\mathbf{f}$, we have

$$
\operatorname{IvIn}_{\mathbf{f}}(H)=\bigcup_{i=1}^{I} \bigcap_{j=1}^{J_{i}} \operatorname{IvIn}_{\mathbf{f}}\left(\mathcal{S}\left(p_{i j} \triangleright 0\right)\right)
$$

Accordingly,

Theorem 28. For any polynomial $p$ and vector field $\mathbf{f}$,

$$
\begin{aligned}
& \operatorname{IvIn}_{\mathbf{f}}(\mathcal{S}(p>0))=\mathcal{S}\left(\varphi_{+}(p, \mathbf{f})\right), \text { and } \\
& \operatorname{IvIn}_{\mathbf{f}}(\mathcal{S}(p \geq 0))=\mathcal{S}\left(\varphi_{+}(p, \mathbf{f}) \vee \varphi_{0}(p, \mathbf{f})\right)
\end{aligned}
$$

where

$$
\begin{align*}
\varphi_{+}(p, \mathbf{f}) & \widehat{=} \bigvee_{i=0}^{N_{p, \mathbf{f}}} \varphi^{(i)}(p, \mathbf{f}) \quad \text { with }  \tag{16}\\
\varphi^{(i)}(p, \mathbf{f}) & \widehat{=}\left(\bigwedge_{j=0}^{i-1} L_{\mathbf{f}}^{j} p=0\right) \wedge\left((-1)^{i} \cdot L_{\mathbf{f}}^{i} p>0\right) .
\end{align*}
$$

Now we are able to present our main result of automatic SAI generation for PDS.

Theorem 29 (Main Result). A semi-algebraic set $\mathcal{S}(P)$ with

$$
P \widehat{=} \bigvee_{k=1}^{K}\left(\bigwedge_{j=1}^{j_{k}} p_{k j}\left(\mathbf{u}_{k j}, \mathbf{x}\right) \geq 0 \quad \wedge \bigwedge_{j=j_{k}+1}^{J_{k}} p_{k j}\left(\mathbf{u}_{k j}, \mathbf{x}\right)>0\right)
$$

is a continuous invariant of the $\operatorname{PDS}(\mathcal{S}(H), \mathbf{f}, \Xi)$ with

$$
H \widehat{=} \bigvee_{m=1}^{M}\left(\bigwedge_{l=1}^{l_{m}} p_{m l}(\mathbf{x}) \geq 0 \quad \wedge \bigwedge_{l=l_{m}+1}^{L_{m}} p_{m l}(\mathbf{x})>0\right)
$$

if and only if $\mathbf{u}=\left\langle\mathbf{u}_{k j}\right\rangle$ satisfy

$$
\forall \mathbf{x} \cdot\binom{(\Xi(\mathbf{x}) \rightarrow P(\mathbf{u}, \mathbf{x})) \wedge}{\left(P \wedge H \wedge \varphi_{H} \rightarrow \varphi_{P}\right) \wedge\left(\neg P \wedge H \wedge \varphi_{H}^{\mathrm{IV}} \rightarrow \neg \varphi_{P}^{\mathrm{Iv}}\right)},
$$

where

$$
\begin{aligned}
\varphi_{H} & \widehat{=} \bigvee_{m=1}^{M}\left(\bigwedge_{l=1}^{l_{m}} \psi_{0,+}\left(p_{m l}, \mathbf{f}\right) \wedge \bigwedge_{l=l_{m}+1}^{L_{m}} \psi_{+}\left(p_{m l}, \mathbf{f}\right)\right), \\
\varphi_{P} & \widehat{=} \bigvee_{k=1}^{K}\left(\bigwedge_{j=1}^{j_{k}} \psi_{0,+}\left(p_{k j}, \mathbf{f}\right) \wedge \bigwedge_{j=j_{k}+1}^{J_{k}} \psi_{+}\left(p_{k j}, \mathbf{f}\right)\right),
\end{aligned}
$$

$$
\varphi_{H}^{\mathrm{IV}} \widehat{=} \bigvee_{m=1}^{M}\left(\bigwedge_{l=1}^{l_{m}} \varphi_{0,+}\left(p_{m l}, \mathbf{f}\right) \wedge \bigwedge_{l=l_{m}+1}^{L_{m}} \varphi_{+}\left(p_{m l}, \mathbf{f}\right)\right)
$$

$$
\varphi_{P}^{\mathrm{Iv}} \widehat{=} \bigvee_{k=1}^{K}\left(\bigwedge_{j=1}^{j_{k}} \varphi_{0,+}\left(p_{k j}, \mathbf{f}\right) \wedge \bigwedge_{j=j_{k}+1}^{J_{k}} \varphi_{+}\left(p_{k j}, \mathbf{f}\right)\right)
$$

with $\psi_{0,+}(p, \mathbf{f}) \widehat{=} \psi_{+}(p, \mathbf{f}) \vee \varphi_{0}(p, \mathbf{f})$ and $\varphi_{0,+}(p, \mathbf{f}) \widehat{=} \varphi_{+}(p, \mathbf{f}) \vee$ $\varphi_{0}(p, \mathbf{f})$.

Proof. This theorem is a direct consequence of Theorem (19) 20, 26, 27 and 28.

Note that $\varphi_{H}$ and $\varphi_{H}^{\mathrm{Iv}}$ are trivially "true" when $H$ is the whole space $\mathbb{R}^{n}$.

Compared to related work, e.g [17, 19, 20, 24, our method for SAI generation based on Theorem [29] has the following two features:

1. Given a PDS (with arbitrary semi-algebraic domain and initial states), we consider arbitrary semi-algebraic sets as invariants, which are of complicated forms and may be neither open nor closed.
2. Our criterion for checking semi-algebraic invariants for PDS is sound and complete; our method for automatically generating semi-algebraic invariants is sound, and complete w.r.t to the predefined template.

Now we demonstrate how our approach can be used to generate a general SAI by the following example.

Example 30. Let $\mathbf{f}(x, y)=\left(\dot{x}=-2 y, \dot{y}=x^{2}\right)$ with $H \widehat{=} \mathbb{R}^{2}$ and $\Xi \widehat{=} x+y \geq 0$. Take a template: $\tau \widehat{=} x-a \geq 0 \vee y-b>0$.

By Theorem [29, $\tau$ is an SAI of $(H, \mathbf{f}, \Xi)$ iff $(a, b)$ satisfies the following two formulas

$$
\begin{align*}
& x+y \geq 0 \rightarrow(x-a \geq 0 \vee y-b>0)  \tag{17}\\
& (\tau \rightarrow \zeta) \wedge(\neg \tau \rightarrow \neg \xi) \tag{18}
\end{align*}
$$

for all $(x, y) \in \mathbb{R}^{2}$, where

$$
\begin{aligned}
& \zeta \widehat{=}(x-a>0) \vee(x-a=0 \wedge-2 y>0) \\
& \vee\left(x-a=0 \wedge-2 y=0 \wedge-2 x^{2} \geq 0\right) \\
& \vee(y-b>0) \vee\left(y-b=0 \wedge x^{2}>0\right) \\
& \vee\left(y-b=0 \wedge x^{2}=0 \wedge-4 y x>0\right) \\
& \vee\left(y-b=0 \wedge x^{2}=0 \wedge-4 y x=0 \wedge 8 y^{2}-4 x^{3}>0\right) \\
& \xi \widehat{=}(x-a>0) \vee(x-a=0 \wedge-2 y<0) \\
& \vee\left(x-a=0 \wedge-2 y=0 \wedge-2 x^{2} \geq 0\right) \\
& \vee(y-b>0) \vee\left(y-b=0 \wedge x^{2}<0\right) \\
& \vee\left(y-b=0 \wedge x^{2}=0 \wedge-4 y x>0\right) \\
& \vee\left(y-b=0 \wedge x^{2}=0 \wedge-4 y x=0 \wedge 8 y^{2}-4 x^{3}<0\right)
\end{aligned}
$$

By applying quantifier elimination to this formula, we get $a+b \leq 0 \wedge b \leq 0$. Let $a=-1$ and $b=-0.5$, and it results that $\left\{(x, y) \in \mathbb{R}^{2} \mid x \geq-1 \vee y>-0.5\right\}$ is an SAI for this PDS, which is shown in IV of Figure 2 .

Note that in the above example, the generated SAI is a general semi-algebraic set that is a union of two simple semialgebraic sets, which is neither closed nor open.

## 7. CASE STUDY

In this section, we show that our method presented above can be used to generate continuous invariants for some real systems.

### 7.1 Formal Verification of CTCS-3

In [15, the authors use $H C S P$ [11, 33 to formally model the Chinese Train Control System at Level 3 (CTCS-3) 32. They also propose a calculus of HCSP for the purpose of verifying safety properties of CTCS-3. For this calculus to work, effective techniques for dealing with continuous dynamics must be incorporated.

Consider the following fragment of the HCSP model of CTCS3:

$$
P_{e b i} \widehat{=}\langle\dot{s}=v, \dot{v}=a\rangle \rightarrow v \geq v . S e g ; \text { flag }_{E B}:=\text { true } ; P_{E B} .
$$

Process $P_{e b i}$ models the running of a train, with $s, v, a$ representing its position, velocity and acceleration ( $a$ is a constant) respectively. Once $v$ exceeds the speed limit $v$. Seg of the current segment, flag $_{E B}$ for emergency brake is set to true and the train starts braking immediately, expressed by the subprocess $P_{E B}$.

The safety property needs to be verified about $P_{e b i}$ can be stated as

$$
\text { Inv } \hat{=} v \geq v \cdot S e g \rightarrow \text { flag }_{E B}=\text { true },
$$

which means whenever the train's speed exceeds certain limit, it must execute the emergency brake process.

To verify this property, i.e. to check that $I n v$ is indeed an invariant of $P_{e b i}$, according to the calculus in 15], it amounts to check that $v<v$.Seg is a continuous invariant of the $\operatorname{PDS}(H, \mathbf{f}, \Xi)$, where $H \widehat{=} \mathcal{S}(v<v . \operatorname{Seg}), \mathbf{f} \widehat{=}(v, a)$ and $\Xi \widehat{=}\left\{\left(s_{0}, v_{0}\right)\right\}$ with $v_{0}<v . S e g$. According to our method, this can be further reduced to the checking of the validity of

$$
\forall v .(v=v \cdot \operatorname{Seg} \wedge v<v . \operatorname{Seg} \rightarrow a \leq 0),
$$

which is obvious.
Perhaps this example seems a bit trivial, for the continuous dynamics is an affine system and the required invariant coincides with the domain. What we want to stress here is the completeness of our criterion for checking continuous invariants compared to others. For example, the principle given in 17 requires the directional derivative of an invariant in the direction of the vector field to have the same sign in the domain. As a result, it may fail to generate the above invariant $\mathcal{S}(v<v$.Seg $)$, because

$$
\forall v .(v<v . S e g \rightarrow \dot{v}=a<0)
$$

is false when $a \geq 0$.

### 7.2 Collision Avoidance Maneuvers

We consider the following two-aircraft flight dynamics from 18:

$$
\mathbf{f} \widehat{=}\left[\begin{array}{llll}
\dot{x}_{1}=d_{1} & \dot{y}_{1}=e_{1} & \dot{d}_{1}=-\omega d_{2} & \dot{e}_{1}=-\theta e_{2}  \tag{19}\\
\dot{x}_{2}=d_{2} & \dot{y}_{2}=e_{2} & \dot{d}_{2}=\omega d_{1} & \dot{e}_{2}=\theta e_{1}
\end{array}\right] .
$$

System (19) has 8 variables: $\left(x_{1}, x_{2}\right)$ and $\left(y_{1}, y_{2}\right)$ represent the positions of aircraft 1 and 2 respectively, and $\left(d_{1}, d_{2}\right)$ and $\left(e_{1}, e_{2}\right)$ represent their velocities. The parameters $\omega$ and $\theta$ denote the angular speed of the two aircrafts.

We shall apply our method to generating special invariants of form $p=0$ for $\operatorname{PDS}(H, \mathbf{f}, \Xi)$ with $H \widehat{=} \mathbb{R}^{8}$ and $\mathbf{f}$ defined in (19). For simplicity, we take $\Xi$ to be a singleton $\left\{\left(x_{1}^{0}, x_{2}^{0}, d_{1}^{0}, d_{2}^{0}, y_{1}^{0}, y_{2}^{0}, e_{1}^{0}, e_{2}^{0}\right)\right\}$.

In order to determine candidates for invariants of $(H, \mathbf{f}, \Xi)$, we enumerate parametric polynomials $p \widehat{=} p(\mathbf{u}, \mathbf{x})$ by the degree of $p$ and the number of variables appearing in it. For example, we can choose the linear template $p(\mathbf{u}, \mathbf{x}) \widehat{=} u_{1} x_{1}+$ $u_{2} x_{2}+u_{3} d_{1}+u_{4} d_{2}+u_{0}$.

According to Theorem [29] it is easy to check that $p(\mathbf{u}, \mathbf{x})=0$ is an invariant of $(H, \mathbf{f}, \Xi)$ if and only if $\mathbf{u}$ satisfies

- $\forall \mathbf{x} . \Xi \rightarrow p=0$; and
- $\forall \mathbf{x} \cdot p=0 \rightarrow \bigwedge_{i=1}^{N_{p, \mathrm{f}}} L_{\mathbf{f}}^{i} p(\mathbf{u}, \mathbf{x})=0$.

For the template defined above, we can get $N_{p, \mathrm{f}}=2$. By applying quantifier elimination to the corresponding constraint, we get $u_{2}-u_{3} \omega=0 \wedge u_{1}+u_{4} \omega=0 \wedge u_{0}+u_{1} x_{1}^{0}+$ $u_{2} x_{2}^{0}+u_{3} d_{1}^{0}+u_{4} d_{2}^{0}=0$. Thus we can obtain the following invariants by assigning suitable values to $u_{i} \mathrm{~s}$ :

$$
\begin{aligned}
& \text { - } \omega x_{2}+d_{1}-\omega x_{2}^{0}-d_{1}^{0}=0 \\
& \text { - }-\omega x_{1}+d_{2}+\omega x_{1}^{0}-d_{2}^{0}=0 ;
\end{aligned}
$$

$$
\bullet-\omega x_{1}+\omega x_{2}+d_{1}+d_{2}+\omega x_{1}^{0}-\omega x_{2}^{0}-d_{1}^{0}-d_{2}^{0}=0 .
$$

If we use the quadratic template $p \widehat{=} u_{1} d_{1}^{2}+u_{2} d_{2}^{2}+u_{0}$, we can also get $N_{p, \mathbf{f}}=2$, and the constraint for $\mathbf{u}$ is $u_{1}-u_{2}=$ $0 \wedge u_{0}+u_{1}\left(d_{1}^{0}\right)^{2}+u_{2}\left(d_{2}^{0}\right)^{2}=0$. Let $u_{1}=u_{2}=1$ and we obtain an invariant

$$
d_{1}^{2}+d_{2}^{2}-\left(d_{1}^{0}\right)^{2}-\left(d_{2}^{0}\right)^{2}=0
$$

Using arbitrary semi-algebraic templates, we can generate invariants beyond polynomial equations for $(H, \mathbf{f}, \Xi)$, at the cost of heavier computation.

## 8. CONCLUSIONS

In this paper, we present a sound and complete criterion for checking SAIs for PDSs, as well as a relatively complete method for automatic SAI generation using templates. Our approach is based on the computable algebraic-geometry theory. Our work in this paper actually completes the gap left open in 27. Compared with the related work, more invariants can be generated through our approach. This is demonstrated by simple examples and case studies.

In the future, we will concentrate on the following problems. Firstly, we believe that our method can be applied to generate invariance sets for stability analysis, controller synthesis and so on in control theory, in particular for construction of Lyapunov functions. Secondly, we will consider how to extend the approach to more general dynamical systems whose vector fields are functions beyond polynomials. Since our approach makes use of first-order quantifier elimination which is with doubly exponential cost 7, how to improve the efficiency of our approach will be our main future work. For instance of linear templates, it is helpful to reduce the complexity via linear programming.
