Abstract

To facilitate research in the field of reverse engineering and system renovation we[5] have compiled an annotated bibliography. We put the contributions not only in alphabetical order but also grouped by topic so that readers focusing on a certain topic can read their annotations in the alphabetical listing. We also compiled an annotated list of pointers to information about reverse engineering and system renovation that can be reached via Internet. For the sake of ease we also incorporated a brief introduction to the field of reverse engineering.

Key Words & Phrases: Reverse engineering, Annotated bibliography, System renovation
1991 CR Categories: A.2, D.2.2, D.2.7, D.2.m, K.6.3

1. Introduction

There is a constant need for updating and renovating business-critical software systems for many and divers reasons: business requirements change, technological infrastructure is modernized, the government changes laws, or the third millennium approaches, to mention a few. Therefore, that in the area of software engineering the subjects of reverse engineering and system renovation become more and more important. The interest in such subjects originates from the difficulties that one encounters when attempting to maintain extremely large software systems. Such software systems are often called legacy systems, since it is a legacy of many different people that have developed and maintained them. It is not hard to understand that it is very difficult—if not impossible—to maintain them.

To make the problems a bit more concrete we will compare such software renovation projects to the renovation of a house. The problem that software engineers encounter could very well be stated in house renovation terms as the query: "How to renovate your house with the additional constraint that you want to use all the facilities of it during this renovation?" For many business-critical systems the same situation holds: how to renovate your software system while at the same time business continues as usual. An often heard (naïve) solution is to throw away the software as soon as a totally new system is finished (this is sometimes called shadowing). In house renovation terminology this would mean that you would have to build a completely new house and when this is finished you have to move the furniture from the old house to the new house before you can start using the new one. Then you can tear down the old one. It will be clear that this will be too expensive and that the shipping of the furniture will take too much time to meet the additional constraint. In software renovation terms the option of building a totally new system and throwing away the old one is for the same reasons as with a house renovation project usually too expensive and often even impossible since the shipping of the "furniture" (say, databases) from the old system to the new system will take weeks. So a more sophisticated renovation strategy seems necessary.

Before the actual renovation can start it will be necessary to make an inventory of the specification and the documentation of the system to be renovated. Also at this point there is a challenge for software engineers since the old systems lack mostly these sources of information. It is our experience that either there is no documentation at all, or the original programmers that could possibly explain the functionality of parts of the system have left, or both. The only documentation that is left is the source code itself. Thus, since the vital information of the software is solely accessible via the source code it will be necessary to develop tools to facilitate the renovation—a task for software engineers.

We hope to have elucidated that there is a need for sophisticated analysis of software to be used in renovation methodologies for large software systems, and that research on this issue is useful and important. A step towards a sound analysis of software renovation research is to study and analyze the literature on this subject, hence, this annotated bibliography.

We want to stress that the bibliography is intended to be useful for people who want to know more about reverse engineering and system renovation. More precicely, many of the entries in our bibliography are of a techical nature so researchers, practicioners and students interested in reverse engineering will hopefully benefit from them. We also included pointers to management issues and legal sides of reverse engineering and system renovation meant for people interested in those aspects.

It is not complete but instead gives pointers for further reading.

1.1 Related work

In [4] contains another annotated bibliography. We discuss some on-line bibliographies in section 4.

[5] The authors were all in part sponsored by bank ABN AMRO, software house DPFinance, and the Dutch Ministery of Economical Affairs via the Senter Project #ITU95017 "SOS Resolver". The last author was also supported by the Netherlands Computer Science Research Foundation (SION) with financial support from the Netherlands Organization for Scientific Research (NWO), project *Interactive tools for program understanding*, 612-33-002.

1.2 Organization of the paper

In section 2 we give a brief impression of terminology in reverse engineering where we follow [25]. In the next section (section 3) we sort the selected references by topic. In section 4 we give pointers to other sources of information: we provide a list of so-called universal resource locators. We give a short description of what can be expected when connecting to them. Finally, in section 5 we provide the annotated bibliography.

Acknowledgements We thank Arie van Deursen for discussions and comments on an earlier version of this paper.

2 Reverse engineering and system renovation in a nutshell

The term reverse engineering finds its origins in hardware technology and denotes the process of obtaining the specification of complex hardware systems. Now the meaning of this notion has shifted to software. As far as we know there is not (yet) a standard definition of what reverse engineering is but in [25] we can read:

> "Reverse engineering is the process of analyzing a subject system to identify the system's components and their inter-relationships, and to create representations of the system in another form at higher levels of abstraction."

According to [25] the following six terms characterize system renovation:

- forward engineering,
- reverse engineering,
- redocumentation,
- design recovery,
- restructuring,
- reengineering (or renovation).

Forward engineering moves from a high-level abstraction and design to a low-level implementation. *Reverse engineering* can be seen as the inverse process. It can be characterized as analysing a software system in order to, firstly, identify the system components and their interactions, and to, secondly, make representations of the system on a different, possible higher, level of abstraction.

Reverse engineering restricts itself to *investigating* a system. Adaptation of a system is beyond reverse engineering but within the scope of system renovation. *Redocumentation* focuses on making a semantically equivalent description at the same level of abstraction. It is in fact a simple form of reverse engineering. Tools for redocumentation include, among others, pretty printers, diagram generators, and cross-reference listing generators. In *design recovery* domain knowledge and external information is used to make an equivalent description of a system at a higher level of abstraction. So, more information than the source code of the system is used. The notion *restructuring* amounts to transforming a system from one representation to another one at the same level of abstraction. An essential aspect of restructuring is that the semantic behaviour of the original system and the new one should remain the same; no modifications of the functionality is involved. The purpose of *reengineering* or *renovation* is to study the system, by making a specification at a higher abstraction level, adding new functionality to this specification and develop a completely new system on the basis of the original one by using forward engineering techniques.

3 Classification

Papers addressing reverse engineering and system recovery can be classified in various categories. The classification that we propose is based on the material that we found. First, we list some introductory contributions and mention conferences dedicated to reverse engineering. Then we will proceed with program understanding and design recovery, reusability, maintainability, and program slicing. Then we list contributions that deal with the reverse engineering of more specific topics: data and data bases, user interfaces, and reverse engineering for a number of languages. Then we list formal techniques, tools and their implementation issues, restructuring and regeneration, testing, management, and miscellaneous contributions.

Introduction and general topics Articles that give an introduction to the field of reverse engineering and that define the relevant notions are [14, 19, 25, 71]. Books that put the subject in context and contain a lot of introductory material are: [4, 18, 58, 110]. A book that is possibly interesting is [92], but since it is in Japanese we are not able to give more information. A recent overview of research questions is given in [90]. A tutorial on reverse engineering is [80].

Several conferences and workshops exist in this field, such as *Conference on Software Maintenance* (e.g., [53]) and *Working Conference on Reverse Engineering* (e.g., [102]).

Program understanding and design recovery There are many recent papers on this subject. We provide an extensive list: [12, 85, 9, 16, 13, 14, 30, 28, 23, 29, 31, 26, 24, 32, 33, 41, 42, 48, 44, 50, 67, 69, 68, 70, 74, 78, 86, 84, 83, 51, 98, 108, 102, 105, 110].

Reuse In these papers the focus is on how to prevent the situation of legacy systems, that is, make the software easier to maintain by programming in replaceable and reusable components. [36, 40, 54, 64, 104],

Maintainability To give an impression of the status of maintainability as a research field we give 2 quotations. Schneidewind [88] wrote in 1987 in his introduction to a special section on software maintenance that this "subject has received relatively little attention from the research community." Gallagher and Lyle write in [35] "While some may view software maintenance as a less intellectually demanding activity than development, the central premise of this work is that software maintenance is *more* demanding." Here are some pointers to the maintainability subject: [6, 11, 34, 35, 45, 89, 53, 75, 73, 43],

Program slicing A survey of program slicing techniques is given in [96]. Other references are: [9, 67, 31, 35, 68, 15, 41, 103, 38].

Reverse engineering of data and databases One the first books on data reverse engineering is [1]. Other references are: [2, 77, 39, 84, 18, 94, 93].

Reverse engineering of user interfaces [63].

Reverse engineering of specific languages Many business-critical systems are written in COBOL. So a number of papers geared towards this language are available. For other languages there are also contributions.

COBOL [57, 33, 33, 37, 67, 31, 39, 84, 66, 110, 91]

Pascal [23]

C [27, 68, 105],

Lisp [108].

Ada [21, 30, 37].

Fortran [20]

CHILL [99].

Formal techniques In the following list formal techniques are used in which CCS, Denotational semantics, Petri nets, Z, and Z++ are applied to approach certain problems in reverse engineering. [17, 8, 7, 47, 52, 57, 63, 100, 110, 11]

Tools and implementation techniques Many tools have been implemented to aid in various reverse engineering tasks. For an elaborate hypertext page on CASE tool vendors we refer to section 5.2, where a pointer to an electronically available index is given. [8, 7, 81, 67, 22, 23, 31, 52, 65, 62, 68, 30, 82, 81, 108, 100, 106, 66, 110, 11, 50, 29, 73, 61, 95, 83]

Restructuring, transformation, and regeneration In this category, methods and tools are described to perform actual reverse engineering tasks. [11, 27, 55, 49, 65, 66, 72, 76, 51, 97, 101, 107, 100, 79, 110, 26]

Testing After modification of software systems it is necessary to test the new system. Some pointers are [56, 15, 59, 38, 43]

Management Many reverse engineering projects are huge. The management of such projects is not at all trivial and gets attention in: [2, 4, 100, 110]

Miscellaneous Certain issues that are important, but do not fit our classification in a natural way are [3, 46, 60, 10, 5, 87, 109]. We mention that the subjects go from go to elimination to legal aspects of reverse engineering.

4 Other sources of information

In [4] another annotated bibliography can be found. Noteworthy, perhaps, is that this annotated bilbiography mainly contains other references than ours.

Nowadays, much information is not only available via books and journals but also via Internet. In this section we listed some universal resource locators (URLs) that are related to reverse engineering and system renovation, including some that contain an on-line bibliography. Of course, we have made ourselves a page that contains the URLs below. Contact `http://adam.fwi.uva.nl/~x/reverse.html` for both a dvi file of this bibliography and an hypertext version of the list below.

- `http://www.cc.gatech.edu/reverse/` is a site where the Georgia tech reverse engineering group presents their papers, tools and members. Moreover, pointers to other groups are given.
- `http://www.erg.abdn.ac.uk/users/brant/sre/` is a site that gives information like who is who in reverse engineering. Hyperlinks to research institutes, universities, and other sites are grouped together in a number of interest areas. Furthermore, some introductory information is available. Researchers in the field are encouraged to contribute to this WWW site under construction.
- `http://www.year2000.com/cgi-bin/clock.cgi/` This is a site of a firm specialized in the year 2000 problem. It contains information on how to join a mailing list on this subject.
- `http://www.software.ibm.com/year2000/index.html` This is a URL also dedicated to the year 2000 problem. A comprehensive set of services, tools and support is available to help customers prepare for the Year 2000 transition.

- `ftp://lscftp.kgn.ibm.com/pub/year2000/y2kpaper.ps` is a URL from which a manual can be obtained dedicated to the year 2000 problem.
- `http://www.qucis.queensu.ca/Software-Engineering/vendor.html` is a URL to a CASE tool vendor index. This is useful for tools that can be used in reverse engineering.
- `http://www.csc.tntech.edu/~linos/` is a page describing research activities related to program comprehension and reengineering performed at the CARE (Computer-Aided Reengineering) Laboratory in the Computer Science Department of Tennessee Technological University.
- `http://stout.levtech.com/levtech-marketing/papers.html` this is a bibliography of reengineering papers based on software refinery.
- `http://www-cs.open.ac.uk/~jonrob/bibliog.html` this is an online bibliography on software and reuse. At the time of writing this paper contained 114 items.
- `http://www.scism.sbu.ac.uk/cios/islam/ReuseBib.txt` This URL is a bibliography of software reuse papers written after 1990.
- `http://www.informatik.uni-stuttgart.de/ifi/ps/reengineering/reengineering.html` is an on-line bibliography on reverse engineering. It contains also the abstracts of the papers.
- `http://128.172.188.1/isydept/faculty/paiken/drebib.htm` is a pointer to a reengineering bibliography that can be obtained on a floppy disk. For more details please contact the owner of the page.

This is indeed useful when a system that is developed while saving such information needs reverse engineering but for legacy systems this is too late.*

Supporting queries on source code: A formal framework. *International Journal of Software Engineering and Knowledge Engineering*, 4(3):325–348, 1994. *A source code query system is a powerful mechanism to obtain crucial information necessary to successfully performing a reverse engineering task. A source code algebra (SCA) is developed which is strongly based on relational algebras as well as on many sorted algebras. Two types of data types are distinguished in the source code algebra model:*

- *atomic data types, such as integer, float, etc.*
- *composite data types (so-called objects):*
  - *singular objects, such as while-statement, identifier, etc.*
  - *collective objects, such as statement-list, etc.*

The objects are extended with four kinds of attributes, namely, components, references, annotations, and methods. An extensive set of source code algebra operators are defined, such operators defined for atomic data types, individual objects, and collections, i.e., sets and sequences. The operators for the collections are strongly influenced by the operators from the relational algebra domain.

Most generic reverse engineering environments break down if they have to deal with millions of lines of code. The constructed abstract syntax trees contain too much information. The reverse engineering environment should allow a flexible gathering of information, not only based on abstract syntax trees. The way the information is gathered should be programmable. The reverse engineering environments should be reusable in various application domains. The user of the environment should be able to program the the environment to make it suited for a specific application domain.*

Abstract

Information requirements have traditionally been collected separately for different business functions and then integrated into an overall specification. The recent orientation to a process perspective in managing business activities has emphasized early integration, by concurrently analyzing business processes and information requirements. Accordingly, information requirements analysis methodologies should take into account these new integration needs. In the paper, we discuss these new integration needs. Traditional methods for requirements integration from database design are analyzed and unfulfilled integration needs are highlighted. Then, other research fields are surveyed that dealt with problems similar to integration and offer interesting results: Recent developments in database design, software engineering and requirements reuse. Finally, we compare the different contributions and indicate open research directions.

1. Introduction

Information requirements analysis and engineering in information systems implementation typically follow the same orientation of business and of its administration. Information systems projects are broken down into parts that mirror the main business activities. Historically, information systems have supported organizations that were organized along functional lines [Mintzberg 1979]. Accordingly, information requirements have been collected by business function and then later integrated into an overall specification [Nolan 1973, Batini et al. 1986].

The recent emphasis on the process perspective in managing business activities has raised new demands that necessitate the streamlined integration of data across organizational functions [Venkatraman 1994, Hammer and Champy 1993, Davenport and Stoddard 1994]. In order to ensure the alignment between process and information system design, requirements should now be integrated at the process level from the beginning rather than as an after thought to requirements derived from a function-based analysis [Cattaneo et al. 1995].

Processes are commonly seen as transformations of resources into products. Information is included among process inputs
