A Nominal Exploration of Intuitionism

Vincent Rahli*

Abstract

This papers extends the Nuprl proof assistant (a system representative of the class of extensional type theories à la Martin-Löf) with *named exceptions* and *handlers*, as well as a nominal *fresh* operator. Using these new features, we prove a version of Brouwer's Continuity Principle for numbers. We also provide a simpler proof of a weaker version of this principle that only uses diverging terms. We prove these two principles in Nuprl's meta-theory using our formalization of Nuprl in Coq and show how we can reflect these metatheoretical results in the Nuprl theory as derivation rules. We also show that these additions preserve Nuprl's key meta-theoretical properties, in particular consistency and the congruence of Howe's computational equivalence relation. Using continuity and the fan theorem we prove important results of Intuitionistic Mathematics: Brouwer's continuity theorem and bar induction on monotone bars.

Categories and Subject Descriptors D.3.1 [*PROGRAMMING LANGUAGES*]: Formal Definitions and Theory; F.4.1 [*MATHE-MATICAL LOGIC AND FORMAL LANGUAGES*]: Mathematical Logic

Keywords Intuitionistic Type Theory, Nuprl, Coq, Continuity, Nominal Type Theory, Exceptions, Squashing, Truncation

1. Introduction

Continuity. There are two principles that distinguish Brouwer's mathematics from other constructive mathematics, namely *bar induction* and a *continuity principle* [11, 19, 37, 53, 74, 81, 82, 84, 85]. In this document we consider the following weak and strong continuity principles on the Baire space $\mathcal{B} = \mathbb{N}^{\mathbb{N}} = \mathbb{N} \to \mathbb{N}$ (Π, Σ are the logical \forall, \exists ; as explained below, Σ is a truncated/squashed existential quantifier; + in the context of types is the disjoint union type; inl is the left injection constructor; isl checks whether a term is a left injection; \mathbb{N}_n is the type of natural numbers strictly less than n; and $t =_T u$ expresses that t and u are equal in type T):

$$\begin{split} \texttt{WCP} &= \mathbf{\Pi} F : \mathcal{B} \to \mathbb{N}. \\ \mathbf{\Pi} f : \mathcal{B}. \\ & \underline{\boldsymbol{\Sigma}} n : \mathbb{N}. \ \mathbf{\Pi} g : \mathcal{B}. f =_{\mathbb{N}^{\mathbb{N}n}} g \to F(f) =_{\mathbb{N}} F(g) \end{split}$$

Mark Bickford

Cornell University, USA markb@cs.cornell.edu

$$\begin{split} \mathtt{SCP} &= \, \mathbf{\Pi} F{:}\mathcal{B} \to \mathbb{N}. \\ & \underline{\boldsymbol{\Sigma}} M{:}(\mathbf{\Pi} n{:}\mathbb{N}{\cdot}\mathbb{N}^{\mathbb{N}_n} \to (\mathbb{N}{+}\mathtt{Unit})). \\ & \mathbf{\Pi} f{:}\mathcal{B}. \\ & \underline{\boldsymbol{\Sigma}} n{:}\mathbb{N}. \\ & M \; n \; f =_{\mathbb{N}{+}\mathtt{Unit}} \; \mathtt{inl}(F(f)) \\ & \wedge \; \mathbf{\Pi} m{:}\mathbb{N}{\cdot}\mathtt{isl}(M \; m \; f) \to m =_{\mathbb{N}} n \end{split}$$

WCP is the usual *pointwise continuity principle* on natural numbers, sometimes called *weak continuity principle*. It says that given a function F of type $\mathcal{B} \to \mathbb{N}$ and a function f of type \mathcal{B} , F(f) can only depend on an initial segment of f. The length of the smallest such segment is called the *modulus of continuity* of F at f. Kleene used some version of the *strong continuity principle* SCP¹ to prove bar induction on monotone bars from bar induction on decidable bars [53, pp.78]. SCP says that there is a uniform way (called M in the formula) to decide whether n is the modulus of continuity of Fat f, and if so returns the value F(f) [53, pp.70–71].

Truncation/Squashing. Escardó and Xu [39] proved in Agda [2, 17] that WCP is false when Σ is the sum type Σ of Martin-Löf's type theory. They also mention that this principle is consistent when Σ is truncated at the propositional level [83, pp.117]. In Nuprl [6, 26], propositional truncation corresponds to squashing a type down to a single equivalence class (i.e., all inhabitants are equal) using quotient types [28]: |T = T//True| |T is a proof-irrelevant type. Its members are the members of T, and they are all equal to each other because if $x, y \in T$ then $(x =_T y \iff \text{True})$. In Nuprl we often squash types in a much stronger sense by throwing away the evidence that a type is inhabited and squashing it down to a single inhabitant using, e.g., set types: $\downarrow T = \{ \text{Unit} \mid T \}$ (this is the same definition as in [26, pp.60]). The only member of this type is \star^2 , which is the single inhabitant of Unit, and \star inhabits $\downarrow T$ if T is true/inhabited, but we do not keep the proof that it is true. Note that $|T \to \downarrow T$ is true because it is inhabited by $\lambda x.\star$, but we cannot prove the converse because to prove |T| we have to exhibit an inhabitant of T, which $\downarrow T$ does not give us because we have thrown away the evidence that T is inhabited (only \star inhabits $\downarrow T$). Appendix F of [72] discusses derivable inference rules that one can use to reason about these two squashing operators.

In this paper we prove that versions of WCP and SCP are true facts about Nuprl's functions. We carry out these proofs in Nuprl's meta-theory [4, 5] using our formalization of Nuprl in Coq [13, 33], which contains among other things: (1) an implementation

^{*} This work was partially supported by the SnT and the National Research Fund Luxembourg (FNR), through PEARL grant FNR/P14/8149128.

¹ Rathjen calls it "Strong Continuity for Numbers" [74] and names it C-N (as in [82]). Dummett refers to it as "a stronger version of the Continuity Principle", names it $CP_{\exists n}$, and later calls it "the Continuity Principle" [37, pp.59–60]. Troelstra [81, pp.1006] calls it CONT₀. This is Kleene's *27.2 principle [53, pp.73], which he calls "Brouwer's principle (for numbers)". Bridges and Richman [19, pp.119] mention that SCP is equivalent to a "principle of continuous choice", which they divide into a continuous part, namely WCP, and a choice part, namely the axiom of choice AC_{1,0} (see Sec 5.3). Note that AC_{1,0} is also sometimes used to refer to SCP [45, 86].

 $^{^{2}}$ The term \star can be thought of as () in, e.g., OCaml, Haskell or SML.

of Nuprl's computation system; (2) an implementation of Howe's computational equivalence relation [50] and a proof that it is a congruence; (3) a definition of Nuprl's *Constructive Type Theory* (CTT), where types are defined as *Partial Equivalence Relations* (PERs) on closed terms following Allen's PER semantics [4, 5]; (4) definitions of Nuprl's derivation rules and proof s that these rules are valid w.r.t. Allen's PER semantics; (5) and a proof of Nuprl's consistency [7, 8].

In Sec. 3 we prove WCP where $\underline{\Sigma}x:T$. *P* is defined as $\downarrow \underline{\Sigma}x:T$. *P*, and refer to this principle as WCP_↓. We call WCP_↓ the version of WCP where $\underline{\Sigma}$ is $\lfloor \underline{\Sigma}$. In Sec. 4 we prove SCP where the first (outer) $\underline{\Sigma}$ is $\downarrow \underline{\Sigma}$ and the second (inner) is $\downarrow \underline{\Sigma}$, and refer to this principle as SCP_↓. There proofs are carried out using our Coq formalization of Nuprl. We make these results available in Nuprl as inference rules, and show how we can derive directly in Nuprl a proof of SCP_↓ without the second (inner) squashing operator. Sec. 5 shows that SCP_↓ and WCP_↓ are equivalent. Even though the implication WCP_↓ \rightarrow WCP_↓ is trivial, we believe our proof of WCP_↓ in Sec. 3 is still valuable because of its simplicity and because \downarrow is often enough.

An important point is that we add operations sufficient to prove these principles to the Nuprl proof assistant without breaking any property of its type theory such as Nuprl's consistency or the congruence of Howe's computational equivalence relation.

Effectful computations. Following Longley's method [59], we use computational effects [10], namely named exceptions, to derive SCP_{\downarrow} . The basic method to find the *n* such that F(f) depends only on the first *n* elements of *f* is a program P(F, f) that works as follows: *P* tests whether *F* applies its argument *f* to a number *n* by running the sub-routine (written in an ML-like language):

```
let exception e in
```

```
(F (fun x \Rightarrow if x < n then f x else raise e);
true) handle e \Rightarrow false
```

Then by testing F on increasingly larger n's, if the continuity principle is true, P eventually finds an n such that the test returns true³. However, for extensionally equal F and G, P(F, f)and P(G, f) could return different numbers. For example, if P(F, f) = m and G is constructed from F by replacing an expression t occurring in F with (let _ := f(m + 1) in t), that first evaluates f(m + 1) and then evaluates t, then P(G, f) is not guaranteed to be m. This is why we only realize squashed versions of the above mentioned continuity principles.

As Longley mentions, if F can catch the exception e then P(F, f) will not necessarily compute F's modulus of continuity at f. Therefore, we have extended Nuprl with exception handlers that can only catch exceptions with a specific name, and we have added the ability to generate fresh names (Sec. 7 discusses related nominal systems).

Related proofs of continuity. This is not the first (formal) proof that a type theory satisfies Brouwer's continuity principle. Coquand and Jaber [30, 31] proved the *uniform* continuity of a Martin-Löf-like intensional type theory using *forcing* [9, 11, 24, 25, 61]. Their method consists in adding a generic element f as a constant to the language that stands for a Cohen real of type $2^{\mathbb{N}}$, and defining the forcing conditions as approximations of f, i.e., finite sub-graphs of f. They then define a suitable *computability* predicate that expresses when a term is a computable term of some type up to approximations given by the forcing conditions. The key steps are to (1) first prove that f is computable and then (2) prove that well-typed terms are computable, from which they derive uniform continuity (the uniform modulus of continuity is given by the approx-

imations). The uniform continuity principle is, where F is now a function on the Cantor space $\mathcal{C} = 2^{\mathbb{N}}$ instead of the Baire space: $\text{UCP} = \mathbf{\Pi} F: \mathcal{C} \to \mathbb{N}. \underline{\Sigma} n: \mathbb{N}. \mathbf{\Pi} f, g: \mathcal{C}. f =_{2^{\mathbb{N}_n}} g \to F(f) =_{\mathbb{N}} F(g)$. Escardó and Xu [39] showed that in the case of uniform continuity $\underline{\Sigma}$ can equivalently be Σ or $|\Sigma$. In [31], Coquand and Jaber provide a Haskell realizer that computes the uniform modulus of continuity of a functional on the Cantor space⁴.

Similarly, Escardó and Xu [89] proved that the definable functionals of Gödel's system T [46] are uniformly continuous on the Cantor space (without assuming classical logic or the Fan Theorem). For that, they developed a constructive continuous model, the C-**Space** category, of Gödel's system T, and proved that C-**Space** has a *Fan functional* that given a function F in $\mathcal{C} \to \mathbb{N}$ can compute the modulus of uniform continuity of F. Relating C-**Space** and the standard set-theoretical model of system T, they show that all Tdefinable functions on the Cantor space are uniformly continuous. Finally, using this model, they show how to extract computational content from proofs in HA^{ω} extended with a uniform continuity axiom UC, which is realized by the Fan functional.

In [42] Escardó provides a simple and elegant proof that all T-definable functions are continuous on the Baire space and uniformly continuous on the Cantor space using a generic element as in [30] but without using forcing. His method consists in providing an alternative interpretation of system T, where a number is interpreted by a dialogue tree that "describes the computation of a natural number relative to an unspecified oracle $\alpha : \mathbb{N}^{\mathbb{N}}$ " [42]. Such a computation is called a *dialogue*, which is a function that given a dialogue tree, returns a function of type $\mathcal{B} \to \mathbb{N}$. Escardó first proves that dialogues are continuous. This means that a function is continuous if it is extensionally equal to a dialogue. The key steps are to (1) define a suitable logical relation between the standard interpretation and the alternative one that relates numbers and dialogues w.r.t. a given oracle; and (2) prove that all system T terms are related under the two interpretations. It then follows that for all system T term t of type $(\iota \Rightarrow \iota) \Rightarrow \iota$ (where ι is the type of numbers), there is a dialogue tree d such that the standard interpretation of t and the dialogue on d are extensionally equal functions, from which he derives uniform continuity. The dialogue d is built using a generic sequence that allows dialogue trees to call the oracle.

Results. Our proof method differs from the ones discussed above in the sense that it is "mostly" computational. In Sec. 3 we use diverging terms to prove WCP₁, and in Sec. 4 we use computational effects (named exceptions) to probe terms and derive SCP₁ using (non-strict) lock-step simulations of these effectful computations. Sec. 5 shows that SCP_{\downarrow} and WCP_{\downarrow} are equivalent. To prove SCP_{\downarrow} , we added named exceptions as well as a *fresh* operator to Nuprl's computation system, and showed that these additions preserve Nuprl's key meta-theoretical properties, such as consistency (see Sec. 2.3 and 4.3) and the congruence of Howe's computational equivalence relation (see Sec. 2.2 and 4.2). As mentioned in Sec. 4.9, SCP₁ justifies a corresponding inference rule that we added to Nuprl. Sec. 5 discusses the relation between WCP and SCP and the connection with the axiom of choice, as well as the status of the (squashed) axiom of choice in Nuprl. Using those continuity rules, as explained in Sec. 6, we have proved in Nuprl (1) a fully unsquashed version of UCP using Escardó and Xu's method [39]; (2) that all real functions defined on the unit interval are uniformly continuous [37, pp.87]; and (3) that bar induction on monotone bars follows from bar induction on decidable bars following Kleene's proof [53, pp.69–73].

2. Nuprl

Nuprl is an interactive theorem prover that implements a type theory called Constructive Type Theory (CTT) [6, 26]. Nuprl's CTT "mostly" differs from other similar constructive type theories such as the ones implemented by Agda [2, 17], Coq [13, 33], or Idris [18, 51], in the sense that CTT is an extensional type theory (i.e., propositional and definitional equality are identified [49]) with types of partial functions [29, 34, 80]. This section presents some key aspects of Nuprl that will be used in the rest of this paper.

2.1 Nuprl's Computation System

Fig. 1 presents a subset of Nuprl's syntax and small-step operational semantics [6, 8]. Nuprl's programming language is an untyped (à la Curry), lazy and applied (with pairs, injections, a fixpoint operator,...) λ -calculus. For efficiency, integers are primitive and Nuprl provides operations on integers such as addition, subtraction,..., a test for equality and a "less than" operator. Nuprl also has what we call canonical form tests [73] such as ifint, which are used to distinguish between our different kinds of values. These canonical form tests are especially useful when working with (nondisjoint) union types, which are sometimes easier to work with than disjoint unions because one does not need injections.

A term is either a variable, a value (or canonical term), or a noncanonical term. Non-canonical terms have one or two principal arguments (marked using boxes in Fig. 1). A principal argument of a term t is a term that has to be evaluated to a canonical form before checking whether t can be reduced further. For example the application f(a) diverges if f diverges, and the canonical form test ifaxiom(t, a, b) diverges if t diverges.

Nuprl uses a uniform syntax for terms [7, 8], and the terms in Fig. 1 are "display forms" for some specific Nuprl terms. An advantage of having a uniform syntax is that operations that work uniformly on terms are easier to define-they do not have repetitive cases as when using one constructor per operator. In Nuprl a term is of the form $\theta(b)$, where θ is its operator, and b is a list of bound *terms*. A bound term b is of the form $\overline{l}.t$, where \overline{l} is a variable list. For example, the underlying representation of a λ -abstraction is $\{lambda\}(x.t)$. For convenience, we use the uniform syntax to, e.g., define Howe's computational equivalence relation below.

Fig. 1 also shows part of Nuprl's small-step operational semantics. We omit the rules that reduce principal arguments such as: if $t_1 \mapsto t_2$ then $t_1 u \mapsto t_2 u$. As usual, \mapsto^* is the reflexive and transitive closure of \mapsto , and $t_1 \mapsto^k t_2$ is defined inductively on $k: t \mapsto^0 t$ and $t_1 \mapsto^{k+1} t_2$ if there exists a t such that $t_1 \mapsto t$ and $t \mapsto^k t_2$. We now define a few useful abstractions:

$\perp = \texttt{fix}(\lambda x.x)$	$\mathbb{N}_{?}$	$=\mathbb{N}\cup \texttt{Unit}$
$\mathtt{tt} = \mathtt{inl}(\star)$	isint(t)	= ifint(t, tt, ff)
$ff = inr(\star)$	isl(t)	$= ext{if } t ext{ then tt else ff}$
if t_1 then t_2 else $t_3 = case$	se t_1 of in	$\operatorname{nl}(x) \Rightarrow t_1 \mid \operatorname{inr}(x) \Rightarrow t_2$

We sometimes write $a =_T b$ for the type $a = b \in T$. Also, we sometimes write b for (if b then Unit else Void), where Unit and Void can, e.g., be defined as $0 =_{\mathbb{Z}} 0$ and $0 =_{\mathbb{Z}} 1$ respectively. We define True as Unit and False as Void.

2.2 Howe's Computational Equivalence

It turns out that Nuprl's type system is not only closed under computation but more generally under Howe's computational equivalence \sim , which he proved to be a congruence [50]. In Nuprl, in any context C, when $t \sim t'$ we can rewrite t into t' without having to prove anything about types. We rely on this relation to prove equalities between programs (bisimulations) without concern for typing [73]. Howe's computational equivalence is defined on closed terms as follows: $t \sim u$ if $t \preccurlyeq u \land u \preccurlyeq t$. Howe coinductively defines the approximation (or simulation) relation \preccurlyeq as the largest relation R on closed terms such that $R \subset [R]$, where $[\cdot]$ is the following closure operator (also defined on closed terms): t [R] uif whenever t computes to a value $\theta(\bar{b})$, then u also computes to a value $\theta(\overline{b'})$ such that $\overline{b} R \overline{b'}$. To make that precise we have to extend R to open and bound terms: see [7, 8, 50] for details. By definition, one can derive, e.g., that $\perp \preccurlyeq t$ for all closed term t.

2.3 Nuprl's Type System

Following Allen's PER semantics, Nuprl's types are defined as partial equivalence relations (PERs) on closed terms [4, 5]. Allen's PER semantics can be seen as an inductive-recursive definition of: (1) an inductive relation $T_1 \equiv T_2$ that expresses type equality; and (2) a recursive function $a \equiv b \in T$ that expresses equality in a type. We write type(T) for $T \equiv T$, and $t \in T$ for $t \equiv t \in T$. Among other things, it follows that the (theoretical) proposition $a = b \in T$ is true (inhabited by \star) iff $a \equiv b \in T$ holds in the meta-theory. See [7, 8] for more details.

Nuprl's type system includes Martin-Löf dependent types, identity (or equality) types, a hierarchy of universes, W types, union and intersection types, quotient types [28], set types, and partial types [34]. The top part of Fig. 1 lists some of Nuprl's types. Among these, Base is the type of all closed terms of the computation system with \sim as its equality. The type $t_1 \preceq t_2$ is true if the meta-theoretical statement $t_1 \preccurlyeq t_2$ is true, and $t_1 \preceq t_2$ and $t_3 \preceq t_4$ are equal types if $(t_1 \preccurlyeq t_2 \iff t_3 \preccurlyeq t_4)$. Similarly the type $t_1 \simeq t_2$ is true if $t_1 \sim t_2$ is true, and $t_1 \simeq t_2$ and $t_3 \simeq t_4$ are equal types if $(t_1 \sim t_2 \iff t_3 \sim t_4)$ (see [73] and [72, Appendices A&B] for more details). For example, it is enough to prove that t_1 and t_2 are members of Base to prove that $t_1 \simeq t_2$ is a type. Also, it turns out that $t \simeq t$ is a true type in any context. These types allow us, to some extent, to reason about Nuprl's computation system directly in the theory. Nuprl has a rich type theory that makes type checking undecidable. In practice this is mitigated by type inference and type checking heuristics implemented as tactics.

We have implemented Nuprl's term language, its computation system, Howe's \sim relation, and Allen's PER semantics in Coq [7, 8]. We have also showed that Nuprl is consistent by (1) proving that Nuprl's inference rules are valid w.r.t. Allen's PER semantics, and (2) proving that False is not inhabited. Using these two facts, we derive that there cannot be a proof derivation of False, i.e., Nuprl is consistent. (In addition to [7, 8], see also [72, Appendix A] for more details regarding Nuprl's consistency.)

We are using our Coq formalization to prove all the inference rules of Nuprl, and have already verified a large number of them. This paper presents extensions we made to Nuprl in order to prove SCP₁. It includes adding some nominal features such as a fresh operator, named exceptions, and exception handlers. Using our Coq formalization, we provide in Sec. 3 a simple proof that WCP_{\downarrow} is true w.r.t. Nuprl's PER semantics using the fact that \perp diverges, and in Sec. 4 we prove SCP₁ using the nominal features mentioned above.

3. Weak Continuity Principle

Our proof of WCP $_{\perp}$ uses \perp and the fact that it diverges. For further details regarding this proof conducted in our implementation of

Nuprl in Coq, the interested reader is invited to look at https://g ithub.com/vrahli/NuprlInCoq/blob/master/continuity/conti nuity_roadmap.v. The same proof would not work for \downarrow , because using \downarrow we can compute the modulus of continuity of a function in the meta-theory (this computation does not have to be expressible in the theory because only \star inhabits \downarrow -squashed types), while using \downarrow we would have to come up with a Nuprl term t that does the computation (Sec. 4 shows how to do that), i.e., such that $t \in WCP_{\downarrow}$.

Let $F \in \mathbb{Z}^{\mathbb{Z}} \to \mathbb{Z}$ and $f \in \mathbb{Z}^{\mathbb{Z}}$ (we use \mathbb{Z} here instead of \mathbb{N} , but we proved a slightly more general result for functions of type $T^{\mathbb{Z}} \to \mathbb{Z}$ where T is a non-empty subtype of \mathbb{Z} , such as \mathbb{N} or \mathbb{N}_2).

Step 1. By typing, this means that $F(f) \in \mathbb{Z}$, i.e., F(f) computes to an integer *i*.

Step 2. It might seem that in that computation f only gets applied to integers, however, this is not necessarily true in an untyped language such as Nuprl. To remedy this issue, let $force(f) = \lambda x$.let x := x + 0 in f x. Because $f = force(f) \in \mathbb{Z}^{\mathbb{Z}}$, by typing again we get $F(force(f)) \mapsto^* i$. Let us call that computation C_1 . We use force to ensure that f's arguments are integers. If force(f) was to be applied to a term that is not an integer then the computation would either get stuck or diverge. We know that this cannot happen because $F(force(f)) \mapsto^* i$.

Step 3. Let bound $(t, b) = \operatorname{let} x := t \operatorname{inif} |x| < b \operatorname{then} x \operatorname{else} \bot$. By computation we prove that there exists a number b such that $F(\lambda x.\operatorname{let} x := \operatorname{bound}(x, b) \operatorname{in} f x) \mapsto^* i$. We can get such a b in the meta-theory by computing the largest number occurring in the computation C_1 , i.e., if $t_1 = F(\operatorname{force}(f)) \mapsto t_2 \mapsto \cdots \mapsto i = t_n$, then let b be the largest number occurring in one of the t_i . We have to squash WCP's existential quantifier using \downarrow because this meta-theoretical computation of b is not a Nuprl term. We prove this step using a *simulation* technique that we will reuse over and over again in this paper. We prove that given a context G, if G[x+0] computes to a value v then $G[\operatorname{bound}(x, b)]$ also computes to v, assuming that b is greater that any number occurring in the computation $G[x+0] \mapsto^* v$. Note that we have not yet used the fact that \bot diverges. This will be used in step 5. Let us call C_2 the computation $F(\lambda x.\operatorname{let} x := \operatorname{bound}(x, b)$ in $f x) \mapsto^* i$.

Step 4. We can now instantiate our conclusion using b. It remains to prove that $\Pi g: \mathbb{Z}^{\mathbb{Z}}$. $f =_{\mathbb{Z}^{\mathbb{Z}_b}} g \to F(f) =_{\mathbb{Z}} F(g)$. Because f and g agree up to b, and because the computation C_2 converges, by computation we know that $F(\lambda x. \text{let } x := \text{bound}(x, b) \text{ in } g x) \mapsto^* i$. We prove this by showing that given a context G, if G[let x := bound(x, b) in f x] computes to a value, then G[let x := bound(x, b) in g x] computes to the same value. We still have not used the fact that \perp diverges, because we could use any number in bound's definition instead of \perp , such as 0, and make sure that 0 < b.

Step 5. Again by computation: $F(\texttt{force}(g)) \mapsto^* i$. We prove this by showing that given a context G, if G[bound(x,b)] computes to a value then G[x+0] computes to the same value because the "less than" operator in bound's definition ensures that x is an integer, and because we know that G[bound(x,b)] does not diverge.

Step 6. Finally, by typing, $F(g) \mapsto^* i$, i.e., $F(f) =_{\mathbb{Z}} F(g)$.

4. Strong Continuity Principle

We now prove SCP₁ [53, pp.69–73] (Sec. 5 shows that SCP₁ and WCP₁ are equivalent). We need to come up with a Nuprl term of type $\Pi n: \mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}+$ Unit that checks whether we have reached the modulus of continuity of a function. For that, we now use exceptions as a probing mechanism to compute the modulus of continuity of a function. Instead of SCP₁, we prove the following equivalent but slightly simpler statement [53, pp.71-72] (where the T in SCPT is for Test—see below):

Using our Coq formalization and making use of computations on terms that are only possible in the meta-theory, we proved that SCPT is true w.r.t. the PER semantics of Nuprl extended with the nominal features mentioned above. We then proved directly in Nuprl that SCPT and SCP₁ are equivalent. We prove SCPT rather than SCP₁ mainly because its realizer is simpler. Intuitively, the *M* part of SCPT's realizer is a simple test function (top), while the one for SCP₁ is a recursive search function of the form (bottom):⁵

fun test n f = let exception e in (let v = F (fun $x \Rightarrow$ if x < n then f xelse raise e) in Some v) handle e \Rightarrow None

⁵ In both functions, None means that n is less than the modulus of continuity of F at f. In the test function, Some v means that v is F(f) and n is greater than or equal to the modulus of continuity of F at f, while the search function returns F(f) only when n is the modulus of continuity of F at f (and not when n is past the modulus as in the test function).

let fun search n m f =
if m <= 0 then test n f
else case test m f of
| Some k
$$\Rightarrow$$
 None
| None \Rightarrow search n (m - 1) f
end
in search n (n - 1) f

4.1 Extension of Nuprl's Computation System

4.1.1 Syntax

We extend Nuprl with *names* (or unguessable atoms [14]), *named* exceptions, exception handlers, and a fresh operator as follows:

Name is a type of names (constants) and a stands for a name. Names were introduced in Nuprl to reason about logical foundations for security [14]. To account for names, Allen generalized his PER semantics [5] to a so-called *supervaluation* semantics that quantifies over all possible implementations of the Name type [3]. Names come with two meta-theoretical operations: a fresh operator to generate a fresh name w.r.t. a list of names, and a test for equality. As in Pitts and Stark's ν -calculus [68] or Odersky's $\lambda\nu$ -calculus [63], we add two corresponding operators to Nuprl.

Our exceptions and handlers are similar to Lebresne's [57]. In Nuprl, an exception e has two subterms: the first one is e's name and the second one is some piece of data that can be used if e is caught. The type $\text{Exc}(t_1, t_2)$ is the type of exceptions with names of type t_1 and data of type t_2 . In general exceptions can be named with terms other than names. For example, if a and b are names, both exc(a, 0) and exc(b, 0) have type $\text{Exc}(\text{Name}, \mathbb{Z})$ (among others); and exc(1, 0) has type $\text{Exc}(\mathbb{Z}, \mathbb{Z})$. We also add exception handlers of the form $\text{try}_n t$ with x.c, where t is the term we try to evaluate, and $c[x \setminus d]$ is the code we run if we catch an exception with name n and data d. Therefore, a handler cannot catch all exceptions. A canonical operator is now either a value or an exception.

Let us define a few useful abstractions/abbreviations:

$$\begin{array}{lll} \operatorname{Name}_n &= \{x:\operatorname{Name} \mid x \simeq n\} \\ \operatorname{Exc}_n(T) &= \operatorname{Exc}(\operatorname{Name}_n,T) \\ \operatorname{Exc}_n &= \operatorname{Exc}_n(\operatorname{Unit}) \\ T_{?n} &= T \cup \operatorname{Exc}_n \\ \operatorname{exc}_n &= \operatorname{exc}(n,\star) \\ \operatorname{try}_n t &= \operatorname{try}_n t \text{ with } x.\star \end{array}$$

If T is not an exception type, $T_{?n}$ is the type of terms that either compute to elements of type T or that compute to exceptions with name n and data \star .

The type $T_{?n}$ is similar to Lebresne's type $A \boxtimes \{\epsilon\}$, where A is a type and ϵ is an exception [56, 57]. In addition Lebresne also introduces *corruption* types of the form $A^{\{\epsilon\}}$. A term in $A^{\{\epsilon\}}$ is a term in A where some part has been replaced by the exception ϵ . As he mentions, an expression of that type does not necessarily evaluates to an exception. For example, if Nuprl had such a type, $inl(exc_a)$ could be of type $(\mathbb{N}+Unit)^{\{\alpha\}}$. We leave adding corruption types to Nuprl for future work (Sacchini [75] shows that corruption in the presence of dependent types has interesting consequences).

Exceptions are a standard programming language feature. In the interactive theorem proving realm they are "well-adapted to pro-

gramming strategies which may be (in fact usually are) inapplicable to certain goals" [48, pp.11]. However, exceptions are often not accounted for in types. As mentioned above, Lebresne's Fx system [57] provides type constructors to express two different levels of *corruption*. Lebresne [57] mentions that to get exceptions one could either directly encode them in the language (e.g., using monads) or add them as primitive. We decided to add them as primitives for the same reasons (e.g., compositionality) stated in his paper. David and Mounier [36] introduced EX₂ as an extension of Krivine's FA₂ system [55] with exceptions. As in Nuprl, both Fx and in EX₂ implement call-by-name exceptions. Also, in all three systems exceptions and handlers are named, and handlers can only catch exceptions with the correct name.

4.1.2 Operational Semantics of ν

Let us now precisely define how fresh and handlers compute. A fresh expression of the form $\nu x.t$ computes differently depending on whether t is a variable, a canonical term, or a non-canonical term. Let us consider each of these cases.

Variable. If t is the variable x then $\nu x.t$ reduces to itself and therefore diverges. Therefore, one can prove that $\nu x.x \sim \bot$. This differs both from Odersky's [63] approach where $\nu x.x$ is stuck and from Pitts' approach [66] where $\nu x.x$ is a normal form. If t reduces to another variable than x then the computation gets stuck because the term is open.

Non-canonical. If t is non-canonical then

$$\boldsymbol{\nu} x.t \mapsto \boldsymbol{\nu} x.u[\boldsymbol{a} \backslash x] \quad \text{if} \quad t[x \backslash \boldsymbol{a}] \mapsto u$$

where a is a fresh name w.r.t. t (written a#t), and $t[a \setminus u]$ is a capture avoiding substitution function on names (similar to the usual substitution operation on variables). This ensures that fresh names do not escape the scope of ν expressions. As expected (if $x \neq y$):

$$\nu x. \nu y. \text{if } x=y \text{ then tt else ff } \mapsto^* \text{ff}$$

We cannot simply reduce ν as follows: $\nu x.t \mapsto t[x \setminus a]$, because Howe's computational equivalence would not be a congruence. For example, $\nu x.inl(x) \mapsto inl(a)$ and (let $y := a \text{ in } x) \sim x$ but $\nu x.inl(let y := a \text{ in } x) \not\rightarrow^* inl(a)$.

Canonical. If t is a canonical form (a value or an exception), then we "push" ν "down" the expression as in Odersky's $\lambda\nu$ -calculus [60, 63] (as opposed to using, e.g., stateful dynamic allocation [60] or the notion of *prevalues* [52], which are values prefixed with a list of "fresh name" binders):

$$\boldsymbol{\nu} x.t \mapsto \Downarrow_x t$$

where \Downarrow computes as follows on terms:

$$\Downarrow_x \theta(b_1; \cdots; b_n) = \theta(\Downarrow_x b_1; \cdots; \Downarrow_x b_1)$$

and as follows on bound terms:

$$\Downarrow_x (\bar{l}.t) = \bar{l}.\boldsymbol{\nu}x'.t$$

where, in order to avoid variable capture, x' is x if $x \notin \overline{l}$, and a fresh variable w.r.t. t otherwise. For example $\nu x.\langle 1, x \rangle \mapsto \langle \nu x.1, \nu x.x \rangle$ and $\nu x.\lambda y.t \mapsto \lambda y.\nu x.t$ if $x \neq y$. Note that when $x \in \overline{l}$, we could have defined $\Downarrow_x(\overline{l}.t)$ to be $\overline{l}.t$. However, this would make the definition less uniform and therefore harder to reason about. To this effect, we proved $\nu x.t \sim t$ if t is closed.

4.1.3 Operational Semantics of try

Handlers of the form $\mathtt{try}_n e$ with x.c catch exceptions of the form $\mathtt{exc}(n,d).$ For example,

$$\operatorname{try}_{\boldsymbol{a}}\left(1+\operatorname{exc}(\boldsymbol{a},\lambda x.x+1)\right) \text{ with } f.f(2)\mapsto^* 3$$

When its principal argument is non-canonical or a variable, a handler computes exactly like the other non-canonical operators (except ν). Let us consider the exception and value cases.

Exception. If t is an exception of the form exc(n, d) then we have to check whether the handler has the right name as follows:

$$\begin{array}{l} \operatorname{try}_m \operatorname{exc}(n,d) \operatorname{with} x.c \\ \mapsto \operatorname{if} m{=}n \operatorname{then} c[x \backslash d] \operatorname{else} \operatorname{exc}(n,d) \end{array}$$

This computational rule also has the following effect that if m computes to an exception e, then $\operatorname{try}_m \operatorname{exc}(n, d)$ with $x.c \mapsto^* e$. Also, if m is a name and n computes to an exception e then $\operatorname{try}_m \operatorname{exc}(n, d)$ with $x.c \mapsto^* e$.

Value. A naive way or reducing a handler when its principal argument is a value would be to simply return the value as follows:

$$\operatorname{try}_n v$$
 with $x.c \mapsto v$

However, note that in the case where the principal argument of a handler is an exception, we have to evaluate the "name" part of the handler to check whether the exception has the correct name. This means that if we were to simply return the value here and if the "name" part was \perp for example, raising an exception in an expression that is "well-behaved" could cause the expression to diverge. For example, using the above rule: $try_{\perp} 1 \mapsto 1$, and if we replace 1 by exc_a , then $try_{\perp} exc_a$ diverges. This is undesirable, especially in the context of using exceptions to probe a function, e.g., to compute its modulus of continuity. Therefore, instead of simply returning the value, we first check that *n* is something that we can compare:

 $\operatorname{try}_n v \operatorname{with} x.c \mapsto \operatorname{if} n = n \operatorname{then} v \operatorname{else} \bot$

4.2 Howe's Computational Equivalence in the Presence of ν

To prove that \sim is a congruence, Howe first proves that \preccurlyeq is a congruence [50]. Unfortunately, this is not easy to prove directly. Howe's "trick" was to define another relation \preccurlyeq^* , which is a congruence and contains \preccurlyeq by definition.

Howe's definition of \preccurlyeq^* does not use types, but to account for the fact that the binders of ν expressions are only meant to be names (as opposed to the binders of, e.g., λ -abstractions, which can be substituted by any term when applied), rather than turn Nuprl into a typed language, we added "simple" type information to the definition of \preccurlyeq^* . We define a function BT that, for a given operator, returns the types of the binders of its bound terms. The type of a binder can either be NAME or ANY. $BT(\nu) = [[NAME]]$ because ν has one subterm (the outer brackets) that has one binder (the inner brackets). The type of all the other binders is ANY. For example, $BT(\lambda) = [[ANY]]$ because a λ -abstraction has one subterm which has one binder. When extending the definition of \preccurlyeq^* from terms to bound terms, BT is used to restrict what terms can be substituted for free variables. This modification of \preccurlyeq 's definition was inspired by Gordon's [47] and Jeffrey and Rathke's [52] adaptations of Howe's method to typed λ -calculi. It is interesting to note that until we added the ν operator to Nuprl, there was no need to use type information in the proof that \sim is a congruence.

Howe defines $t \preccurlyeq^* u$ by induction on t: if t is a variable then $t \preccurlyeq^* u$ if $t \preccurlyeq u$; and if t is of the form $\tau(\overline{b})$ then $t \preccurlyeq^* u$ if there exists $\overline{b'}$ such that $\overline{b} \preccurlyeq^* \overline{b'}$ and $\tau(\overline{b'}) \preccurlyeq u$. To prove that \preccurlyeq^* and \preccurlyeq are equivalent and therefore that \preccurlyeq and \sim are congruences, it suffices to prove that \preccurlyeq^* respects computation, i.e., given that $t \preccurlyeq^* u$, if t computes to a value of the form $\theta(\overline{b})$ then u also computes to a value $\theta(\overline{b'})$ such that $\overline{b} \preccurlyeq^* \overline{b'}$. Howe's Lemma 2 in [50] shows that this is true when t is a value.

Howe then defines a condition called *extensionality* that noncanonical operators of lazy computation systems have to satisfy for \preccurlyeq^* to imply \preccurlyeq , and therefore for \preccurlyeq and \sim to be congruences. First, we extended all these definitions to deal with the fact that canonical forms can either be values or exceptions. Then, using our new definition of \preccurlyeq^* we were able to prove that ν is extensional (see [72, Appendix D] for more details).

4.3 Consistency

As mentioned above, Nuprl's consistency follows from the fact that all its inference rules are valid w.r.t. Allen's PER semantics and from the fact that False is not inhabited. In addition to extending Nuprl's computation system, and fixing its properties including Howe's computational equivalence relation, we had to re-run all the proofs that Nuprl's inference rules are valid. Most of these rules and proofs did not have to change. The only one that had to change is discussed in details in [72, Appendix C] (see [72, Appendices A&B] for details regarding the validity of rules). Let us summarize this discussion here.

First, note that because exceptions are canonical forms as mentioned in Sec. 4.1.1 above, if $a \mapsto^* exc(t_1, t_2)$ then $a \preccurlyeq b$ if there exists u_1 and u_2 such that $b \mapsto^* \exp(u_1, u_2)$, $t_1 \preccurlyeq u_1$, and $t_2 \preccurlyeq u_2$. Therefore, even though we cannot have a canonical form test (such as ifint or ifaxiom) for exceptions that would check whether a term computes to an exception because we cannot catch an exception without having its name (i.e., we have no way of catching all exceptions), we can define a proposition isexc(t) that asserts that a term t computes to an exception as follows: $isexc(t) = exc_{\perp} \leq t$, where $exc_{\perp} = exc(\perp, \perp)$. Similarly, the following proposition halts(t) asserts that t computes to a value: halts $(t) = \star \preceq (\text{let } x := t \text{ in } \star)$. By definition of Howe's approximation relation, before adding exceptions, when proving a proposition of the form $t_1 \preceq t_2$ we could assume halts (t_1) . This was captured by our old [convergence] inference rule described in [72, Appendix C]. This is no longer true because we also have to consider the case where t_2 is an exception. To that effect our new [convergence] inference rule generates (among others) two subgoals: one that assumes $halts(t_1)$ and one that assumes $isexc(t_1)$. Alternatively, we could capture that a term t computes to either a value or an exception using the type: $\operatorname{exc}_{\perp} \preceq (\operatorname{let} x := t \text{ in } \operatorname{exc}_{\perp})$. We have not yet investigated the usefulness of such a type.

4.4 Computing the Modulus of Continuity

We now have the tools in hand to compute the modulus of continuity of a functional using exceptions as described above:

$$\begin{array}{ll} \texttt{force}(k,t) &= \texttt{if} \ k < 0 \ \texttt{then} \ \bot \ \texttt{else} \ t \\ \texttt{bound}(n,f,e,k) &= \texttt{force}(k,\texttt{if} \ k < n \ \texttt{then} \ f(k) \ \texttt{else} \ \texttt{exc}_e) \\ \texttt{bound}(n,f,e) &= \lambda x.\texttt{bound}(n,f,e,x) \\ \texttt{test}(F,n,f) &= \nu x.\texttt{try}_x \ F(\texttt{bound}(n,f,x)) \\ \texttt{M}(F) &= \lambda n.\lambda f.\texttt{test}(F,n,f) \end{array}$$

i.e., unfolding the definitions, M(F) is

$$\lambda n.\lambda f. \boldsymbol{\nu} x. \mathtt{try}_x F \begin{pmatrix} \mathtt{if} \ y < 0 \ \mathtt{then} \ \bot \\ \lambda y. \\ \mathtt{else} \ \begin{pmatrix} \mathtt{if} \ y < n \ \mathtt{then} \ f(y) \\ \mathtt{else} \ \mathtt{exc}_x \end{pmatrix} \end{pmatrix}$$

Also, let $force(f) = \lambda x.force(x, f(x))$. As in our proof of WCP₄, we will partly use typing, partly use computation to prove that M(F) is indeed our witness for SCPT. This is why bound starts off by checking whether its argument x is an integer less than 0. If a computation that uses bound converges and along the way applies f to some term k, we will be guaranteed that k is a natural number.

4.5 Well-Typedness

To prove SCPT, we first prove that M(F) has type $\mathbf{\Pi} n: \mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}_{?}$. As mentioned above, this term does not respect computation, it is not functional over $F \in \mathcal{B} \to \mathbb{N}$. However, given a

term F, we can still prove that M(F) has the right type. For that, we have to prove that for all closed terms n and m such that $n \equiv m \in \mathbb{N}$, and for all closed terms f and g such that $f \equiv g \in \mathbb{N}^{\mathbb{N}_n}$, we have $\texttt{test}(F, n, f) \equiv \texttt{test}(F, m, g) \in \mathbb{N}_7$. By definition, $n \equiv m \in \mathbb{N}$ means that there exists a natural number k such that both n and m compute to k. Therefore, let us assume $f \equiv g \in \mathbb{N}^{\mathbb{N}_k}$ and let us prove $\texttt{test}(F, k, f) \equiv \texttt{test}(F, k, g) \in \mathbb{N}_7$. Unfolding test's definition, we have to prove

$$\begin{split} & \boldsymbol{\nu} x. \mathtt{try}_x \ F(\mathtt{bound}(k, f, x)) \\ & \equiv \boldsymbol{\nu} x. \mathtt{try}_x \ F(\mathtt{bound}(k, g, x)) \\ & \in \mathbb{N}_2 \end{split}$$

As we show below in Sec. 4.6, to prove that it is enough to prove

$$\operatorname{try}_{\boldsymbol{a}} F(\operatorname{bound}(k, f, \boldsymbol{a})) \equiv \operatorname{try}_{\boldsymbol{a}} F(\operatorname{bound}(k, g, \boldsymbol{a})) \in \mathbb{N}_{?}$$

where a is such that a#F, a#f, and a#g. Again, it is enough to prove

$$F(\texttt{bound}(k, f, \boldsymbol{a})) \equiv F(\texttt{bound}(k, g, \boldsymbol{a})) \in \mathbb{N}_{?\boldsymbol{a}}$$
(1)

By typing again, from $f \equiv g \in \mathbb{N}^{\mathbb{N}_k}$, we deduce that

$$\operatorname{bound}(k, f, a) \equiv \operatorname{bound}(k, g, a) \in (\mathbb{N}_{?a})^{\mathbb{N}}$$
(2)

A general fact about exceptions is: if $F \in \mathcal{B} \to \mathbb{N}$ and a # F then

$$Force(F) \in (\mathbb{N}_{?a})^{\mathbb{N}} \to \mathbb{N}_{?a} \tag{3}$$

where $\operatorname{Force}(F) = \lambda f.F(\operatorname{force}(f))$. Is Force necessary? Can't we simply prove $F \in (\mathbb{N}_{?a})^{\mathbb{N}} \to \mathbb{N}_{?a}$? In other words, can we find a F in $\mathcal{B} \to \mathbb{N}$, such that a # F, and an f in $(\mathbb{N}_{?a})^{\mathbb{N}}$ such that F(f) is not in $\mathbb{N}_{?a}$? Yes we can: take

$$\begin{split} F &= \lambda f.f(f(0)) \\ f &= \lambda x.\texttt{let} \; z := (\texttt{try}_a \; x \; \texttt{with} \; z.\bot) \; \texttt{in} \; \texttt{exc}_a \end{split}$$

(Note that in f's definition \perp could be any term not in \mathbb{N} .) These expressions are of the right type, but F(f) computes to f(f(0)), which computes to $f(\exp a)$, which computes to let $z := \perp$ in $\exp a$, which diverges and is therefore not of type \mathbb{N}_{2a} . Proving 3 is the crux of proving that $\mathbb{M}(F)$ is well-typed. To prove that we use the same technique as in $\mathbb{WCP}_{\downarrow}$'s proof. Given 3, it is trivial to deduce that the equality 1 is true using equality 2.

Let us now prove 3. We have to prove that for all F in $\mathcal{B} \to \mathbb{N}$, and f and g such that $f \equiv g \in (\mathbb{N}_{?a})^{\mathbb{N}}$,

$$F(\texttt{force}(f)) \equiv F(\texttt{force}(g)) \in \mathbb{N}_{?a}$$

First, we define a function force0 so that the function $f' = \lambda x.force0(x, f)$ computes as the function $f_0 = force(f)$, except that on natural numbers, when f_0 returns exc_a , f' returns 0 (this 0 could be any natural number):

$$extsf{force0}(x,f) = extsf{if}\; x{<}0 extsf{then} \perp extsf{elsetry}_{m{a}}\; f(x) extsf{with}\; z.0$$

Let $g_0 = \operatorname{force}(g)$. Note that $f_0 \equiv g_0 \in (\mathbb{N}_{?a})^{\mathbb{N}}$. Because f' is in \mathcal{B} , we get that F(f') computes to a natural number. Let us now use again the same simulation technique as before. Let us prove that in any context C with no occurrence of a, if C[f'] computes to a natural number j, then either both $C[f_0]$ and $C[g_0]$ also compute to j or both $C[f_0]$ and $C[g_0]$ compute to exc_a . We prove that by induction on the length of the reduction $C[f'] \mapsto^* j$. For that we prove that if $C[f'] \mapsto u$ and u computes to a canonical expression, then there exists a context C' such that $u \mapsto^* C'[f']$ and either both $C[f_0] \mapsto^* C'[f_0]$ and $C[g_0] \mapsto^* C'[g_0]$ or both $C[f_0] \mapsto^* \operatorname{exc}_a$ and $C[g_0] \mapsto^* \operatorname{exc}_a$. This gives us that $F(f_0) \equiv F(g_0) \in \mathbb{N}_{?a}$

4.6 Interlude: Reasoning About ν

In Sec. 4.1.2 we saw how ν computes. We show here how to reason about ν . One can prove that $\nu x.t_1 \equiv \nu x.t_2 \in T$ by proving that $t_1[x \setminus a] \equiv t_2[x \setminus a] \in T$, assuming $a \# t_1$ and $a \# t_2$, and that T

is *flat*, meaning that its inhabitants compute to terms that have no subterms and that are not names, such as integers or \star . This follows from the way ν computes. If $t[x \setminus a] \mapsto^* u$ such that a#t then $\nu v.t \mapsto^* \nu x.u[a \setminus x]$. In the integer case, if $t_1[x \setminus a] \mapsto^* i$ then $\nu x.t_1 \mapsto^* \nu x.i$ and $\nu x.i \mapsto i$. We get that $\nu x.t_1 \sim t_1[x \setminus a]$. Because the union of flat types is flat, \mathbb{N}_7 is flat.

We can prove similar rules for the other types. For example, one can prove that $\nu x.f_1 \equiv \nu x.f_2 \in \Pi a:A.B$ by proving that $\Pi a:A.B$ is a type, and that for all a_1 and a_2 such that $a_1 \equiv a_2 \in A$, $\nu x.f_1(a_1) \equiv \nu x.f_2(a_2) \in B[a \setminus a_1]$ (see lemma fresh_in_function in https://github.com/vrahli/NuprlInCoq/blob/master/continuity/stronger_continuity_props1.v).

4.7 1st Condition

The first property we prove about the function M defined above in Sec. 4.4 is that for all f in $\mathcal{B}, \downarrow \Sigma n: \mathbb{N}.\mathbb{M}(F)$ $n \ f =_{\mathbb{N}} F(f)$. This condition says that for all f there exists a n such that M only requires an "initial sequence" of length n of f to compute the same result as F(f). This n is therefore at least the modulus of continuity of Fat f.

As before, by typing we get that $F(f) \equiv F(\texttt{force}(f)) \in \mathbb{N}$. Hence, there exists a natural number k such that $F(\texttt{force}(f)) \mapsto^* k$. As in the proof of $\mathsf{WCP}_{\downarrow}$, we first compute the maximum of all the numbers occurring in that computation, and we instantiate our conclusion with b a number which is strictly greater than this maximum. We now have to prove: $\mathbb{M}(F)$ b $f =_{\mathbb{N}} F(f)$, or equivalently $\texttt{test}(F, b, f) =_{\mathbb{N}} F(\texttt{force}(f))$. Unfolding test's definition, we have to prove:

$$\nu x. \operatorname{try}_x F(\operatorname{bound}(b, f, x)) \equiv F(\operatorname{force}(f)) \in \mathbb{N}$$

As in Sec. 4.5, because we're trying to prove that this ν is in \mathbb{N} and because \mathbb{N} is flat, it is enough to prove for some name a such that a#F and a#f:

$$\operatorname{try}_{\boldsymbol{a}} F(\operatorname{bound}(b, f, \boldsymbol{a})) \equiv F(\operatorname{force}(f)) \in \mathbb{N}$$

Again, let us use the same simulation technique as before to prove that in any context C with no occurrence of \boldsymbol{a} , if $C[\texttt{force}(f)] \mapsto^*$ k then $C[\texttt{bound}(b, f, \boldsymbol{a})] \mapsto^* k$. We prove that by induction on the length of the reduction $C[\texttt{force}(f)] \mapsto^* k$. For that we prove that if $C[\texttt{force}(f)] \mapsto u$ such that u computes to a canonical expression, and all the numbers occurring in C[force(f)] are strictly less than b, then there exists a context C' such that $u \mapsto^*$ C'[force(f)] and $C[\texttt{bound}(b, f, \boldsymbol{a})] \mapsto^* C'[\texttt{bound}(b, f, \boldsymbol{a})]$.

Using this result, we get that $F(\text{bound}(b, f, a)) \mapsto^* k$, from which we deduce that $\text{try}_a F(\text{bound}(b, f, a)) \mapsto^* k$, and finally $\text{try}_a F(\text{bound}(b, f, a)) =_{\mathbb{N}} F(\text{force}(f))$.

4.8 2nd Condition

The second property we prove about the function M defined above in Sec. 4.4 is that for all f in \mathcal{B} and n in \mathbb{N} , if $\mathbb{M}(F)$ n f computes to a number then $\mathbb{M}(F)$ n $f =_{\mathbb{N}} F(f)$. In order to implement our search function to realize SCP₁, we need to return the smallest n, say m, such that $\mathbb{M}(F)$ n f computes to a number. However, if $\mathbb{M}(F)$ could return different answers for different n's, we would not know whether $\mathbb{M}(F)$ m f returns F(f) or some other value.

Let us prove that if $\mathbb{M}(F)$ $n f \sim k$ for some $k \in \mathbb{N}$ then $F(f) \sim k$. As before, we can assume that $\mathtt{try}_a F(\mathtt{bound}(n, f, a)) \sim k$, for some a such that a#F and a#f. By typing we get that F(f) computes to a natural number k'. Because $\mathtt{try}_a F(\mathtt{bound}(n, f, a))$ computes to a canonical form (the natural number k), we deduce that $F(\mathtt{bound}(n, f, a))$ also computes to a canonical form. This canonical form is either (1) an exception or (2) a value.

(1) If F(bound(n, f, a)) computes to an exception then we get a contradiction: either the term computes to \exp_a and then we obtain that $\operatorname{try}_a F(\operatorname{bound}(n, f, a)) \mapsto^* \star \operatorname{and} \star \neq k$; or it

computes to an exception e with some other name than a and then $try_a F(bound(n, f, a)) \mapsto^* e$ and $e \neq k$. In both cases we get a contradiction.

(2) We now assume that F(bound(n, f, a)) computes to a value. If so, it has to compute to k. We now prove that k = k'. As before, because $F(f) \equiv F(\text{force}(f)) \in \mathbb{N}$, we get that $F(\text{force}(f)) \mapsto^* k'$. The rest of this proof closely follows the one in Sec. 4.7. We prove that in any context C with no occurrence of a, if C[force(f)] computes to the natural number k' then C[bound(n, f, a)] computes to either k' or \exp_a . We prove that by induction on the length of the reduction $C[\text{force}(f)] \mapsto^* k'$. For that we prove that if $C[\text{force}(f)] \mapsto u$ such that u computes to a canonical expression then there exists a context C' such that $u \mapsto^* C'[\text{force}(f)]$ and $C[\text{bound}(b, f, a)] \mapsto^* C'[\text{bound}(b, f, a)] \mapsto^* k'$ and therefore k = k'; or (2) $F(\text{bound}(b, f, a)) \mapsto^* \exp_a$ and we get a contradiction because $k \neq \exp_a$.

4.9 Nuprl's Strong Continuity Inference Rule

Using the fact that SCPT (defined at the beginning of Sec. 4) is true in Nuprl's meta-theory, we proved that the following inference rule, called [StrongContinuity], is true w.r.t. Allen's PER semantics (for further details regarding this proof conducted in our implementation of Nuprl in Coq, the interested reader is invited to look at https://github.com/vrahli/NuprlInCoq/blob/master/c ontinuity/continuity_roadmap.v):

$$\frac{H \vdash F \in (\mathbb{N} \to T) \to \mathbb{N} \qquad H \vdash \downarrow T \qquad H \vdash T \sqsubseteq \mathbb{N}}{H \vdash \mathsf{M}(F) \in \mathsf{SCPF}(F)}$$

Using this inference rule, we proved a version of SCPT in Nuprl, where the first (outer) existential quantifier is \downarrow -squashed and the second (inner) one is not squashed (this lemma can be accessed by clicking the following hyperlink: strong-continuity2-no-inner-squash).⁶ We get rid of the second squash operator using the usual unbounded search μ operator. As expected the extract of that lemma is (we use colored parentheses for visual convenience):

 $\lambda F. \langle \texttt{M}'(F), \lambda f. \langle \mu(\lambda n.\texttt{isl}(\texttt{test}'(F, n, f))), \langle \star, \lambda m. \lambda i. \star \rangle \rangle \rangle$

where

$$\texttt{test'}(F, n, f) = \texttt{let} x := \texttt{test}(F, n, f) \texttt{in}$$
$$\texttt{ifint}(x, \texttt{inl}(x), \texttt{inr}(\star))$$
$$\texttt{M'}(F) = \lambda n.\lambda f.\texttt{test'}(F, n, f)$$
$$\mu(f) = \texttt{fix} \left(\begin{array}{c} \lambda F.\lambda n. \texttt{if} f(n) \texttt{then} n \\ \texttt{else let} m := n + 1 \texttt{in} F(m) \end{array} \right) 0$$

We then derived a version of SCP where, as mentioned in the introduction, the first (outer) $\underline{\Sigma}$ is $\downarrow \Sigma$ and the second (inner) one is Σ (see/click Nuprl lemma strong-continuity2-no-inner-squash-unique). Therefore, because these versions of SCP are equivalent of SCP_{\downarrow}, we also refer to them as SCP_{\downarrow}.

5. Relations Between WCP and SCP

As mentioned in Sec. 1, Bridges and Richman [19, pp.119] state that SCP is equivalent to WCP plus some form of the axiom of choice—some version of $AC_{1,0}$. As we saw above the existential quantifiers in these statements have to be truncated using \downarrow (see Escardó and Xu [39]). Therefore, for that equivalence to be true, we probably need the \downarrow -truncated version of $AC_{1,0}$, which is true in Nuprl as discussed below in Sec. 5.3. Therefore, we only need to prove that SCP_{\downarrow} and WCP_{\downarrow} are equivalent. We prove below that WCP_{\downarrow} is a trivial consequence of SCP_{\downarrow} , and that SCP_{\downarrow} is a consequence of WCP_{\downarrow} using the same "trick" as the one used by Bridges and Richman to prove that UCP follows from the Fan Theorem and WCP [19, pp.113] (see Sec. 6.1 below on uniform continuity).

5.1 SCP | Implies WCP

Let us sketch the proof that $SCP_{\downarrow} \rightarrow WCP_{\downarrow}$. For convenience, we will write \mathbb{N}_{U} for $\mathbb{N}+Unit$. Let $F \in \mathcal{B} \rightarrow \mathbb{N}$ and $f \in \mathcal{B}$. We prove the formula $C = \downarrow \Sigma n: \mathbb{N}$. $\Pi g: \mathcal{B}. f =_{\mathbb{N}^{N_n}} g \rightarrow F(f) =_{\mathbb{N}} F(g)$. From SCP_{\downarrow} , we get a $M \in \Pi n: \mathbb{N}. \mathbb{N}^{\mathbb{N}_n} \rightarrow \mathbb{N}_{U}$ (we can unsquash SCP_{\downarrow} 's outer Σ because our conclusion C is squashed) and a function

$$A \in \mathbf{\Pi} f: \mathcal{B}. \mathbf{\Sigma} n: \mathbb{N}. \quad M \ n \ f =_{\mathbb{N}_{\mathsf{U}}} \operatorname{inl}(F(f)) \\ \wedge \ \mathbf{\Pi} m: \mathbb{N}. \operatorname{isl}(M \ m \ f) \to m =_{\mathbb{N}} n$$

By applying A to f we get a $n \in \mathbb{N}$ such that:

- $M n f =_{\mathbb{N}_U} \operatorname{inl}(F(f))$
- and $B \in \mathbf{\Pi}m: \mathbb{N}.isl(M \ m \ f) \to m =_{\mathbb{N}} n$.

We unsquash and instantiate with n our conclusion C, and we now get to assume that there is a $g \in \mathcal{B}$ such that $f =_{\mathbb{N}^{\mathbb{N}_n}} g$. It remains to prove that $F(f) =_{\mathbb{N}} F(g)$. By applying A to g we get a $n' \in \mathbb{N}$ such that:

- $M n' g =_{\mathbb{N}_{U}} \operatorname{inl}(F(g))$
- and $B' \in \mathbf{\Pi}m:\mathbb{N}.\mathtt{isl}(M \ m \ g) \to m =_{\mathbb{N}} n'.$

Because $f =_{\mathbb{N}^{\mathbb{N}_n}} g$, we get that $M \ n \ f =_{\mathbb{N}^{\mathbb{U}}} M \ n \ g$. Because $M \ n \ f =_{\mathbb{N}^{\mathbb{U}}} \inf(F(f))$, we get $\operatorname{isl}(M \ n \ f)$ and therefore also $\operatorname{isl}(M \ n \ g)$. Then, by applying B' to n we get $n =_{\mathbb{N}} n'$. Therefore, $\operatorname{inl}(F(f)) =_{\mathbb{N}^{\mathbb{U}}} \operatorname{inl}(F(g))$, and finally we get that $F(f) =_{\mathbb{N}} F(g)$.

5.2 WCP₁ Implies SCP₁

In this section we prove that skWCP implies SCP₁ (see Nuprl lemma weak-continuity-implies-strong1), where skWCP is the following "skolemized" version of WCP₁:

$$\begin{split} \mathsf{skWCP} &= \, \Pi F{:}\mathcal{B} \to \mathbb{N}. \\ & \downarrow \mathbf{\Sigma} M{:}\mathcal{B} \to \mathbb{N}. \\ & \Pi f, g{:}\mathcal{B}. (f =_{\mathbb{N}_{M(f)} \to \mathbb{N}} g) \to (F(f) =_{\mathbb{N}} F(g)) \end{split}$$

It is easy to prove that skWCP and WCP₁ are equivalent using our proof that the \downarrow -truncated axiom of choice AC_{1,x} discussed below in Sec. 5.3 is true (see Nuprl lemma axiom-choice-1X-quot).

Let us assume skWCP and let $F \in \mathcal{B} \to \mathbb{N}$. We have to prove the following formula C:

$$\begin{array}{l} \downarrow \boldsymbol{\Sigma} M: \boldsymbol{\Pi} n: \mathbb{N}. \mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}_{\mathtt{U}}. \\ \boldsymbol{\Pi} f: \mathcal{B}. \quad \boldsymbol{\Sigma} n: \mathbb{N}. M \ n \ f =_{\mathbb{N}_{\mathtt{U}}} \mathtt{inl}(F(f)) \\ & \wedge \ \boldsymbol{\Pi} n: \mathbb{N}. \mathtt{isl}(M \ m \ f) \to M \ n \ f =_{\mathbb{N}_{\mathtt{U}}} \mathtt{inl}(F(f)) \end{array}$$

Instantiating skWCP with F we get (because our conclusion C is \downarrow -truncated, we can unsquash our hypothesis):

- a $M \in \mathcal{B} \to \mathbb{N}$ (F' modulus of continuity)
- and a $G \in \Pi f, g: \mathcal{B}.(f =_{\mathbb{N}_{M(f)} \to \mathbb{N}} g) \to (F(f) =_{\mathbb{N}} F(g))$

Bridges and Richman's trick is to also use the modulus of continuity of M. Therefore, instantiating skWCP with M we get:

- a $X \in \mathcal{B} \to \mathbb{N}$ (*M*'s modulus of continuity)
- and a $K \in \Pi f, g: \mathcal{B}.(f =_{\mathbb{N}_{X(f)} \to \mathbb{N}} g) \to (M(f) =_{\mathbb{N}} M(g))$

Let us now unsquash our conclusion C and instantiate it with

 $B = \lambda n.\lambda a. \text{if } M(a_{n,0}) \leq n \text{ then inl}(F(a_{n,0})) \text{ else inr}(\star)$

⁶ Alternatively, the reader can search for the lemma with that name available here: http://www.nuprl.org/LibrarySnapshots/Published/Vers ion1/Standard/continuity/index.html, and similarly for the other Nuprl lemmas mentioned below and highlighted in green (or gray).

where $a_{n,k} = \lambda x.if x < n$ then a(x) else k (this is the infinite sequence consisting of the first n values of a followed by k's— $a_{n,0}$ is sometimes denoted $\overline{a,n}$, e.g., in [12, 38]). If $a \in \mathbb{N}^{\mathbb{N}_n}$ and $k \in \mathbb{N}$ then $a_{n,k} \in \mathbb{N} \to \mathbb{N}$. We now have to prove that assuming that $f \in \mathcal{B}$ then:

$$\Sigma n: \mathbb{N}.B \ n \ f =_{\mathbb{N}_{U}} \operatorname{inl}(F(f))$$
(4)

$$\mathbf{\Pi} n: \mathbb{N}. \mathtt{isl}(B \ n \ f) \to (B \ n \ f =_{\mathbb{N}_{\mathrm{III}}} \mathtt{inl}(F(f))) \tag{5}$$

Equality 5 follows from G. We now prove 4 by instantiating it with $m = \max(M(f), X(f))$. We have to prove $B \ m \ f =_{\mathbb{N}_{U}} \operatorname{inl}(F(f))$, i.e.,

if
$$M(a_{m,0}) \le m$$
 then $\operatorname{inl}(F(a_{m,0}))$ else $\operatorname{inr}(\star)$ (6)
=_{Nn} $\operatorname{inl}(F(f))$

Because $f =_{\mathbb{N}_{M(f)} \to \mathbb{N}} a_{m,0}$, then using G we obtain: $F(f) =_{\mathbb{N}} F(a_{m,0})$. Therefore, to prove equality 6, it remains to prove that its conditional is true, i.e., $M(a_{m,0}) \leq m = \max(M(f), X(f))$. If we instantiate K with f and $a_{m,0}$, we have to prove $f =_{\mathbb{N}_{X(f)} \to \mathbb{N}} a_{m,0}$, which is true by definition of m, and get to assume $M(f) =_{\mathbb{N}} M(a_{m,0})$ which gives us that $M(a_{m,0}) \leq m$.

5.3 Axiom of Choice

The following axiom of choice is usually trivial in constructive type theories such as Nuprl when $\underline{\Sigma}$ is Σ (where A and B are types):

$$AC = \mathbf{\Pi} a: A. \underline{\Sigma} b: B. P a b \Rightarrow \underline{\Sigma} f: B^A. \mathbf{\Pi} a: A. P a f(a)$$

It follows from the usual rules of the universal and existential quantifiers. We can prove that these rules are true in our predicative Coq model [7, 8] without assuming any axiom. In that predicative model we can model n Nuprl universes using n + 1 Coq universes. However, in our impredicative model we have to assume some axiom of choice, namely FunctionalChoice_on (see http://coq.inria.fr/cocorico/CoqAndAxioms), to prove some of these rules.

However, the non-squashed version of AC is not always enough because as we saw above existential quantifiers cannot always be interpreted as Σ but sometimes as truncated Σ 's. Therefore, we sometimes need instances of AC where $\underline{\Sigma}$ is either $|\Sigma \text{ or } \downarrow \Sigma$. In that case it is not obvious anymore which instances of AC are consistent or provable in Nuprl.

Some versions of AC for particular choices of types A and B are of particular interest. One can often find in the literature the name AC_{n.m}, where $n, m \in \{0, 1\}$ [82, pp.238]: n = 0 means that $A = \mathbb{N}$ and n = 1 means that $A = \mathcal{B}$; similarity m = 0 means that $B = \mathbb{N}$ and m = 1 means that $B = \mathcal{B}$.

Using a technique similar to the one discussed in [71], we proved the \downarrow -squashed version of AC_{0,0}, where $\underline{\Sigma}$ is $\downarrow \underline{\Sigma}$, once again conducting the proof first in the meta-theory, and then reflecting the meta-theoretical result in the Nuprl theory as an inference rule: see lemma rule_ACO0_true in https://github.com/vrahl i/NuprlInCoq/blob/master/axiom_choice/axiom_choice.v. We also proved directly in Nuprl the \downarrow -squashed versions of AC, where $\underline{\Sigma}$ is $\downarrow \underline{\Sigma}$, namely AC_{0,X} (see Nuprl lemma axiom-choice-0X-quot) and AC_{1,X} (see Nuprl lemma axiom-choice-1X-quot)—X here indicates that the type *B* above could be anything. These two lemmas are instances of the more general Nuprl lemma: axiom-choice-quot.

6. Applications

Using SCP₁ we proved in Nuprl a \downarrow -truncated version of UCP (see Sec. 1) from the fan theorem, and then a fully unsquashed version of this principle using Escardó and Xu's method [39] (see Sec. 6.1). We write UCP₁ for the version of UCP where Σ is $\downarrow \Sigma$. Using UCP₁ we then proved that real functions defined on the unit interval are uniformly continuous (see Sec. 6.2).

We have recently proved that Bar Induction on Decidable bars (BID) is consistent with Nuprl using our Coq model of Nuprl [71], and this for free choice sequences of natural numbers. Following Kleene, given that SCP_1 is true we can now prove Bar Induction on Monotone bars (BIM) [53, pp.78] (see also Dummett's Thm 3.8 [37, pp.64]): see Nuprl lemma monotone-bar-induction1.

We have also recently used exceptions to implement the constructive content of the completeness result of intuitionistic firstorder logic proved in [27]. As in the present paper, exceptions are used to probe how a computation uses its arguments. Given a uniform evidence for a proposition, we construct a proof of that proposition by using this probing mechanism to determine the next step of the proof.

6.1 Uniform Continuity

6.1.1 UCP₁ Follows From FT and SCP₁.

Using BID we prove that the Fan Theorem (FT) is true: see Nuprl lemma fan_theorem. We then derive UCP₁ from FT and SCP₁: see Nuprl lemma strong-continuity2-implies-uniform-continuity. Let us sketch that proof. The version of FT that we have proved in Nuprl is (if X is a bar and is decidable then it is uniform):

$$\begin{aligned} \mathsf{FT} &= \mathbf{\Pi} X : (\mathbf{\Pi} n : \mathbb{N} . 2^{\mathbb{N}_n} \to \mathbb{P}). \\ \mathbf{\Pi} f : \mathcal{C} . \downarrow \mathbf{\Sigma} n : \mathbb{N} . X \ n \ f \\ &\to \mathbf{\Pi} n : \mathbb{N} . \mathbf{\Pi} f : 2^{\mathbb{N}_n} . \mathsf{Dec}(X \ n \ f) \\ &\to \mathbf{\Sigma} k : \mathbb{N} . \mathbf{\Pi} f : \mathcal{C} . \mathbf{\Sigma} n : \mathbb{N}_k . X \ n \ f \end{aligned}$$

We also use the following corollary of SCP $_{\downarrow}$ for functions on the Cantor space instead of the Baire space:

$$\begin{array}{l} \text{SCPB} \\ = & \mathbf{\Pi} F : \mathcal{C} \to \mathbb{N}. \\ & \downarrow \mathbf{\Sigma} M : (\mathbf{\Pi} n : \mathbb{N}. 2^{\mathbb{N}_n} \to \mathbb{N}_{\mathtt{U}}). \\ & \mathbf{\Pi} f : \mathcal{C}. \\ & \mathbf{\Sigma} n : \mathbb{N}. M \; n \; f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f)) \\ & \wedge \; \mathbf{\Pi} n : \mathbb{N}. \texttt{isl}(M \; n \; f) \to M \; n \; f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f)) \end{array}$$

Let us start proving UCP₁. Let F be in $\mathcal{C} \to \mathbb{N}$. We have to prove

$$|\Sigma n:\mathbb{N}. \Pi f, g:\mathcal{C}.f =_{2^{\mathbb{N}_n}} g \to F(f) =_{\mathbb{N}} F(g)$$
(7)

We start by instantiating SCPB with F and we unsquash the resulting formula (which we can do because our conclusion is squashed), i.e., we get to assume:

• $M \in \mathbf{\Pi} n: \mathbb{N}.2^{\mathbb{N}_n} \to \mathbb{N}_{\mathbb{U}}$ and

•
$$G \in \Pi f: \mathcal{C}$$
. $\Sigma n: \mathbb{N}.M \ n \ f =_{\mathbb{N}_{\mathbb{V}}} \operatorname{inl}(F(f))$
 $\wedge \Pi n: \mathbb{N}. \operatorname{isl}(M \ n \ f) \to M \ n \ f =_{\mathbb{N}_{\mathbb{V}}} \operatorname{inl}(F(f))$

We now instantiate FT using $X = \lambda n.\lambda f.isl(M \ n \ f)$. We now have to prove (1) $\Pi f: \mathcal{C}.\downarrow \Sigma n:\mathbb{N}.isl(M \ n \ f)$, which follows from G; and (2) $\Pi n:\mathbb{N}.\Pi f: 2^{\mathbb{N}_n}.\text{Dec}(isl(M \ n \ f))$, which is trivial; and we get a $k \in \mathbb{N}$ and $A \in \Pi f: \mathcal{C}.\Sigma n:\mathbb{N}_k.isl(M \ n \ f)$. We unsquash and instantiate our conclusion 7 using k - 1. We have to prove that $F(f) =_{\mathbb{N}} F(g)$ assuming that $f =_{2^{\mathbb{N}_k}} g$ for f and g in \mathcal{C} . From Gwe get:

- $G(f) \in \mathbf{\Pi} n: \mathbb{N}. \mathtt{isl}(M \ n \ f) \to M \ n \ f =_{\mathbb{N}_{U}} \mathtt{inl}(F(f))$
- $G(g) \in \mathbf{\Pi} n: \mathbb{N}. \mathtt{isl}(M \ n \ g) \to M \ n \ g =_{\mathbb{N}_{U}} \mathtt{inl}(F(g))$

and from A (applying A to f) we get a $i \in \mathbb{N}_k$ and that $isl(M \ i f)$. Therefore, because $f =_{2^{\mathbb{N}_k}} g$, we get $M \ i f =_{\mathbb{N}_U} M \ i g$ and $isl(M \ i g)$. Which means that (from G(f) and G(g)):

- $M \ i \ f =_{\mathbb{N}_U} \operatorname{inl}(F(f))$
- $M \ i \ g =_{\mathbb{N}_{U}} \operatorname{inl}(F(g))$

We conclude that $F(f) =_{\mathbb{N}} F(g)$.

6.1.2 UCP | Follows From FT and skWCP.

Following Bridges and Richman's proof of their Theorem 3.2 [19, pp.113], the following Nuprl lemma proves that UCP₁ follows

from FT and skWCP: fan+weak-continuity-implies-uniform-continuity (as mentioned in Sec. 5, skWCP and WCP₁ are equivalent). Their proof is slightly more involved than the one presented above in Sec. 6.1.1 and uses the "trick" of building a bar that uses both the skolemized modulus of continuity M of type $C \to \mathbb{N}$ of a functional F of type $C \to \mathbb{N}$ and the (skolemized) modulus of continuity of M. As mentioned above skWCP is a trivial consequence of SCP₁: see Nuprl lemma strong-continuity2-implies-weak-skolem-cantor-nat.

6.1.3 Unsquashed UCP Follows From UCP₁.

We can then get rid of the truncation operator \downarrow in UCP₁ following exactly Escardó and Xu's proof [39, Sec.4]: see Nuprl lemma strong-continuity2-implies-uniform-continuity2. Their proof consists in proving that (1) the existence of a uniform modulus of continuity is equivalent to (2) the existence of the smallest uniform modulus of continuity. Because (2) is a proposition in HoTT's sense [83], we can "untruncate" it. Their proof goes in three steps: Nuprl lemma uniform-continuity-pi-dec corresponds to their Lemma 4; Nuprl lemma uniform-continuity-pi-pi-prop2 corresponds to their Lemma 5; and Nuprl lemma uniform-continuity-pi-pi-prop2 corresponds to their Lemma 6.

6.2 Brouwer's Theorem on Uniform Continuity

In Nuprl, a real number $\alpha : \mathbb{R}$ is a regular sequence of integers. This means that $\alpha : \mathbb{N}^+ \to \mathbb{Z}$ and $\forall n, m. | n * \alpha(m) - m * \alpha(n) | \leq 2(n+m)$. This differs from, but is equivalent to, Bishop's definition of real numbers as regular sequences of rationals [15]. Two regular sequences α and β represent the same real number if $\forall n. |\alpha(n) - \beta(n)| \leq 4$, and this is an equivalence relation, $\alpha =_r \beta$, on regular sequences. If $\alpha(n) + 4 < \beta(n)$ for some n, then $\alpha < \beta$, and $\alpha \# \beta$ (α is apart from β) if $\alpha < \beta \lor \beta < \alpha$. If $\forall n. \alpha(n) \leq \beta(n) + 4$, then $\alpha \leq \beta$.

The closed interval $[\alpha, \beta]$ is the type $\{x : \mathbb{R} \mid \alpha \leq x \leq \beta\}$. Bishop calls a member f of the type $[\alpha, \beta] \rightarrow \mathbb{R}$ an *operation* on the interval $[\alpha, \beta]$, and reserves the word *function* for those operations that satisfy

$$FUN(f, \alpha, \beta) = \forall x, y : [\alpha, \beta]. \ x =_r y \Rightarrow f(x) =_r f(y)$$

A stronger condition—called strong extensionality in Coq's CoRN library [54]—is

$$SFUN(f, \alpha, \beta) = \forall x, y : [\alpha, \beta]. \ f(x) \# f(y) \Rightarrow x \# y$$

An operation is uniformly continuous on $[\alpha, \beta]$ if

$$\begin{split} & \operatorname{CONT}(f,\alpha,\beta) \\ &= \forall \epsilon > 0. \\ &\quad \exists \delta > 0. \; \forall x,y: [\alpha,\beta]. \; |x-y| \leq \delta \rightarrow |f(x) - f(y)| \leq \epsilon \end{split}$$

(The Nuprl lemmas mentioned below are available at the following addess: http://www.nuprl.org/LibrarySnapshots/Publishe d/Version1/Standard2/reals/index.html.) Using the fact from Sec. 6.1 that functionals of type $\mathcal{C} \to \mathbb{Z}$ are uniformly continuous, we proved in Nuprl that for *proper* intervals $[\alpha, \beta]$ (where $\alpha < \beta$), we have (see Nuprl lemma real-continuity4):

$$\text{CONT}(f, \alpha, \beta) \Leftrightarrow \text{FUN}(f, \alpha, \beta)$$

In the proof, we construct the usual map from C onto $[\alpha, \beta]$, using a tree of nested, decreasing intervals. However, we can not show that this is an onto map without using the condition $\alpha < \beta$. Using the fact that we can decide whether a functional of type $C \rightarrow \mathbb{Z}$ is constant, we could extend the proof to the case of intervals that are not necessarily proper—for which only $\alpha \leq \beta$ to show that (see Nuprl lemma real-continuity3):

$$\operatorname{CONT}(f, \alpha, \beta) \Leftrightarrow \operatorname{SFUN}(f, \alpha, \beta)$$

Thus, for Bishop's definition of real function, it is correct to say that all functions on the unit interval [0, 1] are uniformly continuous

(Brouwer's theorem). But it is not correct to say that functions are uniformly continuous on all closed intervals $[\alpha, \beta]$ —only on proper closed intervals—unless the strongly extensional definition of real function is used. The two definitions are equivalent only when Markov's principle holds [15].

7. Related Work on Nominal Systems

Nominal systems. There has been a tremendous amount of work on nominal approaches to logic and programming starting from Gabbay and Pitts' work on using Fraenkel-Mostowski's permutation model of set theory to formally reason about abstract syntax in the presence of α -equivalence and variable binding [44]. This work then led to the design of the so-called Nominal Logic [65], which provides primitives and axioms to reason about names, name-swapping, freshness, and name-binding. These ideas were then later used and implemented in programming languages and type theories [16, 20–23, 35, 43, 64, 66, 67, 69, 70, 77–79, 88] (to cite only a few). We know describe some of these systems.

FreshML. For example, FreshML [67, 79] is an extension of ML with constructs for declaring and manipulating data with binding structure that provide support for object-level α -equivalence, such as constructs for binding names, declaring new types of bindable names, and generating fresh names. Nuprl does not yet have such a name-abstraction construct. Also, our paper does not try to tackle the issue of reasoning about α -equivalence classes of terms using names. This provides an alternative approach to, e.g., using de Bruijn indices or HOAS in order to deal with names and binders. These ideas were then also ported to OCaml [78]. Following this line of work, Pure FreshML [69] is a pure (in the sense that name generation is not an observable side effect) version of FreshML [79] that ensures fresh atoms do not escape their scopes.

Nominal type theories. Schopp and Stark [76, 77] developed a *bunched* dependent type theory for programming and reasoning with names, based on a categorical axiomatization of names, and taking freshness as the central primitive instead of swapping. Bunches are typing contexts that have a tree-like shape instead of a list-like shape, where branching is used to model the disjointness of names spaces. In their theory, α -equivalence classes can be either modeled as "fresh functions" or as pairs, which are members of "non-standard fresh" Π^* and Σ^* types. It turns out that these types are isomorphic when indexed by names, giving rise to a *hiddenname* type constructor **H** which can either be interpreted as a sum or a product, and which corresponds to Gabbay and Pitts freshness quantifier **I** [44]. In our paper, we only focus on computational aspects of freshness.

Cheney designed SNTT [20], which is a nominal simply-typed λ -calculus with names as well as name-abstraction and nameconcretion operators (but no name-generation operator such as ν). SNTT contexts are expressive enough so that one can state the freshness constraint on name-concretions. It is also designed with decidable typechecking in mind. Cheney extended SNTT to a dependent type theory, called λ^{III} [21], with dependent products (Π) and dependent name-abstraction types (I). As for SNTT, one of his main focus was to provide a strongly normalizing theory with decidable type checking.

Westbrook's CNIC calculus (the Calculus of Nominal Inductive Constructions) [87, 88] can also be seen as an extension of SNTT with inductive constructions, or similarly as an extension of CIC [32] with nominal features such as name abstraction and concretion operators, and pattern matching operators for names and name abstractions.

Pitts' Nominal System T [66] extends System T with nominal features such as a fresh operator ν à la Odersky and a nameswapping operator. As opposed to the systems mentioned above, this system has ordinary non-bunched contexts. FreshMLTT [64] is a dependent type theory that has name-abstraction and nameconcretion operators, as well as a name-swapping operator and a fresh operator ν à la Odersky, which allow them to derive expressive name-concretion rules.

8. Conclusion and Future Work

This paper provides "mostly" computational proofs of two Brouwerian continuity principles that use (1) diverging terms to prove that the modulus of continuity of a function on the Baire space exists in the meta-theory (Sec. 3), and (2) named exceptions to exhibit it in the theory (Sec. 4). We proved that all functions of type $T^{\mathbb{N}} \to \mathbb{N}$ are continuous, where T is a subtype of \mathbb{N} . It is not clear how to adapt our proof for other types than subtypes of \mathbb{N} . This is left for future work.

In Sec. 4.8 we used the fact that the exception $\exp c_a$ cannot be caught by F if a # F. This would not longer be true if our computation system was non-deterministic or if we allowed parallel computations. For example, let $t_1 \parallel t_2$ be an operator that dovetails the computations of t_1 and t_2 . If t_1 computes to $\exp c_a$ then this exception might get "caught" if t_2 computes to a canonical expression "before" t_1 . Once we add non-determinism to Nuprl, we might be able to use non-deterministic computations to compute the modulus of continuity of functions in a similar fashion as done by Coquand and Jaber [31]. This is left for future work.

Finally, many more inference rules can be derived (and verified in our Coq model) from the definitions of our new computations and types than the ones discussed in Sec. 4. Investigating these rules is left for future work.

Acknowledgements

We would like to thank our colleagues Robert L. Constable, Ross Tate, Rich Eaton, Abhishek Anand, and Evan Moran for their helpful criticism.
