# A Fourth-Order-Accurate Fourier Method for the Helmholtz Equation in Three Dimensions 

RONALD F. BOISVERT<br>National Bureau of Standards

#### Abstract

We present fourth-order-accurate compact discretizations of the Helmholtz equation on rectangular domains in two and three dimensions with any combination of Dirichlet, Neumann, or periodic boundary conditions. The resulting systems of linear algebraic equations have the same blocktridiagonal structure as traditional central differences and hence may be solved efficiently using the Fourier method. The performance of the method for a variety of test cases, including problems with nonsmooth solutions, is presented. The method is seen to be roughly twice as fast as deferred corrections and, in many cases, results in a smaller discretization error. Categories and Subject Descriptors: G.1.8 [Numerical Analysis] Partial differential equationselliptic equations; G. 4 [Mathematics of Computing] Mathematical Software-algorithm analysis General Terms: Algorithms, Theory Additional Key Words and Phrases: Fast-direct method, finite differences, Fourier method, Helmholtz equation, High-order accuracy, HODIE method

## 1. INTRODUCTION

Fast direct methods have proved to be very effective techniques for solving separable elliptic boundary value problems. These include cyclic reduction, Fourier analysis, FACR(l), and tensor product matrix decomposition [6, 24]. Each exploits, in some way, the tensor-product nature of the discrete problem obtained by applying standard second-order accurate finite differences on a rectangular domain. Problems on nonrectangular domains may be solved by using fast-direct methods after suitable preprocessing to extend them to an enclosing domain [16, 20].

Recently, there has been much interest in combining fast-direct methods with high-order-accurate discretizations to produce software that is both very fast and very accurate. There are a variety of techniques for attaining high-order accuracy while maintaining the special form of discrete problem required for fast-direct solution techniques. The accuracy of standard second-order finite differences can be extended using deferred corrections [18]. This is done for two-dimensional problems in the FISHPAK subprograms SEPELI and SEPX4 [1] to attain fourth-order accuracy. In [19] the Dirichlet problem for Laplace's equation is solved for nonrectangular planar regions to fourth-order accuracy by using the

[^0]capacitance matrix method and deferred corrections. A similar technique is employed to obtain sixth-order accuracy in [21].
An alternative to deferred corrections is the use of high-order-accurate compact finite differences. This was done in [10] to attain fourth- and sixth-order accuracy for the two-dimensional Helmholtz equation with Dirichlet boundary conditions. Similar techniques have also been applied to the three-dimensional Poisson equation [12, 17]. Finite-element discretizations based upon tensor products of one-dimensional spline functions also yield discrete problems to which fast-direct methods can be applied $[9,11]$.

In this paper I describe new fourth-order-accurate compact discretizations of the two- and three-dimensional Helmholtz equations. I demonstrate how such compact discretizations can be extended to maintain fourth-order accuracy at boundary points where Neumann boundary conditions are specified. These discretizations are the basis for a suite of Fortran subprograms that solve the Helmholtz equation on rectangular domains in two and three dimensions with any combination of Dirichlet, Neumann, or periodic boundary conditions [5]. The discrete problem is solved using the Fourier method. This software differs from [10], [12], and [17] in the variety of boundary conditions handled, as well as in the details of the direct solution. The software described here is roughly twice as fast as fourth-order solvers based on deferred corrections and does not require significantly more working storage.

## 2. HODIE DISCRETIZATIONS

We consider the problem

$$
\begin{equation*}
\frac{\partial^{2} u}{\partial x^{2}}+\frac{\partial^{2} u}{\partial y^{2}}+\frac{\partial^{2} u}{\partial z^{2}}+\lambda u=g(x, y, z) \tag{1}
\end{equation*}
$$

( $\lambda<0$ constant) on an open rectangular domain $R$ in three dimensions; on the boundary $\partial R=\partial R_{1} \cup \partial R_{2} \cup \partial R_{3}$ we have

- $u$ prescribed (Dirichlet condition) on $\partial R_{1}$, - $u_{n}$ prescribed (Neumann condition) on $\partial R_{2}$,
-the solution is periodic on $\partial R_{3}$.
( $\partial R_{1}, \partial R_{2}$, and $\partial R_{3}$ are each unions of sides of $R$.) To discretize the problem, we first place a uniform grid of mesh width $h$ over $R$ (with $N X$ by $N Y$ by $N Z$ grid lines) and define $R_{i j k}=\left\{(x, y, z) \mid(x, y, z) \in\left[x_{i-1}, x_{i+1}\right] \times\left[y_{j-1}, y_{j+1}\right] \times\left[z_{k-1}, z_{k+1}\right]\right\}$.

### 2.1 Interior Point Discretizations

At grid points ( $x_{i}, y_{j}, z_{k}$ ) in $R$ we use the following discrete analogue of (1).

$$
\begin{equation*}
L_{i j k} U=h^{2} I_{i j k} g \tag{2}
\end{equation*}
$$

where

$$
\begin{aligned}
L_{i j k} U & =\sum_{l} \alpha_{l} U\left(p_{l}\right) \\
I_{i j k} g & =\sum_{l} \beta_{l} g\left(q_{l}\right)
\end{aligned}
$$

The set $\left\{p_{l}\right\}$ is called the discretization point set, and the set $\left\{q_{l}\right\}$ is called the evaluation point set. Both $\left\{p_{l}\right\}$ and $\left\{q_{l}\right\}$ are subsets of $R_{i j k} ;\left\{p_{l}\right\}$ contains only grid ACM Transactions on Mathematical Software, Vol. 13, No. 3, September 1987.
points, whereas $\left\{q_{l}\right\}$ does not have this restriction. The number and location of the evaluation points may be chosen to decrease the truncation error of the difference equations. Once an appropriate set of evaluation points has been selected, one may obtain $O\left(h^{N}\right)$ accuracy by choosing the coefficients in (2) so that the truncation error $L_{i j k} v-h^{2} I_{i j k} L v=0$ for all $v \in P^{N+1}$, the space of polynomials of degree $N+1$ or less. Discretizations of this form are studied in [2] and [13], where they are called HODIE methods; they are related to Mehrstellenverfahren [8] and operator compact implicit (OCI) methods [7]. Alternate methods for deriving such formulae are considered in [15].

Our discretization of (1) at the (i,j,k)th grid point uses operators $L_{i j k}$ and $I_{i j k}$ of the form

$$
\begin{align*}
L_{i j k} U= & a U_{i j k} \\
& +b\left[U_{i+1, j, k}+U_{i, j+1, k}+U_{i, j, k+1}+U_{i-1, j, k}+U_{i, j-1, k}+U_{i, j, k-1}\right] \\
& +c\left[U_{i+1, j, k+1}+U_{i, j+1, k+1}+U_{i+1, j+1, k}+U_{i+1, j, k-1}\right. \\
& +U_{i, j+1, k-1}+U_{i+1, j-1, k}+U_{i-1, j, k+1}+U_{i, j-1, k+1}  \tag{3}\\
& \left.+U_{i-1, j+1, k}+U_{i-1, j, k-1}+U_{i, j-1, k-1}+U_{i-1, j-1, k}\right] \\
& +d\left[U_{i+1, j+1, k+1}+U_{i+1, j+1, k-1}+U_{i+1, j-1, k+1}+U_{i+1, j-1, k-1}\right. \\
& \left.+U_{i-1, j+1, k+1}+U_{i-1, j+1, k-1}+U_{i-1, j-1, k+1}+U_{i-1, j-1, k-1}\right] \\
I_{i j k} g= & \beta_{0} g_{i j k} \\
& +\beta_{1}\left[g_{i+1 / 2, j+1 / 2, k+1 / 2}+g_{i-1 / 2, j+1 / 2, k+1 / 2}+g_{i+1 / 2, j-1 / 2, k+1 / 2}\right. \\
& +g_{i-1 / 2, j-1 / 2, k+1 / 2}+g_{i+1 / 2, j+1 / 2, k-1 / 2}+g_{i-1 / 2, j+1 / 2, k-1 / 2}  \tag{4}\\
& \left.+g_{i+1 / 2, j-1 / 2, k-1 / 2}+g_{i-1 / 2, j-1 / 2, k-1 / 2}\right] \\
+ & \beta_{2}\left[g_{i+1, j, k}+g_{i-1, j, k}+g_{i, j+1, k}+g_{i, j-1, k}+g_{i, j, k+1}+g_{i, j, k-1}\right]
\end{align*}
$$

with the coefficients $a=-24+5 \Lambda-\Lambda^{2} / 4, b=2-\Lambda / 24+\Lambda^{2} / 48, c=1+$ $5 \Lambda / 48, d=0, \beta_{0}=2-\Lambda / 4, \beta_{1}=\frac{1}{2}$, and $\beta_{2}=\Lambda / 48$, where $\Lambda=h^{2} \lambda$. This discretization has truncation error $O\left(h^{4}\right)$ and is of positive type [8]; hence for problems with Dirichlet and/or periodic boundary conditions, it follows that the resulting global error is at most $O\left(h^{4}\right)$. The discretization (3-4) reduces to the standard second-order accurate 7-point discretization of the Helmholtz equation with the choices $a=-6+\Lambda, b=\beta_{0}=1, c=d=\beta_{1}=\beta_{2}=0$. An alternate secondorder discretization is obtained with the choices $a=-24+6 \Lambda, b=2, c=1$, $\beta_{0}=6, d=\beta_{1}=\beta_{2}=0$.

### 2.2 Discretization of Neumann Boundary Conditions

At grid points ( $x_{i}, y_{j}, z_{k}$ ) in $\partial R_{2}$, we augment the difference equation to obtain

$$
\begin{equation*}
L_{i j k} U=h^{2} I_{i j k} g+h J_{i j k} u_{n} \tag{5}
\end{equation*}
$$

where the functionals $L_{i j k}$ and $I_{i j k}$ are defined as in (2), with the point set $\left\{p_{l}\right\}$ and $\left\{q_{l}\right\}$ restricted to $R_{i j k} \cup R$. The functional $J_{i j k}$ is defined by

$$
J_{i j k} s=\sum_{l} \gamma_{l} s\left(r_{l}\right)
$$

where the boundary evaluation points $r_{l}$ are taken on $\partial R_{2}$ near ( $x_{i}, y_{j}, z_{k}$ ). The evaluation points and coefficients are chosen so that the truncation error $L_{i j k} v-I_{i j k} L v-J_{i j k} v_{n}=0$ for all $v \in P^{N}$. Difference approximations of the general form (5) are described in more detail in [3].

The specific discretization considered here uses the $L_{i j k}$ and $I_{i j k}$ of (3-4), except that values of $U$ and $g$ outside the domain are defined by reflection through the boundary. A similar reflection symmetry is present in the standard second-order case obtained by applying (2) at a boundary point and then eliminating unknowns outside $R$, using central difference approximations to the normal derivative. Not every choice of evaluation points in (2) leads to a boundary point discretization (5) with the proper reflection symmetry, as the following simple theorem shows.

Theorem 1. No boundary discretization of the form (5) with $L_{i j k}$ of the form (3) with reflection symmetry and $\left\{q_{l}\right\}=\left\{p_{l}\right\}$ can be exact on $P^{4}$, unless $2 b+8 c+$ $8 d=0$.

Proof. It is sufficient to consider the case $\left(x_{i}, y_{j}, z_{k}\right)=(0,0,0)$ with $x=$ $x_{N X}=$ and $u_{n}=u_{x}=s$. In this case we seek a discretization with $L_{i j k} u$ $h^{2} I_{i j k} g-h J_{i j k} s=0$ for all $u \in P^{4}$, where

$$
\begin{aligned}
L_{i j k} u= & a u(0,0,0) \\
& +b[2 u(-h, 0,0)+u(0, h, 0)+u(0,-h, 0)+u(0,0, h)+u(0,0,-h)] \\
& +c[2 u(-h, h, 0)+2 u(-h,-h, 0)+2 u(-h, 0, h)+2 u(-h, 0,-h) \\
& +u(0, h, h)+u(0, h,-h)+u(0,-h, h)+u(0,-h,-h)] \\
& +d[2 u(-h, h, h)+2 u(-h, h,-h)+2 u(-h,-h, h)+2 u(-h,-h,-h)] \\
I_{i j k} g= & \beta_{0} g(0,0,0)+\beta_{1} g(0, h, 0)+\beta_{2} g(-h, 0,0)+\beta_{3} g(0,-h, 0) \\
& +\beta_{4} g(0,0, h)+\beta_{5} g(0,0,-h)+\beta_{6} g(-h, h, 0)+\beta_{7} g(-h,-h, 0) \\
& +\beta_{8} g(0, h, h)+\beta_{9} g(-h, 0, h)+\beta_{10} g(0,-h, h)+\beta_{11} g(0, h,-h) \\
& +\beta_{12} g(-h, 0,-h)+\beta_{13} g(0,-h,-h)+\beta_{14} g(-h, h, h)+\beta_{15} g(-h,-h, h) \\
& +\beta_{g} g(-h, h,-h)+\beta_{17} g(-h,-h,-h)
\end{aligned}
$$

and $J_{i j k} s$ is any linear combination of evaluations of $s$ along $x=0$. Let $\beta=$ $\beta_{2}+\beta_{6}+\beta_{7}+\beta_{9}+\beta_{12}+\beta_{14}+\beta_{15}+\beta_{16}+\beta_{17}$. Taking $u=x^{3}$ and $u=x^{4}$, in turn, yield the requirements that $\beta=2(b+4 c+4 d) /\left(6+h^{2} \lambda\right)$, and $\beta=$ $2(b+4 c+4 d) /\left(12+h^{2} \lambda\right)$ for $h$ sufficiently small. These cannot both be satisfied unless $b+4 c+4 d=0$.

Since discretizations of (1) of positive type have $b, c$, and $d$ of one sign, the theorem implies that useful boundary discretizations consistent with (3) cannot have fourth-order accuracy unless evaluation points that are not grid points are included.

The exact form of the functional $J_{i j k}$ that we use depends upon whether the point ( $x_{i}, y_{j}, z_{k}$ ) is on a side, an edge, or a corner of the domain. At a point on the side $x=x_{N X}$ (not an edge or corner); where $u_{n}=u_{x}=s, J_{i j k}$ takes the form

$$
\begin{equation*}
J_{N X, j, k} u_{n}=\gamma_{0} s_{N X, j, k}+\gamma_{1}\left[s_{N X, j+1, k}+s_{N X, j-1, k}+s_{N X, j, k+1}+s_{N X, j, k-1}\right] \tag{6}
\end{equation*}
$$

At a point on the edge with $x=x_{N X}$ and $y=y_{N Y}$ (not a corner), where $u_{n}=$ $u_{x}=s$ for $x=x_{N X}$, and $u_{n}=u_{y}=t$ for $y=y_{N Y}, J_{i j k}$ takes the form

$$
\begin{align*}
J_{N X, N Y, k} s= & \delta_{0}\left[s_{N X, N Y, k}+t_{N X, N Y, k}\right] \\
& +\delta_{1}\left[s_{N X, N Y-1, k}+t_{N X-1, N Y, k}\right]+\delta_{2}\left[s_{N X, N Y-2, k}+t_{N X-2, N Y, k}\right] \\
& +\delta_{3}\left[s_{N X, N Y-3, k}+t_{N X-3, N Y, k}\right]  \tag{7}\\
& +\delta_{4}\left[s_{N X, N Y, k+1}+t_{N X, N Y, k+1}+s_{N X, N Y, k-1}+t_{N X, N Y, k-1}\right] \\
& +\delta_{5}\left[s_{N X, N Y-1, k+1}+t_{N X-1, N Y, k+1}+s_{N X, N Y-1, k-1}+t_{N X-1, N Y, k-1}\right]
\end{align*}
$$

At a point at the corner with $x=x_{N X}, y=y_{N Y}$, and $z=z_{N Z}$, where $u_{n}=u_{x}=s$ for $x=x_{N X}, u_{n}=u_{y}=t$ for $y=y_{N Y}$ and $u_{n}=u_{z}=w$ for $z=z_{N Z}, J_{i j k}$ takes the form

$$
\begin{align*}
J_{N X, N Y, N Z} s= & \epsilon_{0}\left[s_{N X, N Y, N Z}+t_{N X, N Y, N Z}+w_{N X, N Y, N Z}\right] \\
& +\epsilon_{1}\left[s_{N X, N Y-1, N Z}\right. \\
& +t_{N X-1, N Y, N Z}+w_{N X-1, N Y, N Z} \\
& \left.+s_{N X, N Y, N Z-1}+t_{N X, N Y, N Z-1}+w_{N X, N Y-1, N Z}\right] \\
& +\epsilon_{2}\left[s_{N X, N Y-2, N Z}\right. \\
& +t_{N X-2, N Y, N Z}+w_{N X-2, N Y, N Z}  \tag{8}\\
& \left.+s_{N X, N Y Y Z-2}+t_{N X, N Y Y Z-2}+w_{N X, N Y-2, N Z}\right] \\
& +\epsilon_{3}\left[s_{N X, N Y-3, N Z}\right. \\
& +t_{N X-3, N Y, N Z}+w_{N X-3, N Y, N Z} \\
& \left.+s_{N X, N Y, N Z-3}+t_{N X, N Y, N Z-3}+w_{N X, N Y-3, N Z}\right] \\
& +\epsilon_{4}\left[s_{N X, N Y-1, N Z-1}+t_{N X-1, N Y, N Z-1}+w_{N X-1, N Y-1, N Z}\right] \\
& +\epsilon_{5}\left[s_{N X, N Y-1, N Z-2}+t_{N X-1, N Y, N Z-2}+w_{N X-1, N Y-2, N Z}\right. \\
& \left.+s_{N X, N Y-2, N Z-1}+t_{N X-2, N Y, N Z-1}+w_{N X-2, N Y-1, N Z}\right] \\
& +\epsilon_{6}\left[s_{N X, N Y-2, N Z-2}+t_{N X-2, N Y, N Z-2}+w_{N X-2, N Y-2, N Z}\right]
\end{align*}
$$

Discretizations for all other boundary points may be obtained from these by symmetry. Values of coefficients yielding $O\left(h^{4}\right)$ and $O\left(h^{2}\right)$ truncation error are listed in Table I as Method A and Method B, respectively.

Since the operators $L_{i j k}$ and $I_{i j k}$ are obtained in each case from (3-4) by reflection symmetry, we have that all difference equations are of a positive type, which implies that the global error is the same as the truncation error in each case. Thus, methods A and B of Table I have order of accuracy $O\left(h^{4}\right)$ and $O\left(h^{2}\right)$, respectively.

### 2.3 Matrix Formulation

After incorporating Dirichlet and periodic boundary conditions in the usual way and using the natural ordering of grid points, one obtains a linear system $M u=$ $g$. The nonzero elements of a row given in $M$ correspond to the coefficients of the associated functional $L_{i j k}$. The right-hand side contains the contributions from the operators $I_{i j k}$ and $J_{i j k}$, as well as terms eliminated from $L_{i j k}$, to account for Dirichlet boundary data.

To describe the structure of the matrix $M$, we first develop a notation for a certain class of nearly tridiagonal matrices. Define

$$
T(a, b ; \mu, \nu, \rho ; n)=\left[\begin{array}{cccccccc}
a & \mu b & & & & & & \rho b \\
b & a & b & & & & & \\
& b & a & b & & & & \\
& & \cdot & \cdot & \cdot & & & \\
& & & \cdot & \cdot & \cdot & & \\
& & & & \cdot & \cdot & \cdot & \\
\rho b & & & & & b & a & b \\
& & & & & \nu b & a
\end{array}\right]_{n \times n}
$$

In tensor-product notation [14] this may be written as

$$
T(a, b ; \mu, \nu, \rho ; n)=I_{n} \otimes a+J_{n}(\mu, \nu, \rho) \otimes b
$$

where

$$
J_{n}(\mu, \nu, \rho)=\left[\begin{array}{cccccccc}
0 & \mu & & & & & & \rho \\
1 & 0 & 1 & & & & & \\
& 1 & 0 & 1 & & & & \\
& & \cdot & . & . & & & \\
& & & \cdot & . & . & & \\
& & & & \cdot & . & . & \\
\rho & & & & & 1 & 0 & 1 \\
\rho & & & & & \nu & 0
\end{array}\right]_{n \times n}
$$

and $I_{n}$ is the identity matrix of order $n$. In terms of these we define matrices $A$, $B, C, J_{y}$, and $J_{z}$ by

$$
\begin{aligned}
A & =T\left(a, b ; \mu_{x}, \nu_{x}, \rho_{x} ; n\right) \\
B & =T\left(b, c ; \mu_{x}, \nu_{x}, \rho_{x} ; n\right) \\
C & =T\left(c, d ; \mu_{x}, \nu_{x}, \rho_{x} ; n\right) \\
J_{y} & =J_{m}\left(\mu_{y}, \nu_{y}, \rho_{y}\right) \\
J_{z} & =J_{l}\left(\mu_{z}, \nu_{z}, \rho_{z}\right)
\end{aligned}
$$

The scalars $\mu_{x}, \nu_{x}, \rho_{x}$, and $n$ depend upon the boundary conditions in $x, \mu_{y}, \nu_{y}, \rho_{y}$, and $m$ depend upon the boundary conditions in $y$, and $\mu_{z}, \nu_{z}, \rho_{z}$, and $l$ depend upon the boundary conditions in $z$. Table II gives this dependence explicitly. The scalars $a, b, c$, and $d$ are from (3-4). In terms of these quantities, the matrix $M$ may finally be written as

$$
\begin{equation*}
M=I_{l} \otimes\left(I_{m} \otimes A+J_{y} \otimes B\right)+J_{z} \otimes\left(I_{m} \otimes B+J_{y} \otimes C\right) \tag{9}
\end{equation*}
$$

ACM Transactions on Mathematical Software, Vol. 13, No. 3, September 1987.

Table II. Dependence of $\mu, \nu, \rho$, and $n$ on
Boundary Conditions

| Boundary Conditions |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :---: | :---: |
| Left | Right | $\mu$ | $\nu$ | $\rho$ | $n \dagger$ |
| Dirichlet | Dirichlet | 1 | 1 | 0 | $N-2$ |
| Dirichlet | Neumann | 1 | 2 | 0 | $N$ |

| Neumann | Neumann | 2 | 2 | 0 | $N$ |
| Periodic | Periodic | 1 | 1 | 1 | $N-1$ |

$\dagger N$ is the number of grid lines.

### 2.4 The Two-Dimensional Case

One may obtain a related discretization for the Helmholtz equation in two dimensions by considering the application of the three-dimensional discretization to a problem whose solution $u$ is independent of $z$. When this is done, one obtains the fourth-order accurate discretization displayed in [4]. The resulting matrix problem $M u=g$ has a matrix of the somewhat simplified form

$$
\begin{equation*}
M=I_{m} \otimes A+J_{y} \otimes B \tag{10}
\end{equation*}
$$

where $A$ and $B$ have the same form as the matrices $A$ and $B$ described in Section 2.3 above.

## 3. THE FOURIER ALGORITHM

The solution of linear algebraic systems involving matrices of the form (9) or (10) are the prototypical discrete problems for which fast-direct methods have been developed. Our software is based on the fact that high-order-accurate discretizations may be obtained by a proper choice of $a, b, c$, and $d$, and a perturbation of the right-hand side. We use the Fourier method, since software for the discrete Fourier transform is readily available, and the algorithm is adaptable for use on parallel or vector processors [23, 25]. We describe the Fourier algorithm only briefly; details may be found in [6] or [24]. We first consider the two-dimensional problem $M u=g$, with $M$ defined as in (10); this yields the matrix problem

$$
\left[\begin{array}{cccccccc}
A & \mu_{x} B & & & & & & \rho_{x} B  \tag{11}\\
B & A & B & & & & & \\
& B & A & B & & & & \\
& & \cdot & \cdot & \cdot & & & \\
& & & \cdot & \cdot & \cdot & & \\
& & & & \cdot & \cdot & \cdot & \\
& & & & B & A & B \\
\rho_{x} B & & & & & & \nu_{x} B & A
\end{array}\right] \quad\left[\begin{array}{c}
\mu_{1} \cdot \\
u_{2} . \\
u_{3} . \\
\cdot \\
\cdot \\
\cdot \\
u_{m-1, \cdot} \\
u_{m}
\end{array}\right]=\left[\begin{array}{c}
g_{1} . \\
g_{2 \cdot} \\
g_{3} . \\
\cdot \\
\cdot \\
\cdot \\
g_{m-1, \cdot} \\
g_{m \cdot} .
\end{array}\right]
$$

Note that we use double indices to denote the elements of the unknown vector $u$ and the right-side vector $g ; u_{i j}$ denotes the value of $u$ at the $(i, j)$ th grid point, $u_{\text {, }}$ denotes the $j$ th column of $u$, and $u_{i}$. denotes the $i$ th of row of $u$. The Fourier

$\dagger$ Eigenvalues are $a+2 b \sigma_{j}, \quad j=1, \ldots, n$
method relies on the fact that the matrices $A$ and $B$ have a common set of linearly independent eigenvectors of a very special form; see Table III. Let $Q$ be a matrix of these eigenvectors, and let $\omega_{i}(A)$ denote the eigenvalue corresponding to the $i$ th eigenvector of $A$. If we premultiply each block equation in (11) by $Q^{-1}$ and scale each block of unknowns by $Q^{-1}$, the system decouples to the solution of $n$ tridiagonal systems of size $m$ by $m$. The two-dimensional algorithm may be summarized as follows.

## Algorithm: 2D Decomposition

(1) (Transform $x$ variable.) Compute $g_{. j} \leftarrow Q^{-1} g_{. j}$ for $j=1, \ldots, m$.
(2) (Solve $n 1 \mathrm{D}$ problems in $y$.) Solve $T_{i} u_{i .}=g_{i}$. for $i=1, \ldots, n$.
(3) (Back transform $x$ variable.) Compute $u_{. j} \leftarrow Q u_{. j}$ for $j=1, \ldots, m$.
$T_{i}$ is the tridiagonal matrix $T\left(\omega_{i}(A), \omega_{i}(B) ; \mu_{y}, \nu_{y}, \rho_{y} ; m\right)$. Multiplication by $Q^{-1}$ is equivalent to performing a discrete Fourier transform and hence may be computed using FFT techniques. As a result, for $N X-1$ a power of two, the algorithm requires only $O\left(2 m n \log _{2} n\right)$ floating point operations on a scalar computer. Note that no matrix need be stored, and the arrays $u$ and $g$ may coincide in memory, so that the algorithm is quite storage efficient.

In the three-dimensional case, we consider a problem $M u=g$, with $M$ defined by (9) and triply subscripted $u$ and $g$. In this case, after premultiplying each block equation by $Q^{-1}$ and scaling each block of unknowns by $Q^{-1}$, one obtains a set of decoupled block tridiagonal systems. The three-dimensional algorithm may be summarized as follows.

## Algorithm: 3D Decomposition

(1) (Transform $x$ variable.) Compute $g_{. j k} \leftarrow Q^{-1} g_{. j k}$ for $j=1, \ldots, m$, $k=1, \ldots, l$.
(2) (Solve $n$ 2D problems in $y z$.) Solve $M_{i} u_{i . .}=g_{i . .}$ for $i=1, \ldots, n$.
(3) (Back transform $x$ variable.) Compute $u_{. j k} \leftarrow Q u_{. j k}$ for $j=1, \ldots, m$, $k=1, \ldots, l$.

The matrices $M_{i}$ are given by

$$
M_{i}=I_{l} \otimes A_{i}+J_{z} \otimes B_{i}
$$

ACM Transactions on Mathematical Software, Vol. 13, No. 3, September 1987.
where $A_{i}=T\left(\omega_{i}(A), \omega_{i}(B) ; \mu_{y}, \nu_{y}, \rho_{y} ; m\right)$, and $B_{i}=T\left(\omega_{i}(B), \omega_{i}(C) ; \mu_{y}, \nu_{y}, \rho_{y} ; m\right)$. The $n$ subproblems in Step 2 may be solved by the two-dimensional algorithm. Thus, in the three-dimensional case, when $N X-1$ and $N Y-1$ are powers of two, the Fourier method requires only $O\left(2 n m l\left(\log _{2} n+\log _{2} m\right)\right)$ floating point operations on a scalar computer.

## 4. COMPUTATIONAL EXAMPLES

The algorithms described in Sections 2 and 3 are the basis of a suite of Fortran subprograms for the solution of the Helmholtz equation on rectangular two- or three-dimensional domains with any combination of Dirichlet, Neumann, or periodic boundary conditions. This subprogram package, called HFFT, is described in [5]. It is also available as part of the ELLPACK system [22]. Its two primary entry points are HFFT2 and HFFT3, for two-dimensional and threedimensional problems, respectively. In each case the user may select either a fourth-order accurate or a second-order accurate discretization; the discretizations used are those discussed in Section 2.

We illustrate the performance of the HODIE-based algorithms by comparing the software in HFFT with other widely available software for this problem. HFFT2 is contrasted with the subprogram SEPX4 [1], which uses standard second-order differences to solve the discrete problem using recursive cyclic reduction, an algorithm of the same complexity as the Fourier method. Optionally, SEPX4 will produce fourth-order accuracy using deferred corrections; this requires a second fast solve using a modified right-hand side. HFFT3 is compared with HW3CRT [1], which implements the Fourier method for the standard fivepoint second-order accurate discretization. In summary, we consider the following programs.

Two-dimensional software
HFFT2(2) HFFT2 with second-order accurate compact nine-point discretization. (Fourier method)
HFFT2(4) HFFT2 with fourth-order accurate compact nine-point discretization. (Fourier method)
SEPX4(2) SEPX4 with second-order accurate five-point discretization. (Recursive cyclic reduction)
SEPX4(4) SEPX4 with second-order accurate five-point discretization. Fourthorder accuracy obtained by deferred corrections. (Recursive cyclic reduction)

Three-dimensional software
HFFT3(2) HFFT3 with second-order accurate compact 19-point discretization. (Fourier method)
HFFT3(4) HFFT3 with fourth-order accurate compact 19-point discretization. (Fourier method)
HW3CRT Second-order accurate seven-point discretization. (Fourier method)

Table IV. Raw Timing Data in Seconds on Cyber 180/855

| 2D | Second order |  | Fourth order |  |
| :---: | :---: | :---: | :---: | :---: |
| $n$ | SEPX4 | HFFT2 | SEPX4 | HFFT2 |
| 8 | 0.01 | 0.01 | 0.01 | 0.01 |
| 16 | 0.01 | 0.02 | 0.03 | 0.02 |
| 32 | 0.05 | 0.05 | 0.12 | 0.06 |
| 64 | 0.20 | 0.18 | 0.51 | 0.22 |
| 128 | 0.84 | 0.69 | 2.09 | 0.82 |
| 3D | Second order |  | Fourth order |  |
| $n$ | HW3CRT | HFFT3 |  |  |
| 8 | 0.10 | 0.11 |  |  |
| 12 | 0.25 | 0.27 |  |  |
| 16 | 0.51 | 0.52 |  |  |
| 20 | 0.91 | 0.94 |  |  |
| 24 | 1.56 | 1.50 |  |  |
| 28 | 2.90 | 2.75 |  |  |

All our tests are run in single precision on a Cyber 180/855 computer (FTN compiler, version 5.1, OPT = 2). Timing data include time to evaluate the forcing function $g$ and the boundary conditions. Since HFFT2 requires only one fast solve, we expect its basic execution time to be roughly the same as SEPX4(2) which, in turn, should be half that of SEPX4(4). Similarly, we expect execution times for HW3CRT, HFFT3(2), and HFFT3(4) to be roughly the same. These are verified in Table IV where we present timings for the homogeneous Dirichlet problem for Laplace's equation on a sequence of square grids (a problem for which the cost of function evaluations is minimum).

Figure 1 displays the results obtained by running the two-dimensional software on six additional test problems. These plots display maximum error (scaled by the maximum value of $u$ in the domain) versus computing time, plotted on a log$\log$ scale. The data points correspond to grids of $9 \times 9,17 \times 17,33 \times 33,65 \times$ 65 , and $129 \times 129$. These are listed below:

Two-dimensional test problems
A2 $L u=\Delta u, u$ is prescribed $(=0)$ on $x=0, x=1, y=0, y=1$, and $u=$ $3 x y(1-x)(1-y) \exp x+y$. Solution is entire and slowly varying.
B2 $L u=\Delta u-5 u, u_{n}$ is prescribed on $x=0, x=1, y=0$, and $u$ is prescribed $(=0)$ on $y=1$; solution is the same as in problem A2.
C2 $L u=\Delta u-20 u, u$ is periodic in $x$ and $y$, and $u=\cos 4 \pi y+\sin 4 \pi(x-y)$. The solution is entire and slowly varying.
D2 The same as problem C2 with $u$ prescribed on $y=0, u_{n}$ prescribed on $y=1$, and $u$ periodic in $x$.
E2 $L u=\Delta u, u$ is prescribed on $x=1, y=1$, and $u_{n}$ is prescribed on $x=0$, $y=0, u=(x y)^{5 / 2}$. The solution has singular third derivatives along $x=0$ and $y=0$.
F2 $L u=\Delta u, u$ is prescribed on $x=0,1, y=0,1, u=f(x) f(y), f(x)=\left(x^{3 / 4}-x\right)$. The solution has singular first derivatives along $x=0$ and $y=0$.

Fig. 1. Maximum error at grid points versus computing time for six two-dimensional test problems. Each line corresponds to a different software module: $\square$ denotes SEPX4(2), ■ denotes SEPX4(4), O denotes HFFT2(2), and © denotes HFFT2(4). The data points on each line correspond to grids of size $9 \times 9,17 \times 17,33 \times 33,65 \times 65$, and $129 \times 129$.

Since the solutions to problems A2, B2, C2, and D2 are entire, the observed convergence rate of each method is as expected. The two second-order methods, HFFT2(2) and SEPX4(2) have nearly the same behavior for all these problems. HFFT2(4) shows no clear advantage over SEPX4(4) for problem A2 (a Dirichlet. problem for Poisson's equation), although, for a given grid, it runs twice as fast. However, when normal derivative or periodic boundary conditions are present (problems B2, C2, D2), the error produced by HFFT2(4) is much smaller (10 times smaller in problem B2, 45 times smaller in problem D2). When combined with the faster execution times of HFFT2(4), these problems clearly show the advantage of HFFT2(4). For problems E2 and F2, which have solutions with singular low-order derivatives, the observed convergence rates were 1.5 and 0.7 for all methods. In contrast to SEPX4(4), which shows no advantage over SEPX4(2) for these problems, HFFT2(4) again produces a smaller error, although this effect is less prominent in problem F2.

Figure 2 displays the results obtained by running the three-dimensional software on six similar problems. These plots display maximum error (scaled by maximum value of $u$ in the domain) versus computing time, plotted on a $\log -\log$

${ }^{-}$ig. 2. Maximum error at grid points versus computing time for six three-dimensional test problems. Each line corresponds to a different software module: $\square$ denotes HW3CRT, O denotes HFFT3(2), and denotes HFFT3(4). The data points correspond to grids of size $9 \times 9 \times 9,17 \times 17 \times 17,21 \times 21 \times 21,25 \times 25 \times 25$, and $29 \times 29 \times 29$.
scale. The data points correspond to grids of $9 \times 9 \times 9,13 \times 13 \times 13,17 \times 17 \times$ $17,21 \times 21 \times 21,25 \times 25 \times 25$, and $29 \times 29 \times 29$. These are as follows:

## Three-dimensional test problems

A3 $L u=\Delta u, u$ is prescribed $(=0)$ on $x=0, x=1, y=0, y=1, z=0, z=1, u=$ $x y z(1-x)(1-y)(1-z) \exp (x+y+z)$. Solution is entire and slowly varying.
B3 $L u=\Delta u-5 u, u_{n}$ is prescribed on $x=0, x=1, y=0, z=0$, and $u$ is prescribed $(=0)$ on $y=1, z=1$; the solution is the same as in problem A3.
C3 $L u=\Delta u-20 u, u$ periodic in $x, y$, and $z, u=\cos 4 \pi y+\cos 4 \pi z+$ $\sin 4 \pi(x-y)$. The solution is entire and slowly varying.
D3 The same as problem C3 with $u$ prescribed on $y=0, z=0, u_{n}$ prescribed on $y=1, z=1$, and $u$ periodic in $x$.
E3 $L u=\Delta u, u$ is prescribed on $x=1, y=1, z=0, z=1$, and $u_{n}$ is prescribed on $x=0, y=0, u=(x y z)^{5 / 2}$. The solution has singular third derivatives along $x=0$ and $y=0$.

F3 $L u=\Delta u, u$ is prescribed on $x=0,1, y=0,1, z=0,1, u=f(x) f(y) f(z)$, $f(x)=\left(x^{3 / 4}-x\right)$. The solution has singular first derivatives along $x=0$ and $y=0$.

The relative performance of these programs is seen to be similar to the twodimensional case.
