# A Note on the Midpoint Method of Integration* 

Mark Lotkin<br>AVCO Manufacturing Corp., Stratford, Conn.

When integrating numerically systems of ordinary differential equations of the standard form

$$
\begin{equation*}
y^{\prime}=f(x, y), \quad y\left(x_{0}\right)=y_{0} \tag{1}
\end{equation*}
$$

by difference methods, probably the simplest stable procedure that can be used is Euler's method [1]:

$$
\begin{equation*}
y_{n+1}=y_{n}+h y_{n}^{\prime}, \quad h=x_{n-1}-x_{n} . \tag{2}
\end{equation*}
$$

This method requires only one substitution into the differential equation, and has a truncation error of the order $O\left(h^{2}\right)$.

A prosedure of slightly higher accuracy is due to Heun [2]:

$$
\begin{align*}
& \bar{y}_{n+1}=y_{n}+h y_{n}^{\prime} \\
& \bar{y}_{n+1}^{\prime}=f\left(x_{n+1}, \bar{y}_{n+1}\right)  \tag{3}\\
& y_{n+1}=y_{n}+\frac{1}{2} h\left(y^{\prime}{ }_{n}+\bar{y}_{n+1}^{\prime}\right) .
\end{align*}
$$

Its application requires two substitutions into eq. (1), but its truncation error is $O\left(h^{3}\right)$.

An alternate method of great simplicity, namely the "midpoint" method, which seems to be in favor in some places, makes use of the following relationships:

$$
\begin{align*}
& y_{n+\frac{1}{3}}=y_{n}+\frac{1}{2}\left(y_{n}-y_{n-1}\right)  \tag{4}\\
& y_{n+\frac{1}{2}}^{\prime}=f\left(x_{n+\frac{1}{2}}, y_{n+\frac{1}{3}}\right)  \tag{5}\\
& y_{n+1}=y_{n}+h y^{\prime}{ }_{n+\frac{1}{3}} . \tag{6}
\end{align*}
$$

Thus it necessitates only one substitution into eq. (1), and consequently requires essentially the same amount of computational labor that is involved in Euler's method. However, it has an accuracy that is comparable with that of Heun's method.

To substantiate this claim, we assume that the numerical information available at $x_{n-1}, x_{n}$ is correct. Let us denote the exact solution by $y(x)$. Then we put

$$
\begin{aligned}
& y_{n+\frac{1}{3}}=y\left(x_{n}+\frac{1}{2} h\right)+T_{1} \\
& y^{\prime}{ }_{n+\frac{1}{2}}=f\left(x_{n}+\frac{1}{2} h, y\left(x_{n}+\frac{1}{2} h\right)\right)+T_{2} \\
& y_{n+1}=y\left(x_{n+1}\right)+T_{n n} .
\end{aligned}
$$

*Received January, 1956.

Now, by (4),

$$
y_{n+\frac{1}{3}}=y\left(x_{n}\right)+\frac{1}{2}\left[y\left(x_{n}\right)-y\left(x_{n-1}\right)\right],
$$

and since

$$
y\left(x_{n}\right)-y\left(x_{n-1}\right)=h y^{\prime}\left(x_{n}\right)-\frac{1}{2} h^{2} y^{\prime \prime}\left(x_{n}\right)+O_{1}\left(h^{3}\right)
$$

it follows that

$$
y_{n_{+1}}=y\left(x_{n}\right)+\frac{1}{2} h y^{\prime}\left(x_{n}\right)-\frac{1}{4} h^{2} y^{\prime \prime}\left(x_{n}\right)+O_{2}\left(h^{3}\right) .
$$

On the other hand, the exact expansion is

$$
y\left(x_{n}+\frac{1}{2} h\right)=y\left(x_{n}\right)+\frac{1}{2} h y^{\prime}\left(x_{n}\right)+\frac{1}{8} h^{2} y^{\prime \prime}\left(x_{n}\right)+O_{3}\left(h^{3}\right) .
$$

Thus

$$
\begin{equation*}
T_{1}=-\frac{3}{8} h^{2} y^{\prime \prime}\left(x_{n}\right)+O_{4}\left(h^{3}\right) \tag{7}
\end{equation*}
$$

Consequently, by (5),

$$
\begin{aligned}
y_{n+\frac{1}{2}}^{\prime} & =f\left(x_{n}+\frac{1}{2} h, y\left(x_{n}+\frac{1}{2} h\right)+T_{1}\right) \\
& =f\left(x_{n}+\frac{1}{2} h, y\left(x_{n}+\frac{1}{2} h\right)\right)+f_{y} T_{1}+O_{5}\left(h^{4}\right)
\end{aligned}
$$

with the partial derivative $f_{v}$ to be evaluated at $x_{n}+\frac{1}{2} h, y\left(x_{n}+\frac{1}{2} h\right)$. Finally, then, by (6),

$$
y_{n+1}=y\left(x_{n}\right)+h y^{\prime}\left(x_{n}+\frac{1}{2} h\right)+h f_{y} T_{1}+O_{5}\left(h^{5}\right)
$$

However,

$$
y^{\prime}\left(x_{n}+\frac{1}{2} h\right)=y^{\prime}\left(x_{n}\right)+\frac{1}{2} h y^{\prime \prime}\left(x_{n}\right)+\frac{1}{8} h^{2} y^{\prime \prime \prime}\left(x_{n}\right)+O_{6}\left(h^{3}\right)
$$

Therefore,

$$
y_{n+1}=y\left(x_{n}\right)+h y^{\prime}\left(x_{n}\right)+\frac{1}{2} h^{2} y^{\prime \prime}\left(x_{n}\right)+\frac{1}{8} h^{3} y^{\prime \prime \prime}\left(x_{n}\right)+h f_{y} T_{1}+O_{6}\left(h^{4}\right)
$$

This is to be compared with the exact expansion

$$
y\left(x_{n+1}\right)=y\left(x_{n}\right)+h y^{\prime}\left(x_{n}\right)+\frac{1}{2} h^{2} y^{\prime \prime}\left(x_{n}\right)+\frac{1}{6} h^{3} y^{\prime \prime \prime}\left(x_{n}\right)+O_{7}\left(h^{4}\right)
$$

It follows that

$$
\begin{equation*}
T_{M}=-\frac{1}{24} h^{3}\left[y^{\prime \prime \prime}+9 y^{\prime \prime} f_{z}\right]_{n}+O_{M}\left(h^{4}\right) \tag{8}
\end{equation*}
$$

A similar discussion of Heun's method (3) shows that

$$
\begin{equation*}
T_{H}=-\frac{1}{24} h^{3}\left[-2 y^{\prime \prime \prime}+6 y^{\prime \prime} f_{y}\right]_{n}+O_{H}\left(h^{4}\right) \tag{9}
\end{equation*}
$$

Thus both methods are exact for differential equations (1) whose solutions are polynomials of degree not exceeding two.

It is not too difficult to think of cases where the midpoint method is more accurate than Heun's method. Such a case is

$$
\begin{equation*}
y^{\prime}=\left(1+y^{2}\right)^{-1}, \quad y(0)=0 \tag{10}
\end{equation*}
$$

in the interval $0 \leqq x \leqq 1.0$. The integrations, carried out for $h=0.1$, are shown in Table 1. Results due to Euler's, Heun's, and the midpoint method are listed in columns (1), (2), (3), respectively. The exact solution $y^{3}+3 y-3 x=0$ is tabulated in the next column. The resulting errors $E_{B}=y_{B}-y(x), E_{H}=$ $y_{B}-y(x)$, and $E_{M}=y_{M}-y(x)$ are exhibited in columns (5), (6), (7); they bear out the claim made above.

Of interest is also the closeness of the leading terms in the expressions (8) and (9). In the case of equation (10) it turns out that

$$
\begin{aligned}
& T_{H} \approx-\frac{1}{6} h^{3}\left(y^{\prime}\right)^{4} \\
& T_{H} \approx-\frac{1}{12} h^{3}\left(y^{\prime}\right)^{4}\left[-1+24 y^{2} y^{\prime}\right]
\end{aligned}
$$

Integrations starting with $y(1.0)$ yead to the values at $x=1.1$ shown in Table 1 below the line. Therefore,

$$
T_{B} \approx-2.1 \times 10^{-5}, \quad T_{M} \approx-9.5 \times 10^{-5}
$$

while the exact values for truncation (and rounding) are

$$
T_{\text {H }}=-1.8 \times 10^{-5}, \quad T_{M}=-9.1 \times 10^{-5} .
$$

The truncation expressions in (8) and (9) are thus sufficiently close to be of practical utility.

In conclusion it might be stated that the midpoint method defined by equations (4), (5), (6) is only a special case of a whole class of such methods:

$$
\begin{aligned}
y_{n+\theta} & =y_{n}+\theta\left(y_{n}-y_{n-1}\right), \quad 0<\theta<1 \\
y^{\prime}{ }_{n+\theta} & =f\left(x_{n+\theta}, y_{n+\theta}\right) \\
y_{n+1} & =y_{n}+\alpha h y^{\prime}{ }_{n+\theta},
\end{aligned}
$$

with $\alpha$ and $\theta$ denoting constants. For $\alpha=1$ and $\theta=\frac{1}{2}$ this method has a truncation error of the order $O\left(h^{3}\right)$; for other values of $\alpha$ or $\theta$ the truncation error is of lower order.
