

ALGORITHM 604

A FORTRAN Program for the Calculation of an Extremal Polynomial

FREDERICK W. SAUER

MRC, University of Wisconsin

Categories and Subject Descriptors: G.1.2 [Numerical Analysis] Approximation—*minimax approximation and algorithms*; G.1.3 [Numerical Analysis] Numerical Linear Algebra—*linear systems (direct and iterative methods)*, G.m [Mathematics of Computing]. Miscellaneous—*FORTRAN*

General Terms: Algorithms

Additional Key Words and Phrases: Remes, extremal polynomial, Richardson iteration

DESCRIPTION

Let S be the union of finitely many compact intervals in $\mathbf{R}$ such that $S \cap (-\infty, 0] \neq \emptyset$, $S \cap [0, +\infty) \neq \emptyset$, and $0 \notin S$. Let λ be the linear functional on π_n (π_n := the polynomials of degree n or less) whose value at p is $p(0)$. An *extremal* for λ is any polynomial of norm 1 at which λ takes on its norm, that is, $p \in \pi_n$, $\|p\|_S = 1$, and $\lambda p = \|\lambda\|$. Here

$$\|p\|_S := \max_{s \in S} |p(s)|$$

and

$$\|\lambda\| := \sup_{p \in \pi_n, \|p\|_S = 1} |\lambda p| = 1/\min\{\|p\|_S : p \in \pi_n, p(0) = 1\}.$$

In [1] it is proved that for a given S and n there exists a unique extremal polynomial. The program presented here is a FORTRAN implementation of the Remes algorithm outlined in [1] to calculate the extremal polynomial given S and n .

The extremal polynomial can be used for the determination of the iteration parameters α_n for Richardson's iteration

$$\mathbf{x}^{n+1} = \mathbf{x}^n - \alpha_n (A\mathbf{x}^n - \mathbf{b})$$

to solve a linear system of equations $Ax = b$. Defining $e^n := x^n - x$, the error in the n th iterate, we have

$$e^n = (1 - \alpha_{n-1}A)e^{n-1} = \dots = \prod_{j=1}^n (1 - \alpha_{j-1}A)e^0 = Q_n(A)e^0,$$

where Q_n is the polynomial of degree n , which vanishes at $1/\alpha_0, \dots, 1/\alpha_{n-1}$ and is 1 at 0. If the spectrum of A is known to lie in some compact set S , then one should choose the parameters so as to minimize $\|Q_n\|_S$; that is, one should choose the parameters to be the inverse of the roots of the extremal polynomial for n and S . The resulting polynomial P_n is then the error in the *best Chebyshev approximation on S from $\{\sum_{j=1}^n \beta_j t^j\}$* .

A description of how to use this program is given in the comments in subroutine **EXTREM**. In addition, two sample programs are provided. The first is a simple example how **EXTREM** can be called. The second uses Richardson's iteration to solve the linear system $(B^2 - \mu I)x = b$, with $\mu = \sqrt{3}$ and B the tridiagonal matrix with 2 on the diagonal and -1 on the off-diagonals.
