A New Immersed Finite Element Method for Two-Phase Stokes Problems Having Discontinuous Pressure

https://doi.org/10.1515/cmam-2022-0122 Received June 9, 2022; revised December 13, 2022; accepted March 1, 2023

Abstract: In this paper, we develop a new immersed finite element method (IFEM) for two-phase incompressible Stokes flows. We allow the interface to cut the finite elements. On the noninterface element, the standard Crouzeix–Raviart element and the P_0 element pair is used. On the interface element, the basis functions developed for scalar interface problems (Kwak et al., An analysis of a broken P_1 -nonconforming finite element method for interface problems, *SIAM J. Numer. Anal.* (2010)) are modified in such a way that the coupling between the velocity and pressure variable is different. There are two kinds of basis functions. The first kind of basis satisfies the Laplace–Young condition under the assumption of the continuity of the pressure variable. In the second kind, the velocity is of bubble type and is coupled with the discontinuous pressure, still satisfying the Laplace–Young condition. We remark that in the second kind the pressure variable has two degrees of freedom on each interface element. Therefore, our methods can handle the discontinuous pressure case. Numerical results including the case of the discontinuous pressure variable are provided. We see optimal convergence orders for all examples.

1 Introduction

Recently, there have emerged many unfitted grid methods to solve interface problems involving interface between two materials. The extended finite element method (XFEM) [4, 5, 8, 21, 26, 27, 29] is one of the popular methods to solve for interface/crack problems based on uniform grids. Some additional basis functions constructed by truncating the shape function along the interfaces are added to the trial/test spaces. Thus, the number of degrees of freedom increase near the interface. For Stokes interface problems, Gross and Reusken proposed a method that adopt an XFEM enrichment of the pressure space, incorporating functions that are discontinuous at the interface in [9, 10, 28].

Meanwhile, Hansbo et al. introduced a so-called cut-FEM, combining XFEM and Nitche's method for elliptic interface problems [3, 11]. For the Stokes interface problem, an iso P_2 - P_1 element based cut-FEM-type method was proposed [12] where ghost penalty stabilization is used near the interface to avoid instabilities. Also, Wang and Chen introduced the P_1 -nonconforming based cut-FEM method for Stokes interface problems [31], where stabilization terms defined on the transmission edges are used to ensure stability condition. However, all of the methods mentioned above require additional degrees of freedom than the nodal basis functions.

On the other hand, Z. Li et al. [22, 23] introduced the immersed finite element method (IFEM) for elliptic problems, where the basis functions are modified to satisfy the flux-type continuity conditions along the interface. The advantage of this scheme is that it does not require additional basis functions. Since then, the error estimates for IFEMs were developed for various elliptic interface problems, see [6, 14, 19, 24] and references therein. The Crouzeix–Raviart P_1 -nonconforming based IFEMs [19] were used to solve elasticity interface problems in [18]. Also, IFEMs have been applied to various problems, including plasma particle simulation, electric field simulation in composite materials, electroencephalography, fluid-structure interaction, multiphase flows in porous media, elasticity, and Poisson–Boltzmann equation [13, 15, 17, 20, 25, 30, 32].

For Stokes equations, Adjerid et al. [1, 2] introduced the immersed discontinuous finite element method, which uses modified Q_1/Q_0 basis functions in the frame work of discontinuous Galerkin methods. The velocity and pressure variables are modified on the interface element so that the basis functions satisfy Laplace–Young condition (see details in [1, 2]). An IFEM based on P_1/Q_1 nonconforming elements is introduced in [16], where the modification process is similar to [1, 2]. We remark that the pressure variable in the immersed finite element (IFE) space of [1, 2] or [16] uses the average (on each element) as degrees of freedom on the interface element. Clearly, these elements cannot approximate the pressure variable in general.

In this paper, we develop a new P_1 -nonconforming based IFEM for Stokes interface problems where modification of basis functions are different from that in [1] or [16]. On the interface element, we construct two kinds of basis functions for the velocity variables. First kind is related to the continuous pressure. Second kind is of bubble type in the sense that velocity variables has vanishing averages on the edges, and it satisfies the Laplace–Young condition for discontinuous pressure. In this way, we construct velocity basis on interface element which is less coupled to pressure basis compared with [1] or [16]. Another aspects of our IFE space is that the pressure basis has two degrees of freedom on the interface element so that it can handle the discontinuity of pressure variable. For the bilinear form, we add stabilization terms across edges as in [12, 18] to make the system stable. The numerical examples including the case of the discontinuous pressure variable are provided. We see optimal convergence rates for both the pressure and velocity variables.

The rest of the paper is organized as follows. We describe an incompressible Stokes interface problem in Section 2 and develop IFEM for the Stokes problems in Section 3. Numerical experiments are reported in Section 4 and the conclusion follows in Section 5.

2 A Model Problem

Let Ω be a connected polygonal domain in \mathbb{R}^2 which is divided into two subdomains Ω^+ and Ω^- by a C^2 interface $\Gamma = \partial \Omega^+ \cap \partial \Omega^-$ (see Figure 1). We assume that subdomains are filled with two incompressible fluids of different viscosities. The equation describing the steady-state of such fluids is given by

$$-\operatorname{div}\boldsymbol{\sigma} = \boldsymbol{f} \qquad \text{in } \Omega^+ \cup \Omega^-, \qquad (2.1a)$$

$$\sigma(\mathbf{u}, p) = 2\mu\epsilon(\mathbf{u}) - p\mathbf{I} \quad \text{in } \Omega^+ \cup \Omega^-, \tag{2.1b}$$

$$\operatorname{div} \mathbf{u} = 0 \qquad \qquad \operatorname{in} \, \Omega^+ \cup \Omega \ , \tag{2.1c}$$

$$\mathbf{u} = \mathbf{g}$$
 on $\partial \Omega$ (2.1d)

with the interface conditions

$$\llbracket \mathbf{u} \rrbracket_{\Gamma} = 0 \quad \text{on } \Gamma, \tag{2.2a}$$

$$\llbracket \boldsymbol{\sigma}(\mathbf{u}, p) \cdot \mathbf{n} \rrbracket_{\Gamma} = 0 \quad \text{on } \Gamma, \tag{2.2b}$$

where $\boldsymbol{\epsilon}(\mathbf{u}) = \frac{1}{2}(\nabla \mathbf{u} + \nabla \mathbf{u}^T)$ is the strain tensor, the vector \boldsymbol{f} is a body force, $\mu > 0$ is a piecewise constant function of the viscosity

$$\mu = \begin{cases} \mu^+ & \text{in } \Omega^+, \\ \mu^- & \text{in } \Omega^-, \end{cases}$$

Figure 1: A domain Ω with an interface Γ .

and **n** is the outward unit normal vector to Γ . For the simplicity, we may assume $\mathbf{g} = 0$. The bracket $[\![\cdot]\!]_{\Gamma}$ means the jump across the interface

$$\llbracket u \rrbracket_{\Gamma} := u |_{\Omega^-} - u |_{\Omega^+}.$$

We use standard Sobolev space notations (see Section 4). Multiplying $\mathbf{v} \in H_0^1(\Omega)^2$ to the left-hand side of equation (2.1a), we get by Green's formula

$$\sum_{s=+,-} \left(-2\mu \int_{\Omega^{s}} \sum_{i,j} \frac{\partial \epsilon_{ij}(\mathbf{u})}{\partial x_{j}} v_{i} + \int_{\Omega^{s}} \sum_{i} \frac{\partial p}{\partial x_{i}} v_{i} \right)$$

$$= \sum_{s=+,-} \int_{\Omega^{s}} \left(2\mu \boldsymbol{\epsilon}(\mathbf{u}) : \boldsymbol{\epsilon}(\mathbf{v}) - \int_{\Omega^{s}} p \operatorname{div} \mathbf{v} \right) \mathrm{d}x + \sum_{s=+,-} \left(\int_{\partial \Omega^{s}} (p\mathbf{n} - 2\mu \boldsymbol{\epsilon}(\mathbf{u})\mathbf{n}) \cdot \mathbf{v} \right).$$
(2.3)

Using the jump conditions (2.2a) and (2.2b), we obtain the following variational formulation of problem (2.1a) and (2.1c): Find the velocity $\mathbf{u} \in (H_0^1(\Omega))^2$ and the pressure $p \in L_0^2(\Omega)$ satisfying

$$a(\mathbf{u}, \mathbf{v}) - b(\mathbf{v}, p) = (\mathbf{f}, \mathbf{v}) \quad \text{for all } \mathbf{v} \in H_0^1(\Omega)^2,$$
(2.4a)
$$b(\mathbf{u}, q) = 0 \qquad \text{for all } q \in L_0^2(\Omega),$$
(2.4b)

where

$$\begin{aligned} a(\mathbf{u}, \mathbf{v}) &\coloneqq \sum_{s=+, -\sum_{\Omega^s}} \int 2\mu \boldsymbol{\epsilon}(\mathbf{u}) : \boldsymbol{\epsilon}(\mathbf{v}) \, \mathrm{d}x \\ b(\mathbf{u}, p) &\coloneqq \sum_{s=+, -\sum_{\Omega^s}} \int p \, \mathrm{div} \, \mathbf{u} \, \mathrm{d}x. \end{aligned}$$

3 An IFEM Based on the Crouzeix–Raviart Element

Let $\{\mathcal{T}_h\}$ be a any structured triangulations of Ω by the triangles of maximum diameter h. We allow the grid to be cut by the interface. We call an element $T \in \mathcal{T}_h$ an *interface element* if the interface Γ passes through the interior of T, otherwise we call it a *noninterface* element. Let \mathcal{T}_h^I be the collection of all interface elements.

Let the collection of all the edges of $T \in \mathcal{T}_h$ be denoted by \mathcal{E}_h . We denote the set of edges cut by the interface Γ by \mathcal{E}_h^I , its complement is denoted by \mathcal{E}_h^N . Even though the interface Γ is a curve in general, we replace for the simplicity of presentation, the part of interface in T by the line segment connecting the intersection points with ∂T . Therefore, the interface Γ is assumed to be polygonal for the rest of the paper.

3.1 Construction of IFEM Basis for Stokes Interface Problem

For the noninterface elements, we use the classical Crouzeix–Raviart element [7] for the velocity variable which consists of piecewise linear polynomials whose degrees of freedom are the average value along each edge. In

Figure 2: A typical interface triangle.

other words, for $T \in \mathcal{T}_h \setminus \mathcal{T}_h^I$, let $\mathbf{N}_h(T)$ denote the linear space spanned by the six Lagrange basis functions, $\boldsymbol{\phi}_i = (\phi_{i1}, \phi_{i2})^T$, i = 1, ..., 6,

$$\mathbf{N}_{h}(T) = \operatorname{span}\left\{\boldsymbol{\phi}_{i} \in (P_{1})^{2} : \frac{1}{|\boldsymbol{e}_{j}|} \int_{\boldsymbol{e}_{j}} \boldsymbol{\phi}_{i1} = \delta_{ij}, \ j = 1, 2, 3, \ \frac{1}{|\boldsymbol{e}_{j}|} \int_{\boldsymbol{e}_{j}} \boldsymbol{\phi}_{i2} = \delta_{i-3,j}, \ j = 4, 5, 6\right\}.$$
(3.1)

We define the pressure space $M_h(T) \equiv P_0(T)$ to be the space of constant on *T*.

Now, we consider the interface elements. We adopt the broken P_1 -nonconforming finite element introduced in [18, 19] for the velocity. For the pressure we use two pieces of piecewise constant function for the interface element. An important property of the IFEM basis is that it should satisfy the Laplace–Young condition (2.2b) at least weakly. For that purpose, we shall construct two kinds of basis functions: The first kind is unrelated to the pressure; the second kind is coupled with pressure. We assume the three vertices are given by $A_1 = (0, 1)$, $A_2 = (0, 0)$, $A_3 = (1, 0)$ (see Figure 2). For any interface element $T \in \mathcal{T}_h^I$ in general position, all the constructions to be presented below carries over through affine equivalence. Let \overline{DE} be the line segment connecting the intersections of the interface and the edges of a triangle T. This line segment divides T into two parts T^+ and T^- .

We describe the first type. We set, for i = 1, 2, ..., 6,

$$\boldsymbol{\phi}_{i}(x,y) = \begin{cases} \boldsymbol{\phi}_{i}^{+}(x,y) = \begin{pmatrix} \phi_{i1}^{+} \\ \phi_{i2}^{+} \end{pmatrix} = \begin{pmatrix} a_{1}^{+} + b_{1}^{+}x + c_{1}^{+}y \\ a_{2}^{+} + b_{2}^{+}x + c_{2}^{+}y \end{pmatrix}, & (x,y) \in T^{+}, \\ \boldsymbol{\phi}_{i}^{-}(x,y) = \begin{pmatrix} \phi_{i1}^{-} \\ \phi_{i2}^{-} \end{pmatrix} = \begin{pmatrix} a_{1}^{-} + b_{1}^{-}x + c_{1}^{-}y \\ a_{2}^{-} + b_{2}^{-}x + c_{2}^{-}y \end{pmatrix}, & (x,y) \in T^{-}, \end{cases}$$
(3.2)

and require these functions satisfy the six degrees of freedom (3.1), the continuity condition (2.2a), and the Laplace–Young condition with zero pressure along the interface $\Gamma \cap T$. In other words, let

$$\widehat{\mathbf{N}}_{h}(T) = \operatorname{span}\{\boldsymbol{\phi}_{i}^{s} \in (P_{1}(T^{s}))^{2}, s = +, -, \text{ satisfying (3.4) below}\},$$
(3.3)

where

$$\frac{1}{|e_j|} \int_{e_j} \phi_{i1} = \delta_{ij}, \qquad j = 1, 2, 3,$$
(3.4a)

$$\frac{1}{|e_j|} \int_{e_j} \phi_{i2} = \delta_{i-3,j}, \quad j = 4, 5, 6,$$
(3.4b)

$$\llbracket \boldsymbol{\phi}_i \rrbracket_{\Gamma} = 0, \tag{3.4c}$$

$$\llbracket 2\mu\boldsymbol{\sigma}(\boldsymbol{\phi}_i, 0) \cdot \mathbf{n} \rrbracket_{\Gamma} = 0. \tag{3.4d}$$

We state a proposition regarding the existence and uniqueness of the basis functions.

Proposition 3.1. The function $\hat{\phi}$ in (3.2) is determined uniquely by conditions (3.4).

Proof. The proof can be found in [18].

Now, we define the global IFE space $\widehat{\mathbf{N}}_h$ for the velocity variable to be the set of all functions satisfying

$$\begin{cases} \phi|_T \in \mathbf{N}_h(T) & \text{if } T \text{ is a noninterface element,} \\ \phi|_T \in \mathbf{N}_h(T) & \text{if } T \text{ is an interface element,} \\ \int_e^{e} \phi_1|_{T_1} = \int_e^{e} \phi_1|_{T_2} & \text{if } e \text{ is the common edges of } T_1 \text{ and } T_2, \\ \int_e^{e} \phi_2|_{T_1} = \int_e^{e} \phi_2|_{T_2} & \text{if } e \text{ is the common edges of } T_1 \text{ and } T_2, \\ \int_e^{e} \phi = 0 & \text{if } e \in \partial T \text{ is a part of the boundary } \partial \Omega. \end{cases}$$

We also need the usual space of piecewise constant for all *T* for pressure:

$$M_{h,0} = \{p_h \in L^2_0(\Omega) : p_h|_T \in P_0(T) \text{ for all } T \in \mathcal{T}_h\}.$$

However, the space $\widehat{N}_h \times M_{h,0}$ cannot satisfy the interpolation property for the pressure when pressure variable is discontinuous across the interface.

Now, we describe the second type of basis functions. Given a typical interface element *T*, we take $\phi^{E}(x, y)$ as in (3.2) and set the piecewise constant pressure as

$$p^{E}(x,y) = \begin{cases} p^{+}, & (x,y) \in T^{+}, \\ p^{-}, & (x,y) \in T^{-}, \end{cases}$$
(3.5)

and require the pair (ϕ^E, p^E) satisfy the following conditions:

$$\frac{1}{|e_j|} \int_{e_j} \phi_1^E = 0, \qquad j = 1, 2, 3, \qquad (3.6a)$$

$$\frac{1}{|e_j|} \int_{e_i} \phi_2^E = 0, \qquad j = 1, 2, 3, \qquad (3.6b)$$

$$\boldsymbol{\phi}^E]\!]_{\Gamma} = 0, \tag{3.6c}$$

$$[\![2\boldsymbol{\mu}\boldsymbol{\epsilon}(\boldsymbol{\phi}^{E})\cdot\mathbf{n}]\!]_{\Gamma} = [\![\boldsymbol{p}^{E}\cdot\mathbf{n}]\!]_{\Gamma}.$$
(3.6d)

This is a system of twelve equations in fourteen unknowns. We add the following equations:

 \llbracket

$$p^+ = 1$$
 on T^+ , (3.7a)

$$p^- = 0 \quad \text{on } T^-.$$
 (3.7b)

The fourteen conditions (3.6)–(3.7) lead to a system of linear equations in fourteen unknowns $a_{\ell}^s, b_{\ell}^s, c_{\ell}^s, p^s, \ell = 1, 2, s = +, -$.

Proposition 3.2. Systems (3.6)–(3.7) have a unique solution pair (ϕ^E , p^E).

Proof. For each $p^E = (p^+, p^-)$ satisfying (3.7a)–(3.7b), the system of equations (3.6a)–(3.6d) is exactly the same as (3.4a)–(3.4d) with modified right-hand side. Hence the existence proof is the same.

Changing the role of p^+ and p^- in (3.7a)–(3.7b), we obtain another enriched pair of functions for the interface element *T*. If $p^+ = 1$ on T^+ and $p^- = 0$ on T^- in (3.7), we denote the pair as $(\phi_T^{E^+}, p_T^{E^+})$. On the other hands, if $p^+ = 0$ on T^+ and $p^- = 1$ on T^- , we denote the pair as $(\phi_T^{E^-}, p_T^{E^-})$. We name the set of such pairs as $E_h(T)$, i.e.,

$$E_h(T) := \operatorname{span}\{(\phi_T^{E^+}, p_T^{E^+}), (\phi_T^{E^-}, p_T^{E^-})\}.$$

By combining $\widehat{\mathbf{N}}_h \times M_h$ and the above bubble-type pairs, we define the immersed finite element space Ψ_h for Stokes equation to be set of pairs of functions (ϕ , ψ) satisfying

$$\begin{aligned} (\phi, \psi)|_T \in \mathbf{N}_h(T) \times M_h(T) & \text{if } T \text{ is a noninterface element,} \\ (\phi, \psi)|_T \in \widehat{\mathbf{N}}_h(T) \times \{0\} \oplus E_h(T) & \text{if } T \text{ is an interface element,} \\ \int_e^{\tau} \phi_1|_{T_1} &= \int_e^{\tau} \phi_1|_{T_2} & \text{if } e \text{ is the common edges of } T_1 \text{ and } T_2, \\ \int_e^{\tau} \phi_2|_{T_1} &= \int_e^{\tau} \phi_2|_{T_2} & \text{if } e \text{ is the common edges of } T_1 \text{ and } T_2, \\ \int_e^{\tau} \phi = 0 & \text{if } e \in \partial T \text{ is a part of the boundary } \partial \Omega, \\ \psi \in L_0^2(\Omega). \end{aligned}$$

We give some remarks regarding the proposed space.

Remark 3.1. The space Ψ_h is not equal to the IFE space proposed in [16]. Consider a typical interface element *T*. The pressure variable of Ψ_h has degrees of freedom on each subregion T^s (s = +, -), while the pressure variable in IFE space of [16] has one (average) degree of freedom on the whole *T*. An advantage of our scheme is that one can handle discontinuous pressure (see next section).

We give a lemma regarding the satisfaction of Laplace-Young condition.

Lemma 3.3. For any pair of functions (ϕ, ψ) in Ψ_h , we have $[\![\sigma(\phi, \psi) \cdot \mathbf{n}]\!]_{\Gamma} = 0$.

Proof. It suffices to consider interface element only. Suppose (ϕ, ψ) is any pair of basis functions in Ψ_h and let *T* be any interface element. We can decompose it as

$$(\boldsymbol{\phi}, \boldsymbol{\psi})|_T = (\mathbf{v}^0, 0) + (\mathbf{v}^E, \boldsymbol{\psi}),$$

where $\mathbf{v}^0 \in \widehat{\mathbf{N}}_h^0(T)$ and \mathbf{v}^E is velocity part of pairs $E_h(T)$, i.e., $(\mathbf{v}^E, \psi) \in E_h(T)$. Then

$$\llbracket \boldsymbol{\sigma}(\boldsymbol{\phi}, \boldsymbol{\psi}) \cdot \mathbf{n} \rrbracket_{T \cap \Gamma} = \llbracket \boldsymbol{\sigma}(\mathbf{v}^0, 0) \cdot \mathbf{n} \rrbracket_{T \cap \Gamma} + \llbracket \boldsymbol{\sigma}(\mathbf{v}^E, \boldsymbol{\psi}) \cdot \mathbf{n} \rrbracket_{T \cap \Gamma} = 0,$$

by the definitions of the space $\widehat{\mathbf{N}}_h^0$ and $E_h.$ This completes the proof.

The Associated Variational Form

We define the associated variational form for problem (2.1). For this purpose, we let

$$\mathbf{H}_h(\Omega) := (H_0^1(\Omega))^2 + (\text{velocity part of } \Psi_h).$$

We define two bilinear forms

$$a_{h}(\mathbf{u},\mathbf{v}) := \sum_{T \in \mathcal{T}_{h}} \left(\int_{T \cap \Omega^{-}} 2\mu \boldsymbol{\epsilon}(\mathbf{u}) : \boldsymbol{\epsilon}(\mathbf{v}) \, \mathrm{d}x + \int_{T \cap \Omega^{+}} 2\mu \boldsymbol{\epsilon}(\mathbf{u}) : \boldsymbol{\epsilon}(\mathbf{v}) \, \mathrm{d}x \right) + \sum_{\boldsymbol{e} \in \mathcal{E}_{h}^{N}} \frac{\gamma}{|\boldsymbol{e}|} \int_{\boldsymbol{e}} \llbracket \mathbf{u} \rrbracket_{\boldsymbol{e}} \llbracket \mathbf{v} \rrbracket_{\boldsymbol{e}} \, \mathrm{d}s, \tag{3.8}$$

$$b_h(\mathbf{u},\psi) := -\sum_{T \in \mathcal{T}_h} \left(\int_{T \cap \Omega^-} \psi \operatorname{div} \mathbf{u} \, \mathrm{d}x + \int_{T \cap \Omega^+} \psi \, \mathrm{div} \, \mathbf{u} \, \mathrm{d}x \right), \tag{3.9}$$

where $\mathbf{u}, \mathbf{v} \in \mathbf{H}_h(\Omega)$ and $\psi \in L^2(\Omega)$. Here, $\llbracket \cdot \rrbracket_e$ denotes the jump along the edge *e* and *y* is some positive parameter. We remark that we need stability terms in $a_h(\cdot, \cdot)$ to ensure a coercivity property as in [18].

Finally, we propose IFEM scheme for Stokes problem: Find (\mathbf{u}_h, p_h) in Ψ_h such that

$$a_h(\mathbf{u}_h, \mathbf{v}_h) - b_h(\mathbf{v}_h, p_h) = (\mathbf{f}, \mathbf{v}_h)$$
$$b_h(\mathbf{u}_h, q_h) = 0$$

for all (\mathbf{v}_h, q_h) in Ψ_h .

4 Numerical Results

In this section, we present numerical examples. The errors in L^2 and H^1 norms for the velocity and pressure variables are reported on a rectangular domain. The numerical simulations are carried out on uniform triangulation \mathcal{T}_h by right triangles having size $h = h_0 \cdot 2^{-k}$ (k = 1, 2, ...) for some h_0 . We define the interface as the zero set of some level function L(x, y) which is used to separate sub-domains, i.e., $\Omega^- = \{(x, y) \in \Omega : L(x, y) < 0\}$ and $\Omega^+ = \{(x, y) \in \Omega : L(x, y) > 0\}$. We consider three problems. In first two examples, some known exact solutions are given to satisfy the Laplace–Young condition. In particular, we consider the case of discontinuous pressure variable in Example 4.1. In the third example, we consider a *driven cavity* benchmark problem.

In all the examples, we choose penalty parameter $\gamma = 20\mu$ in (3.8). In Example 4.1 and Example 4.2 we observe the optimal orders of error.

Example 4.1. In this example, the interface is given by zero sets of L(x, y) = x + y - r = 0 with r = -0.1. The parameters are $\mu^- = 10$ and $\mu^+ = 0.1$. Exact solutions are

$$\mathbf{u} = \begin{cases} \left((x+y-r)e^{(x+y-r)^2} + y^2, -(x+y-r)e^{(x+y-r)^2} + x^2 \right)^T & \text{on } \Omega^+, \\ \left(\frac{\mu^+(e^{x+y-r}-1) + \mu^- y^2}{\mu^-}, \frac{\mu^- x^2 - \mu^+(e^{x+y-r}-1)}{\mu^-} \right)^T & \text{on } \Omega^-. \end{cases}$$
$$p = \begin{cases} p_0 & \text{on } \Omega^+, \\ 2(\mu^+ - \mu^-)(x+y) + p_0 & \text{on } \Omega^-, \end{cases} \text{ where } p_0 = 5.220703125. \end{cases}$$

The errors in L^2 and H^1 norms for \mathbf{u}_h and L^2 error for p_h are reported in Table 1. We observe that both variables converge in optimal orders. The graphs of $u_{h,1}$, $u_{h,2}$ and p_h are shown in Figure 3.

Figure 3: Plots of $u_{h,1}$ (left), $u_{h,2}$ (right) and pressure (bottom) for Example 4.1.

$\frac{1}{h}$	$\ \mathbf{u}-\mathbf{u}_h\ _0$	Order	$\ \mathbf{u}-\mathbf{u}_h\ _{1,h}$	Order	$\ \boldsymbol{p}-\boldsymbol{p}_h\ _0$	Order

Table 1: L^2 and H^1 errors for the velocity and pressure variables of Example 4.1.

Example 4.2. The interface is the zero set of $L(x, y) = x^2 + y^2 - r^2$ with r = 0.31. The parameters are $\mu^- = 1$ and $\mu^+ = 100$. The exact solutions are

$$\mathbf{u} = \begin{cases} \left(\frac{1}{\mu^{+}}2(x^{2}+y^{2}-r^{2})y, -\frac{1}{\mu^{+}}2(x^{2}+y^{2}-r^{2})x\right)^{T} & \text{on } \Omega^{+}, \\ \left(\frac{1}{\mu^{-}}2(x^{2}+y^{2}-r^{2})y, -\frac{1}{\mu^{-}}2(x^{2}+y^{2}-r^{2})x\right)^{T} & \text{on } \Omega^{-}, \end{cases}$$

$$p = 100xy.$$

Errors for \mathbf{u}_h and p_h are reported in Table 2. We see the optimal convergence. The graphs of the vector field and the pressure variable are shown in Figure 4.

Example 4.3 (Driven Cavity). We consider a well-known driven cavity problem. The following Dirichlet boundary condition is imposed: $\mathbf{u} = [0, 1]$ on y = 1 and $\mathbf{u} = [0, 0]$ if x = -1, x = 1 or y = -1. The interface is the zero

Figure 4: Plots of velocity field (left) and pressure (right) for Example 4.2.

$\frac{1}{h}$	∥u – u _h ∥₀	Order	$\ \mathbf{u}-\mathbf{u}_h\ _{1,h}$	Order	$\ \boldsymbol{p}-\boldsymbol{p}_h\ _0$	Order
2 ⁰	2.009×10 ⁻¹		1.398×10 ⁰		3.724×10 ¹	
2 ¹	1.313×10 ⁻²	3.935	1.185×10 ⁻¹	3.560	1.983×10 ¹	0.910
2 ²	8.338×10 ⁻³	0.655	1.331×10 ⁻¹	-0.168	1.024×10 ¹	0.953
2 ³	3.063×10 ⁻³	1.445	6.676×10 ⁻²	0.995	5.159×10 ⁰	0.989
24	1.233×10 ⁻³	1.313	4.384×10 ⁻²	0.607	2.591×10 ⁰	0.994
25	2.945×10 ⁻⁴	2.066	1.948×10 ⁻²	1.170	1.295×10 ⁰	1.001
2 ⁶	7.415×10 ⁻⁵	1.990	8.895×10 ⁻³	1.131	6.472×10 ⁻¹	1.000
27	1.844×10 ⁻⁵	2.008	4.064×10 ⁻³	1.130	3.235×10 ⁻¹	1.001

Table 2: L^2 and H^1 errors for the velocity and pressure variables of Example 4.2.

Figure 5: Graphs of the velocity field (left) and the pressure variable (right) for Example 4.3.

set of $L(x, y) = x^2 + y^2 - 0.4^2$ and the parameters are $\mu^- = 1$ and $\mu^+ = 100$. Finally, we let the forcing vector $\mathbf{f} = (0, 1)^T$ on the right-hand side of (2.1a). The graphs of the vector field and the pressure variable are shown in Figure 5. We see that there is no spurious oscillation near the interface for both the velocity and pressure variable.

5 Conclusion and Future Work

In this work, we have developed a new IFEM for Stokes interface problems by modifying Crouzeix–Raviart element. We introduce two kinds of basis functions in such a way that the coupling between the velocity and pressure variable is different. First basis functions are constructed under the assumption of the continuity of the pressure variable. In the second kind, a bubble-type velocity variable is coupled with the discontinuous pressure variable. In each case, basis functions satisfy the Laplace–Young condition. Also, the pressure variable has two degrees of freedom on each interface element. Therefore, our methods can handle the discontinuous pressure case. We observe optimal convergence rates for all numerical examples.
