Figure 6 represents the 'tendering process' ontology of the Ontologging (www.ontologging.com) system. In a more sophisticated approach, the system is in charge with the selection of relevant knowledge assets for the user (the most suited items). The system evaluates how closed the knowledge assets match the user's background and interests, and it presents the best ones. In an ontology-based KMS, the system selects the concepts that match the user's background and interests. A sub-ontology of the domain ontology is further displayed to the user. Such techniques for selection of relevant items according to the user's profiles were described by Ardissono and Goy (2000).

Adaptation of Content

The users give different relevance to information and knowledge assets according to their goals, interests, backgrounds, or hobbies. Adaptation of content refers to the process of dynamically tailoring the information that is presented to the different users according to their specific profiles (needs, interests, level of expertise, etc.). The adaptation of content is an added value service as it facilitates the process of filtering and retrieval of relevant information. These techniques of adaptations enable users to spend less time searching and retrieving relevant knowledge. Techniques for adaptation of content are often inspired by the research on intelligent tutoring systems and adaptive explanations. The main objective of intelligent tutoring systems is to tailor and adapt the content of the presented material according to the learner's needs and goals in order to maximise the learning benefits. The user's characteristics and the process of cognitive modelling are the basis for providing support for the learners, for suggesting learning material, and for adapting the learning content to the user's needs. A large range of techniques for adaptation of content for improving online customer relationship are overviewed by Kobsa et al. (2001).

In a KMS, recommender systems, information filtering agents, and collaborative filtering techniques can be explored with the purpose of adaptation of content. More appropriate for the use within KMSs are the following techniques:

- Filtering of content: Techniques for filtering the content help the user to select and retrieve information. Different systems integrate various filtering mechanisms. Amongst the well-known engines enabling filtering and automatic classification of content are: Verity (2003) and Autonomy (2003). For example Autonomy integrates techniques such as: 'active matching and content matching'. Active matching enables users to enter the task and to extract a list of relevant documents for the task at hand. Content matching extracts conceptually related documents.
- Personalised recommendations: Inform users about available relevant information in the system. Recommendations can be provided via human (collaborative filtering) or artificial agents. In the category of recommender systems based on collaborative filtering, Xerox research park developed systems such as KPump and CWall (Snow-

don & Grasso, 2002). KPump allows users to submit recommendations of URLs, local files (via upload), or text. A recommendation consists of a rating and, preferably, a comment, along with the user's classification of the item into one or more communities. In turn, the Knowledge Pump calculates a personalised set of recommendations for a user for each community to which s/he belongs. Communities are built based on domains of interest: "A community is a set of domains of interest plus the people in the organisation with that set of interests."

- Personalised hints for marking presumed interests. Different types of agents can acknowledge to the users new knowledge assets available in the system related to their interests and expertise (notification agents, etc.). Different relevant events can also be delivered to the users based on their interests and hobbies.

Let's have a look at some specific examples. All users interested in a certain domain (knowledge management) can be notified by the agents about various events related to their domain of interests. The domain of interest corresponds to the Interest_area in the user ontology. For instance, let's consider the following event: Mr. Popescu is in charge of a new project in the area of knowledge management. The notification agent system tells all users interested in KM (via a pop-up or via e-mail, depending on their preferences) that:

"George Popescu from Competence Centre team has started a new project in the area of knowledge management."

Another example: when Mr. Ionescu submits a new document into the system, all users interested in KM are notified that:

"A new document related to Knowledge Management authored/submitted by Adrian Ionescu is available in the system."

- Optional detailed information and automatic summarisation: Filtering certain parts of the documents could be provided based on semantic annotations included in the document. For example paragraphs of HTML documents can be annotated in order to enable to adapt the content of the displayed pages according to the user's interests and preferences. Such techniques for tailoring Web pages to the user's needs and interests are presented by many researchers (Signore, Bartoli, & Fresta, 1997; Calvi & De Bra, 1997; Milosavljevic & Oberlander, 1998).

Techniques of automatic summarisation enables the automatic generation of summary from a certain piece of content. Autonomy (2003) is an example of knowledge management system embedding techniques of automatic summarisation. This summary can be displayed by default to the users based on his preferences.

ADAPTATION OF PRESENTATION AND MODALITY

The adaptation of presentation empowers the users to choose between different presentation styles, such as different layouts, skins, or fonts. Other preferences can include the presence or absence of anthropomorphic interface agents, the preferred languages, and so forth. Different types of sorting, bookmarks, and shortcuts can also be included in a high functional system. Adaptation of presentation overlaps in a certain extent with interface customisation. New modalities of information visualisation have recently emerged. These new forms of information visualisation try to go beyond a tree-based view of documents or knowledge assets. Intelligent information portals bring new designs of the user interface with a graphical view representation (Kartoo, Brain, ClusterMap, etc.). The adaptation of modality enables changes from text to other types of media to present the information to the user (image, video, animations, or audio) if they are available in the system. In modern adaptive hypermedia, different types of media can present the same content. The adaptation of modality enables the automatic selection of the media type based on various criteria such as: cognitive style, learning style, preferences, and so forth. The Avanti system (Fink & Kobsa, 2000) explores such changes of modality and different types of adaptations to the user's preferences and to the user's physical abilities.

CONCLUSIONS AND FUTURE TRENDS

Knowledge management systems tend to become high functionality systems as they need to integrate complex business processes. The research on user modelling is motivated by four main reasons: (1) the users are the key element in the management of tacit knowledge; (2) the characteristics and the needs of the individual users are very different (work tasks, expertise, responsibilities, backgrounds); (3) the heterogeneity of the different groups of people (i.e., work units, teams); and (4) user models and user modelling are the basis for achieving personalised interaction and enhanced user support.

Knowledge workers want convivial, simple systems adapted to their specific needs. Personalisation and adaptive features for KMSs are becoming inescapable features of the current KMSs. Personalisation has a utility function and a conviviality function.

From the utility perspective:

- personalisation helps fitting the functionality of the system to the user's needs; and
- personalisation reduces the information overflow by providing users with the most relevant information.

From the conviviality perspective:

- personalisation helps to bridge the gap between the 'designer's view of the system' and the end-user's view of the system, and to take into account the user's preferences.

The main contribution of this work is to demonstrate the role of user modelling in KMSs. This chapter has emphasised the different ways in which user modelling can be applied in a KMS. User modelling has an essential role for enhanced user support within KMSs. Different types of adaptations and personalised services have been presented. It has been shown how user modelling can be used for: personalisation, expertise discovery, networking, collaboration, and learning.

ACKNOWLEDGMENTS

Research for this chapter was partially done within the Ontologging project, an IST-2000-28293 project financed by the EU, as a member of CALT team (Centre of Advanced Learning Technologies) at INSEAD France. Special thanks for feedback, suggestions, and comments on this chapter are due to: Ken Koedinger, Thierry Nabeth, Albert Angehrn, and Bharat Rao.

Chapter 2.13
Integrating Knowledge Management with the Systems Analysis Process

Doron Tauber
Bar-Ilan University, Israel

David G. Schwartz
Bar-Ilan University, Israel

INTRODUCTION

Information systems research has clearly recognized that knowledge management systems (KMSs) have different characteristics and requirements than those of a classic management information system (MIS). Beginning with the relationship drawn between data, information, and knowledge (Alavi & Leidner, 1999, 2001; Bhatt, 2001; Ulrich, 2001; Spiegler, 2000, 2003; Tuomi, 2000), through to the essential nature of unstructured and semi-structured information vs. structured information (Wu, Ling, Lee, & Dobbie, 2001; Lai, Carlsen, Christiansson, & Svidt, 2003; Fensel et al., 2002; Chou & Chow, 2000), there are many elements and areas in which the two diverge.

However although the definition, description, and implementation of a KMS has been recognized as sufficiently distinct from an MIS (Alavi & Leidner, 2001; Hahn & Subramani, 2000; Plass & Salisbury, 2002; Malhotra, 2002), there is no single clear approach to develop a systems analysis and development process that is tailored specifically for a KMS (Alavi & Leidner, 2001; Hahn & Subramani, 2000; Plass & Salisbury, 2002). While the first generation of KMS has been developed as add-on or parallel systems living alongside pre-existing structured management information systems, the next generation of systems development needs to deal with fusion systems. A fusion system (Gray et al., 1997) is a system that integrates structured and unstructured knowledge in real time, allowing for full situational assessment based on both information and knowledge resources.

MIS has a long and illustrious history of research and development focusing on creating and refining the systems analysis process. KMS has no such legacy other than what it has inherited directly from MIS. The purpose of this article is to articulate the unique systems analysis and development issues presented by KMS in organizations, explain why tight integration between MIS and KMS development processes is desirable, and illustrate how such integration can be achieved through a modified Knowledge Integrated Systems Analysis (KISA) process for knowledge management.

The KISA process evolved from a series of action research cycles conducted over an information system development project within the Information Systems Development Department and the Chief Information Office of the Israeli Navy. Beginning with a classic IS development approach, each development cycle added new modifications to the process, until a fully integrated process was reached and then applied, without modification, to new integrated KMS-MIS development. The result is a process that is tailored to the needs of fusion systems. The result is an integrated (knowledge and process) system to support the Navy mission lifecycle.

BACKGROUND

According to Demarco (1978):

Analysis is the study of a problem, prior to taking some action. In the specific domain of computer systems development, analysis refers to the study of some business area or application, usually leading to the specification of a new system. (p. 4)

Whitten, Bentley, and Dittman (2001) state that the systems analyst will study "the problems and needs of an organization to determine how people, data, processes, communications, and information technology can best accomplish improvement for the business" (p. 14). No matter what methodology of system analysis is chosen—structured, information modeling or object-oriented methodology—this statement by Demarco made over 25 years ago is still correct. Although methodology changes, still the systems analyst as specified by Yourdon (1989) is the key member of any systems development project and, in fact, this role has not changed. Sircar, Nerur, and Mahapatra (2001) showed that a controversy exists in the literature about the magnitude and nature of the differences between object-oriented (OO) and structured systems development methods. Some authors, as cited by these researchers, believe that the OO approach is merely an evolution from the structured systems development approaches. Others cited by these researchers claim that OO requires an entirely new approach and mindset; still the researchers' emphasize that the primary task of system analysis within the systems development process is to capture the essence of a real-world system through models. This fundamental task has been incorporated into both the structured and the OO development approaches.

Knowledge in an organization can be characterized as unstructured or semi-structured, whereas information and data are fully structured and can be managed by common information management methods. Estimates show that unstructured and semi-structured information account for about 80% of the information volume within organizations (Corp, 2001; Lindvall, Rus, & Sinha, 2003; Ferrucci & Lally, 2004). Therefore, a structured MIS that aids organizational processes will only be addressing 20% of the information management needs. KM flourishes in this gap. Within this gap, most KM projects place an emphasis on knowledge "stock," which tends to dominate an organization's thinking about knowledge (Fahey & Prusak, 1998). According to Schwartz and Te'eni (2000) and Fisher (1999), the problem is "getting the right knowledge to the right person at the right time," or in other words, "delivery of the knowledge to the point of action where it can be applied to the issue at hand" (Schwartz, Divitini, & Brasethvic, 2000).

However, the "right knowledge" is not necessarily the sole property of the knowledge management domain, nor is it to be wholly found in the management information systems domain. The right knowledge is often a fusion of what resides within an MIS with what resides within a KMS. To produce a full knowledge-based situational assessment, fusion between the different systems is required. We need to look beyond placing knowledge management systems alongside our management information systems and strive to have them tightly integrated or intertwined.

The need to utilize new or revised systems analysis methods is founded upon few basic phenomena. First, over time, systems analysis methods have evolved in response to the growing complexity of software systems (Booch, 1994). The two main methods of systems analysis—the Structured (Demarco, 1978; Gane & Sarson, 1979; Yourdon 1989) and Object Oriented (Rumbaugh, Blaha, Premerlani, Eddy, & Lorensen, 1991; Jacobson, Christerson, Jonsson, & Overgaard, 1992; Booch, 1994)—are mainly focused on the structured information as part of the business process. Considering the increase in complexity caused by KM mainly from a technical point of view—the dominant unstructured or semi-structured nature—new or revised methods of system analysis methods are indicated.

Second, as suggested by Jayaratna and Sommerville (1998), current methods and techniques for classic systems analysis lack the ability to close the gap between the ordered world of formality and the complex real world. Adding the lack of structure found in KM to this equation only widens this gap. Since the real world has become more complex, it is the formal methods and techniques that are to be changed.

Third, KM is intended to be viewed as a natural extension of the IS function, and studies show that IS remains responsible for most KM implementation and management (King, Marks, & McCoy, 2002). However, approaching the new field of KMS with the old tools of systems analysis is a recipe for failure. This confusion leads to facts mentioned by researchers, that there is no single clear approach to the development of KMS (Alavi & Leidner, 1999), and that KMSs are developed in ad-hoc and trial-and-error modes (Plass & Salisbury, 2002; Nissen, 2001). The classic system analysis process tends to ignore organizational knowledge and KM process, focusing instead on the organizational processes that involve data and information.

NIMSAD (Normative Information Model-based Systems Analysis and Design) is a systemic framework created by Jayaratna (1994). It is used to understand and evaluate methodologies. Using this framework to examine the structured analysis methodology shows clearly that the classic systems methodology focuses on the flows and structures of formal data and data-related activities, while any aspect beyond this remains outside the area of the practitioner concern (Jayaratna, 1994).

KISA: KNOWLEDGE INTEGRATED SYSTEMS ANALYSIS

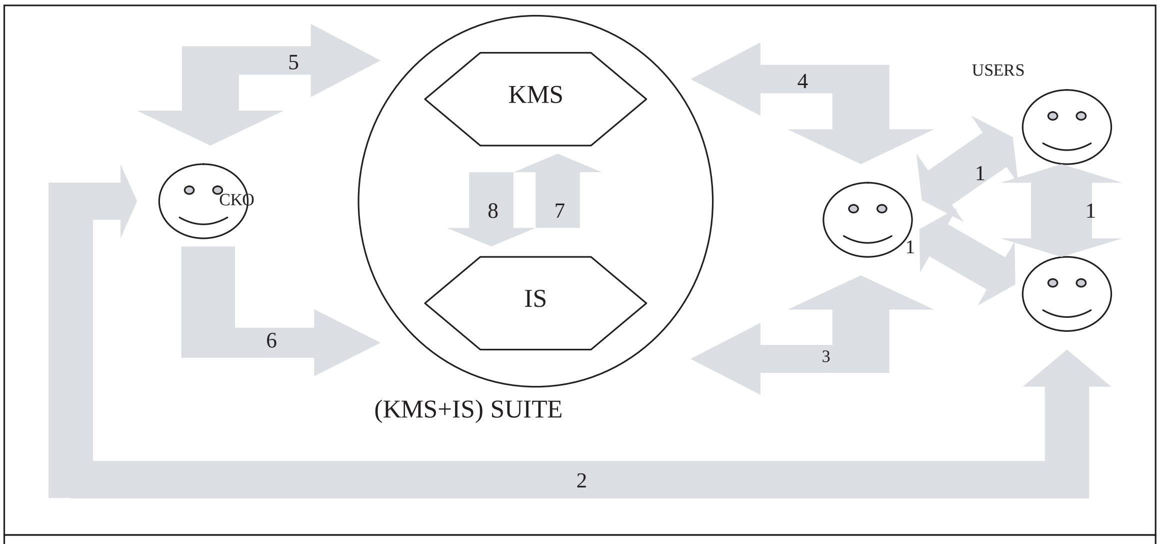
One strategy to accomplish this tight coupling between KMS and MIS is to specifically integrate knowledge items (or knowledge artifacts) into the information system. The approach illustrated here is based on the popular UML (Unified Modeling Language) methodology for systems analysis and design. The modified system analysis phases include building the KMS as part of the system analysis process, and adding the knowledge items into the UML charts. The final product of this approach is a unified system that contains two cooperative but independent subsystems, which allow the users to accomplish their processes and use knowledge artifacts at the right time, in the right way. UML is a unification of three methods (Jacobson, Booch, & Rumbaugh, 1999); the unified process is use-case driven, which is a piece of functionality in the system that gives a user (or another system) a result of value. All the use cases together make up the use-case model, which describes the complete functionality of the system. The main reasons for using the use-case model (and the UML as a whole) are the ability of reuse (since use case offers systematic and intuitive means of capturing functionality) and the ability to support the whole development process (most activities such as analysis, design, and testing are performed starting from use cases). According to Fowler and Kendall (2000), the fundamental reason to use the UML involves communication: "I use the UML because it allows me to communicate certain concepts more clearly than the alternatives" (p. 7).

Macro-Level KISA

An Integrated IS + KMS Suit

Information systems cannot be viewed as stand-alone systems, but as interrelated systems that need continuous management rather then one-time planning (Lindgren, Hardless, Pessi, & Nulden, 2002). A system analysis process for a single system that ignores the overall picture is strategically wrong. In other words, planning a system should be part of the information strategy and needs to integrate with the present and future systems. Therefore a KMS should always be part of the overall picture, and a KMS analysis process is part of an overall analysis process. Only the planning of KMS+IS will lead to streamlined, seamless business processes. Today, because most organizations have already established procedural information systems, a new KMS analysis process should be part of the strategy and lead to integration with the organizations' legacy systems. Davenport and Glaser (2002) call this approach "just-in-time delivery," stating that the key to success is "to bake specialized knowledge

Figure 1. KMS+IS suite and user roles



1. Communication and collaboration of the individuals within the organization.
2. Communication of individuals with the CKO with respect to the organization's knowledge needs.
3. A user approaches the suite to fulfill the structured organizational procedural activities (use the IS module).
4. A user approaches the suite to acquire knowledge for unstructured activities (use the KMS module).
5. The CKO organizes, formalizes, and stores the knowledge to the suite (to the KMS module).
6. The CKO is actively part of changes in the suite (the procedures within the IS), to align with the knowledge used by the process.
7, 8. The IS module "calls" the KMS module for knowledge at the moment it is the most valuable.

into the jobs of highly skilled workers—to make the knowledge so readily accessible that it can't be avoided."

The integrated suit is illustrated in Figure 1. It should be emphasized that the KMS component or module within the suit allows not only integrated knowledge within the process, but also allows free retrieval of knowledge. For example, knowledge as lessons learned should be available while performing an organizational procedure, like preparing the next week work plan, and also available for a new worker learning the job, by using free retrieval of knowledge.

A Moderated System Analysis Process

Our point of departure is that the IS+KMS suit (as illustrated in Figure 1) is the product of combining IS and KMS methodologies. A classic system analysis process contains the following phases (Whitten et al., 2001; Yourdon, 1989; Demarco, 1978; Gane & Sarson, 1979; Booch, 1994; Pressman, 2000):

1. initial problem/opportunity identification (including feasibility testing)
2. study of the current system
3. requirements discovery and analysis
4. data modeling
5. information modeling
6. process modeling

In order to emphasize the main modifications of the integrated system analysis process, we will discuss it from both macro-moderation and micro-moderation points of view.

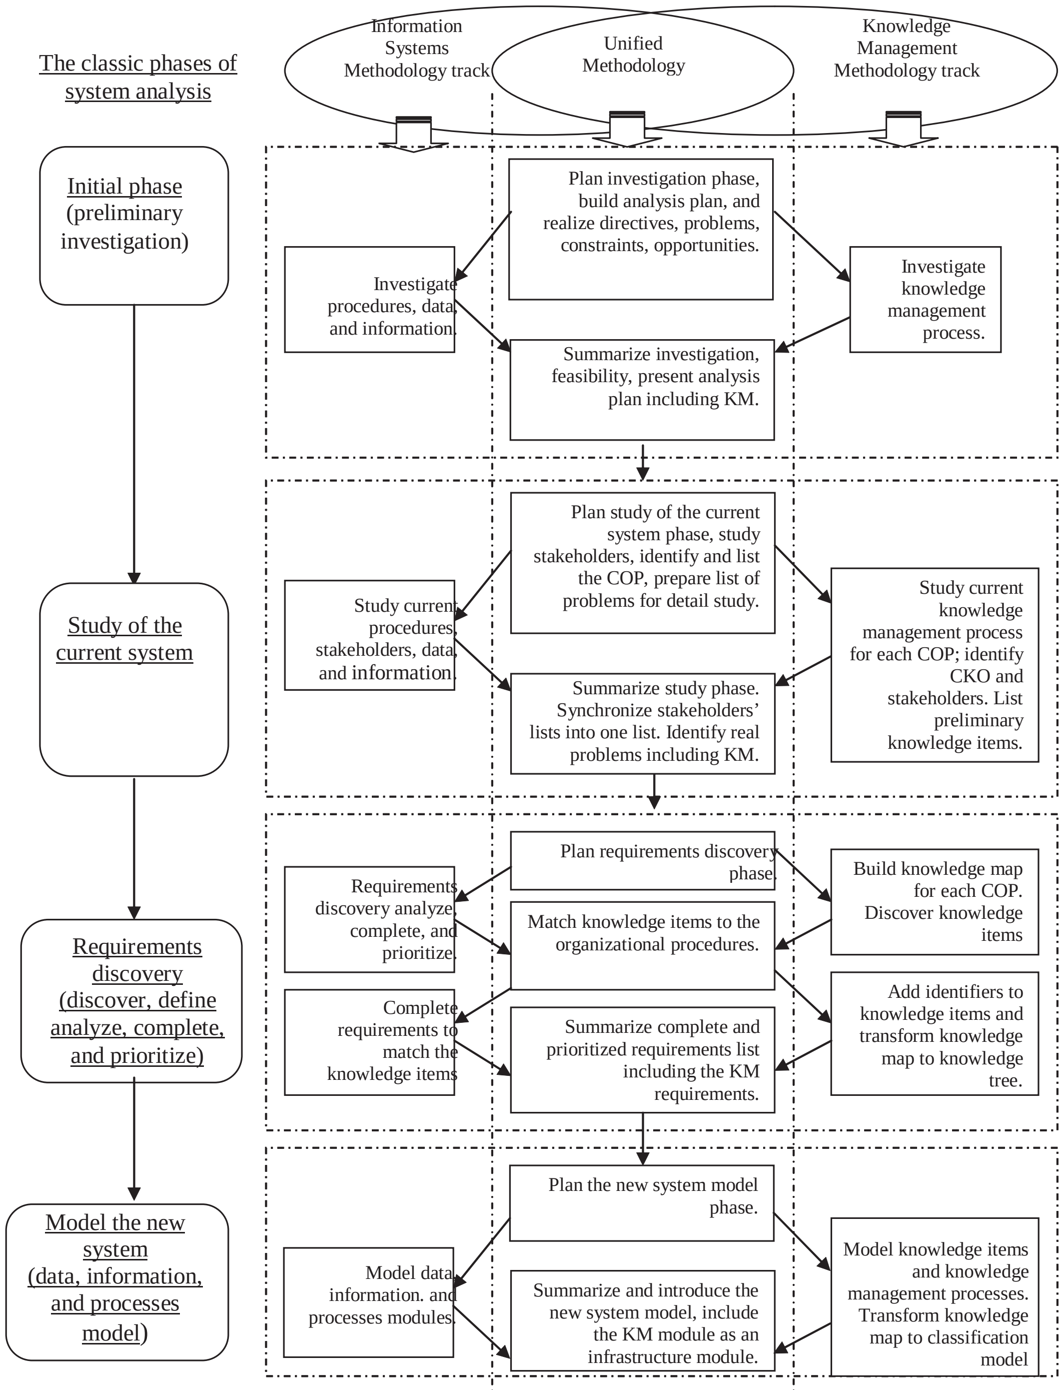
The main macro-modifications result in the bifurcation of well-known classic system analysis processes into two tracks. As shown in Figure 2, the IS track and the KMS track run in parallel with clearly defined points of intersection. The two tracks must be well planned and synchronized so the work in the two tracks will be able to be done independently (because the tools and the techniques are different) yet synchronously. Each phase begins by planning the KMS and the IS activities to be accomplished within this phase, then allowing the two tracks to diverge and be done according to their distinct methodologies (meaning IS or KMS methodology). However, as planned, the synchronization demands that the KMS will serve the IS and thus results in a situation in which knowledge serves the organizational procedures by nourishing the organizational procedures with the knowledge items at the appropriate action points.

For example, a well-known tool of KMS methodology is the knowledge map (Vail, 1999). This tool will be still used by the KMS track, but it will also be directed to serve the organizational procedural process as the IS track see and define it. Specifically, the knowledge items to be mapped will have process notification. In other words each item will be able to address the organizational procedures it serves. Another example shows that the modeling of the new organizational procedures as done in the IS track (by UML, DFD, or any other technique) will include the detailed exits points where the user should reach the knowledge items, which had been identified in the KMS track.

The summary of each phase of the KISA process is again the convergence of the two tracks. The synchronization between the two tracks is crucial for the success of the whole process. It demands a clear definition of the activities in each track so full cooperation and no unnecessary overlapping will result. This is actually the fusion that is reached by the meeting of the IS group and the KMS group. The process involves not only data and information modeling, but also the knowledge modeling. The system analyst is required to define not only the organizational work procedure, but also the knowledge artifacts that serve each event of these procedures. The new system model also handles the knowledge management process as one of the organizational procedures.

The product of the KISA process is a full systems design, which usually contains the module

Figure 2. Macro view of the moderated system analysis process



blueprints. Some of these will be infrastructure modules (which handle the users, workflow mechanism, etc.), while others are operational modules (marketing, finance, etc.). The KM component in the system is the KMS and considered as one of the infrastructure modules; this module will include the KM basic activities such as collect, formalize, store, organize, and share the knowledge that serves on demand (or request) the IS operational modules.

Micro-Level KISA

Micro-moderations are the moderations to the activities within each phase of the system analysis process. Here we describe the interface at requirements elicitation. This activity is the base for the construction of the interface between the operational IS modules that are responsible for the organizational procedures, and the KM module. The process of interface requirements elicitation can be understood as shown in Figure 3. The knowledge items were elicited prior (using the knowledge map in the KMS track), and the requirements for the organizational procedure were discovered in advance (using the UML or the DFD notation). Since not all the knowledge items and not all the organizational procedures were discovered, the meeting point of the two tracks is the place to reveal the missing parts. Now the interface modeling starts by the system analyst in each of the two groups (the IS operational modules group, and the KM module group) working synchronously in the two tracks and matching the knowledge items to their right organizational procedure.

The following example illustrates: Consider that the organizational procedure is Maintenance Planning for a ship type of A. The planner of this process needs the right lessons learned, which were recognized as knowledge items in the KMS. Receiving the right lesson learned at the time of planning is using the right knowledge at the right time for the right person in the right way. In the interface requirements elicitation and modeling stage, the lessons learned that reside in the KMS should be pointed to their right place within the Maintenance Planning procedure. The system analysts from the two groups (accompanied by the top user and the chief knowledge officer) must identify the location in the procedure and the exact identifiers which allow the IS module to request the knowledge items and the KM module to deliver. In this example, the ship type, the location of the maintenance (which shipyard), the time of year, and so forth, will serve as identifiers for these knowledge items of the type of lesson learned. The identifiers of the knowledge items can also be viewed as the knowledge items metadata.

FUTURE DIRECTIONS

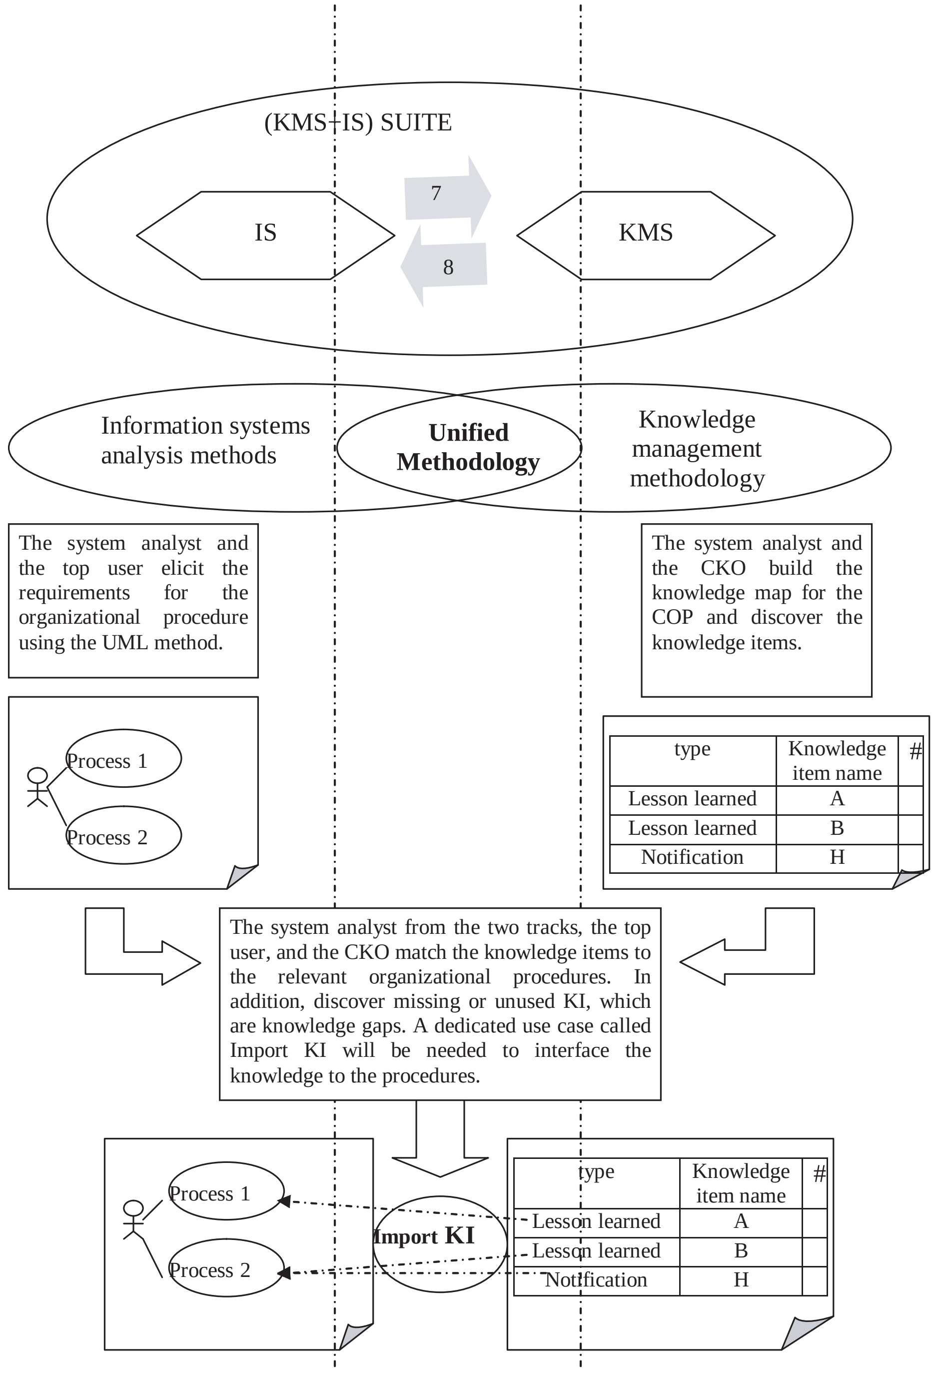
The integration of MIS and KMS analysis and design processes will surely lead to the development of new software tools to support increasingly complex interactions between analysts and users. While the development of such tools will probably grow out of the current base of modeling software, there are important techniques from the KM analysis world such as knowledge maps and social network analysis that need to be integrated.

Although the unified methodology presented in this article is robust, as we gain more experience in the analysis and design of fusion systems, we would expect the KISA process to evolve. A finer-grained bifurcation of additional steps in the analysis process will surely lead to tighter integration between KMS and MIS—both in terms of project scope and team composition.

CONCLUSION

Integrating KMS into the system analysis process requires some major modifications, and this integration affects every phase of the systems devel-

Figure 3. Micro view of the KM-IS interface requirements



opment process (as shown in Figure 2) and could well be considered a new analysis methodology in its own right. This system analysis approach combines knowledge management and traditional or classic IS system analysis. The approach requires the use of two separate but synchronously integrated tracks, the IS methodology track and the KMS methodology track. Two groups of system analysts conduct the system analysis phases: the KM group is accompanied by the CKO (chief knowledge officer), and the IS group is accompanied by the user representative who operates the organizational procedures. The two groups plan each phase activities together and meet several times along the phase. As the focus of this article was the system analysis process, it was not emphasized that the organizational knowledge management process needs to be modeled and implemented as part of any such integrated project, in order to insure that the KM modules continue to nourish the operational MIS modules.

London School of Economics and Political Science, UK

INTRODUCTION

Knowledge management (KM), as a topic for academic research and practical implementation, has had a short history dating back only to the early 1990s. Due to knowledge management's recent debut as we know it, it is not surprising that much of the writing and research on the subject is controversial. In this article we note the need of a critical awareness of desirable and undesirable shades of knowledge management processes (Land, Nolas, & Amjad, 2005).

BACKGROUND AND FOCUS

Knowledge is both disseminated and acquired. As observers we cannot know what intentions lay behind the act of dissemination, or what motivates the acquirer to acquire. We cannot blindly assume information—a major component of knowledge—as interpreted, facilitated, conceptualised, or experienced, is automatically for everyone's benefit. The process of knowledge management may have a desired or detrimental outcome for society, an organisation, a team, or the individual. Indeed, the outcome of a KM activity, say knowledge sharing, is largely unpredictable. The reality is the outcome may benefit one group at the expense of another. Benefiting one group at the expense of the other is addressed by the following conceptual fusions.

KM is a continuum of desirable and undesirable political processes. This article suggests that the combined concepts of knowledge management, organisational politics (OP), and coevolution (CE) make a contribution to the understanding of KM, whether in its benign or its darker manifestation.

Because knowledge management is a purposeful activity, it can never be neutral. Hence the article sets out to forewarn practitioners and thinkers in the area of KM that care must be taken since knowledge (K) can be manipulated for both altruistic and selfish purposes.

If the study of KM is to have an enduring future, it must take a more holistic stance. We suggest the concept of "coevolution" (McKelvey, 2002; Lewin & Volberda, 1999; Lewin et al., 1999) provides a way of understanding the implications of knowledge management on the organisation and its employees. Coevolution describes the mutual influences among actors in a collective, as well as their environment. Mutual influences can have desirable and undesirable, constructive and destructive effects. In the case of an organisation, coevolution can be envisaged as being effected in a set of multi-dimensional networks, themselves part of a larger set of networks to which they are linked.

Any event or activity will have some (possibly unknown) impact on other succeeding or collateral activities. Their responses will in turn trigger impacts and responses in further activities, including possibly in the activity that acted as the initial trigger. Each activity evolves on a trajectory which may have been planned, but the outcome and direction is often unexpected. The pattern of responses in diverse activities leads to their coevolution. The coevolution of power and knowledge contribute to the discussion of the darker sides of knowledge management by offering an understanding of shades of desirable and undesirable forms of knowledge management. The concept of coevolution permits us to replace the simple ethical/non-ethical dichotomy and attempts to explain the dynamics in a continuum of knowledge management processes, actuated by motives, mediated by sources, and realised via the dissemination and acquisition of knowledge. Nevertheless, the complex pattern woven by coevolution remains uncertain, and permits the emergence of the unexpected.

KM occurs at all levels in the organisation. It may be a planned formal process supported by KM software designed to increase the effectiveness of a team of knowledge workers. Equally it may be a hidden process of knowledge manipulation by a group attempting to direct the organisation on a path away from its formal objectives. It may be an informal process, the reaction of a group of people responding to an initiative they believe will damage them. But whatever the intention behind the process, both the study of organisational politics and coevolution suggest that the outcome will be uncertain. Outcomes, sometimes unexpected, emerge from the responses of organisational actors. In order to deal with the problem of uncertainty and emergence, at both an analytical and practical level, the article introduces the concepts of desirable and undesirable coevolution for looking at was is and not what ought to be.

CORE IDEAS OF THE ARTICLE

Knowledge, Power, and Their Dynamic Interactions

This article links together:

- Knowledge Management (KM)
- Organisational Politics (OP) and
- The concept of Coevolution (CE)

All three share a common concept: power. Knowledge management, despite much of the rhetoric surrounding the concept, is not a power-neutral process. If, as has been suggested (Land et al., 2005), knowledge is managed in order to achieve goals, be they benign or corrupt, political processes are invoked in the management process.

KM, OP, and CE all involve power, and each is profoundly affected by the way power is distributed. Knowledge management in its idealised form is independent of power. In reality the existence of an asymmetric power balance enables those with the power, often those who have formal authority, to present knowledge in directions of their choosing. Those with lesser power may respond by using knowledge to achieve their ends in more subtle and primarily informal ways, of which the spreading of rumours is one typical way. A central idea of KM is that knowledge, if considered a commodity, is manoeuvred toward shades of desirable and undesirable directions by multiple stakeholders.

OP, summarised as a wide range of descriptions of formal and informal power relationships in organisations, has been studied and documented at least since the 1970s (e.g., Pettigrew, 1973; Mintzberg, 1983; Pfeffer, 1997). OP provides a theoretical lens with which to conceptualise and observe both constructive and destructive aspects of KM.

Most academic literature agrees KM is an essential activity for a modern enterprise to flourish in a global competitive economy, and many practicing managers share this view. Despite the slippery meaning of KM, a positive relationship between knowledge and truth—and hence KM—is implicitly assumed. An interpretist view of KM is that people are capable of being aware of their own actions, further assuming knowledge and understanding are 'good' or at least neutral (Schultze, 1999). In other words, interpretivists take for granted people are self-aware, but optimistically believe knowledge management to be an inherently constructive and positive process. However, Schultze also notes that the open sharing of knowledge may not occur in competitive business environments associated with competitive advantage.

The inspiration for thinking about the interrelationship of knowledge management and power is found in the following concepts of coevolution and organisational politics.

Organisational Politics

The study of organisational politics suggests the driving force enabling organisational politics to occur is power, and in particular the asymmetrical distribution of power. Organisations are overlapping sets of political networks, rule, and role systems, engaging in coalition building as part of manipulative, selfish, under-the-table dealings, as well as for constructive purposes aimed at furthering the aims of that organisation.

The informal and formal organisation becomes part of the discussion, since it is the informal organisation where much of the political activity occurs—behind the scenes. Pfeffer (1997, p. 136), in support of this position, notes: "…these less formal methods rely more on power and influence, leverage individuals' positions in social networks, and entail ongoing negotiations among organisational participants." However, identifying political behavioural patterns for the sake of efficiency is not enough. "The skill is to try and prevent individual and organisational pathological circumstances from arising by recognising the appropriate and inappropriate behaviours that individuals and groups will and will not be able to accept" (Kakabadse & Parker, 1984, p. 101).

Three aspects of KM as a political process within an organisation are dependency, strategies for enacting power, and decision making.

Taking Pettigrew's (1973, p. 26) position that "Power is…a property of social relationships, not an attribute of the actor…Dependency is…a product of an imbalance of exchange between individuals and the ability of one actor to control others through his [/her] possession of resources," knowledge can be a critical resource. Hence the desirable or undesirable directions of K manipulation can trigger that dependency to be constructive or destructive. For example, a senior manager may become dependent on the knowledge (experience) of a junior manager, therefore strengthening the expertise and performance of the team. The senior manager is dependent on the knowledge of the junior manager. Her/his own performance is governed by the presence or absence of the subordinate.

A specific arena in an organisational politics context is a decision-making process, which determines specific actions to be taken. Influencing a decision in the making is more effective than attempting to do so after action on the decision has been taken (Mintzberg, 1983, p. 206). In practice, manipulation of information and knowledge, designed to influence the decision maker, takes place at all levels in the organisation and for many reasons.

Organisational politics provide the geo-political landscape for describing KM processes, alerting us to the manipulative nature of KM. Viewing KM as political is not an end in itself. Kakabadse and Parker (1984, pp. 104-105) summarise organisational politics and offer a remedy:

Problems arise when an individual group rejects, misunderstands, or responds with inappropriate behaviours [for example, providing false information] to the actions of other individuals or groups. In the literature, it is their negative interactions that have, to date, been labelled 'political.' We suggest that one way of reducing negative interactions is to strive for multi-rationality. Multi-rationality is a process whereby actors begin to understand their own values, beliefs, and norms; are able to assert their individuality but are equally able to accept that others hold a different rationale.

Coevolution

Tasaka (1999) describes coevolution as "a process in which each part interacts with and influences the other parts, thereby stimulating their mutual development." The coevolution of power and knowledge contribute to the discussion of knowledge management by emphasising the intricacy of the interactions, the uncertainty of what the outcomes of the interactions will be, and the opportunities the interactions provide for the manipulation of information and knowledge.

Interactions cannot be clearly classified as desirable or undesirable. Every process creates interactions. As knowledge management creates interactions, we cannot predict that the outcome of coevolution will yield what was intended. As a consequence of the multi-rationalities operating in the real world, some individuals or groups may see the outcomes as desirable, where others judge them detrimental to the organisation or to themselves. Ignoring the 'power' dimensions of the situation being studied gives the impression that organisational space is neutral, and that the action of entering the space is also neutral (Land et al., 2005). Constant change and mutual influencing among actors, processes, and scenarios add to the awareness of the non-neutrality of KM.

Coevolution explains how first-order effects trigger other second-order effects, which in turn trigger further effects. Further effects produce a cascade of non-deterministic effects where the impacts will be emergent and cannot be second-guessed. An example of this is the desire for clarity of organisational strategy, leading perhaps, in the interest of clarity, to rigidly defined organisational roles. But the imposition of stricter controls to enforce the predefined organisational architecture may have the undesired consequence of inhibiting innovation and stifling initiative.

The following two examples illustrate power dynamics and KM processes. CE is used to highlight the intricate interaction in these instances of post-merger integration (PMI) and water management. PMI is an example of what happens inside an organisation, and the case of water management here is an example of inter-organisational relationships.

Example 1: Post-Merger Integration

Organisation, a national leader in its sector, experienced a merger in 2000. The results of the merger were Organisation's unclear strategic goals, as voiced through semi-structured interviews in 2002. This lack of clarity trickled down to a particular department (henceforth Department) and other teams that interacted with the Department. Unclear strategic goals and how to operationalise them on an individual, team, and department level emerged in the following ways. Hierarchical relationships and prioritisation of work tasks are very much interrelated. The essence of this is that senior-level management commented on being out of touch with what is happening at middle-management levels. Being out of touch with middle-management levels—clearly a failure of KM—translates into prioritisation problems, where the operational levels know what the daily capabilities are and the senior management may have an overall understanding of what needs to be done to achieve organisational goals, but not the knowledge of realistic capabilities on everyday tasks. For example, a new deadline must be met sooner than previously understood by the operational and middle-management levels. Pressure is then put on the subsequent levels to produce for this deadline. The operational levels become frustrated because a particular piece of equipment is down for the moment, making the task even more difficult, and further delaying other needed, regular tasks. Being out of touch with what is happening in daily routines then becomes a vicious cycle of no space for initiative and heavy-handedness from senior management, toward operational management.

The primary problem identified here is ambiguity of roles and strategy. One common solution to alleviate such ambiguity is increasing the amount of information to the same people and to more people. In other words, change the KM processes with higher volume of information and more interaction. However, increasing the quantity of knowledge to alleviate the management levels' ambiguity of roles and strategy is not the straightforward solution. Becker (2001, pp. 1046-1048) argues for acknowledging a difference between the meanings of uncertainty and ambiguity. He states "ambiguity" is structural uncertainty, whereas "uncertainty" is stochastic, in other words random or probabilistic uncertainty. The point being that, faced with a decision problem that is due to structural rather than random uncertainty, increasing the knowledge and information at hand may further increase the structural uncertainty (ambiguity) instead of alleviating it. "What is required is to make people communicate, assimilate cognitive frameworks, and develop understanding…to support processes that lead to understanding, not just access to information"(Becker, 2001, p. 1048).

The implementation of organisational strategy is shaped by the individual priorities of the relevant organisational actors. And the implementation process is itself driven by KM processes employed by stakeholders operating in various hierarchical levels in the organisation. Ambiguity in priorities and ambiguity in roles can facilitate perverse knowledge management outcomes.

Past research identifies inherent ambiguity and issue politicisation as impediments to effective post-merger integration (Vaara, 2002, p. 887).1 Merger failure has been linked to lack of clearly defined roles, responsibilities, and incentives (Deloitte & Touche, 2002). "Increased ambiguity—due to unclear goals, roles, and procedures—allows greater opportunity for political behaviour to be employed in reaching objectives" (Parker, Dipboye, & Jackson, 1995). Political behaviour can be a problem if the power dynamics of KM processes are not realised for their constructive and destructive implications. What this means for KM processes is that multiple interpretations imply conflicting discourses which can be both constructive and destructive. People in the organisation may have a different idea of where the organisation should be headed, how it should get there, and who is responsible for getting it there. How each person at each organisational level is shaping the motivation, transfer, interpretation, and implementation of

KM processes brings into question the desirable or undesirable dimensions of KM.

Returning to the case study's ambiguity of roles and strategy during their post-merger integration, KM processes are seemingly part of the problem, and instinctively part of the solution—in terms of simply increasing information flows. Cyclical misinterpretation of expectations and responsibilities among organisational levels demonstrates miscommunicated and misunderstood knowledge management processes. However, the desired perception of clarity does not necessarily mean a desirable set of KM processes exists. Where 'better KM' may be considered part of an eventual solution, we might actually ask: How are the KM processes occurring within an arena of organisational politics or power relationships?

Example 2: Water Management

Knowledge management power relationships also exist among organisations. The following illustrates how inter-organisational relationships relate to each other in the case of water regulation in England and Wales. Every five years a review of water prices occurs. The changes in water pricing for all consumers stem from EU and UK regulatory requirements ranging from water quality, to the cost of infrastructure improvement. Maloney (2001) describes the multi-stakeholders' interactions as processes of negotiation and sanctions. The regulatory review of water price limits in England and Wales illustrate a form of knowledge management as multi-stakeholders coping with ever-changing rules (regulations) and the blurred boundaries of organisations' roles (expectations and responsibilities as public, private, and civil society).

The purpose of the periodic review, according to the Office of Water Services (OFWAT), the independent economic regulator for water for all of England and Wales, is "…to make sure that the companies are able to carry out and finance their functions under the Water Industry Act 1991" (OFWAT, 1998). OFWAT also claims they aim to set price limits that allow each company to carry out their functions while protecting the interests of customers in two ways: (1) enabling well-managed companies to finance the delivery of services in line with relevant standards and requirements, and (2) providing incentives for companies to improve efficiency and service delivery. Notice how these two main objectives already imply the non-neutrality of the ensuing knowledge management processes. First, each organisation will interpret and implement "relevant standards and requirements" to the advantage of each organisation, perhaps even unintended conflicting interpretations. Second, "providing incentives for companies to improve efficiency" is a form of KM manipulation. The water companies must provide draft business plans early in the regulatory review process to the independent economic regulatory agency (OFWAT), along with more public sector organisations such as the Environment Agency and Department for Rural Affairs and Agriculture. The negotiations that take place between the regulators and the regulated—how the business plans fit with regulatory requirements, while simultaneously sustaining the companies—illustrates how a KM process can move in many directions. The way a draft business plan is presented can persuade how the regulators decide to advise on reshaping the business plan to adjust with newer EU regulations, for example.

Governance according to the Global Water Partnership includes power and different levels of authority, and regulation is housed under the broad roof of governance—governance that in itself lends to KM manipulation.

The Global Water Partnership argues:

Governance looks at the balance of power and the balance of actions at different levels of authority. It translates into different systems, laws, regulations, institutions, financial mechanisms, and civil society development and human rights, essentially *the rules of the game. Usually improving governance means reform. (GWP, 2003)*

To organise how we approach thinking and acting on these observations may be to identify the changes of multi-level (EU-UK) organisations and types (public-private-civil society), recognising power asymmetries and their interconnections. For example if the European Union's Water Framework Directive is raising the standards in London, by driving the 2004 regulatory review process toward more stringent policies, we may want to ask how London's customers and the water company Thames Water is adjusting to these new standards, and doing to affect the new standards?

FUTURE TRENDS

As KM becomes a more comfortable topic for researchers, and numerous governments and private sector organisations buy into the language and concepts of KM, a responsibility resides with the advocates of KM of the potential abuse of KM processes. The maturing of the eventual field of KM is on the horizon. KM is slowly moving away from defining it, debating its use, gathering, storing, sharing it, toward questions of what does it essentially mean for communication and productivity. KM for better or worse—as some would say "repackaging old ideas with glossy new ones"—is here to stay. How are we going to welcome this emerging discipline that seemingly unites information systems, organisations, and politics, to name a few? One of those ways may include obvious answers such as further empirical work and sharpening of definitions. Behind any method researchers and other applied practitioners of KM choose, they should note that control is not the solution and where attempted, frequently backfires.

CONCLUSION

This article proposes the significance of conceptualising KM as a political process, with notions from OP and CE. OP provides a familiar and documented contextual boundary where power-ridden processes of KM interact. CE further energises the explanation of power-ridden KM processes by giving vocabulary and meaning to changing patterns of interaction. The PMI and water management examples illustrate KM as a political process in the real world. In this specific case of PMI, information travels among hierarchical levels of an organisation, producing conflicting expectations that worsen the politics within that organisation. As for the water management case, local, national, and international levels of organisation interact with different types of organisations—public, private, and to some extent civil society. The inter-organisational dynamics lend to multi-layer knowledge management processes among them: infrastructure improvement needs based on changing water quantity/quality, what can be reasonably charged to customers, and the question of the regulations imposing desirable behaviour.

KM processes are manipulated for constructive and destructive purposes. A context of organisational politics and a paradigm of coevolution are not the only ways of highlighting an agenda for KM. OP and CE provide ways of highlighting and connecting what we already understand as relationships of power and knowledge. KM as a growing area of research and practice has and will open new ways of thinking, while revisiting old. Wielding KM's full capabilities also includes responsibly using and interpreting the hidden and obvious agendas.

Chapter 2.15
Inter-Organisational Knowledge Transfer Process Model

INTRODUCTION

Knowledge management (KM) is an emerging discipline (Ives, Torrey & Gordon, 1997) and characterised by four processes: generation, codification, transfer, and application (Alavi & Leidner, 2001). Completing the loop, knowledge transfer is regarded as a precursor to knowledge creation (Nonaka & Takeuchi, 1995) and thus forms an essential part of the knowledge management process. The understanding of how knowledge is transferred is very important for explaining the evolution and change in institutions, organisations, technology, and economy. However, knowledge transfer is often found to be laborious, time consuming, complicated, and difficult to understand (Huber, 2001; Szulanski, 2000). It has received negligible systematic attention (Huber, 2001; Szulanski, 2000), thus we know little about it (Huber, 2001). However, some literature, such as Davenport and Prusak (1998) and Shariq (1999), has attempted to address knowledge transfer within an organisation, but studies on inter-organisational knowledge transfer are still much neglected.

An emergent view is that it may be beneficial for organisations if more research can be done to help them understand and, thus, to improve their inter-organisational knowledge transfer process. Therefore, this article aims to provide an overview of the inter-organisational knowledge transfer and its related literature and present a proposed inter-organisational knowledge transfer process model based on theoretical and empirical studies.

BACKGROUND: AN OVERVIEW OF KNOWLEDGE TRANSFER AND RELATED LITERATURE

Knowledge Transfer within an Organisation

Knowledge transfer implies that knowledge is transferred from the sender(s) (person, group, team, or organisation) to the recipient(s) (person, group, team, or organisation) (Albino, Garavelli & Schiuma, 1999; Lind & Persborn, 2000). It may happen within an organisation or between organisations. Szulanski (2000) argues that knowledge transfer is a process in which difficulty should be seen as its characteristic feature. This process view may help organisations identify difficulties in the knowledge transfer. He further proposes a process model for intra-organisational knowledge transfer as shown in Figure 1, which contains four stages: initiation, implementation, ramp-up, and integration.

In the initiation stage, the effort aims to find an opportunity to transfer and to decide whether to pursue it. An opportunity to transfer exists as soon as the seed for that transfer is formed, that is, as soon as a gap is found within the organisation, and the knowledge to address the gap is thought to be available. In the implementation stage, following the decision to transfer knowledge, attention shifts to the exchange of information and resources between the source and the recipient, that is, "learning before doing" for the recipient. In the ramp-up stage, the recipient begins using acquired knowledge, and tries to ramp-up to satisfactory performance, that is, "learning by doing" for the recipient. In the integration stage, the recipient takes subsequent follow-through and evaluation efforts to integrate the practice with its other practices (Szulanski, 2000).

The process model demonstrates that knowledge transfer within an organisation is complex and difficult. However, knowledge transfer between organisations is even harder and more complicated. When knowledge is transferred within an organisation, the organisation should try to expand the amount of shared knowledge among its employees to an appropriate level (or to the highest level possible) (Lind & Seigerroth, 2000) so as to develop (or preserve) its competitive advantage. When transferring knowledge between organisations, the organisations have to face "the boundary paradox" (Quintas, Lefrere & Jones, 1997), which involves more complicated factors impinging on the transaction. It also requires the negotiation between participating parties, strict governance mechanisms to regulate the transfer content, and higher loyalty by relevant employees.

Inter-Organisational Knowledge Transfer

Inter-organisational knowledge transfer may have different types. For instance, von Hippel (1987) classifies know-how trading between firms into two types: informal and formal. He defines informal know-how trading as the extensive exchange of proprietary know-how by informal networks in rival (and nonrival) firms. Here is an example, when a firm's engineer who is responsible for obtaining or developing the know-how his/her firm needs finds that the required know-how is not available in-house or in public sources; the engineer may, through his/her private relationships, seek the needed information from professional counterparts in rival (and nonrival) firms. Formal know-how trading is referred to as official knowledge exchange agreements between firms such as agreements to perform R&D cooperatively or agreements to license or sell proprietary technical knowledge (von Hippel, 1987). von Hippel further argues that the main differences between the informal and formal trading are (1) the decisions to trade or not trade proprietary know-how in the former are made by individual, knowledgeable engineers; no elaborate evaluations of relative rents or seeking of approvals from firm bureaucracies are involved; however, the decisions for the latter are made by firm bureaucracies; (2) the value of a particular traded module in the former is too small to justify an explicit negotiated agreement to sell, license, or exchange, but the traded module in the latter is of considerable value. In fact, the fundamental difference between the so-called informal and formal inter-organisational knowledge transfer is that the former is carried out through employees' private relationships without the direct involvement of their corporate management, but the latter has direct involvement of their corporate management.

This article is mainly concerned with the formal knowledge transfer process between organisations.

Inter-Organisational Learning

From an organisational learning perspective, inter-organisational knowledge transfer is actually the process of organisations learning from each other, that is, inter-organisational learning.

Organisational learning may occur when the organisation acquires information (knowledge, understanding, know-how, techniques, or practices) of any kind and by whatever means (Argyris & Schon, 1996). It is individuals that make up an organisation; thus each organisational learning activity actually begins from individual learning. Individual learning is a necessary condition for organisational learning which is institutionally embedded (Beeby & Booth, 2000). However, individual learning is not sufficient. It is generally accepted that the acquisition of knowledge by individuals does not represent organisational learning (Beeby & Booth, 2000; Nonaka & Takeuchi, 1995). To achieve the necessary cross-level effects, that is, successful organisational learning, individual learning should be on the organisation's behalf (Argyris & Schon, 1996) and must be shared through communication which is supported by institutional processes for transferring what is learned by individuals to the organisation as well as for storing and accessing that which is learned (Beeby & Booth, 2000).

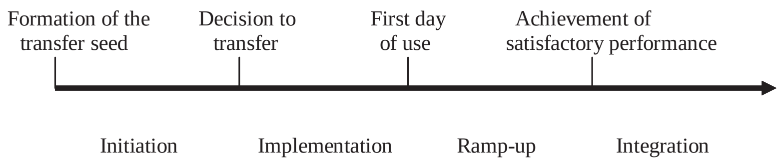
Literature review shows that study on organisational learning mainly focuses on learning within an organisation, that is, on how to convert individual learning into organisational learning once the individuals have acquired the needed knowledge. Issues related to how and from where the individuals acquire the needed knowledge are more or less ignored. When organisations learn from each other, it is normally some individuals who learn on their organisation's behalf from other individuals on another organisation's behalf. Then the learner's individual learning will be further converted into organisational learning. Therefore, inter-organisational knowledge transfer process, as a kind of inter-organisational learning, can be divided into two subprocesses: (1) inter-employee learning between employees from different organisations and (2) organisational learning within the receiving organisation by converting individual learning to organisational learning through the organisation's internal mechanisms (Chen, Duan & Edwards, 2002).

Social Networks

Social relationships play an important role in social networks. Granovetter (1985) points out that all activities are embedded in complex networks of social relations which include family, state, educational and professional background, religion, gender, and ethnicity.

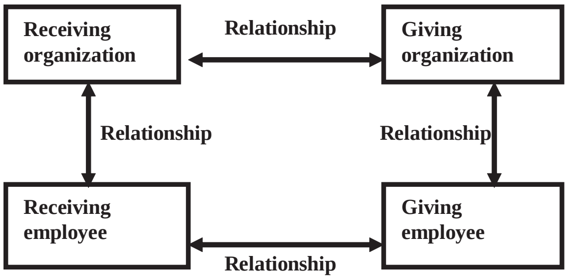
From the social network perspective, inter-organisational knowledge transfer activities can be regarded as activities within social networks. Assuming the influence from a third party is ignored, the network may have four actors: receiving organisation and receiving employee, giving organisation and giving employee. The actors' behaviours will be influenced by their relationships. In the first subprocess (i.e., inter-employee learning between employees from different or-

Figure 1. The process for knowledge transfer within an organisation (Szulanski, 2000)



ganisations), when the receiving organisation requests knowledge from the giving organisation, they will establish their own knowledge transfer strategies based on the relationship between two organisations. Then the organisations may use their relationships with their own employees to influence and guide the employees' learning behaviours to conform to their knowledge transfer strategies. The personal relationship between the receiving and giving employees will also influence their individual learning effectiveness. In the second subprocess, the relevant actors will be the receiving organisation and receiving employee. The key point for the receiving organisation is to establish its internal mechanisms to promote the conversion from the receiving employee's individual learning into organisational learning. The internal mechanisms may be considered as being embedded in the relationship between the receiving organisation and receiving employee.

Figure 2. The relationship mechanism for inter-organisational knowledge transfer



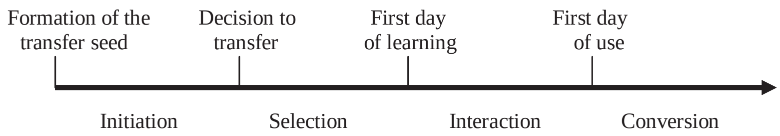
Therefore, there is a relationship mechanism, as depicted in Figure 2. This mechanism coordinates and influences the relevant actors' behaviours for inter-organisational knowledge transfer.

AN INTER-ORGANISATIONAL KNOWLEDGE TRANSFER PROCESS MODEL

Through the above review, it is known that inter-organisational knowledge transfer process can be divided into two subprocesses. Drawing on Szulanski's (2000) process model in Figure 1, the first subprocess can be further divided into three stages: initiation, selection, and interaction; the second subprocess may be called conversion. So, a similar four-stage model for inter-organisational knowledge transfer is offered in Figure 3.

In the initiation stage, two organisations try to find an opportunity to transfer and to decide whether to pursue it through negotiation. In the selection stage, the receiving and giving organisations select an employee as a receiving and giving employee respectively (more than one employee may be involved, of course, in either organisation). In the interaction stage, the giving employee transfers his/her knowledge to the receiving employee. In the conversion stage, the receiving employee transfers his/her acquired knowledge to his/her employer— the receiving organisation. The conversion stage is only related to the receiving organisation and receiving employee.

Figure 3. The inter-organisational knowledge transfer process



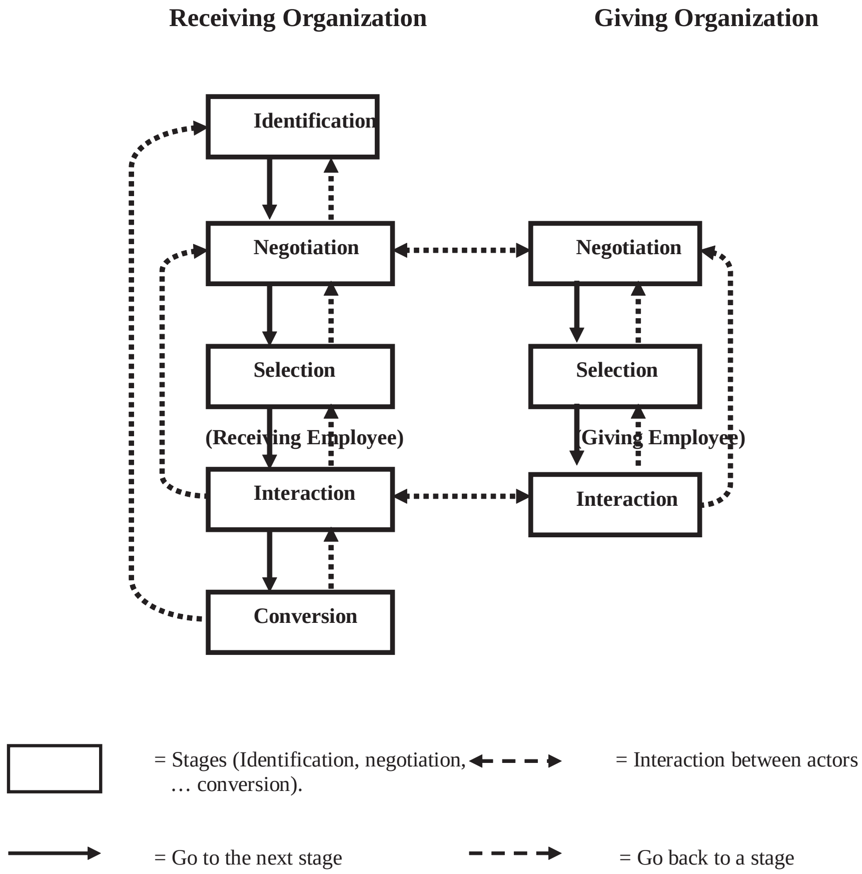
The relationship between the process model in Figure 3 and Szulanski's (2000) process model may be seen as follows: (1) The initiation and interaction stages of the former are similar to the initiation and implementation stages of the latter. (2) In the conversion stage of the former, the receiving employee plays two roles: first, he/she, as a recipient, will apply his/her acquired knowledge to his/her work and have to experience the ramp-up and integration stages; second, he/she is also a source for his organisation as his/her colleagues may learn from him/her. So, the conversion stage contains the ramp-up and integration stages, as well as the whole transfer process within an organisation.

Based on Figures 2 and 3, annd in addition to suggestions from some empirical evaluation with company managers (e.g., the initiation stage should be further divided into two stages: identification and negotiation to highlight their importance), a process model can be proposed for the inter-organisational knowledge transfer and is illustrated in Figure 4. The following explanation is provided for the five stages, although there may be no clear-cut division between them.

1. Identification: In this stage, the receiving company internally finds its knowledge gap, identifies its needs for acquiring external knowledge and the external knowledge source.
2. Negotiation: In this stage, the receiving company negotiates (or discusses) with the giving company on the knowledge transaction, or any problems happening in the transfer process, to reach an agreement or oral commitment.
3. Selection: It is a stage in which a giving (or receiving) employee is selected by the giving (or receiving) organisation to specifically carry out the agreed transfer task.
4. Interaction: It is a stage in which both the giving and receiving employees iteratively contact each other to transfer the agreed knowledge.
5. Conversion: It occurs when the receiving employee contributes his/her acquired knowledge to the employer (i.e., the receiving organisation), the individual learning will be converted into organisational learning to successfully improve the receiving organisation's business.

The proposed process model not only identifies the important stages in the inter-organisational knowledge transfer process, but also shows the dynamic interactions between the organisations involved. More importantly, the model emphasises the repetitive nature of the process among stages and demonstrates the necessity of iterative loops between some stages. The transfer process may, sometimes not simply progress in the stage sequence but in iterative loops, as it may be necessary to go back to the previous stage. For example, once the receiving organisation initially identifies its needs for acquiring external knowledge and

Figure 4. The inter-organisational knowledge transfer process model



the external knowledge source (i.e., the giving organisation), the former will negotiate or discuss with the latter to further clarify what the former exactly wants. Sometimes, the needs initially identified by the receiving organisation may be found to be inaccurate; thus it is necessary for the receiving company to go back to the identification stage to further clarify its needs. Then it will negotiate or discuss with the giving organisation again. This process may carry on until the true needs for the receiving organisation are correctly identified. Although the selection of a receiving employee is the receiving organisation's internal affair, sometimes the receiving organisation may inform or consult the giving organisation about its arrangements for the receiving employee. So, there is a feedback loop that goes from the selection stage to the negotiation stage until the receiving employee is finally selected. Further, the transfer process in the receiving organisation may also have iterative loops during its interaction with the giving organisation. Similar things may happen in the giving organisation as well.

In the conversion stage, the receiving employee will apply the acquired knowledge into the receiving organisation's business. The receiving employee may still need the giving employee's help because he/she may not fully understand the acquired knowledge or not fully absorb the knowledge needed for the application. This will initiate a feedback loop from the conversion stage to the interaction stage, then back to the conversion stage again. Furthermore, different organisations have different environments. The application of the knowledge in the new environment may trigger some new problems, which may cause the receiving organisation to identify its new needs for knowledge acquisition. Some of them may be internally met in the conversion stage. Some of them may cause the receiving organisation to seek a new external knowledge source and begin a new round of inter-organisational knowledge transfer. So, there is a backward loop from the conversion stage to the identification stage.

CONCLUSION

Through a review of the relevant literature on knowledge transfer, organisational learning and social networks, an inter-organisational knowledge transfer process model is developed. As shown in the model, inter-organisational knowledge transfer is a complex process and difficult to understand. As a result, the success of the transfer can be affected by many factors and pose serious challenges to organisations. Some empirical research has been carried out to test the model, and the preliminary findings suggest that managers feel that the process model is a sound attempt to reflect companies' knowledge transfer practices and can help the companies to better understand the nature, the mechanism, and the process of the knowledge transfer.

FUTURE TRENDS

Future research needs to be undertaken to identify the important factors in each stage. For instance, in the interaction stage, the receiving employee will learn from the giving employee, the former's absorptive capacity and prior experience, the latter's openness, prior experience and expressiveness, as well as the trust between both of them (Cohen & Levinthal, 1990; Wathne, Roos & von Krogh, 1996; Chen, Duan, & Edwards, 2002) could be identified as the important factors for the stage. Furthermore, inter-organisational knowledge transfer strategies for both receiving and giving organisations can be developed to help them to address the "boundary paradox" (Quintas, Lefrere, & Jones, 1997) more effectively and maximise the potential benefits of knowledge sharing for both organisations involved.

Chapter 2.16
Organizational Semantic Webs

Jean-Yves Fortier
University of Picardie Jules Verne, France

Gilles Kassel
University of Picardie Jules Verne, France

INTRODUCTION

The main subject tackled in this article is the use of knowledge technologies to develop corporate memories or (stated more generally) "organizational memories" (OMs) (Dieng, Corby, Giboin, & Ribière, 1999).

At the end of the 1990s, AI technologies, in general, and knowledge technologies, in particular, were recognized as pertinent and promising tools (in addition to information technologies) for the design of OMs (Buckingham Shum, 1997; O'Leary, 1998; Milton, Shadbolt, Cottam, & Hammersley, 1999). These very diverse technologies (concepts, methods, and tools) have been conceived to assist knowledge acquisition, modeling, and discovery, as well as the development of knowledge-based systems (Studer, Benjamins, & Fensel, 1998). In this article, we focus on knowledge modeling and formalization techniques, since our prime interest is the preservation of knowledge within OMs and its impact on the exploitation of this knowledge.

In practice, the use of these technologies generates two complementary proposals: (1) the formalization of a part of knowledge to be preserved, which means considering hybrid memories in terms of specification modes (formal, semi-formal, and informal); and (2) the introduction of a formal ontology of the domain in question, in order to facilitate the expression, comprehension, and access to capitalized knowledge. Formalization thus relates to both (1) knowledge (as propositional knowledge) and (2) meaning (as conceptual knowledge).

Regarding the balance between formal and informal specification, a broad spectrum of OM architectures have been proposed, ranging from informal annotation of formal knowledge bases (Euzénat, 1996) to the formal annotation of informal documents (Buckingham Shum, Motta, & Domingue, 2000). It should be noted that these extremes (i.e., the development of a text-documented knowledge base and the publication of scientific articles on the Web, respectively) correspond to atypical OM applications.

The knowledge technologies used in 2004 to develop OMs are generally those of the Semantic Web, where languages like OWL (Antoniou & van Harmelen, 2004) allow us to exchange knowledge bases on the Web. One particular asset of OWL is its ability to offering several dialects with different expressive powers—the choice of the dialect depending on the specific application in question.

A review of the state of the art (cf. section 2) shows that current OM architectures rely on "lightweight" knowledge models, corresponding to formal annotations of textual resources. These approaches focus on document "enrichment" (Motta, Buckingham Shum, & Domingue, 2000), since the knowledge models and ontologies are used to facilitate access to textual resources and the dissemination of the latter to interested users.

In contrast to these initiatives (or rather by extending them), we recommend giving more importance to formalization, by going back to Buckingham Shum's original proposal (1997) of formalizing a part of the knowledge to be capitalized. Such an approach requires us to improve the knowledge technologies used, in order to make it possible to apprehend and reason on the contents of the resources independently of the specification modes (cf. sections 3, 4, and 5).

BACKGROUND

Our current work concerns the conception and development of organizational Semantic Webs (OSWs), that is, OMs whose implementation exploits Semantic Web technologies. The evolution of the Web into a Semantic Web is currently the subject of numerous research programs (Berners-Lee, Hendler, & Lasilla, 2001). The principal aim is to enable software agents to exploit the contents of textual resources present on the Web so that users can ultimately be relieved of certain information searching and combination tasks (Fensel, Wahlster, Lieberman, & Hendler, 2003). The developed technologies apply as much to the Web as a whole as to OSWs in particular.

Current OSW architectures rely on the coupling of a collection of textual resources with formal resources, the latter also being qualified as "semantic" resources. Of these, one can distinguish annotations of textual resources or "metadata" (which express knowledge about textual resources) (Handschuh & Staab, 2003) on one hand, and ontologies (which stipulate the meaning of the terms used to express the textual resources and the metadata) (Davies, Fensel, & van Harmelen, 2003; Abecker & van Elst, 2004) on the other hand. Again, one finds a distinction between knowledge and meaning. In terms of the contribution of these semantic resources, various approaches are being explored. They may thus be used for:

- navigating within a network of annotations, in order to help discover documents and apprehend their contents (Buckingham Shum et al., 2000)
- furnishing the user with the documents likely to interest him or her, by taking into account his or her centers of interest expressed in terms of ontological concepts (Davies, Duke, & Sure, 2003; Middleton, De Roure, & Shadbolt, 2004; Uschold et al., 2003)
- ranking answers to queries by taking into account the annotations' contents (Stojanovic, Studer, & Stojanovic, 2003) and/or the memory's uses such as previous consultations

The study of these architectures shows that they force formal resources into a precise role: constituting an index for textual resources. This type of coupling can be qualified as "weak," to the extent that the only aim of these formal resources is to facilitate the exploitation (access, dissemination) of the textual resources – the capitalized knowledge being only present in the latter. When a user sends a query to this type of OSW, the answer he or she receives is a list (ranked by estimated relevance) of textual resources likely to contain the desired information. This user must then still locate information within these documents.

In order to increase the assistance provided by OSWs, we recommend carrying out "strong" coupling by modeling a part of knowledge to be capitalized, which amounts to distributing the capitalized knowledge between the textual resources and the formal resources. It is necessary to choose which knowledge to model. Several dimensions must be taken into account: the value of knowledge for the organization and its degree of consensuality and stability. In this respect, our priority is to model the organization to which the OSW is dedicated, resulting to some extent in the maintenance of a modeled management report on the organization. This choice appears to us to offer a good return on investment if one compares the assistance provided with information searching on one hand, and the cost of modeling this knowledge on the other hand.

The principal utility of knowledge modeling is to enable an OSW to reason on this knowledge. For example, by reasoning on the organization model, the OSW can build views of the organization suited to the user profile—this profile itself being modeled—thus, facilitating access to the organization's documentation.

At the same time, however, knowledge modeling raises difficulties. First, the distribution of capitalized knowledge across several information sources (according to their specification modes) complicates localization of (and thus access to) this knowledge. In addition, another problem relates to the dissemination of modeled knowledge, which is specified in a formal language not easily understood by a user. One can draw a parallel with the Semantic Web's "metadata": these formal annotations are interpretable by machines but not by humans. Lastly, modeling some pieces of knowledge does not solve the problem of access to information contained within textual resources.

To overcome these difficulties, we recently proposed (1) splitting up the textual resources (in order to reveal information relating to targeted subjects) and introducing a metamodel of knowledge and information contained into the OSW, independently of the way the knowledge/information is specified and located (Fortier & Kassel, 2003a); (2) combining this metamodel with a mechanism for dynamic document generation, created on demand and meeting user expectations (Fortier & Kassel, 2003b).

"STRONG" COUPLING AT WORK

In this section, we present a general view of our proposal by illustrating it with a simple example: the memory of a R&D project. This is inspired by a real application currently conceived within the K²M3 environment (Knowledge Management through Meta-Knowledge Modeling) developed on a multi-agent platform and encapsulating DefOnto as a knowledge representation language (Cormier, Fortier, Kassel, & Barry, 2003).

Example of an OSW consultation

Consultation of an OSW consists of a series of exchanges during which (1) the user expresses a need for information on a given subject and (2) the OSW answers him or her by dynamically generating a document which gathers together relevant information.

Thus, if a participant in a R&D project requests information on a particular project task, the OSW will provide a document similar to that shown in Figure 1. This document contains information about the task, organized by the OSW into a certain order so as to constitute a coherent whole. The text begins with an acronym, followed by the task's full title and category. It continues with the presentation of the general objective as well as the

task's current state of progress, before introducing the work meeting schedule and the partners involved in performance of the task.

Certain pieces of information stem from the organizational model, whereas others are extracted from documents. In our example, the acronym, the heading, the category, the meeting dates, and the involved partners are modeled information, whereas the general objective of the task, its progress report, and the agenda of the meetings of work are extracted from various documents (the project's scientific and technical file, the last progress report, e-mail messages about forthcoming meetings, and meeting reports for previous meetings, respectively).

The generated document comprises moreover two types of links added by the OSW. The first is placed whenever the OSW cites elements for which it is possible to present further information. The activation of this link leads to a new information presentation (document). In our example, these links correspond to the work meeting on June 5, 2003 and the various partners involved in performance of the task. The second type of link appears during the introduction of the document fragments whenever it is possible to consult the corresponding document. It is placed so as to allow the user to consult the entire document if he or she so desires.

The Organization Model

The organization model (with which the OSW is equipped) corresponds to the description of an organization (here a R&D project) according to different viewpoints and at different levels of abstraction. Just like an organization (i.e., a group of people carrying out a project together), a project itself comprises participants (who may be affiliated to various organizations considered as partners) and generally has a leader. As a complex process, a project can be decomposed into tasks, giving rise to the performance of a variety of activities (e.g., work meetings, document writing, software development, etc.). Finally, a project produces results, some of which are material (e.g., software, documents, and other artefacts) and others of which are immaterial (e.g., a conceptual methodology).

Hence, one finds different kinds of objects in such a model. The organization ontology makes the meaning of these different object types explicit, and contains a specification of notions such as “Partner,” “SteeringCommittee,” “FinalReport,” “Task,” and so forth. Such an ontology plays two roles: During the OSW development phase, it helps express the organizational model and thus corresponds to populating the ontology; later, at runtime, the implemented version is used to infer facts which are implicit within the organization model. In our approach, these two roles are exploited in turn.

According to the definition, the organization model includes a description of the organization’s textual resources. Therefore, we can consider that describing an organization according to different viewpoints amounts to extending the metadata approach generally used for the Semantic Web: In addition to document descriptions, we have descriptions relating to other objects. Let us note, however, that this is knowledge about objects and not knowledge about knowledge, which is the aim of the content model.

The Content Model

The content model corresponds to a description of the content of an OSW, according to different viewpoints and at different levels of abstraction. Such a model supposes the reification of the contents so as to make the latter the subject matter of descriptions. For instance, after reifying the content of the sentence “the person in charge of the project is G. Kassel” into an object (called InfoResponsible, for example), it is possible to describe this object by expressing (for example) that “InfoResponsible was made public by the project Steering Committee.” The content model thus contains meta-knowledge.

As a starting point for working out such a model, we consider that content consists of Propositions relating to Subjects and that these Subjects are conceptual in nature. Concepts playing the role of Subjects can be generic (if they classify a set of objects, e.g.: ScanningTask, TechnicalNote) or individual (when they classify only one object, e.g.: SteeringCommittee, ProjectTechnicalFile). This starting point applies indiscriminately to Assertions constituting the organizational model (in terms of Propositions considered as true by the OSW) and Information conveyed in the textual resources (in terms of Propositions stated by an author and intended for another agent). We supplement it by considering that these Propositions may or may not be confidential and that the organizational concepts playing the role of a Subject also can constitute a CentreOfInterest for OSW users.

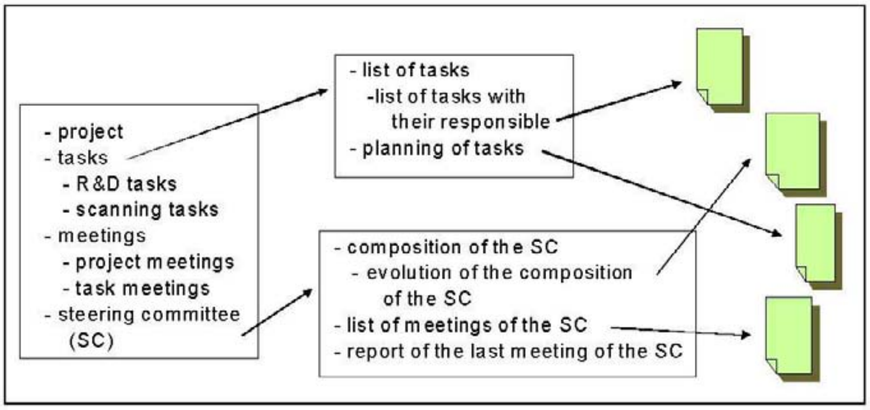
The Assertion model and the Information model rely on the same ontology, being expressed by means of the same concepts. However, the expressed Propositions are not comparable in nature: On one hand, Assertions are simple Propositions because they are formalized by means of a knowledge representation language with limited power of expression; on the other hand, pieces of Information are complex Propositions corresponding to the content of a text. To render the two models homogeneous, it is necessary to describe the text’s content on a finer level of detail. This is why we split up such texts into elementary contents relating to a MainSubject.

Expression of the Information Need

In order to help the user in his or her information search, the OSW generates an index of the different classes of information it is able to provide.

These classes of information are organized as a taxonomy of subjects. A semantic dependency between Concepts playing the role of Subject is to that end calculated. Such a classification allows us to consider, for instance, that information about

Figure 2. Excerpt of a content index



a car's engine constitutes information about the car itself. Let us note, however, that there is no subsumption link between the concepts CarEngine and Car. Following the same principle for a given project task, the OSW will suggest (see Figure 2) information about the task manager, the schedule for future work meetings, and the progress report.

Taking into account the high density of this taxonomy of information, we introduce a complementary index containing concepts of the organization model. This serves as an entrance point to the taxonomy of information by selecting a privileged view of the organization, since each index entry constitutes a partial view of the organization. In our "project memory" example, the OSW enables us to consult information about project partners, tasks, or participants. In the case of generic concepts, the index can be developed according to the subsumption hierarchy and by presenting explicitly the various semantic axis (if they exist) used to define the ontology. For example, the project tasks can be derived into tasks in progress or finished tasks on the "progress stage" axis and into survey, R&D, or management tasks on the "task category" axis. These semantic axes allow better comprehension of the distinctions made between concepts during the ontology design and also help the user refine his or her need for information.

This whole content index (i.e., made up of the two indices presented) appears to us to be more useful than the expression of requests in a dedicated language because it avoids the need to know a query language and furthermore allows the user to find unanticipated information. It is generated for each user group, taking into account its access rights and centres of interest. To that end, the OSW exploits the content model in order to be aware of the users' centres of interest as well as the information subjects.

The Generation of Personalized Virtual Documents

We introduced a mechanism for generation of information presentations by taking what has been developed in the Customized Virtual Document field as a starting point for producing the information presentations. This mechanism allows us to customize the generated presentations according to users' access rights and centres of interests. The mechanism is composed of four steps:

- Relevant information retrieval: The OSW uses an inference engine to deduce all the propositions which deal with the required subject, being formalized or expressed in natural language in textual resources.
- Selection: The OSW carries out an initial sorting by only retaining those propositions which are transmissible to the user. For example, a person outside the project will only obtain general information about the project, whereas a project participant has access to more precise information, such as a task's progress report.
- Scheduling: The OSW must present the propositions in a logical order to the user. This is achieved by using presentation methods which specify order of ranking for different concept categories. Thus, for information in documents, the OSW will add a link to this document and will notably specify the author, the publication date, and the reason for drafting the document: This allows the user to contextualize a document, more easily evaluate its relevance, and only activate the link to consult the full document if it proves to be of interest.
- Composition: Once the presentation's logical structure has been defined, the OSW must generate the physical document. When the presentation mentions other elements on which the OSW is able to give further information, the OSW adds a link which leads to an index of available information on the subject.

FUTURE TRENDS

The approach presented concerning—the implementation of "strong" coupling between textual and formal resources—builds on the modeling of meta-knowledge. The taking into account of such meta-knowledge—on both the conceptual level (via ontologies) and the formal level (via knowledge representation languages)—is now recognized as an important issue for the future of the Semantic Web, and is subject of much research from which OSWs will benefit.

On the conceptual level, there is a need to introduce (meta-)concepts such as Subject, Centre of interest (denoting concepts), or Assertion, Definition, Confidential Information, Hypothesis (denoting propositions) into ontologies. Fox and Huang (2003) thus proposed an ontology of propositions to deal with the origin and validity of information contained in Web pages. Gangemi and Mika (2003) have, for their part, defined an ontology of Description and Situation to allow software agents to exchange information on the Web. Recently, we proposed a synthesis of these efforts with the Information and Discourse Acts (I&DA) ontology, which proposes a set of generic concepts allowing simultaneous definition of contents, the expression of contents, and the discourse acts which create and/or interpret these contents (Fortier & Kassel, 2004).

On the formal level, the issue is one of being able to simultaneously represent the content of propositions (e.g.: "current architectures of OSWs are based on weak coupling between textual and formal resources") and meta-knowledge relating to propositions (e.g.: "this information is a thesis defended by J.-Y. Fortier and G. Kassel") or concepts (e.g.: "the OSW concept is the subject of recent articles by J.-Y. Fortier and G. Kassel"). The OWL-Full language reuses the RDFS primitive "meta-class" and enables representation of certain pieces of meta-knowledge but does not enable one to perform inferences on the latter (Antoniou & van Harmelen, 2004). One of the objectives of our ongoing work on the definition of the DefOnto language is to equip Semantic Web languages with a semantic which enable representation and reasoning on meta-knowledge (Cormier et al., 2003).

CONCLUSION

In this article, we have situated our work within the context of the Semantic Web (a subject that it is impossible to ignore these days), considered the design of "Organizational Semantic Webs" and proposed an approach for the development of a new generation of OSWs—strong coupling between textual and formal resources.

The objective underlying this approach amounts to putting on an equal footing texts and knowledge models for capitalizing knowledge and thus exceeding the simple formal annotation of textual resources. We emphasized the fact that if the scientific community is to reach this objective, it must make progress with Semantic Web technologies, in particular in terms of representing meta-knowledge related to formal or informal contents.

The key issue of this proposal is to confer OSWs with better capacities to exploit their contents. It is a matter of transforming these knowledge and information "repertories"—currently OSWs—into agents which assist users with their work in general and with knowledge management tasks in particular (Baek, Liebowitz, Prasad, & Grangier, 1999).

Chapter 2.17
A Mobile Portal Solution for Knowledge Management

Stefan Berger
Universität Passau, Germany

Ulrich Remus
University of Erlangen-Nuremberg, Germany

ABSTRACT

This chapter discusses the use of mobile applications in knowledge management (mobile KM). Today more and more people leave (or have to leave) their fixed working environment in order to conduct their work at changing locations or while they are on the move. At the same time, mobile work is getting more and more knowledge intensive. However, the issue of mobile work and KM is an aspect that has largely been overlooked so far. Based on requirements for mobile applications in KM an example for the implementation of a mobile KM portal at a German university is described. The presented solution offers various services for university staff (information access, colleague finder, campus navigator, collaboration support). The chapter is concluded by outlining an important future issue in mobile KM: the consideration of location-based information in mobile KM portals.

INTRODUCTION

Today many working environments and industries are considered as knowledge intensive, that is, consulting, software, pharmaceutical, financial services, and so forth. Knowledge management (KM) has been introduced to overcome some of the problems knowledge workers are faced by handling knowledge, that is, the problems of storing, organizing, and distributing large amounts of knowledge and its corresponding problem of information overload, and so forth. Hence, KM and its strategies aim at improving an organization's way of handling internal and external knowledge in order to improve organizational performance (Maier, 2004).

At the same time more and more people leave (or have to leave) their fixed working environment in order to conduct their work at changing locations or while they are on the move. Mobile business tries to address these issues by providing (mobile) information and communication technologies (ICT) to support mobile business processes. However, compared to desktop PCs, typical mobile ICT, like mobile devices such as PDAs and mobile phones, have some disadvantages (Hansmann, Merk, Niklous, & Stober, 2001):

- Limited memory and CPU – Mobile devices are usually not equipped with the amount of memory and computational power in the CPU found in desktop computers.
- Small displays and limited input capabilities – for example, entering a URL on a Web-enabled mobile phone is cumbersome and slower than typing with a keyboard.
- Low bandwidth – in comparison to wired networks, wireless networks have a lower bandwidth. This restricts the transfer of large data volumes.
- Connection stability – due to fading, lost radio coverage, or deficient capacity, wireless networks are often inaccessible for periods of time.

Taking into account the aforementioned situation one must question whether current IT support is already sufficient in order to meet the requirement of current knowledge-intensive mobile work environments. So far, most of the off-the-box knowledge management systems are intended for use on stationary desktop PCs and provide just simple access from mobile devices. As KMS are generally handling a huge amount of information (e.g., documents in various formats, multimedia content, etc.) the management of the restrictions described above become even more crucial. In addition, neither an adaptation of existing knowledge services of stationary KMS nor the development of new knowledge services according to the needs of mobile knowledge workers is taking place.

The goals of this chapter are to identify the main issues when mobile work is meeting knowledge management. In particular the focus lies on mobile knowledge portals, which are considered to be the main ICT to support mobile KM. Further on the applicability of these suggestions is shown with the help of a mobile knowledge portal that was implemented at a German university.

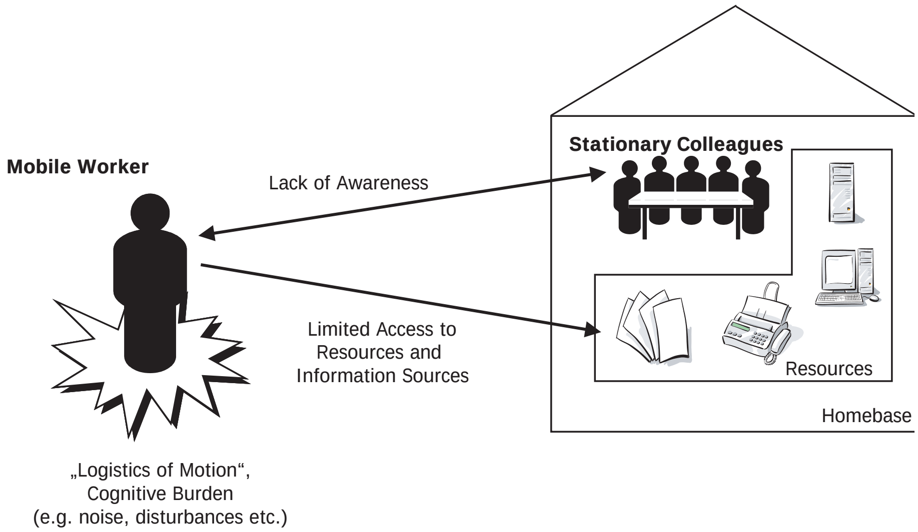
The chapter is structured as follows: Section two will detail the understanding about mobile KM and derive important requirements to be fulfilled. In section three mobile knowledge portals are then described as main ICT to support tasks in mobile KM. As an example the mobile KM portal of the University of Regensburg is presented (section four) whereas section five shows location orientation as the next step in mobile KM. Finally, section six concludes this chapter and gives an outlook on future research issues within the field of mobile KM.

KNOWLEDGE MANAGEMENT MEETS MOBILE WORK

A mobile working environment differs in many ways from desk work and presents the business traveler with a unique set of difficulties (Perry, O'Hara, Sellen, Brown, & Harper, 2001). In the last years several studies have shown that mobile knowledge workers are confronted with problems that complicate the fulfillment of their job (Figure 1).

Mobile workers working separated from their colleagues often have no access to the resources they would have in their offices. Instead, business travelers, for example, have to rely on faxes and messenger services to receive materials from their offices (Schulte, 1999). In case of time-critical data, this way of communication with the home base is insufficient. Bellotti and Bly (1996) show in their survey about knowledge exchange in a design consulting team that it is difficult for a mobile team to generally stay in touch. This is described as "Lack of Awareness." It means that a common background of common knowledge and shared understanding of current and past

Figure 1. Problems related to mobile work



activities is missing. This constrains the exchange of knowledge in teams with mobile workers. In addition, mobile workers have to deal with different work settings, noise levels, and they have to coordinate their traveling. This “Logistics of Motion” lowers their ability to deal with knowledge-intensive tasks (Sherry & Salvador, 2001) while on the move. The danger of an information overflow increases.

Mobile KM is an approach to overcome these problems. Rather than adding to the discussion of what actually is managed by KM—knowledge workers, knowledge, or just information embedded into context—in this chapter, mobile KM is seen as KM focusing on the usage of mobile ICT in order to:

- provide mobile access to KMS and other information resources;
- generate awareness between mobile and stationary workers by linking them to each other; and
- realize mobile KM services that support knowledge workers in dealing with their tasks (Berger, 2004, p. 64).

The next section reviews the state of the art of KMS and reviews if it meets these requirements.

MOBILE KM PORTALS

Currently, many KMS are implemented as centralistic client/server solutions (Maier, 2004) using the portal metaphor. Such knowledge portals provide a single point of access to many different information and knowledge sources on the desktop together with a bundle of KM services. Typically, the architecture of knowledge portals can be described with the help of layers (Maier, 2004). The first layer includes data and knowledge sources of organizational internal and external sources. Examples are database systems, data warehouses, enterprise resource planning systems, and content and document management systems. The next layer provides intranet infrastructure and groupware services together with services to extract, transform, and load content from different sources. On the next layer, integration services are necessary to organize and structure knowledge elements according to a taxonomy or ontology.

The core of the KMS architecture consists of a set of knowledge services in order to support discovery, publication, collaboration, and learning. Personalization services are important to provide a more effective access to the large amounts of content, that is, to filter knowledge according to the knowledge needs in a specific situation and offer this content by a single point of entry (portal). In particular, personalization services together with mobile access services become crucial for the use of KMS in mobile environments.

Portals can be either developed individually or by using off-the-shelf portal packages, for example, Bea WebLogic, IBM Portal Server, Plumtree Corporate Portal, Hyperwave Information Portal, or SAP Enterprise Portal. These commercial packages can be flexibly customized in order to build up more domain-specific portals by integrating specific portal components (so called portlets) into a portal platform. Portlets are more or less standardized software components that provide

Figure 2. Tasklist, calendar, and discussion board of Open Text's Livelink Wireless (Open Text, 2003, p. 12)

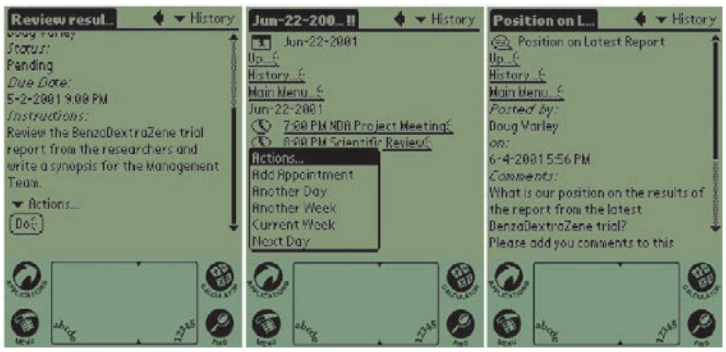


Figure 3. Automatic text summarization (Open Text, 2003, p. 11)

access to a various amount of applications and (KM) services, for example, portlets to access ERP-systems, document management systems, personal information management.

In order to realize mobile access to knowledge portals, portlets have to be implemented as mobile portlets. That means that they have to be adapted according to technical restrictions of mobile devices and the user's context. At the moment, commercial portal packages cannot fulfill sufficiently the needs of mobile KM. Most of the systems are enhanced by mobile components, which are rather providing mobile access to stationary KM services instead of implementing specific mobile KM services.

Hyperwave's WAP (Wireless Application Protocol) Framework, for example, enables mobile users to browse the Hyperwave Information Portal with WAP-enabled devices. The Wireless Suite of Autonomy is a WAP-based solution with the focus on awareness-generating features such as peoplefinder and community support.

At present, the most comprehensive support for mobile KM is provided by the Livelink portal from Opentext Corporation. With the help of the Wireless Server users can access discussion boards, task lists, user directories (MS Exchange, LDAP, Livelink User Directory), e-mail, calendar, and documents (Figure 2). In addition, it provides some KM services specially developed for mobile devices, for example, automatic summarization of text. Hence even longer texts can be displayed on smaller screens (Figure 3).

EXAMPLE: A MOBILE KM PORTAL FOR A GERMAN UNIVERSITY

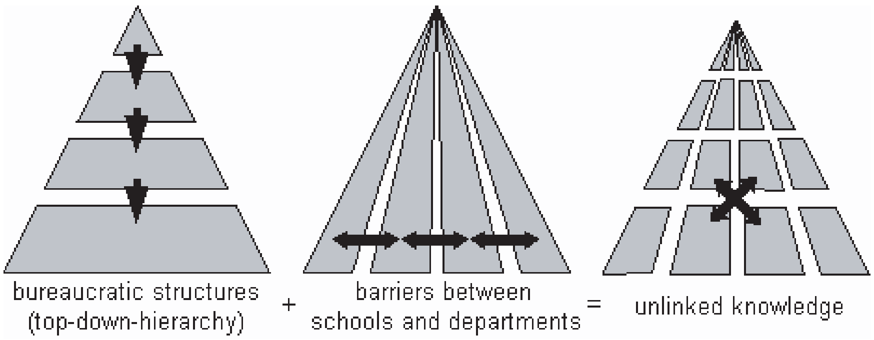
In recent years German universities, which are financed to a large extent by public authorities (federal states and federal government), have been severely affected by public saving measures. As a result lean, efficient administrative procedures are more important than ever. KM can help to achieve these objectives. One example is to provide easy accessible expert directories, where staff members with certain skills, expertise, and responsibilities can be located ("Person XY is responsible for third-party funding") in order to support communication and collaboration.

However, there are several reasons why the access to information of this type is limited at the University of Regensburg. First, there is the decentralized organizational structure. All together about 1,000 staff members are working in 12 different schools and about 15 research institutes at the university, serving about 16,000 students. Because most of the organization units are highly independent, they have their own administrations and the exchange of knowledge with the central administration is reduced to a minimum. Likewise there is hardly an exchange of knowledge between different schools and departments. As a result, knowledge that would be useful throughout the whole university is limited to some staff members ("unlinked knowledge," Figure 4).

A second problem is that many scientific staff members work on the basis of (short-term) time contracts. This leads to an increasing annual labor turnover, comparable to the situation that consulting companies are facing. Important knowledge about past projects, courses, and scientific results is lost very easily. Due to this fact, a high proportion of (new) staff members are relatively inexperienced to cope with administration processes, which can be described as highly bureaucratic and cumbersome.

To overcome these problems—the lack of communication between departments and the need to provide specific knowledge (i.e., administrative knowledge) for staff members—the University of Regensburg decided to build up a knowledge portal called U-Know (Ubiquitous Knowledge). U-Know is meant to be a single point of access for all relevant information according to the knowledge needs described above. When conducting a knowledge audit it became obvious that a large amount of knowledge is needed

Figure 4. Unlinked knowledge because of independent organization structures



when knowledge workers are on the move, that is, working in a mobile work environment. Staff is frequently commuting between offices, meeting rooms, laboratories, home offices; they attend conferences; and sometimes they are doing field studies (e.g., biologists or geographers).

Hence the picture of one single resource-rich office has to be extended towards different working locations, where a large number of knowledge-intensive tasks are carried out as well (Figure 5). Consequently the considered solution should meet these "ubiquitous" knowledge needs of current work practices at a university.

The portal should support staff members by managing the following:

1. Documented knowledge: A knowledge audit was conducted in order to obtain a better picture of knowledge demand and supply. This was mainly done with the help of questionnaires and workshops where staff members were asked to assess what kind of (out-of-office) information is considered as useful.
2. Tacit knowledge: In order to support the exchange of tacit knowledge (which is difficult to codify due to the fact that this knowledge lies solely in the employees' heads, often embedded in work practices and processes), the considered KM solution should enable communication and cooperation between staff members.

In order to meet these requirements U-Know should offer the KM services in Figure 6.

The services can be categorized into information, communication, collaboration, and search. The first category comprises all services that are responsible to manage simple information in the knowledge base. By invoking these services staff members obtain the information they need to perform their daily tasks, for example, news, notifications about changes in rooms, or phone numbers. A very important part of this section is the yellow pages (Figure 7) where all staff members are listed. This list can be browsed by names, departments, fields of research, and responsibilities.

Frequently asked questions (FAQ) answer questions that are typically asked by new staff members. The Campus Navigator helps locate places and finding one's way around the campus. Each room at the university carries a doorplate with a unique identifier. After entering a starting point in form of the identifier and a destination in form of the name of a person, of an office (e.g., "Office for Third-Party Fundings," "Academic Exchange Service"), or just another room number,

Figure 5. Knowledge demand in "mobile" situations

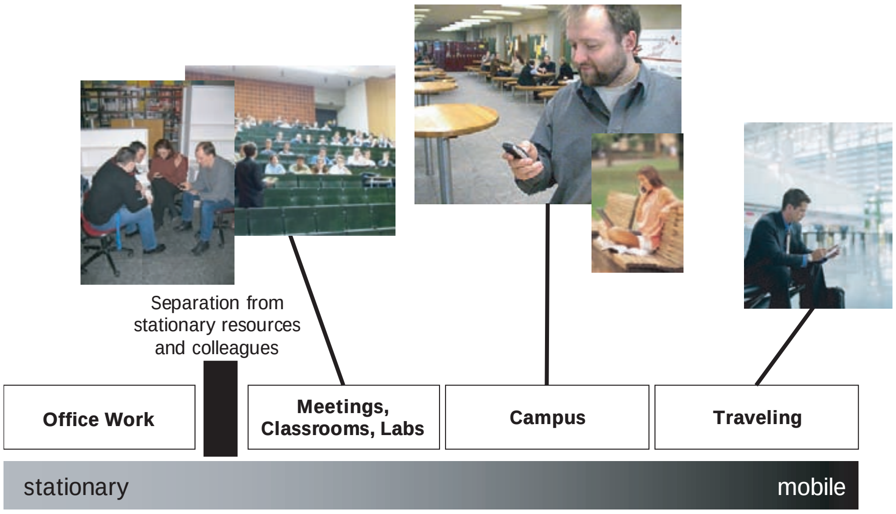


Figure 6. Features of U-Know

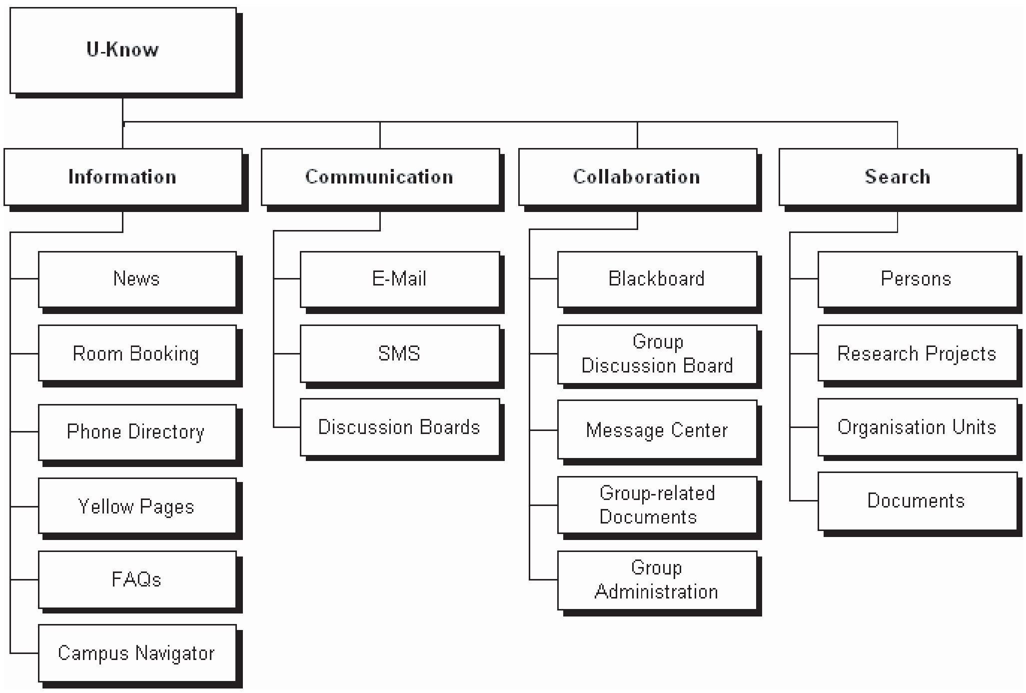

the shortest way to the destination is calculated and shown on maps of different sizes (Figure 8).

Communication-oriented features like e-mail, short message service (SMS), and discussion

Figure 7. U-Know yellow pages

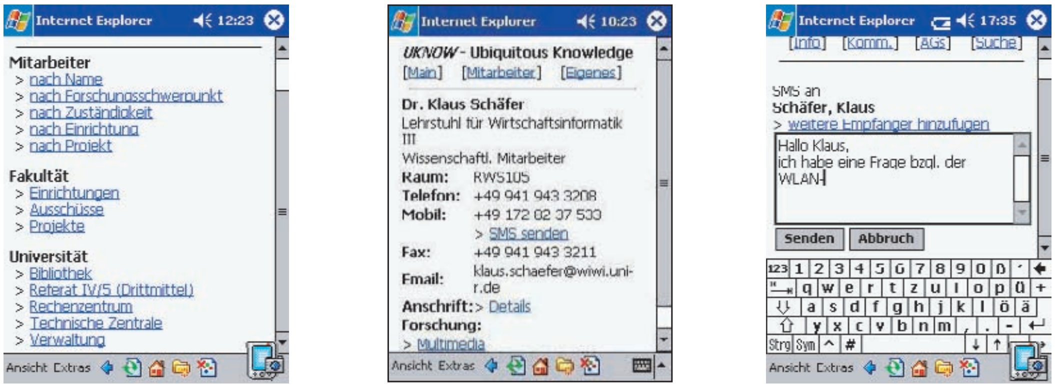

Figure 8. U-Know Campus Navigator

boards are intended to support the exchange of tacit knowledge between staff members.

To foster collaboration, for example, in temporary project groups, staff members can initiate workgroups by inviting colleagues via SMS or e-mail to join a virtual teamspace. After forming a workgroup the participants can use their teamspace for (electronic) group discussions and sharing documents. The blackboard displays all recent events, including new group members, new files, discussion entries, and administrative actions that are taken. In the search section queries can be limited to persons, research projects, organization units, or documents.

To support different networks there are several ways to access the portal. University staff can use the campuswide Wi-Fi network with Wi-Fi–capable devices. Users can also deploy a mobile phone and access the portal via a GSM-network and the Wireless Application Protocol (WAP). Hence it is possible to use the portal even when users are outside the university, for instance, at a conference. The phone directory or the yellow pages can be accessed via voice as the entry of longer words may be cumbersome in many situations. An integrated speech-recognition system "translates" the user's spoken words into database requests and the results back into speech.

LOCATION ORIENTATION AS NEXT STEP IN MOBILE KM

Generally, there is agreement about the distinction between human- and technology-oriented KM approaches which basically reflects the origin of the approaches. KM research should try to bridge the gap between human- and technology-oriented KM. Many authors have propagated a so-called "holistic" approach to KM. However, so far these authors leave it to the interpretation of the reader what such an approach might look like. The examples in the last column of Table 1 should be seen as a step towards detailing this approach which is called "bridging the gap" KM. In Table 1 this classification (Maier, 2004; Maier & Remus, 2003) is enhanced towards the consideration of mobile KM. As mobile KM is mainly focusing on instruments and systems, other dimensions like strategy, organization, and economics are not considered in this table.

In order to structure mobile KM, one can distinguish two dimensions: mobile access and location orientation. Mobile access is about accessing stationary KMS whereas location orientation explicitly considers the location of the mobile worker. The field of location-oriented KM draws attention from research in mobile KM, ubiquitous computing, location-based computing, and context-aware computing (Lueg & Lichtenstein, 2003).

So far, the implemented solution provides mobile access to a broad range of different knowledge sources in a mobile work environment. Univer-

Table 1. Mobile KM approaches (gray highlighted cell is covered by U-Know)

	Technology-oriented instruments and systems	**Human-oriented instruments and systems**	**Bridging the Gap instruments and systems**
Mobile Access	Mobile access to content, e.g. knowledge about organization (e. g. Campus Navigator), processes, products, internal studies, patents, online journals by using mobile devices focusing on services for presentation (e.g. summarization functions, navigation models) and visualization	Mobile access to employee yellow pages, skill directories, directories of communities, knowledge about business partners using mobile devices focusing on asynchronous E-Mail, Short Message Service (SMS) and synchronous communication (Chat), collaboration and cooperation, community support	Mobile access to ideas, proposals, lessons learned, best practices, community home spaces (mobile virtual team spaces), evaluations, comments, feedback to knowledge elements using mobile devices focusing on profiling, personalization, contextualization, recommendation, navigation from knowledge elements to people
Location-orientation	Adaptation of documented knowledge according to the user's current location	Locating people according to the user's location, e.g. locating colleagues, knowledge experts	Personalization, profiling according to the user's location and situation, providing proactive mobile KM services

sity staff can use the KM services provided by U-Know in order to access information, to find colleagues, to navigate the campus, to collaborate, and so forth. These KM services mainly support the human-oriented KM approach. In fact, typical knowledge services were adapted with regard to the characteristics of mobile devices, that is, small display, bandwidth, and so forth.

However, an adaptation of these services according to the user's location has not taken place yet, whereas a customization of services according to the location of the user would enable a mobile knowledge portal to supply mobile knowledge workers with appropriate knowledge in a much more targeted way. At the same time, information overload can be avoided, since only information relevant to the actual context and location is filtered and made available. Think of a researcher who is guided to books in a library according to his/her own references but also according to his/her actual location.

Currently, common "stationary" knowledge portals are ill-suited to support these new aspects of KM derived from a location-oriented perspective (Berger, 2004). One reason is that the context, which is defined by the corresponding situation (tasks, goals, time, identity of the user) is still not extended by location-oriented context information (Abecker, van Elst, & Maus, 2001).

Location-oriented knowledge services could contribute to

- More efficient business processes: Shortcomings arising from mobility can be compensated by considering location-oriented information. Times for searching can be reduced due to the fact that information about the location might restrict the space of searching (e.g., an engineer might get information about a system that he/she is currently operating). Possibly, redundant ways between mobile and stationary work place are omitted when the information is already provided on the move.
- Personalization: When considering the user's location information can be delivered to the user in a much more customized and targeted way (Rao & Minakakis, 2003). For example, an engineer in a production hall is seeking information about outstanding orders, whereas close to machines he might need information about technical issues or repair services. In addition, location-oriented information might be helpful to locate other "mobile" colleagues who are nearby.
- New application areas: The integration of common knowledge services together with location-oriented mobile services may also extend the scope for new applications in KM, for example, the use of contextual information for the continuous evolution of mobile services for mobile service providers (Amberg, Reus, & Wehrmann, 2003). One can also think of providing a more "intelligent" environment where information about the user's location combined with sophisticated knowledge services adds value to general information services (e.g., in museums, where customized information to exhibits can be provided according to the user's location).

To build up mobile knowledge portals that can support the scenario described above, mobile portlets are needed that can realize location-oriented KM services. In case of being implemented as proactive services (in the way that a system is going to be active by itself), these portlets might be implemented as push services. In addition, portlets have to be responsible for the import of location-oriented information, the integration with other contextual information (contextualization), and the management and exploitation of the location-oriented information. Of course, the underlying knowledge base should be refined in order to manage location-oriented information.

With respect to mobile devices, one has to deal with the problem of locating the user and sending this information back to the knowledge portal. Mobile devices might be enhanced with systems that can automatically identify the user's location. Depending on the current net infrastructure (personal, local, or wide area networks), there are many possibilities to locate the user, for example, Wi-Fi, GPS, or radio frequency tags (Rao & Minakakis, 2003).

CONCLUSIONS AND OUTLOOK

The example of U-Know shows some important steps towards a comprehensive mobile KM solution. With the help of this system it is possible to provide users with KM services while being on the move. With its services like yellow pages, messaging features, and so forth, it creates awareness among remote working colleagues and thus improves knowledge sharing within an organization.

With respect to the acceptance of U-Know, two user groups can be distinguished. The first group is characterized by users who already own a mobile device, especially a PDA, in order to organize their appointments and contacts (personal information management). They are the main users of the system because they perceive the additional KM-related services as an extension of the capabilities of their devices. In contrast, staff members who did not use mobile devices for their personal information management are more reluctant to adopt the new system.

The Wi-Fi access soon became the most popular way of accessing the system. This is because of several reasons. Most of the staff members are actually working on the campus and the Wi-Fi access is free of charge for university members. Another reason is probably the higher bandwidth (and therefore faster connections) of Wi-Fi in comparison to a GSM-based access via WAP. Nevertheless, it can be assumed that decreasing connection fees and higher bandwidths of 3G-Networks (UMTS) would encourage staff to use the system from outside the university.

However, in order to fully meet the requirements of mobile KM in the near future, mobile KM portals have to be enhanced with mobile knowledge services that consider location-oriented information. Current work needs once more to address the adaptation of mobile services, the consideration of the user and work context for KM, and the design of highly context-aware knowledge portals.

Chapter 2.18
Organizational Structure

Paul H. J. Hendriks
Radboud University Nijmegen, The Netherlands

INTRODUCTION

For many decades, organization scientists have paid considerable attention to the link between knowledge and organization structure. An early contributor to these discussions was Max Weber (1922), who elaborated his concepts of professional bureaucracy. History shows a multitude of other descriptions and propositions which depict knowledge-friendly organization structures such as the 'organic form' for knowledge-intensive innovation promoted by Burns and Stalker (1961), professional bureaucracies and adhocracies described by Mintzberg (1983), and the brain metaphor for organization structure (Morgan, 1986). Discussions on such knowledgefriendly organization structures led to many neologisms including the flexible, intelligent, smart, hypertext, N-form, inverted, network, cellular, or modular organization.

This article discusses the fundamental importance of organization structure for a knowledge perspective on organizations. This discussion involves two classes of questions. Organization structure can be studied as the backdrop against which the knowledge aspects of organizations take shape. Key questions then are how different structural configurations involve stimuli and barriers to the generation and embedding of organizational knowledge through such processes as knowledge exploration and knowledge sharing. Organization structure can also be studied from the perspective of organization design, which is the premeditated construction or change of organization structure (see Bowditch & Buono, 1985). Questions that appear then include: what are possible design interventions and how does one assess their knowledge-friendliness? The article addresses both classes of questions. Its objective therefore is: (1) to look at what defines a knowledge-friendly organization structure, and (2) to explore which interventions organizations have at their disposal when trying to achieve such a structure.

BACKGROUND

The importance of organization structure is well established in the discussions that address matters of organizational knowledge and associated concepts such as creativity, learning, or R&D activities in organization design (e.g., Myers, 1996). Yet, in the stricter circle of studies that explicitly present themselves as knowledge management (KM) studies, organization structure plays second fiddle to issues of ICT and HRM. Organization structure concerns patterns of work relationships (a more elaborate definition of organization structure is given below). Such work relationships can be predefined (formal organization structure) or organically evolving (informal organization structure). There is a general recognition that relationships among individuals in collectives are centrally important in the organizational production of knowledge and its organizational embedding (e.g., Blackler, 1995). Several trends lend support to the idea that the perspective of knowledge workers and their work relationships should guide discussions of organization design. These trends include the increased complexity in the competitive environment, the greater pressure on innovation and proactive manipulation of markets, and the emergence of provisional structural arrangements such as in network organizations and organizational networks.

A common undertow in these discussions is that knowledge workers need the freedom or autonomy to decide for themselves when to establish work relationships. Such accounts stress that the formal organization structure can be a burden to knowledge aspects of work. They argue that organizational knowledge shows up much better in the informal organization structure (such as communities of practice, e.g., Brown & Duguid, 2001). As Teece (2000, pp. 39-40) puts it: "The migration of competitive advantage away from tangible assets towards intangible ones [forces organizations to] focus on generating, acquiring, transferring and combining such assets to meet customer needs. In order to be successful in these activities, firms and their managements must be entrepreneurial." This implies, according to Teece, that knowledge-intensive, entrepreneurial firms must have:

- flexible boundaries,
- high-powered incentives,
- non-bureaucratic structures,
- shallow hierarchies, and
- an innovative and entrepreneurial culture.

In short, the following suggestions are made for the design of knowledge-intensive forms: reduce hierarchy, only provide the basic outline of production structure, and transfer decisions to connect knowledge worker tasks from the formal to the informal organization structure. Note, however, that loosening control for knowledge work is a disputed issue (e.g., Butler, Price, Coates, & Pike, 1998).

Many of the proposed prescriptions for building knowledge-friendly organization structures (e.g., Quinn, 1992; Sanchez & Mahoney, 1996; Miles, Snow, Mathews, Miles, & Coleman, 1997) share with Teece's prescription a 'one-size-fits-all' character. The assertion that no single organization structure can be a panacea for all management ills, which underlies several organization theories (e.g., the contingency and configurational approaches; see Donaldson, 2001), seems to be fairly broadly accepted. Nevertheless, it appears to be weakly developed where organization structures for knowledge work are concerned. When authors do introduce contingencies (e.g., Nonaka & Takeuchi, 1997; Hobday, 2000), these are usually of a general nature (e.g., complexity or turbulence of the environment, analyzability of the task, size of the firm, type of technology), and not specifically knowledge related. The characteristics of an organization's knowledge base can also serve as contingency variables, as Birkinshaw, Nobel, and Ridderstrale (2002) show in a study of international R&D. Particularly the importance of system embeddedness, which is the extent to which knowledge is a function of the social and physical system in which it exists (Winter, 1987; Zander & Kogut, 1995), emerges from their study as an important contextual variable.

ORGANIZATIONAL STRUCTURE AND ORGANIZATIONAL KNOWLEDGE

Defining Organization Structure

In order to be able to assess the suitability of specific design advice for organizations from a knowledge perspective, we need to understand the denotation of the twin concepts of organization structure and organization design. The division of labor is the key concept underlying organization structure and design. When labor is divided among people and machines, the need also arises to integrate the tasks involved. These two elements, which Lawrence and Lorsch (Lawrence, Lorsch, & Garrison, 1967; Lawrence & Lorsch, 1969) identify as differentiation and integration, are generally recognized as the building blocks of organization structure. For instance, the definition of organization structure that Bowditch and Buono (1985, p. 258) give, which combines Mintzberg's (1979, 1983) well-known definition with the approach taken by Lawrence and Lorsch, states:

Organization structure can be broadly defined as the sum total of ways in which an organization divides its tasks and then coordinates them, in essence balancing job-related specialization (differentiation) with group-, intergroup, and organization-based coordination (integration) as appropriate.

Implied in any system of job definition are the relationships among the totality of tasks. Work relationships therefore define organization structure. A work relationship exists if and when the output of one task is used as part of the input of another task. Work relationships may be distinguished by their content or form. Regarding their content, two types of relationships are commonly discerned. Firstly, relationships exist within the production process (e.g., knowledge workers using the ideas or products of others as inspiration, or input, for their work). The pattern of these relationships defines what is commonly called 'the production structure'. Secondly, relationships can be discerned which affect the definition and realization of work relationships (e.g., knowledge workers deciding for themselves or being directed by a manager to use specific outputs as inputs). The pattern of these relationships is usually referred to as the control structure. As to their form, Thompson (1967) distinguishes three types of input-output connections or—as he calls them—three types of interdependencies: pooled (one actor receives input from multiple others), sequential (one actor transforms the output of an actor before passing it on as input for a third actor), and reciprocal interdependencies (two actors use each other's outputs as input).

The organization structure seen as patterns of work relationships concerns the content side of these relationships. Addressing issues of organization structure implies an abstraction from the personal elements in these relationships, such as individual preferences for work contacts, motivation, trust, and so forth. Obviously, such factors are important in the sense that they are affected by existing organization structures. They are also critical in the sense that they codetermine the success of organizational design choices. Therefore, fully understanding issues of organization structure is not possible when these are addressed in isolation.

From this account it follows that decisions of organization design fall into two basic categories. They concern: (1) either splitting or integrating tasks within production, and (2) either separating production from control or integrating production and control. Four archetypes of organization structures then appear situated on a continuum (see Table 1). The archetype of maximal splitting within production, combined with maximal separation of production from control, defines one end of the continuum (this describes the classical Tayloristic bureaucracy with its focus on specialization within production and elaborate control hierarchies). Full integration on both aspects defines the other end of the continuum (here one finds the team-based or project-based organization in which autonomous, multi-skilled work teams are responsible for their own work; e.g., Sitter, Hertog, & Dankbaar, 1997; Hobday, 2000). Intermediate positions are taken by the two remaining archetypes that combine splitting in production with integration in control and vice versa. A team-based organization becomes a network organization when decisions as to integration within production and control are not specified beforehand, but are left to individual team or network members.

An important question for KM is how different organization structures affect knowledge aspects of work. A basic way of addressing this question is to inspect how splitting or integrating in production and separating or integrating in control affect the knowledge processes within an organization (see Table 1). Splitting production into sub-functions, leading to specialization in the production of knowledge, has both positive and negative impacts on all knowledge processes (knowledge exploration, knowledge exploitation, knowledge sharing, and knowledge retention; see Hendriks & Vriens, 1999). What the effects will be depends on the criteria used for splitting. For instance, splitting according to knowledge domains or areas of expertise will stimulate knowledge exploration within these domains, but it will hinder knowledge sharing across domains. Splitting according to market knowledge, on the other hand, puts more emphasis on individual, tacit elements in knowledge. It comes with the boons of improved customer presence in knowledge exploitation and knowledge exploration. However, it also brings the risks of impaired knowledge sharing and knowledge retention within domains.

The Tayloristic machine bureaucracy is the archetype of an organization that combines maximal splitting in production with maximal separation of production from control. This organizational

Table 1. Effects of separation, splitting, and integration of tasks on knowledge processes

	Separation of production from control	Integration of production and control
Splitting of tasks within production	Tayloristic bureaucracy: knowledge application and retention via formal routines, knowledge transfer via the hierarchy, improved retention and exploitation of explicit knowledge, possible specialization in knowledge development, problems of tacit knowledge sharing.	Professional bureaucracy designed around small cells with specialized task elements within a larger task that manage their own work and connections to other cells within their production chain (e.g., in health services): possible specialization in knowledge development, advantages of tacit knowledge sharing within the cells, but across-cell transfer limited to explicit knowledge.
Integration within production	E.g., the hypertext organization with integral tasks but separate control structures: flexible knowledge exploration within teams and exploitation within the hierarchically organized layer, but possible conflicts of transferring and connecting ideas and plans developed in the project team layer and the application of these in new business (possible clashes between innovatism and conservatism).	The integrated team-based organization: more flexible knowledge development in connected knowledge domains, advantages of within team transfer of tacit knowledge, possible problems of reinventing the wheel by teams, barriers to inter-team cooperation and knowledge sharing.

form is characterized by advantages of possible specialization in knowledge exploration, by the fact that knowledge sharing takes the form of formalized knowledge transfer, and by the fact that procedures mainly address explicit knowledge, which is an important vehicle in knowledge retention.

Combining sub-functions in production, which leads to integrated knowledge in production, may in turn involve problems of knowledge retention associated with the risk of reinventing the wheel by different integrated units. Conversely, it implies combination benefits of knowledge from different knowledge domains in knowledge exploration and knowledge exploitation. An example of the archetype that combines maximal integration in production with maximal integration of production and control is that of the team-based project organization. This organizational form does not stimulate specialization in knowledge exploration, as it aims at broad employability. It focuses on mostly informal knowledge sharing via communication in teams and retains knowledge mainly through the team members. This organization type also aims to facilitate the exchange of tacit, implicit knowledge.

Blackler (1995; Blackler, Crump, & McDonald, 2000) and Lam (2000) provide examples of an alternative way to link organization structure to knowledge. They identify contingencies for organizational effectiveness as dimensions of a matrix, and enter a combined description of design choices and knowledge types of individual organizations or classes of organizations in the

Table 2. Structural configurations and knowledge types (Blackler, 1995; Lam, 2000)

	Focus on problems with low complexity and variability, and high analyzability	Focus on problems with high complexity and variability, and low analyzability
Focus on individual knowledge agents	- *typical organization structure*: professional bureaucracy, which is individualistic, functionally segmented, hierarchical; experts have a high degree of autonomy - *key knowledge type*: embrained knowledge, or knowledge of generalizations and abstract concepts - *learning*: organizations have a narrow learning focus facing problems of innovation; power and status of experts inhibit knowledge sharing	- *typical organization structure*: adhocracy with its diverse, varied, and organic knowledge base, or other knowledge-intensive form - *key knowledge type*: embodied knowledge, or the tacit skills of key members - *learning*: fast and fluid learning and unlearning, but has problems of widely diffusing knowledge
Focus on collective knowledge agents	- *typical organization structure*: machine bureaucracy, which is characterized by specialization, standardization, control, functionally segmentation, hierarchy, seeking to minimize role of tacit knowledge - *key knowledge type*: encoded knowledge, or knowledge in documents and other registrations; a clear dichotomy exists between application and generation of knowledge - *learning*: learns by correction, through performance monitoring; unable to cope with novelty or change	- *typical organization structure*: communication-intensive organization organized as an adhocracy or other knowledge-intensive form; communication and collaboration are key processes; empowerment through integration; expertise is pervasive - *key knowledge type*: encultured knowledge, shared sense-making - *learning*: the organization is adaptive and innovative, but may find it difficult to innovate radically (learning is potentially conservative)

cells of the resulting matrix. Table 2 presents the approaches of these authors condensed into a two-by-two matrix. The arguments presented above calling for openness in the production structure and flat hierarchies imply calls to elaborate the right-hand column of the table.

Designing Knowledge-Friendly Organizational Structures

We now turn to the second theme of this article, which is designing knowledge-friendly organization structures. This theme involves looking at the interventions available for defining or changing organization structures. Two different types of such interventions, or KM practices, exist with respect to the organization structure: (1) practices that involve (re)designing the basic production structure from a knowledge standpoint, adjusting the control structure to the resulting production layout; and (2) practices that involve adapting existing production and control structures to knowledge-related demands with additional interventions of organization design. The following two sections will address both types of KM practices in more detail, under the labels of 'basic structures' and 'support structures', respectively.

Knowledge-Friendly Basic Structures

The literature describes several knowledge-friendly organization structures. Among these, the three that appear to have received the most attention are: the team-based organization, the network structure, and the hypertext organization.

Team-Based Structure

A team is generally defined as a group of people working together towards a common goal. The team concept and the associated project structure (Hobday, 2000) have a rich history in organization studies, which also includes references to knowledge work (e.g., Mohrman, Mohrman, & Cohen, 1995). Two traditions provide the most extensive exploration of team concepts (Benders & Van Hootegem, 1999). The first of these is the sociotechnical system design approach, which focuses on self-managing teams (e.g., Sitter et al., 1997). Team concepts also play a central role in Japanese management studies, which focus on such concepts as 'lean teams' and 'just-in-time' teams. From a knowledge perspective, the team structure involves both pros and cons. The main advantage of a team structure is that teams can be designed to integrate the knowledge needed for a particular task (e.g., a team of experts from various specialties that share the goal of serving a particular regional market). This may lead to improvements in all of the knowledge processes within the team. The main disadvantage of teams is that the cohesion they need for success erects barriers for establishing lateral linkages with other teams. This will impair cross-team cooperation in knowledge exploration and knowledge exploitation. Several authors describe structural configurations that show resemblance to the team concept, but are at best less-developed accounts of elements of team concepts. These include the cellular structure (e.g., Miles & Creed, 1995; Miles et al., 1997) and the inverted organization (Quinn, 1992; Quinn, Anderson, & Finkelstein, 1996).

Network Structure

The network structure involves the largest degree of freedom for knowledge workers to establish work relationships. The term 'network structure' is not a neatly delineated concept in organization studies, but it serves as an umbrella for several organizational forms that show similarities with or are elaborations of the adhocracy structure described above (see Thompson, 2003). The network organization comes under several names: Hedlund (1994) labels it the N-form organization ('N' for 'new'), and Quinn (1992, 1996) uses the term 'spider-web organization'. At least three elements connect the various network concepts of organizations (Hedlund, 1994, p. 83ff.). First, they promote temporary constellations that use the pool of people and their competencies as a touchstone for design. Second, they stress the importance of lateral communication networks within and among production units. Third, they see top management as catalysts, architects, and protectors. Several different variants of the network structure exist. These range from an organization which adopts a web structure to connect its own semi-permanent parts via a network organization that consists as a network of semi-autonomous organizations, to an organizational network that is built around the semi-permanent relationships between autonomous organizations.

Hypertext Organization

Nonaka (1994; Nonaka & Takeuchi, 1995, 1997; Nonaka, Takeuchi, & Umemoto, 1996) describes a structural form that combines the traditional functional structure that is associated with efficiency gains with a project-based organization, that comes with the benefits of flexibility needed for a knowledge-creating company. It is grounded in a business system layer, which is the central layer for normal, routine operations organized as a hierarchical pyramid. On top of that layer, Nonaka identifies a project team layer for knowledge-creation activities. This layer involves the exclusive assignment of team members from different units across the business system to a project team until the project has been completed. These two layers are complementary rather than mutually exclusive. A strong corporate culture is therefore needed to combine the team-based project part of the organization with the hierarchical, bureaucratic part. This connecting culture Nonaka calls the organization's knowledge base. It involves the recategorization and recontextualization of knowledge newly generated in the other two layers. Nonaka uses the term 'hypertext' to indicate that combining knowledge contents more flexibly across layers and over time calls for the existence of dormant links between various parts and layers of the organization that can be activated when needed. This resembles the hypertext links connecting Web sites.

Knowledge-Focused Support Structures

Several mechanisms are described in the literature for improving existing organization structures from the perspective of knowledge processes. These include:

1. Knowledge centers: An organization may decide to assign tasks aimed at furthering the flow of knowledge processes to dedicated departments (e.g., Moore & Birkinshaw, 1998; Hertog & Huizenga, 2000). As an example, consider a library that adopts an active role of offering knowledge mapping services to further possibly fruitful cooperation based on the documents it stores. Thus, it facilitates the processes of knowledge transfer.
2. Knowledge-centered roles and functions, such as chief knowledge officer (CKO), knowledge manager, and knowledge broker (see Davenport & Prusak, 1998; Earl & Scott, 1999; Snyman, 2001; McKeen & Staples, 2003). The tasks involved are typically control tasks at strategic or operational levels that aim at providing knowledge workers with the appropriate infrastructure required for task completion.
3. Den Hertog and Huizenga (2000) describe several forms of lateral knowledge linkages between organizational units that aim to transcend the boundaries involved in the basic structure. These include the establishment of 'expertise circles' that bring together the domain specialists of several teams or other organizational units to discuss developments in that domain and exchange

best practices. Programs of job rotation may also be appropriate tools to install lateral linkages.

4. Communities of practice (CoPs) and communities of interest (CoIs) are elements of the informal organization structure that, because of their organic nature, are generally recognized as important to knowledge flows. Within the domain of formal organizational design, an organization may want to use instruments that aim at facilitating existing communities and stimulating the emergence of new ones. As an example, consider an organization that uses project evaluation procedures as a vehicle to stimulate individuals to explore possibilities for community formation.

FUTURE TRENDS

In the discussions of organization structure, the links to knowledge have played an important role for many decades. Some of these discussions have presented themselves as KM studies, but most of them do not adopt that label. The contribution of KM studies in organization structure usually comes from two areas. The first area concerns the recognition of organization structure as a contextual factor influencing the choice and success rates of KM programs (Bennett & Gabriel, 1999; Gold, Malhotra, & Segars, 2001). The second area involves the design and implementation of concrete measures, management practices, and the like, which all involve an adaptation of the existing organization structure. KM may serve as an integrating umbrella to connect disparate thinking around knowledge aspects of organization structure. One form this integration is likely to take is through a further development of the knowledge element in the contingency theory of organizations. Many discussions of knowledge-friendly organization structures are contemplative in nature, and lack a firm basis in empirical research. Therefore, one would anticipate an increase of empirical studies which address how organizations choose among the alternatives available for making their organization structures knowledge friendly. A final trend that has become more apparent is the trend in which KM research on organization structure has increasingly turned to existing analysis models that allow focusing on relationships, such as social network theory or actor network theory (e.g., Benassi, Greve, & Harkola, 1999; Nelson, 2001; Chang & Harrington, 2003; Sorenson, 2003).

CONCLUSION

Organization structure is an important aspect of knowledge work as it concerns the establishment of work relationships. Any organization structure will stimulate the establishment of certain relationships at the expense of others. It is important to note that flatter, fuzzier, or less structure is by no means inherently superior to crisper or more structure. Too much openness in organization structures not identifying possible work relationships may well result in limited identification and exploitation of such relationships. Too much closure introduces the risk of virtually making it impossible for specific classes of possibly productive relationships to come about. The challenge for knowledge management is to come up with the appropriate mix of design interventions which will guide individuals when they try to establish work contacts, without depriving them of the freedom they need to be knowledgeable and to continue learning. This involves a threefold challenge: (1) choosing a basic structure that honors the key elements of knowledge exploration and knowledge exploitation; (2) identifying the drawbacks of the basic structure for the flow of knowledge processes, and correcting these with the appropriate support structures; and (3) addressing the limitations of organization design with interventions from other management realms, such as human resource management.

Chapter 2.19
Logic and Knowledge Bases

J. Grant
Towson University, USA

J. Minker
University of Maryland at College Park, USA

INTRODUCTION

Knowledge bases (KBs) must be able to capture a wide range of situations. One must be able to represent and answer questions regarding indefinite information where it is not clear that there is a unique answer to a question. One must also represent and answer questions about negative information. We discuss a powerful way to represent such information, namely through reasoning about knowledge bases using logic.

In the real world, information known at one time may change. However, in first-order logic, information once known cannot change. This phenomenon is known as monotonicity. Since KBs deal with incomplete information, they are not monotonic. We shall discuss a form of logic programming, below, which is able to handle nonmonotonic information and situations required by KBs such as definite and indefinite data, and logical and default negation.

The question of how to adapt first-order logic to handle complex situations started in the 1950s. Early systems handled problems in an ad hoc way. Several primitive deductive databases (DDBs), function-free logic programs, were developed in the 1960s. Robinson (1965) developed a general method for automated theorem proving to perform deduction. This method is known as the Robinson Resolution Principle; it is a generalization of modus ponens to first-order predicate logic. Green and Raphael (1968) were the first to recognize the importance and applicability of the work performed by Robinson and developed a system using this principle.

November 1977 is generally considered to be the start of the modern era of DDBs. A workshop, "Logic and Data Bases," was organized in Toulouse, France, by Gallaire and Nicolas in collaboration with Minker. The workshop included researchers who had performed work in deduction from 1969 to 1977 using the Robinson Resolution Principle. The book Logic and Data Bases, edited by Gallaire and Minker (1978), contained these papers. Many significant contributions were described in the book. Nicolas and

Gallaire discussed the difference between model theory and proof theory. They demonstrated that the approach taken by the database community was model theoretic—that is, the database represents the truths of the theory, and queries are answered by a bottom-up search. However, in logic programming, answers to a query use a proof theoretic approach, starting from the query, in a top-down search. Reiter discussed the closed world assumption (CWA), whereby in a theory, if one cannot prove that an atomic formula is true, then the negation of the atomic formula is assumed to be true. The CWA is a default rule that permits one to make a decision on negation even if the decision may not be correct.

Reiter's paper elucidated three major issues: the definition of a query, an answer to a query, and how one deals with negation. Clark presented an alternative theory of negation, the concept of if-and-only-if conditions that underlie the meaning of negation, called negation-as-finite-failure. The Reiter and Clark papers are the first to formally define default negation in logic programs and deductive databases. Several implementations of deductive databases were reported. Nicolas and Yazdanian described the importance of integrity constraints in deductive databases. The book provided, for the first time, a comprehensive description of the interaction between logic and databases, and knowledge bases.

References to work on the history of the development of the field of deductive databases and to a description of early systems may be found in Minker (1996).

BACKGROUND

Much of the world's data is stored in relational databases. A relational database consists of tables, each with a fixed number of rows. Each row of a table contains information about a single object. For example, an employee table may contain columns for an employee number, name, address, age, salary, and department name. Each row contains data about one employee. In the same database a department table may contain department name, department number, phone number, and manager's employee number. The connection between the two tables is provided by the common column on department name. Relational databases also allow for integrity constraints that prevent some types of incorrect updates. For example, the specification of employee number as the key of the employee table means that only one row is allowed for any employee number.

Writing a relational database in logic formalism, we associate a predicate with each table, using the same name for convenience. Then an atomic formula (atom), such as,

Department(sales, 5, 1234567, 11223),

means that there is a row in the Department table with the values listed there. In general, an atom consists of a predicate and a set of arguments which may be constants, variables, or function symbols with arguments. We shall deal only with function-free atoms. Deductive databases extend the concept of relational databases by allowing tables to be defined implicitly by using a formula. In this example, we may define an intensional predicate,

Supervisor(emp1, emp2) ← Employee(emp1, _, _, _,_,, dept1),
Department(dept1,_, _, emp2)

to stand for the fact that emp2 is the manager of emp1's department. We use underscores to indicate irrelevant attributes.

This type of definition is allowed for relational databases, where it is called a view.

However, the following definition:

Superior(emp1, emp2) ← Supervisor(emp1, emp2)

Superior(emp1, emp2) ← Supervisor(emp1, emp3),
Superior(emp3, emp2)

where superior stands for the supervisor, the supervisor's supervisor, and so on, uses recursion and was not allowed in the original relational database framework.

More formally, a deductive database, DDB, is a triple, <EDB, IDB, IC>. EDB, the extensional database, is a set of facts, namely the rows in tables. IDB, the intensional database, is a set of rules that implicitly define new tables. IC is a set of integrity constraints. All three parts of a DDB are written as logic formulas. Queries are also written as logic formulas. For example, the query:

← Employee(_, name, address, _, _, deptname),
Department(deptname, 5, _,_)

asks for the names and addresses of employees in department 5, including the name of the department, while the query:

← Supervisor(11223, emp)

asks for the supervisors of employee 11223.

The IDB, in the general case, contains a set of rules of the form:

A1, . . ., An ← B1, . . . , Bm, not Bm+1, . . . , not Bm+k (1)

where all the Ai, $1 \leq i \leq n$, and Bj , $1 \leq j \leq m + k$, are literals (atoms or logically negated atoms, e.g., ¬p, where p is an atom), and not stands for default negation. Whereas logical negation specifies that an atom is definitely not true, default negation not is an implicit form of negation that permits one to conclude that a defaulted atom is not true, even if it is not explicitly known to be not true. The left-hand side of the reverse implication is called the head and the right hand side is the body. The meaning of such a rule is:

A1 or . . . , or An is true if B1 and . . . , and Bm and not Bm+1 and , . . . , not Bm+k are true.

A logic program is a collection of rules of the form (1). Since we deal only with function-free rules, we call such a set of rules a deductive database. There are different kinds of deductive databases depending upon the rules used.

The first generalization of relational databases permitted function-free recursive Horn rules in a database—that is, rules in which n = 1 and k = 0. These deductive databases are called Datalog databases. Formulas where the head is empty are also allowed: they stand for queries and some types of integrity constraints. When the formula is considered to be a query, Q(X1, . . . , Xn), and hence the head is empty and the free variables are X1, . . . , Xn, an answer to the query has the form < a1, . . . , an > so that Q(a1, . . . , an) follows from the database.

MAIN FOCUS OF THE ARTICLE

Datalog Semantics

Van Emden and Kowalski (1976) formalized the semantics of logic programs that consist of Horn rules, where the rules are not necessarily function-free. They recognized that these programs can be characterized in three distinct ways: by model, fixpoint, or proof theory, leading to the same semantics. When the logic program is function-free, their work provides the semantics for Datalog databases. Horn rules may be recursive, that is, a predicate on the left-hand side of a rule may have the same predicate on the right-hand side of the rule. Hence, Datalog allows for more general knowledge bases than the relational model.

Model theory deals with the collection of models (a set of atoms that are true in the theory) that captures the intended meaning of the database. Fixpoint theory deals with a fixpoint operator that constructs the collection of all atoms that can be inferred to be true from the database. Proof theory provides a procedure that finds answers to queries with respect to the database. Van Emden and Kowalski (1976) showed that there is a unique minimal model, which is the same as all of the atoms in the fixpoint, and are exactly the atoms provable from the theory.

To deal with negation, one can subtract from the set of all atoms formed from the predicates and constants in the database, the minimal set of answers to the DDB. If an atom is contained in this set, then it is assumed false.

Initial approaches to answering queries in DDBs did not handle recursion and were primarily top-down (or backward reasoning). However, answering queries in relational database systems was bottom-up (or forward reasoning) to find all answers. Several approaches were developed to handle recursion to improve search time. Two of them are called the Alexander and magic set methods. They take advantage of constants in the query, and effectively compute answers using a combined top-down and bottom-up approach.

Integrity constraints are important to KBs. They are used primarily to assure that a KB update is consistent. Reiter (1978) showed that Datalog databases can be queried with or without ICs and the answer to the query is identical. However, ICs provide semantic information about the data in the KB and can be used to optimize search for answers to queries. The use of ICs to constrain search is called semantic query optimization (SQO). Semantic query optimization has been incorporated into some relational databases. A topic related to SQO is that of cooperative answering systems. The objective is to give a user the reason why a particular query succeeded or failed (see Minker, 1996, for references).

The first article on magic sets may be found in Bancilhon, Mayer, Sagiv, and Ullman (1986). A description of the magic set method to handle recursion in DDBs may be found in Ullman (1988a, 1988b). For work on the fixpoint theory of Datalog, and the work of Van Emden and Kowalski, see Lloyd (1987). A comprehensive survey and references to work in cooperative answering systems is in Gaasterland, Godfrey, and Minker (1992). References to alternative definitions of ICs, semantic query optimization, and cooperative answering may be found in Minker (1996).

Stratified Deductive Databases

Datalog databases provide additional capabilities for KBs. However, they are still not able to handle more complex situations. There may be a need to handle both logical and default negation in some applications. The logic programming formalism handles these situations by permitting more complex rules which have a literal (i.e., an atomic formula or the negation of an atomic formula) in the head and literals with possibly negated-by-default literals in the body of a rule. Such rules are called extended, where in Formula (1) $n = 1$, $m \geq 0$, $k \geq 0$, and the As and Bs are literals. Such databases combine classical negation (¬) and default negation (not), and are called extended DDBs.

Logic programs that use default negation in the body of a clause were first defined in 1986 by Apt, Blair, and Walker (1988) and Van Gelder (1988) as stratified logic programs in which A1 and the Bj , $1 \leq j \leq m+k$, in Formula (1) are atomic formulas, and there is no recursion through negation. They show that there is a unique preferred minimal model, computed from strata to strata, termed the perfect model by Przymusinski (1988). In a stratified theory, rules are placed in different strata, where the definition of a predicate in the head of a rule is in a higher stratum than the definitions of predicates negated in the body of the rule. The definition of a predicate is the collection of rules containing the predicate in their head. One computes positive predicates in a lower stratum, and a negated predicate's complement is true in the body of the clause if the positive atom has not been computed in the lower stratum. The identical semantics is obtained, independent of how the database KB is stratified. This DDB is termed Datalog¬. If a KB can be stratified, then there is no recursion through negation, and the database is called Datalog¬strat.

If the rule:

Happyemp(emp1) ← Employee(emp1), not
Supervisor(emp1, 11223)

is added to the predicates given earlier, a stratified program is obtained with two strata. The lowest stratum contains Employee, Department, and Supervisor, since Happyemp depends negatively on Supervisor, it must be in a higher stratum.

Non-Stratified Deductive Databases

In some KBs it is useful to allow recursion through negation. Once this happens, the KB is no longer stratified. Consider the following simple example:

r1: rich(X) ← not poor(X)
r2: poor(X) ← not rich(X)
r3: satisfied(joe) ← poor(joe)
r4: satisfied(joe) ← rich(joe).

Non-stratified KBs may not have unique answers to queries. Additionally, there may be more than one semantics that define answers to queries in such KBs, and hence alternative ways to answer queries. One such semantics is the answer set semantics (ANS) developed by Gelfond and Lifschitz (1988), and another semantics is the well-founded semantics (WFS) developed by Van Gelder, Ross, and Schlipf (1991). The different semantics for ANS and WFS are illustrated on the above example.

The first two rules, namely that an individual is rich if not poor and poor if not rich, are recursive through negation. Thus this KB is not stratified. But note that by the last two rules, joe is satisfied if he is poor and also if he is rich. By using the answer-set semantics (ANS), there are two answer sets, namely S1 = {poor(joe), satisfied(joe)} and S2 = {rich(joe), satisfied(joe)}. A query is answered "yes" if it is true in all answer sets and "false" if it is false in all answer sets. In this case we can conclude {rich(joe) or poor(joe), satisfied(joe)},that is, joe is rich or poor, and joe is satisfied.

The semantics for ANS is defined first for programs without default negation as the smallest set of literals S, with the property that if all the literals of a rule in the program are in S, then the head is also in S. Consider now a program P with default negation and candidate answer set C. Obtain a new program P1 without default negation as follows: for any rule that has a default negation not L in the body with L ∈ C, the rule is eliminated (the rule cannot apply); for the remaining rules all the default negations are eliminated (the default negation must be true). Since P1 does not have negation, its semantics may be computed by the first method. If the semantics to P1 is the set C, then C is accepted as the semantics for the original program P. If C is the answer set of P1, it is called an answer set of P.

The well-founded semantics (WFS) coincides with the ANS on stratified programs. In the case of non-stratified programs, WFS uses three truth values: true, false, and unknown. In the example above, all three atoms: satisfied(joe), poor(joe), and rich(joe), would be considered as unknown.

Disjunctive Databases

So far we have considered only definite databases (i.e., where in Formula (1) n = 1). Disjunctive databases are useful for KBs when information, either in the EDB or IDB, is indefinite (i.e., in some formulas n > 1). Hence, disjunctive databases permit the representation of indefinite knowledge such as p∨q, where it is not known if p is true, or q is true, but it is known that p∨q is true. Such KBs are called extended disjunctive deductive databases (EDDDBs) or Datalog¬disj,ext. An important special case, disjunctive deductive databases (DDDBs), or Datalog¬disj, allows only atoms in Formula (1). Minker (1982) started the study of DDDBs and showed how to answer both positive and negated queries.

For positive queries over DDDBs, it suffices to show that the query is satisfied in every minimal model. For negated queries, Minker developed the Generalized Closed World Assumption (GCWA), which assigns the value true to a negated atom if the atom does not appear in any minimal model. Minker and others then developed various techniques for answering queries in DDDBs.

Various semantics have been given for EDDDBs. The most prominent of these is the Answer Set Semantics (ANS) modified appropriately from the definite case.

TOOLS FOR IMPLEMENTING KBS

The development of KB systems using logic has been facilitated by enhancements made to relational databases through techniques within DDBs added to the language SQL, through deductive database implementations, and through implementations of the well-founded and answer set semantics for non-stratified and disjunctive databases. In addition, we discuss the use of logic in a large knowledge base system, Cyc.

SQL

The SQL:1999 standard includes queries involving recursion and hence recursive views. The recursion must be linear with at most one invocation of the same recursive item. Default negation is stratified and applies only to predicates defined without recursion. SQL:1999 allows a general class of ICs, called Asserts, that allow for arbitrary relationships between tables and views that express types of ICs generally associated with DDBs.

Linear recursion is implemented as a part of the client server of IBM's DB2 system using magic sets. Techniques from semantic query optimization also have been incorporated into DB2.

Datalog

Several prototype implementations of Datalog¬ have been developed; however, only two systems are active: Aditi, developed at the University of Melbourne under the direction of Dr. K. Ramamohanarao (1993), and LDL++, developed at UCLA under the direction of Dr. Carlo Zaniolo (see Arni, Ong, Tsur, Wang, & Zaniolo, 2003).

Well-Founded Semantics and Answer Set Semantics

The most important implementations for extended DDBs are the Well-Founded Semantics and the Answer Set Semantics. See Minker (1996) for a discussion of alternate proposals and alternative systems. Rao, Sagonas, Swift, Warren, and Friere (1997) developed a system, XSB, that computes the well-founded semantics. The system extends the full functionality of Prolog, an important logic programming language, to the WFS. The use of XSB for medical diagnosis is described in Swift (1999). XSB also permits the user to employ Smodels, discussed below, and is available on the Internet as open source.

Niemelä and Simons (1996) developed Smodels to compute the answer sets of programs in Datalog with negation. Smodels is presently considered the most efficient implementation of Answer Set Semantics. The system can be licensed from a company in Finland called Neotide.

Implementation of Disjunctive Deductive Databases

Eiter, Leone, Mateis, Pfeifer, and Scarcello (1997) developed DLV (DataLog with Or) to compute answer sets for disjunctive deductive databases. The work is a joint effort between the Technical University of Austria and the University of Calabria, Italy.

Cyc

Cyc, developed by Lenat (1995), is both a knowledge base and a system that contains a set of tools to manipulate the database. The Cyc KB consists of a large quantity of basic human knowledge: facts, rules of thumb, and heuristics for reasoning about objects and events that arise in normal life situations. There are approximately 200,000 terms and several dozen assertions about and involving each term. The database is being continually updated by human knowledge experts.

The Cyc system contains an inference engine that performs logical deduction (including modus ponens, and universal and existential quantification). It also contains special inferencing mechanisms, such as inheritance and automatic classification, as special cases. It also includes special purpose inferencing modules for handling a few specific classes of inference such as handling equality, temporal reasoning, and mathematical reasoning. It contains a variety of interface tools that permit the user to browse, edit, and extend the Cyc KB, to pose queries to the inference engine, and to interact with the database integration module and other features in the system.

Knowledge Base Management

A knowledge base consists of a large set of data, the description of the data (metadata), and a potentially large set of rules. A Knowledge Base Management System (KBMS) provides the capabilities to manage, manipulate, and handle the KB. Many capabilities may be required of a KBMS. We discuss some of the more important ones.

The KBMS must provide a language to represent the facts, the description of the facts, the integrity constraints associated with the database, and the rules in the KB. Facts may be temporal in nature. Users may specify preferences in what they would like for answers to queries, and may also specify priorities. The language must provide a capability to enter, delete, or modify data and rules in the KB. It must provide an ability to query all parts of the KB: the data, the description of the data (metadata), and the rules.

In addition to the language, the underlying system should permit many of the following capabilities:

1. An inference capability to use the rules, the data description, and the facts to derive new information: The inference capability must have a nonmonotonic reasoning capability. This is needed since it is not possible to include all the negative data that might be known in any realistic problem, and one must make conclusions in the absence of information. The inference mechanism should also permit the mixing of the metadata (that is, the description of the data), together with the rules and facts.
2. A mechanism to update (i.e., enter, delete, or modify) the KB: Depending upon the inference mechanism used, this might require careful attention (e.g., Fernandez, Grant, & Minker, 1996).
3. A capability to optimize a query: Unless there is a query optimizer, queries may take excessive amounts of time. This is true even in relational database systems that do not have an inference capability.
4. The ability to integrate multiple KBs: This is required in many KBSs such as in organizations that are distributed. Inconsistencies may arise when integrating such systems, and there is the need for handling the integration to provide correct answers to users (see Grant & Minker, 2002; Levy, 2000).
5. The ability to provide cooperative answers to users: For example, there is a need to know when a query can never be answered because

of the nature of the database, or because there may be no data about the query currently in the database (see Gaasterland et al., 1992). The user might require that a route for a trip not go through a particular city, or a plane have at most one intermediate stop.

6. The ability to provide data mining, or the discovery of knowledge in a database: There are several distinguished forms of human reasoning identified by the philosopher Pierce (1883). Deduction is an analytic process based on the application of general rules to particular cases, with the inference as a result. The focus of this article is on providing explicit knowledge that exists in a database through deduction. Data mining or discovery are forms of analytic reasoning called induction, which infer the rule from the case and the result. That is, it discovers a general rule (see Plotkin, 1969; Shapiro, 1981; Hand, Manilla, & Smythe, 2001). Another form of reasoning, abduction, uses synthetic inference, which generates hypotheses H such that (KB U H), where KB is the knowledge base, implying a consequence, C' (see Kakas, Kowalski, & Toni, 1993).

Logic-based languages provide a powerful method for constructing KBMSs. All work developed for DDBs and extended DDBs concerning semantics and complexity apply directly to KBMS. Baral and Gelfond (1994) describe how extended DDBs may be used to represent KBs. The features of KBMSs as described in this section can be used to implement all of the capabilities discussed above. Many of the systems already have these capabilities. Hence, they can allow the KB experts to focus on the database, the description of the data, the specification of the rules, and integrity constraints of the KB. They can then employ an appropriate DDB system that has the required semantics.

Applications

Many applications of KBs exist in a wide variety of fields. We mention only a few here. Abduction is a method of reasoning used to find explanations of observations. This concept has been used in areas such as medical diagnosis and legal reasoning. Information agents, able to handle data on the World Wide Web, have been proposed for solving information retrieval problems. Data integration deals with the integration of data in different databases. The planning problem in artificial intelligence is closely related to the ANS. The handling of preferences and inconsistencies are other areas where KBs are useful.

We illustrate the use of a DDB formalism for KBs with two examples. Consider a family KBs with the following rules and data:

parent(pat, mike) ←
father(X, Y), mother(X, Y) ← parent(X, Y).

The first statement is a fact, the second is a disjunctive rule. From this KB we conclude that pat is mike's father or mike's mother.

A second example deals with eligibility for a scholarship in a university KB. Basically, students with a high grade point average (GPA) or who are athletes and have a good GPA are eligible. Some students are not eligible. Students who are neither eligible nor not eligible are interviewed.

eligible(X) ← gpa(X, high)
eligible(X) ← athlete(X), gpa(X, good)
¬eligible(X) ← ¬gpa(X, good), ¬gpa(X, high)
interview(X) ← eligible(X), not ¬eligible(X)
gpa(sam, good) ←
athlete(sam) ←
gpa(mary, good) ←
¬athlete(mary) ←.

From this KB, eligible(sam) and interview(mary) can be deduced using the answer set semantics.

FUTURE TRENDS AND CONCLUSION

The field of KBs has been enhanced by developments in DDBs. Future developments, discussed briefly below, will make it easier for users to develop KBs.

Relational databases have already incorporated techniques from DDBs. Other tools such as the incorporation of join elimination, and SQO techniques such as equalities and arithmetic constraints can be added to the SQL language. Additional tools that provide cooperative responses to users can also be incorporated in future versions of SQL. It is unclear if additional features of DDBs can be added without major revisions to the relational systems.

DDBs have not yet been made available as commercial systems. The future of commercial systems in this area is not promising except for the XSB system that provides the well-founded semantics; Smodels that provides the answer set semantics; and DVL that provides a disjunctive semantics. These systems already are in use, primarily in university communities. KB systems have been implemented using these systems. Should such systems become commercial, they will make it easier to develop KBs.

Chapter 2.20
A Knowledge Management Portal System for Construction Projects Using Knowledge Map

H. Ping (Jack) Tseng
National Taiwan University, Taiwan

Yu-Cheng (Vincent) Lin

ABSTRACT

Knowledge management (KM) has become an important term in the construction industry. Knowledge management involves creating, securing, capturing, coordinating, combining, retrieving, and distributing knowledge. Most know-what, know-how, and experience exists only in the minds of individual participants during the construction phase of construction projects. The knowledge can be reused and shared among the involved engineers and experts to improve the construction process and reduce the time and cost of solving problems. Sharing and reusing knowledge depends on acquiring and preserving of both tacit knowledge and explicit knowledge as the property of a corporation. This study addresses application of knowledge management in the construction phase of construction projects and proposes a construction activity-based knowledge management (ABKM) concept and system for general contractors. This chapter proposes a practical methodology to capture and represent construction project knowledge by using knowledge maps. Using knowledge maps, users can get an overview of available and missing knowledge in core project areas and take appropriate management in tacit and explicit knowledge. Also, a Web-based system is developed to assist and present project-related knowledge by providing keyword and map search on the Internet environment. The ABKM system is then applied in a case study of a construction precast building project in Taiwan to verify our proposed methodology and demonstrate the effectiveness of sharing knowledge special in the construction phase. By effectively using information and Web technologies during the construction phase of a project, knowledge can be captured and managed to benefit future projects. The combined results demonstrate that an ABKM-like

system can be an effective tool for all experts and engineers participating in construction projects by utilising the knowledge management concept and Web technology.

INTRODUCTION

Knowledge is the true asset of a marketing-oriented organisation, and its integration across departments and disciplines should be emphasised (Carneiro, 2001). Many organisations are now engaged in knowledge management (KM) efforts in order to leverage knowledge both within their organisations, and externally to their stakeholders and customers (Malhotra, 2000, 2001). These assets, or knowledge, can be classified as either tacit or explicit. Explicit knowledge is that which has been codified and expressed in formal language; it can be represented, stored, shared, and effectively applied (Nonaka & Takeuchi, 1995). Tacit knowledge is knowledge that is difficult to express, represent, and communicate (Nonaka & Takeuchi, 1995). The distinction between these two types of knowledge is relevant because each must be managed differently. Knowledge management in the construction phase mainly deals with the process of creating value from construction operation, organisation, to company knowledge. Valuable knowledge can be available in different forms and media, such as in the minds of experts, in operation procedures, and in documents, databases, intranets, and so forth; however, knowledge management in the construction phase of projects aims at effectively and systematically collecting and sharing the experience and knowledge of the project by Web-based and intranet technologies.

The reuse of information and knowledge minimises the need to refer explicitly to past projects, reduces the time and cost of solving problems, and improves the quality of solutions during the construction phase of a construction project. If experience and knowledge are shared, then the same problems in construction projects do not need to be repeatedly solved. Reduced problem solving has the following advantages: (1) the cost of problem solving is reduced; and (2) the probability of repeated problems is decreased. Several enabling activities should be considered to help to achieve the ultimate goal of efficient experience and knowledge reuse; experience and knowledge should be preserved and managed—that is, they should be captured, modelled, stored, retrieved, adapted, evaluated, and maintained (Bergmann, 2002).

Knowledge reuse and update improves the performance of future activities and projects. Most of the data and information for construction projects are stored in paper-based documents; these consist of contracts, specifications, notes, discussion, and field reports. In order to facilitate the information management and enable knowledge reuse, it is important to convert the paper document into electronic versions to be shared and applied in other and future projects. Information and knowledge of a project can then be identified as project components in the project management and preserved in a Web-based system that provides the platform for the exchange and storage of information and knowledge.

LEARNING OBJECTIVES

1. Understand the application of knowledge management for construction projects.
2. Understand each phase of knowledge management specific for construction projects.
3. Form a case study for knowledge management using knowledge map in the construction phase.
4. Study procedures of implementing knowledge management for construction projects.
5. Study procedures of applying knowledge mapping in knowledge management.

PROBLEM STATEMENT

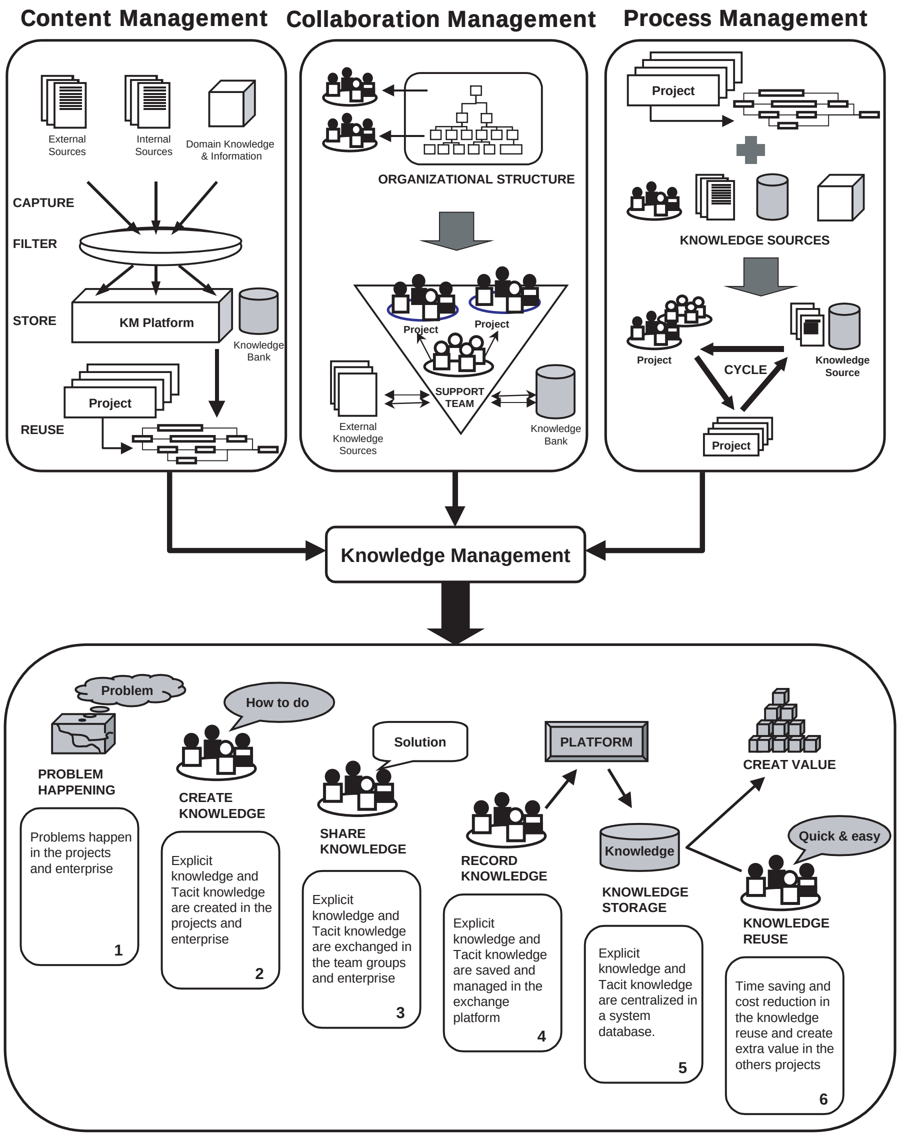
Construction projects are complex and time consuming. Construction projects are characterised by their complexity, diversity, and the non-standard nature of the production (Clough, Sears, & Sears, 2000). Professional competency in project management is attained by combining knowledge acquired during training and skills developed through experience, as well as the application of the acquired knowledge (Edum-Fotwe & McCaffer, 2000). Whatever successful and unsuccessful projects have been executed by general contractors, a valuable record of each one should be kept to identify best and worst company practices. During the construction phase of projects, an effective means of improving construction management is to share experiences among engineers, which helps to prevent mistakes that have already been encountered in past projects. Drawing on experience avoids the need to solve problems from scratch: Problems that have already been solved do not need to be solved again. According to a survey conducted for this study, most engineers and experts agree that KM is necessary and expect that knowledge management may benefit a construction project. However, no suitable platforms exist to assist senior engineers or experts in sharing and collecting their know-how and experiences when general contractors execute a project.

This situation represents a major loss for general contractors who do not preserve the know-how and experiences of senior engineers and experts. When these engineers and experts complete projects or leave the company, they normally take domain knowledge with them and leave little or nothing that will benefit subsequent projects or the company. From the perspective of knowledge management, this know-how and these experiences of construction engineers and experts are the most valuable, because their accumulation depends not only on manpower, but also on the spending of much money and time.

RESEARCH OBJECTIVES

The main purpose for conducting this research is to develop an activity-based knowledge management (ABKM) system for construction projects, to provide knowledge exchange and management service in the construction phase of a project for the reuse of domain knowledge and experience in future and other related projects. Usually, the management of knowledge in a general contractor revolves around projects. Thus the capture, transfer, reuse, and maintenance of the construction project knowledge are critical (Kamara, Augenbroe, Anumba, & Carrillo, 2002). Knowledge management in the construction phase of a project is a knowledge-intensive organisational environment where knowledge creation has critical importance for general contractors. To be competitive, a general contractor has to make innovative use of knowledge created and accumulated through project activities, and share it across other relative projects. Engineers and experts participating in projects act as knowledge workers, facilitating the collection and management of knowledge between current and past projects. In order to apply knowledge management to construction projects, the process and content of working construction knowledge need to be modified because of construction project characteristics. In order to improve the knowledge capture function, a knowledge map as a tool allows the user to quickly note key concepts, identify important processes and tools, and gain insights into associated behaviours. Figure 1 illustrates the main concepts of knowledge management applied in construction projects. With appropriate modification, the ABKM system can be utilised in construction companies to support knowledge management functionality for any construction project.

Figure 1. Knowledge management applied in construction projects



KNOWLEDGE MANAGEMENT IN CONSTRUCTION PHASE

In construction projects, knowledge management is a discipline that promotes an integrated approach to the creation, capture, access, and use of a profession's domain knowledge on products, services, and processes. During the construction phase of a project, most project-related problems, solutions, experiences, and know-how are in the heads of individual engineers and experts. Implicit knowledge usually is not documented or stored in a system database. To reuse the knowledge in other projects and also preserve it as corporation property, how to capture the implicit knowledge and make it become available as explicit knowledge is important in the execution of knowledge management in the construction phase. Experience, problem solving, know-how, know-what, and innovation are created in the construction phase of any project. By practicing knowledge management, tacit knowledge can be reused for other projects and speed the improvement of operations in the construction phase.

LIFE CYCLE OF CONSTRUCTION KNOWLEDGE MANAGEMENT

There are five phases in the construction knowledge management life cycle as shown in Figure 2. They are knowledge acquisition, knowledge extraction, knowledge storage, knowledge sharing, and knowledge update. Each phase is briefly outlined in the following descriptions.

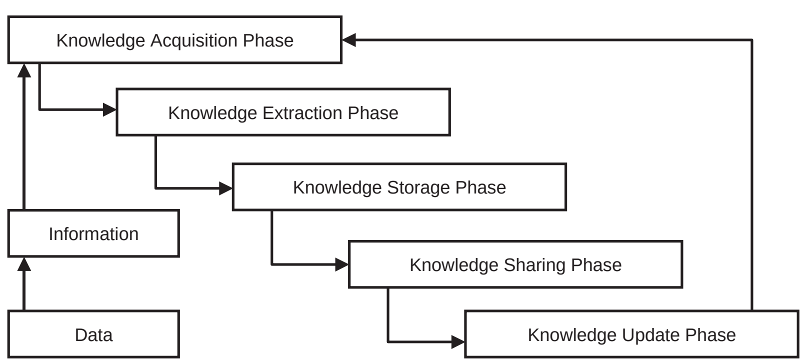
Knowledge Acquisition Phase

The knowledge to be shared must be acquired. In the construction phase, most information and knowledge is acquired on the job site. Hence, the collection of knowledge on a job site plays an important role in the knowledge acquisition phase. Most work of knowledge acquisition is done in the office, because all information and tacit knowledge sent back from the job site can be transferred to explicit knowledge.

Knowledge Extraction Phase

In this study, we define knowledge extraction as a process by which the expert's thoughts and experience are captured. Some knowledge that must be extracted for reuse and storage may only be available from the memories of experts and engineers. In a broader view, knowledge extraction may also include capturing knowledge from other sources such as problem-solution descriptions, construction operation process digital record, virtual communication, and collaboration. However, knowledge is usually captured when the knowledge worker interviews the experts or engineers who answer the questions. In the system, all the descriptions of experience and know-how knowledge are necessary to be edited directly by experts or engineers using unstructured text ways because the knowledge is not necessary to convert into rules or a decision tree. Furthermore, knowledge work will assist with experts and engineers, and deal with the digital process recording work

Figure 2. Five phases of construction knowledge management



if they are important or valuable enough to be kept as the company asset.

Knowledge Storage Phase

The collected knowledge can be stored for future use. During knowledge storage, all information and knowledge are centralised and stored in the knowledge bank (central database) to prevent the collection of redundant information and knowledge. All information and knowledge can be stored in the system by ensuring that data are all electronic and in standard format for each type of file, such as a specific document format or a drawing format.

Knowledge Sharing Phase

Knowledge sharing is the ultimate goal of knowledge management. After the development of knowledge management, people who need to apply knowledge on a particular project can access relevant knowledge for reuse. If necessary, they can adapt it to a new project and solve the new problem.

Knowledge Update Phase

Available knowledge and experience should be continually updated. Reused experience can be evaluated in the context of a new problem to be solved. It can be evaluated in terms of the appropriateness of the selected experience, or in terms of the accuracy of the retrieved experience. Such evaluation is important to ensure the continued improvement of the process by which experience is reused. Invalid knowledge must be identified and be removed or updated. The updating of knowledge can be triggered by a negative experience evaluation or can be conducted as a precaution.

KNOWLEDGE CONTENT IN CONSTRUCTION PROJECTS

Most knowledge content in the construction phase of a project can be classified into two broad categories—tacit knowledge and explicit knowledge. Tacit knowledge is personal, context-specific knowledge that is difficult to formalise, record, or articulate; it is stored in the heads of people (Hart, 1992). The tacit component is primarily developed through a process of trial and error in practice. Tacit knowledge is personal knowledge embedded in individual experience, and shared and exchanged through direct, face-to-face contact (Tiwana, 2000). Tacit knowledge can be communicated directly and effectively. In contrast, the acquisition of explicit knowledge is indirect: It must be decoded and re-coded into one's mental models, and is then internalised as tacit knowledge. Explicit knowledge can be codified and transmitted in a systematic and formal language. Explicit knowledge is formal knowledge that can be packaged as information. It can be found in the documents of organisations, including reports, articles, manuals, patents, pictures, images, video, audio, software, and other forms. It can also be found in organisational documents, such as organisational charts, process maps, mission statements, domains of experience, and others.

Explicit knowledge is easier to collect and manage during the construction phase of a project because the information and knowledge are available in document form. Document management can preserve and manage information and knowledge without extracting explicit knowledge. Therefore, explicit knowledge is easier than tacit knowledge to manage. However, the main problem with tacit knowledge concerns its effective extraction into structured information and unstructured information. After tacit knowledge is extracted, the structured information and unstructured information can be maintained and managed with the assistance of document management tools.

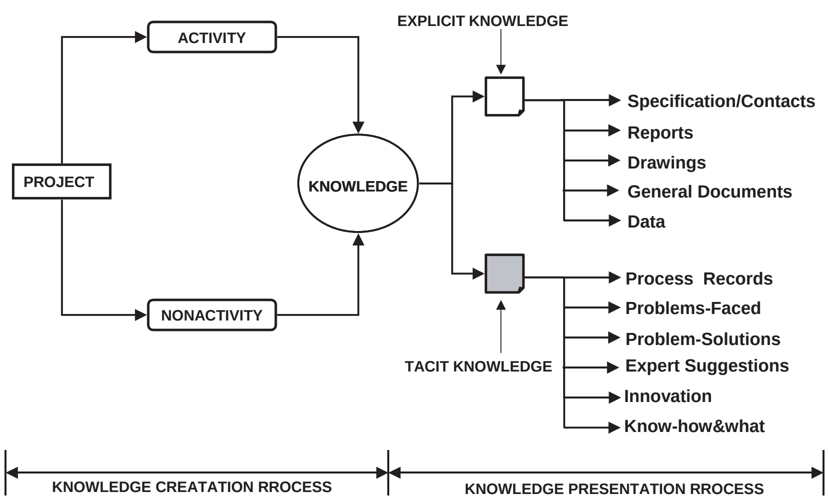
CONCEPTS OF ACTIVITY-BASED KNOWLEDGE MANAGEMENT

Similar to project scheduling management, knowledge management is based on the concept of undertaking activities of project planning and control. Figure 7 presents an overview and conceptual framework of activity-based knowledge management used in construction projects. Knowledge and information associated with activities in previous projects may be reused and applied in future projects. Information and domain knowledge from all projects are divided and saved as "activity" units in categories related to the projects for collection and management. The main advantage of activity-based knowledge management is the ease with which the information and knowledge can be understood and reapplied.

When knowledge is saved in project units, the knowledge includes both tacit and explicit knowledge. In terms of explicit knowledge, project-related information or knowledge usually include specification/contract, reports, drawing, change order, and data. Actually, each project does not contain one-to-one information or knowledge because some of them belong to activity-based information. In contrast, tacit knowledge may include process records, problems faced, problems solved, expert suggestions, know-how, innovation, and experience notes. The information and knowledge is better saved as activity-based units because the result makes it easier to be classified and searched by users. In addition, users may search and refer to related information and knowledge from related activities in past projects. The tacit and explicit knowledge of activity-based knowledge management is the same as the duration and relationship of activity-based project management.

The relationship of current and past activities is important for users to link related information and knowledge together. According to Figure 3, not only the information and knowledge of the current project can be applied, but also same or similar activities of past projects can be referred to as experiences are recorded. When experts or engineers enter related information and knowledge into the system, they need to add the relationships for the activities in the project. Of course, the system is designed to link same or similar activities together based on high similarity automatically or manually.

Figure 3. Activity-based knowledge management



Some of the information and knowledge belongs to the whole project without clear classification of project units. To let users access the information by the Web-based portal, the basic electronic information concerning the project (i.e., specifications, contracts, reports, and drawings) may be saved as explicit knowledge. In terms of tacit knowledge, advanced electronic information and knowledge for the project (i.e., meeting records and e-courses) are saved in the system. The information and knowledge will be saved under the catalogue of current projects. The benefit of non-active classification is the collection of related electronic information in the centralised system.

KNOWLEDGE BANK

To enrich the knowledge bank in the system, the system is designed to encourage all engineers and experts to submit their domain knowledge and valuable experience to the knowledge bank. Traditionally, companies included mostly numeric, structured data in their data warehouse. From this point of view, decision support systems are divided into two components: data warehouses deal with structured data; knowledge management involves unstructured data (Ponniah, 2002). It is a need to integrate both structured (such as data and text) and unstructured information (such as image, video, audio, image, and drawing) in the knowledge bank for further reference and decision making. The main purpose of a knowledge bank is to provide the rich source of content concerning all projects and gather project-related explicit information and tacit knowledge together for involved engineers and experts.

KNOWLEDGE MAP

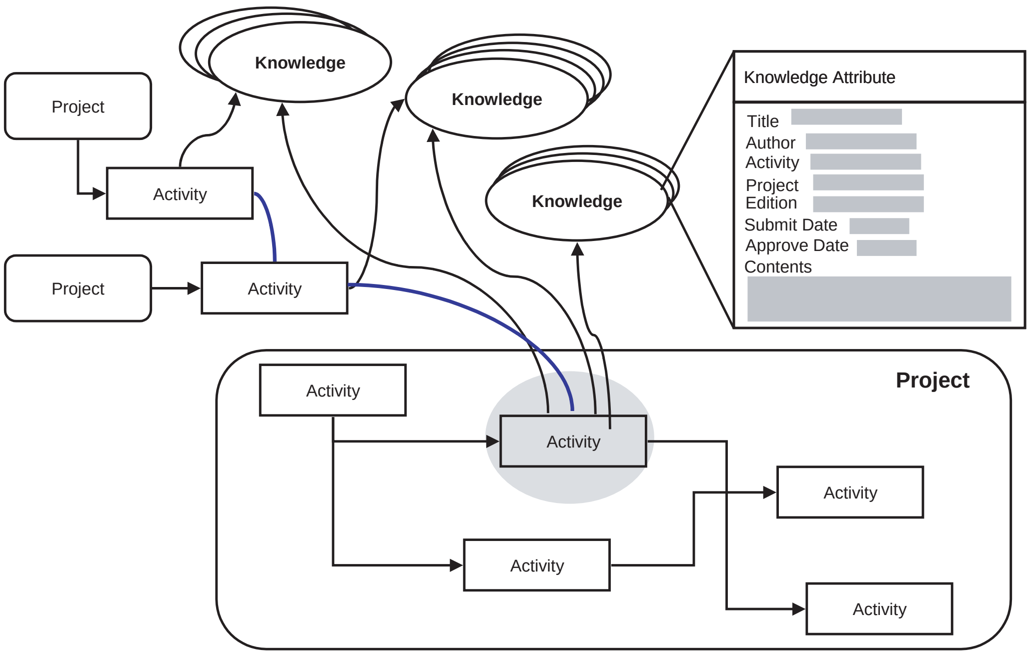
A knowledge map is used to categorise the content within a particular discipline area. A knowledge map (Wexler, 2001) is a consciously designed communication medium using graphical presentation of text, models, numbers, or symbols between makers and users. Knowledge mapping helps one understand the relationships between knowledge stores and dynamics. Davenport and Prusak (1998) note that developing a knowledge map involves locating important knowledge in the organisation and then publishing some sort of list or picture that shows where to find it. The knowledge map plays important roles in implementing knowledge management. All captured knowledge can be summarised and abstracted through the knowledge map. The knowledge map also gives a useful blueprint for implementing a knowledge management system.

The knowledge map in the system mainly deals with the assistance to find the needed knowledge easily and effectively. Furthermore, applying a knowledge mapping technique has the following two advantages. First, the knowledge map is represented in a simple, clear, visual presentation in the knowledge management system. Second, the mapping methodology helps users to identify key critical and available knowledge areas to the project.

A knowledge map can be defined as a diagrammatic and graphic presentation of knowledge linking the relationships between knowledge and knowledge attribute. As shown in Figure 4, a knowledge map consists of two components:

1. Knowledge diagram: Graphical representation of knowledge, having node, sub-node, and linkage:
   - Node: Rectangular object (denoting project or activity representation)
   - Sub-node: Ellipse object (denoting captured knowledge)
   - Linkage: Arrow between nodes implying relationships among knowledge
2. Knowledge attribute: Descriptive representation of knowledge feature

Figure 4. A concept map of the activity-based knowledge management



A knowledge map approach is employed in this chapter to represent explicit and tacit knowledge location within a construction project. A knowledge map in the system provides users with a robust foundation to capture, share, and use project-related or activity-related knowledge. Advantages gained from building the knowledge map in the system can be summarised as follows:

- efficient capture of knowledge;
- understanding of relationships between knowledge; and
- formalisation of all knowledge inventories within a construction project.

PROCEDURES FOR BUILDING THE KNOWLEDGE MAP

According to the knowledge management framework, procedures are proposed for building the knowledge map using the ABKM system. The procedure consists of the following five phases: knowledge determination phase, knowledge extraction phase, knowledge attribute phase, knowledge linking phase, and knowledge validation phase.

Knowledge Determination Phase

The purpose of this phase is to provide a uniform, text-based intermediate representation of the knowledge types specific to construction projects. This phase covers defining knowledge and baseline taxonomy within a project. The scope of the knowledge map decides whether the knowledge map is constructed throughout a specific project. After deciding the scope, we determine the detail level of knowledge analysis. It is necessary and important to determine the proper level of detail to meet project-based knowledge demand effectively. When analysing the source of knowledge within a project, activity is suggested as a unit to analyse the construction project knowledge. We analyse related knowledge based on an activity-unit of the construction project. In other words, we consider which experience and know-how should and can be captured according to the activity of the selected

Description	The new method of erecting steel is proposed for the project 345c. The result of applying new method approves time and cost saving. The name "Smartsteel" is used for the new method. A detailed description is illustrated in the attaching files.

project. After the analysis process of this phase, the types of tacit and explicit knowledge specific to the activity will be considered. Furthermore, all capturing and documenting knowledge with regards to the activity are saved in this activity category.

Knowledge Extraction Phase

Knowledge is extracted through the project execution. There are two types of knowledge extracted from the projects. They are tacit knowledge and explicit knowledge. Tacit knowledge and explicit knowledge may exist in any project. After identifying knowledge through those activities of the project, we decide which knowledge needs to be extracted from the activities of the projects. Suggested knowledge extraction techniques include interviewing with experts, making system analysis, and digital process record.

Knowledge Attribute Phase

Knowledge attributes illustrate the basic description of extracted knowledge and derive relationships with project and similarity activity (see Figure 4). The main purpose of knowledge attribute is to provide the relationship and available knowledge information for knowledge workers and general users. Knowledge attributes include the keywords, description, project name, activity name, contributor, and attached files. Figure 5 illustrates an example using the knowledge attribute with the help of a knowledge map.

Knowledge Linking Phase

The knowledge link is identified after completing the knowledge attribute. The knowledge link is first indicated when the tacit or explicit knowledge is available and documented, and is later confirmed. Three types of knowledge linking are proposed in the chapter. One is activity link activity based on high similarity. Second is activity link knowledge based on the relationship between activity and knowledge. The third is knowledge link knowledge based on high knowledge similarity. When the contributor creates a new link, the link needs to be examined and confirmed before the knowledge map is published.

Knowledge Validation Phase

All knowledge maps need to be validated before a map is published. All the validation processes must be communicated with domain experts, knowledge workers, and knowledge map producers in the enterprise knowledge management division.

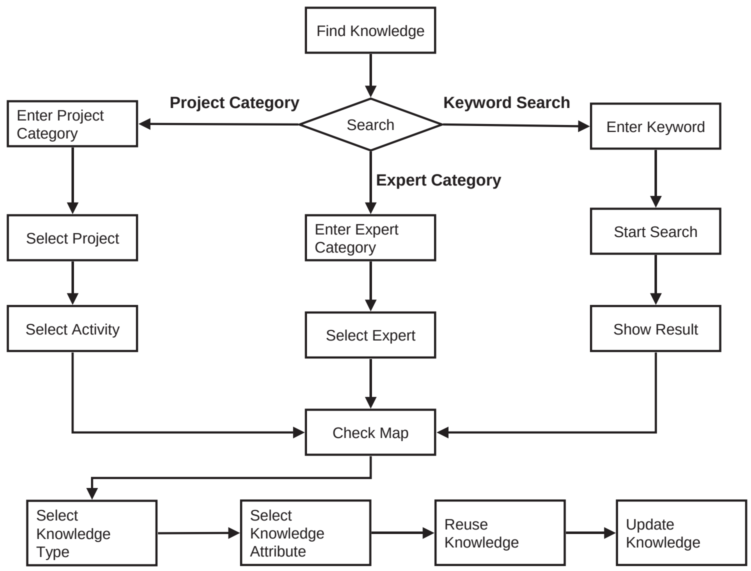
THE SYSTEM

This section describes in detail the ABKM system. There are three search functions supported in the system. They are project category search, keyword search, and expert category search. With the function of keyword search and project category, users can find the knowledge they need directly form the activities of selected projects. Also, the system provides another service for users to find the related knowledge of the domain experts. The information of each domain expert is provided to the people who want to find the domain knowledge-related experts (Figure 6).

Figure 7 illustrates the system architecture. The server of the ABKM system supports four distinct layers— interface, access, application, and database layers; each has its own responsibilities.

The interface layer defines administrative and end-user interfaces. Users can access information through Web browsers such as Microsoft Internet Explorer or Netscape Navigator. Administrators can control and manage information via the Web browser or using a separate server interface. The access layer provides system security and restricted access, firewall services, and system administration functions. The application layer

Figure 6. Knowledge searching process



defines various applications for collecting and managing information. These applications offer indexing, full text search, collaborative work, and document management functions. The database layer consists of a primary SQL Server 2000 database and a backup database (also based on SQL Server 2000).

All project information and knowledge in the ABKM system is centralised in a system database. Project participants may have access to all or some of these documents through the Internet, as determined by their levels of access authorisation. Any information/knowledge about the project can be obtained from and deposited into the system database only through a secure interface. The Web and database servers are distributed on different computers, between which a firewall can be built to protect the system database against intrusion.

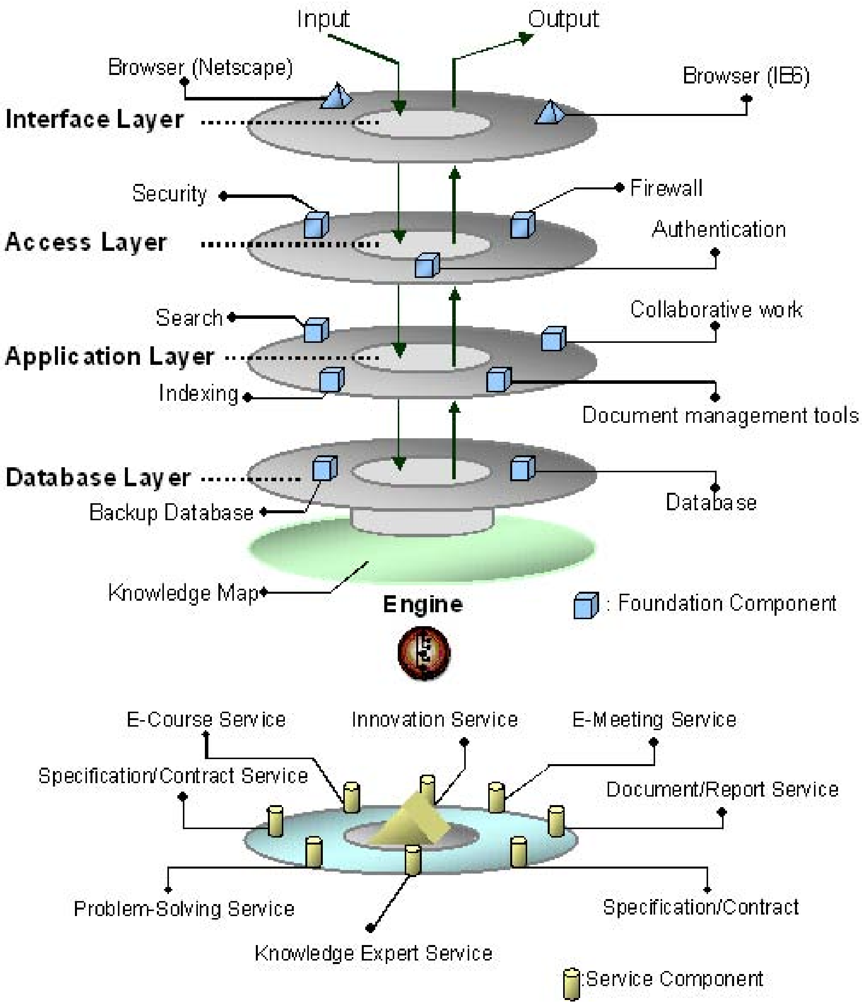
The ABKM portal services described in this study are made available to all participants of the corporation through a specially designed portal, which also serves as a messaging (mail) server for the company (organisation). The portal is a key element of the proposed system and consists of three content areas - public, member, and knowledge manager areas. The public area is open to anyone who is interested in the project. The project member and knowledge manager are accessible only by members with passwords.

Anyone can access information in the public area, so project managers can reasonably use this space for public relations, for example, by posting project descriptions, news, and announcements.

In the project member area, project members can use ABKM services, such as messaging, accessing data, and accessing files. Only project members can access information and knowledge concerning the projects.

Only knowledge managers can log into the manager area, where they can access all information in the project server. Knowledge managers have the right to use the administration service to: (1) post and edit news and announcements, and (2) add new user accounts.

Figure 7. System architecture



All project-related information and knowledge in the ABKM system are classified and stored in the system database. Different kinds of project information/knowledge are stored in different tables in the system database. The ABKM system backs up all databases in the system to ensure the reliability of data storage. The backup database is in another building to protect it against disasters such as earthquakes or fire. All functions are briefly outlined in Table 1, and Figure 8 illustrates some applications of knowledge sharing in the ABKM system.

CASE STUDY

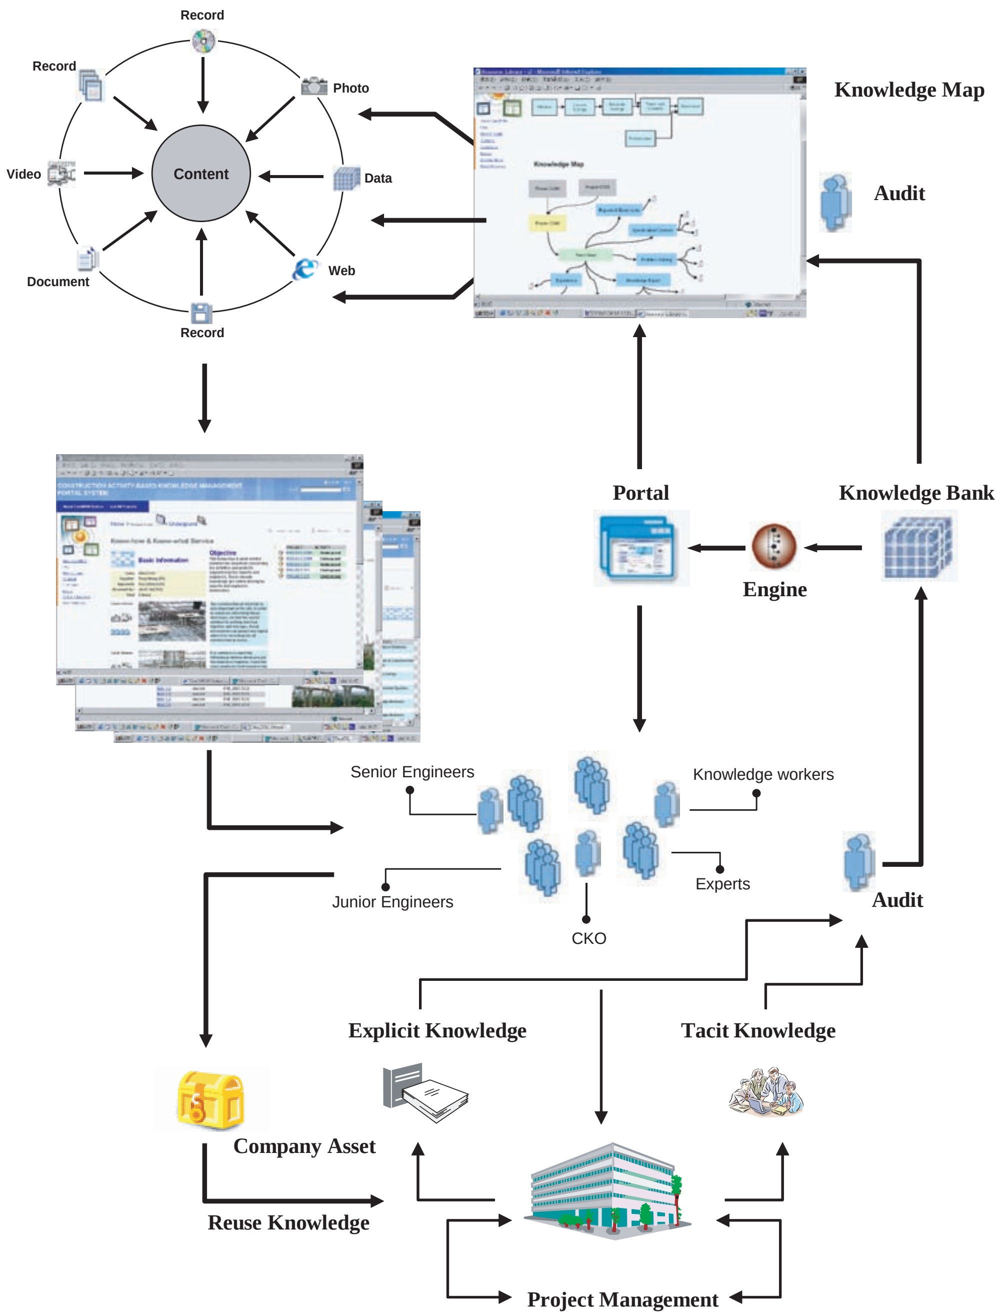
In the following case, the general contractor won the bid of a precast project, to construct a high-tech office building within seven months in Taipei. However, the contractor has no experience of precast construction, and the contractor estimates that the construction period might need to extend to nine months at least to complete the project. Therefore, the contractor decided to hire two construction specialists, particularly in precast

Table 1. The descriptions of function provided by ABKM services

Category	*Function description*
Specification\Contract Managers	Each project's specifications and contracts are stored in the active and non-active categories of a project category. One of the best benefits of this is it is easy to find all specifications and contracts for all projects without wasting time and mass storage space. Paper-based specifications and contracts from past projects need to be scanned by knowledge workers into electronic format (PDF files) then subsequently saved into the system database. All specifications and contracts of past and current projects can be found and downloaded in PDF format from the ABKM system.
Document/Report Managers	All project-related documents and reports are centralized in the server of the ABKM system. The main purpose of these services is to be the e-information center for the company. All users who need to find project-related information or documents can just access the system and get what they need. Therefore, project-related documents must be transferred to electronic format so they can be preserved in the system and be accessible. These documents and reports will be saved under the categories of active and non-active for related-project categories. In the ABKM system, documents and reports files must be uploaded in PDF format, the standard file format. It is convenient for users to reuse these documents and reports without the problems of different software versions or file format.
Video/Photo Managers	In order to reduce the cost of training for problem-solving, it is necessary to record videos and photos by the on-site engineers during the construction phase of a project. With the use of digital cameras and camcorders, all operational processes and problem-solving of a project can be recorded and preserved as company knowledge asset. For future related-projects, digital records can be reused and shared for experts and managers to reduce the time to solve problems.
E-Courses Services	The purpose of e-course services is to provide e-learning to all participants in the construction phase of a project. Without time and location limitations, it is helpful to provide e-courses for needed people via the internet or intranet. Especially for junior engineers, it is convenient for them to learn and understand how a project operates in the construction phase.
E-Meeting Services	The purpose of e-meeting services is to record all project-related meetings and discussions. All meetings or discussions are recorded and saved as digital files in the ABKM server. Also, video conferencing is one of the e-meeting services. The contents of meetings or discussions can be recorded and preserved in the ABKM system.
Expert Yellow Page Services	Experts Yellow Page is a service that assists with finding related experts in the enterprise. It is just like a yellow page. All related-area experts will be mapped in the system based on their specific and professional trade. Users can access this service to find and contact the experts they need in a project.
Problem-solving Services	During the construction phase of a project, lots of problems may occur in the construction phase. Some problems may be solved or improved by engineers or experts, and some are unsolved. To avoid making similar mistakes in other projects, the valued experience and know-how can be saved using problem-solving services. During or before the same problems happen, engineers may find existing solutions concerning the problem.
Collaboration Services	During the construction phase of a project, collaboration services allow experts and engineers to perform tasks and work on projects together by the collaborative communication platform. The communications support video conferencing, voice, multimedia, and conversations.
Knowledge Communities	Knowledge communities provides the platform to let experts and engineers to discuss the project-related topic and share their idea and concept with others or participants. The benefit of knowledge communities in the system is to store the all unstructured project-related information.
Message Services	The message manager is a web-based project-oriented mail system that allows project participants to receive notice mail when the knowledge bank is updated.

construction, to assist the senior engineers in order to finish the project on time as required. For the future, precast projects could process more easily; the company decided to take a good advantage of knowledge management to pass on the valuable know-how to the engineers and manage it well to keep the knowledge inside the company. In the following case study, the contractor applied

Figure 8. The application of knowledge sharing in the ABKM system



and practiced knowledge management by using the knowledge management concept and map. In addition, Table 2 presents the details of various stages for construction knowledge management implementations.

Table 2. Scenario description for using ABKM system

Step		Phase	Scenario
Knowledge Acquisition	1	Collect Information	Senior engineer collects all activities-related documents/information/data
	2	Digital Information	Senior engineer transfers paper-based information/documents into the digital information/data set
	3	Edit Information	Senior engineer edits the description and comment/note for digital document/information
	4	Package Information	Senior engineer packages the description and comment/note with attaching related files that can illustrate the explanation or example
	5	Submit Information	Senior engineer submmits package that includes the description and comment/note with attaching related files for approving
Knowledge Extraction	6	Record Operation & Event	Senior engineer or a knowledge worker records digital related process information for the operation of successful and failure events
	7	Edit Knowledge	Senior engineer or a knowledge worker edits the description and note/comment for the records of video and photo
	8	Manage Knowledge	Knowledge workers collect and manage the coordinated information (includes grouping the meeting records and knowledge communities)
	9	Package Knowledge	Senior engineer or a knowledge worker packages the description and comment/note with attaching related files
	10	Submit Knowledge	Senior engineer or a knowledge worker submmits the package that includes the description and comment/note with attaching related files
Knowledge Storage	11	Approve Knowledge	knowledge worker audits; knowledge worker/expert checks and approves the submission of knowledge package before the classification and storage
	12	Classify Knowledge	Knowledge worker attributes knowledge and classifies this knowledge by placing it in an appropriate position (the activities of project map) in the system.
	13	Store Knowledge	Knowledge worker stores knowledge package into knowledge bank based on the classification.
	14	Backup Knowledge	Knowledge Package is automatically backuped from the knowledge bank to another database for the safety purposes.
	15	Publish Knowledge	Knowledge package is published after knowledge map is validated and announced for the re-use and application
Knowledge Sharing	16	Search Knowledge	Junior engineer found past related knowledge/experience by using knowledge map and keywords or domain expert search
	17	Refer Knowledge	Junior engineer refers and studies past existing knowledge/experience that is stored in the activities of knowledge map
	18	Modify Knowledge	Junior engineer modifies the original knowledge package based on new projects or others existing projects
	19	Apply Knowledge	Junior engineer applies the modified existing knowledge package in other existing projects or future projects
	20	Collect Feedback	Junior engineer collects feedback from the applied-original or modified knowledge package
Knowledge Update	21	Collect Information	Junior engineer collects all paper-based and electronic format of document/information/data
	22	Renote Knowledge	Junior engineer edits the digital document/information by adding detail description and comment/note
	23	Repackage Knowledge	Junior engineer packages the description and comment/note with attaching related files that can illustrate the explanation or example
	24	Approve Knowledge	Knowledge package would be approved to be processed under an accurate procedure before saving in the knowledge bank
	25	Republish Knowledge	Knowledge package is republished in the knowledge map and announced for the reuse or application, based on the original knowledge

Knowledge Acquisition Phase (Step 1-Step 5)

A senior engineer collects related information/ documentation and coverts it into digital format. After the related information and documentation have been digitised, the senior engineer writes descriptions/notes concerning that digital information and packages them as a knowledge set for submission.

Knowledge Extraction Phase (Step 6-Step 10)

A senior engineer and a knowledge worker record all the operating procedures by taking digital video and photographs. The senior engineer discussed progress with two experts every two days to accelerate the solving of the problem in question. All discussions were recorded and summarised as suggested by experts. Discussions with experts continued for five months, until the problem was solved. The senior engineer recorded and summarised his experience and domain knowledge in the system to enable the problem's solution to be reused in other and future projects. The domain knowledge included the problem description (including documents, photographs, drawings, and specifications), the problem's solution (including related documents, photographs, and video of processes), and expert suggestions (such as notes, discussions, and meeting records). Knowledge was extracted according to each process defined as related to the activity of a project. Domain knowledge and experience was organised according to the attribute of the activity concerned. Most senior engineers are required to provide their own knowledge concerning the tasks for which they are responsible.

Knowledge Storage Phase (Step 11-Step 15)

When the submitted knowledge set is approved, a knowledge worker attributes knowledge and classifies this knowledge by placing it in an appropriate position (the activities of project map) in the system. In other words, users can find and read related domain knowledge directly, just by clicking these activities of the project (see Figure 5). All knowledge maps need to be validated to perform well before the map is published. All the validations must be conducted with domain experts, knowledge workers, and knowledge map producers in the enterprise knowledge implantation term. Finally, the knowledge set is automatically backed up from the knowledge bank to another database. After approving and storing knowledge, the system sends a message regarding the updating of the knowledge to the appropriate users automatically.

Knowledge Sharing Phase (Step 16-Step 20)

In a new project that began just after the precast building was constructed three month ago, a junior engineer with no prior experience meets a similar problem and tries to locate past knowledge/information to help him solve the problem. The junior engineer uses the keyword search to find the expert who has domain knowledge concerning the precast building. The junior engineer finds the experts and retrieves, refers to, and studies the knowledge set (including digital video and documentation) supported by these senior engineers. He starts to apply and reuse the knowledge in his own project. Also, the junior engineer gives some feedback and offers knowledge that can be reused when others face new problems. Additionally, some senior engineers in other projects reuse the same knowledge to solve the same problem at reduced cost.

Knowledge Update Phase (Step 21-Step 25)

After applying knowledge and information to the other similar projects, the junior engineer solves his problem and finds a new solution in collaboration with some senior engineers. Finally, the junior engineer notes and submits the new suggestion and experience to the project map, associated with the original knowledge. Furthermore, the knowledge is updated later because of further feedback, and another solution is provided regarding the same problem. After the approval process has been completed, the updated knowledge set is republished in the activities of the project map, and a notice message will be sent to the authorised members.

CONCLUSION

Web technologies and knowledge management concepts can be effectively used during the construction phase of a project, to enable knowledge to be captured and reused in similar projects in the future. This study presents the application of knowledge management in the construction phase of construction projects by using a Web-based portal. The concept of activity-based knowledge management (ABKM) is presented, and a system for use as a knowledge-sharing platform in construction projects is presented. The construction activity-based knowledge management system maps valuable information and knowledge into activity units during the construction phase of a project. The ABKM system is advanced, at least in the following respect: The ABKM system provides insight into the factors that have an impact on construction management activities, and so helps engineers to share knowledge and improve the results of the entire construction project. Junior engineers can interact with the computer to gain domain knowledge, and thus prepare for and participate in a construction project. Briefly, the ABKM system can assist engineers by providing structured and unstructured information to support reference to, and the reuse of, explicit and tacit knowledge. The integration of knowledge management and Web-based technologies appears to be a promising means of improving construction operation and management, especially in the construction phases of projects.

The content of the knowledge bank in the system not only provides specific problem-solutions, but also includes all domain knowledge and experiences gained on projects. Although effort is required to update the explicit/tacit knowledge, the developed system will support construction management by: (1) providing an effective and efficient computerised environment to support knowledge management tasks, and (2) facilitating the implementation of a Web-based knowledge management system pertinent to these activities in the projects.

The demonstration of the system in a case study of the new precast office building located in Taipei indicates that the ABKM system effectively promotes the sharing and reuse of knowledge for new construction projects. The case study also highlighted the need for improving knowledge management and exchange platforms. However, the received feedbacks based on the use of the system are as follows: (1) the content of knowledge bank in the system is not enough to support and provide the junior engineers to get past experience and knowledge in the beginning; (2) most of senior engineers and experts have a low willingness to share their knowledge and experience without the proper reword policy and strategy; (3) it takes time and is very inconvenient for senior engineers to edit and record the knowledge without any assistance form knowledge workers, and (4) most senior engineers agree the ABKM system is a useful platform for them to edit and manage their knowledge and experience.

The knowledge map in the system mainly deals with the assistance to find the needed knowledge easily and effectively. The primary purposes of using a knowledge map in the system are as follows: The knowledge map (1) is represented in a clear and visual way to identify key knowledge areas that are most strategic and critical to the project, and (2) deals with the assistance for users to find the needed knowledge easily and effectively.

The major contributions of the study are as follows: (1) elucidating the content and procedure of knowledge management in construction projects; (2) proposing procedures for building knowledge maps for construction projects, and (3) developing a construction knowledge management system specific for managing construction projects with reference to activities by using a knowledge map.

PRACTICAL TIPS AND LESSONS LEARNED

- Knowledge management is necessary in any life cycle phase of construction projects.
- The content and method of knowledge management in a construction project will be different in each life cycle phase.
- Without the Internet, it is impossible to run knowledge management successfully for construction projects.
- A knowledge map is one of best ways to illustrate whether the knowledge is available and where the knowledge is located in construction projects.
- The way and method of application in construction knowledge management will differ from the size and culture of various construction corporations.

Chapter 2.21
A Model of Knowledge Management Success

Murray E. Jennex
San Diego State University, USA

Lorne Olfman
Claremont Graduate University, USA

ABSTRACT

This article describes a knowledge management (KM) success model that is derived from observations generated through a longitudinal study of KM in an engineering organization and KM success factors found in the literature, which were modified by the application of these observations and success factors in various projects. The DeLone and McLean (1992, 2003) IS Success Model was used as a framework for the model, since it was found to fit the observed success criteria and provided an accepted theoretical basis for the proposed model.

INTRODUCTION

Knowledge management (KM) and knowledge management system (KMS) success is an issue that needs to be explored. The Knowledge Management Foundations workshop held at the Hawaii International Conference on System Sciences in January 2006 discussed this issue and reached agreement that it is important for the credibility of the KM discipline that we be able to define KM success. Also, Turban and Aronson (2001) list three reasons for measuring the success of KM and KMS:

- To provide a basis for company valuation
- To stimulate management to focus on what is important
- To justify investments in KM activities.

All are good reasons from an organizational perspective. Additionally, from the perspective of KM academics and practitioners, identifying the factors, constructs, and variables that define KM success is crucial to understanding how these initiatives and systems should be designed and implemented. It is the purpose of this article to present a model that specifies and describes the antecedents of KM and KMS success so that researchers and practitioners can predict if a specific KM and KMS initiative will be successful. The article assumes that KM and KMS success cannot be separated, which is based on a broad, Churchman view of what constitutes KMS and a definition of success that is not reliant solely on technical effectiveness. The other basic assumption for this article is that success and effectiveness, as used in the KM literature, are synonymous terms. The remainder of the article uses the term KM to refer to KM and KMS and the term success to refer to success and effectiveness. The reasoning for these assumptions is discussed later in the article.

The proposed KM Success Model is an explication of the widely accepted DeLone and McLean (1992, 2003) IS Success Model, which was used since it was able to be modified to fit the observations and data collected in a longitudinal study of Organizational Memory, OM, and KM. It fit success factors found in the KM literature, and the resulting KM Success Model was useful in predicting success when applied to the design and implementation of a KM initiative and/or a KMS. Additionally, the stated purpose of the DeLone and McLean (1992, 2003) IS Success Model is to be a generalized framework that describes success dimensions for which researchers can adapt and define specific contexts of success (DeLone & McLean, 2003). Before presenting the KM Success Model, we will discuss the concepts of knowledge, KM, KMS, and KM/KMS success. We then will discuss briefly the DeLone and McLean (1992, 2003) IS Success Model, present the KM Success Model, and discuss the differences. We will conclude by summarizing studies that support the KM Success Model and will present operationalizations that can be used to evaluate the constructs used to define the KM Success Model dimensions.

KNOWLEDGE, OM, AND KM

Alavi and Leidner (2001) summarize and extend the significant literature relating to knowledge, knowledge management, and knowledge management systems. They view organizational knowledge and OM as synonymous labels, as do Jennex and Olfman (2002). This is useful, as it allows for the combination of research results from OM and KM. It is also born out in the literature. Huber, Davenport, and King (1998) summarize OM as the set of repositories of information and knowledge that the organization has acquired and retains. Stein and Zwass (1995) define OM as the means by which knowledge from the past is brought to bear on present activities, resulting in higher or lower levels of organizational effectiveness, and Walsh and Ungson (1991) define OM as stored information from an organization's history that can be brought to bear on present decisions.

Davenport and Prusak (1998) define knowledge as an evolving mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. Knowledge often becomes embedded in documents or repositories and in organizational routines, processes, practices, and norms. Knowledge is also about meaning in the sense that it is context-specific (Huber et al., 1998). Jennex (2006) extends the concepts of context also to include associated culture that provides frameworks for understanding and using knowledge. Ultimately, we conclude that knowledge contains information, but information is not necessarily knowledge. Also, we conclude that OM contains knowledge. However, for the sake of simplicity, we will use the term knowledge to refer to OM and knowledge throughout this article.

Various knowledge taxonomies exist. Alavi and Leidner (2001) and Jennex and Croasdell (2005) found that the most commonly used taxonomy is Polanyi's (1962, 1967) and Nonaka's (1994) dimensions of tacit and explicit knowledge. This article uses this taxonomy for knowledge. Tacit knowledge is that which is understood within a knower's mind. It consists of cognitive and technical components. Cognitive components are the mental models used by the knower, which cannot be expressed directly by data or knowledge representations. Technical components are concrete concepts that can be expressed readily. Explicit knowledge also consists of these technical components that can be directly expressed by knowledge representations. KM in an organization occurs when members of an organization pass tacit and explicit knowledge to each other. Information Technology (IT) assists KM by providing knowledge repositories and methods for capturing and retrieving knowledge. The extent of the dimension of the knowledge being captured limits the effectiveness of IT in assisting KM. IT works best with knowledge that is primarily in the explicit dimension. Knowledge that is primarily in the tacit dimension requires that more context be captured with the knowledge where context is the information used to explain what the knowledge means and how it is used. Managing tacit knowledge is more difficult to support using IT solutions.

Jennex (2005) looked at what KM is and found no consensus definition. However, using the review board of the International Journal of Knowledge Management as an expert panel and soliciting definitions of KM that were used by the board members, the following working definition is used to define KM for this article:

KM is the practice of selectively applying knowledge from previous experiences of decision making to current and future decision making activities with the express purpose of improving the organization's effectiveness. (Jennex, 2005, p. iv)

KM is an action discipline; knowledge needs to be used and applied in order for KM to have an impact. We also need measurable impacts from knowledge reuse in order for KM to be successful. Decision making is something that can be measured and judged. Organizations can tell if they are making the same decisions over and over and if they are using past knowledge to make these decisions better and more quickly. Also, decision making is the ultimate application of knowledge. This working definition provides this direction for KM and leads to a description of success for KM as being able to provide the appropriate knowledge for decision making when it is needed to those who need it.

KNOWLEDGE MANAGEMENT SYSTEMS

Alavi and Leidner (2001) defined KMS as "IT (Information Technology)-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application" (p. 114). They observed that not all KM initiatives will implement an IT solution, but they support IT as an enabler of KM. Maier (2002) expanded on the IT concept for the KMS by calling it an ICT (Information and Communication Technology) system that supported the functions of knowledge creation, construction, identification, capturing, acquisition, selection, valuation, organization, linking, structuring, formalization, visualization, distribution, retention, maintenance, refinement, evolution, accessing, search, and application. Stein and Zwass (1995) define an Organizational Memory Information System (OMS) as the processes and IT components as necessary to capture, store, and apply knowledge created in the past on decisions currently being made. Jennex and Olfman (2002) expanded this definition by incorporating the OMS into the KMS and by adding strategy and service components to the KMS. We expand the boundaries of a KMS by taking a Churchman view of a system. Churchman (1979) defines a system as “a set of parts coordinated to accomplish a set of goals” (p. 29) and that there are five basic considerations for determining the meaning of a system:

- System objectives, including performance measures
- System environment
- System resources
- System components, their activities, goals, and measures of performance
- System management

Churchman (1979) also noted that systems are always part of a larger system and that the environment surrounding the system is outside the system’s control but influences how the system performs. The final view of a KMS is as a system that includes IT/ICT components, repositories, users, processes that use and/or generate knowledge, knowledge, knowledge use culture, and the KM initiative with its associated goals and measures. This final definition is important, as it makes the KMS an embodiment of the KM initiative and makes it possible to associate KM success with KMS success.

KM SUCCESS

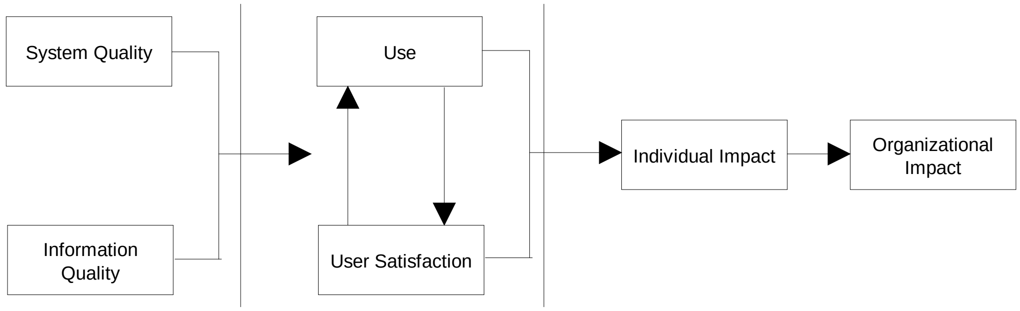
The previous paragraphs define KM success as reusing knowledge to improve organizational effectiveness by providing the appropriate knowledge to those that need it when it is needed. KM is expected to have a positive impact on the organization that improves organizational effectiveness. DeLone and McLean (1992, 2003) use the terms success and effectiveness interchangeably. This article uses KM success and KM effectiveness interchangeably by implying that increasing decision-making effectiveness has a positive impact on the organization, resulting in successful KM. KM and KMS success also is used interchangeably. KMS success can be defined as making KMS components more effective by improving search speed, accuracy, and so forth. For example, a KMS that enhances search and retrieval functions enhances decision-making effectiveness by improving the ability of the decision maker to find and retrieve appropriate knowledge in a more timely manner. The implication is that by increasing KMS effectiveness, KMS success is enhanced, and decision-making capability is enhanced, which leads to positive impacts on the organization. This is how KM success is defined, and it is concluded that enhancing KMS effectiveness makes the KMS more successful as well as being a reflection of KM success.

DELONE AND MCLEAN IS SUCCESS MODEL

In 1992 DeLone and McLean published their seminal work that proposed a taxonomy and an interactive model for conceptualizing and operationalizing IS success (DeLone & McLean, 1992). The DeLone and McLean (D&M) (1992) IS Success Model is based on a review and integration of 180 research studies that used some form of system success as a dependent variable. The model identifies six interrelated dimensions of success, as shown in Figure 1. Each dimension can have measures for determining their impact on success and on each other. Jennex, Olfman, Pituma, and Yong-Tae (1998) adopted the generic framework of the D&M IS Success Model and customized the dimensions to reflect the System Quality and Use constructs needed for an organizational memory information system (OMS). Jennex and Olfman (2002) expanded this OMS Success Model to include constructs for Information Quality.

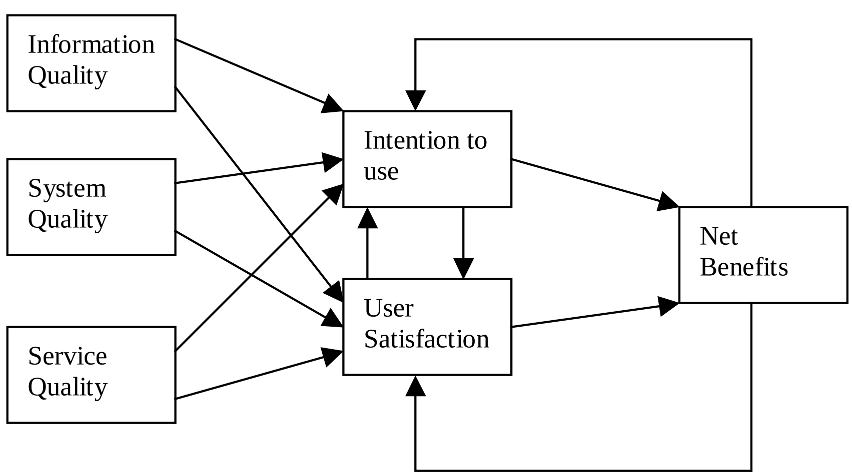
DeLone and McLean (2003) revisited the D&M IS Success Model by incorporating subsequent IS success research and by addressing criticisms of the original model. One hundred forty-four articles from refereed journals and 15 papers from the International Conference on Information

Figure 1. DeLone and McLean's (1992) IS success model



Systems (ICIS) that cited the D&M IS Success Model were reviewed, with 14 of these articles reporting on studies that attempted to empirically investigate the model. The result of the article is the modified D&M IS Success Model shown in Figure 2. Major changes include the additions of a Service Quality dimension for the service provided by the IS group, the modification of the Use dimension into a Intent to Use dimension, the combination of the Individual and Organizational Impact dimensions into an overall Net Benefits dimension, and the addition of a feedback loop from Net Benefits to Intent to Use and User Satisfaction. This article modifies the Jennex and Olfman (2002) OMS Success Model into a KM Success Model by applying KM research and the modified D&M IS Success Model.

Figure 2. DeLone and McLean's (2003) revisited IS success model



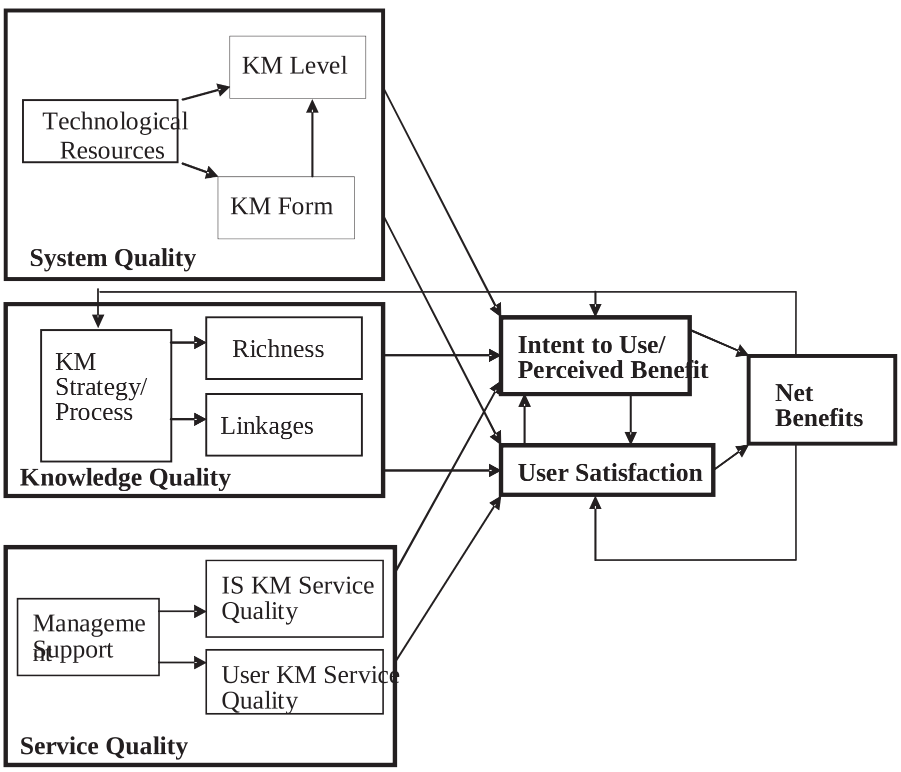
KM SUCCESS MODEL

The model developed in this article was initially proposed by Jennex, et al. (1998) after an ethnographic case study of KM in an engineering organization. The model was modified by Jennex and Olfman (2002) following a five-year longitudinal study of knowledge management in an engineering organization and is based on the DeLone and McLean (2003) revised IS Success Model. This final model was developed to incorporate experience in using the model to design KMS and for incorporating other KM/KMS success factor research from the literature. Figure 3 shows the KM Success Model. The KM Success Model is based on DeLone and McLean (2003). Since the KM Success Model is assessing the use of organizational knowledge, the Information Quality dimension is renamed the Knowledge Quality dimension. Also, because use of a KMS is usually voluntary, the KM Success Model expanded the Intention to Use dimension to include a Perceived Benefit dimension based on Thompson, Higgins, and Howell's (1991) Perceived Benefit model used to predict system usage when usage is voluntary. Finally, since KM strategy/process is key to having the right knowledge, the feedback loop is extended back to this dimension. Dimension descriptions of the model follow.

System Quality

Jennex and Olfman (2000, 2002) found infrastructure issues such as using a common network structure; adding KM skills to the technology support skill set; and using high-end personal computers,

Figure 3. KM success model



integrated databases; and standardizing hardware and software across the organization to be keys to building KM. The System Quality dimension incorporates these findings and defines system quality by how well KM performs the functions of knowledge creation, storage/retrieval, transfer, and application; how much of the knowledge is represented in the computerized portion of the OM; and the KM infrastructure. Three constructs—the technological resources of the organization, KM form, and KM level—are identified. Technological resources define the capability of an organization to develop, operate, and maintain KM. These include aspects such as amount of experience available for developing and maintaining KM; the type of hardware, networks, interfaces, and databases used to hold and manipulate knowledge, capacities, and speeds associated with KM infrastructure; and the competence of the users to use KM tools. Technical resources enable the KM form and KM level constructs.

KM form refers to the extent to which the knowledge and KM processes are computerized and integrated. This includes how much of the accessible knowledge is online and available through a single interface and how integrated the processes of knowledge creation, storage/retrieval, transfer, and application are automated and integrated into the routine organizational processes. This construct incorporates concerns from the integrative and adaptive effectiveness clusters proposed for KMS effectiveness used by Stein and Zwass (1995). This construct, along with the technological resources construct, influences the KM level construct.

KM level refers to the ability to bring knowledge to bear upon current activities. This refers explicitly to the KM mnemonic functions such as search, retrieval, manipulation, and abstraction, and how well they are implemented. The technological resources and form of the KMS influence this construct in that the stronger the technical resources and the more integrated and computerized knowledge is, the more important this construct is and the more effective it can be.

Additional support for these constructs comes from Alavi and Leidner (1999), who found it important to have an integrated and integrative technology architecture that supports database, communication, and search and retrieval functions. Davenport, DeLong, and Beers (1998) found technical infrastructure to be crucial to effective KM. Ginsberg and Kambil (1999) found knowledge representation, storage, search, retrieval, visualization, and quality control to be key technical issues. Mandviwalla, Eulgem, Mould, and Rao (1998) described technical issues affecting KMS design to include knowledge storage/repository considerations; how information and knowledge is organized so that it can be searched and linked to appropriate events and use; and processes for integrating the various repositories and for reintegrating information and knowledge extracted from specific events and access locations, as users rarely access the KMS from a single location (leads to network needs and security concerns). Sage and Rouse (1999) identified infrastructure for capturing, searching, retrieving, and displaying knowledge and an understood enterprise knowledge structure as important. Finally, several of the KMS classifications focus on KM support tools, architecture, or life cycle, which all require strong system quality.

Ultimately, given the effectiveness of information technology to rapidly provide search, storage, retrieval, and visualization capabilities, it is expected that a more fully computerized system that utilizes network, semantic Web, and data warehouse technologies will result in the highest levels of system quality.

Knowledge Quality

Jennex and Olfman (2000, 2002) identified that having a KM process and an enterprise-wide knowledge infrastructure, incorporating KM processes into regular work practices, and that knowledge needs were different for users of different levels, were key issues in order to determine and implement what is the right knowledge for KM to capture. Additionally, it was found that KM users have formal and/or informal drivers that guide them in selecting information and knowledge to be retained by KM and formal and informal processes for reviewing and modifying stored information and knowledge. The Knowledge Quality dimension incorporates this and ensures that the right knowledge with sufficient context is captured and available for the right users at the right time. Three constructs: the KM strategy/process, knowledge richness, and linkages among knowledge components are identified. The KM strategy/process construct looks at the organizational processes for identifying knowledge users and knowledge for capture and reuse, the formality of these processes including process planning, and the format and context of the knowledge to be stored. This construct determines the contents and effectiveness of the other two constructs. Richness reflects the accuracy and timeliness of the stored knowledge as well as having sufficient knowledge context and cultural context to make the knowledge useful. Linkages reflect the knowledge and topic maps and/or listings of expertise available to identify sources of knowledge to users in the organization.

Hansen, Nohria, and Tierney (1999) describe two types of knowledge strategy: personification and codification. They warn of trying to follow both strategies equally at the same time. These strategies refer to how knowledge is captured, represented, retrieved, and used. However, KM strategy/process also needs to reflect that the knowledge needs of the users change over time, as found by the longitudinal study (Jennex & Olfman, 2002) and that new users have a hard time understanding codified tacit knowledge (Koskinen, 2001). For example, new users will follow personification until they understand the context in which knowledge is captured and used, and then they are willing to switch to a codification strategy. Personification corresponds to linkages in the model shown in Figure 3 and refers to the situation in which new users initially feel more comfortable seeking knowledge contexts from recognized human experts on a particular subject. Following this phase, these users tend to switch to codified knowledge; thus, codification corresponds to richness in the model. Additionally, Brown, Dennis, and Gant (2006) found that as the procedural complexity and teachability of knowledge increased, the tendency of users to rely on linkages (person-to-person knowledge transfer) also increased. Jennex (2006) discuses the impact of context and culture on knowledge reuse, and the conclusion is that as knowledge complexity grows, the ability to capture the context and culture information needed to ensure the knowledge is usable and, used correctly, becomes more difficult, and the richness of the stored knowledge is less able to meet this need, which results in users shifting to using linkages and personification. This model disagrees with Hansen, et al.'s (1999) finding that organizations need to select a single strategy on which to concentrate, while using the other strategy in a support role by recognizing that both strategies will exist and that they may be equal in importance.

Additional support for these constructs comes from Barna (2003), who identified creating a standard knowledge submission process, methodologies, and processes for the codification, documentation, and storage of knowledge, processes for capturing and converting individual tacit knowledge into organizational knowledge as important. Cross and Baird (2000) found that in order for KM to improve business performance, it had to increase organizational learning by supporting personal relationships between experts and knowledge users, providing distributed databases to store knowledge and pointers to knowledge, providing work processes for users to convert personal experience into organizational learning, and providing direction to what knowledge the organization needs to capture and from which to learn. Davenport, et al. (1998) identified three key success factors for KM strategy/process: clearly communicated purpose/goals, multiple channels for knowledge transfer, and a standard, flexible knowledge structure. Mandviwalla, et al. (1998) described several strategy issues affecting KM design, which include the KM focus (who are the users); the quantity of knowledge to be captured and in what formats (who filters what is captured); what reliance and/or limitations are placed on the use of individual memories; how long the knowledge is useful; and the work activities and processes that utilize KM. Sage and Rouse (1999) identified modeling processes to identify knowledge needs and sources, KM strategy for the identification of knowledge to capture and use and who will use it, an understood enterprise knowledge structure, and clear KM goals as important.

Service Quality

The Service Quality dimension ensures that KM has adequate support in order for users to utilize KM effectively. Three constructs—management support, user KM service quality, and IS KM service quality—are identified. Management support refers to the direction and support an organization needs to provide in order to ensure that adequate resources are allocated to the creation and maintenance of KM; a knowledge sharing and using organizational culture is developed; encouragement, incentives, and direction are provided to the work force to encourage KM use; knowledge reuse; and knowledge sharing; and that sufficient control structures are created in the organization in order to monitor knowledge and KM use. This construct enables the other two constructs. User KM service quality refers to the support provided by user organizations to help their personnel to utilize KM. This support consists of providing training to their users on how to use KM, how to query KM, and guidance and support for making knowledge capture, knowledge reuse, and KM use a part of routine business processes. IS KM service quality refers to the support provided by the IS organization to KM users and to maintaining KM. This support consists of building and maintaining KM tools and infrastructure; maintaining the knowledge base; building and providing knowledge maps of the databases; and ensuring the reliability, security, and availability of KM.

Our previous KM success model versions included the previous constructs as part of the system quality and knowledge quality dimensions. These constructs were extracted from these dimensions in order to generate the constructs for the service quality dimension and to ensure that the final KM success model was consistent with DeLone and McLean (2003).

Additional support for these constructs comes from Alavi and Leidner (1999), who found organizational and cultural issues associated with user motivation to share and use knowledge to be the most significant. Barna (2003) identified the main managerial success factor as creating and promoting a culture of knowledge sharing within the organization by articulating a corporate KM vision, rewarding employees for knowledge sharing and creating communities of practice. Other managerial success factors include obtaining senior management support, creating a learning organization, providing KM training, precisely defining KM project objectives, and creating relevant and easily accessible knowledge-sharing databases and knowledge maps. Cross and Baird (2000) found that in order for KM to improve business performance, it had to increase organizational learning by supporting personal relationships between experts and knowledge users and by providing incentives to motivate users to learn from experience and to use KM. Davenport, et al. (1998) found senior management support, motivational incentives for KM users, and a knowledge-friendly culture to be critical issues. Ginsberg and Kambil (1999) found incentives to share and use knowledge to be the key organizational issues. Holsapple and Joshi (2000) found leadership and top management commitment/support to be crucial. Resource influences such as having sufficient financial support and skill level of employees were also important. Malhotra and Galletta (2003) identified the critical importance of user commitment and motivation but found that using incentives did not guarantee a successful KMS. Sage and Rouse (1999) identified incentives and motivation to use KM, clear KM goals, and measuring and evaluating the effectiveness of KM as important. Yu, Kim, and Kim (2004) determined that KM drivers such as a learning culture, knowledge-sharing intention, rewards, and KM team activity significantly affected KM performance

User Satisfaction

The User Satisfaction dimension is a construct that measures satisfaction with KM by users. It is considered a good complementary measure of KM use, as desire to use KM depends on users being satisfied with KM. User satisfaction is considered a better measure for this dimension than actual KM use, as KM may not be used constantly yet still may be considered effective. Jennex (2005) found that some KM repositories or knowledge processes such as e-mail may be used daily, while others may be used once a year or less. However, it also was found that the importance of the once-a-year use might be greater than that of daily use. This makes actual use a weak measure for this dimension, given that the amount of actual use may have little impact on KM success, as long as KM is used when appropriate and supports DeLone and McLean (2003) in dropping amount of use as a measurement of success.

Intent to Use/Perceived Benefit

The Intent to Use/Perceived Benefit dimension is a construct that measures perceptions of the benefits of KM by users. It is good for predicting continued KM use when KM use is voluntary, and amount and/or effectiveness of KM use depend on meeting current and future user needs. Jennex and Olfman (2002) used a perceived benefit instrument adapted from Thompson, et al. (1991) to measure user satisfaction and to predict continued intent to use KM when KM use was voluntary. Thompson, et al.'s (1991) perceived benefit model utilizes Triandis' (1980) theory that perceptions on future consequences predict future actions. This construct adapts the model to measure the relationships among social factors concerning knowledge use, perceived KM complexity, perceived near-term job fit and benefits of knowledge use, perceived long-term benefits of knowledge use, and fear of job loss with respect to willingness to contribute knowledge. Malhotra and Galletta (2003) created an instrument for measuring user commitment and motivation that is similar to Thompson, et al.'s (1991) perceived benefit model but is based on self-determination theory that uses the Perceived Locus of Causality that also may be useful for predicting intent to use. Additionally, Yu, et al. (2004) found that KM drivers such as knowledge-sharing intention significantly affected KM performance.

Net Impact

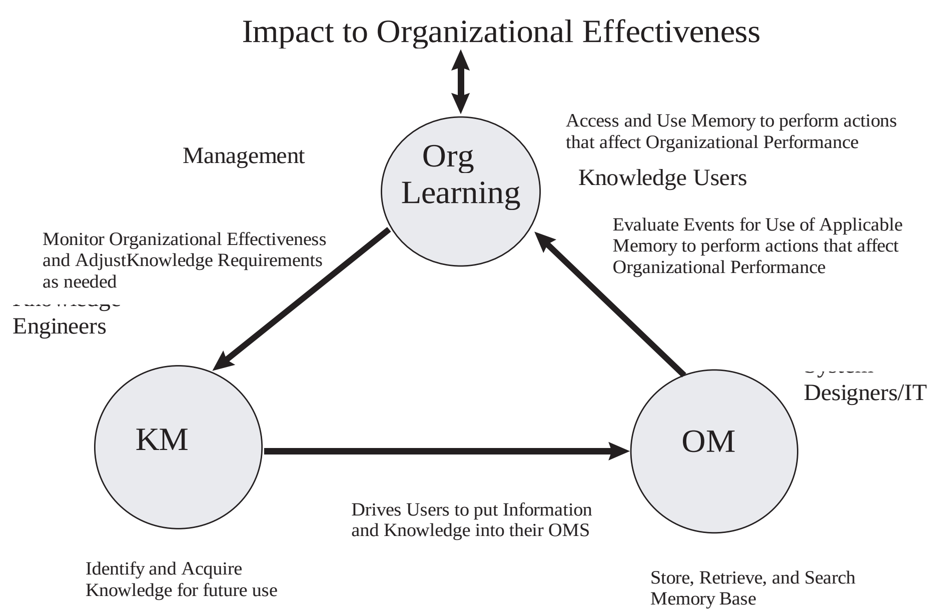
An individual's use of KM will produce an impact on that person's performance in the workplace. In addition, DeLone and McLean (1992) note that an individual impact also could be an indication that an information system has given the user a better understanding of the decision context, has improved his or her decision-making productivity, has produced a change in user activity, or has changed the decision maker's perception of the importance or usefulness of the information system. Each individual impact should have an effect on the performance of the whole organization. Organizational impacts usually are not the summation of individual impacts, so the association between individual and organizational impacts is often difficult to draw. DeLone and McLean (2003) recognized this difficulty and combined all impacts into a single dimension. Davenport, et al. (1998) overcame this by looking for the establishment of linkages to economic performance. Alavi and Leidner (1999) also found it important to measure the benefits of KM, as did Jennex and Olfman (2000).

We agree with combining all impacts into one dimension and the addition of the feedback loop to the User Satisfaction and Intent to Use/Perceived Benefit dimensions but take it a step further and extend the feedback loop to include the KM Strategy/Process construct. Jennex and Olfman (2002) showed this feedback in their model relating KM, OM, organizational learning, and effectiveness, as shown in Figure 4. This model recognizes that the use of knowledge may have good or bad benefits. It is feedback from these benefits that drives the organization either to use more of the same type of knowledge or to forget the knowledge, which also provides users with feedback on the benefit of the KMS. Alavi and Leidner (2001) also agree that KM should allow for forgetting some knowledge when it has detrimental or no benefits. To ensure that this is done, feedback on the value of stored knowledge needs to be fed into the KM Strategy/Process construct.

OPERATIONALIZATION OF THE SUCCESS MODEL

Jennex and Olfman (2002) performed a longitudinal study of KM in an engineering organization that identified a link between knowledge use and improved organizational effectiveness. Although a great deal of quantitative data were taken, it was not possible to quantify productivity gains as a function of knowledge use. KM was found to be effective and to have improved in effectiveness over a five-year period. Additionally, the engineers were found to be more productive.

Figure 4. The OM/KM model



Jennex (2000) applied an early version of this model to the construction and implementation of a knowledge management Web site for assisting a virtual project team. It was found that applying the model to the design of the site resulted in the project going from lagging to a leading project in just a few months.

Hatami, Galliers, and Huang (2003) used the KM Success Model to analyze knowledge reuse and the effectiveness of decision making. They found the model useful in explaining the effects of culture and knowledge needs on the overall KM success.

Jennex, Olfman, and Addo (2003) investigated the need for having an organizational KM strategy to ensure that knowledge benefits gained from projects are captured for use in the organization. They found that benefits from Y2K projects were not being captured, because the parent organizations did not have a KM strategy/process. Their conclusion was that KM in projects can exist and can assist projects in utilizing knowledge during the project. However, it also led to the conclusion that the parent organization will not benefit from project-based KM unless the organization has an overall KM strategy/process.

The following discussion combines these studies to provide methods of operationalizing the constructs proposed previously. Table 1 summarizes the various measures applied in these studies.

System Quality

Three constructs were proposed for the system quality dimension: technical resources, KM form, and KM level. Jennex and Olfman (2002) found that the capabilities of the IS organization

Table 1. KMS success model data collection methods

Construct	Data Collection Method
Technical Resources	User competency survey, observation and document research of IS capabilities, interview with IS Manager on infrastructure
Form of KMS	Interviews and survey of knowledge sources and form
Level of KMS	Survey of satisfaction with retrieval times, usability testing on KMS functions
KM Strategy/ Process	Survey on drivers for putting knowledge into the KMS and for satisfaction with the knowledge in the KMS, check on if a formal strategy/process exists
Richness	Usability test on adequacy of stored knowledge and associated context, interviews and satisfaction survey on adequacy of knowledge in KMS
Linkages	Usability test on adequacy of stored linkages, interviews and satisfaction surveys on satisfaction with linkages stored in KMS
Management Support	Interviews and Social Factors construct of Thompson, Higgins, and Howell’s survey on perceived benefit
IS KM Service Quality	Interview with IS Manager on IS capabilities. Interviews with users on needs and capabilities. Suggest adding user satisfaction survey on service issues
User Organization KM Service Quality	Interview with user organization KM team on capabilities and responsibilities, and needs from IS. Interview with users on needs and capabilities. Suggest adding user satisfaction survey on service issues
User Satisfaction	Doll and. Torkzadeh (1988) End User Satisfaction Measure, any other user satisfaction measure
Intent to Use/ Perceived Benefit	Thompson, Higgins, and Howell’s (1991) survey on perceived benefit
Net Impacts	Determine Individual and Organizational productivity models through interviews, observation, tend to be specific to organizations

and the users can impact the success of KM. IS infrastructure and organizational capabilities that enhanced KM effectiveness included a fast, high-capacity infrastructure, strong application development skills, network skills, and awareness of the user organization's knowledge requirements. Users' capabilities that enhanced KM effectiveness included a high degree of computer literacy and high-end personal computers. Given the importance of these technical resources, operationalization of the technical resources construct can be accomplished by focusing on the overall experience of the development group in building and maintaining networked systems that support KM; the computer capabilities of KM end users; and the quality of hardware, network, application, and operating system capabilities of workstations supporting KM.

KM level was defined as the ability to bring past information to bear upon current activities. This can be measured in terms of Stein and Zwass' (1995) mnemonic functions, including knowledge acquisition, retention, maintenance, search, and retrieval. It is expected that more effective KM will include more sophisticated levels of these functions. For example, more sophisticated KM should contain the ability to do filtering, guided exploration, and to grow memory. Usability testing of these functions can serve as measures of how effective they are implemented.

KM form refers to the extent to which knowledge is computerized and integrated. In essence, the more computerized the memory (personification and codification approaches), the more integrated it can be. That is, if all knowledge sources are available in computer-based form, then it will be possible to search and retrieved knowledge more effectively. Integration also speaks to the external consistency of the various KM tools. Jennex and Olfman (2002) found that although much of the KM used by the engineering organization was computerized, there were many different KMS components, each with varying kinds of storage mechanisms and interfaces. These components were poorly integrated, relying mainly on the copy-and-paste features of the Windows interface and, therefore, limited the ability of workers to utilize KM effectively. It was evident that more sophisticated technical resources could produce a more integrated set of components. Surveys of actual knowledge repositories that are used for KM can determine how much knowledge is stored in computerized forms. It is desired but not practical to have all knowledge in a computer. Assessment of this construct should focus on how much of the knowledge that is practical for computer storage is computerized.

Knowledge Quality

Knowledge quality has three constructs: KM strategy/process, richness, and linkages. Jennex and Olfman (2002) used surveys of users to determine drivers for putting knowledge into KM repositories and user satisfaction with the knowledge that was in these repositories. Jennex, et al. (2003) surveyed organizations to determine if they had a KM strategy and how formal it was. Jennex and Olfman (2002) used interviews of KM users to determine their satisfaction with the accuracy, timeliness, and adequacy of available knowledge. The need for linkages and personification of knowledge was found through interviews with users on where they went to retrieve knowledge. Additionally, it was found that users' KM needs vary, depending on their experience levels in the organization. Context of the knowledge is critical. New members did not have this context, and the knowledge repositories did not store sufficient context in order for a new member to understand and use the stored knowledge. It was found that new members need linkages to the human sources of knowledge. It is not expected that KM will ever be able to do an adequate job of storing context, so it is recommended that KM store linkages to knowledge.

Service Quality

Service quality was defined previously as how well the organization supports KM. Three constructs are proposed: management support, IS KM service quality, and user KM service quality. Jennex and Olfman (2002) identified these constructs through interviews that found evidence to show that the service quality of the IS and user organizations can impact KM success and that service quality was determined by the organizations that possess certain capabilities. IS KM service consisted of IS being able to build and maintain KM components and to map the knowledge base. IS organizational capabilities that enhanced this service effectiveness included data integration skills, knowledge representation skills, and awareness of the user organization's knowledge requirements. User organization KM service consisted of incorporating knowledge capture into work processes and being able to identify key knowledge requirements. User organization KM capabilities that enhanced this service effectiveness included understanding and being able to implement KM techniques, such as knowledge taxonomies, ontologies, and knowledge maps, and to process analysis capabilities. Additionally, service was enhanced either by the IS or the user organization providing training on how to construct knowledge searches, where the knowledge was located, and how to use KM.

The key construct—management support—was measured by using interviews and the social factors measure of Thompson, Higgins, and Howell's (1991) survey on perceived benefit. The social factors measure uses a Likert scale survey to determine perceptions of support from peers, supervisors, and managers, and gives a good view of the ability of the organizational culture to support KM and management support for doing KM. Additionally, individual and organizational productivity models were generated by using interviews with managers that provide an assessment of the impact of knowledge use on individuals and organizations and what incentives are being used to encourage KM participation.

IS organization KM support was measured by determining the overall experience of the development group in building and maintaining networked systems that support KM and the satisfaction of the KM end users with this support. User organization KM support was measured by determining what support was provided and how satisfied the users were with it. Measures assessing specific areas of capability can be used, should less-than-acceptable service satisfaction be found.

User Satisfaction

User satisfaction is a construct that measures perceptions of KM by users. This is one of the most frequently measured aspects of IS success, and it is also a construct with a multitude of measurement instruments. User satisfaction can relate to both product and service. As noted, product satisfaction often is used to measure knowledge quality. Product satisfaction can be measured by using the 12-item instrument developed by Doll and Tordzadeh (1988). This measure addresses satisfaction with content, accuracy, format, ease of use, and timeliness. Additionally, measures addressing satisfaction with interfaces should be used. Other user satisfaction measures can be used to assess the specific quality constructs, as discussed in previous paragraphs.

Intent to Use/Perceived Benefit

Jennex, et al. (1998) used Thompson, Higgins, and Howell's (1991) Perceived Benefit Model to predict continued voluntary usage of KM by the engineering organization. The following four factors from the model plus one added by Jennex and Olfman were in the survey:

- Job fit of KM, near-term consequences of using KM

- Job fit of KM, long-term consequences of using KM
- Social factors in support of using KM
- Complexity of KM tools and processes
- Fear of job loss for contributing knowledge to KM

All five factors were found to support continued KM use during the initial measurements. Jennex and Olfman (2002) found continued KM use throughout the five years of observing KM usage and concluded that the Perceived Benefit model was useful for predicting continued use. Jennex (2000) used these factors to design the site, work processes, and management processes for a virtual project team, using Web-based KM to perform a utility Year 2000 project. Promoting the social factors and providing near-term job fit were critical in ensuring that the virtual project team utilized KM. KM use was considered highly successful, as the project went from performing in the bottom third of utility projects to performing in the top third of all utility projects.

Net Benefits

The net benefits dimension looks for any benefits attributed to use of the KMS. We attempted to measure benefits associated with individual and organizational use of KM through the generation of productivity models that identified where knowledge use impacted productivity. KM benefits for an individual are found in their work processes. Jennex and Olfman (2002) queried supervisors and managers in order to determine what they believed was the nature of individual productivity in the context of the station-engineering work process. The interviews revealed a complex set of factors. Those benefiting from KM include the following:

- Timeliness in completing assignments and doing them right the first time
- Number of assignments completed
- Identification and completion of high-priority assignments
- Completeness of solutions
- Quality of solutions (thoroughness and accuracy)
- Complexity of the work that can be assigned to an engineer
- Client satisfaction

While many of these factors are measured quantitatively, it was not possible to directly attribute changes in performance solely to KM use, although improvements in performance were qualitatively attributed to KM use. Additionally, Jennex and Olfman (2002) asked 20 engineers to indicate whether they were more productive now than they were five or 10 years ago, and all but one thought that they were. This improvement was attributed primarily to KM use but also was a qualitative assessment.

Organizational impacts relate to the effectiveness of the organization as a whole. For a nuclear power plant, specific measures of effectiveness were available. These measures relate to assessments performed by external organizations as well as those performed internally. External assessments were found to be the most influenced by KM use. Jennex and Olfman (2002) found measures such as the SALP (Systematic Assessment of Licensee Performance) Reports issued by the Nuclear Regulatory Commission and site evaluations performed by the Institute of Nuclear Power Operations (INPO). Review of SALP scores issued since 1988 showed an increase from a rating of 2 to a rating of 1 in 1996. This rating was maintained through the five years of the study. An INPO evaluation was conducted during the spring of 1996 and resulted in a 1 rating. This rating also was maintained throughout the five years of the study. These assessments identified several strengths directly related to engineer productivity using KM, including decision making, root cause analysis, problem resolution, timeliness, and Operability Assessment documentation.

This demonstrates a direct link between engineer productivity and organization productivity. Also, since organization productivity is rated highly, it can be inferred that engineer productivity is high.

Two internal indicators were linked to KM use: unit capacity and unplanned automatic scrams. Unit capacity and unplanned scrams are influenced by how well the engineers evaluate and correct problems. Both indicators improved over time. These two indicators plus unplanned outages and duration of outages became the standard measure during the Jennex and Olfman (2002) study, and reporting and monitoring of these factors significantly improved during the study.

The conclusion is that net benefits should be measured by using measures that are specific to the organization and that are influenced by the use of KM. Suitable measures were found in all the studies used for this article, and it is believed that they can be found for any organization.

CONCLUSION

The DeLone and McLean IS Success Model is a generally accepted model for assessing success of IS. Adapting the model to KM is a viable approach to assessing KM success. The model presented in this article meets the spirit and intent of DeLone and McLean (1992, 2003). Additionally, Jennex (2000) used an earlier version of the KM Success Model to design, build, and implement intranet-based KM that was found to be very effective and successful. The conclusion of this article is that the KM Success Model is a useful model for predicting KM success. It is also useful for designing effective KM.

AREAS FOR FUTURE RESEARCH

DeLone and McLean (1992) stated, "Researchers should systematically combine individual measures from the IS success categories to create a comprehensive measurement instrument" (pp. 87–88). This is the major area for future KM success research. Jennex and Olfman (2002) provided a basis for exploring a quantitative analysis and test of the KM Success Model. To extend this work, it is suggested that a survey instrument to assess the effectiveness of KM within other nuclear power plant engineering organizations in the United States should be developed and administered. Since these organizations have similar characteristics and goals, they provide an opportunity to gain a homogeneous set of data to use for testing the model and, ultimately, to generate a generic set of KM success measures.

Additionally, other measures need to be assessed for applicability to the model. In particular, the Technology Acceptance Model, Perceived Usefulness (Davis, 1989) should be investigated as a possible measure for Intent to Use/Perceived Benefit.

Chapter 2.22
Knowledge Management System Success:
Empirical Assessment of a Theoretical Model

Shih-Chen Liu
Chihlee Institute of Technology, Taiwan

Lorne Olfman
Claremont Graduate University, USA

Terry Ryan
Claremont Graduate University, USA

ABSTRACT

This article presents the empirical testing of a theoretical model of knowledge management system success. The Jennex and Olfman model of knowledge management system success was developed to reflect the DeLone and McLean model of information systems success in the knowledge management context. A structural equation model representing the Jennex and Olfman theoretical model is developed. Using data from a prior study aimed at knowledge management system use and individual learning, this model is tested. The overall fit of the model to the data is fair, although some interpretation of the estimated model parameters is problematic. The results of the model test provide limited support for the Jennex and Olfman theoretical model, but indicate the value of continued investigation and refinement of it. Suggestions for future research are provided.

INTRODUCTION

Involvement with a knowledge management system (KMS) generally leads to the desire to determine how successful it is. Practically, the measurement of KMS success (or effectiveness) can be valuable in a number of ways, including the justification of knowledge management (KM) investments (Turban & Aronson, 2001). Academically, the conceptualization of information system (IS) effectiveness is one of the most important research domains in the IS discipline (ISWorld, 2004a). A valid specific model of KMS success would have value for KM researchers in much the same way that a valid general model of IS success would have for the IS field.

The DeLone and McLean (D&M) model of IS success (1992, 2002, 2003) is currently the most widely accepted conceptualization of IS effectiveness among researchers (ISWorld, 2004b). The D&M model comprises six theoretical dimensions: Information Quality, System Quality, Service Quality, Intention to Use/Use, User Satisfaction, and Net Benefits (DeLone & McLean, 2003). Each of these dimensions constitutes a well-trodden research path in its own right, as indicated by the separate pages devoted to each on the ISWorld Web site (ISWorld, 2004a). Figure 1 illustrates the model.

The DeLone and McLean model is a general framework for understanding IS effectiveness and must be adapted to specific contexts. For example, DeLone and McLean (2003) provide an adaptation of the most recent iteration of their model to e-commerce. Jennex, Olfman, and their colleagues have adapted the D&M model to the KM context (Jennex, Olfman, Pituma, & Park, 1998; Jennex, Olfman, & Addo, 2003; Jennex & Olfman, 2002, 2004). This adaptation—which can be labeled as the Jennex and Olfman (J&O) model—can claim both empirical and theoretical justification. The earliest version of the model (Jennex et al., 1998) was informed empirically by an ethnography concerning KMS use in an engineering setting and theoretically by the 1992 D&M model, along with thinking at that time about KM and organization memory (such as Stein & Zwass, 1995). A revision of the model was informed empirically by a longitudinal study of engineering use of a KMS over a five-year period and theoretically by the 2002 revised D&M model, along with thinking at that time about KM (such as Alavi & Leidner, 2001). The latest version of the J&O model reflects the reasoning given for the latest version of the D&M model (DeLone & McLean,

Figure 1. DeLone and McLean (2003) IS success model

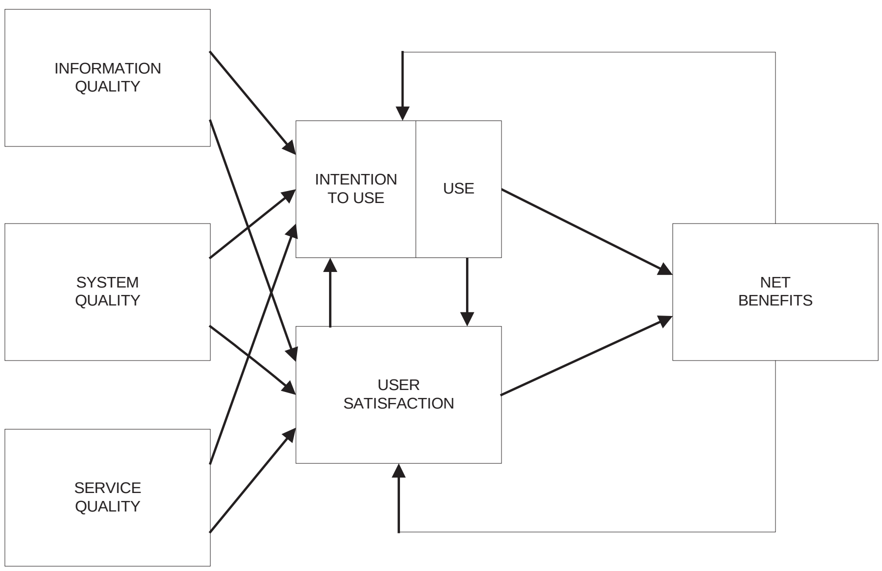

Figure 2. Jennex and Olfman (2004) IS success model

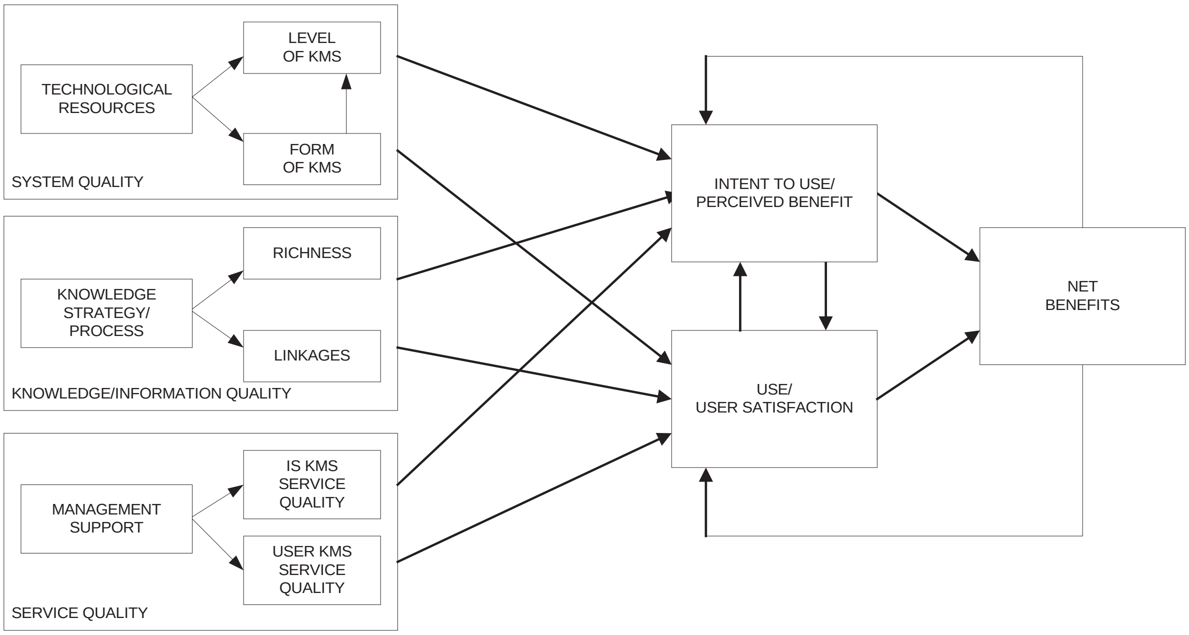

2003), along with the maturation of thinking of researchers in the KM field. Figure 2 depicts the J&O model in its current incarnation (Jennex & Olfman, 2004).

Although the J&O model was developed to reflect system success in a KM context, as is true for any theoretical model, its value as an explanation is open to empirical test. This research constitutes such a test; that is, it aims to assess how well the J&O model describes KMS success in the world. More specifically, the article reports the testing of a structural equation modeling (SEM) model conforming to the J&O theoretical model, with survey data collected from KMS users. This test provides an evaluation of the adequacy of the J&O model in its present form, along with suggestions of improvements that might be made to it.

BACKGROUND

Relationship Between the D&M Model and the J&O Model

The J&O model is an adaptation to the KM context of the well-accepted D&M model of IS success. The J&O model conceptualizes the basic dimensions of success in much the same ways that the D&M model does, but the ideas involved in the J&O model are more targeted to the KM setting than are the concepts constituting the D&M model. The J&O model consists of the same number of dimensions, with the same fundamental relationships among them, as the D&M model; the differences between the two models lie in the sub-dimensions proposed by Jennex, Olfman, and their colleagues to map the D&M dimensions to the KM setting. In the following paragraphs, the mapping is explained between each D&M dimension and its corresponding J&O dimension.

The D&M System Quality dimension is conceptualized in the J&O model as involving three sub-dimensions. The first of these sub-dimensions is Technological Resources, which involves "the capability of an organization to develop, operate, and maintain a KMS" (Jennex & Olfman, 2004). This construct captures ideas about the networks, databases, and other hardware involved in the KMS, as well as the experience and expertise behind the KMS initiative and the usage competence of typical KMS users. The second System Quality sub-dimension is Form of KMS, which has to do with "the extent to which the knowledge and knowledge management processes are computerized and integrated" (Jennex & Olfman, 2004). This concept reflects the amount of knowledge that is accessible through the KMS interface, as well as the extent of automation and integration of the interface and the activities of knowledge creation, storage, retrieval, transfer, and application. The third System Quality sub-dimension is Level of KMS. This is defined as the ability of the KMS "to bring knowledge to bear upon current activities" (Jennex & Olfman, 2004); it is centered on the nature and implementation of the KMS's search and retrieval functions. These sub-dimensions jointly cover the aspects of a KMS that theory and empirical observation point to as most critical in understanding what system quality is in KM settings.

The D&M dimension Information Quality is relabeled in the J&O model as Knowledge/Information Quality. A high value for this dimension occurs whenever "the right knowledge with sufficient context is captured and available for the right users at the right time" (Jennex & Olfman, 2004). The dimension involves three sub-dimensions. The first of these, Knowledge Strategy/Process, captures three ideas: the processes used for identifying the knowledge that can be captured and reused (and the users who can capture and reuse it); the formality of the processes, including how much planning occurs; and the format and content of the knowledge to be captured. This sub-dimension has evolved to reflect ideas of personalization and codification (Hansen, Nohria, & Tierney, 1999); it recognizes that evolution occurs in how knowledge is captured and reused. The second sub-dimension involved in Knowledge/Information Quality is Richness. This notion "reflects the accuracy and timeliness of the stored knowledge as well as having sufficient knowledge context to make the knowledge useful" (Jennex & Olfman, 2004). The third sub-dimension for this dimension, Linkages, is intended to "reflect the knowledge and topic maps and/or listings of expertise available to the organization" (Jennex & Olfman, 2004).

The D&M dimension Service Quality is defined in the J&O model as being those aspects of a KMS that ensure "the KMS has adequate support for users to use the KMS effectively" (Jennex & Olfman, 2004). The dimension comprises three sub-dimensions. The first of these, Management Support, has to do with the allocation of adequate resources, encouragement and direction, and adequacy of control. The second Service Quality sub-dimension, User KM Service Quality, involves support from the user organization in how to use the KMS, how to capture knowledge as part of the work, and how to use the KMS in the normal course of business processes. The third of these sub-dimensions, IS KM Service Quality, centers on support from the IS organization in KMS tools, maintenance of the knowledge base, maps of databases, and reliability and availability of the KMS.

The D&M dimension Intention to Use/Use in the J&O model becomes Intent to Use/Perceived Benefit. This dimension "measures perceptions of the benefits of the KMS by the users" (Jennex & Olfman, 2004). It reflects intention to use, in that it concerns prediction of future usage behavior; it does not reflect use, which Jennex, Olfman, and their colleagues view as a different matter—in the

J&O model use is aligned with user satisfaction (see below). The reflection of intention to use in the J&O model is extended in theoretical terms by incorporating perceived benefit, a concept originally advanced by Triandis (1980) and adapted to the IS context by Thompson, Higgins, and Howell (1991). This extension of the dimension allows it to reflect social and job-related characteristics of KMS user expectations that would not otherwise be captured (Jennex & Olfman, 2004).

The D&M dimension User Satisfaction maps to Use/User Satisfaction in the J&O model. The J&O dimension combines use and user satisfaction because Jennex, Olfman, and their colleagues see the two concepts as complementary notions in the KM setting. In their view, when system use is optional, how much the system is used serves as a good indicator of success, and user satisfaction can be considered a complementary indicator. User satisfaction becomes a more useful indicator of success when system use is not optional. Beyond this, in situations where a KMS is only needed occasionally—in situations where the absolute amount of usage is unimportant—employing use as a measure would underestimate KMS success; satisfaction provides a better indicator in that case.

The final D&M dimension, Net Benefits, corresponds to a J&O model dimension of the same name. The conceptualizations of this dimension are essentially the same in the two models.

Relationship Between the J&O Model and the SEM Model

The SEM model tested in this study corresponds to the J&O model in most respects. Figure 3 depicts the dimensions in the SEM model and the scales—corresponding to sub-dimensions—used in this study. Figure 4 depicts the structural aspects of the SEM model.

The J&O model and the SEM model differ in two important ways. The first involves the elimination of feedback paths in the SEM model to allow its estimation as a recursive model. The second involves the limitation of certain theoretical content in the SEM model's dimensions to map them to the data available in this study.

Figure 3. Indicators of SEM model dimensions

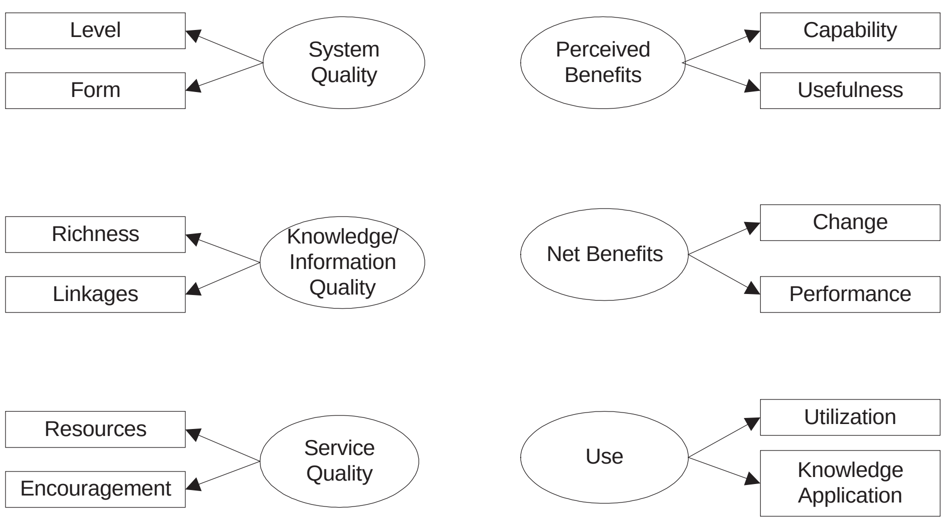

Figure 4. SEM structural model

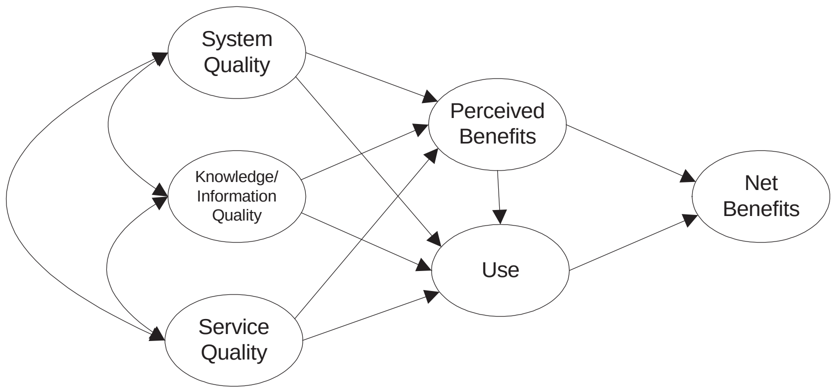

According to Kline (1998), the statistical demands for SEM analysis are greatly simplified for recursive models—those in which all causal effects are unidirectional and all disturbances are mutually independent. "The likelihood of a problem in the analysis of a nonrecursive model is much greater than for a recursive model" (p. 107). Formulating the SEM model as a recursive one (with one-way causal effects among endogenous variables, but without disturbance correlations) guaranteed it would be identified (Kline, 1998).[1]

To convert the J&O model to a recursive form, three feedback paths were dropped: 1) from Net Benefits to Intent to Use/Perceived Benefit, 2) from Net Benefits to Use/User Satisfaction, and 3) from Use/User Satisfaction to Intent to Use/Perceived Benefit. The first two of these paths were viewed as being more appropriate for inclusion in a longitudinal study, which this study was not intended to be. The third path was viewed as less important theoretically than the path from Intent to Use/Perceived Benefit to Use/User Satisfaction. It was felt that perceptions of possible benefit influence system use more strongly than the other way around. As compromises to allow the testing of a recursive form of the SEM model, it was felt that these path deletions were reasonable.

The dimensions of the SEM model are limited in terms of how much of the conceptual content of the J&O model's dimensions they carry. The primary reason for this limitation is that the data used to test the SEM model were collected in an earlier study aimed at assessing individual learning in KMS situations (Liu, 2003). The data from Liu's study reflect most of the theoretical content of the J&O model's dimensions, but not all of it.[2] Where some theoretical content was not reflected in the indicators Liu selected or created for her study, at least two reasons were active. First, Liu did not feel such content to be relevant in understanding individual learning. Second, Liu had reference to an earlier version of the J&O model (Jennex & Olfman, 2002). Nonetheless, the indicators Liu used show enough correspondence to the theoretical content of the current (2004) J&O model to allow a SEM model reflecting it to be tested here. Table 1 summarizes the theoretical dimensions of the J&O model reflected in the SEM model. Note that 12 of the 15 sub-dimensions included in the J&O model are mapped to the SEM model.

It is prudent to be concerned that three of the 15 sub-dimensions of the J&O model (Technical Resources, Knowledge Strategy/Process, IS KM Service Quality) are not represented in the SEM

Table 1. Correspondence of dimensional theoretical content between J&O and SEM models

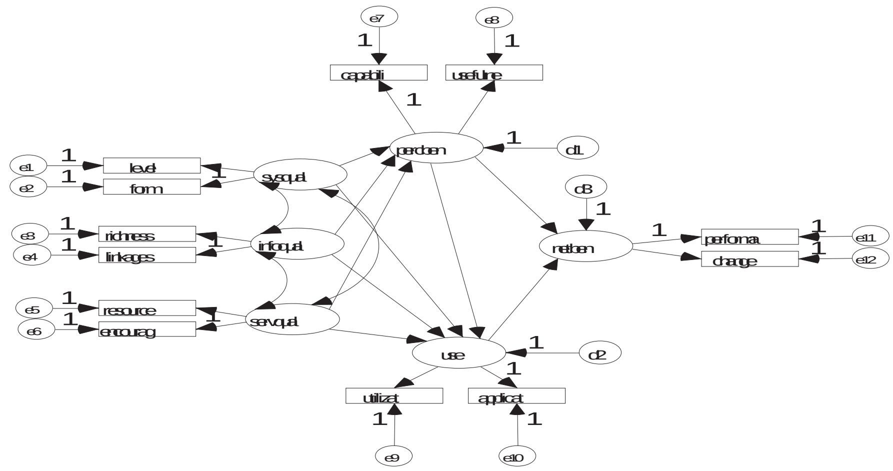
model. On the other hand, the SEM model only employs the J&O model's sub-dimensions as indicators of its dimensions. Keeping in mind that any indicator reflects only imperfectly the theoretical ideas it represents, it was decided that the SEM model that could be specified with the available indicators was acceptable as a representation of the J&O model. Figure 5 depicts the modified SEM model in its full form.

Connecting the SEM Model with Type of System and Stakeholder

Seddon Staples, Patnayakuni, and Bowtell (1999) assert that how one assesses information systems success should reflect the type of system and the system's stakeholders. They present a taxonomy of IS effectiveness measures, organized by six types of system and five types of stakeholder. For this study, a type of IT application (KMS) is considered, as it is used to benefit individual stakeholders (distinct KMS users).[4] These two focuses lead to a concentration on a benefit that any KMS might provide to any individual user. For purposes of this study, this benefit is individual learning, an outcome of KMS use that leads to "individual better-offness" (Seddon et al., 1999, p. 7). Individual learning is unquestionably important as a KMS outcome. Argyris and Schön (1996) argue that "individuals are the only subjects of learning" (p. 188), asserting that organizations learn only through the experiences and actions of individuals. While outcomes of KMS use other than individual learning might be considered, it appears to be one acceptable point for anchoring the Net Benefits dimension in terms of outcomes

Figure 5. Proposed SEM model (full)



that would matter to individual stakeholders. The focus on individual learning, along with the emphasis on use by individual users, allows reconciliation of this study's investigation of the J&O model with Seddon et al.'s advice about assessing IS effectiveness.

METHOD

Liu (2003) gathered the data used to assess the SEM model tested in this study through a study of individual learning in a KM setting. Liu designed an online survey, using an early version of the J&O model (Jennex & Olfman, 2002) as a general guide. The survey included 54 items and was developed using, with some modification, the three-stage instrument development process proposed by Moore and Benbasat (1991). First, an initial version of the survey instrument was developed based on theory grounded in operationalization of the constructs. Additionally, demographic items were included in the survey to capture information about gender, age, length of time with the organization and in current position, years using KMS, industry employed, job title and function, and the highest education attained. Published forms of items were used whenever possible, relying on work by Jennex and Olfman (2002), Dewitz (1996), Doll and Torkzadeh (1988), Bahra (2001), Gold, Malhotra, and Segars (2001), Thompson et al. (1991), King and Ko (2001), and Davis (1989), and constructing new items only when necessary. Second, based on solicited input from people with expertise in KMS and instrument development, the instrument was restructured and reworded to make it focused, brief, and clear (Alreck & Settle, 1995). Third, the instrument underwent a pilot study utilizing 56 KMS users from different firms to pretest the revised questionnaire, resulting in the final revision of the instrument.

This study uses data items from Liu's (2003) survey assembled into sub-dimension scales to serve as indicators for the SEM model depicted in Figure 3. Appendix 1 details the items as they were worded in the survey and assembled into sub-dimension scales for this study. Respondents rated each item on a rating scale from 'strongly agree' (5) to 'strongly disagree' (1), although they had the option of rating any item as 'not applicable'. Analysis of items and sub-dimension scales was done with SPSS; estimation of the SEM model was done with Amos, a package for SEM analysis.[5]

Individuals were invited to participate who, through a business firm or other organization, used a KMS for acquisition, organization, storage, or dissemination of knowledge. This sampling procedure was purposive in nature: it was oriented towards obtaining as many survey responses as possible, rather than sampling from a particular sampling frame.

RESULTS

Three hundred sixty-nine (369) people provided responses to Liu's (2003) survey. Nine cases were dropped due to non-completion of the survey or non-use of a KMS, leaving a total of 360 respondents. The majority of these (52.8%) were from engineering or manufacturing organizations, 61.9% were male, and 71.2% were between 30 and 49 years of age. This analysis dropped an additional six cases due to one or more missing scale values, leaving a sample size of 354.

Scale scores were calculated as the averages of relevant item scores to serve as measured variables in the SEM model. Table 2 provides descriptive statistics for the scale scores, as well as reliability coefficients for each scale and R2 estimates for the regression of each scale score on the set of all the others (as a basis for judging multivariate multicollinearity). Tables 3a and 3b provide a correlation matrix for the scale scores.

To avoid problems in SEM analysis, one must check the data for normality, outliers, and multicollinearity (Kline, 1998). The distributions of scale scores are roughly symmetrical, and estimates of skewness and kurtosis are not too large. There are no outliers, with no scale score as much as three standard deviations from its mean. There are no extremely large bivariate correlations, and none of the R2 values for regressions of scale scores on the sets of all other scale scores exceed 0.90, indicating no multivariate multicollinearity problems. The data, at least in these terms, seem to be adequate to conduct SEM analysis.

Byrne (2001) describes the core parameters of the SEM model (those that must be estimated typically) as including the regression coefficients for measurements and structure, the variances for errors and disturbances, and the factor variances and covariances. Based on these rules for counting parameters, the proposed model requires that 36 parameters be estimated. With 12 observed variables, there are 78 available data points. This implies that the SEM model is over-identified, having 43 degrees of freedom above what would have been a just identified model.[6]

As indicated by Nidumolu and Knotts (1998), sample size significantly influences statistical conclusion validity. Sample size requirements for SEM models are related to model complexity, but no definitive relationship exists between sample size and model complexity (Kline, 1998). One standard dictates that the sample size must be 50 observations more than eight times the number of variables (Garson, 2004); by this rule, the minimum sample size for this study would be 194 respondents. Another standard says that there should be 15 cases for every indicator (Stevens, 1996, reported by Garson, 2004); given this model has 12 indicators, the implication is that at least 180 respondents would be needed. Yet another standard advises that there should be 10 cases per parameter estimate (Kline, 1998), which means a sample size of 360 would be required. Irrespective of the guideline followed, the achieved sample size, 354, can be considered adequate.

Evaluating the Proposed Model

Evaluation of a SEM model considers both the estimates of individual parameters and the overall fit of the model to the data (Byrne, 2001). According to Byrne, there are three aspects of individual parameters to consider:

1. all should be reasonable (no correlations larger than 1, no negative variances, and positive definite matrices of correlations and covariances);
2. estimates should be significant, having critical ratios greater than or equal to 1.96; and
3. standard errors should not be too large or too small (although no clear standards available for what too large or too small would be).

Table 4 presents values for individual parameter estimates and related statistics. In these terms, the proposed model can be considered to produce fairly reasonable individual parameters. The greatest problem noted with individual parameters is the occurrence of some low values for critical ratios, particularly for two of the structural regression coefficients. The estimates for the paths from Service Quality to Perceived Benefits and from System Quality to Perceived Benefits have critical ratios of 0.601 and –0.875, respectively. This indicates that the values for

Table 4. Individual parameter estimates and related statistics for proposed SEM model

these parameters cannot be distinguished with confidence from 0.

Three other regression parameter estimates have low critical ratios as well, but not so low as the ones just mentioned, and probably within the range of acceptability.

Besides individual parameters, the overall fit of the model must be examined. It is common in reports of SEM analysis to present a variety of statistics that reflect different aspects of overall model fit.

Kline (1998) describes a variety of indicators of overall model fit. He asserts that a minimum set of these indicators should be reported, including:

"…the X2 statistic and its degrees of freedom and significance level; an index that describes the overall proportion of explained variance; an index that adjusts the proportion of explained variance for model complexity; and an index based on the standardized residuals…." (p. 130)

Kline (1998) cautions that researchers should bear in mind the limitations of fit indexes: 1) they are indicative of average fit; 2) they are not indicative of theoretical meaning; and 3) they are not indicative of a model's predictive power (p. 130). Table 5 presents overall model fit indexes for the proposed SEM model.

For a model to have a fair level of fit to data, according to Kline (1998), "low and non-significant values of the X2 index are desired" (p. 128). Because the X2 index is sensitive to sample size, researchers sometimes employ X2/df. A significant X2 value means: "an unconstrained model fits the covariance/correlation matrix as

Table 5. Overall model fit indexes for the proposed SEM model

Model	NPAR	CMIN	DF	P	CMIN/DF
Default model	36	253.327	42	.000	6.032
Saturated model	78	.000	0		
Independence model	12	2508.159	66	.000	38.002

GFI	CFI	IFI	NFI	NNFI (TLI)	RMR	RMSEA
.894	.913	.914	.899	.864	.041	.119

well as the given model" (Garson, 2004); a non-significant value suggests the fit of the data to the model is adequate. The X2 statistic calculated for the proposed model is significant (CMIN=253.3, df=42, p=.000), which suggests that the fit of the model is not entirely adequate. On the other hand, according to Garson (2004):

"Many researchers who use SEM believe that with a reasonable sample size (ex., > 200) and good approximate fit as indicated by other fit tests (ex., NNFI, CFI, RMSEA, ...), the significance of the chi-square test may be discounted…." (p.11)

The GFI (Goodness of Fit Index) reflects the degree to which the observed covariances are explained by the covariances implied by the proposed model. The standard for GFI values to indicate a good fit is values greater than or equal to .90 (Garson, 2004). The GFI value achieved for the proposed model is .894. Although this is below the conventional cutoff value, GFI values are biased downward at times, such as when the number of degrees of freedom is large relative to the sample size and when the number of parameters is not large. Garson reports Steiger's suggestion to use an adjusted GFI to account for GFI's downward bias. The adjusted GFI for this study, calculated with the formula Garson provides, is .980.

The CFI (Comparative Fit Index) contrasts the fit of the proposed model with that of a model that assumes no correlation among the latent variables (Garson, 2004). Values above .90 indicate a good fit of the model to the data. The value of CFI for this study is .913.

The IFI (Incremental Fit Index) "should be equal to or greater than .90 to accept the model" (Garson, 2004). The IFI value obtained in this research is .914.

The NNFI (Non-Normed Fit Index) is also known as the TLI (Tucker-Lewis Index). It expresses, in a manner adjusted for model complexity, how much the proposed model improves fit, compared with a null model—one having random variables. Garson (2004) reports several guidelines for judging goodness of fit using the NNFI, with the most lenient being values greater than or equal to .80, and the most strict being values greater than or equal to .95. The value of NNFI achieved for the proposed model is .864.

The RMR (Root Mean Square Residual) is an index that indicates good fits with small values—the closer to 0, the better. According to Kline (1998), "in a well-fitting model this value will be small, say, .05 or less" (p. 82). This index represents the average of residual differences between the variances and covariances observed and those hypothesized. In this study, RMR had a value of .041.

The RMSEA (Root Mean Square Error of Approximation) "takes into account the error of approximation in the population." RMSEA values over .10 indicate poor fit (Byrne, 2001). The value achieved for the proposed model is .119.

Across the set of indicators, the proposed model shows some evidence of having an acceptable fit to the data (in terms of the Adjusted GFI, CFI, IFI, NFI, NNFI/TLI, and RMR), and it shows some evidence of unacceptable fit (in terms of the X2 and RMSEA).

DISCUSSION

The J&O model of KM success received fair support from the results presented above. Although the data used were collected in an earlier study with different research aims, being concerned with the intersection of KMS use and individual learning (Liu, 2003), and hence were not explicitly intended to serve for testing the J&O model, the fit of the proposed SEM model to the data can be characterized as adequate, if not particularly good.

To the extent that the J&O model is more credible as a whole in light of these findings, some implications of the research merit additional attention. First, the relationships involving Perceived Benefit, Use, and Net Benefits in the J&O model can be treated as more plausible. The regression coefficients corresponding to these relationships were significant and substantial. These findings support the theoretical relationships, flowing through the J&O model from the D&M model, that higher levels of Perceived Benefit associated with a KMS leads to higher levels of Use—users make use of the system when they perceive benefits from doing so.

Second, the covariance relationships involving System Quality, Knowledge/Information Quality, and Service Quality were confirmed as well. The coefficients calculated for these relationships in the model were all sizeable, but not too large. This finding supports the ideas from the J&O (and D&M) model that the three KMS (IS) quality factors are inter-related, but distinct, qualities.

Third, the relationships involving the effects of System Quality, Knowledge/Information Quality, and Service Quality on Perceived Benefits and Use were not consistently confirmed. The calculated coefficients—six in all—showed a decidedly mixed pattern of significance: two of the calculated coefficients should not be viewed as significant, three should be taken as marginally significant, and one should be considered significant. The significant coefficient for the influence of Knowledge/Information Quality on Perceived Benefit had a value of .698 (p=.02). This estimate confirms the notion that an increase in the amount of knowledge a KMS provides leads to an increase in the amount by which individuals view the KMS as providing benefit. As such, this is good news for the J&O model. The marginally significant estimates provide news of a more mixed nature. Two of these—from System Quality to Use (1.631, p=.12) and from Service Quality to Use (.400, p=.08)—provide the suggestion of support to the J&O model, but the other—from Knowledge/Information Quality to Use (-2.296, p=.09)—is in the opposite direction suggested by the J&O model. The non-significant estimates—from System Quality to Perceived Benefits (-.250, p=.382) and from Service Quality to Perceived Benefits (.050, p=.548)—are not supportive of the J&O model.

What to make of these estimates as a group is somewhat puzzling. While together they do not overwhelmingly support the J&O model, neither do they disconfirm it. Rather, one should conclude from these findings that there is now enough empirical support for the J&O model to justify additional efforts to confirm and refine it. The following section contains suggestions for how such research might be done effectively.

To provide a convincing test of the J&O model, better data will be needed. For the data employed in this study to have been completely acceptable, several changes would have been needed. Most important of these changes would have been the inclusion of omitted scales. The data Liu (2003) collected did not include items that could serve to represent several sub-dimensions of the J&O

model, including Technological Resources, Knowledge Strategy/Process, IS KM Service Quality, and User KM Service Quality. While other data from the Liu study allowed a partial coverage of the conceptual content of the System Quality, Knowledge/ Information Quality, and Service Quality dimensions, it is likely that the theoretical under-representation of the J&O model in the data used made the test conducted here less precise than it might have been. Future research attempting to assess the J&O model should be sure to represent all sub-dimensions.

A second change in the data that would have likely improved the fit to the proposed model would have involved additional refinement of the scales employed. Since the Liu data was not collected explicitly to represent the sub-dimensions of the J&O model, they do not provide as many items for each sub-dimension as would be desirable, nor do they obviously represent the constructs related to these sub-dimensions in any certain fashion. Future research would benefit from instrument development and validation efforts targeted explicitly to the testing of the J&O model's conceptualizations of dimensions and sub-dimensions of KMS success.

A third change in the data that would have improved the fit to the proposed model would have involved a different sampling strategy. The Liu (2003) sampling strategy, which amounted to "snowball sampling" (Atkinson & Flint, 2001), did not assure that all respondents had interacted with similar KMSs. Neither did it employ random selection of participants from a well-defined sampling frame. If future research can identify a group of potential respondents who all employ information systems that are similar in their adherence to some definition of a KMS, then random selection of individuals from this group would probably improve the research's chances of reducing the level of extraneous variance. This should allow better estimates to be derived. Future research should strive to attain a random sample of users of a known type of KMS.

A fourth change in the data that would have improved fit would have been to recruit a larger sample size for the study. The sample Liu collected (N=354), although not small, was certainly no larger than what the analysis minimally required. If a future study could attract a much larger group of respondents, the chances of calculating better estimates would improve. It would also make it possible to retest the model in the form it was tested here and then test re-specifications of it that might be suggested by such retests. One of the virtues of a SEM approach to research is that, given sufficient sample size, researchers can identify opportunities for model improvement with one sub-sample and then attempt to confirm such improvements with another sub-sample. The current study had insufficient data to take on this task, but replications might have adequate numbers of respondents to do so. Future research should strive to attract enough respondents to allow the testing of multiple versions of the model.

Despite the need for future research to be conducted somewhat differently in order to foster progress in confirming and modifying the J&O model of knowledge management success, the current research provides some support for the model, certainly enough to prompt continued investigation. Additional work to develop this model will result, it is to be hoped, in an improved version that will provide researchers and practitioners with a sound explanation of success in knowledge management.

ENDNOTES

[1] If a model is not identified, it is not theoretically possible to calculate unique estimates of its parameters references.

[2] The data collected in the Liu (2003) model are discussed when the survey that collected them is described.

[3] No data included in Liu (2003).

[4] Seddon et al. (1999) found that the combination of type of IT application and individual stakeholder was the second most common of the 30 possible combinations in their taxonomy, in terms of its appearance in an analysis they performed of 186 studies in three journals over a nine-year period.

[5] Information about Amos can be found at Assessment Systems Corporation (http://www.assess.com/frmSoftCat.htm).

[6] To be able to test a SEM model, it must be over-identified.

APPENDIX 1

Model Dimensions, Scales, and Items Used in Study

System Quality

Level

1. Completeness of search: Your KS allows you to do both information and people searches.
2. Effectiveness—knowledge base: Whenever you search the KS knowledge base and/or yellow pages, the retrieved knowledge is always what you need.
3. Effectiveness—linkage: Whenever you search the KS knowledge base and/or yellow pages, the returned linkage always directs you to the right person.
4. Speed of retrieval: Whenever you search the KS knowledge base and/or yellow pages, the retrieved results normally display quickly.
5. Ease of search: Your KS search function is easy to use.
6. Reliability: Your KS is not subject to frequent problems and crashes.

Form

1. Computerization: Your KS allows you to find most of the organizational information/knowledge online.
2. Integration: Whenever you search the KS, you don't need to try different ways to locate the needed information.
3. Integration: Whenever you search the KS, you don't need to try different ways to locate the right person.
4. Integration: Whenever you search the KS, you don't need to access more than one system to locate the needed information.
5. Integration: Whenever you search the KS, you don't need to access more than one system to locate the right person.

Information Quality

Richness

1. Relevance: Your KS provides information/knowledge that is exactly what you need.
2. Understandability: Your KS provides information/knowledge that uses recognized vocabulary rather than highly specialized terminology.
3. Adequacy: Your KS provides information/knowledge that is adequate for you to complete tasks.
4. Contextuality: Your KS provides contextual information/knowledge so that you can truly understand what is being accessed.
5. Contextuality: Your KS provides contextual information/knowledge so that you can easily apply it to your work.
6. Currency: Your KS provides up-to-date information/knowledge.

Linkages

1. Completeness of linkage: The knowledge portal of your KS links you to a complete collection of documents and data.
2. Accuracy of linkage: The yellow pages of your KS guides you to connect to the people with the know-how for which you are seeking.
3. Currency of linkage: Your organization keeps updating its knowledge portal so that you have access to current documents and data.
4. Currency of linkage: Your organization keeps updating its yellow pages so that you can locate newly hired or acquired expertise without a problem.

Service Quality

Resources

1. Technical support: Whenever you have difficulties with your KS, there is a specific person (or group) exist to help you.
2. Allow sufficient time for dialogue: You have sufficient time to engage in dialogue online with your coworkers about important problems and solutions.

Encouragement

1. Encouragement from peers: You are encouraged to engage in online exploration and experimentation by your peers.
2. Encouragement from supervisor: You are encouraged to engage in online exploration and experimentation by your supervisor.
3. Endorse knowledge sharing: Your organization actively endorses knowledge sharing.
4. Encourage online discussion: Your organization encourages online discussion of new ideas and working methods.

Perceived Benefits

Capability

1. Self-efficacy: You can use your KS without needing someone's help.
2. Cognitive capability: You find it easy to understand the information/knowledge you found in the knowledge base.

3. Cognitive capability: You find it easy to use the information/knowledge you found in the knowledge base.

Usefulness

1. Willingness to search: When job-related problems occur, you are willing to do an online search of your KS for solutions.
2. Tendency to analyze: You analyze and interpret what is brought to your attention in your KS.
3. Perceived usefulness: You find your KS useful in your job.

Use

Utilization

1. Distribution: Your KS helps your daily work by distributing customized knowledge to you.
2. Distribution: Your KS helps your daily work by distributing customized knowledge to others.

Knowledge Application

1. Decision making and problem solving: You use knowledge from the KS to perform decision-making and problem-solving tasks.
2. Questioning rules and routines: You use knowledge from the KS to question existing rules and routines.
3. Exploring alternatives: You use knowledge from the KS to search for and explore alternatives.

Net Benefits

Change

1. Cognitive change: Your KS helps you to detect work-related problems.
2. Cognitive change: Your KS enlightens you to new ways of thinking.
3. Behavioral change: Your KS changes the way you do things in a way beneficial to the organization's overall interest.

Performance

1. Better decisions: Your KS improves the decisions you make.
2. Fewer mistakes: Your KS helps you to make fewer mistakes.
3. Better experience transfer/knowledge reuse: Your KS allows better experience transfer and knowledge reuse.
4. Reduce duplicate work: Your KS reduces duplicate work.
5. Better cycle time: Your KS allows you faster cycle time to problem resolution.

Chapter 2.23
Extracting Knowledge from Neural Networks

Christie M. Fuller
Oklahoma State University, USA

Rick L. Wilson
Oklahoma State University, USA

INTRODUCTION

Neural networks (NN) as classifier systems have shown great promise in many problem domains in empirical studies over the past two decades. Using case classification accuracy as the criteria, neural networks have typically outperformed traditional parametric techniques (e.g., discriminant analysis, logistic regression) as well as other non-parametric approaches (e.g., various inductive learning systems such as ID3, C4.5, CART, etc.).

In spite of this strong evidence of superior performance, the use of neural networks in organizations has been hampered by the lack of an "easy" way of explaining what the neural network has learned about the domain being studied. It is well known that knowledge in a neural network is "mysteriously" encapsulated in its connection weights. It is well accepted that decision-makers prefer techniques that can provide good explanations about the knowledge found in a domain even if they are less effective in terms of classification accuracy.

Over the past decade, neural network researchers have thus begun an active research stream that focuses on developing techniques for extracting usable knowledge from a trained neural network. The literature has become quite vast and, unfortunately, still lacks any form of consensus on the best way to help neural networks be more useful to knowledge discovery practitioners.

This article will then provide a brief review of recent work in one specific area of the neural network/knowledge discovery research stream. This review considers knowledge extraction techniques that create IF-THEN rules from trained feed-forward neural networks used as classifiers.

We chose this narrow view for a couple of important reasons. First, as mentioned, the research in this area is extraordinarily broad and a critical review cannot be done without focusing on a smaller subset within the literature. Second, classification problems are a familiar problem in business. Third, creating basic IF-THEN rules from a trained neural network is viewed as the most useful area in the entire research stream for the knowledge management and data mining practitioner.

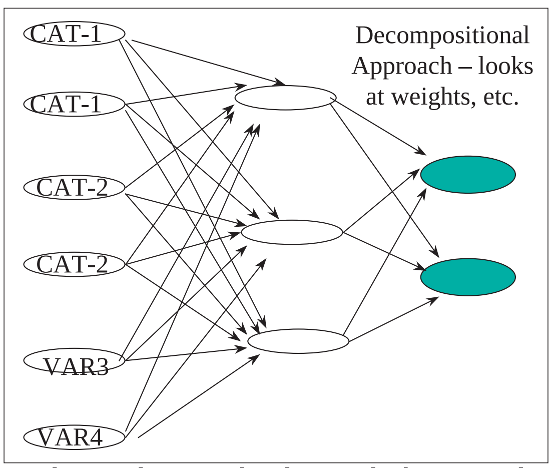
With this narrow focus, some aspects of knowledge extraction from neural networks are obviously not mentioned here. With the focus on deterministic IF-THEN rules, outputs that include "fuzziness" (fuzzy logic) are omitted. In addition, research that involves different neural network architectures (e.g., recurrent networks) and/or different knowledge discovery problem areas (e.g., regression/prediction rather than classification) are also excluded from the review.

BACKGROUND

The discussion of the different neural network knowledge extraction techniques are organized around the fundamental premise or process used for rule extraction. Previous researchers (including Tickle, Maire, Bologna, Andrews, & Diederich, 2000) have used the following terms to help segment the different approaches: decompositional, pedagogical, and eclectic.

Decompositional techniques for rule extraction are approaches that perform rule extraction at the individual neuron (or neural component) level. Pedagogical approaches, on the other hand, extract knowledge by treating the entire NN as a "black box," creating rules by correlating inputs to the neural network to the resultant outputs (without considering anything about the structure or weights of the NN). It is reasonable to think of these two terms as extreme points in a continuous spectrum of approaches. Eclectic approaches are techniques that borrow some aspects from each of the two extremes.

Figure 1.



Pedagogical Approach – does not look at internal weights – just inputs and outputs

Figure 1 helps visualize how these algorithms work. Figure 1 shows a 6-input, 3 hidden neuron, 2 output neural network. Assuming no bias inputs and a fully connected neural network, there would be 24 connection weights (not shown) which represent the knowledge stored in the neural network (after, of course, the NN has been trained on a set of data). The decompositional approaches will examine (at least) the connection weights that lead to each hidden neuron and will "discover rules" such as IF X2 < 7, THEN CONCLUDE Class A. Pedagogical approaches would present systematic random inputs to the neural network, observe the output of the neural networks, and "learn" rules like above through studying the relationship between input and output variations.

The review of pertinent neural network rule extraction algorithms also will include three different measures of technique usefulness (accuracy, fidelity, and comprehensibility) when such measures have been studied. These three different measures of technique usefulness are important in assessing the quality of the different methodologies. Accuracy measures the ability of the derived rule set to classify cases from the problem domain. This is typically reported as percentage correctly classified. Fidelity measures how well classification of cases using rules extracted from the trained NN mimic the classification of just the original NN. Comprehensibility measures the size of the rule set extracted from the neural network, looking at both number of rules and the number of antecedents in the rule. This is a measure of rule complexity.

Additionally, any empirical comparisons to other "competing" rule extraction techniques will also be shared, as well as any empirical comparisons to other comparable well-known knowledge discovery techniques such as inductive learning systems (which might include such well-studied techniques as ID3, C4.5, CART, and See5, among others).

The comparisons to other knowledge discovery techniques that result in decision trees, rules, and so forth are particularly relevant to practice. The techniques discussed in this article use a two-step approach to knowledge elicitation: first, one trains a neural network on a set of cases, and then rules are found through the specific technique. Inductive learning approaches accomplished this in one step directly from the cases. The ongoing research into the two-step neural network process seeks to explore the contention by Tickle et al. (2000) and others who claim that rule extraction from trained neural networks will (someday) be a better approach than inductive learning systems. This claim stems from the potential for realizing additional correct classifications (which is well documented) possible with neural networks. The quest for this still continues, and results (as shown) show promise. The next section outlines recent progress in this area.

NN RULE EXTRACTION REVIEW

Decompositional Approaches

Su, Hsu, and Tsai (2002) present a decompositional methodology that is similar to many in this category. After a feed-forward NN is trained, important inputs are identified and unnecessary connections are pruned from the network in an iterative fashion. Input data is then transformed into binary form, and then the knowledge (in rules) is extracted by building truth tables for each hidden neuron. The rules are simplified using Karnaugh maps and removing repetitive statements. The classification accuracy of this algorithm showed mixed results when compared to the original neural network model and the inductive learning approach See5. However, their algorithm had increased comprehensibility compared to See5, requiring far fewer attributes to classify the data.

The GLARE approach (GeneraLized Analytic Rule Extraction) is similar, extracting rules from standard feed-forward backpropagation networks requiring binary inputs (Gupta, Park, & Lam, 1999). First, weights between input nodes and hidden nodes are ranked, determining the largest connection weights. Next, another index calculates the importance of the connections between the hidden and output layers using the ranking. This step leads to the extraction of symbolic rules. Using classification accuracy as a benchmark with strictly categorical datasets, GLARE performs as well or better as the inductive learning system C4.5 and the original backpropagation NN. When used with datasets possessing continuous inputs that were converted to Boolean inputs, GLARE's performance suffered significantly.

Vaughn, Cavill, Taylor, Foy, and Fogg (2000) report on a rule extraction method developed for mutli-layer feed-forward neural networks with binary inputs. Their method ranks the activation contributions to each of the hidden neurons, and then repeats the process to determine the significant input neurons. Rules are extracted by combining the significant inputs related to a particular class, in ranked order.

The FERNN (Fast method for Extracting Rules from NN) approach applies a different strategy to the problem. It uses two primary components to generate rules from a neural network (Setiono & Leow, 2000). First, the neural network is trained using an algorithm that seeks to minimize the connection weights of irrelevant inputs. Then, a decision tree is generated from the network's single hidden layer. The algorithm identifies and removes irrelevant inputs while maintaining the network's accuracy. Unlike other algorithms that may apply pruning, FERNN does not require the network to be retrained after connections are removed, which makes rule extraction faster. Rules can be generated from datasets with both continuous and discrete attributes. Empirically, this algorithm was shown to be more accurate than C4.5 for most datasets, while also creating smaller trees. The authors report that FERNN has a high degree of fidelity with the original neural networks.

Fan and Li (2002) present a method for rule extraction in which the hidden neurons are used to partition the input space into subspaces. There are as many partitions as hidden neurons in the network. To extract rules, the data that "fall" in the subspaces are analyzed based on their "classes." The derived rules from this step are then reduced and simplified. The methods were compared to the original NN, genetic algorithms, C4.5, and rough set approaches using the linearly separable IRIS dataset. In this domain, the proposed rule extraction method showed better accuracy and greater comprehensibility than the other methods.

Tsukimoto (2000) presents a decompositional method for extracting rules using Boolean functions. The algorithm is not dependent on any particular network structure or training algorithm and can be applied to NN's with both discrete and continuous values. The only specific requirement is that the NN must have a monotone output function. Experimental results of this algorithm show its accuracy to be slightly better than C4.5 for a binary dataset and slightly worse for discrete and continuous datasets. The comprehensibility of the rules extracted using this method was about the same as C4.5.

Continuous/discrete Rule Extractor via Decision tree Induction (CRED) is another decompositional algorithm that can be used with both discrete and continuous input variables (Sato & Tsukimoto, 2001). In contrast to previous "old" approaches TREPAN (Craven & Shavlik, 1996) and the method of Krishnan et al. (1999) mentioned later in this article, CRED extracts separate trees at the hidden-to-output and input-to-hidden layers instead of a single tree. Rules are formed from these trees, which are then merged and simplified. CRED was tested on several datasets and demonstrated acceptable accuracy levels, but was not compared to other rule extraction or data mining methods.

Schmidt and Chen (2002) use an Aggregate Feed-Forward Neural Network (AFFNN) as a foundation for their rule extraction/neural network approach. The AFFNN is a fully connected network with a single hidden layer, using a combination of pre-and post-processing operations with a modified training routine. The proposed algorithm begins at the output layer, working backward to discover the supporting or related hidden nodes to the specific output neuron, then likewise finds the corresponding supporting input nodes. Fifteen rules were created from the AFFNN in analyzing the well-known MONK-2 dataset with 100% accuracy, compared to inductive learning system ID3 which created a tree with 66 nodes and 110 leaves and had 67.9% accuracy.

Finally, a greedy clustering algorithm (GCA) which fits the decompositional approach was proposed by Setiono and Liu (1998). The GCA creates clusters based on the activation values of the hidden neurons of the neural network. After clusters are formed, they are used to associate output neurons to relevant inputs. For the classic Pima Indian Diabetes dataset, GCA created a more accurate network than C4.5 on testing data and required only one rule to classify the data, compared to 12 rules (with up to ten antecedents) for C4.5. Also, for the aforementioned MONK-2 problem, the GCA created a 100% accurate network requiring one rule to classify the data.

In summary, many different decompositional approaches have been proposed, but few of these studies have directly compared the different approaches. There remain numerous choices for the data mining practitioner, but no clear cut "best" approach. It is interesting to note that much of the early work in this area focused on converting continuous data to binary or discrete data values prior to knowledge extraction. This may be a big drawback of such techniques in real-world settings unless little is lost in accuracy when discretizing the variables.

Pedagogical Approaches

Taha and Ghosh (1999) present a family of approaches for the neural network rule extraction problem starting with BIO-RE, a pedagogical approach. BIO-RE requires a trained network with binary inputs. The authors claim their method is suitable only for a small number of inputs but does not require a particular network structure or training algorithm.

If binary inputs are not suitable or the number of inputs is large, Partial-RE is their alternative approach. Partial-RE identifies dominant node combinations in the network, and extracts rules according to user-specified parameters on completeness. However, performances were problematic if data was not in binary or discretized form.

Finally, the authors also propose Full-RE, a decompositional variant of this rule extraction family that can extract rules from networks with continuous, normal, or binary inputs and is claimed effective for networks of any size. For the IRIS and Wisconsin Breast Cancer data, Full-RE performed favorably to older rule extraction techniques such as NeuroRule (see Setiono & Liu, 1995) and inductive learning approaches such as C4.5, extracting fewer rules with the same or less number of antecedents and had comparable accuracy.

Krishnan, Sivakumar, and Bhattacharya (1999) present a pedagogical method based on genetic algorithms for extracting decision trees from trained neural networks. The method first determines which inputs are relevant to build the decision tree. The tree is then modified systematically to increase comprehensibility or accuracy. This algorithm was less accurate than the original neural network and ID3, but did produce a much smaller tree than ID3. The decision trees resulting from this algorithm were shown to have fidelity over 90%.

Palade, Neagu, and Puscasu (2000) propose a method of rule extraction by interval propagation of an inverted neural network. Their extraction algorithm calculates the required input of the NN for a specified output. The method does not require a particular neural network structure and can utilize continuous inputs and outputs. Unfortunately, this method was not compared to other approaches.

Shigaki and Narazaki (1999) employed a similar approach in the domain of modeling the sintering process used in iron and steel making industry. Their algorithm estimates monotonic regions in the neural network by sampling input vectors. These regions are composed of points with the same class membership and consider various sensitivity patterns. Their approach was not compared to other methods.

Artificial neural-network decision tree algorithm (ANN-DT) is a pedagogical rule extraction technique similar to the inductive learning approach CART (Schmitz, Aldrich, & Gouws, 1999). ANN-DT does not require a particular network structure and input can be discrete or continuous. The algorithm samples the input space of the network, resulting in reduction of the number of rules needed to accurately describe the data. ANN-DT uses a statistical pruning technique similar to that employed by CART. Experimental results showed the ANN-DT algorithm is at least as accurate as CART and has increased fidelity. However, the decision trees created by ANN-DT were more complex for most of the datasets tested.

STAtistics-based Rule Extraction (STARE) is another pedagogical approach. This algorithm limits extracted rules to three antecedents, which increases comprehensibility (Zhou, Chen, & Chen, 2000). The STARE approach also does not require a specific type of network or training method. The rule discretizes continuous attributes while rules are generated. Fidelity also is evaluated as part of the algorithm. Rules not meeting user-specified criteria are not be added to the rule set. Due in part to the limit on the number of antecedents per rule, STARE created more rules than Craven and Shavlik's (1994) approach to rule extraction, but with greater fidelity. Also, STARE had greater classification accuracy when compared to C4.5 for most datasets utilized.

Interestingly, the basic principles of STARE also have been applied to trained neural network ensembles using the Rule Extraction From Neural Network Ensemble (REFNE) approach (Zhou, Jiang, & Chen, 2003). REFNE prioritizes rules and discretizes attributes in a similar manner. Experimental comparisons have been made between REFNE, a trained ensemble, a single neural network, and C4.5. REFNE showed better accuracy than the other three methods. REFNE created more rules per dataset than C4.5, but the rules created by C4.5 had more antecedents per rule.

Again, as with the decompositional approaches, very little comparison has been done between the pedagogical approaches. Many techniques still require discretization of continuous inputs. Systematic analysis of these similar techniques remains lacking in the research literature.

Hybrid/Eclectic Approaches

We end our article by discussing techniques that fit somewhere between the two extreme approaches. Bologna (2000a, 2000b) proposed the Discretized Interpretable Multi Layer Perceptron Model (DIMLP) where neurons of the first hidden layer are connected to only one input neuron. The rest of the network is fully connected. A staircase activation function is used in the first hidden layer (instead of the usual sigmoid function) to transform continuous inputs into discrete values. The extraction technique determines discriminant hyper-plane frontiers, builds a decision tree from this result, and then further prunes and modified the resultant rules. Thus, it uses components of decompositional approaches (pruning, hidden layer analysis) and pedagogical (use of hyper-plane frontiers).

In analyzing the results of DIMLP, it had nearly the same classification accuracy as the original NN on test data and had 100% fidelity on training data. DIMLP also was more accurate than C4.5 on several datasets, but demonstrated less comprehensibility (i.e., more rules and more antecedents per rule).

Interestingly, much like the aforementioned REFNE, DIMLP has recently been extended to generate rules from ensembles of DIMLP networks (Bologna, 2001; Bologna, 2003). Rule extraction from the ensembles showed improved accuracy over rule extraction from single DIMLP networks. Therefore, as more and more practitioners use an ensemble approach in their data mining applications, DIMLP offers additional promise.

Finally, Garcez, Broda, and Gabbay (2001) present a method for extracting rules that they claim has high accuracy and fidelity. Their algorithm performs a partial ordering on the set of input vectors of a neural network and then uses a related set of pruning and simplification rules. The method is unique in its use of default negation to capture nonmonotonic rules from the network. This algorithm is slightly less accurate than the classic M of N approach and Setiono's method (Setiono, 1997; Towell & Shavlik, 1993), but the method shows increased fidelity. To achieve this fidelity, the algorithm produces a larger set of rules. The algorithm requires a network with only one hidden layer, but has no specific training requirements.

FUTURE TRENDS

It is clear that no technique or tool has emerged as useful in all (or most) knowledge discovery/data mining circumstances for extracting rules from classification neural networks. Many techniques show promise, but there is a clear lack of systematic study and analysis in the literature. Few comparative studies of rule extraction techniques have been done, and even when such studies have been undertaken, small datasets have been employed. Table 1 provides a comprehensive summary of the techniques previously discussed.

Decision-makers in the knowledge-enabled organizations of today need more than just the high "classification" accuracy that sophisticated techniques like neural networks deliver to their desktop. They also want to gain insight into the problem domain; thus, the explanatory or "lessons learned" knowledge from their analyses is

Table 1.

extremely important. Conventional wisdom also would indicate that the simpler the explanation or knowledge extraction results, the higher desirability, larger user acceptance, and bigger payoff to the organization. Thus, the attraction of using NN's (shown to be, for the most part, empirically superior knowledge discovery tools) to provide IF-THEN level explanations (simple yet effective explanations of organizational phenomenon) normally provided by inductive learning systems or by expert knowledge seems worthy of more in-depth study.

We expect future data mining researchers to begin to focus more in this area of knowledge extraction and elicitation, rather than seeking new classification algorithms. Clearly, the potential exists for the organizational usefulness of neural networks to be enhanced by continued progress in this area.

CONCLUSION

The potential of neural network use as data mining tools has not been fully exploited due to the inability to explain the knowledge they learn. In reviewing the literature in this article, it is apparent that there are techniques that may offer this ability, but systematic study of such approaches has been minimal. Our hope is that once this "gap" is filled in the literature, and assuming positive results are found, neural network use by practitioners will be greatly enhanced, which will serve to increase the usefulness and profitability of knowledge management initiatives in many organizations.

Chapter 2.24
Critical Success Factors of ERP Implementation

Leopoldo E. Colmenares
University Simon Bolivar, Venezuela

Jim O. Otieno
Middlesex University, UK

INTRODUCTION

An enterprise resource planning (ERP) system is an integrated set of programs that provides support for core organizational activities, such as manufacturing and logistics, finance and accounting, sales and marketing, and human resources. An ERP system helps the different parts of an organization share data and knowledge, reduce costs, and improve management of business processes. In spite of their benefits, many ERP systems fail (Stratman & Roth, 1999). Implementing an ERP system is a major undertaking. About 90% of ERP implementations are late or over budget (Martin, 1998), and the success rate of ERP systems implementation is only about 33% (Zhang et al., 2003).

Over the past few years, limited research has been conducted about ERP implementation issues: mainly, case studies in individual organizations have been reported. A major problem with such ERP case studies is that very few implementation failures have been recorded in the literature, and thus, the reasons why implementations fail are not known to practitioners and researchers. That is a motivation toward conducting empirical studies to explore critical factors that affect ERP systems implementation. A recent summary of ERP literature stated that research of critical success factors (CSFs) in ERP implementation is rare and fragmented (Nah, Lau, & Kuang, 2001). The idea of identifying CSFs as a basis for determining the information needs of managers was popularized by Rockart (1979). CSFs are those factors that are critical to the success of any organization, in the sense that, if objectives associated with the factors are not achieved, the organization will fail—perhaps catastrophically (Rockart, 1979). In the context of ERP project implementation, CSFs represent the essential ingredients, without which a project stands little chance of success. This study examines the CSFs for implementing ERP systems in Venezuela. Managers from seven corporations, who were identified as having key roles in ERP systems implementation, were surveyed in order to assess empirically which CSFs are critical in leading a successful implementation of ERP systems in Venezuela. This article is organized into four sections. First, ERP-related literature is reviewed. The next section introduces the research methodology, followed by presentation of the results. The article ends with the conclusions and implications for future research and practice.

BACKGROUND

Implementing an ERP system is not an easy task. It can cause dramatic changes that need to be carefully administered if the potential advantages of an ERP solution (Al-Mudimigh, Zairi, & Al-Mashari, 2001) are to be gained. In some well-documented cases, spectacular results have been achieved (Johnston, 2002). There is, on the other hand, a relatively high failure rate: it was reported that three-quarters of ERP projects were judged to be unsuccessful by the ERP implementing firms (Kyung & Young, 2002). Also, failures are much less extensively documented. As a result, pitfalls to be avoided tend to be less well known. Venezuelan companies are just starting to use ERP systems. They started applying ERP concepts late in the 1990s. Because of the complex and integrated nature of ERP, and the large investment involved, it is imperative for organizations to study the experiences of others and to learn from their practices and success factors (Zairi et al., 2000). Identifying CSFs relevant to local companies is one way to increase the chances of a successful local implementation (Sum, Ang, & Yeo, 1997).

A literature review was conducted to understand the CSFs in successful ERP implementations. The review covered numerous articles (Bingi, Sharma, & Godla, 1999; Esteves & Pastor, 2001; Falkowski et al., 1998; Holland & Light, 1999; Nah, Lau, & Kuang, 2001; Rosario, 2000; Stefanou, 1999; Sumner, 1999; Wee, 2000). The literature varies according to the variables required for implementation success, so there is no general consensus as to the factors that are key to success in ERP implementation. It is probably a combination of factors that is important in explaining ERP implementation success (Zhang et al., 2003). From the review, 20 factors emerged as critical to the successful implementation of ERP systems. They were obtained after careful analysis and grouping of related subfactors:

1. Top management support
2. User training
3. Use of consultants
4. User participation
5. Vendor package selection
6. Use of steering committee
7. Discipline and standardization
8. Minimal customization
9. Use of vendor's development tools
10. Best people full time
11. Technical and business knowledge
12. Implementation approach
13. Clear goals, focus, and scope
14. Business process reengineering
15. Project management
16. Effective communications
17. Presence of a champion
18. Interdepartmental cooperation and communication
19. Management of expectations
20. Vendor/customer partnership

RESEARCH METHODOLOGY

The choice of an appropriate research methodology is critical in guiding researchers on how best to meet research objectives. In this study, the purpose was to discover the perceptions and experiences of companies using ERP systems in Venezuela, and to use that information as the basis of data collection. The analysis has enabled the identification CSFs of ERP systems implementation in Venezuelan companies.

The targets of the study were the organizations that implemented ERP systems successfully. The key informant method was used for collecting information in a social setting by surveying (or interviewing) a selected number of participants. Seven firms were identified from the list provided by ERP vendors. We contacted the ERP project managers in charge of ERP implementation of each company. About 100 questionnaires were sent to the ERP project managers of each firm, who forwarded the questionnaires to the project team members in charge of individual processes. A total of 72 questionnaires were returned, of which 69 were valid.

The questionnaire consisted of two main parts: the company background and the CSFs. The first part was designed to determine characteristics such as size of the company, type of industry, location of company, etc. The second part consisted of 20 statements about the success factors of ERP systems implementation derived from the literature review. The language used in the survey was Spanish. Translation was easy, because Venezuelans used original English terms for many technical and management concepts and especially for information systems and computing concepts.

Participants were requested to rate the importance of each CSF using a five-point Likert scale, where a score of 5 indicated “extremely critical,” and a score of 1 indicated “not critical.” This method was employed on the grounds that a rating method avoids the problem of having to consider 20 CSFs simultaneously in order to rank them. The data collected were then analyzed by using SPSS. Based on the responses, descriptive statistics, factor analysis (FA), and reliability tests were carried out to identify the CSFs for the successful implementation of ERP systems and data validity, respectively.

RESULTS

Ranking

The importance rating of the 20 CSFs is listed in Table I.

The individual mean value of the Likert rating scale is the popular usage indicator for measuring an item’s importance, without regard to the other items; therefore, the higher the value, the more important the factor. Most items are rated above the 3.0 scale (midpoint). The three most important factors, in order of declining importance, are top management support, presence of a champion, and project management, with a mean value ranging from 4.80–4.64. Just as the literature argues, these are key items for ERP implementation management (Johnston, 2002). Conversely, use of steering committee, business process reengineering, and use of vendor’s development tools, are the three items lowest in the list, with a mean value ranging from 2.95–2.06.

Factor Analysis

In an attempt to reduce the number of items (CSFs), and to understand their underlying structure, a factor analysis (FA) was performed. FA is a data reduction technique that uses correlations between data variables. The underlying assumption of FA is that a number of factors exist to explain the correlations or interrelationships among observed variables (Chatfield & Collins, 1992). For the present study, FA was performed on all 20 variables using principal components extraction (Tabachnick & Fidell, 1989). The goal of this method is to extract maximum variance from the data set within each factor. It is basically used to reduce a large number of variables to a smaller number of components. The measure of sampling adequacy for the 20 items was 0.87, indicating that the items were suitable for factoring (Kaiser, 1974).

Table 1.Ranking of CSFs

Rank	CSF	Mean	Standard Deviation
1	Top management support	4.80	0.62
2	Presence of a champion	4.75	0.85
3	Project management	4.64	0.92
4	Best people full time	4.58	0.60
5	Effective communications	4.51	0.85
6	Interdepartmental cooperation and communication	4.40	0.91
7	Management of expectations	4.36	1.02
8	Technical and business knowledge	4.33	1.21
9	User participation	4.22	0.82
10	Discipline and standardization	4.09	0.85
11	Vendor package selection	4.02	0.61
12	User training	4.01	1.12
13	Implementation approach	4.00	1.20
14	Clear goals, focus, and scope	3.89	1.14
15	Use of consultants	3.75	0.85
16	Minimal customization	3.68	1.52
17	Vendor/customer partnership	3.15	0.52
18	Use of steering committee	2.95	0.63
19	Business process reengineering	2.84	0.55
20	Use of vendor's development tools	2.06	0.42

Notes: N: 69; Scale: 1–5 (5: "extremely critical," 1: "not critical").

A three-stage factor analysis was conducted with an orthogonal (varimax) rotation to obtain a stable factor structure (Rai et al., 1996), resulting in easily interpretable factors. Under this three-round factor analysis, items were omitted according to the following two criteria: (1) no loading greater than 0.35, or (2) loading greater than 0.35 on two or more factors (Kim & Mueller, 1978).

Table 2 shows the results of this analysis. A first-factor analysis was conducted and produced five factors. According to the two criteria, three items were dropped. A second factor analysis on the remaining 17 items resulted in four factors and the dropping of three items. Finally, a three-factor structure was derived that kept a total of 14 items after three iterations. The minimum eigenvalue from a varimax rotation for which a factor was to be retained was set at 1.0 in order to satisfy the minimum eigenvalue criterion (Nunnally, 1978). The three factors are as follows:

1. Factor 1, named "ERP implementation management," comprises six items relating to implementation management: top management support, presence of a champion, project management, management of expectations, implementation approach, and clear goals, focus, and scope.
2. Factor 2, named "user aptitudes and communication," comprises four items relating to user participation: effective communication, interdepartmental cooperation and communication, user participation, and user training.
3. Factor 3, named "technical knowledge," comprises four items relating to knowledge

Table 2. Results of factor analysis

CSF	Mean	Factor Loading (Final Factor Structure 3rd FA) F1	F2	F3
Top management support	4.80	0.608		
Presence of a champion	4.75	0.541		
Project management	4.64	0.586		
Best people full time	4.58			0.741
Effective communications	4.51		0.565	
Management of expectations	4.40	0.420		
Interdepartmental cooperation and communication	4.36		0.452	
Technical and business knowledge	4.33			0.584
User participation	4.22		0.562	
Discipline and standardization	4.09			0.387
Vendor package selection	4.02			
User training	4.01		0.510	
Implementation approach	4.00	0.478		
Clear goals, focus, and scope	3.89	0.411		
Use of consultants	3.75			0.573
Minimal customization	3.68			
Vendor/customer partnership	3.15			
Use of steering committee	2.95			
Business process reengineering	2.84			
Use of vendor's development tools	2.06			
Eigenvalue		7.56	2.54	1.20
Percentage of variance		58.50	14.36	8.65
Cumulative percentage of variance		58.50	72.86	81.51
Cronbach alpha coefficient		0.88	0.74	0.56

N: 69.

Scale: 1–5 (5: "extremely critical," 1:"not critical").

F1: ERP implementation management.

F2: Users' aptitudes and communication.

F3: Technical knowledge.

of business and ERP: best people full time, technical and business knowledge, use of consultants, and discipline and standardization.

Cronbach alpha coefficients were calculated to test the reliability of these CSFs, as shown in the last row of Table 2. The reliability of coefficients obtained ranges from 0.56 (Factor 3) to 0.88 (Factor 1). Srinivasan (1985) proposed that a coefficient of 0.7 or higher is acceptable, while a coefficient of 0.5 or higher is considered sufficient when dealing with exploratory research combined with unvalidated data. Thus, the reliability coefficients in this study are deemed acceptable. The strength of factor analysis is that it provides a basis for data reduction. Rather than look at all 20 items, only three factors need be examined. That simplifies the rankings and clarifies the most important items. Rather than focus on individual items, practitioners and researchers can focus on the broad set of items represented by the essential factors.

FUTURE TRENDS

Many companies around the world are following the trend toward making large investments in implementing ERP systems. Several approaches and methodologies of ERP project implementation recognise a series of critical factors that must be carefully considered to ensure successful implementation of an ERP system project. In essence, there are dominant critical factors hypothesised to play an overriding role in the implementation of an ERP project, and they should be ongoing throughout all implementation levels. Clearly, the dominant factors are those that will shape the overall project culture and, subsequently, the organisational cultura, as ERP is far reaching in nature.

Post-ERP activity seems to follow a clear path. A Deloitte Consulting study of 62 companies segments post-ERP activity into three stages. The first stage entails a three- to nine-month productivity decline that is overcome by redefining jobs, establishing new procedures, fine-tuning ERP software, and taking charge of the new streams of information created by the platform. The second stage, which lasts from six to 18 months, involves skills development, structural changes, process integration, and add-on technologies that expand ERP functionality. The third stage, of one to two years in duration, is one of transformation, where the synergies of people, processes, and technology reach a peak. Perhaps most important, ERP forces discipline and organization around processes, making the alignment of IT and business goals more likely in the post-ERP era.

CONCLUSION

Despite the benefits that can be achieved, there is already evidence of failure in projects related to ERP systems implementation (Davenport, 1998). It is, therefore, important to find out what the CSFs are that drive ERP project success.

According to the respondents in this study, the six top CSFs for ERP systems implementation in Venezuelans firms are top management support, presence of a champion, project management, best people full time, effective communications, and management of expectations.

This research has derived three composite CSFs in ERP systems implementation in Venezuela:

1. ERP implementation management
2. User's aptitudes and communication
3. Technical knowledge

Four of the six top individual items contribute to the composite factor of ERP implementation management, which is, by far, the most important. It is made up of items that are concerned with the management of ERP systems implementation projects.

The results of ranking ERP CSFs in this study are largely consistent with the literature review, though the relative ranking of some factors varied. In the literature, top management support, change management, presence of a champion, and management of expectations are the four most often cited critical factors.

A majority of factors, 12, were rated as critical (rating >4). Only one factor, business process reengineering, which is rated as critical in most articles reviewed, was not rated as critical in this study (rating <3). Hence, the perceptions on CSFs of Venezuelan managers involved in ERP systems implementation projects are largely consistent with the findings reported in the literature.

There are a number of questions still to be determined. For example, although this article establishes the relative importance of CSFs in seven firms, it has not established the reasons. Future studies could look at differences by size of firms, by industry type, by number of locations, by number of customers, etc.

Finally, it should be noted that all CSFs are based on previous research; the success items can be modified when further research is conducted. For instance, discovery-oriented research through comprehensive interviews with several top-level managers in an attempt to identify new CSFs is an option.

Chapter 2.25
Communication Security Technologies in Smart Organizations

Raphael C. W. Phan
Swinburne University of Technology (Sarawak Campus), Malaysia

ABSTRACT

In this chapter, we discuss the security technologies that are important in guaranteeing the good quality of communication within smart organizations. We first briefly review the various forms of communication that can be used in the current information age, before outlining the possible threats that can be faced in each communication medium. We then describe the relevant security technologies that help to protect communication media from common threats, as well as the security tools available in the market that implement these technologies. The topics discussed in this chapter would serve to educate the smart organizations towards securing their various means of communication, which is vital for a business establishment to exist and coexist with peers and partners.

INTRODUCTION

Smart organizations are knowledge-driven, internetworked, dynamically adaptive to new organizational forms, agile in ability to create and exploit opportunities offered by the new economy (Filos & Banahan, 2000). Being internetworked, therefore, some form of communication has to exist between two or more parties. This communication has to be effective and dependable, and furthermore the parties would have to know what is basically happening behind the scenes, and be ever ready to upgrade their knowledge with the latest in technology. Otherwise, this may result in communication breakdowns and hence prevent transactions from being accomplished or contracts from being sealed properly with peers and business partners. What this means is dependability of the communication process, and is the focus of this chapter.

Dependability means that our system can be trusted to perform the service for which it has been designed, and can be decomposed into specific aspects as follows. Reliability characterizes the ability of a system to perform its service correctly when asked to do so. Availability means that the system is available to perform this service when it is asked to do so. Safety is a characteristic that quantifies the ability to avoid catastrophic failures that might involve risk to human life or excessive costs. Finally, security is the ability of a system to provide the following services (Stallings, 1999; Menezes, van Oorschot, & Vanstone, 1996) to communicating parties:

- Confidentiality: Ensures that the communicated information is accessible only by authorized parties.
- Authentication: Ensures that the origin of the message is correctly identified.
- Integrity: Ensures that only authorized parties can modify the communicated information, or enables parties to detect any unauthorized modifications to the information.
- Non-Repudiation: Ensures that neither party can deny having made any previous communications.

This chapter presents a discussion of security technologies available today to ensure the dependability of the communication process, which is vital within smart organizations since its parties are internetworked with each other, and therefore prone to network attacks and exploits by malicious crackers. One of the most important ways that smart organizations use to communicate is via the Internet. Performing transactions online via the Internet is an effective means (VeriSign, 2002) by which organizations can advertise and perform transactions with customers and other parties. However, online transactions will only be popular if the public trusts in their security (Amazon, 2003; Bolivia, 2003; Harris, 1998; Rawal, 2003; Tedeschi, 2000). Therefore, for an organization to be able to compete and advance, it needs knowledge, and hence careful management, of the various security technologies (Anderson, 2001; Garfinkel & Spafford, 1997) that help protect and safeguard public trust in its online transactions. The interested reader is also referred to the chapter on “New Challenges in Smart Organizations: Demands of Mobility” that also appears in this book for a discussion of other relevant future trends.

At the end of this chapter, we hope that the reader would have obtained a general perspective of communications security technologies that can be used in smart organizations. In particular, the objectives of this chapter include:

- Understanding of the various types of communication techniques
- Understanding of the possible threats faced by the communication process
- Familiarity with communication security technologies such as encryption, digital signatures, and message authentication codes (MACs)
- Familiarity with common software and hardware tools used to provide security technologies

BACKGROUND

Security is an important criteria these days, especially with in current information age in which information is available and accessible everywhere, in any form and with any means. The largest depository of information is the Internet, where infinite information is speedily available at one’s fingertips.

With this vastness and freedom of information also comes the threats of abuse and misuse by malicious parties whose intent could be to deceive, steal, impersonate, cheat, or merely intrude into others’ privacy.

Smart organizations are equally affected by this, since the communication process within such establishments requires speed, ease of access, and wide coverage, and further they have to readily adapt to using the latest communication techniques such as the Internet, high-speed networks, and wireless communications. Nevertheless, one has to do so with caution since new technologies are at times not fully tested, and may further have bugs exploitable by attackers to gain entry into the organization's network. Also, smart organization personnel should each be fully aware of how to use such technologies, the possible weaknesses inherent in them, plus how to prevent attacks of any kind.

Protecting the security of the communication process is indeed very important. Based on the recent 2004 Computer Crime and Security Survey (CSI, 2004) by the U.S. Computer Security Institute (CSI) and FBI, it was shown that the Internet connection is increasingly becoming the most frequent point of attack, mostly due to viruses, abuse of net access, unauthorized access, system penetration, and denial of service. Other popular attacks include sabotage, financial fraud, and telecom fraud, which also target the communication process.

WAYS OF COMMUNICATION IN SMART ORGANIZATIONS

In this section, we will look at the ways in which two or more parties can communicate within smart organizations. The main characteristic of communication these days is that it is mainly done via the internet or wireless networks. In other words, communication is online.

World Wide Web (WWW)

One of the earliest ways of communicating online at high speed was via the World Wide Web (WWW), which incorporates all Internet services and allows various parties to access documents, images, music, videos. These are all hosted on computers that run special software called server software and are online all the time. One simply uses a Web browser software such as Netscape's Navigator or Microsoft's Internet Explorer in order to view these online information. Websites in the WWW start with the header "http://www"—for example, http://www.google.com.

File Transfer Protocol (FTP)

Another popular way of communication that has been popular since some time ago is via the file transfer protocol (FTP). This is a specially dedicated specification of how one could transfer files from one computer to another. This is similar to sharing folders or directories in your computer with everyone in the world, and they can log in and access them as if they were physically sitting in their own computers. FTP sites can also be accessed via web browsers or special FTP client software. FTP addresses start with the header "ftp://"—for example, ftp://ftp.example.com.

Electronic Mail (E-Mail)

By far the most popular and commonly-used communication technique is the electronic mail (e-mail). These are messages sent through the Internet from one party to another. Not only that, but other files such as images, music, and video can be included as attachments to these e-mails. Every party communicating via e-mail has an e-mail address, with the format username@emailserver.domain—for example rphan@swinburne.edu.my.

Telnet

Telnet is a terminal emulation program for the Internet. This means that when you run a telnet program on your computer, you can connect your computer to another telnet server on the Internet so you can interact with it by typing in commands, as if you were physically sitting at that server machine and typing at its keyboard. This allows you to remotely control computers and servers.

Chat

Internet chat is popular especially among the young and young at heart. You could chat either using special chat software such as ICQ or Internet relay chat (IRC), or on specific chat Web sites. A chat window is open throughout the chat period and you can type your message and the person at the other end would almost immediately see it. Advanced chat features also include chats among more than two parties (called meetings or conferences), voice chats, and streaming video of the chatting parties.

Short Message Service (SMS) and Multimedia Message Service (MMS)

Meanwhile, the mobile phone revolution started several years ago and never looked back. These days, almost everyone has a mobile phone; for instance, the 2004 mobile penetration rate (Netsize, 2005) in European countries including the UK, Italy, and Sweden has crossed 100%. Although mobile phones were initially used mostly for voice conversations, another revolution ensued, namely the Short Message Service (SMS). This allows parties to send short text messages (up to 160 characters) to one another by using their mobile phones. Following this is an advanced version known as the Multimedia Message Service (MMS), which also allows short videos—including sound—to be sent as messages to other mobile phones. This is just starting to become popular, and is also envisioned to revolutionize the way people communicate in future.

THREAT MODELS FOR THE COMMUNICATION PROCESS

Threats faced by communicating parties are generally grouped into threats from two types of attackers: namely, passive attackers and active attackers (Stallings, 1999).

Passive attackers are those who eavesdrop on or monitor the communications channel, but do not affect or interfere with the communication in any way. Therefore, such attackers are very hard to detect since there is no straightforward way of knowing when communication is being monitored.

Considering the previously discussed ways of communication, passive attacks on the WWW, FTP, and e-mail services, for example, could involve simply monitoring which addresses (WWW, FTP or e-mail) that a certain party is accessing or communicating with. This is possible because these communication services by default simply involve the communication of messages that are in the clear, meaning in readable form. So an attacker could obtain information related to the personal life of a party—for example, which types of Web sites he has visited,what type of files he has accessed, what e-mail addresses he sends to, and so forth. This of course intrudes on the privacy of communicating parties. Individual communicating parties are often not aware of such threats, and do not bother to customize default security and privacy settings within the communication software they use.

Mobile communications via mobile phone conversations, SMS, and MMS are also potentially susceptible to passive attacks. Messages are communicated via microwave signals, which can be easily intercepted by specially built receivers that tune in to the same frequency. Further, since these signals are free to propagate through the air, they are out in the open and so it is almost impossible for one to detect if they are being read by passive attackers. This is in contrast to a telephone line, where a passive attacker would have to make a physical tap somewhere along the line in order to do any eavesdropping. Therefore, there is a need in mobile communications to cover up the meaning of the message. This is usually achieved via the technology called encryption, which will be discussed in the next major section. Doing so ensures that even if a message were intercepted, a passive attacker would not be able to understand what it is.

Active attackers, on the other hand, are those who directly interfere with the communication, either by interrupting, modifying, or fabricating messages. Interruptions of messages are direct attacks on the availability of the communication service, while modifications are attacks on the integrity of the service. Finally, fabrications are attacks on the authenticity of the communication service. All these are serious attacks and should be guarded against.

An active attacker would be able to mount more devastating attacks on the above communication services. For example, he or she could modify the e-mail messages being sent from one party to another and hence cause reputation-damaging consequences. Since e-mails are by default sent in the clear, spoofing such as this can be done easily. Similarly, he or she could masquerade as a certain Web site and dupe WWW browsers into providing information that he is not supposed to have; for example, passwords and credit card information. This is known as "phishing," and is a huge threat because there is a serious lack of public awareness on this. The reason is partly also due to most parties being unfamiliar with the latest technologies, such as the WWW. Therefore, they do not know what is really happening and simply trust such Web sites for what they claim to be. For this reason, commercial banks are starting to give warnings to their customers not to trust any Web site claiming to be them (Personal Computer World, 2004) because Web sites are so easily set up. Another common type of active attack is the Denial of Service (DoS) attack on e-mail servers and WWW servers that intentionally makes limitless accesses to a communication service and heavily overloads the service provider until it disrupts the provision of service to authorized and legal customers. What aids this is the fact that unsuspecting computer users could be forwarding interesting e-mail attachments to friends and colleagues that contain Trojans—malicious software that appear innocent but are doing malicious activities in the background. Such Trojans can be used to collectively mount DoS attacks on Web sites.

Another example of active attack is hacking into a network via a computer within the network, such as through the telnet service provided by the computer to outsiders. Aiding the increase of such hacks is the fact that the learning curve for hackers is decreasing with the vast availability of easy-to-use hacking tools freely downloadable from the Internet (Yunos, 2004).

Finally, viruses and worms are active attacks and really devastate an organization's networks and operations. The damages done could cause losses in millions of dollars (Yunos, 2004) to both the government and the affected organizations themselves. Viruses and worms spread easily due to individual computer users' unawareness of how to safeguard their own computers against these threats. Often, these threats enter an organization's network via an innocent and ignorant employee's computer. The easy availability of virus authoring tools also means new variants can be speedily created by amateurs, and may escape detection by antivirus software.

ESSENTIAL SECURITY TECHNOLOGIES IN SMART ORGANIZATIONS

The most fundamental (primitive) security technologies (Stallings, 1999) that allow one to ensure the security of communication are known as encryption, digital signatures, and message authentication codes (MACs). These fundamental security technologies provide the basic security services of confidentiality, authentication, integrity, and non-repudiation described in the preceding introduction section. We also include in this section a discussion of security protocols and standards that make use of these security primitives.

Encryption

Encryption is basically the process of transforming an original confidential message (plaintext) into unreadable form (ciphertext), and is done by using a key, often generated from a password that is specified. Only the persons who know the key can reverse the process (decrypt) to get back the original message. This clearly ensures that only those who are supposed to read the message can do so. Encryption provides the confidentiality service.

The method to do encryption is called an algorithm. There are generally two types of encryption algorithms, namely symmetric and asymmetric algorithms. Symmetric algorithms use the same key for doing encryption and decryption. This is shown in Figure 1.

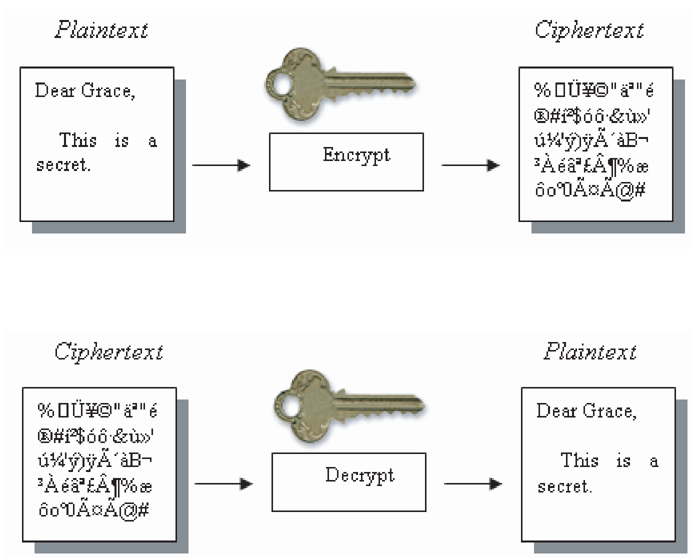
By using a secret key, the original message (plaintext) is encrypted into ciphertext. Once in this form, someone who happens across it would not be able to discern its meaning. In order to get back the original message, the same secret key is used to decrypt the ciphertext (Refer again to Figure 1).

One problem with symmetric algorithms though, is how to share the secret key with others whom you trust. Suppose you want to send an e-mail to your wife. By using a symmetric algorithm, you encrypt your email with a secret key. Then you send the encrypted email to your wife. The problem is how to let her know what is the value of the secret key that you used? You could call her up and whisper it over to her on the phone, but what if the phone line is tapped into? E-mailing the secret key to her is pointless because the fact that you do not trust the telephone line was why you wanted to encrypt your email in the first place.

Figure 1. (a) Symmetric encryption with a secret key; (b) symmetric decryption with the same secret key

(a)

(b)



Asymmetric (public-key) encryption algorithms overcome this problem by using two keys, called the public key and the private key. Each person has his own public key and private key. When you want to send an e mail to your wife, you use her public key to encrypt the e mail. Then when your wife wants to read the e-mail, she simply uses her private key to decrypt the e-mail. This is shown in Figure 2.

Anyone else who tries to decrypt the e-mail would obtain nonsense because only one private key, in this case your friend's private key, can correctly decrypt the e-mail. Your friend can tell everyone what his or her public key is so that anyone who wants to send e-mails to him or her can use th public key to encrypt the message. But knowing the public key does not help an unauthorized person to decrypt the e-mails because only his or her private key can do that.

Obviously, asymmetric encryption algorithms seem more desirable than symmetric encryption algorithms. However, they tend to be slower than symmetric algorithms, especially when the message to be encrypted is large. Due to this fact, the best solution then is to combine the advantages of both methods, as is the current practice by most e-mail security standards.

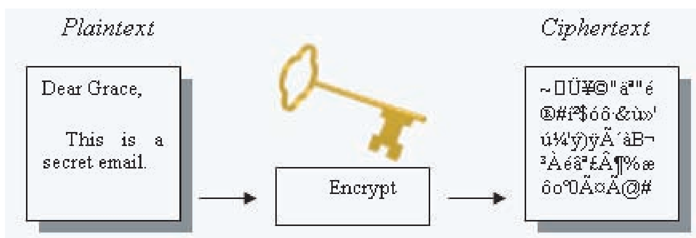
Whenever an e-mail message is to be sent, the following steps are taken, as illustrated in Figure 3:

1. A random secret session-key, K, is generated.
2. The email message is encrypted by a symmetric encryption algorithm with the secret session-key K.
3. The session-key K is encrypted using the recipient's public key.
4. The encrypted session-key K and the encrypted e-mail message are sent to the recipient.

Both the encrypted e-mail message and the encrypted session-key K would be sent together

Figure 2. (a) asymmetric encryption with the public key of the recipient; (b) asymmetric decryption with the private key of the recipient

(a)



(b)

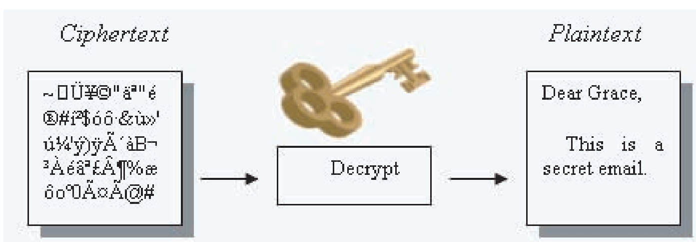


Figure 3. Encryption by the sender: (a) Symmetric encryption of the e-mail with a secret session-key, K; (b) Asymmetric encryption of the secret session-key, K, with the public key of the recipient

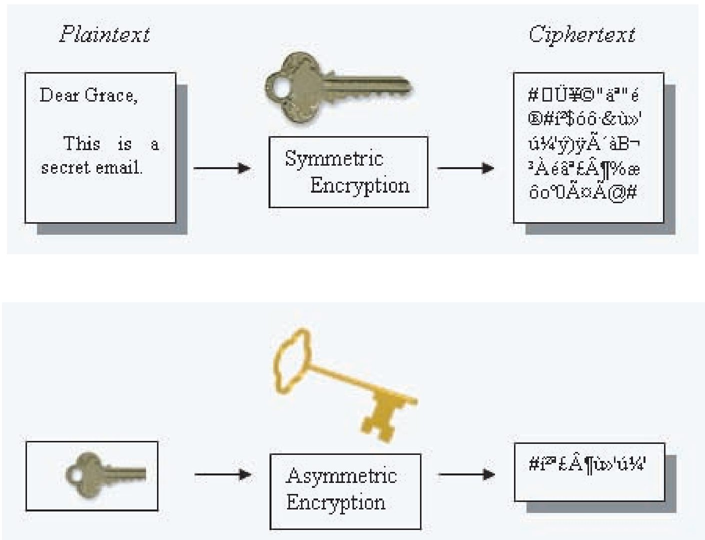
(a)

(b)



over the Internet as one e-mail to the recipient. This is shown in Figure 4.

When the e-mail is received by the recipient, the following is done, as in Figure 5:

1. The recipient uses her private key to decrypt the encrypted session-key, so that she can get back the session-key K that was used to encrypt the e-mail message.
2. She uses the session-key K to decrypt the e-mail message.

An e-mail message could be quite large, so it is encrypted by using symmetric encryption because symmetric encryptions are faster than asymmetric encryptions. Then, in order to solve the problem of having to inform the recipient of the value of the secret key used in the encryption, asymmetric encryption is used to encrypt the secret key. Since the secret key is small compared to the email message, it does not take up much time.

Digital Signatures

A digital signature is a way to ensure that an electronic document (your e-mail or MS Word document, for example) is authentic. Being authentic means two things:

1. You can verify the identity of the person who sent the document
2. You can verify that the contents of the document have not been altered by a third party in any way since it was written

This makes a digital signature analogous to its handwritten counterpart in the pen and paper world. Digital signatures therefore provide the authentication and non-repudiation services.

A popular method of making use of digital signatures is through a public-key encryption system. In such a system, each user has two keys, a public key and a private key. The public key is

Figure 4. Sending both the encrypted e-mail and encrypted session-key over the Internet

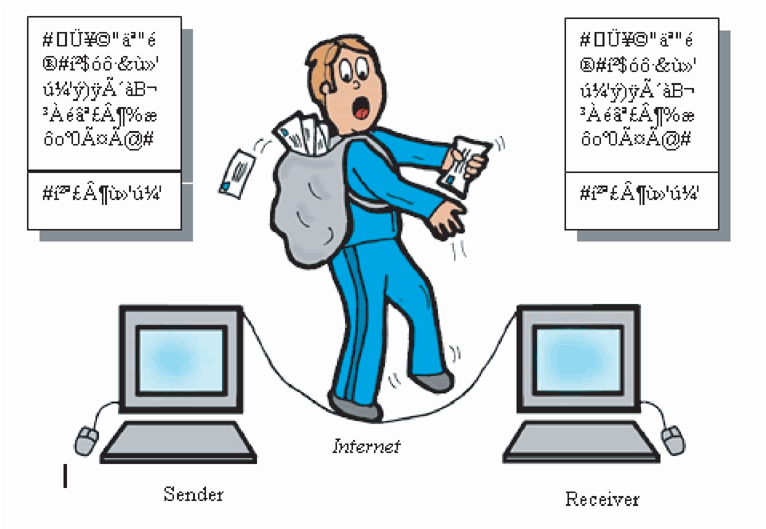


Figure 5. Decryption by the recipient: (a) Asymmetric decryption of the session-key, K, with the private key of the recipient; (b) Symmetric decryption of the e-mail with the secret session-key, K

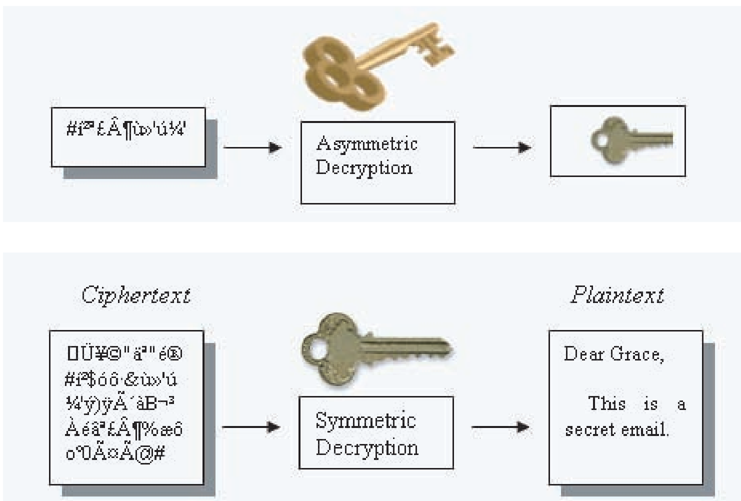
(a)

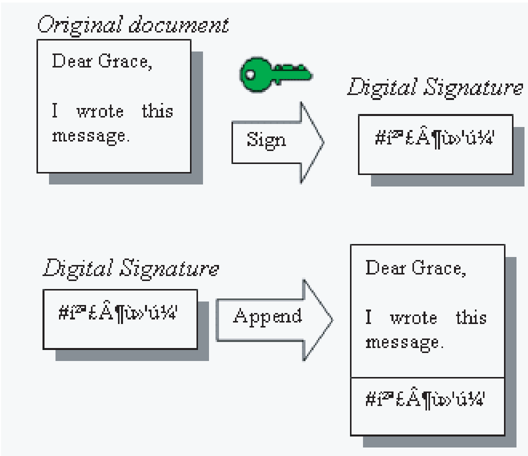
(b)



widely known to the public. However, the private key is secret and known only to the user.

Most of the time, since documents are quite large in size, they are first hashed to produce a compressed version of the document, called the message digest. The message digest is encrypted (signed) with your private key, and this will be your digital signature. The digital signature is then appended to the end of the document, as illustrated in Figure 6.

Figure 6. Digitally signing a document



The document, along with the appended digital signature, is then sent to the recipient, Grace. To verify the document, Grace first hashes the document to get the message digest. She then uses your public key to decrypt the appended digital signature. The decrypted digital signature should be the same as the message digest that she obtained by hashing the document (See Figure 7).

The fact that the digital signature is correctly decrypted into the message digest verifies that the document was written by you, since it was signed by using your private key, which only you will have. If the message digest obtained by hashing the document is the same as the decrypted value of the digital signature, it proves that the document has not been altered since it was sent, otherwise a different message digest would be obtained if you hash it.

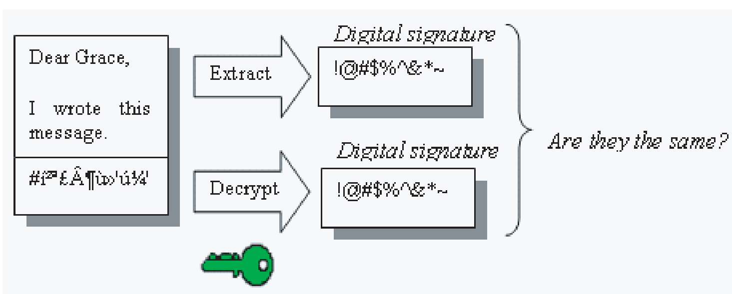
Notice how elegant a public-key encryption system is. You can have encryption or digital signatures depending on the way you use the public and private keys of the sender and recipient. It can be summarized as follows:

- For encryption, the sender encrypts with the recipient's public key. The recipient decrypts it back with her private key.
- For digital signatures, the sender encrypts with his own private key. Anyone who wishes to verify the digital signature uses the sender's public key to decrypt it.

Encryption of a document with the intended recipient's public key ensures that anyone can encrypt and send to the recipient since his public key is publicly known, and is meant to be so. Decryption of that document can only be done with the recipient's private key, and since this key is only known to the recipient, no one can decrypt back the document except the intended recipient himself.

As for digital signatures, a document to be signed is encrypted with the sender's private key.

Figure 7. Verifying the authenticity of a signed document



This ensures that only he can sign since his private key is known to him alone. On the other hand, anyone can verify whether the digital signature is authentic by using the sender's public key, which is again widely known.

Message Authentication Codes (MACs)

Message authentication codes (MACs) are used to ensure the integrity of messages communicated between two parties in order to prevent active attackers from modifying or tampering with them in any way. A MAC works similarly as the secret-key encryption since it also depends on a secret key. The only difference is that it generates a small encrypted output, called a MAC, in contrast to normal encryption where the output is the same size as the input.

Let's assume that two parties, Alice and Bob, share a common secret key. Then when Alice wants to send a message to Bob, she inputs the message into a MAC generator and also puts in the secret key. The result is a MAC with a size much smaller than the original message. Alice next appends this MAC to the message and sends it to Bob.

When Bob receives this, he uses the same secret key to regenerate the MAC from the received message and then compares this with the MAC he received from Alice. If they are the same, this means that the message has not been modified while it was being sent over, since if an attacker had done so, the two MACs would be different. The attacker would not have been able to alter the MAC to correspond to the modified message since he does not know the secret key used to generate the MAC. Therefore, this guarantees the integrity of the message.

Security Protocols and Standards

A protocol is a formal sequence of steps taken by two or more communicating parties. A security protocol specifies what the parties do in order to communicate securely. Security protocols make use of the primitives, Encryption, digital signatures, and MACs, in order to achieve this goal.

The de facto standard protocol for securing online transactions (i.e., buying things from the Internet, sending confidential information, etc.) is the Secure Sockets Layer (SSL) by Netscape Inc (Anderson, 2001). It allows a Web browser client and a visited Web server to authenticate each other, and to further exchange a secret session key for secure communication of sensitive information between them. Browsers secured with SSL would have a header of "https" instead of the normal "http." The Internet Engineering Task Force (IETF) is in the process (Stallings, 1999) of formalizing a similar standard, the Transport Layer Security (TLS), which is based on the SSL protocol.

The standard for secure credit card transactions on the Internet is the Secure Electronic Transaction (SET) standard developed by a consortium including Microsoft, Netscape, VISA, and MasterCard (Anderson, 2001; Stallings, 1999), basically allowing customers and merchants to authenticate each other via digital signatures, and to communicate confidentially via encryption. SET nevertheless does not seem to fully penetrate the market (Anderson, 2001) due to high costs and impracticality, and lack of response from customers.

A public key infrastructure (PKI) is basically a term given to systems that use public-key encryption and digital signatures, where each user (customer, merchant, etc.) has a pair of public and private keys, and where each has a digital certificate certified by a trusted Certification Authority (CA), containing the public key and personal details while the private key is kept secret. a party, Alice, wishing to communicate with another party, Bob, would access Alice's digital certificate for her public key, which can then be used to encrypt confidential information for Alice, or to verify digital signatures signed by Alice. In principle, the above SSL and SET protocols can be viewed as PKIs.

TOOLS FOR SECURITY TECHNOLOGIES IN SMART ORGANIZATIONS

The tools by which smart organizations could provide security technologies such as those described in the previous section could generally be classified into software-based and hardware-based approaches.

Software-Based Tools

The most common software-based tool that provides security services are security software developed by security-based software companies such as anti-viruses, or those that allow computer users to perform encryption, digital signatures, or MACs—for example, the Pretty Good Privacy (PGP) software (Stallings, 1999). Anti-viruses are commonly installed at individual computers and used to scan files commonly prone to viruses. Most anti-viruses these days are also able to be triggered into execution and remain in the background, monitoring the file activity and warning the user of suspicious actions by those files. Meanwhile, security software that provides encryption, digital signatures, and MACs are very useful in that they allow the computer user to protect the confidentiality of his files, authenticate other users, or check the integrity of received files for possible modifications. This software can also be used in relation to e-mail client software and hence help to provide these security services in e-mails, as well.

Another type of anti-virus software is the virus filter (Stallings, 1999), which sits at the server computer and scans files passing through the server for possible virus infections before they enter into the network. This helps to reduce the spread of viruses considerably, since virus filters are maintained by system and network administrators who have the technical know-how on viruses, in contrast to normal anti-virus software sitting on each computer, typically managed by users who sometimes even disable the real-time virus scanning feature in exchange for higher efficiency.

Other such security software tools include firewalls (Stallings, 1999). A firewall is a program running at a network gateway server that protects the files and other resources of the network from other outside networks. Such tools are especially important against active attackers such as hackers or crackers to prevent them from gaining access to computers within the network.

When one connects to a remote computer, the common Telnet session is known to be insecure as messages are transmitted in the clear. To combat (Anderson, 2001) network attacks and hacks, a secure alternative is the secure shell (SSH), which encrypts all messages and so whatever info such as login passwords that are transmitted will be save from eavesdroppers. Internet users also have the option of using encryption and authentication at the Internet Protocol (IP) layer, provided as IPSec in the IPv6 (IP version 6). Yet another alternative is using virtual private networks (VPNs), where several companies communicating with each other would have their firewalls arranged with each other to encrypt all traffic between them. Having said this, though both IPSec and VPNs prevent external network attacks, they do not tackle the issue of insider attacks, and so in general they should be used along with a complementing tool (such as multi layers of conditional access, security logs, frequent updates of keys) to also prevent insider attacks.

Hardware-Based Tools

Hardware-based security tools are gaining popularity these days, including password systems, magnetic stripe cards, smart cards, and biometric systems.

Password systems (Anderson, 2001) are the oldest hardware-based systems and these include those such as safes in banks and locks on briefcases. More advanced versions of these are those such as the automatic teller machines (ATMs) that employ both passwords and magnetic stripe cards to authenticate the legal party. Old versions of credit cards also use magnetic stripes for reading and verification. Nevertheless, the recent widespread cases of credit card cloning (Yunos, 2004) has raised concern on the security of magnetic-striped based cards.

Smart cards (Anderson, 2001) have been increasingly used in recent years in place of magnetic stripe cards since they are tamper-resistant and also contain a built-in microprocessor that processes and executes programs from within the smart card. The tamper-resistance of smart cards also appear to complicate active attackers from cloning them and using them for impersonations. The physical tamper-resistance in smart cards are usually implemented by using tamper-detection wires that immediately cause the memory within smart cards to be erased the moment illegal tampering is detected. Nevertheless, smart cards can still be hacked or cloned, though with a bit more effort compared to magnetic stripe cards, as clearly detailed in Anderson (2001).

Biometric systems (Anderson, 2001) are also widely used currently, and these make use of a person's fingerprints, eye pattern, face patterns, voices, hand geometry, and even typing behavior. These eliminate the need to carry a foreign object such as a smart card, since a person needs only to use his or her own body for authenticating himself to the system. Some important security issues (Anderson, 2001) regarding the proper use of biometrics include:

- False positives and false negatives: The former means a fake biometrics being falsely taken to be true, while the latter means a true biometrics being taken as a fake one. These are mostly due to careless biometrics laboratory procedure.
- Freshness: It is hard to tell the age of a biometrics print, and therefore there are issues of how fresh it is, or if it could have been planted there by someone else, since most biometrics such as voice, eye patterns, and fingerprints can be recorded and replayed at a later time.

In summary, it is preferred to use various tools such as smart cards and biometric systems in combination for extra security, and such that compromising one would still not compromise the entire system.

FUTURE TRENDS

The introduction of the computer caused a digital revolution where vast amounts of information are expressed, communicated, stored, and processed in digital form. This revolution was also propelled considerably by the popularity of the Internet. This was followed by the mobile phone revolution, leading to the popularity of instant messaging via mobile communication networks. The trend is emerging where multimedia-based services via mobile devices would be at the forefront of the communication process. Also looking very prospective is the trend toward interactivity in communication; for example, viewers being able to interact with cable TV services via their televisions, mobile service subscribers downloading packages onto their devices, customizing their devices, and even more flexibility and customization by the car owner in the latest designs of high-tech cars. With each new communication trend comes new potential threats against the communication process, hence this area of communications security is an ever-changing field that improves over time and would never remain stagnant.

CONCLUSION

In this chapter, we first discussed the communication process and various forms in which it can take place. We then proceeded to the possible threats that might be faced by the communication techniques and then described the basic security technologies that could be used to guard against the attacks. This was followed by a discussion of the different software and hardware tools used to provide the previously-mentioned security technologies. The concepts discussed in this chapter are essential since an appreciation of these concepts would help the reader to better understand how the security technologies can be provided in the communication process, and also help personnel (both the leaders and subordinates) in smart organizations to manage and handle such security technologies better.

Chapter 2.26
Knowledge Visualization

Martin J. Eppler
University of Lugano, Switzerland

Remo A. Burkhard
University of St. Gallen, Switzerland

INTRODUCTION

Making knowledge visible so that it can be better accessed, discussed, valued, or generally managed is a longstanding objective in knowledge management (see Sparrow, 1998). Knowledge maps, knowledge cartographies, or knowledge landscapes are often heard terms that are nevertheless rarely defined, described, or demonstrated. In this article, we review the state of the art in the area of knowledge visualization, and describe its background and perspectives. We define the concept and differentiate it from other approaches, such as information visualization or visual communication. Core knowledge visualization types, such as conceptual diagrams or visual metaphors, are distinguished, and examples of their application in business are shown and discussed. Implications for research and practice are summarized, and future trends in this domain are outlined.

The Concept of Knowledge Visualization

Generally speaking, the field of knowledge visualization examines the use of visual representations to improve the creation and transfer of knowledge between at least two people. Knowledge visualization thus designates all graphic means that can be used to construct and convey complex insights. Beyond the mere transport of facts, people who employ knowledge visualization strive to transfer insights, experiences, attitudes, values, expectations, perspectives, opinions, and predictions, and this in a way that enables someone else to re-construct, remember, and apply these insights correctly. Examples of knowledge visualization formats are heuristic sketches (e.g., ad-hoc drawings of complex ideas), conceptual diagrams (such as Porter's Five Forces diagram), visual metaphors (such as Plato's cave metaphor of reality), knowledge animations (such as a rotating double helix), knowledge maps (such as a landscape of in-house experts), or domain structures (e.g., a co-citation network of knowledge management literature). All these formats capture not just (descriptive) facts or numbers, but prescriptive and prognostic insights, principles, and relations. They are used as indirect (and at times ambiguous) communication in order to trigger sense-making activities and to motivate viewers to re-construct meaning. Thus, the 'what' (object), the 'why' (goal), and the 'how' (methods) of knowledge visualization differ from information visualization. These differences are further described in the following section.

The Differences Between Knowledge and Information Visualization

A related field and precursor to knowledge visualization is information visualization. Information visualization is an advancing field of study both in terms of academic research and practical applications (Card, Mackinlay, & Shneiderman, 1999; Chen, 1999a; Spence, 2000; Ware, 2000). Information visualization offers novel visual applications for the interactive browsing and analysis of data with the aim to derive new insights by seeing trends, outliers, or clusters. Card et al. (1999) define information visualization, as "the use of computer-supported, interactive, visual representations of abstract data to amplify cognition." This definition is well established among computer scientists active in this field. The information visualization fields neglects, however, the potential of visualizations as a medium for the transfer of complex knowledge. Another neglected aspect relates to the integration of non-computer based visualization methods (e.g., posters, physical objects, etc.) as architects, artists, and designers use them. This is the objective of knowledge visualization and at the same time the main difference to information visualization: information visualization and knowledge visualization are both exploiting our innate abilities to effectively process visual representations, but the way of using these abilities differs in both domains. Information visualization aims to explore large amounts of abstract (often numeric) data to derive new insights or simply make the stored data more accessible. Knowledge visualization, in contrast, facilitates the transfer and creation of knowledge among people by giving them richer means of expressing what they know. While information visualization typically helps to improve information retrieval and access, and generally optimizes the presentation of large data sets—particularly in the interaction of humans and computers—knowledge visualization primarily is used to augment knowledge-intensive communication among individuals. Such visual communication of knowledge is relevant for several areas within knowledge management, as described in the next section.

Application Areas within Knowledge Management

Knowledge visualization can help to solve several predominant, knowledge-related problems in organizations. First, there is the omnipresent problem of knowledge transfer (or knowledge asymmetry). Knowledge visualization offers a systematic approach to transfer knowledge at various levels: among individuals, from individuals to groups, between groups, and from individuals and groups to the entire organization. To do so, knowledge must be recreated in the mind of the receiver (El Sawy, Eriksson, Carlsson, & Raven, 1997). This depends on the recipient's cognitive capacity to process the incoming stimuli (Vance & Eynon, 1998). Thus, the person responsible for the transfer of knowledge not only needs to convey the relevant knowledge at the right time to the right person, he or she also needs to convey it in the right context and in a way so that it can ultimately be used and remembered. Graphics such as rich but easily understandable visual metaphors can serve exactly this purpose, as the brain can process images often more easily than text. In this context, visualization can also facilitate the problem of inter-functional knowledge communication—that is, the communication among different stakeholders and experts with different professional backgrounds. Visual methods for the transfer of complex knowledge are thus one emergent sub-discipline within knowledge visualization.

Another application area of visualization within knowledge management is knowledge creation. Knowledge visualization offers great potential for the creation of new knowledge in groups, thus enabling innovation. Knowledge visualization offers methods to use the creative power of imagery and the possibility of fluid rearrangements and changes. It inspires and enables groups to create new knowledge, for instance by use of heuristic sketches or visual metaphors. Unlike text, these graphic formats can be quickly and collectively changed, and thus propagate the rapid and joint improvement of ideas.

A further, more general, application goal of knowledge visualization is its use as an effective strategy against information overload. Information overload (see Eppler, Mengis, 2004) is a major problem in knowledge-intensive organizations. Knowledge visualizations help to compress large amounts of reasoned information with the help of analytical frameworks, theories, and models that absorb complexity and render it accessible. This can be a vital prerequisite for the three application domains mentioned previously (transfer, creation, and communication).

Although these application fields have existed for several years, the potential of visual representations is often lost because there is little assistance for non-professional visualizers to make use of the power of complex visualization. Thus, a conceptual framework should be developed that enables practitioners to better use and apply visual representations of knowledge. In the next section, we briefly outline relevant background areas that have paved the way for knowledge visualization as a new discipline. Then, we will present a first general framework to guide the application of knowledge visualization.

BACKGROUND

The field of knowledge visualization is an emerging one, merging approaches from information visualization, didactic techniques, visual cognition, and visual communication research, as well as more practical approaches, such as business diagramming or visual programming languages. Below, we briefly review two of these central disciplines.

Visual Cognition and Perception

A majority of our brain's activity deals with processing and analyzing visual images. Several empirical studies show that visual representations are superior to verbal-sequential representations in different tasks (Larkin & Simon, 1987; Glenberg & Langston, 1992; Bauer & Johnson-Laird, 1993; Novick, 2001). Similarly, Miller (1956) reports that a human's input channel capacity is greater when visual abilities are used. The reason for this has been researched by Gestalt psychologists. Their findings indicate that our brain has a strong ability to identify patterns in graphics (Koffka, 1935). In addition, research on visual imagery (Kosslyn, 1980; Shepard & Cooper, 1982) suggests that visual recall seems to be better than verbal recall. It is still not entirely clear how images are stored and recalled, but it is clear that humans have a natural ability to remember and use images. Three related fields of research—instructional psychology, MIS, and media didactics—investigate the learning or performance outcomes of text-alone versus text-picture. Again, visualization seems to outperform text alone. Mandl and Levin (1989), Weidenmann (1989), and Swaab, Postmes, Neijens, Kiers, and Dumai (2002) present clearly different results in knowledge acquisition or task performance from text and pictures. All of these studies lead to one unambiguous conclusion: If visualization is applied correctly, it dramatically increases our ability to think and communicate.

Visual Communication Studies

Different isolated research fields contribute valuable results for the visual communication of knowledge. These are contributions in the field of visualizing information in print (Bertin, 1974; Tufte, 1990, 1997), cognitive art and hypermedia design (Horn, 1998), information architecture (Wurman, 1996), and contributions in the fields of graphics design, interface design, interaction design, and human-computer interaction. From a theoretical perspective, there are different contributions that help to improve the transfer of knowledge, particularly communication science (Fiske, 1982), visual communication sciences (Newton, 1998; Stonehill, 1995), and cognitive psychology (Farah, 2000). These contributions show how visual representations affect our social cognition processes both positively (improving understanding) and negatively (manipulating perception and interpretation). Many systematic approaches that examine visualization in communication, however, have so far been rooted in the mass media sector. They have primarily described how newspapers and television use graphic representations to convey meaning. How to use such formats actively for knowledge transfer is rarely discussed in these contributions. We use insights from these and other domains to categorize the main application parameters of knowledge visualization in the next section.

A Framework for Knowledge Visualization

For an effective creation and transfer of knowledge through visualization, at least three perspectives (Table 1) should be considered. These perspectives answer three key questions with regard to visualizing knowledge, namely:

1. What type of knowledge is visualized (object)?
2. Why should that knowledge be visualized (purpose)?
3. How can the knowledge be represented (method)?

The answers to these three questions are obviously highly interconnected. Listing possible answers to these key questions leads to a first conceptual framework that can provide an overview of the knowledge visualization field (see Table 1).

The knowledge type perspective can be used to identify the type of knowledge that needs to

Table 1. The three different perspectives of the knowledge visualization framework

Knowledge Type *(what?)*	**Visualization Goal *(why?)***		**Visualization Format *(how?)***
Know-what	Transferring (clarification, elicitation, socialization)	1.	Heuristic sketches
Know-how	Creating (discovery, combination)	2.	Conceptual diagrams
Know-why	Learning (acquisition, internalization)	3.	Visual metaphors
Know-where	Codifying (documentation, externalization)	4.	Knowledge animations
Know-who	Finding (e.g., experts, documents, groups)	5.	Knowledge maps
	Assessing (evaluation, rating)	6.	Domain structures

be transferred. For our framework we distinguish among five types of knowledge: declarative knowledge (know-what), procedural knowledge (know-how), experiential knowledge or experience (know-why), orientation knowledge (know-where), and people-related knowledge (know-who) (for this distinction, see for example Alavi & Leidner, 2001). Today, there is no validated prescriptive framework that links visualization formats to knowledge types and that offers specific representation formats for particular knowledge types.

With the help of the visualization goal perspective, we distinguish among several reasons why a visual knowledge representation is used. Goals for knowledge visualization use that can be anticipated are knowledge sharing through visual means, knowledge crafting or creation, learning from visual representations, codifying past experiences visually for future users, or mapping knowledge (Vail, 1999) so that experts, for example within a large organization, can be more easily identified.

The visualization format perspective structures the visualization methods to six main groups: heuristic sketches, conceptual diagrams, visual metaphors, knowledge animations, knowledge maps, and domain structures.

Having given an overview of the main formats of knowledge visualization, we will discuss each of the six types, and how they can be matched with adequate knowledge types and applied for specific application contexts.

Heuristic Sketches: Creating New Insights Individually or in Groups

Heuristic sketches are drawings that are used to assist the group reflection and communication process by making knowledge-in-progress explicit and debatable. Generally a sketch is defined as "a rough drawing or painting in which an artist notes down his preliminary ideas for a work that will eventually be realized with greater precision and detail."1 In the context of knowledge management, we call these sketches heuristic sketches to highlight their problem-solving potential. The main benefits of heuristic sketches are: (1) they represent the main idea and key features of a preliminary study; (2) they are versatile and accessible; (3) they are fast and help to quickly visualize emergent notions; (4) the use of a pen on a flipchart attracts the attention towards the communicator; and (5) heuristic sketches allow room for one's own interpretations and foster the creativity in groups. Examples of heuristic sketches are shown in Figures 1 and 2.

Figure 1. Freud's heuristic sketch for theory development [2]

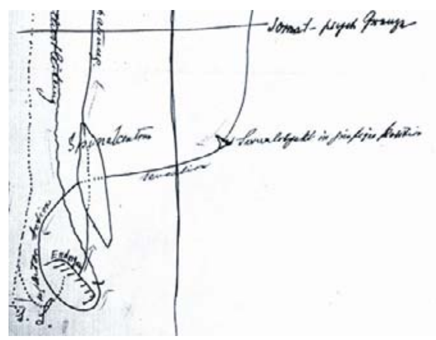

Figure 2. Various sketches helped to assist and inspire the group reflection processes in an urban planning workshop[3]

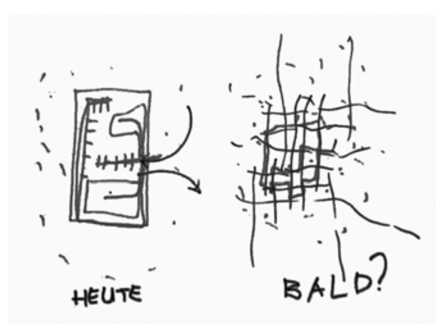

Conceptual Diagrams: Structuring Information and Illustrating Relationships

Conceptual diagrams as seen in Figure 3 are schematic depictions of abstract ideas with the help of standardized shapes (such as arrows, circles, pyramids, or matrices). They are used to structure information and illustrate relationships. For the transfer and creation of knowledge, conceptual diagrams help to make abstract concepts accessible, to reduce the complexity to the key issues, to amplify cognition, and to discuss relationships (Eppler, 2003).

An example of a particularly knowledge-intensive conceptual diagram is the Toulmin chart, based on the argumentation theory of Steven Toulmin (1964). Such a chart helps to breakdown an argument into different parts (such as claim, reasons, and evidence); this is useful when evaluating the validity of a claim.

Visual Metaphors: Relating Domains to Improve Understanding

A metaphor provides the path from the understanding of something familiar to something new by carrying elements of understanding from the mastered subject to a new domain. This is why Aristotle calls the metaphor a tool of cognition. A metaphor provides rapid information, is highly instructive, and facilitates the process of learning. As Worren, Moore, and Elliott (2002, p. 1230) have pointed out, metaphors can also improve memorability and coordination in groups. Visual metaphors used for knowledge transfer or creation can either be natural objects or phenomena (e.g., mountains, icebergs, tornado), or artificial, man-made objects (e.g., a bridge, a ladder, a temple), activities (e.g., climbing, etc.), or concepts (e.g., war, family). Their main feature is that they organize information meaningfully. In doing so, they fulfill a dual function. First, they position information graphically to organize and structure it. Second, they convey an implicit insight about the represented information through the key characteristics (or associations) of the metaphor that is employed.

In Figure 4 the metaphor of a bridge was used to convey how to lead successful negotiations.

Knowledge Animations: Dynamic and Interactive Visualizations

Knowledge animations are computer-supported interactive visualizations that allow users to con-

Figure 3. An overview of frequently used conceptual diagrams

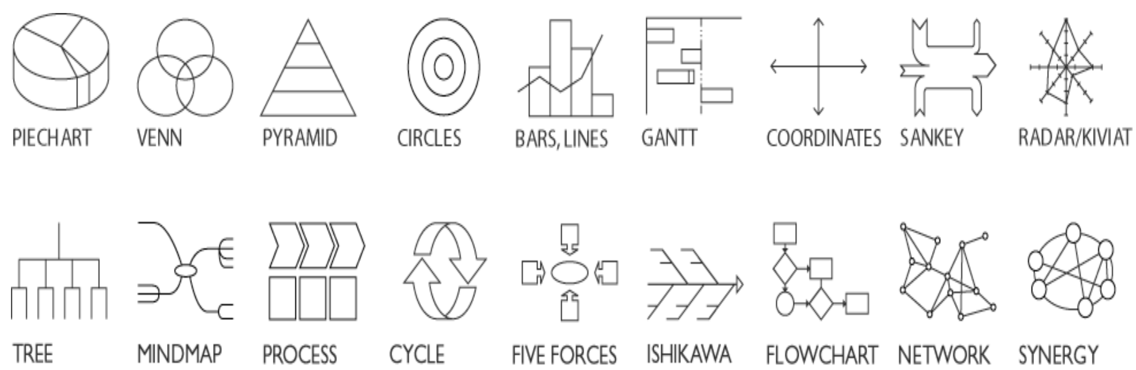

Figure 4. The negotiation bridge: A visual metaphor that outlines a negotiation method[4]

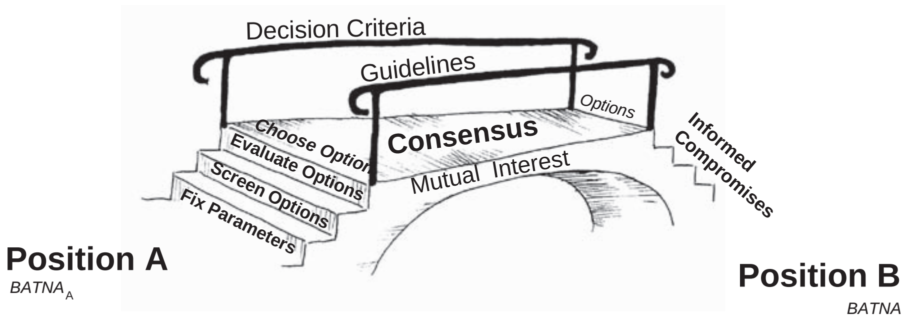

Figure 5. The Infoticle application allows exploring large-time varying datasets[5]

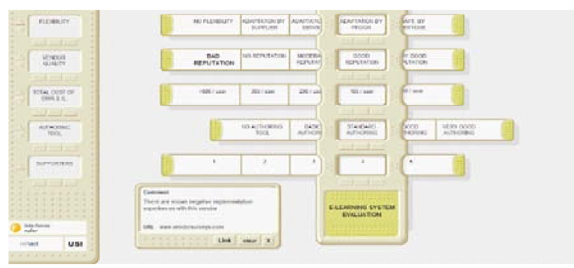
Figure 6. The interactive parameter ruler enables teams to explore alternatives in real time[6]



trol, interact, and manipulate different types of information in a way that fosters the transfer and creation of knowledge. By interacting with the information, new insights are created or shared. Knowledge animations help to fascinate and focus people, to enable interactive collaboration and persistent conversations, and to illustrate, explore, and discuss complex issues in various contexts. In the Infoticle application (Vande Moere, Mieusset, & Gross, 2004), the animation of data-driven particles (Infoticles) helps to explore large time-varying datasets and allows seeing the behavior of individual data entries in the global context of the whole dataset.

In similar ways, the interactive parameter ruler (Figure 6; Eppler, 2004) enables teams and individuals to explore alternatives in real time through sliders in the ruler application. As they enter evaluation criteria or decision options and move them into various positions, participants develop a common understanding regarding a complex issue. The joint visual interaction is thus a catalyst for collective knowledge development and transfer in groups.

Knowledge Maps: Navigating and Structuring Expertise

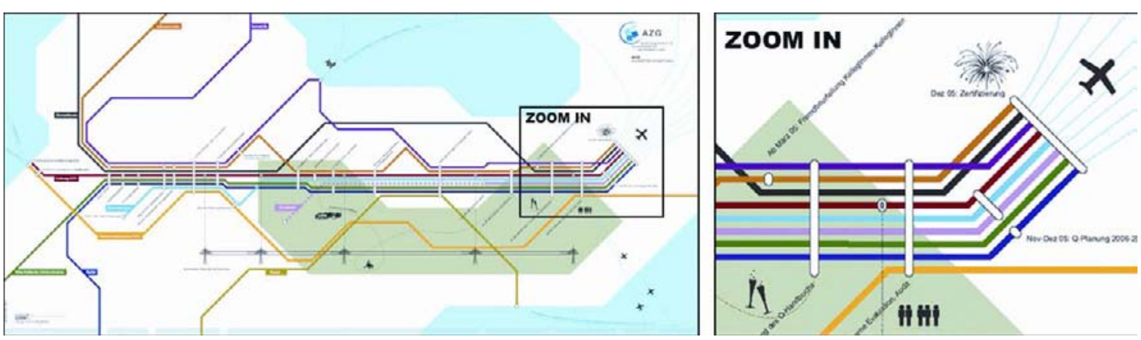
Knowledge maps (Eppler, 2002) are graphic formats that follow cartographic conventions to reference relevant knowledge. A knowledge map generally consists of two parts: a ground layer which represents the context for the mapping (such as an island), and the individual elements that are mapped within this context (e.g., towns). The ground layer typically consists of the mutual context that all employees can understand and relate to, such as a business model, a product, the competency areas, or a geographic map. The elements that are mapped onto such a shared context range from experts and communities of practice to more explicit and codified forms of knowledge such as articles, patents, lessons learned bases, or expert systems. Knowledge maps are thus graphic directories of knowledge-sources, -assets, -structures, -applications, or -development stages.

In Figure 7 the customized Tube Map Visualization7 illustrates a five-year quality development project. The subway-lines represent individual target groups and the stations milestones. The knowledge map was printed on a poster (2.4×1.2 meters) and located in front of an elevator to foster creativity and initiate discussion. An evaluation can be found in Burkhard and Meier (2004).

Domain Structures: Visualizing Intellectual Structures

Knowledge domain visualization focuses on identifying and visually representing the dynamics of scientific frontiers in a multidisciplinary context and allows new ways of accessing knowledge sources (authors, institutions, papers, journals, etc.) by visualizing linkages, relationships, and structures of scientific domains (Chen, 1998, 1999b, 2000, 2003). New algorithms can be integrated in novel interfaces for the exploration of digital libraries where new search paradigms become decisive (Kleiboemer, Lazear, & Pederson, 1996; Chen, Houston, Sewell, & Schatz, 1998; Sebrechts, Vasilakis, Miller, Cugini, & Laskowski, 1999; Sutcliffe, Ennis, & Hu, 2000). Examples for such systems are Envision (Fox et al., 1993, 2002) or Gridvis (Weiss-Lijn, McDonnell,

Figure 7. The tube map visualization (1.2×2.4 meter) presents an overview and details on a project. Each line represents one target group, each station a project milestone. Each line (target group) stops at the stations (milestones) where the target groups are involved. The stations are tagged with descriptions, dates, or instructions.



& James, 2001). An overview of such systems is presented by Nowell, France, Hix, Heath, and Fox (1996) and Börner and Chen (2002). While this knowledge visualization format is currently only used for knowledge management in scientific communities, future application in corporate settings can be envisioned (for communities of practice).

CONCLUSION

Knowledge visualization offers solutions for the transfer and creation of knowledge, and stresses an important and often neglected potential that knowledge management researchers and practitioners can exploit: our innate ability to effectively process visual representations. Knowledge visualization also offers new development roads for the discipline of information visualization, as it extends the field with regard to other knowledge types and knowledge processes other than information exploration (namely knowledge transfer and knowledge creation in groups), because: (1) it uses computer-based and non-computer based visualization methods; (2) it points to psychological, social, and cognitive factors of different recipients; and (3) it integrates findings from other research fields such as knowledge management, communication science, architecture, or psychology. This article presented both a theoretical framework and application examples to highlight the great potential of visualization for knowledge management. Specifically, this potential relates to cognitive (c), social (s), and emotional (e) benefits of visualization. These factors can be summarized in the CARMEN acronym:

- Coordination: Visual representations help to coordinate knowledge workers, and to structure communication and group processes (e.g., knowledge maps, visual tools for collaboration, heuristic sketches). (s)
- Attention: Visual representations allow users to gain attention by addressing emotions (e.g., advertising) and to keep attention (e.g., sketching on a flipchart) by identifying patterns, outliers, and trends (e.g., information visualization). (c)
- Recall: Visual representations improve memorability, remembrance, and recall, because we think in images (e.g., visual metaphor, stories, and conceptual diagrams). (c)
- Motivation: Visual representations inspire, motivate, energize, and activate viewers (e.g., knowledge maps, mutual stories, instructive diagrams). (e)
- Elaboration: Visual representations lead to further understanding and appreciation of concepts and ideas as one interacts with them (e.g., discussing scenarios of a new product by the use of heuristic sketches or a physical model). (c)
- New Insights: Knowledge visualizations can reveal previously hidden connections and lead to sudden insights—'a-ha' experiences. By visualizing experiences in a group, for example, root causes of certain errors can surface. Visual representations support the creation of new insights by embedding details in context and showing relationships between objects (e.g., information visualization, visual metaphors). (c)

As far as the limitations are concerned, there is evidence that visualization can have drawbacks with regard to specific contexts. One should thus not neglect the risks inherent in using such forms of visualization, namely the difficult maintenance of the diagrams and maps, the reification of (at times) invalid views, and hence the possible manipulation of users, or the possible distortion of reality through misinterpretations. Future research will have to investigate these potential negative effects empirically in authentic application contexts (e.g., Blackwell & Green, 1999). As a reminder, we summarize the potential drawbacks of knowledge visualization with the COMMA acronym:

- Confusion: If knowledge visualizations do not respect certain rules and conventions, or if the used metaphors or analogies are difficult to understand, they can be confusing and obstruct knowledge transfer.
- Overload or oversimplification: Knowledge visualization that does not respect the cognitive constraints of visual perception quickly becomes overloaded and de-motivating. On the other side of this spectrum, visualizations may also simplify ideas or concepts by leaving out too many vital elements.
- Misuse or misrepresentation: Visualizations may also be used where they are not really necessary and where a text may convey an insight (e.g., because of its sequential structure) more adequately than a text. They may misrepresent a given domain, for example, by employing an unfit metaphor or diagrammatic template. Misuse may also result from a haphazard look at a picture.
- Manipulation: As stated above, visualization is a powerful instrument that can be used to cover up logical flaws, incomplete reasoning, or distorted evidence. Consequently, visualizations must always be viewed critically.
- Ambiguity: As graphic symbols are typically open to various interpretations, compilations of such symbolic forms in knowledge visualizations may at times be ambiguous. Because of this, it is crucial to provide written or verbal explanations to accompany complex graphics.

In terms of future trends, knowledge visualization will evolve with regard to new formats and new application areas. The potential to combine various formats (such as diagrams, maps, and metaphors) in a complementary way (as architects use them) seems obvious. It also seems clear that knowledge visualization will be used in other settings than just the traditional computer desktop environment. Examples of new application areas for knowledge visualization can be found in the visual communication of corporate missions, strategies, value propositions, and business scenarios. New applications can also be envisioned by combining knowledge visualization with other innovative approaches in knowledge management, such as storytelling. Storytelling is in fact a closely related knowledge management tool, as it strives for rich, mental imagery (Loebbert, 2003). We believe that stories can be combined with knowledge visualization formats (as in visualized story trails) to trigger and accelerate the creation and dissemination of knowledge in organizations.

In conclusion, we believe that additional time and budget for knowledge visualization should be allocated in future corporate KM initiatives and in future research initiatives on knowledge management. Knowledge visualization clearly is an idea whose time has come. To put this idea into practice, however, requires not only imagination, but also dedication to continuous assessments and improvements.

Chapter 2.27
Web GIS and Knowledge Management Systems:
An Integrated Design for Collaborative Community Planning

Brad C. Mason
Community Mapping Network, Canada

Suzana Dragićević
Simon Fraser University, Canada

ABSTRACT

Environmental problems are multidimensional and usually complex. Collaborative integration of multiple forms of knowledge is one approach used to develop meaningful solutions to complex problems. In this regard, spatial data and knowledge about the environment have been managed extensively with Web geographic information systems (Web GIS). However, past Web GIS research has focused mostly on using spatial tools to manage explicit (codified) knowledge. This has reduced the complementary contribution that tacit (experiential) knowledge can provide to environmental solutiodragns. In this study, Web GIS and knowledge management technologies are used to integrate multiple forms of spatial knowledge in support of collaborative community planning. The system design included a customized end-user interface for data entry, georeferencing tools for asynchronous collection of local data, and protocols for knowledge management dealing with species location, ecological habitats, and environmentally sensitive areas among others. The system enabled access, query, sharing, and updating of environmental knowledge using visual map-based tools. The utility of the integrated system design is discussed.

INTRODUCTION

Environmental problems are affected by many factors that can be classified along physical, ecological, socio-cultural, and political-legislative dimensions (Gunderson & Holling, 2002). These factors interact nonlinearly and with feedback such that the system outputs influence the system inputs. The emergent complexity is a challenge for environmental management, planning and decision making. The literature suggests that approaches that consider collaboration, data partnerships, and knowledge management can provide an effective means to manage the complexity of environmental systems (Andelman, Bowles, Willig, & Waide, 2004; Blumenthal & Jannink, 2000; Jankowski & Nyerges, 2001; Johnson & Singh, 2003). In this study, a collaborative Web GIS and knowledge management system is presented to support access, query, sharing, and updating of environmental knowledge using visual map-based tools.

Collaboration in a spatial context has its roots in the participatory planning literature, and involves the inclusion of a wide range of individual perspectives in the decision-making process (Hemmati, Dodds, Enatati, & McHarry, 2002; Jankowski & Nyerges, 2001). In order to facilitate partnerships and collaborative interactions among stakeholders and planners, extensive use has been made of community GIS (Ghose, 2001; Talen, 1999) and Web GIS (Houle, Dragicevic, & Boudreault, 2000; Kangas & Store, 2003; Rinner, 2003). One limitation of community GIS is that increasing the involvement of individuals demands more efficient management and spatial support tools to reduce process delays. Because the planning process is temporal, Web GIS has increasingly been used to continually engage a wider cross section of stakeholder groups. Moreover, the open source Web GIS movement has positively impacted the adoption and use of Web GIS among individuals and groups. As such, Web GIS can provide a robust infrastructure to support collaboration across multiple spatial and time scales.

Web GIS are designed to integrate the distributive capabilities of the Internet with the spatial analytical features of geographic information systems (Peng, 2001; Peng & Tsu, 2003). Web GIS uses the multimedia protocols of the Internet and forms a focused subset of Internet GIS. The early implementations of Web GIS were limited to static maps and simple navigation such as pan and zoom (Plewe, 1997). Web GIS has now rapidly evolved to offer a full suite of interactive spatial data management, analysis, and mapping capabilities (Dragicevic, 2004; Gitis, Andrienko, & Andrienko, 2004; Tsou, 2004). An advantage of Web GIS is that they integrate stakeholders, planners, and spatial data in synchronous and asynchronous implementations to search for joint solutions (Dragicevic & Balram, 2004; Kingston, Carver, Evans, & Turton, 2000). The research and applications of Web GIS have mostly focused on designing and using spatial tools to manage explicit (documented) knowledge. This has reduced the complementary contribution that tacit (personal experiences) knowledge can provide to environmental solutions. Extending current Web GIS to support knowledge processes requires that knowledge management systems (KMS) capabilities be integrated in complementary designs.

Knowledge management systems contain tools, techniques, and processes to elicit, assess, organize, expand, and share expertise (McElroy, 2003). Expertise is classified generally as tacit knowledge or explicit knowledge (Fuller, 2002). Tacit knowledge is personal knowledge that has evolved within individuals or communities and has been passed on from one generation to another. This type of knowledge is difficult to transfer to a spatial and digital environment because it is not easily codified. For example, the location of traditional hunting grounds for a First Nation community is common oral knowledge and difficult to translate into a map. The consequence is that tacit knowledge is usually excluded from the map-driven planning process. Researchers have also used the term "local knowledge systems" to describe frameworks for operationalizing tacit knowledge (Lawas & Luning, 1997). Local knowledge, traditional knowledge, and traditional ecological knowledge are other terms that describe tacit knowledge (Zurayk, el-Awar, Hamadeh, Talhouk, Sayegh, Chehab et al., 2001). Explicit knowledge is documented knowledge obtained by systematic means that can be transferred between sources. Explicit knowledge is derived from the formal scientific data collection and synthesis process (Robiglio & Mala, 2005). The aim of KMS in the environmental planning process is to combine tacit and explicit knowledge in order to develop more comprehensive knowledge bases that can improve problem understanding, create environmental learning forums, and enhance environmental sustainability (McElroy, 2003).

The integration of Web GIS and KMS provides benefits for the collection and management of multiple forms of knowledge in spatial contexts (Goran & MacGillivray, 2003). While both systems deal with data in general, they differ based on the attribute-spatial distinction. KMS are well suited to represent attribute data and corporate knowledge, but are not well suited to represent the spatial aspects of environmental knowledge. Web GIS is explicitly designed to deal with spatial data. Integrating Web GIS and KMS provides a useful approach to develop systems that can handle multiple forms of knowledge within a spatial context. Benefits of the integration include encouraging human interactions by the new perspectives gained from spatial data, promoting dialogue about future scenarios from past attribute data, and sharing and reusing knowledge for future planning (Goran & MacGillivray, 2003).

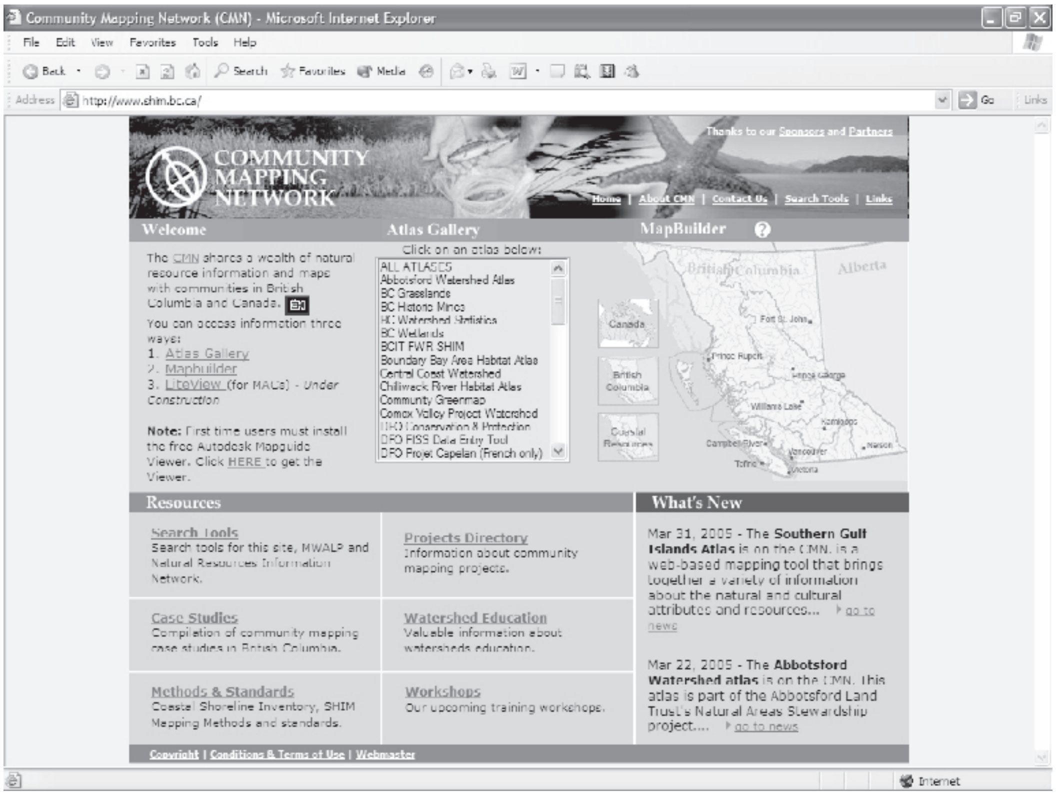
In this study, Web GIS and KMS were integrated to form a collaborative distributed system called the Community Mapping Network (CMN). The system design included a customized end-user interface for data entry, while the georeferencing tools enabled asynchronous collection of local knowledge about the location of species, ecological habitats, and points of interest, among others. The integrated system was implemented for collaborative community planning and management in British Columbia, Canada. This chapter begins by outlining the need for systems integration generally and the integration of Web GIS and KMS specifically, followed by the architecture and knowledge integration aspects of the CMN, then discusses implementation experiences, and finally concludes with future design improvements of the developed system.

INTEGRATED DESIGN FOR COLLABORATIVE PLANNING

The Community Mapping Network (http://www.shim.bc.ca) is an evolving knowledge base that provides a service to government agencies by integrating multiple natural resources information across jurisdictional boundaries (Figure 1). The system was created in response to demands from communities, stewardship groups, nongovernmental organizations, and governments (federal, provincial, local) in British Columbia, Canada to improve understanding about natural resources in the province. The integration of information through a single access point using data server links and access agreements is intended to build capacity within communities to compile local knowledge, access natural resource information, and promote sustainable community planning.

The focus of CMN is on data collection and knowledge integration for the province of British Columbia, Canada. In the arrangement, the CMN acts as a data steward for contributing organizations, with the data remaining the property of the contributor. Data updating and permission for downloading remains the responsibility of the data contributor. Data entry for new information requires password authorization for security and confidentiality reasons. Using the Web-mapping data entry tools, end users can add new and timely information. Although some information about British Columbia's coastal resources is available in multiple data warehouses, there is a much larger area of the province's coast for which there is no information. The cost of conducting detailed surveys along the entire BC coast is prohibitive, and one estimate is that it would take over 60 years with the best available technology to map the BC coastal seafloor and inshore (Berry, 2003). Using

Figure 1. The community mapping network Web site and access interface



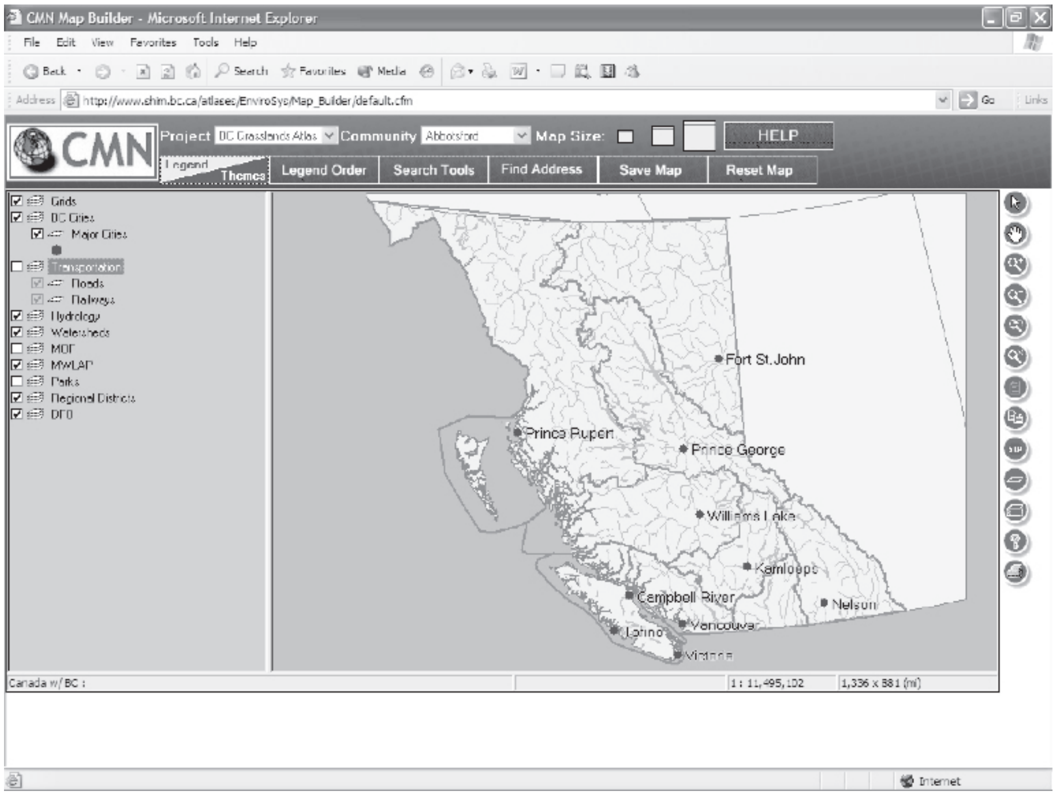
local knowledge is an attractive option that can also encourage residents to use natural resources responsibly.

Study Site and Context

The study area is the Lower Mainland of British Columbia (Figure 2), which is one of North America's most biologically diverse areas. The resources in these areas are especially valuable given the increasing trends and patterns towards human population expansion (Porter, 2002).

The roles and capabilities of the federal, provincial, regional, and municipal levels of government also need to be taken into consideration in these conservation efforts. At many levels of governments, sufficient funds are not available to acquire or manage all sensitive natural areas that need protection. Also, the ability of governments to regulate potentially detrimental activities on public or private lands is limited by a shortage of staff, political mandate, conflicting policies, and a complex array of regulations. Federal and provincial agencies are tasked with the environmental review of development projects, but this has been rather fragmented and municipal governments have often refused to accept the guidance of these review agencies. Moreover, the rapid growth and development in these areas often overwhelms the capacity of local planners to manage land and preserve sensitive habitats. Sometimes the development proposals are received late in the planning process and may be reviewed without detailed knowledge about the value of sensitive

Figure 2. Map showing the British Columbia study area from the CMN Map interface



habitats at the location. The levels of government are under increasing pressure to respond to the expanding resource development in current and emerging populated areas.

The information available from government sources alone is not comprehensive or detailed enough for land-use planning in settlement areas. Existing federal and provincial geospatial databases do not have adequate site-specific information about sensitive habitats, and are usually not available at a scale (1:5,000) required for local land-use planning. The process to update the government databases or to record observations about new species of concern or marginal habitats that are important to communities is also problematic. Valuable local knowledge and unpublished environmental surveys can be lost with time as people relocate. Sensitive habitats such as urban and smaller rural watercourses, eelgrass beds, riparian areas and wetlands remain unknown and poorly understood. There is a need to collect new information about the distribution and growth of invasive species as well as the location of wildlife, and rare and endangered species. Some groups have also started to collect local data to support community planning and management; for example, the Wildlife Tree Atlas hosted on the CMN Web site.

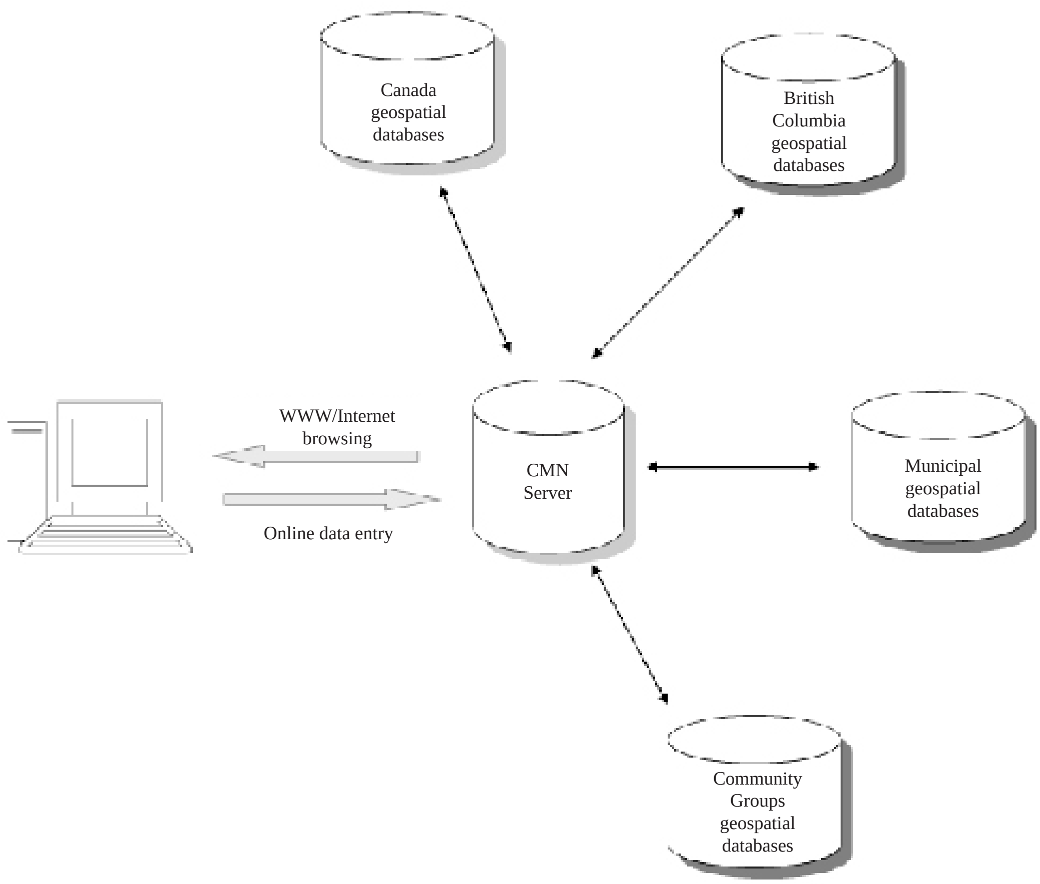
Establishing collaborative partnerships between local stakeholders and government is an effective means to complement available knowledge about the environment. This requires local communities to access, understand, and contribute relevant information and resources necessary to practice stewardship and conservation more effectively.

Web GIS System Design

The Web GIS system design integrates community-based and government natural resource information into geospatial databases for display on the Web using the Autodesk MapGuide GIS software (http://www.mapguide.com). There are three components to the MapGuide software that facilitate the Web GIS process. First, the MapGuide Server handles requests by the Web browser and returns map data in the form of image snapshots. Second, the MapGuide Author creates digital maps that can then be published on the Web server. Maps are published by copying the generated map file to the Web server, and either embedding the map in an HTML Web page, or pointing users directly to the map file. Third, the MapGuide Viewer allows client-side access and manipulation of the maps. The viewer requires a free plug-in to be installed at the client-side to enable the maps to be displayed in the Web browser.

The design included multiple Web servers to share the workload of serving province-wide base maps, high-resolution orthophotographs, and

Figure 3. The CMN distributed network of data and Web servers



other thematic maps (Figure 3). The databases are hosted on several servers and connected by a computer network. For example, watercourse features on the CMN server are linked to the federal/provincial Fish Wizard and Fisheries Information Summary System. Reports are generated in real time from the federal and provincial systems by querying and selecting individual watercourses from the CMN server map interface. Also, the map display can be customized by choosing layers of information from among those available in both raster and vector GIS format. Navigation and mapping tools allow users to move around the map, query the data, add information, and edit existing data.

The CMN application is password controlled with four levels of users: government agencies who manage their own data, community data editors who enter information about local knowledge, system administrators and data verification personnel, and the general public.

The maps and natural resources data are "Web served" by CMN to assist communities and local governments with land-use planning, promote conservation and protection of sensitive habitats, and raise awareness about ecological values. There are currently over 33 separate atlases being developed and used on the CMN with different levels of support, functions, objectives, and audiences. The atlases vary in the amount and quality of information collected. Table 1 shows three of the atlases currently available as cases to demonstrate the general focus, content, and objectives of the CNM-community collaborations.

Table 1. Three CMN atlases developed with communities and stakeholders

British Columbia Invasive Species (BCIS) Atlas The Langley Environmental Partners Society (LEPS), a non-government environmental organization, created this atlas to assist mapping invasive species that are jeopardizing the ecological balance in southwestern British Columbia. The purpose of this Atlas is to inform public of the growing concerns associated with invasive exotic, alien and noxious plants. Specifically, this site describes key features of ten common invasive plants, emphasizing identification and control techniques. Hopefully, the following information will be of use to community groups and individuals who are interested in taking an active response to the escalating problems associated with invasive plants.	
Sensitive Habitat Inventory and Mapping (SHIM) Atlas The SHIM Atlas allows users (with password access) to digitize new map layers and enter new information on local resources directly into the Atlas over the Internet. This user provided mapping information is intended to augment and potentially enhance local land use planning maps and/or specific site or detailed planning surveys. The primary functions of the atlas are to identify sensitive habitats, integrate spatial knowledge about sensitive areas, and establish partnerships with governments, stakeholders and the public.	Wildlife Tree Stewardship (WTS) Atlas The Vancouver Island Wildlife Tree Atlas is an online database of known Wildlife Trees on Vancouver Island showing locations, observations, and productivity of Eagle nests. The Atlas helps to keep the community informed, interested, and participating in land stewardship. The Atlas leads to an increase in the protection of valuable wildlife habitats in the form of stewardship agreements, land covenants, municipal plans and bylaws, and enforcement of current provincial and federal wildlife tree protection.	

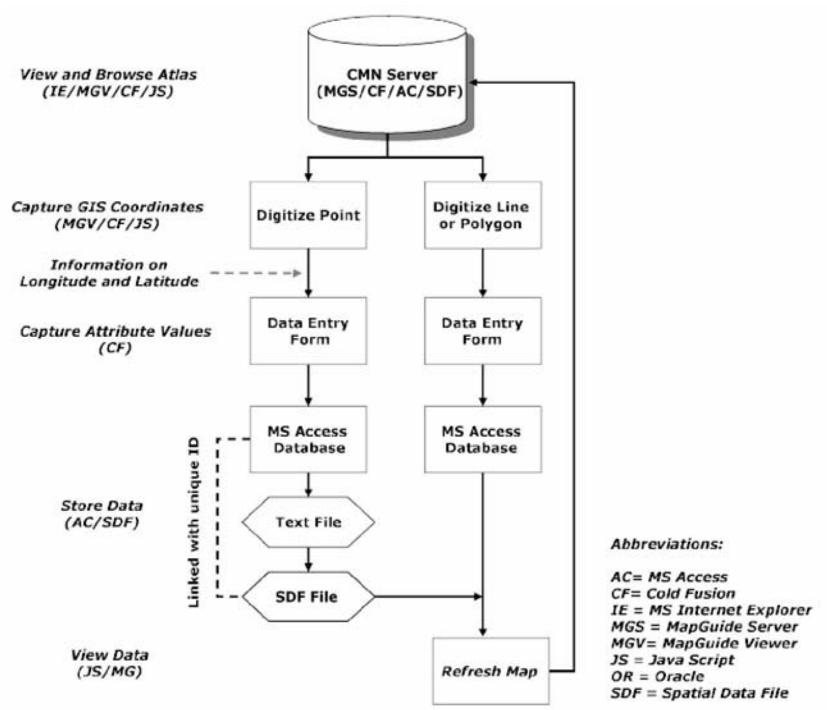
Knowledge Management Design

Knowledge management consists of the tools, techniques, and processes to collect, retain, analyze, organize, improve, and share understanding about data and information, and to use that understanding towards meaningful action (Wang, Hjelmervik, & Bremdal, 2001). The action that results is a consequence of understanding past experiences and potential solutions for addressing a particular problem. In this regard, the knowledge tools, techniques, and processes developed by CMN for two data entry workflow processes are presented and discussed.

In the first workflow (Figure 4), data entry can be initiated using the Internet Explorer browser by downloading and installing the MapGuide viewer or plug-in. The viewer or plug-in can automatically be installed when accessing a map from the CMN Web site, or loaded manually from the Autodesk MapGuide Web site. The viewer allows the end user to interact with the Cold Fusion (http://www.macromedia.com) functions of the CMN Web server. Password protection prevents unauthorized access to the data entry tools. Both vector and raster maps from various sources with different levels of resolution are provided to assist in locating a position of interest. The common

Figure 4. Example of a data entry workflow process for the CMN system



zoom, toggle, and go-to map queries allow users access to specific locations such as place names, map sheet numbers, and coordinates collected through global positioning surveys. Users can also request summary reports about the various spatial data on the map.

Users must zoom in below a predetermined scale before digitizing and data entry tools become functional to help improve precision (Figure 5). The data entry process is initiated by clicking with the computer mouse on the desired location on a map. A JavaScript function captures the latitude and longitude of the location and passes this information as text to a Cold Fusion data entry form. For points, lines, and polygons, all the coordinates are captured. Alternatively, another function is available to translate the latitude and longitude of the locations to the projection of the current map.

The end user must fill in the data about the new digitized feature and submit the form (Figure 6). Information entered in the form as well as the coordinates captured from the map are transmitted to a Microsoft Access database on the CMN server. For points, the latitude and longitude fields of the database are used to display them directly on the map. For lines and polygons, a spatial data file (SDF) is generated. This SDF is created by exporting a unique ID for each set of coordinates to a temporary text file. A batch file is then executed to activate the MapGuide SDF Loader program which then translates the text file to an SDF file. The SDF file contains lines or polygons coordinates with their unique ID used

Figure 5. Navigation tools to improve precision of digitizing and data entry

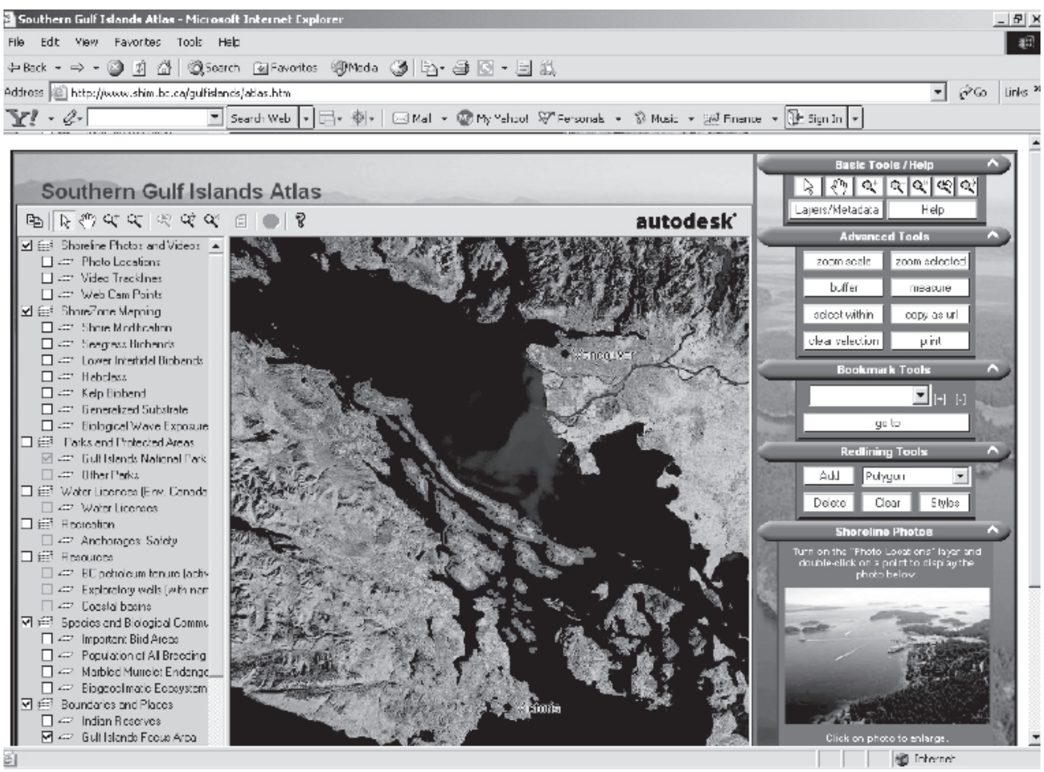


Figure 6. Data entry tools interface with the entry form and editing toolbar

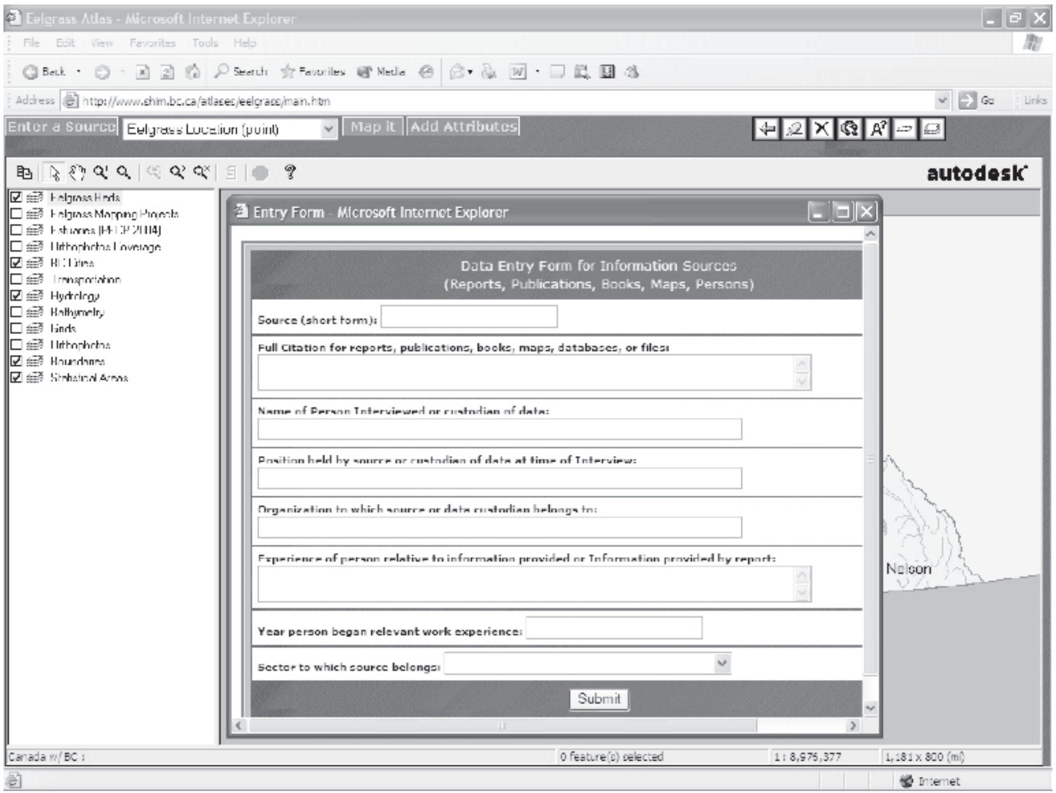


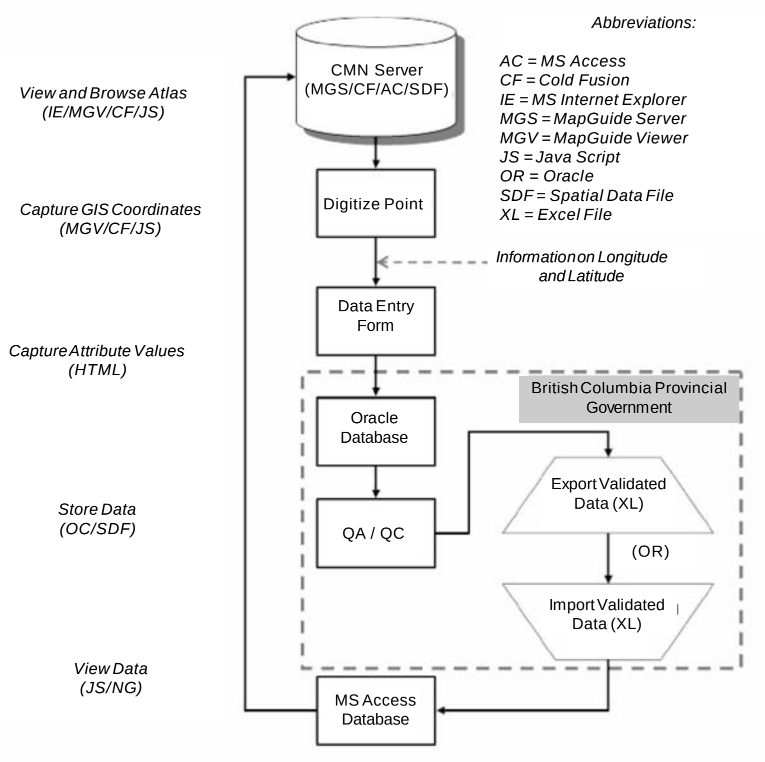
to link with the data in an MS Access database. The map is automatically refreshed and the new digitized features plotted on the Web map.

In the second workflow (Figure 7), the capability of the end user to install the MapGuide viewer and digitizes a point is shown. The Cold Fusion link starts an HTML form on the provincial government's Water, Land, and Air Protection web site using an embedded JavaScript function. The user completes the data about the new digitized feature and submits the form. The information entered in the form and the coordinates from the map are transmitted to an Oracle database on the province's server.

The data entered are validated before they are plotted. The provincial government further reviews and refines the data accuracy. Validation and quality control of the input data are accomplished by training of end users, password protection at multiple levels, data checks by CMN staff, and by correlations with orthoimagery and map overlay analysis. The validated data is then exported to a Microsoft Excel spreadsheet and sent to CMN. The CMN server imports the spreadsheet into a Microsoft Access database and displays the map data in a browser window.

The focus of the application is to represent and combine multiple forms of knowledge. The knowledge may be in the form of data, information, methods, tools, and processes that provide some understanding about a problem situation. The knowledge can be derived using scientific

Figure 7. Example of a data entry workflow with automatic file conversion



methods or can be based on individual experiences. The spatial framework of the Web GIS allows these forms of knowledge to be stored and related to a spatial entity on the map. In this study, the goal is on knowledge storage and not knowledge conversion or validation. Before "tacit knowledge" can be converted to "explicit knowledge" it must first achieve a state of "common knowledge" that is understood and accepted by the user community. The CMN facilitates the process of forming common knowledge as a pre-requisite to examine more closely in the future the issues related to knowledge conversion, validation, and transfer.

THE EELGRASS MAPPING APPLICATION: A CASE STUDY OVERVIEW

The CMN contains many mapping applications arranged according to ecological themes. The general knowledge collection and data integration processes are the same for all the mapping applications. The Eelgrass mapping application is discussed in more detail in this section.

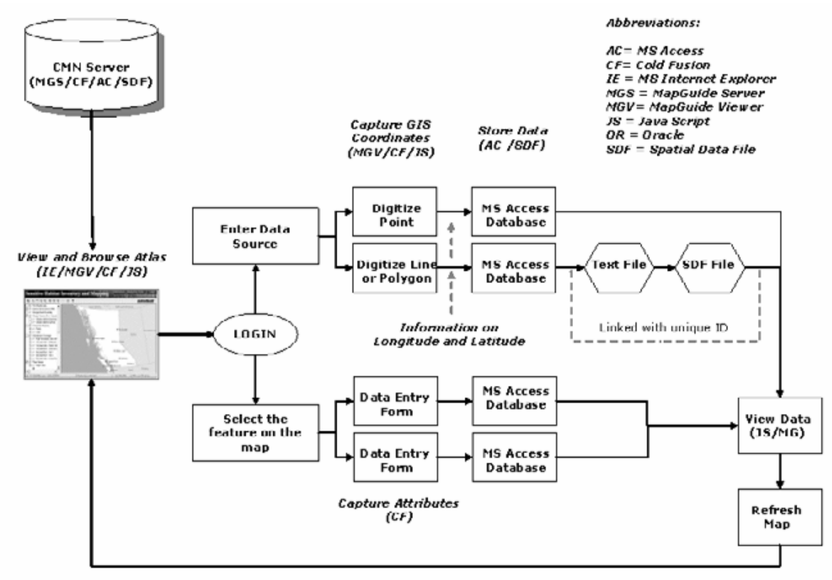
The Eelgrass beds such as those found in Boundary Bay, British Columbia (BC) provide complex and intricate food webs that rival the world's richest farmlands and tropical rainforests (NOAA Auke Bay Laboratory). Eelgrass beds grow on mud and sandy intertidal and subtidal areas and provide a diverse habitat of leaves that supply nutrients to fish, shellfish, waterfowl and numerous other faunal invertebrates. Many species use Eelgrass beds as nursery areas and others burrow in the sediments. Dungeness crabs, a valuable commercial species, often move into Eelgrass meadows to molt in the spring. Breeding occurs in the nearshore areas and females move to deeper water to hatch eggs. The juvenile crabs live in intertidal areas, hiding beneath and among plants, rocks, and Eelgrass beds. Threats to crab habitat include shoreline modifications and disruption of Eelgrass beds. Eelgrass beds help prevent erosion by cushioning the impact of waves and currents and hold sediments in place. This protection helps preserve highly productive bacteria in the sediments which nourish the invertebrate crab population. During low tides, eelgrass provides shelter for small animals and plants from extreme temperatures by retaining moisture and providing cover (Wright, 2002). Within the Eelgrass beds there is food and shelter for a wide variety of sea anemones, marine worms, snails, limpets, crabs, birds, and fishes.

There is now increasing interest among local communities in BC to map and monitor Eelgrass beds in the coastal parts of the province (Dunster, 2003). In 2003, the CMN developed the Eelgrass atlas to streamline the collection and dissemination of spatially geo-referenced information for coastal BC. Although much of our coastal resources knowledge still remains in the form of unwritten traditional ecological knowledge, there are also many databases and GIS layers that reside on different servers in a range of agency data warehouses (Booth, 2005). The Eelgrass atlas is designed to integrate this information and make it accessible to users using a central internet location. As such, local and regional agencies and non-government organizations can access the best available information for their area. There are many uses for mapping and monitoring eelgrass beds including habitat referrals for foreshore leases and licenses; oil spill contingency planning and response; community shoreline planning and zoning; provincial coastal planning; provincial and Federal Marine Protected Area analysis; and fisheries research which looks for correlation of marine resources with habitat.

In the Eelgrass mapping application, authorized users login to the web site and browse the contents using interactive maps containing detailed resource information. Users can digitize the location of new Eelgrass beds as a point, line or polygon, enter attribute information and submit the new information to the CMN server for validation (Figure 8). The new Eelgrass bed location is immediately published back to the Internet map for viewing and querying. This "real-time" application also provides other features including updating or deleting previously digitized data and generating customized data reports. When the shape of the new feature is digitized, a customizable HTML form is provided to enter attribute information. Features must be selected on a map to obtain an up-to-date report generated directly from the database.

The metadata for each observation is also collected with the location and attribute information (Figure 9). For example, the information source and mapping method must be provided. The system allows users to review the sources of the information and the relative accuracy of the observations. In time, any observation that does not have adequate ground-truth information can be subjected to more detailed examination and

Figure 8. Data entry workflow for the eelgrass example



updated. Nevertheless, the "suspected presence" (of any species or habitat) presents a foundation to begin coastal resource planning decisions.

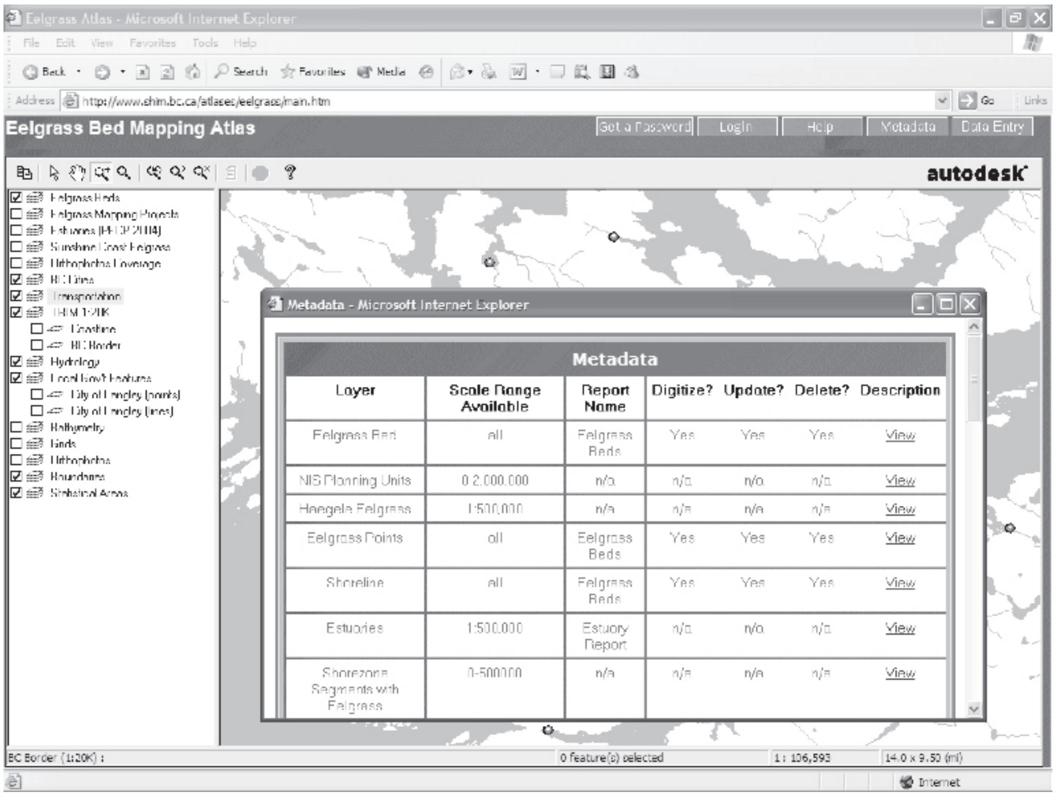
Training related to mapping Eelgrass beds and data entry was provided to over 20 coastal communities. At present there are 28 user accounts for data entry and 9 users have so far entered data online or provided spatial databases. Most Eelgrass beds data were initially geo-referenced as points using a GPS in the field as compared to using visual cues from memory. The GPS points were digitized online using the data entry tools of the CMN application. Some Eelgrass data was submitted on disk in various file formats including Microsoft Excel and ESRI shapefiles. These were integrated into the application. Once the Eelgrass beds are shown on the map, users can update the attributes and metadata information on individual Eelgrass beds.

One benefit of this work is that the provincial government has now acknowledged the presence of data gaps in the coverage of critical resources and will use the data collected by communities if the data is accurate and to some standard. CMN has created a number of standards to ensure that the collected data is of a good quality. The foundation is now in place for communities to work closely with government in managing local resources.

CHALLENGES AND FUTURE DEVELOPMENT

The development of online tools that connect spatial observations to attributes is a large step towards improving data collection efficiency. The CMN applications provide a suite of tools for data

Figure 9. Metadata tools interface for an observation in the eelgrass atlas



collection, access and query, sharing, and updating of environmental knowledge. However, a challenge for users is digitizing the geographic features online when the UTM projection coordinates are obtained from sources such as a hard copy map, Microsoft Excel spreadsheet or ESRI shapefile. The coordinates must be integrated into the web application and this represents a tedious task. A function to upload a set of coordinates and automatically generate lines or polygons would be an ideal solution. Also, creating a function to upload a background ESRI shapefile or a geo-referenced image can enhance the digitization process (Hu, Gabriel, & Bodensteiner, 2003). General issues of importance when integrating community participation and mapping technology for planning and decision making include institutional conflicts, the lack of end user training, no consistent standards for data collection, and the need for more data and information (Al-Kodmany, 2000; Balram, Dragicevic, & Meredith, 2004; Kyem, 2004). The feedback obtained from the forms available on the CMN website together with comments and suggestions gathered at community workshops were used to refine and update the application.

The ability to easily access existing digital databases is essential for timely planning and decision making (Laitinen & Nuevonen, 2001). However, this can be a challenge because of copyright, privacy and security reasons (Foo, Leong, Hui, & Liu, 1999). In the CMN infrastructure, existing information is made available and an understanding of data gaps is highlighted to encourage more collection and updates. It is important that new environmental information is added to the system. When end users see that their contributions are integrated into the system, they can be motivated to continue providing more information. User-interface design is also an important factor to be given continuous consideration when modifying existing systems (Guttler, Denzer, & Houy, 2001). Another issue is expertise level needed to use the system. User interface and expertise level can affect the choice users make about digitizing real world features as points, lines, or polygons. Login procedures, databases and attributes needed, and internet access speeds are other factors influencing how users interact with the technology.

The use of GPS field measurements allows easy data entry and integration. However, compiling information especially spatial information from interviews or from memory is problematic. It is difficult to digitize the location of features for a number of reasons including the concern that the information provided may not be accurate. Error estimates can be incorporated in the metadata.

Developing knowledge management systems (KMS) from the ground up and for long term sustainability require that these systems are embedded in the community. Communities depend on information from sources such as a KMS to make informed planning choices and management decisions. Also, communities understand the issues involved in the local planning processes (Pettit & Nelson, 2004). Hence, building a system to address local issues is much easier than building a regional or provincial system. The CMN has a role in building regional and provincial systems and integrating them with community data. This raises the issue of system and data standardization that is suitable for all interested participants. A system design that meets the needs of all communities is more difficult than customizing applications for local use. The process of building a system within a community ensures buy-in as opposed to getting people to conform to a pre-built system (Kelsey, 2003; Lewan & Soderqvist, 2002).

CONCLUSION

The Community Mapping Network provides a robust infrastructure for spatial data collection, access and query, sharing, and updating of environmental knowledge. The system was developed and customized to meet the specific needs of local community planning. The Autodesk MapGuide software was used as an "out of the box" solution for publishing digital maps on the Internet. Further, additional data entry, query, and update functionality were embedded in the application using the Cold Fusion, Javascript and Visual Basic programming languages.

New methods and standards were developed by the Community Mapping Network and included a Sensitive Habitat Inventory and Mapping methods for fresh water and coastal areas. These methods and standards are freely available; new projects are also assisted with the provision of training, loaning of equipment, and securing of funds (CMN, 2005). The standards and quality assurance procedures ensure that any new information about knowledge becomes fully integrated within existing systems and serve the needs of a wide user community. Additional information about the standards and methods are available on the CMN website.

The CMN facilitated the sharing of basemaps and natural resource information related to communities in British Columbia, Canada. The growth of the system depends on continuing efforts to build and serve local databases and integrating them with province-wide basemaps and databases. This also depends on the ability to establish new partnerships and data sharing arrangements and building community capacity to manage local datasets. Community groups and natural resource managers are always being encouraged to form partnerships with the CMN to continue building new systems and expanding the knowledge base about the region. The sharing of basemaps and databases among partners using a distributed data model allows a more seamless display of information layers.

The CMN is built incrementally for targeted end uses and is sensitive to users' needs. By streamlining data distribution and decision support across communities in British Columbia, operational costs can be reduced and maps and data delivered to communities that need them. Computer code is re-used to build on existing applications and so reduce costs for new application development. Reducing decision times will allow communities to better address development proposals and planning initiatives. The CMN is designed to improve planning and decisions by making information and knowledge more easily accessible and available.

There are many ongoing mapping projects. These projects provide an opportunity to refine and modify the overall CMN approach. Local habitat atlases, customized for use by local government planners and developers, have been used to support Local Resource Management Plans, Official Community Plans, and Watershed Management Plans in a number of BC regional districts (CMN, 2005). The resulting atlases have helped to define Development Permit Areas and have been used to identify candidate areas for protection, enhancement or restoration. The atlases have also assisted local regulators in administering the Forest Practices Code, the Water Act, the Land Development Guidelines, and the Local Government Act, and will assist in future implementations of the Riparian Area Regulation (BC Reg. 376, 2004). Placing environmental information in the hands of the communities and local governments can encourage a sense of ownership and more collaborative stewardship of natural resources. If governments, planners and decision makers are to leverage the information society for the benefit of society, then they must lead by example. The CMN is an ongoing initiative and is being aligned to address this need.

ACKNOWLEDGMENTS

The authors are thankful to Suzanne Richer, GIS Analyst of the Community Mapping Network (CMN) Project for maintaining the CMN website and for providing some figures used in this chapter. Suzana Dragicevic was supported by a Simon Fraser University President Research Grant (PRG) and a Social Sciences and Humanities Research Council (SSHRC) small grant. In addition, the authors are thankful to the reviewers for their valuable comments and suggestions that improved the quality of the manuscript.

Chapter 2.28
Building a Dynamic Model of Community Knowledge Sharing

Geoffrey A. Walker
University of Northumbria, UK

INTRODUCTION

Many case studies have been undertaken about how informal, sponsored, and supported communities of practice operate within private and public sector organizations. To date, however, no examination has been made of how informal communities of practice operate within the third sector, the sector of community, and voluntary organizations. The third sector has a long history of using community space, in various forms, either physical or notional, to engage individuals in discourse and informal learning. The rise of the network society has added value to this process by allowing active individuals to personalize networks through the use of technologies which enhance communication. The third sector is now demonstrating that individuals and groups are seeking to create open access knowledge-sharing spaces which attempt to combine face-to-face networks with computer-mediated communications to support informal learning between community development practitioners.

This article examines the role of Sunderland Community Development Network in the creation of informal communities of practice. It pays particular attention to three key areas:

1. Community space: How core, active, peripheral, and transactional community spaces within third sector partnerships create an ebb and flow of informal communities of practice.
2. Personalized networking: How issue-based activity, inside and outside communities, can lead to the rapid appearance and disappearance of informal communities of practice.
3. Knowledge-sharing space: How core members of a third sector organization can create a dynamic model of roles within informal communities of practice capable of impacting upon processes of governance beyond the organization.

BACKGROUND: SUNDERLAND AND THE COMMUNITY DEVELOPMENT NETWORK

Sunderland is a new city in the North East of England with a population of 300,000. Toward the end of the last century, it suffered adversely from the post-industrialization process. Both shipbuilding (ships had been built on the River Wear for over 1,500 years) and coal mining (Monkwearmouth Colliery was one of the largest deep mines in Europe) went into terminal decline. The dawn of the new millennium, however, has witnessed an economic, social, and cultural renaissance in the city. Sunderland's Nissan car plant is now the largest in the UK with 12,000 employees. Sunderland University has a new riverside campus adjacent to a thriving marina and an emerging shellfish industry. Sunderland Football Club has a new arena (built on the former site of Monkwearmouth Colliery), boldly titled "The Stadium of Light", and there is an award-winning museum and winter gardens in the heart of the city center.

Sunderland Community Development Network (SCDN) forms the neighborhood-based component of the city's renaissance and is open to community groups, community networks, voluntary sector organizations, volunteers and residents who are, or want to be, active in their communities.

The aims of SCDN are to link together neighborhood renewal (Social Exclusion Unit 2000) areas of the city in communities of practice; maximize the power of communities to shape the future of the city; provide a decision-making and discussion forum for communities; provide effective, meaningful, and coordinated representation at all levels of the city council's Local Strategic Partnership (LSP); and provide a structure of accountability for community representation and the communication of information. The concept of partnership working in this manner was first suggested in a document produced by the Neighbourhood Renewal Unit (2001). In summary, SCDN aims to capture, store, and transfer the wide range of knowledge contained within Sunderland's community-based organizations and make this knowledge accessible to other sectors.

THE EMERGENCE OF SCDN

SCDN has been emerging as a meta-network since September 2001 under the innovatory leadership of VOICES. VOICES was originally established as Sunderland Voluntary Sector Partnership (VSP) in 1994, and since September 1994, has played an active role on the City of Sunderland Partnership (CoSP). Three community development workers were appointed in May 1998 to develop networks in areas where there was no existing infrastructure and to build the community and voluntary sector in the city. In 2000, the VSP gained charitable company status in the name of Sunderland Voluntary and Community Sector Partnership. The official launch of the new company was held in October 2000 to coincide with the signing of the local compact between the CoSP and the voluntary and community sector. The name VOICES was adopted to reflect the role of the VSP in ensuring local people's needs, views, and opinions are integral to the decision-making processes of policy makers at local, regional, and national levels.

The core group of VOICES has many years of experience of community development activity, stretching back to the 1970s, long before the introduction of the Internet and other network technologies. Some members of the core group have taken readily to e-mail and other network technologies while others struggle with it. All, however, are very skilled face-to-face networkers and demonstrate a high level of trust in the communities they support.

The meta-network provides a range of knowledge-sharing platforms through which dialogue can flow, both formally and informally. These platforms include formal strategy meetings, informal lunches, events and residential conferences, and seminars as well as sharing documents and discussion via e-mail and the Internet. Key informants constantly refer to the informal dialogue, which takes place before, after, and around meetings. The informal sharing of knowledge is seen to lie at the hub of the collective learning and knowledge-sharing process, which takes place within the meta-network. Access to knowledge is sought in a seamless way by combining face-to-face informality with document sharing and the use of e-mail, firmly grounded in the needs of communities. Knowledge is also accessed via the mobile telephone and text messaging which adds value to the use of other technologies. A high level of trust is placed upon individuals with key skills and competencies within the network, as containers and carriers of knowledge on community development.

SCDN has been debating, for more than 2 years, the importance of legitimizing peripheral participation (Lave & Wenger, 1997) within the network and the LSP. Legitimate peripheral participation provides a way to speak about the relations between newbies, veterans, activities, identities (Wenger, 1998), communities of knowledge (Brown & Duguid, 1991), and practice. It is concerned with the process by which newcomers become part of a community of practice (Wenger et al., 2002). As a result of this debate, a model has been devised which aims to provide a means of legitimizing peripheral participation within it.

In this model, members of the network are divided into a tripartite framework of community development responsibilities within each of the 12 themed and 6 area-based neighborhood renewal groups of the LSP, as follows:

1. Capacity-builder: With previous partnership-working experience, well-developed informal and formal meeting skills and knowledge of decision-making structures.
2. Mentor: With experience of representation or other partnership working.
3. Learner: With experience of meetings at a neighborhood level but no previous representation experience.

Clearly, individuals tend to exhibit all of these roles to a greater or lesser degree. In terms of the meta-network, however, these three roles form a dynamic learning framework for the community participants within the 18 working groups of the LSP. It is clear that this tripartite framework creates a dynamic model for developing informal communities of practice as the three roles constantly combine and disperse leaving critical masses of knowledge which can be accessed in a number of ways through:

1. The manipulation of the spaces where communities are formed.
2. The establishment of personalized networks.
3. The creation of knowledge-sharing spaces.

COMMUNITY SPACE

The traditional gathering place of community activists for centuries has been the village hall, community center, or their physical equivalent: the place of democratic engagement and dialogue on issues affecting the community. Community activists often put forward the view that it is possible to create an equitable community space, both mental and physical, where the views of individuals and groups can be freely exchanged in a form of true participatory democracy. Such a belief can be seen as an extension of the concept of agora where the creation of a level playing field, by definition, leads to engagement in the free expression of ideas, opinions, and innovation.

Does such a shared mental and physical community space exist, however, when the barriers to effective use of place, space, and cyberspace are manifold?

Several commentators have grappled with the concept of community space. They have revealed a complexity, which goes far beyond that manifest in village halls and community centers. In order to understand this complexity, the following concepts are now examined in turn: community space, liminal space, reproduction of space, defensible space, the space of flows, and the semiotics of global space.

Wenger (1998) talks of community space in which groups operate. The facilitators, innovators, and leaders occupy the core space. Active, interested individuals inhabit the active space. Interested individuals who are not necessarily active occupy peripheral space, and the transactional space is where partnerships are forged. This paradigm suggests the existence of four distinct community spaces. It does not, however, explain how groups apparently move with ease from one space to another or alternatively occupy several spaces simultaneously. For example, individuals may well occupy core space in one group, active space in another, and so on. SCDN's tripartite framework means that the dynamic roles cut across the boundaries of community space.

By introducing the concept of liminal space, we can envisage how individuals and groups journey between the spaces outlined above. Liminal space, an anthropological term, refers to the limbo which an individual inhabits while performing a rite of passage between one space and another. A physical example of this space is the Aboriginal "Walkabout" where teenage aborigines must spend time alone surviving in the outback prior to acceptance as an adult member of the group. A comparison can be made here with the concept of a lurker in an electronic environment or a learner within SCDN. Lurking in an electronic environment would be considered a form of situated learning by Lave and Wenger (1997) and, as such, a legitimate form of peripheral participation. Adding the concept of liminal space to the paradigm creates a new dynamic, which does, at least, appear to go some way toward illustrating how individuals and groups occupy several spaces simultaneously.

Puttnam (2000) refers to the bridging and bonding of social capital within communities. Social capital is created either by forming bridges between communities or bonding communities where they share common characteristics. It is, therefore, legitimate to suggest that social capital is formed in liminal space.

Lefebvre's (1991) discourse on the relationship between mental and physical space highlights not only the production of community space but also the reproduction of this space:

The problematic of space, which subsumes the problems of the urban sphere…and of everyday life, has displaced the problematic of industrialisation. It has not, however, destroyed that earlier set of problems: the social relationships that obtained previously still obtain; the new problem is, precisely, the problem of their reproduction. (p. 89)

In physical terms, former British Prime Minister, Winston Churchill, went some way to expressing the relationship when he said:

There is no doubt whatever about the influence of architecture and structure upon human character. We shape our buildings and afterwards our buildings shape us.

SCDN, like many other networks, has experimented extensively with variations in physical space in order to facilitate knowledge sharing. However, are there human and psychological constructs which influence individual and group behavior in community spaces?

Building upon the idea of human structures, Goffman (1959) derived the concept of defensible space, the cognitive space between individuals where they form opinions and assumptions of others. In physical space, we can visibly assess people's changing opinions through human interaction, which is supported by body language. In cyberspace, however, where body language can play a different part, defensible space becomes the space of legitimate peripheral participation. Discourse and dialogue in cyberspace can often be viewed as significantly more reflective than that which takes place in physical space. The roles of capacity-builder, mentor, and learner assist discourse and dialogue through enabling conversations on who is learning what, from whom, and the impact of this upon the network.

Castells (1989) argues that access to flows of information and resources is the key to participation in the networked society. He refers to a subtle interaction between physically colocated resources and virtual information-based resources. He calls this space the space of flows. He suggests a further dimension to community space. The space of flows is the personal space, which individuals manipulate, in and around the groups they populate. They create this space by constructing complex problem-solving, personal, social networks. These networks manipulate information and resources on a personal level through a complex web of digital technologies and face-to-face interactions.

Due to the constant and rapid evolution of community space within networked society, SCDN has attempted to create dynamic issue and area-based thematic communities of practice which accommodate the informality of the relationships created. Each member of an issue or area-based group has to relate to other members of the groups in terms of their ability to act as capacity-builder, mentor, and learner. This interaction leads to semiotic relationships between communities of practice with high levels of synergy capable of rapid transformation and dissolution around a particular theme or issue. Such interaction also relies on high levels of personal interaction within networks and meta-networks.

PERSONALIZED NETWORKING

Human networks are hugely complex phenomena. We are only just beginning to understand the implications of understanding networks:

Today we increasingly recognize that nothing happens in isolation. Most events and phenomena are connected, caused by, and interacting with a huge number of other pieces of a complex universal puzzle. We have come to see that we live in a small world, where everything is linked to everything else. We are witnessing a revolution in the making as scientists from all different disciplines discover that complexity has a strict architecture. We have come to grasp the importance of networks. (Barabasi, 2003, p. 7)

In this small world, individuals and groups are as likely to reach out around the globe for knowledge as they are to visit their next door neighbor in search of information (Watts, 2003).

Given this complexity, how do we provide a platform for a networked community?

While face-to-face contact is paramount within SCDN and often cannot be replicated in electronic systems, the constraint of time and space on active individuals has led to the network accepting that the community is not necessarily located in a fixed space. The idea of community being with you wherever you are is a welcome and reassuring idea associated with the trust, strengths, and connections needed for effective networking. As a result, SCDN has begun to use ICT to add value to human systems in a personalized manner, often referred to as personalized networking.

Research into personalized networking (Wellman, 2001a, b) has shown that knowledge transfer and the idea of communities of practice (groups of people that create, share, and exchange knowledge) is relative to situated learning (how useful the knowledge is within a particular situation or toward a particular end). This requires multi-faceted means of creating dialogue where meaning flows through individuals and groups. Initially, however, the quality of the dialogue may not be as important as the process of democratic engagement, as it is often about allowing people to explore new ideas and discarding those that are not fit for purpose. Evidence also suggests that network identity can also emerge through consensual agreement on what is community-based knowledge in the emerging dialogue.

The division of responsibility into capacity-builder, mentor, and learner creates dynamic spaces within personalized networks where knowledge can be shared informally.

Personalized networks appear to vary not only with regard to the skills and experience of capacity-builders, mentors, and learners but also in relation to where the networker is located within community space. It would be relatively easy to map personalized networks if community spaces were mutually exclusive and static. However, such spaces are mutually reliant and dynamic; as such, they are capable of potential highly complex topologies of personalized networks.

Social network analysis tools prove difficult to deploy in such a complex context. A high reliance on subjective and qualitative analysis is needed to understand the complexity of personalized networks within meta-networks. SCDN has attempted to create matrices of cross-cutting usage of technologies such as e-mail, Web, and text-messaging within the tripartite framework. This has proved difficult to progress in a collaborative computer-mediated environment, and progress has been limited to face-to-face workshops.

FUTURE: KNOWLEDGE-SHARING SPACE

In partnership with Sunderland City Council's E-government Unit, SCDN is developing an appropriate architecture for a community technology, into which its collective knowledge can be filtered and codified (http://www.sunderland-communitynetwork.org.uk). Data, information, and knowledge is drawn from a wide range of cross-cutting sources emanating from core groups, activists, peripheral groups, and transactional partners at varying levels. Taxonomies and topologies are created which are dynamic and organic, developed through user-defined language in detailed consultations with network members. For example, knowledge is coded as theme-based, issue related, or network representation related and, in turn, validated through dynamic use by members. All types of knowledge are upheld as equally valid. As more and more people search and use the network's knowledge, the more common definition naturally surfaces according to the emerging dialogue. The key is to build intelligence into analysis of the use of language in the dialogue that emerges.

From the outset of the project, it was clear that a cultural shift was required to get beyond data and information and move toward knowledge sharing among network members. Such cultural problems are widely recognized by academics and practitioners, as most individuals and groups within organizations are comfortable dealing with hard facts and figures rather than soft outcomes as a starting point. This marks the first phase of development of cultural shift and is only useful in the network's thinking if it is accompanied by a roadmap toward appropriate and effective management of knowledge in the long term.

SCDN's first stage of developing a knowledge base consists of compiling information on the actors within the network. This is the point at which the architecture of shared learning space is structured through recognizing the interaction of actors with the emerging architecture. Such structuration (the structuring of social relations across time and space), however, must contain the flux, which allows actors within the network to customize their own personalized networking structures. Understanding the degree of flexibility that actors need to interpret their personalized networks is paramount.

The second stage is referred to as profiling the key skills and experiences which members bring to the network. Profiling is a mix of knowledge supplied by professional community development workers and network members themselves about the network itself. This extends to a need to determine performance according to both external and internal transactional criteria with other partners. The profiling stage begins the process of monitoring and evaluating the level of participation and reification within the dialogue that populates the shared learning space.

The final stage is tooling of network members to meet the increasing demands of personalized networking. This is the stage at which members' skill gaps are identified and filled. As noted previously, SCDN has divided participants in the shared learning space into three key roles: capacity-builders, mentors, and learners. Each actor-role compliments the other around a particular theme such as, health, diversity, and community safety.

Although paper-based forms of communication and telephone calls may not be easily codified, the idea of a meta-network means that these conversations are likely to become embedded within an online application provided that the dialogue is ongoing, regular, and frequent. This is dependent on the overall utility of the knowledge base that can only be determined through the level of usage. Part of the work of Sunderland City Council's E-government Unit is to allow 60 members of the network access to a portable computer and to the Sunderland E-government Web site. In the short term, these people will be able to use the community-based Web portal to see what they might expect in an online environment run by and for themselves. If this enthusiasm is cascaded throughout the network and access is widespread, most members could be accessing their knowledge base most days to add value to their personalized networking.

CONCLUSION

This article has examined SCDN's role in the creation of informal communities of practice. In particular, it has analyzed the part played by the tripartite framework of capacity-builder, learner, and mentor in progressing flexible and dynamic communities of practitioners. The tripartite framework has been examined within the context of community space, personalized networking, and knowledge-sharing spaces. Outcomes to date, as to the robustness of this dynamic model of community knowledge-sharing, are positive; however, the model has not yet reached a significant level of maturity, and the possibility of long-term success remains uncertain.

While the article offers a positive and transferable model of the creation of informal communities of practice, the development of the model has been subject to a number of barriers:

1. The time spent gaining agreement on the model (almost 18 months) in the meta-network. For people who are unfamiliar with informal, dynamic, and flexible working relationships, the model appears simultaneously complex and radical.
2. Agreeing knowledge-sharing protocols with transactional partners where the shared vision did not appear to be as advanced as that of SCDN. The LSP has a wide range of partners, all from different sectors of the economy and all appear to be at different levels of skills and experience in partnership working.
3. The protracted discussions on the creation of a critical mass for the development of the model within the meta-network was hampered by turnover in key personnel. It was recognized from the outset that champions of the model would play a key role in the creation of this critical mass. The skills acquired by the champions in the dynamic working environment led to their rapid

progression to roles within other networks and organizations with a loss of skills and experience to SCDN.

4. The lack of an education program on the tripartite framework for newbies which makes significant connections with veterans. This has developed on an ad hoc basis. There is now a recognition of the need for a strategy which connects skills and knowledge which is evident in the work with Sunderland City Council's E-government Unit.

Chapter 2.29
KAFRA:
A Context-Aware Framework of Knowledge Management in Global Diversity

Adekunle Okunoye
Xavier University, USA

Nancy Bertaux
Xavier University, USA

ABSTRACT

Multiple case studies in India, The Gambia, and Nigeria are the background for an empirically grounded framework of knowledge management (KM). Cultural diversity and gaps in the provision of infrastructure make managing knowledge challenging but necessary in developing countries. These cultural and infrastructural issues are also related to governmental, educational, political, social, and economic factors. These environmental factors interact with organizational variables and information technology to enable or constrain knowledge management processes in the creation and protection of knowledge resources. The framework can help organizations to prepare their KM projects, to reveal problems during the project, and to assess its outcomes.

INTRODUCTION

KM frameworks assist us in establishing a focus for KM efforts (Earl, 2001). These frameworks can also help organizations to approach KM methodically and consciously. They can help to identify a specific approach to KM, to define goals and strategies, to understand the various knowledge management initiatives, and then to choose the best ones for the particular circumstances (Earl, 2001; Maier & Remus, 2001). There have been several proposed frameworks to guide KM efforts in organizations. However, these frameworks do not address KM across the full spectrum of organizational needs (Calaberese, 2000) but instead address certain KM elements. There is, therefore, a need for a comprehensive KM framework that considers the full range of organizational dimensions.

Three reviews (Holsapple & Joshi, 1999; Lai & Chu, 2000; Rubestein-Montano, Liebowitz, Buchwalter, McCaw, Newman, & Rebeck, 2001) have discussed the components and assumptions of the frameworks proposed to date. There appears to be a consensus on the need for a more generalized framework, and, consequently, these authors also outline recommendations regarding such a framework. All agree that the basic components should be knowledge resources, KM processes, and influences. Even though the existing and the suggested frameworks recognize varying organizational contexts, they have not considered differences in the operating environmental contexts. This is similar to the information systems (IS) literature, where very few studies address global diversity (Avgerou, 2002; Walsham, 2001).

The importance of the local operating environmental context has already received some attention in e-commerce (Simon, 2001), ERP (Wassenar, Gregor, & Swagerman, 2002), and IS development methodology research (INDEHELA Project, 1999). Also, King, Gurbaxani, Kraemer, McFarlan, Raman, and Yap (1994) comprehensively discuss institutional factors in information technology innovation. In knowledge management, however, there is a basic need for consideration of the diverse environmental context and how it could influence other issues involved. The framework described here is designed to address that need, by focusing on the local cultural and infrastructural factors that could interact with organizational factors and information technology and the resultant effect on knowledge processes and resources.

GLOBAL DIVERSITY AND SIGNIFICANCE OF A NEW FRAMEWORK

Our view on global diversity recognizes the existence of different organizational contexts and that assumptions cannot be simply made about the pattern of organizational performance and innovations (Avgerou, 2002). For example, the wide gap in the availability and use of ICT across the world, and the influences ICT exerts on globalization, raise questions about the feasibility and desirability of efforts to implement the development of ICT through the transfer of best practices from Western industrialized countries to developing countries, and whether organizations can utilize such ICT in accordance with the socio-cultural requirements of the contexts (Avgerou, 1998; Morales-Gomez & Melesse, 1998; Walsham, 2001). Previous research (Avgerou, 2002; Bada, 2000; Walsham, 2001) concludes that diversity and local context does matter, and that the global techniques employed in western industrialized countries should not be implemented mechanically in developing countries without consideration for the local context (Bada, 2000).

The concept of description proposed by Akrich (2000) also expresses our understanding of global diversity and the significance of a context-aware framework. Akrich argues that when technologists define the characteristics of their object, they necessarily make hypotheses about the entities that make up the world into which the object is to be inserted. They also assume that the designers define actors with specific tastes, competences, motives, aspirations, political prejudices, and the rest. They assume that morality, technology, society, and the economy will evolve in particular ways. In a nutshell, they inscribe their vision, or prediction about the world, into the technical content of the new object. Karsten (2000, p. 21) also suggests that "the functions of these (technical) systems1 are not predetermined, but only evolve within specific, socio-political contexts." Focusing on specific contexts will help to move away from unfruitful general claims and all-encompassing pictures, enabling us to see a technical change as embedded in a larger system of activity, having consequences that depend on peoples' actual behavior, and taking place in a social world in which the history of related changes may influence the new change.

We are aware of the force of globalization and its assumed homogeneity. However, globalization does not mean imposing homogenous solutions in a pluralistic world. It means giving a global vision and strategy, but it also means cultivating roots and individual identities. It means nourishing local insights, but it also means re-employing communicable ideas in new geographies around the world (Das, 1993). The adoption and usage of such a technology framework will vary according both to local socio-cultural and organizational contexts, and to the national context, including government, economic, and political systems, educational systems, and history, culture, and infrastructure (Schneider & Barsoux, 1997).

A KM framework can be seen as an IS innovation (Avgerou, 2001), a technology (Walsham, 2001), or a technical object (Akrich, 2000). Considering the context in which they are designed and their designers, it can be argued that some basic assumptions (to be discussed later) about the KM processes and influences have been inscribed into these frameworks. An attempt to describe and apply the framework in another context might be problematic. Hence, a context-aware framework, with specific consideration for the operating environmental factors and for the organizational factors that are closely related to the environment, could help to move us toward a more universally applicable KM framework, as well as increasing our sensitivity to the importance of global diversity.

TOWARD A CONTEXT-AWARE FRAMEWORK

Theoretical Background

In this paper, we synthesize some of the insights from our studies to build a context-aware framework, including an explanation of its components. The framework is called KAFRA (an abbreviation of Kontext Aware FRAmework). In building KAFRA, we relied on some well-known concepts and theories in organization studies in order to support our arguments. Leavitt (1965) calls for interdependence of organizational variables for effective organizational change, and Scott (1998) asserts that environment and organization are inseparable. The institutionalist perspective of Powell and DiMaggio (1991) also supports the argument on the need to consider the operating environment in a KM framework. Following Pettigrew's contextualist approach (1987), for a study on change to contribute toward a robust theory or framework that can guide practice, it must examine change as a process and in a historical and contextual manner (Bada, 2000). Hofstede's (1997) cultural model and Galbraith's (1977) concept of organization design are also brought in to strengthen the arguments for the KAFRA framework. Initially, the design of the study, data collection and analysis and subsequent theorizing and building of the framework was influenced by socio-technical systems (STS) theory. Thus, we next present a brief overview of the STS theory and knowledge management.

Socio-Technical Systems Theory and Knowledge Management

A socio-technical system is defined as a combination of a social and a technical subsystem (Trist, 1981). Rather than insisting that individual and social units must conform to technical requirements, the socio-technical systems theory emphasizes the needs of both (Scott, 1998). One of the guiding premises of this approach is that work involves a combination of social and technical requisites and that the object of design is to jointly optimize both components without sacrificing one to others. This approach provides a broad conceptual foundation as well as insights into the nature of routine and non-routine work design. STS has been applied both in systems development practice and in the analysis of ICT functionality and organizational changes (Avgerou, 2002; Lyytinen Mathiassen, & Ropponen, 1998; Mumford & Weir, 1979). There has also been application of socio-technical systems theory in KM (Coakes Willis, & Clarke, 2002; Pan & Scarbrough, 1998; Sena & Shani, 1999).

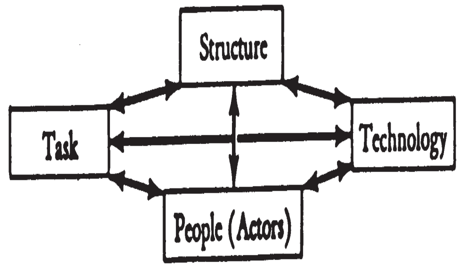
In a similar manner, Leavitt (1965) recognized the complexity and diversity of organizations by identifying four socio-technical variables (structure, task, technology, and people) that need to interact together in a balanced way to bring about organizational change. Scott (1998) added environment as another element, suggesting that organizations and environments are interdependent in terms of information systems and cognitive processes and in terms of environmental effects on organizational outcomes. They are also interdependent in more direct ways, since organizations attempt to directly influence environments and vice versa.

Leavitt's Diamond Organization Model

The Leavitt Diamond (Figure 1) gives a balanced view of the complexities that affect KM framework by positioning technology in strong relationships to the tasks carried out, the people participating in these, and to the organization of the tasks and the people, for example, the structure. It has been widely adopted and cited (e.g., El Sawy, 2001; Mumford, 1993; Schäfer, Hirschheim, Harper, Hansjee, Domke, & Bjorn-Andersen, 1988; Wiggins, 2000) as a basis for understanding organizational changes.

Leavitt's Diamond shows four sets of organizational variables: task, people (actors), technology, and structure. According to Leavitt (1965), these four groups of variables are highly interdependent, as indicated by the arrowheads, so that change in any one usually results in compensatory or retaliatory change in others. Technologies are considered tools that help organizations to get work done and mechanisms for transforming inputs to outputs.

Figure 1. Leavitt's diamond organization model (Leavitt, 1965)



This view corresponds to ours: knowledge management is not only about managing knowledge-work processes or the people that carry out these processes, since technology and organizational structure are also affected. A position explored in the framework is that by studying the balance of all these variables, it is possible to bring out the value of the knowledge management efforts in an organization. Therefore, rather than trivializing any one of the variables or neglecting one set (such as technology), the framework considers all equally and gives priority to all the variables so that knowledge management efforts can achieve maximal success.

Summary

The work of knowledge-based organizations is usually non-routine and needs to be supported by balancing all the variables mentioned earlier. Thus KM from the socio-technical perspective will require all activities that support the social subsystems (the nature of human capital, i.e., the people with knowledge, competencies, skills, experience, and attitudes), a technical subsystem (the production function, i.e., the inputs and the technology that convert inputs into outputs), and an environmental subsystem (including customers, competitors, and a host of other outside forces) (Sena & Shani, 1999). Any framework to support KM should integrate these main variables and put proper emphasis and consideration to diversity in various environments, since all organizations exist in a specific geographical, cultural, technological, and social environment to which they must adapt.

To these general theoretical perspectives on the influence of local diversity in an organization's environment, we add our own insights concerning cultural and infrastructure diversity and their influences on KM based on findings from the multiple case study. The diversity in our study organizations — which include national and international organizations in different research fields — formed the basis for the evidence on contextual issues in organizational variables and information technology. We next present the methodology and approaches to data collection.

The Study

Most of the studies that form the basis of the existing frameworks have been carried out in organizations in Western industrialized countries where there can be similar assumptions about the components of the framework. To add a new perspective, we conducted our study in developing countries. These countries afford us an opportunity to see the differences in culture (Hofstede, 1997) and infrastructure provision (The World Bank Group, 2004) at the local level. An empirical study was conducted on KM in six research organizations in Nigeria and The Gambia and two research organizations in India. Nigeria is representative of countries in sub-Saharan Africa due to its large population and huge natural resources. Oil exploration has particularly attracted many multinational companies that are characterized by Western management styles. The Gambia presents a contrast to Nigeria as one of the smallest countries in sub-Saharan Africa but with a reliable infrastructure. India is representative of countries in South Asia, by population, culture, and business environment. India is a major site for offshore software production (Lateef, 1997), and it was anticipated this would be evident in both the environmental context and the organizational variables. The advances of India in software business and the commitment of government in knowledge-based activities make it a strategic place to study KM. However, these industries are in the minority and could not be viewed completely as indigenous. The methodology used was a multiple case study (Yin, 1994) with data analysis carried out on the organizational level (Korpela, Mursu, & Soriyan, 2001). Both quantitative and qualitative data was collected using questionnaires, interviews, nonparticipant observation, and reviews of historical documents.

The discussion in this paper summarizes relevant aspects of these studies. The results show differences in assumptions on the influence of KM, especially when the local operating environment context is considered. Our study shows how the availability and use of information and communication technologies could support KM processes and how the Internet especially appears to provide a gateway to the international research community. This would suggest raising IT to be a major component in a comprehensive KM model. These findings also indicated some issues about leadership, structure, and culture that are contextual to each organization and the environment in which they operate. A conclusion of our study is that a KM framework needs to have contextual relevance for organizations in diverse social-cultural environments. It should align information technology, people, structure, knowledge processes, and socio-cultural and organizational influences to make knowledge management sustainable.

Research Methods

The contextual issues in a KM framework were studied through a multiple-case study and analysis of eight different research organizations. Yin (1994) observed that the triangulation of multiple sources of evidence permits convergence and corroboration of findings and building a stronger, more convincing basis for conclusions. While the conduct of a multiple-case study can require extensive resources and time, the evidence is often considered more compelling than from a single case, and the study can be regarded as more robust. We carried out our study in two countries in sub-Saharan Africa, in Nigeria and The Gambia, and in two organizations in India. These countries have different levels of infrastructure and cultural differences. For example, in telecommunications, The Gambia has a significantly higher penetration (The World Bank Group, 2004). We assumed there would also be differences in organizational infrastructures across countries.

The Case Organizations

Of the six organizations in Nigeria, three are international: International Institute of Tropical Agriculture (IITA), Medical Research Council Laboratories (MRC), and International Trypanotolerance Center (ITC). Three are national: National Agricultural Research Institute (NARI), Nigeria Institute of Social Economic Research (NISER) and Nigerian Institute of Medical Research (NIMR). The national organizations are mainly dependent on the national government for their basic funding. Usually the international organizations have a substantial number of expatriates working in them for the duration of their project. Three of the organizations are large, with more than 500 staff members. The smaller three have 100-200 staff members. All of the organizations carry out their research within several sites. Also, all of them have in-country and international collaboration with other institutions. Thus, they all work in a wide network of sponsors, customers, and cooperating institutions. India's two organizations are International Crop Research Institute for the Semi Arid Tropics (ICRISAT), an international organization with a staff of more than 500, and National Institute of Mental Health and Neuroscience (NIMHANS), a national organization also with a staff of more than 500.

The study used several methods of data gathering. The two main questionnaires were the KM diagnostic and the information technology infrastructure (ITI) services assessment instrument (see Okunoye & Karsten, 2001 for more details). These were complemented by semi-structured interviews and short-time on-site observations of knowledge management enablers.

Organizational documents and presentations by senior management about their KM-related initiatives were collected and analyzed. A similar approach in data gathering has been applied in a study on the relationship between IT infrastructure and business process re-engineering (Broadbent, Weill, & St. Clair, 1999). Between January and March 2001, we visited all six organizations in Nigeria and during the summer of 2002, we visited the two organizations in India. The visits lasted for about two weeks each. Some of the research sites of each organization were visited and as many as possible of the relevant people were interviewed, especially the heads of sections, the IT managers, and the librarians, to fill out the questionnaires and to provide the documents. Individual researchers provided valuable insight into the actual work processes. In the Nigeria study, a total of 48 people participated in the research: 29 were interviewed and did the questionnaire, eight did the questionnaire only, and 11 were interviewed only. However, only 31 out of the 37 questionnaires were included in the final analysis, because six of them had to be eliminated due to low responses to the questions. In India, 26 people participated: 16 people were interviewed and completed the questionnaire, six did the questionnaire only, and four were interviewed only; 19 out of 22 questionnaires were included in the final analysis and three had to be eliminated due to low responses to the questions. The interviews were recorded on audiotape and in a field diary and later transcribed. As the visits were brief and as all instruments had to be filled out with the researcher present, the time was only sufficient for observation of some KM practices (see Okunoye & Karsten, 2002a, 2002b, 2003; Okunoye, Innola, & Karsten, 2002 for detailed results).

COMPONENTS OF KAFRA FRAMEWORK

Environmental Factors

Environmental factors include those factors outside the organization that directly influence its activities. Holsapple and Joshi (2000) include governmental, economic, political, social, and educational factors (GEPSE) here. There are also indirect factors such as culture and national infrastructure. The operating environment varies from organization to organization, between countries, and also from one site to another within a country. Yet many frameworks that guide organizational strategies and development simply assume a homogeneous environment and thus exclude it from their design. A common assumption is that organizations will consider the GEPSE factors that have a direct economic impact on their operation but that indirect factors such as the culture and the infrastructure are irrelevant2. However, our empirical studies tell us that these indirect factors also significantly influence organizational variables. This is consistent with a growing literature in the U.S. that documents the importance of managing cultural diversity factors to improve organizational systems (Cox, 2001; Thomas, Roosevelt, Thomas, Ely, & Meyerson, 2002).

Infrastructural Issues

The national infrastructure can be said to include education, banking, cooperatives, transportation, and communication systems. Scholars have pointed out the influence that these systems have on the organizational IT infrastructure (Weill & Vitale, 2002). The infrastructural issues are derivatives of several other environmental factors, and this discussion thus cuts across many other issues. The infrastructural capability of a country is likely to influence the kind of technology the organization can deploy. It could also determine the extent of the application and sustainability of this technology. The extent to which countries provide infrastructure at the national level clearly affects the infrastructure of organizations in these countries. Most of the technological problems associated with environmental factors are beyond

Table 1. Infrastructural differences between Nigeria, The Gambia, India, and the USA (The World Bank Group, 2004)

ICT infrastructure, computers and the Internet	Nigeria	The Gambia	India	USA
Telephone mainlines/1000 people	4	26	32	700
Mobile phones/1000 people	0	4	4	398
Personal computers/1000 people	6.6	11.5	4.5	585.2
Internet users (‘000)	200	4	5,000	95,354
Internet speed and access[1]	2.5/7		3.6/7	6.6
Internet effect on business[2]	3.3/7		3.2/7	5.0

the control of single organizations. There are considerable differences in the IT infrastructures globally between countries, that is, between Western and developing countries (The World Bank Group, 2004). The differences within developing countries are also wide, as illustrated in Table 1. Specifically, in our study and as evidenced in the literature (Barata, Kutzner, & Wamukoya, 2001; Darley, 2001; Odedra, Lawrie, Bennett, & Goodman, 1993) and available statistics (The World Bank Group 2004), the problem with the IT infrastructure is more pronounced in sub-Saharan Africa (SSA) than in India, where the government has invested heavily in it. Most of the problems in SSA can be attributed to the government's lack of preparedness to commit sufficient resources to develop the national infrastructure, which could as a consequence improve the infrastructures available to organizations. The low availability and utilization of IT infrastructure in sub-Saharan Africa and the lack of expertise to support the physical infrastructure has been widely discussed (e.g., Moyo, 1996; Odedra et al., 1993). According to our study, while the availability of IT infrastructure has the expected significant effect on the knowledge management efforts, its under-utilization and the lack of technical expertise to support its proper application to the knowledge management processes becomes an even bigger problem.

For example, in Nigeria, individuals were expected to bear the cost associated with Internet use in the national research organizations we studied:

…if you understand, it [Internet] is not widely available for some reasons, cost, which implies that cost of access is high, even though you have opened it up to everybody, the cost is scaring them off and they are not using it. That is why I was a bit eh eh, but there is access. You have to pay N200 (about $2) for 15 minutes of browsing, some of them use it when it is very important and critical… (Mr. B, NISER)

This was not the case in India and The Gambia. Also, the Indian government's long-term investment in educational and social infrastructures has provided a large pool of qualified IT practitioners (Lateef, 1997; Tessler & Barr, 1997). This has a high impact on the kinds of technology they are able to use in their organizations. They have been able to design the required KM applications and to provide adequate support, sometimes at a cheaper cost when compared to Nigeria and The Gambia. This was not the case in SSA, where getting qualified IT support and management personnel continue to be a major problem (Odedra et al., 1993).

These examples show the kind of influence the provision of infrastructure in a particular environmental context can exert on the information technology that can be deployed within an organization. It also shows the effect on usage; where individuals are responsible for the cost of using technology, it is likely to discourage the use of this technology. Thus, a framework that could be applicable in this context should provide for the assessment of infrastructural provision in the environment where the organization operates.

Cultural Issues

Several authors have demonstrated how national culture influences management practices. For example, Schneider and Barsoux (1997) relate culture to each of the organizational variables that have been identified as having a great influence on KM (American Productivity and Quality Center, 1996). Weisinger and Trauth (2002) have argued that cultural understanding is locally situated and negotiated by actors within a specific context. In information systems research, national culture has been noted to influence, among others, IT utilization (Deans et al., 1991), IT diffusion (Straub, 1994), and technology acceptance (Anandarajan, Igbaria, & Anakwe, 2000; Straub, Keil, & Brenner, 1997). As noted, earlier KM frameworks (Holsapple & Joshi, 1999; Lai

& Chu, 2000; Rubenstein-Montano et al., 2001) recognize different organizational cultures, but they are generally silent on the effect of different national cultures.

The best-known and most widely used cultural model was developed by Hofstede based on a study conducted among IBM employees working in different countries in the late 1960s (Hofstede, 1997). Hofstede included four dimensions of national culture: power distance, uncertainty avoidance, individualism-collectivism, and masculinity-femininity. He later added a fifth dimension, long- versus short-term orientation, based on a study carried out in Asian countries. The model helps bring out issues related to cultural differences, and it provides some universal measures with which to analyze them. According to Walsham (2001), however, such measures are too general and cannot be used to explain some cultural differences.

According to Hofstede, countries in West Africa differ culturally from the USA, especially in the power distance and individualism-collectivism dimensions. This study and our earlier experiences, however, report some differences within and between the countries in West Africa. In western Nigeria, where three of the study organizations are located, every village has a well-defined hierarchy and family structure. It is a societal norm to treat senior members with absolute respect and obedience. Their views and opinions are often accepted and their judgments are not to be publicly questioned.

…To certain extent, given that for any particular area, the programme leader is the expert in that area, It is a requirement for whoever is heading a particular programme to try during the course of his tenure as the programme leader and get the team under him involve in the day to day activities…the people under you [the leaders] are really undergoing apprenticeship so to say…and they need to show respect. (Dr. SBO, NARI)

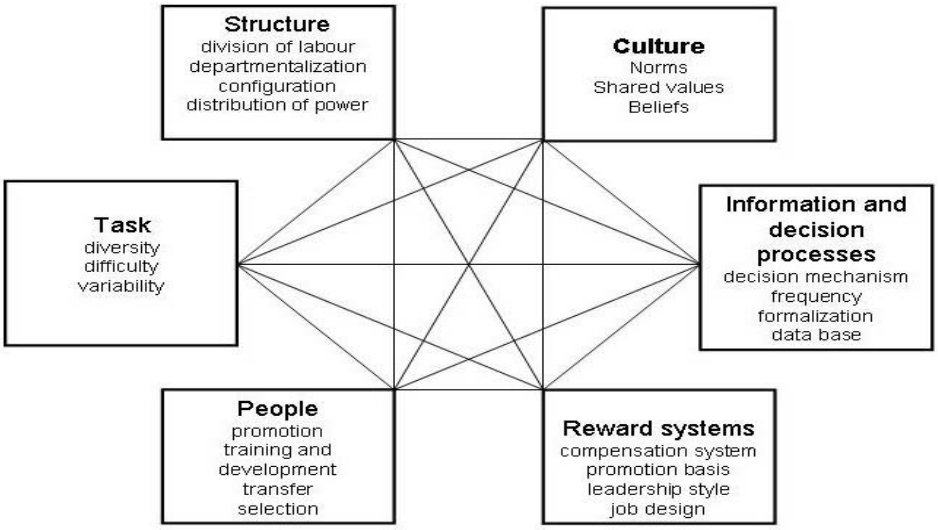
There is thus a substantial gap between the leaders and their subordinates. Contrary behavior (even when not necessarily wrong) by any member of the community can be interpreted as disloyalty and attract punishment. In the Nigerian national research organizations located in western Nigeria, it was very easy to recognize the leaders and people in positions of power. Without careful attention to this, implementing a framework that assumes that everyone has freedom of expression and equal rights could yield undesirable outcomes in these settings. Our argument here is that each organization should be studied in its own cultural context, and thorough knowledge of this should influence the application of the KM framework.

Organizational Variables

The organizational variables as a necessary concern are recognized in our study as well as several other studies and frameworks (Holsapple and Joshi, 2000; APQC 1996). To succinctly describe all organization issues that could influence KM, the conceptual framework (Figure 2) developed by Galbraith (1977) is adopted and modified by adding organizational culture, which is another important component in organizational design (Schein, 1985). Task, culture, structure, information and decision processes, reward systems, and people are the commonly included organizational variables. These need to be aligned for optimal results (Galbraith, 1977; Leavitt, 1965).

Organizational structure is the distribution of power and the shape of the organizational form. People have competence, nature, and attitudes. Information and decision processes include especially the availability and accessibility of information. Reward systems tell how the organization compensates its members for effective performance (Nathanson, Kazanjian, & Galbraith, 1982). The task is the link between choices of strategy and organization structure; decision processes and individual personality vary systemati-

Figure 2. Organizational variables (adapted from concept of organization design, Galbraith, 1977)



cally with the uncertainty of that task (Galbraith, 1977). The organizational culture includes the shared values, beliefs, norms, expectations, and assumptions that bind people and systems. The organizational culture is particularly important in KM because it gives people a basis for stability, control, and direction and helps them to adapt and integrate other variables and technology with the operating environmental factors. This framework enables a complete representation of all the identified organizational enablers of knowledge management. Organizational changes could depend on how well the interrelationship of these variables can support an organization's core activities, considering the available information technology (Markus & Robey, 1988) and the influence of environmental factors.

Organizational variables and knowledge management processes are mutually dependent. For the success of a KM project, Davenport and Prusak (1998) include many of the organizational variables as important factors. We cannot be talking about KM even with all the processes without the organizational variables to support them (APQC, 1996). Due to several factors, such as strategic alliance, internationalization of firms and services, technology transfer, globalization, and recent advances in ICT, Western management styles and forms of organization have a great influence across the world. The success of multinational corporations and consulting firms add to the assumptions about the universality of management strategies, including KM. Nevertheless, significant differences due to cultural diversity exist, as illustrated in subsequent paragraphs.

The people dimension of KM enablers can be problematic in several respects; for example, in our case, the international, expatriate staff members tended to come and go and take their knowledge with them. This had resulted in discontinuity: knowledge could not be assessed, sustained, or divested in any systematic way, as illustrated by the quotes that follow:

…When I came there was a tremendous knowledge gap… because there was no documentation at

all…there was no written information, there was no information on the computer, the people who were there, were only able to provide a little bit of information, but there was an awful knowledge gap. (Dr. SDL, MRC)

…That's true, that sort of information rests with the individual involved. To handle this problem, we want people to be appointed before the previous person has already left to avoid creation of gap. It is a problem. You are right, most of that information is with people that left…Yes that is very true. I think you are right but the knowledge and the expertise is linked to some people. That is certainly true. Not only for us but also for other similar research institutions and local organizations. Institutional knowledge seems to be very fragile. I think that is right. But we have the infrastructure that is required to make sure that knowledge is stored and accessible without really depending on people… (Dr. SA, MRC)

The local staff members were often discouraged from ambitious projects as they were not considered able to perform beyond a certain level. They also often lacked the personal funds that the expatriates might have for supplementing the possibly meager resources at the institutes.

…Surely there is a lot of obvious difference. For instance, the national research institutes and the universities, which we called NARS, we put them under NARS. They are handicapped by funding. Their budgets are in Naira which keeps depreciating every time. And for them to procure materials and whatever, they have to purchase from abroad in dollar which is not available to them, they have to convert, and buy at very high rates and which may not be available. Apart from the facts that they are under-funded, the little they have, they can't convert it to dollars, secondly, most of them do not have the expertise we have, thirdly they lack IT systems …Even they don't have up-to-date books. Because they don't have enough funds to buy them, if you go to their library, they have outdated materials. So, that is why if you go to our library, you find many of them coming to use the library here. Many of their scientists and the lecturer of university come to use the library here… (Mr. YA, IITA)

The people working in an organization are directly influenced by their own identity (Walsham, 2001), which could be influenced by societal norms and values and controlled by social, economic, and educational factors. For example, while training and learning without any formal certification could be acceptable for employees in Western industrialized countries, we found that employees in sub-Saharan Africa would normally like to have a certificate for their training. The reason is the importance attached to a certificate as evidence of knowledge and the prospect of getting a well-paid job, based on the extent of certified training.

…I think the financial incentive has mainly attracted people initially to do the on-the-job training (OJT) and it is also slightly more popular. But some of the main problems of OJT are still there. In the culture here, and I think in Africa in general, people don't see the same value in training unless there is a certificate or qualification attached to it. So that's one big part. Having a qualification attached to OJT is a big issue in giving OJT the credibility that it needs. (Dr. SA, MRC)

Similarly, knowledge as a source of power has a different meaning to Western employees and their developing countries counterparts. In many developing countries, due to high unemployment rates, lack of social security and benefits, and the scarcity of well-paid jobs, employees may wish to protect their source of competitiveness and thus view sharing knowledge as giving away their power.

…they should be jealous of their means of livelihood [their knowledge]… (Professor HOTA, NIMR)

The basic concept of knowledge varies from one culture to another. This could impact the effectiveness of organizational KM initiatives. In each of the countries in our study, there is a long tradition of recognizing some people as a repository of knowledge; for example, the griot in The Gambia, the babalawo in Yorubaland, and the guru in India. Although it may not be formally recognized in research organizations, since it is basically overridden by the professional culture, attention needs to be paid to differences in people's notions of knowledge and the effect of this on organizations.

…The Gurus are those with true knowledge and gives only to his beloved student, only one student. So since you ask about the knowledge and the India traditional culture, let us talk about "AMRITA" [Nectar of life], which if you drink you never die. The people who know the AMRITA never tell anybody. It automatically dies with them. Likewise the gurus committed, unknowingly, they committed…I cannot say sin, they just did not see the importance of their knowledge and never share it widely. They never share their full knowledge, if they did, we would have the entire traditional medicinal things we had in the past… (Mr. Raju, ICRISAT)

One scientist in a national organization explained how ascription is being used to rate people's contributions instead of achievement; that is, people are judged by who they are and not necessarily by what they do.

…There are some people who should be regarded as a source [of knowledge] and not a threat [to the leaders], but when you turn source to a threat, people become discouraged …People are not always evaluated and promoted by what they know but by who they know. (Professor HOTA, NIMR)

As research organizations, our case organizations shared many similar cultural features, and the scientists also shared a similar professional culture. Yet there are notable differences in the organizational culture of national versus international organizations. While international organizations exhibit combinations of cultures (Weisinger & Trauth, 2002), which include corporate culture, industrial culture, professional culture, and some national culture of the local environment, the national organizations are greatly influenced by the regional culture (e.g., western vs. northern Nigeria). Also, the diversity in workforce of international organizations reduces the effect of the interaction of national or societal culture with organizational culture when compared to national organizations.

…The people here are highly educated. The illiterate thinks the moment they share the information, the value is lost. But ours is a different organization. Ours is a multicultural organization and this culture is influenced by western culture and there is free flow of information… (Mr. V, ICRISAT)

The task and structure dimensions had to do with management, which was in some institutes better than in others, and with ability to carry out the tasks planned. Here the external circumstances had their strongest impact: If there is no electricity, no working phone, and very slow mail, work in general is slowed down. Communication between people not working at the same site is greatly hampered. Visiting and sending messengers are the only possibilities, and they take time.

…Of course, when we have electricity blackout and telecommunication breakdown, we can't reach anywhere and we can't physically travel, we just have to wait… (Dr. GE, MRC)

The organizational structure is closely related to the societal structure, and the style of leadership could be influenced by the orientation of the people (Korpela, 1996). In the leadership pattern in western Nigeria, we also observe that superiors are often inaccessible and the power holders are entitled to privileges in the organization. The hierarchies in the community are also reflected in the organization. This is in contrast to organizations in The Gambia. This has implications for KM, as the organizational structure could affect knowledge sharing and communication (Davenport & Prusak, 1998).

Taken together, each of these has implications for KM efforts in organizations. In KM research and practice, it has typically been suggested that particular attention be paid to organizational variables (often called enablers or influences), without which the success of KM cannot be guaranteed. With evidence that the assumptions about these variables are contextual, we contend here that any framework to support KM needs to consider each variable in the context of each organization, with due consideration also for the interaction with the operating environment.

Information Technology

Information technology can support the processes for knowledge creation, sharing, application, and storage (Alavi & Leidner, 2001). It can also enhance the interaction of individual, group, organizational, and inter-organizational knowledge (Hedlund, 1994; Nonaka & Takeuchi, 1995). Information technology availability and use varies between countries, but also within countries and between organizations. When there is little funding for an organization, there are fewer computers and software applications for use, with less access time to the Internet and other IT services.

…The researchers are willing to learn but in a situation where resources are not available, research cannot be carried out without money. It is a money gulping thing, it takes a lot of money and you don't expect immediate results, particularly medical research. It is not something like industrial research where you have a very big breakthrough and you publicize that you have been able to invent these things. I think medical research is not like that. I think the past government was not too keen on that. They didn't make money available for our researchers to work with. They keep on searching for funding, except some of them that are ready to spend their own money. Somebody was just telling me that she needed a reagent for her research work, she had to take a cooperative loan to get it, the loan is not meant for that kind of thing, but she had no alternative for her research work, so that is a kind of problem we have. Maybe with this present government, things may improve. (Mr. A, NIMR)

In contemporary organizations, IT is not only considered to support other organizational processes but a source of competitive advantage and even organizational core capability. IT enables changes in the organizational structure and supports communication within and between organizations. IT can make the information and decision-making processes easier. There is hardly any aspect of organizations that IT has not affected, including the way people think and carry out their work processes (Lau, Wong, Chan, & Law; 2001).

According to Orlikowski and Barley (2001), the transformation in the nature of work and organizing cannot be understood without considering both the technological changes and the institutional (specifically environmental) context that are reshaping economic and organizational activities. They thus emphasize the interrelationship of the environment, organizational variable, and technology. They argue that collaboration between organizational issues and information technology could increase the understanding of changes taking place in the organization. In our study, we found that organizations with high information technology capability were generally able to support knowledge processes better. The application of technology also depends on skills and abilities of individuals and the support of management, which are also organizational issues.

Many technologies can support KM processes. However, these technologies require a basic IT infrastructure, such as local area networking and Internet connectivity, to function optimally. There is also a need for basic hardware and software. The provision of these IT infrastructures varies between organizations (Broadbent et al., 1999), and its use depends on the context of each organization. Apart from the statistic evidence, we also found in our study differences in level of IT capability between national and international organizations, which we attribute to differences in level of funding and other factors (discussed earlier):

…An expatriate usually managed the IT units of the international organizations. The expatriate heads of the IT units were generally more experienced, and had knowledge of relevant modern technologies, due to their training in and access to the Western market. This usually had a positive influence on the performance of the IT unit and the adoption of technologies. The only international organization without a computer unit had an effective outsourcing strategy, which indirectly resulted in better services than national organizations with higher IT infrastructure services. The IT units of the international organizations were better staffed than the national organizations. Most of the staff had a university degree and had received some other special training. LAN and Intranet were only available in the international organizations… (Okunoye & Karsten, 2003)

There were also differences in expertise to support these technologies. Although IT skill shortage is a global phenomenon, its extent varies between countries. Thus, it is important that a framework to support KM efforts in an organization recognizes these different levels of IT availability and use, and that it supports the organization in making the right decision of which technology is most appropriate in their circumstances.

Knowledge Management Processes

Knowledge management processes are socially enacted activities that support individual and collective knowledge and interaction (Alavi & Leidner, 2001). These activities vary depending on which knowledge resources that the organization aims at improving. It is these activities that must be supported by the influences discussed earlier. Since each organization has a different focus, KM processes take place also in different contexts. These processes can be summarized as knowledge creation, knowledge storage/retrieval, knowledge transfer, and knowledge application. Thus the organization should consciously choose which of these activities they intend to support in order to choose appropriate organizational variables and technology to enable them.

For example, research organizations in SSA are particularly interested in knowledge creation and transfer, and they found the Internet to be an effective technology to support this process. One of our case organizations in India focuses on knowledge sharing among the scientists and the rural community, and they also are using a global intranet (ICRISAT, 2001).

Knowledge Resources

The main targets of the knowledge management processes are the knowledge resources. Holsapple and Joshi (2001) present a comprehensive framework of organizational knowledge resources where they consider, including employee knowledge, knowledge embedded in physical systems (Leonard-Barton, 1995), human capital, organizational capital, customer capital (Petrash, 1998), external structures, internal structures, and employee competencies (Sveiby, 1996). Knowledge resources also include intellectual capital (Stewart, 1998). The main goal of knowledge management is the effective marshalling and use of these resources (Lai & Chu, 2000).

The benefit and strategic importance of KM is in the ability of an organization to correctly identify which knowledge resources it can improve to gain sustainable competitive advantage. This is a reason for the popularity of KM, as the process of identifying the resources and subsequent selection of processes are never the same. In addition, organizational variables and technology need to support these processes with varying complexity and with different levels of influence by the operating environment.

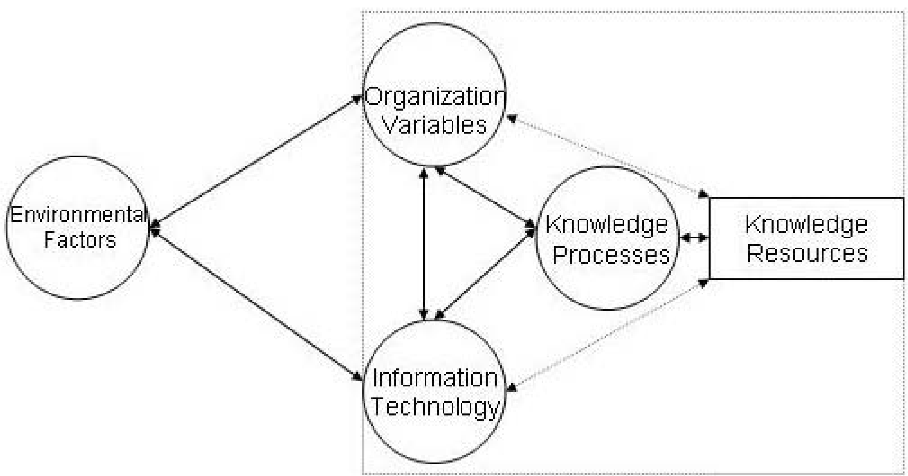
CONTEXT-AWARE FRAMEWORK OF KM

In a context-aware KM framework, KM is seen as an effort to properly put all the organizational variables into best use, with the support of relevant information technology, in order to facilitate the knowledge processes. The main overall goals center on organizational productivity, responsiveness, innovation, and competency through the creation and protection of knowledge resources.

This framework (Figure 3) differs from those presented earlier in that it considers the relationships between and interdependency of all components with particular attention to the environmental context. This framework enables organizations to pay attention to the local context and how this affects the assumptions about each component. The method and research approach used to arrive at the assumption about the components also ensure that the projected users are the actual users and the gap between the world inscribed in it and the world that will be described by its displacement can be expected to be narrowed.

As explained earlier, all the organization-related influences that could enable or constrain KM can be put together as organizational variables. IT is a separate component due to its strategic importance in supporting the knowledge processes of knowledge creation, storage, sharing, and application. All these are directly affected by the environmental factors (e.g., culture and

Figure 3. KAFRA (Kontext Aware FRAmework), a context-based framework of knowledge management



infrastructure in our discussion) where the organization operates. The organizational variables and information technology can influence each other, and they are both enablers of knowledge processes. On the other hand, the kind of knowledge to be created could determine which kind of information technology to be used and which variables in the organization need to be adjusted. Effective handling of knowledge processes yields the main aim of the KM, which is improving the knowledge resources in which the competitive advantage and all other benefits of KM lie. Also, knowledge resources could effectively affect knowledge processes. The double arrow that joins the organizational variables and the technology to the operating environment shows the interdependency between the organization and the environment, ensuring that KM processes are consistent with the external environment in which the organization operates and that those activities meant to improve knowledge resources are undertaken in a coordinated manner. Each component is linked to the others in a cyclic manner, which indicates the continuous dependency and influence between them. There is also a possibility of direct interaction between knowledge resources and organizational variables and also with information technology.

CONCLUSION

The KAFRA presented here represents a move toward a more universally applicable KM framework, one that increases our sensitivity to global diversity. The framework agrees with the recommendations of Leavitt (1965) that call for interdependence of the variables and with Scott (1998) in acknowledging that organizations and their environment affect each other. The consideration for environmental factors agrees with the institutionalist perspective of organizational challenges (Powell & DiMaggio, 1991). The emphasis on the importance of context within which the framework will be applied is informed by Pettigrew's contextualist approach (1987). Our framework recognizes the diversity in the organization's operating environment and utilizes it in its basic design. This framework not only achieves unification both within and across each component (Holsapple & Joshi, 1999) but also addresses the contextual issues at organizational and national levels. The application of this framework requires thorough understanding of the issues related to each component, that is, pre-knowledge of organizational variables and an ability to handle problematic areas are required. Knowledge of the technology and which knowledge processes it can support are also essential for the successful application of the framework. The organization also needs to identify the knowledge resources that are crucial to improving competitive advantage and which knowledge processes could best support this. The framework also requires cultural sensitivity, including cultural knowledge of the environment and a realistic assessment of the available infrastructure. The GEPSE factors are often assessed with easily obtained statistics, but such statistics do not reveal many important qualitative details. Thus, input from local sources and local people are essential.

The KAFRA framework could serve as a link between the organization and its environment, ensuring that KM is approached with consideration to the environment in which the organization operates. The framework also helps to ensure that the activities involved in KM are carried out in a well-guided manner. This framework shows the need for a multidisciplinary team when undertaking a KM project. In a multinational organization, a multicultural team is also required. As long as the world economy continues to tilt toward knowledge-based products and processes, developing countries will increasingly see the importance of KM. This framework could be a good starting point for them. The problems associated with inscription of the outsiders' beliefs, perception, and norms are addressed in the framework. The correct operationalization of the framework, with support from the in-built performance measures, represents a further challenge. For KM practice, this paper has sought to contribute to our understanding of the cultural and infrastructural interaction with organizational variables and technology. It also forms a basis for the composition of a KM team as well as a means of control and balance. For researchers, it contributes to the conceptualization of a more universal framework, which allows for localized specific assumptions.

INTRODUCTION

Knowledge sharing is a collective process where the people involved collaborate with others in order to learn from them (Huysman & de Wit, 2000). This kind of collaboration creates groups of people with common interest called communities of practice where each member contributes knowledge about a common domain (Wenger, 1998).

Communities of practice enable its members to benefit from the knowledge of each other (Fontaine & Millen, 2004). To achieve this, different techniques and technologies can be used, such as shared documentation, groupware tools, lessons learned systems, and so forth. Therefore, to increase and improve knowledge sharing in communities of practice, it is important to study the mechanisms used by a particular community and understand how the knowledge flows through its members (Guizzardi, Perini & Dignum, 2003).

This article presents a qualitative approach for studying and understanding how knowledge flows in communities of practice within organizations. The goal is to provide a methodological guide for obtaining useful information for the development of knowledge management tools for supporting knowledge flows in these communities.

The content of the article is organized as follows. First the importance of supporting knowledge flows in communities of practice is highlighted. Then, a qualitative methodology for identifying knowledge flows in communities of practice is described, followed by some examples from a study conducted in the field of software maintenance. Finally, we present our conclusions of this work and future research.

MAIN BODY: KNOWLEDGE FLOWS IN COMMUNITIES OF PRACTICE

In a knowledge-intensive organization, employees constantly have to deal with a changing environment where knowledge is crucial to make decisions and adapt to these changes. To obtain the required knowledge for making those decisions, employees generate communities where each member collaborates with the others sharing knowledge about a common domain. On the other hand, to facilitate their adaptation, the organization's processes must become dynamic, that is, they must be designed to change based on the knowledge involved and on the activities performed by the members of the organization. Knowledge management (KM) can help address this issue, since it provides methods, techniques, and tools for facilitating organizations to become adaptable to these changing environments (Davenport & Prusak, 2000; Tiwana, 2000).

One of the main objectives of KM is to make available the appropriate knowledge, in the right place, at the right moment, to whoever needs it; therefore the flow of knowledge is very important for managing the knowledge of an organization (Nissen & Levitt, 2002). In fact, it has been considered the central component of a KM system (Borghoff & Pareschi, 1998). Communities of practice stimulate this flow of knowledge through organizations, since knowledge flows easily in these communities because they enable face-to-face interaction between their members (Brown, 2002; Fontaine & Millen, 2004). Even though direct interaction between members of the community is very important for sharing their tacit knowledge, other kinds of knowledge transfer must be considered such as documents sharing. Hence, provision of mechanisms that facilitate, increment, and improve the transfers of both tacit and explicit knowledge into communities of practice it is required. Therefore, knowledge flow must be one of the most important issues for supporting KM in these communities, since the goal is that the knowledge of each member can be used by the others (Borghoff & Pareschi, 1998; Guizzardi et al., 2003).

To provide support to the knowledge flow of a community, it is important to identify specific issues of the dynamics of knowledge flows in the processes and activities performed by the members of that community, as well as the social, cultural, and technological aspects which can affect those flows, in order to provide useful insights for the definition of requirements for designing KM systems that support the flow of knowledge in the community (Rodríguez, Martínez, Favela, Vizcaíno & Piattini, 2004a). A process modeling approach, as used in business processes reengineering (Curtis, Kellner & Over, 1992), can be appropriate for this purpose, since it provides techniques for analyzing technological and social aspects in organizations, as well as for modeling the dynamics of their processes. Once identified and understood how the knowledge flows through the community and which are the main elements that affect that flow, other approaches can be used for implementing the support systems—for example, an agent-oriented approach such as the proposed by Guizzardi et al. (2003, 2004).

In the following section we present a qualitative methodology for identifying knowledge flows in communities of practice; this is a methodology that we have defined and followed to obtain requirements for the design of a KM support system for a software maintenance group.

KOFI: A METHODOLOGY FOR KNOWLEDGE FLOWS IDENTIFICATION

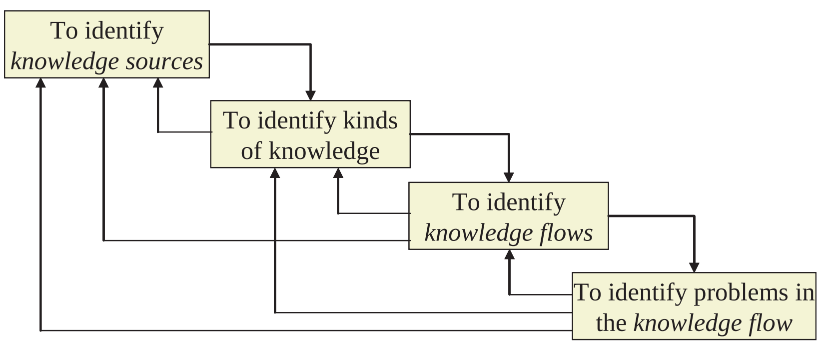
To design and develop support systems, such as for KM, for communities of practice, it is important to consider the contextual issues of the customers or those who will use the system (Beyer & Holtzblatt, 1998). We think knowledge flow must be a central aspect for supporting communities of practice; therefore, to understand the context of those communities, it is important to understand which kinds of knowledge are important for the community, which knowledge sources they share and how to obtain that knowledge, which mechanisms they use to consult the sources, and how all of these interact in the processes and activities performed by the members of the community—in general, how the knowledge flows through the community (Rodríguez et al., 2004a). To obtain answers for these questions, we have defined a qualitative methodology to guide the process of identifying how knowledge flows in a community of practice, and how to provide support to facilitate, increment, and improve the flow of knowledge in the community by identifying the problems that affect that flow.

THE METHODOLOGY

The methodology is composed of four stages, as shown in Figure 1. In stage one the main sources of knowledge and information are identified and classified (documents and people); then, in stage two, the knowledge contained in those sources is also defined and classified; in the third stage the main processes and activities performed by the members of the community are modeled to identify the people involved, how they collaborate to complete their tasks, and how the knowledge and sources interact in those activities; finally, in stage four the main problems that can affect the flow of knowledge are highlighted through the definition of scenarios. The process proposed to carry out the above stages is iterative, since each stage could generate information to complement the others. For example, if we identify a new kind of knowledge source while we are modeling flows of knowledge, we can add the source kind to the ontology and then identify the kinds of knowledge that can be obtained from it.

In the following subsections we describe more details about each stage and present some examples about how they can be carried out. These examples have been obtained from a case study in a software maintenance organization,

Figure 1. Stages of the methodology for identifying knowledge flows



where a multi-agent knowledge management system was designed with requirements obtained from the results of the study (Rodríguez et al., 2004a; Rodríguez, Vizcaino, Martínez, Piattini & Favela, 2004b).

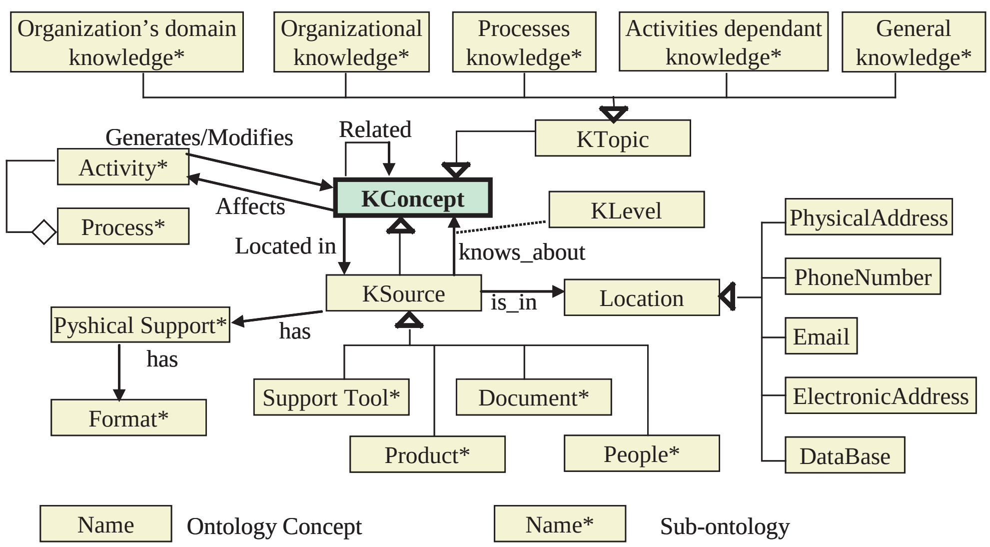
IDENTIFYING AND CLASSIFYING KNOWLEDGE AND KNOWLEDGE SOURCES

The first step starts by identifying the main documents and people involved in the community. Then, in stage two, the documents are analyzed in order to define the kinds of knowledge that can be obtained from those, together with the kinds of knowledge that the people involved can have or require for their activities. Taxonomies can be defined to classify the knowledge sources found and the kinds of knowledge these sources have; also an ontology can be designed to help define the relations between the sources and the kinds of knowledge.

Ontologies are conceptual models for specifying meanings or knowledge about a common domain; they can be used to provide a framework for sharing these meanings or knowledge (Gruber, 1995; Maedche, Motik, Stojanovic, Studer & Volz, 2003). Therefore, ontologies can be used for specifying information sources and the knowledge they can have, as well as the connections between them, in order to develop a conceptual framework of these relations.

Figure 2 presents a general ontology used for classifying knowledge and its sources in the case study carried out. This ontology is used for identifying knowledge concepts (KConcept) which can be both knowledge sources (KSource) or knowledge topics (KTopic). The knowledge concepts involved in an activity can affect that activity in some way; for example, in order to perform an activity, some knowledge topics can be necessary or some knowledge sources can be required; moreover, an activity can generate or modify some topics or sources of knowledge. Some elements of the ontology have been defined as sub-ontologies, and their structure must be specified for the particular needs of the studied organization or community.

Figure 2. A generic ontology of knowledge sources and knowledge topics



Knowledge sources can be people, documents, support tools (such as organizational memories, experience repositories, etc.), and the products developed or built by the organization. For example, in a software organization, the systems developed (source code and executable program) can be a very useful source of knowledge. Each knowledge source can have a specified physical support (such as paper, electronic file, audiotape, videotape, etc.) and a format (such as Word document, PowerPoint presentation, etc.); they can also have one or more locations which define how they can be consulted; and finally, the sources have a level of knowledge about knowledge topics or other knowledge sources.

Knowledge topics have been classified in five main groups:

1. those related to the organization's domain knowledge, for example, if the organization develops software for telephonic services management, it must know about the call fees of the different kinds of calls of each telephone company;
2. knowledge about the structure of the organization, its norms, its culture, and so forth;
3. knowledge about the processes of the organization, for example, the activities, the people involved, and so forth;
4. knowledge dependent of specific activities, for example the procedures or support tools used for performing the activity, and so forth; and
5. other kinds of knowledge that can be important, for example, it can be useful to know which employees speak foreign languages or have other skills that are not used in their daily work.

This ontology can be used for defining and classifying the kinds and sources of knowledge and how all these are related. This information can be later used for defining the structure of a knowledge base, for example, by specifying the most important knowledge topics for the organization, the sources of knowledge available and the kinds of knowledge that can be obtained from those sources.

In the third stage of the methodology, we have followed a process modeling approach to identify the flows of knowledge by modeling the activities performed by the community, the knowledge required and generated in the activities, the people in charge of them, and the sources of knowledge used, modified, or generated during the activities. This approach is presented in the following section.

KNOWLEDGE FLOWS MODELING

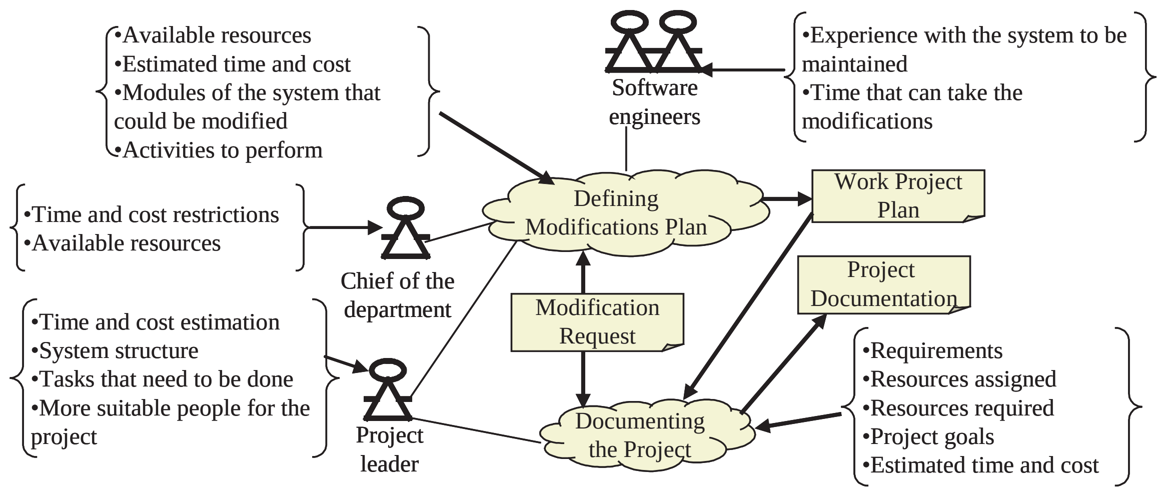
A process modeling (Curtis et al., 1992) approach can be very useful to identify how the knowledge and sources of information are involved in the activities performed by the community. To do this, the main activities of the processes carried out by the community must be identified, as well as the decisions that the people involved must make while they perform those activities. A graphical modeling technique, such as rich picture (Monk & Howard, 1998), can be used to model these activities. Rich pictures are cartoon-like representations that identify actors, roles, their concerns, and some of the structure underlying the work context. Thus, these kinds of representations can be useful to model the people and roles involved in some activities, the knowledge required by them to perform the activities, and the sources they consult or those that could have information to help them to complete their activities. These models can be later used to analyze how the knowledge flows through the group while its members perform their activities.

Figure 3 illustrates an example of a graphical model, which shows the main activities performed in the definition of the modification plan carried out by the group studied. The model shows the people involved in those activities, the knowledge

Table 1. Schema used to identify knowledge in decision making

Role	Project leader	
Activity	To define modification plan	
Decision	To define required resources	
	To define main tasks to perform	
	To assign tasks to the participants of the project	
	To estimate the time the project would consume	
Knowledge	Previous projects experiences	
	Requirements and restrictions of the project	
	Abilities and experience of each of the possible participants of the project	
Sources of information		
Name	**Information**	**Consulted at**
Chief of the department	Available resources; time and cost restrictions	Telephone, Physical address, Email
Software engineers	Experience with the system that will be modified; time that could consume the modifications; time availability	Telephone, Physical address, Email
Previous projects documentation	Resources required by previous projects	Documents' files, modifications' logbook

Figure 3. An example of a model of activities performed by members of a maintenance group



they have together with their relevance to the activities modeled, and the main sources used, created, or modified in the activities.

Once the activities have been modeled, the next step is to define the decisions that must be made by the people involved. To do that, we used the schema shown in Table 1. This schema helps to identify the knowledge that the people in charge of the activities must have to make the decisions required, and the sources they consult to obtain information that helps them to make those decisions. At this step, it is important to identify the mechanisms that people can use to consult the sources, as well as those used to share the knowledge generated in the activities—for example, the documentation of the modifications' plan in Figure 3.

The analysis of the activities performed by the members of the community, using the graphical model and the information from the tables, are later used to understand how the knowledge flows through the community, and what techniques they use to share and obtain that knowledge. Finally this analysis can help to identify the problems that are affecting that flow. We next describe how scenarios can be used for this purpose.

SCENARIOS FOR IDENTIFYING FAULTS IN THE KNOWLEDGE FLOWS

In the fourth stage of the methodology, the models generated in the previous phase are analyzed to find the problems that could be affecting the flow of knowledge—for example, if the information generated from the activities is not captured, or if there are sources that could help in performing some activities, but they are not consulted by the people in charge. In this stage, problem scenarios can help identify how the problems detected affect the knowledge flow, and how these could be addressed. These problem scenarios could be later used to obtain design requirements to the development of tools to address these problems, since scenarios enable the identification of design requirements for software systems and make feasible the participation of users during the requirements specification stage (Chin, Rosson & Carroll, 1997).

A scenario is a textual description of the activities that people might engage in while pursuing a particular concern (Carroll & Rosson, 1992). Hence, the problem scenarios can be structured as a story of particular problems detected from the analysis of the information obtained in the previous stages. Then these scenarios can be studied in order to discuss how those problems

Table 2. An example of a problem description scenario and an alternative scenario

Kind:	Expert finding (knowledge sources management)
Problem description:	
Mary is a software engineer that must make some changes in the finances system. Since her knowledge in the domain of finances is not good enough, the changes to the system are taking more than a week of the estimated time. At the end of the week, Susan, the chief of the department, while she was checking the advances of the project, detects the delay and asks Mary the reasons of that delay. Mary tells Susan the problem and since Susan has experience with finances, she tells Mary how the problem could be solved. Finally, Mary solves the problem the same day.	
Alternative:	
When Mary decides to solve the problem of the finances system, the tool where Mary manages her tasks detects this action. This tool knows about Mary's knowledge, and identifies the kind of knowledge that Mary needs to make the changes in the finances system, so the tool identifies that Mary probably will need to consult some sources of knowledge and decides to search for those sources to help Mary do her Job. The tool founds some sources that can be relevant to the task Mary will perform, thus the tool informs Mary about it. Then, Mary decides to see the kind of knowledge those sources can have, and based on that, decides to consult Susan who is one of the sources found by the tool.	

can be tackled. Table 2 presents an example of the description of a problem scenario obtained from the group studied and an alternative scenario where the knowledge sources are provided by a system. These kinds of descriptions can provide insights, which can later be used for defining requirements for developing support tools focused on addressing the problems identified.

As we mentioned before, the methodology has been applied in a case study in the software maintenance field (Rodríguez et al., 2004a). The first two phases of the methodology helped us to identify the main knowledge sources available for the members of the maintenance groups, as well as the kinds of knowledge these sources have. This information was useful for developing a knowledge base to help find knowledge sources for maintainers to do their jobs. Then, the third phase guided us in identifying the activities where these sources are involved, the kinds of knowledge required or generated in those activities, and the mechanisms maintainers used to consult those sources or to obtain the required knowledge; that is, this last phase helped us to identify how the knowledge was flowing in the maintenance community. Finally, the scenarios defined in the fourth phase were used to obtain design requirements to develop a knowledge management system for helping maintainers to reduce the loss and waste of knowledge by facilitating the search of knowledge sources related to the activities they perform (Rodríguez et al., 2004a, 2004b).

CONCLUSION AND FUTURE POSSIBILITIES

The flow of knowledge is a very important factor for communities of practice, since one of the goals of these communities is to provide an environment where their members could share knowledge with others in order to learn together. Thus, for providing support to these communities, we think that the flow of knowledge through their members must be considered a central aspect of the design of the support tools. To address these issues, in this article we presented a qualitative methodology for studying how the knowledge flows through communities of practice in organizations, and how to identify the problems that can be affecting that flow, in order to use all this information to provide tools to support the flow of knowledge between the members of a community. The proposed methodology has been applied in a case study in a software maintenance group, where an appropriate knowledge management system according to the results obtained in this study has been designed.

We think it is important to consider the particular aspects of each community to provide better support for its particular needs. Thus, it is important to identify the knowledge needed by the members of the community, the sources they use to obtain that knowledge, the particular processes and activities carried out by them, as well as the main decisions they must make. All these aspects are considered by the proposed methodology.

Nevertheless, in order for the methodology to be more useful, we consider it necessary to provide tools for managing the information obtained by applying it—for instance, tools for defining the structure of the ontology of knowledge and knowledge sources, and for capturing information about the specific knowledge topics and sources in a knowledge base that could be later used by the tools developed to support the community. At the moment, we are working on providing this kind of support for the methodology.

Chapter 2.31
IS Design for Community of Practice's Knowledge Challenge

Kam Hou Vat
University of Macau, Macau

INTRODUCTION

The last decade of the 20th century saw explosive growth in discussions about knowledge—knowledge work, knowledge management, knowledge-based organizations, and the knowledge economy (Cortada & Woods, 2000). Against this backdrop, enterprises including educational institutes are challenged to do things faster, better, and more cost-effectively in order to remain competitive in an increasingly global environment (Stalk, Evans & Shulman, 1992). There is a strong need to share knowledge in a way that makes it easier for individuals, teams, and enterprises to work together to effectively contribute to an organization's success.

This idea of knowledge sharing has well been exemplified in the notion of a learning organization (LO) (Senge, 1990; Garvin, 1993; King, 1996; Levine, 2001). Essentially, a learning organization could be considered as an organization that focuses on developing and using its information and knowledge capabilities in order to create higher-value information and knowledge, to modify behaviors to reflect new knowledge and insights, and to improve bottom-line results. Consequently, there are many possible instances of information system (IS) design and realization that could be incorporated into a learning organization. The acronym "LOIS" (Learning Organization Information System) (Williamson & Lliopoulos, 2001) as applied to an organization is often used as a collective term representing the conglomeration of various information systems, each of which, being a functionally defined subsystem of the enterprise LOIS, is distinguished through the services it renders. For example, if a LOIS could support structured and unstructured dialogue and negotiation among the organizational members, then the LOIS subsystems might need to support reflection and creative synthesis of information and knowledge, and thus integrate working and learning. Also, if each member of an organization is believed to possess his or her own knowledge space, which is subject to some level of description, and thus may be integrated into an organization's communal knowledge space (Wiig, 1993; Davenport & Prusak, 1998; Levine, 2001), the LOIS subsystems should help document information and knowledge as it builds up, say, by electronic journals. Or, they have to make recorded information and knowledge retrievable, and individuals with information and knowledge accessible. Collectively, a LOIS can be considered as a scheme to improve the organization's chances for success and survival by continuously adapting to the external environment. That way, we stand a better chance of increasing social participation and shared understanding within the enterprise, and thus foster better learning. More importantly, the philosophy underlying the LOIS design should recognize that our knowledge is the amassed thought and experience of innumerable minds, and LOIS helps capture and reuse those experiences and insights in the enterprise. Indeed, the cultivation of an organization's communal knowledge space—one that develops new forms of knowledge from that which exists among its members, based on seeing knowledge as a social phenomenon, and not merely as a 'thing'—is fundamental to enterprises that intend to establish, grow, and nurture a learning organization, be it physical or digital (Hackbarth & Groven, 1999), where individuals grow intellectually and expand their knowledge by unlearning inaccurate information and relearning new information.

The theme of this article is to examine the knowledge processes required of the learning organization viewed from the community of practice viewpoint, to develop and sustain the communal knowledge space through the elaboration of suitable LOIS support so as to expand an organization's capacity to adapt to future challenges.

THE BACKGROUND OF COMMUNITIES OF PRACTICE

According to Wenger, McDermott, and Snyder (2002, p. 4), communities of practice are groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise by interacting on an ongoing basis. As they spend time together, they typically share information, insight, and advice. They help one another solve problems; they ponder common issues, explore ideas, and accumulate knowledge. Oftentimes, they become informally bound by the value that they find in learning together. This value is not merely instrumental for their work. It also accrues in the personal satisfaction of knowing colleagues who understand each other's perspectives and of belonging to an interesting group of people. Over time, they develop a unique perspective on their topic, as well as a body of common knowledge, practices, and approaches. They also develop personal relationships, a common sense of identity, and established ways of interacting.

Indeed, communities of practice are not a new idea (Wenger, 1998). They were our first knowledge-based social structures, back when we lived in caves and gathered around the fire to discuss strategies for cornering prey, the shape of arrowheads, or which roots were edible. They have captured our focus today because organizations have come to realize that knowledge has become the key to success (OECD, 1996), and their competitive edge is mostly the intellectual capital of their employees (Stewart, 1997), and they need to be more intentional and systematic about managing knowledge through harnessing their human resources in order to stay ahead of the pack. Undeniably, in today's knowledge-intensive economy, organizations are increasingly expecting their employees to continually improvise and invent new methods to deal with unexpected difficulties and to solve immediate problems, and to share these innovations with other employees through some effective channels.

In this regard, the idea of the community of practice has inspired many an organization to initiate their collective learning based not so much on delineated learning paths, but rather on experience sharing, the identification of best practices, and reciprocal support for tackling day-to-day problems in the workplace. Cultivating communities of practice in strategic areas is considered as a practical way to manage knowledge in terms of critical knowledge domains; organizations need to identify the people and the specific knowledge needed for their work, and explore how they connect them into suitable communities of practice so that together they could steward the necessary knowledge. From this viewpoint, the cultivation of an organization's communal knowledge space is literally the cultivation of the various communities of practice throughout the organization.

UNDERSTANDING THE KNOWLEDGE CHALLENGE FOR LEARNING ORGANIZATIONS

Nowadays, enterprises need to understand precisely what knowledge will give them a competitive advantage. They then need to keep this knowledge on the cutting edge, deploy it, leverage it in operations, and spread it across the organization. However, many an organization still has no explicit, consolidated knowledge strategy to steward the required knowledge. Instead, many attempts at knowledge management have simply counted on new information technologies to capture all the possible knowledge of an organization into databases that would make it easily accessible to all employees (King, 1999; Levine, 2001). This philosophy of regarding knowledge as a "thing" that can be managed like other physical assets has not been quite successful for several obvious reasons. One is the apparent difficulty concerned with knowledge capture and the issue of tacit-to-explicit transformation. Another is the question of intellectual asset management. Third is the myopic interpretation of knowledge management in terms of information management, which involves breaking information into smaller chunks that can be detected throughout the organization, stored for later use, manipulated by being combined with other chunks, and transferred where they are needed. The ultimate goal of such knowledge management efforts is to get the right information to the right people at the right place with the right information technologies. It is believed that a knowledge strategy must be based on understanding what the knowledge challenge is. The essence of this challenge comes down to a few key points about the nature of knowing (Nonaka & Takeuchi, 1995; O'Leary, 1998; Wenger, 1998, 2002).

- Knowledge lives in the human act of knowing: In many instances of our daily living, our knowledge can hardly be reduced to an object that can be packaged for storage and retrieval. Our knowledge is often an accumulation of experience—a kind of residue of our actions, thinking, and conversations—that remains a dynamic part of our ongoing experience. This type of knowledge is much more a living process than a static body of information.
- Knowledge is tacit as well as explicit: Not everything we know can be codified as documents or tools. Sharing tacit knowledge requires interaction and informal learning processes such as storytelling, conversation, coaching, and apprenticeship. The tacit aspects of knowledge often consist of embodied expertise—a deep understanding of complex, interdependent elements that enables dynamic responses to context-specific problems. This type of knowledge is very difficult to replicate. This is not to say that it is not useful to document such knowledge in whatever manner serves the needs of practitioners. But even explicit knowledge is dependent on tacit knowledge to be applied.
- Knowledge is dynamic, social, as well as individual: It is important to accept that though our experience of knowing is individual, knowledge is not. Much of what we

> know derives from centuries of understanding and practice developed by long-standing communities. Appreciating the collective nature of knowledge is especially important in an age when almost every field changes too much, too fast for individuals to master. Today's complex problem solving requires multiple perspectives. We need others to complement and develop our own expertise. In fact, our collective knowledge of any field is changing at an accelerating rate. What was true yesterday must be adapted to accommodate new factors, new data, new inventions, and new problems.

In short, what makes managing knowledge a challenge is that it is not an object that can be stored, owned, and moved around like a piece of equipment or a document. It resides in the skills, understanding, and relationships of its members, as well as in the tools, documents, and processes that embody aspects of this knowledge. In response to such knowledge challenge in a learning organization, it is interesting to observe some of the interpretations from the standpoint of the communities of practice (CoPs).

Firstly, it is not a CoP's practice to reduce knowledge to an object. They often make it an integral part of their activities and interactions, and they serve as a living repository for that knowledge. Secondly, a CoP is in the best position to codify knowledge since their members can combine its tacit and explicit aspects. They also can produce useful documentation, tools, and procedures because they understand the needs of practitioners. Such CoP products are often not considered as just objects by themselves, but are part of the life of the community. Thirdly, what counts as collective knowledge is often produced through a process of communal involvement, including all the possible controversies, so as to develop the specific body of knowledge. This collective character of knowledge creation does not mean that individuals do not count. In fact, the best communities welcome strong personalities and encourage disagreements and debates. Besides, that knowledge is not static does not mean that a domain of knowledge lacks a stable core. One of the primary tasks of a community of practice is to establish a common baseline of knowledge and standardize what is well understood so that people can focus their creative energies on the more advanced issues.

CONCEIVING KNOWLEDGE PROCESSES FOR COMMUNITIES OF PRACTICE

In order to create the communal knowledge space through cultivating various communities of practice for the entire organization, it is important to have a vision that orients the entire organization to the kind of knowledge it must acquire, and wins spontaneous commitment by the individuals and groups involved in knowledge creation (Dierkes, Marz & Teele, 2001; Kim, 1993; Stopford, 2001). It is top management's role to articulate this knowledge vision and communicate it throughout the organization. A knowledge vision should define what kind of knowledge the organization should create in what domains. It helps determine how an organization and its knowledge base will evolve in the long run (Leonard-Barton, 1995; Nonaka & Takeuchi, 1995). On the other hand, the central requirement for organizational knowledge synthesis is to provide the organization with a strategic ability to acquire, create, exploit, and accumulate new knowledge continuously and repeatedly. To meet this requirement, we need an actionable framework, which could facilitate the development of this strategic ability through the communities of practice. It is likely that there are at least three major processes constituting this synthesis framework of a learning organization, including the personal process, the social process, and the organizational process. What follows is our appreciation of these three important knowledge processes considered as indispensable in the daily operations of the learning organization. Of particular interest here is the idea of appreciative settings, which according to Vickers (1972, p. 98) refer to the body of linked connotations of personal interest, discrimination, and valuation which we bring to the exercise of judgment and which tacitly determine what we shall notice, how we shall discriminate situations from the general confusion of ongoing events, and how we shall regard them. The word "settings" is used because such categories and criteria are usually mutually related; a change in one is likely to affect others.

- The Personal Process: Consider a human being as an individual conscious of the world outside his or her physical boundary. This consciousness means that we can think about the world in different ways, relate these concepts to our experience of the world, and so form judgments that can affect our intentions and, ultimately, our actions. This line of thought suggests a basic model for the active human agent in the world. In this model we are able to perceive parts of the world, attribute meanings to what we perceive, make judgments about our perceptions, form intentions to take particular actions, and carry out those actions. These change the perceived world, however slightly, so that the process begins again, becoming a cycle. In fact, this simple model requires some elaborations. First, we always selectively perceive parts of the world, as a result of our interests and previous history. Secondly, the act of attributing meaning and making judgments implies the existence of standards against which comparisons can be made. Thirdly, the source of standards, for which there is normally no ultimate authority, can only be the previous history of the very process we are describing, and the standards will themselves often change over time as new experience accumulates. This is the process model for the active human agents in the world of individual learning, through their individual appreciative settings. This model has to allow for the visions and actions, which ultimately belong to an autonomous individual, even though there may be great pressure to conform to the perceptions, meaning attributions, and judgments which belong to the social environment, which, in our discussion, is the community of practice.
- The Social Process: Although each human being retains at least the potential selectively to perceive and interpret the world in his or her own unique way, the norm for a social being is that our perceptions of the world, our meaning attributions, and our judgments of it will all be strongly conditioned by our exchanges with others. The most obvious characteristic of group life is the never-ending dialogue, discussion, debate, and discourse in which we all try to affect one another's perceptions, judgments, intentions, and actions. This means that we can assume that while the personal process model continues to apply to the individual, the social situation will be that much of the process will be carried out inter-subjectively in discourse among individuals, the purpose of which is to affect the thinking and actions of at least one other party. As a result of the ensuing discourse, accommodations may be reached which lead to action being taken. Consequently, this model of the social process which leads to purposeful or intentional action, then, is one in which appreciative settings lead to particular features of situations, as well as the situations themselves, being observed and interpreted in specific ways by standards built up from previous experience. Meanwhile, the standards by which judgments are made may well be changed through time as our personal and

social history unfolds. There is no permanent social reality except at the broadest possible level, immune from the events and ideas, which, in the normal social process, continually change it.

- The Organizational Process: Our personal appreciative settings may well be unique since we all have a unique experience of the world, but oftentimes these settings will overlap with those of people with whom we are closely associated or who have had similar experiences. Tellingly, appreciative settings may be attributed to a group of people, including members of a community, or the larger organization as a whole, even though we must remember that there will hardly be complete congruence between the individual and the group settings. It would also be naïve to assume that all members of an organization share the same settings, those that lead them unambiguously to collaborate together in pursuit of collective goals. The reality is that though the idea of the attributed appreciative settings of an organization as a whole is a usable concept, the content of those settings, whatever attributions are made, will never be completely static. Changes both internal and external to the organization will change individual and group perceptions and judgments, leading to new accommodations related to evolving intentions and purposes. Subsequently, the organizational process will be one in which the data-rich world outside is perceived selectively by individuals and by groups of individuals. The selectivity will be the result of our predispositions to "select, amplify, reject, attenuate, or distort" (Land, 1985, p. 212) because of previous experience, and individuals will interact with the world not only as individuals but also through their simultaneous membership of multiple groups, some being formally organized and others informally. Perceptions will be exchanged, shared, challenged, and argued over, in a discourse that will consist of the inter-subjective creation of selected data and meanings. Those meanings will create information and knowledge which will lead to accommodations being made, intentions being formed, and purposeful action undertaken. Both the thinking and the action will change the perceived world, and may change the appreciative settings that filter our perceptions. This organizational process is a cyclic one and a process of continuous learning; it should be richer if more people take part in it. And it should fit into the context of a learning organization.

AN ORGANIZATION SCENARIO OF KNOWLEDGE SYNTHESIS FOR COMMUNITIES OF PRACTICE

From the discussion built up so far, we can understand that knowledge synthesis is a social as well as an individual process. Sharing tacit knowledge requires individuals to share their personal beliefs about a situation with others (Nonaka, 2002). At that point of sharing, justification becomes public. Each individual is faced with the tremendous challenge of justifying his or her beliefs in front of others—and it is this need for justification, explanation, persuasion, and human connection that makes knowledge synthesis a highly dynamic process (Markova & Foppa, 1990; Vat, 2003).

To bring personal knowledge into a social context, within which it can be amplified or further synthesized, it is necessary to have a field that provides a place in which individual perspectives are articulated, and conflicts are resolved in the formation of higher-level concepts. In the organizational context of our investigation, this field for interaction is provided in the form of a community of practice, made of members perhaps from different functional units.

It is a critical matter for an organization to decide when and how to establish such a community of interaction in which individuals can meet and interact. This community triggers organization knowledge synthesis mainly through several stages. First, it facilitates the building of mutual trust among members, and accelerates creation of an implicit perspective shared by members as tacit knowledge. Second, the shared implicit perspective is conceptualized through continuous dialogue among members. Tacit field-specific perspectives are converted into explicit concepts that can be shared beyond the boundary of the community. It is a process in which one builds concepts in cooperation with others. It provides the opportunity for one's hypothesis or assumption to be tested. As Markova and Foppa (1990) argue, social intercourse is one of the most powerful media for verifying one's own ideas. Next comes the step of justification, which determines the extent to which the knowledge created within the community is truly worthwhile for the organization. Typically, an individual justifies the truthfulness of his or her beliefs based on observations of the situation; these observations, in turn, depend on a unique viewpoint, personal sensibility, and individual experience. Accordingly, when someone creates knowledge, he or she makes sense out of a new situation by holding justified beliefs and committing to them. Indeed, the creation of knowledge, from this angle, is not simply a compilation of facts, but a uniquely human process that cannot be reduced or easily replicated. It can involve feelings and belief systems of which we may not even be conscious. Nevertheless, justification must involve the evaluation standards for judging truthfulness. There might also be value premises that transcend factual or pragmatic considerations. Finally, we arrive at the stage of cross-leveling knowledge (Nonaka, 2002). During this stage, the concept that has been created and justified is integrated into the knowledge base of the organization, which comprises a whole network of organizational knowledge.

CRITICAL CHALLENGES OF ARCHITECTING IS SUPPORT FOR COMMUNITIES OF PRACTICE

Undeniably, setting up an organizational IS support for various communities of practice is a social act in itself, requiring some kind of concerted action by many different people (Vat, 2004a); and the operation of any LOIS subsystem entails such human phenomena as attributing meaning to manipulated data and making judgments about what constitutes a relevant category (Vat, 2004b). Subsequently, an organization is often seen at core as a conversational process in which the world is interpreted in a particular way which legitimates shared actions and establishes shared norms and standards. There is no single body of work which underlies this soft approach to IS, but the works of Sir Geoffrey Vickers (1965) provide quite an interesting reference. For Vickers, organizational members set standards or norms rather than goals, and the traditional focus on goals is replaced by one on managing relationships according to standards generated by previous history of the organization. Furthermore, the discussion/debate, which leads to action, is one in which social action is based upon personal and collective sense making (Weick, 1995). Thereby, organizations are also regarded as networks of conversation or communicative exchanges in which commitments are generated (Ciborra, 1987; Winograd & Flores, 1986). And LOIS support should be thought of as making such exchanges easier—the exchange support systems.

Consequently, a strategy for IS support needs to be thought of, through which desirable change and organizational learning are often considered as the aims. Its stages of development could be characterized as follows with plausible iterations in stages 3, 4, and 5 (Wilson, 2002, pp. 6-10):

1. define the situation that has provoked concerns;

2. express the situation with different sets of concerns;
3. select concepts that may be relevant;
4. assemble concepts into an intellectual structure;
5. use this structure to explore the situation;
6. define changes to the situation as the challenges to be explored; and
7. implement the change processes.

Given the great variety of organizational design problems for CoP-based LOIS support, considerable flexibility must exist in the concepts and structures available to the analysts. It is believed that unless the particular methodology is assembled as a conscious part of the analysis, it is very unlikely that the changes and solutions identified will represent an effective output of the analysis. More importantly, the specific methodology needs to be explicit in order to provide a defensible audit trail from recommendations back to initial assumptions and judgments.

Thereby, thinking about how to think in designing LOIS support is about planning the intellectual process to follow up with the design itself. And there are numerous challenges (Carroll, 1995, 2000) in the underlying process. First, there is often an incomplete description of the problem to be addressed, but it is always necessary to identify the relevant description of the current situation that is to be altered by the design work. Secondly, the problem space of allowable and possible moves is often not determined beforehand. In fact, there is often no guidance on possible design moves in reasoning from a description of the current situation toward an improved version of the situation. Thirdly, design problems themselves characteristically involve many trade-offs; any move creates side effects, such as impacts on human activities. Accordingly, it is by no means a routine process in the IS design for organizational communities of practice.

FUTURE TRENDS OF IS DESIGN FOR COP-BASED KNOWLEDGE SYNTHESIS

According to Checkland and Holwell (1995), the main role of an information system is that of a support function helping people in their purposeful actions. Many of today's information systems are difficult to learn and awkward to use; they often change our activities in ways that we do not need or want. The problem lies in the IS development process. Oftentimes, IS designers have to face convoluted networks of trade-off and inter-dependence, the need to coordinate and integrate the contributions of many kinds of experts, and the potential of unintended impacts on people and their social institutions. It has been observed that traditional textbook approaches to IS development (Checkland & Holwell, 1998) seek to control the complexity and fluidity of design using techniques which filter the information considered, and weakly decompose the problems to be solved. In contrast, the scenario-based design approach (Vat, 2004a, 2004b; Carroll, 1995, 2000) belongs to a complementary tradition that seeks to exploit the complexity and fluidity of design by trying to learn more about the concrete elements of the problem situation. Thereby, John Carroll characterizes scenarios as concrete stories about use through which IS architects could envision and facilitate new ways of doing things and new things to do. Specifically, scenarios provide a vocabulary for coordinating the central tasks of systems development—understanding people's needs, envisioning new activities and technologies, designing effective systems and software, and drawing general lessons from systems as they are developed and used. Namely, scenarios help IS designers analyze the various possibilities by focusing first on the human activities that need to be supported and allowing descriptions of those activities to drive the quest for correct problem requirements. It is expected that through maintaining a continuous focus on situations of and consequences for human work and activities, IS designers could become more informed of the problem domains, seeing usage situations from different perspectives, and managing trade-offs to reach usable and effective design outcomes (Carroll, 1994, 1995).

Consequently, through the appropriate use of design scenarios, the problems of designing CoP-based LOIS support for knowledge work should never be thought of as something to be defined once and for all, and then implemented. Instead, it must be based on the observation that all real-world organizational problem situations contain people interested in trying to take purposeful action (Checkland, 1999). Pragmatically, the idea of a set of activities linked together so that the whole, as an entity called the human activity system (HAS) from the viewpoint of soft systems methodology (SSM) (Checkland & Holwell, 1998; Checkland & Scholes, 1999) could pursue a purpose, could indeed be considered as a representative organizational scenario for architecting LOIS support, which is never fixed once and for all. In practice, given a handful of the HAS models, namely, models of concepts of purposeful activity built from a declared point of view, we could create a coherent structure to debate about the problem situation and what might improve it (Checkland, Forbes & Martin, 1990; Checkland, 1981, 1983).

Subsequently, from the IS architect's point of view, while conceiving the necessary IS support to serve the specific organizational knowledge requirements, the fundamental ideas could be integrated as follows: Always start from a careful account of the purposeful activity to be served by the system. From that, work out what informational support is required (by people) to carry out the activity. Treat the creation of that support as a collaborative effort between technical experts and those who truly understand the purposeful action served. Meanwhile, ensure that both system creation and system development and use are treated as opportunities for continuous learning. In this way, models of purposeful human activities can be used as scenarios to initiate and structure sensible discussion about LOIS support for the people undertaking the real-world problem situations. Thereby, the process of IS development needs to start not with attention quickly focused on data and technology, but with a focus on the actions served by the intended organizational system. Once the actions to be supported have been decided and described, which can usefully be done using activity models, we can proceed to decide what kind of support should be provided. The key point is that in order to create the necessary IS support which serves the intended organizational scenario, it is first necessary to conceptualize the organizational system (different communities of practices) that is to be served, since this order of thinking should inform what relevant services would indeed be needed in the IS support.

CONCLUSION

This article describes an initiative to develop an actionable framework of knowledge processes, which are aimed to facilitate the creation and sustenance of communities of practice in the context of a learning organization. Our discussion has paid particular attention to the design issues in support of participatory knowledge construction, which is essential for the growth of any CoP in the organizational workplace. In particular, we have elaborated the design issues of three important knowledge processes (the individual, the social, and the organizational), which have tremendous implications for the design of suitable IS support (Vat, 2004b) to help structure and facilitate knowledge creation in the specific organizational setting, where a community of people can conceptualize their world and hence the purposeful action they wish to undertake. This renders a perspective of a knowledge context in a learning organization in which social reality is continually defined and re-defined in both the talk and action of the various communities within the organization. The article concludes by reiterating the challenge of designing LOIS support so that the purposeful actions of the CoPs can be accommodated. It is important that the examination of meanings and purposes should be broadly based, and its richness will be greater the larger the number of people who take part in it. This consequently provides the basis for ascertaining the development of an organization's communal knowledge space: namely, what IS support is needed by those undertaking their actions, and how modern information technologies can help to provide that support to the various communities of practice.

Chapter 2.32
Knowledge Management Strategy Formation

Clyde W. Holsapple
University of Kentucky, USA

Kiku Jones
University of Tulsa, USA

INTRODUCTION

Knowledge-based organizations (Holsapple & Whinston, 1987; Paradice & Courtney, 1989; Bennet & Bennet, 2003) are intentionally concerned with making the best use of their knowledge resources and knowledge-processing skills in the interest of enhancing their productivity, agility, reputation, and innovation (Holsapple & Singh, 2001). A key question that confronts every knowledge-based organization is concerned with how to approach the task of forming a KM strategy. Beyond aligning KM strategy with an organization's vision and overall strategy for achieving its mission, how does the creator of a KM strategy proceed? How is the created (or adopted) KM strategy communicated and evaluated? What can be done to avoid blind spots, gaps, and flaws in the strategy?

One way to begin to answer such questions is to study successful cases of organizational knowledge management (e.g., see Smith & McKeen, 2003; O'Dell et al., 2003; van der Spek, Hofer-Alfeis, & Kingma, 2003; Bennet & Porter, 2003; Oriel, 2003; Wolford & Kwiecien, 2003; Kelly & Bauer, 2003; DeTore & Balliet-Milholland, 2003). Such cases can give specific KM strategies to consider emulating or adapting. They can lead to an understanding of various issues to consider in the act of forming a KM strategy. Other cases can even identify dysfunctional elements to avoid during KM strategy formation and use (Malhotra, 2003).

A complementary approach to answering such questions is to employ a general-purpose model as a guide for KM strategy formation. This can be used regardless of the nature of the organization or its particular circumstances. It guides the strategy formation process in the sense of providing a structure for identifying the KM activities that a strategy can or should address in its efforts to maximize performance. A KM director uses the model to assess where the organization presently stands with respect to each of the identified activities, to consider new initiatives for each of the activities (customized to the organization's particular circumstances), and to furnish dimensions for evaluating competitive standing.

Here, we examine the Knowledge Chain Model for guiding KM strategy formation. It is important to understand that this is not a process model that specifies some sequence of steps to be followed in devising KM strategies. Rather, it is a model that identifies key factors that need to be considered in the development of KM strategies. These factors are "key" in the sense that they are potential sources of greater competitiveness. They are areas of activity that, if performed better than competitors, will yield superior organizational performance through better productivity, agility, innovation, and/or reputation. Creators of KM strategies need to pay close attention to the techniques and technologies selected and deployed in each of the key activity areas in both their own organizations and in other (e.g., competing) organizations.

BACKGROUND

The notion of a strategy has varied meanings (Mintzberg & Quinn, 1996). Here, we regard strategy as being a systematic plan of action for deliberately using an organization's resources in ways that fulfill its purpose (e.g., mission, duty, vision). A knowledge management strategy, then, is a plan for marshaling and applying knowledge-oriented resources in the interest of supporting the organization's purpose. These knowledge-oriented resources include the organization's knowledge processing capabilities and its knowledge assets (Holsapple & Joshi, 2004). The classes of knowledge assets include knowledge held by an organization's participants, various artifacts belonging to the organization (e.g., documents, manuals, videos), the organization's culture, and its particular infrastructure of roles, relationships, and regulations. The knowledge processing capabilities include the skills of both individual participants (both human and computer-based processors) and collective participants (e.g., groups, teams, communities) in the organization.

Knowledge Processing Capabilities

An organization's knowledge processing capabilities can be categorized into those that are technologically based and those that are practice based. Capabilities can depend on a combination of these two. In any case, knowledge processing capabilities manifest in the actual activities that an organization performs as it operates on its knowledge assets. KM strategy determines what technologies and practices will be adopted in any given instance of a KM activity.

Information technology (IT) is being subsumed by knowledge technology. IT systems for automated transaction handling, record storage, and reporting remain important. However, the emphasis going forward is on technological systems that support knowledge amplification within and across organizations. This knowledge technology involves the use of computer and communication technologies to automatically acquire, derive, or discover knowledge needed by decision makers and researchers on a just-in-time basis. Knowledge technology fosters knowledge sharing and unleashes the creative potential inherent in knowledge-worker collaboration. It includes technology that measures and coordinates the activities of knowledge workers. Knowledge technology provides a basis for organizational memory and learning. It also involves technology to personalize timing and presentation of knowledge delivery according to knowledge-worker profiles.

Human cognitive and communicative acts are the other part of the KM equation. This part comprises knowledge practices and their alignment with an organization's vision and plans. These practices are based on knowledge ontologies, methods, techniques, metrics, incentives, and processes. They are concerned with issues of organizational infrastructure (roles, relationships, regulations), culture, ethics, training, skills, and core competencies.

Knowledge Assets

One way for an organization to begin developing a KM strategy is to ascertain the competitiveness of its present knowledge position. Zack (1999) suggests that competitive knowledge position can be categorized in terms of the degree of innovation relative to its competitors within an industry:

- Core Knowledge: The basic body of knowledge required of all players in an industry in order to remain competitive.
- Advanced Knowledge: Knowledge that distinguishes an organization from other players in its industry in a degree sufficient for achieving a competitive edge.
- Innovative Knowledge: Knowledge held/applied by an organization that is so distinctive that it is the basis for being a market leader in the industry.

By evaluating its knowledge assets relative to these three categories, an organization's competitive knowledge position becomes evident. Zack goes on to advocate using a strength-weakness-opportunity-threat (SWOT) analysis to recognize deficiencies in an organization's knowledge position, as well as knowledge strengths that can be leveraged. Of course, organizations will differ in both their knowledge positions and in the strategies that they devise for working from these positions within their environments.

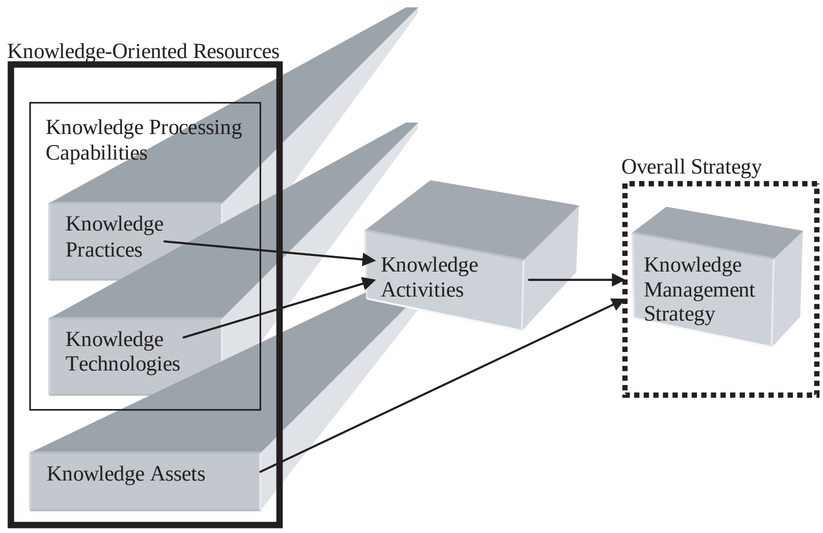
Zack (1999) advises that to find its own unique connection between strategy and knowledge assets, an organization should be alert for the need to increase knowledge assets in a particular area (e.g., ensuring sufficient core knowledge, fending off threats), opportunities to more fully exploit existing knowledge assets, the potential to generate new knowledge internally (especially advanced or innovative knowledge), and the potential of acquiring knowledge from external sources.

Developing KM Strategy

An organization should recognize that its KM strategy can be connected not only to its knowledge assets, but also to its knowledge processing capabilities (see Figure 1). Thus, in addition to guiding KM strategy formation through an analysis of an organization's actual and potential knowledge assets, there needs to be an analysis of possible practices and technologies that may be adopted for operating on those assets. This analysis of knowledge processing capabilities may follow the format used for knowledge assets. The capabilities can be classified into core, advanced, and innovative categories to understand the organization's knowledge processing capabilities relative to those of competitors. Further, via a SWOT approach, an organization needs to ascertain whether to increase knowledge processing capabilities in a particular area such as assimilating knowledge, whether opportunities to more fully exploit existing knowledge processing capabilities exist, whether new practices/technologies can be developed in-house, or whether the practices/technologies can be implemented via outsourcing, alliances, and/or purchase.

What is missing from this consideration of KM strategy development is an appreciation of the fundamental kinds of KM activities that are candidates for strategic focus. More broadly, fundamental kinds of business activities for strategic focus are known. In management theory, the Value Chain Model identifies the basic kinds of business activities that can be focal points for competitiveness (Porter, 1985). The value chain is composed of distinct activities (called "value activities") that an organization performs in the course of doing business. These value activities fall into nine generic categories: five primary and

Figure 1. Aspects of knowledge management strategy



four secondary, and translate an organization's broad competitive strategy into specific action steps required to achieve competitiveness.

By formulating a strategy to perform one or more of the value activities better than competitors, the organization can attain a competitive advantage. Analogously, it would be helpful for KM strategists to have a model that identifies basic kinds of KM activities that can be focal points for competitiveness. By formulating a plan involving practices and/or technologies to perform one or more of these KM activities better than competitors, the organization can attain a competitive advantage. The Knowledge Chain Model identifies these activities, thereby offering guidance to those who formulate KM strategy.

THE KNOWLEDGE CHAIN MODEL

Although it is analogous to the Value Chain Model, the Knowledge Chain Model (KCM) is not derived from the Value Chain Model (Holsapple & Singh, 2000, 2001). Rather, it is derived from a collaboratively engineered ontology of knowledge management. Moreover, the KCM is supported by empirical studies that show a connection between each of its KM activities and organizational competitiveness. It is important to understand that (like Porter's Value Chain Model), the KCM is not a process model. Rather, it identifies activities of particular interest to persons formulating strategy. Instances of the activities occur simultaneously, serially, in parallel, and in loops combining to form various patterns in the course of organizational operations.

Several researchers have proposed models derived from the Value Chain Model to help understand various aspects of IT (e.g., Rockart & Short, 1991). One of these, called the Information/Knowledge Value Chain, adapts the value chain to propose a linear process model that describes stages in an organization's processing of information and knowledge (King & Ko, 2001). The authors use this model as a basis for developing a framework that can be used to evaluate KM efforts in terms of cognitive, post-cognitive, behavioral, learning, and organizational impact assessments (King & Ko, 2001). They briefly suggest another use of the model: namely, that planners sequentially consider each stage in the Information/Knowledge Value Chain to design strategic systems. This consideration can involve brainstorming or other approaches to stimulating ideas about the stage, with the aim of uncovering better ways to implement it. Brainstorming and similar approaches can also be applied to any of the Knowledge Chain Model's activities.

Here, we first present highlights of the original KCM. Because the original model has been further developed, we then describe this more detailed version of the KCM.

The Original Knowledge Chain Model

The Knowledge Chain Model identifies nine crucial activities that knowledge-driven enterprises can perform in ways that yield competitive advantage (Holsapple & Singh, 2000, 2001). These activities are derived from an ontology of knowledge management phenomena that was collaboratively engineered with an international array of KM practitioners and researchers (Joshi, 1998; Holsapple & Joshi, 2002, 2003, 2004). Like Porter's Value Chain Model, it is a basic tool for diagnosing competitive advantage and finding ways to enhance it.

The Knowledge Chain Model includes five primary activities that an organization's knowledge processors perform in manipulating knowledge assets. These five activities are identified in the KM ontology as the five generic KM activities involved within knowledge management episodes: acquiring, selecting, generating, assimilating, and emitting knowledge. In addition, the KCM includes four secondary activities that support and guide performance of the primary activities. These four KM activities are identified in the KM ontology as managerial influences on the conduct of knowledge management: leading, coordinating, controlling, and measuring knowledge management initiatives. The KMC recognizes four ways in which improvements in the design and execution of KM activities can aid competitiveness: better productivity, greater agility, greater innovation, and enhanced reputation (i.e., the PAIR approaches to competitiveness).

Figure 2. The original Knowledge Chain Model

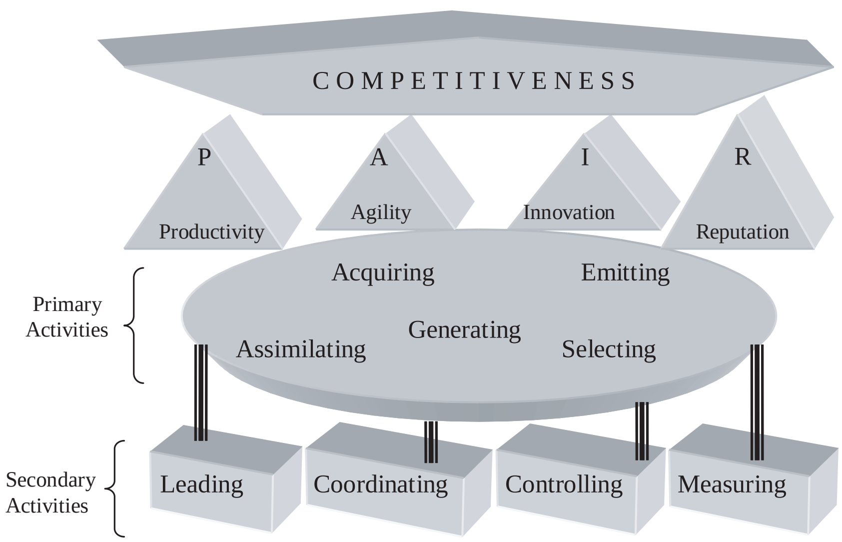


Figure 2 shows how the elements of the Knowledge Chain Model are related. Observe that no process is specified in the model. As with the Value Chain Model, the impetus is on identification of key activities on which to concentrate in formulating strategies for adding value and improving competitiveness. The fact that the Value Chain Model and the KCM each have nine activities appears to be coincidental, as the KCM is not derived from the Value Chain Model and there is no particular correspondence between any KCM activity and any value chain activity. Indeed, all of the KCM activities can be applied to the study or implementation of knowledge processing within any one of the value chain activities.

The KCM disaggregates a knowledge-based firm's knowledge processing and systematically examines all the discrete but interrelated primary and secondary KM activities that the firm performs. The result is a means for analyzing the sources of competitive advantage. The economics of how each KM activity is performed will affect whether a firm's cost structure is high or low relative to competitors. How each KM activity is performed will also affect its contribution to meeting customer needs and hence its degree of differentiation from other firms. Comparing the knowledge chains of competitors can reveal differences that determine competitive advantage.

Table 1 summarizes the KM activities that comprise an organization's knowledge chain. Anecdotal evidence indicates that this set of interrelated knowledge activities appears to be common across diverse organizations, appears to be capable of being performed with various practices and technologies so as to promote competitiveness, and appears to do so in the four PAIR directions (Holsapple & Singh, 2001). Moreover, a survey of KM practitioners indicates that each of the knowledge chain activities can be performed in ways that contribute to competitiveness along the PAIR directions (Singh, 2000).

Table 1. KM activity classes in the Knowledge Chain Model (adapted from Holsapple & Singh, 2001)

Category	Activity Class	Description
Primary	Knowledge Acquisition	Acquiring knowledge from external sources and making it suitable for subsequent use
Primary	Knowledge Selection	Selecting needed knowledge from internal sources and making it suitable for subsequent use
Primary	Knowledge Generation	Producing knowledge by either discovery or derivation from existing knowledge
Primary	Knowledge Assimilation	Altering the state of an organization's knowledge resources by distributing and storing acquired, selected, or generated knowledge
Primary	Knowledge Emission	Embedding knowledge into organizational outputs for release into the environment
Secondary	Knowledge Measurement	Assessing values of knowledge resources, knowledge processors, and their deployment
Secondary	Knowledge Control	Ensuring that needed knowledge processors and resources are available in sufficient quality and quantity, subject to security requirements
Secondary	Knowledge Coordination	Managing dependencies among KM activities to ensure that proper processes and resources are brought to bear adequately at appropriate times
Secondary	Knowledge Leadership	Establishing conditions that enable and facilitate fruitful conduct of KM

KM skills of an organization's participants need to be cultivated and applied in the performance of these activities. When a specific instance of a KM activity occurs in an organization, it is performed by one or more knowledge processors, some human and others computer based. Multiple processors may be able to perform a given type of KM activity. Conversely, multiple types of KM activity may be performed by a given processor.

Knowledge acquisition refers to the activity of identifying knowledge in the organization's external environment and transforming it into a representation that can be assimilated, and/or used for knowledge generation or emission. Selecting knowledge refers to the activity of identifying needed knowledge within an organization's existing knowledge resources and providing it in an appropriate representation to an activity that needs it (i.e., to an acquiring, assimilating, generating, and emitting activity). Generation is an activity that produces knowledge by discovering it or deriving it from existing knowledge, where the latter has resulted from acquisition, selection, and/or prior generation. Derivation involves the use of process knowledge (e.g., procedures, rules) and descriptive knowledge (e.g., data, information) to generate new process and/or descriptive knowledge employing KM skills that are of an analytical, logical, and constructive nature. Although the result is "new" to the processor that derives it, it may have previously existed but not have been assimilated, or it may already exist elsewhere in the organization but not be subject to facile selection. Discovery generates knowledge in less structured ways, via skills involving creativity, imagination, and synthesis.

Assimilating is an activity that alters an organization's knowledge resources based on acquired, selected, or generated knowledge. It receives knowledge flows from these activities and produces knowledge flows that impact the organization's state of knowledge. Emitting knowledge is an activity that uses existing knowledge to produce organizational outputs for release into the environment. It yields projections (i.e., embodiments of knowledge in outward forms) for external consumption, in contrast to assimilation which may also yield projections, but which are retained as knowledge assets. Emission is only partially a KM activity because it also can involve physical activities such as production through raw material transformation.

In characterizing the KCM's primary activities, we have strictly adopted the activity definitions existing in the underlying KM ontology. Some KM authors use some of the same terms but with different meanings. For instance, Davenport and Prusak (1998) use the term "knowledge generation" to mean not only generation as it is defined in Table 1, but to also include knowledge acquisition activity. However, just as there is a fundamental distinction between making something and buying something, the distinction between generating knowledge oneself and obtaining knowledge from external sources deserves to be made. As another example, some authors use the term "knowledge acquisition" to include not only acquisition as recognized in the ontology, but to include knowledge selection as well. However, this suggests that it is possible to acquire what we already possess, as well as what we do not possess. Like the ontology on which it is based, the KCM holds that the distinction between acquiring knowledge that is not possessed and selecting from knowledge that is possessed is an important one. Thus, in using the Knowledge Chain Model, it is important to be true to the definitions of its activities rather than confusing them with alternative definitions that are not as sharp in making distinctions.

Secondary activities support and guide the performance of primary KM activities. Measurement involves the valuation of knowledge resources and knowledge processors, including quantitative methods, qualitative assessment, performance review, and benchmarking. It is a basis for evaluation of control, coordination, and leadership; for identifying and recognizing value-adding processors and resources; for assessing and comparing the execution of KM activities; and for evaluating the impacts of an organization's conduct of KM on bottom-line performance. Control is concerned with ensuring that needed knowledge resources and processors are available in sufficient quantity and quality subject to required security and constraints on integrity and privacy. Quality is controlled with respect to two dimensions: knowledge validity (accuracy and consistency) and knowledge utility (relevance and importance). Controlling the quality of knowledge is a significant issue for KM, because the value of knowledge and returns achieved from knowledge resources depend on its quality. Protection involves protection from loss, obsolescence, unauthorized exposure, unauthorized modification, and erroneous assimilation.

Coordination refers to guiding the conduct of KM in an organization. It involves managing dependencies among knowledge resources, among knowledge manipulation activities, between knowledge resources and other resources (i.e., financial, human, and material), and between knowledge resources and KM activities. It involves marshaling sufficient skills for executing various activities, arranging those activities in time, and integrating knowledge processing with an organization's operations. An organization's approach to problem solving, decision making, experimentation, and organizational learning, all of which are knowledge-intensive endeavors, can depend on how it coordinates its KM activities. Of the four secondary KM activities, leadership is central. It sets the tone (i.e., shapes the culture) for coordination, control, and measurement that manifest. It qualifies the expression of each primary activity. In short, leadership establishes enabling conditions for achieving fruitful KM through the other eight activities. The distinguishing characteristic of leadership is that of being a catalyst through such traits as inspiring, mentoring, setting examples, engendering trust and respect, instilling a cohesive and creative culture, establishing a vision, listening, learning, teaching, and knowledge sharing.

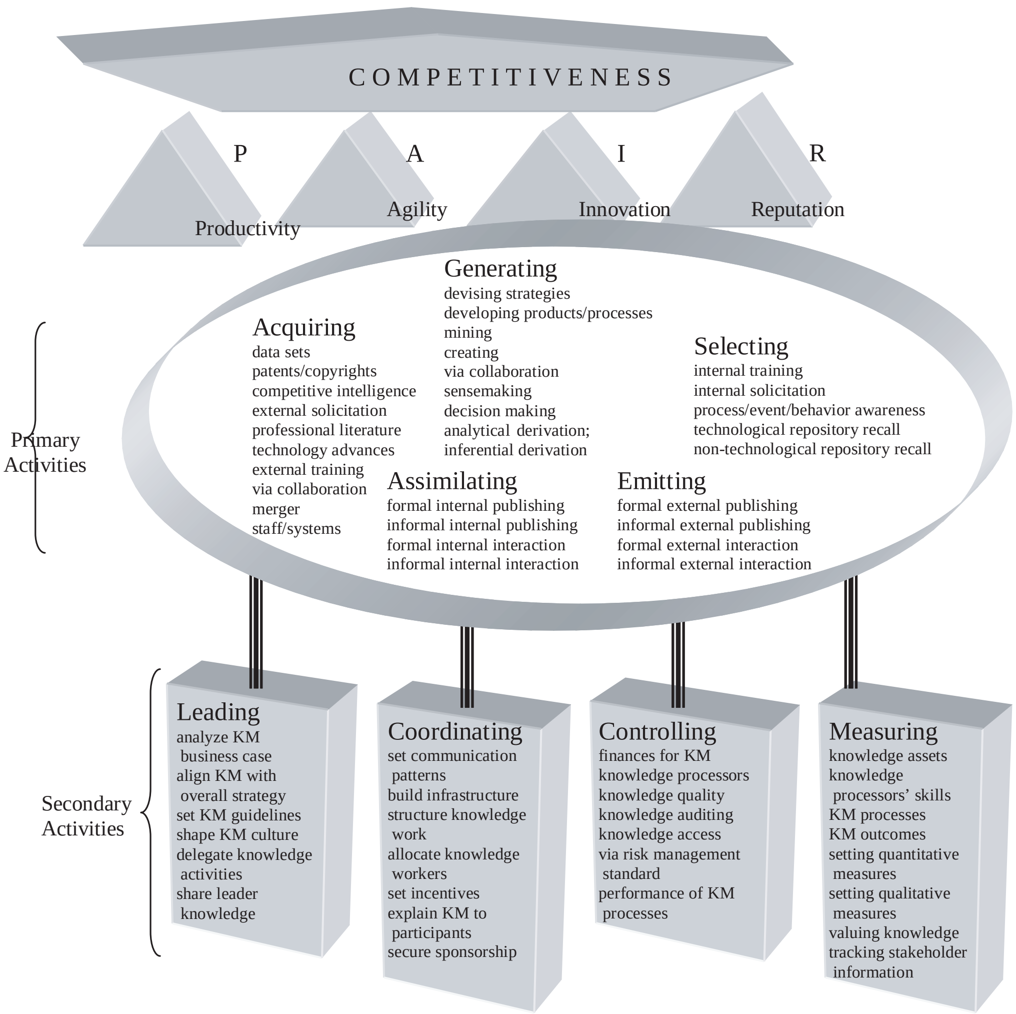
The Extended Knowledge Chain Model

The Knowledge Chain Model can be developed in further detail by identifying specific KM activity types that belong to each of the nine classes shown in Table 1 (Holsapple & Jones, 2003, 2004, 2005). In all, over 60 specific KM activities, organized into the nine classes, have been determined to yield this extended version of the KCM. These more detailed activities have been developed from an interpretive analysis of the knowledge management literature and have been judged in a survey of practitioners who lead KM initiatives as capable of being performed in ways that contribute to organizational competitiveness (Jones, 2004). The distinct KM activity types for each class are illustrated in Figure 3. For full descriptions and examples of each of the detailed KM activities, refer to Jones (2004) and Holsapple and Jones (2004, 2005). These elaborations also include taxonomies for organizing the specific KM activity types within each of the nine KCM classes.

Using the Knowledge Chain Model to Guide KM Strategy Formation

Clearly, formulating a KM strategy is not a trivial task. Moreover, it needs to be developed in concert with other aspects of an organization's overall strategy (e.g., marketing strategy, financial strategy). This development could be after the fact, devised to be aligned with and supportive of pre-existing business strategy. Alternatively, KM strategy formulation may be an integral part of an organization's overall strategy development. In either event, KM strategy is concerned with design and deployment of a suitable mix of practices and technologies for performing the knowledge management activities that can

Figure 3. The extended Knowledge Chain Model



contribute to organizational performance and competitiveness. But exactly what are these crucial KM activities? The extended version of the Knowledge Chain Model answers this question in considerable detail. As such, it can help guide KM strategy formation.

Knowledge technologies, knowledge practices, and knowledge assets are the building blocks of a KM strategy (recall Figure 1). As discussed previously, Zack (1999) has provided a way of analyzing knowledge assets that can guide KM strategy formation. The KCM provides a structure for dealing with the practice and technology aspects of KM strategy. An appropriate combination of the possibilities for these two factors needs to be determined in formulating a plan for implementing each of the KM activities identified by the Knowledge Chain Model. For a given organization, the determination of what specific technology/practice mix is appropriate for each of the KM activities depends on two classes of situational factors: the organization's available assets (i.e., human, financial, knowledge, material) and the nature of the environment (e.g., social, political, regulatory, market, industry) in which the organization finds itself.

As a starting point, the KM strategist needs to understand where the organization presently is with respect to each of the KCM activities. A SWOT analysis for each activity can be helpful. For a particular KCM activity, what are the current practices and technologies (if any) that are being used, to what extent does this approach to implementing the activity contribute to PAIR, what practices/technologies do competitors use to implement the activity? Next, the KM strategist needs to brainstorm and develop insights about possibilities for performing the KCM activity in ways that enhance organizational performance (e.g., in one or more of the PAIR directions). What alternative practices/technologies are feasible candidates for implementing the activity in light of the organization's asset situation and environment situation? Do available knowledge assets (e.g., patents, culture, infrastructure, data warehouses), human assets (e.g., knowledge processing skills), or material assets (e.g., automated knowledge processing skills) allow the strategist to plan on value-adding practices/technologies for implementing the activity? Do present or anticipated environmental factors suggest competitive threats or opportunities in the performance of the activity? These should be factored into KM strategy development relative to the KCM activity.

Another way to look at KM strategy formation is more of a top-down approach. Here, the strategist settles on one (or more) of the PAIR directions as being most consistent with or important to the overall business plan. Suppose that it is agility that the organization most wants to compete on. Each of the KCM activities is then examined from the standpoint of how the present way of performing it contributes to agility. The KM strategist asks whether there are practices/technologies that can be economically adopted as part of the plan to make the organization better able to respond to rapid, perhaps unexpected, changes in its environment or assets. The KM strategy then becomes tied to the overall strategy of excellent response-ability. Empirical study of the original KCM gives clues as to which of the nine activity classes are likely to have greatest potential for impacts on agility (Singh, 2000).

FUTURE DIRECTIONS

While the KMC offers guidance to KM strategists in structuring both the planning and the plan for driving KM initiatives, it does not offer prescriptions about what practices/technologies to adopt in specific asset/environment situations or for achieving results in a specific PAIR dimension.

The KM activities identified by the KMC are not the only determining factors that can lead to competitiveness. There are other forces that influence how the conduct of KM ultimately unfolds in an organization: resource influences (e.g., knowledge assets) and environmental influences (Joshi, 1998). This suggests that the KCM could be extended to include resource and environmental factors, which both constrain and enable the execution of KM activities. One future research direction is to investigate this extension.

The KMC is descriptive in nature. Its intent is to identify KM activities that researchers and practitioners need to consider in managing knowledge to enhance organizational performance. An obvious next step is prescriptive, further developing the KMC to lay out candidate practices and technologies for each of the KM activities.

CONCLUSION

In the interest of being competitive, a knowledge-based organization must adopt, design, and implement knowledge management activities better than other organizations. The Knowledge Chain Model identifies nine classes of KM activities and over 60 specific KM activities that appear to be common across diverse organizations. The KMC holds that individually, and in combination, these KM activities can be contributors to competitiveness. Evidence from the literature provides support for this assertion, as do results of surveys of leaders of KM initiatives. Thus, rather than simply saying that KM can yield a competitive advantage, the Knowledge Chain Model provides structure to designers of KM strategy, ensuring full consideration of the varied KM activities that can be sources of competitiveness in the directions of better productivity, agility, innovation, and/or reputation.

Chapter 2.33
Knowledge Structure and Data Mining Techniques

Rick L. Wilson
Oklahoma State University, USA

Peter A. Rosen
University of Evansville, USA

Mohammad Saad Al-Ahmadi
Oklahoma State University, USA

INTRODUCTION

Considerable research has been done in the recent past that compares the performance of different data mining techniques on various data sets (e.g., Lim, Low, & Shih, 2000). The goal of these studies is to try to determine which data mining technique performs best under what circumstances. Results are often conflicting—for instance, some articles find that neural networks (NN) outperform both traditional statistical techniques and inductive learning techniques, but then the opposite is found with other datasets (Sen & Gibbs, 1994; Sung, Chang, & Lee, 1999: Spangler, May, & Vargas, 1999). Most of these studies use publicly available datasets in their analysis, and because they are not artificially created, it is difficult to control for possible data characteristics in the analysis. Another drawback of these datasets is that they are usually very small.

With conflicting empirical results in the knowledge discovery/data mining literature, there have been numerous calls for a more systematic study of different techniques using synthetic, well-understood data. The rationale for synthetic data is that various factors can be manipulated while others are controlled, which may lead to a better understanding of why technique X outperforms technique Y in some, but not all, circumstances (Scott & Wilkins, 1999).

This call for research dates back to Quinlan's seminal work in inductive learning algorithms. In his 1994 study that analyzed the difference between neural networks and inductive decision trees, Quinlan conjectures the existence of what he called S-problems and P-problems. In his definition, S-problems are those that are unsuited for NN's, while P-problems are those unsuited for decision tree induction. More recently, the review work on neural networks by Tickle, Maine, Bologna, Andrews, and Diederich (2000) propose that determining whether a classification task belongs to the P-problem or S-problem set is a very important research question.

Recently, other researchers have proposed that the composition of the underlying knowledge in a dataset, or knowledge structure (KS), may be pertinent in understanding why knowledge discovery techniques perform well on one dataset and poorly on others. This term has been used by Hand, Mannila, and Smyth (2001), and Padmanabhan and Tuzhilin (2003) to refer to this phenomenon, while Scott and Wilkins (1999) used a similar term, structural regularities, to describe the same concept.

The goal of this article is to explore in more detail how the existence of a database's underlying knowledge structure might help explain past inconsistent results in the knowledge discovery literature. Management scholars will recognize the term knowledge structure, as Walsh (1995) refers to it as a "mental template…imposed on an information environment to give it form and meaning." Therefore, for the knowledge discovery context, we propose that knowledge structure is analogous to the form and meaning of the knowledge to be discovered in a database. Though we will not explore the concept too deeply, one also can define knowledge structure through the use of a parameter set P as proposed by Hand et al. (2001). The parameter set would be attribute-value pairs that detail the existence of a specific knowledge structure for a given knowledge concept/database pair.

This knowledge structure concept is an abstract concept, which may make it hard to visualize. Typically, when a knowledge worker is using a technique to extract knowledge from a database, they will not have any idea about the underlying knowledge structure of the concept of interest. But, researchers have hypothesized that knowledge discovery in a database is optimized when the formalism of the tool matches this underlying structure of the knowledge (Hand et al., 2001). Based on this, we conjecture that if a knowledge worker did know the knowledge structure parameter values prior to exploring the data, he or she could find the optimal tool for the knowledge discovery process.

From a historical perspective, past knowledge discovery and data mining research results could be explained by whether a particular knowledge discovery tool was or was not a good "match" with the underlying knowledge structure. The idea of matching the tool to the structure is somewhat analogous to the concept of task-technology fit, studied in the MIS literature during the mid 1990s (Goodhue, 1995).

Recent research in other related areas has found that contradictory or difficult to explain results could be related to the concept of knowledge structure (Wilson & Rosen, 2003). In this study, the well-known IRIS and BUPA Liver datasets were used to examine the efficacy of knowledge discovery tools in protected (by data perturbation) confidential databases. The IRIS dataset is known to possess linearly separable classes, while the BUPA Liver dataset cases has been historically difficult to correctly classify for all knowledge discovery tools. An outcome of this research was the proposal that knowledge discovery tool effectiveness in a protected (perturbed) database could be impacted by both the database's underlying knowledge structure and the noise present in the database. The concept of noise is simply the degree to which the different classes can be separated or differentiated by the optimal tool, or, alternatively, a surrogate measure of how difficult cases are to classify (e.g., Li & Wang, 2004).

Through a simple example, the article will attempt to provide some evidence that the underlying knowledge structure present in a database could have significant impacts on the performance of knowledge discovery tools. Building on past postulation, the example also will explore whether the so-called "match" between the knowledge structure and the knowledge discovery tools' own formalism is important to the classification accuracy of the knowledge discovery task.

BACKGROUND

To investigate the possible impact of what has previously been defined as knowledge structure, a hypothetical database/classification task will be formulated. Thus, the investigation of knowledge structure in this article will be limited to a classification domain. The concepts of knowledge structure can be extended to all kinds of knowledge discovery tasks: prediction/regression, clustering, and so forth. We choose classification as our focus because it is a well-studied area and is easily illustrated in this experiment.

To this end, a 50,000 record fictitious bank database, previously used in another work (see Muralidhar, Parsa, & Sarathy, 1999), will serve as the database for the study. The data, in its original form, has five attributes (Home Equity, Stock/Bonds, Liabilities, Savings/Checking, and CD's) with known means, standard deviations, and so forth.

To simulate the existence of an important knowledge concept, a sixth binary categorical (class) variable was systematically added to the database, representing some important knowledge to a data analyst (perhaps differentiating between profitable customers and not-so-profitable customers). How the class variable was systematically created is addressed and is related to the knowledge structure parameters.

We chose a very simplistic definition of knowledge structure types in our continuing example. Two different knowledge structures were employed, decision tree and linear. The decision tree (DT) structure means that the researchers created a decision tree using all five variables, and then the data was applied to the tree to determine class membership (either '0' or '1') in the sixth variable, for each individual case. The specific tree used was chosen such that all variables were found in the tree and that there were an equal number of the two distinct classes created (25,000 cases each of 'class 0' and 'class 1'). The tree itself was obviously somewhat arbitrary, but does represent a scenario where the underlying structure of the knowledge concept was in a decision tree form.

The second structure used was a linear format (LINEAR). A strictly linear relationship was created using all five variables, to determine class membership (either '0' or '1') in the sixth variable for each individual case. Again, the resulting values for the sixth variable included 25,000 cases for each 'class 0' and 'class 1.' This again represents the situation where the underlying knowledge concept of interest is in a linear form.

While these two structures may be overly simplistic, their choice allows us to explore the possible impact of the concept of knowledge structure with minimal moderating factors. Ultimately, the notation of Padmanabhan and Tuzhilin (2003) may be a more formal and more accurate approach to describe this phenomenon, and we will return to this later in the article.

For each of the two exemplar knowledge structures (DT and LINEAR), we created another database that involved adding "noise" to the class variable. The purpose of adding noise is to have the synthesized datasets replicate knowledge discovery situations where a perfect discrimination between classes is not possible, as is true in the case of the previously mentioned BUPA Liver dataset. One could argue that real-world databases are more likely than not to have a high degree of noise. To introduce noise into each of the noise-free datasets (referred to as the 0% noise case), the class variable of 25% of the cases in each class were randomly switched. Thus, the balance of the two different classes was preserved (25,000 of each), and 25% of the cases were now put into the wrong class.

Thus, four different datasets were synthesized—a dataset where the underlying knowledge structure was a decision tree with 0% noise, a dataset where the underlying knowledge structure was a linear relationship with 0% noise, and the complimentary datasets where inaccuracy, in the form of 25% noise, was added into the class variable. These four different datasets represent a diverse spectrum of knowledge discovery scenarios.

In our quest to investigate how knowledge discovery tools may be impacted by the structure of knowledge, there are many possible tools that could be utilized. To try to get a wide view of possible impacts, we present the results from four "standard" approaches: discriminant analysis, the decision tree procedure CART (Classification and Regression Tree Analysis), logistic regression, and a standard feed-forward back-propagation neural network.

Discriminant analysis was selected because it uses (for the two class case) a linear regression-based approach for classifying cases. Thus, from Hand et al.'s (2001) contention that classification/knowledge discovery is optimized when the formalism of the tool matches the underlying structure of the knowledge, one would expect discriminant analysis to perform the best when the underlying knowledge structure was linear.

However, there are many citations in the statistics literature that state when dealing with binary (or categorical) dependent variables, logistic regression is superior in performance to discriminant analysis. Thus, we study both approaches, since they represent tools whose underlying formalism is linear. Both were implemented using standard statistical routines in SPSS.

Using the same rationale, the CART algorithm was selected, as it is a well-known and well-documented inductive decision tree algorithm (see Weiss & Kulikowski, 1991). Given the contention of matching structure to tool formalism, one would expect CART to perform better for those datasets with a decision tree knowledge structure. Again, this tool was implemented using standard defaults in the SPSS package Answer Tree.

Finally, feed-forward, back-propagation neural networks were implemented and used in this study. As another non-parametric technique (like CART), neural networks are often times compared to traditional statistical tools in classification problems. Many claim that they are universally the best classifiers, though results do not necessarily support this claim. Neural network researchers might postulate that they may be immune to knowledge structure impacts since they are alleged to be able to find all types of classification knowledge patterns. The neural network software used in this study was SPSS's Neural Connection, again using standard default values for training, network structure, and the like.

The dependent measure of interest in this study was the classification accuracy of the knowledge discovery tool. Since we had datasets of equal class membership, individual class accuracy was not of particular interest. Ten-fold cross-validation (with stratified samples) was used to ensure a robust measure of tool classification accuracy (see Weiss & Kulikowski, 1991, for more details). An instance was labeled as correctly classified when the tool classification matched the actual class value of the database instance. The correct number of classifications was assessed both for the training (development) and testing partitions. Due to the large size of our simulated dataset and the use of cross-validation, the accuracy of the tools for the training and testing set were nearly identical. Therefore, for simplicity, we report only the results of the testing sets.

RESULTS

Table 1 shows the average classification accuracy over the 10 trials for the experiment. The rows represent the four different knowledge discovery techniques used: logistic regression (LR), multiple discriminant analysis (MDA), the decision tree

Table 1. Average classification accuracy

	Noise	Level
KS=Tree	Zero	Twenty Five
LR	72.9	61.2
MDA	72.6	61.2
CART	100	75
NN	98.7	72.5

KS=Linear	Zero	Twenty Five
LR	100	74.3
MDA	98.7	74.2
CART	87.1	68.5
NN	99.9	74.7

inductive learning algorithm of CART, and back propagation neural networks (NN). The columns represent the two different levels of Noise (0% and 25%). The top half of Table 1 shows the results when the decision tree knowledge structure was used to create the synthetic database, the bottom half, the results when a linear structure was used. Figures 1 and 2, respectively, show the results in graphical format.

Knowledge Structure: Decision Tree

For the datasets whose knowledge was generated via decision trees, the CART decision tree approach had 100% classification accuracy for the 0% noise case, and 75% accuracy for the 25% noise case. As the formalism of the knowledge discovery approach exactly matches the knowledge structure, these results are not surprising.

The poor performance of the linear-based methods, multiple discriminant analysis and logistic regression may be surprising. They do a very poor job of classification when applied to the decision tree knowledge structure (approximately 73% correct in the 0% noise case). Thus, the unmatched approaches were approximately 27% worse than the matched approaches. This is fairly strong evidence of the potential impact of matching the knowledge discovery approach to the true underlying knowledge structure. Similar results are also true for the 25% noise rate; however, the impact is dampened in magnitude due to the already poor performance of MDA and LR.

The results of the neural network for both noise levels are very good but are statistically

Figure 1. Tree KS

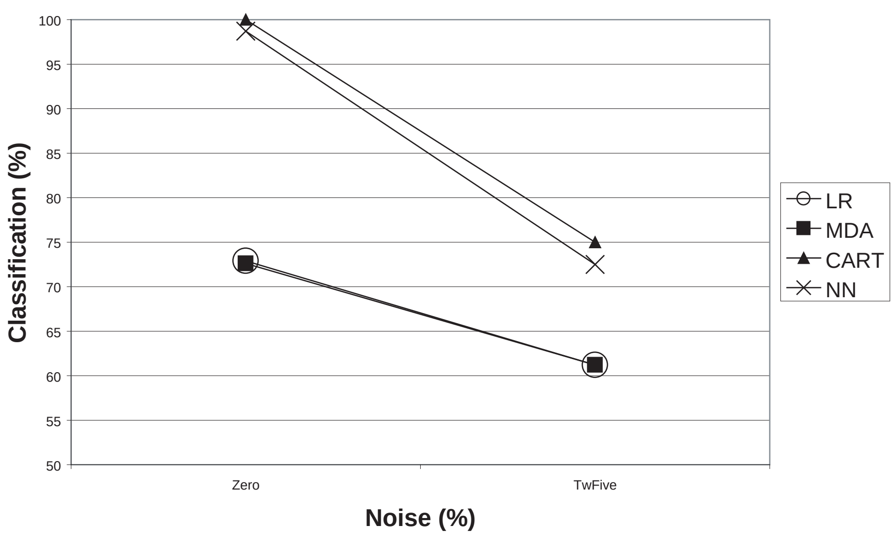

Figure 2. Linear KS

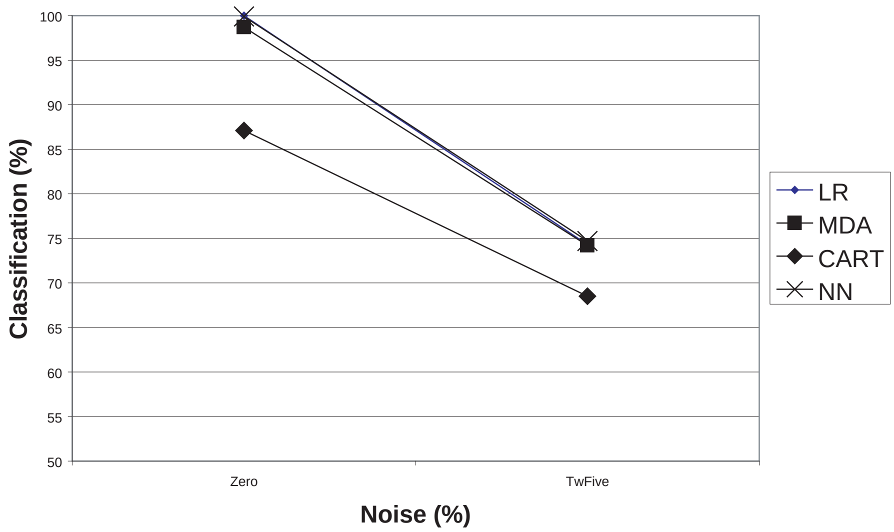

significant different (worse) than CART. Even considering this, the neural network seems less susceptible to performance impact than the linear knowledge discovery techniques. Summarizing from a statistically statistical standpoint, CART performs statistically better than all three other techniques, neural networks performs better than discriminant analysis and logistic regression, and the two linear approaches are equivalent performers.

Knowledge Structure: Linear

Interestingly, for the linear knowledge structure and 0% noise, logistic regression performs perfectly (100% average correctly classifications). Discriminant analysis has just a small average "miss" rate (1.3%). Neural networks also perform very close to perfect (an average of 99.9% correct), while CART performs significantly worse (practically and statistically) at an 87.1% average correct classifications. Of importance is the finding that CART's performance when applied to a database with an unmatched knowledge structure is not nearly as poor as the performance of the linear tools when applied to databases with an unmatched knowledge structure.

With the noise level at 25%, it is surprising to see that neural networks perform better than all other techniques (though their classification accuracy is not statistically different from the two linear approaches). These results provide some credence to the robustness of neural networks when considering potential impacts of knowledge structure. Of course, this may be true only for this study.

Overall, for the linear knowledge structure databases, the two linear approaches and neural networks show no statistical differences, while all three perform statistically significantly better than the performance of CART. This is true for both with and without noise.

FUTURE TRENDS AND DISCUSSION

The results provide some evidence that knowledge structure and its relationship to the tools used could impact the results of knowledge analysis. Certainly, the small study undertaken could not claim to be comprehensive, but the evidence found would suggest consideration should be given to this concept of knowledge structure by practitioners and researchers alike.

Of course, the knowledge possessed by a database will likely never perfectly fit one specific knowledge structure (or at least as generically as they have been defined here). Similarly, the inclusion of noise into the synthetic database is at best a surrogate measure of the inherent difficulty to find hidden knowledge in a set of database cases. This difficulty could stem from relevant attributes not appearing in the database (missing information) or just because the knowledge/relationships resist easy quantification.

How might this knowledge structure concept be implemented or further quantified? Using the notation used in Padmanabhan and Tuzhilin (2003), perhaps the knowledge structure of a database can be identified as an n-tuple of the knowledge concept itself plus some measure (say on a continuous 0 to 1 scale) of how similar the knowledge structure is to a set of exemplars. This 0 to 1 scale also could be a measure of noise as it relates to the exemplar structures.

As a continuing example, consider the database already analyzed here, with five continuous attributes, one class variable indicating good/bad customer (noted by abbreviation GB), and suppose we also have another class variable indicating whether the customer is considered a likely target (0/1 value) for a new marketing campaign for a new product (noted by NP). Let us also assume (unrealistically) that there are four specific exemplar knowledge structures in the universe of knowledge discovery: decision trees (DT), linear (L), type 3 (T3), and type 4 (T4).

The four versions of the synthetic database used in the article might then be defined by a parameterized function KS = f(database, DT, L, T3, T4), such that the database with KS=DT and no noise would be KS=(GB,1,0,0,0), and with 25% noise KS=(GB, .75, 0,0,0). Likewise, the two datasets with underlying knowledge being linear would have parameterized KS values of (GB,0,1,0,0) and (GB, 0,.75,0,0), respectively.

Continuing with the example, if the knowledge structure of the concept new product target (NP) had mixed components of decision tree, linear and Type 4 structure, it might have a parameterized value of (NP, .3, .4, 0, .1). In summary, assuming that knowledge structure does continue to show promise as an explanatory factor in knowledge discovery results, future studies working to formalize and further operationalize this knowledge structure concept seem very important.

Some might view this problem of trying to quantify a database knowledge structure as not useful. We would argue that better understanding the dynamics of data mining and knowledge discovery is exactly the kind of problem that should be studied in academic research. The field needs better ways of ensuring the correct or best tool is used in knowledge discovery rather than depending upon pure chance. The use of multiple tools (and multiple variations of individual tools, such as ensembles of neural networks) is certainly a good strategy, but researchers should continue to look for new and innovative ways to help guide the data mining practitioner. Researchers should help practitioners better understand when and where these tools are most useful, and not just simply continue to deploy new tools.

The results of this article are another example of the potential of neural networks to seemingly approximate many types of functions (or knowledge structures), unlike the other three tools employed. Unfortunately, we cannot yet consider using only neural networks as a knowledge discovery tool given their present inability to explain the knowledge the tool has discovered

(Li & Wang, 2004). There is an ongoing stream of research (e.g, Tickle et al., 2000) focusing on developing techniques whereby neural network knowledge is made more understandable for the decision-maker, but it is still at primitive stages of development. Should this research lead to further enhancement of neural networks to better explain their results, then perhaps the search for the "holy grail" of knowledge discovery tools has been found. Unfortunately, the maturity of this research indicates this is not reasonable over the next few years.

However, neural networks may play an expanded role in knowledge structure determination through this same "natural" ability to learn any function. Perhaps they can somehow be trained to recognize exemplar and combined knowledge structures in various synthetic databases, and then the results of this trained network can be applied to real datasets under analysis. In this way, the decision-maker would have an improved idea on which knowledge discovery tool will likely optimize their results.

CONCLUSION

Many researchers have long been seeking the penultimate knowledge discovery technique. This article has provided evidence that the underlying knowledge structure that exists in a specific database could impact knowledge discovery results. It seems reasonable to further expand and clarify our definition of knowledge structure, work at further understanding how to operationalize this concept, and then merge this with ongoing streams of research that seek to enhance knowledge discovery tools, all resulting in providing better tools for the practitioner. Through this multifaceted approach we can continue to add deeper understanding to the operation of the many powerful analytic tools on the desktops of today's knowledge workers.

ABSTRACT

This paper provides a framework to implement quality function deployment (QFD) with knowledge management (KM) in the form of an integrated quality and knowledge management system (IQKS). This inter-organizational information system enables the sharing of information among customers, manufacturers and suppliers in the new product development process. It links up various strategically independent and autonomous business entities together in a common product platform (CPP). Up to now little has been published academically on sharing vital information involving the give-away of a firm's bargaining position about customers, product specification and process requirement. The common product platform facilitates an innovative organization to persuade like-minds in coming together and opening up useful and relevant information to all parties interested in creating a new level of competitive advantage in assessing the dynamics of market realities. They share knowledge and learn to support new organizational capabilities to leverage information technology that incorporate market knowledge, design knowledge, process knowledge and production knowledge.

INTRODUCTION

In the new economy, customers, manufacturers and suppliers dispersed across various geographical locations use information technology to talk to each other to coordinate engineering design and the flow of materials through different manufacturing operations. Hence, a product can have a choice to be made in various processes across organizations, at different geographical locations and utilizing different logistics for delivery. This enables the entire operational process to be linked up across organizations for customization by the participating firms. A new level of competitive advantage may be achieved when the operational processes of different firms can be adapted with the dynamic market environment.

Such advantage can be crucial to the development of new products. A product is manufactured through subassemblies and parts that can be put together. Each subassembly is represented by bills-of-materials (BOM). They can be deployed in a common product platform (inter-organizational information system) by partnering firms linked together with an information technology network. The coordination, marketing, design, engineering and production control can be more effective.

This chapter is divided into four sections. The first section addresses the view on contract manufacturing. It suggests how a manufacturing organization can leverage IT to compete in the information age. In the second section, relevant literature is reviewed on the area of extended enterprise. It portrays that knowledge has become an important consideration in developing extended enterprise architecture. For the third section, a conceptual framework of extended enterprise architecture is derived from observation on contract manufacturing. It reflects the necessary components and the linkage of quality function deployment (QFD) and knowledge management system (KMS) to form a framework for developing an integrated inter-organization information system. A case study is used to illustrate how the conceptual framework can be operationalized in the form of a common product platform making use of the bill-of-material (BOM) modules.

LITERATURE REVIEW

Contract Manufacturing

Contract manufacturing is more than a firm subcontracting out its manufacturing process and is about a strategy on positioning the firm in the future of providing a service of value. The firm operating with a contract manufacturing strategy is adopting a management paradigm that has far-reaching implications in terms of ownership, management succession planning and resources deployment.

Contract manufacturing is a phenomenon occurring in various manufacturing industries. It extensively aligns partners for collaboration in serving the customers. The firm in focus will only keep those processes that it is strong in and outsource the rest of the processes to suppliers or competitors. Without a good understanding of its implication on the nature of business and investments in appropriate technology, knowledge and research, manufacturing firms are likely to miss business opportunities in the ventures that create wealth and create customers for growth and profits.

Currently, views on contract manufacturing are diversified. In here we summarize a few points that are purported to be the key enablers of contract manufacturing. They are:

1. Changed view of international production strategy from “stand alone” operations to “deep integration” of operations with partners in a supply chain.
2. The increasing separation between the supply side and demand side of business: e.g.,

supply-side consolidation for economies of scale; demand side fragmentation enabled by e-commerce.

3. Knowledge separation enabled by digital factory concept. Manufacturing knowledge can be separated from design knowledge; or marketing knowledge can be separated from design knowledge.
4. The transition from a "command and control" style of management to a "one-stop shopping" self-adaptive supply chain style of management to enable customization of value.

The Change of International Production Strategy

A "stand-alone" operation for control is leveraging on a level of technology investment that encourages the moving of production facilities to a low-wage manufacturing environment for competitiveness. (Most Hong Kong manufacturing companies have relocated their production bases to Mainland China after China announced its open door policy in 1978). However, a "deep integration" operation is about the strategy of developing an integrated production system to support disserting the different steps of a production process and have different parts undertaken by different countries according to their relative cost and logistical advantages. (UNCATDA, 1993, 1999).

Increasing Separation Between Supply and Demand Side

The advance in information technology and networking economy, the development of electronic commerce and the proliferation of B2B online exchanges further separate the supply and demand sides of many industries. On the demand side, there is a rise of customer expectation. Customer relationships or learning relationships are being developed to retain future business value and growth (Peppers & Rogers, 1997). On the supply side the pressure of getting economies of scale and scope lead to changes in the traditional industry structure. Many companies are now consolidating to realize economies of scale and scope to recoup their investment in business infrastructure (Hagel & Singer, 1999).

The Observation of Knowledge Separation

In many industries, design knowledge is being separated from manufacturing knowledge. This knowledge was once difficult for articulation but now can be made explicitly with substantial organizational implications. Manufacturing organizations can outsource even more to a network of suppliers (Magretta, 1998a). Central to this development is the development of "connected assets" (Blitz, 1999). Today contract manufacturing thrives on this trend with the development of subsystems template and the setting up of a common product platform that can be readily integrated upon customers' desire (Meyer & Lehnerd, 1997). The ability to develop and quantify these assets is the key for future business development.

The Self-Adaptive Supply Chain Style of Management

The ability for a team of organizations working as an extended enterprise through dynamics partnerships is the key for future success. The existence of a partnership ties the stakeholders of organizations together in developing commitments and sharing a risk-taking culture. Corporate competence will have to be integrated to address changing market opportunities. The cost of maintaining a set of vertically integrated competencies is prohibitive for many businesses (Agility Forum, 1997). The ability to interface with others within a value net is the key for future success.

Table 1. A summary of recent contract manufacturing activities

Case	
2001 Ericsson and Flextronics (Gartner, 2001)	
Outsourcing	Outsource the manufacturing of mobile phone to Flextronics by transferring plants and employees from Ericsson
2000 Motorola and Flextronics (Thurm, 2000)	
Outsourcing	Motorola hire Flextronics to manufacture consumer electronics
Alliance	Cross investment in stake-holdings
2000 Arima and Compaq–Notebook Contract Manufacturer in Taiwan (Baum, 1999)	
Partnering	Notebook research centre assists the manufacturing of notebook computers
1999 Nortel Network(Royal, 1999)	
Outsourcing	Outsourcing the manufacturing of telecommunication equipment
1999 Sara Lee (Royal, 1999)	
Outsourcing	Selling factories and outsourcing manufacturing of food products. Concentrate on servicing brand name

Table 1 illustrates some of the contract manufacturing activities recently found in various manufacturing organizations and industries.

The reported contract manufacturing scenarios revealed that manufacturers organize themselves to leverage IT to share information and compete more effectively. The reported cases led manufacturing management to a new era of competition. The new competition is not based on economies of scale, but much depends on how quickly enterprises are aligned together to come up with new business processes tailored to the market requirement. This resembles the business model of mix and match in a real-time exchange market. Thus, contract manufacturing here is defined as a partnership among manufacturing organizations, customers and suppliers working together as an extended enterprise using IT links. Such an alignment model requires the support of extended enterprise architecture.

Modeling Extended Enterprise

An extended enterprise can be described as a partnership between enterprises where the goal is to achieve competitive advantages by forming formal linkages (contracts) and maintaining cooperation distributed throughout the network. In the extended enterprise the collaborating firms are encouraged to focus on their core competencies (Szegheo & Andersen, B, 1999). With the partnering elements becoming more important, extended enterprise modeling seeks a holistic view to avoid the optimization of one partner at the expense of the others.

Activities are used as the basic elements for modeling an extended enterprise. The challenge is that the activities are dispersed across the network, crossing organizational boundary, making information collection and modeling very difficult. IT linkages will have to be deployed more systematically to collect the necessary information to enable such a model to become a reality.

CONCEPTUAL FRAMEWORK

A knowledge-based view is proposed as the basis for the formulation the extended enterprise architecture, hence the term "knowledge-based extended enterprise architecture." The idea is to encourage partnering in the extended enterprise to form the basis of developing a knowledge-sharing practice. Four core components of the extended enterprise architecture have been identified. They are market knowledge, design knowledge, process knowledge and production knowledge.

Market Knowledge

Market knowledge such as customer lists, market research, data on service or demand patterns are considered to be an important element for the existence of an extended enterprise. Market knowledge serves as the primary input to the extended enterprise and is translated into specific customer needs, perception and preferences. It is a conduit to enable the extended enterprise to interact with the market in order to reconfigure itself for the market. Sometimes, discovering hidden value propositions of the market can assist extended enterprise to move away from manufacturing a "me-too" product.

Design Knowledge

Design knowledge is associated with research and development efforts. It embraces the technological content of the product, essential to a business, and is supplied by knowledge workers within the participating firms of the extended enterprise. The design knowledge is very important in supporting the product requirement derived from market knowledge. In many circumstances, combining market and design knowledge uncovers hidden value propositions for new customers. Early involvement with customers to design a new product can be beneficial to reduce design lead-time. Thus, participating extended enterprise organizations that contribute or invest in activities to make instrumental goods early in new product development can improve overall extended enterprise performance.

Process Knowledge

Process knowledge is a derivative of manufacturing knowledge. It is concerned with workflow management, capacity management, logistic arrangement and scheduling arrangement. Knowledge workers contributing these kinds of knowledge can be sourcing managers, supply chain managers and schedulers. They ensure the order fulfillment process is in place for delivery purposes. The knowledge in this area is generated and acquired through extensive work and know-how in infrastructure management.

Production Knowledge

Production knowledge is also a derivative of manufacturing knowledge. It is associated with production of physical goods. Investment in manufacturing technologies and management helps develop such knowledge in a manufacturing organization. Smart use of manufacturing technologies and management of knowledge work give insights into the development of instrumental goods that can be deployed for improving realization activities. The performance is usually associated with volumes, quality and cost. When material costs and overhead costs represent a large proportion of overall product costs, product knowledge is essential in trying to keep the cost structure under control. Production knowledge can combine with other types of knowledge in the extended enterprise architecture to improve performance. For example, early supplier involvement enables the sharing of knowledge by both manufacturers and suppliers, and they can benefit by shortening the time to market.

Common Product Platform—Embedding Knowledge in Product

A common product platform is proposed as a vehicle to establish a knowledge-sharing routine within the extended enterprise. This provides participants a reference model of a product that can be modified by the different partners of the extended enterprise architecture.

Figure 1 shows the concept of a common product platform supporting the use of different knowledge to customize a product. As a knowledge-sharing routine, the common product platform allows knowledge from different areas to interact with each other to create new ones. For example, design knowledge can interact with manufacturing knowledge in a way that the product can be designed more effectively for production.

Develop a System to Leverage the "Voice of Customers" with Knowledge Management

Based on the common product platform, a system for integrating quality function deployment (QFD) with a knowledge management system (KMS) is to be developed. It incorporates the QFD and the KMS systems. The QFD is a tool for enterprise modeling that allows internal as well as external staff to communicate and contribute knowledge in a systematic manner. It is a useful modeling approach to discover the interrelationship among customer demands, engineering requirements and manufacturing processes. Central to the QFD is the house of quality that defines the WHAT and HOW as part of the relationship. The WHAT and HOW is captured by a knowledge management system (KMS). Conceptually thinking, the captured interrelationship can be shared and reused. The knowledge management component is to facilitate sharing and reuse by providing functions such as capture, filter, storage, distribution and applications.

Figure 2 illustrates the concept of Integrated QFD and KMS (IQKS). To operationalize the common product platform, the BOM can be built into different phases of the quality function deployment to support the phased operation of the QFD process. The four phases of QFD are linked together for information and through sharing of embedded knowledge. The KMS provides the knowledge repository to share information regarding the captured QFD interrelationship.

Figure 1. The concept of a common product platform (CPP)

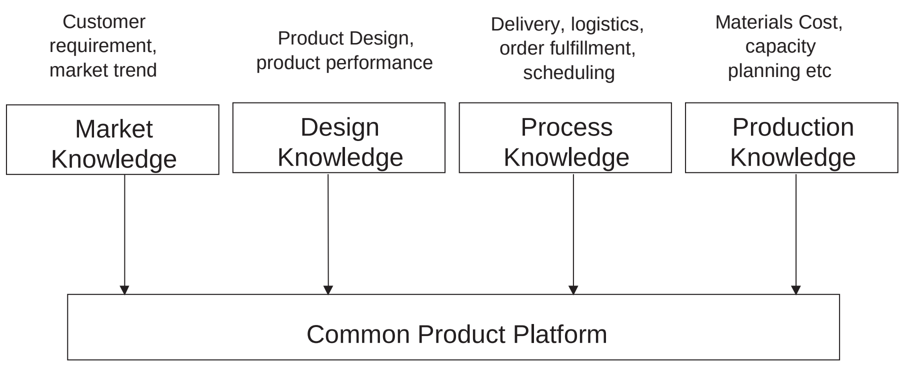

Figure 2. The common product platform architecture (IQKS) supported by QFD and KMS

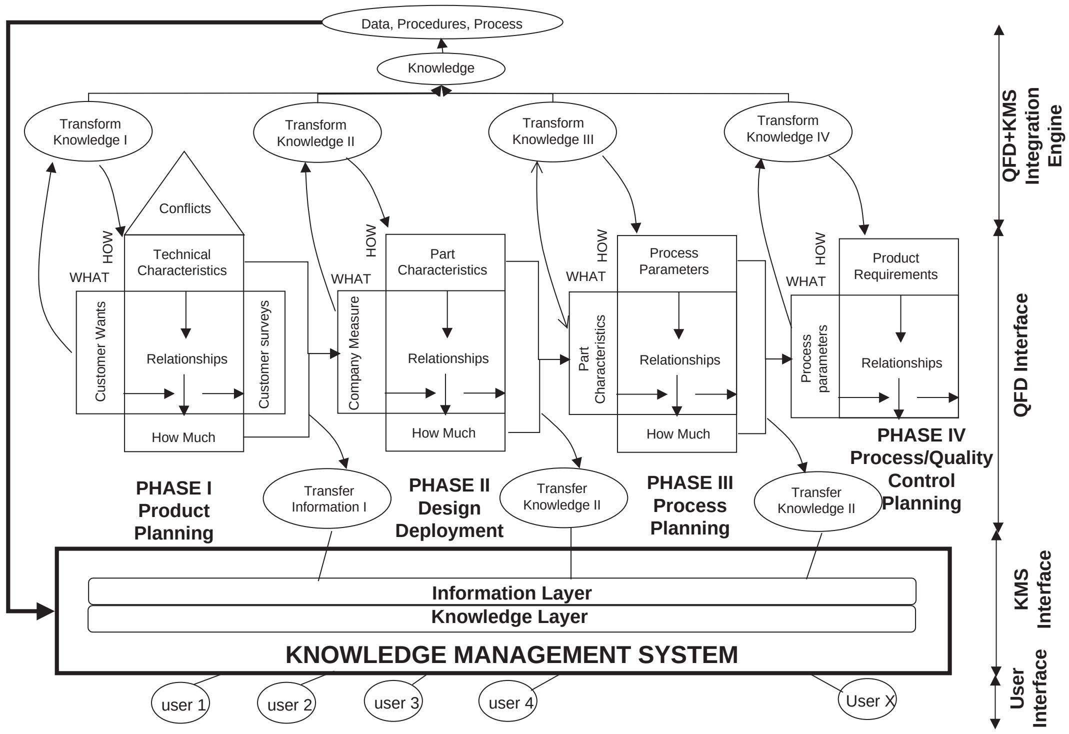

The migration from HOW to WHAT, and the translation of information from one phase to another in QFD, indicates transform knowledge. The information collected and processed serves a common language for exchange in product and process information. As a result, guiding the collection of useful information (transfer information) gradually builds up the knowledge management system.

The knowledge layer is an open-type pool, which allows user interface involvement to collect, retrieval knowledge for specific application. The layer captures the relationship within the QFD matrix. The accumulation of this captured knowledge is stored in the knowledge layer embedded within the KMS.

CASE STUDY

Background

The motor fabrication company (MFC) is one of the world's largest component manufacturers. It manufactures a range of electric motor products to cater for industries like automotive, home appliance, personal goods, consumer electronics, etc. Their existing customers are associated with well-known brands with their products for worldwide distribution.

MFC is engaged with their customers extensively in contract manufacturing initiatives such as outsourcing, partnering and alliance. MFC provides customer support to serve the needs of their customers in new product development. The customers are getting enhanced services from MFC rather than the product itself, and these services include co-design, R&D, engineering, logistics, etc. MFC customers do not need to be concerned with supply chain management, procurement and shipment logistics of the motor products, because all these functions are taken care of by MFC. In many instances, there are a range of products that are similar. For example, MFC manufactures the moving components for the consumer printers' market. MFC makes assessment on each of the product within the market based on each of their customer's product mapping.

MFC gains competitive advantage through providing better services to customers. By establishing the position of the customer in the product map (Figure 3), the company interacts with customers and gives tailored services of attractive value. Interacting with customers at MFC is a very complex task. It involves contributions from numerous parties from sales, research and development, costing, engineering and procurement to the external suppliers. Figure 4 shows the complexity involved.

Interacting with the customers and providing support by answering their queries involves the participation of executives in the organization engaged in knowledge-intensive work. The interaction pattern typically starts with receiving the "customer voice" to the actual commitment of production of electric motors. It is not limited to communication with customers but to a range of parties, including suppliers and logistics services providers.

Interactions with the customers at this stage are complicated, and information flow has significant impact on most manufacturing organizations. Success in the venture very much depends on leveraging the use of knowledge for a speedy response.

It is critical to embed information into the product. By offering services of value in the value chain, each customer concern may be addressed differently. Products that do not appear as high-value to one customer may appear to be

Figure 3. Customer-product mapping in consumer printer market

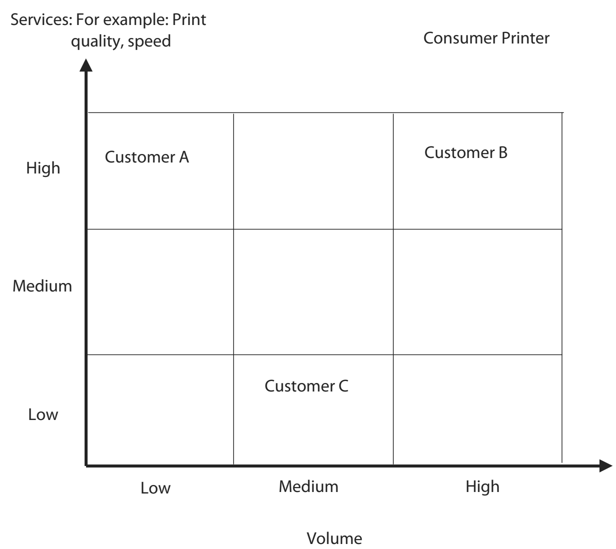

Figure 4. Organising to provide a service of value to the customers

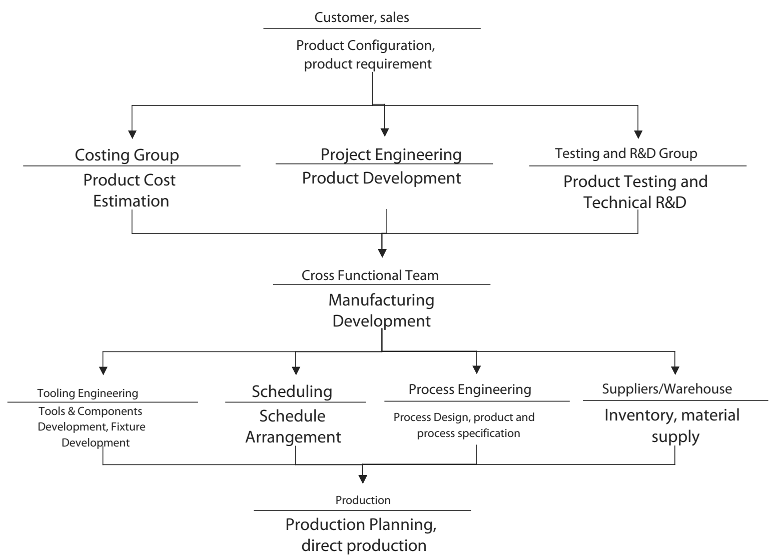


highly valued to another. Furthermore, a previous customer may provide misleading data to MFC in handling other customers. Since the number of parts and associated fixtures proliferate, it requires huge efforts to coordinate.

The erosion of value-adding activities creates difficulties for MFC in integrating their performance with the value chain. They can be seen as the limiting factors for higher performance from the perspective of customers. There is an urgent need to streamline the information flow for managing the interactions with customers.

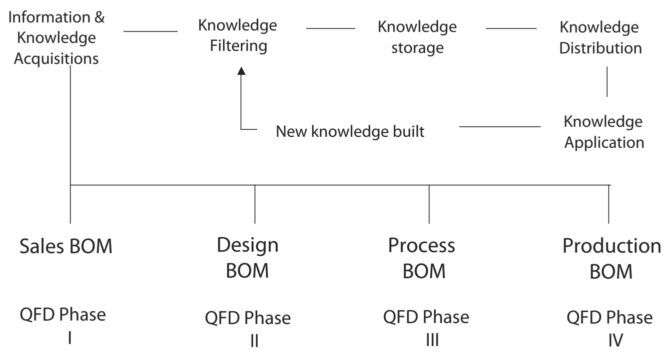
A Knowledge Management Process Model

An integrated quality knowledge System (IQKS) is conceived at MFC to link all the knowledge silos with the bills-of-materials (BOM) structure of electric motors. The knowledge silos are represented by the pools of knowledge accumulated as a result of specialization in sales and marketing, product design, process planning and production. Each knowledge silo corresponds to a phase of the quality function deployment (QFD). When arranged in this way, the knowledge silos enable knowledge input into the WHAT and HOW of the QFD tool. The BOM information model combines the data in a structure for sharing. The BOM information is embedded into a knowledge management system to support the four core activities of value creation: 1) information and knowledge acquisitions; 2) knowledge filter; 3) knowledge storage; and 4) knowledge distribution (see Figure 5).

The BOM information models are run with the support of databases, intranet, extranet and internet. The purpose is to physically enable the communication of more accurate customer requirements, including target price, development cost and product attributes.

In Figure 2, the architecture of the IQKS system consists of information the layer and the knowledge layer. The information layer has BOM databases for internal and external users. The internal BOM databases collect the product

Figure 5. A learning model to link up knowledge silos



design phase information, which is captured from each QFD phase migration under a FORMAL practice. The external BOM databases differ from the internal ones in that they are used to collect any INFORMAL information, which at the collecting moment may not be very useful to anyone but its owner; however, it might also make a difference in the long term. The users can get access to the information using simple searching and browsing criteria.

The knowledge layer is a combination of information, data and graphical display. The accumulation of the captured knowledge is stored under the knowledge layer. This knowledge layer is an open-type pool, which allows user interface involvement to collect and retrieve knowledge for specific application. A pre-defined search criterion is created to capture queries. The system is linked with internal departments, customers and suppliers. Users are granted with different access rights depending on their status.

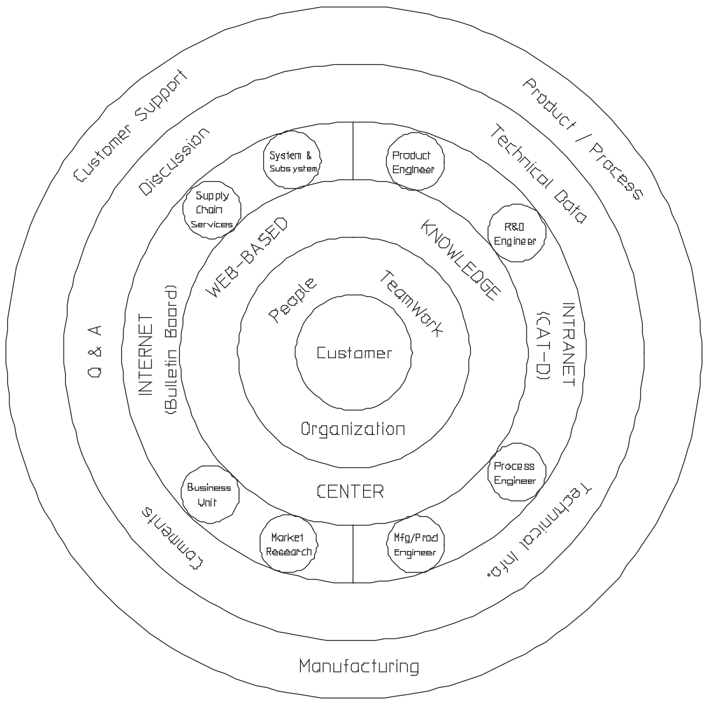
The information layer allows the users with a knowledge perspective to add into the BOM databases (under the QFD structure) for knowledge capture and retrieval. The QFD structure enables transition of information on the nature and underlying links between WHAT and HOW.

At MFC, the implementation of an integrated QFD knowledge system (IQKS) represents an achievement of leveraging knowledge-based manufacturing technologies to bring in the needed information at the early stage of the internal business operations. The implementation has the steps:

a. To link up each QFD phase.
b. To link up every individual or department and show the detail job progress, under a common information technology platform.
c. To capture the employees' routine deliverables and output to fulfill the knowledge acquisition
d. To share the useful information and knowledge for corporate growth.
e. To provide a freedom searching under web-based infrastructure.

The IQKS defines the tasks that a knowledge worker needs to perform at each phase of the QFD. These tasks are, as mentioned previously, product planning (house of quality), design deployment (parts deployment), and manufacturing planning (process planning) and production planning (production operations planning) in relation to customer's want (requirement). The WHAT and HOW govern the formalization of knowledge by introducing a common platform to synchro-

Figure 6. Knowledge management infrastructure model



nize the use of information. These represent the knowledge that can be captured and disseminated as the means of future production. The means of production also serves as the manufacturing input to internal business operations in order to make the operation more responsive to the external environment.

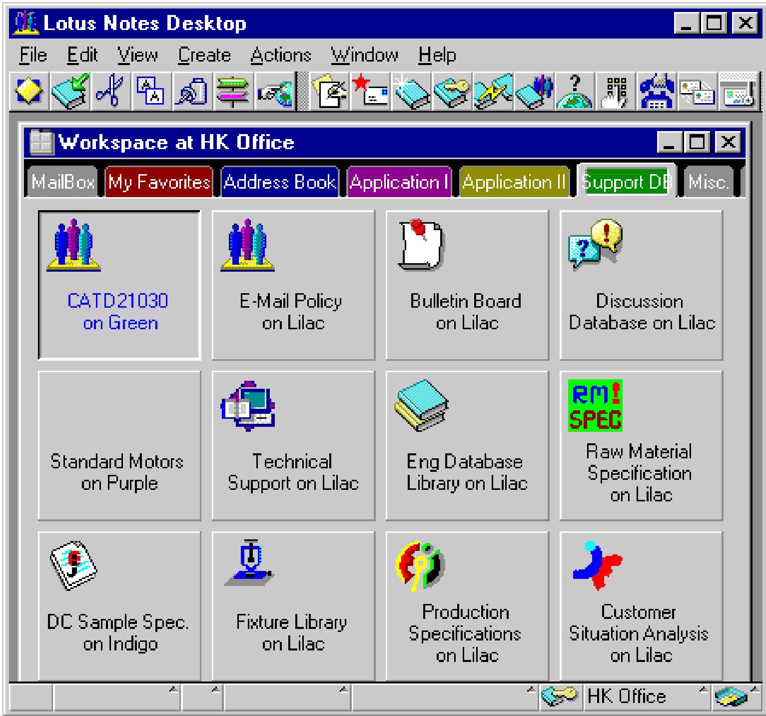
The knowledge management infrastructure is to be overlaid on the existing corporate environment. It utilizes the IT network to link up the different personnel together including sales, design engineers, process engineers and production engineers (see Figure 6).

A Knowledge Management Prototype

This section describes the user's interface for using the system of Web-based knowledge center. The internal portion (intranet) is rolled out first to structure the group use of the knowledge framework, thus allowing the QFD phase IV of information (Figure 2) to be shared and distributed on a daily basis. Next is to establish the web-based knowledge center via the Internet portion. The illustration is shown in Figure 7.

The core of the prototype was produced under Lotus Domino Notes environment as shown in Figure 7. While the Lotus Domino Notes enables data to be captured under an Internet framework, the user interface of the IQKS system includes certain database classifications with respect to the usage nature under QFD phases. Figure 7 shows the basic database icons, which formulate the basic IQKS system's components and are defined below. Different manufacturers (due to product nature's variance) could have more or less or different icons but the database must be under the common-BOM-platform with monitor and control by a centralized system (IQKS: CAT-D).

Figure 7. The IQKS system interface on Lotus Notes



CAT-D

CAT-D is the component architecture technology database. It serves as the global common-BOM platform to link communications of each QFD phase. It is a tool for global transparency of information. Throughout the input from various persons and departments, information is able to be shared and distributed as knowledge through this layer. CAT-D is divided into internal and external portion with support from intranet (organization users) and Internet (customers) respectively.

E-mail Policy

E-Mail Policy states and clarifies the company policy as well as security warning to all users, internal and external to MFC.

Bulletin Board

This is essential for organization cross-communication (geographical aspects and business unit nature) purposes, as well as capturing and sharing the external information. The board is pre-defined by expert team and it stipulates what kinds of information are allowed to be placed in the system. Since employees or customers already "think" (filter) what should be put on the board, filtered and valued information can be stored.

Discussion Database

Discussion Database acts as an Information Record Buffer to temporarily collect and store communication information such as meeting minutes. The users are allowed to write down discussion about anything, but IQKS classifies these as vast unstructured information and are stored for general discussion only. The inside contents are cleaned every two months to free up server space. Any information considered valuable for permanent storage is transferred into Bulletin Board for corporate distribution.

Standard Product

Standard Product (motor) holds the records of company standard products. It is linked with the Internet for customer selection or for placing an order. Considered to be the primary form of electronic business over the web, it facilitates the transactions of "commodity" motor products of MFC. It also acts as a product catalog. The "hit-rate" shall be recorded for sales and marketing in support of customer relationship management to analyze the number of interests and demands from real-time market.

Technical Support

Technical Support directs question and answer services from internal and external customers. This database has links with standard product databases. This is because a customer, having once selected their favorite products and who might like further customizations, would like to receive direct confirmation of technical possibilities. It is part of introducing engineering services to the front line of customer services.

Engineering Database Library

Under the CAT-D framework, Engineering Database Library captures and stores the engineering information such as product testing record and characteristics. It facilitates the empowerment of internal staff by sharing critical engineering knowledge.

Raw Material Specification

This is a library of raw material specifications and is shared among staff at MFC. The main users of such library include supply chain department, purchasing department, engineering department, R&D, and design & product engineers. Each of them uses the information in a very different perspective.

DC Sample Specification

This stores product sample records, BOM, specifications and quality test results. Engineers routinely input their design specifications and the BOM information. Product-testing workers and testing engineers input the quality test records. The information is combined in such a way that any new knowledge arising from the know-how in routine capturing can be articulated through some pre-defined information transformation criteria.

Fixture Library

Fixture Library facilitates process planning through hyper-linkage to engineering database that contains the process details such as fixture design and setting and so on. The engineering database is dynamically linked with other databases to derive information stored under the fixture library.

Production Specification

Production Specification facilitates production and workflow design by recording the production line layout, workflow design, existing line utilization rate and capacity.

Customer Situation Analysis

Customer Situation Analysis facilitates quality control. It captures planning records of product complaint history, its subsequent quality improvement analysis along with the failure report. A group sharing of failure know-how from quality audit is preferred to traditional handling by a single person, from a learning perspective.

The IQKS Phases

The sales, agent or customer service can use the IQKS system and input the customer requirement into the CAT-D system (through Internet portion). The "hit-rate" for specific items and products reflects the market trends and demands and fulfills the QFD phase I where information is retained for future searching and references. The senior management (sales & marketing, business manager) derives appropriate actions.

Figure 8 shows internal staff accessing the customer historical inquiries through an internal Lotus Notes system. The information regarding customer requirement is stored as list of requirements (LOR), which defines customer specifications of the motor product. The LOR is a combination of information from database and various documentation including drawings and associated graphical presentation on performance. The Lotus Notes system supports these documents with its document management system.

In product design phase (QFD phase II), the LOR (or Sales BOM) from phase I is linked to the product design BOM using the same project number. Basically, LOR is translated into product design BOM by a group of experts and stored under a database accessible in the Lotus Notes environment (see Figure 9). This BOM is able to match and merge with the product information; Figure 10 exemplifies the result.

Searching and selecting is allowed by referring to product models, component part names or part number. Referring to these keys allows associated information to be extracted. This directly shows whether the product design is capable of

Figure 8. IQKS phase I

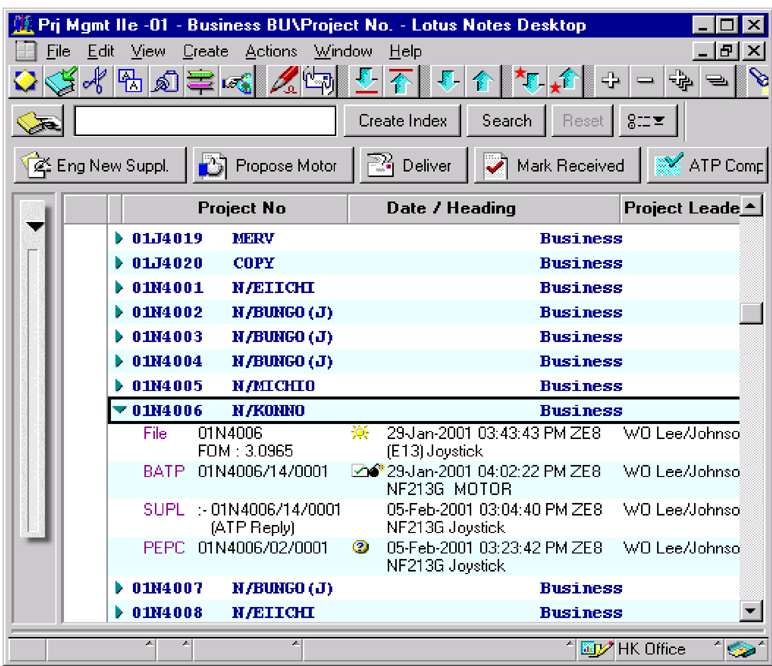


Figure 9. The translation of LOR to design BOM, QFD phase II

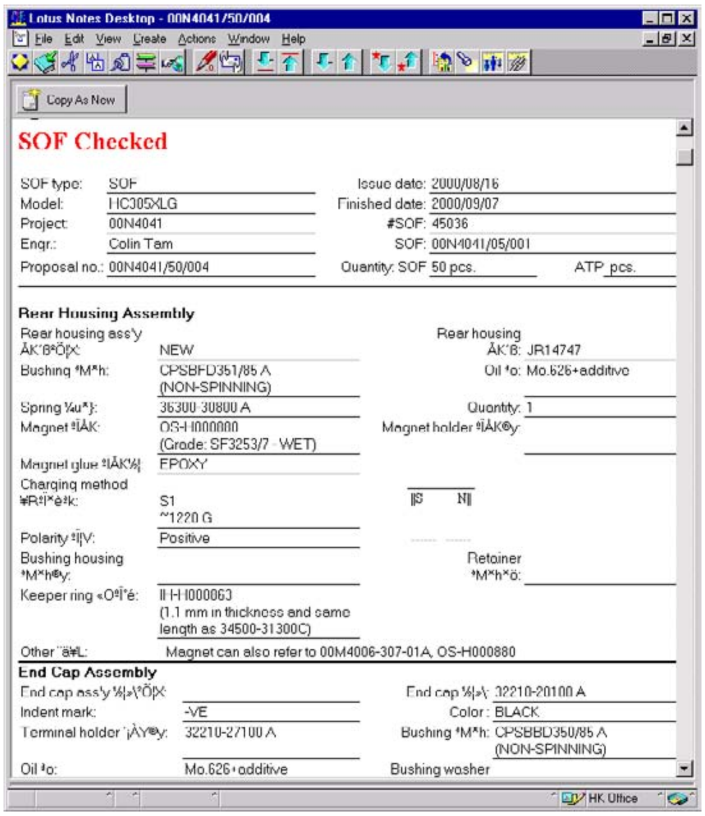

fulfilling the customer requirements. With the Lotus Notes documents sharing environment, file attachment and graphical presentation is technically feasible.

The following scenario demonstrates what key deliverables can be provided by showing what was known and what was unknown on a daily basis.

1. A standardized terminology of products, product attributes (process/production, planning quality) can be mapped out, particularly to products of similar nature (see Figure 10). This serves as a common basis of knowledge sharing as part of the common product platform. Design lead-time can be reduced because inexperienced staff can pick up the product design by using the appropriate information. In short, the common basis of knowledge enables self-learning to occur among inexperienced staff.
2. What is known can be captured explicitly under a structured format. Design processes on product characteristics, causes and solutions can also be captured.

The process BOM equivalent to QFD phase III can be accessed under the Lotus Notes environment (see Figure 11). The information is stored in the database dynamically linked with design BOM information. The project numbers, product models and components all serve as the common searching criteria. Documents regarding fixtures,

Figure 10. Integrated LOR with design BOM to facilitate learning

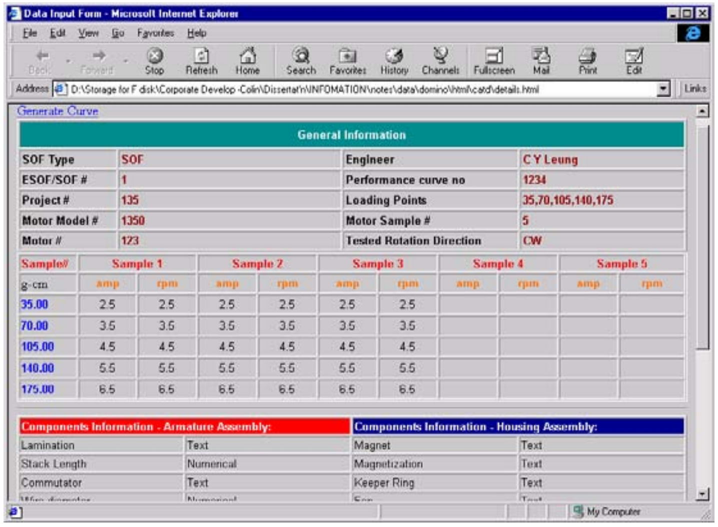

Figure 11. Process BOM

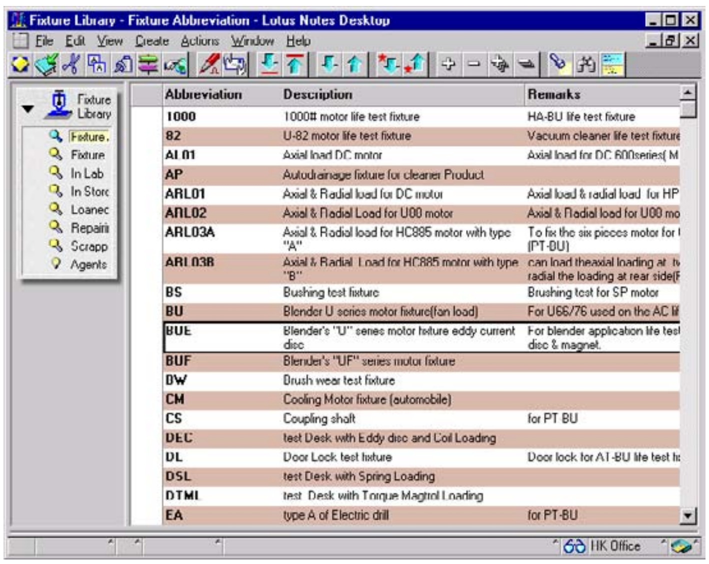

machines settings, maintenance record and application records are shared within the document management system of Lotus Notes.

The last phase of QFD phase IV gives the production BOM that is linked to the IQKS architecture. It deliberately combines quality control with product specification information together as production and quality control information. The commonly used searching criteria are also supported by the Lotus Notes.

Figure 12. Production BOM and QFD phase IV

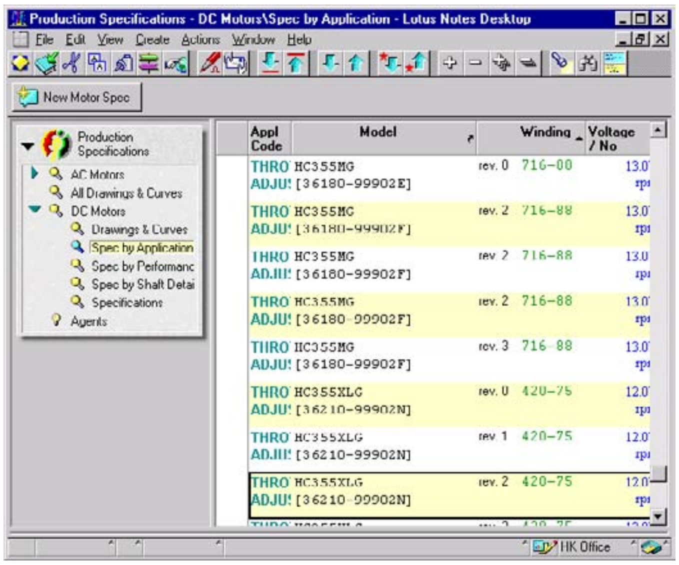

Figure 12 illustrates the production BOM interface under the Lotus Notes environment. Traditional practice may only share pieces of information, and it is up to the staff to put them together in a meaningful way. Performance information can be presented in a graphical format important to the user.

DISCUSSION

The prototype of the common product platform is currently being expanded to cover suppliers and customers in order to enable a true collaborative mode in the customization of business process. However, since separate organizations are different in many ways (for example, the difference in part specification), the difference in manufacturing environment can very much compromise the progress of the common product platform. If the participating organizations are not quickly realizing the potential benefits of the platform, the implementation team can lose control of the project with a consequence of budget overruns and resulting cooling down of interests of sponsors from senior management.

The central accomplishment of this common product platform is the idea to facilitate extended enterprise responsiveness, which in turn represents a large portion of competitive advantage for the participating organizations. Extended enterprise responsiveness focuses on change and dynamic business reconfiguration at the process level. Each participating organization must manage their performance for the benefits of the entire value network through the exchange of information.

Since each participating organization must manage their own performance, this means they will perform activities that are most likely to be in their best interest. For example, suppliers that aim to utilize low-cost labor for manufacturing will most likely incline towards economies of scale, thereby producing product in large quantities. Low cost is their order-winning criteria, and they can squeeze reasonable profit margin from the low-cost commodity parts or suppliers. When complex products require the support of these commodity parts, other participating organizations within the extended enterprise can join in the collaboration to deliver complex products while retaining product performance such as low cost or time-to-market. The only challenge is that they must be previously aligned together to allow such business configuration to be engaged.

Since manufacturing organizations must manage their own manufacturing environment for performance, more understanding is needed in how collaboration can be materialized in different conditions. More importantly, these conditions govern the coordination of economic activities dispersed across enterprises. Therefore the attempts to make individual enterprise systems compatible to each other are the key concern for extended enterprise operations. New understanding should focus on how the market knowledge, design knowledge, process knowledge and production knowledge impact on different manufacturing environments: make to stock, make to order and engineer to order. A lack of protocol or standardization is the major attributing factor that inhibits individual enterprise systems from being more compatible with each other.

SUMMARY AND CONCLUSION

The challenge of managing information for product development must be addressed for many manufacturing organizations entering into the new economy. The creative nature of work or "not invented here syndrome" inherited in generating new products or new services discourages knowledge workers to reuse information and lures them into solutions that involve redesigning the entire part which ultimately affect the efficiency of partnering with suppliers during early supplier involvement. The excessive amount of time spent and cost involved in searching for right information and assuring their relevancy are unnecessary in the first place because parts can be reused with slight modification.

This chapter operationalizes the concept of common product platform for contract manufacturers to manage the product development. It makes use of databases to facilitate the reduction of a wide variety of parts in order to simplify communication and to provide speedy customer responses. The platform merges the concepts of QFD and knowledge management to form an integrated IQKS system. The core is a knowledge-based system aimed at facilitating communication with customers and empowering knowledge workers. The bill-of-material becomes the backbone of the system in managing knowledge for use and reuse.

Chapter 2.35
Data Semantics

Daniel W. Gillman
Bureau of Labor Statistics, USA

INTRODUCTION

Almost every organization, public or private, for profit or non-profit, manages data in some way. Data is a major corporate resource. It is produced, analyzed, stored, and disseminated. And, it is poorly documented.

Descriptions of data are essential for their proper understanding and use by people inside and outside the organization. For instance, systems for disseminating data on the Internet require these descriptions (Census Bureau, n.d.). Either inside or outside the organization, functions of the system support finding the right data for a study, understanding data from a particular source, and comparing data across sources or time (Gillman, Appel, & LaPlant, 1996).

Descriptions of data and other resources are metadata (Gillman, 2003). Metadata are part of the corporate memory for the organization, and preserving corporate memory is one of the basic features of knowledge management (King, Marks, & McCoy, 2002). Metadata include the meaning, or semantics, of the data. In some countries, such as the U.S., a large percentage of the population is reaching retirement age. As a result, recording the memories of these workers, including the meaning of data, is increasingly important. Preserving metadata is crucial for understanding data years after the data were created (Gillman et al., 1996).

Traditionally, the metadata for databases and files is developed individually, without reference to similar data in other sources. Even when metadata exist, they are often incomplete or incompatible across systems. As a result, the semantics of the data contained in these databases and files are poorly understood. In addition, the metadata often disappear after the data reach the end of the business lifecycle.

Techniques for documenting data are varied. There are CASE (Computer-Aided Software Engineering) tools such as Oracle Designer® (Oracle, n.d.) or Rational Rose® (IBM, n.d.). These tools produce models of data in databases (Ullman, 1982). The models provide some semantics for the data. For social science data sets, metadata is described in an XML (eXtensible Markup Language) specification (ICPSR, n.d.). For geographic data sets, the U.S. Federal Geographic Data Committee developed a metadata framework, clearinghouse, and supporting software (FGDC, n.d.).

Metadata are data, too. They are structured, semi-structured, or unstructured (Abiteboul, Buneman, & Suciu, 2000), just as data are. Data are structured if one knows both the schema and datatype, semi-structured if one knows one of them, and unstructured otherwise. From the perspective of their content, documents are unstructured or semi-structured data. Their schemas come from presentation frameworks such as HTML (Hyper-Text Mark-up Language) (W3C, 1997) or word processor formats. Documents with the content marked up in XML (W3C, 2004) are semi-structured. When using the full datatyping capability of XML-Schema, the document is structured with respect to the content. However, the colloquial use of the term "document" begins to lose its meaning here.

In describing some resource, the content is more important than the presentation. The content contains the semantics associated with the resource. If the content is structured data, this increases the capability of performing complex queries on it. Retrieving unstructured documents using search engine technology is not as precise.

It turns out there are structured ways to represent the semantics of data. Ontologies (Sowa, 2000) are the newest technique. Traditional database (or registry) models are examples of ontologies. This article describes the constituents of the semantics of data and a technique to manage them using a metadata registry. The process of registration—an approach to control the identification, provenance, and quality of the content—is also described and its benefits discussed.

SEMANTICS OF DATA

Terminology

To begin, we describe some useful constructs from the theory of terminology. These come from several sources (Sager, 1990; ISO, 1999, 2000). We use these constructs to describe the semantics of data. The terms and definitions follow in a list below:

- Characteristic: Abstraction of a property of a set of objects.
- Concept: Mental constructs, units of thought, or unit of knowledge created by a unique combination of characteristics.
- Concept system: Set of concepts structured according to the relations among them.
- Definition: Expression of a concept through natural language, which specifies a unique intension and extension.
- Designation: Representation of a concept by a sign, which denotes it.
- Extension: Set of objects to which a concept refers.
- General concept: Concept with two or more objects that correspond to it (e.g., planet, tower).
- Generic concept: Concept in a generic relation having the narrower intension.
- Generic relation: Relation between two concepts where the intension of one of the concepts includes that of the other concept and at least one additional distinguishing characteristic.
- Individual concept: Concept with one object that corresponds to it (e.g., Saturn, Eiffel Tower).
- Intension: Sum of characteristics that constitute a concept.
- Object: Something conceivable or perceivable.

- Property: Attribute used to describe or distinguish an object (e.g., "Dan has blue-gray eyes" means "blue-gray eyes" is the property of Dan associated with the characteristic "eye color" of people.)
- Specific concept: Concept in a generic relation having the broader intension.

Designations come in three types: an appellation is a verbal designation of an individual concept; a term is a verbal designation of a general concept; and a symbol is any other designation.

The ancient Greek philosophers began the study of terminology and concept formation in language (Wedberg, 1982), and they discovered a useful relationship between designation, concept, object, and definition which is illustrated in Figure 1 (CEN, 1995).

Figure 1 shows that concepts, designations, objects, and definitions are related but separate constructs. Each plays a role in our understanding (i.e., the semantics of) data.

An important observation is that concepts are human constructions (Lakoff, 2002). No matter how well we define a concept, a complete description is often impossible. Identifying the relevant characteristics is culturally dependent. So, some objects in the extension of a concept fit the characteristics better than other, so-called prototypes.

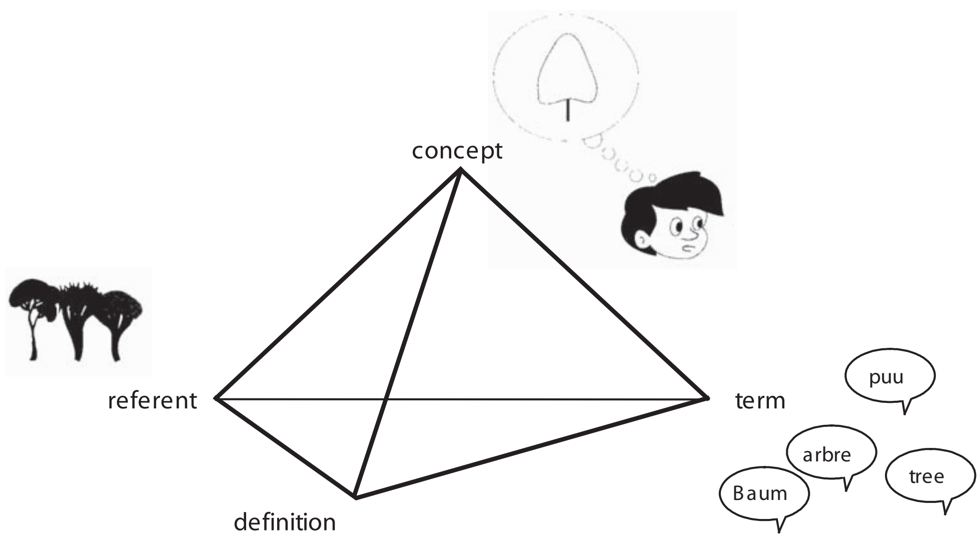
Framework for Understanding Data

Here, we present a general framework for understanding data. Some terminology comes from the area of statistics. Statisticians view a datum as a designation of a class in a partition of a population of objects, where the partition1 is defined for some characteristic of the population (Froeschl, Grossmann, & Del Vecchio, 2003). Here, the population is either a general or individual concept, and the objects are the extension of that concept. Four examples illustrate the ideas:

Example 1

- Population: Adults age 16 and older in the U.S.

Figure 1. Illustration of the differences between a referent (an object), a concept, a term (more generally a designation), and a definition in language



- Characteristic: Sex
- Partition: {Male, Female}
- Designations: 0 for Male 1 for Female

Example 2

- Population: The set of adults age 16 and older in the U.S.
- Characteristic: Proportion of females
- Partition: {x | 0 <= x <= 1}
- Designations: Real numbers between 0 and 1, with precision to 3 decimal places

Example 3

- Population: Shoe sales
- Characteristic: Type of shoe
- Partition: {Basketball, Business, Casual, Formal, Running, Tennis}
- Designations: Ba for Basketball
  Bu for Business
  C for Casual
  F for Formal
  R for Running
  T for Tennis

Example 4

- Population: Stars of the Milky Way Galaxy
- Characteristic: Number of known planets
- Partition: {n | n >= 0 and n is an integer}
- Designations: 0 for no known planets
  1 for one known planet
  etc.

Populations

The idea of a population requires some additional explanation. In one sense, it is a concept represented by a definition or description. In another sense, it is the extension of the concept, the set of objects about which we collect or observe data. We refer to both the concept and its extension as a population.

Also, a population is either an individual concept or a general one. In the ordinary sense, populations are general concepts (see Examples 1, 3, and 4). However, aggregate data requires a population with one object. In Example 2, the characteristic "proportion of females" applies to the entire set of adults age 16 or older in the U.S., not to each person. So, the set consisting of "the set of adults age 16 or older in the U.S." has one element. It is a set whose lone element is a set! But, it is this entirety (an aggregate) that has the characteristic "proportion of females," not the individual people. So, "proportion of females" is not a characteristic of people, "sex" is. Likewise "sex" is not a characteristic of the aggregate, "proportion of females" is.

Every object has an individual concept associated with it. When one thinks of a particular object, the conception of that object is an individual concept. Data associated with a particular object is descriptive of that object. This characterization is necessary but not sufficient to be metadata. Data are only metadata when they are used to describe some object. However, metadata are similar to aggregate data, their populations are individual concepts.

Types of Semantics

Characteristics applied to populations are concepts themselves. So, the characteristic of a population is a concept, and it represents, in part, the contextual semantics of the data (e.g., the sex of U.S. people). The designations denoting the classes of the partition defined for the characteristic represent the symbolic semantics—for example, M is for male and F is for female. Therefore, data have both contextual and symbolic semantics (Gillman, 2003).

The contextual semantics describe, in part, the kinds of objects for which data are collected and the particular characteristic of those objects being measured. The symbolic semantics describe the set of categories, not necessarily finite, representing the meaning of the values that data take.

The set of values that data take has additional descriptions, in particular a computational model for the values, which is called the datatype (ISO, 1995).

Value Domains

As defined above, the set of designations for the classes of a partition determined by a characteristic is called a value domain. In a value domain, a designation is known as a value, the associated class of the partition is described by a concept called the value meaning, and each value and associated value meaning pair is a known as a permissible value (ISO, 2004).

A set of value meanings is called a conceptual domain. It is a concept, and its value meanings are its characteristics. Every value domain is in the extension of some conceptual domain.

Value domains and conceptual domains come in two (non-exclusive) sub-types:

- Enumerated: A domain specified by a list of its elements.
- Non-Enumerated: A domain specified by a description of its elements.

An enumerated value domain contains a list of all its permissible values. An enumerated conceptual domain contains a list of all its value meanings. Non-enumerated value domains and non-enumerated conceptual domains are specified by descriptions. The non-enumerated value domain description describes precisely which permissible values belong and which do not belong to the value domain. The non-enumerated conceptual domain description describes precisely which value meanings belong and which do not belong to the conceptual domain.

Some value domains contain very similar permissible values from one domain to another. Similarity is based on how much the value meanings overlap. When these similarities occur, the value domains are in the extension of one conceptual domain. The following two examples taken from ISO (2004) illustrate several things:

- Example of non-enumerated value domains and a non-enumerated conceptual domain
- Example of enumerated value domains and an enumerated conceptual domain
- Use of conceptual domains to manage similarities between value domains

Example 5: Similar Non-Enumerated Value Domains

- Conceptual domain name: Probabilities
- Conceptual domain definition: Real numbers greater than 0 and less than 1
- Value domain name (1): Probabilities—2 significant digits
- Value domain description: All real numbers greater than 0 and less than 1 represented with 2 digit precision.
- Precision: 2 digits to the right of the decimal point
- Value domain name (2): Probabilities—5 significant digits
- Value domain description: All real numbers greater than 0 and less than 1 represented with 5 digit precision.
- Precision: 5 digits to the right of the decimal point

Example 6: Similar Enumerated Value Domains

- Conceptual domain name: Marital Status Categories
- Conceptual domain definition: Lists of categories for marital status

- Value domain name (1): Marital Status Codes (1)
- Permissible values: <S, Not married>
  <M, Married>
- Value domain name (2): Marital Status Codes (2)
- Permissible values: <1, Not married>
  <2, Married>

Data Element Concepts

A data element concept is a concept that contains a population and one of its characteristics. It is the conceptual part of data, that is, independent of the values (i.e., the value domain). The classes (or entities) and attributes in data models approximate populations and characteristics.

A concept may be both a population and a characteristic, depending on its use. For instance, "occupation" is a characteristic of a person. On the other hand, as a population we care about its characteristics, such as physical requirements for a job in that occupation.

Populations and characteristics often are specialized to account for data associated with domains (of populations) or narrower properties. The generic relation is used, and value meanings from enumerated conceptual domains (i.e., classifications) provide the additional characteristics to narrow the concept. Here is an example:

Example 7: Specializing Populations and Characteristics

- Population: Persons of the U.S.
- Classification: Sex {Male, Female}
- Specialized Population: Male Persons of the U.S.
- Characteristic: Income
- Classification: Income Type {Wages, Retirement, Dividends, Interest, Inheritance, Other}
- Specialized Characteristic: Income derived by wages only

Data Elements

Data elements are containers for data, and in some sense, they are indivisible (i.e., elemental). A data element is the association between a data element concept and a value domain. Both data element concepts and value domains may be associated with many data elements.

The term data element is synonymous with the term variable, as it is understood by programmers. Thus, the datatype associated with a data element is important. The data element concept and the value domain provide a semantic model for a data element. The datatype provides a computational model.

METADATA REGISTRIES

Introduction

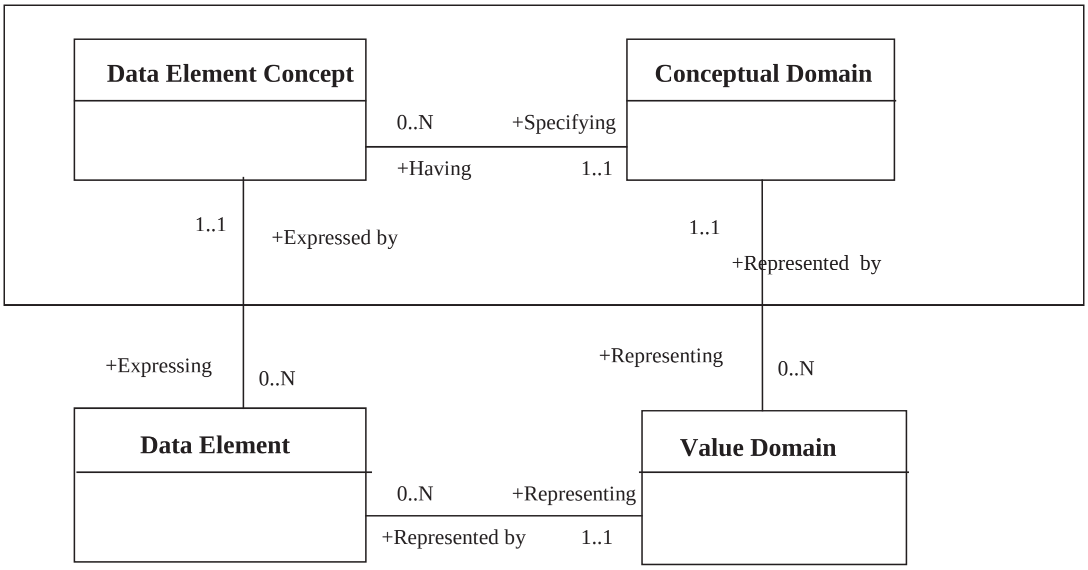
A database of metadata that supports the functionality of registration is a metadata registry. A metadata registry contains metadata describing data constructs (i.e., data elements, data element concepts, value domains, conceptual domains, populations, characteristics, and value meanings) that retain data semantics.

Of course, the metadata registry contains descriptions of data constructs, not the constructs themselves. This is analogous to the registries maintained by governments to keep track of motor vehicles. A description of each motor vehicle is entered in the registry, but not the vehicle itself.

Metadata Registry Model

The international standard ISO/IEC 11179 (ISO, 2003) contains a metadata registry model for data semantics. It contains two main parts: the conceptual level and the syntactical level. The conceptual level contains the data element concept and conceptual domain. Both are concepts as described above. The syntactical level contains

Figure 2. Overview of basic metadata registry model for data semantics (adapted from ISO/IEC 11179)



the data element and value domain. Both are containers for data values.

Figure 2 pictorially represents the following facts, some of which were previously mentioned:

- A data element is the association between a data element concept and a value domain.
- Many data elements may share the same data element concept.
- Many data elements may share the same value domain.
- Value domains are not necessarily related to any data element.
- Two value domains that share all the value meanings are conceptually equivalent and share the same conceptual domain.
- Two value domains that share some value meanings are conceptually related and share the same conceptual domain in a concept system containing each of their conceptual domains.
- Many value domains may share the same conceptual domain.
- A data element concept is related to a single conceptual domain, so all the data elements sharing the same data element concept share conceptually related representations.
- In addition to the facts illustrated in the Figure 1, there are two other important facts that need stating:
    - Relationships among data element concepts may be maintained in a metadata registry, which implies that a concept system of data element concepts may be maintained.
    - Relationships among conceptual domains may be maintained in a metadata registry, which implies that a concept system of conceptual domains may be maintained.

Registration

Registration functions separate a metadata registry from a database of metadata. Registration is the set of rules, operations, and procedures that apply to a metadata registry. The three most important outcomes of registration are the ability to monitor the quality of metadata, provenance (the source of the metadata), and assigning an identifier to each object described.

Registration also requires a set of procedures for managing a registry, submitting metadata for registration of objects, and maintaining subject matter responsibility for metadata already submitted. For actual implementations of a metadata registry, there may be additional requirements.

Each description of a data construct is maintained in a uniform and prescribed manner. Identifiers, quality measures, responsible organizations, names, and definitions are recorded for every data construct.

There are several purposes to monitoring metadata quality. The main purposes are:

- Monitoring adherence to rules for providing metadata
- Monitoring adherence to rules for forming definitions and following naming conventions
- Determining whether a description still has relevance
- Determining the similarity of related data constructs and harmonizing their differences
- Determining whether it is possible to ever get higher quality metadata for some data constructs

Every data construct registered in a metadata registry is assigned a unique identifier. Identifiers are a means to keep track of descriptions for administration purposes, to refer to descriptions by remote users of the registry, and to aid in metadata transfer between registries.

The registration authority is the organization responsible for setting the procedures, administering, and maintaining a registry. The submitting organization is responsible for requesting that a new description be registered in the registry. The steward is responsible for the subject matter content of each registered item. Each of these roles is described in ISO/IEC 11179 (ISO, 2003).

Implementations

Organizations for which data is a major corporate asset or share that data outside the organization have a need to describe the semantics of their data. Many organizations around the world use metadata registries. Some of these exist, and others are under construction. The U.S. Environmental Protection Agency (EPA, n.d.) and the Australian Institute for Health and Welfare (AIHW, n.d.) have functioning metadata registries on the Web. Statistics Canada (Johanis, 2000) and the Australian Bureau of Statistics (Oakley, 2004) are building metadata registries for internal use to support the business lifecycle.

CONCLUSION

This article describes how to manage the semantics of data. It incorporates ideas from statistics that generalize to all data. Data have conceptual and representational components. The conceptual component has contextual and symbolic semantics. The contextual semantics describes the population of objects being described and a characteristic of that population. The symbolic semantics describes the meaning of the categories defined for the characteristic. The representational component includes the values used to represent the categories in the symbolic semantics.

Metadata registries, such as those that conform to the international standard for metadata registries, ISO/IEC 11179, describe and manage data semantics. Many organizations are building metadata registries, and some are available on the Web.

ENDNOTE

1. A partition is a non-empty set of mutually exclusive and exhaustive subsets of some other set. The number of subsets is not necessarily finite.

Chapter 2.36
Knowledge Management in Supply Chain Networks

Dolphy M. Abraham
Loyola Marymount University, USA

Linda Leon
Loyola Marymount University, USA

INTRODUCTION

This article reviews current research and practice of knowledge management (KM) and inter-organizational learning in supply chain networks. Knowledge management is the organizational process for acquiring, organizing, and communicating the knowledge of individual employees so that the work of the organization becomes more effective (Alavi & Leidner, 1999). Knowledge management is an increasingly important process in business organizations because "managing human intellect—and converting it into useful products and services—is fast becoming the critical executive skill of the age" (Quinn, Anderson & Finkelstein, 1998). Grover and Davenport (2001) state that KM becomes "an integral business function" when organizations "realize that competitiveness hinges on effective management of intellectual resources." Grover and Davenport also argue that knowledge management works best when it is carried out by all the employees of the organization and not just KM specialists.

Business organizations frequently partner with other firms to complement their core competencies. To collaborate effectively, partner firms have to communicate with each other information about business processes as well as share ideas of how to design or improve business processes. This phenomenon of knowledge sharing across organizational boundaries is called inter-organizational learning (Argote, 1999). Knowledge management, we posit, is necessary to facilitate inter-organizational learning and direct it in a way that supports the organization's overall objectives.

Supply chain systems are an example of business networks. Supply chains involve not only multiple corporate entities but also organizational units within a single organization. We present practices used in business organizations and networks of businesses to manage the information and knowledge sharing processes using the context of supply chain systems.

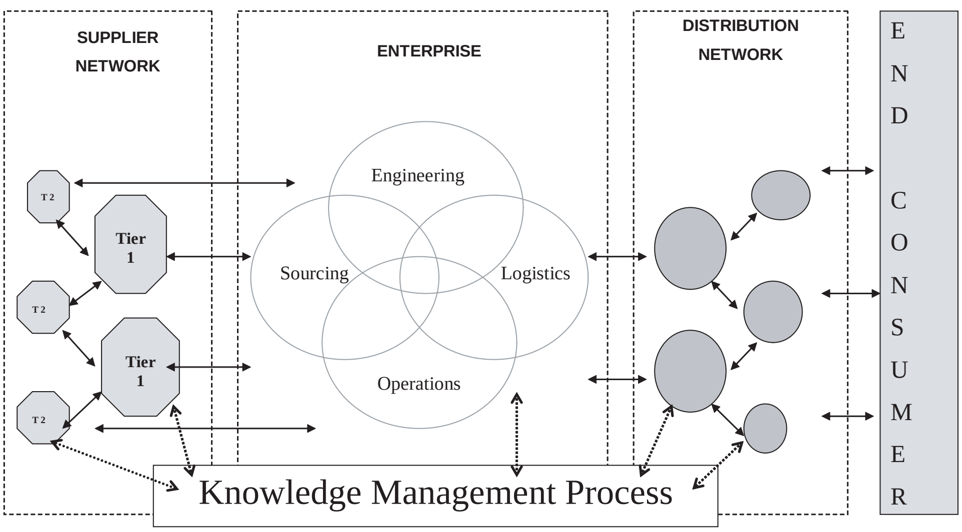
BACKGROUND

A supply chain consists of all parties involved, directly or indirectly, in fulfilling the end consumer's request. Its primary purpose is to satisfy customer needs while maximizing the overall profitability of the chain. A typical supply chain involves a variety of stages that may include customers; a distribution network of retailers, wholesalers, and distributors; manufacturing enterprises; and tiers of suppliers (Figure 1). Information, knowledge, funds, products. and services flow along both directions of the chain, where more than one player is often involved at each stage. The structure of supply chain systems can be described as a business network where inter-organizational learning and information sharing are critical factors in determining the chain's competitiveness.

The performance of a supply chain depends upon how well its processes are managed for the type of product that is associated with the chain. Fisher (1997) classifies products on the basis of their demand patterns, claiming that a product falls into one of two categories, either primarily functional or primarily innovative. Functional products satisfy basic needs and include the staples that people buy in a wide range of retail outlets such as grocery stores and gas stations. These products have stable, predictable demand, and long life cycles. Due to well-developed competition, low profit margins occur, requiring the chain to focus almost exclusively on minimizing physical costs. Companies need to coordinate the ordering, production, and delivery of supplies in order to minimize inventory and maximize production efficiency in order to meet predictable demand at the lowest cost.

Innovative products, such as fashion apparel and technology products including plasma TVs, cellphones, and iPods, are differentiated from competition by their designer options and new features and capabilities. The novelty of these products allow higher profit margins, but also result in more demand uncertainty as it is difficult to predict how the market will respond to

Figure 1. The integrated supply chain



the newest design features and options. The life cycle for innovative products is short as ensuing competition forces companies to introduce newer innovations in order to maintain the higher profit margins. The short life cycles and the great variety typical of these products further increase demand unpredictability. The demand uncertainty from the market environment increases the risk and costs of shortages and excess supplies throughout the chain. To mitigate this risk, it is crucial that information flows not only within the chain but also from the marketplace to the chain. Fisher (1997) describes managers' primary focus in supply chains for innovative products as market mediation, the need to read early sales numbers or other market signals and have the chain respond quickly. The critical decisions to be made are not about minimizing costs but about where in the chain to position inventory and available production capacity in order to hedge against the uncertain demand and be responsive. Supply chain systems reduce the external environmental uncertainty by introducing formal information and knowledge transfer mechanisms between supply chain partners. In supply chains with innovative products, suppliers are evaluated based on their reliability, speed, flexibility, and product development skills as well as for their cost.

Due to the emphasis on market mediation, supply chains for innovative products require more collaboration about product design and improvement of business processes than supply chains for functional products. While information sharing can improve the performance of functional product supply chains, inter-organizational learning is essential to support the overall objectives of the innovative product supply chain.

KNOWLEDGE MANAGEMENT IN SUPPLY CHAINS

As the goal for functional products is to minimize the physical costs associated with the production and delivery of the product, many supply chains have improved their coordination efforts by sharing information. Efficient Consumer Response (ECR) and Quick Response (QR) initiatives are efforts that certain industries have implemented to reengineer the supply channel to make it more responsive to customer demand. Controlling the flow of information and product between different stages within the chain is a major focus of these initiatives as it helps decrease the costs of inventory and shortages. Chains have used technologies such as electronic data interchange (EDI), the Internet, and satellite systems for transmitting point-of-sale data to provide real-time information. Improved coordination is achieved with this information even when the decision-making responsibilities remain decentralized. A $14 billion savings in the food service industry (Troyer, 1996) and $30 billion savings in the groceries industry (Kurt Salmon Associates, 1993) have been documented as a result of implementing these initiatives. Current MS/OR research (e.g., Lee, So & Tang, 2000) studies the value of different types of information that can be shared given the decentralized decision-making framework. For example, Wal-Mart's Retail Link program provides an online summary of point-of-sale data for Johnson & Johnson and Lever Brothers as well as direct satellite transmitted point-of-sale data. Cachon and Fisher (1997) describe the cost savings that Campbell Soup's continuous replenishment program generated for the grocery supply chain. In this instance, retailers transmitted daily inventory information via EDI to Campbell Soup, and the manufacturer assumed responsibility for managing retailer inventories, a process commonly referred to as vendor managed inventory. This particular continuous replenishment program reduced inventories in retailer distribution centers by 50%, while increasing service levels from 98.7% to 99.5%.

Some chains have extended their collaborative efforts to include information about processes as well as more centralized decision making. Aviv (2001) and Raghunathan (1999) describe Collaborative Forecasting and Replenishment (CFAR) as a new inter-organizational system that enables retailers and manufacturers to forecast demand and schedule production jointly. CFAR allows the exchange of complex decision support models and manufacturer/retailer strategies so that the two supply chain parties can reduce demand uncertainty and coordinate their decisions. Wal-Mart and Warner-Lambert embarked on the first successful CFAR pilot, involving Listerine products in 1996. Since then several major manufacturers of functional products, such as Procter and Gamble, have undertaken CFAR projects.

Due to the demand uncertainty and short life cycle, supply chains for innovative products need to develop strategies that will create flexibility and responsiveness within the chain. The exchange of knowledge about processes, innovations, and market interest are vital to the members of the chain as it works to design and distribute the newest product to the market quickly. The Knowledge and Learning in Advance Supply Systems (KLASS) pilot project (Rhodes & Carter, 2003) seeks to develop collaborative learning in networks of suppliers in the automotive and aerospace sectors. Focusing on the tiered supplier network, as illustrated on the left side of Figure 1, KLASS utilized an inter-company, computer-mediated learning network that focused on both immediate performance improvements and longer term objectives. It developed learning and knowledge to advance collaborative functioning and improved performance between the tiered companies linked in the supplier network. Similarly, to manage knowledge across the supplier network and enterprise boundaries, as shown in Figure 1, Chrysler developed a successful supplier-suggestion process to reduce costs and build collaborative relationships with its suppliers (Hartley, Greer & Park, 2002). Both of these are examples of inter-organizational systems.

In another example of an inter-organizational network, Mak and Ramaprasad (2003) introduce the idea of knowledge supply networks, which they define as "integrated sets of manufacturing and distribution competence, engineering and technology deployment competence, and marketing and customer service competence that work together to market, design and deliver end products and services to markets." They outline the nature of the business processes associated with designing and delivering innovative products and describe the need to effectively coordinate the knowledge in the market, design, and supply distribution chains. As costs for product development increase and faster time-to-market is expected, more and more original equipment manufacturers (OEM), such as Motorola and Nokia, are refocusing their competence on marketing, research and design, and critical high level design, and outsourcing everything else to contract manufacturers. This changes the chain structure as outlined in Figure 1 and requires the OEM to create a knowledge management network that will allow them to leverage the supplier and contract manufacturer knowledge, yet still preserve their own knowledge and control.

In order to be competitive, supply chains for innovative products must have processes in place to exchange product and market knowledge. Unlike the chains associated with functional products, innovative chains will not incur much competitive advantage as the result of demand and inventory information sharing. Due to high future demand uncertainty and potentially high profit margins, there is often distrust between the stages of the chain. This distrust can result in parties making uncoordinated decisions that are in their best individual interest (local optimization) and not in the best interest of the supply chain.

For instance, in the PC market, manufacturers suspect their distributors of inflating orders to ensure availability of the product. Dell Corporation removed the distributor stage in its supply chain so that it could improve its market mediation and receive end-consumer information directly. In the automotive and aerospace industry, manufacturers provide suppliers with forecasts that are often wrong, resulting in extreme shortages or excess capacity with no return on investment for the suppliers. Suppliers often make locally optimal decisions as a result. When a supplier could not provide an adequate supply of ashtrays and glove compartment doors, GM lost nearly two months of production of the Buick Roadmaster (Suris & Templin, 1993). In 1999, GM canceled two new models, leaving their suppliers with newly developed capacity and no return for their investment (Pryweller, 1999). In 1997, Boeing could not fill their plane orders largely due to a shortage of 500 different parts from 3,000 part suppliers who did not have enough capacity, resulting in a $1.6 billion charge against Boeing's third-quarter earnings (Cole, 1997).

A survey done by Lee and Whang (2000) identifies that firms are also concerned about the confidentiality of shared information when competition exists, and that it is one of the major hurdles that information sharing in a supply chain must overcome. Besides intentional information leaks, Li (2002) defines the leakage effect as the indirect effect of vertical information sharing that occurs when the shared information becomes known to competition as the result of observing the behavior of the party that receives the information. Li illustrates how competing firms can react to the observed behavior and how this reaction can change the strategic interaction, causing additional gains or losses to the parties between which the information was directly exchanged. Powell, Koput, and Smith-Doerr (1996) point out that firms will continue to work with their partners, once the risks are managed at a "tolerable level."

In addition to trust, several other factors impact the ability of a firm to share information and knowledge productively with other parties in a supply chain. These include the technology infrastructure, application software used to manage the supply chain operations, and the culture of knowledge sharing within a firm as well as within the supply chain.

Scott (2000) studied the process of and reasons for information technology (IT) support for inter-organizational learning. Studying the disk drive industry, Scott identified the need for inter-organizational learning to help "cope with the complexity of new products and the capital intensity" in the industry. She noted that the industry had consolidated with several firms working very closely in a "vertically integrated virtual organization." IT helps the organizations streamline the information flow between them, making it easier to provide feedback between partners and facilitate learning across organizational boundaries. The model developed by Scott helps to explain the role of IT in lower and higher levels of inter-organizational learning. In lower level learning, an organization makes changes to its operations based on feedback from a partner. In higher order learning, partners change operating assumptions and procedures based on a new understanding typically resulting from collaborative work. An important finding from her study was that inter-organizational learning strategies "with customers and suppliers in the disk drive industry were facilitated by IT and constrained by lack of trust."

Kent and Mentzer (2003) conducted a study of the impact of inter-organizational information technology (IOIT) in a retail supply chain. They found that when suppliers invest in IOIT, retailers perceive a commitment to the relationship from the suppliers and are willing to reciprocate. The commitment to the relationship leads to the partners working together to improve logistics efficiency. Therefore, the payoff from the investment in IOIT comes from the reduction of costs in the supply chain as a result of improvements in logistics efficiency. Their findings also support Scott's (2000) observation about the role of trust between partners in a supply chain. In addition to the investment in IOIT, they show that firms must also "demonstrate characteristics of trust such as integrity and faithfulness." Only then will partners perceive the commitment to the relationship. As

Kent and Metzer state, “relationship trust and investment in IOIT can lead to relationship commitment that can lead to logistics efficiency.”

The above examples pertain to inter-organizational systems; however, KM plays an important role even within a single organization. Intra-organizational systems and initiatives are needed to facilitate knowledge sharing across organizational units. Edwards and Kidd (2003) treat knowledge management “as a process rather than as an organizational system” or a piece of technology. In order for this process to work across organizational boundaries, they identify trust, organizational culture, and the “relationship between top down strategy and bottom up organizational learning” as enabling factors. Trust needs to exist between individuals as well as between organizations. There needs to be compatibility between the cultures of organizations for knowledge management processes to work. Aligning the top down strategy with bottom up learning requires the organization to make its strategy for KM clear and create and maintain an atmosphere that supports organization learning. Trust between individuals and organizations can be enhanced by setting up exchange programs and by facilitating voluntary exchange of knowledge.

Another set of factors that Bessant and Kaplinsky (2003) recognize as necessary for learning in supply chain is the “accumulation and development of a core knowledge base,” as well as the “long-term development of a capability for learning and continuous improvement across the whole organization.” In order for each organization in a supply chain to manage how learning takes place, they need to have formal mechanisms and a clear understanding of the value of learning. Only then can long-term efforts be sustained.

This set of factors is based on the concept of absorptive capacity (Cohen & Levinthal, 1990). Cohen and Levinthal describe this as the capacity of an organization to “recognize the value of new, external information, assimilate it, and apply it to commercial ends.” Lane and Lubatkin (1998) suggest that the absorptive capacity of a firm is relative to its partner firms and is dependent on “the similarity of both firms’ knowledge bases, organizational structures and compensation policies,” and one firm’s familiarity with the other firm’s “set of organizational problems.” Szulanski (1996) shows that a unit’s lack of absorptive capacity, a distant relationship with other units and lack of a clear understanding of cause and effect relationships can all become impediments to intra-organizational learning.

In addition to efficiency in logistics is the issue of effectiveness of sourcing in enterprises that have multiple personnel handling the purchasing task. Rozemeijer, Van Weele, and Weggeman (2003) identify three constructs to help corporate purchasing officers create coordinating mechanisms that facilitate purchasing synergies within the corporation. The constructs include purchasing maturity, corporate coherence, and business context. The mechanisms they identified include:

- formal organizational mechanisms such as corporate steering boards or commodity teams;
- informal networking mechanisms such as annual purchasing conferences and job rotation;
- enterprise-wide information and communication systems; and
- advanced management and control systems.

These four mechanisms or systems represent different options for intra-organizational KM. These mechanisms were illustrated for a supply chain with functional products. Rozemeijer et al. (2003) also point out however that purchasing performance depends on increased coordination between multiple purchasing officers and requires constant monitoring to ensure that the purchasing function is aligned with the business context and corporate strategy, which is associated with the type of product and supply chain objectives involved.

CONCLUSION

As the studies cited above show, information technology that supports information sharing is a necessary element for knowledge management processes to work in supply chains. In supply chains for functional products, decentralized decision making can result in good decisions when IT support is effective. However, in innovative supply chains, IT by itself is not sufficient. The other factors are needed as well. Without the other factors, such as trust within and across organizations or an organizational culture that supports learning, the supply chain does not benefit. Even with good IT and information sharing, each company is likely to make decisions that are locally focused, resulting in suboptimal supply chain performance.

Practitioners interested in creating and managing knowledge management efforts in supply chains should consider the following issues carefully:

- The information flow between the tiers in the supply chain and how the systems and organization support information sharing.
- The utilization of information within an organization, especially to support decision making. Decentralized decision making can be beneficial for the supply chain as long as the firms trust each other and want to optimize the performance of the chain. Incentives need to be in place to ensure that each party is motivated to maximize the performance of the chain.
- The organizational culture with respect to learning within each firm and across the tiers in the supply chain. The culture must support learning and facilitate the process of learning.
- Trust between organizations in the supply chain is critical. Unless the firms develop this trust, they will make decisions solely based on their self interest, and that may be detrimental to supply chain performance.
- How the network assimilates the information and how the network changes its actions based on what it has learned is the effect of the knowledge management effort. In the case of functional products, this can be in the form of firms modifying processes to increase efficiency. In the case of innovative products, suppliers may be elevated to status of true partners, taking on more responsibility and risk and sharing in decision making as decisions are made in a more centralized manner.

Chapter 2.37
Frequent Itemset Mining and Association Rules

Susan Imberman
City University of New York, USA

Abdullah Uz Tansel
Bilkent University, Turkey

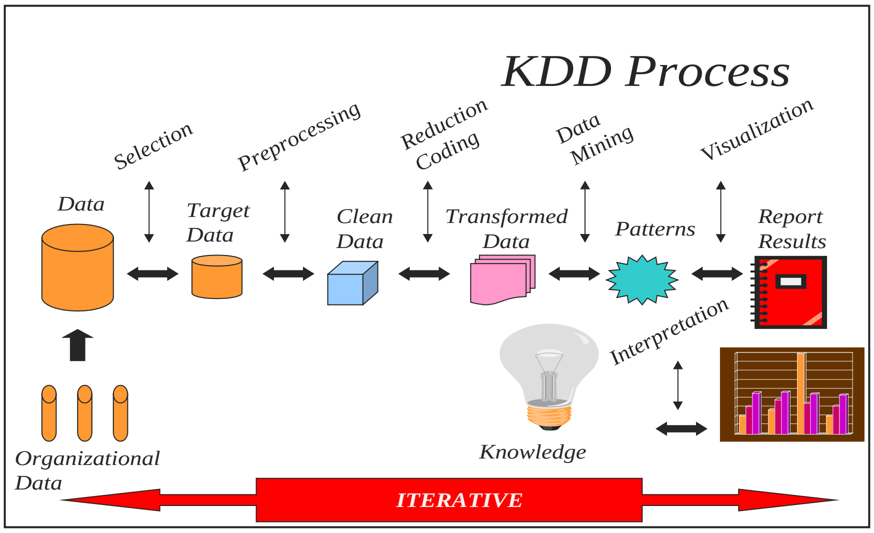
INTRODUCTION

With the advent of mass storage devices, databases have become larger and larger. Point-of-sale data, patient medical data, scientific data, and credit card transactions are just a few sources of the ever-increasing amounts of data. These large datasets provide a rich source of useful information. Knowledge Discovery in Databases (KDD) is a paradigm for the analysis of these large datasets. KDD uses various methods from such diverse fields as machine learning, artificial intelligence, pattern recognition, database management and design, statistics, expert systems, and data visualization.

KDD has been defined as "the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data" (Fayyad, Piaetsky-Shapiro, & Smyth, 1996). The KDD process is diagramed in Figure 1.

First, organizational data is collated into a database. This is sometimes kept in a data warehouse, which acts as a centralized source of data. Data is then selected from the data warehouse to form the target data. Selection is dependent on the domain, the end-user's needs, and the data mining task at hand. The preprocessing step cleans the data. This involves removing noise, handling missing data items, and taking care of outliers. Reduction coding takes the data and makes it usable for data analysis, either by reducing the number of records in the dataset or the number of variables. The transformed data is fed into the data mining step for analysis, to discover knowledge in the form of interesting and unexpected patterns that are presented to the user via some method of visualization. One must not assume that this is a linear process. It is highly iterative with feedback from each step into previous steps. Many different analytical methods are used in the data mining step. These include decision trees, clustering, statistical tests, neural networks, nearest neighbor algorithms, and association rules. Association rules indicate the

Figure 1. The KDD process



co-occurrence of items in market basket data or in other domains. It is the only technique that is endemic to the field of data mining.

Organizations, large or small, need intelligence to survive in the competitive marketplace. Association rule discovery along with other data mining techniques are tools for obtaining this business intelligence. Therefore, association rule discovery techniques are available in toolkits that are components of knowledge management systems. Since knowledge management is a continuous process, we expect that knowledge management techniques will, alternately, be integrated into the KDD process. The focus for the rest of this article will be on the methods used in the discovery of association rules.

BACKGROUND

Association rule algorithms were developed to analyze market basket data. A single market basket contains store items that a customer purchases at a particular time. Hence, most of the terminology associated with association rules stems from this domain. The act of purchasing items in a particular market basket is called a transaction. Market basket data is visualized as Boolean, with the value 1 indicating the presence of a particular item in the market basket, notwithstanding the number of instances of an item; a value of 0 indicates its absence. A set of items is said to satisfy a transaction if each item's value is equal to 1. Itemsets refer to groupings of these items based on their occurrence in the dataset. More formally, given a set $I = \{ i1, i2, i3, \ldots in \}$ of items, any subset of I is called an itemset. A k-itemset contains k items. Let X and Y be subsets of I such that $X \cap Y = \varphi$. An association rule is a probabilistic implication $X \Rightarrow Y$. This means if X occurs, Y also occurs. For example, suppose a store sells, among other items, shampoo (1), body lotion (2), hair spray (3), and beer (4), where the numbers are item numbers. The association rule shampoo, hair spray $\Rightarrow$ beer can be interpreted as, "those who purchase shampoo and hair spray will also tend to purchase beer."

There are two metrics used to find association rules. Given an association rule X ⇒ Y as defined above, the support of the rule is the number of transactions that satisfy X ∪ Y divided by the total number of transactions. Support is an indication of a rule's statistical significance. Interesting association rules have support above a minimum user-defined threshold called minsup. Given the database represented in Figure 2, the support of the association rule shampoo, hair spray ⇒ beer is equal to the number of transactions where shampoo, hairspray, and beer are equal to 1. This is equal to the shaded region and consists of a support of 4 out of 12 transactions, or 33%. Frequently occurring itemsets, called frequent itemsets, indicate groups of items customers tend to purchase in association with each other. These are itemsets that have support above the user-defined threshold, minsup.

Given an association rule X ⇒ Y as defined above, the confidence of a rule is the number of transactions that satisfy X ∪ Y divided by the number of transactions that satisfy X. In Figure 3, the shaded portion indicates the support of Shampoo and Hair Spray. The confidence is then the support of the itemset Shampoo, Hairspray and Beer, divided by the support of Shampoo and Hairspray which equals 4/6 = 66%. It is common practice to define a second threshold based on a user-defined minimum confidence called minconf. A rule that has support above minsup and confidence above minconf is an interesting association rule (Agrawal, Imielinski, Swami, 1993; Agrawal & Srikant, 1994; Agrawal, Mannila, Srikant, Toivonen, & Verkamo, 1996).

FINDING ASSOCIATION RULES

Finding association rules above minconf, given a frequent itemset, is easily done and linear in complexity. Finding frequent itemsets is exponential in complexity and more difficult, thus necessitating efficient algorithms. A brute force approach would be to list all possible subsets of the set of items I and calculate the support of each. Once an itemset is labeled frequent, partitions of the set's items are used to find rules above minconf. Continuing our example, assume minsup = 65%. Figure 4 lists all the subsets of the set of the items in Figures 2 and 3. The shaded areas indicate the frequent itemsets with support equal to or above

Figure 4. Itemsets and their support

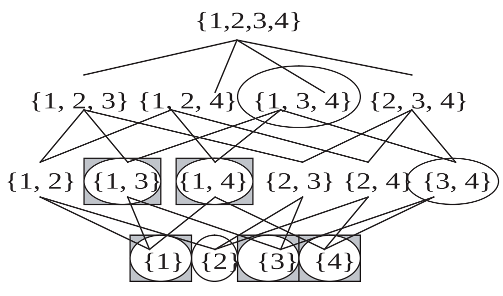
Itemset	Support (in percent)	Itemset	Support (in percent)
{1}	83	{2}	58
{3}	75	{4}	83
{1,2}	50	{1,3}	75
{1,4}	66	{2,3}	50
{2,4}	41	{3,4}	58
{1,2,3}	50	{1,2,4}	33
{1,3,4}	58	{2,3,4}	33
{1,2,3,4}	33		

65%. The set of all itemsets forms a lattice, as seen in Figure 5.

One can see that the brute force method grows exponentially with the number of items in I. In a database containing thousands of items, a brute force approach can become intractable. Algorithms that are exponential relative to the number of variables are said to suffer from "the curse of dimensionality."

If we look at the 1-itemsets in Figure 4, we notice that itemset {2} is below minsup. In fact, all supersets of itemset {2} are below minsup as well. This is illustrative of the upward closure property of support. If an itemset is not frequent, then the itemset's supersets will not be frequent. Many association rule algorithms use this property to prune the search space for frequent itemsets.

Figure 5. Lattice of itemsets



Apriori is one such algorithm (Agrawal et al., 1993; Agrawal & Srikant, 1994; Agrawal et al., 1996).

APRIORI ALGORITHM

Apriori uses the upward closure property of support to move level wise through the lattice. To find frequent itemsets, Apriori first scans the data set for the counts of 1-itemsets, since all 1-itemsets are candidates to be frequent. Those frequent 1-itmesets are used to generate the 2-itemsets that are candidates to be frequent. In general, Apriori generates candidate itemsets at a particular level k from the k-1 itemsets at level k-1. This is done in the algorithm's join step. If two frequent itemsets at level k-1 have the same k-2 items in common, we form the union of these two sets. The resulting set is a candidate k-itemset. Each of these candidate itemsets are checked to see if any of their subsets are not frequent. If so, they are pruned from consideration in the prune step, since if you recall, supersets of itemsets that are not frequent, are themselves not frequent. Candidate itemsets that do not have support equal to or above minsup are also pruned. The algorithm proceeds level wise through the lattice, until there are no more candidate itemsets generated.

Using the data set from Figure 1, in level 1 of Figure 5, the algorithm starts with all the 1-itemsets as candidate itemsets. Candidate itemsets in the figure are circled. Counting the support of each itemset, we see that all but {2} are frequent. A box indicates frequent itemsets. Itemsets {1}, {3}, and {4} combine to form candidate 2-itemsets {1,3}, {1,4}, and {3, 4}. From the data we see that itemsets {1, 3} and {1, 4} are frequent. Since {1, 3} and {1, 4} have k-1 items in common, these itemsets are combined to form the candidate 3-itemset {1, 3, 4}. Itemset {3, 4} is a subset of {1, 3, 4}. Since {3, 4} is not frequent, {1, 3, 4} cannot be frequent. The algorithm stops since we cannot generate any more candidate itemsets.

VARIATIONS ON APRIORI

Researchers have devised improvements to overcome the bottlenecks in the Apriori algorithm. One bottleneck is the time needed to scan the dataset since the dataset is huge, normally terabytes large. Because of this, a lot of the work done by these algorithms is in searching the dataset. The authors of Apriori realized that transactions that do not contain k large itemsets would not contain k+1 large itemsets. Thus avoiding further scans of the dataset (Agrawal et al., 1996). Another improvement was to implement the use of transaction identification lists (TID lists). These are the lists of transactions an itemset is contained in. The dataset is scanned only once to create the TID lists for the 1-itemsets. The TID lists for itemsets on any level k+1 is created by taking the intersection of the TID lists of the itemsets from level k used in their creation. The problem with TID lists is that initially, the size of the list has the potential to be larger than the dataset. In recognition of this, the authors of Apriori developed Apriori Hybrid, which scans the dataset in the beginning levels of the algorithm, and then switches to TID lists.

Other researchers have taken different approaches to the problem of scanning large datasets. In Dynamic Hashing and Pruning (DHP), it was recognized that in level wise algorithms like Apriori, much of the work is done in generating and counting the 2-itemsets (Park, Chen, & Yu, 1995). The approach here was to hash the candidate 2-itemsets. The number of itemsets in each bin is stored. If the total count of the itemsets in a bin is not larger than or equal to minsup, then the itemsets in that bin cannot reach minsup. These itemsets are pruned, and the algorithm proceeds as in Apriori.

Another approach was to break the dataset into n partitions such that each partition fits into main memory (Savasere, Oiecninski, & Navathe 1998). The premise is that any global large itemset must also be one of the local frequent itemsets found in a partition. Once frequent itemsets in local partitions are found, the dataset is scanned to determine which of these is global.

Another approach has been to create a random sample from the dataset large enough to fit into memory (Toivonen, 1996). The sample is then used to find frequent itemsets. In order to increase the probability that those itemsets found in the sample would include all frequent itemsets from the dataset, the sample is scanned with a lower support than that used for the dataset. The transactions of the dataset, not in the sample, are then used to check the support counts of the sample frequent itemsets. Thus only one scan of the dataset is required, but there is no guaranty that all frequent itemsets will be found.

Datasets that are increasing in size pose the problem of how to efficiently mine the new data. One could run an algorithm like Apriori on the "new" larger dataset, but this ignores all previous work done in discovering frequent itemsets. In addition it is costly and inefficient since most of the work done in finding frequent itemsets is in scanning the dataset. To avoid redoing one can take an incremental approach whereby you use the information obtained in previous association rule processing to reduce the amount of dataset scans when new transactions are added (Ayan, Tansel, & Arkun, 1999).

Below, we list the notation used in incremental association rule mining.

- DB is the set of old transactions from the original database.
- db is the set of new incoming transactions (the increment).
- DB+db is the set of old and new incoming transactions (the resulting combined dataset).
- SCDB (X) is the support count of itemset X in DB.
- SCdb (X) is the support count of X in db.
- SCDB + db (X) is the support count of X in DB+ db.

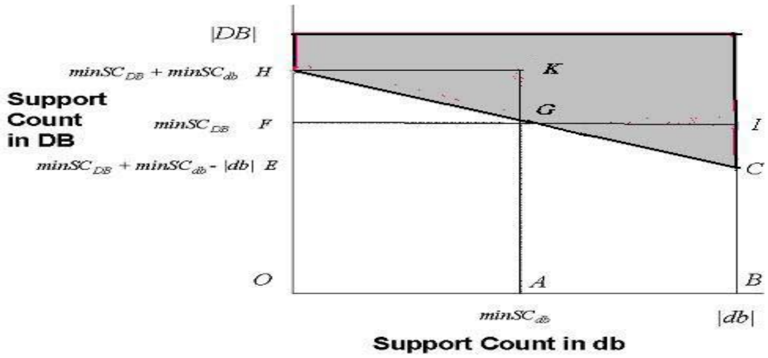
Assume that the size of the increment db is less than the size of the original dataset DB. Define the support count (SC) of an itemset as the number of occurrences of that itemset in the dataset. Figure 6 is an illustration of the incremental approach in terms of the support count of DB (SCDB) plotted against the support count of db (SCdb) (Imberman, Tansel, & Pacuit, 2004). For each point (SCdb, SCDB) in Figure 6, SCdb + SCDB = SCDB+db, which is the support count of the new dataset. Let minSCdb be the minimum number of transactions to be frequent in db and minSCDB be the minimum number of transactions to be frequent in DB. Therefore, for all points G on line HC, SCdb + SCDB = minSCDB+db. Line HC partitions the space of itemsets. All itemsets above and including HC are frequent. All itemsets below HC are not frequent. Triangle HFG represents those itemsets that have become infrequent or have submerged. Triangle GIC represents those itemsets that have become frequent or emerged. The incremental discovery problem can be thought of as efficiently identifying those itemsets in triangles GIC and HFG.

Update With Early Pruning (UWEP; Ayan et al., 1999) has been shown to be an efficient incremental association rule algorithm. Like most incremental algorithms, UWEP uses information found in the increment to prune the search space. First UWEP scans db to find the counts for all the 1-itemsets. In the pruning step, the supersets of the itemsets in DB that are found not frequent in DB + db are pruned from DB + db. The frequent itemsets in DB, whose items are absent in db, are checked to see if SCDB (X) >= SCDB + db (X). Frequent itemsets in db are looked at to see if they are frequent in DB. These are frequent by definition. Lastly, for all itemsets that are frequent in DB or db and have not yet been looked at, they are checked to see if they are frequent in DB + db.

Besides researching new ways for efficiently finding association rules, researchers have looked at the rules themselves, finding new types of association rules. Association rules are Boolean, looking only at the positive associations between items. Some researchers have looked at the negative dependencies as well, calling these rules dependency rules (Silverstein, Brin, & Motwani 1998). A dependency rule can express concepts such as males age 60 or greater = yes and smokes = no ⇒ buy beer = no. Imberman et al. (2002) have shown that dependency rules are more expressive for medical data miming than association rules.

Since most data is not Boolean by nature, how can one show associations with numeric and categorical data? Quantitative association rules

Figure 6. The incremental association rule problem



express associations such as Age: 30 to 39 and Owns car = yes $\Rightarrow$ Median Income = 40,000. One approach was to map each category in a categorical variable, to a Boolean variable and discretize the quantitative variables into intervals (Srikant & Agrawal, 1996). Each interval is mapped onto a Boolean variable. Then any Boolean association rule algorithm can be used to find rules. However, care needs to be exercised in partitioning each variable appropriately. If a quantitative variable is partitioned into too many smaller intervals, minimum support may not be found in any one interval. Therefore some well-supported rules may be missed. Also, confidence can decrease with larger intervals affecting the attainment of minimum confidence. Thus, small intervals might not get minimum support, while large intervals might not get minimum confidence. An approach to solve this problem is to consider all possible continuous ranges (Srikant & Agrawal, 1996). If we were to increase the interval size then we would have no more minsup problem. To take care of this we can combine adjacent intervals. But we may still have minconf problems. We can solve minconf problems by increasing the number of intervals. But doing both leads to two more problems. Given n intervals, there are on average O(n2) possible ranges. There is therefore a blow up in execution time. Given an interval with support, any range containing that interval also has support. This can lead to a blow up in the number of rules known as the many rules problem. Srikant and Agrawal (1996) posed a solution by setting a user-defined maximum on the size of the interval and using an interestingness measure to filter out uninteresting rules.

The ‘many rules problem’ has motivated research into the ‘interestingness’ of rules produced by association rule algorithms. Methods for interestingness involve ordering and grouping association rules in order to facilitate their use and interpretation. Metrics for ordering rules include measures such as confidence, added value, mutual information (Sahar & Mansour, 1999), and conviction measures (Brin, Motwani, Ullman, & Tsur, 1997). Objective interestingness measures seem to cluster into three groups when support and confidence levels are low. Interestingness measures in the same cluster produce similar rule orders. Sahar (1999) along with Mansour (1999) pruned the rule set by discarding ‘uninteresting’ rules. Sahar worked under the premise that simple rules would already be known by the user and can thus be pruned from the rule set. Sahar (2002) used clustering to group similar rules.

FUTURE TRENDS

Association rule discovery algorithms feed their results into organizational knowledge bases. An important issue is the maintenance and update of discovered association rules as new data becomes available. The incremental algorithms we have summarized above are very useful and cost effective for knowledge management. Research into the combination of sound knowledge management techniques and data mining techniques can make significant contributions to the business environment.

Research into the types of rules that can be generated using the techniques outlined in this article is ongoing. Reduced database scanning by improvements on the basic algorithm is another area of research activity. In addition much current research is being concentrated on finding better data structures for more efficient itemset processing (Gosta & Zhu, 2003). Association rule mining is a very active research field.

CONCLUSION

Association rule algorithms show co-occurrence of variables. One of the major problems inherent in Apriori, and algorithms like Apriori, is that there tends to be a large number of rules generated, some of which are commonly known. In addition, attempts to use the rules generated by association rule algorithms has met with mixed results. On the other hand, Apriori has also been shown to find less obvious patterns in the data (Cox, Eick, Wills, & Brachman, 1997), thereby discovering very valuable knowledge.

Chapter 2.38
Learning Networks and Service-Oriented Architectures

George Tsekouras
University of Brighton, UK

George Roussos
University of London, UK

INTRODUCTION

The value of knowledge assets in creating competitive advantage and subsequently wealth through innovation has never been greater (Teece, 1998). It is increasingly being acknowledged that the resources and the competencies developed within the organisation as well as the mechanisms for building up and reconfiguring these competencies is the only defence against a fierce competition (Penrose, 1959; Prahalad & Hamel, 1990; Teece, Pisano & Shuen, 1997). However, the nature of knowledge production has changed dramatically over the last years. According to Gibbons et al. (1994), the knowledge production has moved from mode 1 to mode 2. The new mode:

- requires transdisciplinary approaches
- is characterised by heterogeneity of skills
- is context-sensitive involving an intense interaction between producers and users of knowledge

The highly complex and rapidly changing character of contemporary knowledge production makes it almost impossible for single organisations to acquire the full set of required skills. Even large corporations with abundant resources need to turn to other organisations in order to cope with new knowledge requirements. Learning through networking with other firms gives the opportunity not only to share expenses and resources, but more significantly, to listen to new ideas, challenge one's own inherent assumptions, and embrace new perspectives.

The challenge associated with this is to set up an infrastructure to support shared learning and reflection on a regular and sustainable basis. To answer this problem, the mechanism of the so-called learning networks (LN) has been introduced. Learning networks do not refer to networks of organisations where learning simply happens—as is the case with every network—but to interorganisational networks where structures have been established with the primary purpose of increasing the participants' knowledge. These networks:

- involve representatives of different organisations, mainly but not exclusively, private firms
- are formally established with clear and defined boundaries for participation
- have an explicit structure for operation with regular processes that can be mapped to the learning cycle
- have a primary learning target—some specific learning/knowledge which the network is going to enable
- can assess the learning outcomes which feed back to the operation of the network.

The formal character of the network provides an institutionalised organisational platform which represents a permanent structure for identifying knowledge gaps and satisfying knowledge needs, allows evaluation, and accumulates experience regarding the support required by learners. More significantly, the lasting character of membership in learning networks facilitates the development of trust relationships among learners.

Information technology can play a critical role in supporting LNs. Yet, the majority of current KM systems have been designed under the assumption that they will be used within a single organisation or that a single organisation will be responsible for their operation. KM systems appropriate for interorganisational use dictates that several challenges are met. For example, interorganisational information systems must not only provide reliable infrastructures for the organisation itself but also must be capable of sharing resources seamlessly within their network of learning partnerships. These operating conditions demand that such systems are both flexible and operate transparently. Over the past few years, service-oriented architectures have emerged as a framework that addresses this requirement both effectively and efficiently. In this article, we discuss the current use of Web-based service architectures to support LNs and then outline future trends.

BACKGROUND

The new rules of competition (Teece, 1998) have demanded from organisations to build a concrete strategy for learning and continuous change (Argyris & Schon, 1996). Initially, loads of competent tutors and specialised trainers stormed the companies and apparently their resources, delivering high-quality training courses and material. It was only when Orr (1990a, 1990b) observed technicians in Xerox that it was realized that real value learning is intrinsically blended with communities which:

- make their own decisions
- practice the acquired knowledge
- improvise their approaches

In a similar vein, Lave and Wenger (1991) have talked of situated learning—learning that is intrinsically linked to the environment where it is situated—while Cook and Brown (1999) regard organisational learning governed by epistemology of practice rather than epistemology of possession (i.e., knowledge is fundamentally associated with practice and cannot be transferred as a commodity). These contributions have made Stamps (2000) wonder whether "learning is social [and] training is irrelevant" and Wenger (1998, 2000) suggest that real value learning can only happen in "communities of practice." Behind all these approaches, there is the notion that knowledge management cannot be separated from the tacit knowledge (Polanyi, 1966), that is, the knowledge we possess but we cannot tell. Nonaka and Takeuchi (1995) observed the process of knowledge creation within an organisation to conclude that knowledge is generated by regular exchanges between tacit and explicit knowledge. Tsoukas (2002) argues that tacit knowledge cannot be translated or converted into explicit knowledge:

We cannot operationalise tacit knowledge but we can find new ways of talking, fresh forms of interacting and novel ways of distinguishing and connecting…New knowledge comes about…when our skilled performance is punctuated in new ways through social interaction.

Meanwhile, a variety of scholars and policy-makers have noticed the phenomenal success of clusters of different companies. Becattini (1989, 1990) described the Italian experience where networks of small firms and other institutions have helped certain regions to achieve one of the highest rates of economic development and one of the lowest rates of unemployment in Europe. Several case studies point to the same conclusion: Southern Germany, South-West Belgium, Northern Denmark, M4 corridor in UK, Silicon Valley in California (Sengenberger & Pyke, 1990; Saxenian, 1991). Even in less developed economies like Brazil and Pakistan, the collective efficiency developed within clusters has phenomenal results (Bessant & Tsekouras, 2001). It is becoming clear that simple factors such as proximity do not, of themselves, explain the success of clustering. Humphrey and Schmitz identify the importance of developing trust relations, whilst Sengenberger and Pyke (1992) point out the readiness amongst firms for cooperation which help the firms to build shared learning mechanisms.

Building on the understanding developed in the two areas, a new approach has been developed to combine the virtues of both. More specifically, it was realised that significant knowledge benefits can be captured when communities of practice develop across firms boundaries, sharing experiences from their organisations. Using the mechanism of learning networks, practitioners groups are set up to reflect collectively and learn from each other, following a number of principles:

- Firms1, represented by managers, are allocated in small groups with up to 20 members
- All necessary decisions for learning are made by the learners themselves rather than experts and tutors
- Learning is practical and derives from the discussion of the concrete experience of the group members rather than the introduction of abstract concepts
- Part of the participants duties is to go to their own organisations, try out the learned approaches, come back to the group, and report their experience
- The group becomes a forum for sharing concerns, get psychological support, but also receive feedback on their own ideas from other practitioners.
- Experts and tutors may be invited occasionally, only when needed
- Knowledge resources are used but only in conjunction with their practical learning

Of course, knowledge interactions between different firms is not a new phenomenon (Nonaka & Takeuchi, 1995; Von Hippel, 1988). The challenge presented to learning networks was to develop the managerial capabilities required for sustaining and improvising these activities on a long-term basis2. In other words, the challenge for learning networks is to develop the organisational processes and the managerial capabilities which allow the systematic emergence and development of communities of practice between different firms. A critical enabler of this strategy is the appointment of a specially dedicated facilitator to assist the group's practitioners in their structured reflection. The facilitators have gone through special training (e.g., how to enhance group dynamics, how to tackle disagreement between members) and accumulate relevant experience over time. The learning groups receive further support by the network, that is, a wider organisation which includes all group members as well as those which are not in any group at a certain time. The network has its Managing Director, usually called the Network Moderator, who is responsible for providing a common ground for all different groups operating at a time, ensuring the interface between them and the cross-fertilisation of their experience.

The so-called learning networks range from networks focusing on:

- single issues (e.g., the British Quality Foundation)
- particular sectors (e.g., Industry Forum by the Society of Motor Manufacturers and Traders, CIRIA for the construction industry in UK)
- specific regions and particular sectors (e.g., AC Styria for the automotive sector in the Austrian region of Styria)
- specific regions without any sector or topic focus (e.g., Plato network in Ireland)

The benefits of the learning network approach is obvious for SMEs because it gives them a permanent forum for obtaining knowledge in an inexpensive way. Convinced by the advantages of the approach, multinational enterprises have also adopted the concept in three forms:

- internal learning networks between different units or departments of the enterprise, sometimes located in different parts of the world (e.g., Black & Decker)
- joint learning networks among themselves and their suppliers (e.g., the suppliers clubs in TOYOTA / Bessant et al., 2003)
- inter-corporations learning networks among the main players of a sector to share ideas, reflect jointly, and exchange good practices (e.g., SCRIA in the aerospace industry and CRINE in the energy sector in UK)

The potential of KM systems can contribute significantly to the improvement of the learning network processes. On one hand, the innovative scheme of learning networks represents a unique opportunity for KM systems to offer added value to businesses and their managers. Time after time, systems developers discover that successful and cost-effective design of information systems require a combination of theory and practical experience as well as dynamic and proven organisational designs which the information architectures can match.3 A good match between the information systems and the organisational layout can speed up the development process, reduce costs, increase productivity, improve the quality of software, and more significantly increase the relevance of KM systems to users. The next section reviews the value added that KM systems can offer to learning networks and their members.

PORTAL SERVICE ARCHITECTURES FOR LEARNING NETWORKS

Learning networks face the challenge of increasing the level and the knowledge-intensity of interaction among their members while at the same time they want to shorten the cycle of formation, trust development and knowledge sharing within groups. In order to do so, they have to improve their organisational processes that support directly or indirectly the knowledge interactions between the members. These processes include the decision-making, collaborative learning, and dissemination of and harvesting knowledge. Traditionally, all learning network processes were carried out primarily through physical meetings. This imposed significant limitations to the network activities due to severe time and travelling restrictions. For instance, if a manager-member of a group missed a session, he or she could not make up for it while the communication with other group fellows, the group facilitator, or even the network moderator was limited to the times of actual meetings.

The development of Web-based information systems gave the opportunity to learning networks to:

- facilitate planning and management of learning activities, including the decision-making for a number of issues such as the focus of learning, the strategic direction of the network, and so forth
- enhance communication and informal knowledge sharing among the network members
- support organisation of and access to network resources including learning material and "members details and photos" of other network fellows4
- facilitate the knowledge dissemination to the organisations of the firms represented in a group, namely the managers not participating to a group

Most often such activities are supported via a portal operated by the network broker. The network moderator and the group facilitators are ultimately responsible for the content, although virtual interactions such as net meetings and asynchronous communications are encouraged among the network and group members. Needless to say, implementation of a Web-based system does not automatically solve all the problems and the cautious reader should keep in mind the multitude of problems related to the architecture and deployment of IT in any organisational context.

The economics of rolling-out, populating with content, and maintaining such portals are more complex. Three distinguishing strategies have been identified (Tsekouras et al., 2004). Firstly, the liberal approach, where a general support effort is assumed by the broker to "have the ball rolling" in different areas. The broker's effort is rather limited and hopes to see the main initiative—and therefore its cost—undertaken by the network members.

Second is the catalytic intervention strategy, similar to what is called the "Clinton approach" (Greenstein, 2000). This strategy consists of very focused intervention by the broker, who therefore undertakes limited effort to roll out the system. The broker uses its intelligence to identify the critical, for its network, portal areas, and concentrates all its efforts to these areas. This strategy is definitely more intelligent than the liberal approach, but it also carries a significant higher risk since it puts "all its eggs in one basket."

Finally, the heavyweight strategy is where the network moderator is very active in uploading resources, updating the portal with the forthcoming events and learning sessions, filling in the personal details of the network members, and so forth. This incurred the broker a heavy cost in terms of days of work which is undertaken with the hope of high return on investment. This strategy is the most resource-intensive but also the less risky one. However, it requires the broker to be absolutely convinced for the potential benefits.

On the demand side, three generic patterns of usage have been identified regarding the practitioners-members of the network. The first pattern is reading in connection with the networks conventional activities namely physical learning sessions and events. The primary objective of this behaviour is to get prepared for or remembered of the organised sessions of the network, most of which are—at least currently—physical meetings.

The second pattern aims to improve the communication with the network broker in order to exploit his cognitive capability and accumulated experience to direct their own learning. In this pattern, the network members rely on the brokers' capability to direct them to useful news, new learning developments, and new sources of knowledge in order to update their knowledge and their own skills.

The third pattern is the one with the objective of bringing the learners-network members directly in touch with other fellow members or experts in order to learn from them. This virtual and direct transfer of knowledge can happen either in association with an actual meeting or on its own merit—as is the case with the virtual sessions at predefined times.

Despite the significant enhancement of the learning network processes by the LN portal, careful study reveals a broad set of challenges still unresolved by these systems. Although current Web technologies have provided the means for extensive electronic interaction between the network members, the sharing of information and knowledge resources must always go through the central network portal, creating a number of economic or cognitive bottlenecks. Indeed, before a network member can access network information or resources, a person must identify the relevant information or resource, seek the licence from the owner of the relevant information to share it in the network, upload the content in the network portal, and dispatch a notification to network members to alert them to the relevant update.

Carrying out these activities in full requires that considerable resources be consumed. Hence, the most effective strategy for increasing the knowledge-intensive interactions between the members is not necessarily the most efficient one from the resources point of view—what is called the heavyweight approach. Moreover, although individual organisations willingly participate in network exchanges, they remain independent and they want to keep control of their own resources. In other words, organisation's members may accept to share access to part of their own resources with other organisations' members but it is unlikely to consent to pass ownership of these resources to the network broker or other network members.

Third, in distributed computing systems the only trusted party to carry out the required steps is the network brokers, namely the network moderator or the group facilitators. However, the network brokers face significant cognitive limitations. For instance, it is almost impossible for the brokers to be aware of the full set of available knowledge resources existing in different members; even if he or she was, he or she would not be able to review, select, and disseminate all these resources on his or her own.

Finally, as the network grows, the brokers find it increasingly difficult to cope with the escalating responsibilities and demands of their tasks. As a result, the network should move from a "solar configuration" where the broker is the central node of interaction to a "spider web configuration." This configuration presupposes intelligent brokers, concentrating on the most critical aspects of learning networks such as building trust, resolving conflicts, and removing barriers, with the network members turning into active nodes of interaction and learning.

In short, while Web technologies have provided the means for extensive electronic interactions between network members, such interactions are significantly limited by financial and cognitive factors. In consequence, such interactions rarely go beyond the simple exchange of information. In the following section, we discuss how the emerging next generation service architectures can potentially help overcome these restrictions flexibly and transparently.

FUTURE TRENDS

Service-oriented architecture (SOA) (Stojanovic & Dahanayake, 2003) shifts the emphasis of information systems design from particular applications and application development frameworks toward well-defined and self-contained elements of functionality that do not depend on external context or state. Thus, systems are constructed by linking together services as needed so as to achieve specific goals. The value of SOA lies in the fact that it can effectively abstract enterprise architectures using the concept of the so-called

Service Bus, that is, a shared communications medium on which services may connect to and use in a plug-and-play manner.

In particular, in the case of highly decentralized, heterogeneous, and geographically distributed systems, SOA offers distinct advantages. In this context, SOA can help develop systems: that are scalable and can cater to large numbers of ever-changing users; that are trustworthy so as to protect confidential information; and last but not least, that are not constrained in terms of the particular technical choices. In particular, heterogeneity and distribution imply that there are frequent non-trivial issues regarding synchronization and concurrency as well as compatibility. To address these issues, numerous frameworks have been developed over the past decades, which employ middleware services and may rely heavily on reusable code and design patterns. Such frameworks need to address multiple issues including efficient and effective handling of remote processes, data, and input/output; naming; brokering, trading, and leasing resources; multiple levels of software abstractions; multiple attributes; security and trust management; threading and synchronization; and, finally, distributed transaction processing. In this context, SOA provides a novel solution which offers a significant advantage over all other solutions, namely its conceptual simplicity.

In the context of learning networks, SOA fulfils well a number of core requirements:

- Individual organisations can participate in a SOA by offering their resources to other network members without sacrificing control. In fact, they can define their own security policies and trust relationships and enforce them at the service level.
- Brokering and mediation bottlenecks can be readily bypassed, thus removing the information management limitations of the portal approach. In fact, relationships can be developed bilaterally in a peer-to-peer manner.
- Networks become scalable with additional members joining without unbalancing the existing relationships and systems. Moreover, network configurations can evolve in time and change with the topology of partner relationships without disturbing the established relationships of knowledge sharing.
- Different types of resources can be made available under the same service-based interface. For example, structured and unstructured information as well as computational resources can be made readily available under the common interaction paradigm of a service interface.
- Finally, it becomes possible to integrate the resources and process of the learning network to the internal workings of the network members as appropriate. Use of the services is automated and thus less manual effort is required in updating and maintaining resources.

Different technologies can be used to develop SOA. Currently, two candidates seem to attract most interest, namely Web services and the Grid. A Web service is a software system identified by its location on the World Wide Web and whose interface and supported modes of interaction are described using XML. The use of XML-based technologies, including the Universal Description, Discovery and Integration Protocol, and the Web Services Description Language, allow other systems to discover and use the service transparently as well as adapt their operation to meet its requirements. Interaction between systems using the Web service is also carried out using XML messages transferred over the Internet. Web services allow for the loose integration of service components and have the distinct advantage of employing widely available and standardised Web technologies.

Using Web Services, we can develop learning network infrastructures for controlled but open resource sharing especially where we have to deal with well-defined and possibly structured knowledge sources. For example, the case of the spider model architecture can be directly translated into a Web-based distributed and decentralised infrastructure, where network partners are in control of their own resources and are given discretionary access to resources of other members.

Often, the functionality offered by Web services does not fulfil all the requirements of a specific situation. In this case, a set of technologies that have become known as the Grid can be used to provide tighter coupling.

The Grid (Foster & Kesselman, 2003) is an umbrella term used to refer to a selection of technologies, protocols, services, application programming interfaces, software development kits, and turnkey systems to support coordinated resource sharing and problem-solving in dynamic, multi-institutional, virtual organisations. Although the Grid was initially focused primarily on advanced distributed supercomputing applications with emphasis on extreme computational power and data storage, today it commonly includes major technology trends, such as Internet, enterprise, distributed, and peer-to-peer computing to address much more mainstream situations. Indeed, resource sharing supported by the Grid can cater for process building through direct access to computers, software, data, and other resources, as is required by a range of collaborative problem-solving and resource brokering strategies. This type of sharing and collaborative learning is highly controlled, with resource providers and consumers defining clearly and carefully just what is shared, who is allowed to share, and the conditions under which sharing occurs. A set of individuals and/or institutions defined by such sharing rules form what is referred to in Grid parlance as a virtual organisation.

An early example of the use of SOA to support LNs can be observed in the Bloomsbury Bioinformatics Consortium (Orengo, Jones, & Thornton, 2003). This LN brings together researchers and practitioners in institutes located in the Bloomsbury of London with the common aim of developing innovative bioinformatics solutions for the medical industry. Interorganisational learning is assisted by the operation of a network infrastructure developed on the peer-to-peer Grid model, which allows for sophisticated levels of control over shared resources. Moreover, sharing of resources can be carried out in a cost-sensitive manner while embracing issues of quality of service, scheduling, co-allocation, and accounting. Finally, learning resources are annotated following a scheme which is uniform and representative of the particular learning network structure. To this end, the Consortium employs Semantic Web technologies, namely the Resource Description Framework, to describe themes and relationships between the different elements. Development of domain-specific ontologies is seen as a key element for collaborative relationships.

CONCLUSION

The blending of action learning with the network approach has produced a very powerful mechanism for sharing knowledge between different organisations, what has become known more widely as learning networks. This has generated unique results of learning and upgrading not only in terms of the skills of the involved individuals but also in terms of the processes of the relevant organisations. However, physical and practical constraints have limited the amount and the quality of the knowledge interactions among the members of the network. The first generation of Web technologies have enabled virtual and thus more convenient and longer lasting communication with other network partners as well as the network moderator and facilitators. The Web-based information systems also have given network members the opportunity to share resources through a centralised portal. However, these systems request major resource investment from the network brokers, generating a new set of constrains mainly related to the cognitive and practical limitations of the broker. In addition, these systems could not resolve the critical issues of efficient accumulation and ownership of the network resources.

The service-oriented architecture offers the opportunity to tackle these issues in an efficient and transparent way. Sharing of resources is feasible without losing the ownership rights, while the network brokers have to define the rules of sharing rather than collecting and disseminating the resources. The biggest advantage of these solutions is that they enable the transformation of learning networks from a solar broker-critical configuration to a spider web open resource configuration, allowing the flexible development of bipolar knowledge interactions without disturbing the overall balance of the system. Yet, the issues associated with the implementation of these new technologies need to be thoughtfully deliberated and carefully resolved.

ENDNOTES

1. These firms can be even in the same sector, but they should not be direct competitors in the sense of targeting the same market niche.
2. The effectiveness of communities-based learning has been a concern for managers in intraorganisational context (Buchel & Raub, 2002).
3. The failure of developers to take sufficiently into account these issues have led to a significant amount of criticism against KM systems (McDermott, 1999; Beamish & Armistead, 2001).
4. The access to contact information of other network fellows has been acknowledged as a very important contribution by the network members "as we only meet monthly [and] it's handy to refresh memory (face to name)" (Tsekouras et al., 2004).

Chapter 2.39
Distributed Learning Objects: An Open Knowledge Management Model

Veronica Diaz
The University of Arizona, USA

Patricia McGee
The University of Texas at San Antonio, USA

ABSTRACT

This chapter analyzes the emergence of learning objects as a dynamic and interactive relationship between technology and the organization. We examine the way that organizational objectives are embedded within selected technologies. In other words, how is the selected technology addressing the organization's needs? Further, we argue for a socially-constructed model of knowledge management. Specifically, we utilize Demarest's (1997) four-step process of the construction of a knowledge economy. From these processes, via a constructed technological system, a learning object economy emerges, which includes various constituents: the 21st century learner, the subject matter expert (university professor), vendors who support or enable knowledge management, and populaces that harvest and benefit from the collection of knowledge.

INTRODUCTION

As state and federal funds diminish and as higher education resources and university budgets become more restricted, postsecondary institutions are becoming increasingly entrepreneurial in pursuing and developing technological solutions. Meyer (2002) describes a changing marketplace, increasingly global in orientation, where technology enables the provision of adult education, executive training/retraining, competency-based programs, and education to remote geographical areas. Knowledge management,1 in higher education, is a way to retain and manage knowledge products. As higher education organizations increasingly interact with other organizational types, such as corporations, consortia, and other educational institutions, knowledge products become critical in the exchange process. Technological systems are designed to manage knowledge and are situated in social systems with corresponding cultures, values, and beliefs. As such, higher education, as an organizational structure and a social system, must consider processes, policies, and embedded assumptions about technology, teaching, and learning, not only within their own institution, but also across those with which they interact.

The trend toward knowledge management is evidenced in the myriad of technological artifacts that have emerged to capture, categorize, and manage learning objects. During their evolution, learning objects have come to be defined in a number of ways, depending on the context and culture from which they emerge, for example, computer science, education, instructional technology, and so on. For our purposes, we define a learning object as any digital asset that is intended to be used to achieve a learning objective and can be re-used in different contexts. Learning objects may be data or data sets, texts, images or image collections, audio or video materials, executable programs, courses offered through Learning/Course Management Systems (L/CMS), or other resources that can be delivered electronically. Learning objects should be re-useable and re-purposeable over time and location and interoperable across systems and software (see Downes, 2002; Robson, 2001; Wiley, 2000). Additionally, learning objects can be combined or aggregated in different ways providing the potential for individualized learning experiences for specific learners in which their learning styles, prior knowledge, and specific learning needs are accounted for. They may also offer great value in terms of saving time and money in course development, increasing the reusability of content, enhancing students' learning environment, sharing knowledge within and across disciplines, and engaging faculty members in a dynamic community of practice (Bennett & Metros, 2001). Learning objects may be created by individuals or institutions and therefore require consideration of digital rights as well as storage and distribution.

How learning objects are stored and subsequently accessed has been primarily addressed through technology systems known as digital learning object repositories. Thomas and Home (2004) have identified four rationales, not only for the development of learning objects, but also for their storage in these digital containers.

1. The Efficiency Route: The more institutions work together, the less likely replication of efforts and therefore reduced costs based on the idea that learning objects "deliver industrial economies of scale" (p. 12).
2. The Teacher-Centered Route: The more that educators share resources and best practices, the more likely teaching will improve. In this manner learning object "creation [is] co-production" (p. 12).
3. The Pupil-Centered Route: Learners who have access to a variety of objects designed with different learning needs in mind, can be better supported. In this sense, learning objects become "scalable and networked" (p. 13).
4. The Freedom Argument: Educators should take ownership and be able to disseminate freely to the larger educational community without struggling with or against issues of institutional ownership, intellectual property or even censorship.

These rationales serve to illustrate the value structures within organizational cultures that determine how technology is used to make knowledge accessible and the reasons for doing so. Such positions are reflected in organizational policies and are particularly critical within cross-institutional interactions.

This chapter analyzes the emergence of learning objects as a dynamic and interactive relationship between technology and the organization. We examine the way that organizational objectives are embedded within selected technologies. In other words, how is the selected technology addressing the organization's needs? Further, we argue for a socially-constructed model of knowledge management. Specifically, we utilize Demarest's (1997) four-step process of the construction of a knowledge economy. Next, we examine the way that knowledge is transmitted through a selected technological system. From these processes, via a constructed technological system, a learning object economy2 emerges, which includes various constituents: the 21st century learner, the subject matter expert (university professor), vendors who support or enable knowledge management, and populaces that harvest and benefit from the collection of knowledge. We discuss four current models of knowledge management found in higher education: the traditional model, the intellectual capital/appropriative model, the sharing/reciprocal model, and the contribution pedagogy model. We propose a new, relativist model of knowledge management for higher education that accommodates cross-institutional cultures and beliefs about learning technologies, construction of knowledge across systems and institutions, as well as the trend toward learner-centered, disaggregated, and re-aggregated learning objects, and negotiated intellectual property rights.

A STARTING POINT: THOMAS'S THEORY OF ORGANIZATIONAL TECHNOLOGY

Thomas (1994) argues that a technical system utilized within an organization can be objective, but also infused with objectives, reflective of the interests or goals of particular groups within the social system. A technological system, he contends, has the ability to define and redefine tasks, responsibilities, and relationships or to evoke or reinforce change. Further, the eventual selection of a specific technology reflects the interests and ideologies of the organizational structure. Organizations are composed of interdependent social and technological systems where changes in one usually occasion adaptation in the other (e.g., a course management system many interact with a registration system). However, the relationship between technology and the organization is dynamic and interactive, that is, technology may cause organizational change and organizational objectives may produce a change in the technological system. Thomas explains that in order for the technology to be incorporated into organizational life, it must be transformed from a physical object into a social one. In other words, organizational members must recognize that the technology exists and then negotiate a set of understandings about what it is, what it means, and how it defines and redefines tasks, responsibilities, and relationships. Thomas proposes a model of organizational technology whose adoption and use is shaped or determined, to some extent, by the organization that selects it. While he acknowledges that the technological system interacts with the organization and its objectives and vice versa, this model is limited to some extent by those very things: the organization and its objectives.

Current knowledge management models are organizationally-centered and are thus limited by the values and interests of their constituents. However, others are arguing for a transformation of the knowledge economy from one that is proprietary to a freestanding, shared knowledge community (Norris, Mason, & Lefrere, 2003). Norris et al. point to eight external and internal forces that are producing this shift: (1) Investments in infrastructure and best practices by "early adopters" of e-knowledge (e.g., associations, governmental agencies, corporations, universities) deliver results that encourage wider adoption, and also facilitate new generations of enterprise applications; (2) Global enterprises that increase competitiveness by developing faster ways to manage their knowledge and strategic learning by creating tools that non-experts can use; (3) Growth in expert networks and easier, more productive participation in communities of practice that push e-knowledge practices and competencies; (4) Increasing sophistication by users, who develop an appetite for services that provide significant gains in their capacity to access and assimilate knowledge; (5) Advances in Internet and intranet-based capabilities that enable jump shifts in creating and accessing knowledge stores; (6) Innovations in mobile communications that provide ubiquitous access to perpetual learning solutions, as well as new ways to meet demands for e-commerce in any place or time; (7) Insight into new and more effective ways of experiencing how knowledge drives innovation; and (8) Increased understanding about how to deploy international standards in ways that ensure useful return on investments (e.g., through interoperability) that stimulates continued investment. We believe that these are just some of the local and global changes occurring that are motivating higher education to explore a system of knowledge management that is socially-constructed rather than organizationally-determined. As this trend unfolds, there is an increasing demand for collaborative discourse and negotiation, not just about what technology means, but also how it is designed and how artifacts such as learning objects are shared. This trend is evidenced by such efforts as the IMS Global Learning Consortium, Inc., in which members from around the world work together to develop specifications for e-learning technologies.

SOCIAL CONSTRUCTION OF KNOWLEDGE AND LEARNING OBJECTS

The global nature of education within a distributed learning context requires that higher education, particularly considering learning objects as a valuable commodity that can be traded and exchanged, is part of an evolving knowledge economy. Texts, videos, and other materials have proven the value of institutionally-generated knowledge, but traditionally these products have produced revenue for an individual with value capital for the institution. Learning objects are forcing institutions to examine the economic exchange of the knowledge capital they are generating as they search for strategies to manage and negotiate value.

Following Thomas's theory of the social or organizational construction of technological systems and drawing from an economic business perspective, Demarest (1997) postulates that organizations value knowledge based on "what works." Business uses resource capital in order to develop processes and structures that result in increased sales and revenue. Davenport, DeLong, and Beers (1998) found four distinct types of knowledge management initiatives in corporations that were intended to:

1. Provide repositories for internally generated policy and informational knowledge;
2. Provide access to knowledge or transfer among individuals;
3. Facilitate the generation and use of knowledge; and
4. Manage knowledge assets in such a way that value is apparent.

Corporate knowledge management comes from an economic model that is based on a knowledgeable workforce that increases the organization's return on investment. Davenport, et al. believe an economic model is appropriate for learning objects in higher education in that they are, by definition, designed to be re-used and shared. Whether or not they have a monetary value assigned to them is incidental, it is the investment of development and dissemination that belies their institutional value. In higher education, "what works" is similar to that of business, but involves "human capital," which may result in increased enrollments, higher post-graduation employment rates, and academic recognition and prestige for the knowledge generated and disseminated. It is the latter that applies most directly to learning objects in that academic recognition comes from the intellectual production of knowledge that is to be disseminated across institutions, and to a large extent contributes to the knowledge base of those institutions.

Higher education values philosophical and scientific knowledge that is generated by the scholarship of its members. Such knowledge has traditionally driven innovation and production (Lyotard, 1984). The commodification of knowledge through information distributed through technologies such as the Internet has expanded the power of university-generated knowledge that can reach beyond business and government to everyone with access to the Internet. However, the value of philosophical and scientific knowledge may be confused with knowledge that keeps the organization performing. For Demarest (1997) this includes:

- A shared understanding of how value is determined, assigned, maintained, and communicated throughout the organization and with external groups or individuals with whom the organization interacts.
- A set of processes and systems—technical or human—that support and help channel the [organization's] value-creating activities (p. 1).
- A set of indicators that associate the value-creation process with the measures of the organization's success.
- A set of systems that as a part of the "knowledge management infrastructure that monitor the efficiency and effectiveness of that value creation process, indicate opportunities for performance improvement and generally signal the relative rise or decline in value creation" (p. 1).

Higher education has parallel types of performance knowledge manifested in standards for knowledge acquisition by the learner (program requirements, degree audits, grades), standards of academic knowledge (criteria for merit and tenure, peer review of intellectual property), structures and processes for control of organizational knowledge (publications, events, training), and standards for institutional knowledge (internal reviews, accreditation). The sum total of these types of knowledge and the mechanisms through which their value is determined and tied to performance is what allows the institution to function and yet varies among institutions, challenging the cross-fertilization and reciprocation that goes hand-in-hand with exchange of resources. Demarest believes organizational knowledge is socially constructed, and shared. This occurs through four processes: construction, embodiment, dissemination, and use.

Construction is "the process of discovering or structuring a kind of knowledge" (p.6). Organizations that are learning-focused (i.e., K-12, higher education, and workplace professional development departments) utilize specific processes of identifying valued knowledge. Value propositions in such organizations, and to a certain extent in industry where learning is seen as training, may come from external events or forces (community needs, governmental mandates, etc.) or from experience through interaction with client populations (focus sessions, course or training evaluations, documented complaints, etc.). Valued knowledge emerges through an iterative process of examining and implementing the governing body's mandates (government, professional organization, and certifying agencies), determining community- or client-based values and needs, and identifying best practices and policies that support the identified organizational outcomes.

Embodiment is "the process of choosing a container for knowledge once it is constructed" (p. 6). The container may take a variety of forms, most typically a document: manual, memoranda, report, tutorial, or speech. In higher education, such embodiments may be captured as learning objects and stored in a repository or learning content management system (L/CMS). How the embodiment is conceptualized may reflect the organizational cultural beliefs about the social relationships, communication processes, and the structures of authority. For example, L/CMSs that are course-based and only accessible to registered members of the course may indicate intellectual property controls or return on investment as indicated by course registration.

Dissemination "refers to the human processes and technical infrastructure that make embodied knowledge, such as documents, available to the people that use the documents and the bodies of knowledge" (p.6) that serve a function to achieve the organizational goals. Such knowledge dissemination is increasingly digital, although issues of access through systems and (perhaps) limitations of user's technical skills may be why some educational organizations rely on printed media. Digitization has enabled knowledge updates, re-organization, and re-purposing to be quickly and easily possible. Communication about such changes however must be made to the population who uses the knowledge.

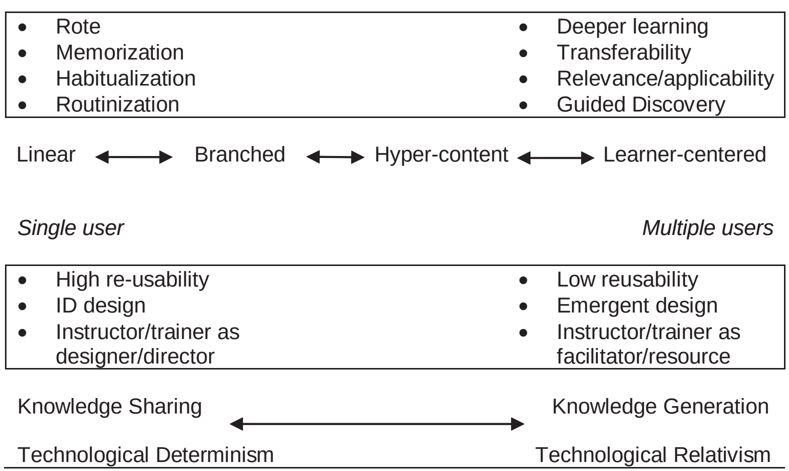
Use refers to the ultimate objective of any knowledge management system: the "production" (p. 6) of value. At this point, Thomas's value proposition is most evident. Organizational knowledge may be constructed, embodied, and disseminated but until it is used, its value is only a construct. Use, it can be argued, is what determines the value of any knowledge. Learning objects stored in repositories or located by "Googling," but finding out by whom, when, or for what reason (much less for what outcome) is marginally addressed through metadata, but more directly addressed through strategies such as Digital Rights Management (DRM). DRM identifies the rights of holders, permissions, and tracks usage. The Digital Object Identifier (DOI®) system identifies and tracks use of digital objects, primarily to protect and document how intellectual property is being used, but not to discover the knowledge value of an object. As tracking strategies become adopted and uniformly used, we suspect value will be determined more by frequency of use than by other indicators, such as return on investment (ROI), or by the knowledge value to the user. Most importantly, the social construction of organizational knowledge does not address knowledge acquisition, which is a primary function of higher education.

TECHNOLOGY-SUPPORTED KNOWLEDGE ACQUISITION AND CONSTRUCTION IN HIGHER EDUCATION

The US history of funding technology as a strategy for reform illustrates the theory of technological determinism3, but belies the reality of the application and adoption of technology and the difficulty, if not impossibility of its predictability and control (Hughes, 2001). Technological relativism4 embraces this ambiguity and better reflects what actually occurs in the post-structuralist learning environment where faculty conduct scholarship and the learner engages in social learning through a variety of technologies, in a variety of ways, in different contexts that support the institutional goals and philosophy. Sørensen (1996) discusses the prevailing discourse about learning through doing, using, and interacting by which a learning economy is produced, based on the notion that learner actions involve production that is supported by various technological systems. As learners increasingly access objects within structured learning experiences they are also generating objects that document, describe, illustrate, or share their own knowledge acquisition. This process reflects Demarest's focus on performance enacted through his social model of knowledge management. In higher education, performance outside of pedagogically-driven environments is less valued because it occurs outside of the economy. The organization assigns value based on the source of the knowledge. Because the learner can access knowledge anywhere or anytime, value propositions erode and are relative, at least for the learner.

The nature of learning object construction and re-use as disaggregated5 course content that may be re-aggregated in different ways reflects current thinking about the social construction of knowledge espoused in pedagogical models of online learning (Simonson, Smaldino, Albright, & Zvacek, 2003), the commodification of the course (Diaz, 2004), and the instructional use of learning objects (Higgs, Meredith, & Hand, 2003). Figure 1 below illustrates learning designs in distributed learning systems. Linear learning designs are more content-driven with little deviation from the instructional path and low interactivity with others or the content that is predetermined and a strategy for sharing knowledge. Such designs are highly re-usable and functional when concept, principle, and procedural knowledge are the goal. As the learner moves to the right of the continuum they are afforded more choices about the path of instruction, information formats, and sources, and how they will demonstrate and document their knowledge acquisition. The learner becomes, to a degree, a designer of their own instruction and a generator of knowledge. Difficult to replicate and re-use, this design holds more promise for transfer of knowledge to other contexts and deeper learning (Carmean, 2002). The generation of knowledge and eventual dissemination via learning objects represents a shift, not only in who generates and how generation occurs, but also in how constituencies receive the knowledge. Didactic instruction is a universally used approach to teaching in classroom settings. The traditional approach to instruction in higher education is instructor-dependent, content-driven, and situated in knowledge transfer (Gibbons & Wentworth, 2001). This is at odds with what is known about adult learning in college and the workplace (Mentkowski, 2000) and in research indicating that as educators use technology in general, their role as subject matter expert shifts to that of guide and facilitator, reflecting an epistemological shift with a variety of associated outcomes (Reeves, 2002). A learning object pedagogy, unlike the traditional model, is one in which the learner makes decisions and choices about a task or problem as they locate relevant information, and construct and generate knowledge eventually embodied in a learning object. The instructor and LCMSs, serve as guide and facilitator.

Figure 1. Learning designs in distributed learning systems



Objects that are used within larger pedagogical frameworks, classrooms, L/CMSs, or blended learning environments, have embedded systems which determine or sanction the function of the object and which operate within the instructional designer's pedagogical determinism. Although objects that are learner-centered achieve multiple objectives and are more likely to be generative, they are also confined to some degree by the system, process, and technology within which they operate. The disaggregation of the course has provided a natural opportunity for the learner to modify existing objects or create new ones that become a part of the knowledge used by others to learn (Collis & Stijker, 2003). It is the opportunity for knowledge generation that informs the social model of knowledge management through knowledge management learning designs that operate across institutions, through cross-fertilization, be it intentional (determinist) or selected (relativist).

TRANSMISSION OF KNOWLEDGE ACROSS, THROUGH, AND IN SPITE OF ORGANIZATIONS

The challenge of any institutionalized knowledge base and system of transmission, transferal, or adoption is that no learner remains within the organizational context throughout their day-to-day life, and they move between contexts across their learning and working life. As workers who are engaged in continual learning, we move between and among organizations that use technologies, the use of which, for the most part, is defined for us by the organizations in which we are situated. Learning environments, rules, procedures, and intended outcomes change as we move from school to work to training. Thus within an institution, the individual acts and interacts from a personal point of view.

In post-secondary education, technology is used to support learning, primarily as an Information Communication Technology (ICT) through which knowledge is constructed, learning is managed, or learning objects are disseminated. E-learning has become standard in higher education, as evidenced by the burgeoning and robust market for course management systems, Web-based tutorials and simulations, and mobile computing. Of course, learners in formal educational environments also acquire knowledge from family, social groups, and other social, religious, or civic organizations (Bransford, Brown, & Cocking, 2000). Social learning is ill-structured and not necessarily outcome-driven, while learning that is not situated in work or education is typically uniquely structured and without conditional assessment measures. For most of us, our preparation to learn strategically in formal and organized settings begins at an early age in traditional educational institutions. The nature of this type of learning is so institutionalized that it crosses most cultures, economic groups, and generations. Yet when we leave an educational setting and are required to learn in workplace environments, the nature of learning shifts.

In the workplace, technology is also used as an ICT although the focus is more on job skills training for just-in-time, just-in-need, or just-in-case learning that relates to job tasks, seen as performance support. Designs for workplace knowledge management systems are equally recommended to be learner-oriented in interface and content as well as management design (Raybould, 2002). Over the developmental life of the learner, then, the organizational uses and expectations of technology shifts at the macro level as well as the micro level as discussed by Thomas (1994).

An often-missing component from the decision to implement a technology-mediated learning strategy is evaluation or effectiveness studies to determine if the selected technology has the ability to address institutional goals and concerns. The literature in this area looks at "satisfaction" in a way that does not always address actual learning outcomes and overall, there exists a lack of empirical studies showing that the use of instructional technology actually improves learning regardless of the context (Arbaugh, 2002; Buckley, 2002; McClelland, 2001; McGorry, 2003; Neal, 1998). Studies conclude that the full potential of instructional technology is reached only by a full transformation of the learning process, faculty development, and institutional systems (Buckley, 2002; Jamieson, Fisher, Gilding, Taylor, & Trevitt, 2000; Moore, 2002). The research on the effectiveness of distance education or online learning programs shows difficulty with student-instructor communication, lack of socialization both with the instructor and other students, student engagement and interaction, innovation in teaching, and technical difficulties or support (McGorry, 2003; Salisbury, Pearson, Miller, & Marett, 2002). Finally, the instructor's actual technological expertise (Lea, Clayton, Draude, & Barlow, 2001; Webster & Hackley, 1997) along with their ability to overcome interaction problems (Berger, 1999) has been found to be important both in faculty member's decisions to adopt instructional technology and in students' satisfaction and learning outcomes. These findings are at odds with return on investment (ROI) arguments that distributed education can serve large populations without denigrating effectiveness, a trend seen in higher education.

Technology has shifted the nature of traditional learning and training by removing the learner from contexts, such as school and workplace. Taylor (2001) has developed a model that describes the shift in distributed learning from linear and print-based to flexible and modular/digital based:

- The "correspondence model" relies on print-based resources.
- The "multimedia model" provides learning resources through a variety of media including print.
- The "tele-learning model" incorporates modes of presentation of materials to include audio or video-conferencing and broadcast TV or radio.
- The "flexible learning model" requires that students engage in interactive, online computer-mediated resources and activities.
- The "intelligent flexible learning model" is the next generation model in which the learner accesses learning processes and resources through portals.

Learning through and with learning objects enables the learner to self-direct their experiences and engage with others for purposes that best support their learning, while utilizing objects that best match their needs. Diaz (2004) notes that the more complex and autonomous the system, the more it allows the learner to manage their own learning, but the higher the degree of technical skills necessary, and the larger the institutional investment. Conversely (or perversely), the more the learner is engaged in making choices and directing learning experiences, the greater the likelihood they will generate knowledge. Personally constructed knowledge is then influenced by the organizational knowledge that shapes our behaviors, values, and norms that we bring to learning or working context. The process of knowledge construction is reflected in the way organizations approach knowledge management. Learner- or worker-generated knowledge is not without limitations and barriers within certain models of knowledge management.

FOUR MODELS OF KNOWLEDGE MANAGEMENT

Existing models of knowledge management have emerged from policy and practice. Although the tradition of distributed instructional materials is not new for higher education, the shift toward digitalization has affected the nature of distribution, as well as policy decisions. Learning objects are a relatively new concept with regard to knowledge management, and the idea of re-use and re-purposing has necessitated specific management and ownership considerations. Typically, learning objects originate with ideas generated by faculty members and are created with supports from the university, then distributed through a local or external repository. Rights of ownership and attribution are critical as are permissions to re-use, revise, and maintain the objects. Pre-learning object policy has not fully accounted for the unique provisions of reuse. In this evolving context of learning objects, we have identified four models that address control and ownership in varying ways: traditional pre-digital, intellectual capital/appropriative, sharing/reciprocal, and contribution-pedagogy.

Traditional Pre-Digital Model

The traditional model of ownership in the area of copyright predates technology. Up until the passing of the Digital Millennium Copyright Act of 1998 (DMCA), and perhaps after, long established legal principles grant to employees, such as faculty members, the inherent right of ownership to their inventions (Chew, 1992). Intellectual property policy language, especially in the area of digital works such as learning objects, can sometimes be ambiguous. McMillen (2001) finds that academic custom, the informal principles of university practice, impact copyright ownership in two ways. First, if there is ambiguity in a faculty member's contract or other written document that expressly assigns copyright ownership, courts may look at custom and usage to determine the university and professor's intent regarding ownership. In other words, courts could decide to take into account an institution's established practices in deciding who should retain property rights. Second, if no contract, policy, or written document regarding copyright ownership exists, courts are permitted to use the academic custom and usage within or outside the institution to determine what the parties would have agreed to had they addressed copyright ownership.

In Rhoades (1998) examination of the actual ownership of faculty products, he found that, of the contracts analyzed, a majority of them had extensive provision for faculty ownership; in fact, the institution does not always claim ownership, even when it is a "work for hire." The "conditions" of production or use of resources are pivotal in determining ownership and assigning profits. In her analysis of intellectual property ownership in the institution of higher education in the United States, Chew (1992) reexamines ownership via social tradition and case law. Surprisingly, her findings reveal that, despite common assumptions, long established legal principles grant to employees, such as faculty, the inherent right of ownership to their inventions. Faculty members' claims on their inventions and the enforceability of university policies are unclear. However, as distributed learning technology evolves and requires greater use and infusion of institutional resources, ownership, and control may begin to away from individual creators and contributors and toward resource providers. Further adding to the ownership ambiguity is the vast array of digital products that are being produced within commercial and non-commercial collaborations and partnerships.

Intellectual Capital/Appropriative Model

The intellectual capital or appropriative model holds that ownership, control, and maintenance of intellectual property, especially in the area of distributed learning, is important. Under this model, institutional resources expended are carefully monitored and among other factors, become the criteria for ownership and control. Further, the vast majority of higher education institutions' intellectual property policies are increasingly based on this model (Diaz, 2004). The arrival of technology into the area of copyright has created a new market for products that previously had little or no commercial value. In fact, many copyright sections of intellectual property policies differentiate between digital and non-digital property and contain specific and substantial rights over these economically viable products. The intersection of intellectual property rights, specifically in the area of copyright, and technology in higher education is the realm of distributed learning, including distance education, learning objects, digital repositories, and electronic courseware products.

Consistent with previous studies in the area of intellectual property copyright policy transformation and the corresponding commodification of educational products (Chew, 1992; Lape, 1992; Packard, 2002; Slaughter & Rhoades, 2004), Diaz (2004) finds that policies are evolving to further address distributed learning products in a variety of ways. Findings indicate that institutions are revising policies to further deal with and capture instructional products. Policies are aligned with the organizational change that is occurring in higher education within a larger context of an information-based economy (Castells, 2000). Additionally, the new instructional model is heavily dependent on information technology in the form of network connectivity, infrastructure and support staff, thus making it resource intensive. Policies reflect this change by mimicking the shift in ownership conditions away from those required in a traditional setting to those required in a high technology setting. Use of institutional resources in the instructional process has been nominal (i.e., secretarial support, libraries), compared to those required now: media specialists, instructional designers, and so on. Ownership terms changed to address the new instructional model, but claims on instructional products have appeared where there were previously none.

Institutions are asserting ownership where they previously had not because online courses and course materials present a potential source of revenue from which the institution could benefit. Several explanations exist for this increasingly appropriative behavior. Faculty-developed electronic content and courseware materials (especially in specialized academic areas where the market is deficient) present a potential source of revenue and savings, as the institution will not have to pay costly licensing fees to purchase or utilize externally developed products. Increasing “contracted” education serves the dual purpose of producing salary savings while providing one-on-one attention to students and improving their performance (Twigg, 2000). The appropriation of digital knowledge may also be a preemptive move on behalf of universities that fear faculty members will package their courses and make them available to multiple markets (while employed at the present institution or after they have left), perhaps in competition with the college or university that employs them.

Sharing/Reciprocal Model

The sharing reciprocal model is based on shared value and the exchange of learning objects and other digital materials across organizations and institutions (Diaz & McGee, 2004). The focus here is on the support of learning activities. Individual institutions support the assembly of learning objects, which may be shared across departments but, more commonly, objects are imported from many other places. Table 1 illustrates the many partners that may be involved in these consortia. Organizational support mechanisms and systems moderate costs. Many institutions join consortium in order to create a system for storing and distributing objects in what becomes a mutually beneficial learning object economy (Learning Content eXchange, 2003). Consortia often articulate content and evaluation standardization as a strategy to increase the market value of an object. DRM, Royalty Rights Management (RRM), index, and search functions as well as supporting technologies are collectively addressed and operated through a well-organized consortia

Table 1. eLearning partnerships

Organizational Partnership	Partners
EDUCAUSE Corporate Partner Program (http://www.educause.edu/partners/about.html)	• IT professionals (public/private) • Technologists • Managers • Higher education executives
Massachusetts Institute of Technology DSpace Federation (http://dspace.org)	• Columbia University, Cornell University, Ohio State University, and the Universities of Rochester, Toronto, and Washington • Hewlett-Packard • MIT Libraries
The Fedora Project (http://www.fedora.info/)	• University of Virginia • Andrew W. Mellon Foundation • Cornell University

initiative. Such collaboration allows members to establish pre-determined policies and procedures that articulate a negotiated value and standard of quality for the objects that are shared.

Learning object registries can provide standards and access for institutions that may not be interested in partnerships. One example is the Learning Object Network (LON) (http://www.learningobjectsnetwork.com) that uses Digital Object Identifier (DOI) as the identifier mechanism and collects object metadata and location information so they can direct potential users to the source. Institutions or consortia must determine the degree of access and set policy that sets the rights of the owner of the object. One approach to DRM is the Creative Commons Project6 that provides no-cost licenses so that copyright holders can inform potential users about copyright restrictions. Knowledge management systems that can serve consortia provide customizable interfaces that can meet the unique needs and preferences of a group regardless of their funding level or size. For example, EZ Reusable Objects (EZRO) is an open source, free Web application that requires little to no technical expertise to configure and operates to manage learning objects. EZRO is scalable and responds to the specific needs of consortia driven by a variety of goals and directed by institutional policy.

The first three models discussed above fail to address the value of knowledge acquisition acquired through learner-object interaction, which should be an expectation and criteria in the learning object economy. Instead, they focus specifically on the exchange of goods in terms of the agreed-upon market value rather than the knowledge value that informs the "buyer" of whether or not, as Demarest would argue, the product "works." For higher education the value should reside in the object's actual knowledge value.

Contribution Pedagogy Model

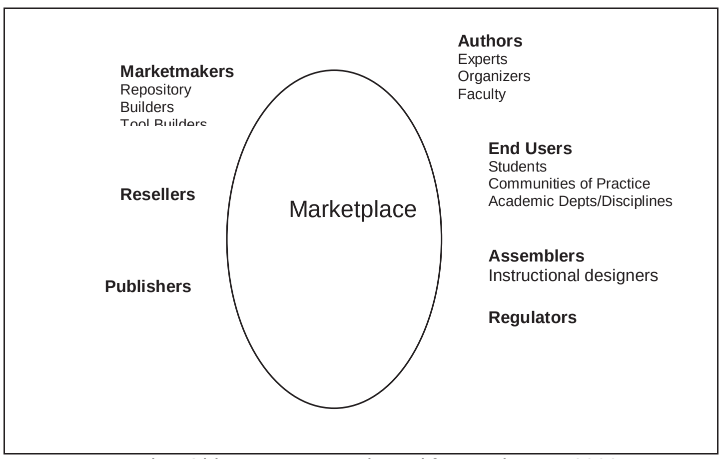
The focus of the contribution-pedagogy model is that learners contribute to object development or generate objects themselves, thereby contributing to the knowledge base of the institution. This reflects the shift toward a learning object pedagogy in which learners, not only learn from experience by participating in the generation of the object, but by contributing to the learning of others through object development and re-use. Collis and Striker (2003) suggest that by having learners generate learning objects, and contribute to a course repository that grows with each offering of the course, the burden of producing objects is shifted away from the institution and the instructional process. This results in a variety of benefits: time is saved for the instructor or content-generator, resources are designed by the population for which they are intended by providing a locally better "fit" with the intended audience, learners can contribute and revise objects over time by updating content or presentation, and the tacit knowledge of the learner is transparent and can be shared or studied by the institution (Collis & Winnips, 2002).

Laurillard and McAndrew (2003) illustrate the contribution-pedagogy model in their design of generic learning activities that shift teaching from a transmission model to a construction model. A design of generic learning activities shifts teaching from a transmission model to a construction model as illustrated by Laurillard's "Conversational Framework" for learning. This iterative process requires the learner to engage, act, and reflect upon what they know and how they come to learn. An analysis of scalable (individuals or groups) and sustainable (efficient and economic) learning designs address how to design for diversity of learner experiences, goal-based learning, re-use of objects, use of online learning tools for learning outcomes, clear and succinct instructions, and dynamic technology function. Specific recommendations are made for the design of objects to be used in multiple courses. When multiple applications are considered at the design stage, there is an increased likelihood of increased re-use across disciplines. Additionally, objects can be easily re-versioned depending on the needs of new or revised courses and pedagogy is wrapped around objects, activities, and supports. The Sharing/Reciprocal and Contribution-Pedagogy models impact how value is attributed, estimated, and assigned to learning objects and reflect Thomas and Home's (2003) Student-centered Route and Freedom Argument for the distribution and access of learning objects that suggests a new economy.

Learning Object Economy

Higher education's new approach to its knowledge products has led to the emergence of a learning object economy. Johnson (2003) notes that the learning object economy has at least five markets of exchange: proprietary, commercial, free, shared, and peer-to-peer. Each of these "markets" has a corresponding culture and has been met with varying degrees of success. He argues that a fully functioning learning object economy would satisfy the needs and requirements of its constituents: market-makers (repository builders), instructors, end users, assemblers, regulators, publishers, resellers, and authors. Figure 2 illustrates the way that various constituents intersect and exchange in this new economy (Johnson, 2003).

Figure 2. Learning object economy (Learning Object Economy adapted from Johnson, 2003)



Learning Object Economy adapted from Johnson, 2003.

Technologies, if they resonate and are adopted, can generate an economy that is derived from the value placed on them by a social group. Groups may have different interpretations of the basis of the value. Since learning objects require group collaboration, represent knowledge construction, and are disseminated across populations, there is a high level of mediating variables and processes.

Technological systems, if they resonate with the organization and are adopted, can generate an economy that is derived from the value placed on them by a social group. Groups may have different interpretations of value, and since learning objects require group collaboration, represent knowledge construction, and are disseminated across varied populations, a high level of mediating variables and processes exist. Johnson (2003) describes five markets, each with a different exchange approach, in which learning objects operate. These markets—proprietary, commercial, free, shared, and peer-to-peer—are described in Table 2.

Each of the aforementioned four knowledge management models (traditional-pre digital, intellectual capital/appropriative, sharing/reciprocal, and contribution pedagogy) intersects with one or more of Johnson's learning object economy markets. For instance, the traditional-pre digital, intellectual capital/appropriative models exist within the value system of the proprietary and commercial markets. The last three markets, free, shared, and peer-to-peer, also exist in higher education settings. It is possible for appropriative and non-appropriative models to coexist, for instance within a college or department. Each market satisfies those constituents' needs and is aligned with a set of culture-specific values. Implicit needs must also be met in order for exchange to flourish. For instance, learning objects must be credible or carry some quality assurance regardless of the system within which they operate.

Although the literature (Hart, 2004; Kidwell, Vander Linde, & Johnson, 2000; Norris et al., 2003) suggests a maturing of knowledge management practices that have resulted in a myriad of systems, the learning object economy in all markets is still weak at best. As Johnson (2003) points out, the current level of activity has not yet reached a "tipping point." The solution, he postulates, is an "economy of content in which individuals and organizations can acquire, adapt, and repurpose content" (p.7). Table 3 presents a summary of Johnson's drivers, enablers, and mediators to a thriving learning object economy.

Several of these drivers, enablers, and mediators are present in the models discussed earlier and suggest some explanation for the under use of learning objects. For instance, higher education intellectual property policies governing the control and ownership of digital instructional products or learning objects are often structured in such a way as to inhibit development and sharing outside of the originating institution (Diaz, 2004). This type

Table 2. Learning object economy and the five markets

Market	Product Example
Proprietary	Private company training repository
Commercial	E-learning companies selling learning objects
Free	MERLOT or the Educational Learning Object Exchange
Shared	Higher education LO consortia
Peer-to-peer	Sharing systems between higher education institutions

Table 3. The learning object economy: Drivers, enablers, and mediators (Adapted from Johnson, 2003)

	Definition	Higher Education Example
Drivers	Knowledge, productivity, competition, readiness, infrastructure	Faculty-, student-, staff-produced knowledge; L/CMSs; wireless learning environments.
Enablers	Learning technologies, learning design, standards	A menu of learning technologies available to educators; learning technologists as support staff to enhance learning and teaching functions.
Mediators	Resources, policies, perceived value	Learning technologies centers; flexible and adaptable intellectual property policies.

of behavior, evident in the Intellectual Capital/Appropriative Model, also prohibits the sharing of resources and distribution of costs: mediators in the economy. The Appropriative Model and other models discussed are limited, to some extent, by their social context. Each is operating within the boundaries of their organizational context and corresponding values and is thus limited by those constraints. In response to these limitations, we propose a new relativist model. We argue that in order for a learning object economy to succeed, it must be able to take advantage of and utilize its drivers, enablers, and mediators independently of a social or organizational context.

Open Knowledge Model

Knowledge sharing and re-construction with intellectual property rights attribution and learner-owner intellectual property rights are necessary in an increasingly globalized and distributed learning ecosystem.7 The Open Knowledge Model embodies trends in a variety of disciplines: computer science (see OKI and OSPI), education (see McGee & Robinson, 2004), science (see Cottey, 2003), and social justice (see Open Knowledge Network) in that it utilizes a relativist construction and accommodates cross-institutional cultures and beliefs about learning technologies, the construction of knowledge across systems and institutions, as well as the trend toward learner-centered e-learning, disaggregated and re-aggregated learning objects, and negotiated intellectual property rights.

We build on Thomas' and Demarest's conceptual frameworks in an attempt to address the emergent model of knowledge management in higher education that reflects current beliefs about the learner, the function of the institution, the trend toward knowledge generation, and the evolution of existing models. In that the function, definition, and value of technology are relative to organizational culture and values, we assert that no organizational position is more or less valid than another (Wescott, 2001). The Open Knowledge Model provides for this caveat. This is not to say that value is not shared across higher education systems, but rather that individual organizations and their members have come to contribute to the value given to the knowledge that is generated within them.

The first component of the Open Knowledge Model addresses how the culture and actions of higher education tacitly and explicitly determine the value, purpose, and role of knowledge for the institution at large. The culture of each higher education institution determines the value and use of knowledge, rather than the technology. This is clearly reflected in institutional efforts such at MIT's OpenCourseWare project in which course syllabi and materials are accessible to all in an effort to support their "mission to advance knowledge and education, and serve the world in the 21st century. It is true to MIT's values of excellence, innovation, and leadership" (MIT, 2004). MIT has chosen to share intellectual property that represents the values, norms, and standards of learning of their unique and specific mission. We see such efforts as supporting the inherent purpose of higher education: as a primarily generator of bodies of knowledge that should be made freely available to the public. Traditional models of knowledge dissemination that are tied to processes of tenure and promotion (peer-referred journals with limited circulation) restrict knowledge access. In the Open Knowledge Model, intellectual property is digitized and distributed with rigorous standards of review, but made available to anyone who is interested, rather than a privileged few through repositories (Crow, 2002).

Traditionally, intellectual property rights policy has indicated the market value higher education has placed on learning objects, however, documented knowledge acquisition (through learner generation) and use of learning objects (through tracking) is a more authentic indicator of value. In the Open Knowledge Model, intellectual property rights are determined by the generator and negotiated by the end user who may choose to re-purpose the content through licenses allowed through systems. The growing number of

Table 4. Stages of organizational learning

ß	• Proliferation of information technology (IT) in higher education (HED) • Increased entrepreneurial behavior in HED • Increased competition or economic pressure
Learning Stage I	• Emerging HED IT profession • Established HED entrepreneurial behavior (patents) • Collaborative HED/IT professional organizations (EDUCAUSE) • Elite organizational behavior (MIT's OKI, DSpace)
Learning Stage II	• higher education develops L/CMSs • Current technology is expensive and insufficient • Organizations seek to "retain" knowledge
Diffusion	• Social consensus via organizational leaders (in process) • Lower level orgs mimic behavior
Institutional Copyright Policy Transformation	• Whole policy revisions • Addendums to existing policies • Instructional technology/software clauses

repositories and referatories indicates that learning objects are a valid and valued knowledge source both within and outside of any one institution. Additionally, we propose that knowledge value is reflected in use and re-use of learning objects.

The second area of focus deals with the ways in which knowledge is created, embodied, disseminated, and used in higher education; the relationship between knowledge and technological innovations; and the relationship between knowledge, innovations, and performance standards that higher education requires in order to meet its strategic objectives. Higher education, as an institution, embodies cultures that are both shared and not shared. For instance, sharing and collaboration in a learning object economy can occur within and across disciplines, departments, and the institution as a whole. In this sense, the academic setting is unique in that cross-cultural/organizational generation, sharing, and re-purposing, is possible and brings the added benefit of greater innovation and diffusion of knowledge. Further, repositories and referatories, as technological systems, make this possible as learning objects grow and become more meaningful with use and reuse. With successful cross-pollination comes increased funding; consortia and leveraged resources and capital, standardization by industry in accordance with established values to support reuse.

The third area of focus deals with the strategic and material commercial benefits that higher education expects to gain from more effective knowledge management practices and performances. These may include increased revenue, prestige, partnerships, cross-organizational fertilization, and higher skilled faculty and graduates. Several factors have contributed to the development of knowledge management. The literature in the area of globalization in higher education points to information technology, organizational change, and productivity growth (Castells, 1997, 2000; Tiffin & Rajasingham, 2003). The development of new intellectual property policies, and the extensive revision of existing ones (Olivas, 1994), is one signal of the organizational transformation and the effort to harness productivity to the benefit of the institution. Globalization, increased competition among non-profit and for-profit educational entities, and changes in funding structures has all contributed to changes in the way higher education institutions deliver services and leverage their instructional products.

The utilization of distributed learning technologies and systems has several benefits for the academy: increased research productivity, generation of tuition revenue via increased access, institutional acquisition of instructional products, and improved learning. While some of these outcomes are yet unproven, they are well documented in the language that surrounds policy. Several studies have suggested higher education's move toward commercializing instructional products (Anderson, 2001; Slaughter & Rhoades, 2004; Welsh, 2000). One can speculate on what has prompted such activity in this area. Organizational learning theory tells us that a number of precipitating jolts, both external and internal to the organization, can prompt such changes (see Table 4). Such jolts can come from the changing economy, changing technology, and pressure to improve learning outcomes (Castells, 2000).

The Open Knowledge Model represents the drivers of knowledge management: the methods for management and the conceptual framework that guides processes of knowledge generation. It supports a new economy based on authentic knowledge value in which human capital is embraced and recognized as the core of educational institutions and that which higher education can best support and sustain.

ENDNOTES

1. "Knowledge management involves recognizing, documenting, and distributing the explicit and tacit knowledge resident in an organization" (Rossett & Marshall, 1999).
2. A learning object economy requires that individual objects are created and shared across institutions (Johnson, 2003).
3. Technology drives change and events. In teaching and learner this means that pedagogy and learner's actions are determined by technology and indeed effect changes in practice. The authors see this more as a result of technological drift (Winner, 1997) through which organizations have been inattentive to the determinism that has become enculturated (see Perdue, 1994).
4. In our view, technological relativism means that the function, definition, and value of technology are relative to the organizational culture and values and the beliefs about the value within the higher education community. Additionally, we assert that no organizational position is more or less valid than another (Wescott, 2001), but equal consideration must be given to each value position. Additionally, individuals choose what and how they use and adapt technologies to their own purposes (Chandler, 1996).
5. Learning objects typically are parts of a larger course or unit of study. Aggregation involves combining objects to create a scope of learning content.
6. Creative Commons (2004) is a free licensing service that "uses private rights to create public goods: creative works set free for certain uses. Like the free software and open-source movements, our ends are cooperative and community-minded, but our means are voluntary and libertarian. We work to offer creators a best-of-both-worlds way to protect their works while encouraging certain uses of them—to declare "some rights reserved."
7. An ecosystem is a combination of systems that interact to support the survival and generation of organisms that exist within it. The authors see the tools, resources, people, and experiences accessible to the higher education student as constituting a digital learning ecosystem that contributes to a digital knowledge ecosystem (Por, 1997).

ABSTRACT

In this era of information, traditional practices, technologies, skills, and knowledge are becoming obsolete at a much faster pace than ever before. This makes lifelong learning a necessity for everyone. An e-learning system is a promising solution to the demand for a flexible means of delivering knowledge to educate a large number of people over a vast area. Knowledge management systems (KMSs) are a fast growing area of research on the creation and sharing of knowledge. Agent-oriented software engineering is opening up a new horizon for the analysis and development of systems in an open, complex, and distributed environment. This article proposes a conceptual framework and architecture for the development of an agent-oriented e-learning system supported by knowledge management to provide a flexible, self-paced, and collaborative learning environment with the least constraints. The framework is based on the technologies of e-learning systems, multi-agent systems (MASs), and KMSs. The proposed system architecture consists of three levels: user level, domain level, and Web level. The system will provide all of the basic teaching- and learning-related support facilities, plus some enhanced features that are provided by the agents

within the system. The system will also provide the facilities for capturing and sharing the knowledge created during utilization of the system. Finally, conclusions and the potential theoretical and practical implications of the proposed system are presented.

INTRODUCTION

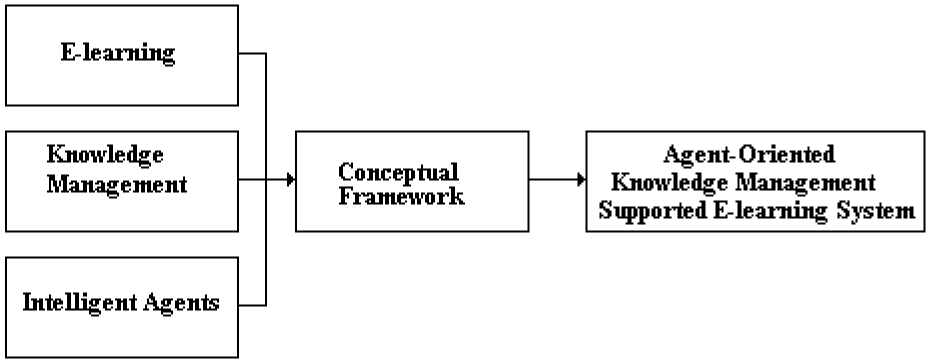
There is no universal definition of e-learning. Broadly speaking, e-learning can be defined as learning activities performed over electronic device(s). Terms such as technology-based learning, computer-based learning, computer-based education, and Web-based training can be classified under the banner of e-learning. E-learning systems embrace a wide collection of applications and processes such as Web-based, computer-based, or digital collaboration. E-learning and distance learning are commonly considered interchangeable (Usnews, 2003). In this study, we define e-learning as credit-granting education or training courses delivered to remote (off-campus) location(s) via audio, video, or computer technologies such as the Internet, including both synchronous and asynchronous instruction (Ozdemir et al., 2000). An e-learning system is well suited for mass education and training. The cost and difficulty of accessing information on the Web are continuously decreasing, given the support of an increasing plethora of portable or hand-held computing devices such as sub-notebooks, palm devices, pocket computers, and WAP phones. E-learning has the potential to become a cost-effective tool for mass education, one of the key applications in e-commerce and the largest information industry in the near future (Cisco, 2004; White, 2003).

Multi-agent systems (MASs) have been given a more general meaning. The term is now used to refer to all types of systems composed of multiple autonomous components that behave like agents (Flores-Mendez, 2001). Wooldridge (1997) stated that the technologies of agents and MASs have brought a new way of visualizing and implementing open, complex, and distributed systems. Different kinds of agents are applied in a wide variety of disciplines (Giraffa et al., 1998; Jennings et al., 1998; Nwana, 1996). With the gradual maturity of agent-developing techniques, people are beginning to apply them in fields other than e-commerce (Guttman et al., 1988; Liang et al., 2000), manufacturing (Lee et al., 1999; Zhang et al., 1995), or multiple-scheduling under a distributed environment (Glezer et al., 1999; Sen, 1997).

Applying agents to increase or enhance the system's features is not new. Researchers or developers have always named their agents in line with the nature of the job or the applied areas of the agents, or even according to the name of the research project. Some typical examples within the field of education are pedagogical agent, tutor, mentor, and assistance (Giraffa et al., 1998). Examples in other fields are information agents, webot, softbot (BotSpot, 2003), personal agents, digital butlers, and virtual secretaries (Vise, 2004). The redesign and modification of the e-learning system utilizing the techniques of agents likely will introduce extra helpful features and can improve the efficiency of the e-learning system. Ritter (1997) highlighted the use of different tools to communicate with an agent tutor in a target learning environment. Lester et al. (1997) reported a simple constraint agent that could enhance learning. Ganeshan et al. (2000) reported the use of pedagogical agents in tutoring on the subject of medical diagnosis.

Knowledge is a justified belief that can increase an entity's capacity for effective action (Huber, 1991; Nokaka, 1994). Commercial KMSs are gaining the attention of users due to their ease of use, functional diversity, and wide availability. They provide functions that support the repository of knowledge — something current e-learning systems lack (Serban et al., 2002). We believe that our proposed framework essentially integrates

Figure 1. The research approach



KMSs and that e-learning systems will post a new challenge to the designing of e-learning systems to share and contribute knowledge.

This chapter is organized as follows. In the background section, a brief review of the literature on KMSs and agent-oriented e-learning systems is presented. The following section presents the foundation of the conceptual framework for the development of an agent-oriented e-learning system supported by knowledge management. The next section describes the construction of the three-level system architecture; namely, the user level, domain level, and Web level. The final section concludes with an overall summary and discussion of the theoretical and practical implications of the proposed system.

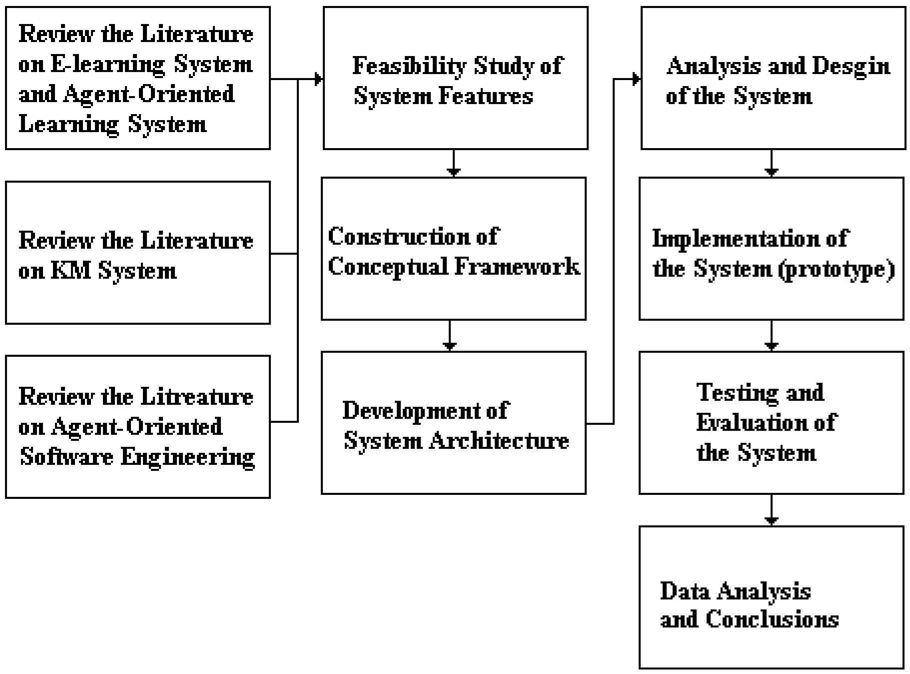
Figure 1 depicts the research path of this study. It begins with a review of the latest concepts, models, and technologies from the three different pertinent areas of e-learning, knowledge management, and intelligent agents. A conceptual framework is constructed and based on the literature review. The next stage is the development of an agent-oriented, e-learning system supported by knowledge management. The system architecture and the prototype are built using the latest computing technologies. Finally, the system is evaluated and validated.

RESEARCH METHODOLOGY

Figure 2 depicts the research methodology of this study. The following research issues are addressed in each phase of the research.

- Literature review of e-learning systems and agent-oriented learning systems, KM systems, and agent-oriented software engineering: Relevant literature related to e-learning systems and agent-oriented systems, KM systems, and agent-oriented software engineering will be studied. Based on an in-depth review of the literature, we propose the use of a conceptual framework that provides a template and gives us a mechanism for understanding the research issues and developing an agent-oriented e-learning system supported by knowledge management.
- Feasibility study of system features: This provides a clear picture of what features the future system should have. Based on available technologies and resources, the careful selection and aggregation of the features that had previously been identified from the literature review enables a logical view of a concrete and developable model.

Figure 2. The research methodology



- Construction of a conceptual framework: The proposed framework will be constructed. Different kinds of agents, KM, and e-learning components will be mapped into the framework to demonstrate how the system will function and to support the system's conceptual objectives.
- Development of the system architecture: A good system architecture provides a solid foundation for the development of the system. A conceptual map consisting of different components of the system with different functionalities is developed. It investigates how the components interact with each other. It maps the relationship of the system components to the required objectives and reduces the risk of missing, redundant, and coupled system functionalities.
- Analysis and design of the system: This is an important step in the development of the system. We need a clear understanding of the domain(s) on which the system rests. Here, different solutions are formulated and selected to meet the objectives and goals of the system.
- Implementation of the system: In this phase, we build the prototype through which the various issues arising in the early stages can be addressed and clarified. The prototype will provide a means by which the designer will attempt to clear up uncertainties or questions about concepts, frameworks, designs, and technical issues.
- Testing and evaluating the system: This is the phase in which the correctness and usability of the system are verified. The actual

expected functionalities of the system are compared for possible modification of the system. When adopting the system, the designer can gain insights into the level of application and look into the users' workload and problems.

- Data analysis and conclusion: Once the system has been developed and tested, the users' attributes, observations, and feedback from previous tests and surveys are examined in detail. Researchers can capture information on the users' acceptance of the system and determine further directions for improvement.

THEORETICAL UNDERPINNINGS OF AGENT-BASED E-LEARNING

This section introduces the background of our study. The discussion of relevant literature in three pillars provides a thorough understanding of the scope and the objectives of our research.

Agent-Based E-Learning Systems

In the past few years, many papers on agent-oriented e-learning systems have been published. Cristea et al. (2000) carried out a study on a Web-based, agent-oriented, long-distance teaching environment for teaching academic English. Thibodeau et al. (2000) developed the White Rabbit, a system to enhance cooperation among a group of people using intelligent agents to analyze their conversations. The aim of the Toolkit for the Management of Learning project led by Liber et al. (2000) was to develop tools to help teachers and students manage learning resources, negotiate learning programs, and develop learning profiles. A project exploring the role of agents as learning companions for humans was carried out by Uresti (2000). Nobe et al. (1997) conducted a pilot study

Table 1. A summary of different applications of agents in education

Nature	References	Areas of Application
Pedagogical agent – is directly involved in the transfer of knowledge	Acros et al. 2000	Agent capacity added to a virtual reality simulator as a demonstrator to teach Laparoscopy and Hystreoscopy surgery.
	Cristea et al. 2000	Using an agent in a web-based system to teach English in an academic environment.
	Ganeshan et al. 2000	Developing an animated agent used to tutor in medical diagnosis for a pedagogical purpose.
	Lester et al. 1997	Applying a simple constrained agent to enhance the effect of learning.
Supportive agent –reduces workloads from supportive activities in related teaching.	Liber et al. 2000	Utilizing an agent to manage learning resources, negotiate learning programs, and develop learning profiles.
	Nobe et al. 1997	Developing an agent with anthropomorphic ability to enhance the effects of learning.
	Ritter 1997	Having the agent act as a tutor to enhance communication between learners and the learning system.
	Thibodeau et al. 2000	Using an agent to analyze the conversation of users to enhance group cooperation online.
Guardian agent – works with the learner in a peer-to-peer manner to assist and reduce the user's workload	Liber et al. 2000	Using agents to manage the learning resources, negotiate learning programs, and develop learning profiles.
	Uresti 2000	Have agents act as learning companions.

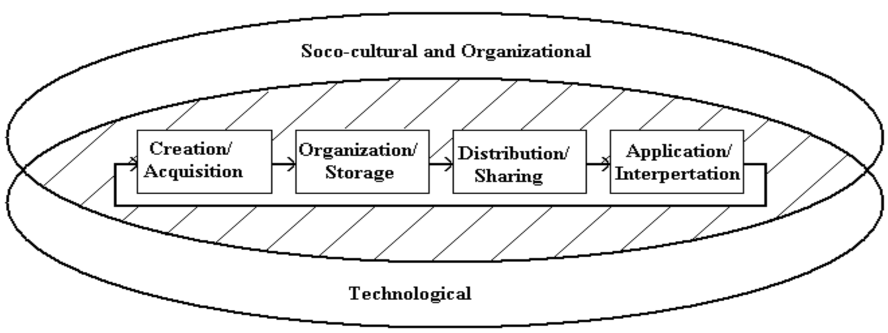
on a gaze-tracking method to access relevant aspects of an anthropomorphic agent's hand gestures in a real-time setting. A study of Adele, an animated pedagogical agent used in tutoring the subject of medical diagnosis, was presented by Ganeshan et al. (2000). The LAHYSTOTRAIN demonstrator, a training system that is combined with a virtual reality simulator and used for training in laparoscopy and hystreoscopy surgery, was developed by Acros et al. (2000). Miller et al. (2000) implemented an intelligent team-training system using an agent-oriented approach. Following this trend of development, an agent-oriented e-learning system for mass education should be in the horizon. The different applications for agents in education are summarized in Table 1.

Knowledge Management Systems

Broderick (2003) pointed out that learning occurs through personal experience or by sharing and repeating the experiences of others. The transfer of knowledge is a form of interaction between people. The knowledge management (KM) processing cycle may include steps such as the creation, capture, organization, accessing, and application of knowledge (Hayward 2000). It is people within the organization that create explicit knowledge or convert implicit knowledge to explicit knowledge. When learning and teaching experiences are documented and processed, they become knowledge. KM helps people to organize, store, distribute, and share knowledge. Procedures to capture and share pedagogical knowledge are equally important to the role of knowledge management within a successful organization. Daveport et al. (1998) stated that between data, information, and knowledge, organizational success and failure often depends on what you need, what you have, and what you do with each. Figure 3 shows the iterative perspective of the KM process (Rhsmith, 2003).

Garrison et al. (2003) pointed out that the latest direction in the development and research of Web-based learning systems (Web base) is to work with the artificial intelligence and introduce the semantic structure. Such new systems will be navigated and processed smoothly by both human and intelligent agents. Lytras et al. (2003) discussed the establishment of knowledge networks for e-learning enhancement through peer-to-peer technology. Kidwell et al. (2000) conceptualized the potential applications and benefits of knowledge management for higher education. In his thesis, Putzhuber (2003) provided a detailed study of the differences and similarities between e-learning and KM, and highlighted the benefits and possibilities of combining the two by building a prototype model.

Figure 3. The process of knowledge management (Rhsmith, 2003)

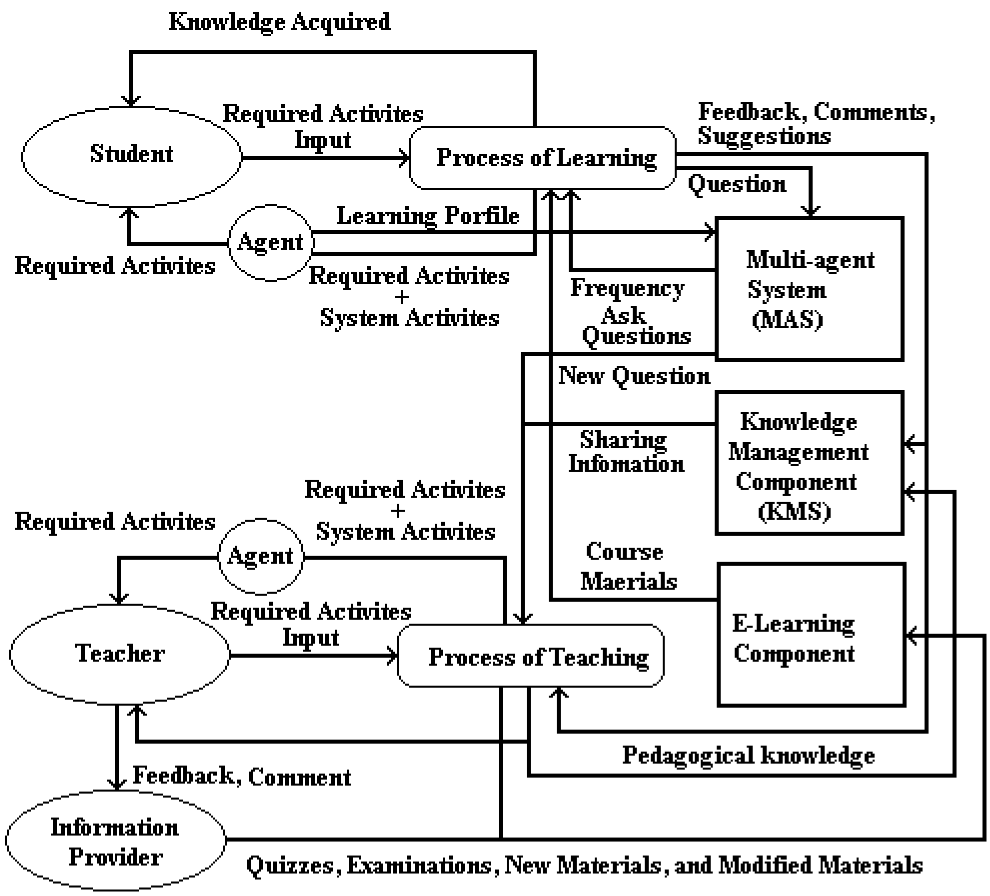


Commercial portals take up many features of KM and combine them with powerful search engines and intuitive and customizable Web interfaces. Strauss (2000) held the view that it should be possible to customize and personalize a portal, and that a portal should be desktop-oriented and adaptive. From a user's point of view, a KMS is a personalized collection of services and information, possibly a single point of access, where searching can be carried out across one or more resources. A KMS provides a tailored view of the aggregated information set, ease for aggregated cross searching, streamlined authentication, and user profiling. All of these features are rarely found in existing e-learning systems.

TOWARD DEVELOPMENT OF A CONCEPTUAL FRAMEWORK FOR AN AGENT-ORIENTED KM SUPPORTED E-LEARNING SYSTEM

A conceptual framework of an agent-oriented knowledge management supported e-learning system is shown in Figure 4. Within the conceptual framework, the student, the teacher, and the

Figure 4. The conceptual framework for the development of an agent-oriented e-learning system supported by knowledge management



information provider are the major users. The two agents as personal assistants of the two users (i.e., the student and teacher) form the basic part of the conceptual framework, together with the process of learning and teaching. For completeness, three major building blocks (i.e., the MAS, KMS, and e-learning system) are added to provide the services needed to support teaching or learning sessions on the Web. Two important features provided by the conceptual framework are illustrated in Figure 4. They include (1) using agents to reduce the workload of the users, and (2) capturing and sharing educational knowledge. Their detailed descriptions are given in the following sections.

In Figure 4, one can see that the student starts the learning process with the corresponding components responding by delivering all of the required materials, learning activities, and support and system activities to the student through the learning process. System activities are not part of the learning activities, but the system needs them to run smoothly. One example is the updating of the user's profile; another is the verification of the user's identity. An agent between the student and the process of learning can help filter out unnecessary information and handle all of the system activities, thus reducing the workload of the student. For the teacher who is involved in the process of teaching and disseminating pedagogical knowledge, the role of the agent is different. A question raised by the student will be sent to the MAS to answer. If the MAS fails to answer, it will pass the question to the teacher. The feedback, comments, and suggestions of the student and the pedagogical knowledge from the teacher will be captured and documented with the aid of the KMS component. After this information is filtered and processed, it may become knowledge that can increase the effectiveness of the system.

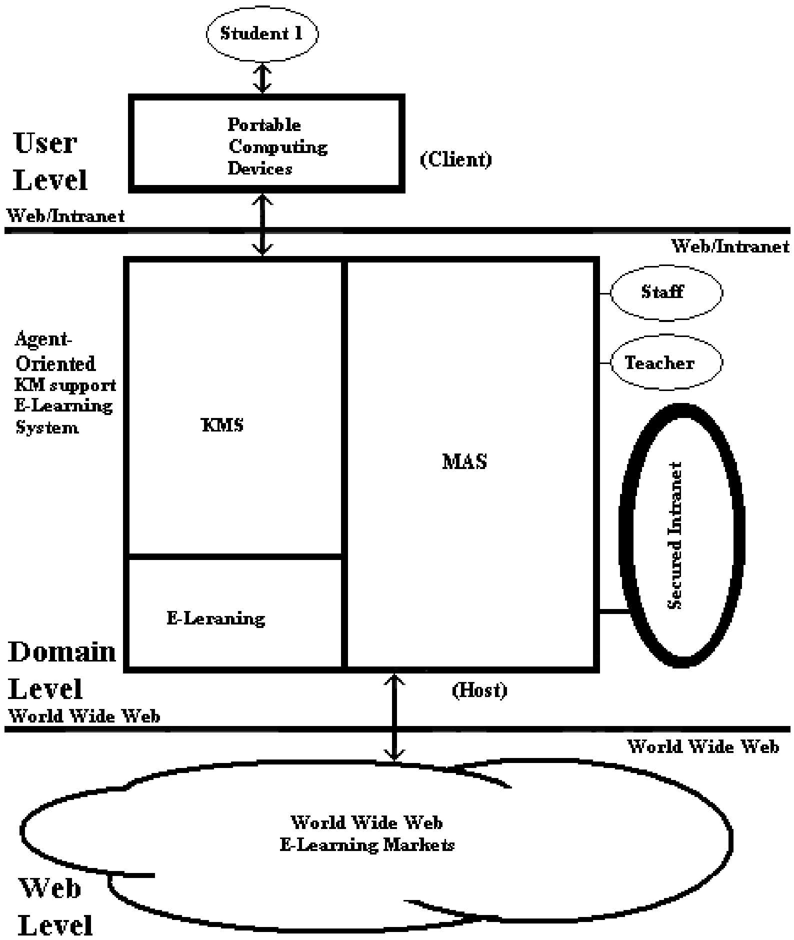
Intelligent agents working in KMS are not rare (Baek et al., 2004; Staniszkis et al., 2004). An online intelligent agent can keep track of the learning sessions. By observing the learner's behavior, the agent can follow the learning strategies or behavior of the learner (patterns, study times, and learning sequences). An agent can also record the learner's sources and methods of accessing supplementary materials that are not found in the teaching materials. The collection of this type of information may produce new knowledge or teaching materials after refinement by teachers or educators. In our framework, the agents take up most of the low-level jobs and indirectly monitor the learner's behavior by streamlining the process of creating, storing, and sharing of knowledge, which is a vital part of a successful KMS.

An agent is defined as a program that works automatically on routine tasks specified by a single user. It seems natural to determine the number of required agents based on different users. Adopting object-oriented analysis (Larman, 2001) and employing techniques such as scenario building, use-case analysis, and object generalization, we identify the following four major groups of users (actors) in an e-learning system: the learning, teaching, supporting, and information provider groups. The last group does not have a significant role to play here. The three-level conceptual model, corresponding to the four identified major groups of users, is shown in Figure 5.

The conceptual model consists of three levels:

- User level: At the user level, the student uses a client machine to access the system through an intranet or the Web. The client machine can be a desktop personal computer or any portable computing device.
- Domain level: At the domain level, a host machine is used to provide the working environment for the MAS, the e-learning system, and the KMS. The host machine(s) can be a single server or a cluster of servers in an intranet form. The duties of the host machine(s) include system security; information storage, update, and access; and learning- and teaching-related activities

Figure 5. Three-level conceptual model



supporting the four major groups of users. The teacher and support staff will access the system through the intranet at the domain level and the Web level.

- Web Level: The third level is the Web level, which is an aggregation of suppliers of the e-learning market. A market consists of exchangeable and reusable information resources, which spans different platforms and is well supported by the current e-learning services providers.

The three-level conceptual model is constructed on the popular client server structure when joined with the Web. Each level is independent of the others, with high-level communication carried out through the agents. Any modification at one level may not cause significant changes at another level, thus reducing the impact of the rapid growth of new technologies that may cause necessary changes at any level. The user level can be any computing device ranging from desktop to hand-held computers. The smaller the size of the learning device, the greater the learning mobility of the users will be. Also, different learners can use different devices to access the system. Finally, the Web level acts as an open architecture for other providers of e-learning services to join in, as long as agent communication is enabled for both parties.

In the next section we will provide a more detailed presentation of our conceptual model. Through this discussion, several critical issues related to e-learning effectiveness will be pointed out.

User Level

Agent at the Client Machine

The client machine is used to support the student's learning, the presentation of course materials, performance evaluations, and monitoring. A Guardian Agent (GA) with certain features similar to the Personal Guardian (Ozdemir et al., 2000) is used here. The GA will filter all messages, materials, and requests from the host, other students, or the Web. Only learning-related activities or requests the agent is unable to handle will be passed to the user.

When a user starts the learning session, the GA can obtain the login information from the user profile and automate the login process. The GA then sets up the environment and sends the user preferences and progress to the Presentation Agent to get the required materials. During the learning session, the GA can filter the incoming mail and messages and reduce the distraction to the user caused by unnecessary conversation. From the progress log, the GA can give reasonable and appropriate advice and reminders about appointments and assignments at the right time. When the user needs to search or get extra information during the learning process, the GA can try to estimate the quickest way and then get the required materials based on the user's past experiences. All the way, the agent can monitor and keep track of the user and collect valuable information online until the session ends. From this scenario, a brief description of the components in the client machine is given as follows:

1. The user interface is a general interface that provides communication between the client machine and the user.
2. The personal profile will provide the user's personal information, preferences, and academic records to the GA.
3. The progress log is the place where the GA stores the information about the learning progress, such as project due dates, appointments, meetings, and so forth.
4. The GA to store performance-related information uses the user library. Such information is needed for the analyses of learning patterns or for the creation of study plans.
5. The personal library is where the locations and passwords for all accessible resources are stored. The GA uses this information to automate the retrieval of information.
6. Correspondence information stores personal information and preferences about the user needed by the GA to communicate or filter information.
7. Working space is simply a place used by the GA to temporarily store information. The objective of the GA is to enable the learner to have more time for core learning activities such as studying lecture notes, practicing quizzes, revising for examinations, doing assignments, attending tutorials, and participating in group projects or discussions. In the next section, a brief tour of the MAS is given.

Domain Level

MAS Module of the Host Machine

The MAS module contains the pedagogical agent, facility agent, presentation agent, help agent, domain agent, search agent, and administrative agent.

1. The pedagogical agent works on behalf of the teacher. It can take over from the teacher any non-teaching related duties and simple routine jobs. Providing help, guidelines, or assistance online, or answering the frequently asked subject questions are good examples of the pedagogical agent's duties.
2. The facility agent works on behalf of the support staff. It can take over from the staff all routine jobs and administrative and support duties that require no decision-making. Examples of such activities are the drawing up of timetables, registration of classes, collection of assignments, and so forth.
3. The presentation agent handles the requests for materials from the students and redirects all of the requests to the appropriate system agents to process. It also acts as the coordinator and makes sure that the correct answer goes to the right person or agent.
4. The help agent handles questions from the students and looks for an answer from the frequently asked questions pool. If the help agent fails to find an answer, the question will be passed to the pedagogical agent and then to the teacher to answer.
5. The domain agent handles all of the communications from the Web between the host and the suppliers of the e-learning markets.
6. The search agent specializes in search for information. It will search the electronic library first, the knowledge base next, and the Web last.
7. The administrative agent is responsible for verifying the user's and GA's identity and authorization of access resources. Any agent accessing the system will have its current status posted on the agent bulletin board when in contact with other online agents.

A brief but complete view of the MAS is presented here. Table 2 summaries the relationships between the actors, the agents, and the levels where the intelligent agents are serving.

Different agents with different goals are grouped together to form the MAS. Together, they reduce the workload and increase the functionality and efficiency of the system. Table 3 gives a brief summary of the relationships between the constructed agents and their boundaries of services.

E-Learning Module of Host Machine

It is a unique challenge for educators to create a cohesive community of inquiry in a medium that

Table 2. The major actor and its related agent with location level

Actor	**Agents**	**Levels**
Student	Guardian Agent	User
System - Information Search	Search Agent	User/Domain
Teacher (teaching staff)	Pedagogical Agent	Domain
Staff (support staff)	Facility Agent	Domain
System - Course Offerings	Presentation Agent	Domain
System - Security Control	Administration Agent	Domain
System - General Support	Administration Agent	Domain
E-Learning Markets	Domain Agent	Domain/Web

Table 3. Agents and boundaries of services

Agents	Boundaries of serving
Guardian Agent	Activities related to supporting studying by learners.
Pedagogical Agent	Activities related to teaching, consultation, and tutoring.
Presentation Agent	Activities related to user and agent authorization, and allocation of system resources to agents.
Admin Agent	Activities related to user and agent authorization, and allocation of system resources to agents.
Facility Agent	Activities related to recording, verification, and administration.
Search Agent	Activities related to searching for information, and acquiring extra materials over WWW.
Help Agent	Questions frequency asked by users.
Domain Agent	Information exchanged by third parties over the WWW.

provides no real human-to-human contact. There are systems that provide many administrative functions for the student and more system support tools than a normal e-learning system provides, such as WebCT (Webct, 2003) and Elearning Software Solutions (Elearningsoftware, 2003). However, these learning management systems are only enhanced and expensive versions of the ordinary e-learning system.

To differentiate the agent-oriented component from the non-agent component, we label all non-agent components as managers. Different managers that provide different features are found in the e-learning component.

1. The material manager controls the accessing and updating of the course materials database.
2. The examination manager controls the accessing and updating of the evaluation and quiz database. The examination manager is also responsible for conducting and marking online examinations or quizzes.
3. The administration manager controls the accessing and updating of the student records database.
4. The library manager controls the accessing and updating of the electronic library database.

Together, they provide the core functions needed to support teaching and learning. Table 4 summarizes the relationships between the e-learning components and the boundaries of their services.

Table 4. E-learning module components and boundaries of services

Components	Boundaries of services
Material Manager	Controls the creating and updating of the course.
Administration Manager	Controls the flow of documents and information, reviewing, and publishing.
Examination Manager	Stores information by categories, meta searching across internet by key words.
Library Manager	Controls activities related to recording, verifying, and offering materials.

KMS Module of Host Machine

The KMS provides some features that most existing e-learning systems lack and that are useful in sustaining a collaborative learning environment. It offers a centralized point of access for finding and managing information. By using a browser to view the dashboard site, the user can perform document management tasks and find information. A KMS with portal features can help both teachers and students to effectively capture and share educational experiences and knowledge. Embedding the KMS in an e-learning system, we make available the following benefits: (1) The portal manager allows the presentation of course materials in the way the user wants and keeps the user's preferences in the user profile database. (2) The workflow manager supports document management. Through it, the user can check documents in and out, review a document's history, apply controls over publishing, and automatically route the documents to reviewers. (3) The content manager controls access to the documents and information for building the personal portal with contents from the knowledge base database, multimedia database, and course materials database. (4) The subscription manager provides functions for use in subscribing to new or changing information. (5) The Web claw manager with the index search workspace database enables information to be browsed through categories, searches using keywords, and searches across trusted intranets

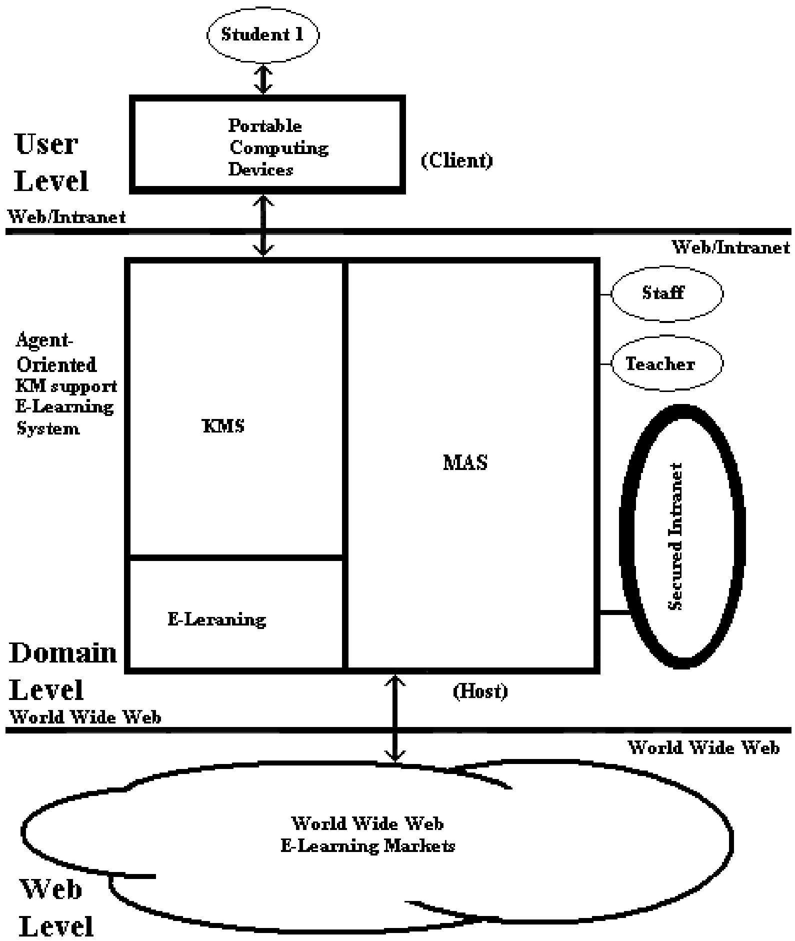
Table 5. Components of the KMS module and boundaries of services

Components	**Boundaries of activities**
Portal Manager	Creates and maintains the learner's personal portal.
Work Flow Manager	Controls the flow of documents and information, reviewing, and publishing.
Content Manager	Controls access to the contents of the course and supplementary knowledge.
Subscription Manager	Controls subscriptions to new or changing information and notifies the users.
Web Claw Manager	Gathers web information from an entrusted intranet. Supports information by categories, key words, or meta searching across the internet.
Dispatcher	Filters all incoming requests and dispatches the requests to the appropriate receiver.

Table 6. Databases and stored related information

Database	**Nature of the Information**
User Profiles	The preferences of each user for use in building the personal portal.
Index Search Workspace	Supports the different modes of searching with the system or the entrusted intranet with help from the Web Claw Manage.
Knowledge Base	The main base for the storing and sharing all knowledge other than the fixed teaching materials.
Multimedia	Is the storage for all information that not in a textual format.
Course Materials	The place for storing all of the course materials.
Student Records	The place where the student's academic records are stored.
Evaluation and Quiz	The place where all the tests and examination papers are stored.
Electronic Library	The place to look for frequently asked questions and answers. Supplemental materials and help files are also found here.

Figure 6. System architecture for the development of an agent-oriented e-learning system supported by knowledge management



in a transparent manner. (6) The dispatcher filters all incoming requests and dispatches the requests to the legitimate owners or handlers.

Table 5 summarizes the relationships between the portal components and their boundaries of activities.

The system architecture of an agent-oriented e-learning supported by knowledge management is shown in Figure 6. Multiple concurrent users from different levels, the managers of the e-learning and KMS module, and the agents from the MAS module are all constituent parts of the architecture. There are eight databases in the host machine to store different types of information at different levels of security. Table 6 summaries the relationships between the databases and the nature of the information stored in them.

Trusted Web servers, database servers, e-mail servers, or communication servers can join the intranet to share their information or services with the system and users. On the client machine, more than one set of personal information and utilities are found so that the student can select different settings when he or she uses a different machine to login or work with another agent-oriented e-learning system.

Web Level

E-Learning Resources at Web Level

The domain agent at the host machine handles all communications between the Web and the system. This communication channel acts as an aggregate of different supporting e-learning resources. The e-learning resources consist of exchangeable and reusable information resources that span different platforms. The members of the e-learning resources include education brokers, global education brokers, online consultants, digital libraries, and information providers. The education brokers from local or global sources can provide new teaching materials, training courses, and other support services. Digital libraries can provide information or resources in both the kind of quantity and quality that no single, privately owned library could offer. Information providers can supply new and updated information in a cost-effective and timely manner. Online consultants can provide services that are not available internally in the system.

A Validation Strategy

The final goal of this research is to validate the model in a real-world setting. More specifically, through an exploratory study, the research is to investigate the learning result of KM activities during the learning process. First, the system will be evaluated with a larger scale test of multiple users in a real environment. The feedback from different users and the performance of the agents will be examined in great detail to see how well agents can fit into the model. Second, a model for evaluation will be developed and used to investigate the impact on the learning of students of the agent-oriented e-leaning system supported by knowledge management. Students of the Hong Kong Polytechnic University and other tertiary institutions will be invited to take part in the evaluation exercises. A control group of students will be set up. Both qualitative and quantitative methods will be used to compare the differences between the two approaches.

CONCLUSION

The study was motivated by the need to design a flexible, self-paced e-learning system with the least constraints for lifelong learners, given that both people and organizations need to remain competitive in this era of information. A solution that would answer the challenge of providing a flexible, continuous education is to enhance the knowledge capacity of agent-oriented e-learning systems. A conceptual framework and the corresponding system architecture for the development of an agent-oriented, knowledge-supported e-learning system are described in this chapter. We present a viable approach by integrating e-learning, KM, and agent techniques to enhance the quality of the support function for lifelong learners. Some of the benefits of integrating e-learning and KMS with an agent-oriented approach include: (1) supporting KM functions such as notifications of subscriptions, workflow control, and aggregation of information over various sources, (2) enhancing the quality of the support provided to students in the spirit of collaborative teamwork learning, (3) facilitating the creation of knowledge for the student and the teacher, and (4) offering a means for the systematic self-adaptive improvement of the system.

As for future research, we are interested in a number of issues. We are interested in applying data mining techniques to look for any interesting patterns or relationships in data collected by an online agent about the activities of learners and the profiles of users. Other research areas that might be interesting to explore are effective learning patterns, the sequence of the presentation of materials in successful learning, or any early observable behavior that indicates poor learning results within the e-learning system.

Another interesting issue relates to the relationship between ontology and e-learning agents. Integration with ontology enables agents to communicate and share different views of the world (i.e., the environment of one agent with one another). Lytras et al. (2003a) pointed out that the construction of an e-learning platform entitled "Semantic for E-Learning" by merging e-learning, KM, and ontology could be one way in which research in this area could be extended.

The mobility of agents is also an exciting area for further research. Mobile agents that travel from one machine to another (e.g., from a desk top to a palm top) enables the learner to take lessons even in a more convenient way but creates the problem of resource availability; namely, the size of the memory which is commonly true for wireless connection handheld devices.

Enhancing e-learning with a KM-oriented metadata schema (Lytras et al., 2002) or with semantic Webs that greatly increase the automatic transferability of knowledge from systems to users or peer-to-peer with other e-learning systems is another direction that we are going to investigate after completing the development of an agent-oriented, knowledge management supported e-learning system.

THEORETICAL AND PRACTICAL IMPLICATIONS

The approach, conceptual framework, and architecture proposed in this paper require a significant amount of integration of research from different fields such agents, MAS, software engineering, pedagogical agents, KMS, e-learning, and agent-oriented software engineering. Some of the challenges in this integration include sorting out the following roles for the different actors: (1) the student's role in effective learning, (2) the reduction of the workload of the user by agents, (3) the role of the central repository in effective learning, and (4) the role of agents in an e-learning system, especially in a cooperative and interactive system.

E-learning, KMS, and agents are still under development, and many areas have not been fully exploited yet. The approach presented in this chapter illustrates the process of starting from the modeling of a conceptual framework to the construction of a system architecture using a system development perspective. Employing such an approach, it is possible to create an agent-oriented e-learning system supported by knowledge management with better overall performance than any specially tuned e-learning system with some enhanced features. This approach poses challenges in the merging of different systems and technologies. It helps the designer minimize the time and effort required to develop the next generation of e-learning systems. From a teaching viewpoint, there is no better instructional system than a cooperative and interactive system. The proposed architecture provides a channel for teachers and students to capture and share experiences, thus providing a better cooperative, interactive learning environment. A companion acts as a personal assistant that can learn the user's habits and preferences and can modify itself with a minimum amount of intervention from the user.

ACKNOWLEDGMENTS

This research was supported in part by a grant from the Hong Kong Polytechnic University, grant number G-W132. The authors are grateful for the constructive comments of the referees on an earlier version of this chapter.

Chapter 2.41
Knowledge Management Agents

Leon Sterling
University of Melbourne, Australia

APPLYING AGENTS WITHIN KNOWLEDGE MANAGEMENT

The agent has existed as a concept for thousands of years. In the human context, an agent is a person that performs some task on your behalf, for example, a travel agent planning flights and accommodation for your holiday, or a real-estate agent helping you buy or sell a house, or someone arranging marriages. Some Biblical laws specifically refer to agents.

In the much more recent software context, an agent is loosely a program that performs a task on your behalf. Agents have grown in popularity since the introduction of the PC (personal computer) as the target environment for application software has increased in complexity. Software systems must now operate robustly in a networked, global environment comprised of diverse, distributed technologies. Furthermore, the environment is dynamic, and frequent change is inevitable. Having automated help is almost a necessity.

Despite many attempts, there is no universally agreed technical definition of agents. An oft-cited reference by Franklin and Graeser (1996) gives almost a dozen different definitions. Let us consider a textbook definition given by Wooldridge (2002, p. 15). An agent is "an encapsulated computer system, situated in some environment, and capable of flexible autonomous action in that environment in order to meet its design objectives."

Essential characteristics of the agent paradigm that can be elicited from this definition are:

- The autonomy of individual agents, or their ability to act for themselves and to achieve goals
- The reactivity of individual agents in response to changes in the environment
- The modularity of individual agents and classes to allow the easy development of complex systems
- The ability of agents to communicate effectively and interact with legacy systems

Optional characteristics of the agent paradigm, which emerge from broader considerations of agents than the above definition, include mobility in moving around a network and the ability to reason.

This article rests on the metaphoric view of agents as entities performing tasks on one's behalf. Agents are presumed useful for building software to interact with complex environments such as the Internet or within complex organizations such as universities and multinational corporations. Expected of a program being viewed as an agent is an ability to sense and be aware of the environment in which it is situated, an ability to communicate with other agents, and an ability to take action in its situated environment. According to these three expectations, sophisticated e-mail programs such as Microsoft's Outlook and Qualcomm's Eudora can be viewed as agents. They are situated on the Internet and sense various aspects of the Internet, including when Internet connections are live and when new mail arrives. They communicate with other e-mail clients by sending and receiving messages. They take actions such as raising alerts when mail has arrived, sending mail that has been queued once an Internet connection is restored, or filtering messages according to rules.

We now connect with knowledge. Organizations operating in today's software environment need to represent, interact with, and above all, maintain a large collection of knowledge, including, for example, business practices, trade secrets, intellectual property, organizational hierarchies, promotional organizational descriptions, and knowledge of both its own policies and policies of relevant, external regulatory bodies. There is out of necessity great diversity in the form, content, and context of the knowledge. Most of this knowledge is in unstructured or semistructured form. The problem of the representation and maintenance of such knowledge within an organization can be loosely called the knowledge management problem.

For the purposes of this article, there is no need to define the knowledge management problem or knowledge management, for that matter, more precisely. However, we note that the term knowledge management subsumes the term content management. Referring to knowledge rather than content suggests some concern with formalizing knowledge explicitly.

How might agents be applicable to the knowledge management problem? As a running, concrete example, consider knowledge management issues related to the responsibilities of a university lecturer in charge of a subject1. She or he must prepare, deliver, and maintain content in a variety of forms, possibly including lecture notes, papers, and media presentations. Let us particularly focus on one component of the task, namely, maintaining a Web site for the subject.

Several possibilities exist for enlisting the help of agents. An obvious first task for agents is to help with the acquisition of knowledge, which is obtaining content and placing it on the Web site.

What type of software agent might be useful for the acquisition of knowledge? It is natural to envisage a custom Web crawler (http://en.wikipedia.org/wiki/Web_crawler), Programs that trawled specified Web sites looking for content were early applications built to exploit the World Wide Web. Building a Web-crawling agent immediately raises important considerations. The agent should be aware of important regulatory issues such as the fact that downloading mp3 files is illegal in some countries without the authorised permission of the copyright holder. The agent should also be aware of conventions such as the robots.txt protocol (http://en.wikipedia.org/wiki/Robots.txt_protocol) in which guidelines are given about parts of a file hierarchy that should be ignored by well-behaved agents. There are many similar policies of which a knowledge-acquiring agent would need to be aware. These policies demonstrate some of the complexities that need to be taken into account in building agents.

Search engines are based on exhaustive trawls and efficient indexing of files using techniques from information retrieval. Agents can also be constructed using techniques derived from experience in building knowledge-based expert systems. Consider the task of tracking down a particular paper by a particular author. One may have been referred to the paper by word of mouth or by the need to cite a final version of the paper for which you only had a preliminary version. A prototype citation-finding agent, CiFi (Loke, Davison, & Sterling, 1996), was built for this task. CiFi used the following three strategies for finding papers. First, CiFi tried to find a link from the author's home page2 using heuristics about possible keywords such as research and publications. Then CiFi looked for a link from a page of publications or technical reports linked from the author's department. Finally, CiFi sent an e-mail to the author asking for the file or citation.

A challenge in building CiFi was making it work on a variety of Web sites. Ideally, a single agent is desirable that can operate successfully over a range of Web sites. CiFi was not particularly intelligent or effective. It clearly reflected a bias to papers written by researchers within universities. It failed, for example, to find white papers written by companies. It would have had difficulty adapting to current spam filters if its e-mail message was blocked. Having agents adapt to changing circumstances is a desirable property. However, CiFi is indicative of an agent that might be applied to a knowledge management task.

Another task that might be assigned to an agent is to look for new articles by particular authors. Suppose you respect the work of a particular researcher and want to be notified of any of his or her new publications. It is possible for an agent to look for changes on a Web site and alert you that a new publication may be present3. In general, reporting changes or the presence or absence of documents is a task that the reader should have no difficulty in identifying as being potentially useful within his or her own organization. Providing new information or reminding participants that the next step in a work flow needs to happen can be helpful. Such an agent can be viewed as being a facilitator. Facilitation was espoused by Winograd and Flores (1987) as an alternative model for agents rather than artificial intelligence.

Let us return to specific tasks within Web-site management. Content on a Web page may be made available through links to other resources. However, it is frustrating when browsing to find outdated links on Web pages. An agent could check periodically whether links are still live. It would need to sense the result of its search and update the links on the page.

Here is another task for an agent. Some of the knowledge on a Web site can be usefully cross-linked. For example, an online quiz would be enhanced for self-study by having links from questions to material where the correct answer can be found. These links may be provided once the student has attempted the quiz. An agent could construct these links automatically. Of course, any changes to content would mean that the cross-links would need to be checked. A prototype agent called QuizHelper that can perform this task has been described in Chan and Sterling (2003).

Several of the above suggestions for agents address the performance of maintenance activities. Maintenance is key for knowledge management. The reader can doubtless imagine maintenance activities in his or her own environment that might be performed by an agent. Some maintenance activities are already happening automatically, for example, through alerts about software updates or the downloading of security patches.

A different type of task that an agent can perform is monitoring the use of a program.

For a program developed to help students learn material, an educator may want an agent to assess if the program is being used properly by the students. The assessment may be used to give feedback to the software developers or to try to ascertain whether the student is meeting learning objectives. The conceiving of agents to monitor student interaction with a program suggests good design questions. How is the agent going to sense what the student is doing? How are student actions going to be interpreted? How can student activities be matched to learning objectives?

Now imagine a system consisting of several of these agents working together performing tasks in a domain. A system consisting of multiple cooperating agents is known as a multiagent system. The conceiving of separate tasks being performed by separate agents simplifies the conceptualisation of how the system may be built. We discuss the building of multiagent systems later.

Agents need to be aware of the environmental context, and there is growing work on the representation of the context and the environment. Explicit models of the environment and context are examples of models of knowledge, our next topic. It is a challenge to handle the knowledge of different agents in a multiagent system, and this leads us to the important but difficult and conceptually rich area of agent ontology.

While ontology is discussed in other articles in this volume, we address it briefly as ontology is an important topic for agents and one that is underestimated by agent researchers. The most common definition of an ontology is "an explicit specification of a conceptualisation."4 In practice, an ontology is an explicit, formal knowledge-representation scheme.

As stated previously, an ability to communicate is intrinsic to an agent. In order for meaningful communication to occur between agents, they must understand what each other's terms mean. Clearly, knowledge management tasks are easier if all agents involved, including humans and software agents, agree on the vocabulary they are using.

Agent developers until now have assumed that each application would have a suitable ontology. Explicit languages have been developed for agent communication, notably KQML as discussed by Finin, Labrou, and Mayfield (1997), and the more recent standard, ACL, being developed by FIPA (Foundation for Intelligent Physical Agent; http://www.fipa.org). Both KQML and ACL are based on the speech-act theory originally espoused by Searle (1969). Communication by an agent using KQML has a field for an ontology. It is presumed that by knowing what ontology an agent uses, correct meaning will be applied. ACL is more sophisticated and even provides a specification for an ontology agent "for registering and serving ontologies to agents" (http://www.fipa.org/specs/fipa00086/).

There are several dimensions to consider with respect to an ontology. Is it general purpose or domain specific? Is it maintained centrally, or distributed among several agents? Do all agents use the same ontology or is meaning negotiated between different ontologies? Does each task have its own ontology? Where should the ontology come from? One possibility is that an organization maintains its own ontology that constitutes its single organizational view of the world. An alternative possibility has been that someone develops a single ontology to which developers refer. The prototypical example of a single ontology is Cyc, which has been under development for 20 years. An open-source version of Cyc is available at http://www.opencyc.org. A recent development with regard to Cyc is the use of contexts to represent local knowledge.

Knowledge depends on context. Different cultures do things differently, and the behaviour of an agent needs to be culturally appropriate. An increasingly common view is that agents should be allowed to have diverse views. Cultural issues should not be underestimated. Even within organizations, there is a need to interact with outside organizations, be they commercial, regulatory, or cooperative. Outside organizations will have a different view of the world and hence a different ontology. When agents communicate or cooperate in tasks, their knowledge may need to be matched, a process we call knowledge mediation.

An approach to achieving knowledge mediation is by viewing tasks as context, as advocated in Lister and Sterling (2003). Agents only need to be able to match up sufficient knowledge to perform a task rather than to match a complete ontology. While partial matching may lead to difficult maintenance issues should a task be repeated, it seems more realistic and akin to how people interact despite clearly different views of the world. This raises the issue of modeling tasks for agents. The knowledge of a domain is usually separate from the knowledge of performing tasks in the domain. In building an agent application, this needs to be taken into consideration.

The next topic to be considered is the practice of building multiagent systems. How should multiagent systems be built for knowledge management applications? Today's dynamic, distributed, heterogeneous environment presents a problem for software developers. Traditional software engineering has demanded the complete specification of a software application before issuing assurances that the application will work correctly. Producing a complete specification of requirements is not realistic and almost certainly impossible given the inevitable changes. It is questionable whether current software-development techniques are adequate5. The relatively new paradigm of agent-oriented programming (Wooldridge, 2002) has emerged as a potential successor to object-oriented programming, and in principle is better able to address the new demands on software.

While substantial experience has been accumulated in building individual agents, building a multiagent system remains a challenge. The first complete methodology proposed to guide the process of developing a multiagent system was Gaia (Wooldridge, Jennings, & Kinny, 2000). According to Gaia, a multiagent system is conceived as a computational organization of agents, with each agent playing a specific role, or several roles, within the organization and cooperating with other agents toward the achievement of a common application (i.e., organizational) goal. The field of agent-oriented software engineering has blossomed since 2001 to address the question of how to develop agents systematically. No single methodology has emerged as the best choice for developers.

A good overview of the range of methodologies for building multiagent systems can be found in Bergenti et al. (2004). Almost all methodologies highlight roles, goals, and agents as important new concepts for building multiagent systems rather than object-oriented systems. However, just as there is no agreed-on definition for agents, there is no agreed-on definition for roles and goals. Let us consider them briefly.

Roles are abstractions of agents, and they specify high-level aspects of an agent such as responsibilities, constraints, and permissions. It is useful to clarify in what role an action to be undertaken by an agent is to be performed. Goals are high-level representations of the purpose of a system. They specify what is to be achieved, the aspect of system analysis, rather than how something is to be achieved, which is system design and implementation. Eliciting system requirements in terms of roles and goals can be intuitive and different than the established object-oriented practice of using cases.

For many applications, we will want to consider a system as consisting of both humans and software agents. Knowledge management certainly involves people. A distinct advantage of the agent paradigm is that it facilitates thinking in terms of systems consisting of both humans and software agents. Thinking of a system in terms of roles and goals blurs the difference between human agents and software agents, which from experience is useful during elicitation.

Design proceeds once roles and goals have been elicited. Agents are chosen to fulfill one or many roles. The agents will perform tasks and activities to achieve goals and follow protocols. There is a growing body of literature on appropriate protocols for multiagent systems. The use of agents can help to abstract interface issues. Agents can serve as a wrapper around legacy systems. The interacting agents are designed to communicate correctly. How an agent communicates with the legacy program becomes an internal matter that does not need to be addressed by the system as a whole. Agents can also be designed to consume services, a view consistent with the current vision of Web services.

This article has been concerned with relating two topics: knowledge management and multiagent systems. We have considered how agents might be applied to knowledge management by identifying some knowledge management tasks that might usefully be performed by agents. We discussed how agents might be developed to perform the tasks, highlighting the extra concepts of goals and roles that are useful for the development of agents. In conclusion, knowledge management can be viewed as a system where humans and software agents cooperate. Research has been performed that indicates that building agents to perform knowledge management tasks is promising.

ENDNOTES

1. In the United States, a subject is called a course, a fact that illustrates the ontology problem discussed later in the article.
2. Finding an author's home page is an interesting task in and of itself, and agents have been developed to accomplish the task. The best known is Ahoy!, which was retired in 2000. More information can be found in Shakes, Langheinrich, and Etzioni (1997). Note that the need for such an agent has been essentially obviated by Google.
3. A free Web service was developed to notify users of Web-site changes several years ago. It is worth commenting that some people view the task an agent performs as a service, and the metaphor of intelligent services is used to describe similar concepts being discussed in this article. This is not the place to debate the relative merits of the agent metaphor vs. the services metaphor.
4. This definition of ontology is given by Gruber, and it is discussed at length in Gómez-Pérez, Fernández-López, and Corcho (2004).
5. It is a belief underlying the article that current software-development methods are inadequate, but the argument is beyond the scope of this article.

Chapter 2.42
Intelligent Agents for Knowledge Management in E-Commerce:
Opportunities and Challenges

Athanasia Pouloudi

ABSTRACT

E-commerce has become a key aspect of the global business environment, causing fundamental changes in markets and organisational structures. This chapter considers how knowledge management, the latest management approach aimed at improving business performance, can create new business opportunities in the new business environment that is defined by electronic commerce. Knowledge management deals with the systematic generation, codification and transfer of knowledge and can be supported by a number of technologies, known as knowledge management tools. It has been argued that intelligent systems can offer additional capabilities and advantages in comparison with more traditional information technologies. This chapter investigates the potential of intelligent agent-based software for more effective knowledge management in the context of e-commerce, adopting the perspective of an SME involved in development of intelligent agents-based knowledge management software. The chapter concludes with a research agenda for knowledge management research in e-commerce.

INTRODUCTION

The importance of knowledge management (KM) as a competitive differentiator is increasingly recognised by both 'traditional' and 'virtual' organisations. A recent OECD report claims that industrial countries are spending as much on intangible knowledge-based investments as on physical equipment (OECD, 1999). There is an expectation that the technical exploitation of knowledge data will improve substantially with the use of intelligent tools that have several additional capabilities in comparison to traditional knowledge management tools, as discussed in this chapter. With improvements in IT-based systems for handling knowledge, knowledge management is becoming an essential theme of research into business success. Yet, it has been argued (e.g., Hlupic et al., 2001; Myers, 1996; Snowden, 1998) that the effective management of knowledge involves more than simply exploiting the data held on information systems. It also requires attention to the 'softer' parts of the corporate knowledge base, as found in the human and cultural aspects of businesses, particularly the experiences and tacit knowledge of employees. There is a growing emphasis on innovation through 'knowledge work' and 'knowledge workers' and on leveraging 'knowledge assets' (Swan et al., 1999).

While some research also makes reference to the organisational context within which the technology will be used (e.g., Delesie and Croes, 2000; Edwards and Gibson, 2000), there is little evidence of whether or how the organisational and technical dimensions have been integrated. The challenges, both technical and contextual, presented in this chapter indicate that electronic commerce creates a new context for knowledge management, not just in terms of the cultural and business environment created, but also in terms of the actual knowledge that is captured, exchanged and exploited. To deal successfully with the latter, it has been suggested that artificial intelligence, and intelligent agents in particular, have a key role to play (Smith and Farquhar, 2000). This chapter will consider how this new technology can be applied in practice. Typically, research in knowledge management would consider the view of the 'client', i.e., how a particular organisation improves its knowledge management practices. Our chapter focuses instead on the ways in which the new context of electronic commerce creates business opportunities for the provider of intelligent technology to support knowledge management. This party, the 'supplier', needs to have a broader view of the new technological and cultural landscape. We access this perspective by researching the case of an internationally oriented SME involved in multi-agent software development used for knowledge management in electronic commerce.

The chapter is structured as follows. The next section presents some of the key organisational and technical challenges for knowledge management, with emphasis on the role intelligent multi-agents and the challenges that electronic commerce presents for knowledge management. Section three introduces the case of an SME involved in development of intelligent agents-based KM software. A research agenda for KM research in e-commerce is then proposed, and conclusions are drawn.

KEY CHALLENGES IN KNOWLEDGE MANAGEMENT

The literature has been unable to agree on a definition for the term 'knowledge management' (Brooking, 1999; Hlupic et al., 2002; Malhotra, 1997; Trauth, 1999). One reason is that discussions of, and approaches to, the subject are rooted in different academic disciplines and areas of professional expertise. From the information systems perspective, for example, KM is often looked upon as synonymous with new forms of 'data mining' and 'warehousing' — the 'hard' tools that allow for sophisticated pattern searches of raw data (Trauth, 1999). From the innovation management perspective, a 'cognitive' approach is adopted, which looks at the transfer of explicit and tacit knowledge through product development and organisational change procedures (Kuhn and Abecker, 1997; Leonard-Barton, 1995; Nonaka and Takeuchi, 1995). The management literature places particular emphasis on issues of 'organisational learning', especially structures which encourage creativity and knowledge sharing (Ruggles, 1997). It is increasingly evident that these definitions do not adopt a multi-disciplinary approach, despite the multi-disciplinary interest in KM (McAdam and McCreedy, 1999; Phillips and Patrick, 2000). Instead, a managerial perspective is often predominant that does not necessarily accommodate the capabilities of information systems. The reverse is also common in research that is intended for a technical audience. We argue that KM must move towards a more holistic approach to nurturing and exploitation knowledge assets in both 'traditional' and 'virtual' business environments. In the chapter we demonstrate this in two ways. First, in this section, we give as much attention to the capabilities of intelligent technology as to the context of electronic commerce applications. Second, in the following sections, we demonstrate how technology and context become intertwined in the empirical evidence that our case study provides. Starting with knowledge management tools, this section presents a technological followed by an organisational perspective on knowledge management.

Knowledge Management Tools

Knowledge management tools, as all tools, aim to assist in the completion of a task with ease and efficiency. Ruggles (1997) suggests that KM tools can be divided into three categories, which are believed to represent the primary knowledge activities of most organisations:

- Knowledge Generation — the creation of new ideas, recognition of new patterns, the synthesis of separate disciplines and the development of new processes.
- Knowledge Codification — the auditing and categorisation of knowledge.
- Knowledge Transfer — the exchange of knowledge between individuals, groups and organisations.

The majority of KM tools are designed to deal with structured data, where information is directly entered into fields or can be categorised in some manner. Each of these stages presents technical challenges. One important issue is indexing, in other words, the appropriate structuring of data or information to facilitate or lead to knowledge discovery (Delesie and Croes, 2000). Knowledge acquisition and representation can also be difficult to address in KM systems, as they are for knowledge-based systems; they are issues that have been recorded extensively in the expert systems literature (e.g., Doukidis & Whitley, 1988; Firlej & Hellens, 1991; Hart, 1986). With KM systems, the key issue is probably the need to move beyond simple structured data mining towards the capture, mining and manipulation of tacit or unstructured data. Practitioners and researchers alike have identified tacit data as a, if not the, corporate resource to be managed and exploited for competitive advantage in the information-intensive economy. In other words, an additional technical challenge for knowledge management is the management of tacit knowledge, which is normally stored and exchanged using unstructured data. Takeuchi (2001) argues that organisational knowledge is created precisely during the time that tacit knowledge is converted to explicit (p. 321). Therefore, a key challenge for the design of KM technology is the identification of patterns (Brash, 2000) in unstructured data that enables reuse of the technology and contributes to system flexibility (Selvin and Buckingham Shum, 2000). There is an expectation that the new generation of KM tools will address this challenge using artificial intelligence (AI) techniques such as case-based reasoning, neural networks and intelligent agents. This chapter focuses on the role of the latter.

Intelligent agents are software objects (special types of computer programs) capable of communicating with each other and reasoning about information contained in messages that pass among them. To justify the adjective intelligent, agents must be able to make decisions under conditions of uncertainty, to act upon incomplete information, albeit in a narrow knowledge domain. Key elements of an intelligent agent, which enable it to achieve a limited-scale perception, cognition and execution, are knowledge bases with domain heuristics, simulated simple values and attitudes, and algorithms for reasoning, learning and pattern recognition. Advanced versions of agents can learn from experience and may even have distinguishing personality traits. Standard artificial intelligence techniques may be used for constructing agents, e.g., predicate calculus, genetic algorithms, fuzzy logic and neural networks. However, the experience indicates that the best results are achieved if a very large number of very simple agents is allowed to cooperate and compete among themselves and thus generate "Emergent Intelligence." Agents could be designed to have a particular attitude towards taking risks under conditions of uncertainty. Thus, a team of agents with different risk-taking characteristics emulates a crew of operators with a variety of attitudes to decision making.

Multi-agent systems use multiple intelligent agents and are characterised by distributed problem solving. They contain software objects (agents) capable of exchanging messages among themselves and their users, interpreting the meaning of messages and negotiating decisions. An interesting development in multi-agent systems is an attempt to provide agents with a mechanism for modifying protocols that regulate negotiations, which they conduct among themselves (e.g., Muller et al., 1996). This capability enables agents to incrementally improve their decision-making performance. These capabilities are particularly useful in electronic commerce (as discussed further on in this chapter) where intelligent agents have been taken up. The concept of multi-agent design and control is well developed, although not necessarily articulated in the context of knowledge management. It has been argued that, in this context, the role of artificial intelligence is "giving powerful assistance to people as they solve problems" (Smith and Farquhar, 2000, p.22). This quotation points to the interdependence of technology and the context of use, and supports the idea that the technological challenges mentioned here are witnessed and can only be addressed within a particular organisational and cultural context.

The Knowledge Management Context: Challenges For E-Commerce

Knowledge management, while supported by technology, remains a complex management practice for all organisations — tools will not work unless they can be integrated in the organisational and cultural context. The following paragraphs consider the reasons why this may be the case at four separate but interconnected levels, where KM benefits are realised: the individual, organisational, interorganisational and international levels. Particular emphasis is given to the additional challenges that are present in an electronic commerce context.

At an individual level, KM provides organisational members with opportunities and tools to operate, and where possible flourish, in an environment of continuous change. Attention to the individual level signifies acceptance of idiosyncratic knowledge, recognising that personality plays a critical role in the way that people acquire, perceive, value and use knowledge as well as that the creation of knowledge is affected by the world view of the individual (Guns and Välikangas, 1998). This is particularly relevant for the e-commerce context. Specifically, in business-to-consumer e-commerce relations, in contrast to traditional commerce, the customer is not visible and typically not known. The technological awareness of individuals also varies. The potential customer population is large (possibly global) and the 'customer' could have any background (cultural, financial or educational). In knowledge management terms, this presents a business opportunity: customer behaviour can be electronically recorded, therefore can be manipulated and exploited for competitive advantage. Some mechanisms, like cookies, try to contribute to 'learning' more about the customer profile and preferences, although in essence there are several limitations related to the authenticity and interpretation of the data they record. Furthermore, given the technical challenges reviewed previously, it is not clear how organisations can manipulate the vast amounts of data and extract meaningful patterns that could be used for 'mass customisation' or differentiating their products in a global market where first mover advantage is visible and can easily be imitated. Intelligent agents can play a key role here by providing personal attention to the customer, learning and remembering individual preferences, which can be communicated or negotiated as needed. The business implication for the company using the technology is dual: customer service can improve as individual traits are catered for and the company gains knowledge about trends and patterns that can be unveiled from customer choice.

At an organisational level, KM supports the streamlining of activities and facilitates improved organisational response to internal and external changes. This often places attention on organisational processes and presents several challenges, not least the difficulty of identifying processes (Nickols, 1998). Huysman and de Wit (2000) have identified several 'traps' that relate to KM at this level:

- An opportunity trap — KM will be more effective if it is problem-driven, i.e., if it responds to concerns that are relevant in the particular organisational context, rather than if it is technology-driven or attempting to imitate other businesses, as is often the case.
- A codified knowledge trap — It is difficult to record previous knowledge for others to access, especially as new knowledge keeps being created and human actors are busy making sense of the new knowledge and conditions.
- A management trap — KM is dominated by management initiatives, but it is unlikely to be effective unless knowledge workers willingly take part in it.
- The operational level trap — KM should not be limited to the operational level, in the same way that knowledge exchange processes cannot be limited to this level.

In organisations that use electronic commerce, either partially or fully (virtual organisations), the notion of business processes maybe entirely different, as these companies are based on different business models (Tapscott et al., 2000). This complicates the significance of these 'traps' for the networked enterprise and its stakeholders. On the one hand, as business processes are predominantly electronic, they should be more transparent and traceable than in traditional business — thus, information about business transactions is structured and explicit, and this should facilitate knowledge management. For example, it should be easier to create an organisational memory about business transactions and make this readily accessible to knowledge workers. On the other hand, several business processes transcend the boundaries of the organisation, as electronic links to customers, suppliers and other stakeholders make the organisation an extended, networked enterprise. This makes it harder to convert information into knowledge: different organisational settings and therefore different cultural environments, with different sets of tacit knowledge, interact. A related difficulty at this level, which also applies to traditional companies, is that the available data about processes, procedures and resources may be incomplete. This makes it harder to uncover patterns that can lead to knowledge codification and possibly the generation of new knowledge. The use of intelligent agents can be helpful in this respect. Specifically, intelligent agents that are characterised by autonomous learning can use previous history, and learn from it even if the way in which it is interpreted changes at a very fast rate.

Interorganisational and international levels (in many cases, these can be used interchangeably in e-commerce) are therefore more relevant in considering the challenges of the knowledge management context in electronic commerce. At the moment, little is known about the transfer of knowledge at an interorganisational level. Arguably, one of the advantages of KM is that it enables organisations, regardless of size and resources, to compete globally against larger regional trading blocs, tending to reduce economy of scale differences. The problem at this level is that different cultures have different mental models of collaboration or trust (Kidd, 2000). Electronic commerce research acknowledges the importance of trust between trading partners (e.g., Hart and Saunders, 1997; Miles and Snow, 1992; Ratnasingham, 1998; Wilson, 1997) but does not consider how this may relate to knowledge creation and transfer in-between different stakeholders. In more mature and structured interorganisational relations, such as outsourcing, KM has yet to receive appropriate attention (Currie and Pouloudi, 2000). The potential role of multi-agents, at this interorganisational level, is in their ability to represent business partners in the networked enterprise and conduct negotiations on their behalf. They can be also utilised for business-to-business types of transactions, operating, for example, in the context of supply chain dealings. Both roles entail technical and organisational issues. From a technical perspective, the use of multi-agent systems eliminates the need for the selection and implementation of optimal algorithms, which is a complex endeavour. Agents will negotiate what to do next in every particular situation, based on local information and a set of general rules, without any need for optimisation algorithms to be programmed into the system in advance.

From a business perspective, the situation is rather complex because it is at present not clear which rules, roles and responsibilities apply in a legal context that is not well defined. Despite the progress in electronic commerce legislature, several issues remain to be resolved at a global scale for transactions occurring entirely in electronic format or crossing national boundaries (see for example Timmers, 1999, pp.171-174, for an overview of key legal and regulatory issues in the European Union and the USA).

Electronic commerce, by its very nature, combines a business with a technological environment, as transactions occur electronically. It is obvious from the discussion in this section that it offers a good opportunity to illustrate the interdependence of technical and organisational (often inter-organisational) factors in knowledge management. In the next section we consider the technical and business environment of a recently established company that develops, supplies and supports multi-agent software, and serves as a case study for considering the potential of intelligent agents for knowledge management in e-commerce.

EMPIRICAL INSIGHTS FROM THE USE OF MULTI-AGENTS FOR KM IN E-COMMERCE

Following from the previous discussion on the interrelations of technical and organisational factors related to knowledge management in electronic commerce, this section presents how these are witnessed in practice. For our description we adopt the perspective of a small enterprise that has strong links with Brunel University. This allows an 'insider view' to the opportunities and challenges it faces in providing multi-agent support for knowledge management in electronic commerce. Starting with a description of the company and its multi-agent software, the section leads on to a discussion of the role of intelligent agents in knowledge management, which serves as a guide for proposing a broader agenda for research in this area.

The Company

The company was established in October 1999 to exploit multi-agent research but it has a long history of informal existence marked by previous international collaboration among its founders. Although its physical premises are in the UK, it is largely a virtual corporation with researchers, system designers and programmers collaborating over intranets and the Internet. For example, the main activities related to software development are carried out in Russia. The company aims to become "virtual" and to sell its products and services mainly though the Internet. In doing so, it would become an e-commerce-based organisation selling products and services that support e-commerce. In practical terms, this means that the company has the advantage that it understands from its own experience the challenges of integrating work processes across different cultural settings, hence it is able to exploit this knowledge for providing better products and support to its customers as well.

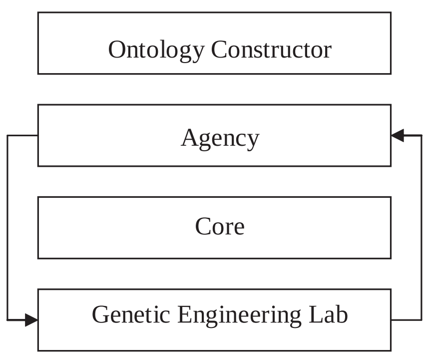
The corporation has a flat structure, where, as described on the company's web site, "teamwork dominates every aspect of corporate life." Also, the corporation considers intellectual capital to be its key asset. Consequently, knowledge management is important for the company not just as a product but as a competitive differentiator: the company is its own customer. For example, organisational memory is facilitated by the company's own knowledge management software. Similarly, the company culture is maintained through an extensive electronic network. The company is currently in the process of extending the functionality of its web site for procurement and selling its product and services. Plans for e-commerce include using the company's web site for selling, in large volumes, scaled down multi-agent tools and shells to small-to-medium software developers around the world.

Capabilities of Multi-Agent Software

Agents are trained (have access to knowledge) rather than programmed to do a particular job. Advanced versions of agents can learn from experience and have distinguishing personality traits. They can be, for example, risk-averse and this will influence their negotiating behaviour. The principal element of multi-agent systems, which enables them to achieve a limited-scale perception, cognition and execution, is an Ontology, which contains knowledge about the domain in which the system operates. To keep the Ontology simple, the domain of agent activity has to be reasonably narrow. The second component of the system is the Engine, shown in Figure 1.

A key advantage of this architecture is that modifications are easy because the agent code is reusable, multi-agent engines are expandable and the Ontology can be updated by operators without any knowledge of computer programming using

Figure 1. The engine of a multi-agent system



a visual tool called Ontology Constructor. The Agency in the above diagram is the space where agents are created and where they work (negotiate), the Core is a set of run-time algorithms enabling parallel work of a very large number of agents and the Genetic Engineering Lab is a place where the performance of agents is monitored and modifications are made to their "genetic code" to improve their performance (e.g., to negotiate more aggressively, or more carefully).

Multi-agent systems are perceived to be cost-effective; each agent has a limited intelligence yet the overall intelligence of a "swarm" of agents is quite impressive. This is because agents cooperate with each other and make decisions through negotiations. Agents act upon locally available information with great speed, but always respect general policies and rules. They consult each other and they bargain with a view to maximising the overall value of the process they are controlling, rather than furthering their own individual interests. In other words, multi-agent systems behave as an effective team, and the effective teamwork results in an emergent performance, a performance that far exceeds the sum of performances of individual team members. The inherent advantage of multi-agent systems is that they work on the principle of a free market. Agents match supply to demand, and if the perfect match is not possible, they negotiate special deals to achieve partial matching.

Supporting Knowledge Management for E-Commerce

In the context of electronic commerce, agents improve the performance of portals and web sites by providing visitors with an intelligent, personalised, one-to-one service. In particular, they communicate with each visitor as an individual, recognising specific needs and expectations. They also recognise visitors when they return to the site. In addition to this customer relationship management role, multi-agents match portal offerings to visitors' demands rapidly and effectively, and negotiate discounts and special deals on behalf of their clients. From a knowledge management perspective, they continuously analyse available data in the background, with a view to discovering, preserving, maintaining and updating knowledge about each visitor. Discovering and managing knowledge through the use of agents can be directed both to the business environment (customers, competitors, investors, administrative and legal factors, new technologies, etc.) but also to the client's own business processes (cost-effectiveness of human and technological resources, organisational structures, business culture, geographical locations, etc.).

The competitive differentiator of a Multi-Agent Knowledge Management System is based on effective clustering algorithms that enable rapid discovery of knowledge, which as discussed in previous sections can be 'buried' in unstructured data. The key to the effectiveness is the use of multi-agent technology, which provides distributed intelligence to help the process of clustering. Principles and rules of clustering, which are obeyed by agents, are in the first instance entered into the system ontology by knowledge management experts. The system is designed to enable operators without knowledge of computer programming to modify and update clustering principles and rules and thus influence the system performance. The company's selling point is that this system is much less expensive than a typical data mining system and far more effective (e.g., as it enables knowledge exploitation of unstructured data) and user friendly. A unique aspect of the system's user friendliness is the capability to provide the user with a graphical representation of clustering results so that stronger links between data elements appear clearly.

It is worth noting that clustering becomes a self-organising process. As new data become available to the system, the clusters of knowledge are re-evaluated and reconfigured, allowing for a dynamic interpretation of business results. Furthermore, the system can provide patterns without 'knowing' much about the data. This means, on the one hand, that the system may highlight relationships between data that is not obvious, even to the knowledgeable human agent, thus unveiling real competitive edge issues for their clients. On the other hand, the clustering process becomes faster if human agents define restrictions for the clustering processes, based on their capability to interpret meaningful associations among data elements. This dilemma between speed and scope of data analysis illustrates the interplay of technical capabilities and organisational priorities. The human agent can improve the efficiency of the technology by a good understanding of the context, which can lead to a better definition of Ontology as well as a more insightful interpretation of the data analysis results. Obviously, the responsibility for the translation of results in appropriate business policies lies also with the human agent.

DISCUSSION AND IMPLICATIONS FOR RESEARCH IN KNOWLEDGE MANAGEMENT FOR E-COMMERCE

The interactive character of electronic commerce enables information (and, hence, knowledge) sharing across organisational entities or individuals, often across national boundaries. Through their electronic commerce interactions and transactions, companies acquire much information that can easily be stored and exploited (as the data is usually in electronic form). However, few users of electronic commerce have considered using this information as a basis for understanding and managing their organisational knowledge better. The potential benefits of more effective knowledge management in the context of e-commerce are apparent for both organisational processes and interorganisational relations, and we argue that multi-agent technology has an important role to play in this area. In the previous section we saw how a software house exploited their multi-agent software for knowledge management in electronic commerce for the company and the company's clients.

Electronic commerce is a unique environment for knowledge management, not only because it uses the Internet as a platform but also because the data available to users of e-commerce become dated very quickly as the electronic market changes at a rapid pace. Therefore 'traditional' information technologies cannot deduce knowledge for the future exclusively from past data because of dynamic changes in the turbulent global economy. Companies that aim to support knowledge management in electronic commerce environments have to investigate novel ways of managing and exploiting the individual, organisational and interorganisational knowledge. Intelligent multi-agent technologies can provide a technological solution for dealing with the uncertain conditions of this context, manipulating incomplete or ill-structured historical data.

At the moment, both research and practice of knowledge management in e-commerce are in their infancy. For example, there are a number of problems that we have identified in current practice as well as in the theoretical understanding of KM, namely:

- the variety of theoretical approaches to KM and the lack of consensus in the literature about what constitutes KM and how effective KM can be achieved;
- the limited availability of empirical reports to support these approaches and provide guidance for further improvements in KM practice;
- the lack of KM tools and the differences in the support that existing tools provide to user organisations;
- the lack of awareness about KM opportunities for both traditional and virtual organisations, either because of technical limitations of the available tools or because user organisations are unable to identify or

communicate their needs for more effective KM and the organisational structures that will support them; and
- the lack of substantial research effort to investigate technical and social aspects of KM in e-commerce environments.

As a result of these problems, it is not surprising that the appreciation of the challenges and necessity to integrate technical and organisational aspects of KM, which we believe is critical for more effective KM, is at best incomplete. As yet, there is no generic model of KM grounded in empirical research, which companies or industrial sectors can use as a basis for organising and managing their information resources. Such a model could allow organisations to leverage their core competencies and key skills. Both organisational and technical issues of KM raise significant challenges. However, it is also evident that, even though they are often separated in the literature, in a practical context they are inseparable as they inform and influence each other. We argue that research in KM should reflect this synergy of organisational and technical issues. Research needs to be directed towards understanding how these areas limit or enhance the competitive benefits of KM theories and models — what this new way of working entails with regard to skills, organisational structures and operations.

In other words, the implementation of a KM tool will not result in a 'knowledge environment' if other knowledge activities are not supported. For instance, knowledge transfer is unlikely to occur if the organisational culture was one of hoarding information (Clegg and Palmer, 1996; Irani and Sharp, 1997; Walsham, 1995). Moreover, in order to combine the expertise of key stakeholders, new forms of working — such as 'cross-functional teams' — may be needed (these may include, for instance, consumer behaviour experts, database marketers and IT experts). These issues have been recognised for some time in the innovation literature (Madhaven and Grover, 1998), although this has not been investigated in the context of e-commerce.

In addition, there is a lack of published empirical work in this area and there is a lack of tools that organisations can utilise and adapt for KM activities in both traditional and virtual business environments. Similarly, evaluation measures for any available tools are lacking. The investigation of the product and approach followed by the case company considered in this chapter provides some insight in the potential of intelligent agents for KM in electronic commerce but clearly presents a specific, sole experience of a recently established company. More research is needed to provided a more in-depth understanding of the way in which companies respond to knowledge management, and in particular to the use of KM technologies to exploit and enhance their electronic commerce activities. We argue that important areas for further research in this area include the following aspects.

First, in order to inform technological improvements, it is necessary to investigate and evaluate knowledge management tools (including multi-agent-based tools) in real e-commerce environments. This should result in a better understanding of the potential and current limitations of such tools, leading, in turn, to specification of requirements for further development of such tools. Second, in order to improve knowledge management at the strategic level in the use of electronic commerce, it is necessary to identify main barriers and driving forces for knowledge management in e-commerce. This involves defining what knowledge is relevant in the context of e-commerce and how it can be captured, stored, refined and applied. A related aspect is the identification of critical success factors for effective knowledge management in e-commerce-based environments, including research on organisational structures that support knowledge management in e-commerce. Third, knowledge management provides an opportunity to improve organisational practices and processes. Therefore, future research should investigate issues related to teamwork, leadership, culture, incentives and motivation for knowledge management, identifying ways for integrating knowledge management into the daily workflow and particularly the types of reward structures to support knowledge sharing and collaboration. An important dimension of this research is exploring how knowledge management can lead to individual and organisational learning as this will lead to sustainable competitive advantage.

CONCLUSIONS

This chapter has discussed the potential of intelligent agents for knowledge management in e-commerce, using insights from an SME providing such knowledge management tools. The chapter emphasised that technical, organisational and interorganisational aspects need to be considered in parallel for providing useful solutions for organisations doing business electronically. The research setting described in this chapter could stimulate interest for identifying opportunities for competitive advantage for e-commerce user organisations from better KM and threats from KM practices in a business context. A number of future directions of research in this area have been identified on that basis. Our main recommendation is for considering the future of technology within the context in which it will be applied.

Chapter 2.43
Knowledge Management for Agent-Based Tutoring Systems

Ping Chen
University of Houston-Downtown, USA

Wei Ding
University of Houston-Clear Lake, USA

ABSTRACT

As the education field is becoming increasingly technology heavy, more educational systems involve line or interactive training and tutoring techniques, and lots of educational information becomes available via the intranet and World Wide Web. Managing large volumes of learning information and knowledge is one of the crucial issues for these educational systems, as appropriate knowledge management is the key to more effective and efficient learning. The chapter first discusses that an intelligent agent system could be successfully applied to the education field and then focuses on how knowledge management techniques play an important role in agent-based tutoring systems.

INTRODUCTION

Computer technologies are making progress rapidly and are becoming more specialized. Many different fields have benefited from newly invented and powerful computer technologies. Therefore, it is not a surprise that education adopts more computer technologies, and students and learners use computers in a lot of courses and labs. New technology integrated into the education or tutoring system can enhance the access to knowledge and improve the efficiency of knowledge transferring to learners. But such integration often requires additional training in order for its users to become familiar with a new learning environment before they can actually benefit from these technology advances; otherwise, new technology will confuse and distract, instead of helping, its users, and slow the learning process. Agent-based tutoring systems can overcome such technical obstacles between knowledge and common users. Then, users are able to focus on information and knowledge that they are interested in and try to learn. Unlike traditional tutoring systems characterized by a stand-alone approach, i.e., autonomous and complete in itself, an agent as a software entity can work continuously and autonomously in a particular environment usually occupied by other agents. And, an agent as a software entity is able to interact with its environment in a flexible and intelligent way without demanding constant human interference or orientation. An agent working continuously for long periods of time should be able to learn from experience. In sharing its environment with other agents, it should be able to communicate and cooperate with them. Therefore, an agent can have the following attributes: reactiveness, autonomy, cooperative behavior, communication ability at knowledge level, interference competence, temporal continuity, personality, adaptability, and mobility. All of these properties will make an agent-based tutoring system more effective and efficient (Silveira, 1998).

Agent-based human-machine interaction was first commonly used in the 1930s, in such applications as autopilot systems, etc. Such agents aided or performed some automatic and simple tasks that human beings would otherwise perform. A human operator will perform supervisory tasks (involving cognitive processing and situation awareness skills) instead of old manipulation tasks (usually involving sensory-motor skills) (Sheridan, 1992).

The use of software agents as intelligent assistant systems was proposed (Alchourron, 1985) to facilitate human-computer interaction to transfer information, as well as human-human interaction for better understanding through new software technology. The adoption of agents in an educational and tutoring system is natural, because information and knowledge transfer is the most important part of learning. Agents can enable the understanding and learning of various kinds of concepts, because they involve active behaviors of the users. They enable users to focus on the content and index content in accordance with specific situations that they will better understand. To be specific, the advantages of using software agents in education may include the following:

- Customized learning environment for individuals
- Unified learning environment
- Integration of local and remote resources
- Transparent process to make users focus on knowledge to be conveyed, not how to use the tutoring tools

In this chapter, we will talk about an agent-based tutoring system architecture design and how to manage knowledge and "knowledge about knowledge" (metaknowledge) in an agent-based educational environment.

BACKGROUND

Learning is an active, interactive, and constructive social process. Technology, especially computer technology, can help learning greatly. Initially, the learning technology focused on individualized instruction, i.e., stand-alone tutoring, a universal environment for all students. The current view of training and education environments must support customized inquiry-based learning and collaboration, and such an environment has the following advantages over the old learning technologies:

- Intelligent tutoring systems have explicit tutoring models and domain knowledge that can serve each individual in a more customized and efficient way.
- Interactive learning systems enable the student to manipulate cognitive artifacts from several perspectives or viewpoints (Norman, 1992).

- Cooperative learning systems provide students with access to other people's ideas and concepts, and this makes it possible to exchange, discuss, negotiate, defend, and synthesize viewpoints (SIGCUE, 1992).

Also, the advances in network technology enable learners far away to communicate with each other more efficiently. A Web-based tutoring system is not only technically possible but also mostly desirable.

Another technical advance comes from object-oriented technology. An instructional technology called "learning objects" currently is the most popular choice in the next generation of instructional design, development, and delivery, due to its potential for reusability, generativity, adaptability, and scalability (Learning Technology Standards Committee).

Learning objects are elements of computer-based instruction based on the object-oriented paradigm (Wiley, 2002). The Learning Technology Standards Committee (LTSC) uses "learning objects" to describe these small instructional components and provides a working definition:

Learning Objects are defined here as any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning. Examples of technology-supported learning include computer-based training systems, interactive learning environments, intelligent computer-aided instruction systems, distance learning systems, and collaborative learning environments. Examples of Learning Objects include multimedia content, instructional content, learning objectives, instructional software and software tools, and persons, organizations, or events referenced during technology-supported learning.

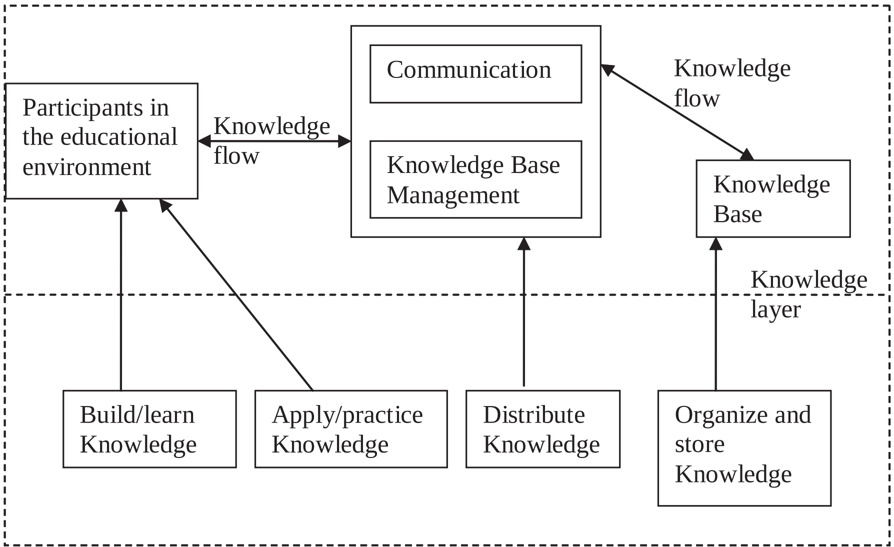
"Learning" is a process in which learners obtain and understand information and knowledge from knowledge bases. How information and knowledge is acquired, stored, represented, accessed, updated, and transferred in an educational environment will determine how effective and efficient the educational system and learning process will be. According to Taylor (Taylor, n.d.), knowledge management is about using models, methods, structures, and techniques for better management and organization of resources. Knowledge management as an ongoing management process is to be embedded in the knowledge-based system. The purpose of knowledge management is to enable effective usage of information and human resources, and based upon this, to act intelligently and be more flexible, and as a result, to be able to improve basic processes of research, production, and maintenance.

Implied in the term "knowledge management" is the notion that every knowledge-based system possesses knowledge and needs mechanisms to gather, store, manipulate, and manage it in order to accomplish the most effective usage of the knowledge.

Karl Wiig described four main knowledge flows functions (Wiig, 1995):

- Building knowledge is achieved through learning, importing knowledge from existing resources, or creating new knowledge through research and development.
- Knowledge is stored in memory, knowledge bases, books or other written materials, videotaped instruction material, and organized in order to be available for specific purposes.
- Knowledge is distributed by assembling relevant knowledge from different sources and distributing it to places of use, and is pooled by assembling different persons in a team and by exchanging knowledge between them.
- Knowledge is used when it is needed to apply to work objects. Value is added by using knowledge to make products or to provide services. Here, the value of knowledge is realized.

Figure 1. Knowledge layer in networked education



Diana and Aroyo used Figure 1 to show where these function are fulfilled (De Diana).

The approach does not specify the details about communication and knowledge base management modules, and there may exist many different ways to implement them. The main advantage of using an agent-based approach in educational systems is that the central control function is devolved to different agents, and there is no need for a centralized control process to oversee the communication and interaction and database management among learners, interfaces, and databases. This results in a robust system with better performance, more availability, and a more customized student learning session (Bruff, 2000).

Diana and Aroyo (De Diana) pointed out that the main tasks and knowledge involved in education can be divided into two levels: (a) tasks and knowledge related to learning and instructional processes and (b) tasks and knowledge (knowledge about knowledge, which is knowledge about how to manage knowledge in the first level) related to the organizational and management level. This two-level model reflects the necessity to separate the knowledge to be learned from managing knowledge (metaknowledge). We will talk more about this in the following sections.

MULTI-AGENT-BASED EDUCATIONAL ENVIRONMENT

Wooldridge and Jennings (Wooldridge, 1994) gave one of the most comprehensive definitions of agents:

…a hardware or (more usually) a software-based computer system that enjoys the following properties: autonomy—agents operate without the direct intervention of humans or others, and have some kind of control over their actions and internal state; social ability—agents interact with other agents (and possibly humans) via some kind of agent-communication language; reactivity—agents perceive

their environment and respond in a timely fashion to changes that occur in it; pro-activeness—agents do not simply act in response to their environment, they are able to exhibit goal-directed behavior by taking initiative.

We call agents used in an education environment the "educational agents." The role of the educational agent is to provide task-related feedback and assistance to the learner and to guide the learner through the learning process and help the learner reach his or her learning goals. In an education environment, multiple agents are usually involved, and each agent plays different roles. There are two aspects to be considered in designing and building educational agents:

- Reusability: Reuse agents in different kinds of systems and environments.
- Interaction: In an environment containing multiple educational agents, tutor agents interact with each other and customize their behaviors based on the behaviors of other agents in the environment.

Norrie and Gaines proposed the following agents in an agent-oriented model for an education environment (Norrie, 1995):

- Knowledge Agent has knowledge in a particular area.
- Knowledge Server Agent stores, retrieves, and manages knowledge; answers queries; and provides information by inferring or reasoning using the stored knowledge bases.
- Interface Agent serves as an interface to learners, monitors and learns from the user's actions, and then functions as an intelligent assistant.
- Coach or Tutor Agent provides guidance to assist in the learning process.
- Mediator Agent coordinates the activities of other agents and resolves conflicts between them.
- Knowledge Management Agent provides the high-level coordination of knowledge activities, such as creation, assembly, manipulation, and interpretation of knowledge, within either an individual or a collective project.
- Information Search Agent searches for specific information and sends the results back to learners.
- Directory Agent points to an appropriate agent, service, or resource.
- Mentor Agent is envisaged as acting in a rather analogous way in the learning environment, as a kind of coach for the higher-level strategies of learning.

Bruff and Williams illustrated an agent-based intelligent tutoring system architecture with the following three kinds of agents:

- Knowledge Management Agent responds to requests from other agents.
- Student Agent is assigned to each student and manages the evolution of a student model, which may include a representation of the student's current knowledge and history about the topic and the student's personal goals and preferences, etc. The student agent's goals will typically vary from student to student or from time to time, even for the same student, and can be customized by a third party such as a human tutor. These goals determine the learning strategies and tasks to be used during a given learning session. The learning strategies together with the database describing the current state of the agent and its knowledge about the student's capabilities will largely control the agent's behaviors, that is, a customized agent for each individual learner.
- Inference Agent provides preset inference mechanisms, which include a group of agents, such as deduction, abduction, and induction agent, belief revision agent,

possibility reasoning agent, nonmonotonic reasoning agent, and theory extraction agent, etc.

In general, all these three kinds of agents can be called tutoring agents, which are able to interact and cooperate with the student for tutoring and learning purposes. In the above architecture, we have three kinds of agents, and we assign more functions to each agent. Many different architectures have been proposed for an agent-based tutoring system. For example, Silveira and Viccari (Silveira, 1998) proposed several different agents: curriculum manager (the agent responsible for registering and controlling the curriculum attended by the students); agent communicator manager (the agent responsible for the agent's society administration and for controlling the communication between agents); interface communication (the agents responsible for peer-to-peer communications between the student's environment and the network environment); and presentation manager (the agent responsible for the browser control in the student's environment). In a finer model, every tutoring agent will perform only one tutoring function. All of these functions should be performed as session-based actions. Tutoring functions may include the following (Morin, 1998):

- Select a subject element.
- Format and present a subject element.
- Format and present an explanation of a subject element.
- Compare different concepts.
- Select, format, and present an example.
- Answer a student's question.
- Evaluate the student's answer to a system-asked question.
- Send feedback to a student about his answer to a system-asked question.
- Diagnose a student's behaviors.
- Update student model.

Tutoring systems for different courses or topics, or for students with different backgrounds, may have different preferences or requirements on system architecture (types and amount of agents, their responsibilities and interactions), and there is no existing universal architecture that will fit all. When designing agents for a learning environment, we have to understand the requirements of the to-be-built learning system first, consider the backgrounds and goals of its users, determine the types and numbers of agents we need, predict the interactions among them, and assign tasks accordingly.

KNOWLEDGE MANAGEMENT FOR A TUTORING SYSTEM

Knowledge is a principal factor that makes personal, organizational, and societal intelligent behavior possible (Wiig, 1995). Knowledge management consists of activities focused on the organization gaining knowledge from its own experience and from the experience of others, and on the judicious application of that knowledge to fulfill the mission of the organization (Wiig, 1995). In the context of a learning environment, such an organization consists of a group of students. These activities are executed by integration of technology, organizational structures, and cognitive-based strategies to convey existing knowledge and produce new knowledge. The critical step is the enhancement of the cognitive system in acquiring, storing, and utilizing knowledge for learning, problem solving, and decision making.

Knowledge management is stated as the management of the organization (an individual student or a group of students in our context of learning environment) toward the continuous renewal of the organizational knowledge base, which may include the creation of supportive organizational structures, facilitation of organizational members, application of IT instruments, with an emphasis on teamwork and diffusion of knowledge (as in groupware) (Bertel). As such, knowledge management is a strategy that turns an organization's intellectual assets (recorded information and the talents of its members) into greater productivity, new value, and increased competitiveness.

For a tutoring system, obviously we need a framework that can support knowledge management: a framework that offers a computational environment in which well-represented knowledge can serve as a communication medium between students and their activities. The indicated framework can consist of a shared knowledge representation and mechanisms for customized routing of knowledge to appropriate students (De Diana).

Models, methods, tools, and techniques for effective knowledge management become increasingly available, which is very important for education, because learning is a highly interactive process, and different kinds of knowledge are transferred among learners, tutoring systems, and human tutors.

An essential aspect of knowledge is that it is contextualized and dependent. This is the reason why knowledge is so difficult to acquire, represent, access, and transfer. Bruff and Williams pointed out that intelligent tutoring systems have to provide mechanisms to deal with the following interrelated knowledge-modeling problems (Bruff, 1999):

- Uncertainty of knowledge
- Conflicts among knowledge
- Dependency among knowledge
- The problem of knowledge granularity
- Incompleteness of knowledge, i.e., all relevant knowledge may not be known
- Fusion of knowledge, where knowledge is merged from different sources
- Revision of existing knowledge base when new knowledge is obtained (This new knowledge may be inconsistent with the existing knowledge base.)

Knowledge that is uncertain or incomplete may need to be revised and refined over time. Therefore, revision of a knowledge base is closely related to modeling both the uncertainty and the incompleteness of information. If readers are interested in these topics, more references can be found in Further Readings section at the end of this chapter.

Besides the problems of knowledge incompleteness, updating, conflicts, granularity, and uncertainty, one of the problems from knowledge modeling in an agent-based tutoring system is dealing with different kinds of knowledge. We discuss how to manage these different kinds of knowledge existing in a tutoring system in the following subsections, which are based mainly on the research by Morin (1998):

1. Domain knowledge (conceptual and procedural) (DK)
   Domain knowledge is the real knowledge we want to teach a student; it contains all conceptual and procedural aspects of the knowledge of one topic or area. Different topics or courses may have domain knowledge with different structures. Usually, domain knowledge may include concepts and relations among concepts, and often, these relations will organize concepts into a hierarchical structure, which will help the learning process greatly and provide a foundation for problem solving or inferential knowledge. For example, concepts can be basic entities like the binary tree or binary search tree. And, there is a "subclass of" relation between them.
2. Problem-solving knowledge (inferential) (PSK)
   Problem-solving knowledge is the knowledge that a student uses to learn domain knowledge. It is usually modeled and stored as procedures, and it contains inferential processes used to solve a problem using re-

lation information from domain knowledge (Lelouche, 1997).

3. Tutoring knowledge (TK)
   Tutoring knowledge includes information about common student errors and misconceptions. Tutoring knowledge is the most important knowledge, because it is the key for us to use to build a customized learning system for each student. This customized learning system can deliver appropriate individualized instruction to help students learn more effectively and efficiently. This ability depends heavily on the availability and accuracy of the information held about the student in the student agent, which holds different types and levels of sophistication of the knowledge and also includes methods with which to elicit and incorporate the new information into the student model.
   Tutoring knowledge is usually session-based, because it varies from topic to topic, from student to student, and from time to time, even for the same student. Moreover, to make a learning process more interesting and efficient, a tutoring system should use a variety of stimuli, such as multimedia techniques, to present a topic in different ways, even to the same student, and to change the ways of presentations of the explanations or answers provided to the student.

FUTURE TRENDS

We believe that agent-based tutoring systems will provide a means of dealing with the knowledge acquisition, revision, and transfer that are essential in a learning process. Agents will use a variety of communication and representation modes to help us to understand and make use of course materials or knowledge. We are sure that learning environments employing multiagents systems allow students, teachers, and courseware developers to add flexibility in achieving their learning objectives. To make such a system more helpful, future study may concern the following problems:

- Different architecture design for different courses, topics, or disciplines
  Because different courses, topics, or disciplines involve knowledge that is very different in presentation or nature, such as history and mathematics, we may need different knowledge management architectures and techniques for them.
- How will Internet technology affect an agent-based tutoring system?
  Modern tutoring systems should be Web-based to maximize accessibility. With the integration of Web technologies, further investigation on tutoring system architecture and knowledge management is needed.
- Cooperation between an agent-based tutoring system and existing software tools
  Existing software tools can help in the development of an agent-based tutoring system and provide insights to a better learning environment. Such cooperation can also help reduce costs.

FURTHER READING

Some researchers (Mizoguchi et al., 1988; Kono et al., 1992; Giangrandi & Tasso, 1995) applied truth (or reason) maintenance systems (TMSs) (Doyle, 1979; DeKleer, 1986) to overcome conflicts between new and old knowledge. The TMS identifies the conflicts, and some domain-specific reasoning system will resolve them. Huang and McCalla (1992) and Huang (1994) developed "Logic of Attention," a variant of the TMS that focuses on the parts of the student model and instructional planner that are relevant to the current subgoals. Bruff and Williams (2000) proposed an architecture in which the problem of conflicting information is resolved using methods based on the AGM paradigm for belief revision (Alchourron et al., 1985). Bruff and Williams used possibility theory (Dubois, 1992) to address the problems of uncertain information, nonmonotonic reasoning, and default logic (Reiter, 1980); the formalism (Antoniou, 1996) to process incomplete information; and Theory Extraction for fusion. Knowledge granularity has been widely discussed (e.g., McCalla & Greer, 1994). Levels of granularity fit naturally into the agent architecture and can be used to help the agent choose an appropriate plan.

CONCLUSIONS

In this chapter, we discussed how agent technology could be used in an education environment and how knowledge is managed in such a system. Although many problems remain to be solved, we believe that agents can model and manage knowledge in an appropriate way, and agent technology will be an important step to improve the effectiveness and efficiency of a tutoring system.

Chapter 2.44 The Use of Fuzzy Logic and Expert Reasoning for Knowledge Management and Discovery of Financial Reporting Fraud

Mary Jane Lenard
University of North Carolina – Greensboro, USA

Pervaiz Alam
Kent State University, USA

ABSTRACT

This chapter examines the use of fuzzy clustering and expert reasoning for the identification of firms whose financial statements are affected by fraudulent financial reporting. For this purpose, we developed a database consisting of financial and nonfinancial variables that evaluated the risk of fraud. The variables were developed using fuzzy logic, which clusters the information into various risk areas. Expert reasoning, implemented in an Excel spreadsheet model, is then used as a form of knowledge management to access the information and develop the variables continuously over the life of the company. At the conclusion of the chapter, the authors discuss emerging trends and future research opportunities. The combination of fuzzy logic, expert reasoning and a statistical tool is an innovative method to evaluate the risk of fraudulent financial reporting.

INTRODUCTION

In the light of recent reporting of the alleged financial reporting abuses in some of the major publicly-held companies in the U.S. (e.g., Enron and WorldCom), it has become increasingly important that management, auditors, analysts and regulators be able to assess and identify fraudulent financial reporting. This chapter is an attempt to use some of the latest statistical methods, expert reasoning and data mining techniques to achieve this objective.

Knowledge management can be used to a company's advantage in day-to-day decision-making. From a financial standpoint, a company must accumulate and disclose information to its employees, customers and investors. This information database can enable a company to support and maintain a competitive position. For instance, one way that a company can justify its financial health is by developing a knowledge management database of financial and nonfinancial variables to evaluate the risk of employee and financial reporting fraud. Collecting data using information processing and organizing the data through knowledge management can create a database for fraud detection and facilitate organizational data mining. Such a database can assist in knowledge discovery and help a company acquire and develop variables useful for the detection of fraud. The database can consist of historical data about the company as well as data for other companies in the industry. This database may be used by banks for lending decisions, by audit firms in an audit or by the company's management to gather and assess new information. These variables could also be evaluated to determine if the company has reached a stress level susceptible to fraud or for identifying fraud indicators.

The auditor's responsibility for detecting financial statement fraud is described in SAS No. 82, Consideration of Fraud in a Financial Statement Audit (American Institute of Certified Public Accountants (AICPA), 1997). Because fraud detection often involves an auditor's judgment in an unstructured environment, there is a possibility that the auditor may enhance the decision-making process with the assistance of a decision model. Using publicly available information, models can be designed to aid an auditor in detecting and evaluating financial statement fraud. Previous studies have focused on the examination of "red flags," or fraud risk factors, as likely indicators of fraud (Bell & Carcello, 2000; Pincus, 1989). Today, the auditor has the responsibility for detecting financial-statement fraud along with the audit of the company's financial statements.

This chapter presents a description, testing and summary of methods of analysis used in fraud determination. First, it is shown how financial and nonfinancial statement data (data based on analysis of company annual reports) can be used to develop membership coefficients that are evaluated in a fuzzy logic approach to data analysis. The fuzzy logic analysis applied to fraud detection is used to cluster the information into various risk areas. The cluster approach also identifies variables that can be used in a logistic regression (logit) model for fraud determination. Expert reasoning can then be applied to "mine" new information and develop the variables continuously over the life of the company. In this chapter, we also discuss the use of an additional fuzzy model for comparison purposes and to assess model accuracy. The chapter contributes to the fraud literature by incorporating a nonfinancial fuzzy logic variable in a statistical model.

The following sections of the chapter provide the background of fraud modeling and of fuzzy logic, and the methodology used to develop the study, including a description of the sample firms. The sample description is followed by a discussion of the financial variables that are developed and used in the models presented in the chapter. The discussion of variables includes a description of the research procedure that identifies nonfinancial variables used in the fuzzy logic clustering method. The next section presents results and analysis of the models. The last part of the chapter discusses emerging trends and future opportunities in this line of research, along with a conclusion.

LITERATURE REVIEW

Fraud Detection

When investigating financial reporting fraud, the auditor looks for “red flags” that might indicate a problem with the financial statements. Lists of questions that an auditor or an analyst should consider asking the client that may help raise red flags have been included in SAS No. 82 (AICPA, 1997), identified in previous studies and have been gathered for this chapter in consultation with auditing experts. SAS No. 82 provides over 30 red flags that may be used to detect fraud in financial statements, but it does not give any guidance of how these factors could be combined to detect fraud. Loebbecke, Eining and Willingham (1989) divided their list into low-, medium- and high-risk indicators of fraud.

Prior research shows that various kinds of decision aids may be used to assist the auditor in detecting financial reporting fraud. Pincus (1989) used a questionnaire and gathered data to predict the presence of management fraud. She found that subjects without the decision aid outperformed those who had the decision aid. Bell, Szykowny and Willingham (1993) used bivariate and cascaded logit to assess the likelihood of management fraud. Their model achieved within-sample correct classification of 97 percent on the fraud observations and 75 percent on the nonfraud observations. Hansen, McDonald, Messier and Bell (1996) used a generalized qualitative response model to predict management fraud. They reported 89.3 percent predictive accuracy over 20 trials. When they adjusted their model for asymmetric misclassifications costs, the model’s accuracy dropped to 85.5 percent but, at the same time, the rate of type II errors, or failure to predict fraud when it was present, decreased considerably. Bell and Carcello (2000) also developed a logistic regression model as a decision aid to assist in the auditor’s fraud decision.

More recently, studies have shown the effect of the company’s internal auditors, auditor tenure and auditor judgment in suggesting reasons for financial reporting failures. Church, McMillan and Schneider (2001) found that internal auditors assign a higher likelihood of fraud when income is greater than expected, and when there is a combination of restrictive debt covenants that impose high costs for additional borrowing and an earnings-based bonus plan for management. In research focused on a company’s external auditors, Geiger and Raghunandan (2002) looked for an association between auditor tenure and audit reporting failures. They found significantly more audit reporting failures in the earlier years of an auditor’s tenure, perhaps indicating a temptation to appease new clients or a lack of knowledge regarding specific tasks associated with a new client (Geiger & Raghunandan, 2002). Other research has examined factors affecting the generation of financial reporting alternatives in a setting where a client uses aggressive financial reporting. Johnstone, Bedard and Biggs (2002) found that auditors with high understanding of accounting rules are better able to negotiate with clients interested in aggressive financial reporting. By proposing various alternatives to a complex accounting issue, an auditor is able to convince the client to use a more conservative financial accounting alternative, thus minimizing the possibilities of a future litigation. These studies show that the auditor’s knowledge of the task or the ability to accumulate knowledge of the task is of utmost importance in the ability to detect fraudulent financial reporting.

Auditors may also use expert systems as a decision aid to assist in fraud determination. Eining, Jones and Loebbecke (1997) examined the effect that the use of an expert system has on auditor decision-making ability in detecting fraud. Their research showed that in allowing the interaction between the auditor and the system, the expert systems that have been used to assist auditors in complex decision processes often give results that are more accurate and consistent. Similarly, Whitecotton and Butler (1998) found that allowing decision makers to select information for the decision aid increases decision aid reliance.

Fuzzy Clustering

When data does not suggest a precise answer, decision makers often recognize patterns or can form groups in the data in order to make a decision (Alam, Booth, Lee & Thordarson, 2000). While discriminant and logit analysis assign observations to groups that were defined in advance, cluster analysis is the art of finding groups in data (Kaufman & Rousseeuw, 1990). Fuzzy set theory, introduced by Zadeh (1965), attempts to classify subjective reasoning (e.g., a human description of "good," "very good" or "not so good") and assigns degrees of possibility in reaching conclusions (Lenard, Alam & Booth, 2000). As opposed to hard clustering, where there is a clear-cut decision for each object, fuzzy clustering allows for ambiguity in the data, by showing where a solution is not clearly represented in any one category or cluster. Fuzzy clustering shows the degree to which (in terms of a percentage) an item "belongs" to a cluster of data. In other words, a data item may belong "partially" in each of several categories. The strength of fuzzy analysis is this ability to model partial categorization.

Lau, Wong and Pun (1999) used neural networks and fuzzy modeling to control a plastic injection-molding machine. They suggested that the neural network and fuzzy technology complement each other and offset the pitfalls of computationally intelligent technologies. Alam et al., (2000) also used a combination of fuzzy clustering and self-organizing neural networks, and were successful in identifying potentially failing banks. Ahn, Cho, and Kim (2000) reported results using these technologies to predict business failure, and stressed the importance of these predictions as useful in aiding decision makers. Lenard, Alam and Booth (2000) used fuzzy clustering to identify two different categories of bankruptcy. Companies placed in the second bankruptcy category exhibited more extreme values in terms of the financial ratios used in the study. Companies either showed much better results (such as a high current ratio) than would be expected for a company facing bankruptcy, or the companies showed very poor results, such as a much higher debt ratio than any of the other bankrupt companies in the data sample. Nolan (1998) used expert fuzzy classification and found that fuzzy technology enables one to perform approximate reasoning (e.g., as when a student assignment is graded as "very good" or "not so good") and improves performance in three ways. First, performance is improved through efficient numerical representation of vague terms, because the fuzzy technology can numerically show representation of a data item in a particular category. The second way performance is enhanced is through increased range of operation in ill-defined environments, which is the way that fuzzy methodology can show partial membership of data elements in one or more categories that may not be clearly defined in traditional analysis. Finally, performance is increased, because the fuzzy technology has decreased sensitivity to "noisy" data, or outliers. Ammar, Wright and Selden (2000) used a multilevel fuzzy rule-based system to rank state financial management. The authors used fuzzy set theory to represent imprecision in evaluated information and judgments.

METHODOLOGY

Sample

The sample of fraud firms was identified using the Wall Street Journal Index for the time period 1992 through 1997. Financial statement data for 30 fraud firms was matched with data from 30 healthy firms, for a total sample of 60 firms. The sample was then randomly divided into a training data set of 15 fraud firms and 15 healthy firms. The remaining 30 firms comprise the test data set on which the predicted results are evaluated. The data for the firms in the study were obtained from the 1998 Compustat tape.

Fuzzy and Logit Models

The fuzzy clustering procedure used here is called FANNY (Kaufman & Rousseeuw, 1990). The program FANNY uses "fuzziness" to partition objects by avoiding "hard" decisions, or clustering into fixed, definite categories. For each item in the data set, the algorithm provides k+1 pieces of information, where k is the number of clusters that are used in the clustering algorithm. The k+1 pieces of information are: Uiv , the membership coefficient of item i in cluster v, v = 1 ... k, and Si , the silhouette coefficient of item i. A higher value of Uiv indicates a stronger association of item i and cluster v. The silhouette coefficients satisfy the constraints $-1 \leq Si \leq 1$ and indicate how a well-clustered object uses average distances from its own cluster to the closest neighboring clusters. The closer Si is to 1 the better the clustering of an individual item. A value of Si close to -1 indicates that an item may be assigned to more than one cluster (Alam et al., 2000). The Euclidean distance measure is used to compute distances between objects and to quantify the degree of similarity for each object. The degree of similarity for each object i and j iscomputed as:

$$d(i,j) = \sqrt{(x_{i1} - x_{j1})^2 + (x_{i2} - x_{j2})^2 + ... + (x_{ip} - x_{jp})^2}, \quad (1)$$

where the pth measurement of the ith object is given by xip and d(i,j) is the actual distance between objects i and j.

For the testing of variables in this chapter, we used a logit model to determine whether a company is likely to commit financial reporting fraud. Our SPSS procedure, which runs the logit model, accepted a variable for entry into the model, if it had a probability of 0.05 or above.

Variables

Various financial accounting textbooks recommend using financial ratios from the three areas representing liquidity, leverage and profitability to evaluate the financial health of a firm (e.g., Meigs, Williams, Haka & Bettner, 2001). Bankruptcy studies recommend similar financial ratios for assessing the financial health of a firm (Altman, 1968; Ohlson, 1980; Mutchler, Hopwood & McKeown, 1997). Additional studies recommend that these variables use logistic regression or discriminant models to predict whether the auditor should modify the audit report to reflect that the firm may not continue as a going concern (Mutchler, 1986; Chen & Church, 1992; Lenard, Alam & Madey, 1995; Nogler, 1995). Person (1997) has suggested the use of a sales variable, or sales weighted by total assets (SATA), to identify what may be fictitious trends in growth. Because we have a relatively small sample size of 30 items each in the training data set and the test data set, we believe that a selection of three to five variables is appropriate. As a result, we have used one financial variable from each financial health assessment category of liquidity, leverage and profitability, based on the most frequently used and successful variables from previous studies. We have also used a second liquidity variable, representing cash flow from operations, because of the reliance on cash in fraud schemes as implied by the high-risk categories featured in the fraud questionnaire reported in this chapter. Therefore, the financial statement variables that are considered in our preliminary analysis of fraud assessment are: (1) CACL: current assets divided by current liabilities; (2) TLTA: total liabilities divided by total assets; (3) NITA: net income divided by total assets; and (4) CFOTL: cash flow from operations divided by total liabilities. CACL and CFOTL are liquidity variables. Healthy firms would have higher values of these variables than a stressed or an unhealthy firm. TLTA determines a company's leverage. A healthy firm would have a lower percentage of total liabilities divided by total assets than a stressed or an unhealthy firm. NITA is a profitability variable, generally referred to as return on assets. In summary, it is expected that for fraud firms the variables CACL, CFOTL and NITA will be relatively small than for healthier firms. On the other hand, the TLTA variable will be relatively large for fraud firms than for healthier firms.

Research Procedure

The first step in defining the nonfinancial variables is to develop a decision table based on all possible answers to a list of fraud questions ("Yes" answers equal high or medium risk; "No" answers equal low risk) as input into the fuzzy logic program. The list of fraud questions appears in Figure 1. These questions were gathered from SAS No. 82 (AICPA, 1997), and modified in consultation with an auditing expert, a manager at a "Big Five" accounting firm. This method of expert system development follows Gal (1985), who used one expert for knowledge acquisition and validation. The four risk categories, described in the questionnaire, are cash risk, earnings risk, industry risk and operations risk. All possible combinations of the answers to the fraud questions are then coded as input into the fuzzy clustering program. For example, cash risk can be low (score of 0) or high (score of 1). Each of the other categories can have low or medium risk — our expert felt that the cash risk was the only category that warranted a high risk. As a result, the risk of fraud is considered high for cash transactions and where fiduciary responsibility exists. Fraud risk can be low or medium in the area of earnings management, where specific industry conditions are indicated, or because of operational characteristics. The score for medium risk in the earnings risk or industry risk categories can range from 0.4 to 0.7. Medium risk for operations is scored as 0.5, if any one of the questions is answered "yes," otherwise risk is low (scored as 0). Again, the expert we consulted felt that any one "yes" answer reflected medium risk in the operations category. So a possible score combination could be a 0 (low) for cash risk, 0.4 (medium risk) for earnings risk, 0.4 (medium risk) for industry risk and 0.5 (medium risk) for operations risk.

The systematic coding of all the possible combinations resulted in 84 observations. These observations represent the database that is used for data mining. Based on membership coefficients of clusters produced by the fuzzy run, each decision situation (combination of high-, medium- and low-risk values for the fraud questions) is then assigned a fraud variable, one variable for each of the clusters produced by the fuzzy clustering program. Once the fraud questions are answered for a company in our data set, the particular observation from the knowledge base is retrieved, and the values of each fraud variable can be entered into the logit model. The logit model predicts the probability of fraud, and the fuzzy model is operationalized in an expert system rule-base or in an Excel spreadsheet, using the spreadsheet's logic capabilities. The logit model accomplishes the prediction of fraud using the financial statement variables and one or more of the fuzzy cluster variables.

RESULTS

We ran the fuzzy clustering program for the red flag indicators, using 2 through 6 clusters. For our variable choices, we used the fuzzy clustering run with four clusters (see Table 1). Table 1 shows the membership coefficients for the four closest hard clustering of each of the data items. The fuzzy clustering program computes Dunn's partition coefficient (Kaufman & Rousseeuw, 1990), which is the sum of the squares of all the

Figure 1. Excel spreadsheet: Implementation of the fraud questionnaire

Fraud Questionaire

Answer each of the questions in the boxes with a "Y" or "N"

Score	**"Y" or "N"**		**Risk Factors**
			Management's Characteristics and Influence
			Cash transactions / fiduciary responsibility - low or high risk
0	Y		Are all officer salaries and bonuses approved and disclosed?
0	Y		Are transactions legitimate / appropriate for stock compensation plans?
0	Y		Are related party transactions properly disclosed?
			Earnings Management - low or medium risk
0.1	Y		Must the company support a high stock price?
	N		Was last audit unqualified, does the company change auditors often?
0	N	OR	Does co. change / have more than one legal counsel, significant legal issues?
0			Is the credit rating high?
0.1	Y	OR	Is the credit rating satisfactory?
0		OR	Is the credit rating poor?
0	N		Is there domination by one person, or are there many officers, directors?
			Industry Conditions - low or medium risk
0.1	Y		Is there a high degree of competition, or is this a rapidly changing industry?
0	N		Are costs and expenses rising faster than sales and profits?
0			Concerning expansion of the business:
0			Is expansion slow?
0.1	Y	OR	Is expansion medium?
0		OR	Is expansion rapid?
0	N		Does co. have little variety of products, a narrow range of customers?
			Operational Characteristics - low or medium risk
0	N		Does the company have trouble meeting debt payments?
0	N		Are there unusual or highly complex transactions?
1	Y		Are there cash flow problems while also reporting earnings growth?
			Total Risk Analysis
			Low risk = 0, Medium risk = .4 through .7, High risk = 1
0			Management (Cash) Risk
0.5			Earnings Risk
0.5			Industry Risk
0.5			Operating Risk
			Link to database to find fraud category:

Link

membership coefficients divided by the number of objects. The normalized version of the Dunn's coefficient falls between 0 and 1, with a coefficient of 0 being completely fuzzy clustering and a coefficient of 1 being completely hard clustering. The normalized value of the coefficient for our model with four clusters was 0.21, which suggests a fuzzy clustering. The membership coefficient values show the portion to which the observation belongs to a cluster.

As noted above, the fuzzy run identified four clusters or variables. We introduced these four

ITS NORMALIZED VERSION = .21

Note: The membership coefficients represent the degree to which an observation belongs to a cluster. For instance, for observation 1, 35% belongs to cluster 1, 28% to cluster 2, 19% to cluster 3, and 18% to cluster 4. The combined "belonging" percent adds up to 100%.

variables along with the four financial statement variables in a logit run. We achieved the highest prediction when only one of the fuzzy variables, FR_1, and the four financial statement variables were used. Results of the logit run, containing five variables and using the training set of 30 firms, appear in Table 2, Panel A. The dependent variable is coded as 1 for fraud firms and 0 for healthy firms. The classification accuracy of the model in the training set is 80.0 percent and the fraud variable is significant. Overall accuracy rate in the test data set is 86.7 percent (see Table 2, Panel B). It is interesting to note in Table 2, Panel A that the sign of the coefficient of the variable CACL is not in the anticipated direction for firms reporting financial reporting fraud. But this variable is one that a company would want to disguise, if they were trying to commit fraud. In addition, by including the fuzzy variable (FR_1), we have operationalized the use of fuzzy logic, which is also the significant variable in our logit regression. The negative sign of the FR_1 coefficient indicates that the probability of fraud is low, when the value of the FR_1 variable is high. Companies with higher values of this variable have lower cash and operating risk. An important component of this analysis is that the auditor or the analyst still gets to apply judgment in responding to fraud questions (see Figure 1), but now has quantitative support for the decision about whether there is fraud in the financial statements.

Sensitivity Analysis

Logit Results

Since the logit model presents its results in terms of a probability, we can analyze the model based

Table 2. Panel A: Results of logistic regression for fraud vs. healthy companies with selected financial variables and a fraud variable

Variable	Expected Sign	Coefficient	T-Value
TLTA	+	1.3402	0.8966
CFOTL	-	- 7.0083	- 0.9811

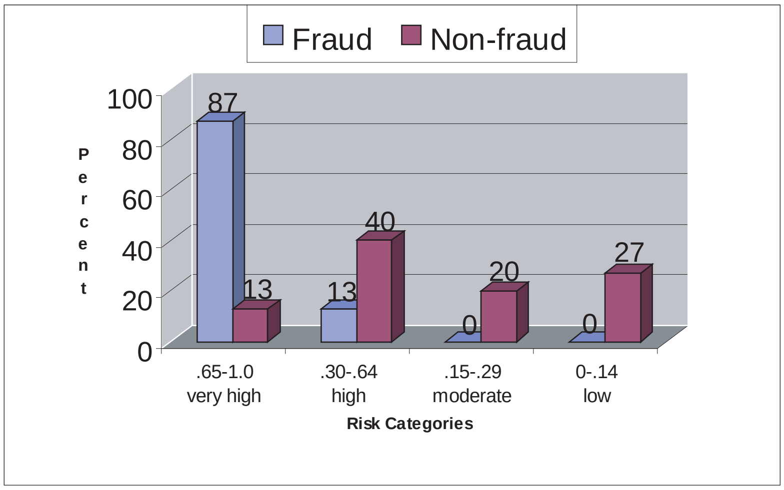
on the likelihood estimate of fraud occurrence. In our model represented in Table 2, we used a cutoff point of 0.5, meaning that a probability of 0.5 or above predicts a "fraud" company. In order to analyze the value of a cutoff point in determining the fraud prediction, we followed the approach of Bell and Carcello (2000) and assessed prediction accuracy for a range of cutoff points from 0.05 to 0.95 (see Table 3). The results show that the logit model is quite sensitive to fraud prediction because the highest accuracy is when the cutoff point for fraud is 0.65 or above. Using this cutoff point, 87 percent of fraud companies and 87 percent of nonfraud companies are correctly classified. That means there are still two nonfraud companies that exhibit fraud characteristics in our test data set. However, that also means the remainder of the fraud companies are correctly classified. We represent this analysis graphically in Figure 2. If we use four subjective fraud categories, representing the risk of fraud as low, moderate, high or very high, according to cutoffs of 0-0.14, 0.15-0.29, 0.30-0.64 and 0.65-1.0, respectively, we see that 87 percent of the fraud companies in the sample are in the very high category. But 40 percent of the nonfraud companies are still in a high-risk category, with a fraud prediction between 30 percent and 64 percent. However, this is possible for companies that have complex transactions that should be looked at more closely.

Fuzzy Clustering

Fuzzy clustering can also be used on the test data set itself, using the variables previously defined in our analysis. This is done for comparison purposes to assess the accuracy of our logit model and also to gain more knowledge about whether a company belongs in a fraud or nonfraud category. As mentioned earlier, fuzzy clustering finds groups in data, instead of assigning data to groups that were defined in advance. The variables that

Figure 2. Graphical categorization of classification accuracy for logit model in various risk categories



achieve a definitive analysis for fuzzy clustering are the financial statement variables SATA, TLTA, CFOTL and NITA and the fraud variable, FR_1. Again, we have maintained the CFOTL variable for liquidity analysis, the TLTA variable to represent leverage and the NITA variable to analyze profitability, along with the SATA variable for firm size. When the test data set is grouped into three clusters, there is a group representing fraud companies, a group representing healthy companies and a mixed group (see Table 4).

The fraud group (cluster 2) has one misclassified firm and the nonfraud group (cluster 3) has two misclassified firms, for a total classification accuracy of 27/30 = 90.0 percent. In the mixed group (cluster 1), the healthy firms that are included are firms 17, 21, 22 and 26. These firms are also classified as marginal firms or fraudulent firms by the logit model. Using the logit model from Table 2 and the analysis of Figure 2, firm 17 has a predicted probability of 0.39, which is in the high-risk group. Similarly, firm 22 has a predicted probability of 0.63, also in the high-risk group. Firm 21, with a predicted probability of 0.98, is in the very high-risk group, while firm 26 is in the moderate-risk group, with a probability of 0.16. For those fraud firms in the mixed group, firm 2 has a predicted probability of fraud of 0.64, which is in the high-risk group. Firms 1 and 6, with predicted probabilities of 0.78 and 0.96, respectively, are in the high-risk group but share similar characteristics to those of the nonfraud companies in the mixed group. So the fuzzy clustering provides additional support for our logit analysis, by creating a separate cluster that includes nonfraud firms that are uncharacteristic of other nonfraud firms and may require closer scrutiny.

Implementation of the Data Mining Application

The determination of the fraud variable, FR_1, for inclusion in the logit model is implemented in an Excel spreadsheet. The spreadsheet runs like an application, with the components of the application linked by macros. A flowchart of the process is depicted in Figure 3.

PARTITION COEFFICIENT OF DUNN = .34
ITS NORMALIZED VERSION = .01

Figure 3 indicates that the process starts with the questionnaire, which uses the logic features of Excel to build a rule-base and compute a score for fraud analysis (see Figure 1). As stated previously and shown in Figure 1, the cash risk (or management risk), can have low risk (a score of 0) or high risk (a score of 1). Each of the other three categories (earnings risk, industry risk and operations risk) can have low or medium risk. The medium-risk scores for earnings risk and industry risk can range from 0.4 (a "yes" answer to one risk question) to 0.7 (four "yes" answers). The medium-risk score for operations risk is 0.5 (a "yes" answer to any of the risk questions). When the spreadsheet has displayed the score for each risk factor, the user presses the "Link" button to progress to the data-mining feature and is instructed through the process that will result in a match of one of the 84 fraud combinations (see Figure 4).

Once the fraud combination has been retrieved, or "mined," from the database, the fraud variable that has been derived for that situation from the fuzzy clustering run can be located. Then the user can link to the model page and enter the fraud variable and the financial statement variables into the spreadsheet. In each cell that is requesting a financial statement variable, the user can double click and see a definition of the variable, described

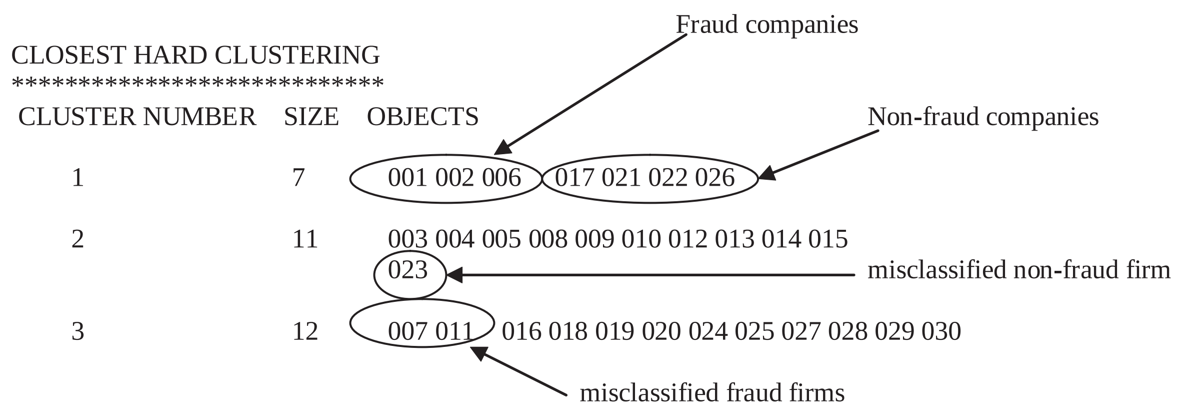

Figure 3. Flowchart: Implementation of the data mining application

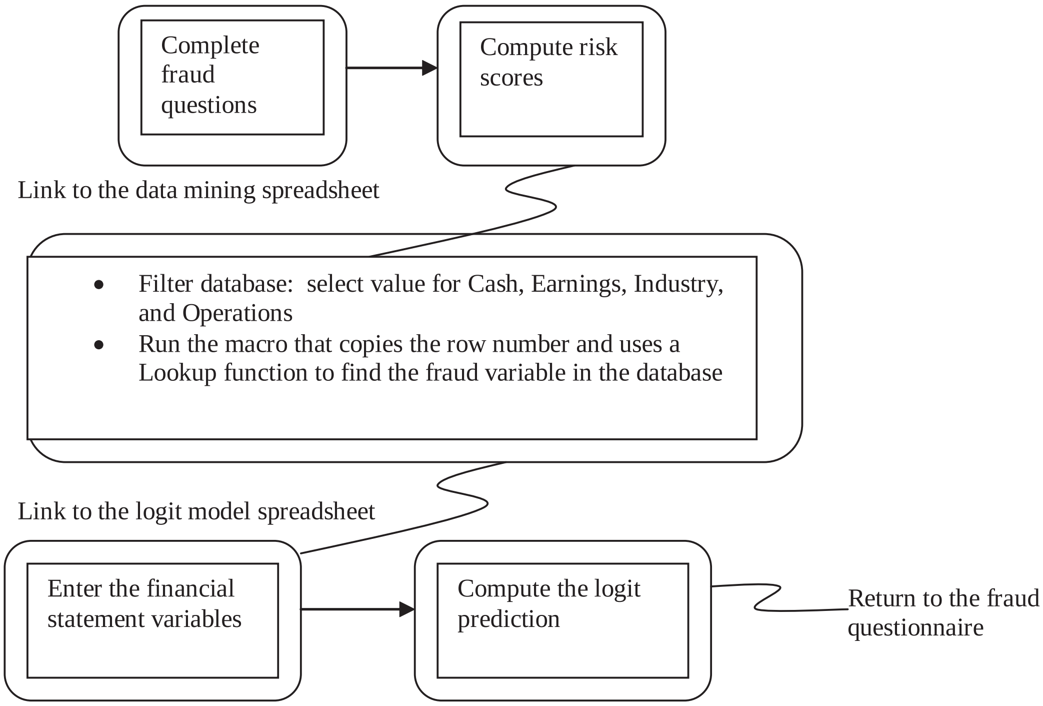

Figure 4. Excel spreadsheet with data mining capability

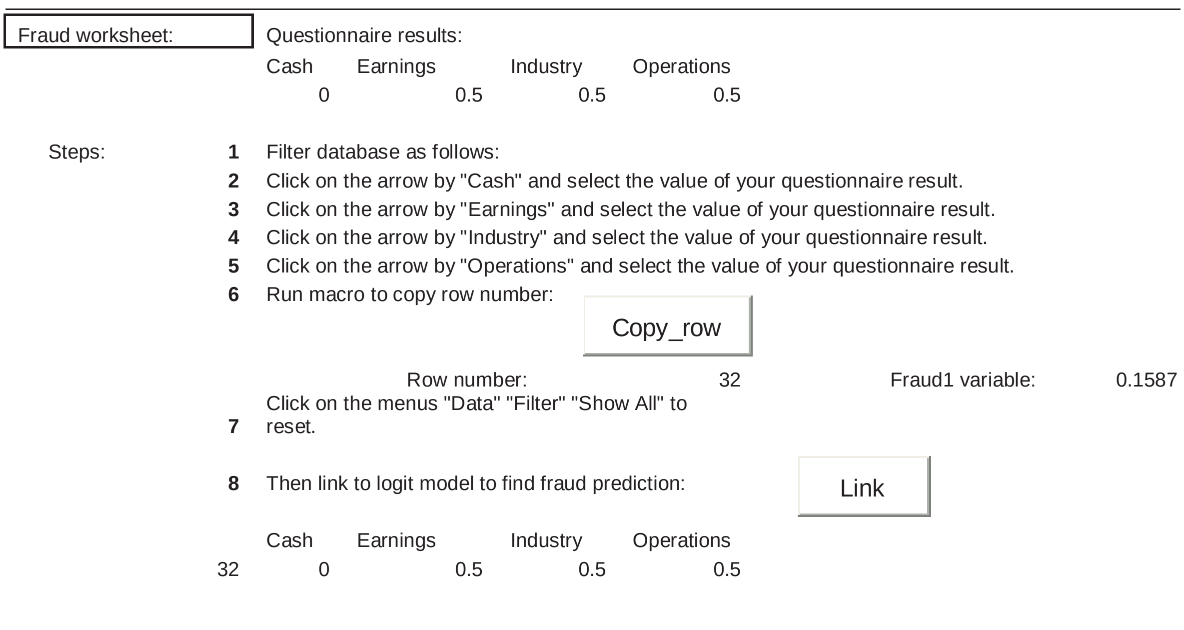
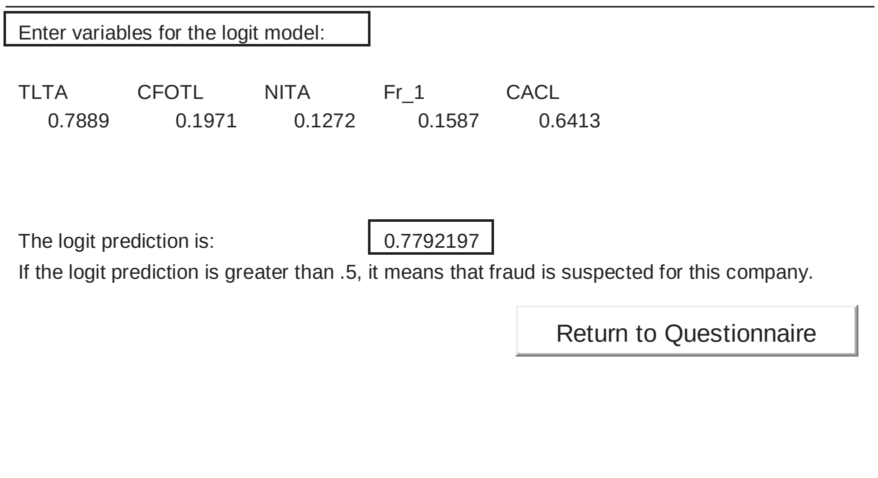


Using the "Auto Filter" feature of Excel, the above figure shows that for this particular example, with cash risk of 0, earnings risk of .5, industry risk of .5, and operations risk of .5, the row in the database that matches this score is line 32, and the value of the fraud variable, FR_1, at this location is .1587.

Figure 5. Excel spreadsheet implementation of the logit model



On this page of the spreadsheet application, each of the variables is explained using the "note" feature of Excel (not visible in this reproduction). TLTA is total liabilities divided by total assets, CFOTL is cash flow from operations divided by total liabilities, NITA is net income divided by total assets, FR1 is the fraud variable derived on the previous page with the data mining feature, and CACL is current assets divided by current liabilities. We make our recommendation of whether to suspect fraud based on the convention used by the logit model, which is that a value or "prediction" of .5 or above from the logit equation is an indication of fraud.

using Excel's "Note" feature. The spreadsheet is programmed with the logit equation and automatically computes a prediction (see Figure 5). This prediction is the probability that a company fits the characteristics of a fraud firm.

CONCLUSION

This chapter has introduced a procedure, implemented through the use of fuzzy logic, to show that red flags in a company's annual audit do contribute to the information that is available to assist in the decision about whether the company may commit financial statement fraud. By using the fuzzy logic model to develop clusters for different statements representing red flags in the detection of fraud, nonfinancial data can be operationalized and included with financial statement variables as a database for knowledge management and discovery of fraud.

Emerging Trends

Financial statement information is used by management, employees, outside analysts, investors and creditors to assess the health of publicly traded companies. Just as this information is now readily available through the Internet and online financial services, so should tools that help in the analysis of that information be readily available or easily obtainable. Although the data mining application described in this chapter is a research model, its implementation through the use of an Excel spreadsheet emphasizes its portability. The application can easily be downloaded for individual use, and the database can be easily updated. It then becomes an important tool for all users.

Future Research Opportunities

The data mining model in this study has been used on a limited basis with a relatively small sample of firms. Further study in fraud research could result in a larger database that involves a more detailed questionnaire. This approach can also be applied to other unstructured decisions. Specifically, in the field of auditing, there is the auditor's decision, reflected in the audit report, about whether the company can continue as a going concern. The auditor uses the analysis of financial variables and a framework of questions to make this judgment. The auditor also applies judgment in the consideration of materiality. Materiality judgment is closely linked to the analysis of fraud, because the auditor must decide the extent to which a discrepancy will affect the financial statements. These decisions can be supported by the use of data mining tools and provide a continuing demand for the development of knowledge management.

ACKNOWLEDGMENTS

We are thankful to D. Dennis for helpful comments and suggestions, and to Casey Harrington for the research work. Earlier versions of this chapter were presented at the 2000 Decision Science Institute, Southeast regional meeting and at the 2001 Ohio regional meeting of the American Accounting Association.

Chapter 2.45

Enhanced Knowledge Warehouse

Krzysztof Wecel

Witold Abramowicz
The Poznan University of Economics, Poland

Pawel Jan Kalczynski
University of Toledo, USA

INTRODUCTION

Enhanced knowledge warehouse (eKW) is an extension of the enhanced data warehouse (eDW) system (Abramowicz, 2002). eKW is a Web services-based system that allows the automatic filtering of information from the Web to the data warehouse and automatic retrieval through the data warehouse. Web services technology extends eKW beyond the organization. It makes the system open and allows utilization of external software components, thus enabling the creation of distributed applications.

The enhanced knowledge warehouse is an add-in to the existing data warehouse solutions that offers a possibility of extending legacy data-based information resources with processed information acquired from Web sources of business information.

eKW is characterized by transparent filtering and transparent retrieval. The system automatically acquires interesting documents from Web and internal sources and enables business users, who view data warehouse reports, to access these documents without the necessity of formulating any document retrieval queries. Instead, the system takes advantages of meta-information stored in business metadata and data warehouse reports, and builds and runs appropriate queries itself. The system also has an event-alerting capability.

eKW, by design, is a part of the semantic Web. The main role of eKW in the semantic Web is mediation between the world (external information) and internal information systems utilized within the organization. One of the most popular ways of conforming to semantics is to use ontologies, which provide a means for defining the concepts of the exchanged data. eKW is a kind of data mediator that employs ontologies as a conceptualization layer (W'cel, 2003).

BACKGROUND

Document management systems may be divided into two major categories: information retrieval (IR) and information filtering (IF) systems.

The classical models of information retrieval systems were defined by Salton (1983). As distinct from structured data management, information retrieval is imprecise and incomplete. This is due to the inaccurate representations of document contents and user information needs. The distinctive feature of information retrieval systems is a relatively constant document collection. The collection stores documents and their representations (indices). When a user submits a query to the information retrieval system, the query is compared against all indices in the collection. Documents whose indices match the query are returned as the resulting subset of the collection. Most search engines on the Web and digital libraries available on the market can serve as examples of information retrieval systems (Baeza-Yates, 1999).

The main objective of information filtering systems is to block unwanted information from the incoming stream of documents. As distinct from IR systems, filters do not have any fixed collection of documents. Instead, they hold a collection of standing queries (profiles). The profiles represent long-term information interests of their owners. When a new document arrives at the filter its representation is created and compared against all profiles in the collection. Some libraries maintain systems that inform users about new volumes included in the library. Such systems are usually based on the server-side filtering architectures and their profiles usually consist of semi-structured elements (e.g., author, subject, title). This idea is referred to as selective dissemination of information (SDI).

JUSTIFICATION

Possessing and maintaining large information resources does not itself provide any guarantees that users will manage to find the piece of information (document) they need. First of all, users must be aware that the particular piece of information already exists in their resources. Yet, even if they are aware, searching may be very labor consuming. Such a situation is highly undesirable for organizations, as they do not exploit their potentials to increase the effects. That is why knowledge management is nowadays considered the capability of re-use of information and is becoming an increasingly vital issue.

Usually, users are not eager to learn how to operate in several different information systems. Integration of information resources enables the exploitation of the capabilities of many systems through a single user interface (UI). Data warehouse users should be capable of finding interesting documents through a single UI. Not only should the users be aware that the desired information does exist, but also relevant documents should be disseminated to them mechanically. Such a mechanical distribution of the relevant information gives more time for other tasks.

Business users have certain problems with finding information sources, building correct retrieval queries and formulating proper filtering profiles. Thus, introducing the system capable of relieving the users from the necessity of formulating queries and solving the most commonly reported problems with accessing information on the Web would increase productivity of those seeking relevant external information.

The constantly growing number of content providers and the exploding volume of business information are not accompanied by the corresponding growth of capabilities of exploitation of the resources by the contemporary organizations. Therefore, automatic acquisition, organization and presentation of information became not only possible but also essential for the performance of today's businesses.

THE IDEA OF EKW

The term data warehouse was defined by Bill Inmon in 1992 as a collection of integrated, subject-oriented databases to support the DSS function, where each unit of data is relevant to some moment in time. Since then a rapid growth of this relatively new idea has been observed.

In the eKW model, Web documents are assumed to be business news published in English by major content providers on the Web (e.g., Reuters, Cnn.com), because this type of external information is the one in favor of business people (Abramowicz, 2000; Webber, 1999). The solution proposed is based on the existing standards in the area of data warehousing, document management, communication among software agents, internetworking and storage.

The basic idea of data warehousing is to create a data model common for the whole organization (metamodel). The model provides a framework for uploading legacy data, stored in heterogeneous databases across the organization, to the warehouse. Before data are uploaded they need transformation that includes filtering, consistency check, field mapping and aggregation.

Data warehouses proved to be useful for the purpose of legacy data analysis and they are commonly implemented by organizations. They provided novel data processing techniques like data mining, basket analysis, dimensional data analysis, drill-down, drill-through or slice-and-dice. These techniques are based on the characteristic features of data and information stored in the data warehouse: non-volatility, relevance to some moment in time (timeliness), correctness, consistency, completeness, business subject orientation, and business descriptions in metadata (Adelman, 1997; Kimball, 1996).

In terms of the data warehouse, metadata1 (warehouse metadata) are data about data. Metadata consist of facts and events concerning database objects. Metadata are usually stored in a database referred to as the metadata repository or the metadata collection. Nowadays, metadata are considered to be an integral part of the data warehouse (Gleason, 1997; Inmon, 1999).

Due to its destination and the sophisticated methods of data processing, the enterprise data warehouse is often claimed to be the corporate knowledge repository. However, we argue that information derived only from structured information (data) produced by the organization is just a fraction of corporate knowledge that may be stored in the repository.

As distinct from database systems, document management systems deal with unstructured and semi-structured information. Because machines are not capable of understanding text, they must rely on mathematical representations of the document content and user information needs.

The most distinctive feature of eKW is that information acquisition, organization and dissemination are performed without any additional actions taken by data warehouse users. In particular, no formulation of keyword-based queries is necessary to access external business news relevant to user information needs. Instead, the queries are formulated mechanically based on business metadata and information stored in the enterprise data warehouse. The system mechanically collects external documents that are potentially interesting to users and stores them in the local collection. Business users who access corporate data are mechanically supplied with documents that match both the context of the data accessed and user interests at the same time. In this way users have easy access to relevant information resources acquired from outside the organization. These resources are being continuously extended and integrated with the data warehouse. In this way enhanced knowledge warehouse provides a framework for more effective (faster and based on more relevant information) decision making in the organization.

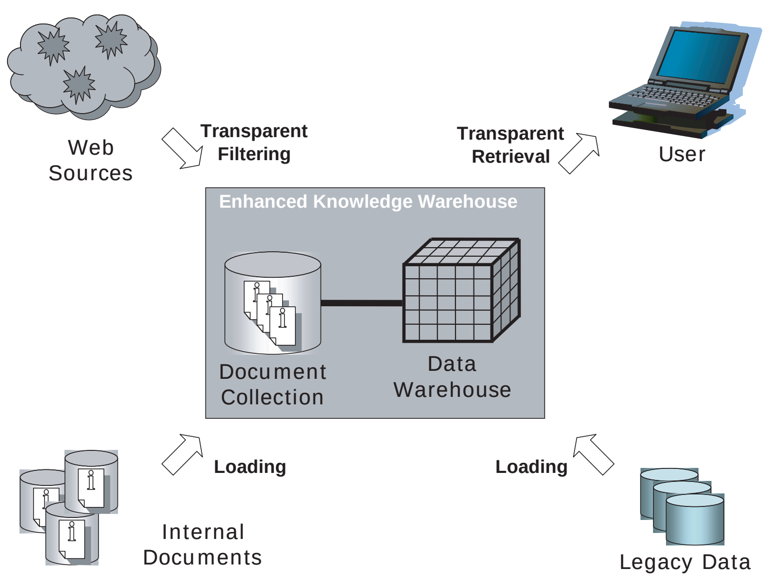
Based on the previous experience with augmenting documents and data, we decided to create a model that would relieve business users from the necessity of connecting to diverse and volatile sources on the Web, formulating queries, and browsing through the results. In order to do this, our system must be capable of mechanical information acquisition from Web sources, adding appropriate descriptions (indices) and precise information retrieval. The first two features imply a continuous series of actions, while the latter requires a trigger that makes the retrieval part of the system run.

The four arrows in Figure 1 represent main processes in the system. The process of loading legacy data to the data warehouse is a typical warehouse loading process defined by the organization. The process of loading internal documents is based on the principles of loading a digital library. In other words, there are two processes that distinguish the enhanced data warehouse model: transparent filtering (continuous) and transparent retrieval (spontaneous). The prefix "transparent" indicates that both processes are see-through for business users.

The enhanced knowledge warehouse is composed of the following Web services that can act independently:

a) Library Service, an implementation of data warehouse library
b) Profiling Service, responsible for data warehouse profiling
c) Filtering Service, responsible for retrieving business information from the Web utilizing filtering machine
d) Indexing Service, responsible for organizing the documents in DWL (Indexing parser)
e) Reporting Service, the front office of the system, responsible for delivering the results to the users.

Figure 1. Overview of the enhanced knowledge warehouse



FUTURE TRENDS

Although both document management and data warehousing systems are designed to supply business users with relevant information that is necessary to solve business problems, they are usually implemented and used separately. Most often, there is no system to store, organize and disseminate information published on the Web. This forces users, who need a broader view of business, to switch between data warehouse applications and content providers on the Web. The latter are usually overloaded with information, require navigation and formulating queries, entering passwords and flood users with commercials. Researchers report that the two most wanted attributes of external information sources are speed and convenience (Webber, 1999), whereas most sources cause frustration and discourage business users from taking any advantages of information available on the Web.

Therefore, the main future trend will be the integration of documents and data. In the eKW model, the problem of consistency of warehouse data and Web documents is addressed.

CONCLUSIONS

Enhanced knowledge warehouse model has certain advantages for business users over non-integrated solutions: instant/extended search, cross-organizational knowledge exchange, personalized event-alerting, and continuous information acquisition.

Because the amount of information produced by content providers on the Web is growing, it is impossible for a human user to process it in the traditional way. Web searches cause frustration, rarely lead to success and waste precious time. eKW was designed to help business people extend their knowledge about the organization by supplying them automatically with documents acquired from Web sources, relevant to their current context and information needs. Transparent filtering function mechanically collects documents potentially interesting to the organization, describes them with commonly accepted terms, and organizes them according to the existing business metadata. Transparent retrieval function supplies data warehouse users with documents relevant to their contexts and their personal interests in business information. The contexts are mechanically extracted from the state of the currently browsed report and personal needs are based on implicit feedback.

The enhanced knowledge warehouse system supplies business users with information based on the legacy data extended by information acquired from the business environment. This gives additional possibilities of business data analysis and provides a framework for better understanding of business processes related to the organization.

Chapter 2.46
Autopoietic Approach for Information System Development

El-Sayed Abou-Zeid
Concordia University, Canada

INTRODUCTION

In the last decade a new generation of information systems (IS), such as enterprise resource planning, Web-based information systems and knowledge management support systems, have emerged in response to ever-changing organizational needs. As these systems are socio-technical phenomena in which social and technical factors interweave the ways in which people work, the issue of "how to integrate the work activity and social context of users into the IS which is being designed" becomes one of the principal problems of IS development (Bai et al., 1999). Therefore, the need for new information system design theories is recognized. According to Walls et al. (1992), an "IS design theory" must have two aspects—one dealing with the description of the system and one dealing with the prescription, that is, the process of developing of the system. The prescription aspect includes a description of procedures and guidelines for system development. In addition, these two aspects have to be grounded on theories from natural or social sciences, that is, kernel theories. Therefore, the development of new IS design theories requires a closer look at the system theories that go beyond the traditional system theory that is based, among other things, on Cartesian dualism, that is, mind/body or cognition/action, and on a model of cognition as the processing of representational information (Mingers, 2001). One of the candidate theories is the theory of autopoiesis, which can be best viewed as a system-grounded way of thinking with biological foundations, together with its extension into social domain.

THEORY OF AUTOPOIESIS

In order to conceive of living systems in terms of the processes that realized them, rather in terms of their relationships with an environment, Maturana and Varela (1980) coined the word autopoiesis (autos = self, poienin = creation, production) to denote the central feature of their organization, which is "autonomy". The meaning of this word coveys the very nature of living systems as systems that maintain their identity through their own operations of continuous self-renewal. Moreover, these systems could only be characterized with reference to themselves and whatever takes place in them, takes place as necessarily and constitutively determined in relation to themselves, that is, self-referentiality.

One of the key concepts of autopoiesis is the distinction between organization and structure. On one hand, organization is the capability of a system to re-produce its identity by referring constantly to itself, through the alternate re-production of its components together with the component-producing processes, that is, the capability of a recursive self-reproduction. On the other hand, structure is the realization of a system's organization through the presence and interplay of its components in a specific realization space. While organization is necessary to establish system unity and identity, structure is necessary because different spaces of its actualization impose different constraints on systems' components (Maturana & Varela, 1980). By rough analogy, an algorithm for solving certain problem can be viewed as a description of the system's organization, whereas the corresponding computer program can be viewed as the realization of this organization (structure) in a certain space (programming language).

Autopoietic Systems

An autopoietic system is defined by Maturana and Varela as

"a network of processes of production, transformation and destruction of components. These components constitute the system as a distinct unity in the space of its actualization and they continuously regenerate and realize, through their interactions and transformations, the network of processes that produce them." (Maturana & Varela, 1980, p. 135)

Among the distinct characteristics of the autopoietic systems, the most relevant ones are:

- The simultaneous openness and closure. Autopoietic systems are open with respect to structural interaction with the environment, that is, structural openness, which is unavoidable consequence of the fact that system elements must satisfy the particular requirements of the physical domain in which they occur, while they are closed with respect to their own organization, that is, organizational closure. The recognition of the simultaneous openness and closure of autopoietic systems is in opposition to the tradition for which a system is one or the other but not both. This interpretation is possible only because of the clear distinction between organization and structure (Bednarz, 1988).
- Structural determination. The state transition a system undergoes in response to environmental perturbations is entirely determined by its structure at that time. Moreover, a system specifies which environmental perturbations may trigger which structural changes. In other words, the environmental perturbations could trigger the system's structural changes but can never determine or direct these changes. Moreover, a system specifies which environmental perturbations may trigger which structural changes. Over time, through ongoing interactions with the environment, an autopoietic system will experience what Maturana and Varela (1992) describe as a structural drift, or a gradual change to their structure. The nature of this change is determined by previous system's history of structural changes, that is, its ontogeny.

Higher-Order Autopoietic Systems

Two (or more) lower-order autopoietic systems can be "structurally coupled" to form higher-order autopoietic system. Structural coupling is the ongoing process of the congruent structural changes between two (or more) systems that results from recurrent interactions between (among) them. Therefore, structural coupling has connotations of coordination and co-evolution. Moreover, following structural determination principle, two structurally coupled systems means that each of them selects from its possible structural changes those which are compatible with those in the other system and, at the same time, are suitable for the maintenance of its identity.

Social systems, such as enterprises, are constituted through the process of third-order structural coupling, or social coupling, the one that occurs between (or among) two (or more) second-order autopoietic systems. However, the unique feature of any human social system, such as an enterprise, is that the social coupling among its constituents occurs through "language in the network of conservations which language generates and which, through their closure, constitute the unity of a particular human society" (Maturana & Varela, 1992, p. 196). From this perspective, language is viewed as an example of social structural coupling that generates the self and creates meaning through interactions with others. Moreover, language represents what Maturana and Varela would describe as a consensual domain, which is the domain of arbitrary and contextual interlocking behaviors (Mingers, 1995a, p. 78). Within a consensual domain, two autopoietic systems would be able to observe the attribution of meaning to common events and undertake coordinated actions.

Autopoiesis and Cognition

Cognition is the term conventionally used to denote the process by which a system discriminates among differences in its environment and potential states of that environment. The evidence for this cognition is effectiveness of system behavior in response to the environmental perturbations. Today's dominant perspective on cognition, and consequently IS, is the idea that effective action is explainable in terms of manipulating formal and static representations of the objective reality (Mingers, 2001).

According to theory of autopoiesis, perception is neither objectivist nor purely constructivist (Varela, 1992, p. 254). Rather, it is co-determined by the linking of the structure of the perceiver and the local situations in which it has to act to maintain its identity. This is the basis of enactive (embodied) cognition, which implies that the autopoietic system's activities condition that can be perceived in an environment, and these perceptions, in turn, condition future actions. In this view, "A cognitive system is a system whose organization defines a domain of interactions in which it can act with relevance to the maintenance of itself, and the process of cognition is the actual (inductive) acting or behaving in this domain" (Maturana & Varela, 1980, p. 13). In addition, cognitive domain of an autopoietic system is defined as the domain of all the interactions in which it can enter without loss of identity (Maturana & Varela, 1980, p. 119).

APPLICATIONS OF THE CONCEPTS OF AUTOPOIESIS IN IS DEVELOPMENT RESEARCH

The use theory of autopoiesis in IS research can be classified into two main categories: metaphoric and theory-oriented approaches (Beeson, 2001).

Metaphoric Approaches

Kay and Cecez-Kecmanovic (2002) used the concepts of social coupling and consensual domain to explain processes underlying the IS-organization relationship and how it impacts on the competitive advantage of an organization. They showed how processes of recurrent interactions between members of different groups, that is, analysts, the IS team, and external clients, within the organizations work environment gave rise to commonalities in understanding, which in turn enabled continual IS organization co-emergence. In the same vein, Maula (2000) used the concepts of structural openness and organizational closure to identify two major knowledge management (KM) functions in four consulting firms. The first KM function, sensory function, is the realization of the structural openness of the firm and its structural coupling with its environment. The second KM function, memory function, is the realization of the concepts organizational closure and self-referentiality that enable the firm's effective functioning and continuous renewal. Finally, Carlsen and Gjersvik (1997) used autopoiesis metaphor to analyze possible organizational uses of workflow technology. They argued against "generic" business processes except as starting points for organizational adaptation. In addition, they indicated that the concept of autopoiesis implies that process models should include references to richer descriptions of the organizational environment and the environment the work process is situated in.

Theory-Oriented Approaches

Bai and Lindberg (1999) used first and second order cybernetics, together with Luhmann's social autopoiesis theory (Luhmann, 1995) and Engeström's activity theory (Engeström, 1987) to develop a framework for studying the relationship between IS design activity, use activity, and the embedded social context. This framework sheds light on the complex social context within which IS development takes place, and provides an epistemological understanding of the relationship among the elements involved in IS development. Moreover, it can be used to develop methodologies for the practice of IS development, and guide various research activities, such as the socio-technical approach.

IMPLICATIONS FOR IS DEVELOPMENT AND RESEARCH

The autopoietic metaphor provides ways of thinking about the mechanisms underpinning the development and the introduction of IS in an enterprise. Here third-order autopoietic system is used as a metaphor to explore referential correspondence between the characteristics of autopoietic systems and an enterprise and its IS. For example, organizational closure of autopoietic system implies that it is homeostatic and its own organization is the fundamental variable to be maintained constant. This concept may be used to explain why the behavior of IS developers and users seems to be stuck sometimes in persistent patterns or repertoires (Beeson, 2001). Moreover, the difficulties of system integration may be better understood from a perspective of structural coupling than from one of rational design or negotiation (Beeson, 2001). Structural coupling concept can also be used to explore the way common understandings between an enterprise's members emerge as a function of interactions in the work environment (Kay & Cecez-Kecmanovic, 2002).

From autopoietic view introducing a new IS in an enterprise can be conceptualized as a kind of perturbation that provokes or triggers an enterprise's structural-determined responses. Therefore, IS development process can be viewed as the means for realizing structural coupling between an enterprise and its new IS and becomes an integrated aspect of the recurrent interactions between developers and users in the work environment. Table 1 summarizes the implications of theory of autopoiesis for IS development process.

Table 1. Autopoietic implications for IS development

Characteristics of Autopoietic Systems	**Implications for IS Development**
Organizational Closure and Self-Referentiality	**Insider frame of reference.** The organizational closure and self-referentiality of an enterprise suggest it is best understood from *inside*. Therefore, an interpretive or hermeneutic approach could more reliably and intelligibly account for the experiences, intentions and interpretations of its members. Moreover, the main role of system developer is the role of "*catalyst* and/or *emancipator*" (Hirschheim et al., 1989), who helps an enterprise's members to develop the necessary inquiring, collaborative and communicative patterns needed to continuously explicate their information requirements. **Historicity.** As an enterprise is continuously reproducing itself, it must do so with constant reference to itself, its past practices, values, decisions, contracts, and commitments (Truex et al., 1999). Therefore, explicating an enterprise's history is an essential element in developing new knowledge and in introducing a new IS (von Krogh et al., 1994)
Structural Determination and Structural Coupling	**Context-dependency of IS development methodology.** Viewing ISD methodology as the means for realizing structural coupling between an enterprise and its new IS implies that it cannot be separated from an enterprise's context. In other words, autopoietic metaphor of an enterprise and its IS suggests "strong" approaches to systems development instead of the commonly used "weak" approaches (see key terms).
Embodied Cognition	**Minimal set of initial requirements.** The autopoietic view of cognition implies that requirements are always in motion, unfrozen, and negotiable (Truex et al., 1999). Therefore, information system development can be viewed as open-ended bootstrapping process that starts with a minimal set of requirements. Moreover, formal representation must be subordinated to the fostering of mutual understanding and coordinated action in the development team and between the team's members and the stakeholders (Beeson, 2001; Kay & Cecez-Kecmanovic, 2002).

Section 3
Knowledge Management:
Tools and Technologies

This section presents extensive coverage of various tools and technologies available in the field of knowledge management that practitioners and academicians alike can utilize to develop different techniques. Readers are enlightened about fundamental research on one of the many methods used to facilitate and enhance the knowledge sharing experience while exploring the intrinsic value of technology and knowledge management. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of knowledge management. With more 28 chapters, this section offers a broad treatment of some of the many tools and technologies within the knowledge management community.

Chapter 3.1
ICT and Knowledge Management Systems

Irma Becerra-Fernandez
Florida International University, USA

Rajiv Sabherwal
University of Missouri – St. Louis, USA

INTRODUCTION

Rapid changes in the field of knowledge management (KM) have to a great extent resulted from the dramatic progress we have witnessed in the field of information and communication technology. ICT allows the movement of information at increasing speeds and efficiencies, and thus facilitates sharing as well as accelerated growth of knowledge. For example, computers capture data from measurements of natural phenomena, and then quickly manipulate the data to better understand the phenomena they represent. Increased computer power at lower prices enables the measurement of increasingly complex processes, which we possibly could only imagine before. Thus, ICT has provided a major impetus for enabling the implementation of KM applications. Moreover, as learning has accrued over time in the area of social and structural mechanisms, such as through mentoring and retreats that enable effective knowledge sharing, it has made it possible to develop KM applications that best leverage these improved mechanisms by deploying sophisticated technologies.

In this article we focus on the applications that result from the use of the latest technologies used to support KM mechanisms. Knowledge management mechanisms are organizational or structural means used to promote KM (Becerra-Fernandez, Gonzalez, & Sabherwal, 2004). The use of leading-edge ICT (e.g., Web-based conferencing) to support KM mechanisms in ways not earlier possible (e.g., interactive conversations along with the instantaneous exchange of voluminous documents among individuals located at remote locations) enables dramatic improvement in KM. We call the applications resulting from such synergy between the latest technologies and social or structural mechanisms knowledge management systems. We discuss the topic of KM systems in detail in the next sections.

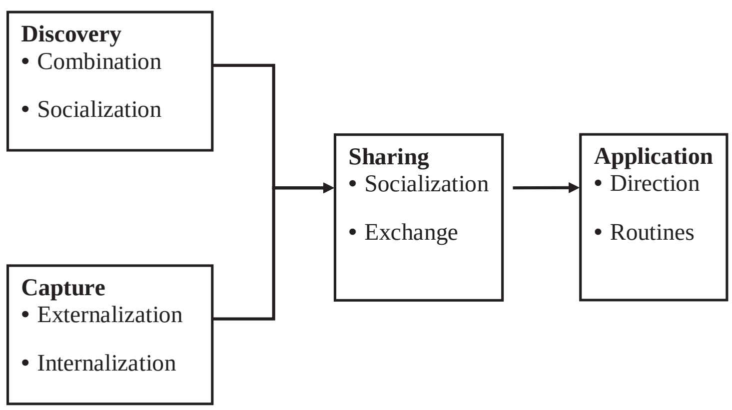
BACKGROUND

We describe the variety of possible activities involved in KM as broadly intending to (a) discover new knowledge, (b) capture existing knowledge, (c) share knowledge with others, or (d) apply knowledge. Thus, KM relies on four kinds of KM processes as depicted in Figure 1 (Becerra-Fernandez et al., 2004). These include the processes through which knowledge is discovered or captured, and the processes through which this knowledge is shared and applied. These four KM processes are supported by a set of seven KM subprocesses as shown in Figure 1, with one subprocess, socialization, supporting two KM processes (discovery and sharing).

Polyani's (1967) distinction between explicit and tacit is at the heart of most KM papers. These constructs follow in that explicit knowledge is knowledge about things, and tacit knowledge is associated with experience. Nonaka (1994) identified four ways of managing knowledge: combination, socialization, externalization, and internalization. Of the seven KM subprocesses presented in Figure 1, four are based on Nonaka, focusing on the ways in which knowledge is shared through the interaction between tacit and explicit knowledge. New explicit knowledge is discovered through combination, wherein the multiple bodies of explicit knowledge (and/or data and/or information) are synthesized to create new, more complex sets of explicit knowledge. Therefore, by combining, reconfiguring, recategorizing, and recontextualizing existing explicit knowledge, data, and information, new explicit knowledge is produced. In the case of tacit knowledge, the integration of multiple streams for the creation of new knowledge occurs through the mechanism of socialization. Socialization is the synthesis of tacit knowledge across individuals, usually through joint activities rather than written or verbal instructions. Externalization involves converting tacit knowledge into explicit forms such as words, concepts, visuals, or figurative language (e.g., metaphors, analogies, and narratives; Nonaka & Takeuchi, 1995). It helps translate individuals' tacit knowledge into explicit forms that can be more easily understood by the rest of their group. Finally, internalization is the conversion of explicit knowledge into tacit knowledge. It represents the traditional notion of learning.

The other three KM subprocesses—exchange, direction, and routines—are largely based on Grant (1996a, 1996b) and Nahapiet and Ghoshal (1998). Exchange focuses on the sharing of explicit knowledge and it is used to communicate or transfer explicit knowledge between individuals, groups, and organizations (Grant, 1996b).

Figure 1. KM processes



Direction refers to the process through which the individual possessing the knowledge directs the action of another individual without transferring to him or her the knowledge underlying the direction. This preserves the advantages of specialization and avoids the difficulties inherent in the transfer of tacit knowledge. Finally, routines involve the utilization of knowledge embedded in procedures, rules, and norms that guide future behavior. Routines economize on communication more than direction as they are embedded in procedures or technologies. However, they take time to develop, relying on constant repetition (Grant, 1996a).

Other KM system characterizations present similar models to describe KM systems. For example, the acquire, organize, and distribute (AOD) model (Schwartz, Divitini, & Brasethvik, 2000) uses a similar characterization to describe organizational memories. Comparing the two models, the acquisition process relates to how we collect knowledge from members of the organization or other resources, and it is related to the processes of knowledge discovery and knowledge capture. The organizing process refers to structuring, indexing, and formatting the acquired knowledge, and it is related to the process of knowledge sharing. Finally, the process of distribution relates to the ability to get the relevant knowledge to the person who needs it at the right time, and it is related to the process of knowledge application.

Knowledge management systems utilize a variety of KM mechanisms and technologies to support the knowledge management processes. Depending on the KM process most directly supported, KM systems can be classified into four types: knowledge-discovery systems, knowledge-capture systems, knowledge-sharing systems, and knowledge-application systems (Becerra-Fernandez et al., 2004). In the next sections, we provide a brief overview of these four kinds of systems and examine how they benefit from KM mechanisms and technologies.

TYPES OF KNOWLEDGE MANAGEMENT SYSTEMS

Knowledge-discovery systems support the process of developing new tacit or explicit knowledge from data and information or from the synthesis of prior knowledge. These systems support two KM subprocesses associated with knowledge discovery: combination, enabling the discovery of new explicit knowledge, and socialization, enabling the discovery of new tacit knowledge. Thus, mechanisms and technologies can support knowledge-discovery systems by facilitating a combination and/or socialization.

KM mechanisms that facilitate combination include collaborative problem solving, joint decision making, and the collaborative creation of documents. For example, at the senior-management level, new explicit knowledge is created by sharing documents and information related to mid-range concepts (e.g., product concepts) augmented with grand concepts (e.g., corporate vision) to produce new knowledge about both areas. This newly created knowledge could be, for example, a better understanding of the products and corporate vision (Nonaka & Takeuchi, 1995). Mechanisms that facilitate socialization include apprenticeships, employee rotation across areas, conferences, brainstorming retreats, cooperative projects across departments, and initiation processes for new employees. For example, Honda "set up 'brainstorming camps' (tama dashi kai)—informal meetings for detailed discussions to solve difficult problems in development projects" (Nonaka & Takeuchi, p. 63).

Technologies facilitating combination include knowledge-discovery or data-mining systems, databases, and Web-based access to data. According to Nonaka and Takeuchi (1995, p. 67), the "reconfiguration of existing information through sorting, adding, combining, and categorizing of explicit knowledge (as conducted in computer databases) can lead to new knowledge." Repositories of information, best practices, and lessons learned also facilitate combination. Technologies can also facilitate socialization, albeit to less extent than they can facilitate combination. Some of the technologies for facilitating socialization include videoconferencing, electronic discussion groups, and e-mail.

Knowledge-capture systems support the process of retrieving either explicit or tacit knowledge that resides within people, artifacts, or organizational entities. These systems can help capture knowledge that resides within or outside organizational boundaries, including within consultants, competitors, customers, suppliers, and prior employers of the organization's new employees. Knowledge-capture systems rely on mechanisms and technologies that support externalization and internalization.

KM mechanisms can enable knowledge capture by facilitating externalization, that is, the conversion of tacit knowledge into explicit form, or internalization, that is, the conversion of explicit knowledge into tacit form. The development of models or prototypes and the articulation of best practices or lessons learned are some examples of mechanisms that enable externalization.

Learning by doing, on-the-job training, learning by observation, and face-to-face meetings are some of the mechanisms that facilitate internalization. For example, at one firm, "the product divisions also frequently send their new-product development people to the Answer Center to chat with the telephone operators or the 12 specialists, thereby 're-experiencing' their experiences" (Nonaka & Takeuchi, 1995, p. 69).

Technologies can also support knowledge-capture systems by facilitating externalization and internalization. Externalization through knowledge engineering is necessary for the implementation of intelligent technologies such as expert systems, case-based reasoning systems, and knowledge-acquisition systems. Technologies that facilitate internalization include computer-based communication. Using such communication facilities, an individual can internalize knowledge from a message or attachment thereof sent by another expert, from an AI- (artificial intelligence) based knowledge-acquisition system, or from computer-based simulations.

Knowledge-sharing systems support the process through which explicit or implicit knowledge is communicated to other individuals. They do so by supporting exchange (i.e., the sharing of explicit knowledge) and socialization (which promotes the sharing of tacit knowledge). Mechanisms and technologies supporting socialization also play an important role in knowledge-sharing systems. Discussion groups or chat groups facilitate knowledge sharing by enabling an individual to explain his or her knowledge to the rest of the group. In addition, knowledge-sharing systems also utilize mechanisms and technologies that facilitate exchange. Some of the mechanisms that facilitate exchange are memos, manuals, progress reports, letters, and presentations. Technologies facilitating exchange include groupware and other team collaboration mechanisms, Web-based access to data, databases, and repositories of information, including best-practice databases, lessons-learned systems, and expertise-locator systems.

Knowledge-application systems support the process through which some individuals utilize knowledge possessed by other individuals without actually acquiring or learning that knowledge. Mechanisms and technologies support knowledge-application systems by facilitating routines and direction.

Mechanisms facilitating direction include traditional hierarchical relationships in organizations, help desks, and support centers. On the other hand, mechanisms supporting routines include organizational policies, work practices, and standards. In the case of both direction and routines, these mechanisms may be either within an organization (e.g., organizational hierarchies) or across organizations (e.g., software-support help desks).

Technologies supporting direction include experts' knowledge embedded in expert systems and decision-support systems, as well as troubleshooting systems based on the use of technologies like case-based reasoning. On the other hand, some of the technologies that facilitate routines are expert systems, enterprise resource-planning systems (ERPs), and traditional management-information systems. As mentioned for KM mechanisms, these technologies can also facilitate directions and routines within or across organizations.

Table 1 summarizes the above discussion of KM processes and KM systems, and also indicates some of the mechanisms and technologies that might facilitate them. As may be seen from this table, the same tool or technology can be used to support more than one KM process.

Table 1. KM systems, subprocesses, mechanisms, and technologies

KM Processes	KM Systems	KM Subprocesses	Illustrative KM Mechanisms	Illustrative KM Technologies
Knowledge Discovery	Knowledge-Discovery Systems	Combination	Meetings, telephone conversations, and documents, collaborative creation of documents	Databases, Web-based access to data, data mining, repositories of information, Web portals, best practices, and lessons learned
		Socialization	Employee rotation across departments, conferences, brainstorming retreats, cooperative projects, initiation	Videoconferencing, electronic discussion groups, e-mail
Knowledge Capture	Knowledge-Capture Systems	Externalization	Models, prototypes, best practices, lessons learned	Expert systems, chat groups, best practices, and lessons-learned databases.
		Internalization	Learning by doing, on-the-job training, learning by observation, and face-to-face meetings	Computer-based communication, AI-based knowledge acquisition, computer-based simulations
Knowledge Sharing	Knowledge-Sharing Systems	Socialization	See above	See above
		Exchange	Memos, manuals, letters, presentations	Team collaboration tools, Web-based access to data, databases, and repositories of information, best-practices databases, lessons-learned systems, and expertise-locator systems
Knowledge Application	Knowledge-Application Systems	Direction	Traditional hierarchical relationships in organizations, help desks, and support centers	Capture and transfer of experts' knowledge, troubleshooting systems, and case-based reasoning systems, decision-support systems
		Routines	Organizational policies, work practices, and standards	Expert systems, enterprise resource-planning systems, management-information systems

INFORMATION AND COMMUNICATION TECHNOLOGY INFRASTRUCTURE IN KNOWLEDGE MANAGEMENT SYSTEMS

The knowledge management infrastructure is the foundation on which knowledge management resides. It includes five main components: organization culture, organization structure, communities of practice, information technology infrastructure, and common knowledge. In this section, we concentrate on the role of ICT infrastructure on KM systems.

Knowledge management is facilitated by the organization's ICT infrastructure. While certain information technologies and systems are directly developed to pursue knowledge management, the organization's overall ICT, developed to support the organization's information-processing needs, also facilitates knowledge management. The ICT infrastructure includes data processing, storage, and communication technologies and systems. It comprises the entire spectrum of the organization's information systems, including transaction-processing systems and management-information systems. It consists of databases and data warehouses, as well as enterprise resource-planning systems. One possible way of systematically viewing the IT infrastructure is to consider the capabilities it provides in four important aspects: reach, depth, richness, and aggregation (Daft & Lengel, 1986; Evans & Wurster, 1999).

Reach pertains to access and connection, and the efficiency of such access. Within the context of a network, reach reflects the number and geographical locations of the nodes that can be efficiently accessed. Keen (1991) also uses the term reach to refer to the locations an ICT platform is capable of linking, with the ideal being able to connect to anyone, anywhere. Much of the power of the Internet is attributed to its reach and the fact that most people can access it quite inexpensively (Evans & Wurster, 1999). Reach is enhanced not just by advances in hardware, but also by progress in software. For instance, the standardization of cross-firm communication standards and languages such as XML (extensible markup language) make it easier for firms to communicate with a wider array of trading partners, including those with whom they do not have long-term relationships.

Depth, in contrast, focuses on the detail and amount of information that can be effectively communicated over a medium. This dimension closely corresponds to the aspects of bandwidth and customization included by Evans and Wurster (1999) in their definition of richness. Communicating deep and detailed information requires high bandwidth. At the same time, it is the availability of deep and detailed information about customers that enables customization. Recent technological progress, for instance, in channel bandwidth, has enabled considerable improvement in depth.

Communication channels can be arranged along a continuum representing their relative richness (Carlson & Zmud, 1999). The richness of a medium is based on its ability to (a) provide multiple cues (e.g., body language, facial expression, tone of voice) simultaneously, (b) provide quick feedback, (c) personalize messages, and (d) use natural language to convey subtleties (Daft & Lengel, 1986). ICT has traditionally been viewed as a lean communication medium. However, given the progress in information technology, we are witnessing a significant increase in its ability to support rich communication.

Finally, rapid advances in ICT have significantly enhanced the ability to store and quickly process information (Evans & Wurster, 1999). This enables the aggregation of large volumes of information drawn from multiple sources. For instance, data mining and data warehousing together enable the synthesis of diverse information from multiple sources, potentially to produce new insights. Enterprise resource-planning systems also present a natural platform for aggregating knowledge across different parts of an organization. A senior IS executive at Price Waterhouse Coopers, for example, remarks, "We're moving quite quickly on to an intranet platform, and that's giving us a greater chance to integrate everything instead of saying to people, 'use this database and that database and another database.' Now it all looks—and is—much more coordinated" (Thomson, 2000, p. 24).

To summarize, the above four ICT capabilities enable knowledge management by enhancing common knowledge or by facilitating the four KM processes. For example, an expertise-locator system (also called knowledge yellow pages or a people-finder system) is a special type of knowledge repository that pinpoints individuals having specific knowledge within the organization (Becerra-Fernandez, 2000, 2001). These systems rely on the reach and depth capabilities of ICT by enabling individuals to contact remotely located experts and seek detailed solutions to complicated problems. Another KM solution attempts to capture as much of the knowledge in an individual's head as possible and archive it in a searchable database (Armbrecht et al., 2001). This is primarily the aim of projects in artificial intelligence, which capture the expert's knowledge in systems based on various technologies, including rule-based systems and case-based reasoning, among others (Wong & Radcliffe, 2000). But the most sophisticated systems for eliciting and cataloging experts' knowledge in models that can easily be understood and applied by others in the organization (see, for example, Ford, Coffey, Cañas, Andrews, & Turner, 1996) require strong knowledge-engineering processes to develop. Such sophisticated KM systems are typically not advocated for use in mainstream business environments primarily because of the high cost involved in the knowledge-engineering effort.

FUTURE TRENDS

The future of knowledge management will be highlighted by three continuing trends: (a) KM will benefit from progress in ICT, (b) KM will continue the shift toward integrating knowledge from a variety of different perspectives, and (c) KM will continue to make trade-offs in numerous important areas.

First, in the future, KM will benefit from continual, and even more dynamic, progress in ICT. Improvements in cost and performance ratios of ICT have caused the cost of digitizing information to approach zero, and the cost of coordinating across individuals, organizational subunits, and organizations to approach zero as well (Grover & Segars, 1996). ICT progress also includes developments in autonomous software-based agents. Thus, the future of KM will be dramatically different due to the inevitable and unpredictable over any long period of time, and quantum changes in ICT and underpinning technologies such as artificial intelligence.

Second, in the future, KM will continue the shift toward bringing together, and effectively integrating, knowledge from a variety of different perspectives. Knowledge management originated at the individual level, focusing on the training and learning of individuals. Over time, the emphasis of knowledge management shifted to groups and entire organizations, and now examples of interorganizational impacts of knowledge management are becoming increasingly common. This trend in the impact of KM is expected to continue with its use across networks of organizations and across governments, enabling collaborations across historical adversaries and integrating knowledge across highly diverse perspectives and disciplines.

Finally, in the future, knowledge management will continue to make trade-offs in numerous important areas. One such trade-off pertains to the use of ICT for sharing. The same communication technologies that support the sharing of knowledge within an organization also enable the knowledge to leak outside the organization to its competing firms. Another trade-off concerns the balance between technology and people. It is essential to maintain a balance between using technology as substitutes for people (e.g., software agents) and using technology to enable collaboration from a wider range of people within and across organizations.

In conclusion, the future of knowledge management is one where people and advanced technologies will continue to work together, enabling knowledge integration across diverse domains with considerably higher payoffs. However, the new opportunities and greater benefits will require the careful management of people and technologies, a synthesis of multiple perspectives, and effectively dealing with a variety of trade-offs. The future of knowledge management will clearly be exciting due to the new opportunities and options, but interesting challenges definitely lay ahead for knowledge managers.

CONCLUSION

We have described the key aspects of knowledge management in this article. We have provided a working definition of knowledge management systems and presented the four types of KM systems: knowledge-discovery systems, knowledge-capture systems, knowledge-sharing systems, and knowledge-application systems. We also discussed how KM systems serve to support KM processes based on the integration of KM mechanisms, technologies, and infrastructure.

Chapter 3.2

Exploring the Selection of Technology for Enabling Communities

Keith Patrick
University of Westminster, UK

Andrew Cox
Loughborough University, UK

Rahman Abdullah
South Bank University, UK

INTRODUCTION

Communities, whilst represented and apparent in their members, are most evident in the technological entity—the technology and tools that support the common and communal activities. Technology acts as the enabler linking a group of individuals who are most likely dispersed, in terms of time and place, and facilitates their interaction.

So you have decided or been asked to create or facilitate the activities of a community, but how do you select an appropriate solution for the requirements of a particular community and its members? Do you follow a traditional systems and software acquisition route: establish the requirement, develop the system, approach a consultant, call the IS department to see how you can adapt existing technologies? Or do you adopt an approach that can also be viewed as part of the community development process through the generation of involvement, engagement leading to ownership of the community and therein its future activities?

The bottom line is that technology—either a system or a tool—is still required; the following exploration is based on the original research of the Knowledge Library project (Cox, Patrick & Abdullah, 2003). The K-Library project, facilitated by Research Development funding from London South Bank University, started from the premise that it would be useful to assemble a group of librarians from across the library sectors to share their understanding of the concept of knowledge management (KM), and to look at how some of the ideas drawn from the KM literature could be applied to library practice. It also reflects the considerations of a project team with its participants for the selection of a suitable system to support this community of interest. This project and subsequent work provided the basis for this exploration of tools and technologies that support communal activity; be that a community of intent, interest, purpose, or practice, which seeks to identify the user requirements for the technology or systems to support the building of an online community. The aim is to review the type of technologies and varying features, and to explore how they can assist a community through its initiation and maintenance phases without intruding or hampering the intention and activities of that community. This has enabled the creation of a list of features supported by explanation of these functions and options, and the creation of a checklist (see Appendix). This checklist can be used to help potential users identify their expected needs by distinguishing essential, useful, and non-essential features. The resulting checklist can be found at the end of the exploration and explanation of functions and functionality that could be adopted in the technology to support a community. From this exercise and other user requirements, it is possible to evaluate different systems for their compliance with user requirements. In the K-Library project, this enabled the selection of a suitable system, replicating the majority of the features the community considered to be appropriate for their activities. This exploration is augmented with observation by the authors and the reflections of the communities arising from the selection and use of a system/technology and the building of the community.

BACKGROUND

On commencing the K-Library project, we found that there was little to directly lead us toward making a choice of supporting technology. A difficulty that lay in the wide and expanding range of technologies available for supporting communities, extending from simple bulletin boards or e-mail archiving systems through to sophisticated suites of integrated software with document repositories and content/records management, calendars, task management, and workflow. Also it was found that at the time of initiating the project, the literature on communities was focused toward the conceptual and practical aspects of running communities. This literature was focussed on selecting technologies rather than more generally on systems and software development, and texts were geared to specific software—groupware or intranets. These texts, whilst relevant, did not offer the fuller picture we initially perceived and then revealed as relevant in the discussions with the K-Library Communities membership.

Additionally, the speed of technological development has continued apace, making much material dated with the arrival of newer technologies and the convergence and integration of these technologies with other broader ranging technologies and standards, like instant messaging, Weblogs, and RSS feed. These are significantly changing how information can be collated and distributed, with increasing opportunity for customisation and personalisation. This is coupled with systems becoming more pervasive with enterprise information portals, integrated content management systems, wireless networks, and mobile commerce, and these devices becoming smaller and more mobile themselves. An important impact can be seen in the increasing standardisation occurring as useful technologies and practice evolve, particularly the Web-based metaphor for the look and feel of systems for familiarity and ease of use, with many of these technologies or practices being viewed as standards in the field. Although in terms of a true defining of a standard reflecting the technology domain, these may be transitional, emerging, de-facto, or proprietary standards like XML, XHTML, Java, or DHTML.

The essential aspect being that this semblance of a common standard is facilitating the development of more consistent systems, and the genuine use and reuse of documents and artefacts for a range of the devices without the need for re-creation, providing the ability to use or adapt them with relative ease, and enabling a group of individuals to form and evolve into a genuine and mutually beneficial community.

MAIN FOCUS

Identifying the Necessary Features

The question therefore is what functions or functionality does your community require? A simple bulletin board or mailing list (e.g., listserv, jiscmail) based on specific software, or a Web-based group with discussion threading and the ability to push e-mails (e.g., e-group or Yahoo group) may be enough. Is real time functionality—like chat or instant messenger (e.g., AOL, MSN, ICQ) or Internet telephony (e.g., Skype)—required? What about reminders for outstanding action 'to-do' or task list activity areas/places (e.g., Groove, Lotus Notes/Domino, First Class)? Are options required relating to the creation and dissemination of work via content management systems, record management, workflow, sign-offs, and portal-based enterprise systems (e.g., Opentext Livelink, or Hyperwave or Microsoft's Sharepoint)? Wenger (2001), in analysing tools for the suitability to run communities of practice, argues that "the ideal system [for this purpose] at the right price does not yet exist." He points out that most available systems were developed primarily with other applications in mind; specifically he identifies tools developed such as: knowledge portals, project type software, Web site communities, discussion groups, online meeting spaces, e-learning spaces, knowledge exchange, and knowledge repositories.

It is very easy in choosing a system to overlook the lack of important features that can be critical as to whether members are encouraged or discouraged from actively and consistently engaging with a community. The stress in functionality varies from system to system; for example, project management tools will stress document management and task listings much more than a Web site community tool. Also the specific terminology used may be appropriate to a particular application—that is, 'task lists' would more appropriately be called 'activity lists', say, in a Web site community as opposed to a project management system. Clearly it makes sense in selecting software for one type of community as far as possible to look for a system that was developed with that type of community in mind.

Conversation Space

This represents the core of any system or tool, the appropriate communication tools being vital to the success of a potential community. The more sophisticated tools will often provide several different spaces for shared and individual activities, and synchronous and asynchronous communication.

Asynchronous Communication

Asynchronous communication comes in two main forms: (1) e-mail-based systems where e-mails to a central account are forwarded to members, with a Web archive existing for reference; and (2) bulletin board systems, where messages are posted on the Web and users have to log in to read messages.

An issue that impacts on discussions lies in how messages are delivered or read via e-mail and reply can be made via e-mail or the Web site. Impacted can be the number of e-mails received in a single day according to energy of the debate and length, when in digest form, characteristically containing messages plus the replies, creates long and difficult-to-comprehend e-mails/documents. It is possible to reply via the individual message and reflect in the discussion as the thread has evolved. How previous messages are shown is significant if they are differentiated from the new message through the use of quotes or indentation, and these can be quite critical to readability. Some systems encourage the use of emoticons to partially overcome the limitations of communication based just on text; or an alternative allows users to add formatting to text, sometimes with HTML coding.

An addition to this is the potential for taking activities offline for contribution, that is, editing or contributing to collaborative documents; however, some form of synchronisation is beneficial for managing version control and ensuring the correct document is being improved.

It may be useful to offer the option to make anonymous contributions, to give users the opportunity to experiment with points of view that are controversial. This would need to address in the communities the development of operating protocols as to how it is used to ensure that it is not used negatively or to the determent of free-flowing discussions.

Synchronous Communication

For highly spontaneous interactions many community building systems offer real-time chat. Ideally there should be some means of archiving these discussions, though the most effective way may be through human reporter. Transcripts are difficult to read, and to respond to, particularly if there are multiple participants, and can quickly disappear off the screen with the lack of threading.

Often the chat facility has the ability to allow a user to check ‘who else’ is logged on—this is apparently a popular feature in some community building systems, even where communication is actually continued using asynchronous channels. This can also include shared activity spaces that allow co-viewing and co-editing.

Announcements

This is different than alerts, which are explained below. It is possible to simply make announcements through the asynchronous communication channel, but it is useful to have another channel through which to issue important community-wide news. Announcements are often posted at the top of the homepage. In some systems different types of announcements are distinguished and colour coded.

What’s New

There are two main approaches to defining what is new: either this can be determined by when the user last logged on, or more simply by elapsed time. The system we selected used the latter, and it was obviously not as satisfactory if one had been away a week; it also alerted one to one’s own postings and uploads.

Ideally the administrator should be able to control what types of items are monitored for changes and be given some options about how new items are marked, such as where they appear on the homepage, colours, and so forth.

Alerts

An alternative approach to making people aware of changes is the option to alert all, or some, users of changes when they are made. This has the merit of putting the choice in the hands of the community member as to who to notify of a particular change. With the system adopted by K-Library, the alerts only contained links to the site, not a direct link to the source of the alert. This additional step to using the system was viewed as detrimental and a hindrance by the members.

Polling

Polls are a powerful tool for helping communities to foster active participation and even to make collective decisions. While it is possible to canvas opinion simply through asynchronous communication channels, this is haphazard and difficult to control. The ability to automatically close a poll at a specific time will also encourage members to cast their votes within the allotted period.

A poll posted on the front page of the site allows members to follow its progress from the start to when the poll is finished and is especially important in circumstances where members are allowed to change their mind while the poll is still open. An additional option to allow anonymous votes can also be beneficial in encouraging members to vote freely.

Ideally there should be the flexibility for the member to add his or her own answer, if the option he or she wants to choose is not listed. Some systems provide automatic e-mail notifications when polls are running, closed, and when results are posted on the site.

Membership Directory

The importance of a membership directory lies in its ability to encourage users to share information about themselves, such as their areas of expertise, interests, and work experience, and so connect people. It might be useful to build a link from postings to membership entry or vice versa.

Ideally the administrator should be able to define suitable fields for entries in the directory, and select what level of information is required to be provided. Users should be able to have latitude to express themselves and reflect their interest and personality. The richer the record they can generate, the more other members will be able to relate to that person. It is useful to allow users to add a photograph of themselves—or links or documents; equally, users must be able to withhold information if they wish. This an area for the community to decide what the criteria is to be; a deadline for this information is also useful, as whilst members may agree, they may still abstain from publishing the agreed information.

Contacts List

Users can be encouraged to share contacts through a dedicated contacts directory; this can allow access or publication of a restricted set of information to that of the membership directory. This also overcomes any potential reluctance to enter full information within the Membership Directory, arising from concern over who will be able to see, use or pass on that information. Some members will find the real value of the community is to be able to access expertise through the back-channel, although the group experts may not take the same viewpoint.

Document Repository

The document repository can be one of the core features of a communications system. It is possible simply to e-mail files to a discussion list, but there are advantages in having a specific document store. Documents in a repository are easier to locate than those that are somewhere in a long-threaded discussion. Some systems offer something approaching a full document management system with check-in/check-out of documents and version control, and an archive of previous versions. This is essential where multiple authors are expected to be working on the same document, as in project work. In other contexts this may feel unnecessarily cumbersome and inhibit usage of the files. We felt it would be useful to build associated discussion areas around a document or to link to other parts of the system.

A large number of documents being shared can rapidly eat into storage space, possibly affecting system performance—or incurring extra expense if an Application Service Provider (ASP) is hosting the service. It is essential that commonly used document formats are supported with the ability to add new ones. If it is a hosted service, the evaluation should include looking for evidence that they will support new file types as they emerge. In a small community it should be possible and fair to negotiate standards about what authoring software to use. In projects it is common to standardise on a version of Word, for example. Selective alerting of major document changes to named individuals or groups is useful.

Link Store

The ability to add links to the site encourages members of the community to share online resources. Systems that have the ability to create folders and sub-folders with clear headings, ideally with additional details such as who added it, a short description, and the dates and times it was created, can make it even easier for members to access the information. Some systems provide additional features that allow for the creation of personal links, which are only visible to the individual member. This can be useful for members to personalise the site, and can help encourage them to visit and use the site regularly, but at the same time can also create an insular environment and can cause barriers to sharing.

Calendar

The calendar can be used as a record of events and to alert users of community events or relevant events in the outside world.

Task Lists

This lists the tasks and activities of the community, typically chronologically ordered, with additional attributes for start/finish, individuals taking part, and can be subdivided. Some systems provide integration with Calendar and Alerts features.

Help

The most common form of help facility is online documentation, which users can access by clicking the help button and going through a series of links. Ideally, the help button should be prominently situated on the front page so that users can see it clearly, and information should be obtained in no more than three clicks. There should also be context-sensitive help.

It would be useful if the administrator could customise the help screens, to use the local version of the language. In our experience we found that the use of American English proved to have a negative impact on the users in attempting to use help, and therein use the tool and participate in the community.

An addition found was the availability of personalised help through an online ‘Live Person’ support through a chat-like system. Off-line telephone communications are similar forms of help facilities that some systems offer, usually during normal office hours. The latter should also be considered in light of global time zones and where the provider may be based, as the K-Library community found there was only a short period where any real-time help was available. Finally, whilst useful, it needs due consideration if the service is not free.

Searching

The internal search facility is important once the size of data archived in the community has reached any size. The search facility should ideally be able to search all internal documents, links, and messages, with an option to search by type of file. Some systems we looked at only searched messages. Full-text searching of deposited documents would be ideal, failing that users should be required to attach an abstract at the point of adding the document or link; otherwise the search will only be on document/link titles.

Many systems offered a ‘search the Web’ option; this only seemed to be of added value if the target search engine could be chosen or if it worked to expand a search on the internal archive.

User Tracking and Statistics

Typically the user tracking functions on most of the systems examined during the study were minimal at best, improving with regard to the size and cost of the system/tool. This feature was more prevalent on the larger and high-end systems/technologies, particularly those with workflow, sign offs, or record management. We wanted to know who was using the site, how often they logged in at what time of day, whether they responded to announcements or alerts by logging in, or primarily used the site habitually at one time of day. It would have been interesting to see whether members were logging in work hours or not. Such tracking is essential, especially as such a high proportion of community members are 'lurkers'.

Clearly there are issues arising from the data protection and privacy perspectives, with this data at an individual level, but pseudonymous data would be invaluable to judge how well the community was working.

Usability and Terminology

It may well be critical to a community how usable the tool or system is perceived to be regardless of whether it is or is not. We found that simple things such as speed of response times may be a key to use of the system. This is obviously a function of many factors: the host system, but also user network connections and the speed of their own machines. For users with a modem connection, a simple e-mail system may be preferred.

Customisation

This is the ability to reorder or personalise the view presented on opening a tool to suit the priorities and interest of the individual user. Typically this is by choosing a theme for the layout or colouring, or the selection via on or off buttons of a series of features available. These methods are not untypical of common applications and grow with the sophistication of the product, especially portal-based solutions.

Security

In a private community a level of security is required, depending on how sensitive the discussions or documents posted are. The option to save one's password as a cookie on one's own machine can be useful.

In the system we used, there was a guest access facility, with very limited rights to view some areas of the site. Ideally there should be scope for the administrator of the community to define precisely what guests can and cannot do at a fine granular level.

Integration and Synchronisation

It most cases the community being created will not be core to participants' work, so it is essential that mechanisms exist to exchange data with other systems, and to maintain some form of version control.

Additional Factors

Clearly in choosing a system or tool, functionality is not the only criteria that is significant or impacts on the selection process.

Cost

There are a number of free services in the marketplace, but there is a price to be paid in using them in terms of intrusive advertising or the risk of the service being withdrawn probably on short notice.

The alternative is to licence software and install it, or to find a third-party ASP who for a fee will run the site for you. The total cost of running a server securely and reliably, along with the support for self-hosting, is likely to be significant.

Third-party services are generally cheaper to set up, but there are likely to be drawbacks. We found limitations on the level of customisation of interfaces and functions, and of usage statistics. Some of these limitations would probably also have existed if we had installed a system ourselves, at least from an out-of-the-box installation. There were limits on the total size of files we could save. We also found that one service (synchronous communication channel) was withdrawn without notice. When we finished using the service, there was no way to archive the site.

Moderation/Facilitation

Is the community to be self-maintaining or does it require a moderator? It should be noted that some systems like e-groups/Yahoo groups require at least one individual to be designated as the administrator/moderator.

Skill Levels

This relates to the technical skills of the community levels of competence and ease with technology, which introduces issues of usability and accessibility, and how adaptable the selected technology is or needs to be. There is also the aspect of the competence and technical skills of those facilitating the community; obviously in-house IS department will have skill levels, if not time. There is an increasing amount of Open Source options, these are packages based on PHP and MYSQL (e.g., Metadot, TYPO3, Invision Power Board). These offer an application-based, typical Web-based front end for the design and administration of a community without the need for detailed knowledge of either PHP or MYSQL, although the ability to customise and differentiate your communities from another design with such a tool is enhanced.

FUTURE ISSUES

As we indicated in the introduction, technological developments continue a pace, with new roles determined for older technologies, and new or recent technologies coming of age as the infrastructure also evolves to cope with their requirements. Changes are reflected in functionality and capability regarding the software, hardware, and the devices we use to access technologies, such as Web-logs—commonly known as blogs—for individual journal/diary-like software publishing via the Internet, which has evolved with a group-based authoring version. RSS feeds are becoming increasingly available, more ubiquitous means of linking and collating disparate information sources and data streams. Many of the 'coffee-and-book' shopping chains offer Internet connections via wireless networks. Link this to the expansion of the 3G mobile telephony networks and the success of the Blackberry handheld device. The technology does not need to be new, but recognition of an existing technology that is underused or could be used differently may be appropriate. The most successful (financially) technology in 2G mobiles was the initially overlooked 'texting' (SMS) facility. Do 3G mobiles have a community-orientated facility yet to be discovered or acknowledged?

CONCLUSION

As with any exercise in gathering users' conscious requirements prior to experience of a specific application, the results can be misleading as a guide to how people will actually use the system that is chosen and value particular functions. The K-Library found this to be an issue with several requested features being turned off, particularly the alerts, although this was followed by comments about not realising anything was happening on the communities online entity! Other analysis is required to identify the full user requirements, but forms a basis for the community, and encouraging involvement and engagement—two prime attributes for creating a successful community.

The checklist tool and descriptions presented here could also be applied to gather users' evaluations of software they have used in a community building exercise, and to triangulate with the results of actual user behaviour captured through site statistics or direct observation of behaviour.

Selecting the most appropriate technology in the form of a system or a tool is a significant part of creating and facilitating a community and can be part of the process of forming the community. It does not have to be sophisticated or heavily featured; it should be related to the community objectives and the community members, its formality or informality, its location outside an organisation or inside an organisation, or bridging organisations or interest groups.

To finish, one should remember Wenger's (2001) consideration that in analysing tools for their suitability to run communities of practice, he argues that "the ideal system [for this purpose] at the right price does not yet exist." It is our hope that our experiences can help you to consider what features your community requires prior to selecting a suitable system/tool for your community.

Chapter 3.3
Intranet and Organizational Learning

Kees Boersma
Vrije Universiteit Amsterdam, The Netherlands

Sytze Kingma
Vrije Universiteit Amsterdam, The Netherlands

INTRODUCTION

In this article, we will analyze the cultural dimension of intranets as knowledge management tools within organizations. An intranet is an information communication technology (ICT) based upon Internet technology (http://www, TCP/IP). The intranet phenomenon was introduced in the early 1990s following the idea that it can integrate all the computers, software, and databases within a particular organization into a single system that enables employees to find and share all the information they need for their work (Bernard, 1997; Cortese, 1996). Intranets function as a computer-mediated communication (CMC) tool and are used as computing networks used for sharing organizational information. While Internet technology is leading, access is restricted exclusively to organizational members (by means of electronic firewalls). In a study to the role of intranets in strategic management decisions, Curry and Stancich (2000) define Intranets as "…private computing networks, internal to an organization, allowing access only to authorized users" (p. 250). The term private indicates that an intranet is a network that can be accessed only by members of a particular organization. The term network emphasizes the connection between computers that enables corporate communication. Intranets run on open but controlled networks that enable organization members to employ the same WWW servers and browsers, which are distributed over the local area network (LAN).

In recent debates on strategic management and learning, an organizational learning culture has been introduced as one of the main 'critical success factors' underlying the effective use of intranets (Carayannis, 1998). The aim of this article is to analyze the cultural aspects of intranets as tools in organizational learning processes. It is not so much a presentation of the instrumental effects of intranets for the learning organization culture—the way an intranet influences organizational learning processes is not taken for granted, but studied by the way it is used in different settings. We will present a framework for analyzing the cultural dimension of intranets within specific organizational contexts.

Many studies of intranets dealing with the effectiveness and efficiency of knowledge sharing and knowledge management take a static and deterministic point of view. That means that the focus is on structural constrains, without paying attention to the actual use of intranets. In contrast with this, we plea for an approach focusing upon communicative actions, and stress the communication between people on the intranet on the basis of normative agreement and feelings of mutual understanding and belonging. We furthermore highlight three dimensions from which this cultural context of an intranet can be defined, studied, and analyzed. These dimensions, which indeed apply to any enterprise system (ES) and which in a way also represent historical phases in the development of technology (Silverstone & Haddon, 1996), will in our contextual analysis be specified as the 'constitution' of an intranet, the intranet as a 'condition' of the learning organization, and the (unintended) 'consequences' of intranet use. An analysis on these levels is crucial for those scholars who want to grasp the cultural dimension in the actual use of intranets as a knowledge management tool.

INTRANET AND ORGANIZATIONAL CULTURE

Often, the objective for the implementation of an intranet is that it will facilitate knowledge sharing among members within a single organization. There is a growing body of publications that see an intranet as a tool for organizational learning (e.g., Carayannis, 1998; Curry & Stancich, 2000; Scott, 1998; Sridhar, 1998; Ottosson, 2003). With regard to knowledge management, it has been analyzed in terms of knowledge banks, e-learning platforms, expert networks, online information sharing tools, and the like. Recently, intranets were identified as an infrastructure supporting knowledge management (Harvey, Palmer, & Speier, 1998; Damsgaard & Scheepers, 2001). In this body of literature, intranets are presented as promising knowledge management ICT tools in the sense that intranets will be complementary to or even replace existing information and communication carriers within and among organizations. In addition, intranets are seen as promising instruments for information sharing and collaboration across departments, functions, and information systems (Damsgaard & Scheepers, 1999). Internet-based ICTs like an intranet are even introduced as radical and disruptive innovations, since the implementation is intended strongly to influence the knowledge base of the organization (Lyytinen & Rose, 2003; Mustonen-Ollila & Lyytinen, 2003).

Together with the stories on the promising aspect of intranets, however, came the stories about organizational restrictions, misalignments, and user resistance. Discussions can be found about organizational constraints, such as the lack of standards, immature interfaces, weak linkages to other information systems, bandwidth availability and information overload, and the lack of an internal organization to authorize, support, and organize the quality of the information. On many occasions, it is the organizational culture that has been introduced as an explanation for misalignments or as a condition for a successful implementation and use of intranets (Damsgaard & Scheepers, 2001, p. 5). Curry and Stancich (2000) state: "To obtain maximum value from an intranet, both the 'soft' cultural issues of information sharing and change in work processes must be addressed alongside the 'hard' systems issues of managing the intranet as an information system and a business resource" (p. 255). Moreover, it has been argued that a cultural shift to information sharing is necessary to solve problems of information sharing by means of intranets (Harvey et al., 1998). A positive culture, in this respect, is the motivation to create, share, and use information and knowledge to solve problems with each other within the organization.

It is, however, difficult and often misleading to establish direct causal links between organizational culture and the performance of intranets, since we must realize that culture is part and parcel of the entire organization and affects all kinds of actions and relations (Alvesson, 2002). The definition of 'organizational culture' is itself problematic. It has been described in the literature as a pattern of shared assumptions often produced by top management (Schein, 1992). Such a description of culture as a set of shared assumptions is rather oversimplified (Martin, 1992). Empirical research provides us with a far more complex picture, and shows that tensions can grow and remain between the individuals' interests and organization aims. Because of cognitive and normative diversity within an organization, the attribution of meaning (which is an important part of the cultural process) is complicated and leads to integration as well as fragmentation, and unity as well as diversity.

In line with this, organizational culture has been defined as a sensemaking process (Weick, 1995). That means that we have to study how individual workers give meaning to their actions. In using intranets, like texts such as reports, statistics, protocols, and minutes, the organizational members give meaning to their activities. In this way "…we can understand such interpretations as stemming from the very use of intranet itself" (Edenius & Borgerson, 2003, p. 131). The use of an intranet can generate a kind of consensual knowledge and, as long as different workers get into mutual trust, this can lead to a feeling of belonging. To use an intranet is making sense of experiences, routines, and insights. On a more abstract level, Wenger introduced the term 'communities of practice' to describe the process of people who share common goals or interests and how the people interact with each other to learn how to do better. These communities are formed by people who engage in a process of collective learning in a shared domain of human endeavor (Wenger, 1998; Wenger, McDermott, & Snyder, 2002). Communities of practice enable practitioners to share knowledge, to create a link between learning and performance, and to make connections among others across structural organizational boarders. Because of this, we will discuss intranet and organizational culture in terms of 'shared' meaningful work practices, while at the same time recognizing the existence of multiple working cultures dealing with intranets.

INTRANET AND ORGANIZATIONAL LEARNING

As argued above, an intranet can facilitate knowledge sharing among organization members. The idea is that the knowledge put on the intranet is explicit knowledge (in the terms of Polanyi) that can easily be shared by members of the user group. However, the term 'knowledge sharing' is problematic, because the people's tacit knowing—that is, how to do things—is never fully shared (Walsham, 2002). Only if the data (the explicit knowledge) on the intranet is connected to the tacit knowing, then can the intranet offer something interesting to that user—it can generate a kind of consensual knowledge. That implies that the user must have the skills and competence in selecting the appropriate explicit knowledge. In other words, the knowledge is not in the computer system, but within the human being. It is the end-users that give sense to the data and messages on the intranet by means of their tacit knowing.

Like other ICTs, intranets are the outcome of choices made by individual actors or groups and of organizational constraints that together influence the character of this particular technology. This is known in the literature as the process of mutual shaping (Williams & Edge, 1996; Orlikowski, 2000). While using intranets, actors produce and reproduce communication and information patterns within organizations. Organizational learning on intranets thus can be analyzed as a social process of structuration (in line with Berends, Boersma, & Weggeman, 2003). From this structurationist framework it has been stressed, in particular by Orlikowski (2000), that individual actors are always situated actors. In using ICT tools actors reproduce at the same time important normative and power relations. Thus linkages can be specified between on the one hand the meanings attributed to technologies and on the other hand the normative prescriptions and power relations of organizations.

It has been argued before that an intranet is as good as its content (Curry & Stancich, 2000; White, 2004). Intranets facilitate communication and information sharing among organization members only if the employees can find the data they need, can judge the information to be valid and current, and can trust the persons—gatekeepers—who are responsible for the content of the intranet. However, Edenius and Borgerson (2003) argue that this idea of the intranet as being a container-like tool, where knowledge is seen as a stable stock of fixed information, takes a conventional rational discussion about knowledge management as a starting point. According to them, this view underestimates that an intranet works as a dynamic configuration that also produces knowledge. In other words, the use of an intranet is part of the living act of knowing.

The use of intranet as a tool for knowledge management needs actors who creatively realize learning practices and communication patterns as part of organizational cultures. That means that organizational learning consists of changing organizational practices via the development of knowledge, realized in social practices (Gherardi & Nicolini, 2001). The benefit of knowledge sharing (i.e., learning processes) throughout the organization via an intranet cannot be reduced to individual learning, or individual learning plus something extra such as the sharing of knowledge. Individuals will benefit from intranets in terms of information sharing only if the technology 'fits' into their daily routines embedded within organizational cultures. In this perspective, the organizational knowledge is part of and lives in a constellation of communities of practice (Wenger, 1998). The intranet can be a challenge for these communities, because it offers a platform for sharing knowledge and mutual understanding.

In defining an intranet from this point of view, three different but mutually related dimensions should be taken into account. These dimensions include the constitution of the intranet (stressing the redefinition of learning practices), the intranet as a condition of organizations (stressing the virtualization of organizations), and the intended as well as unintended consequences of the intranet (stressing the globalization of organizations and power relations). In the interaction between these three dimensions of intranet, we find how organizational cultural aspects shape this technology and how this technology in its turn influences organizational cultures.

THREE DIMENSIONS OF AN INTRANET

The first dimension in our approach is the study of the constitution of an intranet. This dimension refers to the material, time-spatial, appearance of intranets. It concerns the artifacts and persons intranets are made of, including PCs, cables, mainframes, software packages, interfaces, reports, and intranet programmers and operators. Similar to the argument Downey (2001) makes for the Internet, intranet workers can only be revealed if we consider the artifacts, labor, and space simultaneously. Therefore a cultural study of the intranet should pay serious attention to the material and geographical aspects of these systems. Conceptions of organizational culture usually not only refer to values and rules, but also to material artifacts (Schein, 1992), which increasingly consist of ICT systems. In line with the discussion above, the evolution of intranets can only be interpreted by studying the interests and perceptions of the various actors that use this ES. An intranet is not a given technology, although it has some scripts (i.e., standard procedures for users), but is a malleable tool shaped by social forces within the organization.

The second dimension, the intranet as a condition for organizations, refers to the functional integration of knowledge (sub)systems by the use of an intranet. An intranet may contribute to the development of 'network enterprises', defined by Castells (1996). This type of organization is rather flexible because it can both reallocate its means of production and change its goals. The intranet, as a knowledge-sharing tool, can function within network organizations as an enabling tool to reconfigure themselves. Like the Internet, intranets create new patterns of social behavior and communication (DiMaggio, Hargittai, Neuman, & Robinson, 2001). Knowledge sharing within network organizations is facilitated but not determined by ICT systems like intranets. In this respect, the borders within and between organizations are constantly reinterpreted, because the structure of the intranet makes it possible to bind people working at different locations together—it is the virtual space of the intranet that is the new condition for a learning environment. In a way, intranets link employees, divisions, and companies, and provide information anytime and anyplace, and enable and reinforce network structures. The aspect of an intranet as a virtual dimension of an organization where partners are located over a wide area linked seamlessly together, however, is yet to be reached due to the relative recency of the system (Kim, 1998).

The third dimension highlights the consequences of the use of an intranet for organizational culture and the wider environment. This dimension refers to the actual effects of an intranet, and concerns the intended as well as unintended consequences. Effects concerning the scaling-up and globalization and the managerial control over knowledge flows seem particularly relevant for the cultural analysis of an intranet. Organizations are embedded in extended networks and operate often in global markets. In some way they have to control these global operations and manage knowledge flows in this context in a coordinated manner. The intended and unintended use enhances the capacity of panoptic control and disciplinary power—an architecture of power closely associated with ICT systems (Zuboff, 1988). Management can use the stored information on the intranet to monitor and interfere with the performance of individuals and groups. At the same time individuals can be empowered by the system and carry out their tasks with more responsibility based on their own insights, preferences, and information from the intranet. However, there are unintended consequences due to these virtual aspects. While the use of an intranet can lead to a sense of belonging, a possible decrease in face-to-face communication is the other side of the coin (Hine, 2000). This can easily lead to a loss of shared identity and weaken social relationships with colleagues within the same organization. Participation on the intranet in this respect is rather anonymous, without much engagement, and therefore maybe less effective as a tool for knowledge management.

FUTURE RESEARCH

Intranets are likely to be further developed in many organizations in the near future as a new communication infrastructure. It is presented both within popular management literature as in international journals as another promising bandwagon for organizations (Lynch, 1997). There is a growing number of managers that implement intranets as a solution for knowledge sharing within the organization. Future research should study the consequences of intranets as a tool for knowledge management to understand the organizational cultural aspects in the way it is presented in this article. It is the people who work with the system that give meaning to the data on an intranet. To understand how people give meaning to the (data on) an intranet, we have to follow the evolution of intranets (within specific contexts) over a longer period of time. This means that "attempts to create unified, universally applicable models or 'best practice' guidelines for designing and implementing intranets are futile. Instead we have to recognize organizational diversity and that the technology is embedded in, and shaped by, its social context" (Bansler, Damsgaard, Scheepers, Havn & Thommesen, 2000, p. 18). We want to argue that it is necessary to integrate both the individual contributions (i.e., the use of technology), group dynamics, and the organizational cultural aspects in a well-balanced manner during the implementation and use of intranets in the process of organizational learning.

Important questions to raise in this respect are inspired by the way Hine (2000) questions the 'virtual life' on the Internet:

- How do the users of an intranet understand its capacity, and how do they interpret it as a medium of communication?
- How does the intranet affect the organization of social relationships within the organization, and is this different to the way in which 'real life' is organized?
- What are the implications of an intranet for the authority and power relations within the organization?
- How do people define the boundary between the real data and the virtual data on the intranet?

CONCLUSION

Because users give meaning to the intranet, "…organizations need to carefully consider how their intranet should be deployed so as to reap the maximum benefit in terms of knowledge creation" (Damsgaard & Scheepers, 2001, p. 11). Intranets are not a pre-given and unproblematic tool for knowledge management. Instead, the implementation and use of an intranet as a tool for knowledge sharing needs a careful understanding of its social-cultural impact and at the same time has to be seen as a cultural phenomenon in itself. This means that an intranet should not be treated as the explanans (the thing or solution that explains the communication problem); in other words, with the help of the intranet, we can solve our communication problems—but rather as the explanandum (the thing or solution that has to be explained): What are the cultural features that shaped the intranet, and in what way does the use of intranets shape and reshape communication patterns within the organization?

In order to understand the cultural aspects of intranets, we have to incorporate the sensemaking processes both during the managerial implementation process as well as in a socio-cultural analysis. In our approach this means a careful analysis of the condition of intranets (what socio-technical choices are made to build the technology), intranet as a constitution (what kind of organization is made possible by the intranet), and the consequences of intranets (how the intranet affects the communication patterns within the organization). This perspective offers the possibility to integrate the 'virtual' communication on the intranet with the patterns of social behavior in the 'real' world.

INTRODUCTION

Resource retrieval addresses the problem of finding best matches to a request among available resources, with both the request and the resources described with respect to a shared interpretation of the knowledge domain the resource belongs to. The problem of resource matching and retrieval arises in several scenarios, among them, personnel recruitment and job assignment, dating agencies, but also generic electronic marketplaces, Web services discovery and composition, resource matching in the Grid. All these scenarios share a common purpose: given a request, find among available descriptions those best fulfilling it, or at "worse," when nothing better exists, those that fulfill at least some of the requirements.

Exact, or full, matches are usually rare and the true matchmaking process is aimed at providing one or more "promising" matches to be explored. Non-exact matches should take into account both missing information—details that could be positively assessed in a second phase—and conflicting information—details that could leverage negotiation if the proposed match is worth enough pursuing.

Because of its intangibility, it is now a widely shared opinion that knowledge has to be modeled to make unambiguous the interpretation of any information domain. This disambiguation process is usually obtained through an ontology, that is, a specification of a representational vocabulary for a shared domain of discourse—definitions of classes, relations, functions, and other objects (Gruber, 1993).

Once a knowledge domain has been modeled, and several different resources have been described using such a model, issues that need to be faced for efficient knowledge management are: What, if any, kind of retrieval is possible on these resources? How could we benefit both of the model and formalisms used to build the model, in order to perform a "smart" search of described resources matching a request? The above questions focus on important aspects of knowledge-based retrieval:

- formalisms used to model a knowledge domain
- retrieval services that fully use the expressiveness of the formalism to infer new knowledge from the model in order to perform a knowledge-based search

Knowledge domain is modeled with a formalism, whose expressiveness is used in the retrieval process to infer not elicited information from the model. In such a context, choosing this formalism strongly affects the complexity, as well as success probability, of the retrieval process.

In recent years description logics (DLs) have been investigated by both the academic and industrial world as a formalism for knowledge representation. Modeling an information domain through the formalism of a DL allows one to employ reasoning services provided by DLs to perform a knowledge-based search. Knowledge domains are formalized in ontologies, which resource descriptions refer to. The use of ontologies allows elicited descriptions to be stored so that information can be inferred from them to retrieve a resource.

The remainder of this article is structured as follows: Background work is revised, including DL basics with associated reasoning services and previous approaches to resource retrieval, including non-logic- and logic-based alternatives. Then, we introduce semantic-based resource retrieval, first highlighting new non-standard inference services and then showing how they can be used for "smart" resource retrieval. Finally, we propose some future trends and draw a conclusion.

BACKGROUND

Description Logics Basics

Description, or terminological, logics (Baader, Calvanese, Mc Guinness, Nardi, & Patel-Schneider, 2002; Donini, Lenzerini, Nardi, & Schaerf, 1996) are a family of logic formalisms for knowledge representation. All DLs are endowed of a syntax and a model-theoretic semantics. The basic syntax elements of DLs are: concept names, role names, individuals. Intuitively, concepts stand for sets of objects, and roles link objects belonging to different concepts. Individuals are special named elements of the sets of objects concepts represent.

We give a more formal definition of the outlined basic elements by introducing the concept of semantic interpretation.

Definition 1: A semantic interpretation is a pair $I=(\Delta, \cdot I)$ made up of a domain Δ and an interpretation function $\cdot I$, which maps every concept to a subset of Δ, every role to a subset of $\Delta\times\Delta$, and every individual to an element of Δ.

Usually, a so-called Unique Name Assumption (UNA) is made which ensures different individuals to be mapped to different elements of Δ, i.e., $a^I \neq b^I$ for individuals $a \neq b$.

Every DL allows one to combine basic elements using constructors to form concept and role expressions. Each DL has its distinguished set of constructors, though all of them provide the conjunction of concepts, usually denoted as $\sqcap$. Among the distinguishing concept expressions constructors we enumerate disjunction $\sqcup$ of concepts and complement $\neg$ to close concept expressions under Boolean operations.

Role expressions can be obtained by combining roles with concepts using existential role quantification and universal role quantification. Other constructs may involve counting, as number restrictions.

Many other constructs can be defined, increasing the expressive power of the DL, up to n-ary relations (Calvanese, De Giacomo, & Lenzerini, 1998). Nevertheless, it is a well-known result that usually leads to an explosion in computational complexity of inference services (Brachman & Levesque, 1984). Hence, a trade-off is needed between expressivity and expected performance of reasoning services.

Once expressions have been built, they are given semantics by defining the interpretation function over each construct. Concept conjunction is interpreted as set intersection, and the other Boolean connectives also have the usual set-theoretic interpretation. The interpretation of constructs involving quantification on roles needs to make domain elements explicit.

Concept expressions can be used in inclusion assertions, and definitions, which impose restrictions on possible interpretations according to the knowledge elicited for a given domain. Definitions are useful to give a meaningful name to particular combinations. Sets of such inclusions are called TBox (terminological box). A TBox, which basically amounts to an ontology, represents a formal, shared, and objective intensional knowledge on a domain. Individuals can be asserted to belong to a concept using membership assertions in an ABox. An ABox is the extensional knowledge of the domain that can be described based on the TBox. The semantics of inclusions and definitions is based on set containment: An interpretation I satisfies an inclusion $C \sqsubseteq D$ if $C^I \sqsubseteq D^I$, and it satisfies a definition $C = D$ when $C^I = D^I$. A model of a TBox T is an interpretation satisfying all inclusions and definitions of T. DL-based systems are equipped with reasoning services: logical problems whose solution can make explicit knowledge that was implicit in the assertions.

DL-based systems usually provide at least two basic reasoning services for T:

- Concept Satisfiability: Given a TBox T and a concept C, does there exist at least one model of T assigning a non-empty extension to C?
- Subsumption: Given a TBox T and two concepts C and D, is C more general than D in any model of T?

The previous services can be seen, from a knowledge management perspective, in a more informal way:

- Concept Satisfiability: Given an ontology (T) modeling the domain we are investigating on and a description (C) of a resource referring to the ontology: Is the information modeled in the description consistent with the one in the ontology?
- Subsumption: Given an ontology (T) modeling the domain we are investigating on and two resources described by expressions (C, D) referring to the information modeled in the ontology: Is the information about a resource more general than the one related to the other one?

Both Subsumption and Satisfiability are adequate in all those knowledge management contexts where a yes/no answer is enough. For example, given a resource and a request represented respectively by a concept O and a concept R, using Concept Satisfiability we are able to determine whether they are compatible, that is, O models information that is not in conflict with the one modeled by R. This task can be performed checking the satisfiability of the concept $O \sqcap R$.

On the other hand, Subsumption can be used to verify, for example, if a resource described by O satisfies a request R, namely, if the relation $O \sqsubseteq R$ holds, then O is more specific than R and it contains at least all the requested features.

For ABoxes, other standard inference services have been defined. Among the various devised, we point out:

- Instance checking: An assertion α is entailed by an Abox A, if every interpretation that satisfies A also satisfies α.
- Retrieval problem: Given an Abox A and a concept C, find all individuals α such that A entails C(α).
- Realization problem: Given an individual α and a set of concepts, find the most specific concept C from the set such that A entails C(α).

Together with standard inference problems, non-standard ones have been proposed and investigated. The least common subsumer (lcs), most specific concept (msc), unification, matching and concept rewriting have been thoroughly presented by Baader et al. (2002). The application field for lcs and msc is the construction of DL knowledge bases using a bottom-up approach instead of the usual top-down one (Baader & Turhan, 2002). The unification and matching services are useful for large knowledge bases maintenance, allowing knowledge engineers to catch equivalence or subsumption relationships among concept expressions (Baader & Turhan, 2002). With concept rewriting the readability of large concept descriptions can be increased, by using concepts defined in an ontology.

Although the general approach proposed in this article does not depend on a particular DL, it has been fully devised for a particular DL, namely the ALN (Attributive Language with Number Restrictions). Constructs allowed in an ALN DL are:

- $\top$ Universal Concept: All the objects in the domain
- $\bot$ Bottom Concept: The empty set
- A Atomic Concepts: All the objects belonging to the set represented by A
- $\neg A$ Atomic negation: All the objects not belonging to the set represented by A
- $C \sqcap D$ Intersection: The objects belonging both to C and D
- $\forall R.C$ Universal restriction: All the objects participating to the R relation whose range are all the objects belonging to C
- $\exists R$ Unqualified existential restriction: There exists at least one object participating in the relation R. Notice that $\exists R \equiv (\geq 1\ R)$
- $(\geq n\ R) \mid (\leq n\ R) \mid (= n\ R)$ Unqualified number restrictions: Respectively, the minimum, the maximum, and the exact number of objects participating in the relation R. We write $(= n\ R)$ for $(\geq n\ R) \sqcap (\leq n\ R)$

We adopt a simple-TBox, that is, in all the axioms (for both inclusion and definition) the left side is represented by a concept name, and there is only one axiom for each atomic concept.

Ontologies using this logic can be easily modeled using languages for the Semantic Web. These languages have been conceived to allow for representation of machine-understandable, unambiguous, description of Web content through the creation of domain ontologies, and aim at increasing openness and interoperability in the Web environment. The strong relation between DLs and the introduced languages for the Semantic Web also is evident in the definition of the OWL language. In fact, there are three different sub-languages for OWL:

- OWL-Lite: It allows class hierarchy and simple constraints on relation between classes.
- OWL-DL: Based on description logics theoretical studies, it allows a great expressiveness keeping computational soundness and completeness.
- OWL-Full: Using such a language, there is a huge syntactic flexibility and expressiveness. This freedom is paid in terms of no computational guarantee.

The ALN DL is basically a subset of OWL-DL.

Approaches to Resource Retrieval

We start with a description of various approaches to resource retrieval, highlighting limitations of non-logical approaches, then discussing the general knowledge representation principles that a logical approach may yield.

Modeling a resource retrieval framework using standard relational database techniques would require to completely align the attributes of the available and requested resources descriptions, in order to evaluate a match. On the other hand, if requests and offers are simple names or terms, the only possible match would be identity, resulting in an all-or-nothing approach to the retrieval process. Vague query answering, proposed by Motro (1988), was an initial effort to overcome limitations of relational databases, with the aid of weights attributed to several search variables.

Vector-based techniques taken by classical information retrieval can be used as well, thus, reverting the search for a matching request to similarity between weighted vectors of stemmed terms, as proposed in the COINS matchmaker (Kuokka & Harada, 1996) or in LARKS (Sycara, Klusch, & Lu, 2002). Such a formalization for resource descriptions makes retrieval only probabilistic because descriptions lack a document structure, causing strange situations to ensue. Let us consider for example the following sentences, describing respectively competences required for a job in a company and competences provided by a worker: "engineer, with experience of two years as project manager, not full time employed, available to transfers" and "experienced project manager, full time employed as engineer for two years, not available to transfers."

The former is a simple example in which two descriptions in obvious conflict may be considered an exact match because of the formalism chosen to represent them. A further approach structures resource descriptions as a set of words. This formalization allows one to evaluate not only identity between sets but also some interesting set-based relations between descriptions, such as inclusion, partial overlap, and cardinality of set difference. Modeling resource descriptions as set of words is anyway too much sensible to the choice of words employed to be successfully used: the fixed terminology misses meaning that relate words. Such a problem can be overcome by giving terms a logical and shared meaning through an ontology (Fensel, van Harmelen, Horrocks, McGuinness, & Patel-Schneider, 2001). Nevertheless, set-based approaches have some properties we believe are fundamental in a resource matching and retrieval process. If we are searching for a resource described through a set of words, we also are interested in sets including the one we search, because they completely fulfill the resource to retrieve. Moreover, even if there are characteristics of the retrieved resource not elicited in the description of the searched resource, an exact match is still possible because absent information have not to be considered negative. The two statements may be summarized in the following property:

- Property 1 [Open-world descriptions]: The absence of a characteristic in the description of a resource to be retrieved should not be interpreted as a constraint of absence. Instead, it should be considered as a characteristic that could be either refined later or left open if it is irrelevant for the user searching for the resource.

The set-based match evaluation is non-symmetric: If we search for a resource A, whose describing set of words is included in a set characterizing resource B, we may consider B a resource perfectly satisfying the request for A. On the other hand, if we use the description of B for the search, A also may satisfy the request only partially, as some of the terms describing B may be not included in the A set. We formalize this behaviour as follows:

- Property 2 [Non-symmetric evaluation]: Given two resource descriptions A and B, a resource retrieval system may give different rankings depending on whether it is searching A using B description as query, or B using A as query.

From now on, we assume that resource descriptions, requested and offered, are expressed in a DL. This approach includes the sets-of-keywords one, since a set of keywords also can be considered as a conjunction of concept names. We also assume that a common ontology is established, as a TBox in DL.

With reference to recent related work on logic-based matching and retrieval of resources, approaches are concentrated on electronic marketplaces, where resources are supplies and demands, and Web services discovery, where resources are e-services to be discovered and composed. Finin, Fritzson, McKay, and McEntire (1994) and Kuokka and Harada (1996) introduced matchmaking based on KQML, as an approach whereby potential producers/consumers could provide descriptions of their products/needs to be later unified by a matchmaker engine to identify potential matches. A rule-based approach using the knowledge interchange format (KIF) (Genesereth, 1991), the SHADE prototype (Kuokka & Harada, 1996), or a free-text comparison (the COINS prototype) (Kuokka & Harada, 1996) were used. Approaches similar to the previous ones were deployed in SIMS (Arens, Knoblock, & Shen, 1996), which used KQML and LOOM as description language and InfoSleuth (Jacobs & Shea, 1995), which adopted KIF and the deductive database language LDL++. LOOM also is at the basis of the matching algorithm addressed by Gil and Ramachandran (2001).

Sycara et al. (2002) and Paolucci, Kawamura, Payne, and Sycara (2002) proposed the LARKS language, specifically designed for agent advertisement. The matching process is a mixture of classical IR analysis of text and semantic match via Q-subsumption. Nevertheless, a basic service of a semantic approach, such as inconsistency check, seems unavailable with this type of match.

First approaches based on standard inference services offered by DL reasoners were proposed by Di Sciascio, Donini, Mongiello, and Piscitelli (2001), Gonzales-Castillo, Trastour, and Bartolini (2001), and Trastour, Bartolini, and Priest (2002). Di Noia, Di Sciascio, Donini, and Mongiello (2003b, 2003c) described and motivated properties that a matchmaker should have in a DL-based framework, and algorithms to classify and rank matches into classes were presented. Matchmaking of Web services, providing a ranking of matches based on this DL-based approach was presented by Colucci, Di Noia, Di Sciascio, Donini, and Mongiello (2003b). An extension to the approach by Paolucci et al. (2002) was proposed by Li and Horrocks (2003) where two new levels for service profiles matching were introduced. Notice that the intersection satisfiable level was introduced, whose definition is close to the one of potential matching proposed by Di Noia et al. (2003b), but no measure of similarity among intersection satisfiable concepts was given.

Benatallah, Hacid, Rey, and Toumani (2003) proposed an approach to Web services discovery based on the difference operator in DLs (Teege, 1994), followed by a set covering operation optimized using hypergraph techniques.

SEMANTIC-BASED RESOURCE RETRIEVAL

The Need for New Non-Standard Reasoning Services

In all those approaches where no explanation on the obtained results is requested or no belief revision is admitted, Subsumption and Consistency Checking are enough. The following are typical examples of the behaviour the reasoning services would have for resource retrieval:

- Subsumption: "Yes, your request is completely satisfied by resourceX"

  resourceX $\sqsubseteq$ request

- Consistency Checking: "No, your request is not compatible with resourceX"

  resourceX $\sqcap$ request $\equiv \bot$

Unfortunately, in a semantic-based resource retrieval system a simple yes/no answer cannot be enough; the requester is often interested in explanations especially when the system returns a negative answer. Some of the questions are:

- "What should I give up in my request in order to regain satisfiability with the offered resource?"
- "How should I contract my request?"
- "What should I revise in my request in order to be completely satisfied?"
- "What should I abduce in the available resource?"

Colucci et al. (2003a) and Di Noia et al. (2003a) introduced and defined Concept Abduction—for no-Subsumption explanation—and Concept Contraction—both for un-Consistency Checking explanation and for belief revision suggestion—as new non-standard inference services for DLs. In this subsection, we briefly recall their definitions, explaining their rationale and the need for them in resource retrieval.

Concept Contraction

Starting with the concepts O and R, if the conjunction O $\sqcap$ R is unsatisfiable in the TBox T representing the ontology—that is, they are not compatible with each other—we may want to retract requirements in R, G (for Give up), to obtain a concept K (for Keep) such that K $\sqcap$ O is satisfiable in T. This scenario can be formally depicted as:

Definition 2: Let L be a DL, O, R, be two concepts in L, and T be a set of axioms in L, where both O and R are satisfiable in T. A Concept Contraction Problem (CCP), identified by $\langle$L,R,O,T$\rangle$, is finding a pair of concepts $\langle$G,K$\rangle$ $\in$ L×L such that T $\models$ R $\equiv$ G $\sqcap$ K , and K $\sqcap$ O is satisfiable in T. We call K a contraction of R according to O and T.

We use Q as a symbol for a CCP, and we denote with SOLCCP(Q) the set of all solutions to a CCP Q. We note that there is always the trivial solution $\langle$G,K$\rangle$ = $\langle$R,T$\rangle$ to a CCP. This solution corresponds to the most drastic contraction, that gives up everything of R. In our resource retrieval framework, it models the (infrequent) situation in which, in front of some very appealing resource O, incompatible with the requested one, a user just gives up completely his or her specifications R in order to meet O. On the other hand, when O $\sqcap$ R is satisfiable in T, the "best" possible solution is $\langle$T,R$\rangle$, that is, give up nothing, if possible. Hence, a

Concept Contraction problem is an extension of a satisfiable one. Since usually one wants to give up as few things as possible, some minimality in the contraction must be defined (Gärdenfors, 1988). In most cases, a pure logic-based approach could not be sufficient to decide between which beliefs to give up and which to keep. There is the need of modeling and defining some extra-logical information to be taken into account. One approach is to give up minimal information (Colucci et al., 2003a). Another one considers some information more important than other and the information that should be retracted is the least important one, that is negotiable and strict constraints are introduced (Di Noia, Di Sciascio, & Donini, 2004).

Concept Abduction

If the offered resource O and the requested one R are compatible, the partial specifications problem still holds, that is, it could be the case that O—though compatible—does not imply R. Then, it is necessary to assess what should be hypothesized (H) in O in order to completely satisfy R.

Definition 3: Let L be a DL, O, R, be two concepts in L, and T be a set of axioms in L, where both O and R are satisfiable in T. A Concept Abduction Problem (CAP), identified by L,R,O,T$\rangle$, is finding a concept H $\in$ L such that $T \models O \sqcap H \sqsubseteq R$, and moreover $O \sqcap H$ is satisfiable in T. We call H a hypothesis about O according to R and T.

We use P as a symbol for a CAP, and SOL(P) to denote the set of all solutions to a CAP P. Observe that in the definition, we limit to satisfiable O and R, since R unsatisfiable implies that the CAP has no solution at all, while O unsatisfiable leads to counterintuitive results ($\neg$R would be a solution in that case). If $O \sqsubseteq R$, then we have H = T as a solution to the related CAP. Hence, Concept Abduction extends subsumption. On the other hand, if $O \equiv T$ then $H \sqsubseteq R$.

Notice that both Concept Abduction and Concept Contraction can be used for, respectively, subsumption and satisfiability explanation. For Concept Contraction, having two concepts not compatible with each other, in the solution $\langle G,K \rangle$ to the CCP $\langle L,R,O,T \rangle$, G represents "why" O and R are not compatible. For Concept Abduction , having R and O such that $T \not\models O \sqsubseteq R$, the solution H to the CAP $\langle L,R,O,T \rangle$ represents "why" the subsumption relation does not hold. H amounts to what is specified in R and not in O.

Expected performances of inference services are obviously of paramount importance to evaluate the feasibility of an approach. We hence provide some insight into complexity issues of the services. We note that since Concept Abduction extends Concept Subsumption w.r.t. a TBox, complexity lower bounds of the latter problem carry over to decision problems related to a CAP.

- Proposition: Let P $\langle L,R,O,T \rangle$, be a CAP. If Concept Subsumption w.r.t. a TBox in L is a problem C-hard for a complexity class C, then deciding whether a concept belongs to SOL(P) is C-hard.

As Concept Abduction extends Subsumption, Concept Contraction extends satisfiability—in particular, satisfiability of a conjunction $K \sqcap R$.

- Proposition: Let L be a DL containing $\mathcal{AL}$, and let Concept Satisfiability w.r.t. a TBox in L be a problem C-hard for a complexity class C. Then, deciding whether a pair of concepts is a solution of a CCP Q=$\langle L,R,O,T \rangle$, is C-hard.

Both for Concept Abduction and Concept Contraction, for every single CAP—conversely CCP—there is not only one solution. Different kinds of solution can be classified with respect to different minimality criteria. Colucci et al. (2003a), Di Noia et al. (2003a), and Colucci et al. (2004) present the definition of some minimality criteria and corresponding complexity results.

Approximate Resource Retrieval via Concept Abduction and Concept Contraction

We now show how the previously introduced services can help in an approximate, semantic-based search of resources, fully exploiting their structured description. Let us suppose to have request R and an appealing resource O such that $T \models R \sqcap O \equiv \bot$, that is, they are incompatible. In order to gain compatibility, a Concept Contraction is needed so that giving up G in R, the remaining K can be satisfied by O. Now, if $T \not\models O \sqsubseteq K$, the solution HK to the CAP ⟨L,R,O,T⟩ represents what is in K and is not specified in O.

As the O obtained is an approximated match of R, then a measure is needed on how good the approximation is. Given more than one appealing resource, which one is the best approximation? How can it be assigned a numerical score to the approximation, based on K, H and G, in order to rank the resources?

In table 1, we present a simple algorithm to provide answers to the raised issues.

Notice that H = abduce(O,R,T) [rows 3,6] determines H is a solution for the CAP ⟨L,R,O,T⟩; ⟨G,K⟩ = contract(O,R,T) [row 2] determines ⟨G,K⟩ is a solution for the CCP ⟨L,R,O,T⟩.

The algorithm retrieve returns values useful in a retrieval system where explanation of the results is needed and/or a belief revision process is admitted.

[rows 1-4] Having a requested resource R and an offered one O, if their descriptions conjunction is not satisfiable w.r.t. the ontology they refer to (i.e., they are not compatible with each other for some concepts in their descriptions), first a contraction on R is performed in order to regain compatibility [row 2], and then what is to be hypothesized in O in order to completely satisfy R (its contraction) is computed [row 3]. The returned values represent:

- G: What is to be given up in the request in order to continue the process, or, in other words, why R is not compatible with O.
- HK: After the contraction of R, the request is represented by K, that is, the portion of R which is compatible with O. HK represents what is to be hypothesized in O in order to completely satisfy K, or, in other words, why O does not completely satisfy K.

Table 1.

```
algorithm Retrieve(O,R,T,L)
input O, R η K6G concepts in L such that both T □ O and T □ R.
output ⟨G, H⟩,  respectively, the part in R that should be given up and the part in O
that should be hypothesized in order to find an exact match between O and R.
begin algorithm
1:      if T □ R6O η ∩ then
2:              ⟨G,K⟩ = contract(O,R,T);
3:              H_K = abduce(O,K,T);
4:              return ⟨G, H_K⟩;
5:      else
6:              H = abduce(O,R,T);
7:              return ⟨∅, H⟩;
end algorithm.
```

[rows 5-7] If the conjunction of R's and O's description is satisfiable w.r.t. the ontology they refer to, then no contraction is needed and only an abductive process is carried out.

The algorithm does not depend on the particular DL adopted. Based on the minimality criteria proposed by Di Noia et al. (2003a), the length |H| of the solution to a CAP for an ALN DL can be computed as proposed by Di Noia et al. (2003c). Hence, a relevance ranking score can be computed by an utility function defined as U(|G|,|K|,|HK|).

The rationale of the retrieve algorithm is hereafter presented with the aid of a simple example. Let $\mathcal{T}$, R, O be a set of axioms, a searched resource description, and an available resource description, respectively, defined as follows:

$\mathcal{T}$ = {
PC ⊑ Computer ⊓ ∃hasOS
HomePC ⊑ PC ⊓ ∀hasOS.MS ⊓ ∃pointer
HighLevel ⊑ ∃cost ⊓ ∀cost.Expensive
Expensive ⊑ ¬Cheap
MS ⊑ ¬Unix
}

R = HomePC ⊓ ∃monitor ⊓ ∀pointer. ∀cost.Cheap
O = PC ⊓ ∃pointer ⊓ ∀pointer.(Mouse ⊓ HighLevel) ⊓ ∀hasOS.Unix

First, we observe that T ⊨ R ⊓ O ≡ ⊥, due to the specifications on both Operating System and cost of the pointer. Hence, the algorithm performs a Concept Contraction solving the CCP ⟨$\mathcal{L}$,$\mathcal{R}$,$\mathcal{O}$,$\mathcal{T}$⟩. A solution for the previous CCP is:

⟨G,K⟩ = ⟨HomePC ⊓ ∀pointer.∀cost.Cheap, PC ⊓ ∃pointer ⊓ ∃monitor⟩

After the contraction operation, the remaining part of R is not yet satisfied by O. That is, O ⊑ K does not hold. To compute what is needed in order to realize the subsumption relation, retrieve solves the CAP ⟨L,K,O,T⟩. A solution for the previous CAP is: HK = ∃monitor

If the searching agent—with the term agent used in its broadest sense—is interested in O, it must give up HomePC ⊓ ∀pointer.∀cost.Cheap in its R and ask for further information about ∃monitor.

Retrieval performances have been usually evaluated in classical full text information retrieval in terms of precision and recall. Although such measures require large datasets to have any significance, it can be expected that semantic-based retrieval can provide at least a noteworthy improvement in precision, with respect to free-text probabilistic approaches.

FUTURE TRENDS

As the Semantic Web initiative gets momentum, more and more resources described using structured descriptions—based on ontologies—will become available (Schwartz, 2003). Current and future application scenarios of the semantic-based retrieval techniques presented here include: electronic-marketplaces of tangible or intangible goods, skill management systems, mediators for Web service discovery and for grid-based computational resources, and dating and personnel recruitment agencies. The increased availability of semantically annotated descriptions will hence boost the emergence of knowledge-based systems able to take full advantage of these structured descriptions to obtain accurate and efficient retrieval. The framework and services described in this article are general enough to be used in the approximate search and retrieval of a variety of resources, and systems using them can provide—adopting different minimality criteria—logically motivated relevance-based rankings in the retrieval process. The necessary trade-off between expressivity and performance of semantic-based systems is likely to be exploited adopting various approaches. Among them, tableaux-based algorithms (Colucci et al., 2004); careful choice of constructs able to keep complexity tractable, as proposed for example with DL-Lite by Calvanese, De Giacomo, Lenzerini, Rosati, & Vetere (2004), and combined use of DL-based easoners with classical relational databases to face scalability issues when dealing with large numbers of individuals (Horrocks, Li, Turi, & Bechhofer, 2004).

CONCLUSION

We have presented and motivated new DL-based inference services for semantic-based resource retrieval. Currently, our approach is fully devised, and algorithms and a prototype system have been implemented for an ALN description logic. Work also is in progress to extend the approach to more expressive DLs, while keeping time performances still acceptable.

Chapter 3.5
Knowledge Flow

Vincent M. Ribière
New York Institute of Technology, USA

Juan A. Román
National Aeronautics and Space Administration (NASA), USA

INTRODUCTION

Various models and frameworks have been used to represent the flows of knowledge in an organization. The first and most popular of these remains the spiraling SECI (socialization, externalization, combination, internalization) model presented by Nonaka and Konno (1998), Nonaka and Takeuchi (1995), and Nonaka and Toyama (2003), which presents the various knowledge interactions and creations between tacit and explicit knowledge. Knowledge flows can also be represented and assessed through the knowledge life cycle.

Knowledge creation, discovery, capture
⇩
Knowledge storage, retention, organization
⇩
Knowledge transfer, sharing, distribution
⇩
Knowledge use & maintenance

In this article, we describe knowledge flows through a third lens that is based on how people obtain and/or share the knowledge that they need to perform their work. We found a certain agreement on a typology defining two main strategies for knowledge flows: codification vs. personalization.

BACKGROUND

The Codification Strategy

The codification strategy is intended to collect, codify, and disseminate information. It relies heavily on information technology. One of the benefits of the codification approach is the reuse of knowledge. According to Davenport and Prusak (1998, p. 68):

The aim of codification is to put organizational knowledge into a form that makes it accessible *to those who need it. It literally turns knowledge into a code (though not necessarily a computer code) to make it as organized, explicit, portable, and easy to understand as possible.*

The codification strategy has been named and described in different ways by various authors. In 1999, Hansen, Nohria, and Tierney published an article in the Harvard Business Review titled "What's your strategy for managing knowledge?" In this article, they describe how different companies focus on different practices and strategies in order to manage their knowledge. The first approach is called codification, where the strategy centers on the computer:

Knowledge is codified and stored in databases, where it can be accessed and used easily by anyone in the company. Knowledge is codified using a people-to-documents approach: it is extracted from the person who developed it, made independent of that person, and reused for various purposes. (Hansen et al., p. 108)

Hansen et al. illustrate this strategy with the case of two consulting companies, Anderson Consulting and Ernst & Young, which adopted this strategy due to the fact that their activity mainly focused on implementation projects rather than on purely innovative projects. Stephen Denning (1998), former CKO of the World Bank, describes two different ways of sharing knowledge: the collecting dimension and the connecting dimension. The collecting dimension is described as the "capturing and disseminating of know-how through information and communication technologies aimed at codifying, storing and retrieving content, which in principle is continuously updated through computer networks" (Denning, p. 10).

Know-Net (2000), a "Leading Edge Total Knowledge Management [KM] Solution" developed by an European consortium, incorporates such an approach. Know-Net calls it the product view and the process view. The product-view approach is described as focusing on products and artifacts containing and representing knowledge. This implies the management of documents, and their creation, storage, and reuse in computer-based corporate memories. The competitive strategy is to exploit organized, standardized, and reusable knowledge.

Natarajan and Shekhar (2000) present two models, the transformation model and the independent model, that clearly comply with the previous descriptions. The transformation model deals with explicit knowledge, relying mainly on document capture, structured databases, knowledge-extraction tools, text mining, and search and retrieval applications.

A Lotus white paper, describing KM and collaborative technologies, categorizes KM applications as distributive or collaborative: "Distributive applications maintain a repository of explicitly encoded knowledge created and managed for subsequent distribution to knowledge consumers within or outside the organization" (Zack & Michael, 1996).

As we can observe, all these descriptions and definitions are very closely related in depicting a codification strategy. For the remainder of this article, we will adopt the codification naming in order to refer to the type of approaches previously described.

The Personalization Strategy

The personalization strategy focuses on developing networks for linking people so that tacit knowledge can be shared. It invests moderately in IT. This approach corresponds to the Nonaka and Takeuchi (1995), and Nonaka and Toyama (2003) personalization phase of the SECI model where knowledge flow and creation happen during an exchange of tacit knowledge. The authors, who previously defined the codification strategy, also provide their own definition of the personalization strategy. Hansen et al. (1999) named it personalization. It focuses on dialogue between individuals as opposed to knowledge in a database: "Knowledge that has not been codified—and probably couldn't be—is transferred in brainstorming sessions and one-on-one conversations" (Hansen et al.). An investment is made in building networks of people, where knowledge is shared not only face-to-face, but also over the telephone, by e-mail, and via videoconference. Hansen et al. illustrate this strategy with the case of three consulting companies, McKinsey, BCG, and Bain, which adopted this strategy since they mainly focus on customized and innovative projects. Stephen Denning (1998) defines this strategy as the connecting dimension:

It involves linking people who need to know with those who do know, and so developing new capabilities for nurturing knowledge and acting knowledgeably. For example, help desks and advisory services (small teams of experts whom one can call to obtain specific know-how or help in solving a problem) can be very effective in the short term in connecting people and getting quick answers to questions, thus accelerating cycle time, and adding value for clients.

Know-Net (2000) defines this as the process-centered approach, which focuses on knowledge management as a social communication process. It facilitates conversations to exchange knowledge and can be improved by various aspects and tools of collaboration and cooperation support.

Natarajan and Shekhar (2000) use the independent-model designation to describe the tools that attempt to find solutions for the sharing of tacit knowledge. They list a number of technologies that could be used to facilitate the sharing of knowledge. Among them are technologies such as Web-based training used for skill-enhancement programs. Yellow pages, Web crawlers, broadcast applications, communities of practice (using expert locators, collaboration, virtual work-space applications), and the sharing of best practices (using knowledge repositories and discussion-group-based applications) are also examples of knowledge sharing.

Zack and Michael (1996) talk about the collaborative approach that focuses primarily on supporting interaction and collaboration among people holding tacit knowledge. They highlight that:

in contrast to distributive applications, the repository associated with collaborative applications is a by-product of the interaction, rather than the primary focus of the application. This repository of messages is dynamic and its content emergent. The ability to capture and structure emergent communication within a repository provides a more valuable, enduring, and leverageable knowledge by-product than the personal notes or memories of a traditional conversation or meeting. Collaboration technologies, therefore, can support a well-structured repository of explicit knowledge while enabling the management of tacit knowledge. The knowledge repository represents a valuable means to manage the explication, sharing, combination, application, and renewal of organizational knowledge. (Zack & Michael).

Once again, we can observe that all of these descriptions and definitions are very similar and depict the same type of processes and tools. Personalization approaches facilitate the person-to-person knowledge transfer. For the rest of this article, we will adopt the personalization designation in order to refer to the type of approaches previously described.

Codification vs. Personalization

What is the best strategy for managing knowledge? Hansen et al. (1999) noted that effective organizations excel by primarily emphasizing one of the strategies and using the other in a supporting role. They postulate that companies trying to excel at both strategies risk failing at both. They refer to a 20-80 split between codification and personalization. This proposal raised much discussion in the literature (Koenig, 2004) and in the HBR

Figure 1. The codification strategy

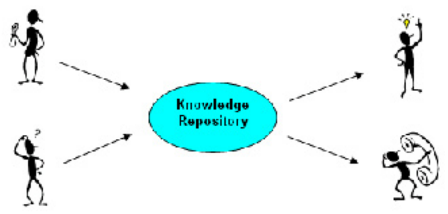

Figure 2. The personalization strategy

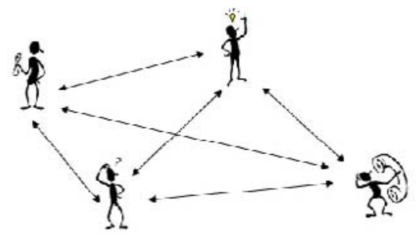

forum referring to this article (HBR Forum, 1999). Denning (1998) mentioned that organizations that focus entirely on a personalization approach, with little or no attempt at codification, can be very inefficient.

In order to select an adoption strategy, Tiwana (2002) designed a checklist based on the recommendations of Hansen et al. They recommended examining the company's competitive strategy (What value do customers expect from the company? How does the knowledge that resides in the company add value to customers' goals?). Once the competitive strategy is clear, three additional questions might be investigated.

- Does your company offer standardized or customized products?
- Does your company have a mature or innovative product?
- Do people rely on explicit or tacit knowledge to solve problems?

Companies having standardized products and/or mature products might want to focus on a codification approach. In contrast, companies having customized and/or innovative products might want to focus on a personalization approach. People relying on explicit knowledge will also be more disposed to adopt a codification approach. Furthermore, recent research highlights the critical role that organizational culture and interpersonal trust have in the selection of these two KM strategies (Ribière, 2001; Ribière & Tuggle, 2005; Román-Velázquez, 2004; Román, Ribière, & Stankosky, 2004). They demonstrated that the success of a KM strategy might be directly impacted by the type of organizational culture present in the organization.

The next section of this article presents the findings of an empirical study of U.S. organizations, covering the government, for-profit, and nonprofit sectors. The study was conducted to characterize the strategic approach for knowledge flow within the different sectors.

EMPIRICAL STUDY

The data analyzed in this article were collected during two independent research studies performed by Ribière (2001) and Román-Velázquez (2004), which evaluated the KM strategy (codification and personalization) that employees predominantly use to facilitate the flow of knowledge throughout the organization. Ribière's research developed a list of 23 items that were theoretically divided into two groups: one for codification and one for personalization. However, Román-Velázquez modified and reduced the list to 20 items based on an extensive literature review (Hoyt, 2001; Kemp, Pudlatz, Perez, & Munoz Ortega, 2001; Marwick, 2001; McKellar & Haimila, 2002; Shand, 1998) and after detailed conversations with expert practitioners in the field of KM, human resources, experiment design, and information technology (Boswell, 2002; Naus, 2002; Reed,

Table 1. Responses by category

	Frequency	Percent	Cumulative Percent
For-Profit	66	15.3	15.3
Government	313	72.6	87.9
Nonprofit	52	12.1	100.0
Total	431	100.0	

2002; Rhoads, 2002). In addition, the model was validated during previous research and found to be accurate and reliable (Román-Velázquez; Román-Velázquez et al., 2004).

For this study, the data were concatenated, creating a new data set with 431 respondents (N = 431) as described in Table 1. A total of 13 indicator variables were retained for analysis. The variables were evaluated using a seven-point scale where 1 is Very Minimum Extent, 7 is Very Great Extent, and 0 is assigned to responses for Don't Know and Don't Exist. This study employed inferential statistical analysis, using the data collected from respondents to make estimates about a much larger population. The confidence levels and confidence intervals are two key components of the sampling error estimates and refer to the probability that our estimations are correct (Babbie, 1998; Sekaran, 1992). Using N = 431 as the responses collected and a 95% confidence level, the confidence interval is calculated to be ± 4.72.

The data analysis revealed mean score values for the 13 indicator variables ranging from 5.47 to 3.14 as shown in Table 2. Their mean score provides an indication of their usage and popularity. The table can be analyzed using two perspectives: by

Table 2. Descriptive statistics for the technologies, support tools, and processes utilized throughout the organization

Technologies, Support Tools, & Processes[1]	**C/P**	**Mean**	**Standard Deviation**
Intranet/Extranet	C	5.74	1.55
Phone calls/Teleconferencing	P	5.40	1.81

Videoconferencing	P	3.77	2.04
Benchmarking/Best Practices	C	3.69	2.00
Multimedia Repositories	C	3.45	2.09
Data Mining/Knowledge-Discovery Tools	C	3.30	2.11
Expertise Locator/Directory of Expertise	P	3.19	2.23
Storytelling	P	3.14	2.13

N = 431   C: codification; P: personalization the absolute mean score compared to all items, and by considering the KM strategy that each item represents independently.

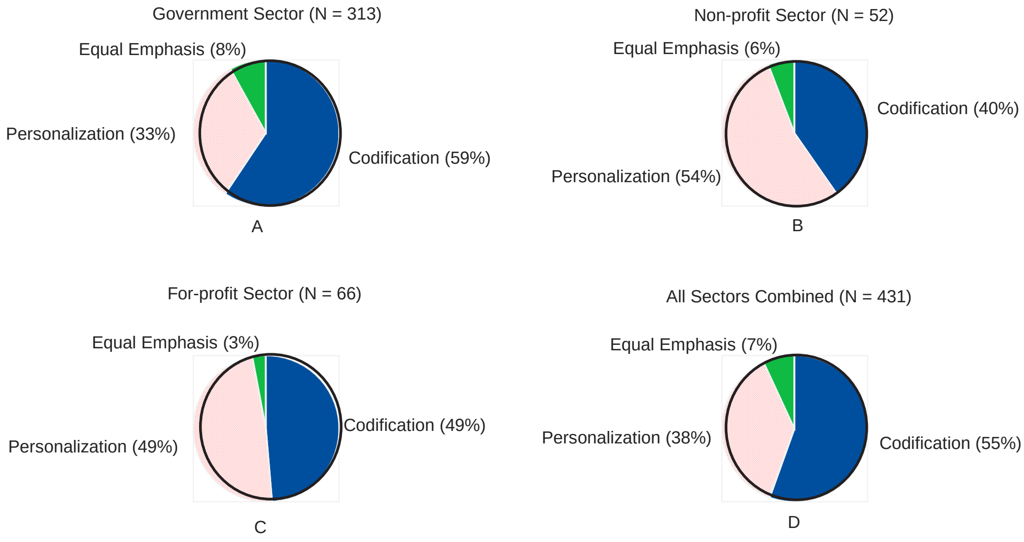
A closer inspection of the results showed that a total of five items had high scores: mean scores above 4.0 (midpoint). They were intranets and extranets, phone calls and teleconferencing, search engines and information-retrieval systems, working groups and communities of practice, and document management and content management. The frequent use of these technologies and tools by employees increases the flow of knowledge within the organization, therefore having a greater impact than all the others.

Intranet/extranet scores at the top of the tools usage for a codification strategy. It is not surprising since intranets and extranets are often the first technology that organizations deploy in order to facilitate intra- and extraorganizational collaboration and knowledge exchange. It is the core component necessary to deploy a portal. Intranet/extranet is followed by search engines and information-retrieval systems, and document management and content management. The easy retrieval and archival of documents and content remain core functionalities of the codification approach that increase the velocity of codified knowledge flow. These technologies within the codification strategy can be categorized as enabling the sharing of knowledge from one to many or many to many, and were utilized by the majority of the respondents within the government, for-profit, and nonprofit sectors.

Regarding the personalization strategy, phone calls and teleconferencing were found to be the most utilized ways to share tacit knowledge between people within all the sectors included in the study. This finding can be explained by the fact that this technology has been available for decades and knowledge workers are familiar with them. Their use is often the employees' first and instinctive reaction when looking for help or advice. In second position are working groups and communities of practice. During the past years, a strong emphasis on communities and their benefits has emerged in the KM literature. This success is due to the fact that their implementation is simple, and knowledge workers perceived them as a good way to learn and connect with other knowledge workers. Furthermore, organizations that have silos utilized them as a good way to breach boundaries across silos and to foster collaboration and knowledge exchanges. Mentoring and tutoring tools take the third position of the personalization strategy. One way to pass on or share the tacit knowledge that older employees have acquired throughout their career is to mentor and/or tutor new or younger colleagues. Once again, this practice is not new, but it remains one of the most popular and the most efficient way to transfer tacit knowledge. Both communities and mentoring and tutoring are support tools and processes that are being widely used within the government sector to address the potential human-capital crisis that is looming with the exodus of baby boomers from the workforce. As of fiscal year 2002, approximately 71% of the government's permanent employees will be eligible for either regular or early retirement by 2010. Of those eligible, 40% are expected to do so (The President's Management Agenda Fiscal Year 2002).

A more in-depth analysis of the data was performed using the validated knowledge-flow model in order to identify the dominant KM strategy within the different sectors under consideration. The analysis reveals that codification is the dominant strategy employed by 59.4% (N = 186) of respondents in the government sector, with 32.6% (N = 102) utilizing a dominant personalization strategy. Only 8% (N = 25) utilized both in a balanced manner (equal emphasis) as shown in Figure 3A. This outcome could be an indication that the large numbers of rules and statutory regulations that guide and define the nature of government business is a major factor driving the dominant KM strategy of codification. However, Figure 3B shows the nonprofit sector having a nearly opposite strategic approach, with

Figure 3. Codification and personalization factors as dominant strategic approaches for the flow of knowledge within the organization



53.8% (N = 28) of respondents utilizing a dominant personalization strategy and 40.4% (N = 21) a dominant codification strategy. It also shows a reduction to 6% in the number of respondents that are utilizing a balance codification and personalization strategies. The results provide evidence that the nonprofit sector leverages more on the flow of knowledge between people than on documents. This characteristic could be due to the business nature of most nonprofit organizations. On the other hand, the data analyzed in the for-profit sector show the respondents are equally divided in their selection of a dominant KM strategy. Figure 3C shows that a total of 49% of respondents utilize a dominant codification strategy with the same number utilizing a dominant personalization strategy. In addition, only 3% of respondents employ a completely balanced approach utilizing both dominant strategies. This balanced approach is the lowest of all the three sectors. Lastly, Figure 3D illustrates all sectors combined.

Based on the above results, if we were to describe the KM strategic approach for knowledge flow as a continuum, we would have the government sector at one end and the nonprofit sector at the other end. The for-profit sector would fall approximately in the middle of the continuum. Moreover, it demonstrates that the sectors are considerably different from each other. This highlights the fact that many organizations have found that both codification and personalization approaches are needed for an effective knowledge-management effort. The emphasis of one approach over the other or its balance depends heavily on the organization's overall strategy. The correct emphasis depends on the manner in which the organization serves its clients and stakeholders, the economics of its business (e.g., for-profit, nonprofit, government), the human capital it possesses, and the culture of the organization. The above results demonstrate that the types of technologies, tools, and processes that CKOs, KM architects, KM managers, and other decision makers should select for implementation need to be carefully evaluated based on the many influencing factors identified above in order to achieve their expected benefits.

FUTURE TRENDS

KM practices and technologies are constantly evolving. The Gartner (2003) research group published a knowledge-management "hype cycle" that describes the evolution and maturity of KM technologies. During the past years, an emergence of synchronous collaborative technologies has emerged, and some have been rapidly adopted to facilitate knowledge flows. As an example, instant messaging is increasingly used for business purposes in order to facilitate presence awareness and knowledge exchange. Portal solutions like Microsoft Sharepoint 2003 already embed this capability. When employees access information on the portal (document, electronic discussion posting, expertise profile, etc.), they can see if the author is currently logged in and can eventually contact him or her by instant messaging or by e-mail. New wireless devices will also provide new ways to facilitate knowledge exchange. New tools, practices, and technologies will provide new knowledge-flow channels, but the underlying knowledge-flow strategies (codification and personalization) will remain the same. We believe that companies will attach more and more importance to personalization strategies since it can be viewed by some companies and authors (Wick, 2000) as a logical evolution from the codification approach.

CONCLUSION

It is important to remember that the codification and personalization KM strategies are not incompatible. Companies must use both strategies simultaneously, but might need to put more emphasis on one of these strategies than on the other. Hansen et al. (1999) suggested a 20-80 split between these two strategies, but our empirical study demonstrated that in practice, there is not such a clear distinction between the emphasis associated to each. Companies interested in launching a KM initiative or companies working on taking their KM initiative to the next level need to asses what strategy will best fit their needs and which will be the most likely to succeed based on their organizational culture. Focusing on the right knowledge-flow strategy is one of the keys to a successful KM journey.

Chapter 3.6
Use and Methods of Social Network Analysis in Knowledge Management

Tobias Müller-Prothmann
Free University Berlin, Germany

INTRODUCTION

Whilst the primary importance of informal communities of practice and knowledge networks in innovation and knowledge management is widely accepted (see Armbrecht et al., 2001; Brown & Duguid, 1991; Collinson & Gregson, 2003; Jain & Triandis, 1990; Lesser, 2001; Liyanage, Greenfied & Don, 1999; Nahapiet & Ghoshal, 1998; Nohria & Eccles, 1992; Wenger, 1999; Zanfei, 2000), there is less agreement on the most appropriate method for their empirical study and theoretical analysis. In this article it is argued that social network analysis (SNA) is a highly effective tool for the analysis of knowledge networks, as well as for the identification and implementation of practical methods in knowledge management and innovation.

Social network analysis is a sociological method to undertake empirical analysis of the structural patterns of social relationships in networks (see, e.g., Scott, 1991; Wasserman & Faust, 1994; Wellman & Berkowitz, 1988). This article aims at demonstrating how it can be used to identify, visualize, and analyze the informal personal networks that exist within and between organizations according to structure, content, and context of knowledge flows. It will explore the benefits of social network analysis as a strategic tool on the example of expert localization and knowledge transfer, and also point to the limits of the method.

BACKGROUND

Words have meanings: some words, however, also have a 'feel'. The word 'community' is one of them. It feels good: whatever the word 'community' may mean, it is good 'to have a community', 'to be in a community'. (Bauman, 2001, p. 1)

The term "community" is widely used, yet imprecisely defined in the sociological literature.

Whilst there is consensus that community is a fundamental unit of social organization, there is little agreement on how best to describe it as a sociological entity (see Poplin, 1979, pp. 11-12). The fact that the term "community" refers to different things, depending upon who is using it and upon the context in which it is used, can render it useless for scientific purposes (see Poplin, 1979, p. 4). Nevertheless, the use of the community concept, or community "metaphor," is flourishing in the social sciences, as well as in political debates and management strategies. One of the foremost applications of the term is in the domain of knowledge communities or communities of practice.

One alternative approach is to view communities as networks. Drawing on the methods and tools of sociometry, the development of formal approaches to social networks began with Moreno (1934), and was systematized and fundamentally elaborated by means of graph theory (König, 1936) through Cartwright and Harary (1956). The breakthrough of social network analysis as a method of structural analysis was reached in the 1960s by White and his Harvard colleagues (see Scott, 1991, pp. 33-38; for a review of the large number of applications of social network analysis, see, e.g., Wellmann & Berkowitz, 1988).

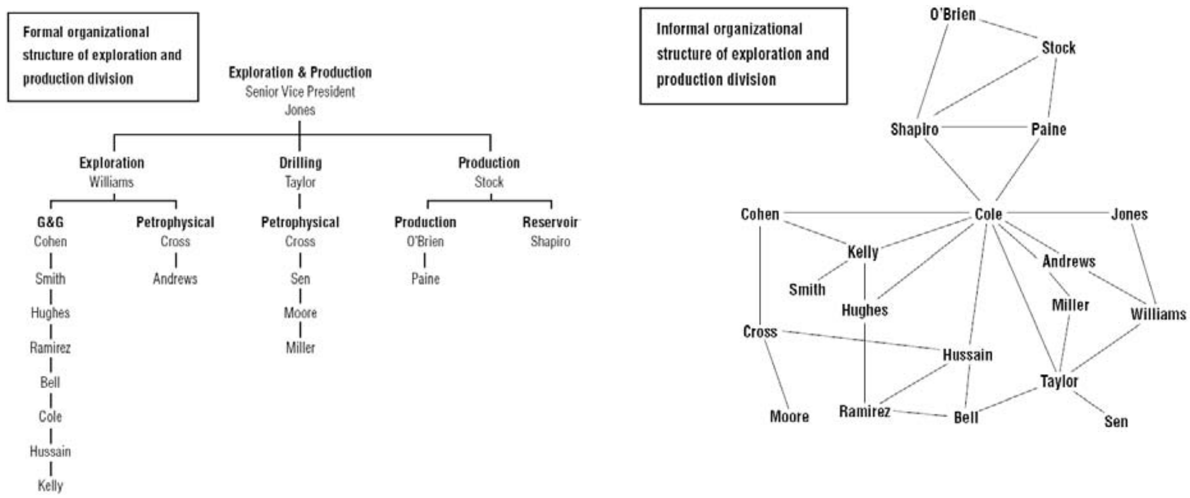
A conceptualization of communities as social networks was outlined by Poplin (1979) in his analysis of community literature as a "network of interaction" (pp. 14-18). In Poplin's view, there is at least one major advantage in conceptualizing communities in this way: "It serves well as a tool by which to describe systematically the interrelationships of the various units that compose the community. This alone can help increase our understanding of community structure and process" (p. 16). Poplin's perspective helps us to build the case of communities of practice as social networks. In doing so, it provides us with both a unit of analysis and the means to develop and employ an empirical method and practical tool, that of social network analysis. The provision of a conceptual framework and powerful tool for the analysis of informal social structures is emphasized here as its major advantages.

USE

Informal knowledge networks are not a new invention in the knowledge management literature. Crane (1972), for example, published her widely recognized study on the diffusion of knowledge in scientific communities. Even earlier, the classic Hawthorne studies included in their principal report of 1939 various sociograms that the research team saw as reflecting the "informal organization" of a bank's wiring room (as opposed to the formal organization depicted by the organization chart) (see Roethlisberger & Dickson, 1947, pp. 500-548). Whether speaking about communities of practice, knowledge communities, or knowledge networks, all these concepts have a common core that can be subsumed under the "social capital" construct. Burt (2000) elaborates upon this point and suggests that the social capital concept is essentially "a metaphor about advantage" (p. 2), that is, the better the social connections between people, the higher the collective and individual returns for them. Cross, Parker, and Borgatti (2002) describe this advantage of connection as "who you know has a significant impact on what you come to know" (p. 2). From here, we can identify the logical underpinning of social network analysis as the empirical study of connections between individuals within communities.

Social network analysis uses several techniques to empirically identify underlying patterns of social structure. It then compares these individual patterns with their influence on specific network behavior variables and performance outcomes. From a knowledge management perspective, social network analysis helps us identify basic network properties, positions of network members, characteristics of relations, cohesive sub-groups, and bottlenecks of knowledge flows. By point-

Figure 1. Formal vs. informal in a petroleum organisation (IBM Institute for Business Value, 2002)[1]



ing to who shares knowledge with whom, social network analysis shows us the informal relations within and between organizations (see Figure 1). In doing so, it allows the researcher to identify and maybe influence a network's and its members' ability to create and to share knowledge.

Although social network analysis must always begin with some initial populations, one important advantage of the method is that it does not view formal boundaries (such as departments) as truly social boundaries. Rather, it traces social relationships wherever they may exist and extend. (Laumann, Marsden & Prensky, 1989, discuss the boundary specification problem in network analysis at length.) In this way, we can identify the following core knowledge management applications from social network analysis that are explained in the following example:

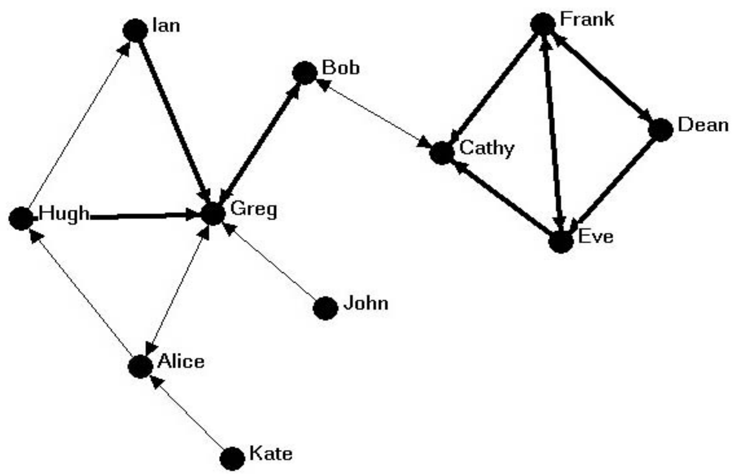
- identification of personal expertise and knowledge,
- research into the transfer and sustainable conservation of tacit knowledge, and
- discovery of opportunities to improve communication processes and communication efficiency.

Other knowledge management applications from social network analysis that go far beyond the scope of this article include studies into the development of core competencies (like leadership development), the identification and support of communities of practice, approaches for the harmonization of knowledge networks (for example after mergers and acquisitions), and the sustainable management of relationships between distributed sites and external partners.

METHODS AND MEASURES

Social network analysis perceives social structure as the pattern organization of network members and their relationships. Network data are defined by the members of the network and their relationships. (Note: Social network analysts talk of

Figure 2. A graph of social relationships



"actors" rather than of "members.") Using graph theory, a sociogram consists of "nodes" (or points), representing individual network members, and "ties" (or lines), representing the connections between the members (relations); these graphs clearly record and visualize social relationships (see Figure 2). Another advocated means to represent information about social networks is in matrices. In their simplest form, network data consist of a square matrix, the rows of the array represent the persons, the columns of the array represent the same set of persons, and the elements represent the ties between the persons (so-called "adjacency matrix"—see Figure 3). Matrices are

Figure 3. Adjacency matrix of social relationships as visualized in Figure 2

	Alice	Bob	Cathy	Dean	Eve	Frank	Greg	Hugh	Ian	John	Kate
Alice	0	0	0	0	0	0	1	1	0	0	0
Bob	0	0	1	0	0	0	2	0	0	0	0
Cathy	0	1	0	0	0	0	0	0	0	0	0
Dean	0	0	0	0	2	2	0	0	0	0	0
Eve	0	0	2	0	0	2	0	0	0	0	0
Frank	0	0	2	2	2	0	0	0	0	0	0
Greg	1	2	0	0	0	0	0	0	0	0	0
Hugh	0	0	0	0	0	0	2	0	1	0	0
Ian	0	0	0	0	0	0	2	0	0	0	0
John	0	0	0	0	0	0	1	0	0	0	0
Kate	1	0	0	0	0	0	0	0	0	0	0

also used as data input for social network analysis processing. (For an introduction to graph theory and the use of matrices in social network analysis, see, e.g., Scott, 1991, pp. 39-65, or Hanneman, 2001, pp. 2-4 & pp. 26-36.)

As this article serves only as an introduction to social network analysis in knowledge management, what follows is a short guide to the analytical concepts and measures that sit at the heart of the technique and are of primary importance for a pragmatic adaptation as a method and practical tool in knowledge management. For a more comprehensive introduction to social network analysis see Scott (1991) or Hanneman (2001).

- Knowledge Flows Within Large and Small Networks—Size: Size is a basic property of a network—sharing knowledge between all members of a large network (say for example, between a total of 25,000 members of a whole business unit) would be extremely difficult compared to sharing knowledge between all members of a small network (say for example, between a total of 11 members—as presented in Figures 2 and 3).
- Linkages of Networks—Density: Density describes the global level of linkage of a network. Even if fully saturated networks are empirically rare (where all possible ties are actually present), measures of density look at "how closely a network is to realizing this potential" (Hanneman, 2001, p. 41). As a measure that is especially relevant for the case of communities of practice, density describes the overall linkage between the community members.
- Expertise and Power—Degree Centrality: Degree centrality is a measure of the incoming and outgoing connections held by an individual network member. Incoming connections (in-degree) define the popularity of a member; those with many ties are members who are considered particularly prominent or—in the case of knowledge networks—have high levels of expertise (like Greg in Figures 2 and 3 for example). Out-degree defines the number of outgoing connections or the power of a member; having a high out-degree, a person is considered as particularly influential in the network (like Frank in Figures 2 and 3). Insufficient member links (as well as links between sub-groups—see below) might indicate the potential resources of network members that are not used. Excessive linkages might indicate the stress and overload of individual members. Degree centrality is a measure that helps to purposefully support individual members of a community of practice.
- Integration or Isolation—Closeness Centrality: While degree centrality is a measure of the immediate ties of a network member, closeness centrality (as well as betweenness centrality) measures the reachability of members. This is achieved by including indirect ties. Closeness centrality focuses on the distance of a member to all others in the network through means of geodesic distance. It determines a member's integration in the network (in Figures 2 and 3, Greg displays high in-closeness and Frank high out-closeness). Thus, high closeness centrality indicates the greater autonomy of an individual person, since he or she is able to reach the other members easily. Low closeness centrality on the other hand indicates higher individual member dependency, that is, the willingness of other members to gain access to the network's resources. By determining the average closeness centrality of a network, the relative isolation or integration of persons can be identified. People who are not well integrated into a group could represent untapped skills. They may be highly expert people who are not being utilized appropriately (see Cross et al., 2002, p. 6).

- Knowledge Brokers and Gatekeepers—Betweenness Centrality: Betweenness centrality is a measure of the extent that a network member's position falls on the geodesic paths between other members of a network. Thus, it determines whether an actor plays a (relatively) important role as a broker or gatekeeper of knowledge flows, with a high potential of control on the indirect relations of the other members (like Greg and Bob in Figures 2 and 3).
- Strength and Weakness of Ties—Multiplexity: Network members may maintain a tie based on one relationship type only (a narrowly specialized relationship, for example, sharing news on only one topic of research). Alternatively, they may maintain a variety of relations—broadly multiplex relationships, for example, sharing information, working together in different projects, and playing golf together. The latter are known as multiplex ties (the example in Figures 2 and 3 shows only two strengths of ties: 1 or 2). On the one hand, multiplex (strong) relationships share more intimate, voluntary, supportive, and durable ties (see Wellman & Wortley, 1990), and thus, form a solid basis for trust. On the other hand, most people only share a small number of strong relationships, so that especially weak ties are warranty for access to a large variety of resources (Granovetter's (1973) popular "strength of weak ties"). With regard to communities of practice, the importance of multiplex relationships gives reason for various kinds of community-building activities.
- Sub-Cultures and Clusters of Expertise—Sub-Groups and Cliques: Sub-sets of members can build dense connections and develop cohesive sub-groups of the network (like Cathy, Dean, Eve, and Frank in Figures 2 and 3). These are known as cliques and clusters (Watts & Strogatz, 1998; Roethlisberger & Dickson, 1947, already wrote about "cliques" in their 1939 report, pp. 508-510).2 Cliques or clusters are of special interest to network analysts as they are important for understanding the behavior of the whole network. For example, organizational subgroups or cliques can develop their own "sub"-cultures and attitudes toward other groups (Cross et al., 2002, p. 6). They can also gain influence over the overall network. Exploitation and integration of the subgroups' potential resources can be a critical factor to failure or success of a community of practice.
- Bottlenecks and Knowledge Gaps—Cut-Points and Structural Holes: Often, networks are not only clustered into cohesive subgroups, but are also split into loosely coupled components. In this case, not all possible connections are present: there are structural holes (Burt, 1992). Persons of pivotal significance in holding components together are called cut-points or bridges: central nodes that provide the only connection between different parts of the network (like Bob in Figures 2 and 3). Cut-points build bridges between sub-groups that would otherwise have been cut-off and split into separate, unconnected components. They represent the network's bottlenecks and are critical to the knowledge flow of a network. Yet too many links can lead to inefficiency of knowledge exchange. Generally speaking, links between sub-groups (for example, between members of different departments) must be coordinated effectively and efficiently (see for example the role of hubs described below).
- Enablers of Effective Knowledge Transfer—Hubs: As networks are clustered, some members are important as simultaneous actors in many clusters. These are known as hubs (Kleinberg, 1999; Rosen, 2000). As Barabási (2003) puts it, these persons "have played in very different genres during their

careers" (p. 61). They can effectively link different sub-groups of the network and can facilitate knowledge flows between different departments or to external organizations.

EXAMPLE

Consider for example that you are working in a research and service organization.3 You have to acquire funding for new research projects, and you know that programs and financing are available from the EU to help you. You have an idea for a new project, but you do not know how best to prepare a project proposal. However, there are other people in your organization who have successfully acquired EU funding for their projects. The question is: How do you acquire the knowledge to know who knows about developing a winning proposal for an EU project acquisition? Who are the experts in your organization, and who do you need to know and contact outside of your organization to assist you (at the European Commission, for example)?

- First, you will have to define the knowledge domain that is relevant. This is what you did already: you want to learn about experts for the acquisition of EU projects within the organization and then contact appropriate persons external to your organization.
- Second, you will need to formulate questions that address your goal adequately and operationalize the survey. Typical questions might be: Who do you know who is an expert about project acquisition? Who do you know who is currently working on an EU project or has just finished one? Whom did you help with regard to project acquisitions? Additionally, your data collection would be best complemented by analyzing other available documents and resources such as project documentations, team meetings, conferences, and so forth.
- Third, after encoding the data you perform procedures of formal network analysis and visualization—for example, using the popular and very sophisticated software for network analysis called UCINET (see Borgatti, Everett & Freeman, 2002).
- Fourth, you will need to analyze your findings from the previous step and interpret the results.
- Finally, you will try to sustainably improve knowledge flows with regard to EU project acquisition. Indeed, you might perform a social network analysis on the same topic on a frequent basis to evaluate success or failure of your interventions.

Based upon the results and their interpretation, interventions (like workshops, dialogues, establishment of communities of practice) are recommended to improve knowledge flows (examples of interventions are outlined in more detail in Müller-Prothmann & Finke, 2004, pp. 697-698). These can be designed to foster knowledge communication, strengthen relationships within the network, build relationships to other networks, and develop strategies for the creation of flourishing knowledge environments and for sustainable knowledge transfer. One very basic intervention would be to simply ask people to spend five minutes on their network visualizations and "to identify what they 'see' in the map, the structural issues impeding or facilitating group effectiveness, and the performance implications for the group" (Cross et al., 2002, p. 11).

This example shows that social network analysis provides a method to trace knowledge flows, analyze network structures and personal expertise, with additional value to a simple knowledge map or yellow pages. On the one hand, social network analysis tries to identify knowledge flows wherever they may go. On the other hand, social network analysis gives us a detailed picture of actors' positions, the characteristics of their connections, and the overall structure of relationships. Social network analysis provides us with a well-elaborated set of methods and measures for various applications in knowledge management that especially help us to foster the development of communities of practice.

FUTURE TRENDS

The application of social network analysis as illustrated in the example above affects all four dimensions that Cross et al. (2002, p. 7) found to be critical for a relationship to be effective in terms of knowledge creation and use. These are: (1) knowing what someone knows, (2) gaining timely access to that person, (3) creating viable knowledge through cognitive engagement, and (4) learning from a safe relationship. Despite the assertions of Cross et al., the use of social network analysis as a practical tool in knowledge management has been limited. To become more widely adopted in practice, the sophisticated scientific methods of social network analysis will need to be pragmatically adapted to suit practical needs.

The future focus of research must be put at two distinct levels of analysis, the individual networker and the organizational level. For both levels, the challenge will be to develop new methods in social network analysis that deliver practical value to knowledge management and provide for new models of interpretation and intervention. This includes methods for: (1) the clear definition of network members and network boundaries (for example based upon focused knowledge domains), (2) faster data collection, (3) efficient analysis and interpretation of results, and (4) effective intervention to improve knowledge sharing, knowledge flows, and network structure based on the given results.

In addition, the success or failure of social network analysis as a valuable knowledge management method depends on the successful integration of specific organizational conditions and requirements into the methodological process. This demands research activities on the cultural factors that influence network structure and performance. Then, insights from the application of social network analysis could provide the basis to develop measures for assessing the contribution of knowledge communities and networks to overall organizational performance and innovation. Especially, it should be strongly considered to integrate basic measures of social network analysis into a knowledge-orientated, balanced score card, and to expand techniques of social network analysis for examination and support of mobile networking and collaboration; without doubt, these technologies will gain influence as communication tools in distributed communities of practice and raise demands for thorough explorations.

CONCLUSION

Social network analysis is a powerful empirical tool for assessing network ties and structure and their influence on knowledge creativity, sharing, and innovation. The brief sociological discussion about the use of the term “community” early in this article shows that the development of a network perspective from a theoretical view on communities provides an adequate analytical framework for communities of practice, knowledge communities, and other social constructs subject to the knowledge management debate. As introduced in this article, social network analysis has practical application beyond a narrow theoretical perspective. By focusing on the social aspects of knowledge management in a methodically rigorous manner, the technique has much potential.

Of course, the limitations of social network analysis cannot be neglected. Since social network analysis is based on the study of bilateral interactions, it provides a merely descriptive picture of structures and positions. Further, aspects and characteristics of communities and social networks, like shared identity or shared norms of the network members for example, cannot be covered through social network analysis in a strict sense. Therefore, knowledge management processes focusing on communication structures and its related aspects, like advice and support networks, knowledge flows, and communication efficiency for example, are best explored through methods of social network analysis. These fields of application could make use of social network analysis as a powerful tool, as well as approaches for sustainable support of communities of practice.

Nevertheless, the use of social network analysis in knowledge management may be limited in environments characterized by high social complexity and a large variety of organizational constraints. Thus, a widespread adoption of social network analysis as a method and tool for knowledge management will depend on evidence provided by further research, case studies, and practical implementation in organizational business strategies in the various fields of application as proposed here.

ACKNOWLEDGMENTS

I am very grateful to Chris Lawer, Cranfield School of Management and The OMC Group, England, for critical and fruitful comments, and his valuable contribution in reviewing and correcting a draft version of this article. I am also very grateful for the unbureaucratic permission by Judith A. Quillard from the IBM Institute for Business Value, Cambridge, Massachusetts, and Rob Cross, assistant professor at the University of Virginia's McIntire School, to publish the network example presented in Figure 1.

Chapter 3.7
Distributed Knowledge Management

INTRODUCTION

In dynamic markets (characterized by the specialization of work, outsourcing processes, just-in-time and distributed productions, etc.), firms have moved from hierarchical structures to networked models. These are based on both intraorganizational networks among strategic units, divisions, groups, and so on; and interorganizational networks, such as industrial districts and knowledge networks (Hamel & Prahalad, 1990). Production is based on the coordination of a constellation of units, some of which are part of the organization (administration, R&D [research and development], etc.), and others refer to different companies (such as specialized outsourcing production, logistics, etc.). All these units might not totally be controlled by a unique subject, and might grow and differentiate their activities in an autonomous way, coexisting as in a biofunctional system (Maturana & Varela, 1980) and creating unexpected combinations of processes and products (Chandler, 1962).

From a knowledge management (KM) point of view, the need of sharing knowledge among units in a very complex organization, or among networked organizations, increases the importance of introducing new ICT technologies and effective KM systems. For a long time, KM systems and ICT technologies have been proposed and applied as neutral tools whose implementation within the firm does not have any impact on knowledge flows. In particular, for technical reasons, centralized systems (for instance, enterprise knowledge portals [EKPs]) have been developed with the aim of making knowledge sharable and available in a general, objective, context-independent form, avoiding the persistence of noncorrect and non-consistent information. Opposed to that point of view, studies focused on structuration theories (Giddens, 1984; Orlikowski, 1991) do not consider technology as a neutral asset of organizations. According to these theories, there are strong relationships and interdependencies among human actions, institutional roles (the organizational model de facto), and the technology architecture of KM systems applied within the company. One of the most important results in this area is that ICT technologies and KM systems should be shaped on the processes, practices, and the organizational models in which they are implemented; otherwise, they are bound to failure. As a consequence, in a complex organization composed by a constellation of units that manage in an autonomous way specialized processes, ICT technologies and KM systems must take into account the distributed nature of knowledge, and should allow coordination among autonomous units. In such a scenario, a KM system should satisfy two different needs: supporting the creation of specialized knowledge within a unit, and enabling the coordination of knowledge (and activities through which knowledge is exchanged) among units. These dual needs reflect the tension between the necessity for both highly specialized organization of work and flexible intergroup cooperation within and outside the organizations. This is reflected in the duality between the need for highly articulated local perspectives that make up the communication and knowledge-creation tissue of each community, and the need for sharing cultures and instruments that allow communication across different units (Mark, Gonzalez, Sarini, & Simone, 2002).

The first aim of this article is to describe how, according to structuration theories, a centralized KM system can be replaced or supported by a distributed one, in which the fact of having multiple and specialized "local knowledge bodies" is viewed more as an opportunity to exploit than as a problem to solve. The second aim of this article is to present a specific approach to designing systems for managing knowledge distributed across different units, called distributed knowledge management (DKM), whose principles and main concepts will be introduced and explained in the second part of this article.

BACKGROUND

Even though current KM systems use different technologies, tools, and methodologies (for in-depth discussion, see Davenport & Prusak, 1997; Nonaka & Takeuchi, 1995; Stewart, 2001; Wenger, 1998), most projects eventually lead to the creation of large and homogeneous knowledge repositories, in which corporate knowledge is made explicit and is collected, represented, and organized according to a single, supposedly shared, vision. Such a vision is meant to represent a shared conceptualisation of corporate knowledge, and thus to enable communication and knowledge sharing across the constellation of units composing the entire organization. All these activities are based on the common assumption that raw forms of knowledge, called implicit knowledge by Nonaka and Takeuchi, and tacit knowledge by Polany (1966), can be "cleaned up" from all contextual elements, and that the resulting "objective form" of knowledge can be explicitly represented in an abstract (independent from the original context) and general (applicable to any similar situation) form. This standard architecture of KM systems reflects a traditional view of management, in which managers try to centralize the control on the company processes by allocating and distributing resources and tasks to employees, and monitoring the proper execution of tasks and use of resources. This view of the managerial function leads to an approach to KM where processes of knowledge (resource) production and dissemination (tasks) must be centrally driven (allocated) and controlled (monitored). This condition is met only if knowledge is thought of as an object, which can therefore be kept separate from the people who produce it. Otherwise, as far as knowledge remains embedded within subjective dimensions, it becomes a resource that falls outside the boundaries of managerial control.

The typical outcome of this kind of vision is the creation of an EKP, namely, an interface (Web based) that provides a unique access point to corporate knowledge (Davenport & Prusak, 1997). Such an architecture is generally based on the following:

- technologies like content management tools, text miners, search engines, and so forth, which are used to produce a shared view of the entire collection of corporate documents
- common formats, such as HTML (hypertext markup language), XML (extensible markup language), and PDF (Portable Document Format), which are used to overcome the syntactic heterogeneity of documents from different knowledge sources
- chats and discussion groups, which are used to enable social interactions

Most business operators claim that this traditional approach is the right answer to the needs of managing corporate knowledge. However, many KM systems are deserted by users, who instead continue to produce and share knowledge as they did before, namely, through structures of relations and processes that are quite different from those embedded within the corporate-wide KM system. For instance, workers continue to use nonofficial tools such as shared directories, personalized and local databases, and so on (Bonifacio, Bouquet, & Cuel, 2002; Bonifacio, Bouquet, & Manzardo, 2000). In theory, KM systems are sold as systems that combine and integrate functions for the contextualized handling of both explicit and tacit knowledge throughout the entire organization or part of it. But, in practice, traditional KM systems manage knowledge according to a technology-oriented approach, which considers the cleaned-up and objective knowledge as the good and sharable knowledge (best practices, documentations, etc.) within the firm and among companies. In spite of the declared intention of supporting a subjective and social approach (through community and groupware applications), the way most KM systems are designed embodies an objective view of knowledge and reflects a marginal notion of sociality. In other words, KM systems aim at managing knowledge in an abstract, general, and context-independent form without taking into account the fact that knowledge is dependent on the context of production (the particular viewpoint of the individual), is embedded within subjective dimensions (the daily practice of work), and is not straightforwardly replicable.

Many authors who stressed the subjective nature of knowledge argued also that meanings are not externally given; rather, individuals give meaning to situations through subjective interpretation. Interpretation is subjective since it occurs according to some internal interpretation schema not directly accessible to other individuals. These schemas have been called, for example, mental spaces (Fauconnier, 1985), contexts (Ghidini & Giunchiglia, 2001; McCarthy, 1993), or mental models (Johnson-Laird, 1992). Internal schemas can be made partially accessible to other individuals through language since language is not just a means to communicate information, but also a way of manifesting an interpretation schema. As a consequence, when interpretation schemas are deeply different, people will tend to give a very different meaning to the same facts. Conversely, in order to produce similar interpretations, people need to some extent to share interpretation schemas, or at least to be able to make some conjectures on what the other people's schemas are. For in-depth discussion, see the notions of paradigms in Kuhn (1970), sociotechnical frames in Goffman (1974), and thought worlds in Dougherty (1992). Since we are talking about organizations, and thus about a collective level, it is relevant to consider that without this intersubjective agreement (or at least believed agreement), communication cannot take place, coordinated action is impossible, and meaning remains connected just at an individual level (Weick, 1993). Thus, this approach leads to some significant consequences.

- Knowledge is intrinsically subjective as the meaning of any statement is always dependent on the context or on the interpreter's schema, which can be either explicit or implicit.
- At a collective level, groups of people can assume they share (or have a reciprocal view on) some part of their intrinsically subjective schemas. These common parts can emerge from participation and reification processes of the community's members, who share (or understand) the others' meanings through practices (Wenger, 1998). In other words, we can say that the intrinsically subjective schema can be shared, or at least coordinated, in the intersubjective agreements of the community's members.

As a result, the notion of knowledge as an absolute concept that refers to an ideal, objective picture of the world leaves the place to a notion of local knowledge, which refers to the different partial interpretations of portions of the world or domains that are generated by individuals and within groups of individuals (e.g., communities) through a process of negotiating interpretations. According to knowledge network theories (see Cross & Parker, 2004; Hildreth & Kimble, 2004), different and specialized actors that coordinate each other move beyond information sharing to the aggregation and creation of new knowledge, and obtain benefits from network communications and engagement strategies. Finally, the network of relationships, the local knowledge developed within a community, the inner motivation that drives people to share knowledge, and the knowledge they produce lead to the creation of an environment that sustains variety and is rich in creativity, namely, one that is innovative. As a consequence, many big organizations now consider communities, their autonomy, and their contextualized and local knowledge as vital components in their organizational KM strategies. Thus, local knowledge appears as the synthesis of both a collection of statements and the schemas that are used to give them meaning. Local knowledge is then a matter that was (and is continuously) socially negotiated by people that have an interest not only in building a common perspective (perspective making for Boland & Tenkasi, 1995, or single-loop learning for Argyris & Schoen, 1978), but also in understanding how the world looks like from a different perspective (perspective taking for Boland & Tenkasi, or double-loop learning for Argyris & Schoen). Therefore, rather then being a monolithic picture of the world as it is, organizational knowledge appears as a heterogeneous and dynamic system of local knowledge that lives in the interplay between the need of sharing a perspective within a community (to incrementally improve performance) and of meeting different perspectives (to sustain innovation).

MAIN FOCUS OF THE ARTICLE: DISTRIBUTED KNOWLEDGE MANAGEMENT

In this article, we present a new approach to KM called DKM. It provides an original managerial and technological solution to the complementary needs of creating and consolidating (local) knowledge within communities, and of sharing and reproducing knowledge across them. It is based on the assumption that subjectivity and sociality are potential sources of value rather than problems to overcome, and on the idea of modeling organizations as constellations of knowledge nodes

(KNs)-this way taking into account autonomous and locally managed knowledge sources-which need to cooperate and negotiate knowledge with others to sustain innovation. Thus, the continuous interplay of multiple instances of local knowledge and the interactions at the boundaries between different communities are critical factors for innovation and for the creation of new knowledge (Brown & Duguid, 1991).

Principles of DKM

DKM is based on two very general principles:

1. Principle of Autonomy: Each organizational unit should be granted a high degree of autonomy to manage its local knowledge. Autonomy can be allowed at different levels. We are mainly interested in what we call semantic autonomy, that is, the possibility of choosing the most appropriate conceptualisation of what is locally known (for example, through the creation of their own knowledge maps, contexts, ontologies, etc.).
2. Principle of Coordination: Each unit must be enabled to exchange knowledge with other units not through the adoption of a single common interpretation schema (this would be a violation of the first principle), but through a mechanism of projecting what other units know onto its own interpretation schema.

These two principles must support two qualitatively different processes: the autonomous management of knowledge locally produced within a single unit, and the coordination of the different units without a centrally defined view.

If a complex organization can be thought of as a constellation of autonomous units, an important issue is how this socially distributed architecture can be modeled to design an architecturally distributed computer-based system for supporting KM processes. To this end, we introduce the concept of the knowledge Node as the building block of a model for designing DKM systems.

The Definition of Knowledge Node

A KN can be viewed as the reification of organizational units, either formal (e.g., divisions, market sectors) or informal (e.g., interest groups, communities of practice, communities of knowing), that exhibit some degree of semantic autonomy. Each unit, in fact, can cope with KM only if the processes of knowledge (resource) production and dissemination (tasks) can be locally driven (allocated) and controlled (monitored). Moreover, each unit exhibits semantic autonomy through the development of local interpretation schemas (visions of the world). Each KN represents the following:

- Knowledge Owner: An entity (individual or collective) that has the capability of managing its own knowledge both from a conceptual and a technological point of view. Notice that most often knowledge owners within an organization are not formally recognized, and thus their semantic autonomy emerges in the creation of artifacts (e.g., databases, Web sites, collections of documents, archives, practices, and so on) that are not necessarily part of the official information system.
- System of Artifacts: An important assumption of DKM is that different organizational units tend to (autonomously) develop working tools that suit their internal needs, and that the choice and usage of these tools is a manifestation of their semantic autonomy. This may be for historical reasons (for example, people use old legacy systems that are still effective), but also because different tasks may require the use of different

applications and data formats to work out effective procedures and to adopt a specific and often technical language. Examples of local applications are software systems, procedures, and other artifacts, such as relational databases, groupware, and content management tools, and shared directories. Even if technologies and data formats are the same for two or more KNs, the appropriation (i.e., the local understanding and using of specific uses in a given setting) of each KN can be very different, depending, among other things, on the local interpretation schema.

- One or More Locally Shared Conceptual Schemata: It is a special artifact that represents (in an explicit or implicit way) a community's perspective. In simple situations, it can be the category system used to classify documents; in more complex scenarios, it can be an ontology, a collection of guidelines, or a business process. We can say that a schema is the reification of a KN's perspective, and its continuous, autonomous management is a powerful way of keeping a unit's perspective alive and productive.
- Brokers and Boundary Objects: They are individuals and objects (Bowker & Star, 1999; Wenger, 1998) legitimated by people to represent and understand (i.e., has direct access to) the locally shared conceptual schema of a KN. Brokers and boundary objects have the main aim of supporting knowledge owners to create and locally manage one or more shared conceptual schemata, and of meeting other brokers or analysing boundary objects that reify and express other local schemata. For instance, a personal agent could be a broker of a KN that knows its locally conceptual schemata and coordinate it with others.

KNs in a Case Study

In the past, we have analysed some complex organizations. A paradigmatic case study is Pizzarotti & C. S. p. A. Its business is focused on construction and prefabricated buildings, and KNs have been unveiled looking at knowledge owners, the systems of artifacts, the locally shared conceptual schemata, and, more importantly, the kind of knowledge that is exchanged within groups and the way in which people negotiate and coordinate knowledge across the whole organization. Through a large number of interviews, we discovered that building yards, registered offices, and cross-organizational communities have their own structures and their own ways of working to solve specific problems that depend on the kind of production and other local environmental factors (e.g., the weather, local customers and suppliers). Then they can be considered KNs. Though the firm does not formally recognize the existence of some of these units, every KN expresses semantic autonomy through specialized systems of artifacts that are used and appropriated in the way that best suits the local needs. For an in-depth description, see Cuel, Bonifacio, and Grosselle (2004).

A Methodology to Unveil Knowledge Nodes within a Complex Organization

In order to develop a KM system based on the DKM approach, an effective methodology of analysis is necessary. This methodology should take into account two relevant aspects, which reflect the two DKM principles.

- identifying the borders of existing KNs within the firm (principle of autonomy)
- identifying the way knowledge is exchanged across the whole organization through negotiation and coordination processes (principle of coordination)

Both aspects are based on social relations within and across communities in the firm, which can be analysed using different methodologies such as social network analysis (SNA) or ethnography. On one hand, SNA and other quantitative methodologies provide a good and general perspective on the organization, and allow the researcher to perceive the real structure of the organizational model by considering the relations among people and groups. They do not allow one to identify the reason why some groups are strategic and others are not. On the other hand, ethnography and other qualitative methodologies are based on the participation of the observer within the firm. The observer tries to achieve a detailed understanding of the circumstances, the strategies, and the power of the few subjects being studied, but cannot determine the significance of what she or he observes without gathering broad statistical information.

In the DKM approach, these two kinds of analysis are not sufficient to unveil KNs since it is difficult to identify the KNs' boundaries and knowledge-exchanging processes. As a matter of fact, individuals belonging to an organizational unit are socially interconnected to achieve different objectives and are often part of two or more units, thus using more than a conceptual schema. Therefore, it seems necessary to develop both quantitative and qualitative analysis in different phases through multiple series of questionnaires, ethnographic interviews (Spradley, 1979), and focus groups. The analysis should be organized in three phases: understanding the main picture of the firm, unveiling KNs and their relations, and validating the first results through focus groups or meetings with experts and workers involved in the organization activity. For an in-depth description, see Cuel (2003).

FUTURE TRENDS

The distributed approach to KM has many important implications, both from a managerial and technological perspective.

Managerial and Organizational Impacts of DKM

From a managerial standpoint, a distributed approach to KM poses fundamental challenges to the traditional model of the managerial function. In particular, managers should abandon the widespread practice of having a unique and homogeneous materialization of knowledge represented as a knowledge-based asset. Managers are requested to change their control processes, imposing strategic directions on innovation processes and enabling knowledge materialization from the ground.

Moreover, even if socially the attitude of sharing knowledge within a group is embedded in worker practices, managers should try to avoid personal or group behaviours of competitiveness and detention of knowledge, and should promote knowledge sharing and coordination across the whole organization. Therefore, managers should work out new roles (for instance, the roles of knowledge manager and broker) that determine new skills for knowledge coordination and negotiation (Argyris & Schoen, 1978; King & Andersen, 2002), and create a culture (using wage incentives, group bonuses, etc.) that allows people to identify themselves within the company as part of a whole and to share knowledge for a common, real gain. People's power should derive more from sharing useful knowledge within the firm and among groups than from owning it.

Technological Impacts of DKM

From a technological standpoint, distributed architectures presuppose the explicit recognition of the distributed nature of knowledge. Distributed architectures should sustain autonomy at different levels: the technological (different groups may use different technologies), the syntactic (different groups may use different information formats), and, most of all, the semantic (different groups may generate different systems of meaning, namely, local schemata). From a group's or a community's perspective, a distributed system supports the exploitation and representation of a community's schemata; this is the layer upon which a community's members produce and negotiate common views. Contexts can be represented as local ontologies (for instance, using Context OWL; Bouquet, Giunchiglia, van Harmelen, Serafini, & Stuckenschmidt, 2003), taxonomies, and, in general, theories through which community members interpret their environment and make sense of organizational events. Although theories conceptualise local events and thoughts, new methodologies and tools are needed for allowing workers (with no knowledge on formal logic or computer science) to create and manage local schemata. These methodologies and tools should allow both the creation of a schemata from scratch (analysing documents, repeated occurrences within databases, etc.) and the chance for management to make sense of processes on concepts through very simple visualization systems.

CONCLUSION

The DKM approach satisfies the managerial needs of creating and consolidating knowledge within each KN and of coordinating it across a constellation of KNs. Therefore, brokers and boundary objects should assume an important role, facilitating coordination processes and allowing communication between KNs, thus increasing innovation opportunities within the organization. As we said, these processes can be facilitated by the creation of a collaborative culture and attitude. Moreover, new organizational roles are needed that allow people to both identify themselves within the firm as part of a whole and to see knowledge sharing as way to achieve a common gain.

The centralized approach is not necessarily in conflict with the decentralized one. Depending on the type of knowledge, the environment, and the structure of the organization, it is beneficial to apply a more centralized (e.g., for secured and general knowledge) or a more decentralized KM approach (e.g., for ad hoc and specific knowledge). In particular, traditional and centralized KM systems, developed according to the technology-driven approach, can be effectively used in an organization in which the environment is stable and the need of efficiency is stronger than the pressure toward innovation. Problems arise when the KM systems create a mismatch between the social process of knowledge creation and sharing (organizational models de facto, processes and practices of KM) and the technological architecture (Camussone & Cuel, 2003). Therefore, two dual processes can be produced by the introduction of a noncoherent KM system: The information systems' architecture will be appropriated or shaped according to the modus operandi of its users (some functionalities of the system will be deserted by users, and others will be shaped on the users' daily work), or the organizational model, processes, and shared practices will change and adapt to the functionalities imposed by the KM system. From this, it follows that a KM system should be designed to be consistent with the distributed social form in which knowledge is created within organizations, finding its right level of centralization and decentralization. As a consequence, the composition of units in the organizational models and the composition of KNs should be compatible, and from this standpoint, they should therefore be analysed or at least planned during the designing phase. Currently, there is not a unique methodology of DKM architecture design, and different types of groups, units, and so forth can be unveiled as KNs. Finally, there are many technology-driven approaches that allow developers to design KM systems, and only few of them take into account organizational features (see Davenport, Long, and Beers, 1998) to analyse how politics, information strategies, behaviours, and culture should be considered for a successful KM system.

Chapter 3.8
Capability Maturity

Alfs T. Berztiss
University of Pittsburgh, USA

INTRODUCTION

The dependence of any organization on knowledge management is clearly understood. Actually, we should distinguish between knowledge management (KM) and knowledge engineering (KE): KM is to define and support organizational structure, allocate personnel to tasks, and monitor knowledge engineering activities; KE is concerned with technical matters, such as tools for knowledge acquisition, knowledge representation, and data mining. We shall use the designation KMKE for knowledge management and knowledge engineering collectively. KM is a very young area—the three articles termed "classic works" in Morey, Maybury, and Thuraisingham (2000) date from 1990, 1995, and 1996, respectively. We could regard 1991 as the start of institutionalized KM. This is when the Skandia AFS insurance company appointed a director of intellectual capital. KE has a longer history—expert systems have been in place for many years. Because of its recent origin, KMKE is characterized by rapid change. To deal with the change, we need to come to a good understanding of the nature of KMKE.

One of the lasting contributions of the business reengineering movement is the view that an enterprise is to be regarded as a set of well-defined processes (Davenport, 1993; Berztiss, 1996). This implies that KMKE also should be a process. Implementation of a process has two aspects: there is need for a procedural definition, and for an understanding of the resources and capabilities needed to implement the procedures and manage the process. Here, we will not be considering the procedures. Our purpose is to set up a model that identifies the capabilities needed to define, implement, and maintain the KMKE process.

The Background section of this article introduces capability models. In the Focus section, we define a capability model for KMKE in general terms and look at the management and engineering sides of this model. Then, we look into the future and offer a conclusion.

BACKGROUND: CAPABILITY MATURITY AND SOFTWARE

One area that has had long experience with processes is software engineering, and we turn to it for guidance on how to construct a capability model for KMKE. The software Capability Maturity Model (CMM-SW) was introduced by Humphrey (1989) and elaborated by a team of researchers at the Software Engineering Institute (1995). A later development is CMMI, which stands for CMM Integration. This is a suite of models where CMMI-SW (CMMI Product Team, 2002) is the model for software development. We shall be guided by the original model for two main reasons: First, there is greater familiarity with CMM-SW than with CMMI; second, the original CMM-SW has inspired a number of models that address the specific capabilities needed for specialized applications. Thus, there are CMMs for reuse (Davis, 1993), formal specification (Fraser & Vaishnavi, 1997), maintenance (Kajko-Mattson, 2001), an initial version for KM (Berztiss, 2002a), e-commerce (Berztiss, 2002b), and data quality management (Berztiss, 2004). An investigation of how to adapt CMM-SW for such nontraditional projects as product-line development, database development, and schedule-driven development also has been undertaken (Johnson & Brodman, 2000). Considerable evidence exists on the effectiveness of CMM-SW and CMMI for improving quality and reducing costs (Goldenson & Gibson, 2003).

The CMM-SW has five maturity levels. Level 1 is the base from which an organization moves upward by satisfying a set of requirements expressed as key process areas (KPAs). This level structure with the total of 18 KPAs is shown in Table 1. All KPAs of Level 2 relate to management, those of Level 3 to management and engineering, and those of Levels 4 and 5 relate primarily to engineering.

In CMM-SW, the definition of a KPA starts with a statement of it "goals," a "commitment to perform," which is essentially a policy statement committing the organization to the satisfaction of these goals, and an "ability to perform" statement, which lists the resources that have to be

Table 1. Key process areas of CMM-SW

Level 3	Level 5
Organizational process focus Organizational process definition Training program Integrated software management Software product engineering Intergroup coordination Peer reviews	Defect prevention Technology change management Process change management
Level 2	**Level 4**
Requirements management Software project planning Software project tracking and oversight Software subcontractor management Software quality assurance Software configuration management	Quantitative process management Software quality management

allocated. Next comes a list of activities that need to be performed in order to achieve the goals of the KPA. This can be regarded as a requirements statement that tells what is to be done without going into details of how the activities are to be performed. In addition, there is an indication of what process measurements are to be made and to what review procedures the activities of a KPA are to be subjected. Both measurements and reviews are important for any CMM. Only by measuring can we tell what does and what does not work, and what is the precise effect of a particular action. The review procedures ensure that the activities are in fact being performed.

FOCUS: A CAPABILITY MODEL FOR KMKE

Considering that the CMM-SW book (SEI, 1995) is about 450 pages, the outline of the CMM-KMKE we present here is very sketchy. The most we can do is define a set of KPAs and assign them to maturity levels. In designing CMM-KMKE, we were guided by our earlier work on the dimensions of the knowledge management process (Berztiss, 2001). Other influences have been the four "success statements" of Smith and Farquhar (2000):

- The organization knows what it knows and uses it, and knows what it needs to know and learns it.
- For any project, for any customer, the project team delivers the knowledge of the overall organization.
- The organization delivers the right information, to the right people, at the right time, with the tools they need to use it.
- The perspective of the employees is aligned with that of the customers.

Reinhardt's (2000) key questions of knowledge management were another source of inspiration. The KPAs of CMM-KMKE are intended to establish capabilities required to answer his questions:

- How can relevant organizational knowledge be identified and new knowledge be created and utilized?
- How can a system of knowledge creation and utilization be designed and organized?
- What measures provide management with information about the quality of the knowledge management process?
- What methods and tools support the implementation of knowledge management?

Table 2. Key process areas of CMM-KMKE

Level 4	Level 5
Integrated KMKE process External knowledge acquisition Qualitative cost-benefit analysis	Technology change management Quantitative cost-benefit analysis
Level 2	Level 3
Knowledge requirements management Internal knowledge acquisition Uncertainty awareness Training	Knowledge representation Knowledge engineering techniques User access and profiling

Table 2 shows the KPAs of CMM-KMKE. We have deviated somewhat from the underlying philosophy of CMM-SW. There, Levels 2 and 3 have a management bias, and Levels 4 and 5 have primarily an engineering orientation. The levels of CMM-KMKE are interleaved: Levels 2 and 4 emphasize KM, Levels 3 and 5 have more to do with the KE aspect. In this way, capability maturity can be achieved for both management and engineering of the knowledge process in parallel. However, it is essential to have in place knowledge requirements management, which is a Level 2 KPA, before any of the Level 3 KPAs are implemented. This KPA establishes what the organization aims to achieve, that is, it draws a road map for all the knowledge-related activities of the organization.

Management-Oriented Levels of the CMM-KMKE

We would need a book, written by a sizable team of experts in knowledge management and knowledge engineering to define the CMM-KMKE in detail. However, by listing a few of the activities for each KPA, we hope at least to suggest the nature and purpose of the KPA. The outlines of the KPAs follow closely their descriptions first presented in Berztiss (2002a).

- Knowledge requirements management (Level 2): The purpose of KMKE has to be clearly understood by the entire organization. The very first step is to set up a KMKE group (K-group) that is to determine the knowledge needs of the organization and to work toward the satisfaction of these needs by institutionalization of KMKE practices. In a smaller organization, the "group" can be a single person. By institutionalization, we mean that the practices are to be documented. A major purpose of a CMM is the distribution of capabilities throughout an organization so that the organization is no longer dependent on single individuals for particular capabilities. The knowledge needs can be expressed as requirements, that is, statements of what is needed without the details of how the needs are to be satisfied. Considerable literature exists on requirements gathering and management for software (for a brief summary, see Berztiss, 2002c). An important part of requirements determination is the identification of stakeholders, who in the KMKE context include gatherers and organizers of knowledge, experts on privacy laws, and people who will benefit from the knowledge.
- Internal knowledge acquisition (Level 2): We distinguish between internal and external knowledge. The former resides in an organization itself, in the form of databases and data warehouses, and, most importantly, the skills of people. External knowledge is gathered via personal contacts and communication media. After the knowledge requirements have been determined, the K-group is to establish a systematic approach to how the requirements are to be satisfied. This means that sources of internal knowledge are to be identified, information gathered from these sources is to be codified, and access to this information is to be facilitated. Abecker, Bernardi, Hinkelmann, Kühn, and Sintek (1998) give an overview of an artificial intelligence approach to the setting up of an organizational memory; Rus and Lindvall (2002) survey the role of KM in software engineering—they provide a very useful list of relevant Web addresses.
- Uncertainty awareness (Level 2): All knowledge is subject to uncertainty to a greater or lesser degree. To begin with, at least the K-group has to understand the issues relating to this. Specifically, it should establish guidelines on how to assign degrees of uncertainty to particular items of knowledge. Klir and Yuan (1995) is still the most useful

text on uncertainty in general; see Berztiss (2002d) for a more recent survey.

- Training (Level 2): The institutionalization of a training program is another priority task for the K-group. Initially, everybody in the organization is to be informed about the purposes of KMKE and how the KMKE processes will affect them. Specialized training needs will become apparent as the KMKE program develops, particularly with respect to KE techniques.
- Integrated KMKE process (Level 4): In order to arrive at an integration of KM and KE, there has to be a thorough understanding of both of them at a state-of-the-practice level, and the organization must make full use of KM techniques. By integration, we mean that KE is being applied to KM itself—KM is to manage the KMKE process, and KE is to look after improvements of this process.
- External knowledge acquisition (Level 4): Organizations do not operate in isolation. They are embedded in an environment—the environment is the context for the operation. It is customary to denote the context as <w, t>, where w is a slice of the "world" at time t. As the context changes over time, an organization has to recognize the changes and has to respond to them. This, of course, has to happen even at Level 1, but this KPA requires that a thorough analysis is undertaken to determine how much of w is relevant, and how this relevant component is to influence the operation of the enterprise.
- Qualitative cost-benefit analysis (Level 4): We should be able to measure the cost of the KMKE process, and we also should be aware of improvements (or the lack of them) in the operation of an organization. But it is difficult to discern cause-effect relationships, that is, to determine that this or that benefit arises from a particular expenditure of resources. The goal of this KPA is to identify cause-effect relationships. Some techniques for this have been developed (Pearl, 2000).

Engineering-Oriented Levels of the CMM-KMKE

- Knowledge representation (Level 3): Various representations of knowledge have been studied, particularly in the context of artificial intelligence (Markman, 1999). For example, Bayesian networks are used to facilitate inferences (Pearl, 2000). A recent trend is the use of ontologies to organize knowledge. There are numerous definitions of ontology. A useful one can be found in a survey by Kalfoglou (2002): An ontology is an explicit representation of a shared understanding of the important concepts in some domain of interest.
- Knowledge engineering techniques (Level 3): These techniques have been developed for extracting knowledge from different representations, but there is no sharp division between knowledge representation and KE techniques. For example, a Bayesian network represents knowledge, but the setting up of the network is a KE technique. Specialized KE techniques include the design of data warehouses, data mining, data filtering, and the management of uncertainty. Note that uncertainty management differs from the Level 2 KPA of uncertainty awareness: To manage uncertainty means that attempts are made to estimate uncertainty quantitatively by, for example, statistical techniques.
- User access and profiling (Level 3): Experience shows that there can be strong resistance to the introduction of KMKE (Kay & Cecez-Kecmanovic, 2000). A common cause of this resistance is that users have to go through complex access procedures and extensive searches to arrive at items of knowledge they are looking for. Moreover, personnel may be unaware of the existence

of knowledge useful to them. User profiles that reflect their interests allow the matching of knowledge needs and knowledge availability.
- Quantitative cost-benefit analysis (Level 5): The advance from qualitative to quantitative cost-benefit analysis requires extensive measurements relating to the KMKE process. Only experience will tell what should be measured, which measurements contribute to cost-benefit analysis in particular instances of benefits, and how a cause-effect relation is to be expressed in quantitative terms.
- Technological change management (Level 5): This is where a transition is made from state-of-the-practice to state-of-the-art. New developments arise constantly. For example, data mining, defined as the analysis of data sets to find unsuspected relationships and to summarize the data in novel ways (Hand et al., 2001), is extending to data mining on the Web. Mining of time series data is one example. Another development is the real-time analysis of streaming data, for example, from cash registers. The K-group must monitor research developments and be ready to introduce new techniques after a careful cost-benefit analysis.

A LOOK TO THE FUTURE

Much remains to be done in the KMKE area, and we cannot expect quick results. Within an organization, even with the best will, the upper levels of a CMM can take a long time to reach. The practices of the KPAs of these levels require reference to measurements relating to the effectiveness of the processes of knowledge gathering, knowledge representation, and knowledge use. In more general terms, the biggest challenge arises from the relative intractability of knowledge. To quote Davenport (1997), "Knowledge can be embedded in machines, but it is tough to categorize and retrieve effectively" (p. 10). We have to find better ways to deal with this aspect of knowledge, which Polanyi (1958) has called personal knowledge.

Most of today's knowledge workers are not particularly knowledgeable in theoretical areas. This will have to change. Data mining cannot be undertaken without statistical skills, and the study of causality is based on probabilities. Increasingly, knowledge workers will have to get accustomed to find out about new developments on the Web. As late as April 2004, the primary source of information about CMMI was the Web. On the other hand, the Web contributes to a managerial information overload (Farhoomand & Drury, 2002). The situation will not improve unless more effective filters based on user profiles are developed.

Under CMM-SW, an organization develops a generic software development process, and this process is adapted to the special needs and circumstances of a software project. The purpose of CMM-KMKE is to define capabilities that will make an organization more effective on its projects, but the knowledge process does not have the same project-dependence as the software process. Still, different organizations may have different needs. Kankanhalli, Tanudidjaja, Sutano, and Tan (2003) classify organizations as being service-based or product-based, and, orthogonally, as operating in a low-volatility or a high-volatility context. Thus, there are four types of organizations, and their KMKE needs will differ. The CMM-KMKE as outlined here is sufficiently general to meet the needs of all four types of organizations.

CONCLUSION

CMMs have provided various application areas with road maps for improvement. The effectiveness of CMM-SW, from which these CMMs derive, is well documented. A comparatively new area, such as knowledge management, can derive greatest benefit from a CMM because a new area is very much in need of guidance based on what has worked elsewhere. The most that has been possible here is to sketch an outline of a CMM-KMKE. Still, the outline should help identify the more critical capabilities needed for effective knowledge management.

Chapter 3.9
Clinical Knowledge Management:
The Role of an Integrated Drug Delivery System

Sheila Price
Loughborough University, UK

Ron Summers
Loughborough University, UK

ABSTRACT

Issues and complexities that arise from the adoption of clinical knowledge management are explored within the context of delivering drugs to the lungs. The move towards electronic data capture and information retrieval is documented together with cross-organisational working and sharing of clinical records. Key drivers for change are identified and their effects on, for example, the patient-clinician relationship are investigated. Conclusions drawn indicate the crucial role that all stakeholders play to bring about effective and efficacious patient care.

INTRODUCTION

Clinical knowledge management is the discipline concerned with the collection, processing, visualisation, storage, preservation, and retrieval of health related data and information, whether on an individual patient or a clinical specialty. Its successful adoption into daily clinical practice requires the use of new technologies such as: electronic health records; standardised medical terminologies, tools and methods to support speedier retrieval and dissemination of clinical information; and reliable networks to facilitate electronic communication in “real time.” Recent advances in Information and Communication

Technologies (ICTs) have facilitated the development of mobile communications, offering the opportunity for integration into existing and planned clinical information systems, and offer solutions for data capture and information retrieval at the point of care. Hidden organisational and cultural complexities arise from the anticipated use of ICTs, such as training needs, clinical acceptance, and a shift in empowerment within the patient-clinician relationship towards the patient. Addressing these issues requires commitment, application and tenacity from all stakeholders involved in the healthcare process.

The management of any clinical condition has traditionally been viewed as a clinician's domain. Data collection and information dissemination is still seen in some places as the preserve of an individual clinician with little evidence of sharing clinical knowledge. However, this established model of care in the UK is now being replaced by patient-centred care in which the patient is viewed as an equal partner in the care process. The Department of Health (DH) is committed to bringing together patients, carers and clinicians to create informal and formal relationships that support the self-management of chronic conditions. The DH also recognises this shift in responsibility for healthcare provision in its publication of documents such as “The Expert Patient” (Department of Health, 2001a). The “NHS Plan” (Department of Health, 2001b) developed from consultations with patients, is committed to the development of ‘high quality patient-centred care’ along with the development of modern ICT systems in primary and secondary care. It acknowledges the effective role that patients can play in the effective management of chronic diseases. Key elements of patient-centred care include, a patient's right to have access to their own medical records, access to identified and appropriate clinicians for treatment, access to information relating to waiting times, information on adverse drug effects and care planning, and the expectation that clinicians will keep accurate and accessible healthcare records. Patient knowledge is recognised as a beneficial asset to the healthcare process and as such is becoming a valuable tool in terms of the management of chronic conditions. In the specific area of management of chronic diseases, the opportunity to capture home-based data offers patients, carers and clinicians the possibility to add value in terms of increasing knowledge to manage the care process more effectively and as a consequence, empower key stakeholders in the healthcare experience.

CLINICAL RECORDS MANAGEMENT

A medical record relating to an individual patient is a collection of information that relates to distinct episodes of care. In the past, medical records were associated with one particular GP Practice or secondary healthcare organisation. In the early days of the NHS, patient notes were exclusively hand-written. Recipients of the information complained that they could not read handwriting, the information contained in the document was not always appropriate to the clinical need at that moment, and that too many documents did not reach the intended recipient in time to be of use for planning of ongoing treatment and care. Medical records such as the “Lloyd George” paper folder can still be found in daily use in some primary healthcare organisations. The transition to an electronic healthcare record is not quite complete, as issues such as scanning of paper notes and training staff to use computers is claimed to be an impediment to progress. Both issues require resource allocation that is not always seen as a priority in organisations with limited resources that exist in an environment of constant change.

As far as clinical records management is concerned, prior to the introduction of an electronic healthcare record, all documents relating to an individual patient remained with the originating organisation. Clinical information was collected and recorded by both nurses and doctors for use within one clinical domain. The main problem with paper note keeping in secondary care was ensuring that the patient notes were in the right place at the right time and in a format in which people could easily retrieve information required.

ELECTRONIC CARE RECORDS

Roll out of electronic healthcare records in the UK is currently underway. In 1998 the NHS launched an IT strategy, "Information for Health" (1998), that aimed to link all GPs with the NHS's own intranet, NHSnet, and to procure basic electronic records for all hospitals and healthcare communities. Financial planning, interest in clinical outcomes data, and computer support for clinical decision making at the point of care are examples of some of the original key drivers that led to this development. To expedite progress of this IT initiative, a national programme for NHS IT (NPfIT) has been created (National Programme for Information Technology). The programme has developed a new vision of an integrated care records service (ICRS) which will be designed around patients rather than institutions, and will be accessible 24 hours a day, seven days a week. An electronic clinical noting system reflects a degree of flexibility in order to provide clinicians with the ability to retrieve clinical information in a format that they require. Certain items of information that relate to the patient (such as name and address) that lie outside the scope of clinical information should always appear in the same place in all clinical documents. Electronic healthcare records that can be shared between staff seem like an obvious solution to support clinical knowledge management; although their potential goes far beyond that of recording clinical information.

NPfIT is setting national standards to ensure that clinicians are provided with real-time access to information, which allows them to share patient and relevant documents with other clinicians and allied health professionals. A key concept in this change is that patient information will cross organisational boundaries allowing documents relating to clinical care, care in the community and social care to be integrated. This concept relies on the establishment of best practice in knowledge management. By 2010, it is envisaged that every NHS patient in England will have an electronic healthcare record that they will be able to access via the Internet regardless of location. To support the key drivers and enable successful integration into the healthcare process, electronic healthcare records must be web-based, and be web-enabled allowing interaction with Internet technologies such as web services.

The current situation regarding clinical note keeping in the NHS shows that communication between organisations remains sketchy and fragmented. The technology is available to support communication across organisational boundaries, however it is fair to say that not all secondary healthcare organisations are as advanced as primary care in their adoption of ICT to support clinical note keeping. Integration of primary, secondary and tertiary healthcare electronic healthcare records is a prerequisite of the practice of clinical knowledge management. Failure to link systems to enable seamless transfer of clinical information between relevant organisations will create a situation little different to that brought about by existing paper based systems.

OPPORTUNITIES FOR SUPPORTING CLINICAL CARE: INTEGRATED DRUG DELIVERY

The development of home-based drug delivery systems offers the opportunity to capture data relating to the use of a device by a patient, collect data to support the assessment of clinical conditions, as well as empowering patients to become more involved in the management of chronic conditions. The data captured by a drug delivery device can be used to create useful information for both clinicians and patients/carers. Care should be taken to ensure that the information generated is about the right person, stored in a medium that is accessible to all who are nominated to use the system, and delivered at the right time to any specified delivery device, such as mobile phones, palmtops as well as desktop PC's. A critical element to the successful integration of informatics into the device must be commitment by all stakeholders, at all stages from development, implementation through to adoption into daily use.

Data integration from electronic healthcare record systems is essential in order to achieve state of the art clinical communication between stakeholders. The data collected must be able to be represented in a ubiquitous format that is acceptable to all those who take part in the care process. Critical elements in successful adoption of a home based drug delivery system into daily clinical use include the identification of the right data, the creation of the right structure, and the integration into the right clinical processes to add value. The care of asthmatic patients will be used to exemplify issues associated with home-based delivery of clinical treatment. If the above elements are addressed then the information architecture developed can be transferred to any clinical condition that requires delivery of drugs to the lungs.

Technology can support the diffusion of healthcare to the home through the development of home-based drug delivery systems. However, patient use of these systems may reveal issues that alter the traditional patient/clinician relationship. For example, clinicians who are not specialist in asthma may be confronted with patients who are considerably more knowledgeable about their condition. Acceptance and adoption into daily care will only be achieved through detailed and thorough integration into clinical practice, along with rigorous evaluation of the impact ICT has upon the care process. The effect of cultural issues will require assessment and evaluation and will influence adoption of novel approaches to patient centred care.

Home-based drug delivery systems are one way of managing clinical decision making at the point of care. They offer the opportunity for healthcare professionals to have instant access to a wide range of clinical information that may refer to individual patients, but the ability to access information such as clinical guidelines and protocols will only enhance and support the care process.

CLINICAL EXEMPLAR

Asthma is a condition that affects the airways (bronchi) of the lungs. From time to time the airways constrict in people who have asthma. The condition can commence at any age, but it most commonly starts in childhood. At least 1 in 10 children, and 1 in 20 adults, have asthma in the UK. Around 1500 people die from asthma in the UK each year (National Asthma Campaign, 2001).

Asthma in the UK places a high economic burden on both primary and secondary healthcare systems, at an estimated annual cost of over £850 million (Office for National Statistics). One in ten asthmatics that experience severe or moderately severe symptoms fail to control their condition adequately, even with the best clinical and preventative management available. Integrated drug delivery systems have the potential for easing the economic burden on the NHS with improved patient care. Improved delivery of drugs to the lungs in terms of both the ability to deliver larger quantities of drugs to the correct region of the lung, combined with improved patient compliance to prescribed treatment regimens, will result in better disease management with less need to resort to expensive "relief care" strategies and will slow down progression to severe disease status.

Also, very few asthmatics have a documented self-management plan that explains when to take their medication, the use of peak flow meters to measure the speed of air blown out of the lungs, and what to do if their asthma condition deteriorates (Lorig, K.R., Sobel, D.S., Stewart, A.L., Brown, B.W., Bandara, A., Ritter P., et al., 1999). Traditionally patients are asked to keep a manual diary over a defined time period such as two weeks, charting peak flow readings as a method of assessing a patient's current clinical state. Regular peak flow readings are a recognised method of assessing how well prescribed treatments are working. As a chronic disease, it is essential to involve patients in decisions relating to the development of a tailored care plan for the treatment of asthma, this will result in the more effective delivery of healthcare to the individual patient and to asthmatics as a whole. Patients (and clinicians) must learn how to use their inhalers correctly. The practice nurse or doctors have pivotal roles to play in educating patients how to use an inhaler properly. It is easy to demonstrate in a healthcare environment but ongoing home-based monitoring may ensure better device compliance for specific groups such as the newly diagnosed or teenagers. Empirical evidence shows that these groups may have compliance issues relating to the use of inhaled therapies. Patients must agree on an "asthma action plan" with a nominated clinician. This means that adjustments to the dose of the prescribed inhalers, depending on the symptoms and/or peak flow readings can be made at a relevant point in time.

STAKEHOLDERS

Patients are now increasingly recognised for the central role they play in the healthcare process. They must be involved and consulted at every stage of the process. For a home-based drug delivery device to provide effective treatment and collect relevant information, the patient and/or carer must understand why the device is being used, agree to its use and understand and accept a degree of responsibility for their role in the changing relationship between clinician and patient. The partnership that develops between patient and clinician will benefit patients' individual knowledge and will complement clinicians' general knowledge about a specific chronic disease. The pooling of this knowledge will in effect support the effective management of chronic diseases.

Clinicians should have skills that allow them to embrace novel innovations in drug delivery systems. Many current clinical practitioners are still resistant to the roll out of ICT within the NHS. This resistance may be explained by a fear of change, the inability to embrace changes in clinical practice, and the empowered role of the patient in the care process.

Home-based drug delivery devices are one of the tools that can be utilised to support clinical knowledge management in the modern healthcare setting by delivering concise, appropriate and timely clinical information relating to an individual patient's clinical state in "real time" to key stakeholders involved in the care and management of chronic clinical conditions. Collection and storage of clinical data electronically at the point of care offers healthcare professionals instant access to clinical data such as medication history and test results from remote locations. Mobile access also allows healthcare professionals to access and update care plans, clinical guidelines and protocols, thus tailoring care by having access to detailed information relating to an individual patient.

However, not all clinicians are comfortable or ready to use mobile devices in clinical practice. The benefits of using mobile health technology at the point of care will only be demonstrated by widespread adoption into clinical practice. For example, the use of handheld computers to access clinical guidelines and protocols etc, especially by junior doctors in secondary care is becoming more widespread. Use by all clinical stakeholders at the point of care should be encouraged, in order to benefit patient care. As adoption of these devices becomes more commonplace, the opportunity arises for innovative uses in the clinical setting to be explored.

The management of chronic clinical conditions often involves community healthcare practitioners. Access to timely information relating to a patients condition will support home-based care. In the past, relatives and neighbours often provided clinical care at home, clinicians and allied health professionals played a small role in the care of the average patient due to the related cost of healthcare. When the NHS was established, the focus of care for chronic conditions transferred to the "free" primary and secondary healthcare systems. Today, home- and self-care are re-emerging in response to cost pressures, the emergence of the Internet as a conduit of health information to patients, and by the diffusion of inexpensive computer technology as an aid to medical decision-making at the point of care. The benefits of home based drug delivery systems will be judged on patient outcomes as well as the reduction in costs relating to the provision of healthcare to support the ongoing treatment of chronic conditions.

STANDARDS

Issues surrounding the security of electronic patient records may impede development and implementation of innovative home-based drug delivery systems. Time spent debating this issue without the underpinning knowledge of international standards can often lead to an insular focus on ICT development and its ongoing benefits to the provision of patient centred care. Security and privacy of clinical data are at the forefront of any debate concerning mobile health. It is essential that uniform data standards for patient information and the electronic exchange of that information be adopted on a worldwide basis and are embedded in system development.

Recently, the US government has recommended that Health Level Seven (HL7) be recognised as the core-messaging standard (Health Level 7). Standards development must address issues such as security and the protection of data privacy, while facilitating communication between individuals. In developing a system for home-based drug delivery systems, patient–clinician communication must be structured and secure to ensure reliability and relationships underpinned by trust to be developed. Essential data must be clearly represented within a document structure (Nygren et al., 1998) Adherence to standards will allow analysis of the data collected and enable clinical outcomes to be communicated to the wider clinical community without an individual patient's privacy being compromised.

Communication of electronic clinical data and information across platforms should not be device specific. The electronic provision of clinical information, using an extensible mark up language (XML) format for interoperability, is a stated UK Government target that is endorsed by the National Health Service Information Authority (NHSIA). Regardless of which device is chosen, the use of XML facilitates electronic document management and workflow, and allows tasks to be distributed amongst multi-professional healthcare personnel that will result in the optimisation of patient care.

CURRENT PRESCRIBING PRACTICE

There is a wide range of inhalers available for the delivery of drugs to the lung. Studies have shown that asthmatics do not use prescribed inhalers correctly (Thompson, Irvine, Grathwohl, & Roth, 1994). The most effective inhaler is one that will be used by the patient on a regular basis and in an effective manner. As "poorly" compliant patients are often at risk of frequent attacks, it may be desirable to develop drug delivery devices that can capture data relating to use and feed this information into an electronic healthcare record system, accessible by all stakeholders in the care process, in order to support home based patient care and facilitate clinical knowledge management.

MOBILE DEVICES

Mobile health solutions allow for a point of care interaction regardless of whether the patient is in hospital, at home or elsewhere in the community (Price & Summers, 2004). Mobile devices can assist health professionals in their day-to-day clinical environment by facilitating the provision of timely information. Mobile devices can also be of use in medical research, used for clinical trials to record and transmit data that are costly to capture by traditional methods. It is essential that the clinical information is delivered in “real time” and can be readily accessed and understood by all stakeholders, including patients, who are involved in the care process. The development of an integrated drug delivery system enables all stakeholders, including patients and clinicians, to add value to the care process. The smart interface and the use of a patient diary provide a solution to the management of complex clinical communication issues by allowing documents to be stored electronically and retrieved at will. It is crucial that these documents are available in various formats and have the capability to be delivered to a wide range of platforms, depending on preference and circumstances of use. The device holds information that can be read in context of the recipient—this means that careful choice terms have to be used so as to avoid misinterpretation. It is clear that the integration of mobile devices into the healthcare process will demonstrate considerable benefit to UK plc by reducing the economic burden on primary, secondary and tertiary care.

CLINICAL KNOWLEDGE MANAGEMENT

Data captured by the drug delivery device can be used to create useful information for both clinicians and patients. The information generated must be about the right person, stored in a medium that is accessible and delivered at the right time by any specified delivery device, such as mobile phones, palmtops as well as desktop PC’s. A critical element to the successful integration of mobile-devices must be commitment by all stakeholders, at all stages from development, implementation through to adoption into daily use. Home-based drug delivery systems must provide efficient and cost effective care for patients, focusing on preventing complications through the use of alerts generated by the system when recorded results fall outside the ‘agreed’ patient profile, negotiated by individual patients and their nominated clinician.

Issues relating to the adoption of home based drug delivery devices include awareness of users previous experience relating to ICT in general, the device used to transmit and receive data, the identification of data that has specific relevance to a nominated clinician and the acceptability of filtering information in order to generate appropriate clinical information to the right person at the right point in time. A rigorous evaluation process will identify further issues generated when the device is integrated into the care process.

In order to take advantage of the developments surrounding electronic clinical note keeping, a device has been developed to deliver drugs to the lungs, initially to treat the symptoms of chronic asthma, but with planned exploitation routes to include diabetes and pain management. An integrated drug delivery system including a smart interface and patient diary capability allows documents to be stored electronically and retrieved at will. It is crucial that these documents are available in various formats and have the capability to be delivered to a wide range of platforms, depending on preference and circumstances of use. The device will also hold information that crosses various organisational boundaries, to be read in context of the recipient—this means that careful choice of terms has been used so as to avoid misinterpretation. It is clear that the device possesses considerable benefit to UK plc by reducing the economic burden on primary and secondary care.

In order to investigate the elements to be utilised for data capture and dissemination of clinical information a set of typical Use Cases was generated, describing patient and clinical aspects, the device to systems interfaces, and administrative functions. Investigation and mapping of e-health capabilities, such as generic search, retrieval and visualisation took place. The first draft of the functional specification required for the integration of data generated and captured from the drug delivery device, is described below.

The system is configured to accept sign-on from patients, carers and clinical staff. Demographic information will initially be populated locally, but later will be drawn from the local Community Index (Exeter system). Patient ID, initially populated locally using NHS numbers where possible, will later be drawn from the Community Index. Patient registration can take place by registering the device against a patient—which would need to be managed carefully. If the device is issued to a new patient without the system being updated, then the data will be associated with the wrong patient. Alternatively, all data are supplied with a patient ID (e.g., NHS number). This would mean that the device is either capable of holding an ID for the user or that the patient submits data in a two-phase process, by signing onto the system and then providing a password. Patient folders are automatically created when the patient is positively identified. In order to achieve maximum coverage for "alerts" to nominated health professionals, it is essential that clinicians are able to select a delivery device that they feel most comfortable with. The options available include: mobile phones, PDAs, land line phones, and fax.

Factors to take into consideration when deciding upon appropriate channels of communication include ability to access "real time" information, the need to communicate quickly with the nominated clinician and to agree the method of communication with the patient. The device supports the delivery of clinical information delivered in "real time", which can be readily accessed and understood by all stakeholders, including patients and their carers who are involved in the management of chronic conditions.

The information held within the system covers:

- Schedules for prescription against which alerts/actions may be triggered. These alerts will be negotiated at an individual patient level and after consultation with the nominated clinician. It is envisaged that these alerts will eventually be sent to a nominated pharmacy to ensure and support efficient and timely prescription of the required drugs to patients.
- Drug dosing information (prescription) received from the devices, these data will be tested against the schedule

Figure 1. E-medic platform

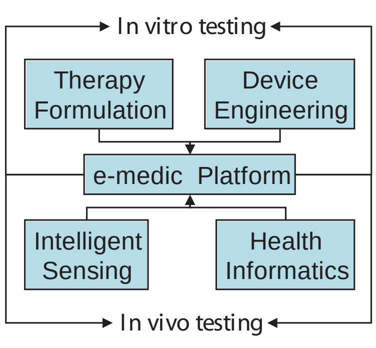

Figure 2. Informatics metrics

    - Drug name—the patient may be taking more that one type of drug therapy and it is therefore important to distinguish which drug has been taken.
    - Dose prescribed
    - Frequency—will enable accurate data to be collected to map actual use against planned use
    - Alerting rules
    - Remaining inhalations
    - Date next prescription is due
- Drug taken—information from the inhaler device
    - Patient ID—NHS number, or device number that matches to the patient
    - Drug name
    - Breathing profile indicator
    - Device malfunction status flag
    - When a drug event is received, it is checked against the most recent schedule.
    - Check for remaining inhalations; if down to last inhalation send "in-tray" alert to nominated clinician
    - Check against Alerting rules; if fails check create "in-tray" item to nominated clinician
    - Check value of Breathing Profile indicator; if outside normal profile create "in-tray" item for nominated clinician
    - Create drug event and store in electronic healthcare record

STRUCTURED EVALUATION

Integration of home based drug delivery devices to capture and disseminate clinical data and information into daily clinical practice must be subjected to thorough and rigorous evaluation at every stage of the procurement and implementation process. A key element of evaluation is the need to identify "best practices" relating to device use and patient feedback, ensuring that is rolled out to the wider clinical community and embedded in the development of future asthma management plans, along with clinical protocols and guidelines.

Unless it can be demonstrated that mobile devices have improved organisational effectiveness as well as contributing to an improvement in patient care, and have subscribed to the development of clinical care in general, their contribution to the clinical knowledge management process will be devalued.

Academic clinical studies will be required to evaluate the benefits of home based drug delivery systems focusing on the possible clinical benefit to the patient and additional benefit to clinical care, looking at the use of the device by patients with little or no ICT skills, an increase in patient involvement in the care management process and the level of patient compliance compared with those patients not using the device. Randomised trials indicate improvement in patient health and reduction in healthcare costs (Simon, Von Korff, Rutter, & Wagner, 2000). The return on investment should be measured in terms of any increase in the level of patient care and any advancement in the knowledge relating to chronic clinical conditions.

FUTURE USES

As adoption of integrated devices into daily clinical practice becomes more commonplace, the opportunity arises for innovative uses in the clinical setting to be explored. The device can be used for clinical trials to record and transmit data that are costly to capture by traditional methods. The ability to record the patients breathing profile could enable the relationship between a successful dose deposition of the drug being delivered to the lungs and the patient ability to match their pre-determined "perfect profile". This information would be of use in the future development of novel drug therapies and would also provide the clinical community with invaluable information relating to patterns of inhaler use and effectiveness.

OUTCOMES

Successful implementation of the device into daily clinical use will require commitment from patients/carers, individual healthcare professionals as well as healthcare organisations. A tailored training infrastructure for all is essential, not only to demonstrate correct use, but also demonstrate benefits that can be achieved from the device on an individual basis. The integration of the device into daily clinical practice will only be achieved if issues associated with it are incorporated into clinical teaching practice and continuous professional development programmes. Although training can be expensive and time consuming, it is an investment that is critical to the acceptance of all home based clinical systems. Home-based drug delivery devices are likely to generate data to populate mature information databases to inform clinical practice and may facilitate the growing trend to decentralisation of care.

CONCLUSIONS

Uptake of novel drug delivery devices will depend on many factors, including organisational support, effective training infrastructure, reliable systems, integration with legacy systems, data standards, workflow patterns, privacy and security, and healthcare standards. In the US, drivers to ensure successful implementation will be improved clinical outcomes and the ability to bill patients for each element of a clinical episode at the point of care. In the UK, more emphasis will be placed on the ability to input and retrieve data and information using an "integrated electronic healthcare record" accessible by clinicians and allied health professionals at the point of care, regardless of location.

It is essential to involve all stakeholders in the debate relating to the goals of clinical knowledge management and the strategies required to achieve them. Presently, clinical information is not currently disseminated in a way that facilitates understanding by patients. Patient awareness of their rights to access clinical data is patchy and channels of access to information are not well developed. The use of abbreviations and codes acts as a barrier to understanding by non-clinicians. Patients with specific knowledge relating to chronic conditions require tailored communication infrastructures to be developed before they can take their place as equal partners in the care process. It is essential that all stakeholders are comfortable with clinicians adopting a supportive role to enable patients to recognise deteriorating asthma and for patients be relaxed about taking a pivotal role in the self-management of their own medication to prevent deterioration in their condition. Discontinuity and lack of communication between primary care, emergency departments, and even within secondary care may hinder the development of an integrated care programme for asthma.

The way to address this is through greater involvement of patients in their own management. The use of a drug delivery device that includes the use of a patient diary will go some way to support an integrated care programme for the management of the asthmatic patient. Thus the drug delivery device is the integrator that underpins the integrated care process. The electronic healthcare record is the repository that is pivotal to the knowledge sharing activity that is required to empower all stakeholders in the care process and capture "real time" clinical information to add to knowledge already held about a chronic clinical condition. Many clinicians complain that they suffer from "information overload"; mobile communication devices are one of the tools that can be utilised to support clinical knowledge management in the modern healthcare setting.

Chapter 3.10
The Role of Organizational Trust in Knowledge Management:
Tools & Technology Use & Success

Vincent M. Ribière
New York Institute of Technology, USA

Francis D. Tuggle
Chapman University, USA

ABSTRACT

The discipline of knowledge management (KM) is no longer emerging, but some organizations are still struggling to find the right approach that will allow them to fully take advantage of their intellectual assets. Having the proper organizational culture remains an important barrier to knowledge management success. This empirical research project, conducted with data from 97 organizations involved in KM, explores relationships between the level of organizational trust and the use of KM methodologies, in particular the use of codification KM methodologies and personalization KM methodologies. The presence of trust can also be used as an indicator of KM initiative success. The contribution of this research may help organizations seeking to launch or adapt a KM initiative to choose which KM tools and technologies to deploy in order to maximize their chance of success. Finally, a rank-ordered list of KM methodologies in descending order of usefulness is reported.

INTRODUCTION

Knowledge management (KM) initiatives are expanding across all types of organizations and companies worldwide. Many benefits resulting from the successful implementation of KM have been demonstrated and published, but unfortunately not all KM initiatives are successful. Studies and surveys looking at some of the causes of

KM initiative failure (Barth, 2000; Knowledge Management Review, 2001; KPMG Consulting, 2000; Microsoft, 1999; Pauleen & Mason, 2002) all come to the same conclusion: Organizational culture is an important barrier to KM success and is an important precondition for KM success (Tuggle & Shaw, 2000). After having primarily focused KM efforts on information technology (IT), practitioners are now realizing the importance of the "soft" aspect of KM initiatives. It seems that the IT tools designed to facilitate knowledge creation, capture, representation, storage, and sharing are now available, but their efficient use and acceptance by knowledge workers remains constrained by organizational culture.

There is a general agreement that a knowledge-sharing organizational culture must be present or nurtured in order to succeed with KM (see, for example, Alavi & Leidner, 2001, and Jennex & Olfman, 2001). However, the current literature is weak regarding the identification of the critical cultural success factors that lie behind the term "culture". Often mentioned as important cultural factors are altruism, reciprocity, trust, repute, openness, solidarity, sociability, motivation, commitment, and others (Davenport & Prusak, 1998; Malhotra & Galletta, 2003; Park, Ribière & Schulte, 2004). Jennex and Olfman (2004) identify 14 KMS success factors, one of which (SF5) specifically states "An organizational culture that supports learning and the sharing and use of knowledge". Based on a literature review, trust seems to be one of the most critical factors among the ones listed previously. If knowledge workers are reluctant to trust each other, they are not likely to share and exchange knowledge. Without the presence of trust, the benefits of reciprocity, repute, openness, solidarity, and sociability will not occur and levels of motivation and commitment might be seriously affected (negatively). "Without trust, Knowledge Management will fail, regardless of how thoroughly it is supported by technology and rhetoric and even if the survival of the organization depends on effective knowledge transfer" (Davenport & Prusak, 1998). Does having a low trust organizational culture mean that a company should not consider launching a KM initiative? Since culture is difficult to change in the short term, are there some KM approaches/tools that might succeed and might also help to evolve the culture? This article will attempt to shed light on these issues.

STATEMENT OF THE PROBLEM

This study attempts to better understand and to measure how organizational trust affects the choice and use of KM tools and technology and the resulting success of the organization's KM initiative, or lack thereof. Our main research question is as follows:

Does the level of organizational trust influence which KM tools & technology will be successful?

In order to study this research question, the level of organizational trust is assessed through a questionnaire distributed to knowledge workers from different organizations involved in KM. Second, the types of KM tools and technology implemented and used in these organizations were evaluated. Finally, the level of success achieved was assessed. The research project reported on herein is a straightforward extension of these pilot activities. The next sections define these aforementioned variables.

Organizational Trust

Considerable research has been conducted concerning the concept of trust, both interpersonal trust and organizational trust. As with the concept of organizational culture, organizational trust has been defined somewhat differently in the literature by numerous authors (Carnevale & Wechsler, 1992; Culbert & McDonough, 1986;

Griffin, 1967; Luhmann, 1979; Matthai, 1989; McKnight & Chervany, 2000). The definitions of trust are numerous and sometimes confusing, mainly due to each discipline viewing trust from its own perspective. Two definitions of KM were selected:

"Trust consists of a willingness to increase your vulnerability to another person whose behavior you cannot control, in a situation in which your potential benefit is much less than your potential loss if the other person abuses your vulnerability" (Zand, 1997).

"Belief that those on whom we depend will meet our expectations of them" (Shaw, 1997).

Research on trust is often associated with research on organizational commitment and work attitudes (Cook & Wall, 1980; Mowday, Steers & Porter, 1979; Nyhan, 1999). Research conducted by Daley and Vasu (1998) examining employee attitudes of organizational trust toward those in top management positions demonstrated that demographic controls (education, pay level, race and gender) exhibited no substantive effect. Attitudes assessing internal job characteristics (benefits, extrinsic rewards and work environment) demonstrated a relationship in fostering trust. External work characteristics (job satisfaction, supervisory evaluation, and political interference) also emerged as determinants of organizational trust (Daley & Vasu, 1998). In addition to the many definitions of trust, many tools have also been created to assess its level in an organization. Among them is the survey tool designed by Cook and Wall (1980) that has been extended by Wilson (1993). Wilson developed a heuristic conceptualization — in the form of an influence diagram- that can be used by managers in assessing the level of organizational trust. Cummings and Bromiley (1996) designed a survey tool named the Organizational Trust Inventory (OTI). This tool is intended to measure the degree of trust between units of an organization or between organizations. Their questionnaire is based on a (3x3) "definitional matrix of trust as a belief" where three dimensions of trust (keeps commitments, negotiates honestly and avoids taking excessive advantage) are mapped against three components of belief (affective state (feel), cognition (think) and intended behavior). Nyhan and Marlowe (1997) developed a 12-item scale to measure an individual's level of trust in his or her supervisor and his or her work organization as a whole. Two books on trust also offered assessment tools. Built on Trust by Ciancutti and Steding (2000) offers an audit questionnaire based on 21 questions as well as six open-ended questions. This questionnaire is designed to detect both the overall level of trust and the type of issues in which closure is a concern. The second book by Lewis (1999) is more oriented toward how companies build mutual trust and how interpersonal relationships are a critical component. The tool presented in this book is defined as a yardstick for measuring how close your company is to building high trust. A set of 21 trust practices is listed and for each of these a low trust behavior as well as a high trust behavior is listed. "Where you and your partner fall in the continuum between high and low trust determines your ability to rely on each other to reach a common objective" (Lewis, 1999). Five trust factors defined by De Furia (1996, 1997) were determined to be most relevant to our research: sharing relevant information; reducing controls; allowing mutual influences; clarifying mutual expectations; and meeting expectations. These factors are described in more detail in the following section of this article. Very often people think that an organizational culture with a high level of sociability also implies a high level of trust. This is not always true. Consider the example of a parent-child relationship: you love your children but it does not imply that you trust them (e.g., you will not leave them by themselves). The opposite is also true: you might trust someone but might not necessarily like this person (e.g., an airplane pilot). One also needs to remember that trustworthiness takes a long time to build, and yet trust can be destroyed in an instant. These different examples show the complexity and fragility associated with trust. The benefits of high trust include (De Furia, 1997):

- Stimulates innovation
- Leads to greater emotional stability
- Facilitates acceptance and openness of expression
- Encourages risk taking

Consequences of low trust include (De Furia, 1997):

- Values, motives of others are misperceived
- Less accurate communication, poor reception
- Diminished ability to recognize and accept good ideas
- Increased attempt to obtain relevant information (grapevine)
- Increased control mechanisms
- Self-control replaced by external controls
- Delayed implementation of actions and projects
- Increased rejection, defensiveness, hostility
- Win-lose mentality replaces win-win

"Trust is the one essential lubricant to any and all social activities. Allowing people to work and live together without generating a constant, wasteful flurry of conflict and negotiations" (Cohen & Prusak, 2001).

Knowledge Management Tools and Technologies

Numerous publications present knowledge management practice/tool/technology frameworks. Most of them are IT oriented, since IT is the main enabler for KM. Nevertheless, other KM practices that are not driven by IT must also be taken in consideration in order to fully understand the KM strategy of an organization. Two main KM strategies or approaches emerged: codification versus personalization. Hansen, Nohria and Tierney (1999) describe how different companies focus on different practices/strategies in order to manage their knowledge. Additional reasons for this particular categorization of KMS approaches are offered by Jennex and Olfman (2003).

The Codification Approach

The first strategy identified by Hansen et al. (1999) is called "codification," which relies heavily on IT. One of the benefits of the codification approach is the reuse of knowledge. "Knowledge is codified and stored in databases, where it can be accessed and used easily by anyone in the company. Knowledge is codified using a people-to-documents approach: it is extracted from the person who developed it, made independent of that person, and reused for various purposes" (Hansen et al., 1999). It has been named and described differently by authors: the cognitive network model (Swan, Newell, Scarbrough & Hislop, 1999), the collecting dimension (Denning, 1998), the product view approach (Know-Net, 2000), the transformation model (Natarajan & Shekhar, 2000), distributive applications (Zack & Michael, 1998), the document-centered approach and the technological approach (Wick, 2000). After a close analysis of these different portrayals, one can conclude that all of these descriptions and definitions are very similar and depict the same type of practices and tools (Ribière, 2001).

The Personalization Approach

The personalization approach (Hansen et al., 1999) focuses on developing networks for linking people so that tacit knowledge can be shared. It invests moderately in IT. This approach focuses on dialogue between individuals, not knowledge in a database. "Knowledge that has not been codified — and probably couldn't be — is transferred in brainstorming sessions and one-on-one conversations" (Hansen et al., 1999). An investment is made on building networks of people, where knowledge is shared not only face-to-face but also over the telephone, by e-mail, and via videoconference. All the previously cited authors who defined the codification approach also came up with their own definition for this approach: the community networking model (Swan et al., 1999), the connecting dimension (Denning, 1998), the process-centered approach (Know-Net, 2000), the independent model (Natarajan & Shekhar, 2000), the collaborative approach (Zack & Michael, 1998), and socio-organizational knowledge management (Wick, 2000).

KM Initiative Success

It is always difficult and open to controversy to define and measure "success". Different metrics (qualitative and quantitative) can be used to measure success. For example, Jennex and Olfman (2004) offer a success model based upon the Delone and McLean (1992) IS Success Model and discuss four different models of KM success: Knowledge Value Chain (Bots & Bruiin, 2002), Massey, Montoya-Weiss and Driscoll KM Success Model (2002), Lindsey KM Effectiveness Model (2002), and Jennex and Olfman KMS Success Model (2003). Four main indicators defined and used by Davenport et al. in their publication concerning "successful knowledge management projects" were adopted (Davenport, De Long & Beers, 1998).

1. Growth in the volume of knowledge available since the KM initiative has been launched (e.g., number of documents available)
2. Growth in the usage of knowledge available since the KM initiative has been launched (accesses to repositories, or the number of participants for discussion-oriented projects)
3. The likelihood that the project would survive without the support of a particular individual or two; that is, the project is an organizational initiative, not an individual project
4. Growth in the resources (e.g., people, money) attached to KM initiatives

Success was measured based on two dimensions. Since the main purpose of a KMS is to facilitate the flow and dissemination of knowledge, an important dimension for success is the fact that different employees use the system. Success factors #1 and #2 were used to measure this dimension of success. The second dimension of success used is based on the "robustness" of the KM initiative. If KM is given the resources and if there is a clear commitment from senior management to make it happen, then robustness is a success factor. Success factors #3 and #4 were used to measure this second dimension of success. Additional success factors could have been used, such as the 12 KMS success factors presented by Jennex and Olfman (2004), but it was easier to work with a smaller number of core variables.

These factors helped us to differentiate highly successful KM projects from less successful projects.

RESEARCH DESIGN AND METHODOLOGY

Research Hypotheses

Three hypotheses were derived from our main research question:

H1: Companies with a low organizational trust culture use/rely more on codification tools than companies with a high organizational trust culture.

H2: Companies with a high organizational trust culture use/rely more on personalization tools than companies with a low organizational trust culture.

H3: Companies with a high organizational trust culture will be more successful with their KM initiatives than companies with a low organizational trust culture.

Assessment of Variables

A survey tool (a questionnaire) was developed in order to assess:

1. The level of organizational trust
2. The level of use of different KM tools and technologies deployed in each organization (codification emphasis vs. personalization emphasis)
3. The perceived success of the KM initiative

Assessing Organizational Trust

The tool selected, the Organizational Trust Survey (OTS), was developed and validated by De Furia (1996, 1997), where trustworthiness (TW) is based on five behaviors:

TW = SI + RC + AI + CE + ME

- Sharing relevant information (SI) refers to the behaviors whereby one individual transmits information to another person.
- Reducing controls (RC) refers to the behaviors affecting the processes, procedures or activities with which one individual (1) establishes the performance criteria or rules for others, (2) monitors the performance of another person, (3) adjusts the conditions under which performance is achieved, or (4) adjusts the consequences of performance (i.e., positive or negative reinforcements).
- Allowing for mutual influences (AI) occurs when one person makes a decision that affects both individuals. Mutual influence means that both individuals have approximately equal numbers of occurrences of convincing the other or making the decision for both individuals.
- Clarifying mutual expectations (CE) refers to those behaviors wherein one person clarifies what is expected of both parties in the relationship. It involves sharing information about mutual performance expectations.
- Meeting expectations (ME) involves any behaviors in which one individual fulfills the behavioral expectations of another person. It is closely related to confidence, reliability and predictability.

The OTS allows organizations to measure the trust-related behaviors of various categories of people within the organization — upper managers, first line supervisors, and coworkers — in relation to how employees' trust-related expectations are being met. It also measures trust-related behaviors between organizational units and the perceived impacts of organizational policies and values on trust-related behaviors. This tool (questionnaire) is based on 50 questions (10 questions for each of the five factors). Because of the existence of a pretested questionnaire with a small number of variables, necessary because of the somewhat limited size of our dataset, the OTS was used.

Assessing the Use of KM Tools and Technologies

For this section of the questionnaire an assessment tool was developed. The most common tools and technologies used for knowledge management initiatives were listed, based on a literature review. Respondents were asked to list the KM tools and technologies used at the organizational level (cf. Table 1). A sense of the degree of use or utilization ranging from "most used" to "least used"

Table 1. Codification and personalization KM tools and technologies

	KM Tools and Technologies
Codification	Email & Listserv
	Corporate Intranet – Extranet – Internet
	Database Management Systems
	Search Engines - Intelligent Agents
	Data Warehouses – Data Marts
	Web-based training – e-learning
	Help-desk applications
	DMS
	Multimedia repositories
	DSS and Expert Systems
	Data mining- Knowledge Discovery
	Knowledge Mapping
Personalization	Expertise locators – Corporate Yellow pages – Who's who
	Communities of Practice (interests in the same topic, field)
	Communities of Purpose (project, task oriented)
	Groupware
	Teleconferencing (shared applications, whiteboards)
	Best practices repository
	Videoconferencing (using audio and/or video)
	Mentoring - Tutoring
	Story Telling
	Desktop computer conferencing
	Online Chat & Instant Messaging

was employed to enrich this insight. Although it might be argued that some of the personalization tools, for example, corporate yellow pages, in fact are examples of codified knowledge, the critical delineator is how the tools are used in practice. For example, the crucial fact about corporate yellow pages is not that it is a knowledge repository, but that employees use it to connect to experts.

KM Initiative's Success

As mentioned earlier in this article, four indicators were used to assess the level of success. Respondents were asked to assess on a five-point Likert scale to what degree they believed that the following statements corresponded to the current success status of their organizational KM initiative (see Example 1).

Validity and Reliability

Designing a new survey instrument is always a difficult task. Finding relevant variables and factors that capture the appropriate dimensions (that prove to be valid and reliable over different samples and over time) is always a challenge. In order to surmount this difficulty, a previously validated questionnaire was adopted in order to assess the

Example 1

Strongly agree - Agree - Neither agree nor disagree - Disagree - Strongly disagree
2 · 1 · 0 · -1 · -2

- I have noticed a significant growth in the volume of knowledge available since the KM initiative has been launched (number of documents available).
  2 · 1 · 0 · -1 · -2
- I have noticed a significant growth in the usage of knowledge available since the KM initiative has been launched (accesses to repositories and number of participants for discussion-oriented projects)
  2 · 1 · 0 · -1 · -2
- I believe that the project would survive without the support of a particular individual or two
  2 · 1 · 0 · -1 · -2
- I believe that resources (e.g., people, money) attached to KM initiatives are going to grow
  2 · 1 · 0 · -1 · -2

trust dimension. This questionnaire was extended to assess the type of KM tools and technologies used by organizations as well as to assess the level of success of KM initiatives. A pre-test or pilot study was undertaken to create a more sensitive instrument. Content validity was demonstrated by the review of 10 knowledgeable people (academics and professional) highly involved in the field of KM and organizational behavior. Only minor modifications were made to those instruments used in the research reported herein.

Cronbach's alpha value was used to assess the internal consistency of the research instruments (cf. Table 2). The overall raw alpha score of .94 indicates that the scales used to measure trust are reliable. Nevertheless, the table indicates that RC2 has the lowest item-total correlation value (.27). This indicates that RC2 is not measuring the same construct as the rest of the items in the scale are measuring. RC2 was removed from the scale in order to make the construct more reliable for use as a predictor variable. The question associated with Reducing Control #2 (RC2) was "My coworkers take the initiative to solve problems sometimes ignoring rules to do so". This question might have been misunderstood or not properly interpreted, leading to its low correlation with the other factors.

Construct validity was assessed using item-total correlation where the average of each construct was correlated with each item in the same construct. The correlation coefficients for all these constructs were demonstrated to be highly significant.

DATA COLLECTION AND ANALYSIS

Data were collected through two main mechanisms. An online version of the questionnaire posted on the Web (http://www.csis.american.edu/kmsurvey) as well as a paper version were used. Most of the responses received (98%) came from the online version. The target population was chief knowledge officers (CKOs), managers, and other employees involved in knowledge manage-

ment initiatives at any level in an organization. A total of 1,050 e-mails asking for participation were sent out to targeted people involved with KM (members of KM groups and associations). A total of 129 responses were received. This represents a response rate of 12%. A fundamental premise of the research was that targeted organizations must have had experience with KM initiatives.

Of the 129 questionnaires received only 97 were complete and were representative of organizations involved in KM.

Organizations that participated were predominantly large organizations in the consulting and IT — telecommunications fields as well as agencies in the federal government. Respondents were mainly service-oriented, offering both standardized and customized products/services, and were predominantly located in the U.S.

DATA ANALYSIS

Research Hypothesis 1

This hypothesis tests the difference between the codification factor score (dependent variable) associated with companies with low and high levels of organizational trust (independent variable).

H1: Companies with a low organizational trust culture use/rely more on codification tools than companies with a high organizational trust culture.

The codification factor score variable was measured on an interval/ratio scale of values ranging from 0 to 60. The level of trust factor score variable was measured on an interval/ratio scale of values ranging from 25 to 125. However, a cutoff point of 75 (the mid-point in the range) was used to divide the variable into two sets. Organizations that obtain trust factor scores greater than 75 were categorized as having a high trust culture, while organizations with scores less than or equal to 75 were categorized as having a low trust culture. An independent-sample one-tailed t test was used to analyze the differences of means between the companies with high and low trust. Table 3 provides some descriptive statistics of the two groups studied.

The probability associated with the F-test for homoskedasticity is 0.9051 (Table 4, row (1)); because this is more than .05, it is not reasonably certain that the variance in the use of codification

Table 3. Descriptive statistics of the two groups studied

	n	$\bar{x}$	Std dev.
High Trust	76	33.066	14.016
Low Trust	23	29.87	14.153

Table 4. Comparison between the codification factor scores of organizations with low and high trust culture

	H_0	H_A	Test	Test Value	d.f.	prob-ability	Accept H_A?
(1)	$\Phi_{HT} = \Phi_{LT}$	$\Phi_{HT} \neq \Phi_{LT}$	**F**-test for homoskedasticity	1.02	(22,75)	0.9051	No
(2)	$\mu_{LT} <= \mu_{HT}$	$\mu_{LT} > \mu_{HT}$	Independent samples **t**-test	0.96	97	0.1707	No

tools differs across the two groups. Applying the pooled/standard form of the independent samples t-test (Table 4, row (2)), statistical theory tells us that a ($\bar{x}_{LT} - \bar{x}_{HT}$) difference more positive than the difference seen here would occur 17 times out of every 100 samples if the null hypothesis was true.

Applying the two-step rule, p=0.1707 (greater than the pre-set ± of .05) and directionality of the difference in sample means is not consistent with HA (29.87<33.066). Thus, H0 is not rejected and HA is not accepted (H1).

Research Hypothesis 2

This hypothesis tests the difference between the personalization factor score (dependent variable) associated with companies with low and high levels of organizational trust (independent variable).

H2: Companies with a high organizational trust culture use/rely more on personalization tools than companies with a low organizational trust culture.

The personalization factor score variable was measured on an interval/ratio scale of values ranging from 0 to 55. The level of trust factor score variable was measured on an interval/ratio scale of values ranging from 25 to 125. Again, a cutoff point of 75 (mid-point score) was used to divide the variable into two sets. Organizations that obtain trust factor scores greater than 75 were categorized as having a high trust culture, while scores less than or equal to 75 were categorized as having a low trust culture. An independent-sample one-tailed t test was used to analyze the differences of means between the companies with high and low trust. Table 5 provides some descriptive statistics of the two groups studied.

The probability associated with the F-test for homoskedasticity is 0.0621 (Table 6, row (1)); because this is more than .05, it is not reasonably certain that the variance in the use of personalization tools differs across the two groups. Apply-

Table 5. Descriptive statistics of the two groups studied

	n	$\bar{x}$	Std. dev.
High Trust	76	29.434	12.16
Low Trust	23	18.174	8.5155

Table 6. Comparison between the personalization factor scores of organizations with low and high trust cultures

	H_0	H_A	Test	Test Value	d.f.	prob-ability	Accept H_A?
(1)	$\Phi_{HT} = \Phi_{LT}$	$\Phi_{HT} \neq \Phi_{LT}$	**F**-test for homoskedasticity	2.04	(75,22)	0.0621	No
(2)	$\mu_{HT} <= \mu_{LT}$	$\mu_{HT} > \mu_{LT}$	Independent samples **t**-test	4.14	97	<.00005	Yes

ing the pooled/standard form of the independent samples t-test (Table 6, row (2)), statistical theory tells us that a difference more positive than the difference seen here ($\bar{x}_{HT} - \bar{x}_{LT}$) would occur less than five out of every 100,000 samples if the null hypothesis was true.

Applying the two-step rule, p<.00005 (less than the pre-set ± of .05) and directionality of the difference in sample means is consistent with HA (29.434>18.174). Thus, H0 is rejected and HA is accepted (H2).

Research Hypothesis 3

This hypothesis tests the difference between the success factor score (dependent variable) associated with companies with low and high levels of organizational trust (independent variable).

H3: Companies with a high organizational trust culture will be more successful in their KM initiative than companies with a low organizational trust culture.

The success factor score variable was measured on an interval/ratio scale of values ranging from 4 to 20. The level of trust factor score variable was measured on an interval/ratio scale of values ranging from 25 to 125. Once again, a cutoff point of 75 (mid-point score) was used to divide the variable into two sets. Organizations that obtain trust factor scores greater than 75 were categorized as having a high trust culture, while scores less than or equal to 75 were categorized as having a low trust culture. An independent-sample one-tailed t test was used to analyze the differences of success means between the companies with high and low trust. Table 7 provides some descriptive statistics of the two groups studied.

The probability associated with the F-test for homoskedasticity is .0869 (Table 8, row (1)); because this is more than .05, it is not reasonably certain that the variance of success differs across the two groups. Applying the pooled/standard form of the independent samples t-test (Table 6, row (2)), statistical theory tells us that a difference more positive than the difference seen here (

Table 7. Descriptive statistics of the two groups studied

	n	$\bar{x}$	Sdt. Dev.
High Trust	69	14.145	3.6125
Low Trust	17	10.882	6.2027

Table 8. Comparison between the success factor scores of organizations with low and high trust cultures

	H_0	H_A	Test	Test Value	d.f.	prob-ability	Accept H_A?
(1)	$\Phi_{HT} = \Phi_{LT}$	$\Phi_{HT} \neq \Phi_{LT}$	**F**-test for homoskedasticity	1.84	(16,68)	0.0869	No
(2)	$\mu_{HT} = \mu_{LT}$	$\mu_{HT} > \mu_{LT}$	Independent samples **t**-test	3.72	84	0.0002	Yes

$\bar{x}_{HT} - \bar{x}_{LT}$) would occur only two times out of every 10,000 samples if the null hypothesis was true.

Applying the two-step rule, p=.0002 (less than the pre-set ± of .05) and directionality of the difference in sample means is consistent with HA (14.145>10.882). Thus, H0 is rejected and HA is accepted (H3).

DISCUSSION

The previous findings helped us to validate some assumptions made regarding the critical role of organizational trust in organizations' use of KM technologies. Companies with a low organizational trust culture do not significantly use/rely more on codification tools than companies with a high organizational trust culture (Hypothesis #1). The codification approach is used by all organizations to different degrees but remains always present. Companies with a high organizational trust culture use/rely more on personalization tools than companies with a low organizational trust culture (Hypothesis #2). In the presence of a trusting culture, knowledge workers are more likely to use personalization tools in order to contact, assist, and share knowledge with their trusted co-workers. If organizational trust is low, knowledge workers are "suspicious" and do not want to increase their vulnerability by sharing their knowledge with co-workers through one-to-one interactions/communications (physical, vocal or virtual). They will then mainly rely on codification tools and technologies to manage knowledge. The efficiency of the codification approach might also be affected by lack of trust. Actually, if knowledge workers do not trust their peers and superiors and if they do not feel inclined to use personalization tools, they will likely not trust codified documents either. Since the main benefit of the personalization approach is to leverage individual knowledge, one can suspect that the level of creativity in low trust organizations might also be affected. Such types of organizations will certainly encounter problems in becoming a learning organization. Finally, companies with a high organizational trust culture are more successful in their KM initiatives than companies with a low organizational trust culture (Hypothesis #3). This last finding makes sense since if knowledge workers do not fully trust their coworkers they are not likely to share their knowledge one way or the other. If knowledge sharing and transfer do not occur, then KM is not likely to succeed.

These findings can be used as guide by organizations interested in implementing KM. Before launching a KM initiative, organizations should assess the level of organizational trust. Based on the obtained score they will have an indicator they could use to decide what type of KM tools and technologies to emphasize. If the level of organizational trust is low, the organization might not want to invest too much in personalization tools since knowledge workers might not use them. Those organizations should prefer to focus their effort on a codification approach and on finding ways to improve the level of trust in their culture. The role of management and leadership should be to craft a solution to such problems (Ribière & Sitar, 2003). If an organization obtains a high organizational trust score, it can be confident that in addition to using codification tools and technologies, personalization tools and technologies will bring value in facilitating tacit knowledge transfer and in enabling innovation.

The study also demonstrated that organizations with high levels of trust are more successful in their KM initiatives than organizations with a low level of trust. Once again, organizational trust can be used as a proactive indicator to gauge chances of success. Before launching a KM initiative, organizations might want to seriously consider this factor.

Finally, the most frequently used KM tools and technology for the 97 respondents of our study were examined. They are ordered by the average score obtained (cf. Table 9).

Table 9. KM tools and technologies most frequently used for knowledge exchanges

Ranking	Technology	KM Tools and Technologies	Average score (1-5)
1	C	Email and Listserv	4.83
2	P	Expertise locators – Corporate Yellow pages – Who's who	4.47
3	C	Corporate Intranet – Extranet – Internet	4.36
4	C	Database Management Systems	4.08
5	C	Search Engines - Intelligent Agents	3.95
6	C	Data Warehouses – Data Marts	3.84
7	C	Web-based training – e-learning	3.82
8	P	Communities of Practice (interests in the same topic, field)	3.78
9	P	Communities of Purpose (project, task oriented)	3.73
10	C	Help-desk applications	3.70
11	P	Groupware	3.68
12	P	Teleconferencing (shared applications, whiteboards)	3.62
13	C	DMS	3.59
14	C	Multimedia repositories	3.58
15	P	Best practices repository	3.51
16	P	Videoconferencing (using audio and/or video)	3.47
17	C	DSS and Expert Systems	3.33
18	C	Data mining- Knowledge Discovery	3.25
19	P	Mentoring - Tutoring	3.24
20	P	Story Telling	3.00
21	C	Knowledge Mapping	2.91
22	P	Desktop computer conferencing	2.91
23	P	Online Chat and Instant Messaging	2.89

***C:** Codification* ***P:** Personalization*

Note that e-mails are by far the most frequently used tool to transfer knowledge. This can be explained by the fact that this is a technology that has been around for a long time and also by the fact that a large majority of knowledge workers use them every day for different purposes. People are more likely to use tools that they are familiar with in order to exchange knowledge rather than learning or using new ones. If knowledge workers are very familiar with a technology, one should not force them to use different tools, but instead one should find ways to build on the familiar technology in order to turn it into a more powerful KM tool (e.g., indexing of e-mail content, expertise profile created based on e-mail content, etc.). This table can be interpreted by looking at the ranking of all the factors but also by looking independently at the most frequently used codification tools and personalization tools. Expertise locator tools (personalization) take the second general position and the first position of personalization tool used. An expertise locator (who is who and who knows what in your organization) is often one of the first KM tools implemented by organizations. They are easy to build, simple to use, and provide rapid benefits. Communities of practice and purpose take the eighth and ninth general position and are in the second and third personalization position. During the past years a strong emphasis on communities and their benefits has emerged in the KM literature. Their implementation is also quite simple, but one needs to be aware that knowledge worker participation relies heavily on organizational culture. Once again, assessing the level of organizational trust might be useful before engaging into such practices.

CONCLUSIONS

If an organization is going to be enduringly successful (Collins, 2001), considerable empirical research clearly indicates that such an organization needs, among other attributes, a single culture that aims all employees at disciplined thought and disciplined action. The bedrock of such a "success culture" is that it must characterize a high-trust organization.

The motive behind this research project is to begin empirically testing the proposition that KM success likewise relies upon the KMS being implemented in an organization with a trusting culture. Our research begins to shed some light upon that phenomenon. In particular, this study indicates that organizations with a higher level of trust are more successful in their use of KM than those organizations with a lower level of trust. (Whether or not those higher levels of trust organizations are also more successful in the marketplace is an intriguing research question left for the future.) Additionally, our work indicates an interesting interaction between the type of KMS used (codification versus personalization) and the level of trust in the organization. Specifically, in low trusting organizations, personalization KM tools tend to not be used — and why should they be used, since co-workers have little faith in one another's reliability?

KM is an IT practice that is implemented in the faith that doing so will lead to higher levels of organizational performance. Our empirical research study begins to establish some of the parameter settings in the domain of characteristics of organizational culture that are necessary for KM success. Clearly, much more research is needed. Data were drawn from one set of organizations, primarily from IT consulting, telecommunications, and the federal government. Our results might be a spurious outcome from peculiar characteristics of this set of organizations. Similar studies restricted to manufacturing firms, retailing firms, financial firms, or non-profits/not-for-profits might yield quite different results. Also, our firms in the sample had existing KM systems. Firms developing KMS might simultaneously take steps to alter organizational policy, procedures, and, yes, even culture, to ensure that those investments in KM would enjoy high payoffs — there are no data to report on that front. And, our organizations all had but a few years' experience with their KMS — the results might be quite different after firms have dozens of years' worth of experience with their KMS.

An organization, of course, is a legal fiction — at heart, an organization consists of a set of people who agree to work together for some vaguely common end. KMS are alleged to assist groups of people into behaving more effectively and more efficiently as they pursue those agreed-upon targets. This study helps shed some light on conditions that make that claim true. However, future KMS work might be directed at other issues relating to KMS success and usefulness, such as how do leadership styles in the organization impact KMS success? How do the presence or absence of particular group norms impact KMS success? When a KMS is successful, what radiates from that project success elsewhere in the organization? When a KMS is not successful, what impact does that have on other IT related projects? What are the causes of KMS failure, and are those failures rectifiable through greater funding, technological advances, culture change, better training, stronger leadership, or some other vehicle?

KM is a technology that is still not completely mature. KM technology holds great promise for organizational rationalization, but there are clearly many issues remaining surrounding KMS that need to be studied. Empirical research of all stripes — laboratory studies, field research, case studies, and so forth — will help scientists and managers put KMS to best use. This can only benefit all of us.

Chapter 3.11
Virtue-Nets

David Croasdell
University of Nevada, Reno, USA

Y. Ken Wang
Washington State University, USA

INTRODUCTION

David Skyrme (1999) has observed that knowledge workers exploit knowledge generated from business activities and turn it into business opportunities. Technical infrastructures enable knowledge workers and improve knowledge processes (Von Krogh, Ichijo, & Nonaka, 2000). Improving knowledge awareness requires creating a dynamic and generative environment for organizational workers (Senge, 1990). Organizations are faced with developing communication strategies that maintain centralized and fully accessible knowledge bases while at the same time trying to compete in a highly decentralized marketplace. Technological solutions for enabling and enhancing communication among knowledge workers are used for activities such as scheduling, negotiating, checking e-mail, revising documents, making reservations, connecting laptops remotely to the Net, problem solving, and decision making. There are numerous electronic devices for communicating between knowledge workers. These networked devices serve the purpose of connecting human-knowledge capital. For many companies, human-knowledge capital is a significant source of competitive advantage, and the dispersion of this capital without effective communication networks can greatly hinder the decision makers and the overall corporate decision-making process. One place to start examining the practices of knowledge workers is to study the networks in which they work.

This article explores knowledge networks and their advantage in grouping data based on qualitative attributes to support knowledge work. Such networks support and enable individual interactions with knowledge systems to enrich understanding. The next section provides a survey of communication technologies and theories to support the need to develop a network infrastructure to enable intelligent business practices. The next section on knowledge sharing proposes a virtue-net network architecture to support network connectivity using qualitative measures as a method for leveraging knowledge networks. The article concludes with a brief discussion and ideas for future research in this area. A glossary of terms for the virtue net is provided as an appendix to the article.

BACKGROUND

Knowledge management (KM) was popularized in the 1990s at a time when the dominant organizational metaphor was "organizations as computers" (Nonaka & Takeuchi, 1995). Knowledge management can be defined as "the process of identifying, capturing, and leveraging knowledge to help the company compete" (O'Dell & Grayson, 1998). Knowledge is key to organizations learning from and about customers, competitors, business partners, and staffs. Skyrme (1999) lists creating, identifying, gathering, organizing, sharing, learning, applying, exploiting, protecting, and evaluating in his representative sample of KM practices reported as key elements of knowledge-management programs.

One basic assumption of knowledge management contends that resource constraints such as time, capital, and understanding limit the ability to reasonably expect that all necessary and relevant knowledge can be captured and disseminated throughout an organization. Nonetheless, mechanisms to capture, encode, and store process knowledge in organizations provide (a) a starting point for future projects, and (b) a basis for avoiding similar mistakes in future projects. Knowing the how and why (i.e., process knowledge) behind the what (i.e., factual knowledge) leads to greater abilities to generate insight and better understanding.

Knowledge-Sharing Networks

Individuals seek information for both normative and informational reasons. Normative-influence theory suggests that human beings usually seek approval, a sense of belonging, and communality, which in some cases could account for the individual decision maker's drive for knowledge and for his or her communication with other knowledge stakeholders (Huang & Wei, 2000). Shared understanding is a relatively strong component that binds individuals in organizational and group settings. Informational-influence theory suggests the search for factual information and task truth can also act as a driver for decision makers seeking knowledge, including those seeking knowledge confirmation (Guenther & Braun, 2001). This sort of environment requires highly efficient, responsive, and self-adaptive information systems. Ideally, the systems are designed to be able to collect and classify information automatically and keep the system updated promptly. Interconnective knowledge-sharing structures are better ways for today's companies to construct their internal knowledge-sharing mechanism. Interconnective knowledge-sharing structures establish a two-way communication pathway across the intranet. The nodes in the system include individuals as well as aggregates of individuals, such as work groups, departments, and organizations within a company.

There are numerous challenges to overcome to effectively share knowledge among organizational members. Many organizations are faced with their own sets of unique challenges. Literature in knowledge management has shown that studies on knowledge reuse need to consider both the knowledge search and transfer processes simultaneously in order to get a full understanding of how knowledge is reused within an organization (Kraemer, 1998). Locating relevant knowledge sources for reuse during problem solving incorporates two separate processes: locating relevant experts and locating relevant expert knowledge (Housel & Skopec, 2001).

Ackerman and Mandel (1995) suggest that decision makers seek expert knowledge either in the form of knowledge artifacts or connections to known experts. Thus, decision makers require access to a set of knowledge stakeholders. In turn, those stakeholders are part of other networks allowing for further access to additional knowledge resources. Among knowledge-sharing methods, personal networks are the most predominate and convenient way for people to locate relevant expertise (e.g., Faniel & Majchrzak, 2003). Unfortunately, key knowledge stakeholders or decision makers are not always readily available for consultation. Knowledge networks provide a virtual network of key knowledge stakeholders and knowledge artifacts regardless of location or time (Skyrme, 1999). The network exists in n dimensions enabling potential benefits through connections along knowledge pathways. This full-time access to relevant knowledge across time and space provides an environment in which knowledge seekers can gain confidence that their decisions consider the most correct and most appropriate inputs (Festinger, 1957).

Knowledge-sharing networks support and enhance communications by integrating knowledge artifacts from different sources and domains across space and time. Research in knowledge networks endeavors to achieve new levels of knowledge integration, information flow, and interactivity among people, organizations, and communities, and to deepen our understanding of the ethical, legal, and social implications of knowledge networking (Skyrme, 1999). The successful implementation of knowledge networks creates rich communication environments for sharing knowledge and reducing decision uncertainty. Knowledge networks can be used to examine the life cycle of ideas in organizations and the role and characteristics of the people who introduce and diffuse new ideas. Tracking and supporting such life cycles will allow organizations to better understand how innovation and knowledge spreads. Effective knowledge networks increase innovation and improve organizational efficiency, and they can have even greater benefits if they are structured to receive management guidance.

SUPPORTING KNOWLEDGE-SHARING NETWORKS IN ORGANIZATIONS

Beyond individual-driven knowledge-sharing methods, businesses are able to organize in-house networks to deliver value by reusing existing company knowledge. The pace of business is speeding up as customer demands become more intense, and competitors move more quickly to meet their needs. Network nodes and network bandwidth need to be improved and expanded to enable the information-carrying capacity of the network. Combining elements of business intelligence and network performance enable real-time business for activity monitoring, process value measurement, and enterprise performance indicators (Huang & Wei, 2000).

A knowledge-content view has demonstrated the importance of relatedness in the skill base, but it does not shed much light on the integrative mechanisms that would allow one business unit to obtain knowledge from another (Kraemer, 1998). Scholars have demonstrated the importance of having lateral linkages among organization subunits for effective knowledge sharing to occur. Research has shown that a subunit's information-processing capacity is enhanced by lateral interunit integration mechanisms (Keen, 1986). Tiwana (2003) has indicated that individuals began to share information, expertise, best practices, and content in a peer-to-peer network created by affinity, while businesses created organization-spanning affinity that expanded such networks, thus facilitating the exchange and sharing of know-how and tacit expertise. Advanced technology, pervasive computing power, ubiquitous wireless communications, and distributed vast storage are triggering effective business knowledge-sharing platforms based on modern networking technologies.

Jarvenpaa and Ives (1994) indicate that the sharing of knowledge requires a "highly adaptive information architecture that can provide anytime-anyplace, multimedia interconnectivity across a constantly changing network of nodes…and must be independent of any organizational structure." The discussion presented in the previous sections suggests it is necessary to develop communication networks capable of supporting and sharing communication and collaboration among knowledge workers. Implementing these types of networks could provide an infrastructure for determining the most important business processes and value-creation measures. In addition, they could establish a working environment to assemble data warehouses, operational data stores, and enterprise applications to get a real-time view of required data elements. Such systems are able to continuously monitor for anomalies and exceptions, and proactively alert key personnel when performance falls outside expected ranges. Finally, these environments allow teams to collaborate and react to perform analysis and take action on detected anomalies and exceptions.

Connecting Knowledge

Associative relationships are defined as those that describe associations. They can be one-to-one or one-to-many relationships. Guided tours and indexes describe navigation between and among entities. Slices group one or more attributes of an object. Associative relationships are then built on the contents of varying attribute slices. This methodology provides for multiple attribute groupings to be associated with a single object. In this way, it may provide for a way to create dynamic links simply by selecting search criteria based on varying sets of object attributes (i.e., different slices). Traversing associative links differs depending upon what slices of information have been specified. The model allows knowledge workers to view knowledge objects in a specific context.

Berryman and Hockenhull (1996) describe associative relationships using interactive media works. Based on a nonhierarchical graph with multiple connections, data elements (i.e., association objects) contain one or more pointers that viewers can follow to reach other related data elements. The authors' vision differs from others by its shift in paradigms. They argue that hypermedia systems are based on a hunting paradigm in which users arbitrarily navigate space to find information. In contrast, an associative paradigm allows for the gathering of information in global contexts and subsequent arrangements to form local contexts. Association is described as a relational activity in which the viewer builds contexts through interaction with the work. Mixed-initiative searching is introduced as a way in which gathering choices are made jointly by the viewer and the system. The system intelligently builds associations from previous searches. As a viewer builds up his or her work space, successive searches tend to find objects that work, thus the system could support continuity and style. The artifacts of the searches may then be preserved and shared as searchable contexts. This model requires the design of the appropriate database structures to support the required collaborative relationships.

Virtue-Nets

Managers invest in telecommunication technology that "increases direct, flexible contact between people" and that "provide simple access to information, simply organized" (Galbraith, 1973). Knowledge networks can be implemented on network infrastructures that have the potential of giving firms instant communication infrastructure with the ability to engage in direct, flexible, anytime, anyplace information exchange and access. The immediate, systematic, and reciprocal nature of discussing new and novel approaches and confirming understanding and clarity has been shown by Kepner and Tregoe (1965) to increase decision efficiency and decision outcomes.

A virtue net describes a knowledge network where nodes are linked using a set of qualitative and dynamic attributes. There are four principle structures: data structures, nodes, communication links, and representation. A discussion of the various elements along with approaches to the four principles is provided in the following paragraphs. The glossary to this article reviews the elements of the virtue net.

Virtue nets provide an alternative mechanism for creating a distributed architecture for handling data attributes. Each data item would exist as an individual node. This data node would reside in a plane of existence of identical determined attributes. Each node is self-aware such that it can "realize" its own set of attributes or virtues. This self-awareness operation replaces the metadata traditionally used to describe the node. Data nodes automatically realize their place in the virtue net, enabling and enhancing search operations and connections to similar nodes. Planes of existence are created by specialized virtue links of dynamically connected data nodes with multiple connections, each of which is specific to an attribute or virtue. Similar to a virtual private network (VPN), these virtue links exist within the total bandwidth allotted to the virtue net. The virtue net is a set of weighted pathways between data nodes based on various attributes, effectively creating a bond between the data nodes with the same virtues: The stronger the similarity of a given virtue, the stronger the bond between the data nodes in a particular plane of existence. The key to the virtue net is the virtue manager, the decision-making heart of the system that makes decisions as if it were a real person.

Each data node has many bonds to many other data nodes. This nth dimensionality is the power of the virtue network, enabling data nodes to connect with numerous other data nodes based on the level of similarity they have with respect to each other. Since each dimension portrays a certain virtue, the need for querying the information is eliminated. By tapping into the virtue plane, every instance of that virtue is simultaneously available since, by definition, this plane would be the sum links of all data nodes with the given virtue. A table is used to associate files with virtues. That table establishes a virtue map used to track a particular virtue's plane of existence.

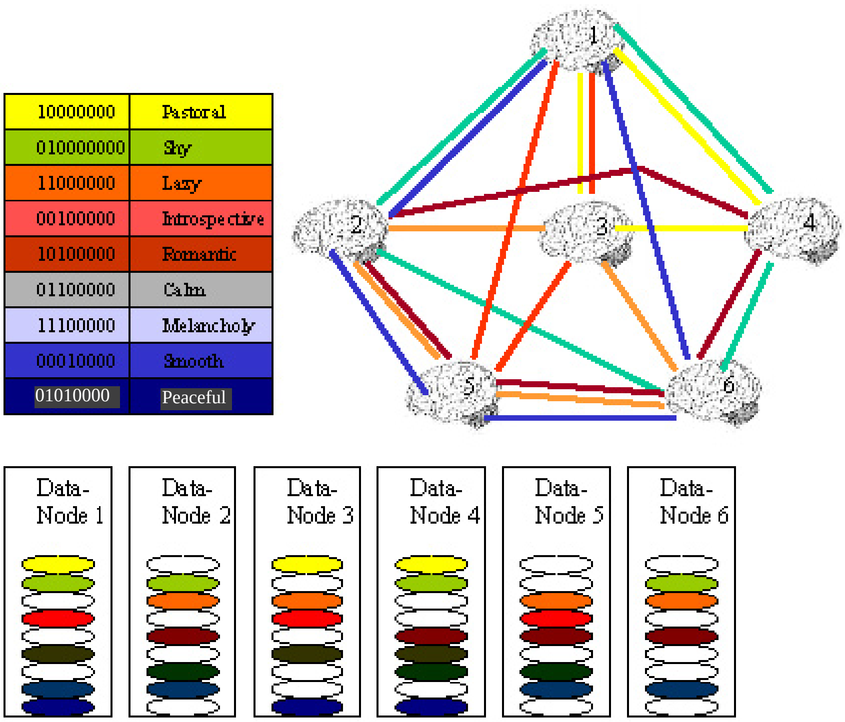
Virtue planes are dynamic since the virtues can be tapped from multiple dimensions. The dynamic nature of these virtue planes suggests network bandwidth must be able to accommodate multiple perspectives. As individuals gain experience with a device or with other entities using a similar device, their total utility with that given device will increase (Carlson & Zmud, 1999). Knowledge networks provide a taxonomy of bandwidth through which the users' manipulation of the bandwidth's attributes yield utility expansion. As people learn to utilize the knowledge bandwidth, or k-band, they learn how to expand their knowledge-accessing capabilities to use a given device by manipulating the k-band attributes.

Naturally, differences in opinion and interpretation will cause conflicts within the system. As such, differences in preference between different users must be managed in some way. One solution is derived from the availability of the fundamental hardware and the more flexible software nature of the system. A virtue map exists in the virtue chip, but it is the virtue manager that manages the links and plane-of-existence assignments. This manager also learns the preferences and habits of the user(s) in a similar way that voice-recognition software learns the nuances of a user's speech. Node managers control files housed within the cognitive node. Owners of each file impose their preferences on their data, so in a file server, the owner—not the server—dictates the preferences. The cognitive node is the computer in which the virtue manager is running. Cognitive nodes are responsible for the management of the files belonging to a user. Servers, SANs, or disk arrays are merely vessels for containing the data. This insures low impact on the server. Cognitive nodes perform the calculations and general housekeeping for the maintenance of the data nodes and their virtue links.

For the purposes of illustration, consider an example in which the virtue links could be color coded (Figure 1).

A table of virtues specifies color-coded virtues. The table is used as an analog for the different paths represented in binary notation readable by the machine. Each data node is connected to other data nodes that have common virtues, thereby creating a web of connections. Connections for a particular color between all the data nodes create a virtue plane for that attribute. For example, in the case of qualifying audio files, sad or happy music types could be recognized by different color codes. Melancholy, contemplative, heartwarming, and funny might be some of the attributes in this group. Once these pathways are in place, the applicable pathways can be connected to all the files they pertain to. So, when searching for performances that contain political humor, the logical intersection of the funny virtue plane and political virtue plane is viewed, which will result in every type of political comedy in all file types. This is of especial value to mobile handheld devices that tend to be more cumbersome to search databases with. Instead of entering all the query, the user can click on the virtue button on the desktop and select one of the primary emotion types (resulting in a specific virtue path) followed by a virtue link, which results in access to the virtue plane for the selected virtue. To widen or narrow

Figure 1. Color code depicts different virtues within each data-node. Each data-node that contains the color of a certain virtue, resides in the plane of existence of that virtue (virtue-plane). The data-nodes existing within the same virtue-plane are linked to each other through that virtue-plane by the virtue-link. The virtue links take advantage of multiple channels that form the knowledge bandwidth.



the search, the previous steps can be repeated using the logical and to narrow the search, or the logical or to widen the search. The virtue paths have the ability to narrow the number of virtues by grouping virtues that are related to one of the fundamental primary emotions.

Virtue-Net Exemplars

There are no examples of systems currently implemented that exhibit all of the characteristics of the virtue net described in this article. However, there are examples of systems that exhibit some of the characteristics. This section compares some of those tools and systems in the context of virtue nets.

ACT-R 5.0 is a cognitive modeling architecture developed at Carnegie Mellon University based on John Anderson's Adaptive Character of Thought: Revised (ACT-R; Anderson & Lebière, 1998). This software is evolving to simulate human thought, knowledge organization, and intelligent behavior.

Lotus Notes and Microsoft Exchange are groupware programs that help people work together collectively even when located remotely from each other. They provide sharing services such as e-mail, calendars, task management, database access, and electronic conferences so that each person is able to communicate and work with others. The groupware programs provide data and information sharing. The links between data or relationships between information must be preset by program or human instruction.

A new generation of search engines has the ability of acquiring, analyzing, and articulating knowledge without the involvement of human intelligence. KartOO.com represents the application of visualized knowledge representation in the practice of virtue nets. Alltheweb.com represents a trend in which language analysis and common-phrase identification technologies are being applied into virtue nets.

CONCLUSION

Virtue nets represent a new way of thinking about managing and utilizing knowledge within organizations. This article has outlined some of the characteristics of such systems. The next step is to design and develop a virtue net that combines the best features of systems described in the previous section. Part of the effort will be to analyze and test prototype systems to determine the effective mechanisms for performing the relevant tasks throughout the knowledge-value life cycle.

Computer and telecommunication networks offer powerful, expressive, and efficient information-access, search, and data-exchange capabilities. Intranet technology dramatically changed the way people are connected within an organization. New technologies built a new way for knowledge-based networks to be perceived, operated, and utilized by their users. However, representing and acquiring knowledge is still a difficult and time-consuming task having to be done by humans. Problem-formulating methods and knowledge-organization approaches are two important issues in further research.

This article has provided a conceptual view of collaborative communication networks to support knowledge processes in organizations. Inherent in such networks are dynamic capabilities for recognizing the value of knowledge elements extant in the network. Virtue nets enhance and support dynamic interactions in organizations by providing necessary knowledge artifacts from different sources and domains across time and space. It has been told that advances in technology will change the way organizations are organized. Knowledge networks and the dynamic support of virtue nets will go a long way toward bringing that vision to fruition.

Chapter 3.12
Coopetition

Claudia Loebbecke
Department of Media Management, University of Cologne, Germany

Albert Angehrn
Centre for Advanced Learning Technologies (CALT), INSEAD, France

INTRODUCTION

Behind the emerging digital façade, companies have started to operate in a distributed fashion. The intricate connectivity among these firms implies the exchange of valuable resources like knowledge and information. Such cooperation or collaboration is what enables organizations and individuals to make decisions collectively, learn from one another, communicate effectively, and thus create knowledge (Brown & Duguid, 1991; Huber, 1991; McDonald, 1995; von Krogh & Roos, 1995).

However, cooperating organizations often simultaneously compete (coopetition). While reciprocal knowledge sharing may enhance the total and individual added value, inter-firm knowledge sharing may also affect the uniqueness and thus competitive contribution of a firm's knowledge repository. Opportunistic behavior of counterparts may erode anticipated benefits of cooperation and result in unevenly distributed value.

The inherent balancing act between cooperation and competition requires designing and implementing specific management processes to enable economic value maximization for participating individuals and firms. The value-driven balancing act is becoming increasingly relevant in business practice.

This article introduces the scientific literature on Knowledge Management Under Coopetition and then describes the concept of Coopetitive Learning and Knowledge Exchange Networks (CoLKENs), their components, and their generic structure. It reviews CoLKEN fundamentals and components, and suggests a CoLKEN taxonomy. Key research questions are followed by generalized key insights from studying CoLKENs as the setting for Knowledge Management Under Coopetition. The article then examines the levers for managing CoLKENs, and closes with future trends and brief conclusions.

BACKGROUND

The following literature review provides broad definitions and discussions relevant to knowledge management under coopetition.

Fundamental Components of Knowledge Management Under Coopetition

Knowledge is a complex concept and difficult to define, and when seen from a management perspective, it exhibits unique properties that are distinctly different from the ones of traditional corporate resources, such as land, labor, and capital. Intellectual resources are not naturally scarce (Suchmann, 1989); knowledge may increase in value the more it is used, with investment in knowledge and knowledge-creating capabilities characterized by increasing returns (Teece, 1998). These properties tend to make knowledge less amenable to management (Polanyi, 1966; Hedlund, 1994; Nonaka, 1994; Boisot, 1995).

Who are appropriate knowledge agents for Knowledge Management Under Coopetition? Who is intellectually capable, the organization or its individual employees? Does knowledge reside at individual and organizational levels? Among others, Drucker (1993) and Grant (1996) stress the predominant importance of individuals. Others (Nonaka & Takeuchi, 1995; Spender, 1996; Boisot, 1998; Lane & Lubatkin, 1998; Matusik & Hill, 1998; Crossan, Lane, & White, 1999; Inkpen, 2000) consider organizational cognition or organizations as cognitive entities a suitable unit of analysis. In the organization science literature, organizational learning is a central tenet (Huber, 1991; Simon, 1991; Argyris & Schön, 1996) and is believed to lead to competitive advantage (Senge, 1990; Moingeon & Edmondson, 1996). It is closely intertwined with inter-organizational learning (e.g., Larsson, Bengtsson, Henriksson, & Sparks, 1998), as the learning entities in both concepts positively affect each other (Doz & Hamel, 1998; Child, 2001; Holmquist, 2003).

Knowledge networks are commonly defined as formally set up mechanisms, structures, and behavioral patterns that connect knowledge agents who were not previously connected because of functional, hierarchical, or legal boundaries between organizations. Inter-organizational knowledge networks (e.g., Mowery, Oxley, & Silverman, 1996; Klein, 1996) provide the setting for Knowledge Management Under Coopetition.

Theoretical Underpinnings of Knowledge Management Under Coopetition

The "resource-based view of the firm," along with its conceptual predecessor, the "industrial organization view," and its extension, the "knowledge-based view of the firm," have shed light on the question of why firms cooperate to learn from one another, share capabilities and knowledge, while—at the same time—manage knowledge as a valuable resource in the competitive environment.

Until the 1980s, competitive thinking—reflected in the "industrial organization view"—has generally been seen focusing on companies' environments (e.g., Porter, 1980; Spender, 1996; Teece, Pisano, & Shuen, 1997). As such, it stands for an outward focus. Since the mid-1980s, the so-called "resource-based approach" (Wernerfelt, 1984; Rumelt, 1987; Prahalad & Hamel, 1990) has partially built on Penrose's conception of the firm as a "collection of productive resources, both human and material" (Penrose, 1959, p. 31). The resource-based approach builds on two basic assumptions: (a) the firm's ultimate objective is to achieve sustained, above normal returns; and (b) a set of resources and their combination transformed into competencies and capabilities are a precondition for sustained superior returns (Rugman & Verbeke, 2002). These resources are to be firm-specific (i.e., imperfectly mobile), valuable to customers, non-substitutable, difficult to imitate, and differently available to firms. Companies are seen as heterogeneous with respect to their resource and capability endowments (Teece et al., 1997). Assets such as knowledge are not readily tradable; they cannot equilibrate through factor input markets. Hence, critical resources can typically not be acquired via the market and consequently need to be developed internally. Competitive advantage is associated primarily with heterogeneous resource endowments of firms (Wernerfelt, 1984; Prahalad & Hamel, 1990; Hamel, 1991; Barney, 1991).

Recent extensions of the knowledge-based perspective (Grant, 1996) are centered around its application to a "network of firms," rather than an individual firm (Hamel, 1991; Prahalad & Ramaswamy, 2000; Dyer & Nobeoka, 2000; Gulati, Nohria, & Zaheer, 2000; Doz, Santos, & Williamson, 2001; Grant & Baden-Fuller, 2004). As developed in the "relational view of the firm," firms ought to look at inter-organizational networks as a source of sustainable competitive advantage (Liebeskind, Olivier, Zucker, & Brewer, 1996; Powell, Kogut, & Smith-Doerr, 1996; Powell, 1998; Dyer & Singh, 1998).

Different scholars hold different views on what criteria need to be applied to differentiate critical from non-critical resources. Barney (1991) proposes "value creation for the company," "rarity compared to competition," "imitability," and "substitutability." Prahalad and Hamel (1990) distinguish "core competencies" from "non-core competencies" by outlining core competencies as being suitable for application in many different markets, creating a significant contribution to customer value, and being difficult for competitors to imitate.

To specify resources that accommodate these criteria is equally controversial (Priem & Butler, 2001a, 2001b; Rugman & Verbeke, 2002). The literature offers a plethora of phrases such as "firm resources" (Barney, 1991, 2001), "invisible assets" (Itami, 1987), or "dynamic capabilities" (Teece et al., 1997).

Roos and Roos (1996) or Drucker (1993) proclaim that knowledge, whether referred to as invisible assets (Itami, 1987), absorptive capacity (Cohen & Levinthal, 1990), core competencies (Prahalad &, Hamel, 1990), core capabilities (Kogut &, Zander, 1996), or organizational knowledge (Nonaka &, Takeuchi, 1995), can be seen as the only—or at least an important resource—that fulfils the foregoing criteria. Teece (1998) even argues that the essence of a firm is its ability to create, transfer, assemble, integrate, and exploit knowledge assets.

These lines of thought match the traditional analysis that both Ricardian and monopoly rent theorists derive in large part from intangible assets, with organizational learning and knowledge being among the most crucial ones (Penrose, 1959; Liebeskind, 1996; McGaughey, 2002). By stressing the outstanding importance of knowledge, they have given birth to the knowledge-based perspective as a special form of the resource-based one.

COOPETITIVE LEARNING AND KNOWLEDGE EXCHANGE NETWORKS (COLKENS) AS THE SETTING FOR KNOWLEDGE MANAGEMENT UNDER COOPETITION

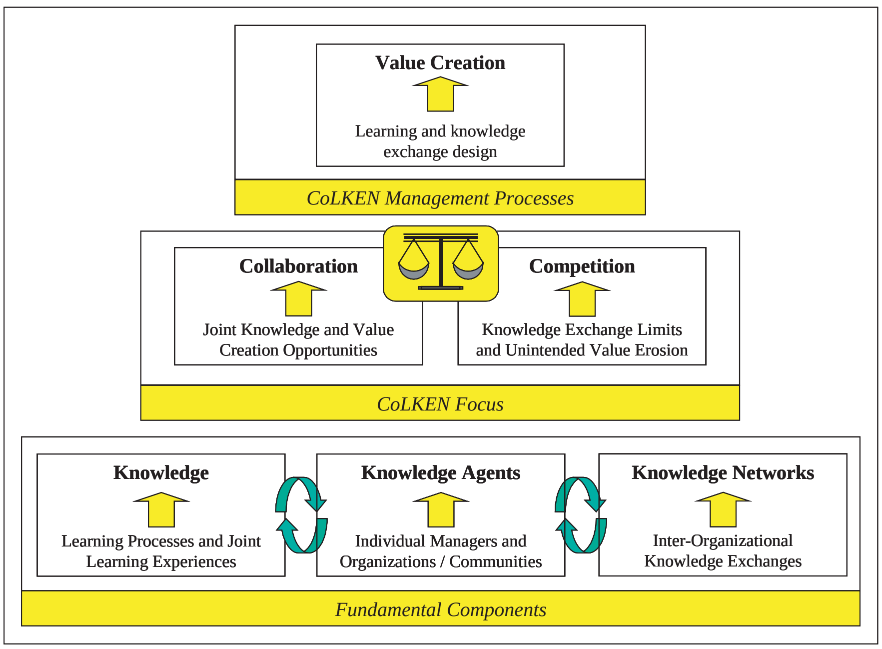
As outlined above, knowledge management has been increasingly considered as a key managerial function necessary for achieving competitive advantage (Tsang, 2002). Economic thinking leaves no doubt that scarcity is a precondition for property and thus commercial value of any resource. Consequently, it puts a question mark on generously sharing knowledge in an economic context. Thus, inter-organizational knowledge-sharing processes revolve around a formidable balancing act between borrowing knowledge assets from partners, while protecting one's own assets (Loebbecke, van Fenema, & Powell, 1999). The challenge is to share enough skills to learn and create advantage vis-à-vis companies outside the network, while preventing an unwanted transfer of core competencies to a partner (Hamel, Doz, & Prahalad, 1989). This challenge is exacerbated when some members in the network are competitors. In such constellations, the danger of becoming "hollowed out" by "predatory" partners (Hamel et al., 1989; Kogut & Zander, 1996) seems particularly evident, suggesting that appropriate steps be taken to ensure mutually beneficial sharing. Nevertheless, many of the skills that migrate between companies are not covered in the formal terms of a knowledge exchange (Loebbecke & van Fenema, 2000). Often, what gets traded—that is, what is learned—is determined by day-to-day interactions between engineers, marketers, and product developers (Hamel et al., 1989).

CoLKEN Fundamental Statements and Components

Following the above insights, a CoLKEN Construct (see Figure 1) is built based on seven fundamental statements (see also Loebbecke & Angehrn, 2003a):

1. Knowledge assets have their foundation not only in data and in information, but also in collaborative learning processes.
2. Both the individual employee as well as the organization should be seen as knowledge agents capable of owning and processing knowledge.
3. Knowledge agents exchange knowledge in knowledge networks within and—in the light of ubiquitous information, communication, and media technologies—increasingly between organizations.

Figure 1. CoLKEN construct



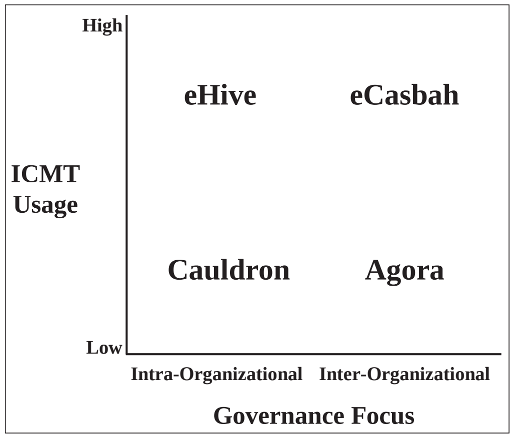
4. The increasing appearance of inter-organizational networks triggers a focus on learning and knowledge exchange processes between organizations during coopetition.
5. Cooperation forms the basis for any knowledge exchange process between organizations as it supports the learning processes through which knowledge is created and acquired, as well as shared and disseminated.
6. In the light of competition, knowledge serves as a critical resource or asset to achieve competitive advantage and above normal rents.
7. Management processes and actively managed strategic interventions (stimuli) in knowledge exchanges allow organizations to create value by significantly impacting the composition, the exploitation and exploitability, as well as the business results of learning, knowledge, and intellectual assets at large.

The three fundamental components, Knowledge, Knowledge Agents, and Knowledge Networks (Statements 1, 2, and 3) lay the foundations for investigating inter-organizational learning and knowledge exchange networks in the context of coopetition (see also 'Background'). The CoLKEN focus is represented as a central platform on which cooperation and competition are performed (Statements 4, 5, and 6). In order to create and extract the maximum economic value, the challenge is to balance both aspects by designing and implementing management processes for active strategic interventions in the CoLKEN (Statement 7).

CoLKEN Taxonomy

Possible dimensions for differentiating CoLKENs are information, communication, and media technology (ICMT) usage, governance focus, size, growth pattern, composition, and degree of internal competition. Selecting the first two dimensions, Figure 2 shows a CoLKEN taxonomy (adapted from Loebbecke & Angehrn, 2003b).

Figure 2. CoLKEN taxonomy



A cauldron, the large kettle or boiler used by witches mixing and cooking ingredients without a clear pattern, stands for intra-organizational and low-technology CoLKENs. An agora, the ancient Greek marketplace, represents inter-organizational, low-tech solutions. An e-hive takes the concept of a hive, a container for housing honeybees, to the virtual level. It describes a busy intra-organizational environment without clear pre-arranged patterns of action or movements. An e-casbah, finally, transfers the concept of the older, native section of a north-African city with its busy marketplaces to the e-world, where it represents inter-organizational settings, with learning and knowledge exchanges taking place solely via ICMT infrastructures.

While the basic assumption of coopetition between organizational units requires some degree of 'inter'-organizational networking, the horizontal axis takes into account the more or less overriding legal structures that may emphasize the 'intra'-setting for competing sub-units.

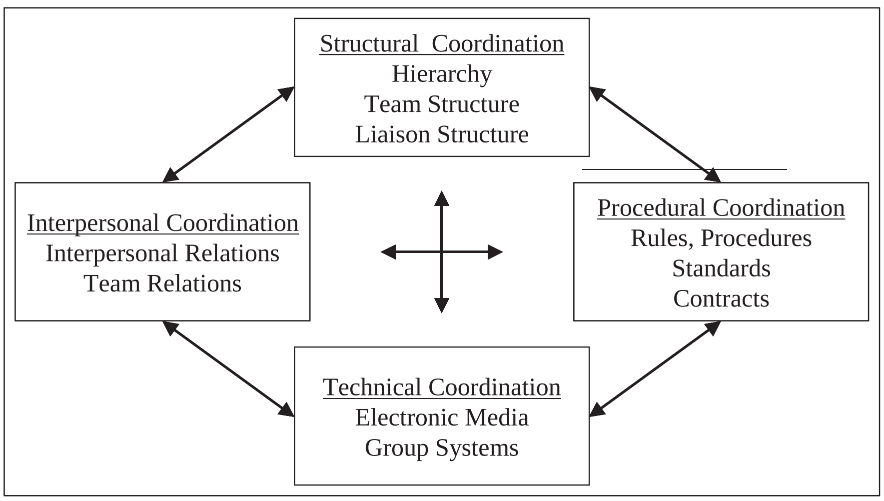
Research Drivers and Key Insights

Research concerning organizational and social aspects of CoLKENs as the setting for Knowledge Management Under Coopetition investigates initiatives ranging from local industry clusters to new forms for organizations with globally distributed knowledge workers operating within Open Source communities. Dominating research drivers are: (1) the motivation for individuals and for companies to participate in the networks (e.g., Argote, McEvily, & Reagans, 2003); (2) issues of leadership, coordination and control strategies, and decision making; (3) the management of collaboration, including knowledge creation, sharing, and management, as well as learning and innovation (e.g., Menon & Pfeffer, 2003); and finally, (4) the management of the competition dimension. These issues ought to be analyzed along the trajectories of who (people), what (topics), and how (processes). Further, various contingencies for inter-organizational knowledge governance based on dominant knowledge types, the assessment of the ease of knowledge sharing and retention, and the direction of knowledge flows (unilateral or bi-directional/reciprocal) play an important role for investigating Knowledge Management Under Coopetition.

Main research insights derived from the above lines of analyses can be summarized as follows:

- Individual managers are mostly motivated by opportunities to engage in new forms of collaborative learning and management development. Organizations aim to achieve their objectives through acquisition of knowledge critical to their processes or strategy.
- The dominant form of collaboration and learning is traditional knowledge transfer, that is, contexts in which members do not need to engage too personally or do not need to contribute their knowledge at all. More experiential forms are rare; they emerge primarily in non-critical domains and after having succeeded in helping members to develop more stable relationships and trust

Figure 3. Coordination and control mechanisms for knowledge management under coopetition



(for the impact of different kinds of interventions, see also Cabrera, 2002).

- The competition dimension limits knowledge exchange to pre-defined domains and formats which are perceived by members as non-competitive in terms of not releasing much critical knowledge to potential competitors.
- By better aligning the motivation of their members and 'selecting' them accordingly, CoLKENs could reduce the negative influence of the competition dimension. On the other hand, ambitious growth strategies lead some CoLKENs to operate less selectively when it comes to assessing and aligning the motivation of their members.
- Appropriate coordination and control mechanisms are crucial for success; structural and interpersonal mechanisms outweigh procedural or technical mechanisms (see Figure 3).

Additionally, for instance, Loebbecke and Angehrn (2003a, 2004), Teigland and Wasko (2003), and Loebbecke and Angehrn (2004) offer contingency-dependent results for various settings of Knowledge Management Under Coopetition.

Levers for Managing CoLKENs

With a significant number of inter-organizational networks failing in some sense (Inkpen & Beamish, 1997; Lam, 1997), there is an established body of literature investigating factors causing such failures together with steps for improvement (Cohen & Levinthal, 1990; Hamel, 1991; Mowery et al., 1996; Powell et al., 1996; Inkpen & Beamish, 1997; Lam, 1997; Dyer & Singh, 1998; Kumar & Nti, 1998; Larsson et al., 1998; Powell, 1998). Possible management levers for dealing with the paradox of simultaneous cooperation and competition have emerged from this literature. The main factors for discussion are: (1) factors influencing the extent of learning and knowledge sharing, (2) factors influencing the stability of the relationship, and (3) factors influencing the ability of CoLKEN partners to collaborate.

As factors influencing the extent of learning and knowledge sharing, Kogut (1988) and Mowery et al. (1996) name alliance contracts and governance structures. For instance, equity joint ventures lead to a higher degree of knowledge sharing than contract-based alliances. Cohen and Levinthal (1990), Dyer and Singh (1998), Kumar and Nti (1998), and Larsson et al. (1998) point to partners' internal capabilities. According to Hamel (1991), Kumar, and Nti (1998), or Larsson et al. (1998), the amount of learning taking place in the relationship depends on each partner's collaborative strategy.

As the main factor influencing the stability of the relationship, Pfeffer and Salancik (1978) relate to bargaining power. If collaboration provides access to other partners' resources (e.g., knowledge and skills), dependencies caused by resource specificity may change or disappear, and the alliance may be terminated (Inkpen & Beamish, 1997). Hence partners who want to ensure alliance stability should prevent outsiders from learning "all there is to learn," create new knowledge, and consider the track record of their partners.

Finally, factors influencing the ability of network partners to collaborate are discussed. For Dyer and Singh (1998), appropriate management processes and governance structures are crucial for turning membership into a source of competitive advantage. They even suggest protection against: (a) opportunistic behavior in the network, (b) high volume of information exchange, (c) knowledge-sharing routines, and also suggest the development of self-enforcing safeguards (trust and incentives) for sharing. The ability to have influence on the network structure and to occupy an information-rich position shall provide network members with promising entrepreneurial opportunities (Powell et al., 1996).

FUTURE TRENDS

Further research is needed to compare traditional settings for Knowledge Management Under Coopetition, where there is less ICMT usage, with more virtual ones. Additional insights are to be sought as to the actual and potential impact of innovative technologies with regard to managing CoLKENs. One should investigate and assess: (a) the real potential of ICMT for the majority of today's CoLKENs, (b) the ICMT-related challenges the organizations in question are likely to face, as well as (c) the new mindsets and competencies members and managers of such networks will require for taking full advantage of distributed approaches to learning and knowledge management.

CONCLUSION

The fact that motivations and incentives for participation vary, makes Knowledge Management Under Coopetition particularly complex. Here CoLKENs as settings for Knowledge Management Under Coopetition represent opportunities for individual managers to engage in new forms of Knowledge Management Under Coopetition: They provide organizations with opportunities to better achieve their objectives through acquisition of knowledge critical to their processes and strategy, or through collaborative knowledge exchanges and initiatives.

Nevertheless, competitive logic can prevent individuals as well as organizations from taking advantage of constructive Knowledge Management Under Coopetition. The competition dimension influences the design of value-creation processes such as collaborative learning, knowledge exchange, and derived initiatives.

To conclude, innovative forms and settings of Knowledge Management Under Coopetition enable contributors to benefit from their participation in such inter-organizational knowledge management initiatives, whereby members may decisively improve learning efficiency and cooperative acting while taking into account competitive positions. To exploit the opportunities derived from Knowledge Management Under Coopetition to the fullest, appropriate coordination and control mechanisms, as well as a deliberate strategic approach towards Knowledge Management Under Coopetition are indispensable.

Chapter 3.13
Knowledge Management Within Collaboration Processes:
A Perspective Modeling and Analyzing Methodology

Jian Cai
Peking University, P.R. China

ABSTRACT

Collaborative projects are relatively complex and hence are difficult to handle. Managing distributed knowledge among stakeholders in a systematic way is crucial to improving the collaboration productivity. This paper provides a generic modeling approach that explicitly represents the perspectives of stakeholders and their evolution traversing a collaborative process. This approach provides a mechanism to analytically identify the interdependencies among stakeholders and to detect conflicts and reveal their intricate causes and effects. Collaboration is thus improved through efficient knowledge management. This paper also introduces a Web-based information system that uses the perspective model and the social network analysis methodology to support knowledge management within collaboration.

INTRODUCTION

The ability to effectively manage the distributed knowledge and business processes is becoming an essential core competence of today's organizations. Various knowledge management theories and approaches have been proposed and adopted (Earl, 2001). These include ways to align knowledge process with strategies (Spender, 1996), to leverage organizational learning abilities (Nonaka & Takeuchi, 1995), and to build IT infrastructures to support knowledge activities (Zack, 1999; Lu, 2000). Knowledge management systems (KMS) can be viewed as the implementation of the knowledge management (KM) strategy. KMS improve the knowledge processes through IT infrastructures and information processing methodologies. Although the importance of knowledge management has been well recognized, organizations are still facing the problems of how to successfully implement knowledge management. In order to effectively utilize these theories and technologies to support teamwork, it is necessary to gain more fundamental understandings of the characteristics of knowledge management within collaboration processes.

Previous knowledge management approaches can be generally classified into two categories (Hanson et al., 1999). The strategies supporting knowledge replication provide high-quality, fast, and reliable information systems implementation by reusing codified knowledge. The strategies supporting knowledge customization provide creative, analytically rigorous advice on high-level strategic problems by channeling individual expertise. The codification approaches view information technology (IT) as the central infrastructure of knowledge-based organizations. KMS are thus treated as system integration solutions or applications that retain employees' know-how. The major concern of these approaches is how to help organizations monitor the trends of rapidly changing technologies and inventions in order to recognize new applications which may provide competitive advantage (Kwan & Balasubramanian, 2003). However, IT is just one of the elements of KMS. As knowledge management involves various social and technical enablers, the scope, nature, and purpose of KMS vary during the collaboration processes. Researches from the knowledge customization perspective focus on understanding knowledge and its relationships with organizations (Nonaka & Takeuchi, 1995; Becerra-Fernanaez & Sabherwal, 2001). A typology of knowledge creation and conversion of tacit and explicit knowledge was proposed (Nonaka et al., 1998). The conversion involves transcending the self of individuals, teams or organizations and reveals the importance of organizational architecture and organizational dynamics to capitalize on knowledge. Recent researches on knowledge management have been focusing on developing models that interconnect knowledge management factors, such as collaboration, learning, organizational structure, process, and IT support (Lee & Choi, 2003). These research works have been mainly addressing understanding the nature of knowledge and knowledge management. Both approaches provide workable models and methods for implementing knowledge management.

In fact, knowledge replication is interlaced with knowledge customization within a collaborative process. In collaborative projects, it is important to systematically integrate these two groups of KM approaches to build methodologies and systems to facilitate the team work. First, KM methodologies should be coupled with process management in collaborative projects. An organization and its members can be involved in multiple knowledge management process chains. The tangible tasks are accompanied by the implicit knowledge integration activities. As such, knowledge management is not a monolithic but a dynamic and continuous organizational phenomenon (Alavi & Leidner, 2001). Second, KM and KMS have to take account of various social factors within collaboration processes. Collaborative projects involve various stakeholders (i.e., all of the human participants and organizations who influence the collaboration process and the results) from different disciplines to work cooperatively over the distance and time boundaries. When many heterogeneous groups work together on large projects over a long period of time, their knowledge of the system, the product, and other people will keep on evolving (Dym & Levitt,1991; O'Leary,1998). The professional expertise in particular is framed by a person's conceptualization of multiple, ongoing activities, which are essentially identities, comprising intentions, norms, and choreographies (Carley & Prietula, 1994; Erickson & Kellogg, 2000; Sowa & Zachman, 1992; Siau, 1999). Although the collaboration process might appear relatively technical, it is essentially a social construction process when different persons perform their tasks within various adaptive situations (Berger & Luckman, 1966; Clancey, 1997; Clancey, 1993).

The situations will eventually impact the evolution of participants' roles and form a shared understanding (Arias et al., 2000). Even within well-defined technical roles, every stakeholder makes the role "his own" by adapting or executing the role based on his conceptions and circumstances. It is the social interaction that determines the variation or adaptability of these roles in a particular application context. As their roles evolve, stakeholders' learning customs and attitudes will vary, which will directly or indirectly affect their internal knowledge and the knowledge creation and conversion processes. Therefore, to manage the distributed knowledge within the complicated collaborative process, it is necessary to have well-developed methodologies for describing and analyzing the social interactions in collaborative contexts of the emerging practice.

This paper presents a methodology for supporting knowledge management within collaboration by modeling and analyzing the stakeholders' perspectives. The methods to depict and control the evolution of distributed knowledge are introduced. This paper also describes a prototype knowledge management system developed for a US government research institute. It implements the methodology and uses the advanced network computing techniques to facilitate stakeholders' interaction within their work practice.

MODELING PERSPECTIVES TO SUPPORT KNOWLEDGE MANAGEMENT

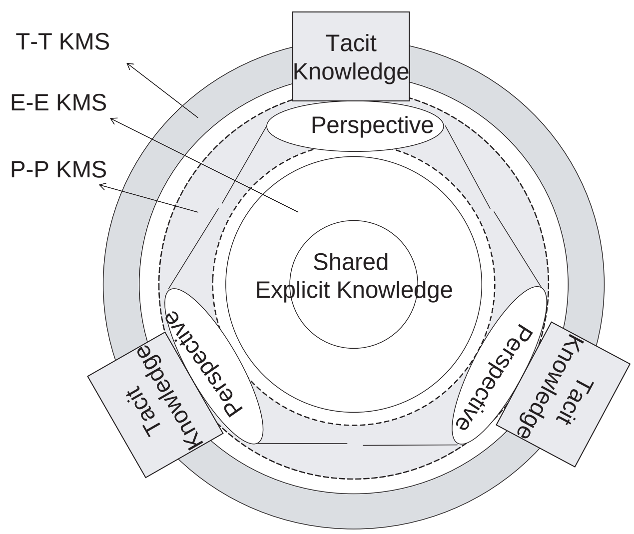
The previous approaches and methodologies for supporting KM in collaborative work have been mainly concentrating on either modeling the explicit knowledge or supporting communication of implicit knowledge. The knowledge management systems built upon these approaches included three types of functions: (1) the coding and sharing of best practices, (2) the creation of corporate knowledge directories, and (3) the creation of knowledge networks (Alavi & Leidner, 2001). Recent researches have proposed systems to support information and knowledge seeking and use within the decision or problem solving process (Rouse, 2002, Shaw et al., 2003, Kwan & Balasubramanian, 2003). Modeling approaches are widely used for developing such methodologies and systems. For instance, activity modeling approach was used to develop a knowledge management system to provide a computer-based guidance and interactive support for office workers (Reimer et al., 2000). Knowledge-engineering processes were modeled to capture, store, and deploy company knowledge (Preece et. al., 2001). However, most of the existing approaches still view stakeholders as homogeneous and do not emphasize their intricate needs at various stages of the processes. Nevertheless, lack of understanding of stakeholders' needs to know—and provision of support systems accordingly—is precisely the missing link in the success of many information and knowledge management systems (Rouse, 2002). This requires understanding multiple aspects of stakeholders' needs in seeking and using of information and knowledge within the collaboration.

Recent published studies have shown that besides technologies, the social aspects are essential to the success of collaboration (Briggs et al., 2003; Erickson & Kellogg, 2000; Easley et al., 2003; Hardjono & van Marrewijk, 2001). One of the key social factors is the cognitive interaction process. As stakeholders' preferences, environments, and knowledge are dynamically changing during their interactions, collaborative activity over the Internet is more than an online data accessing and information sharing process. Accordingly, frequently occurred conflicts influence the project schedule and team performance. Team coordination has to be achieved through not only sharing of data and information, but also the realization of the decision contexts of each other (Kannapan & Taylor, 1994; Chung et al., 1999). The decision context consists of at least two parts:

the circumstances of the decision makers and the stages of the process. When people exchange information, they should understand under what circumstances this information is generated and in which situation it can be potentially used. Otherwise, it is difficult for them to interpret the purposes and implications of each other during the activity coordination. Therefore, to represent and organize the situated knowledge (i.e. the context) is essential to support the coordination among different groups. It is also of immense importance to understand how to design knowledge management systems so that they mesh with human behavior at the individual and collective levels. By allowing users to "see" one another and to make inferences about the activities of others, online collaboration platforms can become environments in which new social forms can be invented, adopted, adapted, and propagated—eventually supporting the same sort of social innovation and diversity that can be observed in physically based cultures (Erickson & Kellogg, 2000).

To address these issues, our research uses a socio-technical framework to model the interactions within collaborations (Lu & Cai 2001). The framework addresses that one cannot utilize information to map from "what-to-do" to "how-to-do" in the collaboration process without knowing the perspective of the "who" that generates the information. A collaborative project is modeled as a co-construction process among a group of stakeholders. The key feature is to explicit model the "who" (i.e. the stakeholders' perspectives) within the process (i.e. the "what", "how", and "when"). During collaboration, each individual has a perspective that evolves over time and acts like a "lens" through which she understands and collects information external to her. Each individual builds over her lifetime an evolving base of information that is "internal" to her. The information that each individual produces, or exchanges through any medium (e.g., computers, speech, and writing), is the external manifestation of her internal information, appropriately filtered through her "perspective lens". Based on the socio-technical framework, knowledge management systems require the explicit modeling of stakeholders' perspectives within their

Figure 1. The perspective modeling approach of knowledge management in collaboration



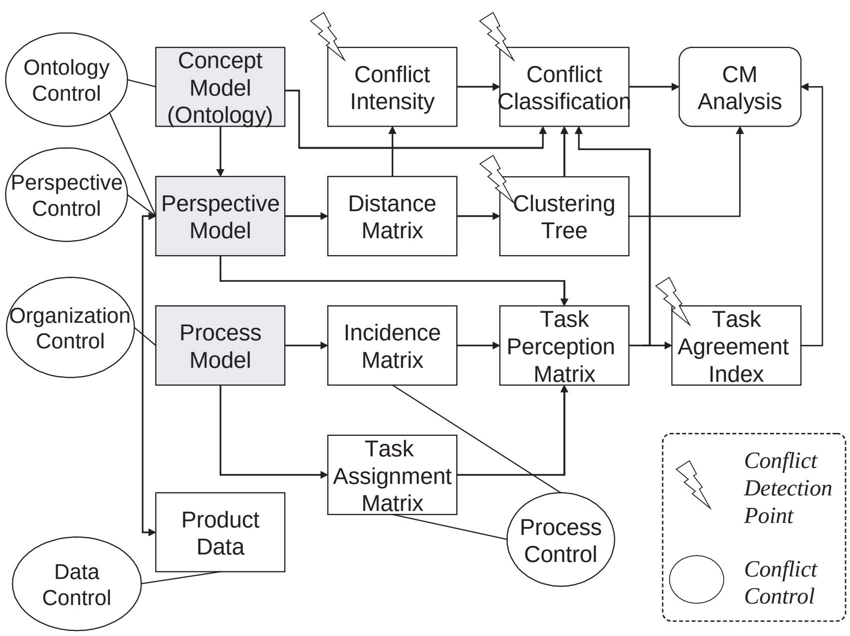
social interactions. The perspective modeling and analyzing methodology focuses on representing and handling the interactions among the heterogeneous stakeholders. It provides associations with other knowledge management and decision support models. It also provides ways to build and integrate various processes with the realization of sharing knowledge and managing conflict. Different from traditional KMS which either focus on the codification of explicit knowledge (E-E KMS) or communication of tacit knowledge (T-T KMS), the perspective modeling approach will realize a new way of building KMS (P-P KMS) through controlling the interfaces between the explicit and tacit knowledge (i.e. stakeholders' perspectives) (Figure 1).

PERSPECTIVE MODELING AND SOCIO-TECHNICAL ANALYSIS

Methodology Overview

The central function of the research framework is the "socio-technical analysis" to model and analyze the perspectives of stakeholders at each step of the collaboration process. The socio-technical analysis methodology takes three input parameters (i.e. the concept model, and the perspective model, the process model) (Figure 2). The concept model is a structure which organizes the ontology models representing the shared or private notions of the stakeholders. The process model is a feasible computational model which represents the interactions of individual tasks. It specifies the sequences and dependencies of de-

Figure 2. The socio-technical analysis methodology for knowledge management



cisions and actions to be jointly performed. The perspective model provides a generic means to formally capture, represent, and analyze stakeholders' perspectives and their interactions with each other. The concept model and perspective models represent the shared knowledge and social characteristics of various stakeholders during the collaboration process. They are derived from the surveys of stakeholders' attitudes towards the ontology models at a point of time.

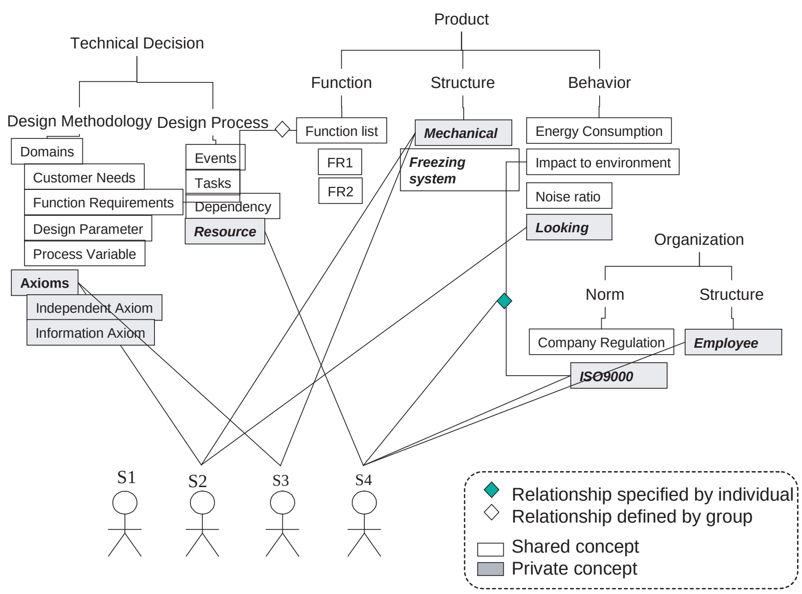
The dependencies among these models are represented as matrices for mathematical analysis. Conflict analysis applies systematic strategies to analyze inconsistencies among these matrices. At a certain stage within the process, conflicts can be detected by tracking and comparing the "perspective states" of different stakeholders associated with a certain task. This analysis will derive three major outputs (i.e., process feasibility, conflict possibility, and perspective network). Then, based on these outputs, the systems can apply various control strategies so that the quality of the collaboration is enhanced. Control mechanisms adaptively handle the interplay among the three factors by systematically reconciling various perspectives, improving the processes, and controlling the product data and organizational structure.

Perspective Modeling

The perspective modeling mainly consists of building the concept model and the perspective model. While the process model depicts the tangible activities of the project, the concept model and perspective model track the knowledge evolution and changes of social behaviors.

The first step is to generate the concept structure hierarchy. A concept model is a hierarchical structure that represents the organization of the ontology (Huhns & Stephens, 1999, Staab et al., 2001) that stakeholders propose and use in their collaboration. Figure 3 shows a concept structure example of a product development

Figure 3. A concept structure built by stakeholders in a collaborative design project



team. Stakeholders may use both top-down and bottom-up construction methods (Vet & Mars, 1999) to build the concept structure. It is possible to apply some templates (e.g. "product function template", "organizational template", "conflict types template", etc.) to clarify the concepts. These templates act as the contend-based skeletons for organizing the external information that stakeholders may share with others.

When stakeholders propose new concepts, the concept structure is updated and is used to systematically organize these concepts and their relationships. Since a stakeholder should first consider whether there are same or similar concepts in the structure, only the novel concepts can be specified and added. The concepts involved within the collaboration are classified into two types. Shared concepts are those that have been well-defined from previous projects. They have widely accepted meaning shared among the stakeholders (e.g., in Figure 3, "Function Requirements", "Product", and "Organization" etc. are shared concepts). Private concepts are perceived only by some particular stakeholders. Their names or meanings are not expressed around the group. If a group of people have a shared purpose toward a concept, everyone will be asked to view it. After the concepts are identified, the dependencies among these concepts can be further clarified by stakeholders.

The second step is to generate the perspective model. A perspective model is the special information representing the status of a stakeholder's perspective at a certain time. A perspective model consists of the purpose (i.e. the intention to conduct certain actions), context (i.e. the circumstances in which one's action occurs), and content (i.e. what one knows and understands) that the stakeholder uses to access the external knowledge and to expose the internal knowledge. In information systems, perspective model can be depicted as a data format relating to other information entities.

Our research develops a format of representing perspectives and a procedure to capture, generate and analyze perspective models. Given the well-organized structure of concepts, it is feasible to ask the stakeholders to build the perspective model state diagrams (PMSD) at a certain time. A stakeholder's PMSD attempts to depict the explicit relationships among his/her concepts (include the shared concepts and private concepts) and his/her purpose, content, and context information. The concepts listed in the PMSD are categories of perspective contents. Using the concept structure to generate the PMSD provides a structured way for us to systematically compare and examine the perspective differences among stakeholders.

Each concept of the concept model can be associated with a stakeholder by a set of purposes, contexts, and contents. The operation is to ask the stakeholders to:

First, relate this concept to their purposes. A stakeholder is able to specify his/her purpose within the project for a given concept. There might be more than one purpose involved. For an abstract concept, the purpose could be more general. For a specific concept, the purpose could be detail.

Second, specify the relationships of this concept with other concepts based on his/her context. If there is a new concept generated, add it to the PMSD architecture and set it as a private concept.

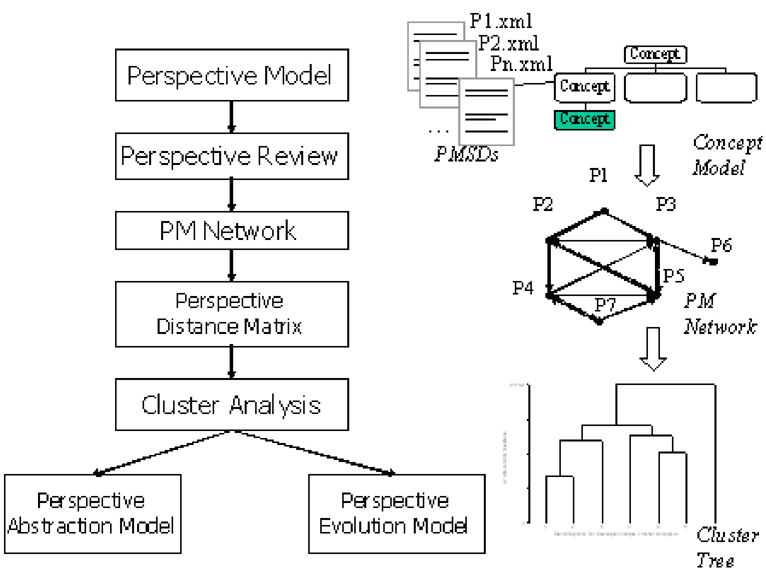
For each concept, declare or relate his/her own knowledge, document, and data about that concept and put them as the elements of the content associated with that concept.

Therefore, a PMSD is the picture that depicts a snapshot of a stakeholder's perception of concepts. It embodies his/her related purposes, context, and content. In a collaboration support system, a PMSD is represented as XML formats to facilitate analysis.

The third step is to conduct the perspective analysis. By comparing and analyzing stakeholders' perspective models it is possible to determine the degree of agreement among their opinions during their interaction. As shown in Figure 4, given the PMSDs for certain stakeholders, we can ask them to review others' perspective models. The review information is used to compare the perspective models and determine the similarity of two stakeholders' perspectives toward a shared concept. We can also aggregate multiple stakeholders' perspective models and compare their general attitudes at different levels of abstraction. Furthermore, we can track the evolution of the perspective model based on the clustering analysis results. The procedure is called perspective analysis (Figure 4).

The first step is to determine the inconsistency (i.e. the "distance") among a group of perspective models. There are two approaches: the intuitive approach and the analytical approach. The intuitive approach relies on the insights of the stakeholders. The analytical approach uses mathematical algorithms to derive the distance through "positional analysis", which is based on a formal method used in social network analysis (Wasserman & Faust, 1994). This approach views the perspective models of a group of stakeholders toward a single concept as a network of opinions associated with each other. In this network, a stakeholder, who possesses a perspective model, has relationships with others' perspective models. We define these relationships as their perceptional attitudes toward each other. A group of perspective models towards a given concept are placed as a graph (i.e., a PM network). Two perspective models are compatible (or similar) if they are in the same "position" in the network structure. In the social network analysis, "position" refers to a collection of individuals who are similarly embedded in networks of relations. If two perspective models are structurally equivalent (i.e., their relationships with other perspective models are the same), we assume that they are purely compatible and there are no detectable differences. That implies that they have the same perception towards others and others have same perception towards them.

Figure 4. The perspective analysis procedure



A distance matrix is derived for each PM network. It represents the situation of perspective compatibility among a group of stakeholders for a given concept. We can also compare stakeholders' perspective models for multiple concepts by measuring the structural equivalence across the collection of perspective model networks. Perspective distance matrices serve as the basis for cluster analysis. Hierarchical clustering is a data analysis technique that is suited for partitioning the perspective models into sub-classes. It groups entities into subsets so that entities within a subset are relatively similar to each other. Hierarchical clustering generates a tree structure (or a dendrogram), which shows the grouping of the perspective models. It illustrates that the perspective models are grouped together at different levels of abstraction (Figure 4).

The cluster tree exposes interesting characteristics of the social interactions. Within a collaborative project, the participants of the organization cooperate and build the shared reality (i.e. the common understanding of the stakeholders towards certain concepts) in the social interaction process (Berger & Luckman, 1966). Understanding the process of building shared realities is the key to managing social interactions. The shared reality can be represented by the abstraction of close perspective models among a group of stakeholders. As a matter of fact, the cluster tree depicts the structures of the shared reality, since a branch of the clustering tree at certain level implies an abstract perspective model with certain granularity. The height of the branch indicates the compatibility of the leaf perspective models. A cluster tree with simple structure and fewer levels implies that all of the perspective models have similar attitudes (or positions) toward others.

While the perspective models are changing, the clustering analysis can be used as a systematic way to depict the transformation of the perspective models. The change of the cluster trees at different stages of collaboration reveals the characteristics of perspective evolution. Investigating the changes of the topological patterns of the clustering trees leads to ways to interfere in the perspective evolutions.

Conflict Management

Given the condition that the social interactions are analytically measured, control mechanisms can be derived to manage the evolutions of the perspective models and therefore to support collaboration. Theses mechanisms could be selected and used by the group managers or coordinators to control conflicts. They can be classified into the following strategies.

- Process control
  The perspective analysis can be performed for all of the stakeholders who might act or influence a task. By evaluating their perspective compatibility and the execution feasibility of future tasks, which are in the plan but have not be conducted yet, we can prevent some conflicts by noticing their potential existence earlier. By providing certain information to stakeholders, it is possible to change the perception matrix and therefore to increase the perspective consistency of a task. It is possible to directly adjust the sequences and dependencies among the tasks to maintain the integrity of the opinions of stakeholders.
- Perspective control and ontology control
  First, it is possible to directly influence stakeholders' perspectives (their content, purpose, and context) to maintain the integrity and compatibility of the opinions toward a certain concept or task. Analyzing social interactions will identify the perspective models with low similarities and reveal the conflicts clearly. Thus, we can focus on the stakeholders who have singular perspectives and understand their rationale. Second, communication channels can be built to increase the interaction opportunities among

stakeholders with different perspective models. The group can manipulate the concept structure through clarifying the meanings and definitions of critical concepts so that people have shared understanding. It is also feasible to serve stakeholders with different concepts to isolate their perspectives. An opposite way is to use conflicting perspectives as means to enhancing brainstorming and innovation. Third, strategies can be derived to manage the conflicts through influencing stakeholders' information access and comprehension. Possible solutions include providing suitable trainings based on their perspectives and the job requirements, assisting the critical stakeholder to review the relevant information during certain conflicting tasks, and recording the discussions about the shared concept for future reuse.

- Organization control

  The clustering tree shows the grouping features of stakeholders' perspectives. Using different organizational structures will change the communication channels and the perception distances. If two stakeholders are separated into different groups, the possibility of interaction will decrease. We can change the task assignment or modify stakeholder' roles to affect their contexts. It is even possible to add or remove stakeholders associated with a certain task to avoid the conflicting situation or to move the stakeholders with similar perspectives together.
- Data and information control

  This control mechanism is to affect the conflicts through appropriately providing and handling external data and information, which will be accessed by the stakeholders. Examples are to use consistent checking and version control mechanisms to maintain the product data integrity, to track the changes of shared data and information by referencing to the perspective changing, and to map the shared data and information to perspective models so that the system realizes the specific impact of the conflicts towards the working results.

BUILDING ELECTRONIC COLLABORATION SUPPORT SYSTEMS USING THE PERSPECTIVE MODELING APPROACH

The perspective modeling and analyzing methodology provides a theoretical basis for building new knowledge management systems. The STARS system is a prototype system to support collaboration over the Internet. It is also developed as an experimental apparatus for testing the research. The system implements the process modeling, perspective modeling, and socio-technical analysis methodologies. On the other hand, it collects process and perspective data once stakeholders use it as a collaboration tool. By investigating the collected experimental data, we can determine the effectiveness of the approach and therefore improve it.

STARS system provides a Web-based environment that supports the collaboration process representation, conflict management, and knowledge integration within a project team. Stakeholders declare, share, and modify their perspective models on the Web. The perspectives models are analyzed in the system and stakeholders' roles in the collaboration tasks are depicted. The system implements the functional modules (e.g. perspective management, process management, conflict management, etc.) by using J2EE1.4 and Web Services technologies (Figure 5). It provides methods to detect, analyze, and track the conflicts during collaboration. It also supports the business-to-business process communications through SOAP and UDDI.

Figure 5. STARS system architecture

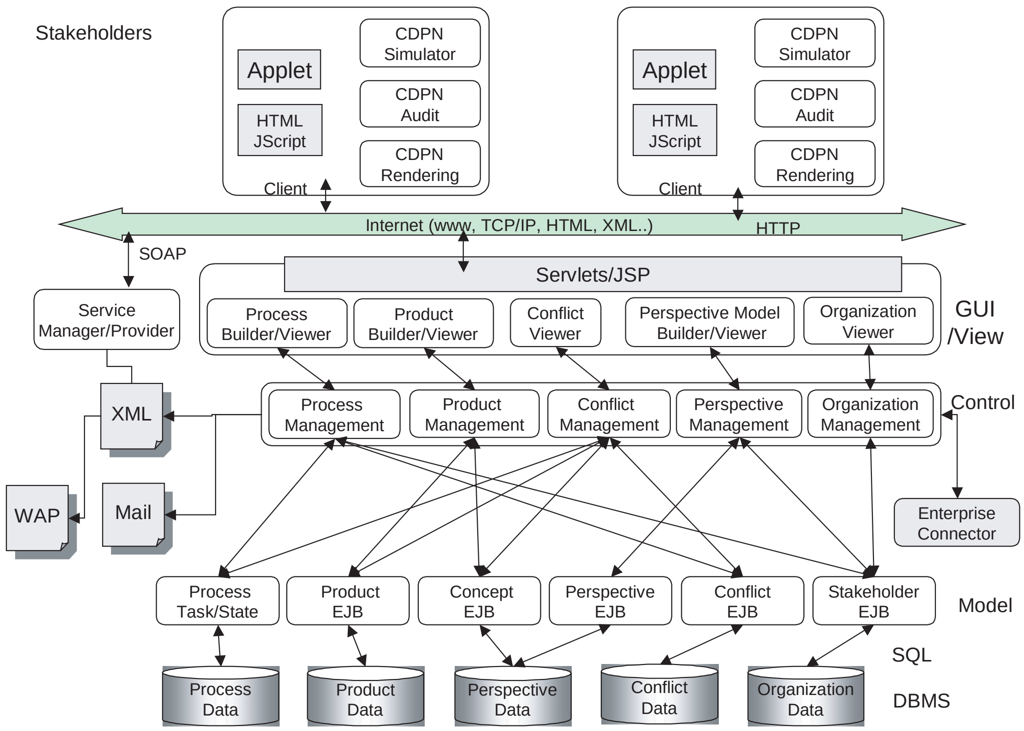


Figure 6 shows the knowledge perspective management module that allows stakeholders to declare and review their perspective information according to a concept structure tree. The system can analyze the perspective models, detect and predict conflicts, and suggest possible control strategies. The process management system of STARS uses a XML based process modeling tool for process planning, scheduling, simulation, and execution. It helps the stakeholders notice what is happening and who is doing what at any time. Stakeholders declare their perspectives during each step of the process. The system determines the conflict ratio of each tasks based on the perspective analysis.

Groups of designers, business analysts, and consultants working in a U.S. national construction research institute have been using STARS in their small projects. Feasibility and computability of the analysis algorithms were proved. Figure 7 depicts an example of using STARS to solve the conflict problem through perspective analysis. Before using STARS, similar cases described as below often happened in one design team:

"Within a design project, at the first meeting, the client's design consultant stated that the building was to be placed at a location on the site. The architect listened to the client's reasoning but noted that this location is not ideal from either an aesthetic or a functional point of view, since it would be too close to a major road intersection."

STARS perspective analyzing functions helped users notice the dependencies and differences of views among the stakeholders. The

Figure 6. The perspective management and conflict management modules of STARS

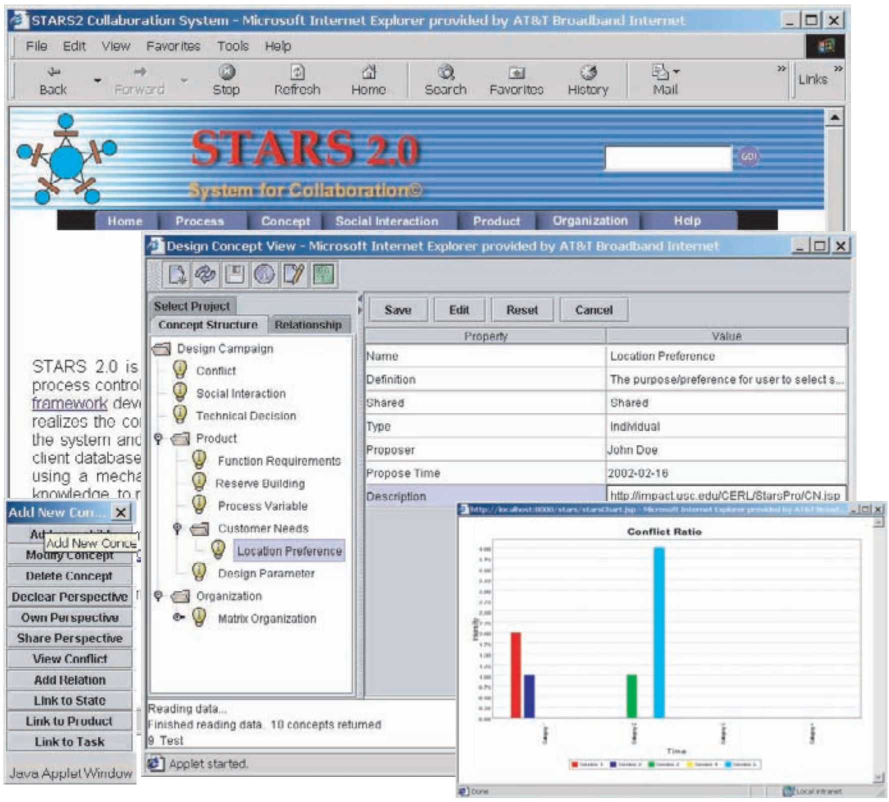

Figure 7. An example of detecting conflicts from perspective analysis

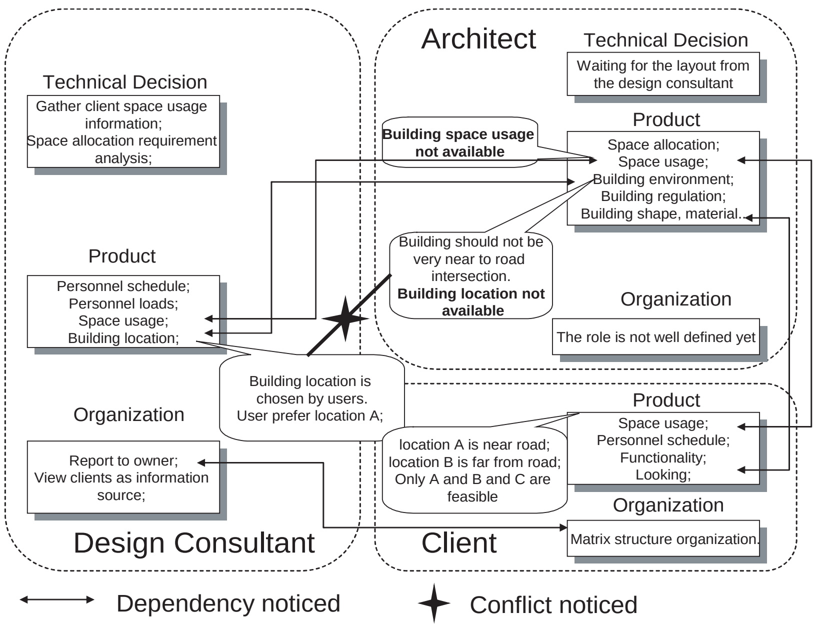

conflict was detected by tracking and mapping the "perspective models" of the three stakeholders. STARS compared the perspective models at early stage of the design. Although there was no direct meeting between the design consultant and the architect, the system detected a potential conflict during the design process.

The stakeholders who participated in the experiment considered that using the perspective modeling methodologies could accelerate their learning process and detect conflicts earlier in their collaborative projects. The causes of breakdowns of collaboration are more comprehensible when applying the analysis methodologies.

CONCLUSION

This paper presents a systematic methodology to supporting knowledge management by modeling and analyzing stakeholders' perspectives and their social interactions within collaborative processes. This approach provides methods for capturing perspectives and understanding their relationships to facilitate the control of the evolution of the shared insights. It avails knowledge management and conflict management by systematically facilitating the manipulation of the process, the perspectives, the organizational structure, and the shard data and information. The STARS system was built to improve the coordination among stakeholders. Its perspective modeling function provides an efficient way for stakeholders to understand the meanings and improve coordination during their collaboration over the Internet.

This research has some limitations. First, the closed-loop perspective management methodology requires stakeholders to be actively involved in the building and updating of perspective models. This might be overkill when the group is already very efficient and stable. Second, using the perspective analysis requires the computing tool and thus introduces a higher level of complexity. The system users have to be able to honestly and clearly specify their understandings toward the concepts and others' perspectives. In the future, the perspective analysis model can be improved by applying advanced statistics and econometrics techniques. It is also important to generate dynamic modeling methods to define the relationships between the evolution of perspective models and the quality of online collaboration.

Chapter 3.14
Web-Based Knowledge Management Model

Pei-Di Shen
Ming Chuan University, Taiwan

Chia-Wen Tsai
Ming Chuan University, Taiwan

INTRODUCTION

Knowledge is a limitless resource in the knowledge-based economy; therefore, organizations should learn, store, transfer and apply knowledge to add value or gain competitive advantage (Sveiby, 1997). Knowledge management (KM) refers to identifying and leveraging the collective knowledge within the organization for competitive advantage (von Krogh, 1998). However, it is usually discussed and implemented in high-tech industries (e.g., TI, TSMC and Winbond) and the software industry (e.g., Microsoft and Oracle). In Taiwan, the upstream firms or suppliers of the electronics industry (e.g., Winbond and UMC) implement KM in their organizations. As well as the suppliers, the downstream firms or manufacturers (e.g., Quanta and ASUS) also put KM into practice. However, in the intermediaries or distributors, only a meager number of firms really implement KM in their companies. Therefore, we have neglected whether KM is still suitable to implement in the distribution industry.

The IC distributors in Taiwan evolved from partnerships or intra-family enterprises into the overall arrangement in Asia, with output value in 2004 beyond $38.7 billion (United States dollars). IC distribution industry outsiders may consider that distributors just transact business, but don't have their own products, even though the scale of IC distributors has expanded. So an inaccurate notion exists that it isn't necessary to innovate or put KM into practice therein. In fact, IC distributors have to face not only the rapidly changing upstream firms, but also the variable requirements of downstream customers. Therefore, distributors have to adapt and learn even faster than their suppliers and customers to face the drastically changing and intensely competitive environment.

LITERATURE REVIEW

Knowledge Management

KM consists of the creation, storage, arrangement, retrieval and distribution of an organization's knowledge (Demarest, 1997; Saffady, 2000). Alavi and Leidner (2001) classified the processes of KM into four steps: knowledge creation, knowledge storage/retrieval, knowledge transfer and knowledge application, representing a detailed process view of organizational KM with a focus on the role of information technology. This systematic framework is shown as Figure 1, and each process will be illustrated in the following subsections.

Knowledge Creation

Organizational knowledge creation involves developing new content or replacing existing content within the organization's tacit and explicit knowledge (Pentland, 1995). New knowledge is a necessary raw material for innovation and the creation of knowledge, both closely tied to new products and services (Hauschild, Licht, & Stein, 2001). When a firm starts to develop new products or services, or when organizational knowledge is antiquated or insufficient, a firm should create new knowledge through organizational learning activities.

Knowledge Storage/Retrieval

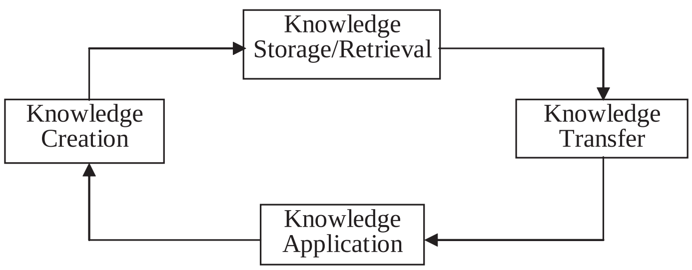
While new knowledge is developed by individuals, organizations play a critical role in articulating and amplifying that knowledge (Nonaka, 1994). Actually, the storage, organization and retrieval of organizational knowledge are referred to as organizational memory (Stein & Zwass, 1995; Malhotra, 2000). An organizational memory includes knowledge residing in various component forms, including structured information stored in electronic databases, written documentation, expert systems, documented organizational procedures and processes, and tacit knowledge acquired by individuals and networks of individuals (Tan, Teo, Tan, & Wei, 1999).

Knowledge Transfer

The distribution and transfer of knowledge is an important process in knowledge management (Alavi & Leidner, 2001; Huber, 1991). Knowledge should be shared and generalized within the organization; generalization occurs not only when single ideas are moved, but also when the entire process of moving ideas becomes institutionalized within an organization (Yeung, Ulrich, Nason, & von Glinow, 1999).

For shared knowledge to be meaningfully used, it needs to be coupled with mechanisms

Figure 1. Four processes of KM (modified from Alavi & Leidner, 2001)



for organization, retention, maintenance, search and retrieval of the information (Stein & Zwass, 1995). Such mechanisms are often computer-based, ranging from simple keyword organizers to complex intelligent agents and neural networks that grow with the growth of knowledge repositories (Ellis, Gibbs, & Rein, 1991; Johansen, 1988; Maes, 1994). Collaborative technologies (CT) application is fundamental to virtual teams. One CT, known as a virtual workplace, should at least be able to record the process of the group, an agenda and libraries of solutions and practices, as well as provide different forms of interaction, meta-information and shared information storage, access and retrieval (Ellis, Gibbs, & Rein, 1991; Ishii, Kobayashi, & Arita, 1994; Kling, 1991; Nunamaker, Briggs, & Mittleman, 1995; Romano, Nunamaker, Briggs, & Vogel, 1998; Thornton & Lockhart, 1994). For knowledge sharing and reuse with CTs, however, they must include mechanisms for exchange (such as e-mail) and access the knowledge repository (Majchrzak, Rice, King, Malhotra, & Ba, 1999).

In newly implemented IT-enabled communications environments, individual media choice was found to be overwhelmingly informed by so-called socialcultural determinants of how these technologies might most adequately and effectively be used (Webster & Trevino, 1995; Fulk & Boyd, 1991). Therefore, management may influence participation in the technologies of choice.

Knowledge Application

Knowledge application means making knowledge more active and relevant for firms in creating value through applying organizational knowledge to a company's products, processes and services (Bhatt, 2001; Demarest, 1997). Employees use all available resources, including the corporate knowledge base, to improve their chance of reaching the goals of the organization (Hauschild, Licht, & Stein, 2001). As stated by Prokesch (1997), using knowledge more powerfully than your competitors is key in the global information era. Knowledge should be applied to create suitable, real value for the company.

CASE STUDY: WORLDPEACE

Company Overview

Worldpeace Group, established in Taipei, Taiwan in 1981, became an OTC-listed company in 1987 and a TSE-listed company in June 2000. Its capital was $0.97 billion in 2004, and its group sales in 2003 were one $160 million. It is the largest and leading electronic component distributor in the Asia Pacific region; moreover, in 2003 it was ranked the sixth-largest among top global semiconductor distributors worldwide by EBN (a dedicated semiconductor Web site). Its suppliers include 60 world-famous firms, like Intel, TI, Philips, Hynix, Vishay and so forth.

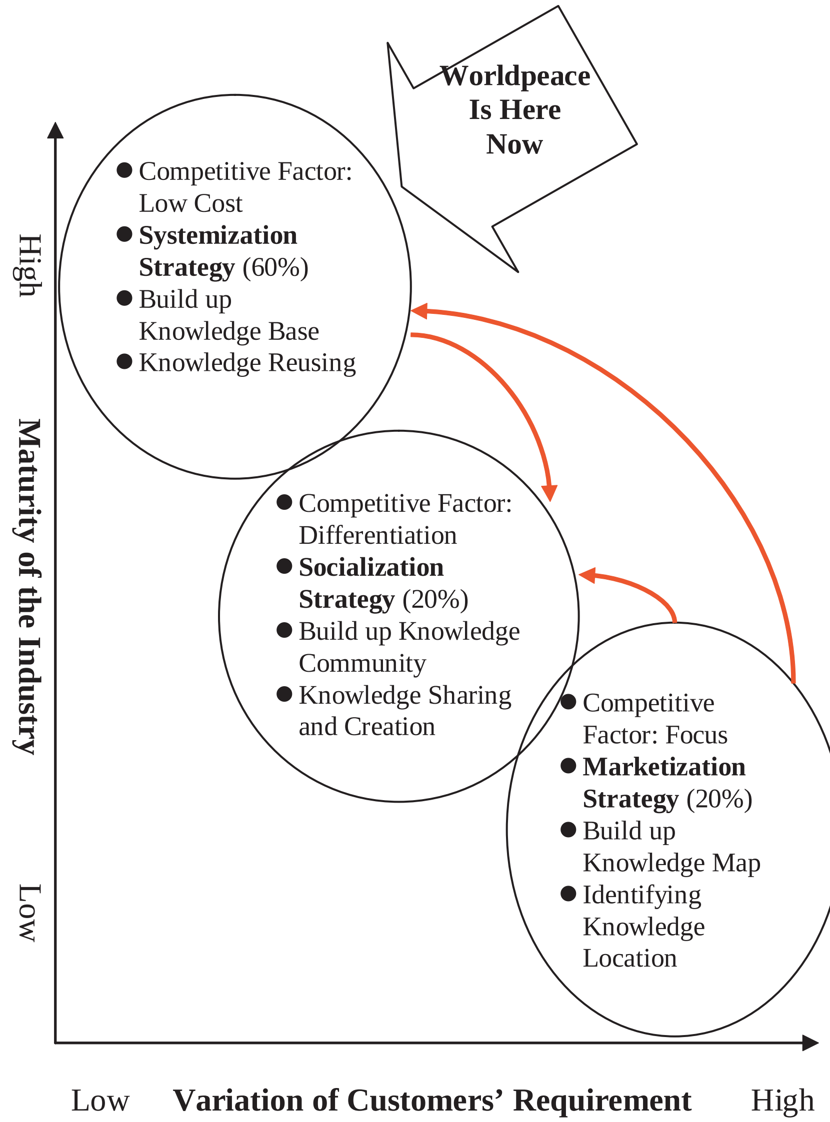
Worldpeace's department of KM was founded to facilitate the implementation of KM. Worldpeace invested positively in the information technologies and systems that help them to gain competitive advantage. They stored and transferred their knowledge, information, order status and market conditions in their self-developed information system named Enterprise Internal Portal (EIP).

KM Strategies

The implementation of KM in Worldpeace was guided according to three weighted strategies (see Figure 2) as follows:

- Marketization strategy: To find the knowledge within the organization, marketization strategy was applied to build up the knowledge map (IP map) to record the locations of knowledge owners, providers or experts. Most knowledge in Worldpeace is explicit,

Figure 2. Three strategies for the implementation of KM in Worldpeace (from Worldpeace, modified from Yu, 2001)



so they just put 20% weight on marketization efforts.

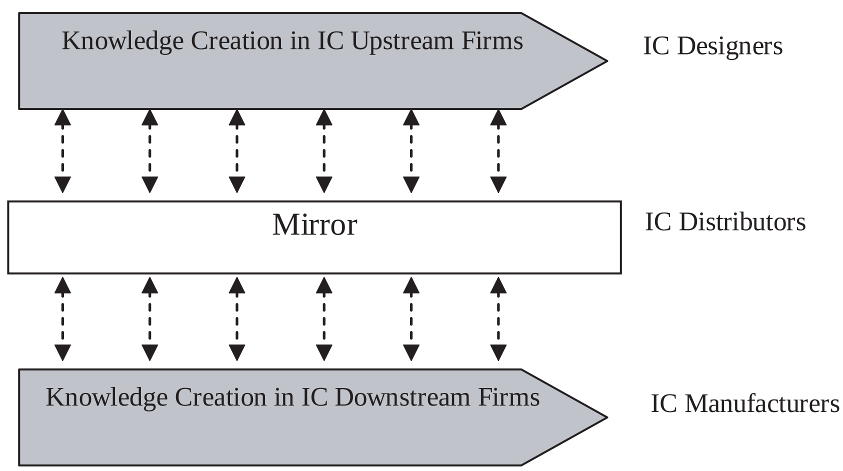
- Systemization strategy: Being in a mature industry and being the largest distributor in Asia, Worldpeace need not provide different products for customers, but rather focus on "low cost" instead. Worldpeace emphasizes the storage of knowledge within the organization. Therefore, Worldpeace put 60% weight on systemization strategy when putting KM into practice. For effective knowledge sharing and optimum users' understanding, knowledge in Worldpeace should be standardized. Hence, a "standard knowledge" mechanism was implemented before storing knowledge or information in the knowledge base. The associate vice president of corporate marketing and communication and assistant manager of knowledge management of Worldpeace announced the "standard knowledge" mechanism, and educated their engineers and employees to write standard documents to store standardized knowledge for months before they implemented KM.

- Socialization strategy: To encourage employees to share knowledge spontaneously and actively, a socialization strategy was implemented to build a "knowledge community." This strategy focuses on conversations (especially for tacit knowledge) among the members of Worldpeace, and knowledge creation through this knowledge community. However, most knowledge in IC distribution industry is explicit knowledge; therefore, they only put 20% weight on socialization strategy.

KM Practice

- Knowledge Creation: In the IC distribution industry, firms have to keep their knowledge consistent with their supply chain; that is, when their upstream firms or suppliers innovate or create new knowledge about IC products, the distributors must get that new knowledge instantly. As many innovations occur and much new knowledge is created in the IC design industry, distributors have to work hard to keep up with suppliers. Worldpeace keeps knowledge consistent with suppliers by being a two-way mirror of the knowledge creation of their suppliers, which means knowledge will be transferred from the IC designer to the distributor as it was created or devised. The distributor plays the same role as the designer in knowledge creation by acquiring knowledge about new requirements from customers or information about market demand. Besides acquiring the knowledge from suppliers and customers, Worldpeace plays an important role in transferring knowledge between upstream and downstream firms whenever knowledge is created (see Figure 3).
- Knowledge Storage/Retrieval: As distributors, they make a profit by managing knowledge and information about products. In

Figure 3. Knowledge creation with suppliers and customers—"mirror"



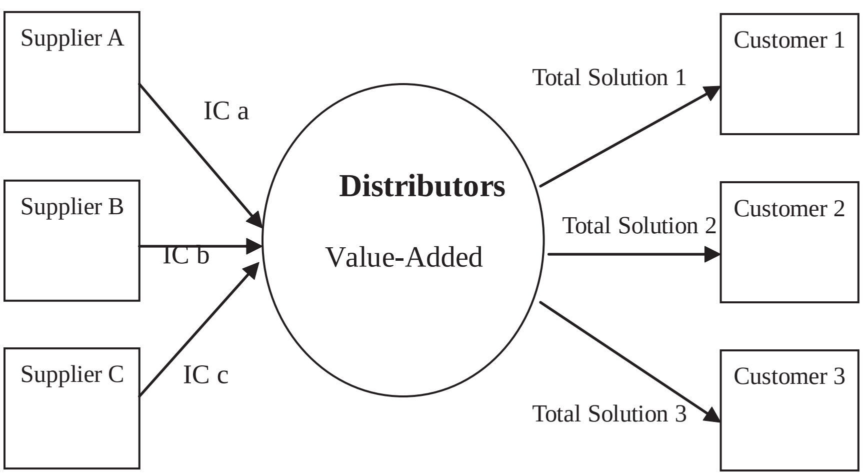
Worldpeace, knowledge and information are stored well in their database, and employees can access it via intranet. Worldpeace has become a distributor for business-to-business (B2B) e-commerce based on the knowledge management platform of its self-developed EIP information system. It established e-service for Customer Relation Management (CRM) to greatly improve the transaction process. The information on order status, accounts receivable and customers is recorded in EIP.

A report must be completed when any project closes. The new knowledge, findings, specifics and experiences in the case must be recorded and stored following a "standard knowledge" mechanism for effective knowledge sharing and understanding. All employees of Worldpeace are educated to write a standard document when they store knowledge, as the policy of "standardized knowledge" is critical when implementing KM.

- Knowledge Transfer: Two approaches were applied in Worldpeace to transfer knowledge. Explicit knowledge is stored in the EIP system in the standard format. Managers, engineers, salesmen and employees could access the knowledge that they need. Worldpeace has a solid Asia-Pacific service network, with more than 20 sales offices around the greater China and Asia Pacific region. Employees everywhere can access the EIP system via Internet. This EIP system is divided into four sections presented in four colors: blue, green, red and orange. The colors represent the Taiwan headquarters, branches in Taiwan, branches in China and branches in ASEAN, respectively. Thus, employees can store and access the information and knowledge within the same color section.

The second approach is for tacit knowledge transfer. In the distribution industry, tacit knowledge could be the experience of sealing a business deal. The salesmen or managers, who are masters in making deals or marketing, are invited to speak to other employees. Besides, some special cases will be studied to discover their characteristics,

Figure 4. The total solutions provided by integrating different IC chips in distributors



called "Worldpeace DNA." The associate vice president of corporate marketing and communication decides which cases are worth publicizing. The case study will proceed, and the assistant manager of knowledge management will have interviews with the salesman or manager to complete this case study. After it is completed, it will be stored in the EIP system for members in the virtual community.

- Knowledge Application: There are three knowledge domains in the distribution industry: first, knowledge about the nature of IC chips; second, knowledge about the purpose, function and application of the products; and third, knowledge about how to integrate IC chips in a module or system. Therefore, distributors build the knowledge base of products first, then understand how and where to apply them. Finally, they try to discover how to integrate different IC chips in a module. Being distributors, they do not design IC nor produce IC chips. They create value for customers by integrating chips from different suppliers in a module and providing total solutions, adding value for their customers (see Figure 4).

DISCUSSION AND INSIGHTS

With stiff global competition, high-tech companies face the challenge of a shorter product life cycle, the rapid depreciation of tangible assets and the transience of employees, especially marketing employees and salesmen in the distribution industry. The most knowledge in the distribution industry is explicit; therefore, it is suitable to put KM into practice through the intranet. Based on the literature and case study of Worldpeace, three insights are provided.

- Insight 1: In order to increase the efficiency of knowledge sharing and understanding among the members of virtual community, a "standard knowledge" mechanism should be implemented first. The standardized knowledge records will increase the readability and help members of virtual communities to understand their meaning. Besides, this "standard knowledge" mechanism also contributes to the storage of knowledge within organizations. Therefore, we suggest that firms set up this mechanism before building virtual communities.
- Insight 2: KM could be implemented in the distribution industry through a Web-based system to help firms strategically apply knowledge and keep robust relationships with their suppliers and customers. A supply chain could profit and grow by implementing KM and applying knowledge efficiently in every link of the chain.
- Insight 3: The critical information technology in Worldpeace's implementation of KM is a self-developed system and virtual community named EIP. Worldpeace invested significant budget to develop this system to help in daily access, storage and transfer of knowledge. According to Worldpeace's associate vice president of corporate marketing and communication, the company invested very generously in technologies that may be the basis of competition or contribute to their market edge. Therefore, we propose that more emphasis on investment in IT may result in a more effective outcome from KM.

CONCLUSION AND SUGGESTIONS

In this article, Worldpeace, the largest and leading electronic component distributor in the Asia Pacific region, was studied to reveal the real practice of how an IC distributor implements KM in a Web-Based Knowledge Management Model. Findings indicate that firms should set up this mechanism before building a virtual community. Furthermore, findings in this study also reveal that emphases on investment in IT and support from executives have the potential to improve the efficiency and favorability in implementation of KM.

Chapter 3.15
Knowledge Management Ontology

Clyde W. Holsapple
University of Kentucky, USA

K. D. Joshi
Washington State University, USA

INTRODUCTION

Many definitions of ontology are posited in the literature (see Guarino, 2004). Here, we adopt Gruber's (1995) view which defines ontologies as simplified and explicit specification of a phenomenon. In this article, we posit an ontology that explicates the components of knowledge management (KM) phenomena. This explicit characterization of knowledge management can help in systematically understanding or modeling KM phenomenon.

In the past decade, KM has received significant attention within the information systems community, however, the community has not provided a well-integrated framework to help unify this sub-discipline. Therefore, in an effort to provide a comprehensive and unified view of KM, we introduce a formal characterization of a KM ontology collaboratively developed with an international panel of KM practitioners and researchers. Prior articles have either detailed various portions of this ontology and described panelists' piecewise evaluations of them (Holsapple & Joshi, 2000, 2001, 2002c) or outlined a more definitional and axiomatic version of this ontology (Holsapple & Joshi, 2004). Here, however, we provide a concise integrated view of the whole ontology.

Several methodologies for designing and developing ontologies have been proposed in the literature for many domains and for various objectives. For instance, Noy and McGuinness (2001) have posited seven steps for developing a basic ontology, whereas others, such as Guarino (retrieved 2004), have discussed the application of ontological principles in various context. Our ontololgy development process, although unique in certain aspects, incorporates many of the principles recommended in the literature.

BACKGROUND

The ontology was developed through a process of four phases including the preparatory, anchoring, collaborative, and application phases (Holsapple & Joshi, 2002a). In the preparatory phase, standards and criteria for ontology development and evaluation were created. In the anchoring phase, an initial ontology by consolidating, synthesizing, organizing, and integrating concepts from the past literature was developed. During the third phase, a panel of 31 KM practitioners and researchers collaborated in two Delphi rounds to further refine, modify, and evaluate the initial ontology. The last phase involved illustrating the application and utility of the developed ontology.

KNOWLEDGE MANAGEMENT ONTOLOGY

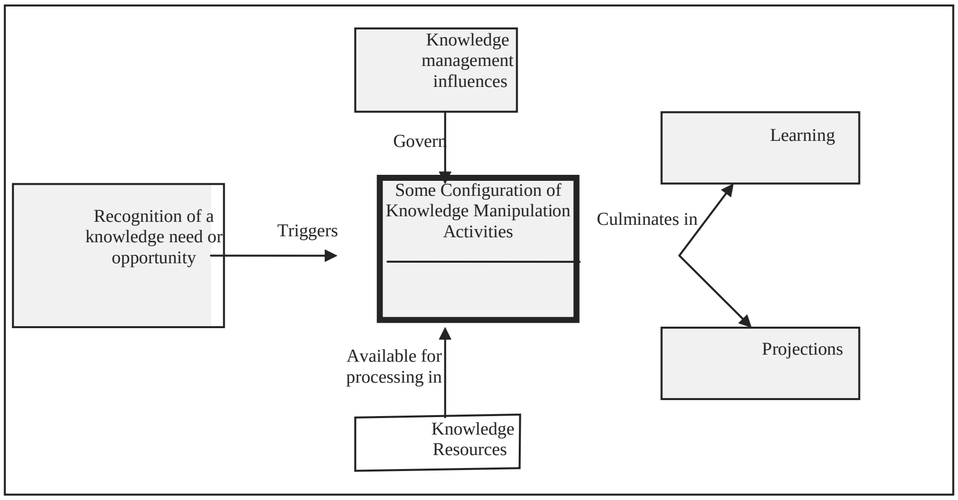
This ontology defines knowledge management as an entity's (such as an individual, group, organization, community, nation) deliberate and organized efforts to expand, cultivate, and apply available knowledge in ways that add value to the entity, in the sense of positive results in accomplishing its objectives or fulfilling its purpose (Holsapple & Joshi, 2004).

Many definitions of knowledge can be found in the literature (see Nonaka, 1994; Alavi & Leidner, 2001; Marshall & Brady 2001; Randall, Hughes, O'Brien, Rouncefield, & Tolmie, 2001; Sutton, 2001). The objective of the Delphi process was to characterize knowledge management behaviors that can accommodate various perspectives on the nature of knowledge. Therefore, no single definition of knowledge was developed or adopted. Knowledge can be represented in mental, behavioral, symbolic, digital, visual, audio, and other sensory patterns that may occur in various object and process formats. Knowledge has a variety of attributes including mode (tacit vs. explicit), type (descriptive vs. procedural vs. reasoning), orientation (domain vs. relational vs. self), applicability (local vs. global), accessibility (public vs. private), immediacy (latent vs. currently actionable), perishability (shelf-life), and so forth. More complete and detailed listings of attribute dimensions for characterizing knowledge have been advanced but are beyond the scope of this article (Holsapple & Joshi, 2001; Holsapple, 2003a) In the interest of being generic, the ontology is neutral on these differential views.

This ontology adopts an episodic view to knowledge work. In other words, an entity's knowledge management work is viewed as a collection of episodes. These episodes, which vary in structure, function, and purpose, unfold in various settings to accomplish a range of different tasks. This ontology characterizes a knowledge management episode (KME) (see Figure 1) as a configuration of knowledge manipulation activities, by a collection of knowledge processors, operating on available knowledge resources, subject to knowledge management influences, and yielding learning and/or projections (Holsapple & Joshi, 2004). Knowledge management episodes are triggered to satisfy a knowledge need or opportunity; it concludes when that need/opportunity is satisfied or terminated. Some examples of KME include decision-making, problem-solving, and brainstorming episodes.

KME is considered to have a learning outcome when the state of an entity's knowledge resources is altered. On the other hand, projection outcomes are expressions or manifestations—in the form of knowledge, material, capital, or behavior—of an entity's KME that are released into its environment. The resulting alteration in the state of the entity's knowledge base or environment due to learning or projection can be functional or dysfunctional in nature. The three primary components that drive the execution of a KME are the knowledge manipulation activities, knowledge resources, and knowledge management influences.

Figure 1. Architecture of a KM episode (adapted from Holsapple & Joshi, 2004)



Knowledge Manipulation Activities Component

Knowledge manipulation refers to the processing of usable knowledge representations embedded within an entity's knowledge resources. Knowledge processors that possess skills for performing knowledge manipulations activities can be human participants or computer-based parts in an entity. Numerous classifications of knowledge manipulation activities have been forwarded by KM researchers (see Alavi & Leidner, 2001; Holsapple & Joshi, 2002c). However, they often fail to provide a unifying view due to the use of differing terminology and varying levels of manipulation activities. This ontology provides a relatively comprehensive, unifying, elemental characterization of the major knowledge manipulation activities that occur during knowledge work.

As illustrated in Table 1, the Delphi process uncovered elemental knowledge manipulation activities, their sub-activities, and their interrelationships. The five types of basic knowledge manipulation activities that can occur during knowledge work include knowledge acquisition, knowledge selection, knowledge generation, knowledge assimilation, and knowledge emission.

The knowledge resulting from the execution of a knowledge manipulation activity by a processor can be transferred for further processing to other instances of knowledge manipulation activities. In other words, knowledge flows into and out of knowledge manipulation activities. A knowledge flow can be initiated through a pull or a push mechanism. So, a processor performing an instance of an activity could push that resulting knowledge to another instance of an activity or it could transfer that knowledge to satisfy the knowledge request from some other activity instance. In order to establish, coordinate, and control the knowledge flows among activity instances, processors also transfer ancillary messages to the interacting instances. These ancillary messages provide feedback, clarification, and evaluation of actual knowledge flow.

The ontology's five elemental knowledge manipulation activities that resulted from the Delphi

Table 1. The ontology's knowledge manipulation activity component (Adapted from Holsapple and Joshi, 2004)

Knowledge Manipulation Activity	Sub-Activities Within This Activity	Knowledge Flows into This Activity from	Knowledge Flows Released from This Activity to
Acquisition	Identification, Capturing, Organizing, Transferring	Entity's Environment	Assimilation, Generation, Emission
Selection	Identification, Capturing, Organizing, Transferring	Entity's Knowledge Resources	Acquisition, Assimilation, Generation, Emission
Generation	Monitoring, Evaluating, Producing, Transferring	Acquisition, Selection	Assimilation, Emission
Assimilation	Assessing/Valuing, Targeting, Structuring, Transferring	Acquisition, Selection, Generation	Entity's Knowledge Resources
Emission	Targeting, Producing, Transferring	Acquisition, Selection, Generation	Entity's Environment

process are characterized as follows (see Holsapple & Joshi, 2004 for a more formal discussion of these activities).

A knowledge acquisition activity involves identification of knowledge from the entity's environment and making it available in a suitable representation to an appropriate activity. The knowledge selection activity is similar to knowledge acquisition with one difference: Knowledge selection identifies knowledge from within an entity's knowledge resources as opposed to from the entity's environment. A knowledge generation activity derives or discovers knowledge in the context of existing knowledge. A knowledge assimilation activity culminates in learning by altering an entity's knowledge resources. A knowledge emission activity applies the existing knowledge to produce projections for release into the environment. The knowledge assimilation and emission activity involves usage and application of entity's existing knowledge to create knowledge.

Each of the five knowledge manipulation activities are comprised of sub-activities. Next, we will describe the sub-activities as well as the incoming and outgoing knowledge flows for each of the knowledge manipulation activities.

Knowledge acquisition (knowledge selection) is accomplished through a set of sub-activities which include identification of appropriate knowledge from the external sources (within the entity's existing resources), capturing the identified knowledge, organizing captured knowledge, and transferring the organized knowledge to an appropriate activity. A knowledge acquisition activity receives knowledge flows from an entity's environment and delivers the acquired knowledge to an activity that immediately uses the knowledge and/or to one that assimilates it within the entity for subsequent use. A knowledge selection activity receives knowledge flows from an entity's knowledge resources and delivers the selected knowledge to the acquisition, use, and/or assimilation activities.

The generation of knowledge entails monitoring the entity's knowledge resources and the external environment and attaining required knowledge (via selection or acquisition), evaluating the obtained knowledge in terms of its utility and validity for the production of knowledge, producing knowledge by creating, synthesizing, analyzing, and constructing knowledge from a base of existing knowledge, and transferring the produced knowledge to an appropriate activity. A knowledge generation activity receives knowledge flows from knowledge selection or acquisition activities and delivers the generated knowledge to assimilation and/or emission activities.

Knowledge assimilation involves assessing and valuing knowledge to be assimilated, targeting knowledge resources where knowledge would be situated, structuring knowledge into forms appropriate for the targets, and transferring the knowledge representations as targeted. A knowledge assimilation activity receives knowledge flows from knowledge acquisition, selection, or generation activities and produces knowledge flows that are transferred/embedded into the entity's knowledge resources.

The emission activity involves targeting elements of the environment to determine what projections need to be produced, producing projections for the target, and transferring the projections to targets which involves packaging and delivery. A knowledge emission activity receives knowledge flows from knowledge selection, acquisition, and/or generation activities and delivers the packaged knowledge (i.e., projections) to targets in the environment.

Knowledge assimilation and emitting activities, which result in learning and projection respectively, are very critical to effective knowledge work. These activities, if executed effectively, can add value to an entity in terms of enhanced knowledge, profits, and performance. The knowledge processed by the knowledge manipulation activities are embedded within different types of knowledge resources that are characterized below.

Knowledge Resource Component

An organizational resource is a source of value, revenue, wealth, or rent to an organization (Holsapple & Joshi, 2004). Traditionally, organizations have recognized and effectively managed three types of resources: financial, human, and material. However, knowledge assets are recognized as crucial organizational resources (Drucker, 1993) for creating and maintaining a competitive advantage (Holsapple & Singh, 2001). More organizations are attempting to manage knowledge resources with a degree of systematic, deliberate, or explicit effort devoted to managing the other three resources. Knowledge resources are entities where organizational knowledge is embedded and can be manipulated by an organization in ways that yield value. A taxonomy characterizing knowledge resources, a component of our knowledge management ontology, which was developed through the Delphi process is described next.

Some classes of knowledge resources exist independent of an entity's existence whereas the others depend on the existence of an entity. The resources that exist independent of an entity are called content knowledge resources. The resources that are dependent on the existence of an entity are called schematic resources. Schematic knowledge is embedded within the behaviors that manifests in an organization. The four kinds of schematic resources include culture, infrastructure, strategy, and purpose. An organization's cultural knowledge resource holds organizational values, principles, norms, traditions, unwritten rules, and informal procedures. An organization's infrastructure structures an organization's participants in terms of the roles that have been defined for participants to fill, the relationships among those roles, and regulations that govern the use of roles and relationships (Holsapple & Luo, 1996). An organization's strategy consists of planning knowledge for utilizing organization's infrastructure, culture, knowledge artifacts, and participants' knowledge (as well as other organizational resources). An organization's purpose consists of directional knowledge used to align entity's strategy, infrastructure, and culture.

The two types of content knowledge resources include participants' knowledge and knowledge embedded within artifacts. These resources can exist without an entity that host, own or create these resources. Knowledge artifacts are objects without any processing skills, but have knowledge embedded within them that can be processed by human or computer processors. Participants' knowledge is the knowledge possessed by knowledge processors that participate in an organization.

The last class of knowledge resources that is accessible to an entity are the resources in its environment. The environment's knowledge resources are a crucial source for replenishing and augmenting an organization's knowledge resources.

Knowledge Management Influences Component

Knowledge influences are factors that shape and govern the execution of knowledge manipulation activities during a KM episode. The Delphi methods revealed three classes of KM influences, including managerial influences, resources influences, and environmental influences. Managerial influences incorporate administrative activities established and executed by an entity that affect its knowledge work. Resource influences are comprised of organizational resources that are employed to carry out entity's knowledge work. Environmental influences are factors external to an entity (i.e., in its environment) that affect its conduct of knowledge management.

The managerial influences include knowledge leadership, knowledge coordination, knowledge control, and knowledge measurement. Leadership facilitates fruitful knowledge work. Knowledge coordination involves management of dependencies among knowledge manipulation activities, knowledge resources, knowledge processors, and knowledge management episodes. Knowledge control involves ensuring that needed knowledge resources and processors are available in sufficient quality and quantity, subject to required security. Knowledge measurement involves assessing and valuing knowledge resources, knowledge processors, knowledge manipulation activities, managerial influences, knowledge management episodes, and overall conduct of knowledge management.

The ontology recognizes an entity's resources as influences on how a KM episode unfolds. This includes not just its knowledge resources, but also the other more traditional resources such as financial, material, and human. The third class of influence includes an entity's environment. Unlike managerial influences (and, to a considerable extent, resource influences), environmental influences are factors over which an entity typically has limited (or no) control. These factors may operate as constraints, impediments, or facilitators of the entity's knowledge management efforts. The Delphi process yielded six major classes of environmental influences: competition, fashion, markets, technology, time, and the GEPSE (governmental, economic, political, social, and educational) climate.

FUTURE TRENDS

This article provides a general purpose ontology that is very generic in nature and applicable to various knowledge contexts. Although, on one hand the ontology's general nature broadens its applicability, it also limits it from capturing the nuances of a specific knowledge context. Therefore, by adopting this ontology as its foundation, future research needs to develop context-specific ontologies that focus on characterizing a specific KM episode in a more detailed fashion. For instance, in order to better understand how the knowledge management conduct unfolds during an information system development (ISD) process, it is crucial to explicate and characterize the KM conduct in the context of an ISD process. Such an effort could entail enumeration of knowledge manipulation activities and its relationships specific to this task, identification of knowledge resources involved in this type of knowledge work, and uncovering influences that facilitate or constrain knowledge processing in an ISD process.

This ontology provides concepts and components associated with KM episodes. However, it does not offer measures for these constructs. Future research needs to create measurement scales that operationalize the ontology's constructs for measuring and testing the execution of KM episodes within organizations.

Future research and practice needs to continually test and examine this ontology's utility and applicability and develop it further through improvements, refinements, and modifications.

CONCLUSION

The posited ontology identifies and characterizes major elements of KM in a unified and relatively comprehensive manner. It provides a characterization of KM episodes that consists of three components: knowledge manipulation activities, knowledge resources, and knowledge influences. Moreover, it provides a taxonomy for an entity's knowledge resources where knowledge may be stored, embedded, and/or represented. It identifies and relates knowledge manipulation activities that operate on those resources. It recognizes factors that influence the conduct of KM in an organization.

The ontology in its current form provides a foundation for systematic KM research, study, and practice. It provides researchers with a unified and comprehensive view of KM that is crucial for studying KM (e.g., Holsapple & Singh, 2000; Holsapple & Singh, 2001; Massey, Montoya-Weiss, & O'Driscoll, 2002; Holsapple & Jones, 2003). It gives practitioners a frame of reference for evaluating KM practices and identifying KM opportunities. It forwards a structure and content for developing a formal KM curriculum (e.g., Holsapple, 2003b, 2003c; Weidner, 2003).

This ontology is an initial step toward initiating conceptual development in the KM field. This ontology can be developed further through added breath and depth. It can be extended in a normative direction by adding elements that prescribe methods and technologies for the conduct of KM.

Chapter 3.16
Discovering Implicit Knowledge from Data Warehouses

M. Mehdi Owrang O.
American University, USA

INTRODUCTION

Today, every corporation faces the problem of how to acquire, store, and share information. Knowledge management (KM) has been introduced to accomplish these tasks (Adams, 2004; Barquin, 2000; Frappaolo & Wilson, 2004). Fundamental to KM is the realization that knowledge exists in two basic forms: explicit and tacit (Adams, 2004; Barquin, 2000; Frappaolo & Wilson, 2004; Orr, 2004). Organizations have data, in the form of operational databases and/or data warehouses, which contain implicit knowledge. Some knowledge believed to be tacit (experiential and intuitive) can be transformed into explicit knowledge. Getting to implicit knowledge requires taking a look at tacit knowledge resources (i.e., domain experts or data warehouses) to determine whether that knowledge could be codified if it were subjected to some type of mining and translation process. Then, it requires implementing that mining/translation process. The majority of an organization's knowledge is presumed to be tacit. Yet, the majority of the KM applications seem to focus on the explicit knowledge base: working on existing corporate knowledge or making individuals more effective at sharing explicit knowledge (Frappaolo & Wilson, 2004). Efforts have been put in creating an organized explicit knowledge repository, called data warehousing (Bischoff & Alexander, 1997) that is continuously fed and leveraged. Knowledge management is not truly possible without data warehousing (Barquin, 2000). It is the real-time access to an enterprise's integrated data stores through data warehousing that complements an individual's tacit knowledge of how something is done.

Knowledge discovery is defined as the nontrivial extraction of implicit, previously unknown, and potentially useful information from data (Adriaans & Zantinge, 1996; Agrawal, Imielinski & Swami, 1993; Brachman et al., 1996; Fayyad, 1996; Inmon, 1996). The automatic knowledge acquisition in a nondata warehouse environment has been on the operational databases which contain the most recent data about the organizations.

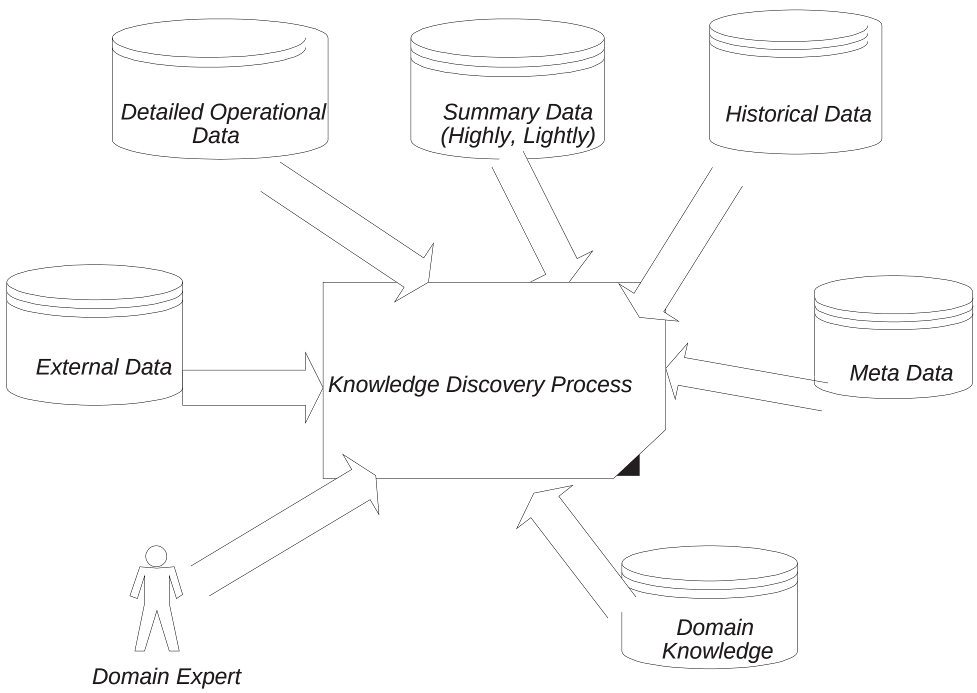
Summary and historical data, which are essential for accurate and complete knowledge discovery, are generally absent in the operational databases. A data warehouse is an ideal environment for rule discovery since it contains the cleaned, integrated, detailed, summarized, historical, and metadata (Bischoff & Alexander, 1997; Inmon, 1996; Meredith & Khader, 1996; Parsaye, 1996).

In this article, we are looking at the discovery of implicit knowledge from the data warehouses. Most of the success of knowledge discovery resides in the ability of the system to elicit the right level of detail as well as accuracy from the data warehouse which has the implicit data. We look at the knowledge discovery process on detailed, summary, and historical data. Also, we show how the discovered knowledge from these data sources can complement and validate each other.

KNOWLEDGE DISCOVERY IN DATA WAREHOUSES

Knowledge discovery on operational relational databases could lead to inaccurate and incomplete discovered knowledge. Without first warehousing its data, an organization has lots of information that is not integrated and has little summary or history information. The effectiveness of knowledge discovery on such data is limited. A data warehouse environment integrates data from a variety of source databases into a target database that is optimally designed for decision support. A data warehouse includes integrated data, detailed and summary data, historical data, and metadata. Each of these elements enhances the knowledge discovery process (Adriaans & Zantinge, 1996; Barquin & Edelstein, 1997; Bischoff & Alexander, 1997; Meredith & Khader, 1996).

Figure 1. A framework for knowledge discovery in a data warehouse environment



There are several benefits in rule discovery in a data warehouse environment. First, in a data warehouse environment, the validation of the data is done in a more rigorous and systematic manner. Using metadata, many data redundancies from different application areas are identified and removed. The cleansing process will remove duplication and reconcile differences between various styles of data collection. Second, data warehouses are not concerned with the update anomalies since update of data is not done. This means that at the physical level of design, we can take liberties to optimize the access of data, particularly in dealing with the issues of normalization and physical denormalization. Universal relations can be built in the data warehouse environment for the purposes of rule discovery, which could minimize the chance of undetecting hidden patterns.

Figure 1 shows a general framework for knowledge discovery in a data warehouse environment. External data, domain knowledge (data that is not explicitly stored in the database, that is, male patient cannot be pregnant), and domain expert are other essential components to be added in order to provide an effective knowledge discovery process in a data warehouse environment.

KNOWLEDGE DISCOVERY FROM DETAILED DATA

Most of the knowledge discovery has been done on the operational relational databases. An operational database stores the most recent and detailed data. In addition, the goal of the relational databases are to provide a platform for querying data about uniquely identified objects. However, such uniqueness constraints are not desirable in a knowledge discovery environment. In fact, they are harmful since from the data mining point of view, we are interested in the frequency with which objects occur (Adriaans & Zantinge, 1996). In the following, we discuss two main problems associated with the knowledge discovery in the operational relational databases, namely, the possibility of discovering incorrect and incomplete knowledge.

INCORRECT KNOWLEDGE DISCOVERY FROM RELATIONAL DATABASES

In general, summary data (aggregation) is never found in the operational environment. Without discovery process on summary data, we may discover incorrect knowledge from detailed operational data. Discovering rules based just on current detail data may not depict the actual trends on data. The problem is that statistical significance is usually used in determining the interestingness of a pattern (Giarrantanto & Riley, 1989). Statistical significance alone is often insufficient to determine a pattern's degree of interest. A "5% increase in sales of product X in the Western region", for example, could be more interesting than a "50% increase of product X in the Eastern region". In the former case, it could be that the Western region has a larger sales volume than the Eastern region; thus its increase translates into greater income growth.

The following example (Matheus, Chan & Piatetsky-Shapiro, 1993) shows that we could discover incorrect knowledge if we only look at the detailed data. Consider Table 1, where the goal of discovery is to see if product color or store size has any effect on the profits. The data are not large, but they show the points.

Assume we are looking for patterns that tell us when profits are positive or negative. We should be careful when we process this table using discovery methods such as simple rules or decision trees. These methods are based on probabilities that make them inadequate for dealing with influence within aggregation (summary data). A discovery scheme based on probability may discover the following rules from Table 1:

Table 1. Sample sales data

Product	Product Color	Product Price	Store	Store Size	Profit
Jacket	Blue	200	S1	1000	-200
Jacket	Blue	200	S2	5000	-100
Jacket	Blue	200	S3	9000	7000
Hat	Green	70	S1	1000	300
Hat	Green	70	S2	5000	-1000
Hat	Green	70	S3	9000	-100
Glove	Green	50	S1	1000	2000
Glove	Blue	50	S2	5000	-300
Glove	Green	50	S3	9000	-200

- Rule 1: IF Product Color = Blue Then Profitable = No CF = 75%
- Rule 2: IF Product Color = Blue and Store Size > 5000 Then Profitable = Yes CF = 100%

The results indicate that blue products in larger stores are profitable; however, they do not tell us the amounts of the profits which can go one way or another. Now, consider the modified table, where the third row in Table 1 is changed for the Profit to be 100 instead of 7000. Rules 1 and 2 are also true in the modified table. That is, from a probability point of view, Table 1 and the modified one produce the same results.

However, this is not true when we look at the summary tables (product color = Blue, Profit = 6400, based on Table 1) and (product color = Blue, Profit = -500, based on modified Table 1). The former summary table tells us that Blue color product is profitable, and the latter summary table tells us it is not. That is, in the summary tables, the probability behavior of these detailed tables begins to diverge and thus produce different results. We should be careful when we analyze the summary tables since we may get conflicting results when the discovered patterns from the summary tables are compared with the discovered patterns from detailed tables. In general, the probabilities are not enough when discovering knowledge from detailed data. We need summary data as well.

INCOMPLETE KNOWLEDGE DISCOVERY FROM RELATIONAL DATABASES

The traditional database design method is based on the notions of functional dependencies and lossless decomposition of relations into third normal forms. However, this decomposition of relations is not useful with respect to knowledge discovery because it hides dependencies among attributes that might be of some interest. To provide maximum guarantee that potentially interesting statistical dependencies are preserved, knowledge discovery process should use the universal relation (Parsaye et al., 1991) as opposed to normalized relations in order to reveal all the interesting patterns.

Consider the relations Sales (Client Number, Zip Code, Product Purchased) and Region (Zip Code, City, Average House Price) (Adriaans & Zantinge, 1996) which are in third normal form. The relation Sales-Region (Client Number, Zip Code, City, Average House Price, Product Purchased) shows the universal relation which is the join of the two tables, Sales and Region. From the universal relation, Sales-Region, we may discover that there is a relationship between the Average Price of the House and the type of Products Purchased by people. Such relationship is not that obvious on the normalized relations.

One possible scheme for validating the completeness/incompleteness of the discovered knowledge is to analyze the discovered rules (known as statistical dependencies) with the available functional dependencies (known as domain knowledge). If new dependencies are generated that are not in the set of discovered rules, then we have an incomplete knowledge discovery. For example, processing the Sales relation, we may discover that if Zip Code = 11111, then Product Purchased = Wine with some confidence. We call this a statistical dependency that indicates that there is a correlation (with some confidence) between the Zip Code and the Product Purchased by people. Now, consider the Region relation, where the given dependencies are Zip Code —> City and City —> Average House Price which gives the derived new functional dependency Zip Code —> Average House Price due to the transitive dependency. By looking at the discovered statistical dependency and the new derived (or a given dependency in general), one may deduce that there is a relationship between the Average House Price and the Product Purchased (with some confidence). If our discovery process does not generate such a relationship, then we have an incomplete knowledge discovery that is the consequence of working on normalized relations as opposed to universal relations.

KNOWLEDGE DISCOVERY FROM SUMMARY DATA

In knowledge discovery, it is critical to use summary tables to discover patterns that could not be otherwise discovered from operational detailed databases. Summary tables have hidden patterns that can be discovered. For example, a summary table (Product Color, Profit) based on Table 1 tells us that Blue products are profitable. Likewise, a summary table (Product, Profit) based on Table 1 tells us that Hat products are not profitable. Such discovered patterns can complement the discoveries from the detailed data (as part of the validation of the discovered knowledge).

Accurate knowledge, however, cannot be discovered just by processing the summary tables. The problem is that the summarization of the same data set with two summarization methods may produce the same or different results. Therefore, it is extremely important that the users be able to access metadata that tells them exactly how each type of summarized data was derived so that they understand which dimensions have been summarized and to what level. Otherwise, we may discover inaccurate patterns from different summarized tables. For example, based on summary tables from Table 1, it is the Green Hat in small stores (Store Size <= 1000) that makes profit, and it is the Green Hat product in large stores (Store Size > 1000) that loses money. This fact can only be discovered by looking at all different summary tables and knowing how they are created (i.e., using the metadata).

VALIDATING POSSIBLE INCORRECT RULES

It is possible to use the patterns discovered from the summary tables to validate the discovered knowledge from the detailed tables. The following cases are identified for validating possible incorrect/correct discovered rules.

- Case 1: If the discovered pattern from the summary tables completely supports the discovered knowledge from the detailed tables, then we have more confidence in the accuracy of the discovered knowledge.

- Case 2: The patterns discovered from the detailed and summary tables support each other, but they have different confidence factors. Since the discovered patterns on the summary tables are based on the actual values, they represent more reliable information compared to the discovered patterns from the detailed tables which are based on the occurrences of the records. In such cases, we cannot say that the discovered pattern is incorrect, but rather it is not detailed enough to be considered as an interesting pattern. Perhaps, the hypothesis for discovering the pattern has to be expanded to include other attributes (i.e., Product or Store Size or both) in addition to the Product Color.
- Case 3: The patterns discovered from the detailed and summary tables contradict each other. The explanation is the same as the one provided for Case 2.
- Case 4: There are cases where the discovered knowledge from summary tables is based on statistical significance. If the discovered knowledge from detailed and summary tables support each other with a different confidence factor, then additional information from other sources (perhaps from domain expert, if possible) is needed to verify the accuracy of the discovered knowledge.

KNOWLEDGE DISCOVERY FROM HISTORICAL DATA

Knowledge discovery from operational/detailed or summary data alone may not reveal trends and long-term patterns in data. Historical data should be an essential part of any discovery system in order to discover patterns that are correct over data gathered for a number of years as well as the current data. For example, we may discover from current data a pattern indicating an increase in students' enrollment in the universities in the Washington, DC area (perhaps due to good Economy). Such pattern may not be true when we look at the last 5 years of data.

Using Historical Data for Knowledge Discovery

There are several schemes that could be identified in using historical data in order to detect undiscovered patterns from detailed and summary data and to validate the consistency/accuracy/completeness of the discovered patterns from the detailed/summary data.

1. Validate discovered knowledge from detailed/summary data against historical data

We can apply the discovered rules from detailed and/or summary data to the historical data to see if they hold. If the rules are strong enough, they should hold on the historical data. A discovered rule is inconsistent with the database if examples exist in the database that satisfy the condition part of the rule, but not the conclusion part (Giarranttanto & Riley, 1989). A knowledge base (i.e., set of discovered rules from detailed and summary data) is inconsistent with the database if there is an inconsistent rule in the knowledge base. A knowledge base is incomplete with respect to the database if examples exist in the database that do not satisfy the condition part of any consistent rule.

If there are inconsistent rules, that means we have some historical data that contradict the rules discovered from detailed/summary data. It means we may have anomalies in some of the historical data. This is the case where any knowledge from external data, domain expert, and/or domain knowledge could be used to verify the inconsistencies. Similarly, if we have incomplete knowledge base, then there are some historical data that could represent new patterns or some anomalies. Again, additional information (i.e., domain expert) is necessary to verify that.

2. Compare the rules discovered from detailed/summary data with the ones from historical data

We perform the knowledge discovery on the historical data and compare the rules discovered from the historical data (call it H_RuleSet) with the ones discovered from detailed/summary data (call it DS_RuleSet). There are several possibilities:

a. If H_RuleSet ∩ DS_RuleSet = Æ Then, none of the rules discovered from detailed/summary data hold on the historical data.
b. If H_RuleSet ∩ DS_RuleSet = X Then
   - If DS_RuleSet - X = Æ Then, all of the rules discovered from detailed/summary data hold on the historical data.
   - If X Ì DS_RuleSet Then, there are some rules discovered from detailed/summary data that do not hold on the historical data (i.e, N_RuleSet - X). We can find the data in the historical data that do not support the rules discovered from the detailed/summary data by finding the data that support the rules in N-RuleSet and subtract it from the entire historical data. This data can then be analyzed for anomalies.
c. If H_RuleSet - DS_RuleSet != Æ (or DS_RuleSet Ì X) Then, there are some rules discovered from historical data that are not in the set of rules discovered from the detailed/summary data. This means we discovered some new patterns.

CONCLUSION AND FUTURE TRENDS

Current research in knowledge management involves the tools and techniques to acquire the tacit knowledge from the domain experts. We presented an approach for the automatic acquisition of some tacit knowledge from the implied knowledge that may be presented in the organizations' data warehouses. There are several issues/concerns that need to be addressed before we could have an effective knowledge discovery process. One major issue is the size of the data warehouses. The larger a warehouse, the richer its patterns would be. However, after a point, if we analyze too large a portion of a warehouse, patterns from different data segments begin to dilute each other, and the number of useful patterns begins to decrease (Parsaye, 1996). We could select segment(s) (i.e., a particular medication for a disease) from data that fits a particular discovery objective. Alternatively, data sampling can be used to foster data analysis. However, we lose information because we throw away data not knowing what we keep and what we ignore. Summarization may be used to reduce data sizes; although, it can cause problem too, as we noted.

In automatic discovering of implied knowledge from data warehouses, there is definitely some tacit knowledge that can be discovered and verified by experts. However, we may find some implied knowledge that may not be verifiable, as even the experts do not know the truth of the discovered knowledge. The significance and interestingness of such knowledge may become apparent in the future after the discovered knowledge is actually used in the organization.

Chapter 3.17
Strategically-Focused Enterprise Knowledge Management

Robert J. Mockler
St. John's University, USA

Dorothy G. Dologite
Baruch College, USA

INTRODUCTION

Many of the knowledge management systems, such as the ones described in this entry, were originally computer information systems to which were added knowledge expertise that complemented the information and data communicated. As use of the Internet expanded and intranets within companies were developed, many new knowledge expertise exchange systems were established. As seen in the following discussions, many knowledge systems are therefore mixed, that is, integrated with traditional information and decision support systems, as at the consulting firm, while many, such as Xerox's, focus specifically on expertise knowledge storage and transfer and so can be designated focused knowledge management systems. Expert knowledge-based systems generally are pure knowledge systems (Mockler, 1992; Mockler & Dologite, 1992).

BACKGROUND

Narrowly defined, knowledge refers to practical skills or expertise gained from actual experience. In practice, however, knowledge management generally refers to the process of identifying and generating, systematically gathering, organizing and providing access to, and putting to use anything and everything that might be useful to know when performing some specified business activity. The knowledge management process is designed to increase profitability and competitive advantage in the marketplace.

As seen in the Key Terms section at the end of this article, since the knowledge management process involves keeping informed about and getting to know anything useful to doing a business task, the process can encompass data, information, and knowledge. Further, the knowledge management process can involve employing any useful and practical means of communication and storage, manual or electronic. Useful manual means might include: service manuals; professional publications; personal correspondence and conversations; special studies and reports; client correspondence and summaries; competitor role-playing; sales force feedback; current news; supplier feedback; and the like. Useful computer-based electronic technologies might include: e-mail; hierarchical, network, and relational databases and data warehouses; group decision support systems; Lotus Notes; intranets and Internet Web sites; browsers and search engines; expert and knowledge-based systems; and the like.

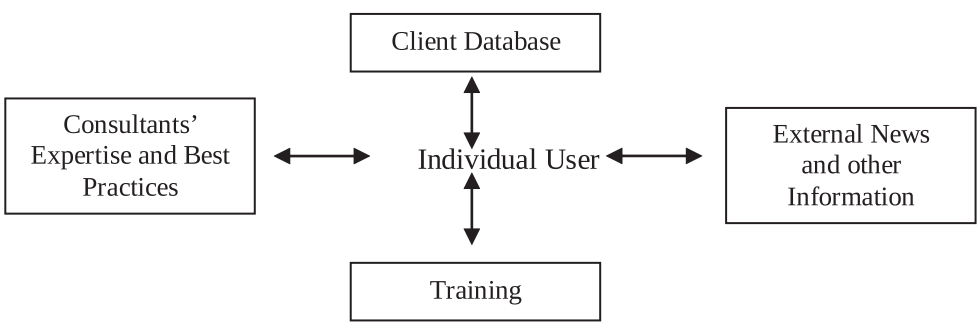
Because of the wide range of concepts and activities involved, the term knowledge management can more easily be understood by examples. Figure 1 outlines the knowledge management system (KMS) at a large consulting firm (Engoron, 1998).

The strategic focus is the individual consultant who needs access to data, information, and knowledge in order to do his/her job. Since consulting is its business, the system is strategic. The system provides this access in large part electronically.

At the top of Figure 1 is a large computer database of information about clients, covering past assignments, consultants who worked on the assigned projects, outcomes, organized data on the company involved, and contacts who can provide further information. On the right, there is a system incorporating expert knowledge-based systems that scans news media and library resources daily and daily directs relevant intelligence material to different consultants. On the left is a database of consultants' expertise or knowledge including that acquired from experience during past assignments. This includes written summaries of what was learned from the assignments, videos in which consultants describe the highlights of their experiences or general knowledge, and contingent best practices guidelines in different areas (such as strategic alliances, all marketing and production areas, human resources management, and the like). At the bottom, there is available a bank of online training programs, which a consultant can make use of (privately) to sharpen skills needed to improve job performance.

On any given day that a consultant receives a new assignment, he/she could immediately review current relevant information in the media (intelligence) about the client and project area, gather information quickly about the client and past assignments involving the client, review the related knowledge expertise of other consultants, and brush up on needed skills. At the same time, the consultant would make use of any relevant personal knowledge sources. The system is a good

Figure 1. Knowledge management system at a major consulting firm



example of using a knowledge system to strategically manage resources; that is, of a strategic management knowledge system.

Not all knowledge management systems are that complex or that multidimensional in scope. Some are narrowly focused on single activities. For example, Xerox in 1996 developed Eureka, an intranet communication system linked with a traditional corporate computer database that helps service representatives share repair tips; that is, knowledge. To date, more than 500 tips have been entered by Xerox technicians, and this practical knowledge is available to all via their laptops. For employees scattered around the world who travel often, the ability to share such know-how means they do not have to miss out on the kind of knowledge typically exchanged at the water cooler (Hickens, 1999).

A number of key characteristics of knowledge management can be identified from company experiences. These can apply to strategic and operational knowledge systems. First, the types of knowledge management systems vary considerably depending on the company situation requirements, a contingency perspective. Second, knowledge generation involves identifying knowledge relevant to strategic business activities, as well as its source and the way it is used or exploited. Third, structuring refers to designing knowledge management systems to capture and deliver the knowledge generated; such structures can range from simple ones involving individual business process areas, as at Xerox, to multidimensional complex enterprise-wide ones, as at the consulting firm. Their content can involve any company activity/business process or combination of them. Fourth, diffusing or communicating any type of relevant data, information, or knowledge involves transferring and absorbing knowledge to put it to work. In the company experiences studied, the main means of diffusion was electronic and audio/video tools. Knowledge is also very often continually transferred and absorbed informally through personal interaction.

Due to the complexity of knowledge management systems, they are best defined by a description of their characteristics, as discussed previously.

ENTERPRISE-WIDE KNOWLEDGE MANAGEMENT SYSTEMS

This section begins by describing a range of systems in use by businesses followed by a discussion of the contingent situation requirement factors of knowledge management systems. This section then continues with discussing the impact of these factors and others on KMS developments as well as their implementation and use in such areas as: knowledge generation and selecting or developing strategic structure, content, and design of the system

Company Examples

The Ford Motor Company case provides an example of how at a large firm the company-wide strategic knowledge systems are closely linked to and dependent on computer information systems (Austin, 1997, 1999). As part of an integration program in the early 1990s, computer information systems at Ford were standardized across the company, which enabled installation of an external Internet network – extranet – with appropriate Web sites linking Ford with its suppliers and with its customers. Most of these were used initially for communication of information on available models, prices and availability of supplies, and other information (that is, targeted organized data). It also enabled development of an internal company intranet system, which also focused mainly on information conveyance initially.

The system also, however, served as a basis upon which to develop broader, more strategic knowledge systems. For example, in the design area, as auto design and development facilities were more closely coordinated worldwide, knowledge about solving design problems and inconsistencies could now be resolved using the intranet, a knowledge exchange process based on experiential expertise. Knowledge about lessons learned from experience in other business process areas, such as manufacturing, could also now be exchanged, since a worldwide system with Web sites was in place.

Complex strategic knowledge management systems can also focus on critical business activity areas. For example, strategic alliances are extremely important to multinational companies today (Mockler, 1999; Sparks, 1999). They involve, however, complex human and business processes whose management requires in-depth expertise gained from experience. Capturing this developing knowledge base is a knowledge management activity. As a company undertakes alliances and begins learning from successes and failures, leaders in alliance management within a company emerge. These leaders, who are essentially gurus with experience and knowledge gained from experience, are the firm's initial imbedded alliance expertise capability. This initial experiential expert knowledge base in successful firms is extended in several ways. First, formal processes and procedures and a staff capable of managing alliance processes are developed. This is the initial knowledge depository for future use. The steps taken to collect, store, and disseminate this knowledge and to train people in order to further institutionalize alliance capabilities vary at different firms (Harbison & Pekar, 1997a, b, c).

Hewlett-Packard (H-P), for example, found that general seminars for managers on alliances were not enough. Managers needed H-P specific information on the best practices guidelines developed from H-P alliance experiences. A database of case histories, tools kits, checklists, and best practices was, therefore, developed and incorporated into training seminars. This database material was supplemented with studies of the best practices of other companies (Harbison & Pekar, 1997a, b, c).

In general, such a knowledge database would include a specific company's experiences with each of its alliance partners in each of the applicable best practices guidelines areas, areas that are outlined in alliance guidebooks (Mockler, 1999). These areas include strategic planning, negotiation, alliance structures and contracts, operational planning and management, and control. Companies such as Ford, IBM, and Dun & Bradstreet, are in various stages of creating such company-specific database repositories; most often these are mixed systems – using computers and other approaches, as for example at H-P. The alliance knowledge bases are Web sites that are accessible from laptop computers by consultants or service personnel at clients' offices (Harbison & Pekar, 1997a, b, c).

As part of their strategic knowledge management systems, dissemination of this knowledge is usually supplemented through seminars and workshops. BellSouth, for example, has offered a two-day alliance workshop for 150 senior managers, a major means of developing personal information networks to encourage ongoing knowledge dissemination. H-P has conducted 50 two-day seminars on alliances for its top 1000 executives prior to 1999 (Harbison & Pekar, 1997a, b, c).

Contingent Solution

As seen from the company experiences described, KM is a contingent process. While it is stimulating and useful to study the different approaches of other so-called models, the final solution will be the one that meets specific situation requirements factors, such as:

- The company's size and nature of its business.
- The company's competitive position.
- The type of business activity(ies) supported.
- The knowledge used for strategic aspects of the business activities targeted.

- The type of knowledge.
- The people involved.
- The state of the organization's culture.
- Available company resources.
- The technologies available and needed.

Knowledge Generation

Knowledge comes from inside and outside the organization. The main criteria are whether and how it is useful in making business activities and processes more effective and efficient (Moore, 1999). Its source – whether created from scratch or borrowed – is a secondary consideration. For example, some companies have an award for the best stolen idea! Five methods of generating knowledge can be identified: acquisition; dedicated resources; fusion; adaptation; and knowledge networking.

Knowledge can be acquired in many ways – for example, through strategic alliances, acquisitions of patents or other companies, engaging consultants, outsourcing research and development, and hiring experts. While each of these sources is useful, additional steps are needed to assimilate acquired knowledge into existing organizations.

Dedicated resources were established at H-P to preserve and transmit company knowledge about strategic alliances. H-P also set up a permanent knowledge system designed to preserve and transmit knowledge to targeted users in a systematic continuing way. This is referred to as institutionalizing or imbedding knowledge within a company.

Fusion involves bringing together people of different perspectives to create new synergies. Sometimes referred to as creative chaos, such interactive collaboration is often needed to create new knowledge. There are several guidelines that help make such brainstorming cross-fertilization work: identify key knowledge workers who might be brought together; provide the time and incentives to fuse knowledge; create specific projects and project goals that inculcate attitudes encouraging such working together; reinforce a sharing culture through incentives and leadership.

Adaptation often arises from competitive market pressures, such as when new technologies are invented, competitors introduce new products, and social changes occur. These pressures can drive knowledge generation. Knowledge is also generated by informal self-organizing networks or "webs" within organizations that may over time become more formalized. There exist communities of knowers within organizations, united by common interests or a common professional vocabulary, who talk with each other in person, by phone or through e-mail or groupware – to share knowledge and solve problems, in essence by word-of-mouth. This kind of knowledge is hard to capture systematically, though at times, such as at Xerox, it can be done. Such informal webs can be nurtured through creating common meeting places, allowing time for people to interact, and generally developing a corporate sharing climate.

Developing Strategic Structure, Content, and Design for the System

These initial decisions are dictated by strategic needs. For example, first the needs of strategic operations are identified – as in the consulting operation described earlier or in the strategic alliance area at H-P. Second, the sources of this knowledge – the people and data/information reservoirs – are identified; for example, the consulting firm's partners' experiences in former assignments, the alliance managers' experiences at H-P, and the repair workers' expertise at Xerox. Third, the form it is in and its suitability to available manual and electronic tools. Five different media were used, for example, at the consulting company: video and audio tools, databases, expert systems, e-mail, and personal interviewing. These were supplemented by personal interaction webs. H-P's system included a variety of electronic and manual approaches in their system, which combined training and computer techniques in a much different way. Fourth, not all knowledge is easily systematically stored, transmitted, and absorbed; for example, knowledge involving planning in rapidly changing markets often requires tacit intuitive knowledge that is not readily articulated and codified. For this segment of a KMS, personal networking or expert systems may be more useful. In contrast, repair procedures learned from experience can be codified, as at Xerox.

Davenport (1997) has described the structure of a KMS at Monsanto. Monsanto's knowledge management architecture system aimed to allow the firm's 30,000 employees to share knowledge and information. In making global knowledge locally available, Monsanto was mimicking GE's strategic posture: combining the knowledge benefits of a large firm (quantity and diversity) with the benefits of a small one (accessibility to knowledge).

As for the system's structure, in classifying existing knowledge and information a distinction was made between quantitative structured content and relatively unstructured qualitative content. Different tools were used to store and manipulate each kind: relational databases with desktop access through appropriate query software for structured material; Web pages and Lotus Notes for unstructured material. This avoided distortions arising from forcing unstructured material into an artificially rigid structure.

The system also provided definitions of key terms, such as "customer," "product" and "material," a necessary step in organizing intellectual material into a single system. Such common definitions were also necessary common ground for communicating and sharing knowledge across boundaries, but they had to be limited to only the most necessary terms, since some local truths and nuances can be lost during the standardization process. Gatekeepers were charged with continually refining this aspect of the system, as well as with organizing and identifying the most important aspects. A large body of material randomly assembled could be counterproductive; editing was needed, as were clearly defined paths to needed knowledge. All of the major systems examined have such gatekeepers and facilitators.

FUTURE OUTLOOK AND CONCLUSION

As discussed in this article, the current and future success of KMS is and will be highly dependent on the strategic fit of structure and content with strategic requirements or critical success factors in the situation. The success of knowledge management also depends and will continue to depend on the participation of people sharing their knowledge expertise with others, which in turn can depend on the way the system is designed, implemented, and managed (the operational fit), as well as on the degree to which a firm has a "learning" organization culture (Lucier & Torsilieri, 1997). Nurturing this sharing culture in the future will require very active leadership by a knowledge management champion, since very often people are reluctant to share their expertise (Manchester, 1999b).

Chapter 3.18
Mentoring Knowledge Workers

Ciara Heavin
National University of Ireland, Cork, Ireland

Karen Neville
National University of Ireland, Cork, Ireland

INTRODUCTION

In an economic environment where organizations have been forced to take a step back and reevaluate their core competencies and ability to innovate, organizational knowledge has come to the forefront as a valuable strategic asset (Haghirian, 2003). While the concept of knowledge management (KM) is not new, the focus on knowledge management as a strategy has increased in recent times as organizations realize the importance of knowledge as an intangible asset contributing to the enhancement of competitive advantage (Bolloju, 2000). In the 21st century, it is believed that successful companies are those that effectively acquire, create, retain, deploy, and leverage knowledge (Cecez-Kecmanovic, 2000). Knowledge work is the ability to create an understanding of nature, organizations, and processes, and to apply this understanding as a means of generating wealth in the organization (Boland & Tenkasi, 1995). Evidently, the focus on knowledge management as a strategy has become central to organizations (Davenport & Prusak, 1998). Ichijo, Von Krogh, and Nonaka (1998) view knowledge as a resource that is unique and imperfectly imitable, allowing firms to sustain a competitive advantage. Additionally, knowledge management as a formalized organizational strategy is supported; it should not be left unintentional to become unsystematic and random (Ichijo et al.). This article provides an example of knowledge workers and experts collaborating to implement successful training and learning programmes to support knowledge-management activities in their organization. The authors hope that the case discussed will inform researchers of an appropriate model in designing an interactive learning environment that enables a positive knowledge-sharing environment and in turn contributes to the growth of an organization's memory.

BACKGROUND

The intensity of competition in the business market, advances in technology (Crossman, 1997), and a strong shift toward a knowledge-based economy have each contributed to the demand for Web-based mentoring systems (WBMSs). According to Emerson (1843), "There is no knowledge that is not power," and the organization (public or private) that can utilize its knowledge resources more effectively than its competitor will persevere (Laudon & Laudon, 1998). An effective mentoring system between knowledge workers and experts can provide an organization with a strategic advantage in the market (Benjamin & Blunt, 1993). Mentoring environments can help create and maintain skills and, therefore, the corporate knowledge base (Garvin, 1993). They both alleviate the strain on corporate resources and facilitate employees' changing training needs (Driscoll, 1998) through knowledge sharing. Therefore, the majority of organizations face the enormous challenge of supporting their employees' thirst for expanding their skill bases and corporate assets effectively as "[k]nowledge implies a knower; the rest is just information." In the case under consideration in this article, the organization implemented a successful mentoring system in order to develop employee skills and knowledge in both IT and managerial issues such as knowledge management. This article is focused on the development of a Web-based mentoring system to mentor workers and enhance learning (Neville, Adam, & McCormack, 2002). The case study indicates a strong requirement for the utilization of such an environment to both increase support for and collaboration between the knowledge workers.

MAIN FOCUS OF THE ARTICLE

Mentoring is a traditional method of teaching that strengthens the concept and objectives of learning and training (Benton, Elder, & Thornbury, 1995). The Oxford dictionary defines the word mentor as a "wise counselor, who tutors the learner in intellectual subjects..." When this model is applied to a learning network, the student is called a teleapprentice who studies using appropriate methods (Levin, 1990). The teleapprentice reads messages, answers questions, participates in discussions, and conducts research online to master his or her subject. Mentorship is a method of teaching that has been used for hundreds of years; this design is incorporated into learning and knowledge networks to develop more effective learning and collaborating practices (Eisenstadt & Vincent, 1998), and to provide additional support and mediation to the learners and workers (Alexander, 1995). Access to experts is one of the many advantages provided through learning networks (Harasim, 1995). Networks are, in fact, modeled on this method (Harasim, Hiltz, Teles, & Turoff, 1995). Therefore, WBMSs allow students and workers to communicate with experts in a field and collaborate with their peers (Crossman, 1997; Dick & Reiser, 1989). WBMSs can be described as learning delivery environments in which the World Wide Web (WWW) is its medium of delivery (Crossman, 1992; Driscoll, 1998; Neville et al., 2002). The possibilities of WBMSs are limited only by constraints imposed by the university or organization in question, such as technological or managerial support (Neville, 2000). Innovative companies and universities are using this implementation for a number of reasons, specifically to keep employees or students abreast of emerging technologies in their fields and to provide effective training to both staff and customers on new products and skills (Khan, 1997). Designing a WBMS requires a thorough investigation into the use of the Web as a medium for delivery (Driscoll; McCormack & Jones, 1997; Ritchie & Hoffman, 1996). The designer must be aware of the attributes of the WWW and the principles of instructional design to create a meaningful support environment (Driscoll; Gagne, Briggs,

& Wagner, 1988). The Web-based training room is viewed as an innovative approach to teaching (Relan & Gillani, 1997). The virtual training room, like the traditional method, requires careful planning to be both effective and beneficial (Dick & Reiser). As stated by McCormack and Jones, a Web-based classroom must do more than just distribute information. It should include resources such as discussion forums to support collaboration between learners and ultimately it should also support the needs of both the novice and advanced learner (Sherry, 1996; Willis, 1995). A WBMS is composed of a number of components that are integral to the effective operation of the environment (Banathy, 1992), for example, for the development of content and the use of multimedia, Internet tools, hardware, and software (Reeves, 1993). A developer must understand the capabilities of these components (search engines, feedback pages, and movie clips) as their use will determine the success or the failure of the learning environment (Driscoll). In this article, we provide an example of a WBMS to help illustrate the main elements, issues, components, and problems encountered through the implementation of learning systems to enhance knowledge management in organizations.

The WBMS (Figure 1) was constructed to support and develop knowledge sharing for personnel who seek to acquire and develop their knowledge-management skills. Training material is available online, but in addition, a discussion forum enables both learners and experts to exchange ideas and add to the environment. This allows learners to provide feedback (anonymously, if desired) to the experts. It also enables them to pose queries, which other participants or the experts can answer. All participants are able to see the initial queries and the discussion stream of answers from other participants and the instructors. This further extends the reach of the training material as employees can log on to the WBMS at home or at work and pose questions for which answers are available when they next log on. The facility also allows the learners to voice their satisfaction regarding the different elements of the environment. This provides the participants with the opportunity to take part in the ongoing design of the WBMS, and therefore increases user acceptance.

Figure 1. The Web-based mentoring system

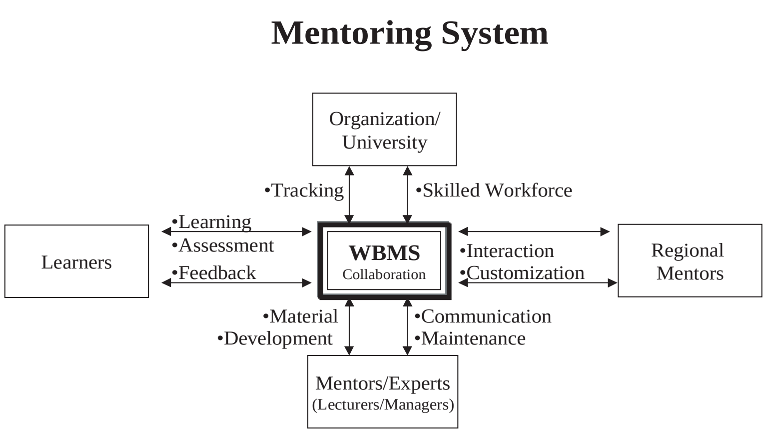

Figure 1 illustrates the opportunities available to the participants of the case. The system provides professional training to a range of employees including full-time staff at all levels and senior management. Its core aim is to further develop the knowledge and abilities of personnel so that they are increasingly aware of IT and management issues within the organization with a particular focus on capturing, storing, disseminating, and creating knowledge. The course is designed on a distance learning basis and is supported by a tutorial system. The main purpose of the tutorials is to facilitate the learning process, assist in the completion of interactive assignments, and encourage team playing within the group. Learners are presented with written modules, which act as the lecture, and the expert plays the role of the facilitator, enabling the students to combine the written materials with their own experiences. Feedback from the students identified the need to provide additional learning support through an online environment. The WBMS has provided an improved learning process and has enabled enhanced collaboration among employees. This article focuses on the development of these requirements through an interactive learning environment for employees, and on the fact that the WBMS is designed or customized for the requirements of the individual learner. This approach accounts for the varying learning abilities of students and overcomes the limitations of traditional training environments that are restricted to rules in order to adequately facilitate the group. The educator or expert instructs a class, but the level of collaboration and the development of problem-solving skills can be directly correlated to class sizes. The greater the size of the group, the less attention individual learners gain or the more intimidated a student is to participate in discussions, thus reducing collaboration. The WBMS, when adequately designed, can reduce the limitations of the classroom and allow the learner to work at his or her own pace with structured support from both the educators and the other learners.

DESIGN CONSIDERATIONS

Web-based learning is regarded as a silver-bullet solution to training issues faced by organizations, therefore it is essential to define the characteristics of interactive education that can be achieved through the WWW and to expand the Web-based mentoring concept to promote learning. The identification of these characteristics is necessary to implement such a concept. Thus, this section reviews 10 dimensions proposed by Reeves and Reeves (1993) for interactive training and collaboration: (a) the educational philosophy, (b) the learning theory, (c) the goal orientation, (d) the task orientation, (e) the source of motivation, (f) the role of the teacher, (g) metacognitive support, (h) collaborative learning, (i) cultural sensitivity, and (j) structural flexibility. The dimensions are proposed to describe the characteristics of a WBMS. Each of the dimensions identified is outlined in the following paragraphs:

1. Educational philosophy emphasizes the belief that learners build their cognitive strategies on previous knowledge and on the learning environment. Therefore, a rich and stimulating environment is required to train different adult learners. Thus, direct instruction is also replaced with challenging tasks.
2. The design of the environment should be based on researched learning theories. The two dominant theories identified in the design of training environments are behavioral and cognitive psychology. Behaviorists believe that the most important factors that should be taken into consideration are the arrangement of stimuli, responses, feedback, and reinforcement to shape the desirable behavior of the learners. By contrast, cognitive psychologists place more emphasis on internal mental states rather than on behavior. As a result, the WBMS design,

using cognitive theory, will be based on direct instruction and practice exercises.

3. The goals for a WBMS can vary from being sharply focused, where a specific environment is required, to a having a more general approach.
4. The orientation of tasks can range from being academic to authentic. As an example, an authentic design for adult education would require the learners to tackle job-related exercises or cases (tacit knowledge). The design orientation of a WBMS should support the transfer of skills to the learners.
5. Motivation is the main factor for the success of any learning environment. The source of motivation ranges from two extremes: from the extrinsic (outside the learning environment) to the intrinsic (a part of the learning environment).
6. Lecturers and tutors fulfill different roles, from the traditional role of instructor (didactic) to the facilitative role.
7. Flavell (1979) described metacognition as the learner's ability to identify objectives, and plan and understand learning strategies. Thus, a WBMS can be designed to challenge the learner to solve course-related problems (Driscoll, 1998).
8. The collaborative learning dimension for a WBMS can also range from a lack of support to the inclusion of facilities to support it.
9. Reeves and Reeves (1993) argue that all training environments have cultural implications. However, the development of a WBMS cannot be designed to adjust to every rule. Therefore, a WBMS should be designed to be as culturally aware as possible.
10. Structural flexibility describes a WBMS as either asynchronous or synchronous (Driscoll, 1998). Open or asynchronous environments refer to the use of such an environment at any particular time or from any location. However, synchronous environments refer to fixed environments that can only be used in the training room of an organization. The WWW provides educators and students alike with the opportunity to avail of resources from more open environments through which students are supported or mentored in the acquisition of both tacit and explicit knowledge.

The dimensions were used as an aid in the production of the generic WBMS (see Figure 1). Both the study of the different dimensions and the factors necessary for the collaboration and structure of learning provide valuable information and steps for the analysis, and therefore the development, of the solutions.

FUTURE TRENDS

Knowledge workers have praised the hands-on approach provided through this expert-driven system. As knowledge sharing has increasingly become a key organizational objective, this type of environment provides an extensive communication channel leveraging technology to support a wide variety of knowledge-sharing activities. It also enables the experts and learners to collaborate, therefore providing 24-hour online support. This case is a prime example of a successful KM-support tool that can and will continue to avail of technological advances to ensure ongoing success. Further research exploring the various pedagogy and technology mixes to produce a set of options, which would identify the integration of a particular pedagogy with an appropriate technology, would prove beneficial if WBMSs are to meet their full potential. Additionally, the WBMS illustrated in this article is primarily concerned with the downstream development process that incorporates key design and development considerations. Therefore, further research exploring the upstream development process would be worthwhile. This would involve exploring some of the development options that were identified in the development of off-the-shelf packages, and exploring the open-source development option for WBMSs. These further studies may yield interesting results and therefore increase the level of understanding of the development of effective WBMSs.

CONCLUSION

After an in-depth analysis, it was apparent that learners lacked an efficient online support system that would complement alternative communication channels such as face-to-face encounters and traditional training classes as a means of knowledge sharing. An effective KM training-support system can provide an organization with a strategic advantage in the market. Learning environments can help create and maintain skills and therefore increase the corporate knowledge base. They both alleviate the strain on corporate resources and facilitate employees' changing training needs. This article focuses on the design of a suitable environment to support knowledge workers and encourage collaboration. The research outlines the factors necessary for the successful implementation and use of the system. It also highlights the potential of the system to overcome the physical barriers of traditional knowledge-sharing and learning channels. Interactive learning environments can, when properly mediated and structured, facilitate cooperation and enhanced learning practices, reduce conflict, and avail of all of the benefits that technology can provide.

Chapter 3.19
RDF and OWL

Gian Piero Zarri
University of Paris IV/Sorbonne, France

INTRODUCTION

As Web-based content becomes an increasingly important knowledge management resource, Web-based technologies are developing to help harness that resource in a more effective way.

The current state of these Web-based technology—the "first generation" or "syntactic" Web—gives rise to well-known, serious problems when trying to accomplish in a non-trivial way essential management tasks like indexing, searching, extracting, maintaining, and generating information. These tasks would, in fact, require some sort of "deep understanding" of the information dealt with: In a "syntactic" Web context, on the contrary, computers are only used as tools for posting and rendering information by brute force. Faced with this situation, Berners-Lee first proposed a sort of "Semantic Web" where the access to information is based mainly on the processing of the semantic properties of this information: "… the Semantic Web is an extension of the current Web in which information is given well-defined meaning [emphasis added], better enabling computers and people to work in co-operation" (Berners-Lee, Hendler, & Lassila, 2001, p. 35). The Semantic Web's challenge consists then in being able to manage information on the Web by "understanding" its proper semantic content (its meaning), and not simply by matching some keywords.

BACKGROUND

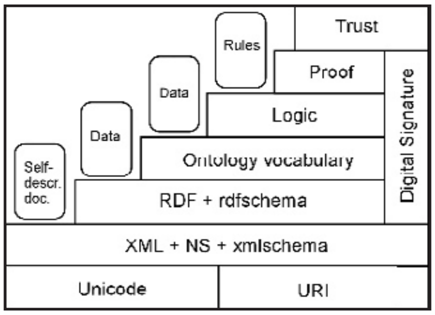
The architecture proposed by Berners-Lee for the Semantic Web is reproduced in Figure 1. "Unicode" and "URI" make up the basis of this hierarchy. The Unicode Standard provides a unique numerical code for every character that can be found in documents produced according to any possible language, no matter what the hardware and software used to deal with such documents. Uniform Resource Identifier (URI) represents a generalization of the well-known Uniform Resource Locator (URL) that is used to identify a "Web resource" (e.g., a particular page) by denoting its primary access mechanism (essentially, its "location" on the network). URI has been created to allow recording information about all those "notions" that, unlike Web pages, do not have network locations or URLs, but that need to be referred to in an RDF statement. These notions include network-accessible things, such as an electronic document or an image, things that are not network-accessible, such as human beings, corporations, and bound books in a library, or abstract concepts like the concept of a "creator."

XML (eXtensible markup language) (see Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2004) has been created to overcome some difficulties proper to hypertext markup language (HTML); this last suffers from a number of limitations, from its lack of efficiency in handling the complex client/server communication of today's applications to the impossibility of defining new tags to customize exactly the user's needs. XML is called "extensible" because, at the difference of HTML, it is not characterized by a fixed format, but it lets the user design its own customized markup languages (a specific DTD, document type description) for limitless different types of documents; XML is a "content-oriented" markup tool. Basically, the syntactic structure of XML is very simple. Its markup elements are normally identified by an opening and a closing tag, like <employees> and </employees>, and may contain other elements or text; the elements must be properly nested and every XML document must have exactly one root element. Markup elements can be specialized by adding attribute/value pairs inside the opening tag of the element, like <person name="Jane">; taking into account the nesting constraint, a very simple fragment of XML document could then be represented as: "<employees> <person name="Jane"> <id>99276</id> </person> </employees>". To allow a computer interpreting correctly a fragment like this, it is necessary, however, to specify the semantics of the markup elements and tags used to make it; a simple way of doing this is to make use of a DTD. A DTD is a formal description in XML Declaration Syntax of a particular type of document: for example, a DTD may specify that every person markup element must have a name attribute, and that it can have an offspring element called id whose content must be text. There are many sorts of DTDs ready to be used in all kinds of areas (e.g., www.w3.org/QA/2002/04/valid-dtd-list.html#full) that can be downloaded and used freely: some of them are MathML (for mathematical expressions), Sync Multimedia Integration Language (SMIL), Chemical Markup Language (CML), Open Software Description (OSD), Electronic Data Interchange (EDI) , Platform for Internet Content Selection (PICS), and so forth. A more complete way of specifying the semantics of a set of XML markup elements is to make use of XML Schema (as mentioned in Figure 1): XML Schema (Thompson, Beech, Maloney, & Mendelsohn, 2001; Biron & Malhotra, 2001) supplies a more complete grammar for specifying the structure of the elements allowing, for example, to define the cardinality of the offspring elements, default values, and so forth.

MAIN FOCUS OF THE ARTICLE: RDF AND OWL

Moving up in the structure of Figure 1, we find now Resource Description Framework (RDF), an example of "metadata" language (metadata = data about data) used to describe generic "things" ("resources," according to the RDF jargon) on the Web. An RDF document is basically a list of statements under the form of triples having the classical format: <object, property, value>, where the elements of the triples can be Universal Resource Identifiers (URIs), literals (mainly, free text), and variables. To follow a well-known RDF example (Manola & Miller, 2004), let us suppose we want to represent a situation where someone named John Smith has created a particular Web page. We will then make use of the RDF triple:

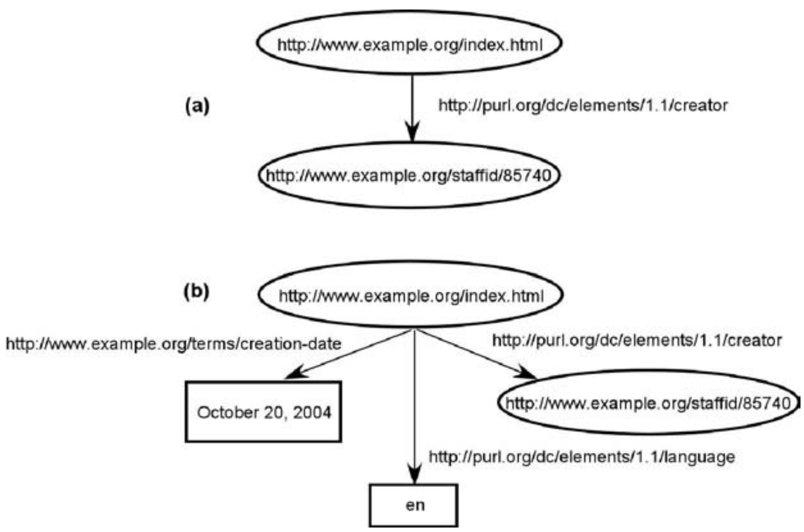
Figure 1. Semantic Web architecture according to Tim Berners-Lee



<http://www.example.org/index.html (object), creator (property), john_smith (value)>. Adding additional information about the situation, by stating, for example, that the Web page was created October 20, 2004, and that the language in which the page is written is English, amounts to add two additional statements: <http://www.example.org/index.html (object), creation_date (property), October 20, 2004 (value)> and <http://www.example.org/index.html (object), language (property), English (value)>. Note that RDF uses a particular terminology for denoting the three elements of the triples, calling then "subject," "predicate," and "object," respectively, the "object," "property," and "value" elements of the triples; this decision is really questionable because it introduces an undue confusion with well-defined and totally different linguistic categories.

RDF triples can be represented as directed labeled graphs, by denoting resources as ovals, properties (predicates) as arrows, and literal values like October 20, 2004 or English within boxes. Figure 2a represents under graph form the original statement: "John Smith has created a Web page"; the addition of information about date and language gives rise to the graph of Figure 2b, given that groups of statements are represented by corresponding groups of nodes and arcs. Note that, to simulate the actual conditions of utilization of RDF, the properties creator, creation_date and language in Figure 2 have been replaced, respectively, by http://pur1.org/dc/elements/1.1/creator, http://www.example.org/terms/creation-date,

Figure 2. RDF statements represented in graph format



and http://pur1.org/dc/elements/1.1/language; analogously, john_smith has been replaced by http://www.example.org/staffid/85740. All these "http://…" terms are URIs that identify in an unambiguous way specific RDF entities; more exactly, they refer to the ontologies/metadata repositories/lists of reserved domain names where these entities are defined. For example, "http://pur1.org/dc/…" refers to the collection of metadata terms maintained by the Dublin Core Metadata Initiative (Dekkers & Weibel, 2003); in this collection, http://pur1.org/dc/elements/1.1/creator is defined as: "An entity primarily responsible for making the content of the resource." The literal en (Unicode characters) is an international standard two-letter code for English, see http://purl.org/dc/elements/1.1/language; the example.org Internet domain name is reserved for documentation purposes.

From what expounded until now, RDF seems to be nothing more than a Internet-oriented, downgraded form of Semantic Networks as they were used in the artificial intelligence domain at the beginning of the 1970s. Its significance in a Semantic Web context becomes more evident when we examine the way of writing RDF statement into XML format – the so-called "RDF/XML syntax" (Beckett, 2004), that is, when RDF is seen as a sort of additional DTD of XML. Table 1 reproduces then the simple example of Figure 2b making use of the RDF/XML syntax.

The first line of the code, <?xml version="1.0"?> is the "XML declaration," which states that what follows consists of XML, and which specifies the version used. In the second line, we find an XML markup element that starts with the tag <rdf:RDF – this tag specifies that all the following XML code, until the </rdf:RDF> tag of the last line, is intended to represent RDF statements – and ends with the '>' symbol at the right limit of line 4. Within this markup element we find three "XML attributes" of the opening <rdf:RDF tag; all these attributes (xmlns attributes) have as values the declarations of the namespaces to be used within the RDF/XML code. An attribute like xmlns:rdf means that, according to the "value" associated with this attribute (after the '=' symbol), all the terms/tags included in this RDF/XML content and prefixed with rdf: are part of the namespace identified with the URI: http://www.w3.org/1999/02/22-rdf-syntax-ns#; analogously for the xmlns:dc (Dublin Core terms) and xmlns:exterms (example terms) attributes.

After these preliminary, "housekeeping" declarations, lines 5 to 9 represent the core of the RDF/XML representation of the example. The rdf:Description start-tag of line 5 indicates that we are now introducing the "description" of a resource; this resource, http://www.example.org/index.html, is identified as the value of the

Table 1. The RDF/XML syntax

```
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:dc="http://purl.org/dc/elements/1.1/"
    xmlns:exterms="http://www.example.org/terms/">
  <rdf:Description rdf:about="http://www.example.org/index.html">
    <exterms:creation-date>October 20, 2004</exterms:creation-date>
    <dc:language>en</dc:language>
    <dc:creator rdf:resource="http://www.example.org/staffid/85740"/>
  </rdf:Description>
</rdf:RDF>
```

rdf:about attribute of the start-tag. The three following lines, 6 to 8, are examples of use of "property element" constructions. In these lines, the tags are built up according to the XML Qname (Qname = Qualified name) convention, which allows shortening the writing of full RDF triples by introducing abbreviations for the URI references. A Qname tag contains, in fact, a "prefix" that denotes a given namespace (e.g., exterms in line 6) followed, after a "colon," by a "local name" (creation-date, i.e., the name of the property); a full URI reference is then created by appending the local name to the URI of the namespace identified by the first part of the Qname. For lines 6 to 8, the full URIs become then http://www.example.org/terms/creation-date, http://purl.org/dc/elements/1.1/Language, and http://purl.org/dc/elements/1.1/creator. Note that the values of the properties corresponding to literals (lines 6 to 7) are directly included within opening and closing Qname tags; for the property of line 8, which corresponds to a resource, the value corresponds to the value of the rdf:resource attribute of the dc:creator Qname tag. The description of the resource introduced in line 5 ends with the closing tag of line 9.

To conclude about RDF, we will note that RDF Schema (RDFS) (Brickley & Guha, 2004) provides a mechanism for constructing specialized RDF vocabularies through the description of domain-specific properties. This is obtained mainly by describing the properties in terms of the classes of resource to which they apply: for example, we could define the creator property saying that it has the resource document as "domain" (document is the value or "object" of this property) and the resource person as "range" (this property must always be associated with a resource person, its "subject"). Other basic modeling primitives of RDFS are used to set up hierarchies, both hierarchies of concepts (i.e., ontologies) thanks to the use of "class" and "subclass-of" statements, and hierarchies of properties thanks to the use of "property" and "subproperty-of" statements. Instances of a specific class (of a specific concept) can be declared making use of the "type" statement.

Passing to the next stage of the structure of Figure 1, "ontologies," we can make three general remarks:

- the basic "nature" of ontologies as described in the article "Knowledge Representation" in this encyclopedia does not change fundamentally in a Semantic Web context: They are still formed by hierarchies (DAGs) of concepts defined through properties and values;
- for their practical implementation, however, these Semantic Web ontologies make a large use of the RDF/XML syntactic/semantic constructs;
- taking also into account that the level that follows "Ontology vocabulary" in the pyramid of Figure 1 is "Logic," the Semantic Web ontologies evidence a very strong logic influence.

On February 10, 2004, the W3C published an official "recommendation" concerning OWL, the Web Ontology Language (Bechhofer et al., 2004); W3C—the World Wide Web Consortium, coordinated by MIT (USA), ERCIM, the European Research Consortium for Informatics and Mathematics, and the Keio University (Japan)—includes all the main bodies on earth interested in the developments of Internet and the Web. At the beginning of this document is stated that: "The Web Ontology Language (OWL) is a semantic markup language for publishing and sharing ontologies on the World Wide Web. OWL is developed as a vocabulary extension of the Resource Description Framework (RDF) and is derived from the DAML+OIL Web Ontology Language…An OWL ontology is an RDF graph, which is in turn a set of RDF triples." The mention of DAML+OIL (McGuinness, Fikes, Hendler, & Stein, 2002) explains the strong logic orientation of OWL, given that Ontology Inference Layer (OIL), the "European" component of DAML+OIL (DAML is the Darpa Agent Markup Language) was implemented in Description Logics (DL) terms—DL (Baader, Calvanese, McGuinness, Nardi, & Patel-Schneider, 2002) have been created to offer, among other things, a formal foundation for frame-based systems.

OWL consists of three subsets (three specific sub-languages) characterized by an increasing level of complexity and expressiveness, OWL Lite, OWL DL (DL stands for Description Logics), and OWL Full.

OWL Lite is the syntactically simplest sub-language; it includes only a reduced subset of the OWL language constructors and has a lower formal complexity than the other OWL versions. It is meant mainly to allow: (1) the implementation of simple classification hierarchies; (2) the familiarization with the OWL approach; (3) the possibility of a quick migration path for existing thesauri/taxonomies and other conceptually simple hierarchies. It employs all the features already introduced by RDFS, making use of the same tags—like rdfs:subclassOf, rdfs:subPropertyOf, rdfs:domain, rdfs:range—with the same semantics. Note that rdfs:subclassOf is the fundamental constructor that is used to set up taxonomies/ontologies in OWL. It relates, in fact, a more specific class (concept) to a more general one; if X is a sub-class of Y, then every instance of X is also an instance of Y. The relation rdfs: subclassOf is transitive: If X is a sub-class of Y and Y is a sub-class of Z, then X is a sub-class of Z. With respect to RDFS, OWL Lite includes several new features:

- Constructors for equality and inequality, for example,owl:equivalentClass,owl: equivalent Property, owl:sameAs (two individuals may be stated to be the same), owl:differentFrom, owl:AllDifferent.
- Constructors used to provide specific information about properties and their values, like owl:inverseOf—for example, stating that the property hasChild is the inverse of the property hasParent, and stating that Mary is endowed with the property (hasParent Lucy), allows then an OWL reasoner to deduce that Lucy is endowed with the property (hasChild Mary)—owl:TransitiveProperty and owl: Symmetric Property.
- Constructors used to impose constraints on the way properties can be used by the instances of a class (concept). They are owl: allValuesFrom and owl:someValuesFrom. For example, owl:allValuesFrom introduces a range restriction, imposing, for example, that the property hasDaughter of the class Person is restricted to obtaining all its values (allValuesFrom) from the class Woman. This allows a reasoner to deduce that, if an individual Lucy is related by the property hasDaughter with the individual Mary, Mary must be an instance of the class Woman.
- Constructors, for example, owl:minCardinality and owl:maxCardinality, used to introduce a limited form of cardinality restrictions, stated on the properties of a particular class, and to be intended as constraints on the cardinality of that property when used in the instances of that class. Note that, for algorithmic efficiency reasons, OWL Lite allows using only the integers 0 and 1 to express the cardinality constraints; this restriction is removed in OWL DL.
- OWL Lite includes a (restricted form) of intersection constructor, owl:intersectionOf, allowing, for example, to state that the class EmployedPerson is the intersectionOf the classes Person and EmployedThings.

OWL DL is much more expressive than OWL Lite and is totally based on Description Logics—this is denoted by the suffix DL. OWL DL makes use of the full set of the OWL constructors, but it also introduces some constraints on their use to give rise to systems that are "complete" (all the possible deductions are computable) and "decidable" (all the computations will be executed in finite time). Mainly, OWL DL implements what is called "type separation," which means that a class (concept) also cannot be an individual or a property, and that a property also cannot be an individual or a class. This restriction is removed in OWL Full. OWL DL adds to the OWL Lite list of constructors some new constructors like owl:oneOf (classes may be described by enumeration of the individuals that make up the class), owl:hasValue (a property is required to have a given individual as value), owl:disjointWith (classes can be described as disjoint from each other, see the classes Man and Woman), owl:unionOf, owl:complementOf, owl:intersectionOf (Boolean combinations of classes), and so forth.

OWL Full is the most expressive of the OWL sub-languages, and should be used in situations where very high expressiveness is particularly important. It is similar to OWL DL but, in the OWL Full case, all the constraints have been suppressed—for example, a class (concept) can be simultaneously treated as a collection of instances (individuals) and as an individual in itself. This can lead to the implementation of systems that are, at least partly, "incomplete" and/or "undecidable": this means that it is not possible to perform automated reasoning on OWL Full hierarchies. Currently, no complete implementation of OWL Full exists.

To give at least a partial picture of the representation of an ontology in OWL format, we reproduce in Table 2 a small fragment of the OWL version of the "wine" ontology, an ontology often used for exemplification's purposes in the Semantic Web milieus (see McGuinness, Fikes, Hendler, & Sten, 2002; Smith, Welty, & McGuinness, 2004). The code in this table can be considered indifferently as OWL Lite, OWL DL, or OWL Full. Note that for simplicity's sake, we have not reproduced in Table 2 and the following the "housekeeping" declarations (see Table 1) that are necessary to identify all the XML namespaces associated with the wine ontology.

In the first line of Table 2, the class Wine is introduced making use of an rdf:ID attribute. At the difference of the rdf:about attribute used in Table 1, rdf:ID introduces as its value only a "fragment identifier" (here Wine) that represents an abbreviation of the complete reference to the URI of the resource being described. The full URI reference is formed by taking the base URI of the wine ontology, for example, http://www.w3.org/TR/2004/REC-owl-guide-20040210/wine, and appending the character # (to indicate that what follows is a fragment identifier) and then Wine to it, giving then the absolute URI reference:

Table 2. A fragment of the OWL wine ontology

```
<owl:Class rdf:ID="Wine">
 <rdfs:subClassOf rdf:resource="#PotableLiquid"/>
 <rdfs:subClassOf>
  <owl:Restriction>
   <owl:onProperty rdf:resource="#madeFromGrape"/>
   <owl:minCardinality rdf:datatype="&xsd;nonNegativeInteger">1</owl:minCardinality>
  </owl:Restriction>
 </rdfs:subClassOf>
 ...
</owl:Class>
```

http://www.w3.org/TR/2004/REC-owl-guide-20040210/wine#Wine. Note that the Wine class can now be referred to by using #Wine; for example, rdf:resource="#Wine" is a well-formed OWL statement. As already stated, the fundamental taxonomic constructor is rdfs:subClassOf; the second line of the code of Table 2 allows the insertion of the class Wine into the global ontology by asserting that it is a specialisation of the class (concept) PotableLiquid (liquid suitable for drinking)—which can be defined, in turn, as a specialisation of the class ConsumableThing.

The third line of the code warns that the class Wine is also a specialisation of a second class: This last is an "anonymous" class, whose definition is included within the opening owl:Restriction markup element in line 4 and ends with the closing /owl:Restriction markup element in line 7. In OWL, in fact, a property restriction on a class is a special kind of class description, that of the anonymous class including all the individuals that satisfy the given restriction. In line 5, the owl:onProperty constructor introduces the name of the property, madeFromGrape, to associate with the class Wine; line 6 specifies that the cardinality of this property is 1. The insertion of this restriction in the definition of Wine states, globally, that every specific wine also must be characterized by at least one madeFromGrape relation. Note that (1) the &xsd;nonNegativeInteger datatype used to introduce the literal 1 in the owl:minCardinality restriction of line 6 is part of the built-in XML Schema datatypes (Biron and Malhotra, 2001): Their use is strongly recommended in an OWL context; (2) the value 1 conforms to the OWL Lite restrictions.

Following (Smith et al., 2004, pp. 11-13), we can now supply, in the upper part of Table 3, the definition of the Vintage class—vintage is a particular wine made in a specific year. The lower part of Table 3 shows how the property vintageOf ties a Vintage to a Wine; the rdfs:domain and rdfs:range features indicate, respectively, that the property vintageOf can only be associated with terms of the Vintage type (e.g., RomaneeConti1998), and that the values of this property can only be specific terms of the Wine hierarchy (e.g., RomaneeConti).

To conclude about OWL, we reproduce in Table 4 another fragment of the wine ontology that makes use of constructors proper to the DL version of the language. The code fragment of Table 4 defines the class RedWine as the precise intersection (logical conjunction, "and") of the

Table 3. Vintage class and vintage of property

```
<owl:Class rdf:ID="Vintage">
 <rdfs:subClassOf>
   <owl:Restriction>
     <owl:onProperty rdf:resource="#vintageOf"/>
     <owl:minCardinality rdf:datatype="&xsd;nonNegativeInteger">1</owl:minCardinality>
   </owl:Restriction>
 </rdfs:subClassOf>
</owl:Class>

<owl:ObjectProperty rdf:ID="vintageOf">
 <rdfs:domain rdf:resource="#Vintage" />
 <rdfs:range rdf:resource="#Wine" />>
</owl:ObjectProperty>
```

Table 4. Use of OWL DL constructors in the context of the wine ontology

```
<owl:Class rdf:about="#RedWine">
 <owl:intersectionOf rdf:parseType="Collection">
  <owl:Class rdf:about="#Wine" />
  <owl:Restriction>
   <owl:onProperty rdf:resource="#hasColor" />
   <owl:hasValue rdf:resource="#Red" />
  </owl:Restriction>
 </owl:intersectionOf>
</owl:Class>
```

class Wine and the set of things that are red in color (anonymous class). The presence of the attribute rdf:parseType="Collection" is mandatory for this type of construction. Note the use of the DL constructor owl:hasValue to impose the value "Red" on the property hasColor of the anonymous class.

FUTURE TRENDS, AND THE IMPLICATIONS FOR KNOWLEDGE MANAGEMENT

Rules—self-contained knowledge units that entail some form of reasoning—are explicitly mentioned in the upper level of the architecture of Figure 1 and are, obviously, an essential prerequisite for a practical utilization of the RDF/OWL data structures. However, rules have not been included in the OWL standard, and they are still a hot topic of discussion in the Semantic Web and W3C milieus.

In RuleML (see Boley, Tabet, & Wagner, 2001), the inferential properties of Prolog/Datalog are associated with an XML/RDF-based rule format—for an introduction to Prolog/Datalog and to their logical support, Horn clauses, see, e.g., Bertino, Catania, and (Zarri, 2001, pp. 112-121, 170-207). The main categories of rules considered in RuleML are the "derivation rules" (i.e., rules used to automatically defining derived concepts), "integrity rules" (constraints on the state space), "reaction rules" (for specifying the reactive behavior of a given system in response to specific events), "production rules" (if-then rules according to the classical expert systems paradigm) and "transformation rules" (used to implement translators between different versions of RuleML, and between RuleML and other rule languages like Jess).

TRIPLE, see (Sintek & Decker, 2002), is a rule language that also follows the logic programming paradigm; its core is based on Horn logic clauses, and it has been syntactically extended to support RDF primitives like namespaces, resources, and RDF triples—these last have given TRIPLE its name. Rules expressed in this core language can be compiled into Horn logic programs and then executed by Prolog inference engines like XSB.

SWRL is a proposal (see Horrocks et al., 2004) based on a combination of OWL DL with the Datalog sub-language of RuleML. Concretely, the proposal extends the set of the OWL axioms to include Horn-like rules, enabling then these rules to be combined with an OWL knowledge base. The rules have the form of an implication between an antecedent (body) and a consequent (head); their meaning corresponds to say that, whenever the conditions specified in the antecedent hold, then the conditions specified in the consequent also hold. Both the antecedent and the consequent consist of zero or more atoms; atoms can be in the form of C(x), P(x, y), sameAs(x, y) or differentFrom(x, y), where C is an OWL description, P is an OWL property, and x, y are either variables, OWL individuals or OWL data values. An XML- and an RDF-based syntax for the rules also have been defined.

Another "hot topic" in a Semantic Web context concerns Semantic Web services. A "normal" Web service can be defined as a Web site that does not simply supply static information, but that also allows the automatic execution of some "actions" (services), like the sale of a product or the control of a physical device; an increasing number of Web services are accessible on the Web, developed by independent operators or large companies such as Amazon and Google. To carry out their tasks, Web services must provide interoperability among diverse applications, using platform and language independent interfaces for a smooth integration of heterogeneous systems. This has led to a standardization of the Web service descriptions, discovery, and invocation, making use of XML-based standards like WSDL (Christensen, Curbera, Meredith, & Weerawarana, 2001), a description protocol, and SOAP (Mitra, 2003), a messaging protocol. However, these standards, in their present form, are characterized by a low level of semantic expressiveness: For example, WSDL can be used to describe the interface of the different services, and how these services are deployed via SOAP, but it is very limited in its ability to express what the overall competences of this service are. Semantic Web services are then Web services that can specify not only their interfaces, but also describe in full their capabilities and the prerequisites and consequences of their use.

OWL-S (Semantic Markup for Web Services) (Ankolekar et al., 2002)—formerly DAML-S—is a specification, in the form of an OWL-based ontology, that describes different Semantic Web services features. It should enable Web users and software agents to automatically discover, invoke, select, compose, and monitor Web-based services. The ontology is structured into three main parts: (1) The "profile" component supplies a general description of a particular Web service by specifying the input and output types, the preconditions, and (3) the effects. (2) The "process model" component describes how the Web service works and the Web service interaction protocol; each service is either an atomic process that can be executed directly or a combination of several processes. An example of atomic process can be a service that returns a postal code, or the longitude and latitude when supplied with an address. A complex service often requires some form of interaction with the user, who can make choices and provide information conditionally: an example can be that of a personal shopping agent, that can assist the user in finding and buying many different sorts of items, requiring, in case, credit card and mailing information. (3) The "grounding" component specifies how the atomic processes defined in the process model can be mapped into WSDL descriptions, able to directly call up the described (atomic) service.

The ODE SWS framework, (see Gómez-Pérez, González-Cabrero, & Lama, 2004) proposes both an ontology to describe Semantic Web services and an environment to support their graphical development. A characteristic of this framework is the use of Problem-Solving Methods to describe these services at the "knowledge level" (see the "Knowledge Representation" article in this encyclopedia), that is, independently of the language in which they will be actually expressed. The ODE SWS ontology reproduces the upper level concepts of OWL-S, with the exception of the concepts associated with the "process model" component that are substituted by method descriptions. The ODE SWS environment is composed of three main layers: (1) The "data source" layer is devoted to the integration of external applications; (2) the "domain" layer includes the main modules of the environment, as the SWSOntologiesManager, the

SWSInstanceCreator—this module creates, from the graphical description of a particular service, the corresponding instance of a concept pertaining to the OWL-S ontology—and the SWSTranslator, which translates the general model of the service into a Semantic Web language description; (3) the "presentation" layer consists of a SWSDesigner module, that is, a user-friendly graphical interface that the user employs to describe a service – according to the authors, this graphically oriented process is more simple and less error prone than manipulating directly instance of the internal OWL-S ontology.

Implications for knowledge management of what expounded in this section and in the previous ones could be very important. There is general agreement that, from a very concrete point of view, the notion of knowledge management amounts, practically, to the set up and management of large corporate memories. These last can be defined (van Heijst, 1966) as the indexing and persistent storing of strategic knowledge about a given organization to facilitate its access, sharing, and reuse by the members of the organization in their individual and collective work. Taking into account the fact that ontologies provide a shared and common understanding of a domain, which can be communicated across people and application systems, corporate memories can, in turn, be materialized as a "Corporate Semantic Web," this last consisting both of ontologies and of Web-stored documents annotated with ontological tools. In this context, all the Semantic Web conceptual tools mentioned in this article, from XML to Semantic Web services, can then contribute—at least in principle, see the next section—to make knowledge management a tangible reality.

CONCLUSION

In spite of the heavy W3C support, the Semantic Web vision outlined in this article has not fully reached the status of "inescapable" standard.

First of all, the intrinsic "binary" nature—based on an "attribute value" approach—of tools like RDF and OWL makes it extremely difficult to use them for dealing with complex "narrative" documents particularly important from a knowledge management point of view, like memos, policy statements, reports, minutes, news stories, normative and legal texts, medical records, many intelligence messages, and so forth. This point is developed in depth in the "Representation Languages for Narrative Documents" article in this encyclopedia.

Moreover, Berners-Lee's architecture has been criticized from the beginning, in particular because it ignores some fundamental components of computer science today, from database technology (the whole world economy runs on SQL) to Unified Modeling Language (UML): UML is the standard modeling language in software engineering and, at the difference of RDF, OWL, and so forth, has received wide attention not only in academia but also in the professional milieus. Note, however, that some researchers are actually investigating the possibility of defining a mapping between UML and OWL-like languages. UML has, in fact, a type hierarchy comparable with OWL and a class diagrams facility that can be compared to a frame-based language (see, in this context, the comparison between UML and DAML in Baclawski et al., 2001). A general discussion about the proposals for defining transformations between UML and the Semantic Web ontology languages can be found in Falkovych, Sabou, and Stuckenschmidt, (2003).

In the context of the Semantic Web architecture, the choice of OWL as paradigmatic language to be used for ontological work also has raised some criticisms, and several knowledge representation specialists have challenged as hastily the endorsement of OWL by the W3C—for the relationships between Semantic Web, artificial intelligence and knowledge representation (see Schwartz, 2003). Apart from the "binary flaw" already mentioned before, criticisms range from the use of a particularly cumbersome syntax, inherited from RDF/XML, to the availability of an expressive power that, from a strict knowledge representation point of view, does not seem to improve so much with respect to "traditional" frame systems like Protégé-2000 (see the article "Knowledge Representation" in this encyclopedia). We can, however, remark, in this context, that an "OWL plugin" for Protégé has been recently implemented (see Horridge, 2004 and http://protege.stanford.edu/plugins/owl/); it allows loading and saving OWL and RDF ontologies, editing and visualizing OWL classes and their properties and, mainly, supporting reasoners such as the description logics classifiers.

Note that, according to OWL's supporters, it is precisely this last characteristic that "makes all the difference" between a simple frame system that utilize pragmatically based inference procedures, and an OWL-based reasoning tool—see, for example, RACER (Haarslev & Möller, 2003)—that employs sound and complete inferencing algorithms supported by the description logics theory. Unfortunately, description logics have been, in turn, criticized in spite (or because) their (too) rigorous formal framework, associated, inter alia, with a reduced expressiveness of their main reasoning component, the automatic classification mechanism. To give only an example, nearly a printed page is needed in McGuinness et al. (2002) to demonstrate that, using the DAML+OIL definitions (DAML+OIL is the ancestor of OWL), we can infer that "Red" can be considered as a sort of "WineColor." A plea for the use, in a Semantic Web context, of knowledge representation languages more "meaningful" than those based on a description logics approach can be found in Zarri (2002).

In spite of all the criticisms, Semantic Web techniques have really represented a quantum leap in the "knowledge management" domain, in the widest meaning of these words, and are surely here to stay.

Chapter 3.20
Interactive Information Retrieval as a Step Towards Effective Knowledge Management in Healthcare

Jörg Ontrup
Bielefeld University, Germany

Helge Ritter
Bielefeld University, Germany

ABSTRACT

The chapter shows how modern information retrieval methodologies can open up new possibilities to support knowledge management in healthcare. Recent advances in hospital information systems lead to the acquisition of huge quantities of data, often characterized by a high proportion of free narrative text embedded in the electronic health record. We point out how text mining techniques augmented by novel algorithms that combine artificial neural networks for the semantic organization of non-crisp data and hyperbolic geometry for an intuitive navigation in huge data sets can offer efficient tools to make medical knowledge in such data collections more accessible to the medical expert by providing context information and links to knowledge buried in medical literature databases.

INTRODUCTION

During the last years the development of electronic products has lead to a steadily increasing penetration of computerized devices into our society. Personal computers, mobile computing platforms, and personal digital assistants are becoming omnipresent. With the advance of network aware medical devices and the wireless transmission of health monitoring systems pervasive computing has entered the healthcare domain (Bergeron, 2002).

Consequently, large amounts of electronic data are being gathered and become available online. In order to cope with the sheer quantity, data warehousing systems have been built to store and organize all imaginable kinds of clinical data (Smith & Nelson, 1999).

In addition to numerical or otherwise measurable information, clinical management involves administrative documents, technical documentation regarding diagnosis, surgical procedure, or care. Furthermore, vast amounts of documentation on drugs and their interactions, descriptions of clinical trials or practice guidelines plus a plethora of biomedical research literature are accumulated in various databases (Tange, Hasman, de Vries, Pieter, & Schouten, 1997; Mc Cray & Ide, 2000).

The storage of this exponentially growing amount of data is easy enough: From 1965—when Gordon Moore first formulated his law of exponential growth of transistors per integrated circuit—to today: "Moore's Law" is still valid. Since his law generalizes well to memory technologies, we up to now have been able to cope with the surge of data in terms of storage capacity quite well. The retrieval of data however, is inherently harder to solve. For structured data such as the computer-based patient record, tools for online analytical processing are becoming available. But when searching for medical information in freely formatted text documents, healthcare professionals easily drown in the wealth of information: When using standard search engine technologies to acquire new knowledge, thousands of "relevant" hits to the query string might turn up, whereas only a few ones are valuable within the individual context of the searcher. Efficient searching of literature is therefore a key skill for the practice of evidence-based medicine (Doig & Simpson, 2003).

Consequently, the main objective of this chapter is to discuss recent approaches and current trends of modern information retrieval, how to search very large databases effectively. To this end, we first take a look at the different sources of information a healthcare professional has access to. Since unstructured text documents introduce the most challenges for knowledge acquisition, we will go into more detail on properties of text databases considering MEDLINE as the premier example. We will show how machine learning techniques based on artificial neural networks with their inherent ability for dealing with vague data can be used to create structure on unstructured databases, therefore allowing a more natural way to interact with artificially context-enriched data.

SOURCES OF INFORMATION IN HEALTHCARE

The advance of affordable mass storage devices encourages the accumulation of a vast amount of healthcare related information. From a technical point of view, medical data can be coarsely divided into structured and unstructured data, which will be illustrated in the following sections.

Data Warehouses and Clinical Information Systems

One major driving force for the development of information processing systems in healthcare is the goal to establish the computer-based patient record (CPR). Associated with the CPR are patient registration information, such as name, gender, age or lab reports such as blood cell counts, just to name a few. This kind of data is commonly stored in relational databases that impose a high degree of structure on the stored information. Therefore, we call such data "structured." For evidence based medicine the access to clinical information is vital. Therefore, a lot of effort has been put into the goal to establish the computer-based patient record (CPR) as a standard technology in healthcare. In the USA, the Institute of Medicine (1991) defined the CPR as "an electronic patient record that resides in a system specifically designed to support users by providing accessibility to complete and accurate data, alerts, reminders, clinical decision support systems, links to medical knowledge, and other aids." However, as Sensmeier (2003) states, "this goal remains a vision [...] and the high expectations of these visionaries remain largely unfulfilled." One of the main reasons why "we are not there yet" is a general lack of integration.

A recent study by Microsoft1 identified as much as 300 isolated data islands within a medical center. The unique requirements of different departments such as laboratory, cardiology, or oncology and the historical context within the hospital often results in the implementation of independent, specialized clinical information systems (CIS) which are difficult to connect (McDonald, 1997). Consequently, main research thrusts are strategies to build data warehouses and clinical data repositories (CDR) from disjoint "islands of information" (Smith & Nelson, 1999). The integration of the separated data sources involves a number of central issues:

1. Clinical departments are often physically separated. A network infrastructure is necessary to connect the disparate sites. Internet and Intranet tools are regarded as standard solutions.
2. Due to the varying needs of different departments, they store their data in various formats such as numerical laboratory values, nominal patient data or higher dimensional CT data. Middleware solutions are required to translate these into a consistent format that permits interchange and sharing.
3. In the real world, many data records are not suitable for further processing. Missing values or inconsistencies have to be treated: Some fields such as blood cell counts are not always available or data was entered by many different persons, and is thus often furnished with a "personal touch." Cleaning and consistency checks are most commonly handled by rule-based transformations.
4. Departmental workflow should not be strained by data copying tasks. Automated script utilities should take care of the data migration process and copy the data "silently in the background."

None of the steps above is trivial and certainly it requires a strong management to bring autonomous departments together and to motivate them to invest their working power for a centralized data warehouse. But once such a centralized repository of highly structured data is available it is a very valuable ground for retrospective analysis, aggregation and reporting. Online analytical processing (OLAP) tools can be used to perform customized queries on the data while providing "drill downs" at various levels of aggregation. A study with an interactive visualization framework has shown that it can massively support the identification of cost issues within a clinical environment (Bito, Kero, Matsuo, Shintani, & Silver, 2001). Silver, Sakata, Su, Herman, Dolins, and O'Shea (2001) have demonstrated that data mining "helped to turn data into knowledge." They applied a patient rule induction method and discovered a small subgroup of inpatients on the DRG level which was responsible for more than 50 percent of revenue loss for that specific DRG (diagnoses related group). The authors describe a "repeatable methodology" which they used to discover their findings: By using statistical tools they identified regions and patterns in the data, which significantly differentiated them from standard cases. In order to establish the reason for increased costs in those regions, they found it necessary that a human expert further analyzes the automatically encircled data patterns. Therefore, a closed loop between clinical data warehouse, OLAP tool and human expert is necessary to gain the maximum of knowledge from the available data.

A recently proposed data mart by Arnrich, Walter, Albert, Ennker, and Ritter (2004) targets in the same direction: Various data sources are integrated into a single data repository. Results from statistical procedures are then displayed in condensed form and can be further transformed into new medical knowledge by a human expert.

UNSTRUCTURED DATA IN BIOMEDICAL DATABASES

As the discussion on hospital information systems shows, interactive data processing tools form a large potential to extract hidden knowledge from large structured data repositories. A yet more challenging domain for knowledge acquisition tasks is the field of unstructured data. In the following we will briefly present the two premier sources of unstructured data available to the healthcare professional.

Narrative Clinical Data

Many hospitals do not only store numerical patient data such as laboratory test results, but also highly unstructured data such as narrative text, surgical reports, admission notes, or anamneses. Narrative text is able to capture human-interpretable nuances that numbers and codes cannot (Fisk, Mutalik, Levin, Erdos, Taylor, & Nadkarni, 2003). However, due to the absence of a simple machine-parsable structure of free text, it is a challenging task to design information systems allowing the exchange of such kind of information.

In order to address the interoperability within and between healthcare organizations widely accepted standards for Electronic Health Records (EHR) are important. Health Level 7 (HL7)—an ANSI accredited organization, and the European CEN organization both develop standards addressing this problem. The HL7 Clinical Document Architecture (CDA) framework "stems from the desire to unlock a considerable clinical content currently stored in free-text clinical notes and to enable comparison of content from documents created on information systems of widely varying characteristics." (Dolin, Alschuler, Beebe, Biron, Boyer, Essin, Kimber, Lincoln, & Mattison,, 2001). The emerging new standard based on HL7 version 3 is purely based on XML and therefore greatly enhances the interoperability of clinical information systems by embedding the unstructured narrative text in a highly structured XML framework. Machine-readable semantic content is added by the so-called HL7 Reference Information Model (RIM). The RIM is an all-encompassing look at the entire scope of healthcare containing more than 100 classes with more than 800 attributes. Similar to HL7 v3, the European ENV 13606 standard as defined by the TC 251 group of the CEN addresses document architecture, object models and information messages. For a more detailed discussion on healthcare information standards see Spyrou, Bamidis, Chouvarda, Gogou, Tryfon, and Maglaveras (2002).

Another approach to imprint structure on free text is the application of ontologies to explicitly formalize logical and semantic relationships. The W3C consortium has recently (as of May 2004) recommended the Web Ontology Language (OWL) as a standard to represent semantic content of web information and can therefore be seen as a major step towards the "semantic Web" (Berners-Lee, Hendler, & Lassila, 2001). In the medical domain, the Unified Medical Language System (UMLS) uses a similar technology to represent biomedical knowledge within a semantic network (Kashyap, 2003). Once an ontology for a certain domain is available, it can be used as a template to transfer the therein contained explicit knowledge to corresponding terms of free text from that domain. For example, the term "blepharitis" is defined as "inflammation of the eyelids" in the UMLS. If a medic professional would search for the term "eyelid" within the hospital's EHRs, documents containing the word "blepharitis" would not show up. However with knowledge from the UMLS, these documents could be marked as relevant to the query. However, the tagging of free text with matching counterparts from an ontology is either a cost intensive human labor or requires advanced natural language processing methods. We shall see below, how computational approaches could address the problem of adding semantics to free narrative text.

Biomedical Publications

For most of the time in human history, the majority of knowledge acquired by mankind was passed on by the means of the written word. It is a natural scientific process to formulate new insights and findings and pass them to the community by publishing. Consequently, scientific literature is constantly expanding. It is not only expanding at growing speed, but also increasing in diversification, resulting in highly specialized domains of expertise.

The MEDLINE database at the U.S. National Library of Medicine (NLM) has become the standard bibliographic database covering the fields of medicine, nursing, veterinary medicine, dentistry, pharmacology, the healthcare system, and the preclinical sciences. The majority of publications in MEDLINE are regular journals and a small number of newspapers and magazines. The database is updated on a regular daily basis from Tuesdays to Saturdays and on an irregular basis in November and December. At the time of this writing, MEDLINE contains approximately 12 million references to articles from over 37,000 international journals dating back to 1966. In 1980 there were about 100,000 articles added to the database, and in 2002 the number increased to over 470,000 newly added entries. That means, currently over 50 new biomedical articles are published on an hourly basis. Clearly, no human is able to digest one scientific article per minute 24 hours a day, seven days a week. But the access to the knowledge within is lively important nonetheless: "The race to a new gene or drug is now increasingly dependent on how quickly a scientist can keep track of the voluminous information online to capture the relevant picture … hidden within the latest research articles" (Ng & Wong, 1999).

Not surprisingly, a whole discipline has emerged which covers the field of "information retrieval" from unstructured document collections, which takes us to the next section.

COMPUTATIONAL APPROACHES TO HANDLE TEXT DATABASES

The area of information retrieval (IR) is as old as man uses libraries to store and retrieve books. Until recently, IR was seen as a narrow discipline mainly for librarians. With the advent of the World Wide Web, the desire to find relevant and useful information grew to a public need. Consequently, the difficulties to localize the desired information "have attracted renewed interest in IR and its techniques as promising solutions. As a result, almost overnight, IR has gained a place with other technologies at the center of the stage" (Baeza-Yates & Ribeiro-Neto, 1999).

Several approaches have shown that advanced information retrieval techniques can be used to significantly alleviate the cumbersome literature research and sometimes even discover previously unknown knowledge (Mack & Hehenberger, 2002). Swanson and Smalheiser (1997) for example designed the ARROWSMITH system which analyses journal titles on a keyword level to detect hidden links between literature from different specialized areas of research. Other approaches utilize MeSH headings (Srinivasan & Rindflesch, 2002) or natural language parsing (Libbus & Rindflesch, 2002) to extract knowledge from literature. Rzhetsky, Iossifov, Koike, Krauthammer, Kra, Morris, Yu, Duboue, Weng, Wilbur, Hatzivassiloglou, and Friedman (2004) have recently proposed an integrated system which visualizes molecular interaction pathways and therefore has the ability to make published knowledge literally visible.

In the following sections we go into more detail and look how computational methods can deal with text.

Representing Text

The most common way to represent text data in numerical form such that it can be further processed by computational means is the so-called "bag of words" or "vector space" model. To this end a standard practice composed of two complementary steps has emerged (Baeza-Yates & Ribeiro-Neto, 1999):

1. Indexing: Each document is represented by a high-dimensional feature vector in which each component corresponds to a term from a dictionary and holds the occurrence count of that term in the document. The dictionary is compiled from all documents in the database and contains all unique words appearing throughout the collection. In order to reduce the dimensionality of the problem, generally only word stems are considered (i.e., the words "computer", "compute", and "computing" are reduced to "comput"). Additionally, very frequently appearing words (like "the" & "and") are regarded as stop words and are removed from the dictionary, because they do not contribute to the distinguishability of the documents.
2. Weighting: Similarities between documents an then be measured by the Euclidean distance or the angle between their corresponding feature vectors. However, this ignores the fact that certain words carry more information content than others. The so-called tf-idf weighting scheme (Salton & Buckley, 1988) has been found a suitable means to deal with this problem: Here the term frequencies (tf) in the document vector are weighted with the inverse document frequency idfi = log(N/sdi), where N is the number of documents in the collection, and sdi denotes the number of times the word stem si occurs in document d.

Although the "bag of words" model completely discards the order of the words in a document, it performs surprisingly well to capture its content. A major drawback is the very high dimensionality of the feature vectors from which some computational algorithms suffer. Additionally, the distance measure typically does not take polysemy (one word has several meanings) and synonymy (several words have the same meaning) into account.

Evaluating Retrieval Performance

In order to evaluate an IR system, we need some sort of quality measure for its retrieval performance. The most common and intuitively accessible measures are precision and recall. Consider the following situation: We have a collection of C documents and a query Q requesting some information from that set. Let R be the set of relevant documents in the database to that query, and A be the set of documents delivered by the IR system as answers to the given query Q. The precision and recall are then define by

$$precision = \frac{|R \cap A|}{|R|} \text{ and } recall = \frac{|R \cap A|}{|R|} ,$$

where R∩A is the intersection of the relevant and the answer set, that is, the set of found relevant documents. The ultimate goal is to achieve a precision and recall value of one, that is, to find only the relevant documents, and all of them. A user will generally not inspect the whole answer set A returned by an IR system—who would want to click through all of the thousands of hits typically returned by a web search? Therefore, a much better performance description is given by the so-called precision-recall-curve. Here, the documents in A are sorted according to some ranking criterion and the precision is plotted against the recall values obtained when truncating the sorted answer set after a given rank—which is varied between one and the full size of A. The particular point on the curve where the precision equals the recall is called break even point and is frequently used to characterize an IR system's performance with a single value.

Therefore, the quality of a search engine which generates hit lists is strongly dependent on its ranking algorithm. A famous example is PageRank, which is part of the algorithm used by Google. In essence, each document (or page) is weighted with the number of hyperlinks it receives from other web pages. At the same time the links themselves are weighed by the importance of the linking page (Brin & Page, 1998). The higher a page is weighted, the higher it gets within the hit list. The analogue to hyperlinks in the scientific literature are citations, that is, the more often an article is cited, the more important it is (Lawrence, Giles & Bollacker, 1999).

The Role of Context

So, we can handle unstructured text and measure how good an IR system works, but a critical question was not answered yet: How do we determine, which documents from a large collection are actually relevant to a given query? To answer this question, we have to address the role of context.

User Context

Consider the following example: A user enters the query "Give me all information about jaguars." The set of relevant documents will be heavily dependent on the context in which the user phrases this query: A motor sports enthusiast is probably interested in news about the "Jaguar Racing" Formula 1 racing stable, a biologist probably wants to know more about the animal. So, the context—in the sense of the situation in which the user is immersed—plays a major role (Johnson, 2003; Lawrence, 2000).

Budzik, Hammond and Birnbaum (2001) discuss two common approaches to handle different user contexts:

1. Relevance feedback: The user begins with a query and then evaluates the answer set. By providing positive or negative feedback to the IR system, this can modify the original query by adding positive or negative search terms to it. In an iterative dialogue with the IR system, the answer set is then gradually narrowed down to the relevant result set. However, as studies (Hearst, 1999) have shown, users are generally reluctant to give exhaustive feedback to the system.
2. Building user profiles: Similar to the relevance feedback, the IR system builds up a user profile across multiple retrieval sessions, that is, with each document the user selects for viewing, the profile is adapted. Unfortunately, such a system does not take account of "false positives", that is, when a user follows a link that turned out to be of no value when inspecting it closer. Additionally, such systems integrate short term user interests into accumulated context profiles, and tend to inhibit highly specialized queries which the user is currently interested in.

Budzik, Hammond & Birnbaum (2001) presented a system that tries to guess the user context from open documents currently edited or browsed on the work space. Their system constitutes an "Information Management Assistant [which] observes user interactions with everyday applications and anticipates information needs […] in the context of the user's task." Another system developed by Finkelstein and Gabrilovich (2002) analyzes the context in the immediate vicinity of a user-selected text, therefore making the context more focused. In an evaluation of their system both achieved consistently better results than standard search engines are able to achieve without context.

Document Context

Context can also be seen from another point of view: Instead of worrying about the user's intent and the context in which a query is embedded, an information retrieval system could make the context in which retrieved documents are embedded more explicit. If each document's context is immediately visible to the information seeker, the relevant context might be quickly picked out. Additionally, the user might discover a context he had not in mind when formulating the query and thus find links between his intended and an unanticipated context. In the following we describe several approaches that aim in this direction.

Augmenting Document Sets with Context

Text Categorization

One way to add context to a document is by assigning a meaningful label to it (Le & Thoma, 2003). This constitutes a task of text categorization and there exist numerous algorithms that can be applied. The general approach is to select a training set of documents that are already labelled. Based on the "bag of words" representation, machine learning methods learn the association of category labels to documents. For an in depth review of statistical approaches (such as naives Bayes or decision trees) see Yang (1999). Computationally more advanced methods utilize artificial neural network architectures such as the support vector machine which have achieved break even values close to 0.9 for the labelling of news wire articles (Joachims, 1998; Lodhi, 2001).

However, in the medical domain, 100 categories are seldom adequate to describe the context of a text. In case of the MEDLINE database, the National Library of Medicine has developed a highly standardized vocabulary, the Medical Subject Headings (MeSH) (Lowe & Barnett, 1994). They consist of more than 35,000 categories that are hierarchically organized and constitute the basis for searching the database. To guarantee satisfactory search results of constant quality, reproducible labels are an important prerequisite. However, the cost of human indexing of the biomedical literature is high: according to Humphrey (1992) it takes one year to train an expert the task of document labelling. Additionally, the labelling process lacks a high degree of reproducibility. Funk, Reid, and McGoogan (1983) have reported a mean agreement in index terms ranging from 74 percent down to as low as 33 percent for different experts. Because the improvement of index consistency is such demanding, assistance systems are considered to be a substantial benefit. Recently, Aronson, Bodenreider, Chang, Humphrey, Mork, Nelson, Rindflesh, and Wilbur (2000) have presented a highly tuned and sophisticated system which yields very promising results. Additionally to the bag of words model their system utilizes a semantic network describing a rich ontology of biomedical knowledge (Kashyap, 2003).

Unfortunately, the high complexity of the MeSH terms makes it hard to incorporate a MeSH-based categorization into a user interface. When navigating the results of a hierarchically ordered answer set it can be a time-consuming and frustrating process: Items which are hidden deep within the hierarchy can often only be obtained by descending a tree with numerous mouse-clicks. Selection of a wrong branch requires backing up and trying a neighboring branch. Since screen space is a limited resource only a small area of context is visible and requires internal "recalibration" each time a new branch is selected. To overcome this problem, focus and context techniques are considered to be of high value. These are discussed in more detail below.

The Cluster Hypothesis

An often cited statement is the cluster hypothesis, which states that documents which are similar in their bag of words feature space tend to be relevant to the same request (van Rijsbergen, 1979). Leuski (2001) has conducted an experiment where an agglomerative clustering method was used to group the documents returned by a search engine query. He presented the user not with a ranked list of retrieved documents, but with a list of clusters, where each cluster in turn was arranged as a list of documents. The experiment showed, that this procedure "can be much more helpful in locating the relevant information than the traditional ranked list." He could even show that the clustering can be as effective as the relevance feedback methods based on query expansion. Other experiments also validated the cluster hypothesis on several occasions (Hearst & Pedersen, 1996; Zamir & Etzioni, 1999). Recently the vivisimo2 search engine has drawn attention by utilizing an online clustering of retrieval sets, which also includes an interface to PubMed / MEDLINE.

Visualizing Context

Another way to create context in line with the spirit of the cluster hypothesis is by embedding the document space in a visual display. By making the relationship between documents visually more explicit, such that the user can actually see inter-document similarities, the user gets (i) an overview of the whole collection, and (ii) once a relevant document has been found, it is easier to locate others, as these tend to be grouped within the surrounding context of already identified valuable items. Fabrikant and Buttenfield (2001) provide a more theoretical framework for the concept of "spatialization" with relation to cognitive aspects and knowledge acquisitions: Research on the cognition of geographic information has been identified as being important in decision making, planning and other areas involving human-related activities in space.

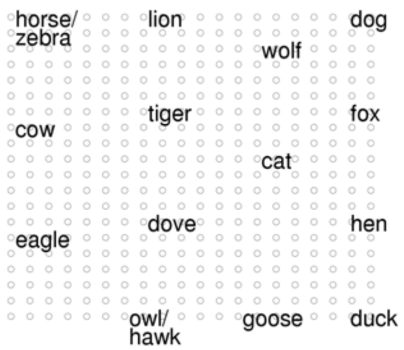
In order to make use of "spatialization", that is, to use cognitive concepts such as "nearness" we need to apply some sort of transformation to project the documents from their high-dimensional (typically several thousands) bag-of-words space onto a two dimensional canvas suitable for familiar inspection and interaction. The class of algorithms performing such a projection is called multi dimensional scaling (MDS). A large number of MDS methods such as Sammon mapping, spring models, projection pursuit or local linear embeddings have been proposed over the years. Skuping and Fabrikant (2003) provide an excellent discussion of the most common MDS variants in relation to spatialized information visualization.

Self-Organizing Maps

The notion of the self-organizing map (SOM) has been introduced by Kohonen (1982) more than 20 years ago. Since then is has become a well-accepted tool for exploratory data analysis and classification. While applications of the SOM are extremely wide spread—ranging from medical imaging, classification of power consumption profiles, or bank fraud detection—the majority of uses still follows its original motivation: to use a deformable template to translate data similarities into spatial relations.

The following example uses a simple toy dataset to demonstrate the properties of the SOM algorithm. Consider a 13-dimensional dataset describing animals with properties such as small, medium, big, two legs, hair, hooves, can fly, can swim, and so on. When displaying the data as a large table, it is quite cumbersome to see the interrelationship between the items, that is, animals. The map shown in Figure 1 depicts a trained SOM

Figure 1. A map of animals



with neurons placed on a 20x20 regular grid. After the training process, each animal is "presented" to the map, and the neuron with the highest activity gets labelled with the corresponding name. As can be seen in the figure the SOM achieves a semantically reasonable mapping of the data to a two-dimensional "landscape": birds and non-birds are well separated and animals with identical features get mapped to identical nodes.

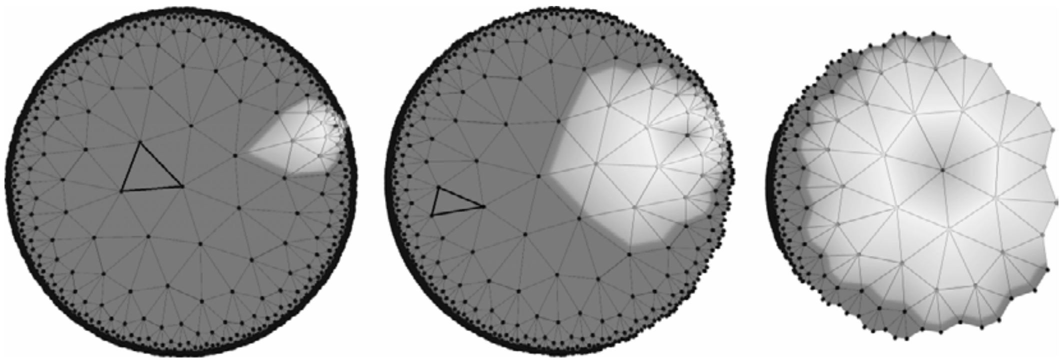
There have been several approaches to use the SOM to visualize large text databases and relations of documents therein. The most prominent example is the WEBSOM project. Kohonen, Kaski and Lagus, (2000) performed the mapping of 7 million patent abstracts and obtained a semantic landscape of the corresponding patent information. However, screen size is a very limited resource, and as the example with 400 neurons above suggests, a network with more than one million nodes—2500 times that size—becomes hard to visualize: When displaying the map as a whole, annotations will not be readable, and when displaying a legible subset, important surrounding context will be lost. Wise (1999) has impressively demonstrated the usefulness of compressed, map-like representations of large text collections: His ThemeView reflects major topics in a given area, and a zoom function provides a means to magnify selected portions of the map—unfortunately without a coarser view to the surrounding context.

Focus & Context Techniques

The limiting factor is the two dimensional Euclidean space we use as a data display: The neighborhood that "fits" around a point is rather restricted: namely by the square of the distance to that point. An interesting loophole is offered by hyperbolic space: it is characterized by uniform negative curvature and results in a geometry, where the neighborhood around a point increases exponentially with the distance. This exponential behavior was firstly exploited (and patented) by the "hyperbolic tree browser" from Lamandpng & Rao (1994), followed by a Web content viewer by Munzner (1998). Studies by Pirolli, Card and van der Wege (2001) showed that the particular focus & context property offered by hyperbolic space can significantly accelerate "information foraging".

Naturally, it becomes apparent to combine the SOM algorithm with the favorable properties of hyperbolic space (Ritter, 1999). The core idea of the hyperbolic self-organizing map (HSOM) is to employ a grid of nodes in the hyperbolic plane H2. For H2 there exists an infinite number of tessellations with congruent polygons such that each grid point is surrounded by the same number of neighbors (Magnus, 1974). As stated above, an intuitive navigation and interaction methodology is a crucial element for a well-fitted visualization framework. By utilizing the Poincaré projection and the set of Möbius transformations (Coxeter, 1957) a "fish-eye" fovea can be positioned on the HSOM grid allowing an intuitive interaction methodology. Nodes within the fovea are displayed with high resolution, whereas the surrounding context is still visible in a coarser view. For further technical details of the HSOM see (Ritter, 1999; Ontrup & Ritter, 2001). An example for the application of the fish-eye view is given in Figure 2. It shows a navigation sequence where the focus

Figure 2. Navigation snapshot showing isometric transformation of HSOM tessellation. The three images were acquired while moving the focus from the center of the map to the highlighted region at the outer perimeter. Note the "fish-eye" effect: All triangles are congruent, but appear smaller as further they are away from the focus.



was moved towards the highlighted region of interest. Note, that from the left to the right details in the target area get increasingly magnified, as the highlighted region occupies more and more display space. In contrast to standard zoom operations, the current surrounding context is not clipped, but remains gradually compressed at the periphery of the field of view. Since all operations are continuous, the focus can be positioned in a smooth and natural way.

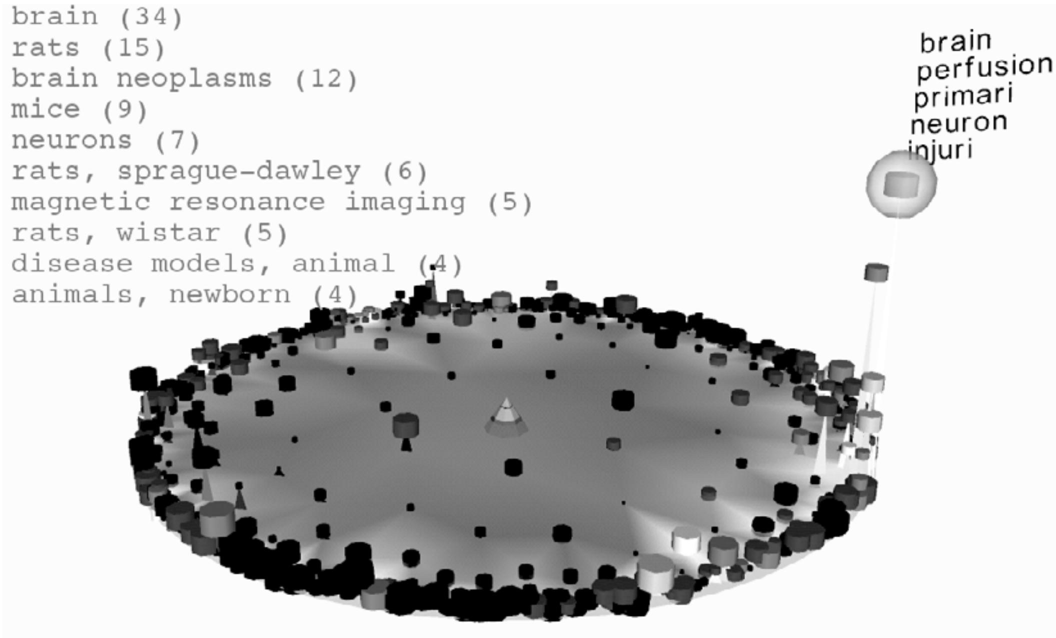
Browsing MEDLINE in Hyperbolic Space

The following example presents a HSOM framework that combines the aspects of information retrieval, context enrichment and intuitive navigation into a single application. The following images show a two dimensional HSOM, where the nodes are arranged on a regular grid consisting of triangles similar to those in Figure 2. The HSOM's neurons can be regarded as "containers" holding those documents for which the corresponding neuron is "firing" with the highest rate. These containers are visualized as cylinders embedded in the hyperbolic plane. We can then use visual attributes of these containers and the plane to reflect document properties and make context information explicit:

- The container sizes reflect the number of documents situated in the corresponding neuron.
- A color scale reflects the number of documents which are labelled with terms from the Anatomy hierarchy of MeSH terms, i.e. the brighter a container is rendered, the more articles labelled with Anatomy MeSH entries reside within that node.
- The color of the ground plane reflects the average distance to neighboring nodes in the semantic bag-of-words space. This allows the identification of thematic clusters within the map.

Figure 3 shows a HSOM that was trained with approximately 25,000 abstracts from MEDLINE. The interface is split into two components: the

Figure 3. MEDLINE articles mapped with the HSOM. The user submitted the query string "brain" and the corresponding results are highlighted by the system.

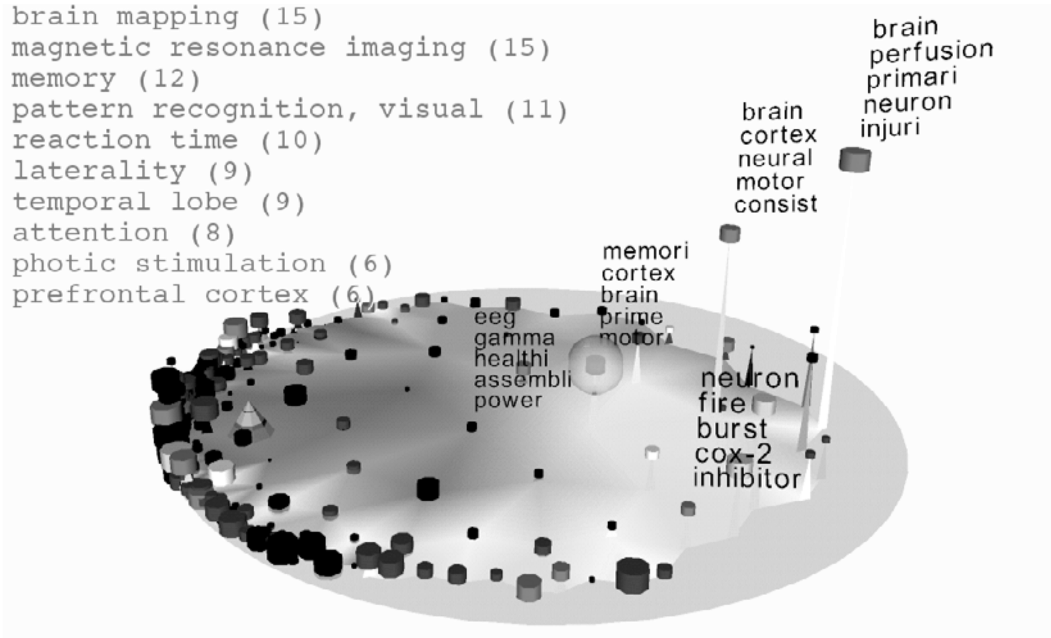


graphical map depicted below and a user interface for formulating queries (not shown here). In the image below, the user has entered the search string "brain". Subsequent to the query submission, the system highlights all nodes belonging to abstracts containing the word "brain" by elevating their corresponding nodes. Additionally the HSOM prototype vectors—which were autonomously organized by the system during a training phase—are used to generate a key word list which annotate and semantically describe the node with the highest hit rate. To this end, the words corresponding to the five largest components of the reference vector are selected. In our example these are: brain, perfusion, primari, neuron, and injuri. In the top left the most prominent MeSH terms are displayed, that is, 34 articles are tagged with the medical subject heading "brain", 15 are tagged with "rats", and so on.

The map immediately shows that there are several clusters of brain-related articles in the right part of the map. Moving the focus into this area leads to the situation shown in Figure 4. By selecting single neurons with the mouse, the user can selectively retrieve key words of individual containers. Additionally, the MeSH terms of the selected node are displayed. As can be seen from the keyword distribution, all nodes share semantically related characteristics. The two leftmost labelled nodes do not contain key words like "brain" or "neuron", but the labelling with "cord", "spinal", "eeg", and "gamma", respectively, indicates a close relation to the selected "brain-area".

The drill-down process to the document level combines the strengths of the graphical and the textual display: After zooming-in on a promising region, the titles of documents pertaining to a particular node can be displayed by a double

Figure 4. The user has moved the focus into the target area and can now inspect the context enriched data more closely.



mouse click. Note, that due to the ordering process of the SOM algorithm these documents are typically very similar to each other—and in the sense of the clustering hypothesis therefore might all provide an answer to the same query. A further double click on a document title then displays the selected abstract on the screen. In this way, the hyperbolic self-organizing map can provide a seamless interface offering rapid overview of large document collections while allowing at the same time the drill down to single texts.

BENEFITS FOR A HOSPITAL INFORMATION SYSTEM

In the framework of a hospital information system, such a context enriched interactive document retrieval system might be of great benefit to the clinical personal. According to Chu and Cesnik (2001) a hospital may generate up to five terabytes of data a year, where 20 to 30 percent of such data are stored as free text reports such as medical history, assessment and progress notes, surgical reports or discharge letters. Free text fields in medical records are considered of invaluable importance for medical relevance (Stein, Nadkarni, Erdos, & Miller, 2000). By using document standards like the CDA as briefly discussed in Section 2.2, the clinician is able to browse and retrieve the data according to the structure provided by the document framework. However, many existing information systems do not yet take advantage of the complex CDA or the even more substantial Reference Information Model—because it is a very time consuming task to transfer documents to the new standards and to fit the enormous mass of model objects to free text data.

Nevertheless, these systems store valuable information—just in a format which cannot be directly analyzed by structured methods. In order to provide access by content, the aforementioned Information Retrieval methodologies can significantly contribute to facilitate these tasks: a self-organizing map creates structure and context purely on the statistical word distributions of free text and thus allows a semantic browsing of clinical documents. This in turn offers the possibility to gain a problem orientated perspective on health records stored in information systems, that is, as Lovis et al (2000) have noted: "intelligent browsing of documents, together with natural language emerging techniques, are regarded as key points, as it appears to be the only pertinent way to link internal knowledge of the patient to general knowledge in medicine."

CONCLUSION

Recent advances in hospital information systems have shown that the creation of organization-wide clinical data repositories (CDR) plays a key role for the support of knowledge acquisition from raw data. Currently, many case studies are published which emphasize that data mining techniques provide efficient means to detect significant patterns in medical records. Interactive OLAP tools support best practice and allow for informed real time decision-making and therefore build the solid foundation for further improvements in patient care.

The next step to further broaden the knowledge base in healthcare environments will be the integration of unstructured data, predominantly free narrative text documents. The nature of this type of data will demand for new approaches to deal with the inherently vague information contained in these documents. We have shown how artificial neural networks with their ability for self-organization of non-crisp data provide an almost natural link between the hard computational world and the soft-computing of the human brain. We believe that interactive information retrieval methodologies that account for the rich context of natural language will significantly contribute to knowledge acquisition through text analysis.

Chapter 3.21
Breaking the Knowledge Acquisition Bottleneck Through Conversational Knowledge Management

Christian Wagner
City University of Hong Kong, Hong Kong, & Claremont Graduate University, USA

ABSTRACT

Much of today's organizational knowledge still exists outside of formal information repositories and often only in people's heads. While organizations are eager to capture this knowledge, existing acquisition methods are not up to the task. Neither traditional artificial intelligence-based approaches nor more recent, less-structured knowledge management techniques have overcome the knowledge acquisition challenges. This article investigates knowledge acquisition bottlenecks and proposes the use of collaborative, conversational knowledge management to remove them. The article demonstrates the opportunity for more effective knowledge acquisition through the application of the principles of Bazaar style, open-source development. The article introduces wikis as software that enables this type of knowledge acquisition. It empirically analyzes the Wikipedia to produce evidence for the feasibility and effectiveness of the proposed approach.

INTRODUCTION

Ever since the development of artificial intelligence (AI) and expert systems, there has been the promise of capturing an organization's knowledge on a large scale and making it available to the entire organization. Unfortunately, these promises did not materialize (Buchanan & Smith, 1988; Ullman, 1989). While there have been several early success stories, such as American Express' Credit Advisor or Digital's Expert Configurer (XCON), attempts to acquire the broad knowledge of organizations have been less fruitful. More than a decade later, a decidedly optimistic survey by Frappaolo and Wilson (2003) found that no more than 32% of the knowledge was available in computerized form. Obviously, knowledge acquisition is a challenge. How can we extract more of the existing knowledge from organizational sources, especially from people? And how can we manage the maintenance so as to assure that the stored knowledge is accurate and up-to-date? Discovering answers to these questions is important for organizations as information work becomes knowledge work, thus requiring knowledge to support non-routine decision making (Drucker, 1993, 1999). It is similarly important for organizations whose corporate portals that were set up years ago increasingly are becoming dated and stale (Newcombe, 2000). Furthermore, it is important for organizations in the business of creating knowledge assets who are faced with increased costs of knowledge creation, shorter knowledge life cycles, and increased knowledge obsolescence.

Seeking a solution to the problems of organizational knowledge acquisition, the article makes the following argument. First, it introduces previous approaches to knowledge acquisition, identifies four limitations, and offers evidence for these limitations. The article then refers to Bazaar style (software) development (Raymond, 2001) as a potential direction for knowledge asset creation. It then explains the concept of conversational knowledge management and advocates wiki technology and the "wiki way" (Leuf & Cunningham, 2001) as a possible approach to using Bazaar-style methods in conversational knowledge management. An empirical analysis of the viability and effectiveness of the approach follows. The article ends with implications and conclusions about the future of conversational knowledge management.

KNOWLEDGE ACQUISITION

Approaches to Knowledge Acquisition

Organizations that try to acquire organizational knowledge formally (based on artificial intelligence methods) have relatively few available alternatives. For application areas with large amounts of transaction data, data mining can induce rules from that data. Data mining solutions work well for high-volume applications such as credit approval. Even then, the knowledge creation effort is highly resource-intensive (Lee, 2001). When insufficient data volumes thwart data mining efforts, the acquisition activity has to elicit knowledge directly from experts as rules and facts or similar formal representations. This should be done under the guidance of knowledge engineers trained in knowledge elicitation, formalization, and representation. Yet a knowledge engineer's productivity is limited to hundreds of rules per year for development and maintenance (Sviokla, 1990; Turban & Aronson, 2000). This productivity level may be acceptable for high value-added projects but limits the broad applicability of the approach. Smaller projects have attempted to rely on capturing knowledge without knowledge engineers, relying on end-user development. The latter has not been very successful (Wagner, 2000, 2003). Wagner found end-user expert systems often to be poorly structured, incomplete, highly coupled, and thus, difficult to maintain. Artificial intelligence-based methods thus are facing considerable applicability constraints. Consequently, organizational knowledge management efforts have sought to capture knowledge in less formal ways; for instance, by extending document management and groupware systems into knowledge management systems (Davenport & Prusak, 1998; Holsapple & Joshi, 2002) in part through better indexing, search engines, and linking.

Yet challenges remain. When organizations try to make sense out of large volumes of documents in their document management systems, they usually need search engines, text mining, and automatic indexing tools, resulting in an expensive solution with limited success (Bygstad, 2003). Furthermore, this approach is well suited only for relatively stable and centralized knowledge bases. Users of such knowledge bases often encounter information overload, irrelevant responses, or no response to queries. Alternatively, organizations might use expert reports and harvest expert knowledge to capture the methods used by domain experts (Snyder & Wilson, 1998). Again, this method often is limited to niche applications, requires considerable effort, and still faces knowledge maintenance difficulties (Malhotra, 2000). Other solutions, such as corporate controlled portals, can quickly suffer from outdated knowledge and lack of maintainability (Newcombe, 2000).

Knowledge Acquisition Bottleneck

In summary, we can describe the knowledge acquisition bottleneck as follows (Wagner, 2000; Waterman, 1986):

- Narrow bandwidth. The channels that exist to convert organizational knowledge from its source (either experts, documents, or transactions) are relatively narrow.
- Acquisition latency. The slow speed of acquisition frequently is accompanied by a delay between the time when knowledge (or the underlying data) is created and when the acquired knowledge becomes available to be shared.
- Knowledge inaccuracy. Experts make mistakes and so do data mining technologies (finding spurious relationships). Furthermore, maintenance can introduce inaccuracies or inconsistencies into previously correct knowledge bases.
- Maintenance trap. As the knowledge in the knowledge base grows, so does the requirement for maintenance. Furthermore, previous updates that were made with insufficient care and foresight (“hacks”) will accumulate and render future maintenance increasingly more difficult (Land, 2002).

Given these challenges, it appears that there are few opportunities for breaking the knowledge acquisition bottleneck. The next section will propose one possible remedy.

LEARNING FROM SOFTWARE DEVELOPMENT

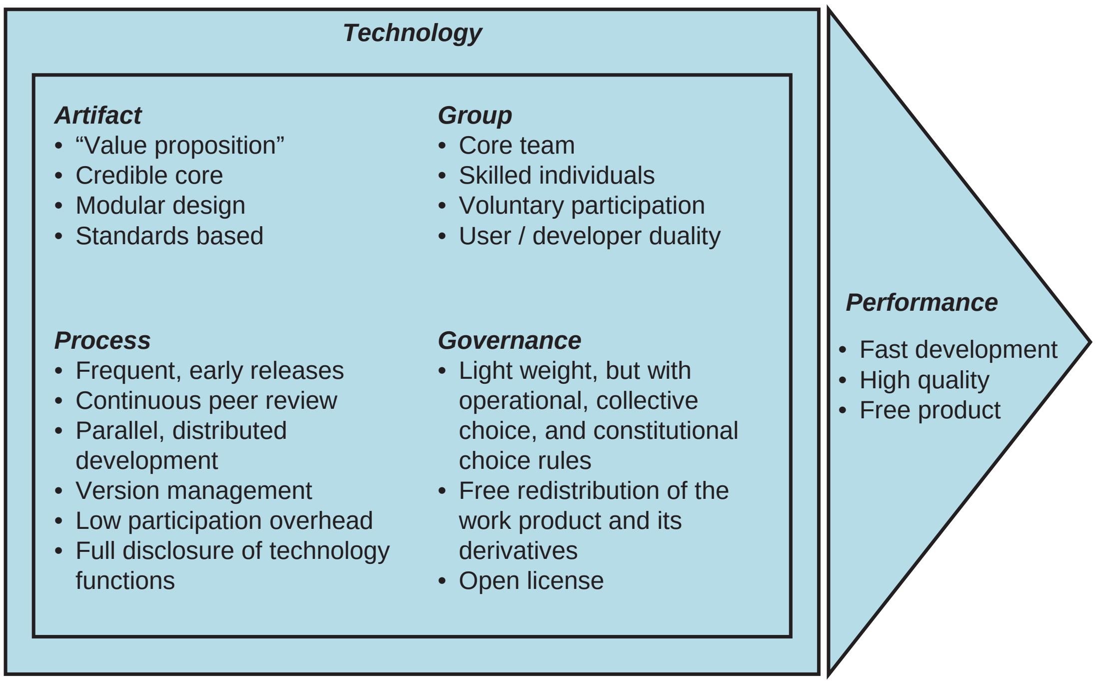
One area that has offered lessons for the successful creation of knowledge assets is software development, and specifically open source software development by distributed teams of volunteers. Open source projects engage software developers, wherever they may reside, and have them collaboratively develop the knowledge asset (the software). Surprisingly, this activity takes place with little centralized management. Raymond (2001) characterized this approach to software development as the Bazaar style in contrast to the traditional cathedral style of development. Cathedral is a metaphor for the development of a large monolithic artifact through a structured and lengthy development process. Fundamental to the cathedral style approach is that source code is only widely available at release dates with access restricted to a few developers between release dates. Bazaar style development, however, occurs over the Internet in constant public view. Raymond identified principles of this development style that challenge the assumption that large and complex software assets need to be built via an a priori, centralized approach. Overall, four themes guide this development approach, which can be characterized as follows: (1) design simplicity of the artifact, (2) team work, (3) frequent creation of a visible work product, and (4) development as an ongoing conversation. This section introduces a framework of open source (software) development, identifies its benefits, and derives lessons about the applicability for knowledge assets other than software.

Open Source Software Development

Open source software development, as described, for instance, by Raymond (2001), Benkler (2002), and Markus, et al. (2000), relies on several factors to achieve success (and thus, performance of the knowledge creation effort). Key success factors (see Figure 1) consist of a suitable artifact, a skilled and motivated team of volunteer users and developers, a lean and transparent development process, and lightweight but effective governance. Added to this is an enabling factor; namely, an appropriate technology infrastructure, which, for instance, permits frequent releases, accommodates voting mechanisms to govern the community, or enables fast and reliable version management, all with little overhead and few transaction costs. With these factors in place, open source software development promises faster development speed than proprietary approaches (including higher developer productivity) and a better quality product, which is also free.

Open source software development has had remarkable successes, creating software that appears to break long-standing rules of software evolution (Scacchi, 2004). For example, open source software size has been shown to grow super-linear (exponential) rather than linear or inverse-square (Mockus et al., 2002).

Figure 1. Framework for open source software development



Bazaar-Style Knowledge Management

Can Bazaar-style development be applied successfully to the creation of knowledge assets other than software? Several leaders of the open source community have hypothesized this, including Torvalds (Hamm, 2004). Yet Torvalds also acknowledged that not all knowledge assets are equally suitable, as the creation process may be too personal or too linear. Hence, in order to extend the lessons and benefits of Bazaar-style development, we should target applications where the core themes can be applied: (1) simplicity of design and frequent redesign (refactoring) to maintain simplicity, (2) teamwork (3) frequent creation of a small work product available for review and testing, and (4) development as conversation to facilitate back-up, clarity, and shared understanding. Applications of this kind exist within organizations, and among organizations and people. For example, companies could conceivably turn their traditional help desks into open help desks, where customers would openly share their problems with others, help each other, and free up company experts to tackle only the most difficult problems. Unfortunately, companies frequently do not want to relinquish control of their (closed) help desk. Open help desks exist on the Web, typically as discussion forums of questions and answers. While they embody teamwork and conversation, the resulting work product often is not simple and well-structured but lacks organization and is filled with repetition and inconsistencies.

Consequently, one necessary condition for this research was to find a knowledge asset that was highly amenable to the Bazaar-style development approach and that used a technology that facilitated this type of development. The selected asset was an online encyclopedia — Wikipedia (wikipedia.org) — that employs wiki technology and the "wiki way" of knowledge asset creation (Leuf & Cunningham, 2001). The article will provide more detail on the Wikipedia application, following a briefing on knowledge management with wiki technology and the wiki way.

CONVERSATIONAL KNOWLEDGE MANAGEMENT WITH WIKIS

Knowledge management with wikis has recently drawn media attention (Brown, 2004; Hof, 2004; Ripley, 2003) as a new, end user developed approach founded on collaboration and conversation. Collaborative knowledge management means that many people work together to create or acquire knowledge instead of a few individual experts. In other words, a community (of practice) will jointly create and maintain the knowledge. Research elsewhere (Cheung et al., 2005) suggests that conversational knowledge management is well suited for this challenge, whereby conversations (i.e., questions and answers) become the source of relevant knowledge.

Conversational knowledge management has become popular in communities that form around discussion boards. Leading solutions such as ezboard or Yahoo groups are now used by millions of communities1. Yet while discussion forums have been a simple and practical solution to share knowledge through conversation, they lack several useful knowledge representation and maintenance features. For example, discussion forum postings, even within a single thread, often do not build upon each other. As a result, the latest post may not be an incremental improvement of earlier ones. An alternative technology, which combines the most desirable features of other conversational technologies, is the wiki. This section discusses wiki technology and its suitability for knowledge management.

Wiki Structure and Principles

A wiki is a set of linked Web pages created through the incremental development by a group of collaborating users (Leuf & Cunningham, 2001) as well as the software used to manage the set of Web pages. Ward Cunningham developed the first wiki in 1995 as the PortlandPatternRepository in order to communicate specifications for software design within a large, heterogeneous community. The term wiki (from the Hawaiian wikiwiki, meaning fast) references the speed with which content can be created with a wiki. Wiki key characteristics are as follows:

- It enables Web documents to be authored collectively;
- It uses a simple markup scheme (usually a simplified version of HTML, although HTML frequently is permitted);
- Wiki content is not reviewed by any editor or coordinating body prior to its publication; and
- New Web pages are created when users navigate a hyperlink that points nowhere.

Underlying these characteristics are specific principles that have shaped wiki software as well as its use. They are intended to produce a development environment where multiple people easily can create and modify a set of jointly owned Web pages. Wiki pages are expected to be open, incrementally developed, and organic; require little markup; have consistent edit functions and clear naming, be heavily hyperlinked and easily observable (found). As a result, wiki pages are expected to change and improve incrementally.

Wikis in Use

Creating Wiki Pages

Creating and editing wiki pages is a simple activity. A wiki author will use a Web-enabled formfield to enter a comment he or she wishes to publish. Authors can use plain text or a simplified markup language. The system then automatically generates and publishes a Web page with a unique URL that can be indexed and linked to. Hence, users with virtually no Web publishing knowledge can create Web content about as quickly as they can write a text document.

Linking Wiki Pages

A fundamental aspect of knowledge management with wikis is the use of simple hyperlinks. Hyperlinks link topics and create context. Wikis drastically simplify hyperlinking. To link pages within a wiki, users do not have to create and use URLs (although they can). Instead, they normally use CamelCase (multiple words capitalized and concatenated) or double parentheses around a term ([[term]]) in order to create a link. Links whose destination (page) does not exist are depicted as question marks (or similar) as if the author were asking a question. Another author (or the original creator) then can respond by clicking on the question mark, thus navigating the hyperlink to a new page and invoking an editor to write that page. Upon completion of the edit, the question mark automatically will be rendered as a regular hyperlink (now underlined text) pointing to the new page.

Versioning

As multi-user systems, wikis enable every user to modify any other user's Web pages (unless explicitly forbidden by access right settings). This creates challenges in version management. Wikis solve them by keeping prior versions of any Web page in memory, and enabling rollback, comparison, difference identification, and similar capabilities, if so desired. Wikis also track the history of prior changes with author, date, and related information.

Wikis and Open Source Principles

Knowledge management using wikis and the wiki way (see, for instance, "WhyWikiWorks" at http://c2.com/cgi/wiki?WhyWikiWorks) appear to bear considerable resemblance to open source software development, described in part by the following traits:

- Sense of responsibility in contributing to a common good;
- Openness to change and modification by anyone;
- Meritocracy (anyone can play, but only good players last);
- Self-governance of the developer team;
- Task decomposition and incremental development;
- Use of technology for communication and coordination, as well as norms for their use, including objectivity (neutral point of view); and
- Ease of use for knowledge creation and maintenance.

Thus, as an enabling technology, wikis establish an environment to develop the right artifact, to use a Bazaar-style process, to engage teams in voluntary collaboration, and to govern the effort with a lightweight structure (Figure 1), thus offering the potential for open source knowledge management. In open source software development, the corresponding results are ultimately lower error rates (compared to closed source); fast(er) development speed; and the ability to develop large(r) applications, accelerated development, and high(er) maintainability of the source code (Mockus et al., 2002). Whether these same benefits accrue in wiki-enabled open source knowledge management must be determined empirically.

ASSESSING CONVERSATIONAL KNOWLEDGE MANAGEMENT

Can principles of Bazaar-style development be applied to knowledge management, and if so, will they improve knowledge acquisition effectiveness? To begin to answer these questions, the research analyzed a single case of wiki-enabled knowledge asset creation — Wikipedia.

Knowledge Asset: Wiki-Based Encyclopedia

Encyclopedias reasonably can be characterized as knowledge assets. While one may debate how much of their content is information instead of knowledge, encyclopedias contain insights (factual), rules (inferential), principles (inferential), and so forth. They also fit the definition of information in context (Davenport &Prusak, 1998), since they frequently link concepts to other concepts (cross-referencing). By design, encyclopedias also are relatively loosely coupled knowledge assets, whose components (articles) can exist independently. Encyclopedias frequently are compiled from the work of a group of authors who know little about each other or each other's work. Encyclopedia articles have common structural elements, since all articles are definitions. They typically also follow some standards for articles of a similar type (e.g., all biographies are structured similarly and different from city descriptions).

The majority of digital encyclopedias, such as Britannica, Encarta, Compton, or Grolier, is closed source. They are compiled by a relatively small group of commissioned writers and editors. The result of their work only becomes available to the readership once the entire edit process has been completed and the new encyclopedia version is released. Yet, because of their loosely structured nature, encyclopedias (and other, similar knowledge assets) also can be created in Bazaar style, given certain conditions. The work product cannot be an off-line product such as a book or a CD; the technology in general has to be amenable to Bazaar-style knowledge acquisition and representation, and the organization creating the encyclopedia has to formulate procedures and methods that enable this type of knowledge acquisition. Bazaar-style knowledge acquisition, therefore, becomes a possibility when the asset is created following the wiki way. Hence, Wikipedia, the online encyclopedia developed as a wiki, was used as the knowledge asset to be analyzed for this research. Wikipedia is one of several knowledge products developed over the last few years with wiki technology and the wiki way of development. Other applications include Wikitravel and Wikibooks. Development of Wikipedia began in 2001. As of May 2004, less than three and a half years later, the (English) Wikipedia contains about 280,000 articles.

Wikipedia, applying wiki principles, appears to enable its developers to use a Bazaar-style approach. Specifically, writers can make incremental changes and then commit and publish them immediately. Also, articles can be written by numerous writers as joint authors, thus building on the work of others or correcting mistakes. Furthermore, Wikipedia rules stress an authoring etiquette that incorporates rules of article design and redesign targeted toward simple and clear articles. In other words, it is possible for Wikipedia authors to follow the main themes of Bazaar-style development. Whether authors do so and whether the outcome of their efforts is consistent in its effectiveness with Bazaar-style software development needs to be determined empirically.

Research Questions

The research sought to address two questions through empirical analysis.

1. Is conversational knowledge management, as demonstrated in Wikipedia, consistent with Bazaar-style knowledge asset creation?
2. Is conversational knowledge management, as illustrated by Wikipedia, able to achieve the benefits of Bazaar-style development?

The research thus needed to determine whether "Wikipedians" would follow Bazaar-style knowledge acquisition and whether the effect would be improved knowledge acquisition. Based on the criteria in Figure 1, numerous questions would have to be addressed. Yet, as Table 2 illustrates, compliance with the majority of criteria was confirmed from Wikipedia information (Wikipedia Web site and Wikimedia Meta-Wiki), leaving four core questions to be answered.

Thus, the research questions focused on the incremental nature of the knowledge acquisition effort, the multi-person effort, and the effect on the growth and quality of the work product, as described in the following subsections.

Incremental Development with Frequent Releases

Incremental development and frequent releases are fundamental to Bazaar-style development. Would Wikipedians follow this approach, or instead would they prefer to write an authoritative article in an effort burst with few revisions in the process and even fewer thereafter?

To answer this question, the research explored (1) the frequency of article edits and (2) the change in article size. If the effort were non-incremental, one would expect a relatively short development period of high activity (since an article is typically a few hundred to a few thousand words long) followed by little editing activity thereafter, possibly with some maintenance and some extensions. An incremental effort, in contrast, would result in a high level of activity with many edits during an extended development period followed by a much-extended maintenance period with lower yet still considerable update efforts. To operationalize the assumption, the research adopted the Pareto rule, thus hypothesizing that if Wikipedia articles were written in a non-incremental effort, then 80% of

Table 2. Wikipedia fit with Bazaar-style development criteria

Dimension	Bazaar Style Development	Wikipedia Adaptation
Artifact	"Value Proposition"	Yes – create free and open encyclopedia
	Credible Core	Yes/No – not a ***content*** core, but a developer group core
	Modular Design	Yes – loosely coupled articles
	Standards Based	Yes – article structures
Group	Core Team	***? - Is Wikipedia development a team effort?***
	Skilled Individuals	Yes/No – participants from the Nupedia initiative were all PhDs, but no control over new participants
	Voluntary Participation	Yes – only one paid "chief editor", Larry Sanger (until 2002)
	User / Developer Duality	Yes – author and users
Process	Frequent, early releases	***? – Are Wikipedia articles developed through an incremental approach with continuous releases?***
	Continuous peer review	
	Parallel, distributed development	Yes – 7,000 authors worldwide
	Version management	Yes – through wiki technology
	Low participation overhead	Yes – through wiki technology
	Full disclosure of (technology) functions	Yes – through wiki technology
Governance	Light weight, operational, collective choice	Yes – Wikimedia organization with meritocracy as governing structure
	Free re-distribution of the work product	Yes – GPL license
	Open License	
Performance	Fast Development	***? – Does conversational knowledge management result in linear or better growth of knowledge assets***
	High quality	***? – Does conversational knowledge management result in improved knowledge asset quality?***
	Free product	Yes – GPL license

their size growth and 80% of the edit efforts should occur during the first 20% of their existence:

H1: Wikipedia articles are the outcome of an incremental development, and therefore, their growth and edit pattern does not follow the 80-20 Pareto rule.

Multi-Person Effort

There is little doubt that Wikipedia is a multi-person effort with presently more than 7,000 people contributing to it and more than 500 people making more than 100 contributions each per month (see Wikistats at http://www.wikipedia.org/wikistats/EN/TablesWikipediaEN.htm). However, according to the principles of Bazaar-style development, one would expect Wikipedia development to be a team effort at a more detailed level with multiple authors working on each article in order to extend it and possibly to correct mistakes. This would reflect one of the key themes of open source, also called Linus' [Torvalds] Law; namely, that "given enough eyeballs, all bugs become shallow." Hence, the research sought to determine whether enough eyeballs were scrutinizing each article, at least more than two. Hence, the analysis focused on whether article publication and maintenance was a multi-person effort.

H2: Knowledge acquisition and maintenance in individual Wikipedia articles is a multi-person effort.

Effectiveness

The research sought to determine whether encyclopedia development adopting the wiki way would be effective. In this exploratory study, effectiveness was measured through two variables; namely, (1) growth of the knowledge asset and (2) quality improvement efforts. Growth of the knowledge asset was determined, based on the increase in the number of articles in the Wikipedia over time. In line with other open source successes (Mockus et al., 2002), the expectation was that growth would be linear or better (super-linear).

H3: Wikipedia growth in terms of number of articles will be linear or super-linear.

Unable to assess the overall quality of the Wikipedia objectively vis-à-vis other encyclopedias, the research focused on process quality and specifically quality improvement efforts. These efforts were operationalized by the ratio of edit efforts vs. the growth of Wikipedia articles. In other words, the research tested whether editing efforts were devoted to increasing the size of articles or to refining existing articles. The assumption was that refinements (without significant increase in size) would improve overall quality, for instance, through an increase in presentation quality, content quality, or the inclusion of more viewpoints (diversity).

Hence, we computed a words-per-edit ratio based on the number of words (per article) written and the number of edits it took to create the article version. This ratio was calculated for articles in their early stages (20% of development effort) and at their present state. Decreasing ratios would indicate more effort being spent over time on article refinement. To exclude insignificant edits, the research only considered non-minor changes (counted separately in Wikipedia). The expectation was that, over time, more effort would be devoted to increased article quality. It is a stated Wikipedia goal to increase quality as articles mature (see, for instance, the reply to objections concerning Wikipedia, which discusses quality and growth issues, at http://en.wikipedia.org/wiki/Wikipedia:Replies_to_common_objections).

The corresponding hypothesis concerning quality improvement was as follows:

H4: Edit effort targeted at quality improvements for individual Wikipedia articles will increase over time, demonstrated by reduced article growth per edit.

Data Source

Wikipedia is an open encyclopedia in many ways. In addition to articles being freely accessible, so is the history of their creation, including dates, content of each version, and author information. Hence, it was possible to trace changes, change frequencies, and author contributions. To address the first two questions, 80 articles were randomly selected with the one qualification that 40 of them had to be created originally in 2001 and 2002. More recent articles were ignored because of their short history. To determine knowledge asset growth, Wikipedia summary statistics were accessed, which logged the number of articles written each month from the start of Wikipedia.

Results

Incremental Development (Release Early and Often)

This analysis focused on two samples of 40 articles from 2001 and 2002. For both of these samples, the edit efforts for the first 20% of each article's existence (up to the measurement point in March 2004) were compared against the entire development effort. The results do not support the notion

Table 3. Wiki development activity

	20% Avg. Actual	**Avg. Expected (80-20 Rule)**	**t (df = 39)**	**Significance p**
2001 Articles, *Size (Words)*	793	1,855	6.468	.0000
2001 Articles, *Edits*	17	230	8.841	.0000
2002 Articles, *Size (Words)*	811	1,795	4.212	.0000
2002 Articles, *Edits*	24	133	6.820	.0000

Table 4. Wikipedia article author statistics

	Min. No. Authors	**Max. No. Authors**	**Avg. No. Authors**	**t-Statistic**	**Significance p**
2001 Articles	33	285	121.4	10.33	.0000
2002 Articles	18	268	70.8	7.870	.0000
All Articles	18	285	96.1	12.21	.0000

of a short effort burst but one of incremental development, as shown in Table 3.

For articles started in 2001, the first 20% of an average article's existence accounted for about 34% of the article's size (793 words out of 2,319) and less than 6% of its edits (17 out of 288). For the 2002 articles, the first 20% accounted for about 36% of article size and 15% of article edits. Overall, this was considerably less than expected according to the Pareto rule. All results are highly significant ($p < 0.0001$). Hence, size grew relatively incrementally with a somewhat larger upfront effort (about 35% of size produced in 20% of the time). Wikipedia edits were even more incremental with a disproportionately small number during the early existence of an article (15% or less of the edits in 20% of the time).

Multi-Person Effort

Each of the 80 articles in the two samples also was evaluated according to the number of authors. None of the articles in the sample was co-authored by fewer than 18 people, and the maximum number of authors for any article was 285. On average, more than 96 authors worked on an article (Table 4).

Given these results, what is the likelihood that articles overall were predominantly single-authored? Virtually none. A t-test showed very significant differences between the actual author numbers and the possibility of single authorship. This is a strong result, yet the reader is reminded that the sample articles were old articles. More than half of the Wikipedia articles were less than 12 months old (as of June 2004) and will have been edited by fewer people. An additional sample of 40 randomly selected articles started in 2003, though, still corroborated the results (average of 48 authors, $t = 7.164$, $p = 0.0000$). In other words, as time progresses, Wikipedia articles are scrutinized by "many eyeballs".

Wikipedia Growth

Data points concerning the growth of Wikipedia illustrate dramatic growth. Although Wikipedia has existed since 2001, more than half of its approximately 280,000 articles (English articles as of May 2004) were written since June 2003. (See http://www.wikipedia.org/wikistats/EN/TablesWikipediaEN.htm).

To explore the growth pattern further, the analysis targeted the numbers of new articles created each month. Three different time series were compared: number of articles, log of number of articles, and square root of number of articles. For each series, the fit was computed to determine which one best predicted Wikipedia growth. As Table 5 illustrates, Wikipedia growth is best explained by a quadratic function (R2 = 0.988, highest). In other words, Wikipedia article growth is most likely quadratic and, thus, super-linear, which is an aggressive growth pattern. Quadratic growth also best explained the increase in the number of Wikipedians and in the number of edits (changes) made to Wikipedia.

Quality Improvement

The second effectiveness measure, the allocation of effort to quality improvement, suggested a shift toward more quality as Wikipedia articles aged. Table 6 illustrates that during the first 20% of an article's existence, each edit resulted in about 60 additional words vs. 11 or fewer words for the remaining 80% of the article's life (up to the measurement date in March 2004).

The differences in the means of these ratios were highly significant, confirming that later effort is an investment in article quality rather than article length.

Discussion

Results of the exploratory study confirm what has been expected. Hypotheses H1, H2, H3, and H4 were all confirmed. Knowledge acquisition efforts apparently can successfully adopt Bazaar-style development with multi-user involvement, incremental changes, and quick releases in an environment that enables conversational knowledge acquisition. In the case of Wikipedia, this was possible for several reasons. First, Wikipedia was able to draw a large and quadratically growing developer group (approximately 7,000 as of May 2004).

Second, Wikipedia pages are highly decoupled from each other so that new authors can write with little concern for the current content of other pages. When an author breaks a hyperlink or negatively affects content, it becomes quickly

Table 5. Growth in Wikipedia articles (articles official count, March 2004)

Relationship	**R^2**	**p**
Linear	.932	.0000
Exponential (log)	.819	.0000
Quadratic (square root)	.988	.0000

Table 6. Words per edit by article age

	20% - Avg. Words / Edit	**80% - Avg. Words / Edit**	**t (df = 39)**	**Significance p**
2001 Articles	57.8	6.7	5.848	.0000
2002 Articles	64.4	10.7	4.239	.0001

apparent, and other Wikipedians will fix the problem. Third, when authors make a contribution, whether writing a new page or changing an existing article, the result is immediately visible to the entire community, thus enabling quick releases with minimal latency and multi-user quality assurance. Therefore, the transaction cost of making a contribution is low, much lower than in any peer-reviewed or closed source authoring environment (Ciffolilli, 2003). Fourth, there is no individual ownership of Wikipedia pages, which are developed by volunteers; thus, everyone works to improve everyone's contributions. Quality is everyone's responsibility. Fifth, Wikipedia has strong editing guidelines that are motivated by the refactoring rules of software development and principles of objectivity. This ensures that articles, which might have suffered in readability from the disjointed work of multiple contributors and commentator, ultimately become very readable again.

As a result, in three and a half years of existence, Wikipedia has challenged the otherwise largest but closed authorship Encyclopedia Britannica (Britannica Online) for leadership in content (Britannica has self-reportedly about 100,000 entries, although with a larger word count per article). Other wiki-supported knowledge assets, such as Wikitravel, for instance, may be able to achieve similar leadership roles in their knowledge domain. The open, multi-user model also appears to scale well by interesting an increasingly larger user population to contribute their efforts, thus keeping the article latency at about 10 days for old articles (initially created in 2001) and less than two days for newer articles (i.e., 2003). However, since wiki technology is relatively new and contrary to many organizations' cultures, we should not expect this approach to become predominant soon. In fact, the successes are few at present. However, one should expect an increasing number of wiki software products to emerge in the future and an increasing number of communities to replace their inferior conversational technologies with wikis.

CONCLUSION

The challenge of capturing and maintaining exponentially growing volumes of knowledge requires new ways of knowledge acquisition; namely, on approaches that rely on the contributions of many rather than the expertise of a few. Wiki technology and the wiki way of collaboration show a feasible model for knowledge acquisition and maintenance. Wikipedia offers an illustration of the effectiveness of this approach. The research demonstrates that users of a wiki-based knowledge asset (i.e., Wikipedia) apply Bazaar-style methods and techniques in their conversational knowledge asset creation. The research also suggests that knowledge acquisition through collaboration and conversation can lead to super-linear knowledge asset growth and continuous quality improvement.

Not surprisingly, there are several caveats. For instance, knowledge quality cannot be measured or managed easily. The quality of Wikipedia articles, for instance, remains a source of arguments. Therefore, future research will need to investigate the quality of the resulting knowledge based on content. In addition, knowledge creation with wikis relies on a strong and positive social contract among its contributors and on subject matters that are not controversial. These conditions are not always present. Wikipedia does have guidelines in place to handle disorderly participants and to maintain a neutral point of view (NPOV) in articles. But Wikipedia clearly relies on the social capital within its community. Studies of less strong communities will have to be part of the future research in order to determine knowledge losses due to lack of social capital. Furthermore, Bazaar-style knowledge management relies on volunteers who are genuinely interested in the cause. This may not be a paradigm for organizations where knowledge assets are not free. Future research will need to explore the applicability of open source knowledge management when the intellectual property is at least partially proprietary. Finally, the discussed approach to knowledge management appears to work, partly because it can engage increasing numbers of participants to deal with a growing task domain. One has to wonder about the limits of growth of this scenario. Considering both the positive findings and the challenging questions, it appears that Bazaar-style knowledge acquisition using wikis will be a promising application for the practice of knowledge management as well as a rich source of interesting research questions.

ACKNOWLEDGMENTS

The research described in this article was supported in part by CityU grant SMA#9030992. The author completed a substantial portion of the research leading to this article during two sabbaticals at the School of Information Science, Claremont Graduate University. The research assistance of Karen Cheung is thankfully acknowledged.

Chapter 3.22
Technical Aspects of Knowledge Management:
A Methodology for Commercial Knowledge Management Tool Selection

Nayna Patel
Brunel University, UK

Vlatka Hlupic
Brunel University, UK

ABSTRACT

One of the repercussions of the ever-rising popularity of knowledge management is a sudden increase in the number and range of knowledge management tools available on the software market. This can present a problem for organisations that are required to sift through the vast number of tools in the hope of finding one that meets their requirements. Moreover, guidelines describing how to go about selecting a commercial knowledge management tool do not currently exist. Therefore, the aim of this chapter is to present a set of guidelines to aid the evaluation and selection of a commercial knowledge management tool. In order to achieve this, a methodology is proposed that outlines factors and issues that could be taken into consideration during the selection of a knowledge management tool. Furthermore, an overview of criteria specific to knowledge management tools that can be used to evaluate and ascertain the features present in a knowledge management tool are also suggested.

INTRODUCTION

Knowledge management has attracted a great deal of interest in the past few years. However, this appears to have focused on the organisational and human aspects (Davenport, 1996). The technical aspect of knowledge management has been acknowledged, but few academic studies have ventured beyond this point. While research efforts have been centred on the organisational and human issues of knowledge management, software vendors have been busy bombarding the market with various knowledge management tools. Consequently, an overwhelming number of knowledge management tools exist on the software market (Angus et al., 1998; Davenport and Prusak, 1998; Silver, 2000). This is not immediately perceived as being problematic since the greater the choice, the more competitive and dynamic the market. However, the overwhelming alternatives can make it difficult for organisations to select a suitable knowledge management tool that adequately meets their requirements. This is further complicated by the fact that, while some of these tools have been designed specifically as knowledge management tools, others have been re-packaged, re-labelled and re-marketed as knowledge management tools (Angus et al., 1998). Other disciplines and even areas within information systems and computing have overcome this problem by creating a set of guidelines that aid the selection of suitable software tools. In light of this, it appears feasible to provide a similar facility for knowledge management tools.

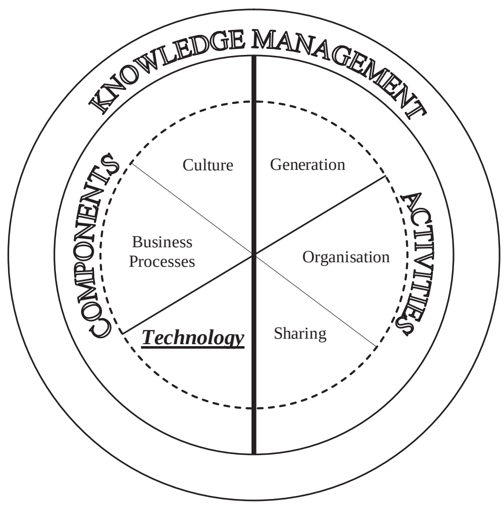
Therefore, the motivation for this research stems from the lack of guidelines available for the selection of knowledge management tools. The purpose of this chapter is to demonstrate a methodology that has been designed to aid the selection of a commercial knowledge management tool. The chapter begins by demonstrating how knowledge management tools fit into the broader context of knowledge management. Following this is an illustration of the methodology and a description of how it was designed. A part of the methodology involves the evaluation of candidate knowledge management tools. Therefore, an evaluation framework that could be used to achieve this is also described. The chapter concludes by reflecting on the methodology and discussing further work in this area.

KNOWLEDGE MANAGEMENT TOOLS IN CONTEXT

The area of knowledge management has been subjected to a great deal of controversy with regards to the lack of a common definition or concept. However, there does appear to be some consistency in relation to the components and the activities, often referred to as processes, which constitute knowledge management. This research can be classified under the ‘Technology’ component of knowledge management which is illustrated in Figure 1.

Figure 1 shows that knowledge management consists of two areas —knowledge management activities and knowledge management components. The former, knowledge management activities, is divided into the three areas of knowledge generation, knowledge organisation and knowledge sharing. These represent the primary activities that can take place, either in

Figure 1. Knowledge management activities and components



isolation or in various combinations, during a knowledge management deployment. The latter components of knowledge management consist of culture, business processes and technology. These reflect the aspects of an organisation that must be taken into consideration for a knowledge management effort to be successful. Unlike the activities, the components must not exist in isolation as part of a knowledge management exercise. In fact, all three components should receive equal, and combined, attention (Borghoff and Pareschi, 1997; Davenport, 1997; Davenport and Prusak, 1998; Milton et al., 1999; Trauth, 1999; Vaas, 1999, Duffy, 2001). Therefore, as mentioned in the previous section, the research specified within this chapter focuses on the technology component of knowledge management. However, prior to addressing knowledge management technology the remainder of this section describes the knowledge activities and components in more detail, in order to provide some background information and to clarify the context of this research.

Knowledge Management Activities

Knowledge management activities refer to the phases that take place in order to achieve knowledge management. Table 1 describes the knowledge management activities specified by various authors. In general, knowledge management activities range from between three and five categories. Although the terms used are very similar, there appears to be some variance in the meanings. For instance, Angus and Patel (1998) claim that knowledge gathering refers to the bringing in of information and data. However, according to Kramer (1998) knowledge gathering entails the process of collecting knowledge. The subtle difference here is reference to what is being gathered. Angus and Patel (1998) are collating information and data whereas Kramer (1998) is gathering knowledge.

Essentially, it appears that the knowledge management activities involve obtaining knowledge in the first place, organising it so that it can be easily accessed at a later date and ensuring that the collated knowledge is exploited by sharing it with the people who require it. A number of authors have sub-divided each of the knowledge management activities further by associating various actions that refer to the way the activity is achieved. For example, Angus and Patel (1998) claim that knowledge can be gathered through pulling, searching, Optical Character Recognition (OCR) or voice input.

Knowledge Management Components

The other aspect of knowledge management that appears to contain some consistency is related to the areas that must be addressed during a knowl-

Table 1. Knowledge management activities according to various authors

AUTHORS	KNOWLEDGE MANAGEMENT ACTIVITIES

Macintosh (1999)	Developing	Preserving	Using	Sharing	

edge management deployment. These include: culture, business processes and technology (Borghoff and Pareschi, 1997; Davenport, 1997; Davenport and Prusak, 1998; Milton et al., 1999; Trauth, 1999; Vaas, 1999, Duffy, 2001). The cultural aspect of knowledge management is often considered as one of the most difficult obstacles to overcome (Bicknell, 1999). This is attributed to traditional business practices of hoarding knowledge (Hibbard and Carillo, 1998). Previously, knowledge was perceived as an individual's power and secured their position, and in some cases led to promotion, within an organisation. However, the repercussions of the knowledge age mean that in order to create a knowledge sharing environment, it is necessary for employees to change their way of thinking. Nevertheless, theory is very different from practice. Many suggestions have been made in order to improve the cultural environment, ranging from story telling (Reilly et al., 1999) to ensuring that employees feel confident that they will still be a valuable asset to the organisation if they share their knowledge (Angus et al., 1998; Hibbard and Carillo, 1998). Unfortunately, the cultural branch remains a major hindrance to the success of many knowledge management deployments.

A number of theorists believe that the key to creating a knowledge sharing environment is to re-design business processes (Angus and Patel, 1998; Hibbard and Carillo, 1998; Klamma and Schlaphof, 2000). This involves the radical re-design of business processes that exist within an organisation without allowing current practices to influence the resulting design (Davenport, 1993; Hammer and Champy, 1993; Robson and Ullah, 1996). Consequently, business processes are re-designed in order to accommodate a knowledge sharing environment. Furthermore, the resulting business processes should also consider, and support, the chosen knowledge management strategy. For instance, an organisation's strategy may consist of capturing information from consultants while they are working at a client site on a project. However, in order to achieve this, it is necessary for the consultants to keep a record of certain activities. This should be taken into consideration, and time to do this should be allocated within the re-designed business processes. Knowledge management strategies are a separate research area altogether and are out of the scope of this research and therefore are not covered in any detail.

According to Ruggles (1997) technology and culture are connected by the condition that technology is compromised if the appropriate knowledge sharing culture is not adopted. Technology, in the form of knowledge management tools, is used to facilitate the knowledge management activities. As described in the previous section (Knowledge Management Activities), these consist of knowledge generation, organisation and sharing (Ruggles, 1997; Angus and Patel, 1998; Davenport and Prusak, 1998; Kramer, 1998; Ferran-Urdaneta, 1999; Jackson, 1999; Macintosh, 1999). One example of a knowledge generation tool is software that creates user profiles according to the parts of a web site a user has navigated. The knowledge collated is exploited during the user's subsequent visits. For instance, if during the initial visit the user shows an interest in the sports sections of the web site, they would be presented with various links connected to sport on their next visit. If during this particular visit they only read the football articles, then the site would prioritise football articles. Each time the user visits the site, more knowledge is collected about them and, it is believed, the better their requirements are understood. Knowledge generation tools appear to vary quite considerably in where knowledge is obtained from and how it is generated. Some tools generate new knowledge by combining knowledge that already exists within an organisation. Others search the Internet to obtain the relevant knowledge.

Knowledge organisation tools are used to store and organise knowledge so that it is quick and easy to access by the people who need it. Although

not immediately obvious, there are various ways that knowledge can be stored and organised. For instance, the method of cataloguing knowledge may be achieved automatically by the tool using a predefined set of criteria. Alternatively, it may be necessary for somebody, often referred to as a knowledge librarian, to organise the knowledge manually.

Davenport and Prusak (1998) claim that knowledge sharing tools are the most valuable of the three. The main aim of knowledge sharing tools is to disseminate knowledge to the relevant people efficiently and effectively. This may be achieved by using utilities such as conferencing, bulletin boards, messaging and file transfer. A conferencing facility would enable a group of people to work together although they may be located in a dispersed fashion. Tools of this calibre allow the use of features such as chat, whiteboard and application sharing so that all group members are able to see and understand what is being demonstrated. Furthermore, an item can be worked on collaboratively, with everyone present being able to view the same information. Table 2 displays a list of knowledge management tools and the functions associated with each. Furthermore, the relationship between the functions and knowledge management activities are also demonstrated.

This is only a small selection of the types of knowledge management tools available, and the list is constantly growing at a rapid pace. Furthermore, the lack of any formal techniques for knowledge management tool selection means that the process of choosing one is the responsibility of the purchasing organisation. This entails time, money and effort to be invested that could be utilised elsewhere, if some form of guidelines were available. It would be possible to use one of the numerous generic techniques that exist (Curry and Bonner, 1983; Martin and McClure, 1983; Lynch, 1985; Breslin, 1986; Klein and Beck, 1987; Anderson, 1990; Le Blanc and Jelassi, 1991; Sharland, 1991; Montazemi et al., 1996). However, these would need to be adapted to accommodate characteristics present in knowledge management tools. Furthermore, other disciplines including education (Berryman et al., 1994; Buckleitner, 1999), the health service (McDonald, 1996) and the military (Parnas et al., 1990; Dupuy and Leveson, 2000) can make use of such guidelines designed specifically for their areas. Therefore, a methodology that aids the selection of a commercial knowledge management tool has been designed and is presented in the following sections.

METHODOLOGY FOR KNOWLEDGE MANAGEMENT TOOL SELECTION

A methodology was designed that illustrates the factors and issues that can be taken into consideration during the selection of a knowledge management tool. It is important to note that the methodology is not intended as a rigid structure that must be followed without any deviation, as is often the associated meaning where the term 'methodology' is concerned. In fact the opposite is true: the methodology is intended as a guideline and aid that can be adapted according to the requirements of the individual organisation. The remainder of this chapter describes the resultant methodology that was designed for the purpose of knowledge management tool selection.

Designing the Methodology

The information used for designing the methodology was obtained predominantly from three different sources. The first resulted from conducting interviews with people involved with knowledge management tools. Prior to conducting the interviews, questionnaires were used in order to obtain a general understanding of the knowledge management tool and the context in which it was being used. Furthermore, this enabled the questions that needed to be asked during the follow-up interviews to be highlighted. Therefore, in total 58 questionnaires were distributed and follow-up interviews were conducted. The questions used in both, questionnaire and interview, were predominantly of an open-ended nature, and the format of the interviews were unstructured.

The second source of information was from existing methodologies designed for the selection of software. These include two different types: 1) generic methodologies (Curry and Bonner, 1983; Martin and McClure, 1983; Lynch, 1985; Breslin, 1986; Klein and Beck, 1987; Anderson, 1990; Le Blanc and Jelassi, 1991; Sharland, 1991; Montazemi et al., 1996) that can be used for the selection of any software tool and 2) specific methodologies intended for the selection of discipline specific tools. An example of the latter is a methodology that is designed specifically for the selection of educational tools and therefore considers educational requirements (Berryman et al., 1994; Buckleitner, 1999). Discipline-oriented methodologies were investigated to establish how the task of designing a discipline-specific methodology is undertaken and how issues that need to be addressed, with regards to the particular area, were obtained. Furthermore, methodologies designed for areas already existing within the discipline of information systems and computing such as simulation (Hlupic, 1997; Nikoukaran et al., 1998) and computer-aided software engineering (Forte, 1992; Mosley, 1992), were also analysed. The reason underlying this was that, being classified under the same discipline parts of the methodology may also apply to knowledge management tool selection.

The third and final source of information was obtained by consulting the literature related to knowledge management. The purpose of this was to identify the factors specific to knowledge management tools that need to be taken into consideration during the selection process. The results from the three different avenues of information were collated and combined in order to create a methodology for knowledge management tool selection.

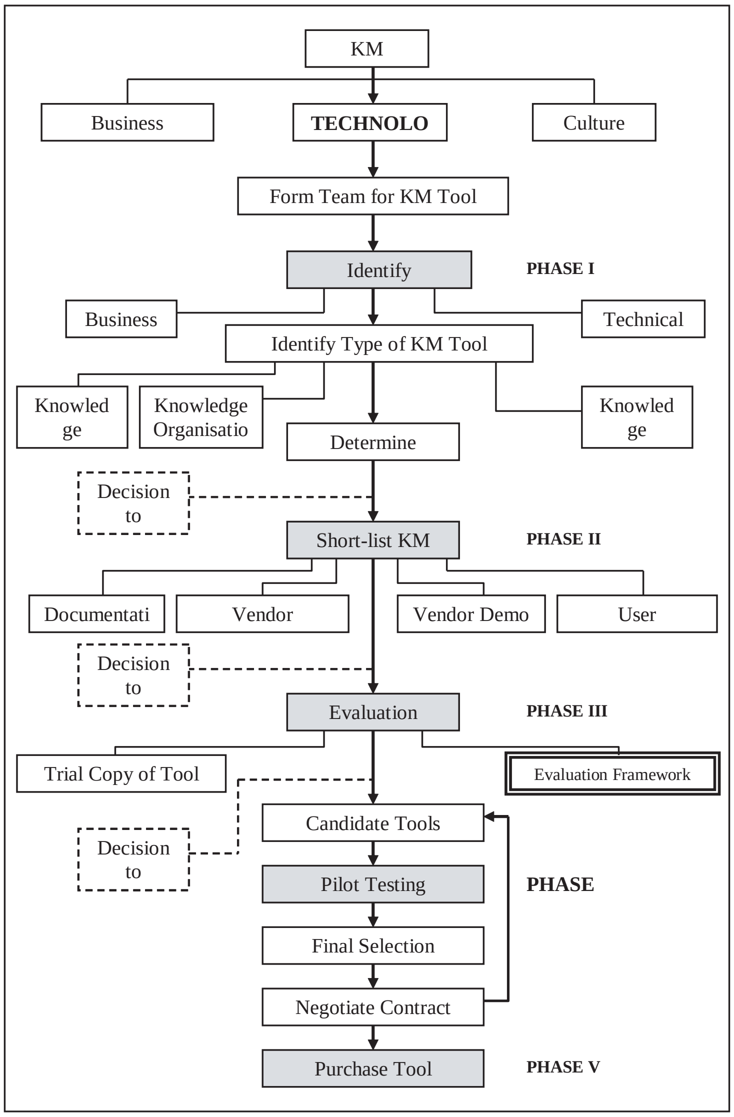
The Methodology

The methodology, illustrated in Figure 2, has been designed to aid the selection of knowledge management tools and can be classified under the 'Technology' component of knowledge management. However, Figure 2 demonstrates that the 'Business Processes' and 'Culture' components have also been included within the methodology. The justification for this is to further substantiate the theory that a knowledge management deployment must take into consideration the three components, in combination, as opposed to one in isolation (Davenport and Prusak, 1998; Milton et al., 1999; Trauth, 1999; Vaas, 1999, Duffy, 2001). The methodology consists of five main phases, each of which requires several intermediate stages to be undertaken. In essence, the methodology involves: identifying requirements, creating a short-list of suitable knowledge management tools, evaluating the tools, conducting pilot tests and finally purchasing a tool. The following sections provide a detailed account of each of the five phases and the associated intermediary steps.

Phase I

In order to achieve Phase I, Identify Requirements, it is necessary for a selection team to be formed. The team should consist of a variety of representatives from all levels of an organisation (McDonald, 1996). Ideally this would include: a chief knowledge officer (CKO), technical staff, managers, knowledge librarians, and potential users. The chief knowledge officer, or equivalent, should be a part of the team because their role is to ensure that the knowledge that exists within an organisation is captured and utilised to its maximum potential (Bonner, 2000). The purpose of technical staff being present on the selection team is twofold. Firstly, they need to ensure that the tool that is eventually selected is compatible with the existing infrastructure. Secondly, since they are the ones that will be supporting the tool,

Figure 2. Methodology for knowledge management tool selection



their input and advice is vital. The involvement of managers within the selection team is crucial since they have a global view of the particular area that they manage, enabling them to specify broader requirements for the tool in question. It is also important to identify and include, in the selection team, the people that will be maintaining the knowledge once the tool is installed, usually referred to as knowledge librarians. Finally, a number of users should figure in the selection team since, ultimately, they are the ones who will be using the tool on a day-to-day basis (Montazemi et al., 1996).

Once a satisfactory team has been formed, their first task is to identify both business and technical requirements (Curry and Bonner, 1983). The former entails specifying the business objectives that need to be achieved, the manner in which each will be addressed and a description of the role of the tool that is to be purchased. For instance, a business objective for an organisation may be to improve customer service. A possible way of addressing this is to reduce the time taken for the Help desk to resolve a query. This could be accomplished by having a system whereby the solutions to queries that have previously been resolved can be easily accessed and used, omitting the need for the same query to be solved time and time again. In light of this, the knowledge management tool required needs to facilitate the storage and retrieval of Help desk queries and their respective solutions.

The identification of the technical requirements consists of establishing what hardware and software currently exists in order to ensure that the purchased knowledge management tool is compatible (Martin and McClure, 1983; Mosley, 1992). Another decision that needs to be considered at this point is if a commercial knowledge management tool would be purchased if it required adapting in order to meet the organisation's requirements. If tools that require adapting are not to be considered, then these need to be discarded from the list of potential tools whenever such a tool is identified. There is no one single point in the methodology that facilitates this consideration since the necessity to adapt may be evident at any number of stages. If the purchasing organisation is prepared to adapt a commercial knowledge management tool, then a number of issues need to be taken into consideration. These include the party responsible for adapting the tool (the vendor or the purchasing organisation), the amount of adaptation required, etc. (Martin and McClure, 1983). If the purchasing organisation is relying on the vendor to adapt the tool, then it needs to be confirmed that the vendor is capable and prepared to do this. If the purchasing organisation has decided to adapt the tool themselves, then they need to ensure that they have the resources and expertise in order to achieve this.

Once the requirements have been established, the next stage involves identifying which of the knowledge management activities need to be supported by the tool. This may include one, two or all three of the knowledge management activities. For instance, referring back to the Help desk example, the knowledge management activities that would be involved are knowledge organisation and knowledge sharing. The former activity will need to be facilitated by the tool in order to store and allow the manipulation of queries and their respective solutions. The latter activity needs to be catered for by the tool so that the knowledge about the queries and respective solutions can be shared between Help desk staff. Having identified the knowledge management activities that the tool is required to facilitate, it is necessary to determine the budget available for purchasing the tool.

In the process of considering this, it is also important to establish whether or not the budget, in addition to the cost of purchasing the tool, will include costs for training, installation, licences, etc. (Mosley, 1992). Once the requirements, the type of tool required, and the budget have been identified, the software market needs to be scoured in order to identify knowledge management tools that meet these criteria. Therefore, prior to preceding to Phase II, a list of all of the knowledge management tools that could potentially be purchased should be created. At this stage it may be indicative that the software market does not provide a knowledge management tool that meets the criteria specified within Phase I. Therefore, it may be decided that the most appropriate option would be to pursue the development angle (Martin and McClure, 1983). This may involve developing the knowledge management tool internally if the expertise and resources are available. Alternatively, a software development company may be utilised to create the required knowledge management tool. Following this route entails a separate study and therefore is not included within this methodology. The boxes in Figure 2 representing the decision to develop are denoted using a dotted line.

Phase II

The aim of Phase II is to take the list created as a result of Phase I of the methodology and produce a streamlined short-list of knowledge management tools. This is achieved by carrying out a sequence of four steps, the objective being to refine the short-list of knowledge management tools with each additional step. The first step involves obtaining an overview and a general idea of the features provided by each of the tools in the short-list. In order to accomplish this documentation, brochures, user manuals and reviews should be gathered and carefully analysed (Sharland, 1991). The tools that are considered unsuitable should be discarded from the list and the remaining tools should be further investigated.

The second step consists of collating information about the actual vendors of the tools. The main aim of this is to ensure, as much as it is possible, that the vendors are reputable and have a stable position within the software market (Martin and McClure, 1983). The level of information gathered during this step depends on the circumstances of the installation and support required for the tool. For instance, if the tool is to be installed, maintained and supported by the purchasing organisation, then the role of the vendor is limited and therefore basic information about the vendor will suffice. However, if the vendor is required to have a major contribution subsequent to the tool being purchased, then a more thorough investigation is required. There are a variety of areas for which information can be collated about the vendor, including the background of the company, contact information and quality of service.

It is important to have some general knowledge about the vendor's background and current stance within the industry to ensure that the vendor is stable and in a position to provide a high-quality service. This may involve gathering information, such as when the vendor was established, whether it is part of another company and a current list of clients. The list of clients can be extremely indicative of the vendor since an association with reputable customers implies the ability to provide a good service (Martin and McClure, 1983). However, it is important to emphasise that the decision of selecting a vendor should not solely be based on the client list. Another way of determining the quality of the vendor by using the client list is to actually contact the vendor's clients and gather their views on the tool and the vendor.

Contact details for the company includes where the vendor is based and the person whom is the main point of reference. The location of the vendor may be important if training is to be conducted at the vendor's site. Consequently the costs of sending employees for training need to be taken into consideration and budgeted for. If possible, it is important to communicate with the same person representing the vendor since this gives the two companies an opportunity to establish rapport. Moreover, the vendor's representative can form a clear idea about the purchasing organisation's requirements (Curry and Bonner, 1983).

The quality of the service provided by the vendor should be continuously recorded, as it is crucial that the purchasing organisation is satisfied and comfortable with dealing with the vendor. Another useful method, recommended by Curry and Bonner (1983), of separating the stronger vendors from the weaker ones is to request the vendor to write a proposal detailing how their particular tool and company can address the purchasing organisation's requirements. According to Curry and Bonner (1983), high-quality and experienced vendors are accustomed to responding to requests for proposals and should do so within a given timeframe (specified by the purchasing organisation). Those that do not respond can be discarded from the short-list.

The third step involves taking the further refined short-list and visiting the vendors of each of the knowledge management tools in order to view a demonstration. Ideally, the demonstration should take place at the vendor site since this provides the purchasing organisation with the opportunity to obtain further insight about the vendor (Curry and Bonner, 1983). During the demonstration of the tool, it is important to ask the vendor to illustrate how to perform functions similar to the ones that the tool is intended to be used for. The responses to these requests can assist the purchasing organisation with determining whether the tool is able to support their needs and how competent the vendor is with the tool. As a result of this step, the tools that appear inappropriate or the vendor that seems weak should be discarded from the short-list.

The final step within Phase II involves contacting actual users of the tools using the clients list that should have been obtained as a part of the second step. The clients should be questioned about the quality of service provided by the vendor and details of any problems encountered. They should also be asked for their opinions with regards to the actual knowledge management tool, and Martin and McClure (1983) suggest approaching the users for their views on how the tool could be improved. After taking all of the information gathered during this step into consideration, a final short-list of knowledge management tools should be drawn up, ready for evaluation. As with the previous phase, the result of this phase may indicate that a suitable knowledge management tool does not currently exist in the software market. Therefore, the option to develop a knowledge management tool may be considered.

Phase III

Phase III of the methodology is concerned with obtaining a trial copy of the tool and conducting evaluation (McDonald, 1996). Therefore, each of the vendors associated with the knowledge management tools contained in the short-list should be contacted and a trial copy obtained. These are usually based on a variation of a limited period of time with access to all features or no time limit but restriction placed on certain features. Once the tool has been installed, it can be explored and experimented with. Trial copies usually come with a tutorial, therefore this is a good place to start becoming accustomed to the tool. Once a certain level of confidence is achieved, a structured and systematic evaluation of the tool should be conducted. For comparison purposes it is advisable to use a framework against which each of the knowledge management tools can be evaluated. An evaluation framework was designed as a broader part of this research and an earlier version of which is published in Patel and Hlupic (2000). The framework is designed to evaluate all aspects of purchasing a commercial knowledge management tool, including areas applicable across all software tools, e.g., costs, training, interface, etc. However, Table 3 demonstrates a small section of the evaluation framework that is applicable to knowledge management tools to enable the understanding of the criteria relevant to this area.

The framework was designed using a similar procedure for data collection as that described in the section about designing the methodology. However, users of knowledge management tools were also interviewed in order to obtain information about criteria that could make up the framework. Furthermore, several knowledge management tools such as those presented in Table 2 were empirically investigated to identify further criteria. As previously mentioned knowledge management tools appear to be designed in

Table 3. Framework for evaluating knowledge management tools

CATEGORY	CRITERIA		DESCRIPTION
General Criteria			
Type	o Generate knowledge o Organise knowledge o Share knowledge		Which of the knowledge management activities does the tool accommodate?
Purpose	o General o Specific		Has the tool been designed for a specific area? E.g. helpdesk
Type of knowledge	o Structured o Unstructured		What type of knowledge does the tool facilitate?
Format of data	o Numeric o Text o Graphics	o Audio o Visual	What format(s) of data does the tool facilitate?
Criteria for Knowledge Generation Tools			
Method	o Acquisition o Synthesis o Creation o Search o User profiling o Agents o Clustering	o Data entry o OCR o Voice input o Analysis o Web spiders o Data mining o Email	What method(s) is used to generate knowledge?
Criteria for Knowledge Organisation Tools			
Method	o Auditing o Categorisation o Manual Cataloguing o Auto Cataloguing o Filtering o App Integration o Portal User Interface o Full text search o Linking	o Indexing o Contextualising o Compacting o Visualisation o Channels o Doc Management o Image/Video search o Structured search o Unstructured search	What method(s) is used to organise knowledge?
Import facility	o Provided o Not provided		Is an import facility provided?
Loading formats	o Text files o Databases	o Spreadsheets o HTML	If an import facility is provided, what types of files can be loaded into the knowledge base?
Criteria for Knowledge Sharing Tools			
Method	o Flow o Push o Communities o App Sharing o Conferencing o Bulletin Boards o Messaging	o Publishing o Notification o Collaboration o Group decisions o Chat o Virtual Teams o File Transfer	What method(s) is used to share knowledge?

order to support one or more of the knowledge management activities. Therefore, the resultant framework was designed to reflect this and consists of four main parts. The first part labelled 'General Criteria' consists of criteria that can be applied to any knowledge management tool regardless of which of the knowledge management activities it has been designed to support. The remaining three parts represent each of the knowledge management activities: knowledge generation, organisation and sharing. The framework can be used in a similar manner to a checklist during the evaluation of the trial copy of the knowledge management tool. This forms a base for the tools to be compared quickly and easily. However, it is important to note that the criteria contained within the evaluation framework are by no means exhaustive and therefore would need updating on a regular basis, particularly considering the frequency of new knowledge management tools appearing on the software market.

Once each of the tools contained in the short-list has been evaluated using the framework, those tools that are considered inappropriate should be discarded. The remaining tools should be listed according to the order of preference. The short-list now becomes a list of 'Candidate Tools' as demonstrated in Figure 2.

Phase IV

This phase involves taking the knowledge management tool positioned at the top from the list of candidate tools and conducting a pilot test (McDonald, 1983). This involves installing the tool in the environment the purchased tool is intended to be used. A selection of users should use the tool for a period of time determined by the purchasing organisation, as though it is a replacement for the existing system. It is probably best, whenever a pilot test is being conducted, to use old data from the existing system so as not to have a negative impact. However, it is important to note that while pilot testing is being undertaken, the old system should continue to support the organisation. In many cases the installation of a knowledge management tool will be a completely new initiative. Under these circumstances the tool should be installed and used by people who intend to use the tool that is finally purchased. If the data for the tool does not exist or is unavailable, then representative test data needs to be created.

Once the time limit for the pilot test is reached, then the users must be questioned about their views and opinions on the tool (McDonald, 1983). If the outcome is positive then the final selection can be made. However, if the outcome of the pilot test is negative then it is necessary to consult the candidate list of tools created as a result of Phase III and the next tool on the list should be pilot tested. If the results from the pilot test indicate an equally divided outcome, then it may be worth extending the testing period and perhaps involving a few more users in the evaluation. This process should be repeated until a suitable tool is identified and a final selection can be made.

Having selected a tool that is approved by both selection team and users, it is possible to approach the vendor to negotiate a contract. Martin and McClure (1983) provide a detailed discussion of what factors to consider when drawing up a contract. In summary, the contract should cover issues such as support, warranties, licences, etc. Furthermore, the contract is likely to be biased towards the vendor. Therefore, it is important to negotiate new terms that favour both parties (Martin and McClure, 1983). If the vendor disagrees to drawing up a new contract, then the purchasing organisation should re-consider carefully another vendor or tool, or both, if necessary. If another suitable vendor that supports the required tool cannot be found, or suitable terms and conditions agreed, then another tool will have to be considered. This involves selecting the next tool from the candidate list produced during Phase III. Once an appropriate knowledge management vendor and contract have been achieved, the tool can be purchased, which is the final phase, Phase V, of the methodology.

Phase V

Purchasing the knowledge management tool is the objective of this methodology and once this is achieved, the procedure concludes. However, at this stage an entirely new procedure begins for the organisation. This involves adapting the tool, if necessary, installing and integrating it into the organisation. This may be done by the organisation itself or the tool vendor. Regardless of who the responsible party is, this can be a long, drawn-out process that may require numerous cycles of testing. Once the knowledge management tool has been integrated, it is necessary to monitor the tool and ensure that it is functioning in the desired manner. It is important to note that this is an extremely brief version of activities that may take place subsequent to the knowledge management tool being purchased. However, the aim of this chapter was to present a methodology for the selection of commercial knowledge management tools, therefore the discussion concludes here.

USABILITY OF THE METHODOLOGY

The methodology presented in Figure 2 can be useful to both industry and academia. The former will be able to use the methodology to facilitate the purchase of a knowledge management tool. This will save them from having to invest time and money developing their own methodology and investigating the knowledge management software market. The latter will benefit because the current literature related to the technical aspects of knowledge management is limited, and this will contribute and help to provide some clarification in the area. The methodology has been used for the evaluation and selection of knowledge management tools by members of the Brunel Centre for Knowledge and Business Process Management (KBM, 2001). Furthermore, companies involved in participating in the interviews in order to share their experiences of evaluating and selecting a knowledge management tool have expressed that had such a methodology been available when they were embarking on purchasing a suitable knowledge management tool, they would have found it very useful.

CONCLUSIONS

In summary, the constant increase in interest in knowledge management has resulted in an overwhelming number of knowledge management tools available in the software market. This presents a problem for purchasing organisations that are required to sift through a vast number of tools. Furthermore, some form of guideline for the selection of knowledge management tools is lacking from the literature. Therefore, the purpose of this chapter was to present a methodology to aid organisations with the selection of an appropriate knowledge management tool. In essence, the methodology aims to identify the organisation's requirements, which are used to select an initial list of knowledge management tools. This list is continually refined until a practical short-list is achieved. A detailed evaluation of each of the tools contained in the short-list is conducted using an evaluation framework. Subsequently, those tools that are considered suitable are ordered according to preference and in turn pilot tested with users. Once the users are satisfied with a tool and a contract negotiated with the vendor, the knowledge management tool can be purchased.

In conclusion, the plethora of knowledge management tools makes a set of guidelines for tool selection essential. The methodology and evaluation framework presented in this chapter achieves this, particularly since no other guidelines for knowledge management tools exist. Furthermore, indications from companies have shown that such a facility would be useful and would be adopted to aid the evaluation and selection process.

Chapter 3.23
Knowledge Management in Safety-Critical Systems Analysis

Guy Boy
EURISCO International, France

Yvonne Barnard
EURISCO International, France

INTRODUCTION

Knowledge management in the design of safety-critical systems addresses the question of how designers can share, capitalize, and reuse knowledge in an effective and reliable way. Knowledge management is situated in groups, organizations, and communities, playing different roles in the design process. Design of safety-critical systems has specific properties, such as dealing with complexity, traceability, maturity of knowledge, interaction between experts, awareness of the status of information, and trust in knowledge. Documentation is of crucial importance in design processes, ensuring that these properties are taken care of in a proper and reliable way. However, writing is not an easy task for engineers, and support is needed. Several knowledge management solutions, both tools and organizational setups, are available to support design work, such as active notification of changes, personal and team workspaces, active design documents and knowledge portal solutions.

SITUATING KNOWLEDGE MANAGEMENT

Knowledge management (KM) has become an important research topic, as well as a crucial issue in industry today. People have always tried to organize themselves in order to capitalize, reuse, and transfer knowledge and skills among each other within groups. Poltrock and Grudin (2001) propose the triple distinction team-organization-community for groups. KM tools and organizational setups usually emerge from the requirements of one of these kinds of groups. Note that we do not dissociate a KM tool from the group that is likely to use it.

A team is a small group of persons that work closely with each other, but not necessarily in the same location. A leader often coordinates its work. Team participants typically fulfill different roles. They strongly need to communicate. The following groups are examples of teams: software development teams, proposal writing teams, conference program committees, and small operational groups such as customer support or research project teams. Support technologies include: buddy lists, instant messaging, chat, Groove (a peer-to-peer team collaboration environment), Quickplace (provides an instant virtual team room where information is managed), BSCW (both a product and a free service for managing information for self-organizing groups, Bentley, Horstmann, & Trevor, 1997), video conferencing, data conferencing, and eRoom (team workspaces with shared workspaces, calendars, and discussions through a Web browser).

The structure of an organization is typically hierarchical. Modern organizations are usually geographically distributed. They strongly need to be coordinated. The following groups are examples of organizations: companies, governments or government agencies, and non-profit organizations. Support technologies include: e-mail, calendars, workflow, Lotus Notes (an integrated collaboration environment), intranet applications and webs, document management systems, and broadcast video.

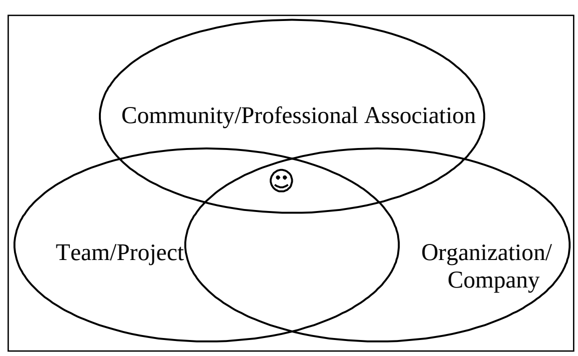
Communities share a common interest but no structure. They are usually geographically distributed and provide services to people (e.g., the European KM Forum, Amazon.com). The following groups are examples of communities: citizens of a city or neighborhood, special-purpose chat groups, virtual world citizens, auction participants, stamp collectors, and retired people. Support technologies include: Web sites, chat rooms, and virtual worlds.

In the field of safety-critical systems, teams, organizations, and communities inter-relate in order to insure quality on both products and processes. They are highly constrained. Usually teams are made to carry out projects and programs; they may be multi-national for example. Organizations are made to manage people within a consistent space, such as a national company that is more appropriate to handle social laws and customs of the country where it is chartered. Communities are made to help people who share the same kind of work practice to refer among each other, such as a community of electrical engineers. We summarize these distinctions in Figure 1.

A project team exists only during the time of the related project. A company may have several projects or programs that themselves may involve people from others companies. A company may become obsolete when the type of products it produces is no longer appropriate with the current market. Professional communities survive the obsolescence of both projects and companies. They actually may also become obsolete when either technology and/or the social world change.

In this article, we will present specific issues brought by the design of safety-critical systems, and human factors related to documentation generated and used in design processes. We will also focus on related current design issues. The specificity of safety-critical design knowledge will be presented. Several KM management solutions

Figure 1. An individual may belong to a project team, a company, and a professional association at the same time.



will be discussed. The article concludes with a discussion on the difficulties and challenges of KM in engineering.

The article is coming from several knowledge management projects performed in cooperation with groups of engineers in large aerospace and telecommunication companies. In particular, most recent findings come from the European Research and Development project WISE (IST-2000-29280; www.ist-wise.org). In WISE (Web-Enabled Information Services for Engineering), we study work-practices of engineers in large manufacturing companies, and we design practical methods to easily share and access essential knowledge and information for their tasks. These methods are supported by the development of an engineering knowledge portal application. The industrial partners involved in this project are Nokia and Airbus. Other partners are Cyberstream Interface SI, PACE, EURISCO International, Norwegian Computing Centre Helsinki University of Technology, and Technical University of Berlin.

Designing Safety-Critical Systems

Safety-critical systems have specific properties that directly affect the way knowledge management is carried out. Examples of safety-critical systems are aircraft, power plants, medical equipment, and telecommunication systems. They are basically complex, as complete as possible, and described by mature knowledge. Safety is not only a matter of end-user emotion, attention, and cognition; it is also a matter of organization and people involved in the whole lifecycle of related products. They involve experts that need to co-operate. For that matter, traceability of decisions is crucial.

Safety-Critical Systems Communities as Families

People working on safety-critical systems, in domains such as aerospace, nuclear power plants, and medicine, form strongly connected communities of practice that could be seen as families. They have their own meetings, workshops and conferences, even journals, where they can exchange experience, foster research, and improve knowledge on safety-critical systems in general. These communities work across organizations and teams. They tend to become references and initiate standards in the related field. They are recognized bodies for knowledge validation, providing principles for assessing knowledge maturity.

Dealing with Complexity

Even if the designers of safety-critical systems should always have in mind to design for simplicity, what they have to do is inherently complex. Systems are complex, and processes to design and develop these systems are complex. In the design process, designers rely on knowledge that is available in the form of handbooks, lessons learned, and best practices. Designers have to take into account the experiences with older systems, on which the new system is usually building, making sure that incidents and accidents that have happened are no longer possible in the new design. Designs are verified and validated in extensive, well-defined processes. In the end of the design process, certification by different authorities and certification bodies can also play a large role. In order to get a system certified, one has to be able to justify the choices that were made, to prove, as far as possible, that all knowledge about problems with similar systems has been taken care of, and that the system will function safely in all kinds of difficult and even disastrous scenarios.

Targeting Completeness in an Open World

Safety-critical systems require complete definition of their (cognitive) functions that they involve in terms of role, context of validity and use, and appropriate resources that they need to accomplish their functions (Boy, 1998). A cognitive function analysis is usually mandatory when we need to demonstrate that the system being designed satisfies a set of safety requirements. Completeness does not apply only to the mandatory kinds of functions, but also to the situations that end-users may encounter when they are using the systems. Completeness is difficult and often impossible to reach. This is why groups that design safety-critical systems use simulators in order to multiply the number of situations and cover a broader spectrum. They incrementally accumulate and articulate related knowledge by categorizing relevant situations.

Maturity of Knowledge and Maturity in Design

We claim that knowledge is constructed—let us say designed. The design of knowledge is incremental. Safety-critical systems are designed over time. They are tested, modified several times, and certified. Their use is carefully observed and documented. The resulting observation product, usually called experience feedback, is provided to designers who use it to modify their current understanding of the artifacts they have designed. Knowledge about these artifacts becomes progressively mature through this incremental process. There are short-loop design-knowledge validation processes that lead to official documents guiding the design process. There are also long-loop design-knowledge validation processes that involve experience feedback on already mature artifacts. In particular, engineers involved in safety analysis have an everyday need in using internal official documents. For example for a system safety analyst, requirements, courses, applicable documents, lessons learned (in-service experience), FAQs, lists of experts, previous similar deliverables, review results, validation and verification checklists/action lists, and system review action lists are crucial information that needs to be easily accessed.

Dealing with Drafts

Not all documents are finalized and approved at any time. Designers have to deal with draft documents, addressing questions such as how one can recognize that a document is ongoing, how versioning is taken into account, how revisions are managed. The validation of a document is related to the appropriate list of signatures. When a document is validated, it becomes "official." Each design rationale description should be appropriately contextualized. including its status (i.e., mainly the revision and approval dates) and background information (where it is coming from and who did it). In order to follow appropriate guidelines to edit and publish such a document, training may be necessary and guidelines should be easily available. From a broader standpoint, our investigations led to the distinction between private and public spaces of a document—that is, each technical document has a private space where it is invisible outside of a specific community, and a public space where it is visible by a wider community.

Awareness and Communication Between Experts

Situation awareness is a key issue in safety-critical systems. It is much studied at use time. However, it requires more attention at design and development times. People may make errors because they are not aware of the current situation or state of the art. Is Team 1 aware of current actions and productions of Team 2 at the right time? Is Team 1 aware of what Team 3 did a few years ago on the same topic or a similar one? How can we increase awareness? In some cases, it would be nice to have the appropriate information pushed to the front so potential users are aware of its existence.

In addition, efficient search mechanisms should provide the necessary means to pull appropriate information when needed. In both cases, context-sensitive algorithms, which may take the form of software agents, are necessary.

When designers know about a type of incident or accident that involved a piece of equipment that they are designing, they (at least try to) design artifacts in order to provide users with the necessary means to handle related situations in the best possible way. They are expert in their field (i.e., design). People who are likely to provide this "incident/accident" knowledge are human factors specialists, end-users themselves or experiences laid down in appropriate databases and knowledge bases. In any case, experts need to communicate either in a live way, such as using computer-supported cooperative work environments, or in a remote way, such as using knowledge bases. Space-time constraints usually impose choices in the way such communication would happen.

Traceability in Space and Time

One of us carried out an exhaustive study on traceability within a large aircraft manufacturing company (Boy, 2001). Traceability is not only information retrieval, it also deals with awareness that potential knowledge exists somewhere, and finally when this knowledge is found, it must be understood correctly. Whether they are project teams, corporate organizations, or professional communities, groups have difficulty providing clear explanations of why things were done in a certain way. This is due to the geographical spread-out of people composing these groups, speed of technology evolution, high turnover of personnel, and lack of documentation of the design process. We will see below that writing is a key issue that cannot be removed from the design activity. People need to know salient reasons that pushed other people to design artifacts they are currently responsible for. This remains true during the whole lifecycle of an artifact.

Trust in Knowledge

Whenever someone gets knowledge from someone else, a crucial issue is to figure out if it is reliable. Do I trust this knowledge without experiencing it? What are the processes that I would need to implement to believe that this knowledge is reliable? The use of Web technology opens our horizons to a wider spectrum of knowledge providers, but we are less sure that acquired knowledge might be trusted. The level of maturity needs to be clearly understood. Consequently, knowledge should come with contextual information that reinforces our understanding of its maturity and context if used.
