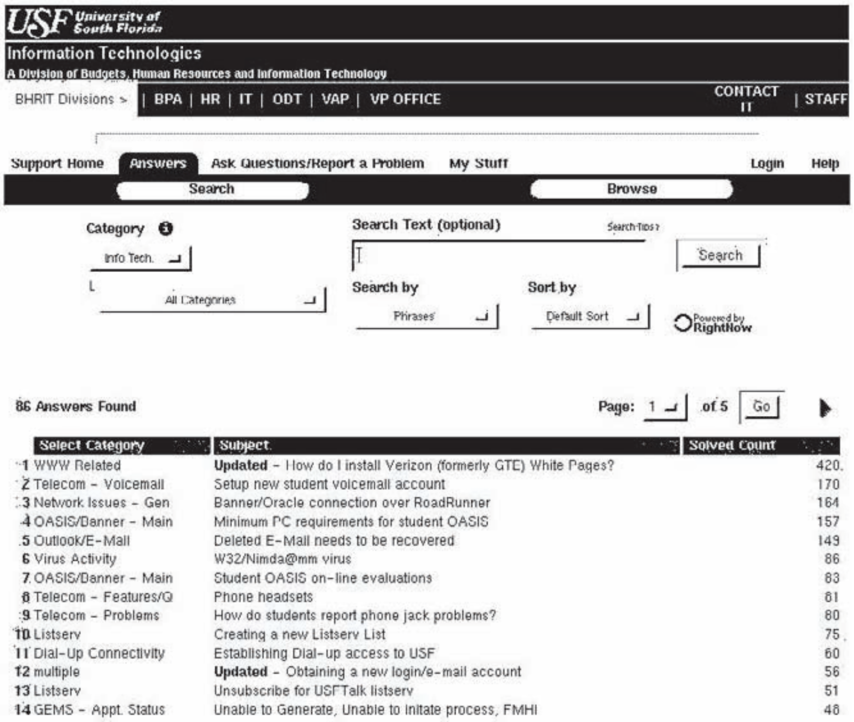
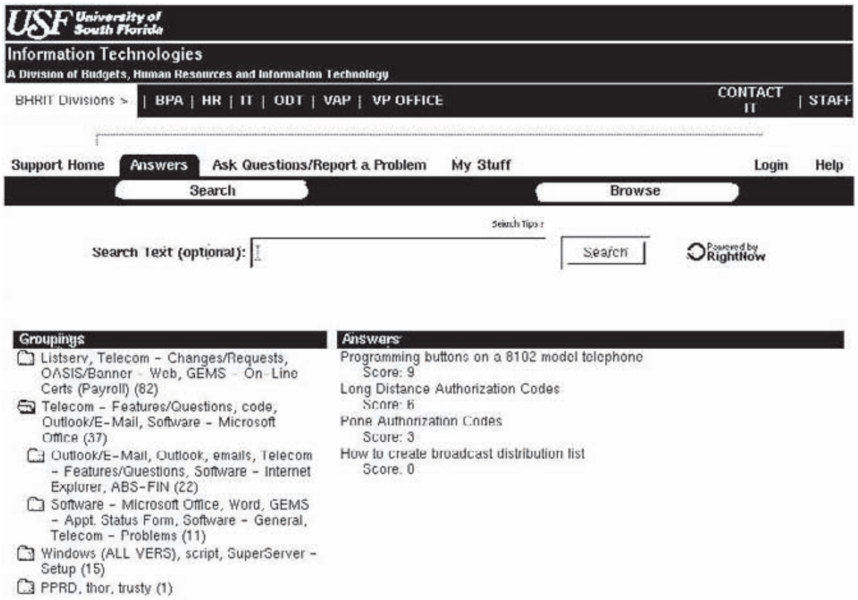
Figure 2. Portion of the Web Browser Display from the Support Page of the University of South Florida Information Technology Division [The page is configured to list by default the historically most useful Answers (i.e., highest solved count). Users may search in various modes by entering search text, and they may contact a CSR via the "Ask a Question" tab.]



products and categories, if such taxonomies have been established. The results of a search can be displayed in order of relevance or solved count.

End-users may or may not come to a support Web site with specific questions, but, in either case, they may find it convenient to browse the knowledge base from a more distant perspective, gaining an overview of the available information. Our system offers a browse mode of access in which categories of documents are displayed as folders, labeled with the key terms most descriptive of their contents (Figure 3). Clicking on a folder opens it to display documents and subfolders corresponding to more specific categories. The automatically determined labels on the folders give a summary of the contents. Because the user can navigate by selecting subfolders and individual documents without needing to type search terms, the browse mode is especially helpful when the user is unfamiliar with the terminology used in the Answers, and, hence, might have difficulty formulating a productive search query. If desired, it is also possible to search within a browse category. In a sense, the ease of browsing is related

Figure 3. Web Browser Display from the Support Page of the University of South Florida Information Technology Division [This page displays a hierarchical set of folders and subfolders, where a given folder (like a typical computer file system) may contain both subfolders and Answer documents.]



to the tacit knowledge of a user about the subject area. Most people are able to recognize what they're looking for much more easily than they can articulate it.

The browse function is made possible by a hierarchical categorization of the text items in the knowledge base. For this we employ a modification of the fast, hierarchical clustering algorithm BIRCH (Zhang, Ramakrishnan, & Livny, 1996), the result of which is used to learn RIPPER-style classification rules (Cohen, 1995). The final topic hierarchy is determined by classifying all knowledge base items according to the learned rules. Because of the inherent multiplicity and subjectivity of similarity relationships, we allow single items to be classified in multiple places where they fit well. This makes using the browse interface much more convenient, as the user can locate an item along various paths and does not have to guess what rigid classification might control the listing. New Answers are, on creation, simply inserted into the hierarchy according to the classification rules. After a predetermined amount of change in the knowledge base, due to modification or addition, a reclustering is performed so that the browse hierarchy reflects the current state of the contents, rather than a fixed hierarchy.

The features on the basis of which the clustering is performed are obtained from the document texts by shallow parsing. The natural language processing starts with part of speech tagging via a transformation-based tagger (Brill, 1994). Rules are the used to identify noun phrases, which receive the highest weight as features, though other selected words are also used. In addition, customer-supplied keywords and product or category names provide highly weighted features. The weights of feature words are additionally adjusted on the basis of the frequency with which users have searched for them, as reflected in a table maintained with the knowledge base. The clustering procedure is actually carried out several times with different sets of parameters, and the best clustering, according to a composite figure of merit, is chosen.

To assist CSRs in composing responses, as well as to optionally supply automated responses to end-users submitting questions, RNeSC can be configured to automatically suggest Answers. This is done by first processing the text of the question as if it were a search query. Simply taking the top-ranked Answers returned can result in spurious matches. Hence, they are filtered by checking whether they would appear in the same cluster as would the question text, now treated as an Answer for categorization. If this feature is used by a CSR, the suggested Answers are directly pasted into a reply form, where they can be edited by the human expert.

As with the solved count and the link matrix, the clustering represents automatically generated metaknowledge that serves to aid knowledge acquisition by end-users. To evaluate scientifically the utility of such aid would require extensive human testing, which we have not carried out. However, both our own observations and, more importantly, the experience of RNeSC users, as described in the next section, indicate that the benefits can be significant.

USER EXPERIENCE WITH RNESC

The system we describe has been used, through several versions, by a wide variety of commercial, educational, and governmental organizations. Drawing from their accumulated experience, we present both aggregate statistics and case studies illustrating the dramatic reduction of time and effort for knowledge-base creation and maintenance, and the increase in satisfaction of knowledge base users. This holds across the spectrum of organizations and applications, including those outside the area of conventional customer service.

Different organizations use the system in a variety of ways. The Rotherham England Metropolitan Borough Council uses it as a community clearinghouse where answers are provided to all kinds of questions about which one might contact a city office. As of this writing, it contains 476 answers to questions ranging from regularly recurring ones, such as “Can I report a pothole in the road?,” to more timely ones, such as “Do you have any information regarding the Queen’s Golden Jubilee?” Statements by the council make it clear that they view this information service for citizens, part of an e-government initiative, as very analogous to a business’ support for customers. Although the majority of the 16,000 daily hits on the site are from the UK, there are also high numbers from the U.S., Taiwan, Germany, France, Sweden and Denmark, some of which, it is hoped, may represent people looking to invest in the UK and attracted by Rotherham’s assets.

Within our own company (RightNow Technologies), independent instances of RNeSC are used for external customer support and for internal company information. More interesting is its use as a resource for developers, who answer each other’s questions — a case of experts and end-users being the same population. It also provides a defect posting and tracking system shared by the development and quality assurance departments. The resulting history of bug fixes, with each incident often carrying contributions from several developers and testers, is a heavily used company resource. In terms of knowledge management theory (see, e.g., Brown & Duguid, 2000), each bug history document constitutes a “boundary object,” collaboratively produced by two groups within the organization, serving to facilitate communication between them.

Due to the high degree of automation of RNeSC, the ease of installation is such that it has been accomplished in as little as a few days, or even one day. Once set up, the knowledge base can grow rapidly. For example, the United States Social Security Administration started with 284 items in their initial knowledge base, and over 200 new items based on user-submitted questions were added within two weeks. After two years, the number has stabilized at about 600, though the composition continues to change. Due to the public availability of the knowledge base, the number of telephone calls has dropped by 50 percent, from 50,000 to 25,000 daily. Similar experiences are common.1

The ability of a Web self-service system to handle dynamic fluctuations in usage can be very important. As one example, an announcement of a rate hike by the U.S. Postal Service led to a short-term increase in visitors to the support site of Pitney-Bowes, which provides mailing services, of nearly 1,000 percent over that for the previous rate hike. Attempting to handle such volume via telephone or e-mail would have resulted in huge backlogs.

One quantitative measure of end-user success in finding information is the self-service index, is defined as the percentage of end-users who are able to find Answers online, rather than sending a message to a CSR. Table 1 is excerpted from a Doculabs study (Watson, Donnelly & Shehab, 2001) in which it was found that the self-service

Table 1. Self-Service Index for Various Types of Organizations Using RNeSC [The self-service index is the fraction of end-users that find needed information in the Answer knowledge base, rather than initiating contact (escalating) with a support person via e-mail or online chat.]

Industry	Visits	Escalations	Self-Service Index
General Equipment	342,728	4,144	98.79%
Manufacturing	22,784	489	97.85%
Education	8,400	317	96.23%
Entertainment/Media	113,047	4,622	95.91%
Financial Services	40,574	1,972	95.14%
Contract Manufacturers	77,838	4,203	94.60%
Utility/Energy	19,035	1,122	94.11%
ISP/Hosting	147,671	8,771	94.06%
IT Solution Providers	53,804	3,277	93.91%
Computer Software	449,402	27,412	93.90%
Dot Coms	267,346	20,309	92.40%
Medical Products/Resources	17,892	1,451	91.89%
Professional Services	24,862	2,142	91.38%
Insurance	40,921	3,537	91.36%
Automotive	3,801	373	90.19%
Retail/Catalog	44,145	6,150	86.07%
Consumer Products	1,044,199	162,219	84.46%
Computer Hardware	101,209	15,759	84.43%
Government	108,955	17,347	84.08%
Travel/Hospitality	27,099	4,610	82.99%
Association/Nonprofit	14,620	2,772	81.04%
Telecommunications	809,320	202,158	75.02%
Overall Total	**3,779,652**	**495,156**	**86.90%**

index for organizations using RNeSC ranged from 75 to almost 99 percent, averaging 85 to 90 percent. The lower values for some categories of organization, such as telecommunications or travel services companies, may be due to a greater number of end-user-specific questions in these areas. Nonetheless, given typical costs of $30 per telephone transaction, $10 per e-mail exchange and $1 per Web interaction, such high self-service rates can lead to dramatic savings. According to anecdotal reports from users, the benefits described are largely attributable to the features of RNeSC described in this paper.

DISCUSSION AND FUTURE TRENDS

We believe that the performance of the RNeSC application in a range of settings is evidence that the underlying principles have a sound practical basis. Nevertheless, there is certainly room to do better. Some improvements are incremental, such as making the clustering algorithm more adaptive to knowledge bases that may differ significantly in the nature and length of the documents they contain, and in the granularity of the product and category divisions they use, if any. More difficult is the issue of descriptive labels for the clusters; the area of multidocument summarization is one of active current research (see, e.g., Mani & Maybury, 1999).

More qualitative enhancements can be obtained from applying AI techniques to a greater number of functions. Advanced machine learning techniques can potentially be employed wherever rules are used, including incident routing, text categorization and natural language processing. In the latter area, sophisticated question-answering systems will probably soon reach the point of being commercially viable, at least within restricted subjects. A fluent conversational interface to a knowledge base would fulfill many developers' dreams. Until that is available, the art is to provide some approximation with capabilities that outweigh the disappointments.

Another trend is toward greater personalization of user interfaces. Care must be exercised to ensure such customization facilitates rather than constrains. The extent to which significant personalization is feasible for frequent and for one-time users remains to be investigated.

Along other lines, the pursuit of applications in different sectors of knowledge management could suggest a new mix of features. RNeSC is already quite flexible and user-configurable and could evolve in many different directions. We believe that many of its advantages as a customer-service application could be realized in related areas as well.

CONCLUSION

We have presented an organic approach to knowledge creation and delivery that emphasizes rapid response for dynamic information environments. The user-driven architecture helps mobilize tacit knowledge and dramatically reduces the time and expense of creating a knowledge base. Facilitated and cooperative creation of knowledge base documents takes place as an extension of the normal activities of experts. Continuous mining of implicit end-user recognition of the importance and relationships of information items enables the system to adapt quickly, while remaining easy to use through automated re-organization. As embodied in the Web-based customer service application Right Now Service Center, the system uses a number of AI techniques to facilitate construction, maintenance and navigation of a knowledge base of answers to frequently asked questions. These techniques include collaborative filtering, swarm intelligence, natural language processing, text clustering and classification rule learning. Many of these individual techniques have been similarly employed in other commercial applications, but we know of no other system that combines all of them. Customers using RNeSC report dramatic decreases in support costs and increases in customer satisfaction due to the ease of use provided by the "self-learning" features of the knowledge base.

We have argued that the principles and methods of our approach are also applicable in other settings, for example, government agencies reaching out to concerned citizens. In fact, organizations and associated constituencies with information needs are ubiquitous in modern society. Ubiquitous also is the need for software tools to assist them. "Since it is the value added by people — context, experience and interpretation — that transforms data and information into knowledge, it is the ability to capture and manage those human additions that make information technologies particularly suited to dealing with knowledge" (Davenport & Prusak, p. 129).

Chapter 4.52
Opportunities for Data Mining and Customer Knowledge Management for Shopping Centers

Charles Dennis
Brunel University, UK

David Marsland
Brunel University, UK

Tony Cockett
Brunel University, UK

ABSTRACT

Shopping centers are an important part of the UK economy and have been the subject of considerable research. Relying on complex interdependencies between shoppers, retailers and owners, shopping centers are ideal for knowledge management study. Nevertheless, although retailers have been in the forefront of data mining, little has been written on customer knowledge management for shopping centers. In this chapter, the authors aim to demonstrate the possibilities and draw attention to the possible implications of improving customer satisfaction. Aspects of customer knowledge management for shopping centers are considered using analogies drawn from an exploratory questionnaire survey. The objectives of a customer knowledge management system could include increasing rental incomes and bringing new life back into shopping centers and towns.

INTRODUCTION

Shopping centers are an interesting topic for knowledge management — relying on interdependency between owner, retailers and shoppers. Why are shopping centers important? Firstly, planned shopping centers comprise a substantial part of the UK economy, employing over three-quarters of a million people and playing a 'key role in the investments of pension funds' (Davies et al., 1993; OXIRM, 1999). Shopping centers are therefore important not just to customers, but also employees and indeed to many others because of the investments of their pensions. Secondly, retail and shopping centers form the heart of UK towns and create a focus for the community. Shoppers tend to follow the provision of attractive shopping areas. Improving shopper satisfaction can lead to changes in population, expenditure, residence patterns and bring new life to run-down areas (Dennis et al., forthcoming 2002b). The findings of the research could be applicable to traditional high streets and towns as they are to purpose-built shopping malls — if there is in place some form of central administration such as Town Center Managers. This chapter considers the possibilities for shopping centers to make their offer more attractive using techniques of data mining and customer knowledge management.

DATA MINING AND CUSTOMER KNOWLEDGE MANAGEMENT IN THE RETAIL CONTEXT

Data mining has been defined as:

"The process of exploration and analysis, by automatic or semi-automatic means, of large quantities of data in order to discover meaningful patterns and rules." (Berry and Linoff, 1997)

Berry and Linoff (2000) list six data mining activities: (1) classification; (2) estimation; (3) prediction; (4) affinity grouping or association rules; (5) clustering; and (6) description and visualization. Retail studies have included many other techniques (e.g., sequence-based analysis; fuzzy logic; neural networks; fractal-based algorithms (Rao, 2000; Rensselaer Polytechnic Institute, 1999). Nevertheless, Berry and Linoff's six categories serve our purposes here.

Data mining has many uses, but the aspect of most concern here is what is usually known as 'Customer Relationship Management' (CRM). Good CRM means: (1) presenting a single image of the organisation; (2) understanding who customers are and their likes and dislikes; (3) anticipating customer needs and addressing them proactively; and (4) recognizing when customers are dissatisfied and taking corrective action (Berry and Linoff, 2000).

Some UK retailers recognize the potential of data mining in discovering customer knowledge. For example, Halfords and Sainsbury's uses Brann Viper software, Tesco and John Lewis Dunn Humby (Computer Weekly, 16 January and 29 May 1997). Most, though, jealously guard their customer knowledge capital. The authors argue that dissemination of this knowledge to a shopping center owner could result in meeting shopper requirements better.

Since the mid-1980s, there has been an increasing recognition that "knowledge is a fundamental factor behind an enterprise's success" (Wiij, 1994) — a statement that applies in the retail industry as in others. This chapter will consider shopping center customer knowledge management from Wiij's (1998) third, broadest focus: "all knowledge activities affecting success … using knowledge assets to realize their value." The specific concern is with customer knowledge management — the management and exploitation of customer knowledge. There are two aspects of this knowledge: (1) knowledge about customers; and (2) knowledge possessed by customers (Rowley, 2001). The empirical study reported here concerns the first aspect, but we will conclude with a recommendation for further research on the second.

Richards et al. (1998) argued that the marketing success of an enterprise is founded on "a continuous dialogue with users, leading to a real understanding … the more mundane the category [shopping centers?], the more dependent on knowledge." In the early 1980s, data warehousing transformed operational data into knowledge for decision-making. As retail IT systems company NCR put it: "For retailers the key … is to establish data warehouses to improve and manage customer relationships" (Teresko, 1999).

Data mining can use programming methods to identify patterns among data objects — for example between products in a shopping basket. The well-known early example is the 'diapers-beer' link on Friday evenings spotted by Wal-Mart in the U.S. By placing the two side by side, more fathers took home extra beer when they went to buy the diapers after work. Woolworths (UK) have installed a system costing UK£2 million, claimed to have boosted sales in women's toiletries alone by more than UK£5 million per year (Bird, 1996). The authors contend that incorporating data mining and customer database aspects within a framework of knowledge management can help increase knowledge value.

The main focus of this chapter concerns the opportunities for data mining and customer knowledge management for shopping centers. Data mining normally refers to large quantities of data, so our survey of 287 respondents must be near the smaller end of the scope. Nevertheless, the dataset has been useful in illustrating the utility of aspects of data mining and customer knowledge management that may be suitable for larger-scale use. Further, the exercise has demonstrated that a full data warehouse is not essential. Rather, effective data mining techniques can be applied to a smaller sample drawn from a large database. Another aspect for discussion (not the main focus of this chapter, though) concerns the possibilities of extending customer knowledge management to the sharing of information between shopping center managers and potentially competing retailers. The case for such sharing is not clear-cut. Howard (1995) pointed out that shopping center landlord/tenant relationships are characterized by bargaining and outright conflict. Most UK shopping centers are not customer-orientated (according to Howard). This statement may be arguable, but we concur to the extent that more customer knowledge could help shopping centers to make their offers more attractive. Howard is on safer ground in pointing out that more marketing success could be achieved by a utilizing a partnership approach for collecting, sharing and using information. Howard (1997) cited a store manager at the successful Lakeside (UK) center as claiming that CSC (the owner of Lakeside) is different and has a more open relationship between retailers and center management. The information-sharing approach (Howard implied) has contributed substantially to CSC's success.

Some retailers, notably the UK market leaders Tesco (supermarkets) and Boots (drugstores), have exploited customer knowledge by means of loyalty schemes. Such schemes have been successful for retailers but are unlikely to pay for themselves by increased loyalty (Field, 1997). Rather, the benefits arise from their function of facilitating the flow of information and rewards between suppliers and consumers (Worthington, 1999), i.e., as part of a customer knowledge management system. Some UK towns and shopping centers have experimented with loyalty schemes, but as far as the authors are aware, the potential knowledge benefits have not been fully explored. In the Cobham (small town in Surrey, UK) and Lakeside (regional out-of-town shopping center in Essex, UK) schemes, data from customer receipts had to be entered by hand. For the town or center management, the method provided access to customer transaction information, without needing the explicit agreement of individual retailers to data sharing. There is, of course, a privacy issue concerning the use of customer data in this way. The shopping centers may well have taken the view that the transaction data belonged to the individual shoppers — who gave written consent for the data use when they requested the loyalty card. Certain large retailer tenant(s), though, are understood to have considered that they owned the data concerning their shoppers' transactions, and to have objected to the use of that data by the shopping center landlord's loyalty scheme. Some schemes including Lakeside and Cobham have been dropped under the burden of paperwork or lack of support from retailers (Hallsworth, 2000). Lakeside replaced the loyalty card with an 'affinity' credit card — the administrative load was transferred to banks, but customer data were lost to Lakeside. Nevertheless, the authors contend that loyalty schemes can be successful. The essential aspect is to design them from the start for customer knowledge management.

In the interests of providing a preliminary illustration, this chapter reports exploratory mall interview surveys at UK shopping centers. In a full-scale application, data mining for customer knowledge management would be applied to a customer database, but such a dataset was not available to the researchers. As an alternative, data mining techniques such as cluster analysis and predictive modeling have been applied to the findings of a questionnaire survey. The standard SPSS program has been used for the analysis, being less expensive and more applicable to this scale of project than would be a custom data warehouse. The authors have explored the differences in behaviour between shoppers and drawn attention to differences between exemplar segments as to which attributes are critical in shopping center choice.

EXPLORATORY STUDY

The results are from a survey of 287 respondents at six shopping centers varying in size from small in-town sub-regional to large regional out-of-town. A 'regional' center is defined as having a gross retail area of greater than 50,000 m2 and a 'sub-regional' one 20,000-50,000 m2 (based on Guy, 1994a, b; Marjenen, 1993; Reynolds, 1993). The objective was to determine which specific attributes of shopping centers were most associated with spending for various subgroups of shoppers. If it can be demonstrated that customer knowledge management can enhance the attractiveness of shopping centers and lead to increased store sales, there will be an incentive for retailers to 'buy in' to the idea of sharing customer data.

The study evaluated shoppers' comparative ratings of two shopping centers, one of them being the center where the interview took place. The alternative center was the one where they shopped most (or next most after the interview center) for non-food shopping. The questionnaire instrument was based on the 'attributes of image' elements employed by McGoldrick and Thompson (1992a; b), together with additional constructs derived from analyses of preliminary unstructured interviews. Respondents stated their perceptions of the 'importance' of each of 38 attributes, including those identified by Guy (1994a; b) as figuring in consumers' choices of shopping destination, for example, 'quality of stores,' 'cleanliness' and 'availability of rest rooms,' following a similar procedure to that used by Hackett and Foxall (1994). Each attribute was also 'rated' for both the center studied and the alternative center. Respondents estimated perceived travel distance and time to both centers, and supplied details such as age, location of residence and occupation of the main earner in the household. Examination of the characteristics of the sample indicated the distribution of socio-economic groups, age and sex reasonably representative of that anticipated at UK shopping centers. The number classified in the higher socio-economic groups of managerial, administrative, professional, supervisory or clerical (ABC1 on the UK JICTAR scale) was 59%. This compared, for example, with a figure of 63% for the Lakeside (UK) out-of-town regional center (owner's proprietary survey of 2,000 respondents over two years) and 55% for the Treaty Centre, in-town, sub-regional (Hounslow, UK — from the center 'Education pack' citing 'street surveys'). The proportion in the younger age groups 16 to 44 years was 65% in our sample compared with 73% at Lakeside and 67% at the Treaty Centre. Our sample was 69% females compared with 60% at Lakeside and 59% at the Treaty Centre.

Further questions concerned typical perceived monthly spending at each of the two centers. As McGoldrick and Thompson (1992b) pointed out, much of the variation in shoppers' expenditure relates to factors such as income or socio-economic groups, rather than travel distance or attributes of the shopping center. Following this approach, the main dependent variable was the 'individual relative spend.' A value of 100 indicated all expenditure at the center studied and none at the alternative center. A value of 50 indicated half of the expenditure at each center. The same approach was used to scale perceived travel distance and time producing the variables 'individual relative travel distance' and 'time.'

The view of 'attractiveness' taken by the authors is that any product (such as a shopping center) "can be seen as a bundle of expected costs and rewards" which East (1997, page 131) found was 'upheld by research.' East drew support from Westbrook's (1980) finding that an overall measure of retail satisfaction correlated well with a simple addition of the satisfactions. In the authors' procedure, the measures of satisfaction and dissatisfaction have been taken from the respondents' ratings of the shopping center compared to their main alternative center (on five-point semantic differential-type scales). These satisfactions for the individual attributes were weighted, firstly by the 'importance' of the attribute to the respondent (also on a five-point scale) and secondly by the degree of association with the stated relative spending. Once weighted, satisfactions were added, giving an overall 'attractiveness' measured value. The next stage was to combine the attractiveness measurements with the relative travel time or distance variables, to derive (statistically significant) models of individuals' relative spending. More detailed derivations of the attributes and models have been reported elsewhere (Dennis et al., 1999; 2000a).

Attribute evaluations have been considered as interval rather than ordinal data (following the approach of Oppewal and Timmermans, 1999). Ordinary least squares regression analysis has been used to investigate associations between shopping center attributes and shoppers' spending at the center studied compared to a competing center. For example, 'cleanliness' was the attribute most associated with the spending of female shoppers, $R2 = 0.075$. Individual regressions were performed for each variable; multiple regression was less appropriate on account of multicollinearity (Dennis et al., 1999). Attribute ratings have been summed and combined with travel distance to allow comparisons between the subgroups of the fit of each model. R2 values were between 0.09 and 0.40 — i.e. 'modest.'

In the analysis of the results, we have firstly used conventional demographics to group shoppers, eliciting the most significant shopping center attributes separately, for example, for females and males. A further stage concerned the identification of attributes for various motivation clusters. Retail data mining schemes have aimed to identify subgroups that share similar shopping motivations. Researchers (Boedeker, 1995; Boedeker and Marjenen, 1993; Jarrett, 1996) have identified shopping center motivation clusters. Targeted marketing mixes satisfy these more appropriately, increasing satisfaction, sales and profits. These researchers identified two subgroups (among others) that could be described as 'shopping' and 'service' motivations. It is hypothesized that members of these two groups can be identified as individuals for marketing communications purposes. Those primarily motivated to shop by attributes such as quality of the stores and selection of merchandise can be contrasted with those more interested in service and experience aspects such as the availability of good rest rooms and cleanliness. Accordingly, our study has also included a cluster analysis approach aimed at identifying the attributes critical for shoppers motivated by the importance of 'shops' vs. 'service.'

RESULTS

Table 1 lists the 'top six' attributes associated with individual relative spending for the subgroups. This table is designed to be read horizontally with comparative groups (e.g., females vs. males) side by side. The R2 columns indicate the coefficients of determination of the specific attributes from linear regression with relative spending. Thus, these R2 values are used here as a parameter to indicate the strength of the association between the attributes for the particular groups and shopper spending. Below the 'females vs. males' comparison follows a comparison of higher vs. lower socio-economic groups. 'ABC1' refers to the (UK, JICTAR) classifications of managerial, administrative, professional, supervisory and clerical. 'C2DE' categories include manual workers, senior citizens and unwaged. Comparisons of higher vs. lower income and age then travel by auto vs. public transport follow. The final comparison is of the shopper clusters that we have termed 'service importance' vs. 'shops importance' motivation.

Conventional Demographics

Females vs. males: The attributes significant for females were clearly different to those for males, with 'cleanliness' top for females, significantly different with respect to the association with spending compared to males. Only one of the 'top six' attributes for females ('nice place to spend time') was significant for males. Conversely, three out of the 'top six' attributes were significantly more associated with spending for males than for females ('lighting', 'sheltered access' and 'no undesirable characters'). Space limitations preclude a full discussion, but for females, two separate factors have been elicited (maximum likelihood extraction and varimax rotation — Kinnear and Gray, 1997). We have named these factors shopping (including, for example 'selection of merchandise') and experience (exemplified by 'friendly atmosphere'). On the other hand, for males the concerns were with the center ('lighting' and 'sheltered access' — the factor analysis did not produce separate factors for males). The interviewers reported that many males were in the center mainly to accompany females. Our interpretation of these results is that females, who were enjoying the trip, were naturally concerned with 'shopping' and 'experience.' Conversely, males who were simply 'there' were more evaluative of the 'center.'

Upper vs. lower socio-economic groups: For managerial, administrative, professional, supervisory and clerical (ABC1s), 'lighting' and 'access by road' were significantly more associated. For manual workers, senior citizens and unwaged (groups C2DE), 'good for children' and 'quality of the stores' were among the most significant. The differences are to some extent understandable in light of our observation that upmarket shoppers are more likely to travel by auto, whereas those from the lower socio-economic groups are more likely to bring children on shopping trips.

Higher vs. lower income groups: 'Lively or exciting' and 'Covered shopping' were significantly more associated for the lower income respondents. The authors speculate that lower income (and lower socio-economic group) shoppers might tend to live nearby, patronizing as alternatives small, unexciting local centers. Therefore, they might tend to appreciate the benefits of lively covered shopping centers more than do the more upmarket customers who may take these benefits for granted.

Older vs. younger shoppers: 'Eating and drinking' was in the 'top six' for the older shoppers who

All listed attributes were significantly associated with individual relative spending at p = 0.05.
The number of respondents and the average monthly spending for each subgroup is indicated in parentheses.
** Segments significantly different at p = 0.05 with respect to the association with spending of these attributes (combination of Monte Carlo and t-test, Dennis et al., 1999b).*

we expect might shop at a slower pace than younger ones and take more refreshment breaks.

Shoppers travelling by auto vs. public transport: 'General layout,' 'choice of major stores' and 'eating and drinking' were in the 'top six' for shoppers travelling by auto, but not significant for public transport. Four of the 'top six' were significantly more associated for 'public transport': 'Shoppers nice people,' 'availability of seats,' 'big shopping center' and 'value for money.' The authors consider that most of these attribute differences are related to differences in spending power. For example, shoppers travelling by public transport are more likely to appreciate (free) seats, compared to the more affluent auto travelers who choose to relax in a restaurant, bar or café.

Cluster Analysis: Shoppers Motivated by the 'Importance' of 'Shops' vs. 'Service'

An alternative to the conventional demographics approach was the search for clusters of buyers who shared needs or wants for particular benefits. A cluster analysis (SPSS 'K-means,' minimizing the squared distances of each value from its cluster center, (Kinnear and Gray, 1997) based on 'importance' scores has identified distinct subgroups of shoppers classified by 'importance motivation.' The main attributes that distinguished the clusters (with the average 'importance' scores on the 1 to 5 scale, where 1 was 'no relevance' and 5 was 'extremely important') are listed in Table 2. These segments were described as 'shops importance

Table 2(a): Shops importance motivation cluster

	Final cluster center 'Importance' scores
Variety of the stores	3.49
Quality of the stores *	**3.41**
Covered shopping	3.30
Access by public transport **	**3.14**

Table 2(b): Service importance motivation cluster

	Final cluster center 'Importance' scores
Parking facilities **	**4.47**
Access by auto **	**4.29**

Availability of good rest rooms **	**4.01**
Value for money **	**3.99**
Helpfulness of the staff **	**3.96**

*Differences between clusters 'Importance' scores significant at: * $p = 0.05$ ** $p = 0.001$. 'Importance' scores are on the 1 to 5 scale, where 1 is 'no relevance' and 5 is 'extremely important.' Only attributes above the scale mid-point (3.00) are listed, and each attribute is listed once only, in the cluster where most dominant.*

motivation' (abbreviated to 'shops'), Table 2 (a), and 'service importance motivation' ('service'), Table 2 (b). The two 'importance motivation' clusters were strikingly different in attributes significantly related to relative spending (the final section of Table 1). As hypothesized, 'quality of the stores' and 'selection of merchandise' were both in the 'top six' for the 'shops' group, with 'quality of the stores' being significantly more associated with spending for the 'shops' group than for 'service.' For the 'service' shoppers, 'availability of good rest rooms' and 'cleanliness' were among the most significant. Not so expected, 'other shoppers nice people' and 'lively or exciting' were significantly more associated with spending for 'shops' than 'service' shoppers. One possible interpretation might be that consumers motivated by 'shops' are evaluating not just the tangible merchandise but also the shopping experience. Our term 'shops' encompasses not just the physical environment of the shops but also the wider systemic shopping environment.

Compared to 'shops,' the 'service' shoppers were slightly higher socio-economic group (63% ABC1s vs. 59%), income (60% UK£20000 per year + vs. 53%) and age (42% 45 + vs. 33%) than the 'shops' group. They predominantly traveled by car (90% vs. 52% — see Figure 1).

MODELS OF RELATIVE SPENDING

The regression models for the various groups are reported in Table 3. These are introduced in the same order as in the reporting of the critical attributes for these groups in the 'Results' section above and in Table 1. The models describe the relationships observed between relative spending for the groups vs. the attractiveness of the centers and the distance shoppers travel. The first column is the group for which the model applies (the numbers of respondents in each group were indicated in Table 1). The second column is the constant from the regression equation, representing the amount of relative spend not associated with the variations in attractiveness and distance. The third and fourth columns are the regression coefficients for attractiveness and distance respectively. The fifth column is the coefficient of determination, R2 of the regression equation, and the sixth the degree

Figure 1. Characteristics of the "service" and "shops" clusters

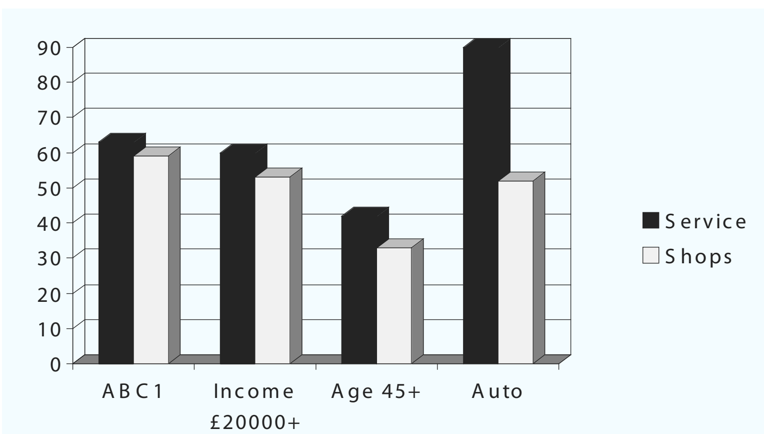

Table 3. Models for shopper segments

	Constant	Attractiveness Coefficient	Distance Coefficient.	R^2	Significance p	Model number
Females	**28.3**	**0.63**	**-0.24**	**0.19**	**<0.0001**	**1**
Males	**21.1**	**0.49**	**0**	**0.09**	**<0.01**	**2**

Income up to UK£19000	**27.0**	**0.58**	**-0.19**	**0.18**	**<0.05**	**6**
Age up to 44	**29.3**	**0.58**	**-0.23**	**0.16**	**<0.0001**	**7**
Age 45 +	**18.0**	**0.61**	**0**	**0.14**	**0.0001**	**8**
Auto	**32.8**	**0.53**	**-0.20**	**0.15**	**<0.01**	**9**
Public transport	**31.8**	**0.58**	**-0.22**	**0.19**	**<0.05**	**10**
'Shops motivation'	**19.4**	**0.70**	**-0.21**	**0.17**	**0.0001**	**11**
'Service motivation'	**39.6**	**0.54**	**-0.28**	**0.22**	**<0.01**	**12**
All respondents	**26.0**	**0.62**	**-0.20**	**0.16**	**0.0001**	**13**

of significance (p-value). These two columns indicate modest correlations. All of the models would be normally be described as 'significant.' All except model numbers 6 (lower income) and 10 (travel by public transport) would actually be considered 'highly significant.' The final column is simply the identification number allocated to each model to facilitate discussion.

For example, for the 'shops' group:

(11) Spending = 19.4 + 0.70 X Attractiveness - 0.21 X Distance

Whereas for the 'service' shoppers:

(12) Spending = 39.6 + 0.54 X Attractiveness - 0.28 X Distance

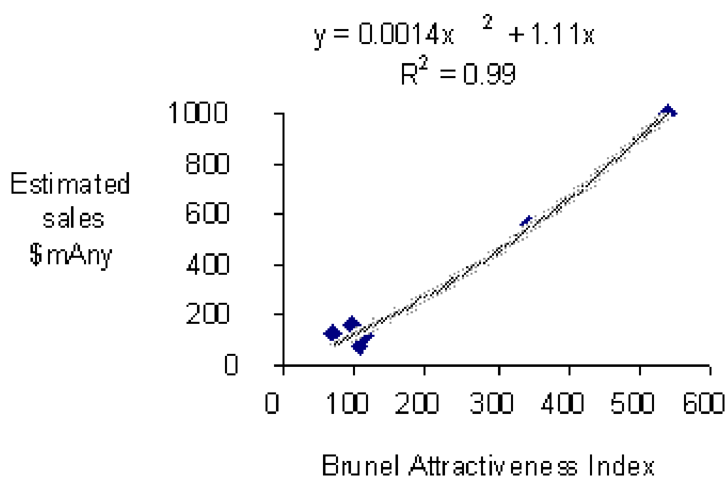
These models mean that we can be confident (at normal test levels) that an increase in the attractiveness of a center would result in an increase in spending at that center. For example, for the 'shops' group (11), the increase in spending for a given improvement in attractiveness would be greater than for the 'service' group (12). By going back to the weighting that each attribute carried in the attractiveness model, it is possible to predict by how much spending would be likely to increase for any given improvement in any attribute. The models also mean that spend was inversely related to the distance that shoppers traveled to the center.

In the 'Exploratory study' section earlier, the procedure for calculating respondents' weighted satisfactions was outlined. The satisfactions for all attributes were summed to give each respondent's total satisfaction score for the center studied. The average of the respondents' satisfaction scores represented a measured attractiveness score for each center, the 'Brunel Attractiveness Index.' This index has been described more fully elsewhere (Dennis et al., 2002a forthcoming, 2002b). Stated briefly, the Brunel Attractiveness Index is an empirically derived measure of shoppers' evaluations of the attractiveness of shopping centers.

The utility of the models has been investigated by examining the relationship between the empirically measured attractiveness and the estimated sales turnover. Figure 2 illustrates the relationship between our measured attractiveness, the Brunel Attractiveness Index and the estimated sales turnover for the six centers. The sales value scale has been changed by an arithmetical factor in order to disguise commercially sensitive data. The sales turnover values are necessarily estimates based on the questionnaire responses plus footfall data of unknown reliability supplied by the center managements. The estimates, though, were made before the models were designed — and were not used in the development of the index. From an inspection of Figure 2, it would appear that the modeling procedure has been effective in measuring attractiveness in a manner relevant to sales turnover.

The models are useful in estimating changes in spending that could result from improving aspects of a shopping center. For the high spending 'service' shoppers (model 12 in Table 3), a 25% improvement in the ratings for cleanliness and rest rooms could be associated with an increase in spending for those shoppers of 10%, equivalent to an increase in the total center sales turnover of over 3%. One measure of the validity of the subgroups is the improvement in 'fit' of the models. 'Service' vs. 'shops' had the best fit, with R2 increased to an average of 0.195 for the two subgroups. Apart from 'income' (average R2 0.175), the models from the other pairs of groups did not improve the fit above the overall level of 0.16. 'Service' vs. 'shops' discriminated well between high and low customer spend, with the 'service' segment's average stated monthly spend UK£82, compared with the overall average of UK£65.

Figure 2. Estimated sales of shopping centers vs. the Brunel Attractiveness Index — Polynomial plot forced through the origin



DISCUSSION AND CONCLUSIONS

Information from a customer database can be used to identify needs of different groups of customers. This knowledge can help shopping centers to improve marketing communications and customer satisfaction. Cluster analysis has identified a group of customers that shopping centers and retailers will want to target: high-spending 'service' shoppers. How can they be identified, given the high costs of a data warehouse? Firstly, this experimental study has demonstrated that a full data-mining system is not essential. Analysis, identification of target segments and assessment of cost-effectiveness can be carried out on a small sample, with only simple processing needed on a complete database. As in this experiment, the SPSS program can be used — saving the costs of custom software. For future, larger-scale projects, though, the authors recommend the use of a multi-agent system. Such systems can handle text alongside quantitative data and furnish individual shoppers with a 'personal agent.' This represents customized marketing segmentation — a software 'personal shopper' for every participating consumer. So far in this chapter, we have considered the knowledge about customers aspect of customer knowledge management. The personal agent system could address the knowledge possessed by customers aspect. It could be argued that such a system might not work in the UK cultural context. For the customers, though, this would be a small step from the well-established loyalty card. The customer might only be aware of the difference when presenting a 'smart card' to obtain benefits or information. Customers having a personal agent could receive communications specifically targeted to their needs and wants. There are a number of ways that this could be achieved, but one of the simplest would be for customers to present their card for reading at an information kiosk in order to receive personalized vouchers and information sheets.

In the 'models of relative spending' section above, it was pointed out that a (probably achievable) improvement of 25% in the ratings for 'cleanliness' and 'rest rooms' could be associated with an increase in spending by the service shoppers of 10%. The 10% increase for this group would add 3% to the total center sales turnover. A regional shopping center would gain tens of millions of dollars sales, with retailers seeing a seven-figure increase in gross profits. In the medium term, rental incomes follow sales: shopping center owners could expect US$2 million in increased rents.

Customer knowledge management systems could be based on data sourced from loyalty schemes. Worthington (1999) reviewed the typology of local loyalty cards in the UK. Integrated chips (e.g., Nottingham), and magnetic stripe payment (Hereford; Lakeside) or non-payment (Chester; Meadowhall) are applicable and cost-effective for cities and regional shopping centers. The main distinguishing feature of the higher-spending 'service' shopper cluster was the preponderance of auto as the means of travel — 90% of the group (illustrated in Figure 1). Therefore, for smaller centers, a scheme could be based on parking. For in-town centers that charge for parking, our solution is the 'parking lot membership scheme.' Shoppers would buy a 'carnet' of tickets at a discount and fill in a detailed 'lifestyle' questionnaire including the information needed for the database. Parking lot schemes are already in use in Australia (Worthington and Hallsworth, 1999). For centers that offer free parking, the suggestion is to recruit shoppers at a kiosk in the parking lot, offering incentives such as a prize drawing.

The results presented in this chapter have demonstrated what can be achieved using some of the typical data mining activities applied to a simple dataset of survey data. In terms of Berry and Linoff's six activities, we have (1) 'classified' using, for example, standard socio-economic groupings, evaluating critical attributes for those segments; have (2) 'estimated' potential increases in sales arising from changes to these critical attributes using (3) 'predictive' modeling. We did not use (4) 'association rules' in the usual basket analysis context. Rather our 'affinity grouping' was achieved using (5) 'cluster' analysis — the most effective classification technique of our modeling exercise. Finally, we contend that our analysis and modeling process has assisted the (6) 'description and visualization' of shopper behavior.

In terms of Berry and Linoff's four components of CRM, we have outlined an effective procedure for measuring the (1) 'image' of a shopping center. Evaluating the image of the different customer groups has led us to (2) a greater 'understanding of who the customers are and their likes and dislikes.' Although the methodology does not (3) 'anticipate' customer needs, the survey approach does at least allow needs and wants to be 'identified and addressed proactively.' Similarly, using survey data in the database has identified a number of instances of (4) 'customer dissatisfaction,' leading to recommendations for 'corrective action.' CRM is normally implemented by a system of personalized communications (e.g., welcome letter, satisfaction questionnaire, special offers and so on). The details are beyond the scope of this chapter, but an applicable strategy should be facilitated by the installation of a simple data mining and customer knowledge management system. Shopping center managers could obtain a similar level of data to ours from (for example) a membership questionnaire, and could use a similar analysis process to that described here. Such activities would have to comply with data protection principles, but in the UK at least, many shoppers are willing to part with personal and transaction information in exchange for benefits — the principle behind the success of the Tesco and Boots loyalty cards.

Adding real sales transaction information would enrich the possibilities (although this raises the possibility of conflict with retailers over ownership of the data). Shoppers might be grouped according to spending on fashion/designer styles rather than bargains? A knowledge management network between retailers and the center would be a further stage — allowing wider access to graphs, patterns and associations in the data. There is a parallel in systems that multiple grocery retailers operate with suppliers. It is understood that supermarkets such as Tesco allow suppliers direct, real-time access to individual store sales and stock data via the Internet. In this model, a retailer and (potentially competing) suppliers share data in a knowledge network managed by the retailer. Bearing in mind the relationships of conflict rather than cooperation (mentioned in the earlier part of this chapter) that, according to Howard (1997), dominate shopping center landlord/tenant relationships, cooperation in a knowledge management network might seem unlikely. Nevertheless, Howard did identify one UK shopping center owner (CSC) that was the exception. On the basis of the limited empirical results reported here, little further analysis of this issue is possible, but we contend that further research into retailer/shopping center networks could be worthwhile for the more enlightened centers and retailers.

Dennis et al. (2002a forthcoming, 2000b) have argued that the most successful shopping centers are those where 'active marketing' and 'pro-active management' feature. Bennett and Gabriel (1999) contended that market orientation is central to the rapid introduction of knowledge management in UK companies, pre-supposing and spreading customer information. Change-friendly enterprises are more likely to have extensive knowledge management systems than others are. The authors predict that a rapid uptake of knowledge management is likely for the most successful, marketing-orientated shopping centers. There are substantial benefits to be gained from the customer knowledge database.

Finally, the authors accept that there have been many limitations in this small exploratory study. A true data mining system would be expected to work on a much larger dataset. The benefits predicted from a customer knowledge management system are purely speculative at this stage. Therefore, a more extensive pilot and research program is recommended. This could take the form of (1) a further questionnaire survey with more respondents and shopping centers, (2) a pilot scheme based on exchange of customer information for parking discount benefits (at a paid-for parking lot), and (3) a pilot 'personal agent' trial based on a smart card. This trial could run on shopper data at a single shopping center gathered by, for example, a parking lot membership scheme as outlined above. If this pilot were to achieve no more success than confirming the effects of cleanliness and rest rooms found in our exploratory survey (which was carried out at nominal cost), the center could expect a medium-term increase in rental income alone of US$2m. In our view, there is a clear case for the cost-effectiveness of further research in this area.

Chapter 4.53
Musical Metadata and Knowledge Management

François Pachet
Sony CSL – Paris, France

INTRODUCTION

Is music a form of knowledge? Probably not, even if music is undoubtedly an important part of our cultural heritage. Music is not a type of knowledge, at least in first approximation, because music has no consensual, shared meaning. One of the main reasons why music has no meaning, as opposed to text or even pictures, is that music is not referential: music is made of elements (notes, chords, sounds) which do not refer to any objects or concepts outside the musical world (Meyer, 1956). Being without meaning, music is not a type of knowledge.

However, our heavily digitized society continuously produces and exploits an increasing amount of knowledge about music. This knowledge, also called metadata, has taken a growing importance in the music industry and deserves a special treatment in this encyclopedia because of the specificities of music. On one hand, music is ubiquitous and pervasive: there are about 10 million music titles produced by the major music labels in the Western world. Adding the music produced in the non-Western world probably doubles this figure. The music industry is one of the prevalent industries in the Western world today. On the other hand, music is elusive, in that it is difficult to define exactly what music is (for instance, distinguishing music from ambient sounds is not always trivial). To make all this music easily accessible to listeners, it is important to describe music in ways that machines can understand. Music knowledge management is precisely about this issue: (1) building meaningful descriptions of music that are easy to maintain, and (2) exploiting these descriptions to build efficient music access systems that help users find music in large music collections.

BACKGROUND

The issue of building music description is the subject matter of the audio part of the Mpeg-7 standard (Nack & Lindsay, 1999). Mpeg-7 focuses only on the notion of metadata, as opposed to its predecessors (Mpeg-1, 2, and 4), and proposes schemes to represent arbitrary symbolic and numeric information about multimedia objects, such as music or movies. However, Mpeg-7 deals only with the syntax of these descriptions, and not with the way these descriptions are to be produced. Here is, for instance, an extract of an Mpeg-7 description of the music title "Blowin' in the Wind" by Bob Dylan. This extract declares the name of the artist, the name of the song, and its genre (here, "Folk," according to a genre classification indicated in the extract itself).

The first step toward music knowledge management is probably music identification. Robust audio fingerprinting techniques have been developed recently to identify music titles from the analysis of possibly distorted sources, such as radio broadcasts, or direct recordings from cell phone microphones (Cano, Batlle, Kalker, & Haitsma, 2002). Audio fingerprinting is not a knowledge management technique per se, but is a prerequisite to build music collections. This technique has received considerable attention in the last few years, and today very robust solutions have been designed and implemented in real-world systems, such as the MoodLogic Music Browser.

To give a concrete idea of typical music descriptions used in musical knowledge management systems, let us give here three examples and their related use.

Figure 1. An Mpeg-7 extract for describing information about a music title

```

Several companies produce and exploit so-called editorial musical metadata—for instance, AllMusicGuide (Datta, 2002) or MusicBrainz (http://www. musicbrainz. org). This information typically relates to songs and albums (e.g., track listings of albums), but also includes information on artists (biographies, periods of activities) and genres. A typical scenario of use is the display in a popular music player of an artist's biography and genre when a title is played. When a title is played, an identification mechanism produces the identity of the title and artist, and a query is made to AllMusicGuide to retrieve more information, for example, the biography of the artist or the photograph of the album the title comes from.

Another popular application of musical metadata is query-by-humming. Query-by-humming consists of letting users sing or hum a melody, and retrieves the songs whose melodies match the input (Birmingham et al., 2002). Technically, query-by-humming is one instance of music information retrieval systems. In terms of knowledge management, this application makes use of the analysis of melodies from the audio signal and the sung inputs, so they fall in the category of acoustic descriptors as described below.

Finally a popular view on music knowledge management is collaborative filtering, as used in music portals such as Amazon. Collaborative filtering makes intensive use of user profiles, and exploits similarity or patterns in large databases of profiles. Technically, collaborative filtering is one instance of so-called cultural descriptors, as we will see below.

The three examples are deliberately chosen to represent three types of information: editorial, cultural, and acoustic. These three types of information actually cover the whole range of techniques for music knowledge management. The next section reviews in more detail each of these types of information and highlights the main technical issues related to each of them.

THREE TYPES OF MUSICAL METADATA

Although there is a virtually infinite number of musical metadata that can be thought of concerning the description of music, we propose here to classify all of them in only three categories: editorial, cultural, and acoustic. This classification is based on the nature of the process that leads to the elaboration of the metadata.

Editorial Metadata

Editorial metadata refers to metadata obtained, literally, by the editor. Practically, this means that the information is provided manually, by authoritative experts. Examples of editorial metadata in music range from album information (e.g., the song "Yellow Submarine" by the Beatles appears on the Album "Revolver" issued in the UK) to administrative information such as the dates of recording, the composers or performers. Because editorial metadata covers a wide range of information, from adminstratrivia to historical facts, it is difficult to define precisely its scope other than by stating how it was produced.

Editorial metadata is not necessarily objective. For instance, the AllMusicGuide editorial metadata portal (Datta, 2002) provides information about artist biographies, which may be biased by cultural factors. In particular, genre information—seen as editorial metadata (i.e., entered by human experts)—is known to be particularly subjective.

Technically, the tasks of organizing editorial metadata raises specific challenges, such as:

- Providing a consensual view on subjective editorial information. For instance, agreeing on a taxonomy of musical genres.
- Coping with the evolving nature of music. New artists, new genres, new events occur all the time in music. The organization of an

editorial information system must be able to cope with these changes efficiently.
- Organizing the human effort into clear and distinct roles. For example, as editorial management and data enterers.

There is another distinction one can make concerning editorial metadata which concerns the nature of the human source: editorial metadata as produced in AllMusicGuide is prescriptive: the information is decided by one well-defined expert or pool of experts.

Editorial metadata can also be produced in a non-prescriptive manner, using a collaborative scheme—that is, by a community of users. In this case, both the nature of the information provided and the management techniques differ.

A typical example of this "collaborative editorial" information is the CDDB effort (www.cddb.com). CDDB is a database of "track listing" (i.e., the information, for each music album produced, of the songs contained in the album). Surprisingly, this track listing information is not systematically present in CD albums, and it is precisely the role of CDDB to fill this gap. The identification technique used is very simple and relies on a hashing code produced by the number of tracks and their exact durations. This signature uniquely identifies most of the albums. To the signature is associated the track listing information. Such editorial information is, however, not prescriptive, and is on the contrary produced by a collaborative effort. When a user fetches a track listing information for a given album, it is retrieved automatically from the CDDB database (provided the media player used has a license with CDDB). If the album is not recognized, then the user can input the information himself, and thus contribute to the database content.

Another example of such an approach is MoodLogic (www.moodlogic.com). The MoodLogic approach consists of building a database of song "profiles" from ratings of users. This database is used to classify and recommend music, and is integrated in various music management tools such as music browsers. When a song is added to a user's collection, a fingerprinting technique identifies the song and fetches the corresponding metadata in the MoodLogic database. If the song is not present in the database, the user is asked to rate the song. This approach has proven to be scalable, as the MoodLogic database now contains profiles for about one million titles. The nature of the information entered is quite different, however, than the information present in prescriptive systems such as AllMusicGuide: MoodLogic includes information such as genres, mood, perceived energy, and so forth.

It is important to stress again here that this information is considered in our context as editorial—more precisely as collaborative editorial—because of the way the information is provided. However, we will see that this kind of information can be used in a totally different context, in particular to produce acoustic metadata.

Cultural Metadata

Cultural information or knowledge is produced by the environment or culture. Contrarily to editorial information, cultural information is not prescribed or even explicitly entered in some information system. Cultural information results from an analysis of emerging patterns, categories, or associations from a source of documents.

A common method of obtaining cultural information is collaborative filtering (Cohen & Fan, 2000). In this case, the source of information is a collection of user profiles.

However, user profiles are a relatively poor source of information, and there are many other cultural information schemes applicable to music. The most used sources of information are Web search engines like Google, music radio programs, or purely textual sources such as books or encyclopedias. The main techniques used borrow from natural language processing and are mostly based on co-occurrence analysis: for a given item of interest (say an artist or a genre), co-occurrence techniques allow one to associate to this item other items which are "close," in the sense that they often appear close to each other. Co-occurrence can be based on closeness of items in a Web page or by neighboring relations in music playlists. The main difficulty in this approach is to derive a meaningful similarity relation from the co-occurrence information. Approaches such as Pachet, Westerman, and Laigre (2001) or Whitmann and Lawrence (2002) give details on the actual language processing techniques used and the evaluation of results. The typical information that can be obtained from these analysis are:

- Similarity distance between musical items such as artists or songs. Such similarities can be used in music management systems such as music browser, or music recommendation systems.
- Word associations between different word categories. For instance, a co-occurrence technique described in Whitmann and Lawrence (2002) indicates which most common terms are associated with a given artist. The same technique can also be used to infer genre information; by computing the co-occurrence between an artist name (say, "the Beatles") and different genre names (say "Pop," "Rock," "Jazz," etc.). In this case, the resulting information may also be called genre, as in the editorial case, but editorial genre and cultural genre will most of the time not coincide (see the section titled "Discussion").

Acoustic Metadata

The last category of music information is acoustic metadata. Acoustic here refers to the fact that this information is obtained by an analysis of the audio file, without any reference to a textual or prescribed information. It is intended to be purely objective information, pertaining to the "content" of the music.

A typical example of musical acoustic information is the tempo, that is, the number of beats per second. Beat and Tempo extraction have long been addressed in the community of audio signal processing, and current systems achieve excellent performances (Sheirer, 1998). Other, more complex rhythmic information can also be extracted, such as the metric structure (is it a ternary rhythm, like a waltz, or binary rhythm?) or the rhythm structure itself.

Besides rhythm, virtually all dimensions of music perception are subject to such extraction investigation: percussivity (is a sound percussive or pitched?), instrument recognition (Herrera, Peeters, & Dubnov, 2002), perceived energy (Zils & Pachet, 2003), or even mood (Liu, Lu, & Zhang, 2003). The results of these extractions are very disparate, and today no commercial application exploits these descriptors. But the robustness of these descriptors will likely greatly improve in the coming years, due to the increase of attention these subjects have attracted recently.

These preceding examples are unary descriptors: they consist of one particular value for a whole title and do not depend on other parameters such as the position in the music title. Non-unary descriptors are also very useful to describe music and manage large music collections. Melodic contour or pitch extraction can be used, for instance, for query-by-humming applications (Birmingham et al., 2001). At a yet higher level, music structure can be inferred from the analysis of repetitions in the audio signal (Peeters, La Burthe, & Rodet, 2002), leading to applications such as automatic music summaries.

The issue of representing in a standardized manner all these metadata is addressed by the audio part of the Mpeg-7 standard (Nack & Lindsay, 1999). However, Mpeg-7 focuses on the syntax of the representation of these descriptors, and it is quite obvious that the success of the standard heavily depends on the robustness of the corresponding extractors.

One major problem this endeavor has to deal with is that there is rarely any "music grounded facts," except for trivial information. Building a grounded facts database is therefore one of the main difficulties in acoustic descriptor design. Information obtained from collaborative editorial sources, such as MoodLogic, can paradoxically prove very valuable in this context.

Another issue is that although there is a lot of formal knowledge about music structure (tonal music in particular), this knowledge is rarely adapted to perceptive problems. For instance, taxonomies of genres or taxonomies of instruments are not directly usable for building ground truth databases, because they are not based on perceptive models: depending on the playing mode, context, and so forth, a clarinet can sound very close to a guitar and very different from another clarinet.

DISCUSSION

Because of the wide diversity of music knowledge types, there is a growing concern about the evaluation and comparison of these metadata. Indeed, the exploitation of large-scale music collections is possible only if these metadata are robust. But what does it mean exactly to be robust?

There are different types of evaluations in our context, some of which do not raise any particular problems. For instance, the evaluation of acoustic descriptors targeting consensual, well-defined music dimensions (such as tempo or instrument recognition on monophonic sources) do not usually raise any particular issues. The evaluation of acoustic similarities is more problematic, as the elaboration of a ground truth reference is itself a hard task (Aucouturier & Pachet, 2004).

However, the most complex evaluation task is probably the comparison of metadata across different categories. For instance, comparing acoustic similarity with cultural similarity is not a well-defined problem. Indeed, cultural metadata can be used to train machine-learning algorithms to produce acoustic metadata or similarities. In this case, the comparison is simple to do, but misleading, since the cultural similarities are known to be based not only on acoustic features. On the other hand, comparing two similarity measures obtained from different sources (e.g., Berenzweig, Ellis, Logan, & Whitman, 2003) produces results that are hard to interpret or exploit.

Another important consequence of this diversity of sources of metadata is that complex information dependency loops can be created which eventually produce meaningless musical knowledge, at least to non-informed users. The example of genre is, to this respect, emblematic, as genre can be produced by any of our three categories of approaches:

- Editorial genre is a genre prescribed by an expert, say, the manager of a label, or the team of AllMusicGuide. In this case, the Beatles can be described as "Pop-Sixties."
- Cultural genre is extracted from an analysis of textual information such as the Web. Depending on the source used, the Beatles can be described, culturally, as, say "Pop" (versus "Jazz" and "Classical).
- Finally, acoustic genre can be extracted too, using audio signal processing techniques (see, e.g., Tzanetakis, Essl, & Cook, 2001). It is important to note that acoustic genre will entirely depend on the learning database used for building the extractor. This database usually comes either from editorial or cultural information sources.

These intricate dependencies of information call for a better realization, by users, of the implications and meanings of the metadata they are provided with for managing their collections. Instead of trying to artificially compare or fit these different sources of knowledge about music, a simpler and more efficient strategy is probably to find simple ways to explain to users what each of them is doing.

FUTURE TRENDS

The representation of musical knowledge, as represented by metadata, is a blooming field. From the early experiments in beat tracking to the industries of metadata, many results have been obtained and problems solved. More are being addressed with promising results, such as the separation of sources in polyphonic recordings, which will bring new descriptions to music management systems.

Important directions concerning the future of music knowledge in this context are:

- The invention of new music access modes. So far, the main use of music metadata has been for implementing efficient music query systems. Metadata can also be used to create new music access modes, for instance integrating performance and music access. Preliminary works have been proposed, such as concatenative synthesis (musaicing) (Zils & Pachet, 2001), which exploits metadata to create new music and not only to listen to songs.
- More subjective measures of user interests. So far, work on evaluation has focused on objective measures. However, users accessing large-scale music collections are often animated by desires such as the quest for discovery or the pleasure of partially controlled browsing. Music access systems would clearly benefit from measures of interestingness combining possibly contradictory similarity relations together.

CONCLUSION

While music itself is not a form of knowledge, musical knowledge is needed to manage large-scale music collections. We have discussed a classification of musical metadata into three basic categories, based on the nature of the process leading to the creation of the metadata and their potential uses. These three categories may intersect, at least superficially, and it is important to understand the possibilities and limits of each of these categories to make full use of them. It is very likely that future applications of music content management will make increasing use of such metadata, and conversely will exert pressure for the creation of new music metadata types.

Chapter 4.54
Why Knowledge Management Fails:
Lessons from a Case Study

Ivy Chan
The Chinese University of Hong Kong, Hong Kong

Patrick Y. K. Chau
The Chinese University of Hong Kong, Hong Kong

EXECUTIVE SUMMARY

Knowledge is increasingly recognized as providing a foundation for creating core competencies and competitive advantages for organizations, thus effective knowledge management (KM) has become crucial and significant. Despite evolving perspectives and rigorous endeavors to embrace KM intentions in business agendas, it is found that organizations cannot capitalize on the expected benefits and leverage their performances. This is a case study of an organization in Hong Kong. It is a typical organization with a strong awareness and expectation of KM, yet its program failed within two years. Our findings show that KM activities carried out in the organization were fragmented and not supported by its members. Based on this failure case, four lessons learned are identified for use by management in future KM initiatives.

BACKGROUND

Founded in 1983, HS (the actual name of the company is disguised for confidentiality) is a Hong Kong-based enterprise with a production plant in mainland China. HS is primarily engaged in the production and export of handbags and leather premium products to the United States and European markets. The current CEO is the second generation of the founder. Like many companies in Hong Kong, HS centralizes all its strategic planning and decisions, as well as sales and marketing functions at its head office in Hong Kong while doing the production and assembly work across the border for low production cost. Appendix 1 is the organizational chart of HS. It is found that the head office has 10 staff including a CEO, a general manager, a sales manager, an operation manager, and six other administrative staff. The production plant in China has 450 staff including 40 managerial, supervisory, or administrative staff and 410 skilled workers. Over the years, HS has expanded its range of products and production capacities and resources in order to seize market opportunities and has enjoyed quite healthy growth in terms of sales turnover and profits.

SETTING THE STAGE

Business began declining with double-digit revenue losses in 1998. This was primarily attributed to the fierce competition in the markets and soaring production cost. For example, some competitors were offering drastic price cuts in order to obtain business contracts. Also, new product designs did not last long before being imitated by the competition. The CEO and the senior management team began planning the future of the company and to look for ways to improve the efficiency and productivity of its employees. Business continued to deteriorate, so that by 2001, in order to find out what had gone wrong, the CEO formed a strategic task force consisting of all managers in Hong Kong, several key managers responsible for the production plant in China, and himself to look into the matter. After two weeks of exploration (including observation and communicating with other staff in the company), the strategic task force concluded that knowledge within the organization was ineffectively managed; specifically, there was low knowledge diffusion from experienced staff to new staff, and high knowledge loss due to turnover. Driven by traditional management philosophy, the CEO and the strategic task force believed that they understood the organizational context better, and thus decided to undertake an in-depth investigation through internal effort instead of hiring an external consultant.

CASE DESCRIPTION

In June 2001, the strategic task force carried out investigation, observation, and interviews of employees in various departments. After three months, they identified the knowledge management (KM) issues summarized in Table 1.

From these findings, the strategic task force determined that open communication and discussion was necessary and effective to further examine the KM problems, and therefore called for a couple of meetings with managers and supervisors. In order to encourage open discussion, the meeting was conducted in an informal manner instead of the frequently used formal discussion (such as predefined order for reporting departmental issues). Furthermore, the room setting was changed with seats arranged in a circle to allow everyone to see each other and a flip chart was made available to jot down immediate thoughts. More importantly, everyone was encouraged to express his/her thoughts, opinions, and feedback from a personal perspective or collective stance (e.g., comments from subordinates).

The results of the meeting were encouraging as many participants expressed their opinions and comments eagerly. In particular, staff in the meeting agreed that KM was neither an extension of information management nor solely a technology application to capture, organize, and retrieve information or to evoke databases and data mining (Earl & Scott, 1999; Thomas, Kellogg, & Erickson, 2001). Instead, knowledge was embedded in people (e.g., skills and actions), tasks (e.g., production process), and the associated social context (e.g., organizational culture) that involved communication and learning among loosely structured networks and communities of people. Therefore, individuals/employees were crucial to the implementation of KM initiatives by utilizing their knowledge and skills to learn, share, combine, and internalize with other sources

Table 1. Diagnosis of KM problems in HS

Issues	Problems from a KM perspective
❖ Supervisors complained about the heavy workload as they were merely the experts/ advisors for their team members. ❖ Supervisors had little interest in what other supervisors were doing and practicing as they considered their tasks were the most important agenda. ❖ Employees demonstrated passivity and taken-for-granted passion while they were learning new skills, e.g., they implemented instructions without asking.	❖ Knowledge was not shared but solely kept by a small group of people. ❖ Learning initiatives among employees was low due to the silo effect of organizational structure.
❖ When skilled workers left HS, specific production techniques were swiftly acquired by other competitors who employed those ex-staff of HS.	❖ Knowledge was lost to competitors.
❖ Supervisors did not have unified standard to extract best practices from experiences. ❖ Employees encountered difficulties in identifying success stories or effective production techniques for respective clients.	❖ Knowledge was not appropriately defined, captured and retained.
❖ Employees did not have strong willingness to learn with new techniques and practices. ❖ Employees took a long time to acquire techniques yet hardly to retain the acquired techniques.	❖ Knowledge creation and development was not encouraged, motivated and nurtured systematically.

of knowledge to generate new thoughts or new perspectives.

With the above results, HS decided to devise and launch a KM program with an aim to institutionalize knowledge diffusion among employees and leverage knowledge creation for quality products. Instead of a top-down approach of policy making, the management adopted a middle-up-down approach (Nonaka, 1994) with supervisors as the major force to leverage and promote KM throughout the organization. To enhance acceptance and lessen resistance to change, HS chose a new product series to try out the KM initiative with a focus on the following four main aspects: strategic, organizational, instrumental, and output.

In the strategic aspect, it was considered that knowledge available and possessed at HS would fall short of the core competence necessary for business success (e.g., chic product design). Therefore, effort was needed to fill this gap by acquiring knowledge from both external and internal sources. From the organizational side, it was thought that knowledge was more valuable when it was shared and exchanged. Thus, a knowledge-friendly culture needed to be promoted through encouraging employees to socialize and share their ideas and thoughts such that new knowledge could be created to broaden their knowledge repositories. At the base level, it was determined that knowledge had to be acquired, stored, and disseminated in a systematic way to enable employees to access and reuse it easily. In doing so, essential knowledge, such as experienced practices in production skills and innovative ideas in product design, could be captured and recorded. Individual employees or teams who contributed knowledge useful and relevant to HS were to be rewarded. Last but not least, from an output perspective, it was realized that periodic reviews were crucial for evaluating KM effectiveness and for devising subsequent corrective action, if necessary. Performance indicators such as production efficiency, adoption rate of good practices identified, and clients' satisfaction were required.

A detailed implementation plan was devised based on the above analysis, which was then agreed to and approved by the top management of HS. The KM program was officially launched in April 2002.

CURRENT CHALLENGES/ PROBLEMS FACED BY HS

After 15 months, HS found that the KM initiative did not generate the positive impact on organizational performance as expected. Organizational performance remained stagnant, revenue continued to decrease, and staff turnover rate stayed high. Our involvement with HS as an external consultant began after the CEO had determined to find out why and/or what happened. Our assistance to HS was clear — to investigate the situation, to uncover the mistakes, and to look for remedies. A series of semistructured interviews with key employees in the managerial, supervisory, and operational levels were therefore conducted. Table 2 summarizes our findings.

As seen, a good start does not guarantee continuity and success (De Vreede, Davison, & Briggs, 2003). First, two crucial reasons were identified as to why HS was unable to bridge the knowledge gap. They were (1) the top management was too ambitious or unrealistic to grasp and incorporate the "best" knowledge in industry into the company and (2) their insufficient role support in encouraging the desired behavior. Similar to many other KM misconceptions, top management wrongly aimed at incorporating other enterprises' best practices (e.g., product design of the fad) or success stories (e.g., cost cutting and streamlining operational processes) into its repositories without considering the relevance, suitability, and congruence to its capabilities. Therefore, this "chasing-for-the-best" strategy soon became problematic and departed from its KM goals. HS did not gain business advantages, such as unique product design and value-added services to customers, and were still unable to respond to the marketplace swiftly.

Second, the mere presence of KM vision is not sufficient to guarantee KM success. Most employees commented that top management involvement in the KM implementation was volatile and appeared to be a one-shot exercise (Gold, Malhotra, & Segars, 2001). For example, the KM program started well with noticeable initiative to identify untapped knowledge from various sources, yet fell behind the expected goals as top management involvement was remote (e.g., leaving the KM effectiveness as departmental responsibility) and support was minimal (e.g., time resources available for knowledge sharing and creation). Thus, the two factors directly hampered the employees' dedication and belief in KM as a significant organizational move.

Third, from the organizational aspect, even though various social activities such as tea parties were used to foster a friendly and open organizational culture, we found that most of these knowledge-sharing activities were futile because no specific and/or appropriate guidelines for such sharing had been devised (Nattermann, 2000). As a result, instead of having discussions that were directly related to tasks, or least contributed to idea generation, frequent chats (e.g., gossiping) among employees and wandering around were found. Many employees were confused with what the sharing was all about. Some employees

Table 2. KM results from 2001 to 2003 in HS

KM Focus	Initiatives in 2001	Results in 2003
Strategic ❖ To determine knowledge gap	❖ Identified core knowledge that led to business success	❖ Unrealistic aims → created fallacies "All the best in HS" to direct KM development ❖ Volatile support → undermined the KM climate
Organizational ❖ To establish knowledge-friendly culture	❖ Shared knowledge in various socialization and informal gathering	❖ Unframed socialization → created more confusion or negative perceptions ❖ Ineffective human resources policy to retain knowledge workers → swifted loss of knowledge
Instrumental ❖ To acquire and stimulate knowledge creation	❖ Acquired knowledge in departmental handbook and rewarded knowledge sharing behaviors	❖ Unlimited definitions or views of sources of knowledge → left individual knowledge untapped ❖ Emphasized monetary rewards to stimulate contributions → created self-defeating mechanism and unfriendly team culture ❖ Perceived IT as cutting-edge solution → led to unduly investment on technology
Output ❖ To evaluate and audit KM development	❖ Conducted periodical review and measured organizational performance	❖ Reviewed infrequently → created pitfalls to learn from mistakes, then moved ahead ❖ Predisposed on efficiency and profitability → overwhelmed short-term benefits to exploit existing knowledge

even perceived KM negatively as interfering with activities important to their daily tasks, creating resistance to participation in what was perceived to be a temporary fad.

Fourth, the instruments used to help acquire and stimulate knowledge creation and sharing encountered problems during implementation. The fallacy of knowledge acquisition with reliance on external sources (such as the existing practices addressed by competitors) undermined employees' intent to explore the available but untapped knowledge resident in their minds (Bhatt, 2001; Nonaka, 1994). The use of information technology to drive knowledge storage and sharing, in principal, was conducive to employees. Yet, the silo organizational structure of HS with disentangled databases for knowledge capture caused more harm than good. Some employees asserted that they did not have the incentive to access or utilize the departmental knowledge handbook and procedural guidance (available from databases) as it is a time-consuming endeavor to dig from the pile of information. Some employees found knowledge incomprehensible as it was presented and stored in various formats, with jargons and symbols that were neither standardized nor systematized across departments.

Fifth, although a reward system was established for knowledge creation and/or sharing, the emphasis on extrinsic terms, such as a monetary bonus, turned out to have an opposite and negative effect on cultivating the knowledge-sharing culture and trust among employees. Some employees commented that knowledge should be kept as personal interest (i.e., not to be shared) until they felt that they could get the monetary reward when shared or recognized by management. Other employees found that harmony and cohesiveness within the team or among colleagues were destabilized as everyone maximized individual benefits at the expense of teamwork and cooperation.

Sixth, there was a misleading notion that IT could be "the" cutting-edge solution to inspire KM in organization. Despite the introduction of IT tools to facilitate knowledge capture, codification, and distribution, it was found that IT adoption and acceptance remained low due to employee preference for face-to-face conversation and knowledge transfer instead of technology-based communication, and the general low computer literacy that intensified the fear of technology. In addition, given the insufficient support from management for IT training and practices, employees, particularly those who had been with HS for a long time, had strong resistance to new working practices for facilitating KM.

Seventh, it was noted that the KM initiatives were left unattended once implemented. It remained unclear as to how to exceed existing accomplishments or overcome pitfalls of the KM initiatives, as there was no precise assessment available. For instance, the last survey evaluating the adoption of best practices from departmental knowledge was conducted a year ago, without a follow-up program or review session. Another example was that the currency and efficacy of the knowledge recorded in the departmental handbook appeared obsolete as no procedures were formulated to revise or update the handbook.

Last but not least, an undue emphasis and concern with the "best-practice" knowledge at HS to improve short-term benefits (e.g., to exploit existing knowledge in order to achieve production efficiency) at the expense of long-term goals (e.g., to revisit and rethink existing knowledge and taken-for-granted practice in order to explore innovation and creativity opportunities). Some employees pointed out that they were inclined to modify existing practices rather than create new approaches for doing the same or similar tasks as recognition and positive impacts can be promptly obtained.

EPILOGUE

To date, KM is considered an integral part of a business agenda. The dynamics of KM as human-oriented (Brazelton & Gorry, 2003; Hansen, Nohria, & Tierney, 1999) and socially constructed processes (Brown & Duguid, 2001) requires an appropriate deployment of people, processes, and organizational infrastructure. This failure case presents the challenges that could be encountered and coped with in order to accomplish effective KM implementation. The people factor is recognized as a key to the successful implementation of KM from initiation, trial, to full implementation. KM is a collective and cooperative effort that requires most, if not all, employees in the organization to participate. KM strategy and planning should be organized, relevant, and feasible within the organizational context. One's best practices and winning thrusts may not be well fitted to others without evaluation for fit and relevance. A balanced hybrid of hard (e.g., information technology) and soft infrastructure (e.g., team harmony and organizational culture) is needed for success.

LESSONS LEARNED

Knowledge management is increasingly recognized but its challenges are not well understood.

To institutionalize a KM program, organizations can draw lessons from this failure case so as to construe what imperatives are needed and what mistakes should be avoided. Management issues and concerns are highlighted as follows.

Lesson 1: Start with a KM Plan Based on Realistic Expectations

The mission and behavioral intentions of leaders have a strong impact on employees and where to aim and how to roll out KM processes (KPMG, 2000). In this case, it is appreciated that top management recognized its organizational ineffectiveness and initiated a KM plan as a remedy. We suggest, however, that planning based on unrealistic expectations undermined its ability to successfully direct future actions. Therefore, management has to be reasonable in setting KM goals, perceptions, and beliefs. It is suggested that a feasibility assessment of organizational infrastructures (e.g., financial resources, technology level) and organizational climate (e.g., employees' readiness to KM, resistance to change) be conducted to define the KM principles and goals. Inspirational aims, which can be reasonably and feasibly accomplished, encourage employees to assess their personal knowledge and transfer others' knowledge when it is shown to enhance existing practices and can help meet new challenges.

Lesson 2: Management Support is a Strong, Consistent, and more Importantly, Cohesive Power to Promote KM

It is evident that vision without management support is in vain and temporary. As valued most by the HS employees, continuous corroboration from top management is indispensable to motivate their commitment toward knowledge-centric behaviors for long-term competitiveness (Lee & Choi, 2003). Therefore, beyond visionary leadership, management should be willing to invest time, energy, and resources to promote KM. At its core, management could show their enthusiasm in a boundless and persistent way, including vocal support, speech, inaugural memo, and wandering around different business units to invite impulsive idea generation and knowledge creation from all levels of staff. Also, management could champion the KM process and lead by example with employees who are receptive to KM.

Lesson 3: Integration of Monetary and Nonmonetary Incentives

To stimulate KM behaviors, specifically sharing and creation, it is important to assure a balanced reward system integrating monetary and nonmonetary incentives that fit various forms of motivation (Desouza, 2003). In the beginning of the KM programs, employees needed to be shown that personal benefits could be obtained from KM success with improvement in products, processes, and competitiveness. Therefore, rewards that are direct, monetary-based, and explicit are useful. For this, management can provide salary increase or promotion. With the passage of time, rewards could be extended to something implicit. For instance, management can publicize those employees' names and respective ideas that contributed to organizational processes, or provide skills-enhancement program to enable employees to see their importance with extended job scopes. Moreover, management can consider rewards systems geared toward individual or team achievement so as to encourage more interaction, creativity, teamwork, and harmony among people.

Lesson 4: KM has to be Cultivated and Nurtured, which is not a Push Strategy or Coercive Task

As shown in this case, KM is not a singly motivated exercise. It requires a collective and cooperative effort to put into effect various resources. Other than the vision and top management support, operational staff can greatly affect the success of the KM program. Their influences affect attitudes, behaviors, and participation in KM and could exert positive impacts on KM effectiveness if managed properly. For attitudinal changes, efforts have to remove or at least alleviate employees' negative perception toward KM. For example, the fear and misconception that KM is a means to downsize organizations for efficiency or as heavy workload which requires much IT expertise. For behavioral changes, we highlight a supportive working environment where employees can have ample time to engage in KM endeavors, such as sharing and creation, a fair and positive culture where everyone is valued and encouraged to contribute to KM effectiveness, is needed. To encourage participation, pushing or mandatory activities are least effective. Coupled with the rewards systems, employees should be inspired to take risks as learning steps for KM success. Unexpected failure or unintended results may cause management to call for a break to identify the causes and remedy solutions. Do not quit or blame, otherwise, mutual trust and commitment to work with the KM processes will be lessened.

Chapter 4.55
Getting Knowledge Management Right: Lessons from Failure

Ivy Chan

ABSTRACT

Knowledge is increasingly recognized to provide a foundation for creating core competences and competitive advantages for organizations, making effective knowledge management (KM) crucial and significant. Despite evolving perspectives and rigorous endeavors to embrace KM intentions in business agendas, organizations cannot always realize expected benefits and improve their performances. This paper reports a case study of an organization in Hong Kong that shares typical characteristics with other organizations with strong awareness and expectations of KM, yet experienced failure of its program in two years. Our findings showed that KM activities carried out in the organization were fragmented and not supported by members. Based on this failure case, four lessons learned are identified for improving KM performance.

INTRODUCTION

Knowledge has been increasingly recognized as an important asset for improving organizational performance. The capability to manage knowledge is deemed crucial to advocate effective KM programs/systems in large-, small- and medium-sized organizations (Alavi & Leidner, 2001, KPMG, 2000, McAdam & Reid, 2001). While many KM success stories have been reported, there are also failure stories. As reported in many management research studies, the challenges of KM implementation are not only dependent on a company's technological abilities, but also its managerial and organizational capabilities (Akbar, 2003; King, Marks Jr. & McCoy, 2002). In this paper, we report on a case study of how an organization in Hong Kong initiated a promising KM project but failed in two years. We know the case because we were called in by the company's top management to uncover why the KM initiative failed. Findings are discussed that reveal a gap between the KM initiatives and unmet practices. Derived from the failure results, we present what we can learn from it and finally conclude with implications for future KM theory and management actions.

PAST STUDIES ABOUT KM

KM researchers have suggested various key elements that contribute to KM success. The mainstream thoughts can be classified as follows:

Knowledge Classification

According to resource-based theory, knowledge is regarded as an object that can be identified, traded like other organizational resources, and captured and documented in information systems (Fischer & Ostwald, 2001; Shin & Holden, 2000). Therefore, it is presumed that the more knowledge objects organizations possess the more likely they are to improve performance and productivity. According to the cognitive perspective, knowledge is viewed as a fluid mixture of experience, ideas and capabilities that are resided in minds of individuals (Kim, 1993; Nonaka, 1994; Tuomi, 2000). Therefore, it is asserted that procedural design in enhancing individual learning and understanding to leverage knowledge to direct decision and action will improve performance. The social view asserts that knowledge is a social asset and is embedded in social context as a dynamic state of knowing leveraged from individuals to groups through collective interaction and learning by doing (Nonaka & Konno, 1998; Swan & Newell, 2000). Therefore, the effectiveness of KM is primarily encouraged by knowledge sharing among and between groups and individuals who are committed for common interests or trust.

KM Frameworks

KM frameworks are categorized into two main groups: descriptive and prescriptive (Holsapple & Joshi, 1999). The descriptive framework characterizes the nature of KM phenomena: the fundamental capabilities that organizations manipulate in their KM activities. For example, APQC (2000) conceptualizes organizational members as engaging seven main KM processes, including create, identify, collect, adapt, organize, share and use of knowledge. It is stated that each process is designed and managed to support one another to ensure the right knowledge gets to the right people at the right time to improve organizational performance. Other studies depict the core work of KM as relying upon the development of organizational memory (Appleyard & Kalsow, 1999) or fostering networked communities (Bowonder, 2000) to enable individuals to share and acquire knowledge in various aspects.

The prescriptive framework characterizes how organizations should structure effective KM implementation guidelines. For example, Allee (1997) suggests that traditional ways of managing physical resources (such as raw materials) do not fit in the context of KM. She advances 12 principles for capitalizing the value of knowledge in regard to its fluid and diverse nature: Knowledge is embedded with individuals and social networks; knowledge is not accountable to a single party, meaning it should be a responsibility for each employee. Lee and Kim (2001) propose four KM stages where organizations nurture and grow their capabilities: initiation, propagating, integration and networking. The first stage, initiation, is regarded as the preparation for enterprise-wide knowledge management efforts. The second stage is focused on the intra-organizational activation of knowledge activities (e.g., reward systems, KM development). The third stage emphasizes integration of KM efforts to organizational outcomes, and the final stage expands knowledge activities with connection to external parties. They suggest that variations and coordination in management plans, organizational members and procedures are necessary for KM effectiveness.

KM Enablers

Enabling factors facilitate KM activities, such as codifying and sharing knowledge assets among individuals. One enabler is organizational culture. Organizational culture is critical to facilitating knowledge sharing norms and learning motivation among individuals (Amabile, 1997; Standing & Benson, 2000). For example, Roberts (1997) explains that KM effectiveness is an integration of people, relationship and technology. He furthers states that employees' enthusiasm and trust in others has direct influence on the ability of information and communication technology (ICT) to transfer knowledge across various departments. In addition, leadership and management initiatives are considered central to direct and evaluate knowledge management practices effectively (April, 2002; Brown & Woodland, 1999; Earl & Fenny, 1994). In a study of chief information officers and senior IS managers, Law and Lee-Partridge (2001) identified that the chief executive officer could be an effective champion and key figure in breaking through long-standing practices in daily work: encourage employees to pay more attention in identifying knowledge, share best practices and create new thoughts for innovative products or services. Other studies emphasize the role of technology and information systems as essential to enabling knowledge acquisition and dissemination (Armbrecht Jr. et al., 2000; Sher & Lee, 2004). Marwick (2001) proposes that a number of IT tools be applied in regard to the different knowledge creation processes. For instance, he states that e-meetings can be an effective means to enable people to chat and discuss for identifying tacit knowledge; while document categorization is useful for employees to retrieve and access explicit knowledge.

KM Strategies

KM strategies encapsulate the strategic directions in managing knowledge and its related processes. In general, there are two main orientations of KM strategy. First, technology-driven KM strategy is characterized by application of information systems such as knowledge directories and chat forums to maximize codification, connectivity, dissemination and reusability of knowledge resources (Hansen, Nohria & Tierney, 1999; Swan & Scarbrough, 2001). In an empirical investigation of KM, Choi and Lee (2001) found that some organizations emphasizing the capability to store and use the explicit and documented knowledge are more likely to put much attention on the technology infrastructure and deployment. Management focuses on a specified set of rules and procedures to determine what knowledge and how knowledge should be manipulated. As a different system emphasis, the human-driven KM strategy is characterized with provision of channels (not necessary technology enabled) such that people-to-people interactions, direct conversation and social contact networks are fostered (Choi & Lee, 2001). It is presumed that knowledge is originated from social networks, story telling or experience sharing through dialogue. Other empirical studies are identified that support similar views of the significant role of human as the knowledge agents (such as knowledge providers, seekers, re-users) (Markus 2001), and the trust and care among individuals to create knowledge communities in order to enable individuals to share, exchange and explore knowledge through personal and unstructured ways (Bhatt, 2000; Von Krogh, Ichijo & Nonaka, 2000).

These studies reveal that the field of KM proliferates with diverse approaches in research and practice. It is deemed that each study provides an explanation of a slice of the KM phenomena, but not in a comprehensive manner (Alvesson, Kärreman & Swan, 2002; Argote, McEvily & Reagans, 2003). A concern is that KM practices within an organization may reflect several or a blend of those elements addressed in past studies. Thus, our case study aims to present and reveal such complexity. The case study illustrates a KM experience that starts with a sound initiative but is not sustained throughout its implementation.

RESEARCH METHODS

The main focus of this research is to explore the underlying reasons why a sound KM initiative did not lead to its expected results. In regard to the complexity of KM issues, this study used case study methods to collect evidence from organizational records and in-depth interviews with employees at various organizational levels (Pettigrew, 1990; Yin, 1994). The analysis of organizational records, including employees' log books, departmental minutes, productivity charts and front-line supervisors' reports, was conducted to diagnose the causes of ineffective organizational performance from which to imply the possible directions of the KM program. Discussion and clarification were made with management in iterative rounds to develop a common discourse on the KM issues. The discussion results, in respect to knowledge categorization, KM enablers and strategies are presented in Table 1.

Interviews were used to investigate the underlying reasons for ineffective KM practices in 2003. Taking into account the complexity of the issues, we sought insights from key informants in various departments. From September to November 2003, 12 in-depth interviews were conducted. Based upon the guides in conducting case study method and qualitative research methods (Boyatzis, 1998; Denzin & Lincoln, 1994; Yin, 1994), the data were transcribed and scrutinized to identify eight flaws in the KM program.

ORGANIZATION BACKGROUND

Founded in 1983, HS (the actual name of the company is disguised for confidentiality) is a Hong Kong-based enterprise with a production plant in mainland China and that engages primarily in the manufacture and export of handbags and leather premium products for United States and European markets. Like many companies in Hong Kong, HS centralizes all its strategic planning and decisions, as well sales and marketing functions, at its head office in Hong Kong, while doing the production and assembly work across the border. The head office has 10 staff, including a CEO, general manager, sales manager, operations manager and six other administrative staff. The production plant in China has 450 staff, including 40 managerial, supervisory or administrative staff and 410 skilled workers. Over the years, HS has expanded its range of products and production capacities and resources in order to seize market opportunities and has enjoyed healthy growth in terms of sales turnover and profits.

Business, however, began to decline, with a double-digit revenue loss since 1998, primarily attributed to the fierce competition in the markets and soaring production costs. Because of this, the CEO and his senior management team began to plan the future of the company and look into ways to improve the efficiency and productivity of its employees. To find out what had gone wrong, in 2001, the CEO formed a strategic task force that consisted of all managers in Hong Kong, several key managers responsible for the production plant in China and himself to look into the matter. After two weeks of exploration (including observation and communicating with other staff in the company), the strategic task force concluded that the ineffective performance could be attributed to the practice in managing the knowledge assets within the organization, with low knowledge diffusion and high knowledge loss as two key issues. Therefore, it was decided to do a more detailed and in-depth investigation.

The strategic task force was responsible for carrying out the analysis. After three months of investigation and observation, they asserted that knowledge should be the strategic assets utilized and developed in their business agenda, despite their lack of experience in managing knowledge. To seek more opinions and perspectives, the strategic task force determined that open communication and discussion was necessary and effective to further examine the KM problems and therefore called for a meeting with managers and supervisors.

The results of the meeting were encouraging, as many participants expressed their opinions and comments eagerly. In particular, staff in the meeting agreed that KM was neither an extension of information management nor solely a technology application to capture, organize and retrieve information, to evoke databases and data mining (Earl & Scott, 1999; Thomas, Kellogg & Erickson, 2001). Instead, knowledge was embedded in people (e.g., skills and actions), tasks (e.g., production process) and the associated social context (e.g., organizational culture) that involved communication and learning among loosely structured networks and communities of people. Therefore, individuals/employees were crucial to drive KM initiatives by utilizing their knowledge and skills to learn, share, combine and internalize with other sources of knowledge to generate new thoughts or new perspectives.

KM IN 2001

In spite of the determination to leverage knowledge assets, the analysis of organizational documents showed that there was little systematic mechanism to collate and assimilate various feedbacks and findings from the employees. For example, the organizational annual plan in 2002 had implicit emphasis and objectives to devise a KM program and institutionalize knowledge diffusion among employees and knowledge creation for quality products. The long-term goal remains broad and conventional, with the aim "to provide quality products at effective cost," in which the role of knowledge is not considerably stated or embraced. In essence, the KM program at HS can be characterized with a sound plan but fragmented and flamboyant process.

Fragmented Plan

Table 1 highlights the ineffective organizational performance and relates it to previously discussed KM elements. Taking into account the categorization of knowledge, it was found that there is neither a working definition of knowledge nor a clear categorization mechanism available to identify knowledge. There is an extensive pool of knowledge existing in HS, as employees in different departments are required to record their tasks, procedures and suggestions in their log books. However, there is scant appropriate policy to unify the presentation and content. The records of critical success factors of a product were perceived and recorded differently and haphazardly across departments: choice of leather color that comply with those promoted in the latest fashion design (design team), the analysis of customers' preference or effective control of cost that contributes to competitive selling price (sales department) and so forth.

In regard to KM enablers, management did not put much effort into creating enablers for its KM activities. It was found that an effective human resources plan was not made to enhance knowledge sharing. For example, a number of supervisors stated that getting new employees to learn the skills is a painstaking process. The production department manager claims, "with inadequate time and people, and tremendous time pressure, as I spend 14 hours a day on my primary tasks, I may not be a trainer … subordinates are too passive and not willing to think out of box, they may not be effective learners or serious about improving their knowledge." Therefore,

Table 1. Diagnosis of KM problems in HS

Issues	Implications to KM initiatives
Knowledge categorization ❖ Supervisors did not have unified standard to extract best practices from experiences. ❖ Employees encountered difficulties in identifying success stories or effective production techniques for respective clients.	❖ Knowledge was not appropriately defined, captured and retained. ❖ Knowledge is diverse and not consistently stated.
KM enablers ❖ Supervisors complained about the heavy workload keeping them from training their team members. ❖ Supervisors had little interest in what other supervisors were doing and practicing as they considered their tasks were the most important agenda. ❖ Employees demonstrated passivity and taken-for-granted passion while they were learning new skills, e.g., they implemented instructions without asking.	❖ Knowledge was not shared across the company but kept by a small group of people. ❖ Learning initiatives among employees was low due to the silo effect of organizational structure.
KM strategies ❖ When skilled workers left HS, specific production techniques were swiftly acquired by other competitors who employed them. ❖ Employees did not have strong willingness to learn new techniques and practices. ❖ Employees took a long time to acquire techniques and had a hard time retaining them .	❖ Knowledge was lost to competitors. ❖ Knowledge creation and development was not systematically encouraged, motivated and nurtured.

there are usual complaints that overreliance on supervisors for advice and expertise affect their productivity on managerial roles and tasks. Employees from the production department and accounting department unanimously reflected that no strong culture promotes personal knowledge within organization. The employee (production department) stated, "if you discuss with your colleagues about knowledge gained from our established sewing procedures, or break-through practices on improving productivity, most of them will see you are self-conceited or extraordinary … I do have the heart and mind to embrace KM, but do not dare to implement it under a strong conformity environment."

In terms of KM strategies, it appears that HS has no clear direction and inclination towards technology or human aspects for coordinating KM processes. For example, a merchandizing supervisor revealed that most skilled workers are competent to their tasks at hand but have little computer literacy. He states, "only a few of people, including one of my subordinates, can manipulate the computers for recording our past experiences, such as details during negotiation with suppliers, or search the Web for prospective suppliers … Sometimes, I do worry about what will happen if he leaves our company …" This implies that the knowledge plan should also account for employee turnover causing knowledge loss. Another merchandizing manager recalled that ex-employees have a lot of good networks with suppliers or subcontractors; "now they use their knowledge to defeat us for their new employers."

Trial Run

Based upon their understanding and investigation of KM, HS intended to enhance employee acceptance and lessen resistance to change. Therefore, HS chose to pilot the KM initiative on a new product series. As mentioned before, there is scant documentation detailing the KM programs. This section uses various departmental minutes and supervisor reports, and presents the results in the following four main aspects: strategic, organizational and instrumental and output (Uit Beijerse, 1999).

In the strategic aspect, it was considered that knowledge available and possessed at HS would fall short of the core competence necessary for business success (e.g., chic product design). Therefore, effort was needed to close this gap by acquiring knowledge from both external and internal sources. From the organizational side, it was thought that knowledge was valuable when it was shared and exchanged. Thus, a knowledge-friendly culture needed to be promoted by encouraging employees to socialize and converse their ideas and thoughts such that new knowledge could be stimulated to broaden their knowledge repositories. At the instrumental level, it was thought that knowledge had to be acquired, stored and disseminated in a systematic way to enable employees to access and reuse it easily. By doing so, essential knowledge could be captured and recorded, such as key experiences in production skills and innovative ideas in product design. Individual employees or teams who contributed knowledge useful and relevant to HS were to be rewarded. Last, but not least, from an output perspective, it was realized that periodical reviews were crucial for evaluating the KM effectiveness and for devising subsequent corrective action, if necessary. Performance indicators such as production efficiency, adoption rate of good practices identified and clients' satisfaction were required.

An implementation plan was devised based on the above analysis, which was then agreed upon and approved by HS' top management. The KM program was officially launched in April 2002.

KNOWLEDGE MANAGEMENT IN 2003 – A FAILURE

After 15 months of implementation, HS found that the KM initiative did not have the expected positive impact on organizational performance. Organizational performance remained stagnant, revenue continued to shrink and the staff turnover rate stayed high. Our involvement with HS as an external consultant began after the CEO decided to find out why and/or what happened. Our assistance to HS was clear — to investigate the situation, uncover the mistakes and recommend remedies. A series of 12 semi-structured interviews with key informants at managerial, supervisory and operational levels were conducted. Table 2 summarizes our findings with respect to four KM focuses (Uit Beijerse, 1999). In essence, it is indicated that the initiatives designated in 2001 cannot be realized in 2003.

As indicated in previous research, a good start for a project does not guarantee its continuity and success (Davenport, Long & Beers, 1998; De Vreede, Davison & Briggs, 2003). First, two crucial reasons were identified as to why HS was unable to bridge the knowledge gap. Most middle managers found KM too difficult to implement, as "the top management was too ambitious or unrealistic to grasp and incorporate the 'best' knowledge in industry into the company, while we were starting as a small bush and couldn't grow into a forest within a short period of time." In addition, a number of operational staff stated: "there is insufficient role modeling to exhibit the desired behavior from our supervisors … we found KM is too vague." Similar to many other KM misconceptions, top management wrongly aimed

Table 2. KM results in 2003

KM Focus	Initiatives in 2001	Results in 2003
Strategic ❖ To determine knowledge gaps	❖ Identified core knowledge that led to business success	❖ Unrealistic aims → created fallacies "All the best in HS" to direct KM development ❖ Volatile support → undermined the KM climate
Organizational ❖ To establish knowledge-friendly culture	❖ Shared knowledge in various social and informal gatherings	❖ Unframed socialization → created more confusion or negative perceptions ❖ Ineffective human resources policy to retain knowledge workers → swifter loss of knowledge
Instrumental ❖ To acquire and stimulate knowledge creation	❖ Acquired knowledge in departmental handbook and rewarded knowledge sharing behaviors	❖ Unlimited definitions or views of sources of knowledge → left individual knowledge untapped ❖ Emphasized monetary rewards to stimulate contributions → created self-defeating mechanism and unfriendly team culture ❖ Perceived IT as cutting-edge solution → led to undue investment on technology
Output ❖ To evaluate and audit KM development	❖ Conducted periodical review and measured organizational performance	❖ Reviewed infrequently → created pitfalls to learning from mistakes, then moved ahead ❖ Predisposed on efficiency and profitability → overwhelmed short-term benefits to exploit existing knowledge

at incorporating other enterprises' best practices (e.g., product design of the fad) or success stories (e.g., cost cutting and streamlining operational processes) into its repositories without considering the relevance, suitability and congruence to its capabilities. Therefore, this "chasing-for-the-best" strategy soon became problematic and departed from its KM goals. HS did not gain business advantages such as unique product design and value-added services to customers and was unable to respond swiftly to the marketplace.

Second, the mere presence of KM vision is not sufficient to guarantee KM success. Most employees commented that top management involvement in the KM implementation was volatile and appeared to be a one-shot exercise (Gold, Malhotra & Segars, 2001). For example, the KM program started well, with a noticeable initiative to identify untapped knowledge from various sources; yet it fell behind the expected goals, as top management involvement was remote (e.g., leaving the KM effectiveness as departmental responsibility) and support was minimal (e.g., time resources available for knowledge sharing and creation). One supervisor recalled that, "the inauguration day for incorporating KM into our business agenda was great and impressive, yet we are not given explicit guides to assess and evaluate knowledge work." Another operational staff member (from the same department) stated that, "at present, I am not sure how KM benefits me; also, I do not find management reports showing how KM helped organizational performance over the past two years." Therefore, it directly hampered the employees' dedication and belief in KM as a significant organizational move.

Third, from the organizational aspect, even though various social activities such as tea gatherings were used to foster a friendly and open organizational culture, we found that most of these knowledge-sharing activities were futile because no specific and/or appropriate guidelines for such sharing had been devised (Nattermann, 2000). As a result, instead of having discussions directly related to tasks, or at least contributed to idea generation, frequent chats (e.g., gossiping) among employees and wandering around were found. Most respondents claimed that a sharing session is a time-killing exercise with superficial issues. One supervisor stated with disappointment that, "I can hardly get a piece of useful ideas from my colleagues through those sharing sessions … their best practices are locked up in the ivory towers and cannot be reached." Some employees even perceived KM negatively as interfering activities in their daily tasks and resisted participating in such a temporary fad.

Fourth, the instruments used to help acquire and stimulate knowledge creation and sharing encountered problems during implementation. The fallacy of knowledge acquisition with reliance on external sources (such as the existing practices addressed by competitors) undermined employees' motivation to explore their own available but untapped knowledge (Bhatt, 2001; Nonaka, 1994). The use of information technology (IT) to drive knowledge storage and sharing, in principle, was acceptable to employees. Yet, the silo organizational structure of HS, with unintegrated databases for knowledge capture, caused more harm than good. Some employees asserted that they did not have the incentive to access or utilize the departmental knowledge handbook and procedural guidance (available from databases), as it was a time-consuming endeavor to dig from the pile of information. Some employees found knowledge incomprehensible as stored using nonstandardized formats, jargons and symbols.

Fifth, although a reward system was established for knowledge creation and/or sharing, the emphasis on extrinsic rewards such as monetary bonuses turned out to have an opposite and negative effect on cultivating the knowledge sharing culture and trust among employees. Some employees commented that the "no free lunch" concept should be applied to the organizational KM program. Therefore, they stated that knowledge should be kept as a personal possession (i.e., not to be shared) until they felt that they would get the monetary reward when shared or recognized by management. Other employees found that harmony and cohesiveness within a team or among colleagues were destabilized as everyone maximized individual benefits at the expense of teamwork and cooperation.

Sixth, there was a misleading notion that IT could be "the" cutting-edge solution to inspire KM in the organization. Despite the introduction of IT tools to facilitate knowledge capture, codification and distribution, it was found that IT adoption and acceptance remained low due to employee preference for person-to-person conversation and knowledge transfer instead of technology-based communication. Another reason is that the widespread low computer literacy causes employee hesitation to use new technology. In addition, given the insufficient support from management for IT training and practices, employees, particularly those who had served HS for a long time, had a strong resistance to new working practices for facilitating KM.

Seventh, it was noted that the KM initiatives were left unattended once implemented. It was difficult to find existing accomplishments or to overcome pitfalls of the KM initiatives, as there was no precise assessment available. For instance, the last survey evaluating the adoption of good practices from departmental knowledge was conducted a year ago, without a follow-up program or review session. A manager recalled that the survey "is the only form I completed about the KM progress … in fact, I do not see how effective KM can be promoted if you do not receive suggestions or comments from the third party." Another example was that the currency and efficacy of the knowledge recorded in departmental handbook appeared obsolete, as there were no update or revision procedures for the handbook.

Last but not least, an undue emphasis and concern with how the "what-best" knowledge at HS could be leveraged for short-term benefits (e.g., to exploit existing knowledge in order to achieve production efficiency) at the expense of the long-term goals (e.g., to revisit and rethink existing knowledge, taken-for-granted practice in order to explore innovation and creativity opportunities). Some employees pointed out that they are inclined to modify existing practices rather to create new approaches in doing the same or similar task, as recognition and positive impacts can be promptly obtained. One manager mused that, "we are usually forced to imitate others' work, particularly those management believe as quality practices; however, the real and innovative ideas would not be reinventing the wheel."

IMPLICATIONS OF THE STUDY

Many organizations try to instill KM into their business agenda and expect to improve organizational performance and profit. Our investigation of this failure has increased our understanding of the challenges and complexity of KM implementations (Choi & Lee, 2003; Gartner, 1999).

Research Implications

This study investigates an unsuccessful experience in implementing KM within a particular organization. Through document analysis and in-depth interviews, the study provides an understanding of KM complexity—a blend of the KM elements and focuses (knowledge categorization, KM enablers, KM framework and KM strategies) that have been addressed separately by multi-disciplinary researchers. The results indicate that each element contributes to KM success or failure, and therefore should be harnessed in an integrative manner. In this regard, future researchers should expand this study to more organizations, industries and KM initiative maturity to identify variations in the KM elements and their interrelationships in influencing organizational performance.

The results also show that a good and sound KM plan is only the beginning of a KM program, while the vital task for management is that of coordinating people and processes for effective implementation. It indicates that the human factor, with employees' perception, motivation and participation towards KM work, is crucial to driving the KM process. In view of the advancement of IT and the expansion of business across different geographical territories, it is deemed appropriate to accommodate different research disciplines to foster KM discourse. Possible lines of inquiry (based upon the information systems field) can be directed to an investigation of knowledge workers in the adoption and deployment of KM systems: How should interdepartmental systems balance between customization and standardization to maintain accuracy and consistency of knowledge and expertise?

Management Implications

In the case of HS, we argue that planning permeated with unrealistic expectation would undermine its efficacy to direct future actions. Therefore, it is suggested that a feasibility assessment of organizational infrastructures (e.g., financial resources, technology level) and organizational climate (e.g., employees' readiness to KM, resistance to change) should first be conducted to define the KM principles and goals. Inspirational aims, which can be reasonably and feasibly accomplished, encourage employees to assess their personal repositories and infuse others' practices to improve existing practices and overcome new challenges.

In addition, employees from HS revealed that vision without management support is in vain and temporary. Therefore, beyond the visionary leadership, management should not downplay its willingness to invest time, energy and resources to promote KM. At its core, management could show its enthusiasm in a boundless and persistent way, including vocal support, speech, inaugural memo and wandering around different business units to invite impulsive idea generation and knowledge creation from all staff levels. Also, management should champion the KM process and lead by example those employees who engage a high receptive attitude towards KM. Furthermore, to stimulate KM behaviors, specifically sharing and creation, it is important to assure a balanced reward system integrating monetary (e.g., bonus) and non-monetary items (e.g., acknowledge excellent performer in creating new work and thoughts through organizational newsletter) that fit in various kinds of motivation.

Last, it is deemed that KM requires continual, collective and cooperative efforts to put various resources together in deployment. It is suggested that management direct an attitudinal change — remove or alleviate employees' negative perception towards KM. For example, the fear and misconception that KM is a means to downsize organizations; or as a heavy workload that requires lots of IT expertise; and behavioral change — requires a supportive working environment where employees can have ample of time to engage in KM endeavor, sharing and creation, a fair and positive culture that everyone is valued and possible to contribute to KM effectiveness is needed. We also advise, in case of unexpected failure or unintended results, that management should address problems positively, such as calling for a break to identify the causes and remedy solutions. Do not quit or look for someone to blame, otherwise mutual trust and commitment for the KM processes will end.

CONCLUSION

To date, KM is considered an integral part of the business agenda. The dynamics of KM, as human-oriented (Brazelton & Gorry 2003; Hansen et al., 1999) and socially constructed processes (Brown & Duguid, 2001), require an appropriate deployment of people, processes and organizational infrastructure. This failure case reflects the challenges that could be encountered and overcome in order to accomplish effective KM implementation. The people factor is recognized as the key to driving KM from initiation to full implementation. KM is a collective and cooperative effort that requires most, if not all, employees in the organization to support it. KM strategy and planning should be organized, relevant and feasible within the organizational context. One's best practice may not be well fitted to others unless evaluation and modifications are made. A balanced hybrid of hard and soft infrastructure (such as team harmony and organizational culture) is needed for success.

This study has the following limitations. First, the current study is based on a single organization from which results may not be generalized to all other situations. Therefore, more organizations with KM initiatives need to be researched to identify the extent and significance of various KM elements. Second, though analysis checklists and iterative rounds of discussions for analyzing the organizational documents are used, there is a possibility of the investigators' subjective judgment being involved during the evaluation. In this sense, future work may involve additional assistants to validate data interpretation.

Section 5
Organizational and Social Implications of Knowledge Management

This section includes a wide range of research pertaining to the social and organizational impact of knowledge management technologies around the world. Introductory chapters provide a comprehensive introduction of the modern-day knowledge organization while further research explores the difference in the community approach versus the process approach to knowledge management within two cultural paradigms. Also investigating a concern within the field of knowledge management is research which provides a study of the varying challenges when implementing knowledge management systems. The discussions presented in this section offer research into the integration of technology to allow access for all.

Chapter 5.1
Knowledge Organizations

Clyde W. Holsapple
University of Kentucky, USA

INTRODUCTION

An important endeavor within the field of knowledge management (KM) is to better understand the nature of knowledge organizations. These are variously called knowledge-based organizations, knowledge-centric organizations, knowledge-intensive organizations, knowledge-oriented organizations, and so forth. One approach to doing so is to study the characteristics of specific organizations of this type such as Chaparral Steel (Leonard-Barton, 1995), Buckman Labs, World Bank, or HP Consulting (O'Dell, 2003). A complementary approach is to study various frameworks that have been advanced for systematically characterizing the elements, processes, and relationships that are found in knowledge organizations. Here, we examine three such frameworks that are representative of the variety in perspectives that have been advocated for understanding the nature of knowledge organizations. These frameworks share a view that sees knowledge as a key organizational asset that enables action. However, they differ in emphases (e.g., asset vs. action) and constructs.

This article is organized as a systematic review of the three frameworks. The content relies heavily on the original presentations found in the referenced publications. Space limitations do not permit a comparative analysis or synthesis of the frameworks. Nevertheless, taken together, the reviews do offer valuable vantage points for studying knowledge organizations and useful departure points for more detailed consideration of these as well as other frameworks concerned with knowledge organizations.

The Intangible Assets Framework of Knowledge Organizations, as developed by Karl Sveiby (1997), is considered first. It relies on the concept of intangible assets and characterizes companies for whom these assets are important. Second, the Knowledge Management Cycle Framework introduced by Wiig, de Hoog, and van der Spek (1997) emphasizes the cyclical nature and means of managing an organization's knowledge assets. Third, the Knowledge Flow Framework advanced by Newman (2003) emphasizes flows of knowledge assets in the sense of agents performing transformations on knowledge-bearing artifacts.

Each framework description starts with a brief overview of the framework from the perspective of its creator(s). It continues by describing and defining the elements, processes, and relationships of the framework in encyclopedic format. Additional references to related works by other authors also are provided for readers who wish to further explore the framework's perspective. Where pictorial renditions of a framework are available, they are reproduced to visually tie together the concepts.

BACKGROUND

Frameworks are cognitive structures used to organize our thinking about a particular domain of interest. They give us concepts pertaining to the domain and guidance about relationships among those concepts, thereby forming a basic understanding of what is observed in a domain, for formulating new ideas about a domain, and for operating or managing in a domain. As such, KM frameworks are useful to academicians in framing research and building theory, to practitioners in learning about and executing KM, and to educators for organizing and presenting KM. Here, the KM domain of interest involves knowledge organizations.

The notion of organizations that explicitly recognize and cultivate knowledge as a key resource began to gain prominence in the 1980s (Holsapple & Whinston, 1987; Paradice & Courtney, 1989). It was seen as being on a par with the traditional organizational resources of people, materials, and finances. Knowledge was seen as pervading all functional areas of organizational management from strategy to operations, from human resources to technological systems, from economics and accounting to finance and marketing. The processing of an organization's knowledge resources was seen as an important (or even indispensable) aspect of nearly all organizational work. A confluence of forces led to the widespread rise of knowledge organizations in the 1990s, and the accompanying interest in more fully understanding these organizations and their possibilities (Bennet & Bennet, 2003).

Growing out of this interest, various frameworks of the knowledge organization have been advanced by researchers and practitioners. Although we do not exhaustively survey them here, we do review three that represent a diversity of views about an organization's knowledge assets and its use of those assets. Thus, the article serves as an introduction to the realm of knowledge organization frameworks and a foundation for review, comparison, and contrast of perspectives on organizational knowledge assets and their utilization.

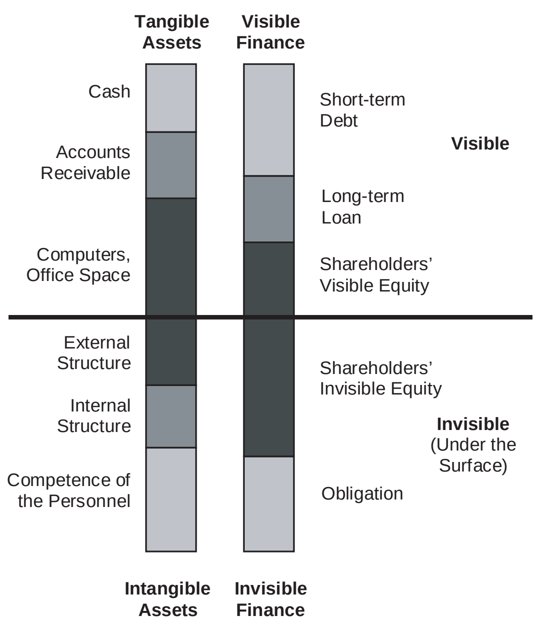
AN INTANGIBLE ASSETS FRAMEWORK OF KNOWLEDGE ORGANIZATIONS

Within the intangible assets (IA) framework, people are the only true agents in business. All assets and structures, whether tangible or intangible, are seen as being the result of human actions. The intangible assets of an organization are those embedded in the competences of its human resources and in its internal and external structures of interactions among these people. Knowledge organizations are those for which the greatest value lies in intangible assets (Sveiby, 1997).

Knowledge and Intangible Assets

The IA framework regards knowledge as being the capacity to take action. It is seen as tacit, action-oriented, supported by rules, and constantly changing (Sveiby, 1997). These assets are invisible in the sense that there is typically no accounting for them. They are intangible in that they are neither brick, nor mortar, nor money. They are comprised of two components: the competences of the organization's personnel and the organizational structures (internal and external) that allow them to interact (Sveiby, 1997). The IA framework does not regard structures as objects, but rather as being constructed in a constant process by people interacting with each other (Weick, 1995). They are not statically visible, but are events that link together. Knowledge management, based on the IA view, is "the art of creating value from intangible assets" (Sveiby, 1997, p. 1).

Figure 1. The balance sheet of a knowledge (Sveiby, 1997)



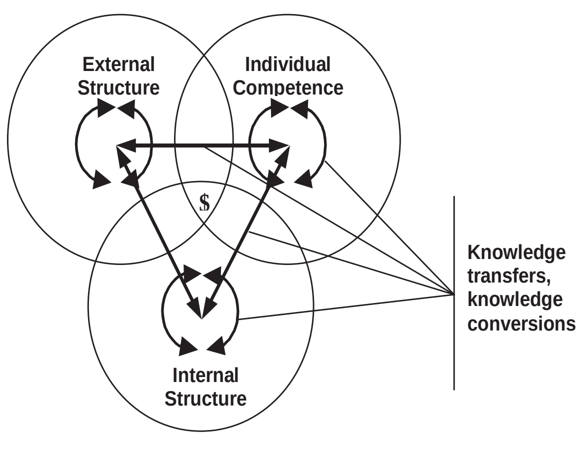
Knowledge Organizations

The IA framework conceives of knowledge organizations as having relatively few tangible assets, and having intangible assets that exceed tangible assets in value. In Figure 1, the dark line separates the visible and tangible from the invisible and intangible. The professional services or business services sector is a close equivalent of knowledge organizations (e.g., DeTore & Balliet-Milholland, 2003). Most employees of these companies are highly qualified and highly educated professionals, that is, they are knowledge workers. Their work consists largely of using their own competencies to produce or transfer knowledge, sometimes with the assistance of suppliers of information or specialized knowledge (Sveiby, 1997).

As indicated in Figure 2, the IA focus in a knowledge organization is on the key concepts of employee competence, internal structure, and external structure. They are defined as follows:

- Individual competence: Employee competence involves the capacity to act in a wide variety of situations to create both tangible

Figure 2. The organization from a knowledge-based organization perspective (Sveiby, 2001)



and intangible assets. Individual competence is comprised of five interdependent elements: (1) explicit knowledge, (2) skill, (3) experience, (4) value judgments, and (5) social network (Sveiby, 1997).

- Internal structure: Internal structure includes patents, concepts, models, and computer and administrative systems. These are created by the employees and are generally owned by the organization. However, they may be acquired elsewhere. In addition, organizational culture is part of the internal structure, as are management, legal structure, manual systems, attitudes, and R&D software (Sveiby, 1997).
- External structure: External structure includes relationships with customers and suppliers. It also encompasses brand names, trademarks, and the company's reputation or image. In the IA framework, to manage the external structure is to manage the flows of knowledge in customer and supplier relationships (Sveiby, 1997).

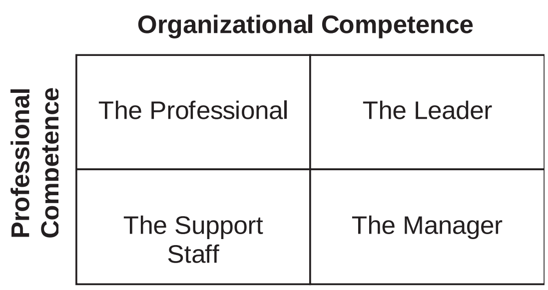
Value is created through knowledge transfers and conversions between and within these three elements. A knowledge organization would not exist if not for their personnel with competences in handling knowledge assets, internal structure that allows them to collaborate, and external structure that allow customers and suppliers to support and enhance their knowledge bases. For a knowledge organization, external structures are based not so much on financial flows as on knowledge flows involving intangible assets.

Personnel Categories in Knowledge Organizations

The IA framework categorizes personnel within a knowledge organization along two dimensions according to levels of professional and organizational competence. This yields the four categories shown in Figure 3, which are defined as follows (Sveiby, 1997, pp. 57-60):

- Support staff: "The support staff assists both the professionals and the managers. They have no special qualifications of their own to give them status in a knowledge organization."
- Professionals: "The most highly skilled professionals—the experts—are the genuine income generators. Experts are characterized by a dedication to their jobs and their professions, a love of solving problems, and a dislike of routine."
- Managers: "Managers are in many ways the opposite of professionals. They are capable of managing and organizing, have learned to work through other people, and enjoy doing so."
- Leaders: Leaders are the people whom others want to follow. They are informally "appointed" by their followers. "Leadership involves two tasks: deciding where the organization should go and persuading others to follow. The most successful leaders of knowledge organizations are usually former experts, but they are rarely the most outstanding experts."

Figure 3. Four personnel categories in knowledge organizations (Sveiby, 1997)



Ensuring suitable quantities, degrees of competence, and interaction structures for these four personnel categories, as well as the appropriateness of the mix among the categories, strongly influence a knowledge organization's performance and viability over time.

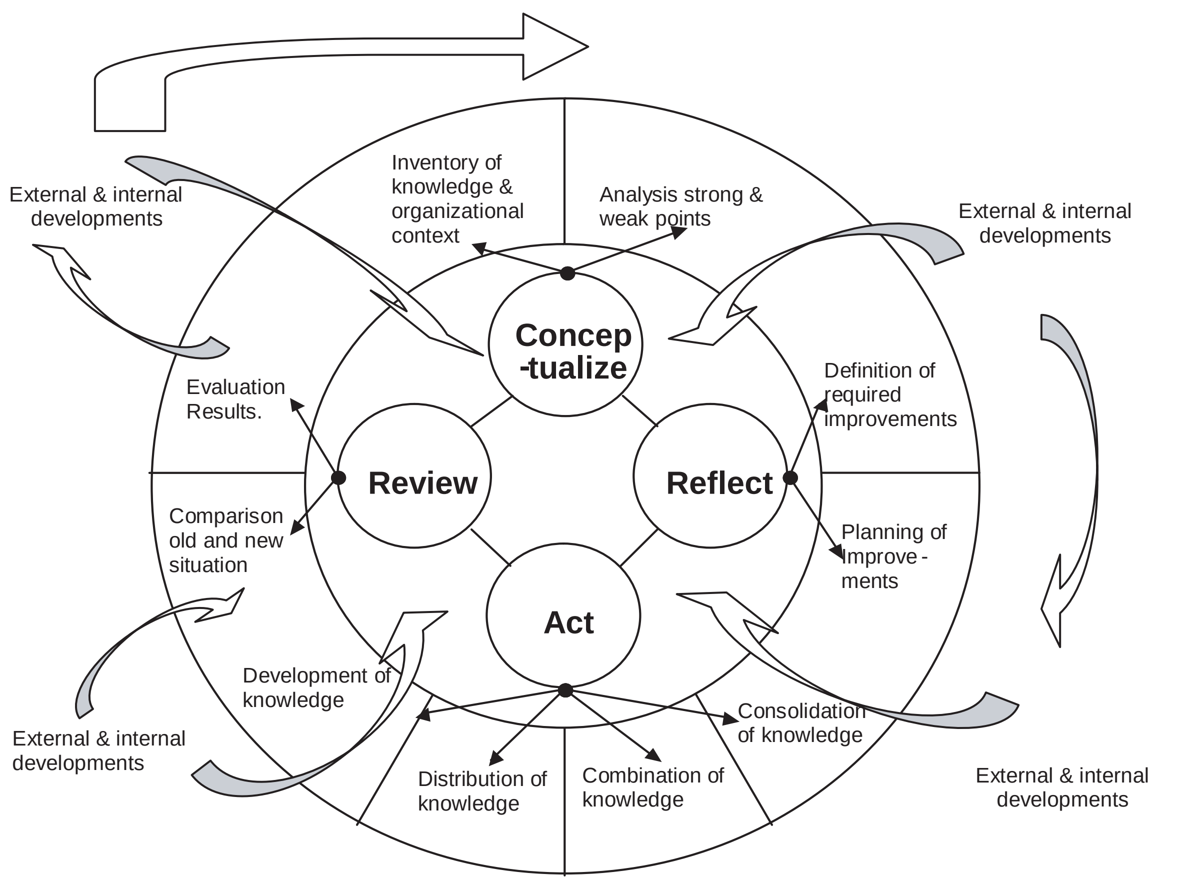
Further Reading

More information on this Intangible Assets Framework of Knowledge Organizations can be found at www.sveiby.com and Sveiby (2001). Related perspectives on the knowledge organization that emphasize intangible assets are found in Stewart (1997), Davenport and Prusak (1998), and Teece (2003).

A KNOWLEDGE MANAGEMENT CYCLE FRAMEWORK

Whereas the IA framework focuses on intangible knowledge assets in people and structures, the Knowledge Management Cycle Framework emphasizes the use of knowledge assets. A knowledge organization is viewed as manifesting a cyclic process of four activities: review, conceptualize, reflect, and act. During the cycle, analysis, plans,

Figure 4. The knowledge management cycle (Wiig, de Hoog, & van der Spek, 1997)



and actions are formulated in terms of four basic operations on knowledge that can be executed in organizations: development, distribution, consolidation, and combination.

Basic Concepts

The Knowledge Management Cycle Framework, illustrated in Figure 4, provides a model for how a knowledge organization's knowledge assets are used. Observe that the cycle proceeds in a clockwise fashion and that it can be impacted by both external and internal influences. The frameworks' specific definitions of terms are given in Figure 4 (Wiig, de Hoog, & van der Spek, 1997).

- Review: In this phase, a knowledge organization monitors and evaluates its performance. Review involves comparing old situations with the new, and evaluating the results of improvement plans relative to original goals and objectives.
- Conceptualize: This part of the cycle involves selecting a knowledge resource in the organization, and analyzing its strong and weak points. This analysis includes developing an understanding of the ways in which knowledge assets are bound to organizational roles participating in business processes.
- Reflect: Reflection is concerned with defining and deciding on knowledge management improvement plans. It includes developing the "optimal" plans for correcting knowledge bottlenecks and analyzing them for risks that accompany their implementation.
- Act: The final phase of the cycle implements plans chosen in the reflect phase. According to the framework, actions entail four basic operations on knowledge assets: development, distribution, consolidation, and combination (Wiig, de Hoog, & van der Spek, 1997).
- Development: Development of knowledge assets is said to occur through purchase, learning programs, and machine-based learning from databases.
- Distribution: Distribution is delivering knowledge assets to the points of action through knowledge-based systems, manuals, and network connections.
- Consolidation: This operation is described as taking steps to prevent an organization's knowledge assets from disappearing. It includes the knowledge-based systems, tutoring programs, and knowledge transfer programs.
- Combination: In this framework, combination refers to finding synergies among and reusing existing knowledge assets.

Within any iteration of the knowledge cycle, the organization takes action based on its knowledge assets. It is through knowledge cycle iterations that an organization's knowledge asset base is enhanced, thereby improving performance and viability of the knowledge organization.

Further Reading

More information about this Knowledge Management Cycle Framework can be found in van der Spek and de Hoog (1995), de Hoog et al. (1999), and van der Spek and Spijkervet (1995). In a related vein, a seven-phase knowledge life cycle has been advanced by APQC and Arthur Anderson: share, create, identify, collect, adapt, organize, apply (O'Dell & Grayson, 1997). Moreover, one portion of the KM ontology deals with specific kinds of manipulations that a knowledge organization can perform on knowledge resources in the context of KM episodes rather than KM cycles (Holsapple & Joshi, 2004).

A KNOWLEDGE FLOW FRAMEWORK

The Knowledge Flow Framework advanced by Newman presents "the foundations for a basic understanding of knowledge flows, agents, artifacts, and transformations critical to any examination of knowledge processing. In doing so, it attempts to bridge the gap between a conceptual understanding of how knowledge contributes to corporate objectives, and the practical issues of knowledge management and knowledge engineering" (Newman, 2003, p. 301). As such, it furnishes a unifying vision for some of the concepts provided by the other two frameworks. This framework focuses on enablers for organizational process tasks, rather than concentrating on knowledge assets or on sequences of knowledge utilization phases. It serves as a basis for analyzing knowledge flows that permeate a knowledge organization.

Knowledge Flows

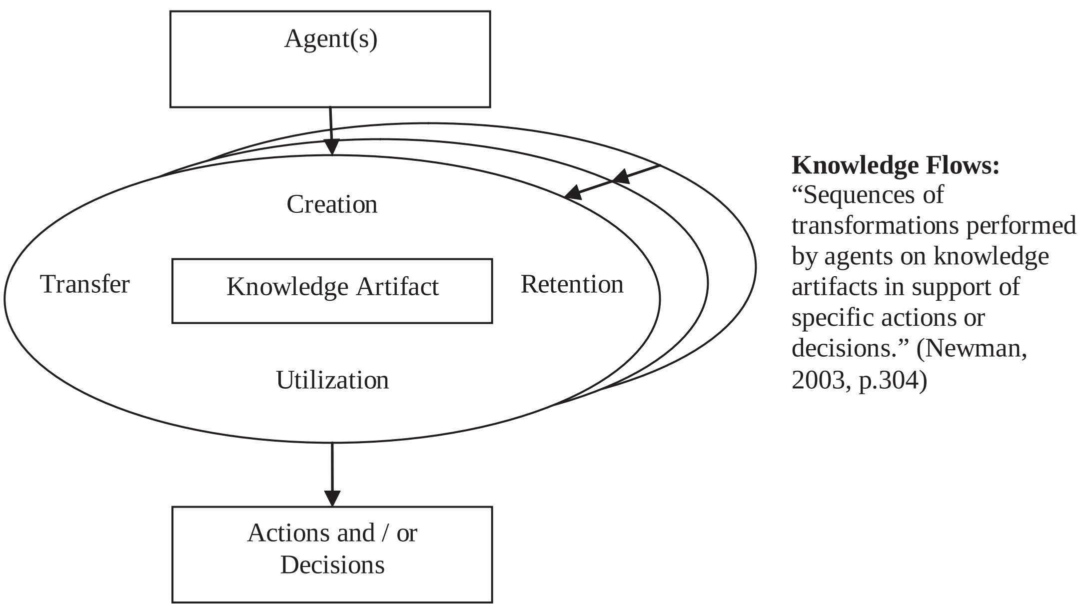
Knowledge flows are "sequences of transformations performed by agents on knowledge artifacts in support of specific actions or decisions" (Newman, 2003, p. 304). As depicted in Figure 5, these include knowledge creation, retention, transfer, and utilization flows.

Agents

Agents are specialized objects or roles played by people, organizations, societies, automata, and so forth. They are the knowledge processors within a knowledge organization and are the active components in knowledge flows (Newman, 2003):

- Individual agents: The framework defines these as being human processors. They sit at the center of every knowledge flow and

Figure 5. Knowledge flows



can deal with tacit artifacts that automated agents cannot.

- Automated agents: Automated agents are non-human processors. They are "any human construct that is capable of retaining, transferring, or transforming knowledge artifacts. They are not exclusively computers, e.g. a camera.…They can perform many types of transformations on explicit artifacts much faster and with a greater degree of repeatability than can individual agents" (Newman, 2003, pp. 308-309).
- Collective agents: Newman (2003) defines these as specific collection of individual and automated agents. They are not necessarily homogeneous and may exhibit characteristics unexhibitable by any single agent. They may possess "group"-level tacit knowledge and may retain knowledge beyond the life of any individual or automated agent.

Knowledge Artifacts

In this framework, knowledge artifacts are "documents, memories, norms, values, and other things that represent the inputs to, and outputs of, the knowledge-enabled activities of agents" (Newman, 2003, p. 303). Essentially, this framework uses the term "artifact" to refer to a representation that is usable for one or more agents in their knowledge work. This notion is consistent with Newell's (1982) conception of knowledge as that which is conveyed by representations that are usable to some processor (i.e., that give that processor the ability to take action).

The phrase "knowledge artifact" refers simultaneously to two kinds of representation: cognitive knowledge artifacts and physical knowledge artifacts. The former deal with mental and behavioral representations. The latter are more concerned with symbolic, audio, video, and digital representations.

- Cognitive knowledge artifact: This refers to awareness and understanding of a particular aspect of our real or metaphysical world. It is commonly referred to simply as knowledge (Newman, 2003).
- Physical knowledge artifact: This is a "representation of the associated cognitive knowledge artifact" (Newman, 2003, p. 305).

Along another dimension, the Knowledge Flow Framework partitions knowledge artifacts into three classes, depending on the extent to which the representation is capable of codification and transfer among agents:

- Explicit knowledge artifacts: These have been codified in a way that makes it possible to touch, see, hear, feel, and/or manipulate them. They can be readily transferred from one person to another (Newman, 2003).
- Implicit knowledge artifacts: These are artifacts whose meanings are not explicitly captured, but can be inferred (Newman, 2003).
- Tacit knowledge artifacts: These defy expression and codification. They may be more prevalent and influential than either explicit or implicit artifacts (Newman, 2003).

TRANSFORMATIONS

Transformations are the behaviors that agents perform on artifacts. The Knowledge Flow Framework organizes transformations into four general categories: knowledge creation, knowledge retention, knowledge transfer, and knowledge utilitzation. Newman (2003) defines them as follows:

- Knowledge creation: In this framework, "creation" refers to all behaviors through which new knowledge enters a knowledge-based system. It can occur internally through knowledge generation or from external sources via acquisition. It includes such activities as knowledge development, discovery, capture, and elicitation.

- Knowledge retention: This refers to an organization's storage, maintenance, and retrieval of previously created knowledge.
- Knowledge transfer: This kind of transformation refers to all behaviors through which agents share knowledge and knowledge artifacts. Knowledge transfer includes, but is not limited to, communication, translation, conversion, filtering, and rendering.
- Knowledge utilization: Finally, there are transformations in which agents use knowledge to further the goals and aims of the organization. All such behaviors are directly concerned with applying knowledge to enable decisions and actions. A "knowledge utilization event" is a specific decision or action enabled by the knowledge flow.

FURTHER READING

More information about the Knowledge Flow Framework can be found in Newman (1996, 2000). This framework's constructs are largely consistent with the KM ontology (Holsapple & Joshi, 2004). For instance, a knowledge utilization event is what the KM ontology recognizes as a particular kind of KM episode, knowledge artifacts are knowledge representations in KM ontology parlance, agents are what the KM ontology calls knowledge processors, and transformations map into the KM ontology's knowledge manipulations.

FUTURE TRENDS

Future efforts at better understanding knowledge organizations will proceed at both micro and macro levels. At the micro level, researchers will study the nature of knowledge work done by an organization's agents (Schultze, 2003). At the macro level, efforts will continue in the direction of devising increasingly complete and unified frameworks for characterizing knowledge organizations. It is likely that some of these efforts will integrate notions of knowledge assets, knowledge processing cycles, and knowledge flows with concepts from business process management (Smith & Fingar, 2002) and social networking (Brass, 1992).

In a prescriptive vein, frameworks of the knowledge organization will be applied to devise specific strategies or prescriptions for how knowledge organizations can enhance performance (Sveiby, 2001). Normative frameworks of knowledge organizations will be devised suggesting what the nature of these organizations should be, rather than describing what is or has been. For instance, knowledge organizations will be seen as intelligent complex adaptive systems (Bennet & Bennet, 2004) and as value networks (Allee, 2003)

CONCLUSION

The frameworks presented here are sampling of efforts made to describe elements and relationships that exist in knowledge organizations. The coverage is more suggestive than exhaustive. Frameworks of knowledge organizations will continue to appear and evolve, symptomatic of the rich and varied nature of these organizations. At some point the diverse frameworks may converge. However, for the present, creative tension still exists in the differing perspectives and, as Sveiby says so eloquently, (Lelic, 2002, p. 1):

The conceptual framework of knowledge management is unusual in its ambiguity, extraordinary in its depth, unfathomable in its rapid expansion, *and—best of all—has no single trademark or copyright owner.*

The frameworks represent a spectrum of current points of view about the nature knowledge organizations and are useful to those pursuing the study and execution of knowledge management. The diversity presented gives even the experienced knowledge manager or academician reason to pause and consider varying perspectives on this topic. For the novice, it presents an approachable and important introduction to the domain of knowledge organizations.

Chapter 5.2
Intellectual Capital

INTRODUCTION

Today's economy is characterized by a rapid rate of change, globalization, and knowledge-intensive products. This makes knowledge management (KM) vital to organizations. The resource-based view of the firm postulates that a firm's profitability is not only a function of its market and competitive position but also a function of its internal capabilities and know-how in combining its resources to deliver products and services and to enhance organizational performance (Alavi, 2000).

The goal of an effective KM strategy should be to enhance the creation, transfer, and utilization of all types of organizational knowledge (Alavi, 2000). Corporations not only realize that knowledge is the critical resource but also try to manage organizational knowledge more intensely and effectively. For example, Stewart (1997) defined intellectual capital (IC) as the intellectual material—knowledge, information, intellectual property, and experience—that can be put to use for creating wealth.

Several researchers (Bontis, 1996, 2001, 2002a, 2002b; Van Buren, 1999; Mykytyn, Bordoloi, Mckinney, & Bandyopadhyay, 2002; Pike, Rylander, & Roos, 2002) identified the importance of intellectual capital (IC) with Bontis (2002a) indicating that human capital is a major component of IC. Human capital, as well as other components of IC (e.g., innovation capital) is an integral part of knowledge in KM research (Bontis, 2001, 2002a, 2002b; Van Buren, 1999; Pike et al., 2002).

Finally, it does the organization little good if effective KM does not lead to success. This success can be defined as how well an organization engages in KM to innovate and reduce uncertainty. Ultimately, an organization should hope to achieve a competitive advantage.

While there is no clear division between KM and IC, there is an intuitive link between them. Numerous researchers have investigated knowledge components, KM issues, and success achievement in organizations. However, none has included IC components into an integrated research framework. This article presents such a framework.

BACKGROUND

According to Barney (2002), firm resources are "all assets, capabilities, competencies, organizational processes, firm attributes, information, and knowledge that are controlled by a firm" (p. 155). These resources enable the firm to implement strategies that increase its effectiveness and efficiency. Most importantly, the resource-based view of the firm focuses the idiosyncratic, costly to duplicate resources that may give the firm a competitive advantage, such as highly skilled and creative workers, effective managers, and institutional leaders. Barney (2002) further defines these too-costly-to-copy resources as "resource immobility."

Dierickx and Cool (1989) point out that firm resources can be divided into tradable (i.e., unskilled labor, raw materials, and common intellectual property) and nontradable (i.e., firm-specific skills/capabilities, quality reputations, partners royalty, R&D capability, brand loyalty, and customer trust). Whereas tradable resources are mobile and can be acquired easily, the nontradable resources are immobile and must be developed, accumulated, and maintained through time (Hunt, 2000).

"Immobility" in this article differs slightly from Barney's definition. The argument is established by the "how" and "what" to produce those too-costly-to-copy resources. For example, a top management of Toyota can move to Ford but cannot perform at the same scale as in Toyota because of different organizational capabilities, structures, dynamics, processes, and culture. The immobile resources are those that cannot be physically moved from one firm to the others regardless of whether they are copied or stolen. This article attempts to distinguish between mobile and immobile assets, and perhaps establish the argument on increasing the value of mobile assets by the facilitation of immobile assets.

In the spirit of Barney (1991, 1997, 2002), a firm's resources were defined as "capitals." As such, the firm's resources can be divided into financial capital, physical capital, human capital, and organizational capital (Barney, 1991, 1997, 2002). Financial capital includes all money resources. Physical capital is physical technology in a firm. Human capital refers to the training, experience, judgment, intelligence, relationships, and insight of individuals. Organizational capital includes a firm's formal reporting structure; formal and informal planning, controlling, and coordinating systems; its culture and reputation, and its informal relations among groups within firm, between firms and those in its environment (Barney, 2002, p. 156).

Bontis (2002a) defined similar concepts, referring to them as human capital, structure capital, and customer capital. Van Buren (1999), however, replaces Stewart's "structure capital" with two new measures: innovation capital and process capital. Innovation capital is the capability of an organization to innovate and to create new products and services, and process capital represents an organization's processes, techniques, systems, and tools.

Among three definitions of IC, Stewart (1997), Van Buren (1999), and Bontis (2002) all include human capital. Customer capital is the relationship between firms and their customers. Pike et al. (2002) referred to customer capital as relational capital; however, customer capital and relational capital are defined similarly. Structure/process capital by Bontis (2002), innovation/process capital by Van Buren (1999), or organizational capital by Pike et al. (2002) are the most controversial components of IC. Those definitions are titled differently, but they are overlapped in terms of the categories of IC.

Quite controversially, the evaluation of IC also inherits split directions. One direction includes accounting cost base and financial value base. The conventional accounting-based evaluation adjusts its traditional instruments, such as historical transactions, and balanced scorecards (Norton & Kaplan, 1996). These accounting indices were criticized as "lagging measures" (Pike et al., 2002) because they are "cost-based." Acting as a supplemental evaluation to cost-based calculation, the financial value-based approach utilizes net present value to estimate a company's IC with a market value. However, it still demonstrates problems of homogeneity, nonfinancial benefits, and forecasting (Lewis & Lippitt, 1999).

Tobin's q gains its prevalence as an indicator of a firm's intangible value (Hall, 1993; Megna & Klock, 1993). It is a ratio of the capital market value of a firm to its replacement value of its assets. These assets incorporate a market measure of a firm value that is forward-looking, risk-adjusted, and less susceptible to changes in accounting practice (Montgomery & Wernerfelt, 1988). Tobin's q can be as high as 7.00 where intellectual capital is resourceful, such as software industry, whereas q is as low as 1.00 where firms have large capital assets (i.e., steel industry) (Bontis, 2002b).

Other than accounting and financial evaluations, a business-based model is assessed by relative effectiveness of different approaches. Four criteria were established by KnowNet Group (EU/ESPRIT, 2000): (1) it is auditable and reliable; (2) it does not impose a large overhead; (3) it facilitates strategic and tactical management; and (4) it generates the information needed by stakeholders in a firm. Incorporating those criteria of a business-based model into Gold's process capabilities becomes our conceptual model.

Knowledge content can be mobile, which is a characteristic of human capital and innovation capital. KM processes and structures can be immobile, and that is structure capital and KM processes capabilities. This article takes an inward look at an organization's KM processes capabilities that specifically include IC. Of particular interest is a firm's effectiveness captured from mobile and immobile assets, that is, IC, through KM processes capabilities and structure capital.

KM Processes Capabilities

In addition to knowledge capital, integral to KM are processes associated with KM, referred to by Gold, Malhotra, and Segars (2001) as organizational capabilities. Gold et al. (2001) studied KM in an organizational capability perspective, and knowledge processes are perceived as an enabler of the organization to capture, reconcile, and transfer knowledge in an efficient manner. Knowledge processes are acquisition-oriented, conversion-oriented, application-oriented, and security-oriented.

Their descriptions of processes are as follows: (1) The acquisition process includes accumulating knowledge, seeking brand new knowledge, and creating new knowledge out of existing knowledge; (2) the conversion process detects the ability to make knowledge useful; (3) the application process offers effective storage and retrieval mechanisms and enables the organization to quickly access the knowledge depository; (4) the protection process is designed to protect the knowledge within an organization from illegal or inappropriate use or theft.

Intellectual Capital (IC)

- Human Capital: Bontis (2001) defined human capital as the combination of knowledge, skill, innovativeness, and ability of a company's individual employees to meet the task. Based on Nonoka (2002), knowledge is created and organized by the very flow of information, anchored on the commitment and beliefs of its holder. Human capital refers to the tacit knowledge embedded in the minds of employees. Ulrich (1998) proposed a measurable definition of human capital which is the product of "competence" and "commitment."

Competence is defined with two aspects: (1) competencies must align with business strategy; (2) competencies need to be generated through more than one mechanism, such as buy, build, borrow, bounce, and bind (Ulrich, 1998). Commitment reflects in how employees relate to each other and feel about a firm (Ulrich, 1998). To foster commitment, Ulrich (1998) indicated three ways: (1) reduce demands, (2) increase resources, and (3) turn demands into resources.

- Structural Capital: Bontis (2002a) defined structure capital as the organizational routines and processes that contain the nonhuman storehouses of knowledge. Two components are included in structural capital: a technological component and architectural competencies (Bontis, 2002a). The technological component can be defined as the local abilities and knowledge that are important to day-to-day operation, such as tacit knowledge, proprietary design rules, and unique modes of working together (Bontis, 2002a). The architectural competencies refer to the ability of the firm to integrate its component competencies together in new and flexible ways and to develop new competencies as they are required, for example, communication channels, information filters, and problem-solving strategies that develop between groups, control systems, cultural values, and idiosyncratic search routines (Bontis, 2002a).
- Innovation Capital: Innovation capital stands out from all other IC research in that it separates structure/process capital from the companies' capabilities to innovate (Van Buren, 1999). A successful innovation occurs in a cycle, according to Clark (1961). It is developed, profitably utilized, and ultimately loses its value as a source of "rents." An innovation loses its value to produce rents when it is replaced by a latter invention or when it is diffused among rivals. In this article, both objective and subjective measures are accounted for in the intellectual property construct. The objective measure is aligned with Aylen's (2001) audit system of intellectual property, and it includes counts of patents and R&D expenditures (Mykytyn et al., 2002).

The subjective measure includes three dimensions suggested by Teece (1998) for capturing value from intellectual property: (1) appropriability is a function both of the ease of replication and the efficacy of intellectual property rights as a barrier to imitation; (2) markets for know-how are the killer sources to entitle a competitive advantage for intellectual properties, however, they become financial assets when they are traded on the market for monetary rewards; (3) dynamic capabilities are the abilities to sense and to seize new opportunities, and to reconfigure and protect knowledge assets, competencies, and complementary assets and technologies to achieve sustainable competitive advantage.

MAIN FOCUS OF THE ARTICLE

Our article discusses these important KM components in an integrated fashion. The components are addressed below.

Knowledge Process Capabilities and Organizational Effectiveness

Combining or integrating organizational knowledge reduces redundancy, enhances consistency, and improves efficiency by eliminating excess information (Davenport & De Long, 1998). Gold et al. (2001) utilized organizational effectiveness to evaluate the value-added aspect of the organizational resources. Three concepts are used to evaluate organizational effectiveness: improved ability to innovate, improved coordination of efforts, and reduced redundancy of information/knowledge (Gold et al., 2001). Gold et al.'s (2001) results suggested that knowledge infrastructure along with knowledge processes are essential organizational capabilities for effectiveness. Knowledge infrastructure consists of culture, structure, and technology that can be explained by structure capital (Bontis, 2002a, 2002b).

The Mediation of Knowledge Process Capabilities

- Human Capital and Organizational Effectiveness: As the service economy grows, the importance of human capital increases (Ulrich, 1998). An experienced, intelligent workforce can marshal the knowledge needed for an information/service economy. Based on research by Davenport and De Long (1998) involving 31 KM projects, it was found that a KM initiative demonstrated some commitment of human capital resources. Ulrich (1998), too, felt that human capital must include an individual's commitment in addition to competence.

An important element of knowledge creation is the focus on the active, subjective nature of knowledge represented by such terms as "belief" and "commitment" that are deeply rooted in the value systems of individuals (Nonaka, 2002). A human capital index created by Ulrich (1998) may predict other positive outcomes, such as customer loyalty, productivity, and profitability. Bontis (2002b) did not support the relationship between human capital and organizational effectiveness.

The KM processes capabilities are not only embedded in a KM system but also require knowledge workers' inputs and competencies to maneuver around the organizational routines, processes, and functionalities. Human capital is hypothesized to have a positive effect on organizational effectiveness as mediated by KM process capabilities.

- Innovation Capital and Organizational Effectiveness: The innovation-oriented approach focuses on explicit knowledge that will eventually facilitate organizational learning. The learned organization will then have better capabilities to innovate and compete. The explicit knowledge can be a database, intellectual property, business designs, business process techniques, or patterns. Technology held proprietary through patents, copyrights, or trade secrets can deter new entrants and achieve a competitive advantage by exploiting economies of scale and scope or through differentiation (Bharadwaj, Varadarajan, & Fahy, 1993). As a major component of innovation capital, intellectual property can be managed as explicit knowledge or act as repositories in a KM system or a database that can be retrieved and reused repeatedly.

The systematic structure of a KM system made intellectual property more accessible and usable. The emphasis on the development and exploitation of knowledge shifts attention from cost minimization to value maximization (Teece, 1998). Aylen (2001) suggested five steps to establish intellectual property capital: conduct an intellectual property audit, incubate new ideas, reduce the ideas to practical form, protect the idea, and exploit the idea. Aylen (2001) also recommended patent databases as a knowledge bank to track the costs and delay associated with the state of a particular product or process.

Besides intellectual property, research and development exspenditure are included in innovation capital that is further defined by appropriateness, markets for know-how, and dynamic capabilities (Teece, 1988). According to Lynn (1998), a significant component of initial management of intellectual assets at Dow Chemical has been its review of patent maintenance within R&D to create objective, major cost savings for the firm.

One famous e-commerce case involving a patent infringement action is Amazon.com vs. Barnesandnoble.com. This case is about Amazon's patented "1-click ordering system." In December 1999, Amazon won a preliminary injunction against Barnesandnoble.com prohibiting anyone else from employing the "1-click ordering system" (Mykytyn & Mykytyn, 2002). Now Amazon enjoys the increasing rent revenue by leasing the patent "1-click ordering system" to its competitors.

In another patent case involving a deeper understanding of patent application, VisorSoft's newly updated "face-recognition software" was copycatted (Maxwell, 2002) before it went on the market. This software is used in highly secured workplaces, such as airports and banks, that need an accurate identification. It can compare a stored face-print with a person's live image and determine if they were the same. The competitor's software operated exactly like VisorSoft's but was marketed differently. The "continuation patent" known as a "child patent" kept VisorSoft's patent infringement against the competitor, and its argument of being a different process as VisorSoft's was disapproved (Maxwell, 2002). VisorSoft can now recoup its development costs and realize licensing fee from users.

An innovative product goes through creation, conversion, and application processes to present it in the market. It also needs a thorough "protection" process to keep an innovation proprietary. Organizational effectiveness can be defined as a firm's attempts to control and reduce production and marketing costs (Dickson, 1992). Cost-cutting innovations are particularly attractive because their effects are more predictable than other innovations (Dickson, 1992). Innovation capital as evidenced by the accumulation of explicit knowledge is assumed to increase the organizational effectiveness with the facilitation of knowledge process capabilities.

The Mediation of Structure Capital

The essence of structure capital is the knowledge embedded within the routines of an organization (Bontis, 2002a). Also, Bontis' structure capital combined with Van Buren's (1999) process capital echoes knowledge infrastructure in Gold et al. (2001) that involves organizational structure, culture, and technology. Structure capital includes a technological component and architectural competencies (Bontis, 2002a).

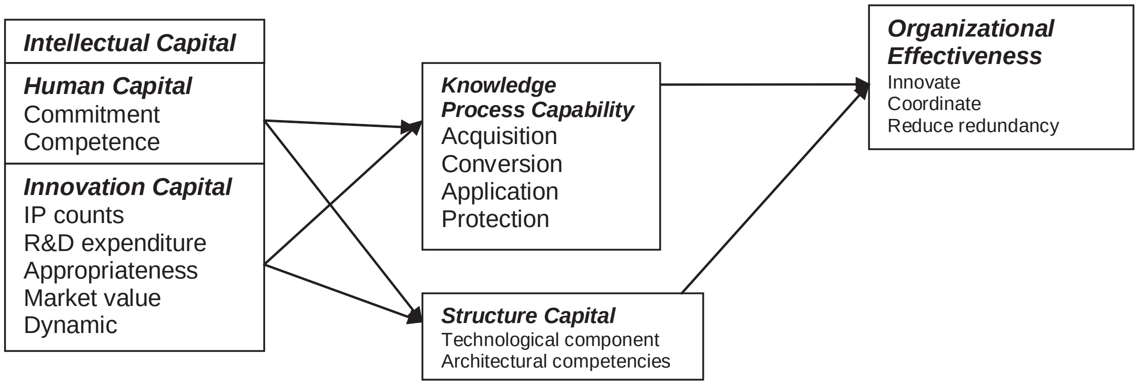
Bontis (2002b) found that human capital was not a significant path to a firm's performance, but that structure capital was. On the other hand, when structure capital was analyzed as a mediator, it facilitated human capital in relation to a firm's performance. It showed a valid path from human capital to structure capital, then to a firm's performance.

Bontis' (2002b) study established a relationship between human capital, structure capital, and a firm's performance in a student sample. This article further extends the rationale from structure capital to innovation capital, and attempts to offer some insights. The innovation capital is in response to the rapidly changing environment, and it leads to a constant learning environment for an organization. The constant learning processes are deeply rooted in formalization and routines of an organization, and, in turn, an organization becomes more innovative to compete.

FUTURE TRENDS

Breaking down these streams of ideas, this article tends to utilize four concepts to link to organizational effectiveness. Knowledge process capabilities and structure capital may be direct links to organizational effectiveness, or they may serve a mediating function between human/innovation capital and organizational effectiveness. The conceptual model underlying this article is shown in Figure 1.

Figure 1. Conceptual model



From the emergent research agenda, this article attempts to examine if there is a division or a link between IC and KM processes. If there is a division, this study attempts to examine the difference between IC and KM. If there is a link, what effect does one have on the other? This study intends to delineate the "mobile" and "immobile" parts of IC. Human and innovation capitals are content that belong to "mobile" category. On the other hand, KM process capabilities and structural capital are structure and/or process that are "immobile."

Alavi and Leidner (2001) drew some different perspectives on knowledge. They indicated knowledge could be data and information, state of mind, object, process, access to information, and capability. Different views of knowledge lead to different KM, and different knowledge management systems (KMS) are built upon different perceptions of KM. "The view of knowledge as capability suggests a knowledge management perspective centered on building core competencies, understanding the strategic advantage know-how, and creating intellectual capital" (Alavi & Leidner, 2001, p. 110). Most KM research focused on knowledge processes, organization structure, or technology utilization, but not knowledge content per se. On the other hand, IC researchers (Bontis, 1996, 2001, 2002a, 2002b; Van Buren, 1999; Pike et al., 2001) included KM in their studies, however, without a clear distinction from KM or definition of IC.

Finally, structure capital was incorporated to emphasize the importance of how to process knowledge, once it is defined. This study enhances the "understanding of know-how" with an organization's "state of mind" in creating intellectual capital. The organization structure becomes alive when information is actively processed in the minds of individuals through a process of reflection, enlightenment, or learning (Alavi & Leidner, 2001). Beyond organization structure, structure capital refers to the "immobile" organization capability that is also hard to imitate.

Many IC researchers have classified many different categories and/or properties to define IC (Bontis, 1996, 2001, 2002a, 2002b; Van Buren, 1999; Pike et al., 2001; Roos, Roos, Dragonetti, & Edvinsson, 1997; Brooking, 1996). Pike et al. (2002) stated, "There has been a steady convergence" (p. 658) in categorizing an IC model. They concluded a convergent IC model that combined elements created value for an individual company. Those elements include: (1) human capital is represented as attributes of the people (i.e., skill, creativity); (2) organizational capital refers to company-owned items (i.e., systems, intellectual properties); (3) relational capital is external relations with customers, suppliers, and partners.

Focusing on internal resources and a resource-based view with an intention, this article demonstrates an inward examination to a firm. Too, as an extended "immobile" concept, this article attempts to investigate the unique "innovation" capital that may be a valid property ignored by most IC researchers but Van Buren (1999). The focus of IC here is organizational flexibility and immobility that may contribute to organizational process capabilities that comply to any emergent competition a firm may encounter in a marketplace.

Additions to this article are the areas of risk and uncertainty, leading edcoordination, and co-competition among increasing numbers of external members, that is, networks of firms, networks of supply chains, make relational capital unpredictable yet vulnerable.

CONCLUSION

This article attempts to delineate KM and IC and more clearly provide definitions that were neglected by either KM researchers or IC researchers. The integration of KM and IC is another goal for this article. Combining the resource-based view and the more recent concept of emergent KM processes, we anticipate introducing innovation capital that consists of intellectual property and other properties. Following Van Buren's (1999) innovation concept, this article focuses more on emergent KM processes rather than static knowledge conversion. Following Ulrich's (1998) human capital index, this article moves forward to more dynamic rather than static working relationships within the firm. Further, we attempt to establish Barney's (1991, 1997, 2002) concepts of "mobile" vs. "immobile" in both KM and IC environment. Finally, this article tries to fill the gaps between the KM and IC research and move forward to an integral explanation to those fields.

Chapter 5.3
Discovering Communities of Practice through Social Network Analysis

Cindi Smatt
Florida State University, USA

Molly McLure Wasko
Florida State University, USA

INTRODUCTION

The concept of a community of practice is emerging as an essential building block of the knowledge economy. Brown and Duguid (2001) argue that organizations should be conceptualized as consisting of autonomous communities whose interactions can foster innovation within an organization and accelerate the introduction of innovative ideas. The key to competitive advantage depends on a firm's ability to coordinate across autonomous communities of practice internally and leverage the knowledge that flows into these communities from network connections (Brown & Duguid, 2001). But how does an organization do this? A key challenge for management is understanding how to balance strategies that capture knowledge without killing it (Brown & Duguid, 2000).

BACKGROUND

Typically, top-down business processes aimed at leveraging knowledge flows end up stifling creativity by institutionalizing structures promoting rigidity. In order to understand knowledge flows, managers need to change their focus away from a process view of knowledge creation to a practice-based view. When individuals have a common practice, knowledge more readily flows horizontally across that practice, creating informal social networks to support knowledge exchange

(Brown & Duguid, 2001). Therefore, the key to understanding knowledge flows within organizations is to switch the conceptualization of work away from formal processes to that of emergent social networks.

Social network perspectives focus on the pattern of relationships that develop between members of a community of practice, suggesting that individuals and their actions are interdependent, rather than autonomous occurrences. In contrast to focusing on work tasks as the unit of analysis, a social network perspective of work focuses on how relational ties between individuals lead to outcomes, such as knowledge exchange and innovation. The ties that develop between community members are characterized by their content, direction, and relational strength, all of which influence the dynamics of individual interactions. The content of ties refers to the resource exchanged, such as information, money, advice, or kinship. The direction of ties indicates the giver of the resource and the receiver. The relational strength of ties pertains to the quality of the tie. For instance, the relational strength of ties indicates the amount of energy, emotional intensity, intimacy, commitment, and trust connecting the individuals.

When the resource being exchanged in the network is knowledge, prior research indicates value is derived from bridging "structural holes" or gaps (Burt, 1992). As a result, individuals who develop ties with disconnected communities of practice gain access to a broader array of ideas and opportunities than those who are restricted to a single community of practice. In addition, individuals who network with others from diverse demographic categories benefit because different people have different skills, information, and experience. Such ties bridge structural holes in the larger organization, and thereby enhance its capacity for creative action.

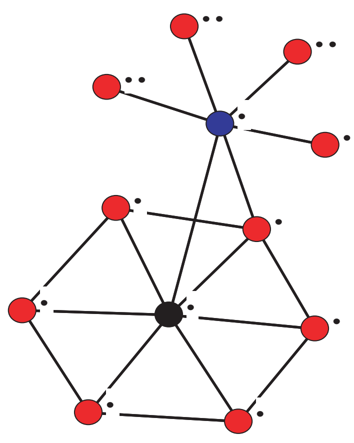
FUTURE TRENDS

Managers interested in understanding where the communities of practice are, and how these communities link to one another, could create a knowledge map of the organization using social network analysis. Social network analysis is a tool that can be used to depict the informal flows of knowledge both within and between communities of practice. By using social network analysis to examine the organization, managers are better able to understand what type of knowledge is being exchanged and the pattern of its exchange. This would facilitate not only the identification of barriers to knowledge exchange and areas of the organization that need better integration into the knowledge network, but would also indicate key personnel in the network through which knowledge is currently flowing.

A picture of a social network resulting from social network analysis is illustrated in Figure 1.

This knowledge map indicates two communities of practice that are bridged by individual 8.

Figure 1. Sample of a social network graph



Individual 1 is central to the network, yet if this individual left the organization, it would have relatively little effect on knowledge flows. Although this would increase the distance between certain individuals, knowledge flows among all individuals remain possible as there is no fragmentation.

CONCLUSION

Social network analysis should be considered an essential tool for mapping actual knowledge flows. In contrast to focusing on business processes to formalize knowledge flows, taking a social network perspective allows management to redesign knowledge flows by adjusting network structures. Using social network analysis techniques to discover communities of practice within the organization allows managers to influence knowledge flows without killing innovation.

Chapter 5.4
Social Network Analysis

David J. Dekker
Radboud University Nijmegen, The Netherlands

Paul H. J. Hendriks
Radboud University Nijmegen, The Netherlands

INTRODUCTION

In knowledge management (KM), one perspective is that knowledge resides in individuals who interact in groups. Concepts as communities-of-practice, knowledge networks, and "encultured knowledge" as the outcome of shared sense-making (Blackler, 1995) are built upon this perspective. Social network analysis focuses on the patterns of people's interactions. This adds to KM theory a dimension that considers the effects of social structure on for example, knowledge creation, retention and dissemination. This article provides a short overview of consequences of social network structure on knowledge processes and explores how the insights generated by social network analysis are valuable to KM as diagnostic elements for drafting KM interventions. Relevance is apparent for management areas such as R&D alliances, product development, project management, and so forth.

BACKGROUND

Social network analysis (SNA) offers a combination of concepts, formal (mathematical) language, statistical, and other methods of analysis for unraveling properties of social networks. Social networks have two building blocks: nodes and ties among the nodes. Nodes may represent people, groups, organizations, and so forth, while the ties represent different types of relationships for example communication flows, collaboration, friendships, and/or trust. As illustration, Figures 1a and 1b represent graphs of the business and marriage network of Florentine families in 15th century (see Padgett & Ansell, 1993). The graphs are created with Netdraw (Borgatti, 2002).

SNA has its origins in the early decades of the 20th century. It draws on insights from a variety of disciplines, most notably social psychology, structural anthropology, sociology, and particularly the sociometric traditions (Scott, 2000). The formal

Figure 1a. Florentine families business network

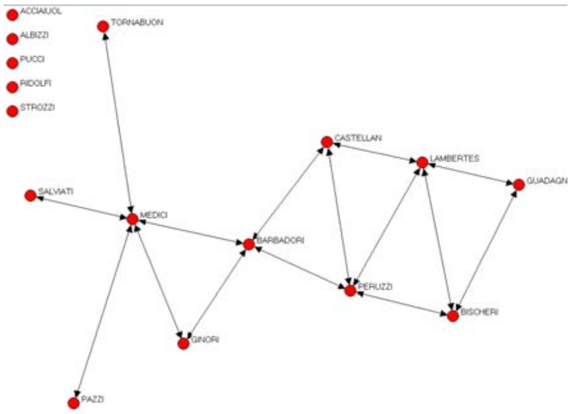

Figure 1b. Florentine families marriage network

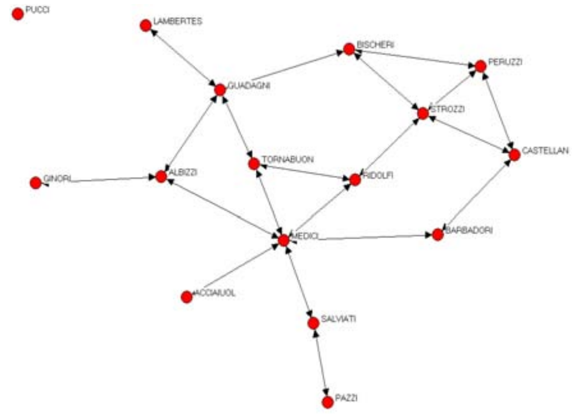


language of SNA is based in the mathematical branch of graph-theory (e.g., Harary, Norman, & Cartwright, 1965).

Network statistics describe characteristics of a network and include network size, density, centrality, and so forth. Social network thinking has produced many such statistics (see Wasserman & Faust, 1994). However, only a limited number have been studied and have known consequences for knowledge management. To analyze and characterize networks, SNA provides statistics of the whole network, groups within the network, individuals, and relationships. The substantive meaning of these statistics often depends on the contents of the ties in the network.

Granovetter's (1973) seminal paper, titled "The Strength of Weak Ties," heralds the central place of social networks in knowledge management and shows the importance of relationship characteristics for knowledge transfer. Others show that social relationships and structures also are important for other knowledge processes, such as creation and retention (e.g., Burt, 2004; Hansen, 2002; Hargadon & Sutton, 1997; Reagans & McEvily, 2003). Granovetter's (1973) title may be a bit misleading. It suggests that "weak ties" will help individuals to get unique beneficial information. However, the paper demonstrates that it is the quality of "bridging ties" that brings this advantage. Bridging ties are relationships in a network that, when they would be removed, would leave the network in two unconnected components. These relationships are often weak in the sense that contacts are less frequent and affect is low. However, as Burt (1992) points out, this is a mere correlation. "Strong bridging ties" would offer the same or even more advantages than weak bridging ties. The advantage of bridging ties Granovetter refers to lies in the structure of all relationships, not the strength of the relationship.

This leads us to focus here on the structural characteristics of networks and their impact on KM goals. This allows tapping into accumulating insights in the KM domain generated by SNA applications. Several recent studies in network literature focus on the (contingent) effects of such dyadic qualities as tie strength, level of trust, and power on knowledge transfer and retention (e.g., Hansen, 1999; McEvily, Perrone, & Zaheer, 2003; Uzzi, 1997).

SNA AND KM GOALS

Many SNA concepts bear relevance for KM research. Recent studies show that four SNA concepts in particular affect KM. These are:

1. Brokerage: Affects creativity, the generation of ideas and knowledge exploration
2. Centrality: Shapes knowledge transfer
3. Cohesion: Influences both knowledge transfer and retention
4. Equivalence: Reflects knowledge retention through common knowledge

Elaborating how the inspection of organizations through the lens of these four concepts is relevant for KM debates presumes an understanding of KM. KM is about an organization selecting appropriate goals with regard to knowledge, selecting a management model, and executing interventions, also called KM practices. Commonly, three KM domains and sets of KM goals are discerned:

1. The domain of knowledge processes that constitute valuable knowledge for an organization, most notably knowledge exploration, knowledge exploitation, knowledge sharing or transfer, and knowledge retention (see Alavi & Leidner, 2001; Argote, McEvily, & Reagans, 2003; Hendriks & Vriens, 1999)
2. The domain of a knowledge infrastructure as the organization setting in which knowledge processes evolve
3. The domain of a knowledge strategy as the set of goals that refer to how knowledge may give an organization its specific competitive position

These three KM domains and the goals they involve are interconnected. The domain of a knowledge infrastructure concerns setting the appropriate conditions for knowledge processes to evolve in such a way that they fit strategic KM goals. Focusing on aspects of social network structure, as this article does, involves paying special attention to the KM domain of knowledge infrastructure and its link to the first domain, that of knowledge processes.

Knowledge managers may benefit from insights in the four SNA concepts that will be presented in more detail in the remainder of this article. As elaborated next, insights into the domain of knowledge infrastructure and knowledge processes may form the basis for an informed selection of interventions for reaching KM goals. These interventions may target individuals (nodes) and/or their ties. Such KM interventions directly change the way knowledge processes develop. As such, the efforts of KM target the level of the individual knowledge worker. For example, SNA may prove useful:

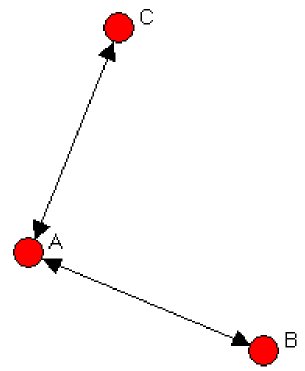
1. in helping these individuals review their personal networks
2. in showing the necessity for them to develop their networking skills (e.g., Baker, 2000)
3. for their career planning

Furthermore, the insights that SNA generates also may allow KM to facilitate conditions for establishing network relationships and affect the resources used in networks. Note that both concern KM at the level of the knowledge infrastructure.

BROKERAGE

The first concept discussed here is that of knowledge brokerage. A broker is defined as someone who holds a position in a network that connects

Figure 2. Node 'A' is a broker between nodes 'B' and 'C'



two or more unconnected parts of that network (see Figure 2). It is closely related to the idea of bridging ties because bridging ties imply brokerage. To emphasize that it is not the bridge itself, but the gap it closes that reflects value, Burt coined the term "Structural Hole" (Burt, 1992). A structural holes reflects the opportunity to connect two or more unconnected others.

Several authors suggest the value of brokerage for the creation of innovative ideas (Burt, 2004; Dekker, 2001; Hargadon & Sutton, 1997). Burt (2004) shows that there is strong evidence that brokerage generates good ideas. He states: "People with connections across structural holes have early access to diverse, often contradictory information and interpretations which gives them a competitive advantage in seeing and developing good ideas." They derive their value by enabling the flow of resources between otherwise unconnected subgroups within a larger network. This induces innovation (Hargadon & Sutton, 1997). Hansen (2002) shows that brokers work best when they use their own contacts and do not depend on other intermediaries. Dealing with fewer intermediaries who serve as boundary spanners provides search advantages, which leads to better knowledge acquisition.

The result that brokers may hold value is not without controversy. It has been shown that the value of brokers depends very much on the content of relationships (Podolny & Baron, 1997). Some relationship contents such as trust or tacit knowledge flow better through nonbridging relationships (Dekker, 2001; Gargiulo & Benassi, 2000).

In short, SNA identifies brokers and shows the conditions under which broker positions become valuable.

KM Interventions

The insights from knowledge brokerage analyses inspire, for example, the following KM interventions:

- Retention of key knowledge brokers in the organization. This could be done by aligning the reward systems with the recognition that informal reputation is central. Formal peer reviews should tap into those mechanisms
- Knowledge brokers need to be managed (or manage themselves) in such a way that they need as little other intermediaries as possible to acquire knowledge. Ideally, every team needs to organize its own "intelligence"
- The structure of work should confront some members of the workforce with a continuous flow of new problems, discourage them to overspecialize, and rotate them between projects on a regular basis. Only then is an "organic emergence of brokerage skills" conceivable
- Management style and the basic management model should reflect norms for collaboration. This could be implemented by avoiding management through normative control and by teaching newcomers the "attitude of wisdom" through brainstorming routines and regular meetings (e.g., Monday Morn-

ing meetings as described by Hargadon & Sutton, 1997)
- Recruitment and employee selection policies should respect the work and management styles and practices described. Peers should play a key role in those policies. Hargadon and Sutton (1997) describe how the product design firm IDEO only hires new personnel when at least 10 peers support these

Another KM intervention would be to find potential brokers to fill structural holes as starting points for idea generation. Other possible interventions include:

- The introduction of programs for team building and the development of networking skills and collaborative exercises may increase the chances that structural holes disappear
- Individuals' motivation to become knowledge brokers may be stimulated, through the reward system, career management, the selection of topics addressed in their development interviews, and personal commitment statements.
- Exit interviews and outplacement procedures may be considered for individuals who prove unfit for any boundary spanning activities

CENTRALITY

Centrality is a network structural characteristic of an individual or a whole network (for an overview, see Wasserman & Faust, 1994). The definition of various forms of centrality we will give focuses on individual centrality or point centrality. On a network level, similar measures have been developed (see Freeman, 1979). Several different types of centrality have been defined. Three well-known measures defined by Freeman (1979) are degree centrality, betweenness centrality, and closeness centrality. Degree centrality is measured as the number of ties an individual has in a network. This measure indicates the potential for communication activity that individual has. Betweenness centrality is based on the number of times that an individual stands between two others. Standing between two others here means being on the shortest path (geodesic) that connects two others. The more often an individual is on the shortest paths between any two others in the network, the higher that individual's "betweenness centrality." This form of centrality says something about control of communication within the network. Closeness centrality measures how close an individual is to the others in a network. Having relationships with everybody implies being closest, while having to depend on others to reach someone implies a greater distance toward that individual. Closeness centrality indicates independence. The higher the closeness centrality the more an individual can avoid the potential control of others (Freeman, 1979).

Centrality of networks has a close relationship to coordination in teams and particularly has an impact on knowledge transfer. For instance, Rulke and Galaskiewicz (2000) show that generalist teams do better than specialist teams in centralized networks. In decentralized networks, generalist and specialist teams perform equally well. Tsai (2002) shows that hierarchy has a negative impact on knowledge sharing, particularly in situations of inter-unit competition for market share. In such situations, informal lateral relations show a positive impact on knowledge sharing. Furthermore, Tsai (2002) shows that the drawbacks of hierarchy for knowledge transfer are less severe when competition among teams concerns usage of internal resources.

KM Interventions

Insights in the centrality of networks provide specific guidance for drafting control structures within project-based or team-based organizations:

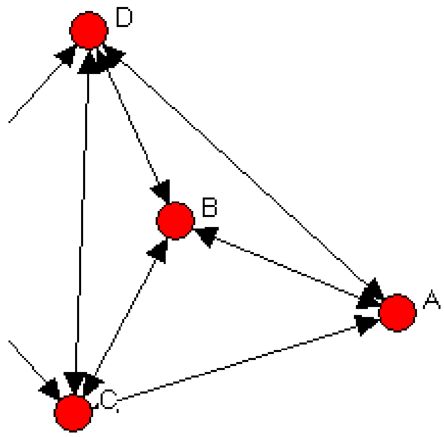
- Especially among specialists, if knowledge sharing is important, centralized, hierarchical control structures as coordination mechanisms in teams should be avoided
- Particularly in situations of inter-unit competition for market share, it may be wise to reexamine the degree of hierarchy in the prevailing control structures
- SNA research also has implications for staffing policies of teams: developing generalist teams puts less pressure on adequacy of existing control structures

COHESIVENESS

Cohesiveness in a network implies that all individuals or subgroups of individuals in that network have strong, direct, intense, frequent, and positive ties (Wasserman & Faust, 1994, p. 249). Several measures to detect cohesiveness have been developed. Probably the most well-known is the clique. Cliques are formally defined as maximal complete subgraphs of three or more nodes (Luce & Perry, 1949). This means a group is a clique if no individual in the network can be added to that group such that all those in the group have a direct tie with each other (see Figure 3). Ties in cliques are sometimes referred to as "Simmelian ties" after the renowned German sociologist Georg Simmel (Krackhardt & Kilduff, 1999). Simmel was the first to discuss the properties of triads, which are the smallest possible cliques. Simmelian ties are super strong, according to Krackhardt (1998), because they create opportunity for norms to arise and the means to enforce these norms (see also Coleman, 1990).

For knowledge management, this means that cohesiveness in networks allows the development, transfer, and retention of routines. Reagens and McEvily (2003) show that cohesion improves knowledge transfers. Hansen (2002) shows that cohesiveness between units may prove counterproductive under circumstances. He argues that

Figure 3. The group of nodes 'A,' 'B,' 'C,' and 'D' form a clique. In the group of nodes 'A,' 'B,' and 'C,' a fourth node 'D' can be added that has ties with all three others. Node 'E' doesn't belong to the clique because 'E' does not have ties with all clique members.



the direct relations that produce cohesiveness are most effective for the transfer of complex knowledge. His research shows that the higher the number of direct relations, the longer the completion time of projects that employ codified knowledge. As to the cost involved in maintaining strong ties, research by Borgatti and Cross (2003) shows that its negative impact on knowledge transfer cannot be substantiated. They do show that awareness of competent knowledge transfer partners and easy access to their knowledge furthers knowledge transfer.

KM Interventions

SNA research shows that stimulating cohesiveness within teams is crucial for the broad spectrum of knowledge processes. If there is a lack of cohesiveness in parts of the organizational network, concrete interventions to help achieve such objectives include:

- The introduction of programs for developing networking capabilities not just for team members but particularly for managers (Baker, 2000). Other research has shown that heavyweight project leaders are needed for successful projects. SNA research shows that networking capabilities skills are crucial in addition to other managerial competencies
- As research suggests that successful teams have both weak and strong ties with other units, recruitment and selection procedures for team composition should ensure an adequate balance between both types of ties
- The introduction of programs for team building including collaborative exercises
- SNA may identify those nodes in the network, for example, team members that contribute most to low cohesiveness scores. These insights may inspire exit interviews with such team members and starting out-placement procedures for them
- The identification and adoption of key tasks and deliverables of teams and subgroups, as these may provide a focus for cohesion
- The introduction of elements of networking by team members in personal commitment statements, career management, and development interviews
- All aforementioned KM interventions should not just focus on intra-unit communication, but also address inter-unit communication. However, it should be considered that cohesiveness based on direct relations across units may only be worth the cost of maintaining for noncodified knowledge

EQUIVALENCE

A fourth SNA concept is equivalence. Equivalence of two individuals in a network indicates that they are embedded in equal or very similar network structures. Note that this does not mean that both need to have a direct contact. Rather, equivalence measures indicate the extent to which two individuals have the same role in a network. Equivalence measures have been developed for sociometric positional and role analyses. These analyses group people on the bases of their similarity in relational patterns. For an overview of different equivalence measures, see Wasserman and Faust (1994). In their study, Reagens and McEvily (2003) suggest that knowledge flows more easily between two equivalent individuals, because they have more common knowledge. More research is needed to show the effects of equivalence on knowledge management outcomes.

KM Interventions

- To the extent that inter-team knowledge transfer is important, staffing policies of teams need to tap into the insights that the existence of common knowledge among team members of different teams is an important precondition for the ease of knowledge transfer between teams, particularly for complex, noncodified knowledge. One way to achieve this is to gather data on the networks of individuals and to use these data to maximize structural equivalence of teams, an insight that may be provided by SNA
- Installing a system of job rotation makes sense because experience at one task is shown to help in performing a related activity
- Dedicated network ability training programs also may help in expanding the capacities of individuals and teams to achieve equivalence with other individuals and teams

FUTURE TRENDS

The increasing attention for knowledge aspects in organizations is likely to boost the interest in SNA research and may be expected to influence the direction that research takes. The KM community may be expected to strengthen its embrace of SNA as a solid basis for diagnosis. As to the development of a knowledge-based SNA, a multitude of suggested research directions, ideas, and developments appear on the horizon. Two of these deserve special attention.

First, we anticipate SNA researchers that show an interest in the knowledge-based view of organizations to expand their focus that is currently mainly on the process of knowledge transfer. Other knowledge processes, particularly knowledge exploration and knowledge retention, have attracted the attention of SNA researchers, but not so much as knowledge transfer. The process of knowledge exploration, for instance, has been approached mainly via related concepts as creativity and idea generation. The process itself and the variety of learning and knowledge development models circulating in KM debates that involve elements of networks still remain largely outside the scope of SNA research. Also, an understanding of the core knowledge processes of knowledge exploitation and knowledge retention may greatly benefit from an inspection from a SNA standpoint. The same goes for the broad spectrum of supporting knowledge processes including knowledge acquisition, knowledge evaluation, knowledge identification, and knowledge combination.

Second, the further integration of SNA can be foreseen with qualitative studies that provide an in-depth examination of the intricacies surrounding the knowledge aspects of work. Hargadon and Sutton (1997) give an outstanding example of combining SNA with an extensive qualitative study of the mechanisms that shape the amalgamation of idea generation and knowledge retention. SNA addresses the crucial structural conditions for knowledge processes to develop. However, the intricate workings of the knowledge component in these processes remain a black box in a SNA. This is indicated by the fact that in much SNA research the term knowledge is easily substituted with the term information. Development of both knowledge-based SNA and qualitative inspections of organizational knowledge will advance due to their mutual connection.

CONCLUSION

Concepts from SNA strike a chord among adherents of a knowledge-based view of organizations. They recognize that knowledge, and especially organizational knowledge, is essentially situated on the fringes of connecting individuals with collectives. These concepts have inspired researchers from different origins and led to elaborations of network thinking into different directions, such as the economic theories of networks as governance modes and organizational theories around concepts of organization structure (Wijk, Bosch, & Volbeda, 2003). Both in the domain of knowledge management research and in the domain of individual organizations drafting their knowledge management diagnosis and design efforts, SNA has great potential to further develop the knowledge-based view of organizations.

Chapter 5.5
A Social Network Perspective on Knowledge Management

Reed E. Nelson
Southern Illinois University, USA

HY Sonya Hsu
Southern Illinois University, USA

INTRODUCTION

Social networks—the sets of relations that link individuals and collectives—have implications for the speed and effectiveness with which knowledge is created and disseminated in organizations Both social networks and knowledge management (KM) are complex, multifaceted phenomena that are as yet imperfectly understood. Not unsurprisingly, our understanding of the interface between the two is similarly imperfect and evolving. There are, however, a number of foundational concepts upon which existing thought converges as well as a body of emerging research that offers practical and conceptual guidance for developing the kind of network best suited for managing different kinds of knowledge. In this article, we introduce rudimentary network concepts, briefly recapitulate KM and organizational learning concepts related to networks, and then explore some of the interfaces between social networks and KM.

RUDIMENTS OF SOCIAL NETWORK ANALYSIS

There are two fundamental dimensions of social networks: transactional content and configuration. These in turn have both direct and indirect interactions on each other and on knowledge dissemination if not on both creation and transfer of knowledge. Configuration refers to "shape" of a network (Nelson, 2001). For instance, some networks look like stars, with actors connected only to a central person. Some look like spider webs, with a dense center, but with some connections between peripheral actors (Handy, 1995). Other networks, such as those typified by unrestricted markets, exhibit more random patterns.

Important for an individual within a network is the degree to which he or she fills a "structural hole" between members of the network. A structural hole refers to a gap in a network which isolates one set of actors from another. Individuals whose personal ties bridge such gaps can exercise a "brokerage" role which benefits them personally and facilitates the flow of information and resources through the network. There are at least two other important configurational aspects of an individuals networks; centrality and structural equivalence. Together they constitute what Galaskiewicz and Wasserman (1993) identified as the core constructs defining of social structure:

1. Actor centrality is the degree to which the ties in a network converge upon an individual actor. Thus, if actor A is connected to everyone in a network and no other actors entertain ties to each other, actor A has maximum centrality. Centrality has been measured in various ways from simple counts of sociometric nominations to measures based on the number of geodesics linking each actor, but space will not permit a discussion of these nuances. Common to all measures is the idea that central actors can reach or directly contact other members of the network more easily than less central actors.
2. Structural equivalence is the degree to which the patterns of individual networks are similar. People who are tied to the same people are said to be structurally equivalent. For instance, two professors who team teach the same course would have rather similar patterns of ties, at least with their students. Supervisors on a day and night shift in the same factory also would have somewhat similar network patterns. Because strict equivalence is quite rare, scholars have sought to develop less constraining definitions of equivalence. Actors with similar network structures but with connections to different actors are said to have "regular equivalence" for instance. An example would be quarterbacks on opposing football teams. In practice, equivalence is usually measured using clustering algorithms which group similar network patterns together.
3. Bridging relationships are idiosyncratic relationships that link otherwise unconnected groups or individuals. This concept is very similar to both Burt's brokerage and Freeman's "betweenness" constructs.

To Glaskiewicz and Wasserman's constructs must be added a fourth—the concept of density. Density refers to the overall number of contacts in a network compared to the number of ties possible. In a "sparse" network, there are few connections between people. In a "dense" network everyone is connected. Density is expressed as a ratio of realized to possible ties. The network of four people sharing six ties has a density of 1. One containing three ties has a density of .5. The overall density of a network or a network's subregion is closely related to virtually every other network dimension.

Transactional content refers to the kind of relationship that exists between two actors rather than the shape of the network or the actor's position within the network. Many types of relationship are possible, including influence, information exchange, advice, emotional support, antagonism, and exchange of goods and services. However, to date, the most commonly used way to classify the transactional content of a network is the concept of "tie strength" developed by Grannovetter (1973). In addition to formalizing the concept of tie strength, Grannovetter was perhaps the first to recognize the relationship between tie strength, network configuration, and the dissemination of information.

The strength of a tie is a combination of the amount of time, the emotional intensity, and the extent of reciprocal services which characterize the tie. In general, the stronger the tie the more easy it is for one actor to influence and convey complex, multifaceted information to another. At the same time, strong ties tend to be resistant to change and stifle innovation. They also tend to clump together into incestuous cliques, creating many structural holes in a network that are difficult to bridge and that create conflict in social systems (Nelson, 1989; Uzzi, 1997). The relationship between tie strength, network configuration, and information transfer is probably the single most important network finding and its implications for KM and surfaces in one way or another in almost all studies of networks and KM.

DIMENSIONS OF KNOWLEDGE AND KM

Although most readers will be acquainted with KM and related concepts, it will be useful here to summarize a few central constructs so that our discussion of the relationship between networks and KM will be based on common understandings and definitions. We briefly restate commonly used definitions of knowledge and knowledge management. Nonoka (1994) defines knowledge as "a justified belief that increases an entity's capacity for effective action." He also affirms that knowledge is created and organized by the flow of information, anchored on the commitment and beliefs of its holder (Nonoka, 2002).

It is important to distinguish between data, information, and knowledge. The primary distinction between the three lies in the degree to which they are organized and useful. Data are raw stimuli with little organization or ready utility (Avali & Leidner, 2001). Data become information when they are processed and organized in a systematic way. Information becomes knowledge when it is ready to be used to orient action. In Davenport, Long, and Beers' terms, "Knowledge is a high value form of information that is ready to apply to decisions and actions (Davenport et al., 1998, p. 43). An important type of knowledge is tacit knowledge, which, while it is useful, is difficult to codify, transmit, and convey (Schön, 1983). Tacit knowledge contains data that are processed, organized, and useful, but the underlying logics of their organization are frequently complex, implicit, and ambiguous. Tacit knowledge is important to the solution of problems that are intractable, complex, extremely variable, or all of the above. As phenomena become better understood and solutions more routine, the knowledge necessary for their processing becomes more explicit, and solution procedures more codified, so that producing information from data becomes simpler and more routine.

Generating knowledge, be it tacit or explicit, is a complex task. Nonoka (1994) identifies four interrelated related processes leading to knowledge creation: knowledge socialization, knowledge internalization, knowledge externalization, and knowledge combination. Almost by definition, the processes of knowledge socialization and externalization if not combination and internalization will be influenced by the nature and distribution of individual and collective networks. Most views of KM recognize that it has both social and technological dimensions which need to be integrated, and that KM has broad aims involving organizational culture, transparency, and agility of processes, and the development of infrastructure that is harmonious with individual needs and organizational context.

For Davenport and Prusak (1998), most KM projects have one of three aims: (1) to make knowledge visible and show the role of knowledge in an organization; (2) to develop a knowledge-intensive culture by encouraging and aggregating behaviors (e.g., knowledge sharing); and (3) to build a knowledge infrastructure—not only a technical system, but a web of connections to encourage interaction and collaboration. Again, social networks would logically limit or enhance visibility, culture, and infrastructure.

Alavi (1997) believes that KM includes both technology and social-cultural factors. This view is supported by Tiwana (2001) who adds that: (1) KM should focus on the flow of information; (2) it is a foremost a management issue—and technology is only an enhancer driven "by the right people in the right place to support knowledge management." A similar but more individualistic perspective is expressed by Alavi and Leidner (2001). For them, KM involves enhancing individual's learning and understanding through provision of information. They also see the role of IT as providing the access to sources of knowledge rather than knowledge itself. Sources of knowledge are the nodes of a social network that create, acquire, or transfer the majority of information/knowledge.

From this brief overview, it would seem clear that: (1) Networks are an important part of the knowledge creation, acquisition, and transmission process; and (2) different network properties will come into prominence at different stages of this process. In the next section, we attempt to identify some of the likely specifics of this relationship.

NETWORKS AND KNOWLEDGE MANAGEMENT

The relation between networks and KM has been recognized and explored by several researchers, some of whom have made extensive use of formal network theory and methods, others who have made fairly little use of the existing network literature. It is generally recognized that early KM initiatives focused too heavily on IT, missing opportunities to improve performance through the knowledge and enhancement of employee networks (Parker, Cross, & Walsh, 2001). Practicing managers especially recognize that human relationships, their deployment, and configuration are critical to KM. For instance, the manager of the technical information center at Xerox emphasized that KM is not technology-driven but "people-driven" (Hickins, 1999). A case study of Xerox affirmed that 80% of KM systems involved adapting to the social dynamics of the workplace.

Beyond this general admission of the importance of human factors, literature on KM has frequently noted that formal vertical relations are not as effective at disseminating knowledge, as are lateral contacts. A number of studies suggest that hierarchical contacts (frequently, equated with "formal structure") are not as effective for knowledge sharing as "lateral" or informal contacts. Knowledge organizations are characterized by weak hierarchies, dense lateral connections, low departmental walls, and openness to the environment (Achrol & Philip, 1999). These studies, however, have made little or no use of network theories, which would help to explain the effectiveness of lateral ties.

Perhaps the most sophisticated work on KM and networks is that of Cross, Parker, Prusak, and Borgatti (2001). They identify four dimensions of network ties which influence a firm's KM capability: (1) Knowledge: "knowing what someone else knows" when managers face a problem or opportunity; (2) Access: being able to contact and secure useful information for an actor in a timely fashion; (3) Engagement: the expert understands the problem as experienced by the seeker and then adapts his or her knowledge to the needs of the person information; and (4) Safety: ease in admitting a lack of knowledge.

Although the work on networks and KM clearly establishes the importance of networks to KM, we as yet have found no integrative statements about the general contours of the relationship between network attributes and knowledge creation and dissemination. In an effort to move toward such a statement, we juxtapose the tacit/explicit knowledge distinction with the various network properties to offer the beginnings of a contingency perspective on networks and KM.

Knowledge creation generally begins with isolated and unintegrated insights, which are brought to bear on a practical problem until a desired result is achieved. At this point, the practitioner has a working ability which we defined above as tacit knowledge. Over time, this tacit knowledge may or may not be distilled into codified information, which is more easily conveyed through written or other transportable means. The degree to which knowledge is tacit is closely related to the kind of network that will best be able to convey and disseminate it.

When knowledge is at the tacit stage, it is only transferable (if at all) through very rich channels requiring frequent face to face interaction. When physical artifacts are involved, the artifact or physical setting must simultaneously be available to all parties. This demands both strong ties and a dense network configuration, which can be quite expensive to develop in terms of time and resources. Although relations in the network may be hierarchical (mentor and apprenticeship relations are prominent), little brokerage occurs because all members of the network know each other and relate on a face to face basis.

As tacit knowledge gives way to at least partial codification, formerly isolated communities of practice trafficking in tacit knowledge come into contact with one another. Brokers then emerge who retain a stake in their original community but who acquire the insights of rival groups or of other disciplines or crafts. These brokers often face ostracism from their own group and suspicion from other groups, but if they succeed in forging connections, they are often richly rewarded. The great tinker-inventors of the 19th century tended to build networks of this type, Edison and his famous Menlo Park facility being the most prominent example. These networks are characterized by tight cliques of strong ties connected by brokers with somewhat weaker ties to other communities. This tradition is carried on today and the organizational mechanisms used to manage such networks are lucidly portrayed in Hargadon and Sutton's (1997) pioneering work on Ebsco, the famed Silicon Valley design firm. Work of this type has generally been ignored by both network analysts and KM scholars and needs to be acknowledged by and integrated into both literatures.

As knowledge becomes codified but still somewhat volatile, networks with weaker ties, less density, and more brokerage are needed. These use channels with less richness and more agility, although even these networks ordinarily build associations and cartels to provide a forum for face-to-face contact and deal-making. Frequently, actors who develop high centrality may drive out other brokers and become dominant in managing and controlling information at this stage. Many of the incidental contacts of the general managers described by Kotter (1982) are with brokers of information which is largely codified but not routine or widely disseminated.

Finally, highly codified and relatively stable information is found in market-like networks which rely heavily on public mechanisms such as publications, bulletin boards, and wire services. These networks are low in density and weak in tie strength and require relatively little conscious understanding or management. Even these networks, however, can only be navigated by people who have been introduced to the conventions and protocols used by someone already initiated in the system. In these situations, information is more prominent than knowledge, but even in these settings, it may take a knowledgeable, initiated person to orient newcomers.

Understanding the continuum of tacit to explicit knowledge and its implications for social network strength and configuration may enhance current thinking and practice in knowledge management as well as the study of social networks. As an example, we return to Cross et al.'s categories of knowledge, access, engagement, and safety. When we examine their typology in the light of tacit knowledge, it seems reasonable to predict that the different dimensions and their configuration will vary by the state of knowledge being developed.

The knowledge (i.e., knowing what someone else knows) dimension will be relatively unimportant during the tacit phase if only because engagement will be almost impossible. When information is more transportable however, knowledge will be very important and will benefit by high density and connectivity with many brokerage relationships. Engagement (expert understands the problem of the seeker) becomes important during the intermediate stages when the ability to find the exact person who can "speak the language" of the information seeker becomes critical. Brokerage relationships become critical here and much time will be dedicated to forging brokerage relations and developing strong ties to diverse actors in a sparse network. When knowledge is generally codified and diffused, safety (ease in admitting lack of knowledge) becomes an issue because of the expectation that people should already know certain information or where to find it. Thus, strong mentoring relationships in otherwise sparse networks composed of weak ties become important when information is explicit rather than tacit.

Cross et al. describe a situation in one firm in which one executive provided the only bridge between two cliques. Their intervention established other brokerage contacts, generally taking pressure off the sole broker and speeding coordination and communication in the workgroup. It is our expectation that in situations high in tacit knowledge, such change in the network might not be practical. In one knowledge-intensive organization to which we consulted, the top executives of the company also occupied important bridging roles in a field high in tacit knowledge. Rather than making their networks denser and more egalitarian, we found it was best to buffer the most knowledgeable executives from administrative duties so they could devote more energy to a brokerage role that was harder to compensate for than their administrative role.

TIE STRENGTH AND KM

In our discussion, we mentioned tie strength, but our focus was chiefly on network configuration and knowledge generation and transmission. Before closing, we turn to a few more detailed predictions about tie strength and knowledge management. The presence of strong ties provides a rich communication channel, which facilitates the accurate transmittal of complex information, tacit knowledge, and development of trust. They also promote commitment and solidarity between actors which is necessary for communication and coordination of large projects that require intensive sharing of knowledge across many actors (Fukayama, 1995).

At the same time, the presence of strong ties requires large amounts of time and psychological energy to develop and maintain, generally reducing the efficiency of the system. They also reduce variability in thought and perspectives at the same time they stifle undesirable deviance and build loyalty. Thus, at the same time, they help convey tacit knowledge, they stifle the "reflection in action" that Schön deems necessary to perfect tacit knowledge. This, in turn, limits that ability to adapt to new circumstances and novel situations. The benefits of strong ties are most evident when producing knowledge for the incremental perfection or improvement of an existing system or technology—in sum, for exploitation rather than exploration.

When competence-destroying innovations are expected or intended, the strength of ties becomes a weight that renders the knowledge system less agile. Tacit knowledge tends to carry with it "irrelevant content" (Nelson, 1997) and superstitions that prevent the system from understanding or recognizing the value of competence destroying innovations. The literature on KM glimpses aspects of this paradox but generally does not see both horns of the dilemma at the same time and tends to be more aware of the value of weak ties than of strong ties. From a network perspective, then, the observation of the KM community that lateral ties are better for information diffusion may be because they are likely weak rather than strong. KM observations of the benefits of laterial ties should include caveats. Lateral ties are more likely to be more adaptable and flexible than contacts with hierarchical content. Lateral ties also would be desirable because they would bridge a number of structural holes in the organization, facilitating information flow. However, they do not convey the solidarity and coercive power of strong and/or hierarchical ties.

CONCLUSION

As the KM field continues to mature, we expect that the social network perspective will play a more prominent role in our understanding of knowledge in organizations. In closing, we suggest a few measures that may be taken to speed up this process. We suspect first that tighter theoretical linkages between social network theory, theories of knowledge, and theories of organizational learning would be useful. Students of organizational learning are generating ever more sophisticated studies using large archival data sets. These studies (Chuang & Baum, 2003; McDonald & Westphal, 2003) contain insights that could be exploited by students of knowledge management who have a basic grasp of network concepts. Second, more complete use of the sophisticated social network techniques available would be useful, especially those methods that consider multiple types of tie simultaneously. The techniques used in the KM literature to date tend to be quite rudimentary and therefore best for case-based research rather than comparative studies which yield higher generalizability. The normative orientation of KM could stimulate network analysts to be less coy about developing prescriptions for managing networks. Much is known about networks' content and morphology but not about how they are actually formed and what specific network properties are efficacious in what settings.

Early network analysts discussed the benefits and drawbacks of highly central networks but turned away from practical concerns in search of ever more esoteric theory. Very little thought at all has been given to the practical impacts of structural equivalence between actors, which would be a natural next step in terms of practical analyses. We suspect that different degrees and types of equivalence may have implications for KM, and research in this area by the KM community is likely to push network theory in interesting directions.

Granovetter's (1973) original formulation of strong and weak has been thoroughly exploited for its practical and theoretical value, and it is time to look at more fine-grained characterizations of relations. The KM community can be of considerable value in taking the notion of "transaction content" from network analysis and giving back a more practical and sophisticated view of the kinds of relations that people develop, how they develop them, and how these relations are mobilized to generate and distribute knowledge.

As is the case with most social endeavors, the different possible configurations of network attributes present contrasting implications for knowledge management, reflecting the tensions and tradeoffs that are inherent in almost any social setting in which goal-oriented performance is sought. Continued integration of these two bodies of thought should ultimately benefit both but also might contribute to the more general debates of our time about solidarity, innovation, change, and the fundamental nature of human systems.

Chapter 5.6
Knowledge Management in Action:
The Experience of Infosys Technologies

V. P. Kochikar
Infosys Technologies Ltd., India

Kavi Mahesh
Infosys Technologies Ltd., India

C. S. Mahind
Infosys Technologies Ltd., India

ABSTRACT

This chapter presents the detailed architecture that Infosys has deployed for implementing KM internally, and the company's experiences in using that architecture for managing its knowledge. A brief historical perspective of the evolution of the Infosys KM effort is discussed and a description of the Infosys Knowledge Shop (KShop), Infosys's integrated knowledge portal that we have built, is given. The real test of the maturity of any organizational initiative is when it becomes invisible, a part of the normal way people work. The aim of the KM initiative is thus to move towards a culture where knowledge sharing is built into the organizational fabric. The chapter elaborates on one key mechanism that has been devised to help create such a sharing culture — the Knowledge Currency Units (KCUs) scheme. Some of the key challenges and success factors the company has faced are discussed, and the approaches used to manage those are described.

INTRODUCTION

Today's organizations face a strategic landscape that is characterized by changing technology, rising stakeholder expectations, shifting competitor profiles and the emergence of new markets. The need to stay competitive in such an environment throws up immense challenges, and leveraging well on knowledge — internal as well as external to the organization — is a key imperative. Knowledge Management (KM) has thus, in recent years, acquired increasing management focus.

A central tenet of KM is to raise the speed and quality of learning, decision-making and customer service at the level of the organization as well as the individual. By institutionalizing best practices existing in pockets, facilitating greater reuse and helping better virtual teamwork, KM also raises the organization's ability to deliver higher quality and achieve faster time-to-market. Overall, KM also reduces risk and makes the organization more robust to thrive in a changing environment.

Given that most KM programs must start out with modest resources, a KM strategy must be optimized to extract the greatest effectiveness from these resources. A key success factor is getting the optimal emphasis on each of the four focal areas — people, process, technology and content — right from the early stages (see, for example, Davenport and Prusak, 1998). The specific emphasis laid on each of these is a function of the organizational culture and business context.

Infosys Technologies Limited (NASDAQ: INFY) is an IT consulting and software services organization headquartered in Bangalore, India. Founded in 1981, the company's revenues in 2001 were $413 million, having grown at a compounded rate of 70% over the preceding decade. The company primarily services Fortune 1000 clients located in North America, Europe and the Asia-Pacific. Infosys has consistently been rated among India's leading wealth-creators, and recorded a net profit of $131 million in 2001, representing 32% of revenues. It was the top-ranked Indian company in the Review 200 listing compiled by the Far Eastern Economic Review, and has been rated the most respected company in India by, among others, Business World and the Economic Times. The company operates globally, with eight development centers in India, five in North America and one in the UK, and has 10,500 employees on its rolls.

The mission of Infosys' KM effort is to ensure that all organizational learning is leveraged in delivering business advantage to the customer. The objectives are to minimize effort dissipated in redoing learning that has already happened elsewhere, and ensuring that Infoscions (as employees are called) in contact with the customer have the collective knowledge of the organization behind them. The company thus aims to move towards a "Learn Once, Use Anywhere" paradigm. Infosys uses the proprietary KMM, or Knowledge Management Maturity model (Kochikar, 2000a), a staged maturity framework, to underpin its KM strategy.

Infosys has devised and implemented a KM deployment architecture that has been found to work well. This chapter presents the detailed architecture that Infosys has deployed for implementing KM internally, and the company's experiences in using that architecture for managing its knowledge. While each company's KM journey is unique, we believe that sharing information about our architecture and experiences will prove useful to other organizations venturing along the KM path. Equally important, we believe that sharing the process by which we arrived at the architecture that is most optimal in our context holds meaningful lessons for other organizations seeking to define their own KM implementations. Thus, we also present here a brief historical perspective of the evolution of the Infosys KM effort.

A description of the Infosys Knowledge Shop (KShop), Infosys's integrated knowledge portal that we have built, is given. The real test of the maturity of any organizational initiative is when it becomes invisible, a part of the normal way people work. The aim of the KM initiative is thus to move towards a culture where knowledge sharing is built into the organizational fabric. We elaborate on one key mechanism that has been devised to help create such a sharing culture — the Knowledge Currency Units (KCU) scheme. This narrative also brings out some of the key challenges and success factors we have faced, and describes the approaches we have used to manage those.

KNOWLEDGE @ INFOSYS– A HISTORICAL PERSPECTIVE

The company started small but has grown explosively over the last 10 years, and now has operations spread out across multiple locations spanning the globe. The effective utilization of the company's knowledge base has always been seen as pivotal to success. Factors that have driven this belief include:

- The quality imperative: The primary mechanism for raising the quality of services delivered to the customer is the institutionalization of best practices residing in organizational pockets — a process which needs the sharing and adoption of these practices across departmental interfaces.
- The revenue productivity imperative: The constant search to provide greater value for each dollar spent by the customer means the company must raise the level of reuse; the cost and effort of redoing something that has been done earlier — and relearning something that has been learned earlier — grow less affordable.
- The risk reduction imperative: Diversifying into new technologies, domains, geographical areas and services means that the organization must learn new ways of doing things; managing changes in team composition resulting from attrition and personnel movements require that as much knowledge as possible be documented.
- The market awareness imperative: As customers as well as competitors become increasingly global, the company needs to have efficient mechanisms to pull in learning from new environments.
- The growth imperative: Maintaining a consistently high pace of growth means an ability to rapidly enable new recruits on technology, process and cultural issues; it also needs the definition and dissemination of scalable processes that support the delivery of high-quality software and consulting.
- The virtual teamwork imperative: Increasingly globalized operations and rising customer expectations have meant a more complex execution model, often requiring teams that are spread across continents to collaborate in delivering a single software service. Such virtual teamwork represents a microcosm of the issues arising in KM, needing good technologies to support communication and collaboration, and a mindset of working with co-workers who may be situated in different time zones, and who may possibly belong to different cultures.

Driven by the above imperatives, several practices have been evolved at Infosys for ensuring the effective sharing and use of knowledge. While many of these pre-date the formal term 'Knowledge Management,' they can nevertheless be retrospectively classified as practices that sought to implement the spirit of KM.

In 1992, the company felt the need for an organization-wide repository that would enshrine experiential learning gained during the execution of software projects, and make it available for 'posterity.' The Education & Research (E&R) department was charged with the responsibility of developing and managing such a system. The system developed by E&R, christened the Body of Knowledge (BoK), was initially implemented by means of a simple, homegrown software application. The BoK system envisaged entries being contributed by Infoscions, with a lightweight review mechanism to screen their content, applicability and presentation aspects. A pre-defined template required a declaration that the work was experiential, and that it did not violate third-party Intellectual Property Rights (IPR) — in case the IPR belonged to a third party such as the customer, clearance from that party was mandatory. In 1997, this system was re-hosted as a web-based application with HTML content, and made available on the then-fledgling intranet. The application — at the time the first to be developed in Infosys that was based on web technologies — featured an easy-to-use interface with search utilities. Incentives for contribution were also defined, as were mechanisms to publicize contributions.

Given the knowledge-intensive nature of Infosys's business, a clear understanding of its 'knowledge capital' has always been considered essential. Traditional financial statements are notoriously ill-equipped to reflect this intangible form of capital. Infosys has adopted a model for evaluating its intangible assets. The methodology used is based on Dr. Karl-Erik Sveiby's Intangible Assets Monitor framework (Sveiby, 1997).

By late 1998, the company was multi-locational and had reached an employee strength of 5,000 — which meant that it was no longer possible for people to rely on informal mechanisms for identifying 'experts' to be consulted for knowledge inputs at various stages of project execution. It was decided then that E&R would develop a knowledge directory, to be christened the People-Knowledge Map (PKM), which would provide pointers to experts within the organization. Before implementing this directory, two fundamental questions needed to be answered. The first was, would the registration of experts in this system be mandatory — i.e., would every employee who met certain pre-defined criteria for 'expertise' on a given subject be entered into the system? After extensive debate and considerable thought, it was decided to make registration purely voluntary, with incentives to promote it. The rationale behind this was that mandatory registration, while ensuring large numbers of registrants, would be unlikely to guarantee a very high degree of commitment to respond on the part of the registrant (unless responding too was made mandatory, which would be unlikely to guarantee a high quality of response!). Voluntary, incentivized registration, on the other hand, would be likely to attract a small number of highly enthusiastic registrants, thus ensuring that the credibility of the PKM system remained high.

The second question to be answered was, at what level of granularity would these experts register? Existing taxonomies, such as those of the IEEE, the ACM, the Dewey Decimal system and various other taxonomies used by the academic and research communities, were considered, but none was found to fit our requirement. Some of the reasons: the 'top levels' of standard taxonomies are too general, yet do not encompass many areas that we needed — for example, vertical domains, culture, etc.; most standard taxonomies have large portions that are not relevant to Infosys's business; many latest terms are not yet included in them; and, these are generally taxonomies of concepts, which do not contain many proper names (of products, technologies, etc.) that are important for our purposes.

The solution was to develop a proprietary knowledge hierarchy — a multi-level taxonomy of topics that represented knowledge in the Infosys context. At the time of definition, the hierarchy consisted of about 780 nodes, with the top level being Technology, Methodology, Project Management, Application Domain and Culture, and deeper levels representing a finer grain of topics. The PKM application developed featured an intranet-based interface that supported registration of or search for experts. Users could also see profiles of experts and contact them to satisfy their knowledge needs.

The company-wide intranet, called Sparsh, has acted as a central information portal since its inception in 1996. The intranet consists of about 10,000 nodes, spread throughout the global development centers (DCs), and marketing offices. Official policies, press releases and articles, and web-based in-house information systems are available from the home page. Sparsh also links project, Practice Unit, department and personal web pages. Protection from external intrusion is achieved by means of firewalls.

The company's e-mailing system, which every Infoscion has access to, supports bulletin boards for official announcements as well as technical and personal discussions. The technical bulletin board has been a vibrant knowledge exchange forum in its own right, generating discussions on technical topics.

A web-based virtual classroom, also developed and managed by E&R, has been deployed on the intranet, and allows access to various courses. This system incorporates a discussion forum where participants can post and respond to course-related queries.

Practices that have worked are also propagated through regular seminars and best-practice sessions, held both within units and organization-wide. There were also a few other knowledge-sharing practices and systems employed by various organizational units, primarily for use within their units.

An Organization-Wide KM Initiative

The formal KM initiative was born in late 1999 when Nandan Nilekani, president and COO, decided that all the knowledge-sharing mechanisms that had existed until then needed to be synergized under a common umbrella, with a clearly articulated vision and strategy for implementation. Widespread consultation and debate helped define the vision, which was to be an organization...

- ..where every action is fully enabled by the power of knowledge;
- ..which truly believes in leveraging knowledge for innovation;
- ..where every employee is empowered by the knowledge of every other employee;
- ..which is a globally respected knowledge leader.

Knowledge Management Adoption — A 'Maturity' View

The first step towards the development of a conceptual framework for implementing KM at Infosys was to define a knowledge life cycle as consisting of the following stages:

Knowledge Acquisition is the stage where the knowledge is first generated/absorbed by any organizational unit. Knowledge Sharing/Dissemination implies packaging the knowledge/expertise in a form fit for use, and delivering it to the point of use, at the time of use. Sharing may be synchronous — direct person-to-person, or asynchronous — through capture, storage and subsequent delivery. Knowledge Reuse represents the stage where the knowledge/expertise shared is actually put to use for performing a task.

In any given organization, each of these stages of the knowledge life cycle can exhibit varying degrees of maturity. Rising maturity of each of these life-cycle stages implies an increase in the overall maturity of KM in the organization. It is therefore possible to map a given degree of maturity of each of these stages to an overall level of maturity of KM of the organization. This is the concept behind the Knowledge Management Maturity model, which characterizes each maturity level of KM in terms of the efficacy of each of the three stages of the knowledge life cycle.

The KMM model, which draws philosophically from the Software Engineering Institute's CMM (Capability Maturity Model) (SEI, 1993), thus envisages five stages of KM maturity — Default, Reactive, Aware, Convinced and Sharing. It is worth noting that in the model:

- A given maturity level implies a certain level of organizational capability (from level 4 onwards, quantitatively) subject to the prerequisites being met.
- Each maturity level clearly maps on to the company's business goals (i.e., the meaning of each level in business terms is clear).

The concept of maturity level of KM thus helps an organization achieve two aims:

- It provides a framework which an organization can use to assess its current level of KM maturity.
- It acts as a mechanism to focus, and help prioritize, efforts to raise the level of KM maturity.

For further details of the Infosys KMM Model, the reader is referred to Kochikar (2000a). We now proceed to explain the architecture that was developed for deploying KM in the organization.

THE KM DEPLOYMENT ARCHITECTURE

As said earlier, deploying KM needs the four major areas of People, Content, Technology and Process to be addressed. In order to understand the most optimal distribution of effort in the Infosys business and cultural context, a detailed survey of various constituencies within the organization — from top management to programmer level — was carried out, and several rounds of discussion of the draft architecture helped converge on the final architecture that is described below. Detailed analyses of the issues faced in the process of evolving this architecture are discussed in Kochikar (2002a, b).

The People Architecture

The people architecture defines the roles and responsibilities for various aspects of the KM implementation. The distribution of responsibilities must strike the right balance between functions that will be managed by a central group, and those that will be performed in a decentralized way. Infosys has chosen a 'facilitated decentralized approach,' which envisages the following: the technology architecture management for KM — development, deployment and maintenance — is done by a central KM group. All stages of the content management process are anchored by the KM group — creation of internal content however must happen in the field, and is facilitated by the KM group.

The conception and implementation of the KM strategy is also anchored by the seven-member central KM group. The group has two sub-groups — one each to oversee KM research and content management, and technology architecture development and maintenance — each headed by a manager. A third managerial role — that of the brand manager — has responsibility for internal publicity and promotion. The research and content management group includes a knowledge content editor whose primary role is to anchor the content management process. Other roles — practice champions who devote time to facilitation of content generation, reviewers and Gurus — are part time and played by appropriately identified individuals from across the organization.

In the early stages of a KM effort, providing the right incentives is a key success factor. The reward and recognition program for KM at Infosys revolves around the Knowledge Currency Unit (KCU) scheme. The scheme incentivizes authors, reviewers and users of knowledge. Authors earn KCUs when their documents/artifacts are accepted for publication in the KM repository. Subsequently, each time a document is used, the user can award KCUs which accrue to the author's KCU account. The user of a document can give on-line feedback on its utility, and suggestions for improvement. The effort spent by subject area experts on reviewing documents for publication also earns KCUs.

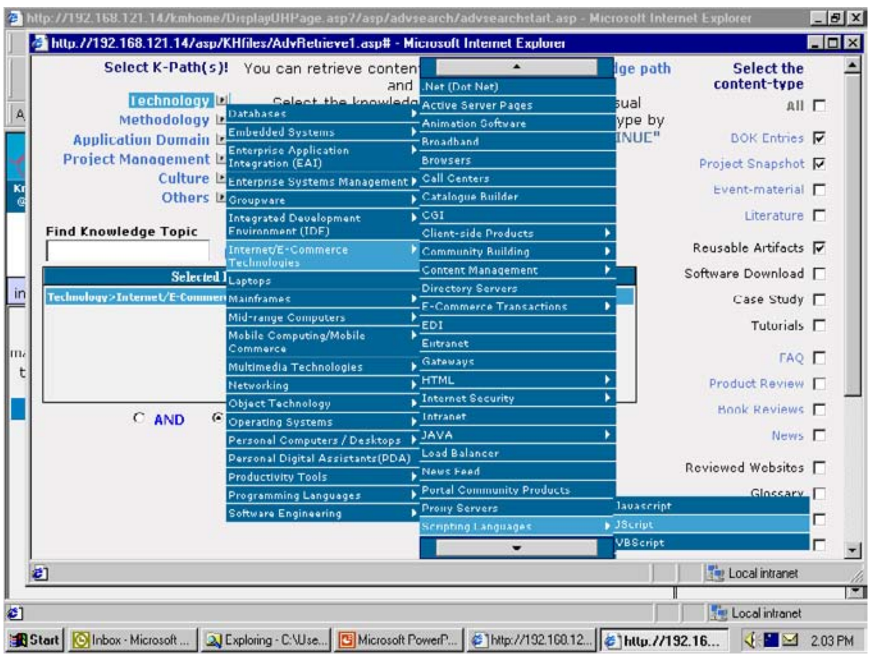
Employees thus build their KCU accounts, whose balance is a measure of their involvement in knowledge sharing. Accumulated KCUs can be redeemed for digital gift certificates that can be used at a specified Internet-based mall.

A successful KM incentive program must, however, go beyond material rewards, and public recognition is a powerful form of motivation. KShop features a KCU Score Board that gives visibility to top knowledge sharers. Periodic Knowledge Summits are held to celebrate knowledge-sharing activities, and publicly recognize and reward leading knowledge sharers.

The Content Architecture

The content architecture specifies how knowledge assets are organized for ease of retrieval. Eighteen distinct content types have been identified, a few examples being white papers, case studies, FAQs and web site reviews. Experiential learning is encapsulated in the form of Body of Knowledge (BoK) documents, which constitute a key content type in the current architecture — BoK entries existing in the legacy BoK system have been migrated to the new architecture. The four-level knowledge hierarchy, initially developed in 1998-99 as described earlier, has been expanded and now contains just over 1,200 topics or subject areas — the explosive growth of Internet technologies alone has contributed over 300 topics. To facilitate easy retrieval, each document is tagged by one or

Figure 1. A partial few of the knowledge hierarchy, showing a subset of topics



more paths through this hierarchy. Thus, a white paper on the eXtensible Mark-up Language (XML) would be tagged by the path Technology>Internet/E-Commerce Technologies>XML. A graphical view of a section of the hierarchy is shown in Figure 1.

Associated with each document is a composite KCU rating, which factors in the KCUs awarded by subject matter experts to the document at the time of reviews, those awarded by users over the document's life cycle, and also the frequency and recency of its use. The composite KCU rating is thus a market-determined indicator of document quality.

Documents are also tagged by the audience role(s) for which they are most suitable, and by security parameters that limit access to a desired subset of the audience.

The Technology Architecture

The Infosys Knowledge Shop (KShop) (Figure 2) provides all of the basic functionality expected of a knowledge portal as well as several applications that are customized to suit the Infosys business processes. Each of the 18 distinct content types has its own home page, which describes the kind of knowledge represented by that content type, and displays the top ranking (by composite KCU rating) documents in the repository of that content type. An advanced search engine helps users find content by knowledge paths, keywords, content types or the other parameters by which content is tagged. Content retrieved is displayed in decreasing order of composite KCU rating — the system thus aims to assist the user in sifting through a possibly large number of documents that may meet the search criteria specified.

Figure 2. Homepage of knowledge shop, the Infosys knowledge portal

KShop, built entirely by the KM group's technology team, also includes basic features such as an on-line document submission facility, a review and publication workflow, several ways of showcasing new and popular content, threaded discussion forums and on-line chat rooms. KShop supports interfaces that allow users to award KCUs to authors while rating their documents, and for KCU account redemption. KShop also hosts the revamped People-Knowledge Map expert locator application.

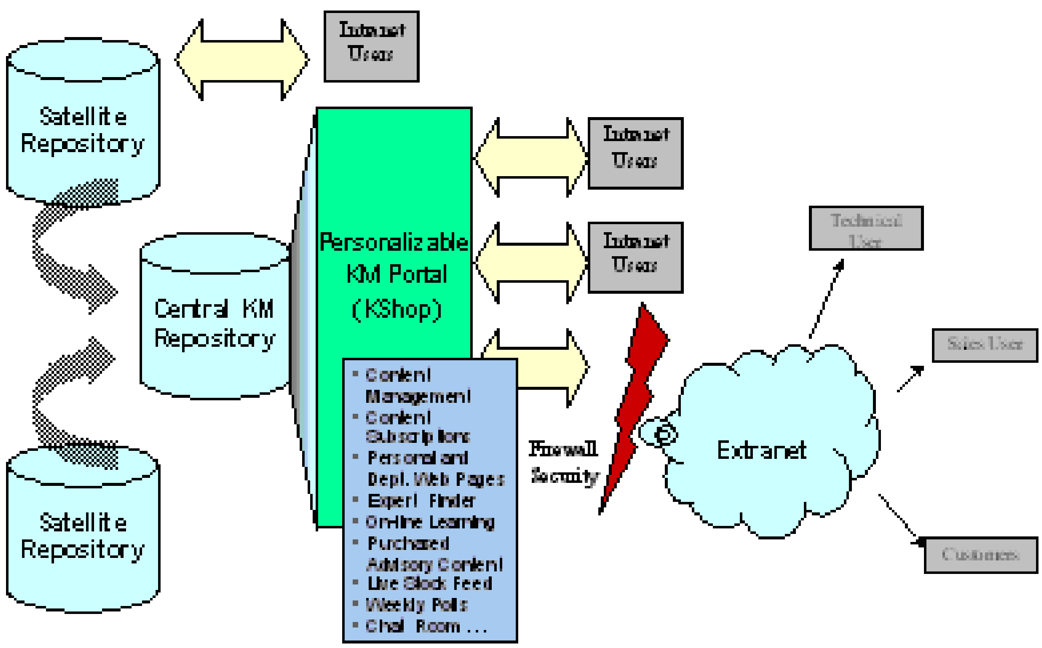
Several other incentives are offered for employees to use KShop on a daily basis. It provides live feeds of stock quotes and sports scores. Its homepage (Figure 2) can be personalized by each user to create their own myKShop, with a customized layout, sizes and colors. In addition, they can 'subscribe' to content by defining the content types and knowledge paths of their interest. Subscribers can see latest content additions that match their subscriptions when they visit the home page. They can also choose to be alerted to additions matching their subscriptions by e-mail at a frequency of their choice. The portal serves about 20,000 requests a day. Each access is also logged so that KM activity can be tracked by parameters such as location, practice unit, department or project.

KShop runs on five PCs, each of which acts as a server. Conventional wisdom has it that an enterprise-grade knowledge portal for a large company must run on high-end, "server class" machines running expensive software such as application servers. Our experience has thus shown that an effective and scalable technology infrastructure can be built for knowledge management without expensive hardware or special KM software products.

Satellite Repositories

The Technology architecture (Figure 3) distributes content storage and management by implementing locally managed content repositories that act

Figure 3. Technology architecture of knowledge shop



as satellites to the central KM repository. The rationale behind this satellite repository system is to permit specialized groups in the organization to own content relevant to their areas. However, the user interface is seamless — a search on KShop's home page retrieves content irrespective of whether it is located in the central repository, or on one of the satellites.

Back-End Data Integration

A variety of corporate data is drawn into the knowledge portal periodically by tight integration of its database with various corporate databases. Employee data, including contact information, location and current project assignment, are synchronized with the corporate HR database on a weekly basis. Data on encashment of KCUs (which are taxable perquisites!) are integrated with the payroll system so that appropriate taxes can be deducted.

The Process Architecture

The process architecture includes processes that are internal to the KM Group and which are used in the management of various KM functions, and those that are developed and deployed to facilitate KM in the field. The content management process comprises different stages such as review by identified internal experts, streamlining and editing, publishing, certification and maintenance. About 170 documents are submitted to KShop each month, and go through a two-tier review process — the first stage of review happens at the content editor's desk where conformance to usability, styling and IPR norms are checked. The second stage of review is done by subject matter experts, and checks for content quality, relevance and utility.

Other defined processes include those for publicity, branding, reporting and benefits measurement. Since the Infosys KM effort is relatively young, ensuring that outdated content is updated or removed is not yet a priority. However, a content maintenance process has been defined, and will use the KCU mechanism to identify documents that potentially qualify for revision or 'retirement.'

A key focus on the process front has been to minimize the overhead associated with creating content. Tweaking existing business processes to facilitate knowledge sharing, and automating certain types of content generation have been two solutions to this vexing problem. For example, 'project snapshots' are now generated 'on the fly' from existing databases containing project management and employee data, thus obviating the need for manual compilation of these snapshots.

In addition to its reward and recognition role, the KCU scheme also provides a mechanism for quantitative management of the KM processes. One aspect of quantitative management is the composite KCU rating mentioned earlier. KCUs are also used as metrics in the measurement of KM benefits and for measuring the level of KM activity in any organizational unit. The average rate of KCU generation is currently 8,000 per month.

EFFECTIVENESS AND BENEFITS OF KM AT INFOSYS

There are, in general, three forms of evidence that can be used in assessing the benefits of a KM program — anecdotal, survey-based and metrics-based. Evolving metrics-based methods to measure benefits is the most challenging — tracing business benefits attributable to knowledge-sharing, defining appropriate metrics, ensuring that the data required to compute the metrics is available, are some of the challenges involved.

In an internal survey based on a sample size of about 600, more than 99% of the respondents said that they believe KM is essential for the company; 79% said the knowledge-sharing environment in the company encouraged the documentation of knowledge for future use; 87% asserted that whenever possible, they tried to reuse existing organizational knowledge rather than start from scratch.

Content submission to the company's knowledge repository has increased nearly 10 fold since the transition from the BoK system to the organization-wide integrated KM implementation. A document is downloaded/viewed by users of KShop every two work minutes. The survey also revealed that users had received distinct benefits from the knowledge-sharing environment that is prevalent in the company:

- More than 80% believe that their team's quality of work and productivity have improved, while 70% said good knowledge-sharing practices had helped in delivering tangible benefit to customers.
- 73% felt they saved more than one person-day in the last six months by using the existing knowledge architecture, with 14% saying they saved more than eight person-days (and 13% saying they saved nothing). Three-quarters said that when needed, they were easily able to tap organizational knowledge in doing their work.

Our approach has been to measure in quantitative terms the impact of knowledge sharing on traditional indicators of project performance, using the KCU mechanism. Several projects have also been able to quantify savings in dollar terms, and also report various other benefits such as improved quality, faster turnaround times, etc. These projects are showcased during the periodic knowledge summits, thus allowing other projects to appreciate the relevance and potential benefits of knowledge sharing.

Up until the date of writing this, 185 employees have crossed the figure of 100 KCUs earned, with eight having crossed the figure of 1,000 (a measure of the vibrancy of the initiative is the fact that, during the time gap of two months between the two revisions of this chapter, the above figures went up from 102 and three, respectively!).

OTHER KM INITIATIVES AT INFOSYS

Apart from defining a greenfield architecture for managing knowledge, a successful KM strategy must usually also integrate existing knowledge-sharing mechanisms and collimate them so that they do not result in duplication or lack of visibility of effort. The satellite repository mechanism described earlier is an example of how the Infosys KM strategy has accommodated the need of groups that maintain specialized knowledge to continue to retain ownership of that knowledge. This section brings out illustrations of how the specific KM needs of a few other groups are addressed.

Infosys's Banking Business Unit (BBU), which provides software products and surround solutions to banks, has a knowledge base — "TechOnline," accessible from the internet home page, www.infosysinbanking.com — that serves to meet the reference needs of its customers, partners and employees at customer sites. This system is linked to the same database into which the global helpdesk logs calls and solutions, thus ensuring the solutions are current. Knowledge gained about the customer, product and deployment scenario is recorded and baselined in a version control system.

As a second example, an offshore development center within Infosys, dedicated to a large telecommunications client, has also developed a customized KM strategy. This center's client is acutely sensitive to intellectual property issues, and requires the center to be isolated from the rest of the Infosys network by a firewall — an artificial barrier to KM. This center thus uses a separate instance of KShop, tailored to its specific needs, which include a focus on the telecommunications domain and the use of local newsgroups.

Newsgroups have been found to be effective in supporting interaction with the client and Infosys communities, as well as between project members. The newsgroups, averaging about 40 posts a day, have contributed to the identification and growth of subject matter experts, reduction in bug-fix time and increase in productivity. Project processes have been tailored to include KM as a stated objective. This center has also included KM in its internal project reviews and performance appraisals.

ACHIEVING THOUGHT LEADERSHIP IN KM

The Infosys KM effort, featuring somewhat seminal aspects in concept as well as in implementation, has received its share of attention from practitioners and researchers worldwide. The KM architecture, the proprietary KMM model and Infosys's experiences in implementation have been published and presented at several academic and industrial events worldwide (see, for example, Kochikar, 2000b; Kochikar and Raghavan, 2000). There have also been several invited presentations and discussion sessions with several companies, including customers, with heartening feedback. The initiative also features in the curriculum at two business schools. An affirmation of Infosys's success on the knowledge-sharing front has been the fact that the company was featured as a finalist for the 2001 MAKE (Most Admired Knowledge Enterprises) awards (Chase, 2001). Infosys was among the 37 companies worldwide that qualified to reach the final round.

In addition to internal implementation, Infosys has also found considerable interest evinced by customers for possible KM services. A prototype of a productized KM solution has been built for a world-leading software product company. The customer has been quoted as saying that the decision to contract Infosys for this engagement came as a natural choice, after seeing the internal KM implementation at Infosys. Infosys has also carried out a KM implementation for a Fortune 250 Personal Computer manufacturing company, with a focus on managing their customer knowledge. The expected benefits of this system were retaining the customer for life, and creating the ability to conduct focused marketing campaigns to get higher return on each advertising dollar spent.

GETTING THERE — CREATING A SHARING CULTURE

Creating a culture of sharing is governed by principles that have much in common with Metcalfe's law — as more people grow convinced of the benefits of participating in the knowledge-sharing movement, it becomes easier to convince still more people to buy in. Thus, as long as steady progress is made on the road towards achieving greater sharing, the pace of adoption accelerates with time. Once a 'critical mass' of users has been reached, the movement reaches a take-off stage beyond which it becomes self-sustaining, without significant effort being devoted to publicity and promotion. Until this stage is reached, however, considerable effort needs to be focused on promoting the initiative. For this reason, the KM group has a full-time brand manager, whose mandate is to constantly promote KM with a view to pushing it higher on the agenda for every quarter of the organization. Over time, as the initiative matures, the brand manager's role is expected to evolve towards sustenance of the initiative. Similarly, as KM becomes part of the organizational fabric, we expect more of KM to happen as an integral part of a variety of roles across the organization, without needing additional staff dedicated to KM.

ACKNOWLEDGMENTS

The authors gratefully acknowledge the guidance and support received from Nandan Nilekani, Kris Gopalakrishnan and S. Yegneshwar in making the Infosys KM initiative a reality. None of the work described here would have happened without the able work put in by the KM team — K. R. Shyamprasad, V. Mahesh, B. Padma, S. Veena and R. Einith. We also acknowledge M. Haragopal, K. Kavitha, G. Lakshmanan and Ashish Goal for the matter included in the section titled, "Other KM Initiatives."

Chapter 5.7
The Readiness of IDSC to Adopt Knowledge Management

Ahmed Abdel Kader Hussein
Maastricht School of Management, MSM, The Netherlands

Khaled Wahba
Cairo University, Egypt

ABSTRACT

Over the last two years Knowledge Management has become the latest hot topic in the business world. Companies are realizing that their competitive edge is mostly the brain power or intellectual capital of their employees and management. Many organizations are drowning in information, but starving for knowledge. In order to stay ahead of the pack, organizations must leverage their knowledge internally and externally to survive. Knowledge management is believed to be the current savior of organizations. Creative and innovative people form the core of any organization. In turn, those people form the corporate memory. The Information Decision Support Center for the Cabinet of Ministers for the Egyptian Government (IDSC) faces a problem of employees' high turnover rate (17%), which threatens to cause IDSC to lose its memory. One common mistake many organizations make when they implement KM initiatives is to place too much emphasis on the technological aspect of KM and ignore the human resources aspects. IDSC developed a knowledge management system called the Organizational Memory (http://www.home.idsc.gov.eg/), but ignored the human factor of KM. The purpose of this chapter is to test the readiness of employees and managers working at IDSC to adopt knowledge management. Human issues were clearly shown to outweigh any technology constraints, and views of managers and employees differed to some extent. It is recommended that these human and managerial concerns be addressed if KM is to be successful in organizations.

INTRODUCTION

Background

A study conducted by KPMG consulting (2000) on 500 companies in USA and UK reveals that 81% of the respondents said they had or were considering a KM Program; 38% had a KM program in place; 30% were currently setting one up; and 13% were examining the need for a KM program.

This chapter focuses on various human issues with regard to KM in the Egyptian Cabinet Information and Decision Support Center (IDSC). These issues are often overlooked and their importance underestimated, and attention needs to be paid to these human aspects so that IDSC can effectively achieve the benefits of KM.

Problem Definition

Creative and innovative people form the core of any organization. In turn, those people form the corporate memory. IDSC faces a problem of employees' high turn-over rate (17%) which threatens IDSC with losing its memory. One common mistake many organizations make when they implement KM initiatives is to place too much emphasis on the technological aspect of KM and to ignore the human resources aspects. IDSC developed a knowledge management system called the Organizational Memory (http://www.home.idsc.gov.eg/), but ignored the human factor of KM .The purpose of this study was to test the readiness of employees and managers working in IDSC to adopt knowledge management by focusing on the various human aspects related to knowledge management.

Research Questions

In order to determine the human factors influencing the development of a successful KM program in IDSC, the research, therefore, focused on questions such as:

- Was IDSC ready to adopt a knowledge management program?
- Are employees and managers working at IDSC ready to be part of a knowledge management program?
- What was the knowledge management environment in IDSC?

And additionally:

- What were the employee perceptions of sharing knowledge?
- What were the impediments to sharing knowledge in IDSC?
- Was privacy of employee information an issue in IDSC?
- What were the difficulties in managing knowledge in IDSC?
- Did IDSC maintain innovation and creativity in its problem solving approaches given the availability of the knowledge base?
- Did conflict arise between an employee's career ambitions and the knowledge management culture of the organization?

Research Methodology

Collected data is the heart of the study. There are many sources of data such as interviews, meetings, etc. Other important sources of information are theory and personal experience. In order to determine the human factors influencing the development of a successful KM program in IDSC, we developed two questionnaires, one aimed at the senior and middle managers in the IDSC and the other aimed at lower ranking employees. Questions were adapted from previous research on KM conducted by Jordan and Jones (1997) amongst others.

The sample was restricted to managers and employees who have spent more than two years working in IDSC and have direct or indirect relation to the success or failure of the KM program. The sample size was 40 employees and 20 managers.

Assumptions and Limitations

Assumptions

This study assumed that there was stability in the organization structure, no management change, cultural stability and no major technology change.

Limitations

However, there were a number of limitations. The number of participants was relatively small. The survey also relied on self-reported responses, and as such is subject to limitations of all such surveys. IDSC can also not be considered to be representative of all market sectors in Egypt. These limitations should be taken into account when considering the findings of this research.

KNOWLEDGE AND KNOWLEDGE MANAGEMENT

What is Knowledge?

The word knowledge can, at a first glance, seem easy to define, but a literature search would seem to indicate otherwise. It defines some abstract material, which we cannot see. We try out apparent synonyms, like information, data or competence, but this does not give us the truth. Discussions of knowledge are becoming increasingly important the more it is recognized that a company's future is largely dependent on its ability to handle this intangible asset. A common element in the discussion and definition of knowledge is that knowledge basically takes two forms, tacit and explicit knowledge.

- Tacit Knowledge: is seen as being subjective, practical, and analog. It is highly personal, hard to formalize and, therefore, difficult to communicate to others. It is deeply rooted in action and in an individual's commitment to a specific context - a craft or profession, a particular technology or product market, or the activities of a work group or team.
- Explicit Knowledge: is seen as being objective, theoretical, and digital. Explicit knowledge is formal and systematic and can therefore be easily communicated and shared, in product specifications or a scientific formula or a computer program (Nonaka & Takeuchi 1995).

A detail that we question in this definition is that explicit knowledge would, by definition, be objective. Is a subjective thought put on paper an objective truth? No! But the words can also have a different meaning. Tacit knowledge is part of a person, a subject, while explicit knowledge exists as an object, a visible form. Sveiby (1997) seems to agree with Nonaka and Takeuchi's definitions, but he gets there in an awkward and sometimes contradictory way. Sveiby reasons that knowledge has four characteristics:

- Knowledge is tacit;
- Knowledge is action-oriented;
- Knowledge is supported by rules;
- Knowledge is constantly changing.

The first characteristic suggests that explicit knowledge is not knowledge. This characteristic derives from a view that knowledge, in a strict sense, cannot exist outside an individual. Some knowledge can be formalized, made explicit, but then it becomes static, whereby it loses another of

Sveiby's characteristics. This means that knowledge that has been made explicit/static must be interpreted and mixed with personal knowledge in order to make it true knowledge again.

Sveiby also splits knowledge along another dimension; he separates know-how from know-what. Know-how is closely related to tacit knowledge. Know-what is closely related to explicit knowledge because it can easily be put on paper. Both are important for the ability to act. It would seem that all knowledge has a dimension of tacitness and is, therefore, difficult to explain in words. Knowledge is also action-oriented through the way we generate new knowledge by analyzing the sensory impressions we receive and because we are constantly losing knowledge. This dynamic quality of knowledge is reflected in verbs like learn, forget, remember, and understand. There are also rules for conscious and unconscious processing of knowledge. These rules help us to act and save us a lot of energy when we do not need to think before we act. The knowledge is, also, constantly changing, but when tacit knowledge is made explicit through language, it becomes static.

Data, Information, and Knowledge

Earl and Scott (1998) characterize knowledge as the final product in a chain where data combined with other data and a context transforms into information; information together with experiences and already known knowledge make up knowledge; see Figure 1.

Theorists do not think that the model can be dismissed that easily. In the light of static knowledge not being "real" knowledge that needs human processing to form "real" knowledge, reminds us of Earl and Scott's model. Additionally, data, and perhaps information, is the only thing we can actually store in computers. The process should also be viewed in reverse. The way it is presented by Earl and Scott, it gives the impression that we should gather as much data as possible in order to transform it to knowledge. A knowledge manager would be at least as interested in the opposite direction. He would want to identify valuable knowledge and then look for the information needed to build that knowledge; and in the end, what data he needs to build the information.

Knowledge Hierarchy

The Knowledge Pyramid

Theorists and practitioners of knowledge management often open the what – is-knowledge discussion with the knowledge pyramid , which portrays the world of knowledge as rising from raw transaction data at the bottom to wisdom

Figure 1. Data, information and knowledge (Earl & Scott,1998)

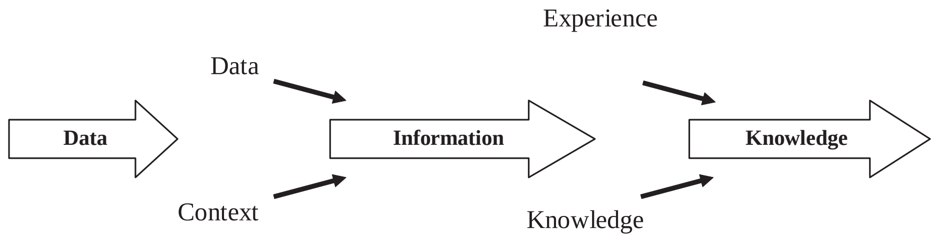

Figure 2. Knowledge pyramid (Alan, Raddund,1998)

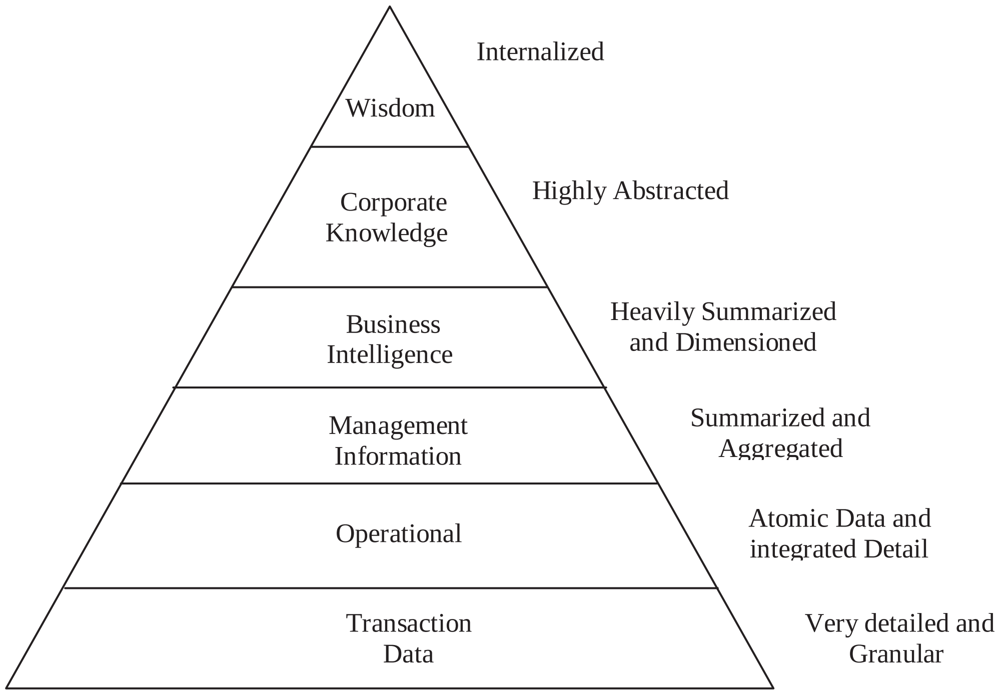

at the top. Some disagreements exists among various parties about specific details, but general consensus has been reached concerning the overall thrust and composition of the knowledge pyramid (see Figure 2).

- Raw transaction data and tacit data are the bottom of the knowledge pyramid. Transaction data is recorded in databases and other data stores and used in a variety of ways.
- Operational data reflects complete, integrated transactions, referred to as atomic detail.
- At the management information level, more significant changes occur. This level contains lightly summarized data that has been grouped, stored, filtered or organized to reveal a context.

Information usually takes the form of aggregated numbers, words, and full statements. It often combines the numbers and statements in a summarized form that conveys a meaning that is greater than any revealed by the raw data alone. Knowledge theorists and practitioners agree, however, that knowledge and information are unclear, and several differentiate between the two (see Table 1).

- Continuing up the knowledge hierarchy, highly summarized information, which many refer to as business intelligence. Busi-

Table 1. Attributes of data, information, and knowledge

Attribute	Data	Information	Knowledge
Level of Detail	• Low level of detail • Atomic detail	Integrated, aggregated detail	• Highly abstracted • Detail removed
Context	No context	Full context	Extended context
Scope	Very narrow scope	Scope limited to the particular context	Extends beyond the scope of the information
Timelines	No timelines	Limited timelines	Timeless

ness intelligence results when data and information are heavily processed, organized, filtered, selected, correlated, and analyzed extensively.

- Further summarization of the initial information leads to knowledge. Knowledge, in this case, can be described as insights derived from the information and data that can be acted upon and shared in a variety of ways and circumstances.
- Finally, at the top of the knowledge pyramid is wisdom. Wisdom appears to be the most abstract and timeless of knowledge.

Knowledge Management

The purposes and tasks for knowledge management must be clarified and defined in order to suggest proper measures for knowledge management.

A Definition of Knowledge Management

Knowledge Management (KM) has had a pervasive presence in recent research and is well recognized as a possible contributor to organizational success and a determinant of sustained competitive advantage. Organizations have embraced KM as a primary focus area, recognizing intellectual capital as an asset that can be leveraged to create value for stakeholders.

Gartner Group (1998) defined Knowledge Management as: "Knowledge Management promotes an integrated approach to identifying, capturing, retrieving, sharing and evaluating an enterprise's information assets. These information assets may include databases, documents, policies, procedures, as well as the un-captured tacit expertise and experience stored in individual heads."

KPMG consultants (2000) define KM as "The systematic and organized attempt to use knowledge within an organization to improve performance." Malhotra (2000) offers the following definition of KM : "KM caters to the critical issues of organizational adaptation, survival, and competence in the face of increasingly discontinuous environmental change. Essentially, it embodies organizational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings."

The Components of Knowledge Management

The components of knowledge each support the other, but one does not depend on the other. An individual may very well protect his knowledge, but without sharing it with others or without using past experience when faced with similar problems.

Knowledge may be captured and shared without anyone ever taking advantage of it. An individual may recycle his personal knowledge in similar situations without sharing it with others.

It is, hence, important to be aware of all of them in order to achieve maximum benefit from Knowledge Management.

Identify Valuable Knowledge

To quote Stewart (1997), "In the new economy, the scarce resource is ignorance." This may seem like a contradiction, but it is very important. Because we collect too much knowledge and information, both personal and corporate, the less important overshadows and hides what is important. We share too much knowledge just-in-case, and too little just-in-time. Today we have so many information systems that provide us with information and knowledge that people get overloaded. It is important to stress that the selection of what knowledge to handle in the KM-Process is a critical success factor and very important to analyze. It must then be presented in a way so as to attract the attention of the person who needs it.

It is, hence, important for Knowledge Management to identify both what knowledge is needed and what ignorance can be accepted. This last point is so important that we grant it its own place in the definition of Knowledge Management. When businesses use a lot of effort and investments to implement Knowledge Management, little or no benefits will derive if the company handles knowledge that is unimportant to the business's activities.

Capture Knowledge

One aspect of Knowledge Management, stressed by some authors including Stewart (1997) - is that the knowledge that is captured in the Structural Capital and, therefore, belongs to the company, is most valuable. These assets - company processes, cook-book solutions, information systems, and computer programs do not leave the office at five o'clock.

One of Knowledge Management's tasks is to capture the individuals' knowledge in a form that is stable explicit knowledge. This makes it more valuable in two senses:

- It makes the company less dependent on the individual (reduced risk),
- and the knowledge can be distributed electronically (made available to the whole organization, independent of time and space).

This is under the condition that the captured knowledge is put to use by someone. Value is only created when the knowledge is used. It is not certain that Structural Capital will be used the most and, thereby, generate the most value. Hence, the Human Capital may still be the most valuable.

Davenport and Prusak (1998) try to differentiate when an organization should capture its knowledge in structural capital and when it is not worth the effort. They argue that small companies (less than 300 employees) have little or no need of capturing knowledge into the Structural Capital. Instead, they should concentrate their efforts on sharing information about who knows what. In a large organization, such as IDSC, the potential gains from mass distribution make the cost of capturing worthwhile.

This also brings us to a more general task for Knowledge Management in connection to sharing, protecting and recycling: "Knowledge Management should connect people to data and it should do this on a just-in-time basis" (Stewart, 1997), not just-in-case.

Create Knowledge – Innovate

Particularly, there are two different views of how knowledge is created. The first is a linear view, building on the view that knowledge is the last step in a refining process of data; data is refined to information, which in turn is refined to knowledge. Nonaka and Takeuchi (1995) criticize this (as they see it, western) view of knowledge creating as an information processing activity. Instead they suggest that it is the interaction and communication of tacit and explicit knowledge that creates new knowledge and innovation. It is through socialization, externalization, combination and internalization that we will create new knowledge and change already existing knowledge. This knowledge spiral will support and catalyze innovation and knowledge creation.

Share and Reuse Knowledge

With Sveiby's (1997) knowledge view in mind, there are two ways of information sharing: through tradition and through information.

By tradition is meant a person-to-person transfer, where I watch you and learn by imitating. Nonaka and Takeuchi would call this a tacit to tacit transfer, or socialization. Through information, knowledge can be transferred with the use of other media, such as paper, drawing, database, etc., i.e., the knowledge is transferred via externalization (combination) and internalization.

If true knowledge can only exist in an individual, this means that knowledge that has been captured in some kind of explicit form - instruction or case description - must be made alive in a person. This is accomplished through interpretation, reflection, testing and mixing with personal experience and knowledge already in the individual's possession. It is a process that takes time and effort.

Both tradition and information have their respective pros and cons. Information has the advantage that it can be mass distributed independently of time and place. The process of making knowledge explicit, and making explicit knowledge tacit, are time consuming processes and much of the knowledge is lost in the process. This can be compensated for by the large potential for sharing. Tradition is the only way to transfer many types of knowledge. On the negative side, its effects are very limited by time and space even if some new technologies, such as video-conferencing, may compensate for some of its limitations.

Reduce Risk

By reducing risk is meant to avoid the loss of important knowledge or experiences. One way of accomplishing this is by capturing the knowledge in an explicit form. Another way is by sharing it with others, thereby also sharing the responsibility of protecting the knowledge. In this second way, reduced risk is achieved through sharing and recycling knowledge.

A negative effect of Knowledge Management is an increased risk of knowledge theft. When tacit knowledge is captured in digital format, it is easier to copy the knowledge and spread it to competitors.

Create Value

To justify Knowledge Management, it must add value or cut costs. Knowledge Management creates value of various kinds. Davenport and Prusak (1998), Stewart (1997), and Nonaka and Takeuchi (1995) echo many of the same values when talking about how Knowledge Management creates value. They argue that Knowledge Management will enable a more efficient way of working and generate revenue in the form of higher productivity and efficiency. With Knowledge management, the employees' motivation when they have access to others knowledge will improve their ability to act, as well as their personal learning.

Values in financial terms can also be distinguished through growth in shareholder value, and lower costs when Knowledge Management enables sharing of knowledge to more people and results in higher quality of delivered products and services. The most important common argument for Knowledge Management is that knowledge is the only source of sustained competitive advantage.

Stewart (1997) argues that when capturing knowledge into Structural Capital, it shortens the lead time between learning and knowledge sharing. Hence, the employees can share the knowledge quicker. Nonaka and Takeuchi (1995) hold that through Knowledge Management, improved innovation rather than higher efficiency is to be expected.

Knowledge Management (KM) Systems

Knowledge management (KM) systems are designed to gather, store and retrieve/disseminate information. These three basic functions are then complemented by incentive structures to ensure that the system is fully exploited.

Establishing the basic requirements of a KM system is fairly straightforward, We are involved in the:

- Gathering of information – to gather information, the company needs to establish procedures for documentation of projects, findings, and so on. The procedures should include how to document the information and how to control the relevance and quality of the selected material. It is important to avoid nonessential information. The main feature should be ease of use.
- Storage of information – storage should be in a database with easy access from all organizational levels.
- Retrieval of information – the system should also be able to compile data according to user needs and preferences. The structure of the database - the number of retrieval dimensions – depends on intended use.

Having established the KM market structure, implementation is not simply a question of employing a suitable IT solution. The challenge is to encourage people to come to market with their information.

Focus on Behavior, not Technology

One common mistake many organizations make when they design KM systems is to place too much emphasis on the technological aspects of the system. Knowledge is primarily a personal and social commodity and should be treated accordingly. The social aspects of knowledge sharing are crucial to the system's success. In order to make the system work it is important that it is easy to use and provides sample opportunities and incentives for personal interactions. This is particularly important for complex and contextual information that is best conveyed person-to-person.

Incentive Systems

Information has a price. It takes time to produce it and to find and consume it. It is, therefore, important to establish an incentive system that rewards knowledge sharing. Usually, employees are rewarded neither for sharing information, nor for searching for it. This lowers the motivation to use the KM system. It is thus extremely important to compensate employees for their work with the KM system, by perhaps providing extra time for them to document their work or by giving a bonus based on their diligence in recording their work.

Challenges Facing Knowledge Management

KPMG Consulting (2000) gave the following reasons for KM failing to meet expectations: lack of user uptake owing to insufficient communication, failure to integrate KM into everyday working practices, lack of time to learn how to use the system, a perception that the system was too complicated, lack of training, and a sense that there was little benefit in it for the user. Suggestions for successfully implementing KM projects also included: focusing on a department or group and building on that success; revamping the incentive system to reward information-sharing behavior (publishers of knowledge), and allocating a specific person(s) to the function of KM (Davenport, 1997; Kowalkowski, Angus, 1998).

Qualitative Research – Exploratory Research

Objectives

The research aimed at testing the readiness of IDSC's people to adopt knowledge management.

Design

The research design is the logical plan for how the study is conducted. It tells us how we got from here to there, where here may be defined as the initial set of questions to be answered, and there is some set of conclusions (answers) about these questions (Yin, 1994).

It is a logical model of proof that allows the researcher to draw inferences concerning causal relations among the variables under investigation. The research design also defines the domain of generalizability, that is, whether the obtained interpretations can be generalized to a larger population or to different situations (Yin, 1994). Also, the research design is the key to validity and reliability.

Two methods were used in the exploratory research:

- Surveys;
- In-depth Interviews.

Surveys

Two questionnaires were developed: one aimed at the senior manager in the IDSC and another aimed at lower ranking employees. The questionnaire aimed at testing the readiness of IDSC's people to adopt knowledge management. The questionnaire covered items such as:

- knowledge acquisition (do employees look for knowledge from internal or external sources, and is knowledge acquired deliberately or opportunistically?).
- ownership (do the employees generally regard their knowledge as highly personal or as being owned at the collective level?).
- memory (is knowledge chiefly held explicitly or tacitly?).
- challenges in implementing KM and in managing knowledge, and how IDSC encourages employees to share, contribute and reuse knowledge.

The employee questionnaire had some similar sections, but also covered areas on sharing of knowledge and barriers, impact on creativity, incentives, and privacy issues. The findings of these questionnaires helped in answering the major and minor research questions.

In-depth Interviews

The in-depth interviews were with the IDSC senior managers in order to assess the current knowledge management environment in IDSC and impediments facing managers in sharing knowledge. The interviews lasted around one hour and were conducted while the managers were filling out the questionnaire.

Defining the Population

IDSC consists of three branches located in three different buildings. There are 600 employees and managers in IDSC, 300 of them are working in support departments (as drivers, security, office boys, etc.). Those 300 were excluded; the other 300 was the survey population.

The sample consisted of 40 employees who spent more than one year in IDSC and 20 middle and senior managers.

About IDSC

The Information and Decision Support Center (IDSC) was initiated to support the Egyptian Cabinet's decision-making process in socio-economic development. It also acts as a catalyst for building Egypt's information infrastructure. Ever since its initiation in 1985, IDSC has been working on the process of building up Egypt's Information Technology (IT) industry and decision-support infrastructure, in addition to developing a base for the nation's software and hi-tech industries.

IDSC evolved around Egypt's dedicated efforts to join the international IT revolution, and institutionalize the decision-making process through accessing information. IDSC was also established with the long-term vision of providing public access to information, particularly business people and investors.

Over the past one and a half decades, the Center has successfully achieved its basic goals of setting up an information core for the Cabinet's decision-making process, and has also created channels for the local and international flow of information.

IDSC Objectives

- Developing information and decision-support systems for the Cabinet and top policy makers in Egypt.
- Supporting the establishment of end-user information and decision-support centers in the different ministries and governorates.
- Encouraging, supporting and initiating informatics projects that will accelerate Egypt's management and technological development.
- Participating in international cooperation programs and agreements, particularly in the areas of information and decision support.

The Organizational Memory

Some months ago, IDSC decided to build an online organizational memory (http:/ /www.home.idsc.gov.eg/) which is a part of a knowledge management initiative in IDSC. The main reason for this initiative was the high employee turnover of experienced staff which threatened the loss of IDSC's human memory .

The main objectives of this organizational memory were to:

- Prevent Knowledge Loss – It enabled IDSC to retain critical expertise and prevent critical knowledge loss resulting from retirement, downsizing.
- Improve Decision-Making – It identified the type and quality of knowledge required for effective decisions and facilitates access to that knowledge.
- Permit Adaptability and Flexibility – It allowed employees to develop a better grasp of their work, propose innovation solutions, work with less direct supervision.
- Provide Competitive Advantage – It increased the competitive advantage of IDSC.
- Develop Assets – It improved the organization's ability to capitalize on legal protection for intellectual property.
- Leverage Investment in Human Capital – Provided through the ability to share lessons learned, document processes, and the handling of exceptions, and capture and transmit tacit knowledge.

THE QUESTIONNAIRE

Part 1: Personal Information

The questions in this part were designed to get general information about the respondent.

Part 2: Questions Concerning the Methods Used by Staff to Acquire Information in IDSC

Questions in this part were each designed to:

- Discover whether the respondents had an overview of the knowledge available in IDSC or not.
- Measure a specific part of the knowledge management definition: identification, capturing, retrieval, sharing and evaluating. The aim was to identify weaknesses and strengths.
- Show how well the external and internal contacts and sources of information were used to spread and gather knowledge.
- Identify IDSC efforts to encourage the capturing and sharing of knowledge.

Part 3: Questions Concerning Knowledge Management in IDSC

- The first two questions in this part were each designed to measure if the IDSC employees understand what is knowledge management and what is the purpose of knowledge management.
- The third question in this part was designed to measure the degree of knowledge sharing between employees in IDSC.
- The fourth question in this part was designed to measure the degree to which tacit knowledge is shared between employees in IDSC.
- The fifth question in this part was designed to identify the barriers to sharing knowledge in IDSC. Employees and managers were asked to rank these barriers in a descending order, from the most important barrier to the least important one.
- The sixth and seventh questions in this part were designed to assess the impact of knowledge management and the availability of a knowledge base on creativity.
- The last three questions in this part were concerned with the privacy issues regarding knowledge sharing and the relation between competitiveness and knowledge sharing from the employee and manager point of view.
- In Part 3 two questions were added to the manager's questionnaire. The first question (question number 16) asked managers to rank difficulties facing them in the management of knowledge, the second question (question 17) asked managers to rank the impediments to knowledge transfer in IDSC.

ANALYSIS

The response rate was 100%, as the authors accompanied the respondent until he/she finished the questionnaire.

Analysis of Part 1

This part tried to find groups of respondents with different or common result profiles (see Table 2).

Analysis of Part 2

Questions in Part 2 concerned the methods used by employees to acquire information in IDSC (see Table 3).

Table 2

Name	31% of the respondents mentioned there names.
sex	62% of the respondents were females.
Group of age	60% of the respondents were under 30, 30% were under 45, 10% were under 60.
Job title	60% of the respondents are technicians(programmers, Web developers), 30% are researcher, 4% are executives, 5 % are head of department, 6% are managers, 1% were general managers.

Table 3. Questions concerning methods used by employees and managers to acquire information in IDSC

Which external sources do you use to obtain information ?	
Internet	90%
Universities	10%
Research institutes	6%
Testing institutes	3%
Other (governmental agencies)	60%
What kind of media do you use predominantly to obtain information?	
Telephone	80%
Facsimile	13%
E-mail	94%
Internet	90%
Intranet	14%
Magazines/Catalogues	4%
Professional literature	11%
Other	-
What additional private efforts do you undertake to obtain personal information benefits ?	
None	30%
Further education and training in my leisure time	55%
Private relation ships	9%
Private research work	20%
Magazines	5%
Others	-
What Kind of information do you need in your work ?	
Technical	40%
Commercial	50%
Product information	8%
Information about other companies	2%
Information about clients	5%
Latest news	18%
Others	6%

Do you have an overview on the knowledge available in IDSC?

This question was designed to test whether employees and managers had an overview of the knowledge available in IDSC as the more they were aware of what knowledge exists in IDSC the higher the chance of sharing knowledge and using knowledge-based and organizational memory.

44% of the respondents proved to have a good general overview of the knowledge available in IDSC; they were mainly managers, heads of departments and team leaders. 36% of the respondents proved to have a good general overview in their field of activities mostly researchers and technicians. The remaining 20% which do not have an overview of the knowledge available in IDSC were executives and technicians (see Figure 3).

How do you start to solve a problem?

This question were designed to test how managers and employees start to solve a problem, with the answer giving us a chance to see how much they depend on know-how available from previous projects which increase the importance of knowledge management as a tool to create organization memory and give IDSC the ability to become learning organization.

59% of respondents started solving a problem by using know-how from previous projects, 21% by telephone inquiries, 14% would establish a team and 7% would delegate the problem to others.

The next four questions were designed to show how well external and internal contacts and sources of information are used to spread and gather knowledge in IDSC and what kind of information they need. Employees and managers were able to choose more than one item.

It is obvious that the Internet and governmental agencies were the main source of information used by employees and managers. Internet, mail, and telephone were the main media used to obtain information. Technical and commercial information was the main kind of information obtained by employees and managers in IDSC.

Figure 3. Staff overview of the knowledge available in IDSC

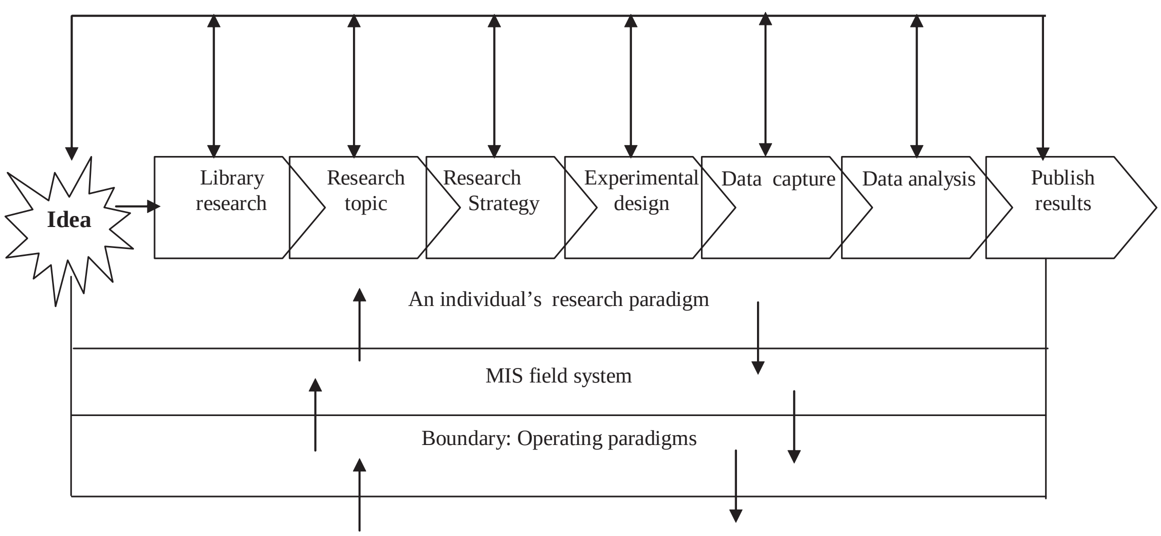

Figure 4. Information exchange occasions in IDSC

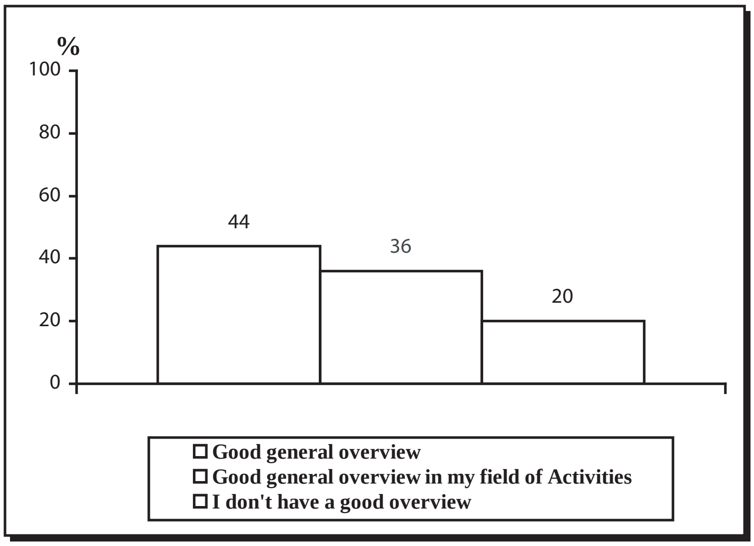

Figure 5. Information exchange among staff in IDSC

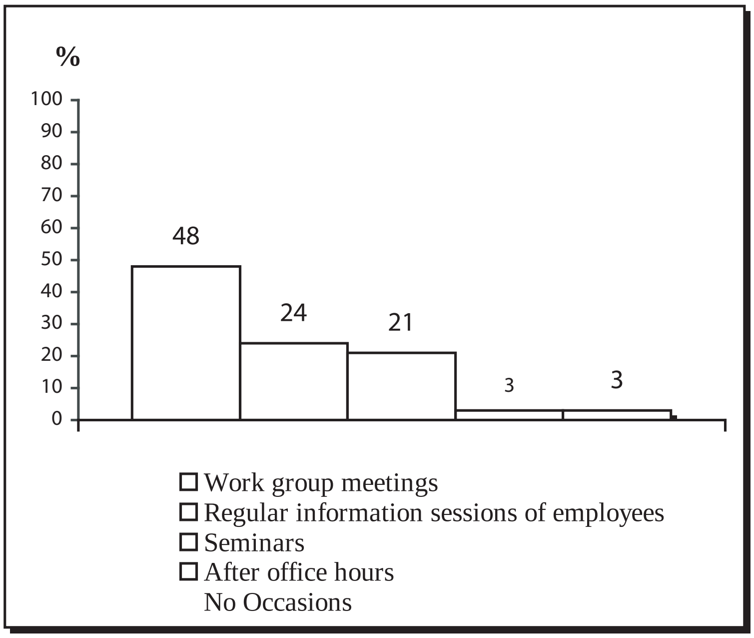


What occasions exist for an exchange of information in IDSC?

This question was designed to identify on what occasions employees and managers share information. Also, there was a weekly meeting for the whole IDSC and every employee can attend the meeting, but only 24% of employees said that it was a useful meeting. 48% of employees said the work group meeting was the most useful occasion to share information in IDSC (see Figure 4).

How does information exchange take place between older experienced employees and younger employees?

This question was developed to investigate whether the tacit knowledge was transferred from managers and experienced employees to new ones and how it was transferred. 54% of the respondents revealed that there was no regular exchange of information, 46% revealed that there was a regular exchange of information through mixed project teams (40%), individual training (4%) and (2%) other ways, like personal contacts inside IDSC (see Figure 5).

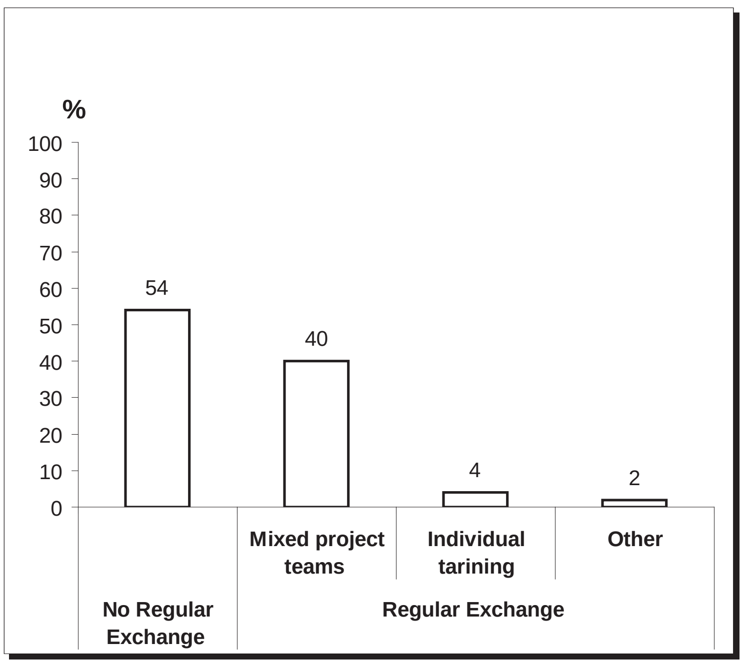
Analysis of Part 3 (Employees Questionnaire)

Questions in Part 3 concern the knowledge management environment in IDSC.

Do you have a general overview of what knowledge management is about?

Even though the IDSC has a KM system in place, 74% of respondents did not have a general overview of what KM is about. This shows that the IDSC management created the Organizational memory system to preserve, share and retrieve information and knowledge without taking into

Figure 6. Staff perception about purpose of knowledge management



consideration the necessity of increasing KM awareness among employees.

What do you think should be the purpose of knowledge management?

Figure 6 shows that 14% of employees and managers who had a general overview on knowledge management thought that the main purpose of KM was knowledge transfer ,10% thought the main purpose of KM was to avoid repetition of mistakes, and 2% think it was for time saving.

Employee Perceptions on Sharing Knowledge

Table 4 shows that 30% of employees in the survey shared knowledge "often" or "always" and 70% "occasionally." Despite this, 28% of the employees felt that it was common or very common for key information to be too localized, creating problems of access.

Employee Barriers to Sharing Knowledge

Employees were asked to rate a list of potential barriers or obstacles to knowledge sharing in their organizations. They were allowed to add any other items to the list (see Table 5).

In the literature, items such as "turf protection" and "people scared that their ideas will get hijacked" were sometimes given as high barriers to knowledge sharing. These research findings indicate that these barriers were ranked second and third respectively.

Table 4. Employee perceptions of sharing of knowledge

How well do employees share data, information and knowledge?	**Do Not**	**Poorly**	**Occasionally**	**Often**	**Always**
	0%	0%	70%	20%	10%
How often is essential Know how available only in the heads of a few employees, (and difficult to access when they are unavailable?	**Very Rare**	**Rare**	**Occasional**	**Common**	**Very Common**
	0%	12%	60%	20%	8%

Table 5. Employee barriers of sharing of knowledge

Average Ranking	***Employee Barriers to Sharing Knowledge***
1	Strong departmental barriers
2	"Turf protection" knowledge is power
3	People scared that their ideas will get hijacked
4	Lack of communication
5	Culture of working alone in closed offices
6	Expert knowledge in the heads of individuals
7	Distrust in other colleagues data
8	Personal data stores are common
9	Organizational rigidity and specialization- lack of multi-skilling
10	Rapidly changing technology- makes keeping up difficult

There was a lot of personal information kept by individuals (often only in their heads) which was not being shared, and there was not enough communication.

Employee Privacy Issues

Some 20% of the employees indicated that they felt compelled to share knowledge with their colleagues because of the knowledge sharing environment at IDSC. They were asked if they felt that privacy was a concern when it came to sharing knowledge. Although most were satisfied, 30% indicated that their privacy was invaded during the process of sharing knowledge. This percentage increased to 90% when personal work documents and e-mails were specifically included. 74% of the employees felt that their sharing of knowledge decreased their competitiveness with other colleagues for promotion. Table 6 shows a summary of the results in this area of research.

Difficulties in Managing Knowledge

Senior and middle managers were asked to rate a set of items which from past research had been shown to cause difficulties in managing knowledge in organizations. Their responses highlight the uncertainty experienced by many organizations with KM. Identifying the right leader/team

Table 6. Summary of employee opinions on privacy issues

Employee Privacy Issues	***Yes***	***No***
Do you feel that privacy of employees is an issue concerning the sharing of knowledge?	30%	70%
Does sharing of knowledge in your job situation decrease your competitiveness with other colleagues for promotions?	74%	26%
The knowledge gathering process may require reviewing your personal work documents and / or emails so as to add information to the knowledge repository. Do you feel this invades your privacy?	90%	10%
Do you feel compelled to share your ideas with colleagues because of the knowledge sharing culture at your firm?	20%	80%

Table 7. Difficulties in managing knowledge in IDSC

Rank	***Managers' Difficulties in Managing Knowledge***
1	Identifying the right leader/team for knowledge initiatives .
2	Attracting and retaining talented people
3	Determining what knowledge should be managed
4	Defining standard processes for knowledge work
5	Changing people's behavior
6	Mapping the organization's existing knowledge
7	Expert knowledge in the heads of individuals

Table 8. Management viewpoint on impediments to knowledge transfer

Rank	***Impediments to Knowledge Transfer***
1	Organizational culture
2	Staff turnover
3	Non-standardized process
4	Incentive system
5	Lack of ownership of the problem
6	Resistance to cultural change
7	Configuration /physical feature of workspace
8	Information/communication technology restraints

for knowledge initiatives, what knowledge should be managed, attracting and retaining the right staff, measurements and standards were added as further problems. And a major concern was the necessity of changing people's behavior. Noticeably "overcoming technical limitations" is last of the 10 items. This shows that IDSC was less concerned about the technical issues than the human and managerial ones. Table 7 gives an ordered listing of the managers' biggest difficulties in managing knowledge.

Management Viewpoint on Knowledge Transfer

Senior knowledge management personnel were given a list of impediments to knowledge transfer, based on prior research, and asked to rate them. Table 8 shows that they ranked organizational structural changes and staff turnover as the key impediments to knowledge transfer. Other management issues were also important, but technology concerns only came in eighth.

CONCLUSION AND RECOMMENDATIONS

Employees in IDSC acknowledge change management efforts to date, but do not feel that they are actively resisting the process of knowledge sharing. They are concerned about losing power they may have through sharing knowledge, and think that this will affect their competitiveness and promotion possibilities. They also perceive that the available knowledge base will aid creativity and productivity. They perceive that the major barriers to sharing knowledge are departmental barriers, expert knowledge often being held in the minds of individuals and lack of communication. Invasion of privacy is particularly an issue with them, especially when personal e-mails and documents are expected to be reviewed for possible addition to the knowledge base. Rapidly changing technology was their tenth rated concern.

A successful KM implementation clearly requires a culture of sharing, and a focus on human beings more than technologies and tools. This research has confirmed this. IDSC is not ready to implement a successful KM program.

There is a need to communicate the role of KM in the IDSC more fully to employees. Job descriptions and performance reviews should take into account the efforts made by employees in this regard. IDSC needs a strong incentive and reward system to encourage employees to share knowledge and to help in building the culture of sharing knowledge. Departmental barriers must be eliminated by forming cross functional teams to foster an environment where employees could walk into anyone's office to seek help. In addition, individual career successes should be tied to leveraging knowledge.

Measures of knowledge sharing must be built into everyone's performance objectives. A tool like the Balanced Scorecard (Kaplan and Norton 1996) could for instance be used to weigh the results of IDSC's knowledge-management initiative. IDSC should not only emphasize on the technological aspect of KM and must increase its effort to improve the humanitarian aspects.

Chapter 5.8
The Role of Culture in Knowledge Management:
A Case Study of Two Global Firms

Dorothy Leidner

Maryam Alavi
Emory University, USA

Timothy Kayworth
Baylor University, USA

ABSTRACT

Knowledge management (KM) approaches have been broadly considered to entail either a focus on organizing communities or a focus on the process of knowledge creation, sharing, and distribution. While these two approaches are not mutually exclusive and organizations may adopt aspects of both, the two approaches entail different challenges. Some organizational cultures might be more receptive to the community approach, whereas others may be more receptive to the process approach. Although culture has been cited widely as a challenge in knowledge management initiatives, and although many studies have considered the implications of organizational culture on knowledge sharing, few empirical studies address the influence of culture on the approach taken to knowledge management. Using a case study approach to compare and contrast the cultures and knowledge management approaches of two organizations, the study suggests ways in which organizational culture influences knowledge management initiatives as well as the evolution of knowledge management in organizations. Whereas in one organization, the KM effort became little more than an information repository, in the second organization, the KM effort evolved into a highly collaborative system fostering the formation of electronic communities.

INTRODUCTION

Knowledge management (KM) efforts often are seen to encounter difficulties from corporate culture and, as a result, to have limited impact (DeLong & Fahey, 2000; O'Dell & Grayson, 1998). An Ernst and Young study identified culture as the biggest impediment to knowledge transfer, citing the inability to change people's behaviors as the biggest hindrance to managing knowledge (Watson, 1998). In another study of 453 firms, over half indicated that organizational culture was a major barrier to success in their knowledge management initiatives (Ruggles, 1998). The importance of culture is also evident from consulting firms such as KPMG who report that a major aspect of knowledge management initiatives involves working to shape organizational cultures that hinder their knowledge management programs (KPMG, 1998). These findings and others (Hasan & Gould, 2001; Schultze & Boland, 2000) help to demonstrate the profound impact that culture may have on knowledge management practice and of the crucial role of senior management in fostering cultures conducive to these practices (Brown & Duguid, 2000; Davenport, DeLong, & Beers, 1998; DeLong & Fahey, 2000; Gupta & Govindarajan, 2000; Hargadon, 1998; KPMG, 1998; von Krogh, 1998).

Studies on the role of culture in knowledge management have focused on such issues as the effect of organizational culture on knowledge sharing behaviors (DeLong & Fahey, 2000; Jarvenpaa & Staples, 2001) and the influence of culture on the capabilities provided by KM (Gold, Malhotra & Segars, 2001) as well as on the success of the KM initiative (Baltahazard & Cooke, 2003). More specifically, Baltahazard and Cooke (2003) ascertained that constructive cultures (emphasizing values related to encouragement, affiliation, achievement, and self-actualization) tended to achieve greater KM success. Similarly, Gold, et al. (2001) found that more supportive, encouraging organizational cultures positively influence KM infrastructure capability and resulting KM practice. Finally, Jarvenpaa and Staples (2001) determined that organizational cultures rating high in solidarity (tendency to pursue shared objectives) will result in a perception of knowledge as being owned by the organization, which, in turn, leads to greater levels of knowledge sharing.

While studies have shown that culture influences knowledge management and, in particular, knowledge sharing, there is little research on the broader aspects of the nature and means through which organizational culture influences the overall approach taken to knowledge management in a firm. The purpose of this research is to examine how organizational culture influences knowledge management initiatives. We use a case study methodology to help ascertain the relationship of the organizational culture to the knowledge management approaches within two companies. The following section discusses knowledge management approaches and organizational culture. The third presents the methodology. The fourth section presents the two cases and the fifth, and discusses the case findings, implications, and conclusion.

LITERATURE REVIEW: KNOWLEDGE MANAGEMENT APPROACHES AND ORGANIZATIONAL CULTURE

Knowledge Management Approaches

Knowledge can be defined as a form of high value information (either explicit or tacit) combined with experience, context, interpretation, and reflection that is ready to apply to decisions and actions (Davenport et al., 1998). While all firms may have a given pool of knowledge resources distributed throughout their respective organization, they may be unaware of the existence of these resources as well as how to effectively leverage them for competitive advantage. Therefore, firms must engage in activities that seek to build, sustain, and leverage these intellectual resources. These types of activities, generally characterized as knowledge management, can be defined as the conscious practice or process of systematically identifying, capturing, and leveraging knowledge resources to help firms to compete more effectively (Hansen, Nohria, & Tierney, 1999; O'Dell & Grayson, 1998).

There are two fundamental approaches to knowledge management: the process approach and the practice approach. The process approach attempts to codify organizational knowledge through formalized controls, processes, and technologies (Hansen et al., 1999). Organizations adopting the process approach may implement explicit policies governing how knowledge is to be collected, stored, and disseminated throughout the organization. The process approach frequently involves the use of information technologies, such as intranets, data warehousing, knowledge repositories, decision support tools, and groupware (Ruggles, 1998), to enhance the quality and speed of knowledge creation and distribution in the organizations. The main criticisms of this process approach are that it fails to capture much of the tacit knowledge embedded in firms and that it forces individuals into fixed patterns of thinking (Brown & Duguid, 2000; DeLong & Fahey, 2000; Hargadon, 1998; von Grogh, 2000).

In contrast, the practice approach to knowledge management assumes that a great deal of organizational knowledge is tacit in nature and that

Table 1. The process vs. practice approaches to knowledge management

	Process Approach	**Practice Approach**
Type of Knowledge Supported	Explicit knowledge—codified in rules, tools, and processes	Mostly tacit knowledge- unarticulated knowledge not easily captured or codified
Means of Transmission	Formal controls, procedures, and standard operating procedures with heavy emphasis on information technologies to support knowledge creation, codification, and transfer of knowledge	Informal social groups that engage in story telling and improvisation
Benefits	Provides structure to harness generated ideas and knowledge Achieves scale in knowledge reuse	Provides an environment to generate and transfer high value tacit knowledge Provides spark for fresh ideas and responsiveness to changing environment
Disadvantages	Fails to tap into tacit knowledge. May limit innovation and forces participants into fixed patterns of thinking	Can result in inefficiency. Abundance of ideas with no structure to implement them.
Role of Information Technology	Heavy investment in IT to connect people with reusable codified knowledge	Moderate investment in IT to facilitate conversations and transfer of tacit knowledge

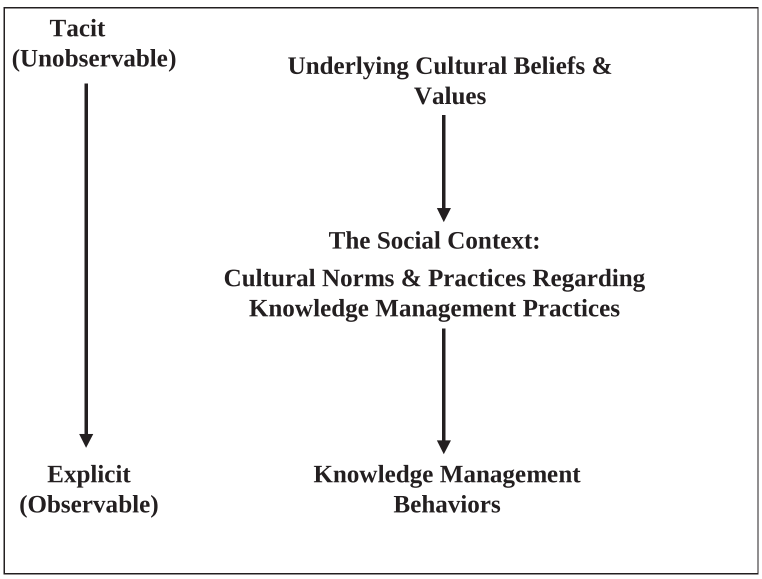
formal controls, processes, and technologies are not suitable for transmitting this type of understanding. Rather than building formal systems to manage knowledge, the focus of this approach is to build social environments or communities of practice necessary to facilitate the sharing of tacit understanding (Brown & Duguid, 2000; DeLong & Fahey, 2000; Gupta & Govindarajan, 2000; Hansen et al., 1999; Wenger & Snyder, 2000). These communities are informal social groups that meet regularly to share ideas, insights, and best practices.

Drawing from this discussion, some key questions emerge. First, how does culture affect organizations' approaches (e.g., process or practice) to knowledge management? Second, as organizations pursue these initiatives, how do cultural influences affect the KM activities of knowledge generation, codification, and transfer? To address these questions, it is necessary to explore the concept of organizational culture.

Organizational Culture

Schein (1985) defines organizational culture as a set of implicit assumptions held by members of a group that determines how the group behaves and responds to its environment. At its deepest level, culture consists of core values and beliefs that are embedded tacit preferences about what the organization should strive to attain and how it should do it (DeLong & Fahey, 2000). These tacit values and beliefs determine the more observable organizational norms and practices that consist of rules, expectations, rituals and routines, stories and myths, symbols, power structures, organizational structures, and control systems (Bloor & Dawson, 1994; Johnson, 1992). In turn, these norms and practices drive subsequent behaviors by providing the social context through which people communicate and act (DeLong & Fahey, 2000). Putting this into the context of knowledge management, organizational culture

Figure 1. The impact of organizational culture on knowledge management behaviors



determines the social context (consisting of norms and practices) that determines "who is expected to control what knowledge, as well as who must share it, and who can hoard it" (Delong & Fahey, 2000, p. 118). Figure 1 illustrates this conceptual linkage between culture and knowledge management behavior.

As Figure 1 depicts, the social context (consisting of norms and practices) is the medium for transmission of underlying values and beliefs into specific knowledge management behaviors. While Figure 1 is useful to explain the conceptual linkage between culture and knowledge management behavior, further explanation is needed to inform our understanding of the types of cultures that exist within organizations.

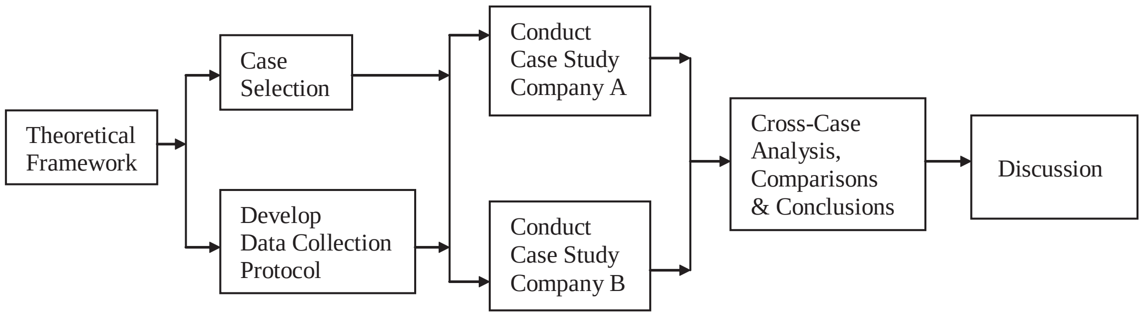
A number of theories have attempted to define culture at the organizational level. Wallach (1983) conceptualizes organizational culture as a composite of three distinctive cultural types: bureaucratic, innovative, and supportive. In bureaucratic cultures, there are clear lines of authority, and work is highly regulated and systematized. Innovative cultures are characterized as being creative, risk-taking environments where burnout, stress, and pressure are commonplace. In contrast, supportive cultures are those that provide a friendly, warm environment where workers tend to be fair, open, and honest. From Wallach's (1983) standpoint, any given firm will have all three types of culture, each to varying levels of degree. Wallach's (1983) cultural dimensions were developed based upon a synthesis of other major organizational culture indices. Wallach's (1983) cultural dimensions were applied by Kanungo, Sadavarti, and Srinivas (2001) to study the relationship between IT strategy and organizational culture. Part of the attractiveness of Wallach's (1983) dimensions, in comparison with other commonly used cultural indices such as the Organizational Culture Profile scale (O'Reilly, Chatman, & Caldwell, 1991); the Competing Values Framework (Quinn & Rohrbaugh, 1983); and the Organizational Value Congruence Scale (Enz, 1986), is that it is highly intuitive. Managers readily can identify with the descriptions of the three general culture types. Consistent with Kanungo, et al. (2001), we will employ Wallach's (1983) approach to describe organizational cultures. Specifically, we are interested in the following question: How does organizational culture influence knowledge management initiatives?

Methodology

A case study method involving multiple (two) cases was used. The approach of the study is depicted in Figure 2. The figure, based on the work of Yin (1994), displays the replication approach to multiple-case studies. As illustrated in Figure 2, the initial step in the study involved the development of a theoretical framework on the relationship between organizational culture and organizational knowledge management (KM) strategies. This step was then followed by the selection of the two specific cases (the data collection sites) and the design of the data collection protocol. Following the case selection and data collection steps, the individual case reports were developed. A cross-case analysis of the findings was then undertaken. This analysis provided the basis for the theoretical and normative discussions and implications presented in the final section of the article.

The two case studies involve two very large global corporations: Company A and Company B. Company A is a global consumer goods company with 369,000 employees worldwide. The company is headquartered in the U.S. and operates in four other regions: Europe, the Middle East and Africa, Central and South America, and Asia. Company revenues consistently exceed $20 billion. In Company A, large-scale knowledge management projects were initiated at the North American region in 1996. Company B is a high-tech global company with multiple product lines and services. Similar to Company A, Company B is headquartered in the U.S. and operates globally

Figure 2. Case study methodology adapted from Yin (1994)



in other regions of the world. With approximately 316,000 employees, its revenues exceed $80 billion. Large-scale knowledge management projects were initiated in Company B in 1995.

These two companies were selected for the purpose of this study for the following reasons. First, significant opportunities and challenges are associated with knowledge management activities in large and geographically dispersed companies. Thus, identification of factors such as organizational culture that may influence KM outcomes in this type of organizations potentially can lead to high payoffs. Second, considering the high levels of organizational resources required for implementation of large-scale knowledge management initiatives, these initiatives most likely are encountered in very large firms. Thus, the phenomenon of interest to these researchers could be best investigated in the context of very large firms with an established track record in KM projects. Finally, past contacts that one of the researchers had with these two firms facilitated their recruitment as case study sites.

Data Collection

Data for this study were collected through semi-structured interviews with a small group of managers and professional employees at the two company locations in the U.S. Identical approaches to data collection were used at Company A and Company B1. Six individuals at each of the two companies were interviewed. In each of the two companies, three of the interviewees were the current or potential users of the KM systems. The remaining three interviewees in each company were the KMS sponsors or supporters. The interviews took between 45 and 85 minutes and were conducted between October 2001 and January 2002. All the interviews were tape recorded and then transcribed for data analysis. The interviews all followed the same protocol. The informants first were asked to characterize their organization's culture in their own words. The three cultures described by Wallach (1983) were then portrayed, and the informants were requested to identify which one best described their organization. The interviewees next were asked to describe and characterize the KM practices in their company. A set of specific questions guided the discussions of these practices. For example, informants were asked to describe the specific KM activities that they engaged in and to discuss the effects of these activities on themselves and/or their peers. Informants were also asked to describe any resistance and impediments to KM that they might have noticed in the organization. The same interviewer, using identical data collection protocols, conducted all the interviews in Company A and Company B. The interviewer carefully read the transcripts to ensure accuracy.

Data Analysis

An author not involved in the interviews and, hence, having no predisposed interpretation of the transcripts, conducted the data analysis. Based upon the transcribed interviews, 12 profiles were written, each one based upon the perspective of a single informant. These profiles described the informants' perspective of culture and their perspective of KM. The profiles of informants for Company A were compared and contrasted with each other, as were those of Company B. Cases for each company, reported in the next section, then were written, based upon the within-case analysis. The cases for each company then were interpreted from the perspective of how the culture appeared to be influencing the organizational KM initiative. This is also reported in the next section. After the two cases and their within-case analysis were complete, a cross-case comparison and contrast was undertaken, leading to the formulation of the discussion section.

CASE DESCRIPTIONS AND ANALYSES

Knowledge Management at Company

Knowledge management at Alpha began as a top-down idea, courted by senior management "as a way of helping the company become more leading edge" according to one informant. A small group of eight or nine individuals at headquarters was charged with driving knowledge management and facilitating knowledge sharing. As a result of larger issues surfacing, most notably the economic downturn that rocked U.S.-based businesses in early 2000, the top-level initiative fell into the background, and the small, dedicated group was disbanded. Thus, at the organizational level, KM was an idea that received neither funding nor action. However, at the business unit level, successful KM initiatives have been built around an intranet or around Lotus Notes team rooms.

Intranet-Based KM Projects

One initiative in the marketing area of corporate headquarters is called MIC — marketing information center. MIC serves the global marketing community of several thousand individuals around the world. It is an intranet-based library containing links to agencies, compensations, human resource information, and contracts, among other things. MIC is opportunity-oriented rather than problem-oriented. The members do not use the community to post a problem inquiry and await responses but rather to look for ideas performed in other parts of the company and think about adopting the ideas to their local group.

MIC is intended to be a catalyst for collaboration and to propel a universal worldwide marketing community. Because the chief marketing officer no longer allows the budgeting of glossy manuals or brochures, MIC is widely accepted as the primary means of obtaining such static information. In fact, as attempts were made to include best practices in MIC, the initiative encountered resistance. Explains one informant, "We could never nudge the culture enough to have people understand and be motivated to enter their information." Another informant felt that there were challenges in overcoming "people's fear of being judged for their ideas and their indifference to yet another information site."

CM connection (CMC) is another KM initiative within the North American marketing unit. This is a Web-based marketing repository used to disseminate information so that wholesalers that are responsible for store-level execution can have access to the most recent information on how to merchandise the latest promotions. As with MIC, the major impact of CMC has been the reduction of the number of printed catalogs; in this case, by 80%. Among the challenges experienced with CM connection has been convincing content providers to own the information in the sense of both providing it and keeping it up-to-date. Another issue has been that CM connection is seen by some as distracting from their relationships with clients. Even while MCC may reduce the amount of time spent traveling, this is not necessarily welcome in "a sales and marketing oriented relationship company because you are taking away relationship points."

The Human Resources unit with the Corporate Functions unit also has an intranet-based KM, referred to as My Career. My Career is designed for managers and employees to help provide information about what tools, classes, and coaching are available for development. One of the goals of My Career has been to merge all of the training information into one place.

Many such intranet-based KM have been developed throughout Alpha, so many that the portal project was initiated to alleviate the problem of "too much information in too many places, different IDs and passwords for each database, having to remember what is in the database to even go to get the information." However, despite some initial receptiveness to the idea from the head of the New Business Ventures unit, IT budgets were frozen and the project never got underway.

The common thread running through the intranet-based KM projects at Alpha is that they all are geared to housing static information with the most major impacts being the reduction in printed catalogs. Among the greatest resistance, according to informants, is that these KM projects appear to try to standardize work practices in a company comprised of "creative assertive people who want to do it their way and make their own individual mark."

Lotus Notes-Based KM

Lotus Notes forms the basis of other KM initiatives within Company A. What distinguishes the Lotus Notes-based KM projects from the intranet-based KM projects is the added focus on facilitating teamwork. The Lotus Notes-based initiatives developed independently from the intranet-based initiatives. The North-American marketing group developed a Lotus Notes-based community of interest. The system contains examples of briefs, shared research, shared examples of different sites, and information on internal research. This micro KM has 50 to 60 regular users. An important feature of the system is that whenever new information is added, community members receive an e-mail. In this way, members visit the community when new information that is relevant to them has been posted. This KM project has served as a means of sharing best practices. For example, a marketing manager from the UK posted information concerning a successful auction initiative, which was then emulated by five other countries. On an individual level, KM has helped to increase the frequency of communication among members of the community. Similarly, HR developed HR Source, a Lotus Notes-based general bulletin board, where meeting notes, follow-up action items, strategy documents, and work plans are placed. It is shared by the HR community on a global basis.

Lotus Notes is also the platform used to develop team rooms. The individual responsible for managing team rooms for North America has what he calls the six-month rule: if a team room is not getting regular utilization for more than six months, it is deleted so that they can save money on the server expense. He says that he deletes about 70 to 80% of team rooms. He thinks the lack of reward is the biggest barrier toward KM system usage: "People who don't have technology in their title don't take it upon themselves and are not generally rewarded for exploiting technology." Also, content management is a barrier: "This is the responsibility of the end user but it is perceived as the responsibility of the technology group." However, a marketing manager had another opinion, attributing lack of use of the team rooms to self-preservation: "Even if someone took the time to put something out there, even if I knew it was there, went and got it, had the time to review it, and understand it, I am going to create this other thing by myself. I might look at that as input, but then it is the new XYZ program and I created it."

ANALYSIS OF ALPHA'S KNOWLEDGE MANAGEMENT: THE IMPACT OF CULTURE ON KM BEHAVIORS AND OUTCOMES

The Perceptions of Culture

While each individual interviewed gave their own perception of the culture at Alpha, and while the perceptions naturally contain some variance, there is a marked theme running throughout the individuals' views. Informants describe Alpha as risk averse and bureaucratic. They speak of an environment where people don't want to be noticed, where direction is unclear, and where individual survival trumps teamwork. Moreover, informants state that people work in silos, feel isolated, and are afraid of being criticized for their ideas. The slow, bureaucratic, hierarchical culture at Alpha has resulted in silos of information. As a consequence, managers indicate that even though they have great consumer and customer information, they end up reinventing the wheel 1,000 times. However, our informants also maintained that although they characterize the culture as bureaucratic, they also sense that Alpha is striving to become more innovative and supportive.

The Possible Impacts of Culture on KM

The statements and observations of our informants point to two largely shared perspectives: (1) the culture emphasizes the individual, and (2) the culture is in a state of transition. In understanding the impacts of KM, one can see the influence of the individuality within Company A. Table 2 lists the characteristics of culture, characteristics of the KM initiatives, and characteristics of KM behaviors as expressed by the informants.

At work within Alpha seems to be a tension between a culture that demands individuality and the communal aspects of KM. The informants talk about a culture that is one of "individual survival" where individuals "fear being judged for their ideas," where there is individual "isolation," and where individuals try to go unnoticed. The overall feeling is that of individuals trying to avoid being noticed. Such a culture does little to foster the sense of community that may be necessary to enable KM to move beyond static repositories of information into the kind of dynamic system envisioned by developers, where ideas flow freely and where KM provides a catalyst for collaborative engagement. Not only are individuals reluctant to share their information for fear of being criticized for their ideas, they also are reluctant to use information posted in a KM for lack of credit for the idea. Such behaviors can spring from a culture that emphasizes individual ideas and contribution.

The individual aspects of the culture go well beyond individuals behaving in a certain way because of a rewards system but reflects an underpinning notion that to succeed in a marketing-oriented organization, one must be creative and that creativity is perforce, of an individual nature, so that to survive as an individual, one must capture ideas and only share them if they are going to be favorably judged. One must not look to others for learning or for problem solving but might look to

Table 2. Characteristics of culture, KM initiatives, and KM behaviors

Culture Characteristics	KM characteristics	KM behaviors
Dominant culture is Bureaucratic Emphasis on individual: *individuals are “risk averse” *individuals fear being criticized for ideas *individuals are uneasy and prefer to go unnoticed *individuals relationships externally, particularly within the marketing unit, are perceived as critical to their success	Intranet-based “static” repositories of information Failed top-down effort Bottom-up initiatives largely targeted creation of repositories Some use of Lotus-Notes to create team rooms Team rooms have high failure rate	Individuals access information on “as-needed basis” Individuals reluctant to contribute information Individuals reluctant to own and maintain content Individuals uncomfortable using ideas from the systems, since they do not own the idea Individuals use repository when rules prohibit printing brochures Individuals reluctant to use tools that would result in a loss of touch points with customers

reuse creative ideas in some circumstances (like the auction site example from the UK) where one may tailor the idea to one’s environment. It is telling that the informants speak of using outsiders (e.g., consultants) to assist with problem solving and learning instead of attempting to use any of the existing KM to post queries, and this in spite of the fact that it is recognized that the company reinvents the wheel 1,000 times.

Another tension within Alpha seems to stem from the expectations of what should occur in a bureaucratic culture and what was occurring. The top-down approach to KM, an approach that would be consistent with a bureaucratic organization, had failed at Alpha. Yet, despite the failure of the top-down approach to KM and the seeming success of several bottom-up approaches, such as MIC and the marketing team room for the community of 50, one informant still proffered the need for top management leadership to be the key to success with KM. He considered the bottom-up approaches as “band-aid-approaches.” In his opinion, power within Alpha comes “from knowledge hoarding, not knowledge sharing.” In order for KM to be assimilated in this environment, “behavior really has to come from the top. Leadership needs to walk the walk.” In a bureaucratic culture, individuals become accustomed to clear guidance from senior management. The absence of clearly stated support from senior management may be sufficient to deter many from experimenting with the KM tools available to help them.

Summary

Alpha has many KM initiatives that were developed largely as bottom-up initiatives. The KM tools seem well designed and housed with valuable information. The informants are able to use the tools to facilitate the retrieval of information that they need in the performance of their jobs. However, the tools have not progressed yet to the level of fostering collaboration. While there are some successful communities from the standpoint of providing a place to share meeting notes and plans, the majority of team rooms remain unused and, if used, become as much a library of information as a communication tool. In some ways, the culture of Alpha appears to foster the types of KM behaviors observed, in that the individual is seen as the primary source of innovation and ideas as opposed to the community being the ultimate source of success. Thus, individuals will use the systems as needed but are occupied mostly with their individual roles and work and do not attribute value to the collaborative features of technology.

The Case of Beta

Beta is organized into seven major units. Our interviews were concentrated within the Innovations Services group of the consulting wing (referred to as Worldwide Services Group, or WSG) of Beta.

Knowledge management at Beta began in 1996 with the view that KM was about codifying and sharing information, leading to the creation of huge repositories of procedures and process approaches. It was assumed that people would go to a central site, called Intellectual Capital Management System (ICM), pull information down, and all would be more knowledgeable. ICM is under the protection of the Beta Corporation. There is a process one must undertake to have information submitted and approved. The process is complicated by legalities and formalities. As a result, ICM is not used as widely as it could be. What was discovered from the initial foray into knowledge management was that the information was not being refreshed and that the approach was not complementing the way people really learned, which was through communities. Consequently, the KM initiative began to shift to providing tools to communities that would help foster collaboration both within teams and within locations and around the globe. Among the tools are team rooms and communities.

Team Rooms

Lotus Notes-based team rooms are widely used at Beta to coordinate virtual teams and to share important documents. Access to team databases are limited to the members because of the confidential nature of a lot of the issues. The project manager or someone delegated by the project manager takes the responsibility of sanitizing the material and posting the most relevant parts to a community system such as OC-zone (to be discussed later) and/or to the ICM after the team's project has been completed.

The team rooms are valuable tools to help members keep track of occurrences as well as to help newly assigned members get quickly up to speed. Because of the itinerant nature of the Beta consultant's life, it is invaluable to have the documents they need stored in an easily accessible manner that does not require sending and receiving files over a network. Team room databases also are used for managing the consulting practices. It is important in helping new people with administrative tasks (e.g., how to order a piece of computer equipment, how to order business cards). The team rooms keep track of such metrics as utilization so that members of the team know "who's on the bench and who's not." One informant gave the example of a recent project she was put on at the last minute that involved selling a project to a government department in another country. She was able to access all the documentation from the team room and become a productive member of a new team very quickly: "I can go in and start getting information about a particular topic and work with colleagues almost immediately. It allows me to work more easily with colleagues across disciplines."

Although team rooms are invaluable in organizing and coordinating project teams, there are also some potential drawbacks. Some view the team rooms as engendering "a false sense of intimacy and connectedness." This sense of intimacy can be productive for the team as long as things are going well. However, "if things go south," says an informant, "you don't have the history or skill set to really deal with difficult situations." As a result, instead of dealing with the conflict, the team is more likely to just take someone off the team and replace the person with another. In this sense, problems are not solved so much as they are avoided, and team members take on an expendable quality.

Communities

Communities serve members based not upon project or organizational position but upon interest. By 2000, a group referred to as the organizational change (OC) group had established a successful community of 1,500 members cutting across all lines of business and was beginning to act as consultants to other groups trying to set up communities. The OC community has gone so far as to quantify the business return of such a community in terms of cycle time reductions and sophistication of responses to clients. The OC community is comprised of tools, events, and organization.

1. Tools. The technology tools at the disposal of the OC community are databases of information submitted by team rooms, including such things as white papers, projects, and deliverables, as well as client information. The databases also contain pictures of community members with personal information about the members.
2. Events. An important aspect of the OC community is the events that are organized for community members. These include monthly conference call meetings, which generally are attended by 40 to 90 members, and replay meetings, which draw another 40 to 70 members. In the past, the community has sponsored a face-to-face conference for members. Members often meet others for the first time, yet they already feel they know each other.
3. Organization. The organization of the community is managed by two community leaders. When people request information or have queries to post to members, they send their messages to one of the community leaders. The leader first tries to forward the message directly to a subject-matter expert (SME). If the leader does not know offhand of an appropriate SME, the leader will post the question to the entire group. In this event, the group members respond to the leader rather than to the community in order to avoid an inundation of messages. The leader normally receives responses within an hour. The leader then forwards the responses to the individual with the query. Later, the leader sends an e-mail to the person who made the inquiry, asking how the response was, how much time it saved, and so forth. The leader normally gets back as many as 28 responses to a particular inquiry. The leader has manually loaded a portion of what he or she has developed in the past seven months. There are 114 pieces of intellectual capital that the leader has loaded, and it is just a portion of what the leader has received.

The community has a structure that consists of a senior global board of 30 members representative of different parts of the business. There is a subject matter council that constantly scans the intellectual capital, as well as an expert council and the health check team.

The health check team examines such things as how well members communicate with each other. They conducted an organizational network analysis to help better understand the communication networks. The team has a series of questions to help assess how they are doing in terms of high performance teaming. They use a survey that measures perceptions from the community members about what they see is happening and do a gap analysis on what is actually happening. Finally, the team does a self-assessment of where it is compared to the community maturity model developed by the OC community leaders. There is a community mission, vision, and goals, and they are working on capturing data to support the metrics to demonstrate value to the company and community members.

The goal is to attain level-5 maturity, which is considered an "adaptive organization." There are 13 areas of focus at which the community leaders look in building a sustained community. While communities are felt to be organic, there is also a community developers kit with an assessment tool to determine at what level of maturity a community is and what steps need to be taken to move the community forward. One community leader says that the purpose of the development kit "is not to confine, but to provide a road map in which to navigate and build." For this leader, the essence of community is continuous learning. Of the initial KM efforts focused on information repositories, the leader says, "I could see the technology coming that was going to enslave people, like an intellectual sweat shop." By contrast, the primary tools for a community are "passion and environment."

Impact of OC

Among the major impacts of the OC zone is that having a community helps people not feel isolated. "People feel they are affiliated, that they are part of the company." Thirty percent of Beta employees do not have offices and work from home or the client sites. Such a work environment easily can be associated with isolation. However, the community is claimed by some to provide clarity of purpose. "I see it as a conduit for both developing thought leadership and enabling thought leadership to get into the hearts and minds of the workers so that they all have a common vision, goals, and objectives."

Community members view the purpose of the community as a knowledge-sharing forum and as a means to create a sense of belonging. One member went so far as to suggest that she would "not be at Beta any longer if it wasn't for this community." The reason is that most of her connections at Beta have been made through the community. Also, being in the community helps her to get assigned to projects. For example, the leader of a new project will call someone in the community and say that they are looking for a person with a certain profile. She finds that she gets asked to work on projects this way.

Other members refer to the community as a supportive family and state that within the community is someone who has already encountered any issue they will encounter on a project, so the community keeps them from reinventing the wheel. The norms of operation exist to help the OC zone be as effective as possible. No one is under obligation to contribute, but individuals contribute in order to help other people. One member credits the success of the community to the two leaders, whom she feels "in their hearts, care about the members of the community." She feels that the community is more than a community of people who like the topic of organizational change, but it is a community of people who support one another.

The primary resistance to the OC community has been the practice managers. Most of the community members report to practice managers. The practice managers are used to thinking in terms of billable hours. Indeed, the performance evaluation system requires that an individual's goals support those of his or her boss, which support those of his or her boss, and so forth. The community leaders hope that one day, participating in a community will be included as a standard part of this evaluation system.

ANALYSIS OF BETA KNOWLEDGE MANAGEMENT: THE IMPACT OF CULTURE ON KM BEHAVIORS AND OUTCOMES

The Perceptions of Culture

All of the respondents from Beta work within the same business unit. The respondents describe the culture of Beta as a blend of hierarchical and innovative. The hierarchical aspects are evident in that little innovation is undertaken until senior management has officially supported the innovation, but once senior management does give the green light to an idea, "everybody jumps on it."

One aspect of culture that is highlighted by the informants is the importance of collaboration. Informants characterize the street values within Beta as win, team, and execute. Beta informants recognize a duality of culture that, on the one hand, gives individuals control over their work and, at the same time, is highly supportive of the individual. The culture is autonomous in the sense of not having someone looking over your shoulder and telling you what to do. While there is certainly competition (i.e., everyone has objectives that they are trying to meet), things "are always done in a collaborative helpful spirit."

The other dominant aspect of culture, as related by the informants, is hierarchy. The hierarchy is as much a hierarchy of experience as of structure. Community members, for example, proffered that becoming a subject matter expert is more about length of service to the company than to one's inherent knowledge. Another aspect of the bureaucratic culture is that "there is very much a correct way to do things."

Table 3 lists the characteristics of culture, KM initiatives, and KM behaviors expressed by the Beta informants.

Table 3. Characteristics of Company B culture, KM initiatives, and KM behaviors

Culture Characteristics	KM characteristics	KM behaviors
Hierarchical, yet collaborative and innovative Individuals largely responsible for their own careers, yet competition is undertaken in a cooperative manner The team is the unit of success, more so than the individual Absence of extreme supervision of individuals' work--individuals have a sense of control	Company-wide information repository consisting of hundreds of information databases Team rooms used by project teams Communities of practice emerging. These communities include: tools, events, and structures The OC community is used as an example of a successful community and as a consultant to other emerging communities	Team members actively coordinate via the team rooms Community members obtain a sense of belonging to the community Community members post information from completed team projects to the community out of a sense of commitment, not coercion Community members are more loyal to the company (less likely to depart) because of their belonging to the community Assignments to projects made through community references

Beta's emphasis on collaboration seems to have enabled the progression of KM from a static information repository system into active, vital communities of interest, wherein individuals feel a sense of belonging to the extent that they identify themselves first with the community and second, if at all, with their actual formal business units. One informant claimed to not identify herself at all with the Innovation Services unit. Of course, one could ponder whether such identity transfer from the business unit to the community serves the best interest of the unit.

At the same time, the bureaucratic and innovative aspects of the culture also have helped. Having senior management show interest in KM was a catalyst to individual groups undertaking KM initiatives with great enthusiasm. In addition, rather than ad hoc communities that are entirely organic, the community model emerging at Beta is a relatively structured one.

While one can make the argument that Beta's culture influences KM development and use, one also can argue that KM at Beta is influencing Beta's culture. OC members claim that without a sense of connection provided by the OC community, Beta would be nothing but a "big and scary" company in which individuals "get lost." The community, though, allows and enables a culture of connection. In effect, one informant believes that the OC community attempts to shift a very technical, phone-oriented, work-product-oriented way of communicating with each other into a more personal work-in-process movement toward what Beta refers to as "thought leadership." When asked why members take the time to participate in the community when there is no formal reward for doing so, one informant said simply, "It's just how we do business." Thus, the community has infused the culture of the members.

Yet, this does not suggest that an organizational utopia has been or will be achieved. While the culture is becoming more connected, there is another angle. One informant believes that when you have widespread access to knowledge management, you also can have a culture where people that know very little about something have access to enough information to be dangerous. People get too comfortable with having access to knowledge and then feel free to share it. This informant remained unconvinced that the knowledge one acquires through the network is as solid a foundation as the knowledge one has acquired through experience and traditional learning. Moreover, she feels that the notion of dialogue can get redefined in a way that you lose the quality of participation that one might be looking for.

Summary

Beta has many KM databases, collectively referred to as Intellectual Capital Management. While these databases serve an important role of housing and organizing information in a huge organization, they do not go so far as to foster collaboration. Instead, team rooms and communities of interest, largely left to the discretion of team members and community members, have proven to be vital tools to achieving collaboration, community, and belonging. As the culture of Beta has been receptive to individual groups setting and pursuing their community agendas, the culture also is being subtly altered by the communities as members feel that they belong more to the community than to their business units.

DISCUSSION

The two cases offer insights into the role that organizational culture plays in the inception and maturation of KM. This section summarizes the key findings that help us to answer the following question: How does organizational culture influence KM approaches? We suggest four responses to this question.

1. Organizational culture influences KM through its influence on the values organi-

zational members attribute to individual vs. cooperative behavior. The two companies we examined share several similarities. Both huge multinational organizations are regarded widely by organizational members as being predominantly bureaucratic in culture. Both organizations had initial KM approaches that were strongly supported by senior management. And both had initial KM approaches focused on the creation of a large centralized repository of organizational knowledge to be shared throughout the organization. These two large bureaucratic organizations began their KM quests with the process approach. The most striking difference between the organizational cultures of these two companies was the emphasis at Alpha on the individual and the emphasis at Beta on collectivity — the team or community. This evinces itself even in the interpretation of innovation. While individuals at both companies spoke of the need for innovation in their organizations and of the striving of their organizations to develop an innovative culture, in the case of Alpha, innovation was perceived as an individual attribute, whereas at Beta, innovation was perceived as a team-level attribute.

The individualistic view of innovation at Alpha seemed to militate against the requisite sharing and cooperation that makes the evolution of KM from process approach to a community of practice approach possible. In both companies, micro-level experimentation of the various possibilities of KM was undertaken within teams or business units. The value placed on individualism vs. cooperativism seems to have played a significant role in the nature and form of the KM approach. The micro-level experimentations by teams or business units were carried out with their own assumptions about the usefulness of repositories of knowledge and the usefulness of communities or practice. We suggest that it is not organizational culture at the organizational level or even the subunit level that has the most significant influence on KM approach, but it is organizational culture as embodied in the individualistic vs. cooperative tendencies of organizational members. Thus, organizational culture influences KM approaches through its influence on individualism vs. cooperativism. From a theoretical view, it seems that Wallach's (1983) cultural dimensions and those of Earley (1994) were both valuable at explaining organizational level culture. However, Earley's (1994) cultural dimensions at the organizational level seem best able to explain why a KM approach tended to become more process or more practice-based.

2. Organizational culture influences the evolution of KM initiatives. Our findings suggest that firms do not decide in advance to adopt a process or practice approach to KM, but that it evolves. The most natural starting point is one of process, perhaps because the benefits seem more evident and because it can align more closely with the existing organizational structure. Moreover, the practice approach may not only fail to align with existing structure, but it may engender a virtual structure and identity. It is interesting that at Beta, a culture that is viewed dominantly as bureaucratic, once the initial organizational change community was established, the evolution of the community then became a highly structured process of maturation. The community leaders developed a toolkit to help other communities develop and developed a maturation model to help them to determine how mature a community was and to develop a plan to move the community forward. What some might see as an organic process (i.e., establishing and developing a community or practice) became a structured process in a bureaucratic organization. Even if the idea for the community emerged from

interested potential members, the evolution took on a structured form with tools, kits, assessments, and plans. The cooperative aspect of culture at the individual level made the community possible; the bureaucratic elements of culture at the organizational level enabled the community to mature. Hence, the evolution of the community was highly dependent on the individual willingness of organizational members to sustain and nurture their community. This appeared tied to the importance they placed on cooperation with their community members, most of whom they had never met.

3. Organizational culture influences the migration of knowledge. In the case of Alpha, where the informants seemed to identify the individual as the ultimate unit of responsibility in the organization, the individuals also were viewed as the owners of knowledge and had the responsibility to share their knowledge. This, in fact, created a major challenge, since the individuals rejected this new responsibility. At Beta, where the team seemed to be the focus of responsibility, knowledge migrated from the team to the community to the organizational level system and back down to the team. The leader of the team would take responsibility for cleaning the team's data and submitting it to the community and to the central information repository. Thus, knowledge migrated upward from the team to the central repository. Interestingly, the most useful knowledge was claimed to be that at the team and community level. Once the knowledge had completed its migration to the central repository, it was seen primarily as an item of insurance for use in case of need. Knowledge sharing and transfer occurred primarily at the team and community level, whereas knowledge storage was the function of the central repository.

   The migration of knowledge also is influenced by the structural processes put in place to ensure that knowledge finds its way to the appropriate persons. Of key importance seems to be the way the queries are handled. The marketing group at Alpha adopted the approach of notifying individuals when new information had been added to the KMS. However, little interference was put in place to either guide people to the appropriate knowledge or to encourage people to contribute knowledge. Conversely, believing that the community should not become a bulletin board of problems and solutions, the leaders of the organizational change community at Beta worked arduously to learn the subject matter experts so that queries would be submitted to the community leader who would serve as an intermediary between the individual with the query and the expert.

   It has been reported widely that the use of knowledge directories is a primary application of KM in organizations. Our study suggests that the facilitated access to experts rather than direct access via the location of an individual through a directory or via a problem posted to a forum may lead to a more favorable community atmosphere.

4. Knowledge management can become embedded in the organizational culture. Over time, as KM evolves and begins to reflect the values of the organization, the KM can become a part of the organizational culture. At Beta, individuals spoke of their community involvement and their team rooms as simply the "way we work." In fact, the communities became so much part of the culture that even though they were not part of the organizational structure, they were part of an individual's implicit structure. The sense of belonging that the individuals reported feeling toward their community suggests

that the community had become an essential aspect of their value system and, hence, had become part of organizational culture. That the organizational change community members at Beta identified themselves first and foremost with their community, in spite of receiving neither reward nor recognition within their formal reporting unit for participating in the community, indicates the extent to which community participation had become a value and an aspect of the individual culture.

Implications and Conclusion

The findings of our study suggest that a dominantly bureaucratic culture seems to tend toward an initial process-based KM approach. Furthermore, a bureaucratic culture seems to create the expectation among organizational members that senior management needs to provide a vision of purpose for KM before the organizational members should embark on KM activities. As well, the members view senior management support as validating any KM activities that they undertake. Innovative cultures, even if not the dominant culture at the organizational level, seem to enable subgroups to experiment with KM or create micro-KMs. In essence, in organizations having dominant bureaucratic cultures with traces of innovativeness, senior management support legitimizes KM, but the innovativeness of the culture enables it to expand far beyond an organization-wide repository. Specific KM behaviors such as ownership and maintenance of knowledge, knowledge sharing, and knowledge reuse seem to be influenced largely by the individualistic or cooperative nature of the culture. Individualistic cultures inhibit sharing, ownership, and reuse, while cooperative cultures enable the creation of virtual communities. Earley's (1994) work on organizational culture emphasized the individualistic and collectivistic aspects of culture. Organizations encouraging individuals to pursue and maximize individuals' goals and rewarding performance based on individual achievement would be considered to have an individualistic culture, whereas organizations placing priority on collective goals and joint contributions and rewards for organizational accomplishments would be considered collectivist (Chatman & Barsade, 1995; Earley, 1994). This dimension of organizational culture emerged as critical in our examination of the influence of culture on KM initiatives. These findings are summarized in Table 4.

Table 4. Summary of organizational culture's Influence on KM

Cultural Perspective	**Influence of Culture on Knowledge Management**
Bureaucratic (Wallach, 1983)	Favors an initial process approach to KM Creates expectation among members that senior management vision is essential to effective KM
Innovative (Wallach, 1983)	Enables subgroups in organization to experiment with KM and develop KMs useful to their group
Individualistic (Earley, 1994)	Inhibits sharing, ownership, and reuse of knowledge
Cooperative (Earley, 1994)	Enables the evolution of process oriented KM to practice oriented KM Enables the creation of virtual communities

This research set out to examine the influence of organizational culture on knowledge management approaches. Using a case study approach, we have gathered the perspectives of individuals in two firms that share some cultural similarities yet differ in other aspects. The findings suggest that organizational culture influences the KM approach initially chosen by an organization, the evolution of the KM approach, and the migration of knowledge. Moreover, the findings suggest that KM eventually can become an integral aspect of the organizational culture. Much remains to be discovered about how organizational cultures evolve and what role information technology takes in this evolution. This case study is an initial effort into a potentially vast array of research into the issue of the relationship of information technology and organizational culture.

Chapter 5.9
External and Internal Knowledge in Organizations

INTRODUCTION: KNOWLEDGE MANAGEMENT AND COMPETITIVE ADVANTAGE

In this article we discuss how knowledge and learning contribute to developing sustainable competitive advantages in firms. We argue that effective knowledge management (KM) initiatives for this purpose should support appropriate learning initiatives (which we define in terms of learning trajectories [LTs] of individuals and groups within the firm) in order to ensure that knowledge needs are adequately covered over time.

Trends in today's environment such as globalization, technological evolution, and deregulation are changing the competitive structure of markets in such a way that the effectiveness of traditional sources of firms' competitive advantage is blurred. More and more, any firm can have access to physical or financial assets, and even to technology, in exactly the same open-market conditions. Consequently, firms need to develop distinctive capabilities, their own "ways of doing things" that are difficult to imitate by competitors. Such capabilities are eventually related to persons in the firm, who at the end of the day develop and apply their abilities and skills, organized in certain ways and based on what these people know. Thus, developing idiosyncratic knowledge that gives meaning to a firm's distinctive ways of doing is increasingly important (Bell, 1973; Drucker, 1993). Idiosyncratic knowledge of this kind is difficult to imitate because it cannot be bought in open markets. That is, it has to be learned, requiring resources, time, effort, and a specific context (organizational, social, etc.) that makes it so path dependent that reproducing it in a firm different from that in which it originated is very difficult (Andreu & Sieber, 2001). In addition, knowledge has three fundamental characteristics that make it especially interesting. First, it is personal in the sense that it originates and resides in persons who assimilate it as the result of their own experiences. They incorporate it into their "base" once convinced of its meaning and implications, articulating it in the context of an organized whole that gives structure and meaning to its different "pieces" (Kolb, 1984). Second, its utilization (through which it does not dissipate) allows persons to understand perceived phenomena (each in his or her own way) and evaluate them, judging how good or convenient those phenomena are for each person at a given time. Third, it serves as a guide for action, helping to decide what to do at a given juncture because action endeavors improve the consequences of perceived phenomena (Andreu & Sieber).

These characteristics make knowledge a solid basis for competitive advantage. As far as it results from the accumulation of persons' experiences, therefore being mainly tacit (Polanyi, 1962), imitating it will be difficult unless precise representations (in the form of explicit knowledge) exist that facilitate its transmission and sharing. The personal experience-accumulation process leading to new knowledge takes place in a social or organizational context (Pentland, 1995; Tyre & von Hippel, 1997), and it unfolds following a different path for each person (dependent, among other things, on his or her previous experience and knowledge). Thus, knowledge is both path and context dependent. To the extent that duplicating contexts and paths in this sense is difficult, knowledge imitation will be costly, and consequently competitive advantages based on it will tend to be sustainable (Grant, 1996; Teece, Pisano, & Shuen, 1997). As a result, knowledge value tends to be higher in the context in which it was developed than it would be in a hypothetical open market. Nevertheless, not all knowledge is the same in terms of potential competitive advantage as we discuss in the next section.

EXTERNAL AND INTERNAL KNOWLEDGE

Competitive forces put pressure on firms not only to streamline their business processes, but also to be able to incorporate relevant knowledge from the environment. In other words, any firm needs access to knowledge that allows it to do something that, although also done by competitors, is demanded and valued by clients. We call this kind of knowledge external knowledge. It is brought into a firm from the environment and is useful not only to a particular firm, but also to their competitors in the marketplace. Hence, its market value is approximately equal to its value within the firm. It can be traded in the market and, in general, it tends to be rather technical and explicit, which makes it relatively easy to acquire, be it through training or simply by hiring or buying it (Becker, 1962; Williamson, 1981).

Relying on external knowledge alone, however, does not lead to competitive advantage. Although it may be a competitive necessity, it needs to be complemented by a different kind of knowledge more idiosyncratic and capable of differentiating a firm's offer in the marketplace. It is an organization-specific knowledge that refers to the firm's particular modes of functioning and to its particular organizational context. It acts as an organizational glue when the fast incorporation of external knowledge into a firm may threaten its cohesiveness and sense of unity. It is therefore more valuable inside the organization than in the market, and is less prone to imitation. Developing this kind of knowledge is much less environment driven, and it belongs more to the realm of organizational routines and organizational idiosyncrasy. We call this kind of knowledge internal knowledge. Although not valued directly by the labor or factor market, it contributes to achieve competitive advantage as it adds critical value for the customer1. Internal knowledge can be understood as the organizational context that

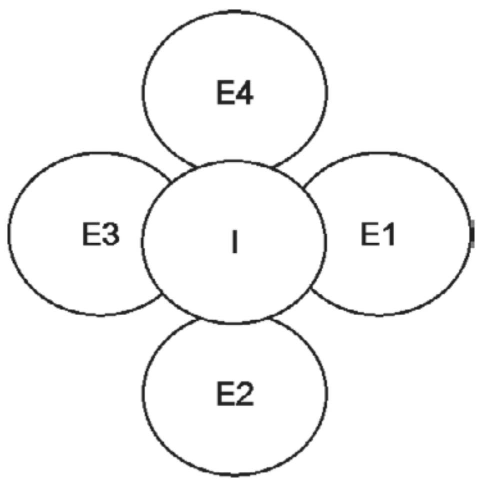
(a) plays the role of a skeleton where new knowledge pieces are attached so as to "make global sense" to the firm tradition, culture, and "ways to understand things" (Spender, 1996); and (b) defines the way in which new knowledge will be put to work, hence giving it the idiosyncratic firm's touch that will distinguish its utilization from that of other firms.

The distinction between these two kinds of knowledge is not new. The economics literature has analyzed the differences between general and firm-specific knowledge basically from three perspectives. Becker (1962) adopted a human-capital approach to study how to price the training of employees, concluding that the firm should cover all firm-specific training while the worker should cover general training as the involved knowledge has a direct market value. Williamson (1981) takes up this argument from a transaction-cost point of view, considering the necessity to protect "skills acquired in a learning-by-doing fashion and imperfectly transferable across employers" (p. 563). From an institutionalist point of view, Doeringer and Piore (1971) consider that the formation of internal labor markets is a consequence of firm-inherited knowledge.

From a more managerial standpoint, there are also contributions that suggest the distinction above. Porter, interviewed by Hodgetts (1999), is very close to the same concept when he distinguishes between "operational improvement" and "positioning." In a similar manner, Edvinsson and Malone's (1997) definition of intellectual capital is close to our concept of internal knowledge. The classic management literature also proposes a similar distinction: Selznick (1957), for example, is very close to the concept of internal knowledge by saying "…we must create a structure uniquely adapted to the mission and role of the enterprise..." More recently, Burton-Jones (1999), starting from a conception of the firm as a "knowledge integrator," proposed the so-called Knowledge Supply ModelTM, where the distinction is made between three internal sources of knowledge and four external sources, the former demanding firm-specific knowledge.

Understood as we propose, a coherent knowledge management initiative has to ensure a proper

Figure 1. Knowledge base of a firm in terms of internal and external knowledge



balance between internal and external knowledge creation and deployment. Our contention is that, thinking in terms of the adequate learning processes leading to the creation and deployment of the appropriate mix of internal and external knowledge in a firm, it is possible to draw conclusions regarding what knowledge management approaches have more or less potential effectiveness for a given firm. Of course, the specificities of each particular firm influence the suitability of a concrete KM approach, but still, a general framework can guide action.

In the context of a generic firm, we propose to think in terms of its knowledge base, understood as a combination of external and internal knowledge components. A schematic representation is shown in Figure 1, where I represents a piece of internal knowledge and E1 to E4 represent four pieces of external knowledge.

We depict I in the center to give the idea of a core, and the different Es around it to indicate both the fact that they are closer to the environment and the relative independence there is among each other. Some overlap between I and the different Es indicates that the part of I geared to put the Es into idiosyncratic action needs to be aware of some of the corresponding Es' characteristics.

Using this knowledge-base representation of a firm, the next section introduces the concept of learning trajectories and explores the different LTs that can be adopted within a firm. Next, we use these concepts to derive general conditions and goals for effective knowledge management initiatives.

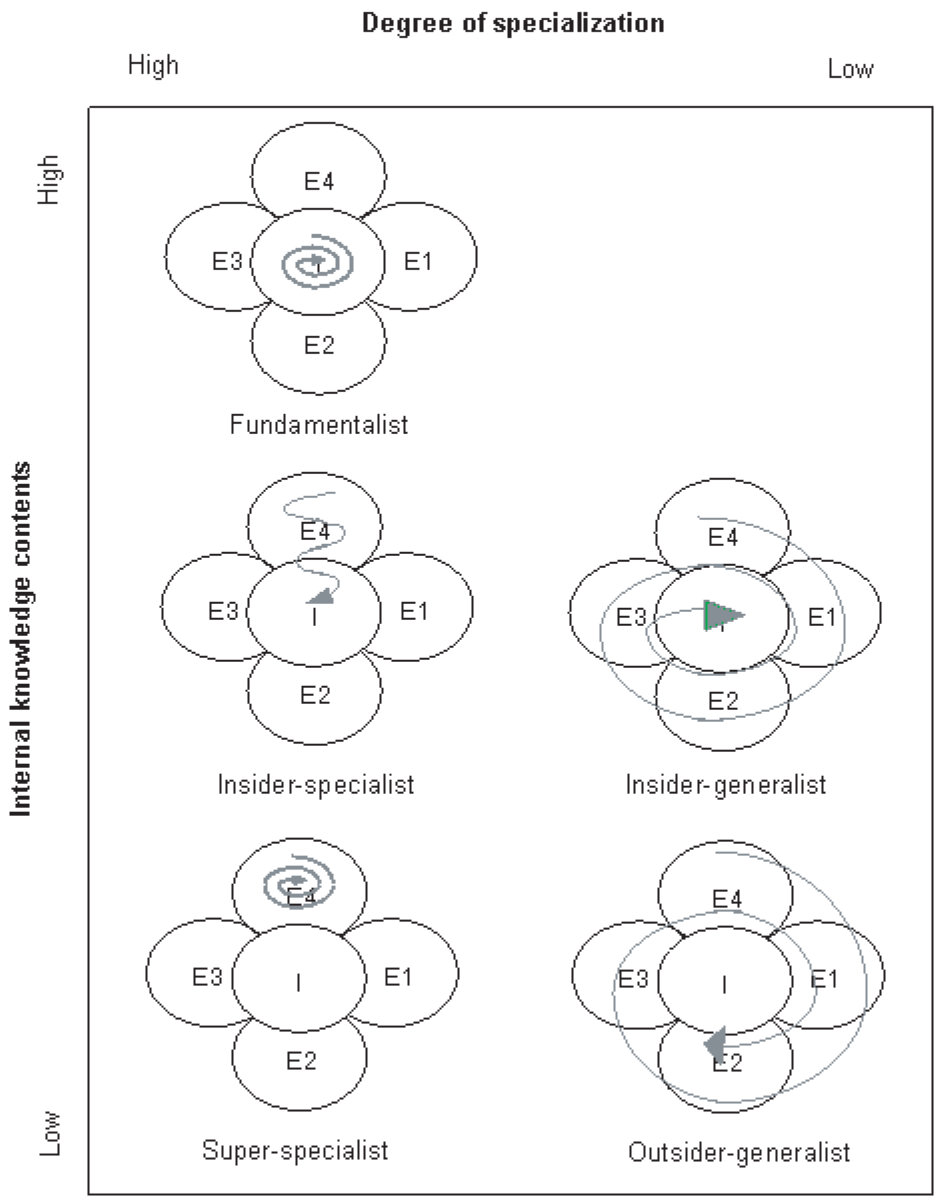
KNOWLEDGE CREATION AND DEPLOYMENT IN THE FIRM: LEARNING TRAJECTORIES

The concept of knowledge-based competitive advantage assumes that a firm has a view of the knowledge base it needs at a given moment. Any firm needs to develop and maintain a mix of internal and external knowledge geared to its particular competitive positioning. One way of configuring this process is through the identification of adequate learning patterns—learning trajectories—that lead to the desired mix of internal and external knowledge. In other words, a firm develops its appropriate mix of knowledge when its members evolve through a right combination of LTs. Thus understood, the LT of an individual is a representation of his or her evolution toward a certain degree of significance to the organization in terms of contributing external or internal knowledge to its relevant knowledge base. Of course, many different individual LTs can be imagined in a firm. Choosing the appropriate ones is a question of matching the knowledge base needed to compete according to the firm's strategy and mission on the one hand, the profiles of the different individuals and groups involved on the other, and the learning procedures judged most effective for each combination of knowledge base and individual or group. Thus, it is impractical to give specific answers for all possible cases. However, the idea of LTs permits us to set up a basic framework useful to design the collection of learning efforts needed and the corresponding KM-based support that might make sense.

One version of such a framework is depicted in Figure 2, where LTs are classified in terms of Internal Knowledge Contents and Degree of Specialization, be it in internal or external knowledge. LTs are represented here as learning paths drawn on the knowledge map of the firm. Depending upon what kind of knowledge the firm needs to develop in order to match its competitive positioning needs, one LT might be more appropriate than another, or a combination of them can be useful across a number of individuals or groups in the firm.

Hence, one can define sorts of stylized LTs that correspond to different career paths of individuals in the organization. In this sense, for example, one LT develops what can be called superspecialists. It corresponds to a career as a

Figure 2. A classification of LTs



specialist in some external knowledge without much idiosyncratic, organization-dependent knowledge. Superspecialists resulting from this kind of LT will probably be highly valued in the market and not as much internally. A firm will not be able to develop competitive advantage with only superspecialists of this kind, however. An extreme example could be that of a movie star who has developed her acting know-how in several movies, but who is not tied to any of them (or their producers) in an organizational sense. The so-called "Hollywood organization" is based in this idea. It consists of a combination of persons, each of whom has excellent knowledge in some specific field, that join efforts toward the achievement of a specific, short-term goal. They stop working together as soon as the goal is achieved as they do not contribute any idiosyncratic knowledge that would give sense to any cooperation over a longer period of time.

On the opposite, an LT targeted only at the development of internal knowledge content is that of the fundamentalist, an organization insider with virtually no external expertise. A firm in which all members have such an LT would not develop competitive advantages, either: It would be like a good movie director without actors. LTs of this kind may make sense in extreme cases, but only if they can be complemented with relevant and valued external knowledge holders.

A more balanced LT can be called an insider generalist: A person starts with some external knowledge and proceeds to integrate other Es while incorporating more and more I. The result, depending on the competitive positioning of the firm, could be an appropriate mix of internal and external knowledge with high competitive-advantage potential. This would correspond to the classical careers of persons who start in one functional department, then pass through other relevant functions, and finally end up at a managing position. During the early stages, these careers incorporate technical skills and add value to the organization through making operating decisions and solving rather structured problems. At later stages, they are valued because they develop integrating capabilities, solving unstructured problems and giving strategic insight to organizational routines.

In contrast, an insider specialist could start from being knowledgeable in an E and intensifying in it while incorporating relevant pieces of internal knowledge. This is a typical trajectory of a person who, without ever abandoning a particular function or department, gets more and more involved in firm-specific issues.

Finally, an LT that we call outsider generalist belongs to a person who keeps incorporating different kinds of external knowledge without complementing them with any internal knowledge element. The result is a profile that can be highly valued in the market, but that has difficulties in being well rooted in a specific enterprise.

We could continue with more archetypical LTs. This would miss the point, however. Taken as individual LTs in the context of a desired knowledge map such as that of Figure 1, the idea is that a proper balance of LTs should be designed and managed in order to develop an organization with competitive-advantage potential. Although not a single LT can be considered to be inherently inadequate for the firm's success over time, failure to balance different LTs may give rise to a collection of LTs that might be detrimental to the organization. Although a firm will hardly be able to successfully compete without a good external knowledge base, it will also need to develop a certain critical mass of internal knowledge. This is important for at least two reasons. First, people that follow outsider-generalist or superspecialist LTs may easily leave the firm because they are likely to be highly valued by the market. Second, especially in conditions of soaring environmental change, it is important to have people who are able to give a sense of unity to the organization, which means taking care of internal knowledge development.

LEARNING TRAJECTORIES' GOALS AND CONDITIONS: A BASIS FOR KM SUPPORT

In order to build up, support, and maintain the appropriate external- and internal knowledge bases of a firm, thus contributing to its sustainable competitive advantage, different kinds of LTs need to be fostered in an organization. A variety of initiatives can be designed and deployed for this purpose.

For the development and maintenance of a firm's external knowledge base, two of the LTs above seem particularly adequate: those of the superspecialist and the outsider generalist. Most actual KM initiatives (intra- or extranets, knowledge databases, distance learning arrangements, groupware and communication infrastructures, etc.) are targeted to the development of a good external knowledge base as they typically cover the following areas.

- Infrastructures for experience sharing: Standard best practices and routines, databases, and so forth
- Infrastructures to facilitate coordination among specialists: To the extent that more effective coordination is possible, specialists can concentrate more on their fields of expertise.
- Yellow-pages-type systems to locate who in an organization or the environment has specific experience or knowledge
- Systematized, well-indexed access to market and industry information from standard sources
- Systems that force the utilization of best practices such as ERP, CRM, and so forth
- Training in standard capabilities, available in the open market

Of course, for these supports to be effective they might need to be complemented with others of a more organizational character. For example, adequate control and incentive systems are important when individuals are not willing to share knowledge with others because it is one major source of their value in the marketplace.

Hence, in order to devise adequate organizational supports, questions about market knowledge and its evolution the main technical constraints, possibilities, and innovations and so forth have to be taken into account. Also, the corresponding external knowledge must be codified to the extent possible in order to reduce the impact of workers leaving the organization.

At least three main areas of external knowledge development need to be taken into account. First is the specialization and coordination knowledge for both individuals and teams inside the organization (using ICT-based initiatives to improve coordination efficiency and effectiveness, for example) and between the organization and its environment: structuring relationships with suppliers and clients, formulating strategic alliances for knowledge-sharing purposes, and so forth.

Second is work practices that may enhance external knowledge development and transfer. For example, these include training and education initiatives, the identification of groups of excellence for practice sharing, or the designing and implementing of systems that encapsulate and foster the utilization of general good practices.

Third is the organizational area: incentive and control systems, convenient information-access structures, and so forth.

On the other hand, from the internal knowledge base standpoint, the appropriate LTs differ significantly from those adequate for external knowledge. We argued that internal knowledge has more of a tacit nature, blurred across the organization and "sticky." It cannot be acquired in the market; it has to be developed within the organization. In this context, the insider generalist, insider specialist, and fundamentalist types of LTs in Figure 2 come to mind. They aim at fostering (a) the organization's basic values, (b) routines that facilitate the effective use of these values, (c) the idiosyncratic behavior styles of the organization, both individual and collective, and (d) personal capabilities that fit these styles, facilitating their adoption by organization members.

The sticky nature of internal knowledge implies, as a first consequence, that the usefulness of technology-based traditional KM initiatives will probably be limited as those systems require the encodability of knowledge. In addition, as internal knowledge is context dependent and blurred among organizational members, LTs aimed at its development have to deal with it more as an aggregate than as a set of individual pieces.

According to Szulanski (1996), stickiness is caused mainly by five factors: (a) causal ambiguity and the unprovable nature of the knowledge transferred, (b) the lack of motivation by the knowledge source, which is perceived as unreliable, (c) the characteristics of the knowledge recipient, (d) the lack of absorptive capacity and retentive capacity, and (e) context characteristics such as a barren organizational context and arduous relationships. As a consequence, knowledge-related barriers due to a lack of absorptive capacity, causal ambiguity, and the arduousness of the relationship between the source and the recipient are the main barriers to knowledge transfer within a firm.

Therefore, to enhance internally focused LTs, it is advisable to respond to these three dimensions. The issue about a lack of absorptive capacity, which Cohen and Levinthal (1990) define as the inability to exploit outside sources of knowledge or radical new ways of doing things, suggests exploring ways of broadening the mind-sets and searching mechanisms of the organization's members. Fostering an open attitude is a first step in this direction. Systems that "are an integral part of the context" because they are deeply embedded in it can contribute to enhance the understanding and transmission of internal knowledge as they render the organization context "more obvious" to its members.

Regarding causal ambiguity, Tyre and von Hippel (1997) see it as a consequence of imperfectly understood idiosyncratic features of the context. Of course, one way of naturally reducing causal ambiguity is by staying in the organization over long periods of time; this increases the individual's tacit understanding of how the organization functions, its power structure, its culture, and so forth. To the extent possible, the unambiguous recognition of the organization's mental model and value applications to everyday situations contributes to reduce causal ambiguity in this sense. This includes practices such as after-the-fact revisions of why things were done the way they were, be it through mentoring or coaching, or, if possible, concrete mental model representations that contribute to reduce ambiguity.

Finally, implicit in the notion of internal knowledge is its contextual and embedded character. Consequently, in order to develop and deploy it effectively, numerous and multiple individual exchanges are needed so that the appropriate critical mass builds up. In this context, arduous (i.e., distant and laborious) relationships hinder the formation of internal knowledge. Again, this implies that an open and good work atmosphere can enhance internal knowledge formation.

Therefore, internally focused LTs are more likely to be implemented in organizations that have in place initiatives to enhance their absorptive capacity, and that allow for open debates of new ideas or new ways of doing things. Also, the degree of employee retention, especially of those persons who have developed a good understanding of the organization's idiosyncrasies, as well as the encouragement of good relationships between key members and its fostering and nurturing, has a positive impact on the development and maintenance of internal knowledge. For this purpose, mentoring and coaching seem to be especially relevant. Finally, a systematic approach putting adequate organizational structures and systems in place that contribute to making values, styles, and context more obvious and easy to assimilate and understand is a fundamental piece to internal LTs.

As an example, we can refer to the case study of Unión Fenosa and its corporate university (Andreu, Grau, Lara, & Sieber, 2004). The very conception, design, and organization of the corporate university and the courses offered there follow the guidelines that a good combination of external- and internal knowledge development and deployment via LTs would advise. Internal knowledge is subtly interspersed with external knowledge, for example, in the organizational structure of the corporate university itself, which mimics the structure of the company and assigns responsibilities according to it. In fact, learning and teaching from experience as an explicit goal in the company's strategy and mission puts the emphasis on well-balanced LTs in the sense above from the start. Accordingly, managers and employees at all levels are evaluated and promoted by taking explicitly into account, to some extent, the degree to which LTs match the company's needs as they evolve over time in response to environmental and competitive conditions.

CONCLUSION

In this article we have proposed to think in terms of learning trajectories in order to analyze how to achieve the development of a balanced knowledge base in a firm. Such a standpoint puts the emphasis on knowledg development needs and somehow de-emphasizes specific technology-based support, although we recognize the potential of such KM initiatives. Our approach has distinguished between external and internal knowledge in order to characterize a set of archetype LTs with which it is possible to describe the most appropriate knowledge-development course for a specific firm at a given point in time. A particular set of LTs considered appropriate for a specific firm situation gives clear clues about how different kinds of knowledge management systems and supports could help to strike the right internal- and external knowledge balance for that firm. A natural consequence of the proposed analysis is that the KM initiatives that a firm identifies are not all strictly technology based; there is an important complement that in fact defines the critical core of an integrated KM proposition. Thus, we join the view of some notorious recent research efforts that favor a view that enlarges the conception of knowledge management from a system-based view to an organization-wide conception.

Chapter 5.10
Siemens:
Expanding the Knowledge Management System ShareNet to Research & Development

Hauke Heier
European Business School, Germany

Hans P. Borgman
Universiteit Leiden, The Netherlands

Andreas Manuth
Siemens Information & Communication Networks, Germany

EXECUTIVE SUMMARY

The case study describes the issues surrounding the expansion of the community-based knowledge management system (KMS) ShareNet to the research and development (R&D) function at Siemens Information and Communication Networks (ICN). It sets the stage for a decision situation that Siemens ICN's vice president business transformation and knowledge management, Janina Kugel, faced in 2003. While R&D usage rates differed not remarkably from other Siemens ICN functions, a strategic emphasis on innovative products and services — as well as ambitious targets for leveraging offshore development resources — necessitated a stronger penetration of this highly relevant function. Could this extension build on earlier experiences gained with the best practice implementation approach at the sales and marketing function? The case description provides a chronological account of ShareNet's conceptualization, development, international rollout, and operation. It pays attention to information systems (IS) implementation issues, change management, and current developments in the field of knowledge management (KM).

ORGANIZATIONAL BACKGROUND

Siemens, headquartered in Munich, is a German-based multinational corporation with a balanced business portfolio of activities predominantly in the field of electronics and electrical engineering. With sales of EUR 74.2 billion and a net income of EUR 2.4 billion in fiscal 2003, it was Europe's industry leader with strong positions in the North American and Asian markets (in August 2003, EUR 1.00 was equivalent to about USD 1.13). Approximately 50,000 researchers and developers were employed; research and development (R&D) investments totaled EUR 5.1 billion. Exhibit 1 shows Siemens' financial performance from 2000 to 2003. Siemens was a conglomerate of six business segments: Information and Communications, Automation and Control, Power, Transportation, Medical, and Lighting. Each business segment was split into several groups with independent profit responsibility and regional sales organizations (local companies) around the globe.

The decentralized matrix structure allowed for entrepreneurial responsibility and the development of close ties to customers. Global, interdivisional cooperation and systematic sharing of best practices enabled the provision of comprehensive and customer-focused solutions. Siemens' managing board confirmed that the "global network of innovation" — over 400,000 employees in 190 countries — was the firm's greatest asset. Linked in a global knowledge network, they were key for innovation and finally for offering technologies, tailor-made solutions, and services.

Siemens' largest business segment, Information and Communications, comprised three

Exhibit 1. Siemens' financial performance from 2000 to 2003 (EUR in millions)

	2003	2002	2001	2000
Net sales	74,233	84,016	87,000	77,484
Cost of sales	(53,350)	(60,810)	(63,895)	(55,949)
Gross profit on sales	20,883	23,206	23,105	21,535
Research and development expenses	(5,067)	(5,819)	(6,782)	(5,848)
Marketing, selling, and general administrative expenses	(13,534)	(15,455)	(16,640)	(14,173)
Other operating income (expense), net (therein gain on issuance of subsidiary and associated company stock)	642	1,321	2,762	7,549
Income (loss) from investments in other companies, net	142	(114)	49	299
Income (expense) from financial assets and marketable securities, net	61	18	173	2,732
Interest income (expense) of operations, net	31	94	(32)	(35)
Other interest income (expense), net	214	224	43	180
Income (loss) before income taxes	3,372	3,475	2,678	12,239
Income taxes	(867)	(849)	(781)	(3,017)
Minority interest	(96)	(29)	(191)	(362)
Net income (loss)	2,445	2,597	2,088	8,860

groups. Siemens Business Services (SBS) offered single source IT solutions and services. Information and Communication Mobile (ICM) covered all mobile communication requirements with network technology, terminal devices, and mobile applications. The case study focuses on Information and Communication Networks (ICN) that developed, manufactured, and sold public communication systems, private business communication systems, as well as related software and services. Impacted by the telecommunications equipment industry's continuing difficulties, Siemens ICN's sales of EUR 7.1 billion resulted in a negative EBIT of EUR 366 million in fiscal 2003 (Siemens, 2003). The 38,000 employees in over 160 countries focused on improving the product base, cost structure, and sales channels.

It was Siemens ICN's strategy to become a solution provider for other "global networks of innovation". Its three business units would provide the physical components of a sales project while the local companies were responsible for customizing and integration into the customer network: Enterprise Networks (EN) offered communications solutions for enterprise customers, Carrier Networks (CN) comprised IP-based convergence solutions, circuit-switched networks, optical networks solutions, and a portfolio of broadband access solutions, and Carrier Service (CS) provided local maintenance, system support, and general services for circuit-switched, IP-based, and hybrid networks (Siemens Information and Communication Networks, 2003). Exhibit 2 depicts Siemens ICN's organizational structure.

Exhibit 2. The Siemens ICN organization

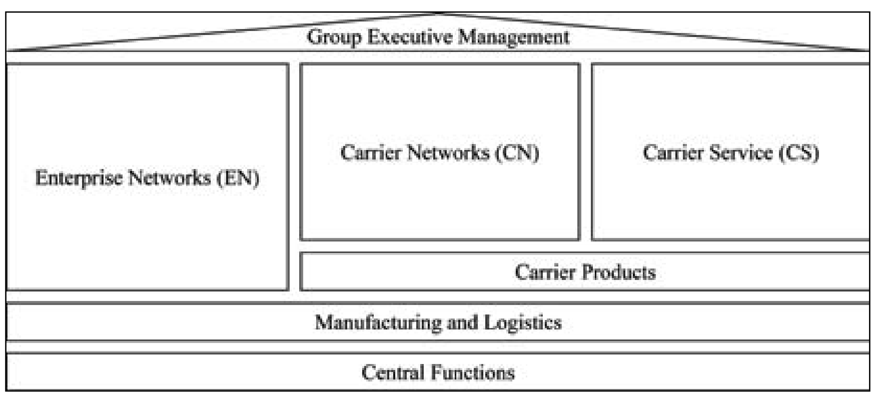

Exhibit 3. Mission statement of the central function knowledge management

- We foster the knowledge management activities within Siemens ICN and leverage our global knowledge sharing network with ShareNet.
- Managing knowledge is not just a matter of transferring information from one place to another, it is a social process which must motivate and encourage people to share that information proactively.

For the case study, mainly the complementary central functions business transformation (BT) and knowledge management (KM), as well as the local companies, are relevant.

Headed by Janina Kugel, vice president of business transformation and knowledge management, a six-person team drove and supported knowledge sharing initiatives in order to enhance Siemens ICN business processes and global cooperation. Exhibit 3 presents the mission statement of the central function KM. Responsibilities included the mapping of business processes to establish supportive KM platforms, the creation of a common knowledge infrastructure and culture, and fostering the awareness that knowledge sharing generates value. This was supposed to facilitate cooperative global learning, as well as cross-divisional and cross-country reuse of global best practices.

SETTING THE STAGE

The case study illustrates the issues surrounding the implementation of the community-based knowledge management system (KMS) ShareNet at Siemens ICN over the period 1998-2003. It sets the stage for a range of decision options that Kugel must incorporate in her upcoming proposal to extend the KMS to Siemens ICN's research and development (R&D) function, by presenting a chronological account of ShareNet's history. Specific attention is paid to information systems (IS) implementation issues (e.g., Ginzberg, 1981; Zmud & Cox, 1979) as well as to change management interventions (e.g., Earl, 2001; Fahey & Prusak, 1998; Seeley, 2000). Kugel was convinced that much could be learned from the sales and marketing rollout history but that recent challenges in the telecommunications sector — as well as the specific needs of the R&D function — would make several adaptations to the system's functionalities and implementation strategy necessary.

ShareNet, a global knowledge sharing network initially developed for the global Siemens sales and marketing community, was conceived in 1998. With the market environment in constant flux, Siemens realized it had to be able to provide flexible bundles of services and products that could be easily adapted to individual customers. To this end, the company recognized that a major improvement in the fast and purposeful identification and exchange of relevant information and knowledge was needed. Hence, Siemens ICN started the development of a community-based KMS under the name ShareNet. For "explicit knowledge," the aim was to provide structured knowledge objects in the form of project descriptions, functional and technical solutions, customers, competitors, and markets. For "tacit knowledge," the system was intended to provide functionalities such as newsgroups, discussion forums, and chats.

As explained next, ShareNet's implementation and rollout across the global sales and marketing function was overall successful. Kugel's challenge now was to extend this success to the R&D community in a much grimmer economic environment. Facing a difficult business situation and outlook in 2003, Siemens ICN's group executive management continuously emphasized the need for innovative products and services. At the same time, all organizational functions had to meet strict cost criteria. In 2003, Siemens developed 5% of its software in low-cost countries. An ambitious program was started to extensively use offshore development resources in order to reduce costs. In addition, Siemens aimed to consolidate development activities to shorten the time to market, to concentrate on core competencies and, thereby, to strengthen its innovative power.

Cost cuttings through decentralization to low-cost sites seemed easy. Keeping R&D quality high — while scattered across the globe — was the real challenge. Knowledge sharing between employees and partners in remote areas was seen as a key driver, again strengthening the call for

ShareNet's R&D expansion. Fueled by the KMS' successful, large-scale rollout at the sales and marketing community, as well as by first evidence for related culture change, the ShareNet operating team had conducted first pilot implementations at R&D.

Besides heading the KM team, Kugel also directed a team of business consultants — the BT team. Just when Kugel had to decide on ShareNet's expansion to R&D, those employees had successfully finished a project to define and implement a process to foster radical new innovations (labeled "disruptive innovations") within ICN and feed these innovations into the well-defined product and service development processes for the carrier and enterprise business. The BT team envisioned a central role for ShareNet in this process, which could give ShareNet a jump-start into the R&D environment. Now Kugel saw basically three options to proceed: first, to simply replicate the sales and marketing implementation approach for the entire R&D community; second, to adapt the implementation process for R&D and to establish several smaller groups of R&D employees; or third and last, to customize the implementation process and expand ShareNet usage step-wise along the R&D process.

CASE DESCRIPTION

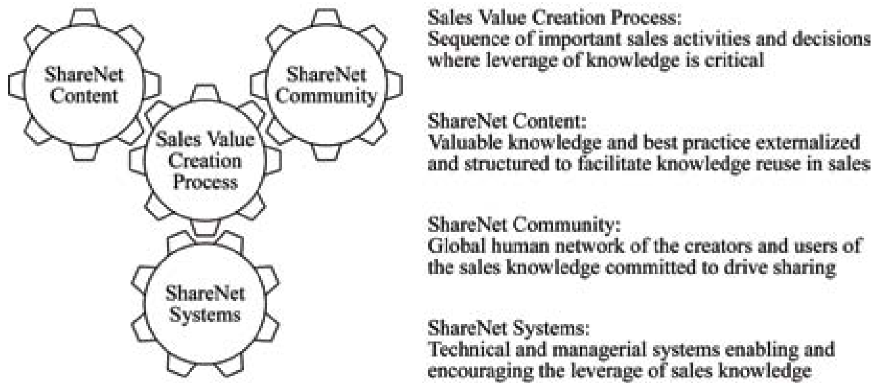
Definition & Prototyping

The initial development of ShareNet started in 1998. ShareNet's first key project stage — "definition and prototyping" — lasted from August 1998 to the end of March 1999. Objectives were to establish the ShareNet project team, to create conceptual definitions and refinements, to start prototyping the technical platform, and to ensure early executive and user buy-in. Soon, the ShareNet project team developed the vision of a structured KM initiative for the sales and marketing function: "ICN ShareNet is the global knowledge sharing network. We leverage our local innovations globally. We are a community committed to increase value for our customers and ICN by creating and re-applying leading-edge solutions." The aim was to change Siemens ICN's communication flow from a broadcast-oriented "enabling" approach that is, headquarters to local companies, to a meshed network approach required for fast global learning.

Several benefits were emphasized: costs should be reduced by avoiding expensive mistakes made in the past, or simply by reusing technical and functional components that had already been developed; project delivery times ought to be shortened through reuse, leading to higher project throughput/utilization by the sales force; quality should improve as reusable modules were repetitively sold and improved; lastly, besides representing benefits in their own right, these would lead to more successful tenders and higher revenues. Four crucial elements were defined to guide the KMS' conceptual development, prototyping, and later implementation. Exhibit 4 depicts the basic components: Sales Value Creation Process, ShareNet Content, ShareNet Community, and ShareNet Systems.

ShareNet's central part — the Sales Value Creation Process — was a sequence of important sales activities and decisions where knowledge ought to be reused. It served as an abstract global sales process definition, where each individual local sales process could be mapped. The ShareNet project team and four consultants from The Boston Consulting Group (BCG) realized early that the KMS' development should be no isolated effort, and later parachuted into the local companies. Consequently, the team was augmented by 40 sales representatives from headquarters and 15 local companies. Their involvement served three distinct change management goals: they specified KMS solutions, supported a network of people experiencing similar difficulties, and set examples

Exhibit 4. ShareNet as an interplay of four crucial elements



for the combined KM and change initiative's progress. Siemens ICN's group president and high ranking sales managers formed the steering committee responsible for project supervision and top management support.

The ShareNet project team was assembled for the first time in October 1998 at the kick-off workshop at Frankfurt airport. Goals were the definition of the KMS' content, objectives, and structure. The project team and BCG presented first ideas for ShareNet's vision, basic concept, and graphical user interface (GUI) mock-ups for prototyping. Afterwards, the participants' team engaged in a joint diagnosis of business problems in order to make sure that the KMS provided value-add to the sales and marketing process. The structure of the KMS was tailored to tackle these problems through global collaboration. All sales representatives were asked to identify projects, solutions, and practices in their home regions that could be leveraged globally, that is, early win-showcases. An Intranet site with a preliminary database, discussion and feedback groups, and core team member profiles was soon established. Altogether, the knowledge of 18 sales projects was captured, more than 30 sales tips and tricks identified, and a first concrete sharing of knowledge initiated.

All content gathered was reviewed in November 1998 at the global exchange workshop in Garmisch. Based on their previous experiences, the ShareNet project team decided early on two ShareNet applications. First, the IS should serve as a document repository for the coding and sharing of best practices in selling solutions. It included structured knowledge about everything needed to create a solution. Second, ShareNet should foster the creation of knowledge networks. Employees should virtually exchange personalized knowledge to promote global cooperation, human networking, and quick help. The option of adding a corporate directory for the mapping of internal expertise (yellow pages functionality) — often found in KMS — was seen as less promising due to a perceived lack of data quality (see Alavi & Leidner, 2001; Earl, 2001, for a typology of KMS and KM strategies).

To accommodate the first application, the explicit knowledge derived from different stages of the solutions-selling process fell into distinct categories of ShareNet solution objects (e.g., technical or functional solution knowledge) and

ShareNet environment objects (e.g., customer or market knowledge). Technical solution components were all technology-related parts of solution packages provided to the customer. Functional solution components were all the non-technical tips and tricks or generic methods offered, for example consulting service, financing, and so forth. Useful documents (e.g., customer presentations, spreadsheets) could be linked and references to other content in ShareNet were supported. The linkage was to some extent inherent in the structure, for example a sales project naturally contained a pointer to a customer, and so forth. Additionally, contact persons were named for further help.

To accommodate the second application, ShareNet's tacit content consisted of urgent requests, discussion forums, news, and chats. The urgent request feature allowed ShareNet members to post an urgent message or question to alert the other ShareNet users. If feedback on general ideas or suggestions to solve low priority issues was needed, discussion forums should rather be chosen. ShareNet news was a specific type of forum that served as a bulletin board for the ShareNet Community. ShareNet chat was the global virtual meeting room for the KMS' members based on Internet relay chat (IRC). The final element in ShareNet's people-to-people section was the ShareNet member directory, comprising a directory of all users with contact information, organizational details and the individual list of contributions to ShareNet.

The ShareNet Systems included both the technical systems to facilitate low effort global publishing and searching, and the managerial systems to encourage the capturing, sharing, reuse, and global leverage of knowledge and best practices. These comprised — among others — incentives and rewards, methodologies to externalize knowledge, and dedicated resources for maintaining and evolving the KMS. The core team decided to start with rapid prototyping of the technical platform and to leave the definition of the managerial systems for the final workshop.

The technical systems employed three-tier client/server architecture. The first tier was the user inter-face/personal workspace accessible via regular Web browsers. The second tier did most of the processing: a SUN SparcServer served as the designated application and Web server for all local companies and business units. It ran a software toolkit based on open Internet standards: open source Web server (AOLServer) and open source community system (ACS - ArsDigita Community System). ShareNet's dynamic Web implementation was based on AOLServer Dynamic Pages (ADP), an HTML derivate. Web pages were generated by scripts loading meta-data (e.g., object structure and graphical layout) and actual data (e.g., customer description) from the relational database management system (Oracle 8i). It was housed on the same server and comprised the third tier.

The third and final workshop in the "definition and prototyping" stage was held at Munich airport in February 1999. Content gathered and reviewed from three regions was posted on the prototype system and set an example for the successful application of managerial innovations. However, the participants were unsure about incentives, rewards, and culture change: how could they ensure that ShareNet was adopted by the whole organization? Joachim Doering, president group strategy, estimated that 80% of KMS failed for non-technical reasons: lack of capability to execute, missing readiness or commitment to change, defunct change communications, limited top management support, and poor strategy. To side-step these traps, he wanted the initiative to simultaneously address all domains of change management: strategic change, process change, technological change, and especially organizational and people change.

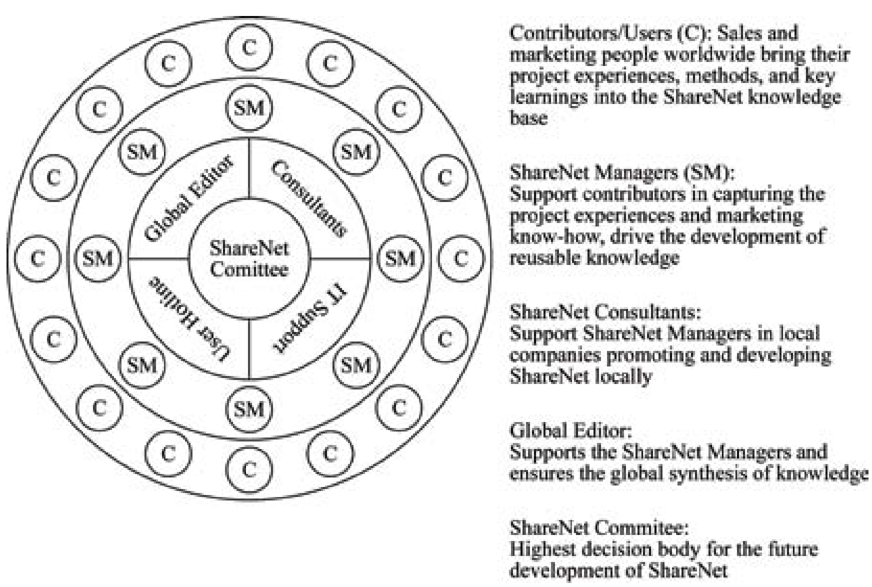
For the managerial systems, the Munich workshop decided on a range of objectives: first, to increase the usage of ShareNet and thereby improve value creation in sales; second, to support the capturing of knowledge created in the sales processes; third and last, to enable ShareNet's further development and growth by rewarding knowledge sharing. In order to ensure that all ShareNet crucial elements (processes, content, community, and systems) were developed and improved further, the Munich workshop participants proposed a consistent organizational structure. Exhibit 5 shows the resulting ShareNet organization, roles, and tasks.

Top management support mainly relied on explicit means of change communications to bundle organizational resources and individual commitment to the project. Line managers rather served as neutral intermediaries to spread ShareNet's idea across organizational levels and functional departments. Nevertheless, in the long term the ShareNet Community should assume responsibility for the KMS' maintenance and evolution through its input and formulation of requirements. In March 1999, Roland Koch, ICN group president, decided to continue the project and to proceed with the next development stage: "This [ICN ShareNet] network will be of key importance for the success of ICN's solutions business, because the company that is able to make use of existing experiences and competencies quickest has a distinct competitive edge over the other players. We need to be among the first to realize this strategic competitive advantage through efficient knowledge management."

Setup & Piloting

The second key project stage — "setup and piloting" — lasted from April to mid July 1999. Objectives were to test and improve the technical platform, to ensure local company commitment to the project, and to develop a phased implementation approach including training material. BCG's assignment ended with the final workshop in Munich. The KMS was rolled out in four pilot countries (Australia, China, Malaysia, and Portugal) chosen for the following reasons: they

Exhibit 5. The ShareNet organization



showed good "fit in" with the core team, represented Siemens' global operations well, and their first cross-regional sharing of experiences set examples for the entire company. A pilot project team conducted informal training sessions with workshops developed by Rolf Meinert, vice president of change management.

The ShareNet team project saw the pilots as an important means to rapidly establish buy-in at headquarters and local companies. Team members and managers from the ShareNet committee began to meet key executives in local companies (i.e., local ICN heads, local company heads) and at headquarters. They made sure that the managers were committed to KM, informed the team about local particularities, and nominated or supported ShareNet managers. Besides the training material, the ShareNet project team had no formal change management strategy, but rather a range of measures to overcome common implementation barriers. Keeping the right balance between challenging and realistic goals avoided "scope creep". Involving users in developing their own KM solutions helped to build personal networks, to create buy-in and trust with internal customers, and to secure top management support.

The team strongly believed in a bottom-up approach for ShareNet manager nominations. Koch sent a personal letter to all local companies to create awareness for the KMS and to request the nomination of one part-time ShareNet manager per country. In addition, Meinert approached potential ShareNet managers all over the world, making use of his large personal network. Only in the case where countries without voluntary participants were detected were the local company heads asked to nominate some of their employees as ShareNet managers. Lack of competence and commitment or too strong a focus on technology were often the result of forced nominations. In very few cases, a removal of ShareNet managers who did not live up to their obligations was necessary.

Technical systems accounted for only 25% of total project costs; the majority was spent on the selection and training of prospective ShareNet managers, communication campaigns, and training material. The ShareNet project team and the external consultancy Change Factory jointly developed a range of user trainings/workshops and tools for the global rollout, for example training videos, illustrated pocket references, and giveaways. A mission statement concretized ShareNet's vision and explicitly linked it to economic benefits: "ICN ShareNet intends to network all local sales efforts to facilitate global learning, local reuse of global best practices, and the creation of global solution competencies. ICN ShareNet shall realize considerable and measurable business impact through time and cost savings and through the creation of new sales opportunities. ICN ShareNet shall be integrated in the daily work of every sales person. ICN ShareNet is a self-organizing growing system."

The ShareNet project team decided on two-sectioned local company workshops as a central element of the change management initiative. The first section — creating necessary know-how for using ShareNet — followed the participants' working routines. They would learn about ShareNet's philosophy, discover its benefits for daily work, and get to know the structure and handling of the technical platform. Coaches would provide walk-through examples, live exercises, and stimulate discussions about the value-add of global knowledge exchange. During the second section — capturing knowledge with ShareNet — the participants would start to capture and peer review some sample projects they brought to the workshop. A positive, knowledge-oriented attitude was considered the basis for success.

The pilot project team began to test the KMS' database, GUI and usability, response times, and reliability. Objectives were to have secure and stable technical systems available for the "global rollout" stage. To ensure smooth integration with Siemens' Intranet, the ShareNet project team took a close look at Siemens ICN's global technology infrastructure and the level of the local sales representatives' Intranet know-how. Early on, the core team planned for integration with other Siemens knowledge sources and systems. However, the full mapping of all content into the ShareNet data model was never realized since speed of implementation was favored over lengthy coordination with other IS owners.

Global Rollout

The third key project stage — "global rollout" — lasted from mid July 1999 to mid February 2000. Objectives were to have ShareNet implemented in 30 major countries, to establish the ShareNet organization and managerial processes, and to capture and reuse valuable knowledge. The ShareNet project team provided user trainings, controlling to steer the global rollout, and communication material. Four phases for the international rollout were decided: buy-in and preparation (partly accomplished in the preceding stage), ShareNet manager handover, ShareNet workshops in local companies, and ShareNet manager review meetings.

Early in the "global rollout" stage, the introduction of the consistent incentive system "bonus-on-top" put even more emphasis on top management support. Some local executives felt threatened by ShareNet because their employees were bypassing traditional hierarchies in search of solutions. A one-time promotion scheme in fiscal 2000 should link knowledge sharing with economic benefits: local ICN heads should now be rewarded for inter-country business generated through substantial international knowledge exchange. "Business generated" was the total order income of projects secured with knowledge from other countries and the revenues from other countries created with knowledge from the ICN head's local company. "Substantial international cooperation" comprised reuse of knowledge via ShareNet and/or a verifiable exchange of human resources, which together accounted for more than 10% of the order income generated, and/or more than 10% of total project cost or time savings.

To be eligible for a bonus of approximately 10% of their fixed annual salary, the overall revenue achieved should sum up to at least 5% (up to 30%) of local ICN revenue (Gibbert, Kugler & Völpel, 2002). The local ICN heads had to complete forms that contained all cases of collaboration, that is, success stories. Several restrictions applied: since a successful knowledge transfer was described, knowledge giver and taker had to work in distinct departments and project groups and the amount of time and money saved or additionally earned turnover had to be stated. For approval, the ShareNet project team required written proof, for example, invoice, purchase order, or delivery confirmation. The success stories could be checked against each other just like consolidated balance sheets to ensure accuracy. Bonus-on-top yielded remarkable results: during fiscal 2000, Siemens ICN reported additional revenue of EUR130.9 million from international knowledge exchange, some 50% obtained through ShareNet.

The ShareNet manager handover took place at the end of July 1999. Participants from some 30 countries were assembled for the first time at a one-week boot camp in Feldafing, Germany. The ShareNet team selected rollout countries primarily on the basis of annual sales, availability of local ShareNet project team members, advanced market stage, and advanced technology infrastructure. The ShareNet managers received in-depth formal training enabling them to take over the responsibility for the introduction and utilization of ShareNet in local companies.

Moreover, the ShareNet project team intended to build-up committed social networks, first among ShareNet managers, and later throughout the sales and marketing community. Team building events, for example, trying to build a raft without tools to cross the Lake Starnberg, and a friendly and relaxed climate were important change management measures. Doering recalled the team spirit at the boot camp: "All they had to work with were steel drums, logs, pontoons, and some rope. Another catch: no talking. The managers, who gathered from offices around the world, could only scribble messages and diagrams on a flip chart. For the better part of the day, it was knowledge sharing at its most basic. Yet the group managed to put together a small fleet of rafts, which they paddled about triumphantly on the placid waters of the lake."

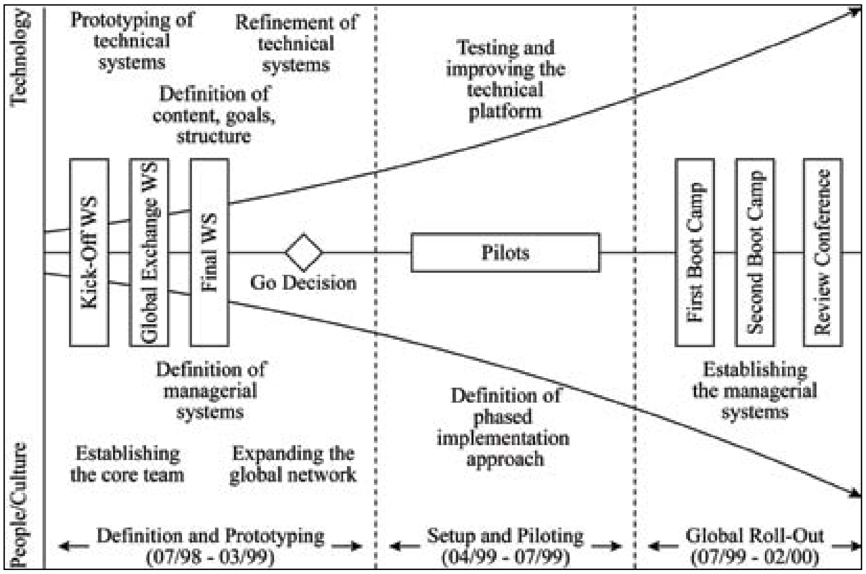
There was low headquarter participation at the first boot camp and the business units showed higher implementation resistance than local companies: they were afraid to lose sales opportunities for internal services, questioned ShareNet's positioning among other IS, and did not fully appreciate value creation in local companies. In addition, headquarters were afraid of sharing centralized knowledge, that is, a source of influence and power. Whereas more than half of the local companies' employees supported the KMS and some 20% resisted its implementation, numbers at headquarters were roughly vice versa. Resistance came in several flavors: inactivity and lack of implementation support, postponing decisions, preventing employees from posting safeguarded knowledge, denying the right to use ShareNet, and all kinds of politics. The ShareNet project team decided to continue the implementation with central funding and a focus on key impact areas, that is, the local companies.

Soon after the boot camps, the ShareNet managers began with the local rollouts. On average, each local implementation required project work for two or three months: one week for "selling" ShareNet in the local companies, three weeks for user training/workshops to teach the necessary skills to capture knowledge, up to two weeks for the review of captured content, two to three weeks for the support of local staff, and two days for a final review meeting. The ShareNet project team and ShareNet committee members visited 18 countries to support the implementation with communication campaigns and workshops. The entire implementation process was centrally driven and monitored, for example, rollout targets, resources, and workshops. Country-specific metrics were tracked and discussed with the local ShareNet managers on a monthly basis.

To formally conclude the KMS project, the ShareNet project team organized a ShareNet manager implementation review conference at Sun City, South Africa in February 2000. Goals were to reinforce community spirit, to exchange experiences with the international rollout, and to define future implementation ideas. Exhibit 6 recapitulates ShareNet's key project stages. Doering felt a substantial commitment to change: "ICN ShareNet is more than a database; it is a new spirit, a new way to cooperate worldwide across country and organizational boundaries. Knowledge reuse is the key to success, e.g., innovation, time to market, etc. With ICN ShareNet we take advantage of our strengths: local innovations and creativity and global leverage of sales power." Approximately 4,200 ShareNet users had registered and posted more then 2,100 public knowledge objects and 490 urgent requests; news and discussion groups enjoyed significant traffic.

To emphasize the project closing's importance, Koch participated via videoconference on the conference's last day. The participants consolidated their key learnings. Everybody acknowledged that ShareNet needed political attention and ongoing top management support, that is, Siemens ICN's group executive management and local ICN heads. Otherwise, time resources and prioritization for ShareNet rollout activities would consequently be too low. An adjustment of goals, incentives, and rewards was required for all members of the ShareNet organization and individual users. ShareNet managers needed sufficient time for support; that is, 25%-50% of their working time; other tasks had to be reduced. During a formal handover ceremony, the ShareNet project team transferred the KMS' ownership to a regular line organization, that is, the new ShareNet operating team. Through their new representatives, users

Exhibit 6. How ShareNet was developed



should finally assume ownership and responsibility for ShareNet's maintenance and evolution.

Operation, Expansion, & Further Development

The fourth key evolution stage — "operation, expansion, and further development" — lasted from mid February 2000 to the end of November 2001. Objectives were to continuously expand ShareNet throughout Siemens ICN and to further refine and develop the technical platform. The ShareNet operating team felt that knowledge exchange did not come naturally to the corporate culture. There were old boys' networks, risk adverse decision making, and a strong engineering "do-it-all yourself" culture that made it difficult to get accustomed to new rules of competition (Gerndt, 2000). Top engineers had adopted a "hero mentality," showing respect only for individual design achievements (Davenport, De Long & Beers, 1998). Innovations no longer originated in central R&D; rather they were derived from customers' needs. Strong hierarchies counteracted an atmosphere of openness, mutual respect, and ambiguity tolerance since they placed value on individual achievements at the expense of teamwork.

The ShareNet operating team recognized that people were slow to change their behavior; first results from culture change after a few years showed that the whole processes needed a decade to become self-sustaining. Albeit "bonus-on-top" had been successful beyond expectations, it was unclear whether ShareNet itself was benefiting. Users commented: "Receiving some […] award naturally serves as an incentive to sharing our knowledge with colleagues worldwide, but it is not the most important aspect. Getting direct recognition for how much our daily job is appreciated is the most important thing. That's what counts and motivates us." The new team decided to focus incentives and rewards more on the users themselves to get a critical mass of content into the system, to make users active contributors, and to create awareness.

Consequently, the ShareNet quality assurance and reward system went live on March 1, 2000. There were no monetary incentives since they encountered ambiguity in local companies; a share system, comparable to frequent flyer miles, faced less obstacles. ShareNet shares could be collected, accumulated, and finally turned into knowledge-related rewards. The share system was a flexible incentive scheme that could be adjusted according to needs for motivation and guidance: for example, objects published and forum responses yielded between three and 20 shares, dependent on a pre-assigned value. One share was equivalent in value to approximately EUR 1.00. ShareNet's technical systems automatically distributed the shares for contributions.

During the first four months, the share system yielded remarkable results: there was more awareness for ShareNet (35% new users), more activity (50% additional active contributors), and increasing content quantity (plus 90% knowledge objects posted). In July 2000, the competitive reward system was turned into an "online shop" where shares could be traded for a defined range of products, for example professional literature and Siemens laptops. But the success in quantity imposed drawbacks on quality. Lots of users — especially ones that joined ShareNet in earlier stages — lamented the decrease of content quality. Thousands of new objects brought the ShareNet managers' formal review process to its limits.

The ShareNet operating team introduced a peer-to-peer review process, that is, feedback from users to contributors. The change became visible through a five-star-rating of objects and urgent request answers. The stars were multiplied by a certain factor to compute the amount of shares the contributor earned. Introducing this new review process boosted the quality (plus 50% reuse feedback per knowledge object). The "ShareNet Special Weeks," that is, doubled shares for promising knowledge objects, aroused even more interest in July 2001. Though many knowledge objects were posted and several new users registered, the ShareNet operating team criticized special events: an artificial and expensive hype was created that rapidly ebbed off.

The ShareNet operating team continued with "networking people" at a second ShareNet manager conference in Istanbul in December 2000. Some 60 participants revised the quality assurance steps, discussed the inclusion of other communities into the KMS, and defined ShareNet manager targets. The basic requirement for the latter was general user support, for example, user trainings, presentations, and monthly reports. Complementary was the establishment of a constant knowledge input, that is, 1.5 knowledge objects per registered user per year, plus/minus 30% flexibility according to local peculiarities (knowledge givers vs. knowledge takers). Further required were the documentation of two success stories per 100 registered users per year and high performance knowledge exchange, that is, an average of 10 shares per registered user per month. As a result some 20 ShareNet managers received 50-120% of an additional fixed monthly salary as a bonus at the end of 2001.

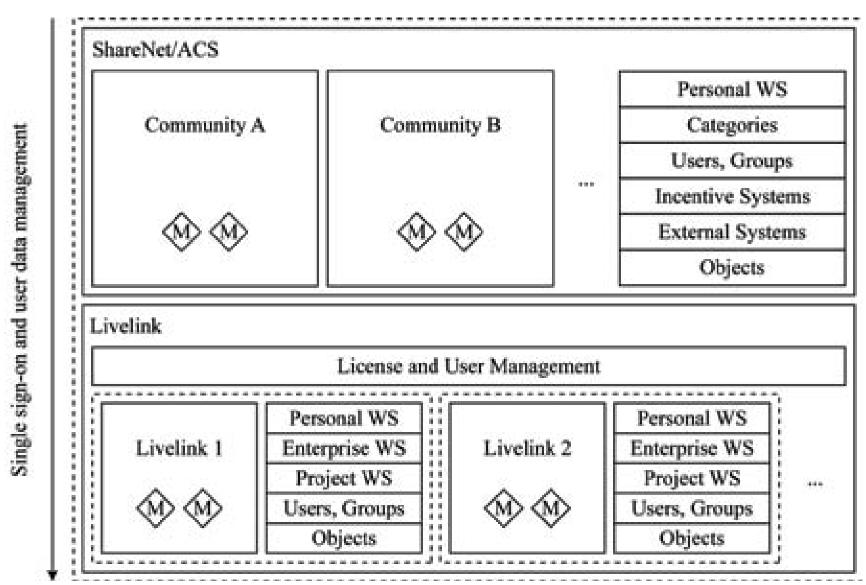
Shifting to a Multi-Community Concept

The fifth and last key evolution stage — "shifting to a multi-community concept" — began in December 2001. ShareNet had aroused much interest within Siemens. Heinrich von Pierer, Siemens CEO and president, declared ShareNet a Siemens-wide KMS best practice. Objectives of this stage were to sharpen the focus on topics leading to more efficiency, to foster the development and progress of smaller communities-of-practice (CoPs), and to delegate maintenance responsibilities to new user groups. The ShareNet operating team had gathered many requests for CoPs focusing on specific topics of interest. Those were seen as a good indicator for an institutionalization of the concepts and meanings inflicted by the culture change. Siemens ShareNet V1.x marked the introduction of a company-wide, multi-community platform.

The former ShareNet became one CoP amongst others but retained the largest number of users. The conceptual change necessitated a personal workspace (WS) with personal data, e-mail alerts, bookmarks, and links to all CoPs for which users had registered. Community homepages provided an overview of community-specific content for each user, for example, new threads since last login. Designated functional modules (M), that is, knowledge libraries, discussion forums, chat, and news, could be flexibly adapted to each CoP's businesses processes to win over users. This design also reflected the security requirements of sub-communities dealing with sensitive topics. In cooperation with other Siemens group divisions an interface/bridge license and user management was designed to ensure information exchange between ShareNet and Livelink Communities (the corporate document management system). Exhibit 7 shows the underlying technologies.

When the new technical platform went live, some users complained about the new layout (adapted to Siemens' corporate identity guidelines), many bugs, and weak performance. The majority of bugs were resolved quickly, while performance tuning required more time. Due to unclear specifications, former functionality was missing in Siemens ShareNet V1.x. ShareNet consultants and the global editor were badly prepared and encountered many obstacles over the first weeks. High user demand could not be met due to a shortage of resources: the central IT function needed additional human resources for timely development, implementation, and documentation; ShareNet consultants lacked money to travel and to train users globally. Top management could no longer provide the usual level of support due to other pending problems, that is, the collapsing telecommunications sector.

Exhibit 7. Application overview Siemens ShareNet V1.x



Through its successes in the sales and marketing functions, ShareNet had always attracted attention from R&D employees. As a result, just before the introduction of the new ShareNet technical platform, the ShareNet team was approached by an R&D department that focused on the development of "carrier products". This specific development process was well established and had not changed for many years. It, however, lacked formal mechanisms to share experiences and ideas across individual projects, for which R&D employees had to rely on their personal networks. As ShareNet had proven its ability to extend private networks within the sales and marketing environment, the R&D initiators expected the same for their community.

Discussions between the ShareNet team, the initiators, and several potential key users led to the development of R&D-specific knowledge objects and a corresponding capturing wizard. Since no further user involvement was desired by the community leaders, only brief training sessions were conducted at headquarters. The first results were disappointing: a general lack of traffic with a narrow focus. The ShareNet operating team members explained this in part by pointing out the proprietary R&D applications as well as (perceived) security concerns that made possible users cautious. A virtual R&D conference set a more positive example. Participants could post presentations with links to discussion threads and knowledge objects. Similar to traditional conferences, presentations were organized by time sequence and were available for a window of time. After a slow start on the first day, lots of comments were posted the following days and active discussions evolved among the virtual participants (MacCormack, 2002).

In September 2002, the ShareNet operating team announced a change in the knowledge sharing incentive system. Two main reasons were given: first, implementation success was established; second, both the current business situation and the business outlook were gloomy. Users could still keep and accumulate shares, but the incentive catalog was discontinued. There was no consensus within the ShareNet operating team whether the intrinsic motivation of knowledge exchange had already made ShareNet's usage self-perpetuating. For compensation, visibility and expert recognition, invitations to high-level events, and integration with business processes, for example employee target agreements, were planned. However, most decisions were neither taken nor implemented since Siemens' decentralized matrix structure required such decisions from local companies and not from Siemens ICN's executive management.

On the one hand, some team members were confident that the power of the ShareNet Community was not founded on incentives only. Users would keep their motivation on a high level since knowledge sharing was needed more than ever with globally distributed expertise and experiences. Thomas Ganswindt, Siemens ICN's new group president, exclaimed: "global networking and sharing knowledge is key to the success of ICN, even more since we will no longer have all the necessary knowledge in all local companies. The same counts for headquarters. And, if people really contribute to the success of ICN, it has to be beneficial to them." On the other hand, some team members argued that a discontinuation of extrinsic motivators would lead to significant drops in contributions and usage or even to a deadlock situation. Existing users might become passive and it would be difficult to attract others.

CURRENT CHALLENGES/ PROBLEMS FACING THE ORGANIZATION

The collapse of the telecommunications sector in 2001 did hurt Siemens ICN as seriously as any of its competitors. As a response, the group executive management started the Profit and Cash Turnaround (PACT) program. Its first phase, "clean-up," aimed for cost reductions through organizational redesign, headcount reduction, and improved asset management. This phase lasted until fiscal 2003. In the same year, the overlapping second phase, "rebuild," started — continuing until 2004. It comprised customer-orientated portfolio adjustments, as well as the implementation of innovative concepts for leveraging the synergies of enterprise and carrier solutions. Beginning in fiscal 2004, the third phase, "growth," emphasized intense customer relationships, streamlined processes, and a balanced portfolio of products and services.

"Rebuild" and "growth" were fuelled by major efforts in the field of innovation. On one hand, the group executive management required Kugel's BT team to design and kick-start a common innovation process and a technology roadmap. In addition to an existing product line process for incremental innovations, Kugel's team implemented a process to fuel disruptive innovations. Linked with ICN's strategy and based on ideas from internal and external sources, both defined innovative projects to be handled in the carrier and enterprise business' product development processes. The technology roadmap unified the view on existing and emerging technologies for all these processes, in order to foster synergies and to avoid double work. On the other hand, the existing R&D function and its product development processes were reconsidered in order to shorten new products' time to market. As one outcome of this revision, the new group president Thomas Ganswindt requested Doering to expand ShareNet throughout the R&D function. In turn, Doering asked Kugel to provide him with a detailed roadmap within one week.

Kugel knew that the "clean-up" phase's headcount reduction had struck the whole organization. Not only was her KM team reduced to three full-time employees — just about able to maintain the existing ShareNet — but the local companies were reducing their ShareNet managers as well. Additionally, the targeted R&D departments were made leaner while simultaneously speeding up their cycle times. Those developments limited the organization's ability and willingness to devote resources to KM. Cost reductions made it impossible to increase funding for external resources unless a striking business case could be presented. This was the only way to imagine a rollout comparable to the sales and marketing implementation.

The extremely difficult business situation and outlook also had severe impact on ShareNet usage. More than ever, employees were complaining about their lack of time for knowledge sharing. Facing massive layoffs, knowledge hoarding was again taken up as a means to make oneself irreplaceable. The discontinuation of the highly efficient ShareNet incentive and reward system and its less successful substitution with the recognition of ShareNet "masters and experts" added to the general challenges. In result the number of visiting users had fallen from some 4,600 (in August 2002) to some 2,100 (in August 2003). Page views declined from 179,000 to 75,000, and the number of contributing ShareNet users dropped from 432 to 190.

Though PACT led to more centralization in terms of target definition and controlling, it still made use of the "networking company" that ShareNet had fostered. Most employees recognized the need to identify and leverage Siemens ICN's knowledge globally in order to remain competitive and innovative. A majority shared knowledge freely without ever making personal contact; rather they were bound together in a global corporate network, worked within the same industry, and had a common code of conduct. It had become a habit for Siemens ICN people to involve local companies into strategic decisions. This approach ensured global applicability and established early buy-in.

While looking at the Alps from her office, Kugel wondered how to capitalize on the earlier experiences and accomplishments. Would the existing ShareNet line organization, training material, user base, brand identity, and culture change allow for a cheap and fast expansion into R&D? What would she present to Doering? A first meeting with her team led to the identification of three major expansion alternatives: first, replicating the original — but expensive — sales and marketing implementation approach with only minor modifications; second, identifying and fostering a range of smaller, topic-driven R&D communities (e.g., for technologies on the roadmap); third and finally, expanding ShareNet step by step along the R&D processes — starting from the recently defined innovation process, taking the adjacent process elements next and finally covering the full R&D process.

Chapter 5.11
Strategic Knowledge Management in Public Organizations

Ari-Veikko Anttiroiko
University of Tampere, Finland

INTRODUCTION

New public management and the more recent concept of new public governance have become the dominant management doctrines in the public sector. Public organizations have become increasingly network-like units with various governance relations with actors from the public, business, and voluntary sectors. Their organization is based more on networks than on traditional hierarchies, accompanied by a transition from the command-and-control type of management to initiate-and-coordinate type of governance.

Among the most critical factors in this transformation is knowledge, for most of what has happened has increased the overall demand to create and process knowledge and to utilize it in the performance of governmental functions. The success of public organizations depends increasingly on how efficiently they utilize their knowledge assets and manage their knowledge processes in adjusting to local and contextual changes, as illustrated in Figure 1 (cf. Fletcher, 2003, pp. 82-83; Gupta et al., 2004, p. 3; Skyrme, 1999, p. 34). This requires that special attention be paid to strategic knowledge management.

In the early organization theories of public administration, knowledge was predominantly conceptualized within the internal administrative processes, thus to be conceived of as bureaucratic procedures, rationalization of work processes, identification of administrative functions, and selected aspects of formal decision-making. New perspectives emerged after World War II in the form of strategic planning and new management doctrines. The lesson learned from strategic thinking is that we need information on the external environment and changes therein in order to be

Figure 1. The public organization as an institutional mediator (Adopted from Anttiroiko, 2002, p. 272)

able to adapt to and create new opportunities from these changes (see Ansoff, 1979; Bryson, 1995). As the complexity in societal life and related organizational interdependency has increased due to globalization and other trends, new challenges of managing organization-environment interaction also emerged (cf. Skyrme, 1999, p. 3).

BACKGROUND

The branch of management doctrine that became known as knowledge management (KM) reflected actual changes and new ideas in the business world. Classic works that inspired later developments included Polanyi (1966) and Drucker (1969). During the 1980s knowledge became widely recognized as a source of competitiveness, and by the end of the 1990s, knowledge management had become a buzzword. Among the best known thinkers who contributed to the rise of this field are Peter Senge (1990), Ikujiro Nonaka and Hirotaka Takeuchi (1995), Karl-Erik Sveiby (1997), and Thomas A. Stewart (1997). (On the evolution of knowledge management see Barclay & Murray, 1997; Gupta et al., 2004, pp. 8-10). It is becoming common understanding that in essence knowledge management is about governing the creation, dissemination, and utilization of knowledge in organizations (Gupta et al., 2004, p. 4; Lehaney et al., 2004, p. 13).

Knowledge cannot be managed in the traditional sense of management. The processing and distribution of information can surely be managed, but it is only one part of the picture. The other concerns knowledge and especially managers' ability to create conditions that stimulate active and dynamic knowledge creation, learning, and knowledge sharing within the organization (e.g., Nonaka, Toyama & Konno, 2000). To systematize this picture we may say that knowledge management includes four core areas (cf. Gupta et al., 2004; Lehaney et al., 2004):

- Information management: managing data and information, and designing information and knowledge systems
- Intellectual capital management: creating and utilizing knowledge assets, innovations, and intellectual capital
- Knowledge process management: organizing, facilitating, and utilizing sense-making and other knowledge processes
- Organizational learning: creating learning and knowledge sharing environments and practices

Traditionally the most widely applied areas of knowledge management in public organizations used to be data and transaction processing systems and management information systems serving mainly internal administrative functions. Yet, since the 1980s authorities started to facilitate the exchange of information by local area networks, followed by the Internet revolution of the 1990s. In the early 2000s the knowledge management agenda has focused increasingly on knowledge sharing and learning, and in inter-organizational network and partnership relations (see e.g., Wright & Taylor, 2003). As reported by OECD (2003, p. 4), knowledge management ranks high on the management agenda of the great majority of central government organizations across OECD member countries, followed with some time lag by regional and local authorities. Many public organizations have even developed their own KM strategies. The leading countries in this respect include France, Sweden, Finland, and Canada (OECD, 2003, pp. 28-29).

As to more operational actions, there has been a wave of intranet projects at all levels of public administration since the late 1990s. The result is that some 90% of state agencies surveyed by OECD in the early 2000s had their intranets in place. Sectors that really stand out as being well above the OECD average include organizations in charge of finance and budget, of justice, and of trade and industry (OECD, 2003, pp. 20-30). To give a concrete example from local level, New York City's Office of Technology set up extranet and intranet projects – the Human Services Extranet Project, to link the city agencies with human service contractors and the NYC Share Project, a citywide intranet that intended to improve the exchange of information among agencies – to facilitate external and internal knowledge processes. Such projects are typical in the public sector in the early 2000s. They indicate a transition from information management towards genuine knowledge management.

FOCUSING ON THE STRATEGIC ASPECT

Combining strategic thinking with knowledge management brings us to the very core of the life of organizations. Strategic knowledge management is a set of theories and guidelines that provides tools for managing an organization's knowledge assets and processes of strategic importance for the purpose of achieving organizational goals. The basic idea of strategic knowledge management in the public sector is to ensure that public organizations are capable of high performance by utilizing knowledge assets and knowledge processes when interacting with their environment.

What is essential in strategic knowledge management is that it needs to be strategic in the true sense of the word, as opposed to operational. Public employees have sometimes a tendency to view their knowledge requirements from the point of view of their current work practices. At an organizational level, too, there is sometimes a temptation to map out the future on the basis of current strengths and well-defined short-term challenges. The strategic approach to knowledge aims to overcome such inertia and narrow perspectives by creative knowledge processes, which help to transform views from introspective to outward-looking, from resources to outcomes, and from formal duties to actual impacts and customer satisfaction.

In the knowledge management literature, knowledge has primarily been approached either as an object or a process (cf. Sveiby, 2001). The main focus of public organizations is on knowledge processes framed by certain institutional arrangements. Among the most important of these are the political dimension and democratic control and legally defined functions, competencies and procedures within territorially defined jurisdictions. This theme will be discussed next.

FACILITATING STRATEGIC KNOWLEDGE PROCESSES

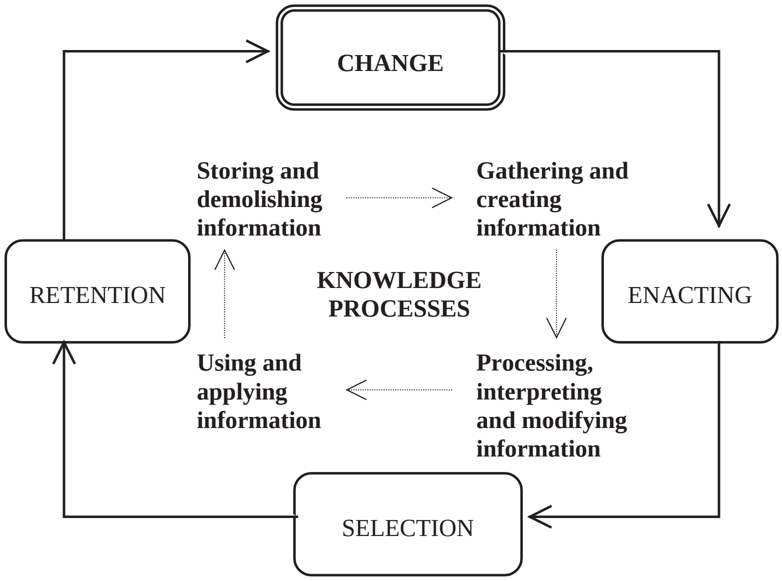
Public organizations possess and process a huge amount of information in their internal operations and external exchange relations. This is why the most important function of their knowledge management practice is to manage knowledge processes and to support knowledge-sharing practices.

Nonaka (1994) considers an organization's ability to accomplish the task of acquiring, creating, exploiting, and accumulating new knowledge. This formulation takes us very close to how the knowledge process can be operationalized. The knowledge process can be defined as an organizational process in which information is gathered, created, processed, used and dissolved in order to form an enriched orientation base for taking care of organization's basic functions (cf. Gupta et al., 2004, p. 3; Mendes et al., 2004, p. 153).

It is important to note that in the actual knowledge process it is more or less meaningless to make a clear-cut distinction between knowledge and information, for both are processed in such a process. For example, knowledge is not simply extracted from information, for knowledge is possessed by human beings and serves as a background and in-built epistemic frame to deal with complexity, novelty, and the requirements of innovativeness (cf. Wiig, 2000). Thus, genuine aspects of the category of knowledge are in question when we deal with statements, assumptions, and understandings and such learning and communicative processes in which these knowledge assets can be shared, assessed, and enriched. Many theorists consider that it is tacit knowledge in particular that is the most challenging and important form of knowledge in organizations (Nonaka, 1994; Polanyi, 1966). It also needs to be stressed that it is not knowledge as something abstract but a "generative dance" or interplay between (a) knowledge we possess and (b) knowing as an epistemic aspect of the interaction with the world that generates organizational innovation and strategic understanding (Cook & Brown, 1999).

Strategic knowledge processes are those aspects of knowledge processes that have the most profound and far-reaching impact on an organization's adjustment to contextual changes and on its core competencies. A paradigmatic form of a strategic knowledge process is the sense-making or strategy process in which an organization devotes effort to analyzing its internal attributes and external conditions and decides on that basis about the action lines in order to achieve its overall goals (cf. Weick, 1995). In such a strategic knowledge process the organization seeks information on environmental changes and utilizes this in strategy formulation, in which such tools as SWOT analysis have traditionally been used. A basic model of the organizational knowledge-based adaptation process is presented in Figure 2 (Anttiroiko, 2002). This model serves as a heuristic tool to conceptualize knowledge processes. Yet, it is important to keep in mind that this is only a starting point. When taking this idea further, clear-cut sequential stages or phases of the KM life cycle need to be "recontextualized" as a set of continuous interdependent sub-processes (cf.

Figure 2. Strategic sense-making and related knowledge process of the organization



Mendes et al., 2004, p. 165). Thus, context-related and situational aspects of knowledge need to be integrated with all essential connections to their environments into the key functions and operations of an organization in order to assess their meaning as a part of actual strategic adaptation and sense-making processes.

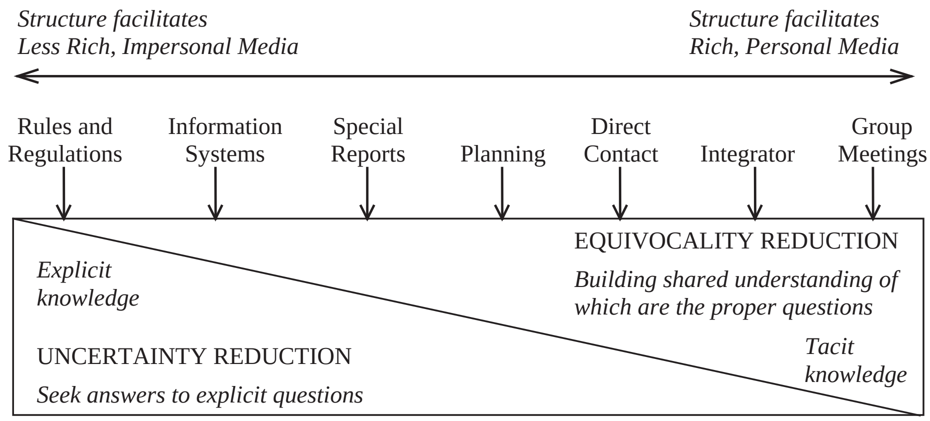
Applying Daft and Lengel (1986), we may ask how organization structures and systems should be designed in order to meet the need to manage knowledge processes. Well designed systems help to decrease the uncertainty and ambiguity faced by an organization by ordering the amount of relevant information and by enabling clarification of problems and challenges. Daft and Lengel propose seven structural mechanisms that can be used to deal with uncertainty and ambiguity in varying degrees, as illustrated in Figure 3. This model resembles the continuum of communication that has explicit knowledge and tacit knowledge as its extremities (Lehaney et al., 2004, p. 21).

The idea is that these mechanisms form a continuum starting from tools to be used to tackle well defined problems and thus to reduce uncertainty, and proceeding towards more communicative mechanisms designed to facilitate sense-making processes that aim at reducing equivocality or ambiguity (Anttiroiko, 2002).

As stated, a paradigmatic case for strategic knowledge management is the strategy process of an organization (on strategy and information resources, see Fletcher, 2003, pp. 82-84). What is of utmost importance is that managers ensure that people feel involved in the strategy formulation process. The staff also needs to understand the meaning of strategy in their own situations. This would help to make strategy documents living guidance that is owned by all in the organization, as concluded by Wright and Taylor (2003, p. 198).

Another important premise relates to organization culture and work practices that often

Figure 3. Continuum of knowledge facilitation mechanisms (Daft & Lengel, 1986)



impede the development of knowledge management. For example, employees may resist a new knowledge management initiative if they perceive it only as extra work. Similarly, employees may be reluctant to share their knowledge if there are no rewards or tangible benefits for themselves or their organizations. In all, the human factor is essential for improving KM practices, for most of the positive outcomes are the result of the commitment of all employees, successful structural changes in the organization, and the development of the organizational culture and climate (OECD, 2003, p. 4).

THE ROLE OF TECHNOLOGY

Information technology (IT) provides a range of new tools that can be effectively used in knowledge management. Relevant applications can support decision making, executive functions, planning, communication, and group work.

Tools and technologies available for knowledge management include generic communication tools (e.g., e-mail), computer-based information and decision support systems, document management systems, intranets and extranets, groupware, geographic information systems, help desk technology, and a range of knowledge representation tools. (Grafton & Permaloff, 2003; Gupta et al., 2004, pp. 17-24).In general, the Internet may be suggested as the KM infrastructure due to its widespread availability, open architecture, and developed interfaces (Jennex, 2003, p. 138).

In real life most of the tools applied in knowledge management are more or less conventional, such as training, seminars, meetings, and the like. Various KM-specific organizational arrangements had been adopted by about half of the organizations studied in the OECD survey on ministries, departments, and agencies of central government in the early 2000s. These measures include central coordination units for KM, quality groups, knowledge networks, and chief knowledge officers. Another important application area is the classification of information, referring to new filing mechanisms, e-archives, and new types of databases. In internal knowledge sharing Intranet projects form the mainstream, combined with wide access to the Internet and having e-mail addresses for the staff. The external knowledge sharing goes largely hand in hand with the emergence of new practices of e-governance. These practices have increased the knowledge sharing in both local and wider governance processes (Anttiroiko, 2004; OECD, 2003, pp. 17-20).

FUTURE TRENDS

The future challenge for public organizations is to increase their responsiveness to stakeholders, especially to citizens. At the same time they need to be capable of strategic institutional mediation in the increasingly turbulent environment, thus bringing an element of continuity and stability to social life and guaranteeing democratic and civic rights at different institutional levels. All this requires increasing capacity to manage knowledge of strategic importance.

CONCLUSION

Strategic knowledge management refers to the theory and practice of managing knowledge assets and processes of strategic importance. Public organizations need to create favorable organization structures and environments for knowledge sharing, organizational learning, and other aspects of knowledge management in order to create all the knowledge they require in their adjustment and trend-setting processes.

A main return of strategic knowledge management is better capability to adjust to contextual changes. This is difficult to measure, even if such tools as Balanced Scorecard (BSC), the Intangible Assets Monitor (IAM), and Intellectual Capital Index (ICI) are available. This is because they provide only a partial picture of KM performance, as claimed by Chaudhry (2003, p. 63). What seems to be needed is more process-focused assessments that are able to analyze the steps of KM processes, thus highlighting the actual changes in organizational knowledge base, capacities, and processes. As usual, there is no measurement system that fits all organizations in all situations. Rather, measurement should be tailored to the actual needs of the organization.

Chapter 5.12

Secure Knowledge Management for Healthcare Organizations

Darren Mundy
University of Hull, UK

David W. Chadwick
University of Salford, UK

ABSTRACT

As the healthcare industry enters the era of knowledge management it must place security at the foundation of the transition. Risks are pervasive to every aspect of information and knowledge management. Without secure practices that seek to avoid or mitigate the effects of these risks, how can healthcare organisations ensure that knowledge is captured, stored, distributed, used, destroyed and restored securely? In an age where risks and security threats are ever-increasing, secure knowledge management is an essential business practice. The cost of security breaches in a healthcare context can range from the unauthorized access of confidential information to the potential loss or unauthorized modification of patient information leading to patient injury. In this chapter the authors highlight different approaches to minimising these risks, based on the concepts of authentication, authorization, data integrity, availability and confidentiality. Security mechanisms have to be in-depth, rather like the layers of an onion, and security procedures have to be dynamic, due to the continually changing environment. For example, in the past, cryptographic algorithms that were proven to be safe, e.g., 56 bit key DES, have succumbed to advanced computer power or more sophisticated attacks, and have had to be replaced with more powerful alternatives. The authors present a model for ensuring dynamic secure knowledge management and demonstrate through the use of case studies, that if each of the security layers are covered, then we can be reasonably sure of the strength of our system's security.

THE CONTEXT FOR SECURE KNOWLEDGE MANAGEMENT

Knowledge is intangible, expensive to obtain, easy to lose and invaluable to organizational success. An organization's knowledge can also be easy to view, steal, manipulate and delete. In the physical world knowledge is protected by structures such as non-disclosure agreements, filing cabinets and shredding machines. In the digital world the same kind of mechanisms are required to ensure our knowledge is well protected.

Security threats to organizational data are increasing exponentially both within organizational boundaries and externally. According to the respected CSI/FBI Computer Crime and Security Survey 2002 (Power, 2002), the largest majority of attacks on computer networks are internal. In this chapter initially we present a conceptual model for ensuring secure knowledge management in healthcare. Then we introduce key security technologies which can be used to implement components of the model, as well as providing background information on how these components have traditionally been implemented within IT systems. Finally we provide case studies of recent implementations that illustrate use of the model. We believe this will convince the reader that security is a necessity in the implementation of Knowledge Management Systems (KMS).

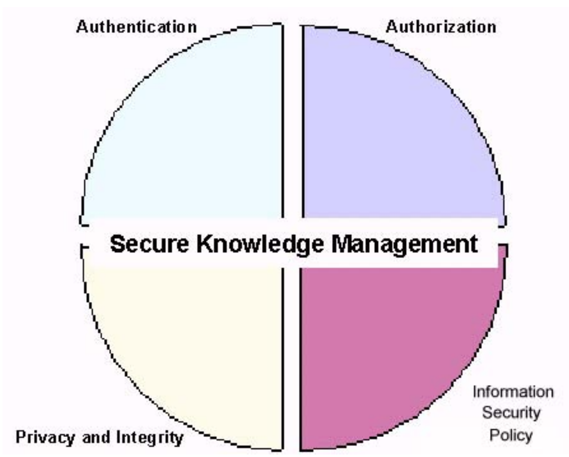
ENSURING SECURE KNOWLEDGE MANAGEMENT IN HEALTHCARE

A model for ensuring secure knowledge management in healthcare is shown in Figure 1.

- authentication: (1) Security measure designed to establish the validity of a transmission, message, or originator; (2) a means of verifying an individual's eligibility to receive specific categories of information (NIS, 1992) (see "Authentication Mechanisms");
- authorization: (1) The rights granted to a user to access, read, modify, insert, or delete certain data, or to execute certain programs; (2) access rights granted to a user, program, or process (NIS, 1992) (see "Authorization Mechanisms");
- data security (privacy): (The) protection of data from unauthorized (accidental or intentional) modification, destruction, or disclosure (NIS, 1992);
- data integrity: 1. (The) condition that exists when data is unchanged from its source and has not been accidentally or maliciously modified, altered, or destroyed (NIS, 1992) (see "Data Security and Integrity during Transfer");
- information security policy: organizational guidelines, rules, regulations and procedures that are used to protect an organisation's information (see "Security Policy").

Each of the four components is essential and mutually supportive. Authentication without authorization would mean that only valid users

Figure 1. Model for secure knowledge management



could gain access, but could execute any operations they wish to within the KMS. For example, in a patient records system, secretaries (who might be authorized to update a patient's name and address only) could execute a command to access health details for all patients or change diagnoses. Conversely, authorization without authentication would mean that anyone could masquerade as anyone else and thus gain his or her access rights. Information security policy provides the risk management, the appropriate controls, the recovery procedures, and the auditing procedures, etc. Without an information security policy there would be no apparent requirement for secure practices, and security would either be ignored or implemented in an ad-hoc manner, with the result that some controls could be too rigid and others completely missing. Finally, a system without privacy and integrity would be untrustworthy, so the knowledge contained within the system would be virtually worthless. For example, in a knowledge base containing details about clinical procedures, erroneous changes could be made to the information without detection, possibly leading to fatal consequences for patients. This model will be examined in greater depth in the next few sections, which provide information about mechanisms for implementing each segment of the model. Following these sections case material will be provided demonstrating the model in action.

AUTHENTICATION MECHANISMS

Authentication

How can you be sure that the user requesting access to your KMS is who they say they are? Traditionally, weak authentication systems, typically based on a username and/or password, have been a key source of unauthorized access to networks and computer systems. From a healthcare KMS perspective, authentication mechanisms provide a means to ensure that external parties that we do not wish to access the KMS cannot gain access without acquiring an authentication token. If we choose a strong authentication mechanism, then it should make it extremely difficult, if not impossible, for these parties to gain access to our KMS. Particular risks of poor authentication in healthcare would include potential unauthorized access to a KMS containing information, for example, on patient conditions, quality of patient care or hospital procedures. All attacks potentially could result in decreased patient care and liability or negligence cases.

In the US and other countries, government regulations such as the Health Insurance Portability and Accountability Act (HIPAA) mandating the privacy of patient identifiable information require that access only be granted to those parties authorized to view the information. Strong authentication of users seeking access to a KMS containing patient-related material will be essential in achieving compliance with these kinds of regulations.

Present Practices: Passwords and their Frailties

Traditionally, authentication to networks and computer systems has been provided by the use of usernames and passwords. In early password authentication schemes, users would simply log on using their username and password and the computer system would do a simple lookup that the password given matched the password stored for the user. However, password files could frequently be obtained from the system itself and then posted for all to see. So developers were required to secure the scheme by taking the password and passing it through a programming routine called a onetime hashing algorithm. The hashing algorithm mathematically reduces the data into a small (typically 128 or 160 bits), indecipherable series of bits. The hashed password can then be stored in the system instead of the clear text password. When the user logs into the system, the password they input is hashed and the new hash and the stored hash are compared to see if they match.

Password hashing is now commonplace, but hashed passwords are still vulnerable to dictionary attacks. This is where the attacker runs all the words in a dictionary through the hashing algorithm, and compares the generated hashes with the stored hashed values. Bad as this might seem, a potentially far greater threat than poorly protected password storage is the threat of human weaknesses. Users are prone to picking poor passwords, writing passwords down, and giving their passwords out, etc. Management steps should be taken to educate users and strengthen password usage. Simple information security policy statements, such as passwords must be eight characters or more in length and must contain a mixture of capital letters, lowercase letters and digits, provide improvements to the basic system and usually render the passwords impervious to dictionary attacks. User education can also lead to a movement away from bad habits such as leaving passwords on post-it stickers and giving passwords out to other people.

However, even with the various protection mechanisms mentioned above, passwords are still relatively weak. To be effective they rely on secrecy and strict policy management. In health environments where perhaps access to PCs is not strictly controlled, especially on wards where patients or other parties could gain unauthorized access to the PC, passwords are not an effective authentication mechanism. To gain effective authentication other mechanisms can be used both in conjunction with and as replacements for passwords.

Key Technology Focus: Biometrics

Biometrics allow users to authenticate themselves using personal characteristics that are less easily stolen or copied. On a user there are certain uniquely identifying attributes that can be used to determine identity, e.g., fingerprints, retinal scans, facial imaging, voice recognition, hand readers, etc. Biometric authentication comprises three phases. Firstly, a template of the user's biometric feature is recorded by the system. A biometric device reads the user's biometric feature several times and stores the average of the readings in the system. Several readings are needed because biometrics vary according to temperature, humidity, blood pressure, etc. Then when the user wishes to authenticate to the system, a biometric device records the user's biometric feature (phase two). Finally, the reading is compared with the stored template using some predefined matching algorithm (phase three). Unfortunately, due to the imprecise nature of the matching, biometric authentication is prone to false positives and false negatives. False positives are when an attacker is wrongly identified as being the user, and false negatives are when the user is not recognised by the system.

Biometrics technology has been piloted in a number of organizations (e.g., Essex Police and Securicor (UK), Washington Hospital Centre (DC)) and full-scale implementations are already in place in a number of business sectors (e.g., Nigerian electoral process, and the City of Glendale (CA)). In future KMS, biometric authentication will increasingly become the authentication mechanism of choice.

Key Technology Focus: Public Key Cryptography, Public Key Infrastructure (PKI) and Digital Signatures

The concept of Public Key Cryptography was introduced to the academic community in 1976 by two researchers called Whitfield Diffie and Martin Hellman (Diffie & Hellman, 1976). Public Key Cryptography was initially applied to encryption (covered in "Key Technology Focus: Data Encryption," basically encryption means to disguise data and decryption means to retrieve the data that was previously disguised), but it also solved the problem of authentication. The basic idea of Public Key Cryptography is to have two different security tokens, called the public and private keys, which work together as a pair. They can be used to perform mathematical operations on data, either digital signing/verification or data encryption/decryption. The public key is viewable to all users whilst the private key remains a secret to the entity to whom the keys have been given. If data is encrypted with the private key, it can only be decrypted with the public key, and vice versa. It is not possible to both encrypt and decrypt the data with the same key, nor is it usually possible to determine one key from the other. When data is encrypted with the private key of a user, this allows the data to be authenticated as coming from that user. When data is encrypted with the public key of a user, this allows the data to be made confidential for that user.

However, public key cryptography is slower to execute than conventional cryptography, which uses a single key. For this reason, when data authentication is required, the data is first condensed using a hashing algorithm. The hash value is called a message digest. The private key of the user is then used to encrypt the message digest. The encrypted digest is known as the digital signature of the data. The digital signature, along with the original data, are then sent to the recipient. On receipt the receiver takes the digital signature and decrypts it using the signer's public key, to reveal the message digest created by the signer. The recipient then creates his own message digest from the data sent by the signer and compares the two. If the two message digests match then the recipient can be sure that the data was sent by the signer and it has not been changed en route.

However, this presupposes that the recipient is in possession of the genuine public key of the signer. Whilst it would be possible for all users to personally meet and exchange their public keys with each other, this is not a scalable solution. Consequently, we need a reliable and trustworthy way of distributing public keys. A trusted third party, called a Certification Authority (CA), is used to digitally sign the public keys of users, to ensure that they cannot be tampered with. A CA would be contained within and managed by a hierarchical authority, for example the Department of Health and Human Services or a hospital's Human Resources department. The CA signs a message containing the name of the user and their public key, and its own name, and these certified public key messages are called Public Key Certificates (PKCs).

Should a user's private key become compromised (e.g., stolen), then we have a requirement to communicate this knowledge to other users. This is generally done using a particular construct called a Certificate Revocation List (CRL). A CRL contains a list of all the public key certificates no longer considered to be valid because the private key has been compromised or revoked, and the CRL is signed and dated by the CA.

A Public Key Infrastructure is seen as, "the set of hardware, software, people, policies and procedures needed to create, manage, store, distribute, and revoke PKCs based on public-key cryptography" (Arsenault and Taylor, 2002). Recently mechanisms for digitally signing the popular eXtensible Markup Language (XML) documents have been introduced (Eastlake et al., 2002). Within a healthcare KMS, users would generate XML documents. The content of these documents would then be digitally signed with the user's private key. When any user wishes to retrieve the document, they can then check the verification of the XML Signature using the public key of the signing user.

Key Technology Focus: Smartcards

Modern smart cards contain a computer embedded chip and user-specific data, which can be used to provide authentication when placed in a smart card reading device. The user-specific data can be anything linked to the user, such as a private key or a digital fingerprint. Traditionally this user-specific data would have been stored as a software token on a PC, making it liable to theft or deletion. Smart cards provide increased security because the user specific data is never allowed to leave the smart card. All processing operations are carried out via the on-board chip so the user-specific data can never be copied. Usually the data is further protected via the use of a password.

Previously high costs and unreliability (Chadwick, 1999) have been a significant factor in the slow adoption of smart card technology. Costs have significantly decreased recently and reliability has improved, so the adoption of smart cards becomes a viable option to the other authentication alternatives.

AUTHORIZATION MECHANISMS

Authorization

Authorization provides assurance that the users accessing the KMS have permission to do so. When authorization is combined with a suitable authentication scheme, we can be sure that the users accessing the system are who they say they are and are authorized to access the resource. Different access control models have been developed to ensure that only authorized users can access resources. From a healthcare KMS perspective, we wish to ensure that users are, for example: authorized to access the system, authorized to generate new knowledge within the system, and authorized to make changes within the system.

Discretionary Access Control (DAC)

Discretionary Access Control (DAC) can be viewed as owner-based administration of access rights. In DAC the owner of an object has discretionary authority over which other users can access the object. For example, Alex has just set up his own KMS and he grants access to Kate and Lee, but denies access to Spencer. There are various types of DAC including a strict DAC where Kate and Lee would not be able to grant access to other users, and a liberal DAC where delegation is allowed either with a strict limitation on the number of delegation levels or with no restriction (i.e., Kate could grant access to Sophie who could grant to Johnny, etc.). The DAC approach has some limitations, the most notable being how the owner can delegate his discretionary power to other people.

Mandatory Access Control (MAC)

Mandatory Access Control (MAC) can be thought of in terms of security labels given to objects and users. Each object is given a label called a security classification and each user is given a label called a security clearance, which includes a classification list. This list identifies which type of classified object a user has access to. A typical hierarchical classification scheme used by the military is unmarked, unclassified, restricted, confidential, secret, and top secret. A MAC policy using such a hierarchical scheme would typically be "read down and write up," which would help stop information leakage. A user with clearance of restricted could read from objects with classifications of unmarked to restricted but only write to classifications of restricted to top secret. The same user could log in as unmarked to enable them to write to levels up to restricted.

Role Based Access Control (RBAC)

In the basic Role Based Access Control (RBAC) model, permissions are granted to roles, then these roles are assigned to users who, therefore, acquire the roles' access permissions. Roles typically represent organisational roles such as secretary, consultant, etc. Roles confer both access rights to resources and the right to assign roles to users. For example, a physician may have read access to a KMS but not have the access right to alter data within it. A KMS security officer may have the right to assign people to roles, but no access rights to the resources itself. A role and its permissions tend to change infrequently over time whereas the users associated with the role will change more regularly. This basic premise makes associating permissions with roles easier than associating permissions with users. Users can change roles and new users can be allocated roles. As needs change, roles can be granted new permissions or permissions can be removed. The main advantages of RBAC are in maintenance and scalability.

Key Technology Focus: Privilege Management Infrastructure (PMI)

Privilege Management Infrastructure is a new development in the world of authorization. A PMI is to authorization what a PKI is to authentication. In a PMI a user is allocated digitally signed privileges, called attribute certificates, and these attribute certificates can be presented to a resource in order to gain access to it. The resource is governed by an authorization policy that says which privileges users must have in order to gain access and under which conditions.

Attribute certificates are allocated to users by attribute authorities (analogous to certification authorities in a PKI). They are digitally signed by the attribute authority, and because of this they can be stored in a public repository or held by the user on their PC. In order to gain access to a resource, the user must first be authenticated by the resource to prove that he has the right to assert the privileges contained within his attribute certificates. This authentication could be by any means, e.g., Kerberos, or a digital signature and Public Key Certificate. After successful authentication, the attribute certificates containing the user's privileges are verified and checked against the authorization policy. If the policy states that the privileges are sufficient then the user is granted access, else access is denied. A number of different PMI solutions are available including PERMIS and AKENTI.

DATA SECURITY AND INTEGRITY DURING TRANSFER

Data Security and Integrity

A healthcare KMS without data security and data integrity should be thought of as being untrustworthy. The information held within the system could have been altered, modified or had key sections removed. Even more importantly a KMS without data security may have leaked sensitive information to unauthorized parties. One of the key stages at which information leakage can occur is during data transfer over the network, Intranet or Internet. From a healthcare KMS perspective, looking at regulations such as HIPAA, poorly configured data security could result in unauthorized users gaining access to patient information and noncompliance. Without data integrity, staff will not be able to use a healthcare KMS effectively, as the information it provides will be unreliable.

Key Technology Focus: Data Encryption

In data encryption understandable data (plain text) is transformed using an encryption algorithm into incomprehensible data (cipher text) under control of a key. When the previous plain text is required the encryption algorithm, the key and the cipher text are used in conjunction to retrieve it. The cipher text looks like a random bit stream and there is no way of establishing the plain text from the cipher text without the key. The key is usually a randomly generated bit string consisting of 64-256 bits (the longer the key, the stronger the encryption). Various symmetric encryption algorithms exist with the most popular being CAST (Adams, 1997), RC2 (Rivest, 1998) and Triple DES (ANSI, 1985).

Encryption provides protection of the information within a KMS from unauthorized viewing as long as the text is cipher text and the attacker does not have access to the key. There are two forms of encryption that can be used, single key (symmetric) or dual key (asymmetric or public key). In single key encryption both parties use the same key for encryption and decryption. Dual key encryption follows the same principles described in the Public Key Infrastructure section. Therefore, encryption comes with the disadvantages of key management (who should generate keys, how to distribute keys, what to do if keys are lost) and a decrease in system performance due to the encryption/decryption process. Also encryption does not actually provide any assurance that the data has not been altered in transit and only some assurance that the data came from the person it is stated to have come from.

Secure Data Transfer Technologies, e.g., Secure Sockets Layer (SSL)

SSL is a security protocol, which can be used to provide a secure channel between two machines (server and client) across an insecure network such as the Internet. The protocol has provisions for the protection of data in transit, using Message Authentication Codes (MACs) (Krawczyk, 1997), and strong authentication of the server using X.509 public key certificates. It can also provide authentication of the client and encryption of the data whilst in transit. An SSL connection consists of two phases; the handshake and data transfer phases. The handshake phase authenticates the server and optionally the client, and also establishes the shared secret that will subsequently be used in the MACs and optional encryption mechanism that will be used to protect the data. Once the handshake phase is completed the data is split up and transmitted in protected packets.

There are a large number of SSL implementations available, ranging from the free and high quality Open SLL implementation (www.openssl.org) to vendor toolkits from organisation such as RSA (www.rsasecurity.com) and IAIK (www.iaik.at). Other mechanisms exist which provide secure data transfer including Transport Layer Security (TLS) (Dierks & Allen, 1999), which is essentially an improved version of SSL, S/Mime (Dusse et al., 1998) to secure email transactions and Secure Shell (SSH) (Ylonen et al., 2000) often used for configuration management. In a healthcare KMS, SSL would be used to provide a protected channel for users to access information from the KMS.

Key Technology Focus: Firewalls

A firewall is a system designed to prevent unauthorized access to and from your private network. The firewall consists of a number of components:

- The Internet Use security policy for the organization. This stipulates at an organizational level the expected security required when connecting to the Internet. (For example, all external access must be through a strong authentication system.)
- The mapping of the policy onto designs and procedures to be observed when connecting to the Internet. (For example, SSL client authentication may be required.)
- The firewall hardware and/or software used to protect the network

Each of the components is required. Without a policy the firewall cannot be correctly configured, as the technical staff will not know which traffic to let in and which to exclude. Without enforcing the procedures then many aspects of the policy may simply be ignored, such as inspecting the logs on a daily basis. Firewalls can be complex. A couple of the techniques used are shown below.

- Packet Filtering. Filters network data packets based on their Internet Protocol (IP) and UDP/TCP source and destination addresses.
- Stateful Packet Inspection. Inspects data packets as they are arriving and filters on a specific set of security rules.

Firewalls help prevent attacks against insecure services, can secure external access to required network services and provide a cost advantage over securing each host on an organizational network. However, firewalls are not without their disadvantages. Like any computer system without regular updates/patches, intruders can gain access to the healthcare network. They may also make it difficult for legitimate users to be able to access required network services. Hackers can also often circumvent firewalls by using "backdoors" into the healthcare network, provided for example by modems situated behind the firewall. However, the biggest disadvantage of firewalls is they provide no protection against the internal hacker. Given that hospitals are public places, this can pose a serious problem. By placing a second firewall directly in front of the healthcare KMS server, this can ensure that requests to that server are authenticated and only passed through on certain ports, thereby restricting the attacker's options.

Key Technology Focus: Wireless Data Transfer

Wireless technology, based on the IEEE 802.11 standard, is increasingly being adopted, especially in areas such as healthcare where the benefits of mobility are great. Unfortunately 802.11 offers only a basic level of security (open or shared-key authentication and static wired equivalent privacy (WEP) keys). But worse still, many wireless LANs are installed with no security at all or are left in default out-of-the-box configurations, thus allowing all comers to gain access to the network. Wireless LANs should always be configured with 128-bit WEP as a minimum, but even this can be compromised by the determined hacker, so wireless technology should not be used for mission critical KM applications unless the basic security is enhanced with technologies such as TLS, VPNs, IPSEC or 802.1X/EAP.

Wireless Access Points are used to set up wireless networks and connect the wireless network to the physical hard-wired network. We can compare a Wireless Access Point directly to an internal modem on the organizational network (i.e., it is a "backdoor"). The addition of wireless to the healthcare network must not come at the cost of reduced security. Therefore, we must think about the key elements in securing this new technology.

- access and authentication – Open authentication involves configuring the correct service set ID (SSID) to the client. This is no more than a shared password, which, without WEP, is transferred in the clear over the airwaves, so anyone with a wireless receiver can capture it and thus gain access. By using WEP (see below), the SSID is encrypted prior to transfer, thus making it difficult for hackers to decipher the SSID. Shared-key authentication on the other hand simply uses the shared WEP key for authentication. The access point sends the client a challenge and the client must then encrypt this with the shared key and return it to the access point to gain access;
- data privacy (provided by using WEP encryption and shared symmetric keys);

- network location and access point security (physically placing the Wireless Access Point outside the healthcare organisations firewall may limit any damage).

Notwithstanding the security concerns above, the benefits of using wireless technology within KMSs are numerous. Specialists can record procedures in places where there might be limited "wired" access and doctors can be permanently online whilst doing their ward rounds.

SECURITY POLICY

Secure Data Management: Storage, Backup and Disposal

An information security policy is the key to secure data management. Without policies in place governing the storage, backup and disposal of information, no attention will be given to the procedures that need to be in place to enforce the policy. A security system is only as strong as its weakest link and the actual computer/storage device on which a KMS is situated can be an easy target if the attacker can gain physical access to it. Therefore, in circumstances where a machine stores confidential information or business critical information its physical security must be assured. Access restrictions to the room holding the machine must be in place and strictly enforced. Furthermore, the machine itself must be protected by secure authentication and authorization mechanisms.

Backup tapes must be treated with the same amount of physical security as the systems they are used to restore. This is because the information stored within your KMS is also stored on the backup medium. If a backup medium is stolen then it is reasonable to expect that your system has been compromised. Thus backup media should be physically secured by either storing them in a locked room or safe. In addition to physical security, the backup medium may also be logically protected either by using data encryption and/or an authentication mechanism to activate the restore process.

Secure disposal of storage media also needs to be an information security policy requirement. There have been instances where confidential data has been left on computers that have been passed on to other organizations. Even worse, computers can be left still set up to access your network or KMS. Simply deleting information on computers is not enough to erase the data from the hard drive. The data either has to be securely deleted using a commercial "secure delete" application or the media destroyed. Without secure deletion procedures the healthcare organization and its systems are not only at potential risk from release of confidential information but also at risk from backdoors into the system.

Key Business Focus: Business Continuity Planning/Disaster Recovery

KMSs are invaluable resources. Losing the knowledge stored within such systems would invariably affect patient care and business continuation. In extreme cases the loss of an IT system can lead to the liquidation of an organisation. In the health community the loss of such a system could have results such as inefficient patient service, inaccurate diagnosis and loss of specialist practices. In extreme cases it could lead to the loss of human life (e.g., if important patient records are lost and diagnoses are lost or inappropriate drugs are prescribed).

The first step in the contingency process is to look at the business impact of losing the particular KMS combined with a risk and threat analysis. This will help to highlight areas of significant risk, which will need to be covered in detail by the contingency plan or mitigated by another measure.

An analysis of the risks and threats facing the KMS will lead us in the second step to the development of a comprehensive contingency and recovery plan, plus risk-mitigating actions. The recovery plan will highlight procedures for ensuring business continuity should any of the risks and threats be realised. The third step will be to test out the recovery plan. A recovery plan which does not work is of little use in an emergency. If backup links and servers have been installed, then time needs to be set aside to test that an operational service can be brought back into use with them. If a third party backup service provider is being used, they will usually allow you time each year to test that their system can run an operational service for you.

The final step in the contingency process is the continual audit, review and update of the contingency plan and risk mitigating actions over the lifetime of the KMS. In other words, this is a continual process that never ends, so as to ensure that the recovery plan remains up-to-date and workable. Further, new risks are continually arising and these have to be taken into account and new mitigating actions devised. It is essential to ensure that key personnel know the recovery plan or know where to obtain it. If, for example, a change has been made in IT personnel between the last audit and the new one then the audit would record if the new personnel knew about the contingency plan.

CASE STUDY: PMI IMPLEMENTATION (AUTHORIZATION SEGMENT OF MODEL)

In this section we present an example of how a PMI implementation can be used to provide strong authorization in our recently developed Electronic Prescription Processing (EPP) Application Programming Interface (API). In the EPP API we have integrated the PERMIS PMI API (Chadwick & Otenko, 2002) so as to control who is authorized to execute commands such as prescribe and dispense prescriptions and also to ascertain patients' rights to exemption from charges (Chadwick & Mundy, 2003). In a KMS one could envisage using PERMIS to control rights to access the system, modify the data, etc.

The overseer of the UK National Health Service, which for all intents and purposes is the Secretary of State for Health in the UK Government, would generate and electronically sign a PERMIS policy stipulating who can carry out which actions in the Prescription Processing System. For example, the policy might state that the General Medical Council is trusted to allocate the role of Doctor to qualified Doctors, and that anyone with the role of Doctor is allowed to prescribe. Therefore, a signatory member of the General Medical Council indirectly gives all General Practitioners in the UK NHS the right to prescribe when they are issued with a Doctor role privilege certificate. When the GP is generating a prescription their prescription program will use the EPP API, and the latter will call the PERMIS decision engine to determine if the GP is authorised to prescribe according to the rules laid down in the policy. As long as the prescriber has the role of Doctor, they will have been granted permission to prescribe and they will be allowed access to the operation to generate an electronic prescription. Similar mechanisms exist for dispensers within the prescription processing system and for determining the exemption qualification of patients.

In a KMS we could reasonably expect the system administrator or systems manager to be the policy owner. The system manager could define roles such as reader, editor, administrator, and grant appropriate permissions to each of the roles. Each of the staff would be allocated one or more role attribute certificates according to their job functions. If for example an editor wished to modify information in the KMS then they would request access, the PERMIS decision engine would be consulted, their role attribute certificates would be retrieved and access granted or denied according to the policy.

CASE STUDY: SECURE DISTRIBUTION OF PATIENT DIABETES INFORMATION

Hospitals in the UK keep a large number of patient information databases recording information about patients with chronic diseases, for both research purposes and clinical health purposes. Most of the information is only available internally to the secondary carers, and no access is provided to other healthcare professionals who may also be involved in the patient's care. The sharing of information between primary and secondary carers will provide a more efficient disease control system and enhanced patient care through a combination of a reduction in the number of duplicate investigations, more accurate information being available to all, and a speeding up of the business processes.

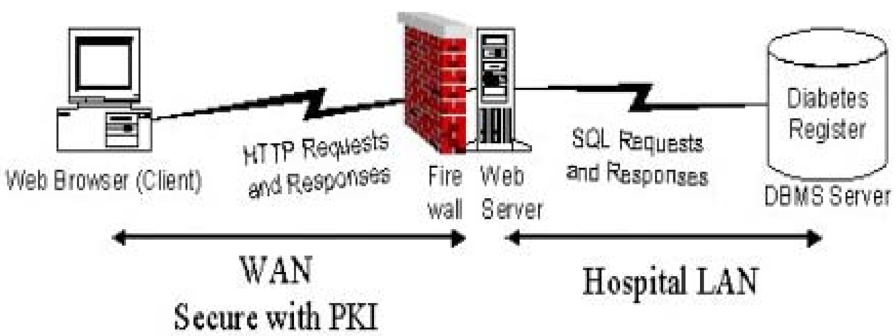
As an example of secure knowledge management, we ran a project to provide primary healthcare professionals with secure Internet access to a hospital Diabetes Information System (DIS). The DIS was implemented in 1992 and provides a complete record of all registered diabetic patients in the local hospital area.

The DIS is situated on the secure hospital Intranet and to provide Internet access to the system we required a strong security infrastructure (Figure 2). This is because the Internet is a highly insecure network and not suitable for the transfer of unprotected, confidential patient information. The backbone behind our secure solution was a Public Key Infrastructure (PKI). The PKI provides the required prerequisites of strong authentication and data privacy through the use of strong encryption from accessing the hospitals internal trusted network.

Requests for patient data are transmitted from the primary carer's PC via the Hyper Text Transmission Protocol (HTTP) using a standard web browser. The HTTP requests are encrypted and digitally signed prior to transmission, using PKI software installed on the user's PC, thus forming a private channel to the hospital firewall from the PC.

The messages are decrypted and the digital signatures checked on the firewall, and then

Figure 2. Distributed diabetes information system security infrastructure



transferred to a web server on the hospital Local Area Network (LAN). Scripts on the web server convert the HTTP requests into Structured Query Language (SQL) requests for information from the DIS. The DIS processes the requests and sends SQL responses back to the web server. The patient information is then routed back to the client PC and displayed as web pages in Hyper Text Markup Language (HTML) format. All information transferred over the private channel is encrypted and digitally signed using either the user's private signing key (for requests) or the hospital's private signing key (for responses). If the user's digital signature is successfully authenticated, that person is allowed access through the firewall and into the DIS. If the hospital's digital signature is successfully authenticated, the patient information is displayed (otherwise it is discarded).

This example shows that secure distribution of knowledge is possible across the Internet, using new security mechanisms with legacy databases. A full description of this is provided in Young et al. (2001). Looking at how the segments of our model for secure KMS have been filled in this example; we have used PKI services to secure the channel between the client and the server thereby protecting the privacy and integrity of the transaction. Authentication is provided by means of the user's digital signature. Authorization is provided through ACLs within the DIS. Security policy is in place at the hospital with strict rules for who can gain access through the firewall, and who can access patient data. A firewall is positioned in front of the hospital network to prevent undesirable users.

SUMMARY

This chapter has provided an introduction to the wide range of different security techniques that can be used to secure knowledge management applications, none of which on their own can be seen as a panacea to all of your security requirements. Simply put, a combination of authentication, authorization, privacy, transmission security and good information security policies and practices are needed to help to ensure a more secure knowledge management environment.

Returning to our model, we have demonstrated through the case studies that if each of the segments is covered, then we can be reasonably sure of the strength of our system's security. We believe the implementation of PKI or the use of third party certification services will become widespread, not only in healthcare environments but also in the general business world. PKI services for authentication, data security and integrity coupled with PMI for authorization and firewalls for restricted access, all underpinned by an enforceable information security policy and procedures, combine together to provide a sound basis for secure KMSs.

Chapter 5.13
Knowledge Management in Telemedicine

Jayanth G. Paraki
Telemedicine Research Laboratory, India

ABSTRACT

Knowledge management (KM) can be defined as the discovery and dissemination of new knowledge. It has also been defined as the efficient utilisation of the existing intangible knowledge-related resources available in every sector of the economy to enhance the productivity of all factors of production. Telemedicine is a tool to enhance equitable distribution of healthcare across the world. In this chapter the author discusses the various aspects of knowledge management and telemedicine and proposes to globalize telemedicine.

INTRODUCTION

Organizations all over the world are adapting to rapid changes in many ways, and an approach that has made significant contributions to the resurrection of postwar Japanese industry is Deming's philosophy of total quality management (TQM). Deming's TQM is indeed applicable to the management of Internet businesses and eminently suitable for telemedicine and data-mining projects in life sciences. The apparent complexity of the system may appear as a deterrent to many, but the inherent simplicity is clear on examination of the Deming charter points. Leaders of Internet business houses will derive rich benefits from applying Deming's TQM to their organization, while investors will find it comfortable to interact with such organizations.

There is an urgent need for healthcare professionals to be multiskilled. Doctors and nurses have to introspect periodically and adopt a plan for self-improvement that should include acquiring new knowledge, developing a positive mental attitude, and learning new skills to meet the rapidly changing health needs of people across the globe.

The methods of diagnosis and treatment of human diseases have altered significantly in the last decade. In the early 1990s, the first signals of change began to surface with patients expressing dissatisfaction and discontent with one or more aspects of their care. Unknown to their primary-care physicians, they began to talk about their experiences with the hope that a degree of attitudinal change would emerge in some physicians, and permanent solutions to chronic health problems would start emerging. Direct patient-doctor communication was not in evidence, and institutions committed to healthcare chose not to encourage free discussions with their clients. This pattern persisted over the best part of that decade and led to strained communications between physicians and patients. This at one time resembled an estranged love affair, with neither party willing to move forward to resolve the conflict. However, before long, the Internet revolution became a phenomenon and made its presence felt in healthcare activities. Curiously, the initial recognition of the value of this phenomenon was made by suffering patients who realized the Internet was a handy tool to share their tales of woe amongst themselves and to obtain a degree of temporary relief and comfort. It was fortunate that some physicians had woken up to this phenomenon simultaneously and had begun to address the different scientific aspects in a proactive manner.

During the period of 1998 to 2000, the undercurrents of rapid information exchange were being felt, with different nations discovering its effects through a variety of experiences. Limiting the discussion on the influence of the Internet phenomenon on healthcare, we begin to see certain common patterns emerging across a wide spectrum of diseases across the globe, making data mining an exciting and profitable activity. The need is to automate:

- The right process,
- To the right population,
- At the right time,
- Through the right channel.

It is obvious that there are many elements of equal importance that have to be brought together in order to succeed at biomedical computing and data mining. What then has to be done to amalgamate these elements into a single whole in order to begin the process of data mining? Simply stated, if we have a foolproof system and the necessary human intelligence, it is possible to build a data warehouse and then mine it into saleable data marts for global consumption. I believe that the global scientific community possesses both the system and the intelligence to do this successfully.

The purpose of this chapter is to highlight the capability of Deming's total quality management to provide the directions and impetus to establish a framework for data mining in life sciences, and to demonstrate through a simple application the different ways to apply Deming's 14 charter points in actual practice (Creech, 1995). The future possibilities are varied and some thoughts will be shared toward creating an international consortium for the research and development of telemedicine applications (Paraki, 2001).

THE CONTEXT

In the last decade, observations of results of treatment with allopathy show it is incomplete and inadequate. This applies to both the outpatient and inpatient care of those with acute and chronic ailments. Patient dissatisfaction is evident in patients with chronic diseases such as arthritis, bronchial asthma, and many functional disorders like migraines, obstinate constipation, and irritable bowel syndrome. Furthermore, extensive interaction with professionals from other disciplines like management, IT, telecommunications, fundamental sciences, psychology, and philosophy has provided a solid basis for the development of holistic medicine as a preferred approach to the prevention and treatment of acute and chronic disease. This is keeping in tune with the current changes in developed nations such as the USA and those in Europe where holistic medicine is gaining popularity.

Management in this context not only implies the way hospitals and health universities function, but also the need for a change in the healthcare systems and processes themselves. Data mining in life sciences will truly and correctly provide the right evidence and direction to nations keen on making holistic medicine a viable, cost-effective alternative to meet their healthcare challenges and needs.

In the year 2000, in a report titled To Err is Human: Building a Safer Health System, the Institute of Medicine estimated that as many as 98,000 deaths per year occur in the United States because of medical errors that could have been prevented. The additional cost in pain and suffering as well as in dollars—estimated between $17 billion and $29 billion—as a result of preventable medical errors is unconscionable in an age where the technology exists to virtually eliminate such occurrences. Worse, these studies account only for hospitals. They do not begin to address the errors and their resulting consequences in other healthcare settings such as nursing homes, home care, day surgery, outpatient clinics, and care delivered in doctors' offices.

According to the Institute of Medicine, the majority of medical errors do not result from individual recklessness, but from "basic flaws in the way the health system is organized."

These flaws reach into every aspect of the healthcare enterprise, from illegible, paper-based medical charts to large segmented health systems that fail to provide for adequate communications among caregivers. Medical care today can be a complex combination of therapeutic treatments and sophisticated drug regimens administered by many different healthcare professionals at different sites. Under these conditions and given more than ample opportunity for human error, it is no mystery we have a problem. Long-term solutions require considerable political will and the ability to attract champions who can help craft answers that will not cripple the process with malpractice litigation. The Institute of Medicine has sounded the alarm. Are we prepared to answer it?

WHY DEMING?

The 1994 Survey on Change Management published by the AMA and Deloitte & Touche says, "It seems that many organizations have to change in order to change. Their present structures and cultures tend to disallow the successful implementation of change initiatives." I find the same in the healthcare industry, too. This change is of a global dimension, and Deming's TQM (Creech, 1995) will be able to bring many organizations and nations together on a common platform to strive for a higher global cause. Telemedicine technology coupled with Deming's TQM will ensure that change initiatives will meet with success. Networked organizations thrive better than others and are ideal for live projects in life sciences (Woodcock, 2001).

Application of Deming Charter Points

Point 1: The constant improvement of health services is a must. Technology integration speeds up the process. Holistic medicine offers paths to total quality health for those with the following diseases: cancer, AIDS (acquired immunodeficiency syndrome), and mental depression. TQM is ideal for securing global cooperation to fight these diseases with vigor and vitality.

Point 2: The philosophy of holistic medicine is the need of the hour. There are different schools of thought, and each nation has to harmonize their philosophical thinking with scientific temper to allow proven benefits to reach the masses.

Point 3: Dependence on laboratory tests alone is to be avoided, and close personal interaction with patients is a must. Furthermore, the careless repetition of tests, too-frequent tests, and inappropriately timed tests are some of the sources of avoidable drain of financial resources to the individual and the organization. Herein lies one of the values of a robust, correctly designed informational database. Later, we will see its relationship to an operational database, which is a part of a data warehouse and its different uses.

Point 4: I have deliberately left out addressing this point at this stage. I believe that this is a very personal issue at this stage of global telemedicine technology development, and while there are several financial and revenue models that have proved successful, none have evolved fully to become a reference model for global following. Continued learning and mature knowledge sharing is essential to enable unshakeable clarity of perception to be gained in the economics of telemedicine technology,1 and this may well prove to become a major aspect of global research study in the future.

Point 5: Improve constantly and forever the diagnostic and therapeutic processes. To do this successfully, baseline data have to be recorded, stored, and retrieved at will. Database systems and data-mining methodology will influence the outcome of disease research and hence is of overriding importance.

What is data mining? Data mining, by its simplest definition, automates the detection of relevant patterns in a database. However, data mining is not magic. For many years, statisticians have manually mined databases, looking for statistically significant patterns. In traditional business use, data mining uses well-established statistical and machine-learning techniques to build models that predict customer behavior. When discussing models in life sciences, the definition of a customer undergoes a bit of a modification in the sense that a patient is not viewed as a customer, and a customer need not be a patient. The need for building models in life sciences exists in diverse situations, and when viewed globally, is a healthy exercise physically, mentally, and financially.

Data Mining and Data Warehousing: The Connection

Data mining describes a collection of techniques that aim to find useful but undiscovered patterns in collected data. The goal of data mining is to create models for decision making that predict future behavior based on analyses of past activity. Data mining supports knowledge discovery, defined by William Frawley and Gregory Piatetsky-Shapiro (1991) as "the nontrivial extraction of implicit, previously unknown, and potentially useful information from data" This definition holds the key to the substantial interest in data warehousing and data mining. The method used today in data mining, when it is well thought out and well executed, consists of just a few very important concepts. The first of these is the concept of finding a pattern in the data. In many cases, this just means any collection of data that occurs a surprising number of times. Usually, surprising is better defined, but in general it means any sequence or pattern of data that occurs more often than one would expect it to if it were a random event. For example, the occurrence of breast cancer in unmarried women in the age group 30 to 40 is significantly higher than in married women of the same age group. What is the relationship between marriage and the incidence of breast cancer? The answer lies in the simple fact that in unmarried women, the intended natural function of pregnancy and subsequent child rearing being denied renders them more susceptible to the development of breast cancer. This piece of data makes it easy to suspect early breast cancer in susceptible women in the age group 30 40, and alerts doctors and/or patients to request for further tests to confirm or refute the suspicion. Data mining will throw further light on various subgroups within this larger main group, allowing far greater precision and control in designing breast-cancer screening programs and the clinical evaluation of various treatment protocols including that drawn from alternative and complementary medicines.

Another very important concept associated with data mining is that of validating the predictive models that arise out of data-mining algorithms. For example, if lesbian women remain unmarried in their lifetime and if it is proved that the incidence of breast cancer is statistically higher in them, then an intervention program based on alternative and complementary medicines is already available for implementation and may prove valuable in the age group 20 to 30 to ward off future threat from this dreaded disease. There is a growing body of scientific literature attesting to this fact, and multination clinical trials are justified to validate the data. If the four parts of data-mining technology are patterns, sampling, validation, and the choosing of the model, then the study of the incidence of breast cancer in lesbian women and its diagnosis and treatment is warranted and justified, and is suitable for multination trial since the disease is ubiquitous in distribution. Equally suitable is the use of data-mining technology to gather data from many different breast-cancer centers around the world.

Point 6: Institute training for both vendor and client organizations is of vital importance vital importance if the intended product or service is to be marketed successfuly. Healthcare professionals engaged in telemedicine activity can ill-afford to neglect this vital exercise. The ranges of skills are varied and are determined by functional needs. Training can be as simple as learning how to use Microsoft Word or as complex as learning Oracle Database Management. Nevertheless, training flows seamlessly with the rest of the activities of the organization and does not usually pose a serious problem.

Point 7: Adopt and institute leadership (Adair, 1993). Successful Leaders are those who convert ideas, contexts, and discoveries into practical undertakings. Greater success will be achieved through the optimal use of technology and team functioning. Highly focused efforts with minimal scattering of energies are more likely to produce noticeable results than diverse activities aimed at several goals. Scaleable-systems development is the need of the hour in life sciences, and it is essential to recognize what the ideal fundamental system is.

Point 8: Drive out fear. Fear as an incentive to improve work performance has been explored at length. Universally, it has a finite limit to induce consistent elevation of performance or to produce quality products and services. Deming realized this during his experience in Japan after World War II and stressed the need for leaders to arrive at suitable methods to drive out fear from within their organizations. One of the possible methods is to structure the primary organization with care with attention to minute details as regards the functional abilities of the hired or chosen people, and to put in place a system of reward and punishment that is attitude based rather than incentive based. Team working and collective consciousness also help to minimize and eliminate fear progressively.

Point 9: Break down barriers between staff areas.Academic and research activities are often slow due to several barriers that exist within a group. While some are necessary and healthy, others are simply laborious and energy sapping and are better removed than allowed to exist undetected. In the modern information age, intellectual property rights have assumed greater relevance than ever before and appear to govern conscious and unconscious thinking to a large extent. Nevertheless, it is mandatory for decision makers to be alert to new opportunities in their primary or related disciplines, and one way to do this successfully is to have highly trained and trustworthy team members to function uninhibitedly and spontaneously at all times.

Point 10: Eliminate slogans, exhortations, and targets for the workforce. The workforce looks at patient care as a divine activity and is prepared to go the extra mile. The attitude of the doctors and nurses is crucial in the affairs of a hospital. They are the pillars of strength of any hospital, and active participation at all levels of the workforce is the key to success. This is determined by the nature of the relationship that exists between top management and the lower levels of professional and nonprofessional staff in a hospital. Charter Point 10 is probably the most vexatious issue in any organization and it is true for hospitals also. A practical approach to minimize this problem is to provide the ownership of smaller satellite hospitals and clinics to teams of doctors and nurses and encourage them to independently manage and produce results. The structure of the parent organization is critical to enable such a relationship to be developed with the workforce, and this reminds us of the statement of Raymond Miles: "The greatest barrier to success will be outmoded views of what an 'organization' must look like and how it must be managed."

Points 11, 12, and 13 are a cohesive interlinked movement of earlier thought processes toward the strong-willed decisive action of the transformation and implementation of a process that has proven benefits in global healthcare. Action at the end will serve to demonstrate the validity of the expressed scientific thinking and stimulate others to follow similar lines of thinking, paving the way for the Internet revolution to make a rapid foray into the domain of life sciences in a convincing and incisive manner.

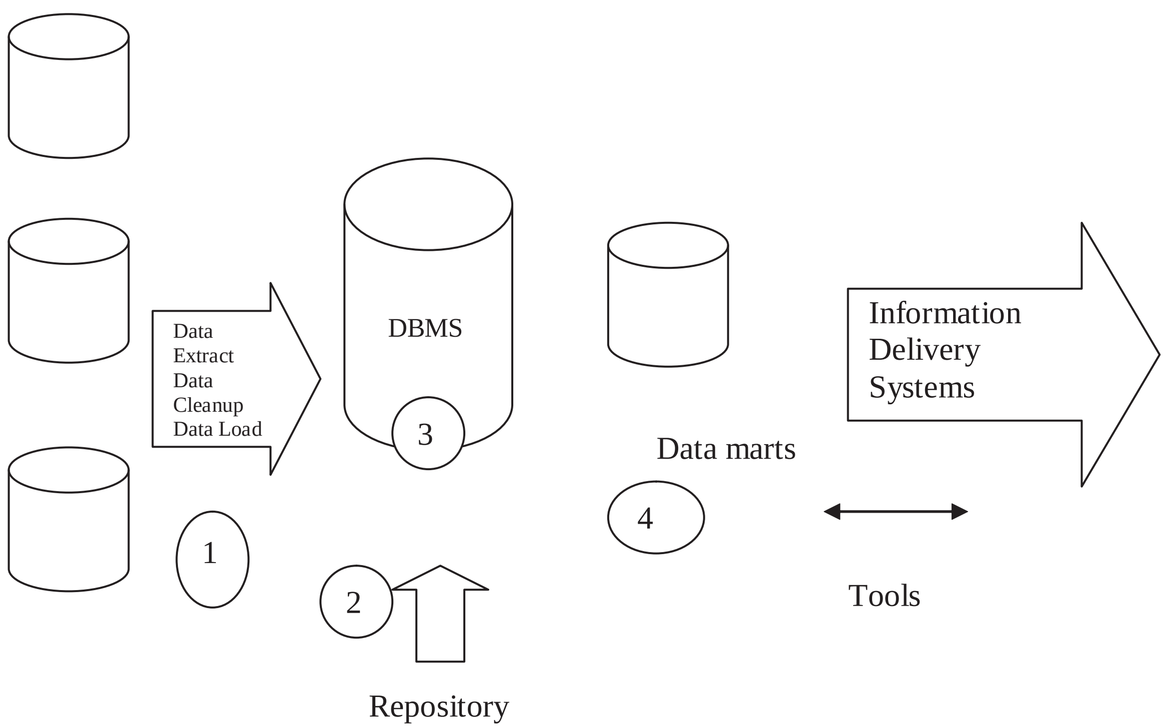
Point 14: Take action to accomplish the transformation.

Data-Warehouse Architecture for a Data-Mining Project in Life Sciences

Operational and External Data

See Figure 1. Example outputs from a data warehouse include the following:

Figure 1.



1. Homeopathic history to maintain transactions
2. Analysis of homeopathic histories to identify patterns
3. Identifying progressive disease patterns to initiate critical treatment measures
4. Mobilizing work-flow processes for emergency and critical situations like natural disasters
5. Recording the evolution of cancers from many patients within a nation and from many nations to create a data background for the comparison and prediction of outcomes of treatment plans, for the study and analysis of demographic patterns, and so forth
6. Creating self-help treatment processes for widespread ailments like chronic nasal allergies
7. Creating products and services for homeopathic students in training
8. To initiate global action against widespread epidemics like gastroenteritis, malnutrition, tuberculosis, and so forth

Relevance of Data Mining to Cancer Research

Models of Human Breast Cancer

The lack of absolute knowledge of the development and progression of cancer has resulted in many empirical and hypothetical treatment models. The number and type of questions that can be answered by controlled trials are limited by logistical and ethical considerations, and it is for this reason that models of human cancer are sought. Cancer is neither a single disease nor a group of diseases. It is a phenomenon of uncontrolled and unrestrained biological activity that alters the basic human functions and eventually kills the host. Hitherto, animal models were employed to understand the biology of cancer and extrapolate the results to humans. The animal model has failed to make us fully aware of the origins of human cancer.

Several models of breast cancer are currently in use, each of which embodies some accepted criterion. However, a universal model does not exist simply because the criterion adopted varies enormously from center to center, and also because the nature of the criterion selected is difficult to determine all over the world. Therefore, it is necessary to establish a set of criteria that is fairly universal and fundamental in order to proceed with a meaningful research program involving large numbers of people and many breast-cancer research centers.

Types of Models Available

The following models are commonly employed in many research centers. They are the canine model, rodent model, and human model. Models are necessary to formulate a scheme for obtaining, analyzing, and testing data in appropriate environments in order to apply the results to a larger population.

The Canine Model

Breast tumors occur commonly in dogs, and these tumors represent a close model of human breast cancer in morphology, clinical behavior, and incidence. However, by virtue of its closeness to the human situation, this model includes all the variables encountered clinically and necessitates the same staging of tumors and randomization of subjects as applied in human clinical trials. In addition, the time required for the evaluation of treatment modalities is long, and together these factors make the cost of using the model to obtain statistically significant results too great.

The Rodent Model

Aside from using different methods to study cancer in rodents, the overall results are not significantly different from the canine model and hence are not suitable for incorporating into a data warehouse.

The Human Model

While it is reasonable to assume that the basic mechanisms of hormone action and metastasis may be similar in human and rat breast cancers, it is less probable that they should show similar sensitivities to chemotherapeutic agents. It is for this reason that a model system that enables human material to be used for experimentation would be of value. Significant developments in this direction are taking place in many centers across the world, and a large amount of scattered data is available for incorporating into a central data warehouse.

The nature of experimental data is different from either epidemiological or clinical data. Epidemiological data is easy to collect and should be drawn from many nations to provide a definite and conclusive base to expand on seamlessly. The attributes of this database are a combination of general and peculiar characteristics spread across several age groups. The peculiar characteristics determine how an injurious agent produces its effect over time. Contrary to the traditional allopathic model of cancer causation, in which there is not much emphasis on a continuous cause operating in the background, the holistic integrated model of cancer causation believes in the existence of smaller cause-effect changes occurring all the time, albeit imperceptible to normal human senses. This resembles a chain of events that occurs in all the links of a computer network when the main switch is turned on.

A. M. Neville (1981) has some insights into the developments in research with relevance to human breast cancer. One overriding conclusion is that we must try to escape from viewing breast disease in a conventional sense as this approach to date has failed. It seems more important to detect those factors that are involved intimately in the control of the growth of breast cells, both normal and neoplastic. An understanding of those factors, and how and where they act will allow us to gain a greater appreciation of the progression of this disease and how it may be modulated to the patients' advantage. Growth factors and their receptors draw attention once more to the properties of the cell surface. Increased appreciation of this aspect of cell biology and biochemistry may well have value in the diagnosis and monitoring of the disease. Without such knowledge, it is unlikely that we will be able to devise meaningful and rational approaches to therapy in the coming decade.

Hopefully, with the advent of RAD tools, research time can be reduced and results made more meaningful and of a uniform quality in all the participating centers in a multination clinical trial. There is reason to believe that light can be shed on perplexing and controversial aspects of breast-cancer treatment within 3 years of beginning an accurately designed study.

SOME ISSUES ADDRESSED AT THE TELEMEDICINE RESEARCH LABORATORY

1. Infrastructure development for e-business and e-health
2. Research into health information systems and the development of prototypes
3. Data warehousing and data mining in life sciences
4. E-publishing
5. E-learning
6. E-communications
7. Mobile technologies and healthcare

CONCLUSION

The last few years have seen a growing recognition of information as a key business tool. Those who successfully gather, analyze, understand, and act upon the information are among the winners in this new information age. Translating this to the domain of life sciences, biological organisms obtain information through sensory and extrasensory means and methodically unravel the continuous flow of information for purposeful behavior. With behavior ranging from simple survival to a life of uninhibited and spontaneous activities, human beings are a different class of biological organisms. This is reflected in one's choice of behavior when faced with many conflicting choices. Of all the physical and mental activities we can perform, there is no other activity as important as decision making in our daily lives. The varied and complex process of decision making is at the soul of all activities in life sciences.

Data mining in life sciences with emphasis on cancer and AIDS will prove to be a profitable e-business opportunity for the current millennium. One of the many interesting business aspects of this opportunity is the profound transformation it can bring about in personal and business relationships, replacing old and worn out ideas with fresh and revolutionary thinking, and paving the way for a new practical approach to the economics of Web businesses. E-business economy will alter the lifestyles of many people, and the only attribute that may leave behind some losers in the bargain is the relative apathy and lethargy of some organizations and an unwillingness to adapt speedily to rapidly changing business processes. "The future allows unlimited and infinite opportunities to those who can discern in the present the mistakes of the past and clearly commit to themselves that they will never again repeat the same or other mistakes in the present or the future." Considering the global epidemic nature of cancer and AIDS, an international consortium for the research and development of telemedicine applications is a distinct reality in the not-too-distant future.

Chapter 5.14
Knowledge Management in Hospitals

Kevin C. Desouza
University of Illinois at Chicago, USA

ABSTRACT

The medical field in recent years has been facing increasing pressures for lower cost and increased quality of healthcare. These two pressures are forcing dramatic changes throughout the industry. Managing knowledge in healthcare enterprises is hence crucial for optimal achievement of lowered cost of services with higher quality. The following chapter focuses on developing and fostering a knowledge management process model. We then look at key barriers for healthcare organizations to cross in order to fully manage knowledge.

INTRODUCTION

The healthcare industry is information intensive and recent trends in the industry have shown that this fact is being acknowledged (Morrissey, 1995; Desouza, 2001). For instance, doctors use about two million pieces of information to manage their patients (Pauker, Gorry, Kassirer & Schwartz, 1976; Smith, 1996). About a third of doctor's time is spent recording and combining information and a third of the costs of a healthcare provider are spent on personal and professional communication (Hersch & Lunin, 1995). There are new scientific findings and discoveries taking place every day. It is estimated that medical knowledge increases fourfold during a professional's lifetime (Heathfield & Louw, 1999), which inevitably means that one cannot practice high quality medicine without constantly updating his or her knowledge. The pressures toward specialization in healthcare are also strong. Unfortunately, the result is that clinicians know more and more about less and less. Hence it becomes difficult for them to manage the many patients whose conditions require skills that cross traditional specialties. To add to this, doctors also face greater demands from their patients. With the recent advances of e-health portals, patients actively search for medical knowledge. Such consumers are increasingly interested in treatment quality issues and are also more aware of the different treatment choices and care possibilities.

Managing knowledge in healthcare enterprises is hence crucial for optimal achievement of lowered cost of services with higher quality. The fact that the medical sector makes up a large proportion of a country's budget and gross domestic product (GDP), any improvements to help lower cost will lead to significant benefits. For instance, in 1998 the healthcare expenditure in the US was $1.160 billion, which represented 13.6% of the GDP (Sheng, 2000). In this chapter, we look at the knowledge management process and its intricacies in healthcare enterprises.

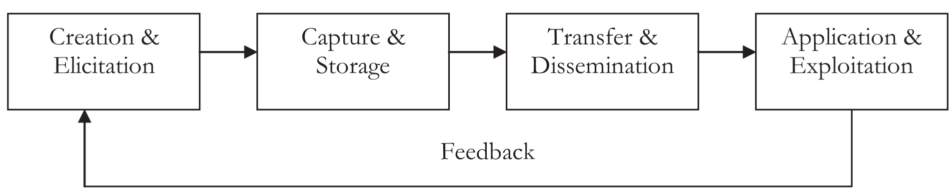
KNOWLEDGE MANAGEMENT PROCESS

Knowledge management from a process perspective is concerned with the creation, dissemination, and utilization of knowledge in the organization. Therefore, a well-structured process needs to be in place to manage knowledge successfully. The process can be divided into the following steps: beginning with knowledge creation or elicitation, followed by its capture or storage, then transfer or dissemination, and lastly its exploitation. We now elaborate on the various stages of the process:

Creation and Elicitation

Knowledge needs to be created and solicited from sources in order to serve as inputs to the knowledge management process. For the first scenario where knowledge has to be created, we begin at the root — data. Relevant data needs to be gathered from various sources such as transaction, sales, billing, and collection systems. Once relevant data is gathered, it needs to be processed to generate meaningful information. Transaction processing systems take care of this task in most businesses today. Just like data, information from various sources needs to be gathered. An important consideration to be aware of is that information can come from external sources in addition to internal sources. Government and industry publications, market surveys, laws and regulations, etc., all make up the external sources. Information once gathered needs to be integrated. Once all necessary information is at our disposal, we can begin analyzing it for patterns, associations, and trends — generating knowledge. The task of knowledge creation can be delegated to dedicated personnel, such as marketing or financial analysts. An alternative would be to employ artificial intelligence-based computing techniques for the task such as genetic algorithms, artificial neural networks, and intelligent agents (Desouza, 2002a). Data mining and knowledge discovery in data bases (KDD) relate to the process of extracting valid, previously unknown and potentially useful

Figure 1. Knowledge management process



patterns and information from raw data in large data bases. The analogy of mining suggests the sifting through of large amounts of low grade ore (data) to find something valuable. It is a multi-step, iterative inductive process. It includes such tasks as: problem analysis, data extraction, data preparation and cleaning, data reduction, rule development, output analysis and review. Because data mining involves retrospective analyses of data, experimental design is outside the scope of data mining. Generally, data mining and KDD are treated as synonyms and refer to the whole process in moving from data to knowledge. The objective of data mining is to extract valuable information from data with the ultimate objective of knowledge discovery.

Knowledge also resides in the minds of employees in the form of know-how. Much of the knowledge residing with employees is in tacit form. To enable for sharing across the organization, this knowledge needs to be transferred to explicit format. According to Nonaka and Takeuchi (1995), for tacit knowledge to be made explicit there is heavy reliance on figurative language and symbolism. An inviting organizational atmosphere is central for knowledge solicitation. Individuals must be willing to share their know-how with colleagues without fear of personal value loss and low job security. Knowledge management is about sharing. Employees are more likely to communicate freely in an informal atmosphere with peers than when mandated by management. Desouza (2003b) studied knowledge exchange in game rooms of a high-technology company and found significant project-based knowledge exchanged.

Capture and Storage

To enable distribution and storage, knowledge gathered must be codified in a machine-readable format. Codification of knowledge calls for transfer of explicit knowledge in the form of paper reports or manuals into electronic documents, and tacit knowledge into explicit form first and then to electronic representations. These documents need to have search capabilities to enable ease of knowledge retrieval. The codification strategy is based on the idea that the knowledge can be codified, stored and reused. This means that the knowledge is extracted from the person who developed it, is made independent of that person and reused for various purposes. This approach allows many people to search for and retrieve knowledge without having to contact the person who originally developed it. Codification of knowledge, while being beneficial for distribution purposes, does have associated costs. For instance, it is easier to transfer strategic know-how outside the organization for scrupulous purposes. It is also expensive to codify knowledge and create repositories. We may also witness information overload in which large directories of codified knowledge may never be used due to the overwhelming nature of the information. Codified knowledge has to be gathered from various sources and be made centrally available to all organizational members. Use of centralized repositories facilitates easy and quick retrieval of knowledge, eliminates duplication of efforts at the departmental or organizational levels and hence saves cost. Data warehouses are being employed extensively for storing organizational knowledge (Desouza, 2002a).

Transfer and Dissemination

One of the biggest barriers to organizational knowledge usage is a blocked channel between knowledge provider and seeker. Blockages arise from causes such as temporal location or the lack of incentives for knowledge sharing. Ruggles' (1998) study of 431 US and European companies shows that "creating networks of knowledge workers" and "mapping internal knowledge" are the two top missions for effective knowledge management.

Proper access and retrieval mechanisms need to be in place to facilitate easy access to knowledge repositories. Today almost all knowledge repositories are being web-enabled to provide for the widest dissemination via the Internet or intranets. Group Support Systems are also being employed to facilitate knowledge sharing, with two of the most prominent being IBM's Lotus Notes and Microsoft's Exchange. Security of data sources and user friendliness are important considerations that need to be considered while providing access to knowledge repositories. Use of passwords and secure servers is important when providing access to knowledge of a sensitive nature. Access mechanisms also need to be user-friendly in order to encourage use of knowledge repositories.

Exchange of explicit knowledge is relatively easy via electronic communities. However, exchange of tacit knowledge is easier when we have a shared context, co-location, and common language (verbal or non-verbal cues), as it enables high levels of understanding among organizational members (Brown & Duguid, 1991). Nonaka and Takeuchi (1995) identify the processes of socialization and externalization as means of transferring tacit knowledge. Socialization keeps the knowledge tacit during the transfer, whereas externalization changes the tacit knowledge into more explicit knowledge. Examples of socialization include on-the-job training and apprenticeships. Externalization includes the use of metaphors and analogies to trigger dialogue among individuals. Some of the knowledge is, however, lost in the transfer. To foster such knowledge sharing, organizations should allow for video and desktop conferencing as viable alternatives for knowledge dissemination.

Exploitation and Application

Employee usage of knowledge repositories for purposes of organizational performance is a key measure of the system's success. Knowledge will never turn into innovation unless people learn from it and learn to apply it. The enhanced ability to collect and process data or to communicate electronically does not — on its own — necessarily lead to improved human communication or action (Walsham, 2001). Recently the notion of communities of practice to foster knowledge sharing and exploitation has received widespread attention. Brown and Duguid (1991) argued that a key task for organizations is thus to detect and support existing or emergent communities. Much of knowledge exploitation and application happens in team settings and workgroups in organizations, hence support must be provided. Davis and Botkin (1994) summarize the six traits of a knowledge-based business as follows:

1. The more they (customers) use knowledge-based offerings, the smarter they get.
2. The more you use knowledge-based offerings, the smarter you get.
3. Knowledge-based products and services adjust to changing circumstances.
4. Knowledge-based businesses can customize their offerings.
5. Knowledge-based products and services have relatively short life cycles.
6. Knowledge-based businesses react to customers in real time.

KNOWLEDGE MANAGEMENT IN HOSPITALS

We now apply the generic discussion of knowledge, knowledge management, and the process in the context of healthcare enterprises. For purposes of this chapter, we focus our attention on hospitals, although much of the discussion can be applied to other healthcare enterprises, such as pharmaceutical companies, insurance providers, etc.

Knowledge in Hospitals

In healthcare, we have the presence of both explicit and tacit forms of knowledge. Explicit knowledge is available in medical journals, research reports, and industry publications. Explicit knowledge can be classified under: internal and external. Internal are those that are relevant to the practice of medicine, such as medical journals and research reports. External are legal, governmental, and other publications that do not directly affect patient treatment methodology but govern general medical practices. Three dimensions in health information outlined by Sorthon, Braithewaite and Lorenzi (1997) include management information, professional information, and patient information. Overlap and commonalties are identified, but fundamental differences exist in the types of information required for each dimension, the way the information is used, and the way standards are maintained. The achievement of a comprehensive and integrated data structure that can serve the multiple needs of each of these three dimensions is the ultimate goal in most healthcare information system development. Tacit knowledge is found in the minds of highly specialized practitioners, such as neurosurgeons or cardiac arrest specialists. Much of tacit knowledge resides in the minds of individuals. Seldom does efficient knowledge sharing take place. One exception to this is where practitioners exchange know-how at industry or academic conferences. This, however, happens on an all-too-infrequent basis.

Knowledge Management in Hospitals

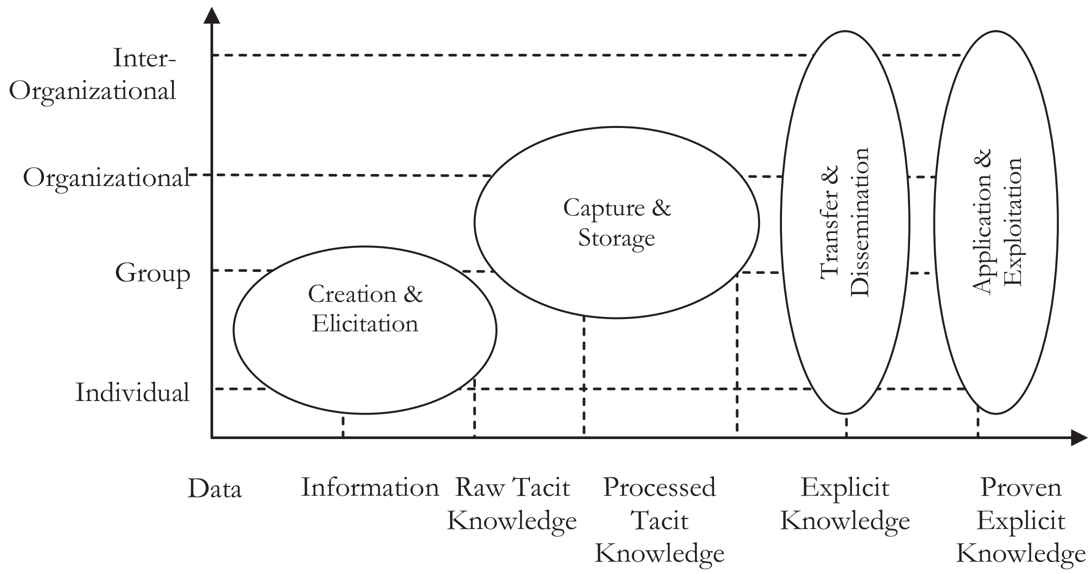
In the following section we step through the various stages of the knowledge management process.

Knowledge Creation and Elicitation

Creation and elicitation of knowledge can be handled in one of two modes: controlled or free form. In the controlled scenario, we can have an individual department responsible for overseeing knowledge gathering from the various functional areas. This department can be in lieu of the current medical records department in most hospitals, which are responsible for centrally storing patient information. We can also have a variation in which control is divested to each department. In this method, each department will be responsible for coordinating knowledge-sharing efforts from their constituents. For instance, a person in the pharmaceutical department will be responsible for gathering all knowledge on drugs administered to patients. In the second approach, i.e., free form, each individual is responsible for contributing to the organization's knowledge resource. A strong locus of control is absent. Individuals as end users of organizational resources share equal burden to contribute into the asset. A variation of the free-form strategy can be one in which each group, rather than individuals, are responsible for knowledge creation and sharing. An example would be a group of neurosurgeons that research new knowledge on surgical practices. Each of the above-mentioned strategies has associated pros and cons. For instance, with a controlled strategy, we need to have dedicated individuals responsible for knowledge creation and elicitation from group members. In the free-form strategy, while we do not have the overhead of a dedicated person, we lose a structured knowledge-creation process. Choosing a given strategy is a function of the hospital's resources. Along with soliciting internal knowledge, a hospital should also acquire relevant knowledge from external entities such as government, regulatory bodies, and research organizations. Gathering of external knowledge is crucial for hospitals due to the high nature of external pressures and their involvement in day-to-day operations.

As portrayed in Figure 2, knowledge creation and elicitation takes place at the individual and group level. Much of the elements gathered at this stage might be raw data, which after processing, becomes information. Information is then applied on experiences, learned associations, and training of employees to generate knowledge. This knowledge remains in tacit form until it is called upon for sharing with peers. Tacit knowledge

Figure 2. Staged look at knowledge management



stored with employees is raw to a large degree, as it is has not been checked for quality or validated against standards.

The other option in the healthcare industry is to generate knowledge through discovery. Data mining and other statistical techniques can be used to sift through large sets of data, and discover hidden patterns, trends, and associations. For instance, in the medical domain all resources are not only very expensive but also scarce. Optimal planning and usage of them is, hence, not a luxury but a requirement. To illustrate this let us take the case of simple blood units. Annually well over 12 million units of blood are transferred to patients (Clare et al., 1995; Goodnough, Soegiarso, Birkmeyer & Welch, 1993) with a cost-per-unit ranging from $48 to $110 with a national average of $78 (Sheng, 2000; Forbes et al., 1991; Hasley, Lave & Kapoor, 1994). Ordering of excess units of blood for operations is the primary cause of waste and corresponding increases in transfusion costs (Jaffray, King & Gillon, 1991). Blood ordered that is not used takes it out of supply for at least 48 hours (Murphy et al., 1995). Even though blood can be returned, it needs to be tested and routed which costs on average $33. In recent years, supply of blood has been decreasing in recent years due to an aging population and increased complexity of screening procedures (Welch, Meehan & Goodnough, 1992). Given these circumstances, any improvements in blood-need prediction can realize significant benefits. Data mining techniques such as artificial neural networks have been employed to sift through large medical databases and generate predictive models which can better forecast blood transfusion requirements. Kraft, Desouza and Androwich (2002a, 2002b, 2003a, 2003b) examine the discovery of knowledge for patient length-of-stay prediction in the Veterans Administration Hospitals. Once such knowledge is generated, it can be made available to external sources.

Knowledge Capture and Storage

Once gathered, knowledge needs to be captured and stored to allow for dissemination and transfer. Two strategies are common for capture and storage: codification and personalization. The codification strategy is based on the idea that knowledge can be codified, stored and reused. This means that the knowledge is extracted from the person who developed it, is made independent of that person and reused for various purposes. This approach allows many people to search for and retrieve knowledge without having to contact the person who originally developed it (Hansen et al., 1999). Organizations that apply the personalization strategy focus on dialogue between individuals, not knowledge objects in a database. To make the personalization strategies work, organizations invest heavily in building networks or communities of people. Knowledge is shared not only face-to-face, but also by e-mail, over the phone and via videoconferences. In the medical domain, the codification strategy is often emphasized, because clinical knowledge is fundamentally the same from doctor to doctor. For instance, the treatment of an ankle sprain is the same in London as in New York or Tokyo. Hence it is easy for clinical knowledge to be captured via codification and to be reused throughout the organization.

Knowledge capture has been one of the most cumbersome tasks for hospitals. Until rather recently much of the patient knowledge was stored in the form of paper reports and charts. Moreover, the knowledge was dispersed throughout the hospital without any order or structure. Knowledge was also recorded in different formats, which made summarization and storage difficult.

Recently we have seen advancements in the technology of Electronic Medical Records (EMRs). EMRs are an attempt to translate information from paper records into a computerized format. Research is also underway for EMRs to include online imagery and video feeds. At the present time they contain patients' histories, family histories, risk factors, vital signs, test results, etc. (Committee on Maintaining Privacy and Security in Healthcare Applications of the National Information Infrastructure, 1997). EMRs offer several advantages over paper-based records, such as ease of capture and storage. Once in electronic format, the documents seldom need to be put through additional transformations prior to their storage.

Tacit knowledge also needs to be captured and stored at this stage. This takes place in multiple stages. First, individuals must share their tacit know-how with members of a group. During this period, discussions and dialogue take place in which members of a group validate raw tacit knowledge and new perspectives are sought. Once validated, tacit knowledge is then made explicit through capture in electronic documents such as reports, meeting minutes, etc., and is then stored in the knowledge repositories. Use of data warehouses is common for knowledge storage. Most data warehouses do have web-enabled front-ends to allow for optimal access.

Knowledge Transfer and Dissemination

Knowledge in the hospital once stored centrally needs to be made available for access by the various organizational members. In this manner knowledge assets are leveraged via diffusion throughout the organization. One of the biggest considerations here is security. Only authorized personnel should be able to view authorized knowledge. Techniques such as the use of multiple levels of passwords and other security mechanisms are common. However, organizational security measures also need to be in place. Once the authorized users get hold of the knowledge, care should be taken while using such knowledge, to avoid unscrupulous practices. Moreover, employees need to be encouraged to follow basic security practices, such as changing passwords on a frequent basis, destroying sensitive information once used, etc. Ensuring security is a multi-step process. First, the individual attempting to access information needs to be authenticated. This can be handled through use of passwords, pins, etc. Once authenticated, proper access controls need to be in place. These ensure that a user views only information for which he or she has permission. Moreover, physical security should also be ensured for computer equipment such as servers and printers to prevent unauthorized access and theft.

Disseminating healthcare information and knowledge to members outside the organization also needs to be handled with care. Primarily physicians, clinics, and hospitals that provide optimal care to the patients use health information. Secondary users include insurance companies, managed care providers, pharmaceutical companies, marketing firms, academic researchers, etc. Currently no universal standard is in place to govern exchange of healthcare knowledge among industry partners. Hence, free flow of healthcare knowledge can be assumed to a large degree. From a security perspective, encryption technologies should be used while exchanging knowledge over digital networks. Various forms are available such as public and private key encryptions, digital certificates, virtual private networks, etc. These ensure that only the desired recipient has access to the knowledge. An important consideration while exchanging knowledge with external entities is to ensure that patient identifying information is removed or disguised. One common mechanism is to scramble sensitive information such as social security numbers, last and first names. Another consideration is to ensure proper use by partners. Knowledge transferred outside the organization (i.e., the hospital) can be considered to be of highest quality as it is validated multiple times prior to transmittal.

Medical data needs to be readily accessible and should be used instantaneously (Schaff, Wasserman, Englebrecht & Scholz, 1987). The importance of knowledge management cannot be stressed enough. One aspect of medical knowledge is that different people need different views of the data. Let us take the case of a nurse, for instance. He or she may not be concerned with the intricacies of the patient's condition, while the surgeon performing the operation will. A pharmacist may only need to know the history of medicine usage and any allergic reactions, in comparison to a radiologist who cares about which area needs to be x-rayed. Hence, the knowledge management system must be flexible to provide different data views to the various users. The use of intelligent agents can play an important role here through customization of user views. Each specialist can deploy customized intelligent agents to go into the knowledge repository and pull out information that concerns them, thus avoiding the information overload syndrome. This will help the various specialists attend to problems more efficiently instead of being drowned with a lot of unnecessary data. Another dimension of knowledge management is the burden put on specialists. A neurosurgeon is paid twice as much, if not more, than a nurse. Hence, we should utilize their skills carefully to get the most productivity. Expert systems play a crucial role here in codifying expertise/knowledge. When a patient comes for treatment, preliminary test and diagnosis should be handled at the front level. Expert systems help by providing a consultation environment whereby nurses and other support staff can diagnose illness and handle basic care, instead of involving senior-level doctors and specialists. This allows for the patients that need the care of experts to receive it and also improves employee morale through less stress.

Knowledge Application and Exploitation

The last stage, and the most important, is the application and exploitation of knowledge resources. Only when knowledge stored is used for clinical decision-making does the asset provide value. As illustrated in Figure 3, knowledge application and exploitation should take place at all levels from the individual to inter-organizational efforts. We draw a distinction here between application and exploitation. Applications are predefined routines for which knowledge needs are well defined and can be programmed. For instance, basic diagnosis when a patient first enters the hospitals, these efforts include calculation on blood pressure, pulse rates, etc. Knowledge needed at this level is well defined and to a large extent is repetitive. On the other hand, exploitation calls for using knowledge resources on an ad-hoc basis for random decision-making scenarios. For instance, if a hospital wants to devise an optimal nurse scheduling plan, use of current scheduling routines, plus knowledge on each individual's skill sets can be exploited for devising the optimal schedule. Decisions like these, once handled, seldom repeat themselves on a frequent basis.

With knowledge management being made easy and effective, quality of service can only increase. A nurse, when performing preliminary tests on a patient, can provide them with better information on health issues through consultation with an expert system. Primary care doctors normally refer patients for hospital care. Some of the primary care doctors may work for the hospital (Network) and the rest are independent of the hospital (Out-of-Network). Today there are a lot of inefficiencies associated with referring patients to hospitals. If a patient is referred, he or she has to contact the hospital personnel who then first take in all patient information and then schedule an appointment. The normal wait time can be any where from one to four weeks depending on seriousness. With the Internet revolution today, all patients, doctors, and hospitals can improve the process tremendously through the deployment of dedicated intelligent agents. Each doctor can be provided with a log-on and password to the hospital's web site. Upon entry to the web site, the doctor can use search agents to browse through appointment schedules, availability of medical resources, etc. These agents can then schedule appointments directly and electronically receive all documentation needed. Hospitals within a certain location can set up independent networks monitored by agents whereby exchange of medical knowledge and resources can take place. Patients can use search agents to browse through hospital web sites, request prescriptions, learn about medical treatments, view frequently asked questions, etc. Intelligent agents can also be trained to learn patient characteristics. Once this takes place, they can be deployed to monitor various medical web sites and send relevant information to the patient in the form of e-mails. Expert systems can be deployed to help the user navigate through the various knowledge bases through recommendations. If a user chooses the main category of "common cold," the expert system can ask for symptoms, suggest medications, etc. Patients can then use these notifications to improve the quality of their health. Intelligent agents also help in improving quality of service through providing only relevant decision-making information. Personnel can then act quickly and reduce time lags. An added benefit of a successful knowledge management system is less burden and stress on personnel. Hospitals are characterized for being highly stressful and always "on pins and needles" when it comes to employees. Through artificial intelligence, much of the routine details can be automated. This reduces the burden on personnel. Also, specialists and highly valued personnel can concentrate efforts on selected matters, the rest can be handled by junior level staff and intelligent systems. This makes for a more welcoming atmosphere.

IMPENDING BARRIERS TO KNOWLEDGE MANAGEMENT

The medical field has to overcome a few hurdles in order to realize the potential benefits of open connectivity for knowledge sharing among the partners of the supply chain and internal personnel such as doctors, surgeons, nurses, etc. We now highlight three of the most prominent issues:

Unified Medical Vocabulary

The first barrier is the development of a unified medical vocabulary. Without a unified vocabulary, knowledge sharing becomes close to impossible. There is diversity of vocabulary used by medical professionals, which is a problem for information retrieval (Lindberg, Humphreys & McCray, 1993). There are also differences in terminology used by various biomedical specialties, researchers, academics, and variations in information accessing systems, etc. (Houston, 2000). To make matters more complex, expertise among users of medical information also varies significantly. A researcher in neuroscience may use precise terminology from the field, whereas a general practitioner may not. Medical information also must be classified differently based on tasks. Researchers may need information summarized according to categories, while a practitioner or doctor may need patient-specific details that are accurate (Forman, 1995).

To help bridge some of the gap in terminology, we have two main medical thesauri in use. Medical Subject Headings (MeSH) and Unified Medical Language System (UMLS) are meta-thesauri developed by the National Library of Medicine (NLM) (Desouza, 2001). UMLS was developed in 1986 and has four main components: meta-thesaurus, specialist lexicon, semantic net, and information sources map. The meta-thesaurus is the largest and most complex component incorporating 589,000 names for 235,000 concepts from more than 30 vocabularies, thesauri, etc. (Lindberg et al., 1993). Approaches to organizing terms include human indexing and keyword search, statistical and semantic approaches. Human indexing is ineffective as different experts use varying concepts to classify documents, plus it is time-consuming for large volumes of data. The probability of two people using the same term to classify a document is less than 20% (Furnas, Landauer, Gomez & Dumais, 1987). Also different users use different terms when searching for documents. Artificial Intelligence-based techniques are making headway in the field of information retrieval. Houston et al. (2000) used a Hopfield network to help in designing retrieval mechanism for the CANCERLIT study. The issue of standardization of terminology continues to be a great debate. The Healthcare Financing Association (HCFA) is adopting some Electronic Data Interchange (EDI) standards to bring conformity to data (Moynihan, 1996). We can expect more standards to be released in the next few years to enable sharing of data.

Security and Privacy Concerns

With sharing of data comes the inherent risk of manipulation and security issues. Security of patients' data and preventing it from entering the wrong hands are big concerns in the field (Pretzer, 1996). Strict controls need to be put in place before open connectivity can take place. Patients' data are truly personal and any manipulation or unauthorized dissemination has grave consequences. Sharing of patient-identifiable data between members of the healthcare supply chain members is receiving serious scrutiny currently. Government and other regulatory bodies will need to set up proper laws to help administer data transmission and security (Palmer et al., 1986). The recent Health Insurance Portability and Accountability (HIPPA) Act can be seen as one of many governmental interventions into the healthcare industry for the protection of consumer privacy rights. Enterprises will have to go to the basics of ethics and operate carefully.

Organizational Culture

In every organization we can see the application of the 20/80 rule. Knowledge providers make up 20% of the workforce, as they possess experiences and insights that are beneficial to the organization. The remaining 80% are consumers of this knowledge (Desouza, 2002a). The providers are often reluctant to share and transfer knowledge as they fear doing so will make them less powerful or less valuable to the organization (Desouza, 2003a, 2003b). Between departments we also find knowledge barriers, in which one group may not want to share insights collected with the other. To help alleviate some of these issues, management should strive to provide incentives and rewards for knowledge-sharing practices. A highly successful approach is to tie a portion of one's compensation to group and company performance, thus motivating employees to share knowledge to ensure better overall company performance. Additionally, Foucault (1977) noted the inseparability of knowledge and power, in the sense that what we know affects how influential we are, and vice versa our status affects whether what we know is considered important. Hence, to alleviate this concern, an enterprise-wide initiative should be carried out making any knowledge repository accessible to all employees without regard to which department or group generated it.

A key dimension of organizational culture is leadership. A study conducted by Andersen and APQC revealed that one crucial reason why organizations are unable to effectively leverage knowledge is because of a lack of commitment of top leadership to sharing organizational knowledge or there are too few role models who exhibit the desired behavior (Hiebeler, 1996). Studies have shown that knowledge management responsibilities normally fall with middle managers, as they have to prove its worth to top-level executives. This is a good and bad thing. It is a good thing because normally middle-level managers act as liaisons between employees and top-level management, hence they are best suited to lead the revolution due to their experience with both frontline, as well as higher-level authorities. On the other hand it is negative, as top-level management does not consider it important to devote higher-level personnel for the task. This is changing, however. Some large companies are beginning to create the position of chief knowledge officer, which in time will become a necessity for all organizations. A successful knowledge officer must have a broad understanding of the company's operation and be able to energize the organization to embrace the knowledge revolution (Desouza & Raider, 2003). Some of the responsibilities must include setting up knowledge management strategies and tactics, gaining senior management support, fostering organizational learning, and hiring required personnel.

It is quite conceivable that healthcare enterprises will start creating the positions of chief knowledge officers and knowledge champions. Top management involvement and support for knowledge management initiatives cannot be underestimated. This is of pivotal importance in hospitals, as their key competitive asset is medical knowledge.

CONCLUSIONS

Some researchers and practitioners have expressed concern about knowledge management being a mere fad (Desouza, 2003b). To deliver promised values, knowledge management must address strategic issues and provide for competitive advantages in enterprises. McDermott (1999) noted that companies soon find that solely relying on the use of information technology to leverage organizational knowledge seldom works. The following chapter has introduced knowledge management and its process. We have also applied it to healthcare enterprises focusing on hospitals. Finally, we justified the knowledge management process by looking through two main strategic frameworks.

Knowledge management initiatives are well underway in most healthcare enterprises, and we can expect the number and significance of such efforts to increase over the next few years. Areas of future and continued research include: automated search and retrieval techniques for healthcare information, intelligent patient monitoring systems, and optimal knowledge representation semantics.

Chapter 5.15
Knowledge Management in Medicine

ABSTRACT

In the last decades, the amount of information has risen because of the technology revolution. The need for organizing information, in a way that the staff and the managers of a hospital require, lead to the generation of a new value, the knowledge management. Its benefits are sensible, not only for the staff, but also for the hospital as an entity. Many techniques are applied to solve all the daily problems in the health sector.

INTRODUCTION

During the last three decades of the previous century, there was a revolution in technology and its applications in medicine and the field of information. The promotion of knowledge and its communicability certainly have profited all the scientific sectors, both in the increase of efficiency and productivity, and in the growth of innovations.

Knowledge management is a notion that is difficult to define. A lot of definitions have been formulated, one of which is that knowledge management is an organism that is constituted of small parts that aim to collect, assess, unify, improve, and produce value from intellectual and information-based resources (Association of State and Territorial Health Officials [ASTHO], 2005).

Progress in medicine is essential; there has always been the mass production of knowledge, and those who are related to this science should take it into account, develop it, and apply it. Traditional sources of information are available, but they usually fail to provide answers whenever and wherever they are needed. Thus, roughly two thirds of problems in clinical practice remain unsolved (Gale Group, 2001). Unfortunately, the information and knowledge that are available to doctors nowadays are poorly organized and old.

In the healthcare field, doctors and patients need help with the choice of better actions for a given situation. The rate of growth and change in worldwide biomedical knowledge leads to the fact that no one is able to know the current practices in a sector without any kind of support (Purves & Robinson, 2003). A partial solution to this problem can perhaps be brought by medical knowledge management. Its aim is the regrouping, incorporation, and connection of any medical knowledge that was produced in the past in order for one to reach a reasonable decision in the present and useful study in the future (Quantum Enterprises, Inc., 2003).

Generally, knowledge management in the medical field can ensure the effective growth and dissemination of better practices, and a continuous assessment aiming at their improvement. Knowledge is created within time. All the data that constitute its base become information when they can be summarized and organized under reasonable models. Information becomes knowledge when it can be managed for active decision making, and knowledge can be turned into perspicacity when it is well developed within regular periods of time (Lobodzinski & Criley, n.d.).

USE AND VALUE OF KNOWLEDGE MANAGEMENT

The continuous effort toward efficiency and economic effectiveness creates a balance among the quality of provided services, and it includes costs that lead to the more effective management of medical knowledge that is derived from biomedical research. The need for a clinical process in the providing of medical care is rather obvious (Stefanelli, 2002). Thus, knowledge management in the field of medicine focuses on the knowledge of technologies used in clinical, administrative, and demographic activity. Today, the pressure of cost also influences the sector of health. The adoption of information technology is considered one of the basic mechanisms for the reduction of cost ("Data and Knowledge Management in Healthcare," 2005).

The society of public health is continuously focused on digital communication for the fulfillment of different kinds of tasks. Although technology has improved for the possibility of the collection, analysis, and dissemination of data, there are still obstacles in the use of information, such as the existence of information that is not well organized and systems that are not complete. The continuous improvement of technology, the lack of resources, the failure to confirm the requirements of data, and complicated data have led experts to the use and exploitation of existing knowledge for the promotion of health (Data and Knowledge Management for Public Health, 2005).

Through knowledge management we can certainly reduce the gap between the lack of data and the lack of systems that develop those data. Starting with the presumption that every problem has a solution, the effective management of knowledge in the health sector can constitute the base of knowledge, which is essential for the presentation of its innovations and distribution in a dynamically regenerative process (Bailey, 2003). Generally, there is a framework in hospitals that can be used as a driver for the management of knowledge. This is a methodology that helps with the designing of a strategy and its processes, and that enriches the transmission of knowledge and tools that support the collection and analysis of knowledge, and the storage and search of information. All these occur in collaboration with the personnel, the economic resources, suitable systems that allow communication in all kinds of situations, and the infrastructure so that the maximum effectiveness, efficiency, and creativity are ensured (Managing Knowledge to Improve Reproductive Health Programs, 2004).

BENEFITS OF KNOWLEDGE MANAGEMENT

In a hospital, even more than in any other organization, knowledge management becomes a necessity since a vast number of research by global organizations, both in Europe and the USA, has proven that a lot of people have died and a great part of the government budget was spent due to errors, which would probably have been avoided with the use of knowledge management. Even though there has been major technological and scientific growth, which has been observed during the last few decades in all the scientific sectors, the medical errors, and, generally speaking, all kinds of errors, that occur in hospitals remain frequent and rather expensive. In the year 2000, the Medical Institute reported that medical errors cost the medical industry and the pharmaceutical industry $37 billion annually, and 100,000 people lose their lives each year because of these errors (Detmer, 2001).

Table 1 presents the basic reasons that led to medical errors.

Table 2 presents the types of errors that occur most frequently.

Table 3 presents errors due to the medical personnel.

Table 1. Causes of errors (Institute of Medicine [IOM], 2000)

✓	Technical errors	44%
✓	Incorrect diagnosis	17%
✓	Failure in damage prevention	12%
✓	Errors in pharmaceutical contact ion	10%

Table 2. Most frequent errors (IOM, 2000)

✓	Incorrect diagnosis	40%
✓	Incorrect issuing of medicines	28%
✓	Errors in medical protocols	22%
✓	Administrative errors	4%
✓	Communication errors	2%

Table 3. Errors due to medical personnel (IOM, 2000)

✓ Negligence / carelessness	29%
✓ Inexperienced / uneducated personnel	14%
✓ Communication	12%
✓ Incorrect diagnosis	8%
✓ Tiredness of personnel	8%
✓ Illegible recipe or incorrect issuing of medicines	6%
✓ Other errors	14%

It is obvious that there are plenty of medical errors, they cost the state a lot of money, they can be dangerous for the lives of patients, and they basically occur due to human factors. About 70% of these errors could have been avoided or even prevented. According to the Medical Company of the USA, in the year 2000, 250,000 deaths were caused due to medical factors (JAMA, 2000). Even though the number seems rather small compared to the entire population of the USA (about the 0.07% of the population), it is very important and should have called to action all experts in the health sector. Knowledge management basically aims to reduce expenses and costs, as well as to increase productivity and efficiency, which will lead indirectly to the reduction of human losses. Each employee should consider his or her knowledge so we can trust him or her when it comes to the resolution of problems, the avoiding of errors, and the assuring of positive results and practices.

OBJECTIVES OF KNOWLEDGE MANAGEMENT: PROBLEM SOLVING

Knowledge management has a very positive impact on all sciences. Its aim is to serve each science separately and minimize the errors derived from the lack of knowledge. Generally, we should choose which information is essential in an organization, such as a hospital, and how we can facilitate the transport of knowledge to it. It is crucial to improve the perception of all the factors involved in the field of health and to support the new methods and technologies, which are not always accepted easily by the personnel of hospitals.

The main objective of knowledge management is to help in the briefing of our knowledge, and to aid its enrichment and exploitation. Today there are systems that aim at improving and promoting knowledge. This can be achieved through the review of practical progress in order to find, develop, disseminate, and use the knowledge for

Table 4. Examples of techniques in knowledge management

- ✓ The best practices on the management of special medical situations
- ✓ Analysis of indications for those situations
- ✓ Report on the existing and new medicines
- ✓ Development of direct and explicit information regarding complicated medical subjects
- ✓ Use of special vocabulary with common language for names of medicines, illnesses etc
- ✓ Determination of the available sources
- ✓ Analysis of data taking into consideration the danger factors
- ✓ Ability for direct access to the data anytime, anyplace
- ✓ Information regarding actions that should be done in case of emergency
- ✓ Creation of protocols under which people in the health field should work
- ✓ Research and better practices for settlement of medical subjects
- ✓ Research for new diseases which appear to the society
- ✓ Finding of information related to the health conditions of the population in a given geographical zone
- ✓ Thorough interconnection of information out of multiple choices e.g. handbooks and depictions
- ✓ Access to descriptions of diseases, ability to practice and research reports
- ✓ Knowledge regarding treatments that can be applied
- ✓ Access to informative pages of the hospital and more important to other hospitals for the acquisition of data and comparison of situations
- ✓ Unified communication and informative sending –receiving data systems

(ASTHO, 2005)

the profit of doctors and patients. Furthermore, these systems achieve an approach among the experts in different kinds of sciences facilitating exchange between the existing and the new techniques in the field of health (Advances in Clinical Knowledge Management Workshops, n.d.).

Table 4 presents examples of techniques in knowledge management in the medical field.

From Table 4 comes the conclusion that the main objectives of knowledge management are the isolation and later development of the structures of knowledge, the production of its gradual structures for the description of a future connection, the proposal to create functional systems for the development of medical knowledge, better comprehension of problems and decision making, and the application of knowledge management in medical information technology in all clinical departments and health systems.

SAFETY OF KNOWLEDGE MANAGEMENT

The information conveyed to doctors is turned later into knowledge, either through the development of computer-based systems or through the development of tools that will be used by experts in the field of information in collaboration with clinical groups. The knowledge and information by themselves are not in a position to improve clinical practices. The organized and professional management of information is required by all professionals (Sozou, 1998).

Knowledge is undefined, is precious in its acquisition, and can be easily lost or stolen in order to be converted or erased afterward. In the world of technologies nowadays, where everything tends to function digitally, a lot of mechanisms as well as structures are used for the protection of knowledge. A model that can ensure knowledge management should ensure its protection as well. In other words, it is essential in an informative

Table 5. Advantages of knowledge management for hospital personnel

- ✓ To avoid errors which happened in the past
- ✓ To reduce the time needed for detection of information, mainly for urgent incidents
- ✓ To assure the best clinical decisions by inexperienced employees
- ✓ To find alternative ways in the care of emergency situations
- ✓ To identify lack of information, which can lead to errors
- ✓ To encourage the flow of ideas, which leads to innovations
- ✓ To avoid unnecessary procedures and increase of cohesion and collaboration among the employees
- ✓ To increase productivity and efficiency

Table 6. Advantages of knowledge management in a hospital

- ✓ Improvement of quality of sanitary care through the increase of efficiency and productivity of personnel
- ✓ Facilitation of communication between medical personnel
- ✓ Reduction of expenses mainly from the pointless use of medicines and unnecessary insertion of patients in the hospital
- ✓ Creation of strategies for a vast number of data
- ✓ Contribution of hospital profits and better use of money, which would be unavailable without knowledge management

system to ensure the authenticity of knowledge; the safety of data from any kind of involuntary or voluntary modification, destruction, or revelation of its elements; the integrity of data; and the general application of political safety to information (Mundy & Chadwick, n.d.).

ADVANTAGES IN THE USE OF KNOWLEDGE MANAGEMENT

Knowledge management has a lot to offer to a hospital, and even more to its personnel. A technical and organizational infrastructure can be achieved. Table 5 presents its advantages for the personnel of a hospital.

Table 6 presents the major advantages of knowledge management in a hospital.

DISADVANTAGES IN THE USE OF KNOWLEDGE MANAGEMENT

Knowledge management has a lot of advantages, but also presents a lot of disadvantages. If there is not an explicit determination of knowledge and we do not recognize its importance, then we will not be able to achieve its appropriate management. In some cases, we focus on the past and the present and care less about the future, giving emphasis on counting knowledge and not on its results.

Generally, despite the increasing power of information technology, knowledge management in the form of supporting decisions and information concerning doctors has minimum impact on the results of healthcare. This occurs due to the fact that knowledge management addresses the relationship between patients and personnel; it does not provide harmony between the complexity of individuals and their regular actions that form special practices (Purves & Robinson, 2003).

Usually the efforts toward the medical management of knowledge are underestimated. As far as the systems are concerned, an uncontrolled increase of medical knowledge can lead to disaster (Quantum Enterprises, Inc., 2003). Table 7 presents some of the reasons why knowledge management is not efficient and presents disadvantages.

THE FUTURE OF KNOWLEDGE MANAGEMENT

Through the practices and techniques, doctors can have easier access to new information concerning

Table 7. Disadvantages presented by knowledge management due to certain reasons

- ✓ Knowledge in medicine is incomplete, vague, inaccurate and requires many years for its acquisition
- ✓ Continuous alteration of knowledge as technology develops
- ✓ Excessive emphasis to the reserve of knowledge and not to its flux
- ✓ Doctors usually forget the aim of knowledge management and do not realize the complexity of knowledge which is distributed

medicine and their applications, diagnostic tests, and the way diseases are treated, as well as established policies and processes. This access will decrease the possibility of costly medical errors and will promote healthcare for patients in the hospital (Detmer, 2001).

It is very important to create a network aiming at collaboration among experts and at the improvement of methods for the collection and analysis of data both for the present needs and the forthcoming ones. The future of medical knowledge management is in the present. We should take advantage of the revolution of technologies and information that has begun during the last decades (Gale Group, 2001). In the future, in order to reach the use and application of knowledge, we should analyze the existing aims, the types of knowledge, the users and their sources, the processes, and the technologies (Bouthillier & Shearer, 2002).

CONCLUSION

Knowledge management is a basic tool for all those working in the health field and for hospitals. It helps in sending the right information to the right person at the right time so that the right decisions can be made depending on the existing problems. It is certain that with the help of knowledge management, effectiveness in the health field will be increased through unified systems, processes, and methods; the cultivation of exchanging knowledge; and the promotion of the effective use of available information.

Chapter 5.16
Knowledge Management in Indian Companies:
Benchmarking the Pharmaceutical Industry

ABSTRACT

In this chapter we look at knowledge management in India with particular regard to the pharmaceutical industry. In India, changes in government policy linked to global factors are bringing about increased pressures to strategically manage knowledge effectively. At the same time, significant knowledge management initiatives are already underway in other industry sectors. We outline some of the changes affecting the pharmaceutical industry globally, and consider India on some relevant activities. The development of IT solutions is seen as enabling effective knowledge management. We look at a range of knowledge management technologies and their existing or planned use in industry. The IT however merely underpins the knowledge management philosophy, which must be incorporated into processes, strategies and organisational culture for successful adoption. India and its indigenous organisations may be characterised by some specific cultural factors.

Effective implementation of KM will depend on a conducive cultural climate, both organisationally and nationally. We also therefore examine the extent of the perceived benefits, that shape the cultural shift from understanding knowledge management as simply an IT problem to recognition of knowledge management as a strategic process as seen by CEOs and top managers in indigenous Indian Fortune 100 companies. We look at how the pharmaceutical industry compares to other organizations of significant size in India across a range of factors concerned with knowledge management activity, using survey and interview techniques. We conclude that while only a few significant sectoral differences are evident, there is generally a heavy orientation towards IT-based conceptions of KM, which may be incompatible with the requirements for future success in the pharmaceutical industry globally.

INTRODUCTION

In this chapter we consider knowledge management initiatives with particular regard to the example of the Indian pharmaceutical industry. This industry exemplifies a knowledge-intensive industry area with an uncertain future due to a required change in practices in the context of international developments. Regulatory compliance, new knowledge creation, patent application and protection, sharing knowledge in partnerships and alliances, and widespread and timely access to information are all indicated areas of knowledge-based activity. The management of these processes entails their embedding into cultural and organisational practice, and this moderates the effectiveness of knowledge management tools. Many organisations face analogous issues of implementing KM strategies, despite sectoral differences, and we contextualise the Indian pharmaceutical industry both in its Indian and in its industry context. Lessons learned by benchmarking it in these contexts allow insights applicable to other healthcare industries. The chapter is organised as follows: first we review the global state of play in KM in large industries, concentrating on their strategic directions in KM, and highlight some issues applicable in specific countries and industries of concern here. Then we examine the particular industry environment surrounding pharmaceuticals, with particular reference to those factors applicable in India and noting the general importance of R+D. We then consider aspects of the Indian culture, at national and organisational levels, which distinguish it from competitor nations but which also potentially impact on the success of KM strategies. Finally we survey how KM is currently being undertaken in major Indian companies and especially compare pharmaceutical companies against other major organisations in relation to their knowledge management capabilities and strategic choices.

Knowledge Management and Industry

Knowledge management (KM) remains a central issue for large organisations. Having moved beyond being seen as a short-term fad, it is now widely recognised as critical to the success of knowledge-intensive industries, such as pharmaceuticals. Such industries, where the key organisational resource is knowledge, and which are often characterised by a focus on innovation and high research and development activity, are seen as taking on increased importance in the future economy (OECD, 1999). This has led to significant commercial and academic activity in information systems, in human resource management, accounting, economics and other disciplines. Surveys of CEO priorities, and numerous consultancy reports, dedicated journals, conferences and professional seminars indicate its continuing importance, as does the increased availability of vendor “solutions” and corporate appointments and internal KM initiatives. An indicative Google search uncovered (February,

2003) about 1,150,000 web pages. In this flurry of recent activity, definitions and understandings have been contested and, while work has separately focussed on IT, economic and human capital aspects, a more sophisticated understanding is emerging of its integrating potential. Earl (2001) has distinguished several schools that emphasise one or another of these various aspects and other frameworks and taxonomies have been proposed to integrate the extensive research underway.

KM, however, is not merely an academic exercise. Major companies have been quick to realise the importance of the assets implied by their data resources, the knowledge of their employees, and the communication of that knowledge in the work context. IT has allowed documents to be electronically preserved, emails to be archived, data to be warehoused, and computer activity to be logged, with management systems placed around those to search, discover patterns and organise for reuse or repurposing. These all, however, require explicated knowledge: the ability to form an intelligent query, to recognise a significant pattern, to relate ideas and to recognise a colleague's worth. In short, to make use of information in documents and databases is a human ability. And humans may not be able to express what they know, may not be willing to share it, and may not have had an opportunity to articulate information of relevance, such as a key connection between something of current organisational interest and something they have learned elsewhere. The concept of tacit knowledge, due originally to Polanyi (1958) and modified, elaborated and reinterpreted by later writers, has come to refer to that aspect in which unarticulated skills, intuitions and personal connections can be brought to bear in useful processes of knowing. According to Polanyi (1958), we know more than we are able to express in words. At the same time we rely on our awareness of what we cannot articulate. "While tacit knowledge can be possessed by itself, explicit knowledge must rely on being tacitly understood and applied. Hence all knowledge is either tacit or rooted in tacit knowledge. A wholly explicit knowledge is unthinkable" (Polanyi, 1969). Knowledge, therefore, can be formalized only in a limited way and any formal system will by necessity be incomplete. "The legitimate purpose of formalization lies in the reduction of the tacit coefficient to more limited and obvious informal operations, but it is nonsensical to aim at the total elimination of our personal participation" (Polanyi, 1958). However, many knowledge management initiatives rely on codification and formalization of knowledge and "tacit knowing is the fundamental power of the mind, which creates explicit knowledge, lends meaning to it and controls its uses" (Polanyi, 1969). Organisations dread losing employees with the ability to mobilise their knowledge in the organisation's service, hence the attempts to make it explicit and codified in transferable forms. The literature, unnecessary to rehearse further here, is replete with considerations of these issues, methods and "solutions" and with critiques of their philosophy. A clear distinction between tacit and explicit knowledge, which seems to underpin many knowledge management strategies does therefore not exist. Although the focus on explicit knowledge, particularly of technology-driven approaches to knowledge management, has significant implications for their success and usefulness.

Practically, there are many activities that have been conducted in an attempt to manage a particular organisation's knowledge, as we will see later. Many of these have been adopted piecemeal in a project context, in addressing a particular problem, or as pilot studies at the business-unit level. Maier and Remus (2002) propose contextualising KM activity centrally within a process-oriented strategy and enumerate eight sets of "strategies" identified from the literature. These include: (1) mapping sources of internal expertise (e.g., expert directories); (2) establishing new knowledge roles (e.g., create a new unit or position for knowledge-related tasks); (3) creating a virtual work environment (e.g., networked knowledge workers); (4) supporting knowledge flows (e.g., communication tools adapted for knowledge seekers and providers); (5) creating innovation and new knowledge (e.g., research and development focused on these). The other three strategic activity sets aim at managing customer information, intellectual assets, and integration with other business strategies.

Maier and Remus (2002) surveyed the top 500 German companies, as well as the 50 major banks and insurance companies in relation to their use of KM systems, and found a lack of process orientation in KM strategy. These authors also considered the numerous KM activities identified in the literature as confounding strategy, supporting activities and instruments. Reframing these activities within a process-oriented KM strategy, relating the activities to business processes, is seen by these authors as advantageous compared to other extant approaches. This is because of the value of an integrated approach, based on business processes.

Integration, focused around IT, has been understood by the Indian company Wipro, which recently achieved recognition for their leadership in knowledge management (Wipro, 2002). The international KM reality award recognises "implementation of knowledge management practices and processes by realizing measurable business benefits." The unified framework developed by Wipro cuts "across the boundaries of Culture, Content, Communities and Business Processes" and has resulted in a widely accessible knowledge base. "All of Wipro's initiatives like Six Sigma, PCMM, CMMi feed into the central knowledge management repository on a continuous basis" (Wipro, 2002).

Recent developments in information technology have inspired many Indian companies to imagine a new way for staff to share knowledge and insights. Instead of storing documents in personal files and sharing insights within a small circle of colleagues, they can store documents in a common information base and use electronic networks to share insights with their entire community. Most companies soon discover that leveraging knowledge is actually very hard and involves more community building than information technology (Gunnerson, Lindroth, Magnusson, Rasmusson and Snis, 2000). This is not because people are reluctant to use information technology, but due to the fact that they often need to share knowledge that is neither obvious, nor easy to document, and typically requires a human relationship to think about, understand and share (Swan, Newell and Robertson, 1999). However, with the growth in information technology capabilities, a clear operational distinction can be drawn between knowledge management as a technology and knowledge management as a strategy. The former can be captured, stored and transmitted as explicit knowledge in digital form (Marwick, 2001). The latter can only exist in an intelligent system (people) and uses information technology as a medium to create and share knowledge (Marwick, 2001). It is vital therefore to identify the interaction between knowledge and information technology and the appropriate balance between them.

The IT infrastructure in these approaches is seen as a key mediating component for explicit knowledge management. This is because information systems, enabling data or knowledge intensive processes operate in large, centralised or distributed organisations and typically require underpinning technologies specifically relevant to the nature of the knowledge work. IT-underpinned strategies have been implemented in several pharmaceutical companies with success.

Snis (2000) for example has described ways in which explicit knowledge in a Danish pharmaceutical company has been managed through, inter alia, IT support mechanisms such as intranet and "narrow-casting" of emails based on user profile matching. Such profiles identify processes and functions of specific concern to that group. Document management systems are also in use, with time-related status codes and access controls on operational documents, and this mechanism, with associated meta-information, allows relevant filtering of effective documents to applicable organisational groups or functional levels. User-owned and designed templates are also at work in functional areas allowing procedures and "better practices" to be shared. These are subject to internal quality controls before acceptance as a local way of working, and are framed by the legislative requirements of the external environment. Although the IT tools reported in her study certainly enabled effective knowledge management to occur, their success is surely dependent on the positive attitudes to knowledge management of those using them and Snis stresses that the IT should be seen in its mediating function. We return to this aspect of organisational culture later.

Knowledge Management and Healthcare

The consulting group KPMG describe various successful healthcare KM systems in their report, "The Knowledge Journey: Pathways to Growth" (KPMG, 2000). These include: Eli Lilly's globally spread intranet providing current information to the field sales force; NovaCare's system for providing regulatory and good practice knowledge as well as other information throughout the company; and Hoffman LaRoche's acceleration of new drug development through making information and knowledge available at every stage.

Eli Lilly, in particular, has led in the area of knowledge sharing by its strategic decision to emphasise alliances, e.g., with universities and biotechnology firms. They have developed tools which identified gaps in knowledge sharing and allowed effective remedial action to take place, in this case a discussion database that overcame geographical dispersion of partners (Futtrell et al., 2001). NovaCare's system is described in Quinn, Anderson and Finkelstein (1996), emphasizing its organisation around the frontline therapists' professional knowledge, in which detailed information on therapeutic care is recorded for use by a range of stakeholders. The (best practice) knowledge the company builds up over time is thus available to its professionals. Like Eli Lilly, Hoffman-La Roche's development of a new drug in conjunction with a range of strategic partners was another catalyst for a KM solution (Davenport and Prusak, 1997). In this case, collaboration tools and the development of a culture of sharing led to success (Vincente, 2002). Sharing knowledge is common to the above examples, and clearly addresses the human activities involved, with the technologies acting as effective supporting mechanisms.

Apart from the Roche example, Vincente (2002) recently summarised some other current KM initiatives of big pharmaceutical players and best practices identified by research. These included successful document management and collaboration at Amgen, and a portal and search solution to manage "overwhelming" unstructured information at AstraZeneca. He notes that the focus to date had been on document management and regulatory compliance, but portals and collaboration technologies are growing. As these latter technologies gain hold, the cultural factors affecting their usage will become significant. Indeed the field has for some time recognised the limits of equating KM with IT-based capture of existing knowledge, moving toward processes that enable new knowledge creation through tacit knowledge sharing, fostering communities and contexts in which this activity can thrive. These activities are more in the domain of human resource management, and processes of knowledge enabling are detailed in Von Krogh et al. (2000). Such a migration of focus will increasingly entail managerial initiatives addressing organisational cultures, not merely adopting IT "solutions." This will thus look to address the human processes of knowledge creation, and what can work culturally.

These examples show some of the current activities in organisations of relevance here, and resonate with the typical range of KM initiatives in knowledge intensive companies, including those that Skyrme (1997) identifies:

- Creation of knowledge databases: best practices, expert directories, market intelligence, etc.;
- Active process management: of knowledge gathering, classifying, storing, etc.;
- Development of knowledge centres: focal points for knowledge skills and facilitating knowledge flow;
- Introduction of collaborative technologies: intranets or groupware for rapid information access;
- Knowledge webs: networks of experts who collaborate across and beyond an organisation's functional and geographic boundaries.

It is clear that while these can be enabled by IT, strategically integrating them with processes that will work within the culture are required (Davenport and Prusak, 1997). This entails assessment of those processes, the available technologies and the perceived benefits and threats related to a KM strategy.

THE PHARMACEUTICAL INDUSTRY

Pharmaceutical companies have an aspirational mission — introducing innovative products to serve the market as quickly as possible followed by enhancing their commercial potential. Four traditional core processes involved include: discovery, development, manufacturing and marketing, and these are closely interrelated. The creation and direction of knowledge, however, is now seen as the newest or fifth process by which a pharmaceutical company creates competitive advantage: it is this that is recognised as "knowledge management" in the Indian pharmaceutical sector.

The inaugural issue of the Pfizer journal (Pfizer, 1997) provided a useful assessment of the global pharmaceutical industry at the start of the new century. Challenges identified in its suite of articles include: market pressure to reduce costs, the R+D impact of biotechnology advances and mergers occurring among significant players, generic competition and "patent pirates," and changing societal demographics and expectations.

These challenges translate into pressures to continue effective innovation, to streamline processes and to establish alliances (e.g., with biotechnology companies) to share findings as Pfizer, for example, has done (Pfizer, 1997, p. 19), and other major players likewise. All of these challenges are clearly critical knowledge-based activities. Innovation is recognised as a required continuing activity in the industry and to support this, growing larger, through mergers and alliances, has been a constant of pharma companies' strategies in recent times (Rasmussen, 2002). The value of scale has been stressed in a McKinsey study (Garg, Berggren and Holcombe, 2001) which notes that greater size "increases the number of bets a company can place on new technologies," as well as allowing faster completion of clinical trials, providing an advantage in launching blockbuster drugs, and increasing "its desirability as a licensing partner." Beyond a certain size, however, communities of practice begin to lose effectiveness and simply increasing size as a strategy is insufficient. Garg et al.'s analysis goes on to suggest that, with respect to new knowledge creation, a restructuring entailing smaller, federated specialist units is likely to be more productive and indicates that some major companies are already moving in this direction.

In addition to industry level challenges, the international and national legislative frameworks shape what is politically possible. For many countries, healthcare is a significant part of the national budget, and one that straddles public and private sector organisations. Although our focus here is primarily on pharmaceutical companies, it is to be noted that healthcare in general is a vastly larger concern, affecting these companies.

In India for example, a new national policy (the first in almost two decades) has been announced in which health sector expenditure is targeted to reach 6% of GDP by 2010 (PTI, 2002). The majority of this, however, is not centrally funded, with the policy aiming to decentralise services to district level and to achieve "gradual convergence of all health programmes under a single field administration" (Sharma, 2002). Currently India has a three-tier public health system, with central responsibility for major disease control (for example) and state governments funding the other two tiers. A convergence in which the responsibility devolves to the district level, and the central government's role becomes reduced to monitoring and funding of essential drug supplies, clearly implies knowledge management activity. Other aspects of the policy therefore indirectly address knowledge management issues, in which an integrated disease control network crossing the tiers of public healthcare can bring the goal of evidence-based policy-making closer. Interconnectivity, training and data integrity issues are indicated here (PTI, 2002), implicating both IT and human resource initiatives. There is a tight link between legislation for healthcare generally and pharma specifically. With respect to our focus on the pharmaceutical industry the policy notes the following two relevant points. Firstly, to avoid dependence on imports at least half of required vaccines or sera would be sourced from public sector institutions, and secondly, production and sale of irrational (understood here as not being science-driven) combinations of drugs would be prohibited (PTI, 2002).

It is not just national policies that impact on the pharmaceutical sector, however. Kuemmerle (1999) has shown that foreign firms invest in R&D sites abroad in order to augment their knowledge base or in order to exploit it. He states that foreign direct investment in Asia is expected to continue growth, with "more firms expected to carry out home-base-exploiting investments in China and India because of the future attractiveness of these countries' markets." The analysis by Atul (2002), however, qualifies this by noting specific relative advantages China has currently secured compared to India and shows how specific national policies have obtained these current advantages. Ganguli (1999) also expects a "sea-change in the pharmaceutical sector in India vis-a-vis business processes and intellectual property rights" due to changes in the patent laws occasioned by required compliance with the provisions of the Trade Related Intellectual Property Rights (TRIPS) following the GATT Uruguay. These particularly concern patent applications and marketing rights but also impact on research and development investments, and on foreign direct investment in R+D.

Policy settings will naturally impact on the strategic initiatives within the industry. With a market of about US$2.5 billion, the Indian pharmaceutical industry is the 12th largest in the world (Ramani, 2002) and other figures suggest a growth rate of 10% annually (Atul, 2002). The Indian pharmaceutical industry has traditionally thrived on rapidly copying Western drugs, often within four to five years of their first appearance in the global market The reverse engineering time includes a lag while likely market success is ascertained, but is much more rapid: both Zantac's and Viagra's marketers respectively met Indian competitors at the Indian and the global launches (Lanjouw and Cockburn, 2001).

Noting that India will implement the WTO-GATT agreement in 2005 (which will bar Indian firms from replicating innovations patented in Western countries), Ramani (2002) discusses approaches to research and development strategy and expenditure in this sector. In the Indian biopharmaceutical sector, this is linked not to firm size, but to research orientation, described in terms of the acquisition, disclosure, and internal creation of knowledge with market performance strongly correlated with a firm's (human) knowledge stocks. Examining a number of biotechnology firms on data from the mid-1990s, they found the counterintuitive result that patents, publications and academic collaborations all correlated negatively with R+D qualification intensity. The explanation provided recognizes the extent of tacit knowledge in biotechnology companies: literature is cited showing that because much of the knowledge created is tacit, residing in individuals or groups, it is hard to explicate, leading to a disincentive to patent. Although the imminent changes in the Indian patent law have led to a slight increase in patents recently (Desai and Agarwal, 2002), patent application processes and infrastructure were also reportedly inefficient at the time of writing, providing further disincentive. Publications and collaborations however do not have this latter problem, so managerial orientation is considered a more likely reason. Ramani (2002) concludes that since increased knowledge stocks impact positively with market performance of large firms, they might wish to reconsider whether increasing the knowledge disclosure parameters through publications and academic collaborations would increase longer term competitive advantage. Managing the intellectual property involved is thus likely to become vital.

It is the ability to create, generate or source knowledge that will provide sustainable advantage, but Kummerle (1999) has suggested that there are only a few outstanding academic clusters generating knowledge in the pharmaceutical industry and therefore, "foreign direct investment in R&D might be geographically more concentrated in only a few countries and regions than is the case in other industries." A WTO consultant (Prakash, 1998) interviewed the director of the Indian Drug Manufacturer's Association. His view was that the big foreign companies had never, and would not in future, conduct R+D outside their own countries, and there was little new internal investment and only a small overall amount in R+D. Without change there would be no indigenous innovation and the industry would be "stagnant." A study by Mansfield (1994) cited in Lanjouw (1999) confirms that the prevailing intellectual property laws in India were seen as so weak as to preclude it from being an acceptable location for basic R+D by multinationals, although there have been a small number of exceptions. The Indian government (2002) has recently announced its upgraded position on patents to comply with the Trade Related IPR agreements of its entry to WTO. The announcement also notes the related Doha declaration's (WTO, n.d.) stress on the affordability and availability of medicines for all. Pharma is not only big business: there are basic humanitarian issues in healthcare at issue. The debates and documents involved in relating IP rights to access to essential medicines are beyond the scope of this paper to review but one relevant source of further information is the Consumer Project on Technology website (http://www.cptech.org/).

Atul (2002) describes the comparative state of the pharmaceutical industries in China and India, and suggests China poses a threat to the Indian industry post 2005. He observes that foreign direct investment in the Chinese pharmaceutical industry is currently 18 times more than in India: a gap that is expected to increase "if India delays implementation of product patents and IPR laws." It is worth noting though that Chomsky (1994) has drawn parallels between the destruction of the French chemical industry when product patents were introduced and the likely impact of GATT on the Indian pharmaceutical industry. Lanjouw (1999) has considered this in some detail and suggested that there are signs that R+D will increase in India and that some companies will emerge as more innovative. But clearly in a sector that is having to change its model from reverse engineering of existing products towards indigenous innovation, the ability to create and share knowledge will be vital. This ability however, rests ultimately within the people making up an organisational and a national culture, and simply having enabling technologies is not sufficient to ensure success.

CULTURAL FACTORS IN RELATION TO KM STRATEGY AND IMPLEMENTATION

Knowledge sharing is essential for the effective implementation of knowledge management. The coupling between behaviour and technology is two-way: the introduction of technology may influence the way individuals work. People can and do adapt their way of working to take advantage of new tools as they become available, and this adaptation can produce new and more effective communication within teams. The history of information systems however is full of examples of user resistance to imposed developments that were "not invented here" or which did not fit the organisational culture or established way of working.

Staples and Jarvenpaa (2000), in a study of collaborative technology use in a Canadian and an Australian university, found that although task and technology factors were salient, indeed organisational culture factors did influence collaborative technology use for information sharing. Issues of trust and power are central here, and in an industry increasingly characterised by strategic partnering, the development of shared trust and a broad base of power is essential for generating a creative environment (Lendrum 1995). Although culture is learned, and ultimately plastic, both national culture and organisational culture have deeply held characteristics that may help or inhibit particular behaviours. Effective knowledge creation is critically dependent on willing workers within the organisation, and their propensity to share their knowledge. It is recognised that although local factors may override any particular predominant stereotype (Maruyama, 1994), such as a hierarchical and bureaucratic culture, entrenched national as well as organisational cultures are likely to play a significant role in determining this propensity.

Cultural factors at the national level, for example, have been shown to apply in a recent study of KM practice and understanding in Hong Kong (Poon Kam Kai Institute, 2000) whose summary of key findings notes the "paternalistic management style of Chinese companies" as being in evidence. Such factors translate into the typical practices of organisations in specific countries — Japan has had economic success in manufacturing through Kaizen (Imai, 1986), an ingrained philosophy to which it is culturally suited. But, when western manufacturers adopted integrated production "their divisions appear to lack the level of liaison and trust that exists between a Japanese manufacturer and its suppliers" (Imai, 1986). Again, the success of any particular organisational process must be attuned to what will work culturally.

The classic work-identifying dimensions by which national cultures are constructed and thereby differ is Hofstede (1980). A statistical analysis of two surveys was conducted in 1968 and 1972 totaling over 116 000 responses from employees of a large multinational firm (IBM was the empirical source). His book shows how his findings correlate to other extant studies and indicators. Considerable research has followed, including the introduction of a fifth dimension (short vs. long-term orientation), more countries and methodological critiques, which are addressed in a later book, revisiting the study and extending its implications (Hofstede, 1991; 1997). Although national culture and organisational culture are not "identical phenomena" (Hofstede, 1997), and the study of national differences has only been partly useful for understanding organisational cultures, organisational practices are shown to be culturally dependent. In the case of Indian companies, Hofstede (1997) suggests that the implicit model of organisation is the extended family, in which authority is concentrated along lines of seniority. In the original work, culture is characterised as "collective programming of the mind." Hofstede scored each of 40 countries on the following dimensions: power-distance, individualism, uncertainty-avoidance and masculinity. These dimensions are generally held to be stable, culturally entrenched and descriptively useful in illuminating cross-cultural differences. Two of these are particularly relevant here.

The first of these dimensions, power-distance, in organisational terms relates to the unequal distribution of power in a hierarchy, accounting for phenomena in which deference, sycophancy and servility are normal organisational behaviours. Hofstede's (1980) original definition is as follows:

"the power distance between a boss B and a subordinate S in a hierarchy is the difference between the extent to which B can determine the behaviour of S and the extent to which S can determine the behaviour of B."

India's score on this index is the fourth highest of all the countries, 77, where the mean is 51. This index has been theoretically related to trust and organisational innovation. It is worth noting that Hofstede (1980) reports other studies where a high score on this index correlates with relatively lower interpersonal trust. In other countries with high scores on power distance, low cooperativeness among employees and a relative lack of identification with cohesive work groups have also been shown. Such a climate would not be conducive to knowledge sharing. In contrast, Denmark has one of the lowest scores (18) on the power-distance dimension. The study reported earlier by Snis (2000) considered the issue of power, and found that in that (Danish) pharmaceutical organisation knowledge sharing was viewed as important and not seen as jeopardising an employee's position of expertise.

The second dimension in which cultures differ is uncertainty-avoidance, defined as "the extent to which members of a culture feel threatened by uncertain or unknown situations" and entails concepts such as the need for security and dependence upon experts and rules. On this index India scores 40, (seventh lowest overall) and well below the mean of 64. Some connotations of a lower value include more risk taking, acceptance of foreigners as managers, and a view that conflict in organisations is natural (Hofstede, 1980). It is also notable that those countries with lower values are held to be "more likely to stimulate basic innovations (but are) at a disadvantage in developing these to full-scale implementation" (Hofstede, 1997). The Australian Financial Review (Mills, 1994) published an assessment of Asian economies in which it viewed India as a "country of great creativity with a deep scientific and mathematical base" despite its commercial markets being "a haven of plagiarism and intellectual piracy." It also considered, however, that India was "a country of competing self-interest, and little concern for the common good." If the culture and incentive schemes are oriented towards knowledge hoarding, rather than sharing, innovation is likely to stall.

India's scores on Hofstede's other two dimensions are around the mean values and are not considered further here. The scores of particular organisations on the dimensions will also be moderated by local factors: Hofstede (1980) reports one study showing differences in structure and control systems between indigenous Indian and U.S. subsidiaries based in India. Although in the Indian pharma industry, the big players are mostly multinationals, Hofstede's original study was with IBM employees and the differences identified could thus be attributed to national factors. Since the employees in Indian pharma companies are predominantly Indian, whilst naturally remaining cautious in making attributions, the values learned in a particular culture can be expected to apply.

Puhlman and Gouy (1999) examined internal barriers to innovation in the international pharmaceutical industry, and noted that sharing knowledge is a major factor in successful companies, defined as those in the top 20% based on product introductions and sales. A lack of knowledge management leading to repeated mistakes was one of the five most common problems in innovation. Success was also seen to be enhanced by innovation in business systems, with information exchanged and disseminated faster, but also targeting the acquisition of new skills and information. Puhlman and Gouy's study showed that companies that use innovation tools and support knowledge management have considerably higher success rates, and note America's comparative advantages in process and strategy definition. They conclude with ten key self-assessment questions pertaining to innovation, addressing, inter alia, the gathering and systematic assessment of new ideas, the dissemination of knowledge, and the conduciveness of the company's culture.

SURVEY

Having covered the cultural issues that may impact on KM strategy success, we now look at some specific approaches to KM strategy in India through a 2002 survey of Indian Fortune 100 companies1, which include leading indigenous companies in the pharma and healthcare sector. In particular the survey, which had 17 respondents, looked beyond a conception of KM as being purely IT-based and emphasised its relation to corporate strategy. However India, which has a recognised strength in IT, has often tended to equate KM activity with IT capabilities and solutions. The following summarises the key points gleaned from the survey.

To determine the technological infrastructure for implementing knowledge management within an organization, respondents were asked the following question:

Has your organization implemented or is it planning to implement the following technologies?

Figure 1 shows the responses.

In the context of technology, respondents were looking at implementing both Internet and Intranet to develop a strong external and internal flow. In the context of the current scenario, developing a strong internal information backbone is of primary interest. This resulted in "document management systems" being the third most effective technology helping respondents in managing information. It is important to note though that technology in itself does not constitute a knowledge management programme; rather it facilitates one, especially in large, geographically dispersed organizations, typical of the participants in this survey. Another important aspect recognized was that, unlike such previous initiatives as Total Quality Management (TQM) and Business Process Reengineering (BPR), the cost of implementation was not budgeted by the IT function, suggesting a whole business strategic perspective.

The state of knowledge management implementation was also addressed, and respondents were asked the following question:

When, if at all, do you intend to do any of the following, or has your organization done them already?

Figure 2 shows that facets of knowledge management practice such as implementing enterprise resource planning, creating a knowledge management strategy and benchmarking the current situation score more than establishing knowledge policies, incentives for knowledge working, creating a knowledge map or measuring intellectual capital. The majority of those interviewed were planning to use these measure to ensure success, but their preliminary focus was on having sound IT systems to facilitate knowledge within the organization. This confirms that less attention had been paid to the non-IT aspects.

The survey questions on strategy began by asking Does your company have a Knowledge

Figure 1. Technologies used for knowledge management

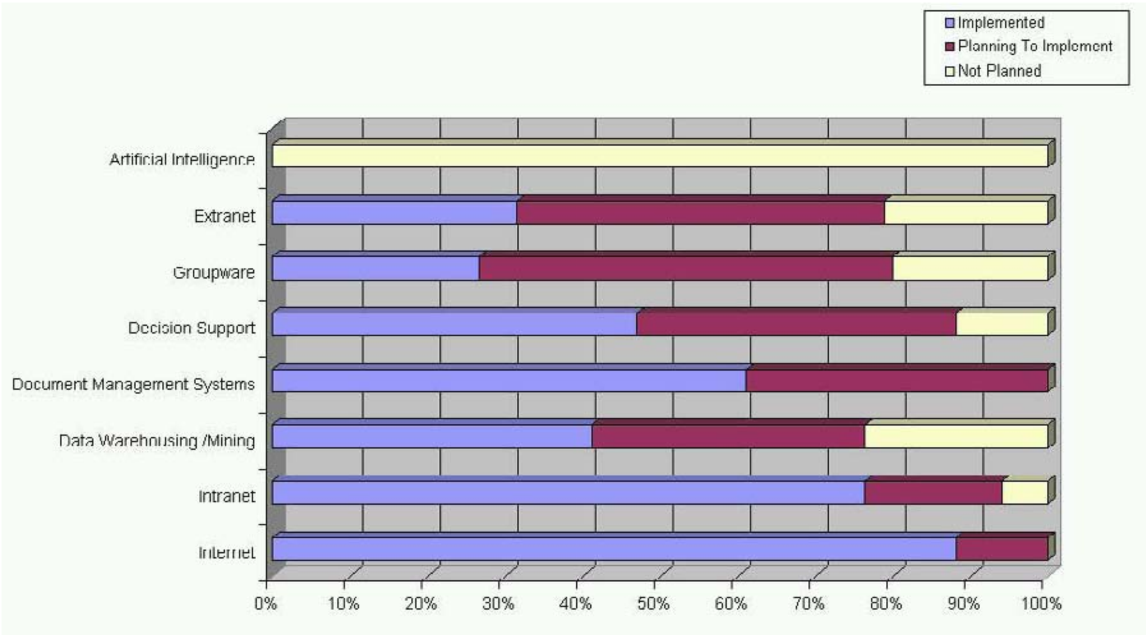

Figure 2. Knowledge management processes

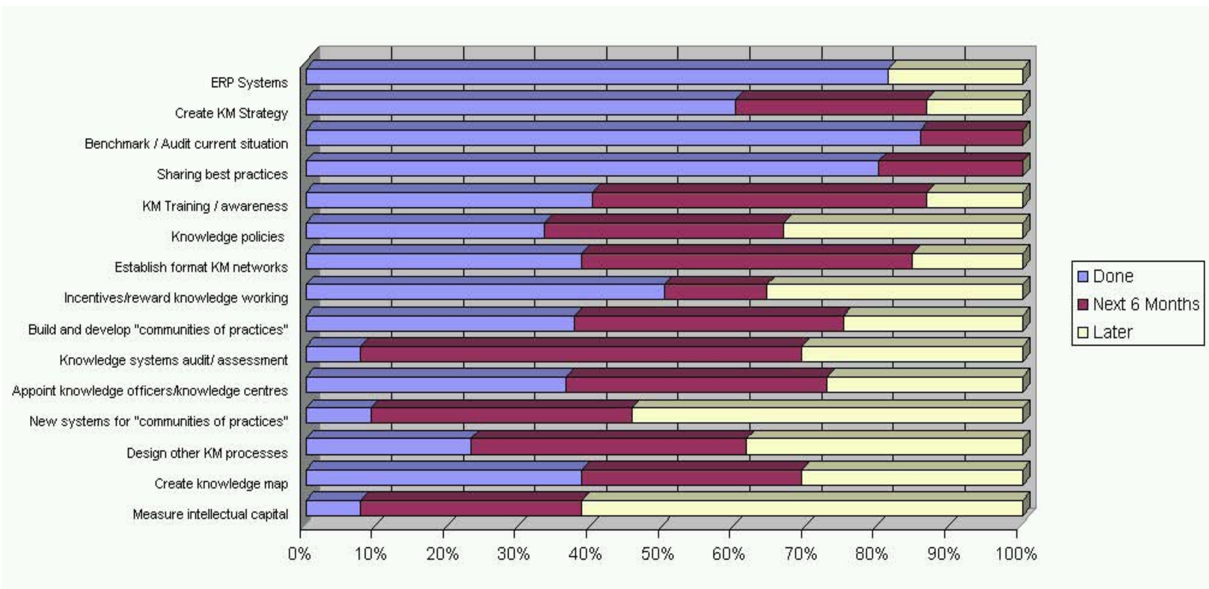


Management Strategy? Seventy-five percent of respondents said that their organization had a knowledge management strategy in place, 19% stated there was no usage of any KM strategy, while 6% were completely unfamiliar with the term knowledge management. The above results demonstrate that most large organizations, including a major pharma, are not only informed about knowledge management but also are making efforts to successfully implement this strategy. However one company, which develops health-care systems, had no internal KM strategy at the time of the survey despite an otherwise strong emphasis on information management solutions in the sector.

To examine the current position of knowledge management programmes within the 75% of organizations with a knowledge management strategy in place, a set of statements was presented and participants were asked: How accurately does each statement reflect your organization? Results revealed that 50% of companies have initiated knowledge in a nonuniform manner with pilot approaches in place. This is a fairly typical "entry-level" approach to KM. Only 12.5% of respondents said their organization had knowledge management as an integral part of their business process where the value of organizational knowledge is reported to their stakeholders.

Most participating organizations in the survey have, however, prioritised knowledge management initiatives on their business agenda. To identify the level at which these organizations have planned to initiate knowledge management activities, the respondents were asked the following question:

Which according to you is the most appropriate level in your organization to initiate knowledge management?

Reflecting an understanding of KM's organisational centrality, 50% of initiators of knowledge management are preparing to initiate knowledge management at all levels, and foresee implementing knowledge management organization-wide. This indicates that at least some drivers of the concept visualize knowledge management activities to spread across the organization. However, 12.5% of respondents plan to initiate knowledge management activities at the business unit or division-level and 37.5% identify the departmental level to be the most suitable, although no pharma companies were in these latter groups.

Another set of questions identified the general issues businesses foresee to encounter within the next five years, beginning with an importance rating on previously identified KM issues. The major issues selected as being important for pharmaceutical companies included responsiveness, in terms of time-to-market, adaptability and quality with, to a lesser extent in the case of pharma, cost-productivity, alliance-networking and outsourcing all seen as relatively important. However, this was generally true across all companies survey, not just pharma, though it is a bit surprising that alliances were not seen as more important than they were. In view of the 1997 (East Asian) recession, which caused a downturn in turnover in the majority of the companies, the biggest threat identified by the respondents was the ability to reduce the time to market to realize competitive advantage. Cost reduction and improved productivity follow this issue. Quality of the product was one of the major concerns but was not identified as an immediate threat to business sustainability.

Respondents were also asked to make a selection from the list of benefits on basis of short-term and long-term gains, through the following question:

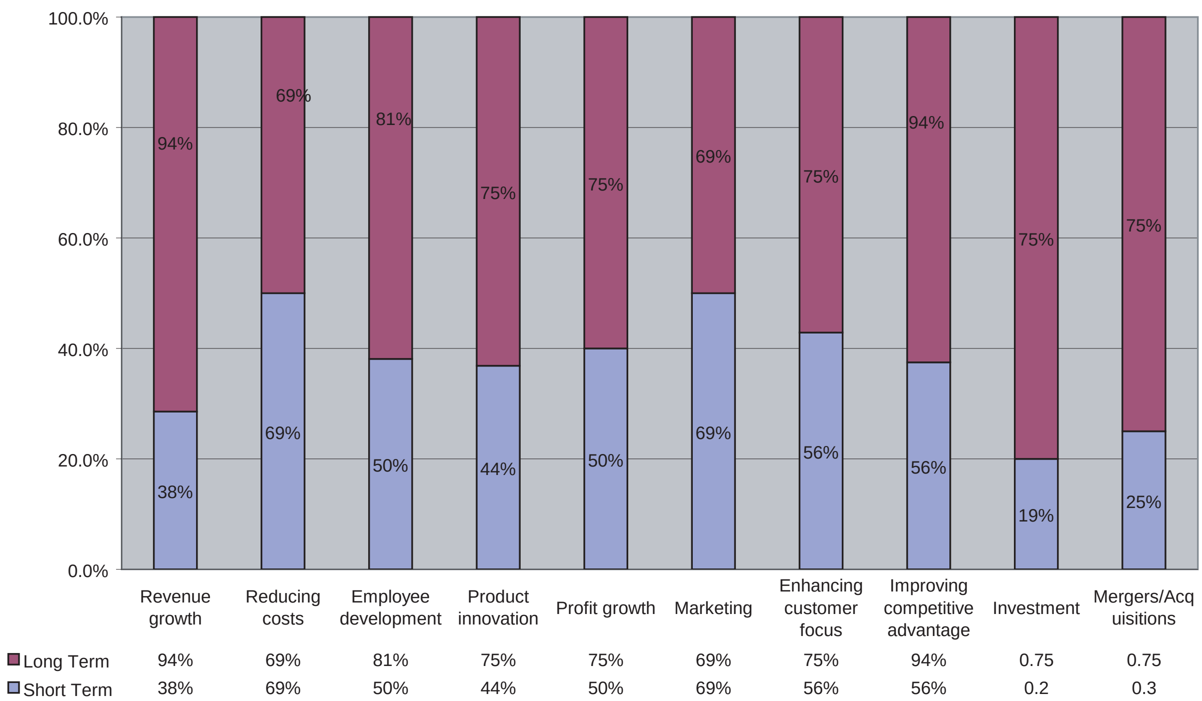
Out of the following, what are the short-term and/or long-term benefits of implementing a knowledge management strategy?

The responses indicated in Figure 3 reveal that the potential benefits on a long-term basis would be in context of improving "revenue growth" and further enhancing competitive advantage. Another potential long-term benefit identified was "employee development" and "product innovation," which are very critical parameters in measuring the success of a knowledge management implementation.

Key short-term benefits expected by respondents would be "reducing costs," "improving marketing strategies," "enhancing customer focus" and "facilitating profit growth." The results indicate that knowledge management is not focused at enhancing a particular business process, but is implemented to achieve all-round benefits for the organization. It reflects more of a traditional conception of companies than a knowledge-centric view and innovation, acquisitions and investment are all seen as of more benefit in the relatively longer term, with less than half of respondents in each case seeing primarily a short-term value. For all categories one major pharma company saw all the benefits as long-term only, at odds with a range of companies in other sectors, the majority of whom also saw short-term benefits in a number of categories.

To measure the success of a knowledge management implementation, it is important also to ascertain the potential threats. Respondents who had a knowledge management strategy in place or were planning to implement a sound knowledge management strategy were thus asked to select the most likely threats from the list provided led by the question: Of the following, what are the most likely threats towards achieving the benefits mentioned in the previous section? The results are shown in Figure 3.

Figure 3. Long-term and short-benefits of knowledge management

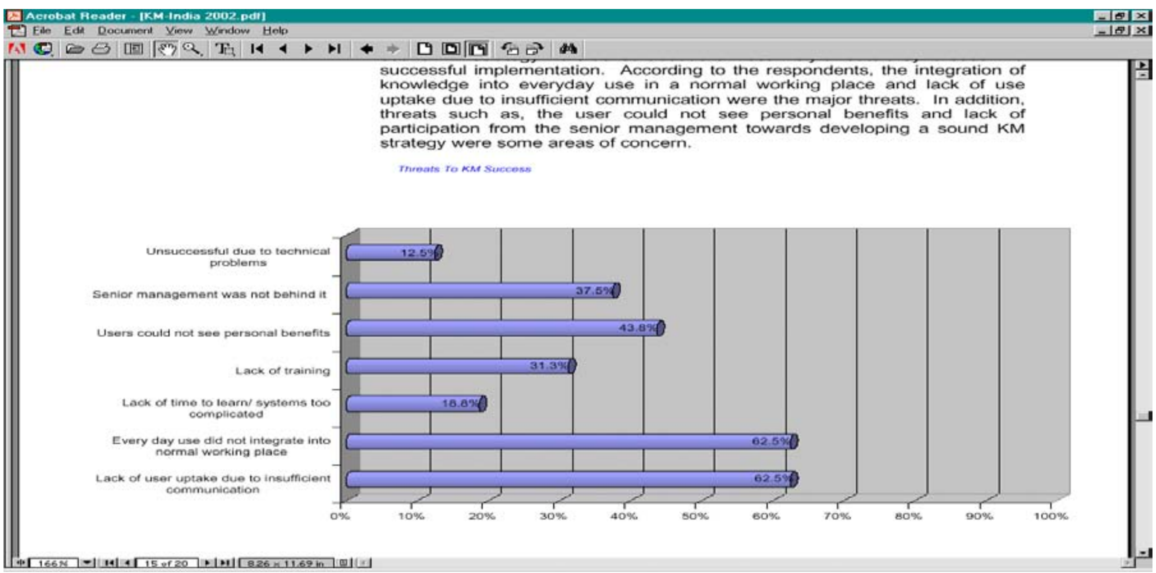


According to the respondents, as indicated in Figure 4, the integration of knowledge into everyday use in a normal work place and the lack of use or uptake due to insufficient communication were seen as the major threats. In addition, threats such as users not being able to perceive personal benefits and lack of participation from the senior management toward developing a sound knowledge management strategy were the prime areas of concern. The responses confirmed the fundamental flaw, i.e., viewing knowledge management only as a technology issue. We may assume from this that it is not the technology that is holding organizations back but a failure to initiate knowledge management into the organization's day-to-day operations and its culture. The communication issues identified as relevant barriers to KM comport with the low cooperativeness found in cultures with high power distance. Lack of senior support is also a substantial barrier for any culture formed along hierarchical authority lines.

CONCLUSIONS

In this concluding section we attempt to identify the current status and implications of knowledge management in organizations currently initiating knowledge management. Characteristics of national culture may at least in part be responsible for the anticipated and actual problems firms encounter in their knowledge management initiatives. They could also explain the focus on technology-driven approaches, as well as the failure to make knowledge management strategies an integral part of organizational life. Understanding of national and organizational culture and selecting a strategy that takes these factors into account seems a necessary prerequisite for successful knowledge management. In particular, barriers due to a prevalent cultural reluctance to share information mitigate against successful KM strategy implementations. Yet the nature of the industry environment in pharma requires effective knowledge sharing processes.

Figure 4. Threats for knowledge management



KM was primarily seen as having long-term, not short-term, benefits in pharma, yet the industry itself is having to change its model rapidly toward one based on innovation. In the survey data, in general however, there were few areas in which a particular sector (in particular pharmaceutical) was significantly divergent from norms in other sectors of Indian industry. The "knowledge management" projects within most of the respondents' organizations are just getting initiated and seem more heavily IT-oriented than HR and process-focused. It is vital to understand how indigenous organizations make an attempt to move beyond this concept and what measures they take to successfully initiate knowledge management. The big challenge, according to comments made by the senior executives who participated in this survey, will be to integrate the "pie in the sky" theories with actual use of "tools and technologies." A narrowly technical focus is likely to limit the potential for knowledge sharing unless coupled with effective human processes, and seeing knowledge as constructed through processes of social interaction among communities of practices means that issues of social networking, power and social inclusion/exclusion come to the forefront. In other cases information technology may actually undermine knowledge sharing and creation by reducing opportunities for informal contact or strengthening electronically the existing organizational walls, based on functional or geographical differentiation. Such issues may be at odds with the prevailing culture. However, although the pharma industry has several large multinational players located in India, our study is primarily concerned with the cultural capability of indigenous players to compete in knowledge intensive industries. Thus careful attention is needed to the potential impact of information technology on knowledge management for businesses in relation to existing social networks and communities within organizations.

Chapter 5.17
Goals and Benefits of Knowledge Management in Healthcare

Odysseas Hirakis
National and Kapodistrian University of Athens, Greece

Spyros Karakounos
National and Kapodistrian University of Athens, Greece

ABSTRACT

The aim of this chapter is to explain the role of knowledge management and how it can be successfully applied in the area of healthcare in order to improve health services and to increase patients' satisfaction. The first part of this chapter is about explaining the theories beyond knowledge management as "what is knowledge" and how it can be transformed and captured across people and organizations. The second part consists of the theory of knowledge management and the benefits of it in the area of healthcare in comparison with the old traditional systems. Knowledge management systems can be used to index and at the same time to spread all that information across people, libraries, and hospitals.

INTRODUCTION

During the last 10 to 15 years, knowledge management (KM) has become more popular day by day. There is a lot of interest in the concept of capturing and sharing knowledge with technology as the enabler. This requires the existence of a knowledge-sharing culture. The KM system stores historical knowledge and knowledge created during exchanges of information among people who are interested in learning. Knowledge management allows everyone to reuse the knowledge (best practice) or to create new ideas (innovation).

According to Syed Sibte Raza Abidi (2001, p. 1), "Knowledge Management (KM) in healthcare can be regarded as the confluence of formal methodologies and techniques to facilitate the creation, identification, acquisition, development, preservation, dissemination and finally the utilisation of the various facets of a healthcare enterprise's knowledge assets."

People in their everyday practice collect massive amounts of data and information that are knowledge poor, a fact that makes their decision about patients' cures more complicated. Knowledge in healthcare is deemed a high-value form of information that is necessary for healthcare professionals to act. For that matter, with the emergence of KM, the raw empirical data can be changed into empirical knowledge and provide professionals with a decision-support tool (Syed Sibte Raza Abidi, 2001).

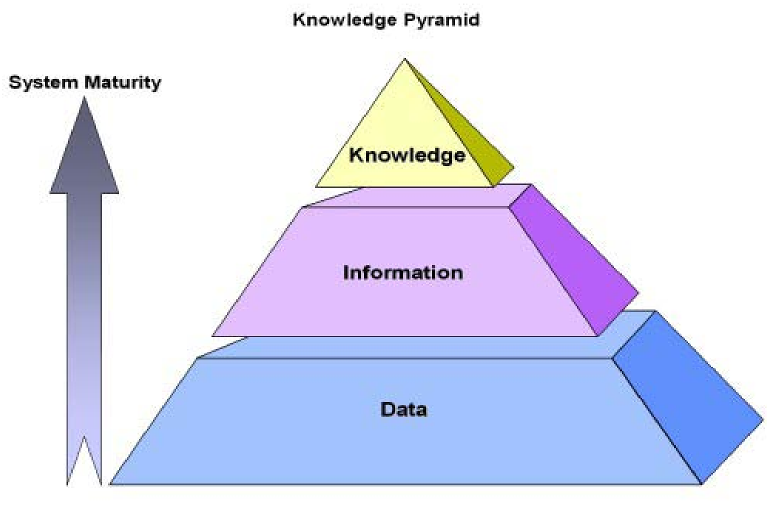
KM in healthcare presents further interest for all those who are involved in the delivery of health services. KM allows rapid access to a knowledge treasure. The KM model goes beyond the need to manage data or information overload. It satisfies the requirements for implementing best practice and supplying high-quality health services, which increase patient satisfaction. The model aims at greater efficiency, coordination, and cost reduction. It is a portfolio of knowledge that increases ealth-care professionals' effectiveness and productivity. A KM system offers them the opportunity to learn how other colleagues successfully carried out similar problems (De Lusignan, Pritchard, & Chan, 2002).

WHAT IS KNOWLEDGE?

According to ITIL People (http://www.itilpeople.com/Glossary/Glossary_k.htm), "Knowledge is part of the hierarchy made up of data, information and knowledge. Data are raw facts. Information is data with context and perspective. Knowledge is information with guidance for action based upon insight and experience."

Knowledge is very difficult to define; it is not just a simple document or something that someone told us. In order for a person to gain knowledge, there are three stages to progress through as the pyramid (see Figure 1) indicates. The actual con-

Figure 1. Knowledge pyramid (Marco, 2003)



tent in each stage becomes smaller, starting with data and finishing with knowledge.

1. Data: Documents, unorganized and unprocessed (raw material)
2. Information: Selected data ➔ Interpretation of the data (processed data)
3. Knowledge: Selected information ➔ Interpretation of the information

Example: In order to complete an academic assignment, some steps need to be taken:

1. Research at libraries and on the Internet; Collect some documents ➔ Data
2. Interpretation of that data ➔ Information
3. Interpretation and evaluation of the information ➔ Knowledge

TYPES OF KNOWLEDGE

Two types of knowledge exist in an organization.

1. Explicit ("Know that"): Something that is written down (informative texts) and can be easily understood if read, for example, technical reports and books
2. Tacit ("Know how"): Something that is written in the mind and cannot be easily expressed, for example, experience gained from a job

Knowledge management refers to the knowledge of a company as an asset, the same as land, for example (Ahmad, 2001).

TRANSFORMATION OF KNOWLEDGE

The transformation of knowledge is very important. The following explains Nonaka and Takeuchi's (1995) model of the four methods of knowledge conversion:

1. Socialization: Convert tacit knowledge into tacit knowledge; share experiences (tacit knowledge)
   Example: Two people discussing
2. Externalization: Convert tacit knowledge into explicit knowledge; write it down
   Example: Writing a report
3. Combination: Convert explicit knowledge into explicit knowledge; combine explicit knowledge
   Example: Reading two theories and from them creating a new one
4. Internalization: Convert explicit knowledge into tacit knowledge; gain experience
   Example: Learning from a book

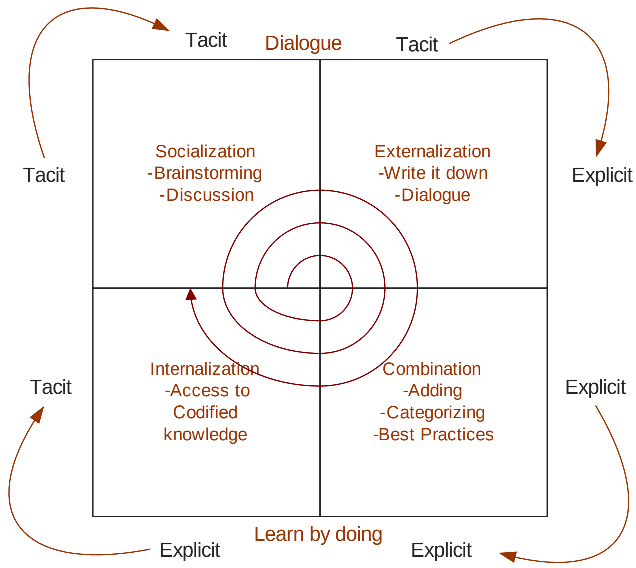
Figure 2 demonstrates the conversion of knowledge according to Nonaka and Takeuchi's model.

KNOWLEDGE MANAGEMENT

Peter Drucker first introduced the terms knowledge work and knowledge worker in the 1960s. Knowledge management as a term was coined back in the 1990s due to the fact that Japanese companies were at the top compared to other companies globally. Knowledge management is about organizing and managing the knowledge of workers.

To begin with, in order for a company to introduce knowledge management, it should first develop a culture of knowledge sharing within the organization. However, in order to develop a culture of sharing in a company, the employees need to trust each other and the company in advance. After the preparation of the ground, the IT part can take place. Workers then must take a training course on the KM software. Additionally, good management of the knowledge database is

Figure 2. Nonaka and Takeuchi's model



vital. This can be achieved by categorizing the knowledge database by subjects and dates, and by means of a search engine (Ahmad, 2003).

Imagine a library (physical) with a list of books that can be traced via computer software that indicates each bookshelf's column code and book details in order for a person to locate and borrow a book. Additionally, there are people (librarians) that make sure that the right book is in the right location. A knowledge-management system without knowledge sharing is like a virtual library that needs librarians to take care of it.

Knowledge management is completely based on a knowledge-sharing culture inside a company or between companies. People, by interacting with each other, create communities of practice. These people have common interests and aims; so, by cooperation, they develop their own kind of communication and rules.

People must share and exchange knowledge in order to find the best practice for a subject orto innovate knowledge. Once the knowledge is in the knowledge base, the knowledge analysts can begin seeking, studying, and analyzing the information in order to pull the quality knowledge. Afterward, the workers or professionals can go through the information, and pull and reuse the knowledge. This avoids the duplication of effort and dramatically reduces decision-making time. Knowledge management supports the requirement that successes and failures have to be recorded. The knowledge can then be accessed by the use of technology (Ahmad, 2003).

Knowledge management refers to knowledge as an asset that the company owns, like, for example, land and machinery. KM supports the fact that the most important resource in an organization is the people's knowledge. As a popular song says, "people have the power…"

A McKinsey survey outlined in the article "Creating a Knowledge Culture" illustrates the importance to create a need for knowledge:

Less successful companies tend to take a top-down approach: pushing knowledge to where it is needed. Successful companies, by contrast, reward employees for seeking, sharing and creating knowledge. It requires effort to develop what we call "knowledge pull"—a grassroots desire among employees to tap into their company's intellectual resources. (Knowledge Portal, http://www.knowledge-portal.com/people.htm)

KM aims at keeping knowledge up to date and correct, providing knowledge in the right location, applying knowledge of the most suitable type, and providing knowledge at the time at which it is needed.

In other words, KM allows for securing and distributing knowledge in order to assure and optimise its availability (Montani & Bellazzi, 2002).

KNOWLEDGE MANAGEMENT IN HEALTHCARE

According to the Royal College of Surgeons in Ireland (http://www.rcsi.ie), there are 10,000 different diseases and syndromes, 3,000 types of drugs, 1,100 different types of laboratory tests, and finally 400,000 articles added per annum to the biomedical literature.

Furthermore, internal medicine includes 2 million facts (Wyatt, 2003). The growth rate in biomedical literature doubles every 19 years (Wyatt, 1991).

Doctors' decisions determine three quarters of healthcare costs and depend critically on medical knowledge (Tierney, Miller, Overhage, & McDonald, 1993). Once knowledge has been captured in some form such as a guideline, it can be managed (Wyatt, 2001).

Knowledge in medicine arrives from reports, libraries, experience, guidelines, laboratory experiments, protocols, practice, group meetings, and so forth. By adding interaction between these forces, then the outcome can be superior.

Because of the above reasons, the use of knowledge management is critical in the healthcare sector. By having a sharing culture with a common aim—the best possible patient care—and by using an information system, not for data warehousing but instead for interpretation and annotation to create knowledge, then the healthcare sector can be dramatically improved.

Healthcare organizations need to improve the quality of patients' treatment. This includes a decision-support system (best practice) and the reduction of errors in patients' diagnoses and treatment.

Two kinds of healthcare information exist: information about patients and information about cases. In order for professionals to be accurate, both kinds of information are needed. By combining these two kinds of information, professionals are able to come up with the right solution (UCL, http://www.ucl.ac.uk/kmc/resources/top_tips.html).

By using a successful knowledge-management system tool, professionals are able to make conclusions by interpreting and understanding patients' data and by carrying out a successful diagnosis in order for the right actions to be applied.

Furthermore, by using a KM system, professionals are able to access the right information and advice at the right time. However, if there is a difference between a theory in the knowledge base and the related practice, professionals can add comments for later improvement.

By implementing knowledge management, professionals can have access to best practices, and if they are able to understand the importance of a knowledge-sharing culture, then there is also some space for development and innovation. Furthermore, a KM system can improve the decision-making time and so also reduce the costs of a hospital (as a famous slogan says, "time is money").

Professionals can explore and learn faster by going through the knowledge database and studying the cases of other patients and the specific treatments that were applied to them. Furthermore, professionals can apply to evidence-based clinical guidelines.

Besides this, each hospital may be positioned in different places globally, which makes it difficult for a person to access another hospital's knowledge. With KM, research (healthcare) departments that are carrying out experiments can provide other hospitals with knowledge by using a KM system.

Imagine that a conference on a new infection is to take place, but not all doctors across the country are able to attend. By using a knowledge-management system, the doctors that were absent could log in and see a video or a tape on a specific subject and contribute later to that problem by using the KM system.

Moreover, other problems based on the management of the hospital's staff and strategies could be discussed between managers or doctors in order to improve the quality of services offered. Afterward, the amount of information could be written down (explicit) for future reuse by other hospitals.

According to Wyatt (2001, p. 8):

The future of knowledge management in health is bright. We already have adequate technology in the shape of the Internet and a good intellectual framework in evidence-based health, which are being used to improve each other. We also have many health librarians who are knowledge management professionals.

The importance of knowledge management can also be justified by presenting Table 1, which illustrates the differences between the old and the new healthcare elements.

Example: Alerts or recommendations described in literature (McDonald, 1976)

If treatment includes cardiac glycoside
and last premature ventricular systoles/minute > 2
then "Consider cardiac glycoside as cause of arrhythmia"

Result: When data matches events, a recommendation is printed out for the doctor.

Impact: The frequency with which doctors responded to target events doubled from 22% to 51%.

Table 1. Old and new health-care paradigms (Olson, 2004)

Old Healthcare Paradigm	New Healthcare Paradigm
• HIS System • Operations-Oriented • Hierarchical Database • Programmer-Centric • Silo-Based • Character-Based • Fragmented Decision Support	• Enterprise-Wide Knowledge Management System • Analysis-Oriented • Relational Database • End user-Centric • Process-Based • GUI/WEB-Based • Holistic Decision Support

GOALS AND BENEFITS OF KNOWLEDGE MANAGEMENT IN HEALTHCARE

- Support in decision making about patients, interference, and the evaluation of research
- Enhanced healthcare system by improving communication between professionals in the decision-making process
- Improved patient healthcare
- Improved quality, access time, and portability of healthcare
- Increased communication between professionals and hospitals
- Improved cost management by reducing the time of patients' hospital treatment
- Reduced time of decision making by using a knowledge database and consequently the reduction of the time of patients' residence in hospitals
- Reduced error rate (defects) in decision making
- Reduced inconvenience
- Increased patient satisfaction

CONCLUSION

Without doubt, the KM model constitutes a hopeful innovation in the health sector with more possibilities and uses. It is about time for a qualitative upgrade of health-services provision to take place. It is obvious that the direct access o all healthcare professionals in KM will minimise medical errors, decrease the medium duration of hospitalisation, reduce the cost of hospitalisation, increase the patient's satisfaction, and have a positive contribution to the relation of cost and effectiveness.

People have to bear in mind that the health-services sector has a specific particularity: Patients are human beings with particular needs, special characters, and different interactions in therapeutic interventions. KM is a tool that helps healthcare professionals to implement the best practices while considering the special needs of each patient, and sometimes to innovate. IT in knowledge management is just the enabler; the idea is for people to start sharing experiences and ideas with a common aim. Finally, healthcare remains a human science with a strong scientific basis; its consultations have such high levels of complexity that they probably can never be completely computerised and automated.

Chapter 5.18
Effects of Knowledge Management Implementations in Hospitals:
An Exploratory Study in Taiwan

ABSTRACT

From the knowledge management point of view, the fundamental mission of hospital management is the delivery of quality medical services, utilizing highly specialized knowledge to solve healthcare problems within various resource constraints. Similar to other knowledge-intensive industries operating in highly challenging business environments, hospitals of all sizes must view the creation, organization, distribution, and application of knowledge as a critical aspect of their management activities. Knowledge management represents a viable strategy as hospitals strive simultaneously to provide quality medical services, improve operational efficiency, and conform to the government's documentation and reporting regulations. This study examines the correlation as well as the causal relationships among knowledge characteristics, knowledge acquisition strategy, implementation measures, and performance of knowledge management implementations in the context of hospital management. Using primary data collected in Taiwan, our analyses show that the characteristics of knowledge affect the ways in which knowledge management is implemented,

and the implementation measures, in turn, have a significant impact on the results of knowledge management implementations.

INTRODUCTION

Hospitals of all sizes currently are faced with a multitude of management pressures, including industry competition, customer satisfaction, shortage of specialized personnel, compliance with government regulations, cost reduction, and the ever-increasing demand for more effective cures (Camilleri & O'Callaghan, 1998; Porter & Teisberg, 2004). In coping with these challenges, hospitals actively are experimenting with various management initiatives and programs, such as total quality management and knowledge management, with varying performance results. Emerging as a new multidisciplinary management field, knowledge management (KM) promises to enhance competitive advantage in the highly dynamic knowledge economy by treating valuable and scarce knowledge as a critical organizational asset and by managing it in a systematic manner (Sharkie, 2003; Ulrich & Smallwood, 2004). From the knowledge management point of view, many hospital services involve knowledge-intensive processes that are carried out to solve patient health-related problems. Because of the knowledge-intensive nature of healthcare services, much of a hospital's success depends on effective and efficient creation, organization, validation, dissemination, and application of its highly specialized medical knowledge.

Traditional knowledge management mechanisms in most hospitals typically include morning meetings, apprenticeships, internships, professional seminars, research partnerships with outside research institutions, and other forms of human interaction. Sophisticated information technologies also are being deployed in some hospitals in order to manage medical images and to capture scarce expertise (e.g., medical expert systems) (Davenport & Glaser, 2002). The addition of Internet technologies to the portfolio of information processing technologies offers a new set of powerful tools in order for hospitals to implement knowledge management programs.

In light of the strategic value of professional knowledge, hospitals increasingly recognize a need to manage more actively their intellectual capitals. The field of knowledge management provides the frameworks and techniques that are required to transform a hospital into a learning organization (Adams & Lamont, 2003; Awad & Ghaziri, 2004; Becera-Fernandes, Gonzales & Sabherwal, 2004; Gupta & Govindarajan, 2000; Hansen et al., 1999; Leonard-Barton, 1995). These frameworks and techniques emerge from the inquiries conducted and the experiences acquired in a variety of contexts, including manufacturing (Kim, Hwang & Suh, 2003), customer relationship management (Gebert, Geib, Kolbe & Brenner, 2003), consulting (Sarvary, 1999), retail chain (Tsai, Yu & Lee, 2005), and health care (Powers, 2004). Much of the literature, however, has been either case studies or conceptual discussions. Empirical studies based on the primary data collected in the field, however, are important for advancing the field of knowledge management toward maturity.

Motivated by the dearth of empirical inquiries in knowledge management that address issues in hospital management, we conduct this study to identify the relationship between some factors that play a significant role in successful knowledge management implementations in the healthcare environment. Our purpose is to understand how knowledge management is practiced and the result of implementation in this knowledge-intensive sector. We also seek to contribute to hospital management by offering empirical evidence for the value of knowledge management in coping with the multi-faceted management challenges faced by today's hospitals.

The remainder of the article is structured as follows. The next section describes an interview process conducted with hospital executives and medical doctors for the purpose of selecting the constructs for our research model. We review some of the existing knowledge management literature that relates to our research constructs. We also discuss our research hypotheses that are formulated as a result of field interviews and literature reviews. The section on research methodology describes the research framework, data collection approaches, and data analysis techniques. This is followed by the results of data analysis. The last section discusses some implications of the research findings for hospital knowledge management in particular and knowledge management in general. Suggestions for future research in knowledge management also are presented.

Identification of Research Constructs

Knowledge management increasingly has received attention as an important multidisciplinary field in both the academic and corporate arenas over the past years (Adams & Lamont, 2003; Becera-Fernandez et al., 2004; Davenport, De Long & Beers, 1998; Gloet & Berrell, 2003; Sharkie, 2003). A common denominator among knowledge management researchers is the belief that in the knowledge economy, which is characterized by rapid change and fierce competition, knowledge should be viewed as a valuable and manageable resource, just like tangible assets such as capital and factory facility (Davenport & Prusak, 2000; Leonard-Barton, 1995; Liebowitz & Wilcox, 1997; Soo, Devinney, Midgley & Deering, 2002). Various conceptual frameworks for effective implementation of knowledge management programs or projects have been proposed in order to facilitate knowledge sharing and to stimulate continuous innovation both within and across organizational boundaries (Awad & Ghaziri, 2004; Davenport & Glaser, 2002; Lee & Hong, 2002; Soo et al., 2002; Tiwana, 2000; Wang, 2002; Wiig, 1994). Due to the knowledge-intensive nature of healthcare delivery processes, there has been a call for implementation of knowledge management in the context of hospital management in the pursuit of sustainable competitive advantage (Davenport & Glaser, 2002; Powers, 2004; Van Beveren, 2003).

In order to better understand the unique features of hospital management as related to knowledge management, we conducted hour-long interviews with two hospital executives and three medical doctors in a regional medical center. A structured questionnaire was used in the interviews, supplemented by open-ended questions, to help us to identify the research constructs for our inquiry. Several points stood out to provide a direction for the study. First of all, medical services (esp. clinical care) are very context-sensitive. A specific clinical care problem may be attributed to the patient's personal condition, disease specifics, disease history, family background, treatment history, medication history, and so forth. Effective treatment collectively must consider a wide variety of factors. The complexity of clinical care knowledge, in other words, often comes from a great number of factors and the subtle relationships among these factors that need to be considered in the treatment decision. The ability to distinguish between the relevant and irrelevant factors and to identify the relationships among these factors is a core competence of a true expert. Also, although theoretical knowledge distributed by such published avenues as books and articles is valuable in developing a medical expertise, ultimately, it is the practical experience in dealing with specific cases that truly builds up a medical doctor's professional expertise and the hospital's knowledge repository. In addition, most medical knowledge accumulated over the years is practical knowledge that is not preserved in any printed media. These findings lead to the selection of knowledge characteristics as a research construct.

We also found from the field interviews that specific implementation measures, such as the availability of information infrastructure that facilitates KM activities, incentive programs, and other people-related factors, play a key role in the success (or failure) of the KM implementation program. Information technologies are used to digitize and to store knowledge content. Once kept in the systems, valuable knowledge content easily can be disseminated, integrated, and deployed. Each specialization unit in a hospital usually represents an organizational silo separated from other specialization units. A well-designed information system enables the sharing of related information and knowledge by baking the system capabilities in the daily business processes (Davenport & Glaser, 2002). Furthermore, the interviews identified two preferred indicators for assessing the performance of the KM implementation: improvement of internal process and overall organizational performance. Two research constructs—KM implementation measures and KM performance—are identified as a result. Finally, the research construct Knowledge Acquisition Strategy is included in the research model in order to evaluate the strategic role of knowledge source in hospital management. Based on the findings of our preliminary inquiry, the scope of this study is limited to four research constructs: the characteristics of medical knowledge, the strategy used to acquire valuable knowledge, how KM concepts are implemented, and the result of KM implementations. The following section reviews the literature relating to these four constructs.

Knowledge Characteristics

As a service-oriented and knowledge-intensive organization, a hospital typically deals with knowledge in a variety of categories: customer (patient) knowledge, service (treatment) knowledge, process knowledge, and account management, to name just a few. In generic terms, knowledge can be characterized in many ways: shallow vs. deep, procedural vs. declarative, explicit vs. tacit, domain-independent vs. domain-specific, common sense vs. professional, static vs. dynamic, and proprietary vs. nonproprietary, for example (Awad & Ghaziri, 2004; Davenport & Glaser, 2002; Gloet & Berrell, 2003; Gupta & Govindarajan, 2000; Howells, 1996; Nonaka & Takeuchi, 1995; Polanyi, 1996; Ulrich & Smallwood, 2004). A recent list of knowledge attributes proposed by Holsapple (2003) consists of 23 items. According to the healthcare practitioners that we interviewed, for the medical and healthcare service industry, four knowledge characteristics are deemed most relevant: knowledge mode (explicit vs. implicit), knowledge complexity, strength knowledge appropriability (ease of replication and transferring), and knowledge volatility (dynamic vs. static). These four characteristics were identified using a rating questions list, augmented by open-ended elaborative discussions.

Explicit knowledge is represented in the form of recorded products, such as printed documents, formulas, software, system manuals, and hardware equipment, while implicit knowledge primarily is undocumented and retained as memory (Howells, 1996; Nonaka & Takeuchi, 1995; Polanyi, 1996; Zack, 1999). Hospitals vary in their perceptions of and relative emphasis on the explicitness—implicitness continuum of their valuable healthcare knowledge. Different perceptions and preferences may lead to different strategies being adopted for knowledge acquisition and other important aspects of knowledge management implementation measures. Explicit knowledge is more amenable to technologically oriented solutions, such as a document base and a knowledge map, whereas implicit knowledge is handled primarily through social networks.

Complex knowledge is difficult for organizations to acquire. Once acquired, however, it can become a valuable source of competitive advantage (Holsapple, 2003; Teece, 1998). Knowledge complexity is determined by the abstract nature of knowledge, the number of knowledge components, and the interaction of these components (Soo et al, 2002). In the healthcare domain, both the great amount and the intricate interactive effect of professional medical knowledge pose a substantial challenge for hospitals that are striving to provide quality healthcare services.

Knowledge that is nonproprietary in nature easily can be transferred across organizational boundaries. The proprietary nature of knowledge usually is determined by the extent to which the knowledge is tightly tied to the specific organization (Teece, 2003; Soo et al., 2002). From the system development point of view, proprietary knowledge usually is domain-specific. Both domain-specific and domain-independent knowledge are important in solving complex problems. However, past successes of expert system technology applications demonstrate that domain-specific knowledge usually contributes more than domain-independent knowledge in solving difficult problems. This notion of organizational specificity associated with knowledge management is illustrated well by Gupta and Govindarajan (2000) in a case study of the Nucor Steel Corporation. The consistently superior performance of Nucor Steel demonstrates that, once knowledge creation and sharing are embedded in the management practice and the daily operational routines, the resultant proprietary knowledge can establish a solid foundation for a truly sustainable competitive advantage (Adams & Lamont, 2003). The value of proprietary knowledge is obvious in hospital management, especially in dealing with challenging healthcare problems.

Currency of knowledge can be an important issue at times when new knowledge renders old knowledge useless. In these cases, knowledge must be subject to frequent updating in order to stay valuable. The optimal updating frequency is determined by the dynamic (or static) nature of the knowledge. The issue of knowledge updating has been addressed in expert systems development (Liebowitz & Wilcox, 1997). In fact, one of the criteria in the selection of knowledge-based expert system application domains is that the domain knowledge must be relatively static. The complexity involved in knowledge updating and validation poses a significant challenge for keeping a knowledge base current and for having the system accessible at the same time. In the broader context of medical care service delivery, updating of the knowledge repository may affect the strategy for knowledge acquisition as well as knowledge management implementation measures.

Knowledge Strategy

A knowledge strategy, as defined by Zack (1999), "describes the overall approach an organization intends to take to align its knowledge resources and capabilities to the intellectual requirements of its strategy" (p. 135). Zack's (1999) knowledge strategy framework consists of two dimensions: exploitation vs. exploration and internal vs. external. While the exploitation vs. exploration dimension distinguishes a creator from a user of knowledge, the internal vs. external dimension describes the organization's primary sources of knowledge. Internal knowledge is characterized as being "resident within people's heads; embedded in behaviors, procedures, software and equipment; recorded in various documents; or stored in databases and online repositories" (Zack, 1999, p. 138). External sources of knowledge include publications, university alliances, government agencies, professional associations, personal relations, consultants, vendors, knowledge brokers, and interorganizational alliances. Using Nucor Steel's experience, Gupta and Govindarajan (2000) argued that internally created knowledge tended to contribute more to an organization's competitive advantage than did external approaches.

Another useful KM strategy framework is represented by a codification vs. personalization dichotomy. According to Hansen, et al. (1999), the codification-oriented KM strategy is suitable for explicit, recordable, formal, and replicable knowledge, and the personalization-oriented strategy works better for implicit knowledge. Whereas information technology plays a central role within the codification strategy, it primarily provides tool support for the personalization strategy. The choice of primary knowledge acquisition strategy usually is determined by a variety of factors, among which is the characteristics of knowledge (Awad, 2004; Davenport & Prusak, 2000; Tiwana, 2000; Wiig, 1994).

Knowledge Management Implementation Measures

Knowledge management generally is viewed as a collection of management practices consisting of knowledge accumulation, knowledge organization, knowledge dissemination, and knowledge application (Awad & Ghaziri, 2004; Davenport & Prusak, 2000). The implementation of organizational KM projects typically involves technical as well as non-technical measures. A flexible and efficient information technology infrastructure is an essential requirement. The subsequent distribution and application of the organizational knowledge depends on digital representation, computerized storage, dissemination of the knowledge content, and the application context. Additionally, properly designed incentive programs must be in place in order to discourage knowledge hoarding and to promote knowledge sharing (Davenport & Prusak, 2000; Soo et al., 2002). Sufficient resources must be committed to encourage active learning and perpetual updating of the professional staff's knowledge base.

Knowledge Management Performance Measurement Issues

Measuring the results of KM projects is a challenging task. The subjective nature of the benefit measurement and the lengthy lead time required in order for the benefit to become quantitatively measurable usually are cited as the main sources of difficulty (Abeysekera, 2003; Stone & Warsono, 2003). Although the organizational benefit resulting from KM project implementation eventually must be expressible in financial terms, a significant portion of the benefit is qualitative and only can be measured subjectively. Most literature, therefore, suggests a portfolio approach to measuring the result of KM implementation, such as innovative capability, which would include both financial and non-financial data (Chourides, Longbottom & Murphy, 2002; Darroch, 2003; Soo et al., 2002). Furthermore, it is recognized increasingly that in order for KM to achieve its greatest success, KM functions must be integrated tightly with major business processes. For example, Davenport and Glaser (2002) indicate that, based on their experience at a major medical center in Boston, medication knowledge must be embedded into a doctor's prescription writing process in order to make knowledge application a natural part of daily work practice. The tight integration of knowledge management process and other business processes contributes at least partially to a straightforward measurement of the result of KM implementation (Darroch, 2003).

The input from the practitioners also suggests the following relationships to be examined in the study:

1. The primary knowledge acquisition strategy is affected significantly by knowledge characteristics (knowledge characteristics → knowledge acquisition strategy).
   Rationale: Knowledge either is created from within the organization or collected from external sources. Each knowledge acquisition strategy has its pros and cons, depending on the nature of business, the available resource, and other factors. Knowledge that is created internally tends to fit the organizational needs better and to and contributes more to the competitiveness, for example. Although both internal and external sources can be used, an organization usually has a primary knowledge acquisition strategy regarding how to build up its knowledge stock. Everything else being equal, the perceived

knowledge characteristics may determine the primary knowledge acquisition strategy that is adopted by the organization.

2. Knowledge management implementation measures are affected significantly by knowledge characteristics (knowledge characteristics → KM implementation measures).

   Rationale: When valuable knowledge is perceived to be primarily tacit, it is less likely that a significant amount of resource will be invested in building sophisticated information systems to support knowledge management activities. Rather, most of the KM implementation measures will be people-oriented. Further, in an effort to cope with knowledge complexity and volatility and to encourage the development of proprietary knowledge, an organization may pay more attention to its incentive program, expertise development, and human resource planning. Therefore, it is reasonable to assume that the way a hospital chooses to implement KM programs is influenced significantly by its perception of knowledge characteristics.

3. Knowledge implementation measures are affected significantly by the primary knowledge acquisition strategy (primary knowledge acquisition strategy → KM implementation measures).

   Rationale: Creating knowledge internally often requires knowledge workers to share knowledge with the rest of the organization. Knowledge sharing usually is not a natural component of organizational culture in most Taiwanese hospitals, where high work pressure and departmental silos tend to encourage knowledge hoarding. In order to encourage internal creation of knowledge through knowledge sharing, hospitals must implement a portfolio of facilitating measures, such as incentive programs, expertise development, human resource planning, and technological infrastructure. Therefore, we postulate that KM implementation measures are affected by the primary knowledge acquisition strategy.

4. KM performance is affected significantly by the primary knowledge acquisition strategy (primary knowledge acquisition strategy → KM implementation performance).

5. KM performance is affected significantly by KM implementation measures (KM implementation measures → KM performance).

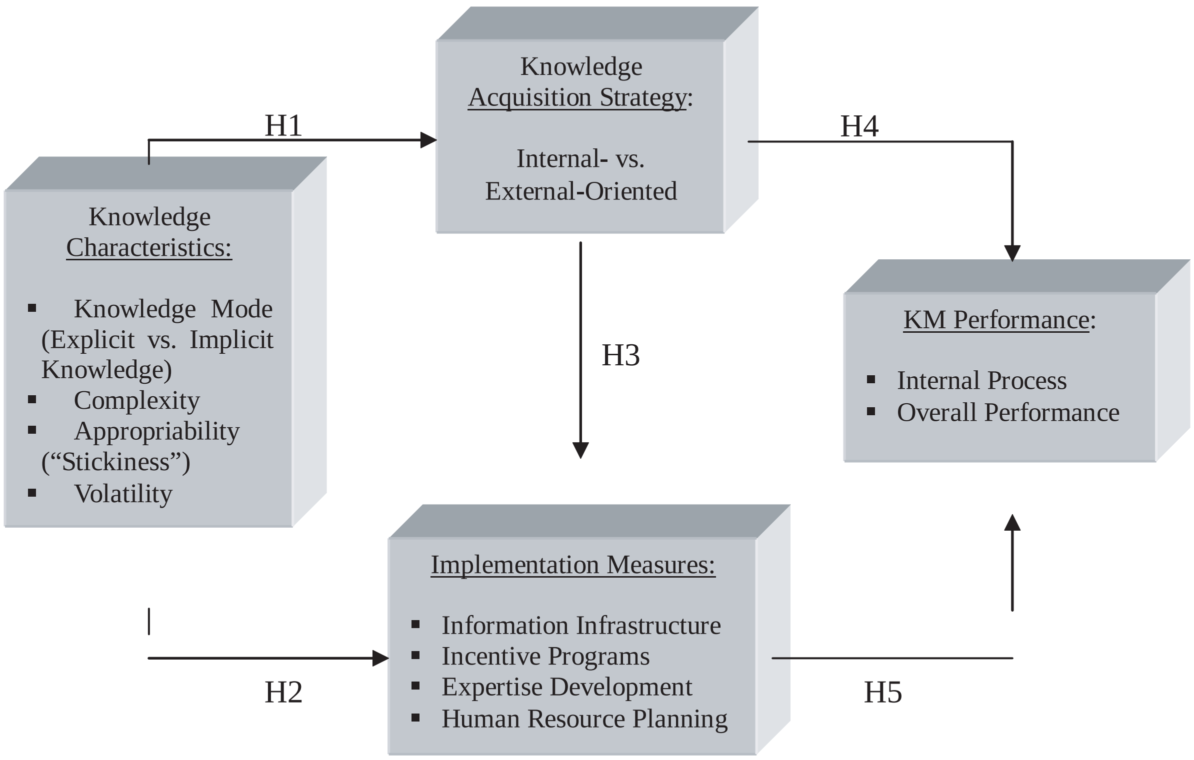
   Rationale: O'Dell, Elliott, and Hubert (2003) identified three general categories of value propositions for KM program implementation—customer intimacy, product-to-market excellence, and operational excellence—as a result of APQC's first benchmarking study on best practices in KM. Operational excellence is the most relevant to the context of hospital management. The value proposition defines the goal for KM implementation. Since the degree to which the goal is achieved can be affected significantly by the approach (strategy) and the specific actions (implementation measures) taken to pursue the goal, we set up these two hypotheses to validate our presumptions.

RESEARCH DESIGN

Research Framework, Variables, and Hypotheses

For the purpose of this research, KM was defined as a management function responsible for the acquisition, organization, evaluation, sharing, distribution, and application of both tacit and explicit knowledge for an organization. In order to gather data to analyze how KM was practiced in Taiwanese hospitals, we postulated that the hospital management professionals' perceptions of knowledge characteristics would affect the primary strategy adopted to acquire knowledge and also would affect the hospitals' KM imple-

Figure 1. Research framework



mentation measures. We further assumed that these latter two sets of variables, in turn, would affect the result of KM implementation. These hypothesized relationships between the research variables were derived from the result of literature and our field interviews with healthcare professionals in Taiwanese hospitals. The diagrammatic depiction of our research model is shown in Figure 1. The five research hypotheses established to validate our presumption also are indicated in the diagram.

Operational Definition of Research Variables

The characteristics of knowledge were represented by four important dimensions of medical and hospital management knowledge that we identified in our preliminary interview with medical professionals: knowledge mode (explicit vs. tacit nature of knowledge), complexity, strength of knowledge appropriability, and knowledge volatility.

The primary strategy adopted to acquire knowledge in this study was dichotomized into internally oriented acquisition and externally oriented acquisition. Internal sources included apprenticeships, intranet, internal documentation, morning meetings, internal medical databases, and department meetings. External sources included collaboration with universities, external consultants, internships in other hospitals, seminars, and professional conferences.

The knowledge management implementation measures were represented by activities in four areas: information infrastructure, incentive programs for knowledge sharing, expertise development, and human resource planning. The first three items corresponded to three basic entities involved in knowledge management programs: people (incentive programs), knowledge (expertise development), and technological tools (information infrastructure). The fourth item (human resource planning) corresponded to both people and knowledge.

Two categories of variables were used to represent the performance measure of knowledge management implementation in hospitals: internal process improvement and overall organizational performance enhancement. Internal process improvements consisted of communications and efficiency improvement measures, such as problem-solving time, employee participation, decision-making cycle time, and employee interaction. Overall organizational performance measures covered such items as service quality, customer focus, absenteeism, and customer (patient) satisfaction. With these definitions of the research variables, the research hypotheses were formulated as follows:

Hypothesis 1 (H1): The primary knowledge acquisition strategy is affected significantly by knowledge characteristics.

Hypothesis 2 (H2): KM implementation measures are affected significantly by knowledge characteristics.

Hypothesis 3 (H3): KM implementation measures are affected significantly by the primary strategy adopted for knowledge acquisition.

Hypothesis 4 (H4): KM implementation performance is affected significantly by the primary knowledge acquisition strategy.

Hypothesis 5 (H5): KM implementation measures affected significantly KM performance.

Questionnaire Design and Data Collection

All research variables except knowledge acquisition strategy were represented by multiple questions using five-point Likert scales, with 1 indicating very poor or highly disagree and 5 indicating very good or highly agree. A checklist was devised for knowledge acquisition strategies. A questionnaire was sent to 20 head physicians in four medical centers. This first version of the questionnaire was tested using results from the 12 respondents. Based on feedback from the pilot test, the questionnaire was revised by removing the questions with low reliability coefficients and by modifying the ones lacking semantic clarity. The revised version consisted of 44 Likert scale questions. There were 15 questions for knowledge characteristics, 18 questions for KM implementation measures, and 11 questions for performance measures. A copy of the questionnaire was mailed to the president of each of the 126 hospitals on the list that was compiled by the Department of Health of Taiwan. Hospital presidents were targeted on the assumption that they were familiar with the issues under study.

Due to the exploratory and empirical nature of the study, the questionnaire was limited in the criterion validity and the construct validity. Both the content validity and the discriminant validity were assumed to be proper, since the questions were based on the literature and the input from the practicing professionals. The reliability measures, as represented by Cronbach, if all research variables are above 0.70, an indication of acceptable reliability (Nunnally, 1978). Table 1 summarizes the reliability measures of all research variables. Note that two questions were removed from the original set of 46 questions as a result of this analysis.

Table 1. Reliability of research variables

Variables	Sub-dimensions	Question Items	Cronbach α
Knowledge Characteristics	Explicitness	1, 2, 3, 4	0.8239
	Complexity	5, 6, 7, 8	0.7605
	Appropriability	9, 10, 11, 12*	0.7187
	Volatility	13, 14, 15, 16	0.7905
Implementation Measures	Information Infrastructure	17, 18,19, 20, 21	0.8827
	Incentive Program	22, 23, 24, 25	0.8191
	Expertise Development	26, 27, 28, 29, 30*, 31	0.8063
	Human Resource Planning	32, 33, 34, 35	0.7674
Performance Measures	Internal Process	36, 37, 38, 39, 40, 41	0.9115
	Overall Preformance	42, 43, 44, 45, 46	0.8374

*: *Questions are subsequently removed due to insufficient reliability measures.*

Data Analysis Method

In order to test the previous hypotheses, several statistical analysis techniques were employed to analyze the data. In particular, t-test was conducted to evaluate the effect of knowledge characteristics on the primary acquisition strategy and the effect of the knowledge acquisition strategy on the KM implementation measures. Canonical correlation analysis was conducted to determine the correlation relationship between knowledge characteristics and implementation measures, both of which are multiple variables. Finally, stepwise regression analysis was used to determine the impact of the KM implementation measures on both of the performance measures.

RESEARCH FINDINGS

The questionnaire was mailed to 126 hospitals in Taiwan, from which 50 questionnaires were returned. The questionnaire was addressed to the person who was most familiar with knowledge management practices in the hospital. Three questionnaires were removed due to incomplete answers. The remaining 47 accounted for an effective response rate of 37.3%. Ten questionnaires were filled out by hospital presidents, seven by vice presidents, one by a physician, and 29 by hospital management staff. The Kolmogorov-Smirnov statistics for knowledge characteristics, implementation measures, and performance measures all exhibited normal distribution at the 0.001 significance level.

Hypothesis 1 stated that the primary knowledge acquisition strategy is affected significantly by knowledge characteristics. The frequency distribution of knowledge acquisition strategies summarized in Table 2 showed that the most common internal source of knowledge was morning meetings, and the most widely used external knowledge source was outside meetings. Table 3 showed the means and standard deviations of each of the four dimensions of knowledge characteristics. The measures of knowledge characteristics were dichotomized, using averages as the thresholds, into two distinct levels: high and low. A t-test was performed to determine the correlation relationship between knowledge acquisition

Table 2. Distribution of primary knowledge acquisition strategy

Types of KA Strategy		Freq.		Freq. Total	
Internal-Oriented	Manual and Instruction Management	1	2.1	20	42.6
	Morning Meeting	12	25.5

Knowledge Characteristics	μ	σ
Knowledge Mode	3.7872	0.5874
Complexity	2.9043	0.4056
Appropriability	3.4752	0.5462
Volatility	3.0691	0.6567

strategy and knowledge characteristics. Table 4 shows that the adoption of internal-oriented strategy was affected significantly by the level of knowledge explicitness (t = 1.152, p-value = 0.012), and the use of external-oriented knowledge was affected significantly by knowledge complexity (t = 1.224, p-value = 0.000). In other words, the internal-oriented strategy was used more to acquire knowledge with high explicit levels, whereas the external-oriented strategy was used more for knowledge with high complexity levels. These were indications that, in general, hospitals in Taiwan tended to rely on external sources to update and upgrade their knowledge bases. The lack of resources and the competitive pressure from the environment were keeping most of them from actively investing in internal research and development in order to create valuable knowledge from within the organization. With a few exceptions (e.g., Chang-Hua Christian Hospital), only the medical centers that are affiliated with research universities had the capabilities and resources with

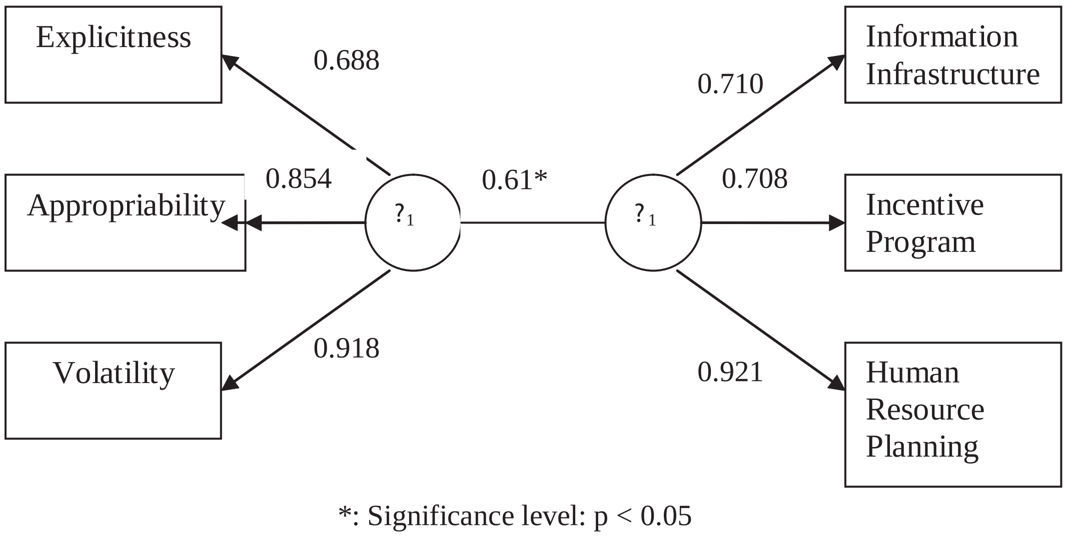
which to carry out knowledge creation activities in a systematic manner.

Hypothesis 2 states that KM implementation measures are affected significantly by knowledge characteristics. Since both knowledge characteristics and implementation measures consist of four variables, canonical correlation analysis was employed in order to determine the correlation relationship. As summarized in Table 5 and as graphically presented in Figure 2, the result of canonical analysis identified that the linear composition of three knowledge characteristics—knowledge explicitness, appropriability, and volatility—were correlated significantly with the linear composition of three implementation measures: information infrastructure, incentive program, and human resource planning. The correlation coefficient (ρ) was 0.61 at the significance level 0.05.

Hypothesis 3 states that KM implementation measures are affected significantly by the primary strategy adopted for knowledge acquisition. The result of the t-test indicated that two implementation measures were affected significantly by the knowledge acquisition strategies. Internal-oriented strategy adopters scored higher in informa-

Figure 2. Path diagram of canonical correlation analysis between knowledge characteristics and implementation measures



tion infrastructure than external-oriented strategy adopters, whereas external-oriented adopters scored higher in incentive measures.

Hypothesis 4 states that the performance of KM implementation is affected significantly by the primary knowledge acquisition strategy. The result of the t-test (Table 6) showed that different knowledge acquisition strategies did not cause significant differences in either dimension (internal process and overall organizational performance) of the performance of KM implementation. Hypothesis 4 was rejected. Since internally created knowledge usually is considered more likely to contribute to an organization's competitive advantage (Gupta & Govindarajan, 2000), this finding indicated that the hospitals in Taiwan still lacked a proper understanding of the strategic value of locally created knowledge.

Hypothesis 5 states that knowledge management performance is affected significantly by implementation measures. Three stepwise regression analyses were conducted to test this hypothesis. The first test was a simple regression analysis, in which both the performance measures and the implementation measures were treated as single, composite variables. The second test treated the performance measures as one variable and the four dimensions of the implementation measures as four variables. The third test treated each of the two dimensions of the performance measures as a dependent variable. The first test resulted in a regression equation:

KM Performance = 1.086 + 0.684 * KM Implementation Measures
F-value = 15.517, ($p < 0.1$ for the intercept and $p < 0.001$ for the regression coefficient), Adjusted $R^2 = 0.24$

Table 6. Effect of knowledge acquisition strategy on knowledge management performance

KM Performance	KA Strategy (μ)		t-value	p-value
	Internal-Oriented	External-Oriented		
Internal Process	3.2583	3.5123	-1.028	0.310
Overall Organizational Performance	3.4500	3.5852	-0.645	0.522

Table 7. Impact of implementation measures on KM performance (stepwise regression analysis)

Implementation Measures	Standardized Regression Coefficient	Correlation Coefficient (R)	R^2	F-value	p-value
Human Resource Planning	0.506	0.638	0.407	30.851	0.000*
Incentive Program	0.305	0.695	0.482	20.510	0.000*
Standardize Regression Equation: KM Performance = 0.506 x Human Resource Planning + 0.305 x Incentive Program					

**: Level of Significance $p < 0.001$*

Table 8. Impact of implementation measures on KM performance

	Internal Process		Overall Organizational Performance	
	Regression Coefficient	p-value	Regression Coefficient	p-value
Intercept	-0.225	0.731	0.615	0.333
Information Infrastructure	-0.231	0.170	0.083	0.602
Incentive Program	0.380	0.019*	0.260	0.016*
Expertise Development	0.046	0.530	0.051	0.469
Human Resource Planning	0.850	0.000**	0.437	0.015*
F-value	11.487		6.258	
p-value	0.000		0.000	
Adjusted R^2	0.522		0.373	

**: $p < 0.05$; **: $p < 0.001$*

This result showed that the implementation measures did exhibit significant influence on the performance measures. The second and the third regression analyses were conducted to further investigate this relationship.

In the second regression analysis, each of the four dimensions of the KM implementation measures was treated as an independent variable, with the performance measures as a single composite variable. The third regression analysis related the four dimensions of the KM implementation measures with the two dimensions of the performance measures. Table 7 shows that only human resource planning and the incentive measures significantly affected the performance of KM efforts. Between the two dimensions of the performance measures, human resource planning and incentive measures contributed significantly to both the internal process and the overall performance, as shown in Table 8. The second and third regression analyses essentially confirmed the result of the first regression analysis and also provided a greater understanding of the importance of people factors in effective KM.

CONCLUSION AND DISCUSSION

This study investigated the practice and the effect of KM in hospital management. It examined the effect of knowledge characteristics on knowledge acquisition strategy and KM implementation measures, the effect of knowledge acquisition strategy on implementation approaches and performance measures, and the effect of implementation approaches on KM performance. Using primary data gathered in Taiwanese hospitals, the study found that knowledge characteristics significantly affected implementation measures, and implementation measures, in turn, had a significant effect on the result of KM implementation. More specifically, the level of explicitness of knowledge (knowledge mode) was found to have a significant effect on the adoption of the internal-oriented knowledge acquisition strategy. The complexity of knowledge was related significantly to the external-oriented knowledge acquisition strategy. In general, people factors, such as incentive programs and human resource planning, appeared to have more impact on the result of KM than technology factors, confirming a popular belief regarding the importance of non-technological factors in KM, as reported in the existing literature.

The correlation relationship between knowledge characteristics and implementation measures is worth noting. In addition to incentive programs and human resource planning, information infrastructure was found to be affected significantly by three knowledge characteristics: explicitness, proprietary nature, and variation. The enabling capability of information technology for knowledge storage, dissemination, and application allows for integration of specialized knowledge with routine business processes, such as disease diagnosis and medicine prescription in the healthcare domain (Davenport & Glaser, 2002). Increasingly, hospitals are relying on technological measures as a strategic vehicle to cope with both professional and managerial challenges. The emphasis of information technology applications can be attributed to the collaboration between major hospitals and universities. Information technology development and applications have been a major thrust in Taiwan. Many universities set up research centers to function as an interface between information system researchers and the regional hospitals. Some technologies resulting from these collaborations either are adopted by or are shared with smaller hospitals. The maximal benefit of information technology deployment has yet to be realized, however. The value of technological tools is maximized when they become integral parts of truly integrated business processes.

This study contributed to the field of KM in several ways. For practicing KM professionals and business functional managers, the study demonstrates the importance of matching KM implementation measures with knowledge characteristics. Understanding characteristics of valuable knowledge in an organization is a prerequisite for effective management of its organizational knowledge. Similarly, knowledge-driven organizations consciously must evaluate and adopt their implementation measures. When properly implemented, KM programs may produce visible benefits, including those associated with operationally oriented goals and those associated with long-term financial outcomes.

For KM research, this study empirically revealed the correlation between knowledge characteristics and KM implementation measures. The performance impact of implementation measures, especially those associated with people elements, also was confirmed. The lack of the knowledge acquisition strategy's influence on performance measures suggested that hospitals may have acknowledged the value of both internal and external sources of knowledge and indiscriminately adopted both strategies in order to enrich their knowledge repositories.

Because of several limitations of the study, however, due caution must be exercised in interpreting and applying the results of this study. For example, since the data were gathered in the hospitals in Taiwan, cultural and other environmental differences may limit one's ability to generalize the research findings. Similar researches must be conducted in a variety of cultural and societal settings in order to establish the external validity in a more general fashion.

Another research limitation was that some questionnaires were filled out by the targeted respondents' delegates, including medical doctors and information technology managers. Although the delegates possessed proper understanding of knowledge characteristics or implementation measures, they might not be the best people to answer the questions about overall organizational performance resulting from KM implementation. Additionally, the subjective nature of the questionnaire responses based on the Likert scale constituted a limitation that might discount the validity of the research results.

Healthcare organizations in the United States use information technology extensively to automate important processes and support other aspects of operations. An industry expert estimated that spending in healthcare information technology will increase about 9% per year for the next three years and will reach $30 million in 2006 (Powers, 2004). In light of the important role played by healthcare organizations in our daily lives, more research is needed to provide knowledge about how to improve the quality of hospital management. Based on the findings of this research, two directions may be suggested for future research in this particular domain. First, in-depth case studies may be conducted to verify the validity of our research findings in specific contexts and to assess how contextual factors impact the linkages among knowledge characteristics, KM implementation measures, knowledge acquisition strategy, and KM performance measures. Second, our research model may be replicated in different societies to allow for cross-cultural comparison. Such comparison is necessary in order for the research model to become better established in the KM literature.

APPENDIX II: SURVEY QUESTIONNAIRE

(Measurement Scale: 1 = Highly Disagree, 5 = Highly Agree)

Questions About Knowledge Characteristics

1. Documentation has been created for all medical expertise.
2. Medical service delivery processes have formal specifications.
3. Doctor's practice experience may be documented in writing.
4. Doctors can share their professional expertise without any obstacles.
5. Major surgical operations are accomplished by task force teams.
6. Significant differences of expertise exist among the doctors in the same specialty.
7. Outside experts often are called upon to assist with major surgery operations.
8. Mutual support among doctors within the same specialty usually is difficult to come by.
9. Medical expertise is integrated tightly with hospital management and organizational culture.
10. Outsourcing often is used due to inadequacy of medical expertise.
11. Innovations of medical practices are difficult to be obtained by competition.
12. Doctors are expected to remain up-to-date with data in their expertises.
13. The frequency of rare case treatment experience is higher than the competition.
14. New and innovative medical knowledge and technology are adopted faster than competition.
15. Knowledge used around here advances fast.

Knowledge Management Implementation Measures:

16. Information systems are developed aggressively to enable organization, dissemination, and application of knowledge.
17. Doctors are strongly encouraged to access document bases and to systematically construct medical databases.
18. Operation automations through information technology are pursued actively to support doctors' work.
19. Substantial amounts of financial resources are invested in information technology.
20. Doctors are encouraged to use the Internet to enhance medical expertise exchange and diffusion.
21. Knowledge sharing is an important criterion in performance evaluation.
22. Proposals for creative ideas are rewarded, even when the ideas prove to be wrong.
23. Knowledge creation and sharing often are rewarded with salary increases and bonuses.
24. Knowledge creation and sharing are rewarded with promotions.
25. Doctors always are willing to accept training and work assignments that are tougher than the competition.
26. The hospital is not hesitant to increase head counts of supporting technical specialists.
27. Doctors are willing to accept the challenges to enhance their professional expertises.
28. Doctors often explicitly reject the idea of being evaluated by personnel from other fields.
29. Competition among doctors in the same field often hinders knowledge sharing.
30. Doctors are strongly encouraged to learn and to innovate.
31. Open and smooth channels of communication exist in the hospital.

32. Doctors frequently are encouraged to engage themselves in experience and expertise exchange.
33. One-on-one mentor and apprentice-style training of resident doctors is common here.

Knowledge Management Performance

(5 = Much Better, 3 = About the Same, and 1 = Much Worse)

34. Doctors' expertise and experience exchange
35. Handling of doctors' suggestions with regard to medical operations
36. Doctors' sense of participation
37. Decision-making speed
38. Proposal preparation cycle time
39. Overall efficiency improvement
40. Overall quality of service
41. Patient satisfaction
42. Decrease of number of administrative personnel
43. Reduction of impact caused by turnover
44. Handling of medical service improvement projects

Primary Strategy for Knowledge Acquisition

Chapter 5.19
Organizing for Knowledge Management:
The Cancer Information Service as an Exemplar

J. David Johnson
University of Kentucky, USA

ABSTRACT

The Cancer Information Service is a knowledge management organization, charged with delivering information to the public concerning cancer. This chapter describes how societal trends in consumer/client information behavior impact clinical knowledge management. It then details how the CIS is organized to serve clients and how it can interface with clinical practice by providing referral, by enhancing health literacy, by providing a second opinion, and by giving crucial background, assurance to clients from neutral third party. The CIS serves as a critical knowledge broker, synthesizing and translating information for clients before, during, and after their interactions with clinical practices; thus enabling health professionals to focus on their unique functions.

INTRODUCTION

The Cancer Information Service (CIS) is essentially a knowledge management (KM) organization, manifestly charged with delivering up-to-date information to the public related to scientific advances concerning cancer. Its latent purpose, increasingly important in a consumer driven medical environment, is to insure the rapid diffusion of state-of-the-art medical care. It is an award-winning national information and education network, which has been the voice of the National Cancer Institute (NCI) for more than 30 years in the US. While the CIS has extensive outreach programs dedicated to reaching the medically underserved, it is probably best known for its telephone service that has a widely available 800 number (1-800-4-CANCER). We will use the CIS as an exemplar in this chapter of issues related to a national information infrastructure that supports clinical knowledge management.

Because of the critical role of broader societal trends we will turn to a discussion of them before describing in more detail the basic services and organizational structure of the CIS and its potential interfaces with clinical KM. Many health organizations have realized that there are strategic advantages, especially in enhancing quality, maintaining market share, and developing innovations, in promoting information technologies. Improving information management, associated analytic skills, and knowledge utilization should be a top priority of clinical practice (Johnson, 1997). It has become commonplace for almost all hospitals and managed care providers to have very active information programs for their clients allowing those in clinical settings to concentrate on their central, unique missions. Government information providers can also act as information services providing knowledge before, during, and after client interactions with clinical organizations. Health professionals can partner with KM services that recognize the public's demand for information and the various difficulties involved in reaching the people who need information. Indeed, the CIS focuses on the classic KM functions of retrieving and applying knowledge, combining it, and finally distributing/selling it.

This chapter's objectives are to answer the following questions:

1. How do societal trends in consumer/client information behavior impact clinical KM?
2. How the CIS is organized to serve clients?
3. How it can interface with clinical practice?
   a. By providing referral
   b. By enhancing health literacy
   c. By providing a second opinion
   d. By giving crucial background, assurance to clients from neutral third party
4. How can the CIS serve as an answer to information explosion?
   a. For client it acts as synthesizer, translator who can relieve clinical settings of this task
   b. Through client it directly acts to disseminate information to improve practice

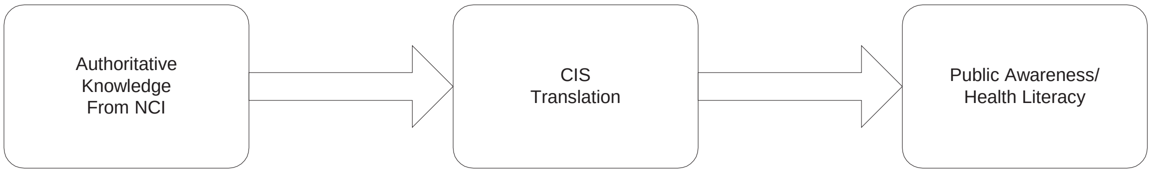
BACKGROUND

Knowledge Management

KM has been loosely defined as a collection of organizational practices related to generating, capturing, storing, disseminating, and applying knowledge (MacMorrow, 2001; Nonaka & Takeuchi, 1995). It is strongly related to information technology, organizational learning, intellectual capital, adaptive change, identification of information needs, development of information products, and decision support (Choo, 1998; Fouche, 1999). They are so intimately related, in fact, that it is often difficult to say where one approach stops and another begins. We will primarily view KM as a system for processing information. This is certainly the organizing thrust of the CIS. The CIS obtains the knowledge it translates to the public from the NCI (Figure 1). It is organized to provide consistent, quality information translated in a manner that can result in meaningful responses on the part of callers (e.g., course of treatment) that transforms basic information into knowledge (and perhaps in some cases even into wisdom and ultimately action). Thus, the KM service the CIS provides makes information purposeful and relevant to individuals that need it, who are often in dire circumstances.

Knowledge itself runs the gamut from data, to information, to wisdom, with a variety of distinctions made in the literature between these terms (e.g., Boahene & Ditsa, 2003). Special weight

Figure 1. Knowledge flow



in the context of the CIS is given to a consensus surrounding refereed scientific findings that can be translated to the public to improve cancer prevention, detection, and treatment. What is knowledge is often a matter of intense negotiation between various stakeholders as evidenced by the recent controversy over the most appropriate ages for screening mammography (HHS, 2002). Accordingly, the KM structure of the CIS is fundamentally a responsive one, very dependent on changes in the larger biomedical environment. It does not have the luxury of operating in a command environment, it must respond to the diversity, complexity, and sense-making abilities (health literacy) of its audience, placing it clearly in more post modern conceptions of KM (Dervin, 1998). So, the CIS must respond to the information environment of an information seeking public, with information specialists acting as the public's human interface in transforming information to knowledge.

PUBLIC INFORMATION SEEKING AND CLINICAL PRACTICE

Information seekers are often frustrated in their attempts to seek information, especially from doctors in clinical settings. A major focus of health communication in recent years has been on the long-standing problems with patient-doctor communication (Thompson, 2003). The amount of information physicians give to patients is correlated with patient satisfaction with healthcare and with compliance (Street, 1990). People are more likely to follow behavioral recommendations when their understanding is high. Lack of communication between doctor and patient has been found to relate to decreased ability to recall information given by the caregiver, patient dissatisfaction, decreased adherence to prescribed regimens, and other forms of non-compliance (Brown, Stewart, & Ryan, 2003).

Cancer-related information seeking is often a great challenge to individuals. They have to overcome their tendency to deny the possibility of bad news and the distasteful problems associated with cancer. They also have to be willing to believe that their individual actions can make a difference, that by seeking information they gain some control and mastery over their problems. They also have to overcome the limits of their education and prior experience. They have to possess skills as information seekers, An awareness of databases, familiarity with the Internet, an ability to weigh conflicting sources of information and to make judgments about their credibility. In short, any one of the factors in this long-linked chain could severely impede, if not halt, the information seeking process. Recognizing this, individuals are increasingly relying on knowledge brokers, such as the CIS, as intermediaries to conduct their searches for them (Johnson, 1997).

There are a number of ways that use of knowledge brokers can complement clinical practice. First, individuals who want to be fully prepared before they visit the doctor often consult the Internet (Fox & Rainie, 2002; Taylor & Leitman, 2002). Indeed, Lowrey and Anderson (2002) suggest prior web use impacts respondent's perception of physicians. Second, there appears to be an interesting split among Internet users, with as many as 60 percent of users reporting that while they look for information, they only rely on it if their doctors tell them to (Taylor & Leitman, 2002). While the Internet makes a wealth of information available for particular purposes, it is often difficult for the novitiate to weigh the credibility of the information, a critical service that a knowledge broker, such as a clinical professional, can provide. This suggests that a precursor to a better patient-doctor dialogue would be to increase the public's knowledge base and to provide alternative, but complementary information sources, by shaping client's information fields. By shaping and influencing the external sources a patient will consult both before and after visits, clinical practices can at one in the same time reduce their own burden for explaining (or defending) their approach and increase the likelihood of client compliance.

Why is Cancer-Related Information Seeking Important?

Information is an important first step in health behavior change (Freimuth, Stein, & Kean, 1989). The consequents of information carrier exposure and seeking are many, including information gain, affective support, emotional adjustment, social adjustment, attitude change, knowledge change, behavior maintenance, a feeling of greater control over events, reduction of uncertainty, and compliance with medical advice (Johnson, 1997). Information seeking can be defined simply as the purposive acquisition of information from selected information carriers. Cancer-related information seeking has become increasingly important over the last decade. Not too long ago, information related to cancer was the exclusive preserve of doctors and other health professionals. Today in the U.S., not only is the diagnosis shared, but individuals have free access to an often bewildering wealth of information. With this access has come an increasing shift of responsibility (some might say burden) to the individual to convert information into knowledge, in the process making decisions concerning his/her treatment and adjustment to cancer (Johnson, Andrews, Case, & Allard, in press).

Individual Responsibility/Client/Consumer Movement

Increasingly the responsibility for health-related matters is passing to the individual, partly because of legal decisions that have entitled patients to full information (Johnson, 1997). The consumer movement in health is in part actively encouraged by hospitals, insurance providers, and employing organizations (Duncan, 1994) who want to encourage health consumers to 'shop' for the best product at the most affordable price (Hibbard & Weeks, 1987). Facilitating and enhancing this consumer movement have been explosive developments in information technologies, which make more specialized media sources available, permitting increased choice in information carriers, and increased connectivity with other interested parties (Case, Johnson, Andrews, Allard, & Kelly, 2004; Duncan, 1994).

Large numbers of patients do not receive state of the art treatments (Freimuth et al., 1989), partly because physicians cannot keep up with the information explosion (Duncan, 1994; NCI, 2003). The overload of information on health professionals today forces decentralization of responsibilities, with increasing responsibility passing to individuals if they are going to receive up-to-date treatment. The physician is no longer the exclusive source of medical knowledge; they must be cognizant of the welter of information available and their role in this complex system (Parrott, 2003). Recognition of the limits of health professionals also requires individuals to be able to confirm and corroborate information by using multiple sources. In fact, patients often call the CIS to verify information they receive elsewhere (Freimuth et al., 1989).

Cancer patients tend to want much more information than healthcare providers can give to them, even if willing (Johnson, 1997). Information that to a client is necessary for coping with cancer, may be seen by doctors as an intrusion into their prerogatives. Exacerbating this problem is the fact that doctors and patients may not share similar outcome goals. Traditionally, doctors have viewed the ideal patient as one who came to them recognizing their authority and who were willing to comply totally (with enthusiasm) with recommended therapies (Hibbard & Weeks, 1987).

Perhaps the most threatening aspect of enhanced information seeking for health professionals is their loss of control. Many doctors have legitimate concerns about self-diagnosis and patients possessing just enough information to be dangerous (Broadway & Christensen, 1993) and the general preferences of consumers may cause them to avoid unpopular, albeit effective, invasive procedures (Greer, 1994). Still, the more control that health professionals have, the less effective they may ultimately be, especially in terms of insuring that clients act according to consensus views of treatment (Johnson, 1997).

SOLUTIONS AND RECOMMENDATIONS

One approach to managing these problems is for those in clinical practice to either create or to partner with KM services that recognize the public's demand for information and the various difficulties involved in reaching the people who need information in the most timely fashion. There are a number of indications that programmatically the best channels for providing cancer-related knowledge are those channels that constitute a hybrid of the positive properties of both mediated and interpersonal channels.

Information and referral centers can take many forms, such as hotlines, switchboards, and units within organizations (e.g., nurse's medical help lines) where individuals can go to get answers to pressing concerns from knowledge brokers. They serve three primary functions: educating and assisting people in making wise choices in sources and topics for searches; making information acquisition less costly; and being adaptable to a range of users (Doctor, 1992). These services have been found to offer considerable help and assistance to callers (Marcus, Woodworth, & Strickland, 1993).

Telephone information and referral services like the CIS represent a unique hybrid of mediated and interpersonal channels, since they disseminate authoritative written information, as well as verbal responses to personal queries (Freimuth et al., 1989). The hybrid nature of telephone services is important, since it can overcome some of the weaknesses of other channels. They have the additional advantage of homophily of source, a crucial factor in effective communication (see Rogers, 2003), since the calls are handled by individuals of closer status and background to potential callers than are physicians. It has been suggested that the CIS provides an important link between symptomatic people and health services, since a substantial proportion of callers follow up with more information seeking, passing on information to others, or consultations with health professionals (Altman, 1985).

The advantages of telephone services as a channel include they: are free, are available without appointment and forms, offer a high level of empathic understanding, offer greater client control, permit anonymity for both parties, bridge geographic barriers, provide immediate responses, the client can take greater risks in expressing feelings, convenience, cost effectiveness, and personalized attention (Johnson, 1997). All these factors are reflected in respondents rating CIS as the highest quality source of cancer information (Mettlin et al., 1980) and the extremely high rate of user satisfaction in subsequent surveys (Morra, Bettinghaus, Marcus, Mazan, Nealon, & Van Nevel, 1993; Thomson & Maat, 1998; Ward, Duffy, Sciandra, & Karlins, 1988).

Knowledge Management Services of CIS

We need every weapon against cancer, and information can be a powerful, lifesaving tool. ... A call is made, a question is answered. NCI reaches out through the CIS, and the CIS is the voice of the NCI (Broder, 1993, pp. vii).

... one phone call, one conversation, can save a life. This is the true essence of the service and the most rewarding aspect of the program (Morra, Van Nevel, O'D.Nealon, Mazan, & Thomsen, 1993, p. 7)

In broad sweep (see Figure 1), the CIS has traditionally been the disseminator/translator of consensus based scientific information from NCI to broader segments of the public, responding to demand characteristics of an increasingly knowledgeable, responsible public. We can easily organize a description of the CIS around the major functions of KM organizations: transforming information into knowledge; identifying and verifying knowledge, capture/securing knowledge; organizing knowledge; retrieving and applying knowledge, combining it, creating it, and finally distributing/selling it (Liebowitz, 2000).

The CIS is one section of the Health Communication and Informatics Research Branch (HCIRB) of the Behavioral Research Program (BRP) of the Division of Cancer Control and Population Services (DCCPS). The DCCPS is a major research division of NCI that also has research programs focusing on Epidemiology and Genetics, Applied Research, and Surveillance Research. The BRP contains additional branches relating to Applied Cancer Screening, Basic BioBehavioral Research, Health Promotion, and Tobacco Control. (For more information see http://dccps.nci.nih.gov). The "HCIRB seeks to advance communication and information science across the cancer continuum-prevention, detection, treatment, control, survivorship, and end of life" (http://dccps.nci.nih.gov/hcirb).

The CIS was implemented in 1975 by the NCI to disseminate accurate, up-to-date information about cancer to the American public, primarily by telephone (Ward et al., 1988; Morra, Van Nevel et al., 1993) and is currently governed by the principles of "responsiveness, tailoring information to audience needs, and proactively sharing information" (http://cis.nci.nih.gov/about/orgprof.html). The CIS was one of the first federally-funded health-related telephone information systems in the US (Marcus et al., 1993).

Information is available, free of charge, in both English and Spanish to anyone who calls 1-800-4- CANCER. In recent years the CIS has added a special telephone service to promotion smoking cessation (1-877-44U-QUIT), as well as services for the hearing impaired, and has instituted a range of web-based services. The CIS responds to nearly 400,000 calls annually and many more requests for assistance on its LiveHelp website feature (http://cis.nci.nih.gov/about/underserved.html). In total, in 2002 the CIS handled over 1.4 million requests for service (NCI, 2003). The impetus underlying the creation of the CIS was the assumption that all cancer patients should receive the best care. To accomplish that end it was felt that free and easy access of consumers to credible information was critical (Morra, Van Nevel et al., 1993).

KM Roles in the CIS

To accomplish its KM work the CIS has developed several specialized, functional roles in its 14 Regional Offices (ROs). The major roles in each of the RO's include, Project Directors (PD), Telephone Service Managers (TSM), and Partnership Program Managers (PPM) and subordinate Partnership Coordinators. These roles differ both in their position requirements and in their organizational status level, with PDs the day-to-day managers for the regional CIS offices (Morra et al., 1993).

TSMs are in charge of managing the Information Specialists (IS) and the referral resources. The IS within the CIS, who serve as knowledge brokers, have a unique cluster of skills: though the CIS is not a help/counseling "hotline," callers are often very anxious; information specialists must be able to communicate highly technical information clearly to callers who come from all demographic groups and who differ considerably in their levels of knowledge (Davis & Fleisher, 1998; Morra, 1998). Performance standards for telephone calls are set nationally and are monitored by an extensive formal evaluation effort unique for telephone services (Kessler, Fintor, Muha, Wun, Annett, & Mazan,1993; Morra, 1998). IS are clearly constrained to be information providers within strict protocols, to not interfere with existing medical relationships, to refrain from counseling, and to provide callers with quality assurances of information they provide (e.g., "this is consensus scientific information") (NCI, 1996).

The CIS Partnership Program is designed to reach out to people, especially the medically underserved and minority communities, who do not traditionally seek health information, providing equal access to cancer information from a trusted source (http://cis.nci.nih.gov/about/orgprof.html). PPMs are responsible for disseminating health messages through networking with other organizations such as local American Cancer Societies, state health departments, and so on. In doing this they serve a strategic multiplier function for the CIS, increasing the health literacy of clients.

Designing for KM

The traditional CIS telephone service is literally the tip of the iceberg of a very sophisticated KM system that has considerable strategic advantages because of its commitment to translating the highest quality, consensus based scientific information to the public. Enhanced information seeking possibilities for the public are created by new technologies, representing an information architecture, in three areas: data storage, data transport, and data transformation (Cash, Eccles, Nohria, & Nolan, 1994). While we will discuss these components separately, increasingly it is their blending and integration that is creating exciting new opportunities for information seeking (Case et al., 2004). Networks, like the Internet, usually combine enhanced telecommunication capabilities with software that allows linkage and exchange of information between users (one of which is often a database). In the health arena these benefits and possibilities are captured under the heading of health informatics. Consumer health information is perhaps the fastest growing area of this specialty (MacDougall & Brittain, 1994).

Telecommunication systems such as fiber optic cables and satellite systems provide the hardware that links individuals and provides enhanced access to systems. Telecommunication systems maintain communication channels (e.g., e-mail) through which information is accessed and reported. They can specifically enhance the information seeking of patients by creating new channels for sending and receiving information (e.g., Live Aid feature on CIS's Web site), helping them in filtering information, reducing their dependence on others, leveraging their times to concentrate on the most important tasks, and enhancing their ability for dealing with complexity. One example of enhanced data transport lies in the benefits of telemedicine: increased access to information, increased consistency in medical decision making, matching diagnostic and management options to patient needs, increased quality of care, more interpretable outcomes, increased efficiency, increased efficacy, decreased costs, and a more uniform structure for healthcare (Turner, 2003).

Essentially databases provide a means for storing, organizing, and retrieving information. Modern conceptions of storage have broadened this function considerably to include verification and quality control of information entering a storage system. Doctors have historically mistrusted medical information systems because they may not capture the subtlety and nuance that only their long experience and training can bring to a situation (Shuman, 1988). They also do not provide much assistance to health professionals in areas where there is low consensus knowledge (Brittain, 1985). Unfortunately, a number of scientific controversies in well established areas have emerged in recent years that even peer review may not successfully address.

To their credit, the authoritativeness of the information they provide has always been a paramount concern for government databases. In the cancer area the NCI's Physician Data Query (PDQ) has been paying systematic attention to these issues for two decades (Hibbard, Martin, & Thurin, 1995). PDQ was originally designed to address the knowledge gap between primary care physicians and specialists. In a 1989 survey of primary care practitioners two-thirds felt that the volume of the medical literature was unmanageable and 78 percent reported that they had difficulty screening out irrelevant information from it (Hibbard et al., 1995). "This knowledge gap is responsible for the prolonged use of outmoded forms of cancer treatment resulting in unnecessarily high rates of cancer morbidity and mortality" (Kreps, Hibbard, & DeVita, 1988, pp. 362).

Fundamental to PDQ is the recognition that the rapid dissemination of health information is critical to successful treatment, since at the time it was created in the early 1980's approximately 85 percent of cancer patients were treated by primary care doctors (Kreps et al., 1988). In its early days one-third of the PDQ usage came from the CIS (Kreps et al., 1988), reflecting a high level of usage by the lay public that has continued to this day.

PDQ seeks to provide a current peer-reviewed synthesis of the state-of-the-art clinical information related to cancer (Hibbard et al., 1995). PDQ contains several components. Cancer information summaries in both health professional and patient versions on adult treatment, pediatric treatment, supportive care, screening and prevention, genetics, and supportive care. A registry of clinical trials and directories of physicians, professionals who provide genetic services, and organizations that provide cancer care is also available.

A critical issue facing all databases is how old, irrelevant information is culled from any storage system. A not so apparent problem of public databases, like many of those available on the Internet, is the potential lack of timeliness of the information. The cancer information file of PDQ is reviewed and updated monthly by six Editorial Boards of cancer experts in different areas. These Editorial Boards have clear guidelines on levels of evidence for information to be considered for the database. CIS IS receive extensive training on cancer-related issues and the use of PDQ (Davis & Fleisher, 1998; Fleisher, Woodworth, Morra, Baum, Darrow, Davis, Slevin-Perocchia, Stengle, & Ward, 1998).

More generally, HHS through the NIH's National Library of Medicine and the Office of Disease Prevention and Health Promotion's National Health Information Center, have devoted considerable resources and given thought to building a national information infrastructure in the U.S. The integration of data storage and transport with sophisticated software offers unique opportunities for solutions that transcend the limits of individual information processing, especially that of novices. Combining databases and telecommunications with software creates telematics that allows for the possibility of increasingly sophisticated searches for information and analysis/interpretation of it once it is compiled. The CIS IS, acting as a knowledge broker, serves a critical function in translating information into knowledge for increasingly literate health consumers.

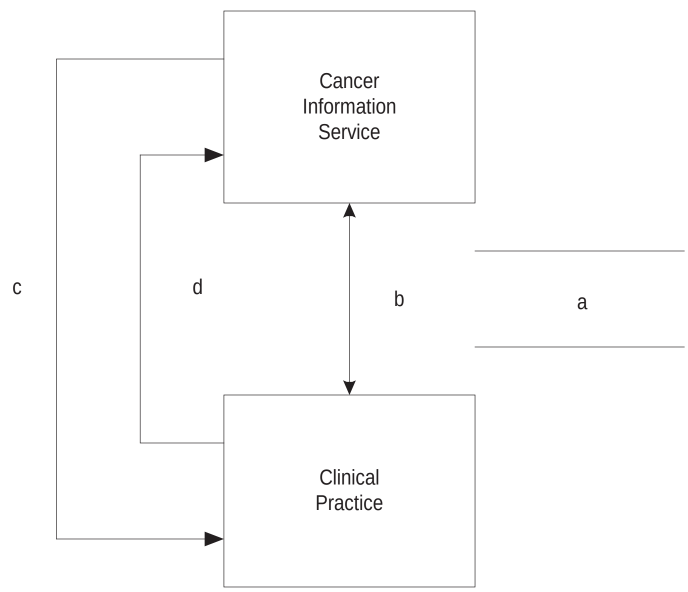
FUTURE TRENDS

Consortia and Clinical Knowledge Management

The future of KM in clinical settings is likely to be a turbulent one. It is clear, however, that those in clinical settings will be asked to do more with less. Thus, increasingly organizations will be looking for partners to provide services they cannot provide—in this role the CIS can be a key strategic partner for clinical practice allowing those in clinical settings to concentrate on their central, unique missions. Government information providers can act as central repositories for information services that would be provided before, during, and after client interactions with clinical organizations. They can do this in the ad hoc, random basis currently characteristic of a client's information environment (pattern a in Figure 2), or they can form explicit partnerships (paths b, c, and d) with clinical practice in consortia.

Consortia are particularly interesting settings in which to examine these issues because of the voluntary nature of relationships within them, which often creates a situation that is a mix of system/altruism and market/self-interest. A consortium can be defined simply as a collection of entities (e.g., companies, occupational specialties, community members) brought together by their interest in working collaboratively to accomplish

Figure 2. Relationships between CIS and clinical practice



something of mutual value that is beyond the resources of any one member (Fleisher et al., 1998; Johnson, 2004).

Organizations often find that they are either strapped for resources or are pursuing projects of such magnitude that they must pool their resources to pursue innovations (Hakansson & Sharma, 1996); developing cooperative relationships with other entities promotes the possibility of resource sharing and greater efficiencies, especially in community (Dearing, 2003) and governmental settings (Dorsey, 2003; Parrott & Steiner, 2003). Fundamentally, consortiums are formed so that their members can accomplish more than they could do on their own. Given the interest in new organizational forms, heightened competition, fractured communities, and declining resources available to any one group, this topic has captured the attention of researchers in a wide range of disciplines (Hakansson & Sharma, 1996; Johnson, 2004).

The focus of these consortiums should be on providing consistent health-related messages and information (resulting from relationships described by b, c, and d in Figure 2) that through their repetition from multiple trustworthy institutions increases the probabilities that clients will comply with the best medical advice. The CIS's existing PPM provides the critical foundations for the development of such consortia (Thomsen & Maat, 1998). Indeed, increasing health literacy by encouraging autonomous information seekers should be a goal of our healthcare system (Parrott, 2003). While it is well known that individuals often consult a variety of others before presenting themselves in clinical settings (Johnson, 1997), outside of HMO and organizational contexts, there have been few systematic attempts to shape the nature of these prior consultations.

If these prior information searches happen in a relatively uncontrolled, random, parallel manner (pattern a), expectations (e.g., treatment options, diagnosis, drug regimens) may be established that will be unfulfilled in the clinical encounter. The emergence of the Internet as an omnibus source for information has apparently changed the nature of opinion leadership; both more authoritative (e.g., medical journals) and more interpersonal (e.g., cancer support groups) sources are readily available and accessible online (Case et al., 2004). This is a part of a broader trend that Shapiro and Shapiro (1999) refer to as "disintermediation"—the capability of the Internet to allow the general public to bypass experts in their quest for information, products and services.

Contemporary views of health communication are more likely to stress a dialogic view of interaction, with both parties initiating and attending to messages in turn (paths b, c, and d). Health professionals' most important role in these more contemporary perspectives is as stimulus or cue to action, defining the agenda of the most important issues that an audience needs to face (path d). For those clients who have had no prior contact with a clinical organization, the CIS can provide referral services (path c in Figure 2) for clients predisposed to act. About 20 percent of callers to Midwest Regional Office of the CIS last year asked for referrals to health professionals, treatment facilities, and/or community services (http://www.karmonos.org/cis/telephone.html). Clinical entities should be familiar with this referral process and the kinds of information provided to insure a smooth encounter with referred clients.

Proactive prior referral and/or exposure to an information source such as the CIS can ease the burden on clinicians by transmitting basic information to clients that then does not have to be repeated in an office visit (path c). Increasingly the focus of health communication campaigns is on getting people to seek more information on health topics (Parrott, 2003; Salmon & Atkin, 2003). Creating rich information fields through such practices as 'self-serving' to information from data bases, for example, should make for a more informed consumer, who is likely to consume less time of health professionals "being brought up to speed" on the basics of his/her disease and its treatment. As we have seen, this enhanced level of health literacy can result in various improved outcomes for clients.

Similarly, as part of a visit clinicians can encourage individuals to use services like the CIS to secure a second, complementary opinion (path d). These services can provide crucial background, support, and assurance to clients from neutral third party. For clients the CIS IS act as a knowledge broker synthesizing and translating information, thus relieving clinical settings of this task. The CIS can perform many of the same functions that call centers and customer relations staff can provide for information technology services. Similarly, it has taken on the increasingly critical role of referral to clinical trials for new and/or experimental treatments (http://cancer.gov/cancerinfo/pdq/cancerdatabase), something that should be done in concert with clinical practice (path b).

While the CIS, and similar government services, have often been viewed as competitors or interlopers into clinical practice, its access to NCI's research infrastructure, the development of authoritative guidelines (PDQ), and its role in translating this information to the public, demonstrate it can be a key contributor to a more effective healthcare delivery system (NCI, 2003). In the past, through clients, it has directly acted to disseminate information to improve practice. The ultimate outcome of effective KM is the rapid adoption or creation of appropriate innovations that can be successfully implemented within a particular organization's context. In the case of the CIS there was an even broader mandate, a latent purpose to insure the rapid diffusion of state-of-the-art medical care to the public. By explicitly recognizing, managing, and supporting this role, clinical entities can more effectively manage their limited resources to insure that consonant information is provided to clients that is more likely to result in positive healthcare outcomes. While often services like the CIS have been viewed as a competitor, it may be better to view it as a complementary/supportive service, especially for government driven healthcare systems.

CONCLUSIONS

In broad sweep (see Figure 1), the CIS has traditionally been the disseminator/translator of consensus based scientific information from NCI to broader segments of the public. Societal trends in consumer/client information behavior make this a critical role in today's broadly envisioned clinical practice environment. While the CIS is organized to serve clients directly, it can also interface with clinical practice by providing referrals, enhancing health literacy, providing second opinions and crucial background, assurance to clients from neutral third party. Thus, the CIS is a partial answer to information explosion: for client it acts as synthesizer, translator who can relieve clinical settings of this task and through clients it directly acts to disseminate information to improve clinical practice.

This chapter highlights how information providers can interface with clinical practice to form a strategic partnership that advances health outcomes for the public. All this suggests the increasing importance of information as a strategic asset that should be systematically incorporated in the planning of health professionals. Health institutions need to recognize the potential benefit of marketing unique corporate knowledge and expertise to other information seekers and to consider their unique role in a complex information seeking environment. Health professionals also need to lobby the government to maintain critical information infrastructures.

While more and more information can be produced more efficiently, there is a concomitant increase in the costs of consuming (e.g., interpreting, analyzing) this information (More, 1990). Thus, proactively working to shape a client's information fields by insuring concordant information is provided may forestall increasing problems for clinical practice in the rapidly growing information jungle.

ACKNOWLEDGMENTS

I would like to thank Dr. Sally Johnson for reviewing an earlier version of this manuscript.

Chapter 5.20
Knowledge Management Governance

Suzanne Zyngier
Monash University, Australia

INTRODUCTION

There are many barriers to the implementation of knowledge management (KM) strategies. These include the lack of time and financial resources allocated to sharing knowledge, a lack of organizational understanding of the philosophy and the benefits of KM, and a lack of skills in KM. However, survey data show that the greatest acknowledged obstacle to the implementation of a KM strategy is the management culture of the organization (Chase, 1997; Zyngier, 2001). These obstacles reveal a problem in the implementation of an organizational KM strategy. The problem lies not in the implementation of a given strategy per se, but in the lack of governance of that strategy.

The governance process is a framework of authority that ensures the delivery of anticipated or predicted benefits of a service or process (Farrar, 2001). The operationalization of that strategy is therefore executed in an authorized and regulated manner. Governance mechanisms must be invoked to guide both the initial implementation and the ongoing control and authority over KM strategies. A governance framework will provide the management of risk, review mechanisms and fiscal accountability in leveraging tacit knowledge, and the sharing of explicit knowledge within an organization. Knowledge is not simply a series of artefacts to be managed. This article identifies the processes in KM that are subject to governance. KM governance centres the decision-making authority as an executive framework to deliver the expected benefits of the strategy and for these benefits to be delivered in a controlled manner. This is achieved by the establishment of checks and balances in the implementation of the strategy. It ensures that evaluation measures feedback that enables deliberate adjustment of the delivery of the strategy, and that needs and expectations are being met. If the needs and expectations of the organization cannot be met, then the governance process should then be able to establish and manage the cause.

The first part of this article discusses KM strategy development and shows the origins of KM governance in the concept of the use of governance principles and practices. The second part will discuss the central issues in KM governance, being authority, evaluation, measurement, and risk management. The third part will suggest a structure or model for KM governance explaining how this operates in an organizational context, and suggests future trends for this research.

BACKGROUND

The Role of Leadership

Executive management leads and establishes the culture and consequent ability of an organization to capture, share, and manage its knowledge. In the past, leaders in organizations were empowered to order changes, and then all that was required of the organization was to implement the plan (Bridges & Mitchell, 2000). The culture of an organization is developed by the structure, attitude, and example of management. Krogh, Ichijo, and Nonaka (2000) describe how effective management and the support of knowledge creation depends on the physical, virtual, and emotional context in which they are manifested. Where there is a strong commitment at the level of executive management to change organizational culture, an organization is able to begin to create the values that lead to knowledge sharing across boundaries (Hackett, 2000; O'Dell, Grayson, & Essaides, 1998). Currently, interpretations of knowledge management leadership (Rumizen, 2002; Tiwana, 2002) endow the leader with the responsibility to direct, conduct, or guide functions in the implementation of such a strategy.

The terms knowledge champion, leader, and sponsor are used interchangeably in the knowledge management literature. The terms variously indicate a person who initiates a KM strategy, or one who supports and promotes the initiation of such a strategy. Therefore, the person or persons responsible for the implementation of a KM strategy may have the sole responsibility for the development and implementation of a KM strategy. This cannot ensure buy in from the organization as a whole. These risks are revealed as found in Australian and international surveys that have disclosed some of the obstacles to KM strategies (Chase, 1997; Davis, McAdams, Dixon, Orlikowski, & Leonard, 1998; DeLong & Fahey, 2000; Ewyk, 1998; Fang, Lin, Hsiao, Huang, & Fang, 2002; Hackett, 2000; IC2 Institute at the University of Texas at Austin, 2001; McAdam & Reid, 2001; Zyngier, 2001).

KM Strategy Development

KM literature describes many approaches to the development of a strategy or plan to be implemented as a means of achieving the organizational objectives of sharing tacit and explicit knowledge within the organization. Strategies are usually grounded in a theoretical methodology that will provide the greatest leverage in implementation (Zack, 1999), with each meeting perceived needs in the organization. There are two categories of strategies: deliberate and emergent strategies. Deliberate strategies must be articulated in a plan that must then be implemented. Emergent strategies are those that emerge in the organization as part of the process of learning what works well and what does not. Mintzberg (1994) suggests that strategic planning processes fail when they are not constructed to understand, internalise, and synthesise, that is, to learn from the successes or failures of the strategic process as it is implemented. In this sense, strategic planning would be a static and inviolate process. This is where the concepts of strategic approaches to KM are vulnerable unless the strategy is conceived of as a learning or evolutionary process. This being so, a KM strategy or plan is not rigid, but is an operational process that will enable learning and can evolve to take into account new and emerging environments within and outside the organization. KM obstacles lie not in the plan, but in the processes of control or regulation that surround the planning, implementation, feedback, and ongoing development of the plan. These processes are governance processes.

Governance Principles and Practice

There are a number of current contending uses of the term governance. In this article, governance refers to the governance processes of control or regulation within companies, interpreted as the implementation of authority through a framework that ensures the delivery of anticipated or predicted benefits of a service or process in an authorized and regulated manner (Weill & Woodham, 2003). This approach forms a context for analysis, management, risk management, and the ongoing development of strategies to manage organizational knowledge. It is also a means of developing measures of the effectiveness of those strategies. Governance will be affected by the composition of the membership of the governing body, the personal characteristics and history of the individuals involved, and the visions and principles enshrined in organizational structures and processes.

There are two main theories in the governance literature that relate to the purpose of the corporation and whose interests it should serve (Farrar, 2001; Van den Berghe & De Ridder, 1999). These are:

1. the shareholder model where the primacy focus of serving shareholder interest and value is the underlying philosophy or driver of governance, and cost minimisation and profit maximisation are paramount, and
2. the stakeholders model where the primary interest is on all stakeholders including the organization's owners or shareholders, creditors, employees, and the local communities in which the firm exists.

The stakeholders or consultative model may be considered a less managerially neat option due to the need to consult and reconcile conflicting interests; however, where decisions are made and endorsed by the majority of stakeholders, there is greater acceptance of decisions and activity around those decisions (Vinten, 2000).

In the stakeholder model, a greater contribution of decision making is expected at all levels. Internal stakeholder governance processes are not merely good management processes, but can also be viewed in terms of ensuring that a wide range of organizational needs are represented and being met. While to-date governance principles have rarely been applied to other managerial strategies, this approach is seen in the work of the IT Governance Institute (2001), the IT Governance Institute and COBIT Steering Committee (2000), and the British Standards Institution and Technical Committee (2002). The notion of IS and IT governance activity is already apparent as a subset of governance. This framework similarly facilitates the provision of feedback mechanisms within other managerial strategies to serve as a model of continuous improvement in organizational structures. Responsiveness to stakeholder interests enhances the capacity of the organization to identify and analyse a greater range of risks and to better deliverservices or products.

Governance is at the centre of the decision-making authority. It is a framework to deliver the expected benefits of investments in a controlled manner through the establishment of checks and balances in the mode of service delivery. It ensures that evaluation feeds back into the service delivery strategy, and that stakeholder needs and expectations are being met. This approach is echoed by Galliers' (1999) sociotechnical approach to business and IS strategy formations, and the management of organizational transformation that takes into account the organizational environment, business strategies and processes, and required infrastructure. He sees that implementation requires the allocation of responsibilities with clearly defined objectives, timescales, and performance measures. This is paralleled by ongoing evaluation and review, including long-term planning and perspective, and the recognition and accounting for consequential or emergent strategies.

Weill and Woodham (2002) propose that the design of governance mechanisms is constructed in the context of the competing operational, structural, and infrastructural forces that operate within a business in harmony with organizational objectives. A governance framework must understand how decisions are made in key domains. These domains are principles, infrastructure strategies, architecture and investment, and prioritisation. Thus, governance will concentrate on the relationships and processes that develop and maintain control over the infrastructure, and human resources utilized in order to deliver the service to the organization. It provides check and balance mechanisms that enable the decision-making processes and results in IT contributing as a value-adding function in service of the enterprise.

An emphasis on strategy, risk management, the delivering of financial value, and performance measurement indicates the ongoing management of best practice. Applied to organizational IT, it is suggested that "at the heart of the governance responsibilities of setting strategy, managing risks, delivering value and measuring performance, are the stakeholders values, which drive the enterprise and IT strategy" (IT Governance Institute, 2001, p. 10). This is not a linear mechanism, but it is intended to feed back both the positive and negative aspects of performance. These response mechanisms will in turn moderate and improve practice in addition to responding to the internal and external effects in the organizational environment.

FOCUS ON KM GOVERNANCE

The delivery of a KM strategy in an organization exists and provides services to meet the needs for the creation, dissemination, and utilization of tacit and explicit knowledge to fulfill organizational objectives. How this function is fulfilled is reflected in the timeliness of service delivery and the satisfaction levels of internal and also, potentially, external clients. The processes and principles that act as a framework for the examination, regulation, supervision, and revision of KM strategies are termed KM governance. Wiig (1997) described governance functions as those of the monitoring and facilitation of knowledge-related activities within the implementation process. There is little in the literature that separates descriptions of strategy implementation from the authority framework that governance provides. Knowledge management governance processes determine organizational knowledge-access conditions, quality maintenance, decision-making processes, and means for resolving KM obstacles.

Authority

KM governance can meet process objectives through the development of an effective understanding of the potential of KM within the organization, an effective understanding of the role of KM within the organization, and the alignment of KM with the value proposition and strategy of the organization. Finally, it also meets process objects through the regular review, approval, and monitoring of KM investments in infrastructure and in human resources. KM governance centres on the decision-making authority, an executive framework to deliver the expected benefits of the strategy. This can then be delivered in a controlled manner through the establishment of evaluation, measurement, and risk management in service delivery. It ensures that these processes feed back into the service delivery strategy, and that all stakeholder needs and expectations are being met. If they cannot be met, then the governance process will be able to establish the reason and resolution.

Risk Management

Governance processes manage the risks of KM to acknowledge and challenge the cultural issues, structural obstacles, and other relevant issues as they arise during the implementation and ongoing operation of the strategy. The management of these risks assists in their resolution and strengthens strategies to manage knowledge within the organization. The need for risk management in KM was formally indicated in 2001 (Standards Australia) with the need to identify the assets, risks, and controls associated with the implementation of strategy. Obstacles to the effective management of organizational knowledge include a management culture in the organisation that hinders KM with concomitant change-management issues. Additionally, the philosophy of knowledge management is often inadequately understood in the organisation, and conflicts of organizational priorities are problematic for the development and initiation of a KM strategy. For many organizations, the development of criteria for knowledge collection is difficult (Chase, 1997; Zyngier, 2001).

Risk management is a proactive strategy of analysis and aids in the anticipation of risks to the KM strategy before they arise (Standards Australia, 2003). By engaging with the risks, it becomes possible to develop a means of risk resolution. The resolution may require organizational change management, the provision of additional financial or infrastructural support, or a realignment of the original strategy in light of unforeseen or emergent activity within the organization. Risk management requires regular evaluation of the strategy and the organization that it serves.

Evaluation and Measurement

Governance in KM implies and demands deliberate consideration of the strategies in place in the long and medium term. KM governance processes incorporate evaluation and measurement in order to prove the value of practices, and to progress and develop existing practices. Governance mechanisms must maintain a collective knowledge of trends in industry, technology, and the corporate structural and social environment.

Evaluation looks at both successes of and obstacles to the implementation of a KM strategy. The evaluation of successes must take into account the contribution made to the aims and objectives of the organization. When the successes make a contribution, they should be continued. When they do not make a contribution, consideration should be given to their continuance. The evaluation of obstacles to the KM strategy implies the capacity to question why the risk may not have been foreseen and therefore managed. The evaluation of obstacles must take into account the barriers they create for the aims and objectives of the organization. When this is the case, can these ends be achieved utilizing an alternative solution or method?

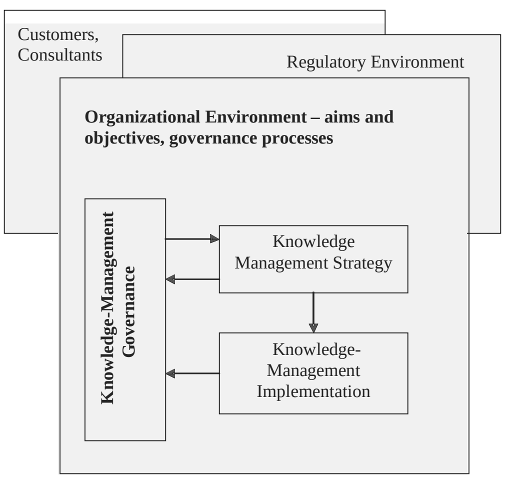
There are a number of criteria currently used to establish the return on investment (ROI) for KM strategies: Liebowitz and Wright (1999) look at human capital growth, Sveiby (1997) uses intangible assets, and some use the balanced scorecard (Kaplan & Norton, 1996) with a number of measures including financial, growth, customer, and internal business processes. Probst, Raub, and Romhardt (2000) look at the normative, operational, and strategic goals of the strategy to see if they are being met. Other common techniques include simple measures of staff retention or an improvement in the product-to-market delivery time, both in quantity, and in quality. If these are evident and are the only variance from usual practice, then the strategy is seen as successful.

A KM Governance Framework

KM literature deals with the need for the alignment of strategy with organizational aims and objectives, and for leadership of that strategy. This process is supported by information and communications technology and operates in the organizational context of the corporate governance principles. There is an explicit link between the market and the organization in its aims and objectives that lead to governance processes.

The governance framework presents the functions of KM as supporting the aims, objectives, and governance processes of the organization in the context of the broader environment of its external stakeholders, which includes its customers and consultants and the regulatory environment. The KM strategy is developed by KM leaders in the planning of a process of the identification, acquisition, development, sharing and distribution, utilization, and finally retention of knowledge (Probst et al., 2000; Tiwana, 2002). The practice of KM implementation follows with the execution of a course of action that is intended to fulfill the aims and objectives of the plan in order to support the aims and objectives of the organization as a whole. The relationship between the KM strategy and the KM implementation is in theory a unidirectional one where implementation is merely the following through of the strategic plan. In practice, this relationship may be more interactive as those responsible for the implementation may also have a level of responsibility for the development of the strategic plan. KM governance is the layer exercising the authority processes and principles that act as a framework for the examination, regulation, supervision, and revision of KM strategies.

Figure 1. Framework for KM governance



The KM strategy is developed by KM practitioners. The interaction between the development of strategy and governance is twofold. The governance process develops the principles and rationale for the impetus and momentum of the strategy, the management of risks, the financial control, and the accountability for stakeholder response. The governance process also evaluates KM activity according to previously defined and articulated performance measures.

The KM strategy is implemented or operationalized by KM staff, and supported and promoted by champions in the organization. The implementation of the strategy is evaluated according to the criteria established by the governance body. Evaluation will also take into account changes in product and customers, changes in the regulatory environment, and inputs from consultants or industry partners. It reflects the aims and objectives of the organization that it serves. The KM strategy is planned and may be revised as the need arises. The evaluation data flows from the KM implementation to the governance body, which then feeds its decision(s) back to the redevelopment of the strategy.

Companies that rely on or utilize KM for the transfer of strategic knowledge should work to establish KM governance committees including one for stakeholder representation. There are two fundamental objectives in this governance process. These are as follow:

- to ensure that KM delivers value to the identified stakeholders. This value is derived from the value proposition of the organization and the organizational strategies put in place to achieve those ends.
- to control and to minimise the risk to the KM strategy. The strategy must be capable of adjustments required in response to perceived flaws in its capacity to effectively transfer knowledge. A KM strategy is not a single prescribed formula that can fit all organizations or even fit organizations within a particular industry segment.

KM governance can meet the previous objectives through:

- the sponsorship of an effective understanding of the role and potential of KM within the organization,
- the alignment of KM with the value proposition and strategy of the organization,
- the regular evaluation review, approval, and monitoring of KM investments in infrastructure and in human resources, and
- the management of the risks of KM.

In acknowledging knowledge as the organization's strategic asset and differentiator, it can be seen that the ultimate responsibility of the KM governance process is to ensure the governance of KM as a means of pursuing success in the implementation of a KM strategy in the organization.

FUTURE TRENDS

KM governance is currently a subject of extensive research that has built the model described. Future research possibilities may lie in looking in depth at the interrelationships between governance and stakeholders, in evaluation and measurement, in risk-management techniques, and in authority over infrastructure and investments.

The governance model described was developed from research undertaken with Australian and global organizations (Zyngier, Burstein, & McKay, 2005). Future research possibilities may lie in testing this model and developing others in other operating environments.

CONCLUSION

Governance processes operate to manage the risks of KM to acknowledge and contend with the cultural issues, structural obstacles, and other relevant issues as they arise during the implementation and ongoing operation of a strategy. The management of these risks will assist in the resolution of such issues and in turn strengthen the strategies to manage knowledge that are employed within the organization. Acknowledging knowledge as the organization's strategic asset and competitive differentiator is not the ultimate responsibility of the governance process. The effective governance of KM may be a means of pursuing success. However, the governance of KM implies more than this. It implies and demands strategic thinking about the strategies in place for long-term and medium-term planning. Such strategies should not be regarded as linear in direction, but they should incorporate feedback both in the positive and negative aspects of the KM strategy that will in turn modify, progress, and develop existing plans and practices.

This article has outlined the theoretical framework of internal organizational governance and its application in strategies to manage organizational knowledge for the implementation of those strategies. Governance functions operate to ensure that KM delivers value to the identified stakeholders and provides a control mechanism to minimise risks to the successful implementation of a KM strategy. The governance framework given for these processes and practices may better enable an effective and coordinated outcome for KM strategies that ensures the delivery of anticipated benefits in an authorized and regulated manner.

Chapter 5.21
Human Resources and Knowledge Management Based on E-Democracy

Niki Lambropoulos
Intelligenesis Consultancy Group, UK

ONLINE RESEARCH AND E-DEMOCRACY

Correspondence between everyday and scientific life is a blessing (Warren & Jahoda, 1966). Although virtual communities are nowadays widely expanded, research online is not fully developed yet, as methodological approaches are not designed specifically for online research. In addition, the results from the evaluation and the reports do not find an immediate space of use. As such, the researchers use methodologies that deal with online situations borrowing methods and techniques from the "real" ones. Although the adaptations have the same principles, there are limitations due to the virtual nature of the research. In addition, multi-disciplinary approaches characterize virtual communities as different fields interact, such as learning approaches, psychology of the individual and the masses, sociology, linguistics, communication studies, management, human computer interaction and information systems. As a result, there is no methodology that, solely used, could bring results for adequate evaluation and implementation of the results in the community. Due to this complexity, we suggest Real Time Research Methodology based on Time-Series Design to study process-based activities; Focus Groups Methodology and Forum Messages Discourse Analysis as two of the most vital parts in the use of a multi-method. The other parts will depend on the nature and culture of the selected virtual community. Both focus groups (FG) and Forum Messages Discourse Analysis are referred as Extraction Group Research Methodology, or X-Groups. The reason for using X-Groups is the actual implementation of members' suggestions into their environment as an interaction into an immediate space of use.

X-GROUPS METHODOLOGY

The individualistic bias of the researcher can be partially overcome by research methods that either engage with people in the social contexts of their lives (such as participant observation) or by questioning them collectively (as in discussion groups of various kinds) (Livingston, 2000). We suggest the wide use of FG of experts as the first approach that has the potential to deliver useful results from the users for the users in virtual communities. FG spring from the active members identifying the important actors based on social network Analysis. FG are contrived settings, bringing together a specific sector to discuss a particular theme or topic, where the interaction within the group leads to data and outcomes (Cohen, Manion, & Morrison, 2000). The reliance is on interaction within the group who discuss a topic (Morgan, 1988), and it is from the interaction of the group that the data emerge. In virtual communities' research-contrived nature, which, according to Cohen et al. (2000), is a limitation, is not so here because the nature of the group is completely natural. As such, FG discussions could be economical in time, yield insights for the discussion topic, have practical and organizational advantages, and bring people together with different opinions or different collectives. In addition, they produce a large amount of data; develop, generate and evaluate the produced data; and gather feedback simultaneously. A strategic plan is needed to identify the actors, the common context and the shared vision to result in a successful intervention. The actors are the individuals who meet the objectives for virtual communities and are able to recognize, deliver new ideas and contribute to the community development and evolution. Extraction of both individuals and data gave the name to the methodology as X-Groups. Following the same democratic principle in X-Groups methodology, patterns recognition, tags and codes are suggested to derive members' suggestions from a pilot study before the main study. The pilot will give the basic tree of tags in order to code the main study towards the ultimate goal of construction of reports based on FG suggestions. X-Groups head toward articulation of a collective reality that encompasses individual views, problems and underlying causes of the problems and solutions, as suggested by the members of the studied community.

X-Groups use Real Time software that has the potential to provide valuable help and economy of time for both the identification of actors and their suggestions. The systemization of the results and the construction of a skeleton could be conducted supporting both the inductive (looking for patterns and associations) and deductive (propositions reached hypothetically) extractions. Research methods borrowed from sociology and software such as "netminer" for Social Network Analysis (SNA) can give the map with the actors and their activities. "ATLAS.ti" for Discourse Analysis (DA) could assist with the identification of tags and code-trees as well as the identification, extraction, indexation and categorization of members' suggestions. Unfortunately, nowadays software for knowledge management is still in a primitive stage, with limited semantic search and automatic indexation. As such, there are two levels of identification and assessment:

1. SNA and DA on the virtual communities level for FG identification and all members suggestions
2. SNA and DA on the FG level for FG suggestions.

The results would portray the souls of the organization and common visions.

IDENTIFICATION OF ACTORS VIA SNA

Following Shneinderman's (1998) concept on information visualization, the decision was made on the use of SNA as it depicts social relationships between a set of actors (Baroudi, Olson, & Ives, 1986). One of the goals of SNA is to visualize communication and relationships between members through diagrams. Following Zaphiris, Zacharia and Rajasekaran (2003), SNA is backed up by social sciences and strong mathematical theories such as graph theory and matrix algebra, which makes it applicable to analytical approaches and empirical methods. SNA uses two approaches; namely, ego-centered analysis and whole-network analysis. In ego-centered analysis, the focus is on the individual rather than on the whole. SNA uses various concepts to evaluate different network properties (Baroudi et al., 1986), such as centrality, the assessment of the power of an actor based on the number of alters that actor is directly connected to, connectivity and cliques. A clique is a subset of actors in a network who are more closely tied to each other than to the other actors who are not part of the subset. Comparison of the graphs illuminates members' roles in the communities in order to identify their interests and their areas of best practice. We used a GUI-based SNA tool called Netminer for Windows. Cyram NetMiner II is an innovative software tool for exploratory network data analysis and visualization. It provides visualization of the social network structures and positions of actors within the network using sociograms, which are graphs with nodes and lines for actors and ties respectively (Netminer, 2003). An example is provided from a study on an online community of online community managers. The degree in Figure 1 (Freeman, 1979) refers to the number of ties to others in an adjacency matrix. There were 47 nodes from 26 participants. Cindy, Rebecca, Chris and Ewan seemed to receive more responses in both Figures 1 and 2. Chris sent only one message, but this message created lots of objections and suggestions.

Centrality in SNA is a structural attribute of nodes in a network and their structural position in the network. It is a measure of the contribution of network position to the importance, influence and prominence of an actor in a social network.

Figure 1. Discussion network nodes

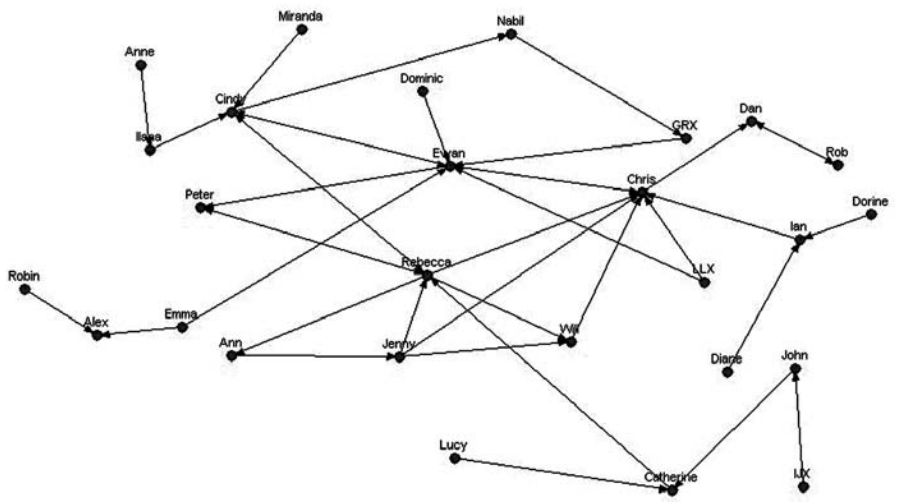

Figure 2. Information centrality

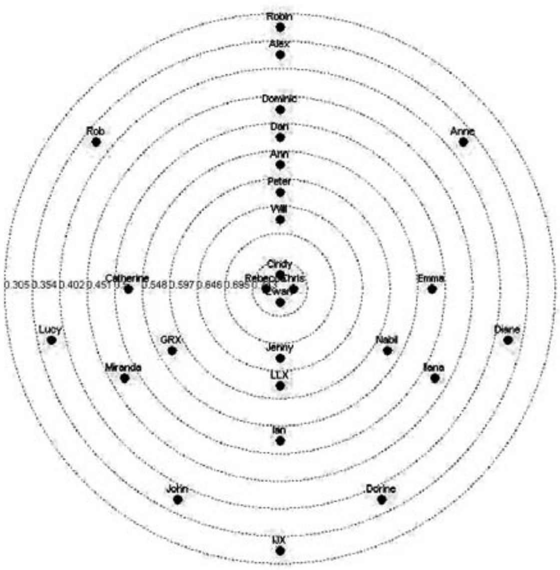

Centralization refers to the extent to which a network revolves around a single node.

The previous four members appear in the center of the activity. Comparisons between graphs could maintain the reliability degree for the selection of actors based on their input in the community. In this study, FG members were selected up to the 5th circle in Figure 2. The number of members is defined by their input in the community and could be limited to the 1st or 2nd circle. Then FG discuss critical issues for a specific period of time (e.g., one week). The next section is mainly centered on Focus Groups Discourse Analysis, as the second stage of the Centrifugal Design for knowledge management and human resources.

IDENTIFICATION OF SUGGESTIONS VIA FORUM DA (DISCOURSE ANALYSIS)

After FG identification and FG discussion, DA for content analysis can be used to identify meaningful material. FG discussions' extractions on critical issues are highly dependent on the context, taking into consideration that "the conventional meaning of an utterance was but a stage of its interpretation" (Sinclair, 1992, p. 79). DA using innovative software based on semantic text extraction and information indexation could provide a basic structure of descriptions, problems, suggestions and ideas. With the advent of such a tool, organizations will be able to automatically educe metadata, contextual meaning and relationships between data. ATLAS.ti software for qualitative analysis handles large bodies of textual, graphical, audio and video data, and offers a variety of tools for accomplishing the tasks associated with any systematic approach to unstructured data; for example, data that cannot be comprehensively analyzed by formal, statistical approaches. The role of the researcher is crucial, so in order to limit subjectivity and due to the absence of suitable software, more than one researcher could work on the same data and compare their findings (Oriogun & Cook, 2003).

DA refers to the analysis of all forms of spoken interaction and all written texts, is concerned with the function of language and its uses for a variety of consequences, considers the way in which language is both constructed and constructive, and recognizes that the same phenomena can be described in different ways (Potter & Wetherell, 1987). Potter and Wetherell insist that DA cannot be readily contained within a fixed methodology. Similarly, Burr (1995) refers to DA as an approach rather than a method. Computer-Mediated Discourse Analysis approach (CMDA) (Herring 1999) is drawing theoretical assumptions from linguistic discourse analysis. “At its core is the analysis of logs of verbal interaction (characters, words, utterances, messages, exchanges, threads, archives, etc.)” (Herring, 2004). It is based on four levels of language interchange: (a) structure: structural phenomena include the use of special typography or orthography, novel word formations and sentence structure, (b) meaning: meanings of words, utterances (e.g., speech acts) and larger functional units, (c) interaction: turn-taking, topic development and other means of negotiating interactive exchanges, and (d) social behavior: participation patterns (as measured by frequency and length of messages posted and responses received).

Turn-taking and time lag in spoken communication is absolutely linear, whereas CMC exhibits numerous violations of both the “no gap, no overlap” principle and the principle of orderly turn alternation (Herring, 1999). As such, Figure 3 is mostly based on Herring et al. (2004), who draw on Bauer’s (2000) useful distinction in content analysis between “syntactic” (structural) and “semantic” phenomena. This maps the content analysis framework (Figure 3).

Extraction of both structural and, in particular, semantic issues could be investigated, recorded and used towards Centrifugal Decision Making and e-democracy by specifying both employee and knowledge updates. Having in mind the limitations of DA, it is an attempt to reveal useful insights to what is presented as fact or common sense and be restricted to the internal working of the text.

Figure 3

DISCOURSE ANALYSIS SEARCH
Keywords and Themes (recurrent terms, concepts)
Compare and contrast Identify ideas and representations (associations, mobility, implications)
Variation in text
Brakes, hesitations, inconsistencies, contradictions
Consistency with and between texts
Intertextuality (repetition of keywords and phrases)
Emphasis and detail
Rhetorical devises used Alliteration Metaphors Taking for granted notions
Deixis
The use of words that make reference to the situation (now, we this etc)
Modality
Judgement (might, regret, correct, right etc)
Online text indications
Use of specific online symbols such as emoticons, stress of text using capital letters, incomplete sentences, dots and dashes, nick names etc
Expression of Feelings
Use of text, symbols, phrases etc for expression of feelings

As a result, reports can be written and proposals could be taken into account from the directors and managers. In our study, the online community managers FG provided specific structures, mechanisms and suggested tools for community organization and online groupz-ware.

CONCLUSION

X-Groups methodology—together with other methodological approaches or solely used—has the potential to provide human potential recognition, skills profiles, staff assessments and training requirements, as well as identify common problems, needs and visions, gaps in communities' policy and updates directly to the knowledge base. Innovative software that will be able to implement X-Groups philosophy could limit subjectivity. We cannot be responsible citizens unless we make our voices heard. Science and technology can enhance e-democracy and help us shout out loud at this crucial moment for humanity. Then, the question that arises is, "Can we survive the process, recognise our own potential and take the responsibility to add our brick on the wall?"

Chapter 5.22
Integration of Knowledge Management and E-Learning

Dongming Xu
University of Queensland, Australia

Huaiqing Wang
City University of Hong Kong, Hong Kong

INTRODUCTION

Knowledge management (KM) and e-learning are two concepts that address the requirements of lifelong learning. Over the past several years, there has been an increasing focus on the integration of knowledge management and e-learning systems. By 2003, 70% of organizations implementing knowledge management were linking it with e-learning technically and organizationally (Gartner, 2000). The integration of knowledge management and e-learning enables the creation of great synergies in organizations and business applications. In this article, these two concepts will be presented and their integration will be discussed in detail.

BACKGROUND

E-learning has its historical roots in more than 30 years of development of computer-supported education. The past decade, in particular, has witnessed a dramatic increase in the development of technology-based teaching and learning (Alavi & Leidner, 2001a). E-learning is an instructional process that gives online learners access to a wide range of resources—instructors, learners, and content such as readings and exercises—independently of place and time (Zhang & Nunamaker, 2003). It represents the conscious learning process where objectives and domains are clearly defined, and the focus is set to individual online learner perspectives and demands. Effective and efficient e-learning methods are generally required to ensure that online learners are equipped with the latest knowledge in a timely manner. The previous research has proposed a framework in which e-learning effectiveness is affected by two major components: the human dimension and the design dimension in virtual learning environments (Piccoli, Ahmad, & Ives, 2001). The technology in this framework is geared toward providing effective e-learning. For example, content management is one of the factors in the design dimension, which includes factual knowledge, procedural knowledge, and conceptual knowledge, that has a positive relationship with e-learning effectiveness. The design of interaction enhances the knowledge sharing among learners, and between learners and the instructor.

In contrast to traditional classroom learning, e-learning has several advantages for learners, such as time and location flexibility, relatively cost and time savings, learner-controlled instruction, unlimited access to electronic learning materials, and flexible collaboration between instructors and learners. The previous research has shown that learners benefit from using a variety of e-learning systems. Many e-learning systems present instructional material in a static, passive, and unstructured manner, and give learners little control over the learning content and process. The adaptive e-learning systems integrate knowledge management activities into their e-learning architectures and provide online learners with tailored instruction.

Individuals and groups learn by understanding and then acting, or by acting and then interpreting (Crossan et al., 1999). The process of change in individual and shared thought and action, which is affected by and embedded in the institutions of the organization, is called organization learning (Vera & Crossan, 2003, pp. 122-141). When individual and group learning becomes institutionalized, organizational learning occurs, and knowledge is embedded and created in non-human repositories such as routines, systems, structures, culture, and strategy (Hardaker & Smith, 2002; Crossan et al., 1999).

Knowledge management (KM), on the other hand, has been developed within the business context. The recent interest in organizational knowledge has prompted the use of knowledge management in order to process and manage the knowledge to the organization's benefit (Alavi & Leidner, 2001b). Knowledge management outcomes fall into three main categories: knowledge creation, retention, and transfer (Argote et al., 2003). Knowledge creation occurs when new knowledge is generated in an organization. Knowledge retention involves embedding knowledge in a repository so that it exhibits some persistence over time. Knowledge transfer is evident when experience acquired in one unit affects another. These three categories are closely related.

Lee and Choi (2003) proposed a research framework for studying knowledge management such that the synergy of information technologies, as one of the knowledge management enablers, is positively related to the knowledge management process. Information technology affects knowledge creation in a variety of ways, such as in knowledge sharing, storage, and knowledge flow. Therefore, knowledge management systems are used to rapidly capture, share, organize, and deliver large amounts of corporate knowledge. Knowledge management systems refer to a class of information systems applied to management of organizational knowledge. They are developed to support knowledge management processes in terms of knowledge creation, storage/retrieval, transfer, and application (Alavi & Leidner, 2001b).

Knowledge management processes, also called knowledge management activities—form a structured, coordinated system for managing knowledge effectively (Becerra-Fernandez & Sabherwal, 2001). Table 1 illustrates knowledge management processes and the potential roles of information technology (IT). For instance, knowledge creation can be achieved through learning tools, such as e-learning systems. Knowledge can be stored/retrieved in/from e-learning sys-

Table 1. Knowledge management processes and the potential roles of IT (Alavi & Leidner, 2001b)

Knowledge Management Process	Knowledge Creation	Knowledge Storage/ Retrieval	Knowledge Transfer	Knowledge Application
Supporting Information Technologies	Data mining Learning tools	Electronic bulletin boards Knowledge repositories Database	Electronic bulletin boards Discussion forums Knowledge directories	Expert systems Workflow management
IT Enablers	Combining new sources of knowledge Just-in-time learning	Support of individual and organizational memory inter-group knowledge access	More extensive internal network More communication channels available Faster access to knowledge sources	Knowledge can be applied in many locations More rapid application of new knowledge through workflow automation
Platform Technology	Groupware and communication technologies			
	INTRANETS			

tem repositories and electronic bulletin boards. Discussion forums and electronic bulletin boards provide knowledge transfer between learners, and course management and content management can be viewed as knowledge application in e-learning environments. Schwartz et al. (2000) stated that knowledge acquisition, distribution, and storage are highly correlated and can fruitfully influence each other. Knowledge acquisition deals with the issues that surround knowledge extraction in its various forms; knowledge distribution tackles the problem of getting the right knowledge to the right place at the right time (Schwartz & Te'eni, 2000), and knowledge storage undertakes the knowledge repository. Knowledge management is a learning process than requires a continuous re-evaluation of the way knowledge is acquired, organized, and delivered (van der Spek & Spijkervet, 1997).

KNOWLEDGE MANAGEMENT ENABLERS AND KNOWLEDGE MANAGEMENT PROCESSES IN E-LEARNING

The integration of knowledge management and e-learning is an elaboration of knowledge management systems and e-learning systems. Knowledge management could be a cornerstone of e-learning. Effective e-learning leverages traditional e-learning technology such as computing, communication, and multimedia technologies, and knowledge management to create learning environments that can be richer and more flexible, scalable, and cost effective than the standard classroom or lecture hall (Piccoli et al., 2001; Becerra-Fernandez & Sabherwal, 2001). Therefore, e-learning systems integrating with knowledge management are designed to support the rapid capture, delivery, and measurement of knowledge in a Web-based fashion. They are designed to consider online learners' attributes and instructional strategies to provide adaptive, learner control and collaborative e-learning environments, and to thereby maximize e-learning effectiveness.

Recent knowledge management developments enable the education community to provide high-quality multimedia content via the Internet, keep track of online learner activities, or support long-distance communication and cooperation. These developments cover the complete cycle of teaching and learning and its many functional aspects. Based on Lee and Choi's (2003) research framework, an e-learning system is considered to be one knowledge management enabler that provides the infrastructure necessary for the e-learning organization to increase the efficiency of knowledge processes. However, from a broader point of view, the knowledge management enablers and the knowledge management processes in e-learning are correlated at different levels. Knowledge storage and retrieval are classified in one knowledge management process in the previous research (Alavi & Leidner, 2001b). In this article, knowledge storage and knowledge retrieval are divided into two separate processes due to the sequence of the knowledge management process. The knowledge storage process normally

Table 2. Relationship between KM enablers/techniques and KM processes in e-learning

		Knowledge Management Processes in E-Learning				
		Knowledge Creation	Knowledge Storage	Knowledge Retrieval	Knowledge Transfer	E-Learning Application

	Evaluation Management	+	+	+	+	++
	Interaction/Collaboration	++	+	+	++	+

Note: - less related; + correlated; ++ highly correlated.

occurs at an earlier stage, while the knowledge retrieval process occurs at a later knowledge management stage.

An e-learning environment includes the following five knowledge management enablers: content management, course management, administration/operation, evaluation management, and interaction/collaboration. They are correlated with the knowledge management process in different ways and at different levels, summarized in Table 2. For instance, knowledge creation is highly correlated to interaction/collaboration, but less correlated to the administration and operation functions. This indicates that interaction/collaboration as a knowledge management enabler has a very positive impact on the knowledge creation process, but the administration/operation function has little or no impact on knowledge creation. One may also conclude that these five enablers have positive effects on e-learning applications of different magnitudes.

The classification and definitions of these five knowledge management enablers in e-learning are described below.

- Content Management: The American Productivity & Quality Center (APQC, 2001) defines content management as "a system to provide meaningful and timely information to end users by creating processes that identify, collect, categorize, and refresh content using a common taxonomy across the organization." Content management covers pedagogical, psychological, and didactic issues, as well as technical questions. It is a major component of knowledge management. Nearly all relevant e-learning environments offer rich content management functionality. Content management enables the knowledge storage process and the e-learning application process.
- Course Management: This includes the ability to share materials and modules across e-learning systems; the ability to edit, comment, and track changes on learners' documents; and the ability to monitor and access learners' e-learning performance. In short, course management offers instructors the ability to electronically maintain and manage class rosters, distribute course materials, administer online exams, and communicate with learners. Course management enables the knowledge creation process.
- Administration and Operation: Administration includes user management, administration of access rights, and all aspects of operation. Administration and operation enable the knowledge retrieval and knowledge transfer in e-learning.
- Evaluation Management: Self-evaluation can foster effective learning and implement a high degree of learning control. Evaluation management is used to guide learners' e-learning and build their knowledge, and to verify if the information is successfully turned into knowledge. In order for e-learning to be proven effective, learners need to verify that they have succeeded in gaining new knowledge or skills. During this phase, the relationship between information and knowledge becomes visible with respect to e-learning.
- Interaction/Collaboration: This supports communicating and collaborating between learner, the systems and organizations, as well as among learners as a pedagogical technique. Interaction and collaboration provide rich functionalities for knowledge sharing, creation, and transfer.

FUTURE TRENDS: INTEGRATING KNOWLEDGE MANAGEMENT AND E-LEARNING

Over the past several years, there has been an increasing focus on the integration of knowledge management and e-learning systems. Both e-learning and knowledge management share a similar focus: how to enhance human knowledge and its use within organizations. Professionals in both fields are increasingly looking for ways to integrate them in order to manage knowledge. The practice of knowledge management has adopted a number of different technologies, from low-tech e-mail to sophisticated, intelligent searches and extended enterprise analytical tools. Whatever the technology, the objective of such adoption is the same: to capture, store, retrieve, and distribute knowledge from internal and external sources, and build upon the intellectual knowledge wealth inherent in the organization. Knowledge management, in general, addresses more of the unintentional, indirect, but continuous learning process. The integrating of e-learning and knowledge management presents exciting opportunities for e-learning systems development and targeted learning based on lifelong learning needs.

Different terminologies have been used for e-learning (Sloman, 2002). Therefore, e-learning environments will be analyzed and classified further. The analysis is based on three main functional dimensions of e-learning systems—collaboration, adaptivity, and learner's control level from low to high—for a particular e-learning system. Combinations of these three dimensions generate eight different scenarios, which show the evolution of e-learning historically, as shown in Figure 1.

In the early days of e-learning, Hypertext Books, Computer-Assisted Instruction (CAI) systems, Communications (CMC), and Group Systems (GSs) were introduced to online learners. These e-learning environments provided online learners with access to up-to-date, relevant learning materials, and the ability to communicate with experts in the field in which they were studying in a very rigid manner. Along with the continuing evolution of information and communication

Figure 1. Evolution of e-learning

ILE: Interactive Learning Environment

GS: Group System

technologies, Virtual Learning Environments (VLEs), Intelligent Tutoring Systems (ITSs), Intelligent Computer-Assistant Instruction (ICAI) systems, Adaptive Instructional Systems (AISs), Interactive Learning Environments (ILEs), and Adaptive Virtual Learning Environments (AVLEs) are developed, Those e-learning environments are making improvements to give online learners more flexibility in their e-learning in terms of collaboration, adaptivity, and learner control to overcome one-size-fits-all instruction, and to provide contextual and adaptive supports for e-learning.

This e-learning evolution framework is proposed based on the analysis of eight scenarios integrating increasing amounts of knowledge management into an e-learning environment (Figure 1). Levels of collaboration, the adaptive learning process, and learner control are measurements used to classify these eight scenarios. As an example, the Hypertext Book-based e-learning systems correspond to a low degree of collaboration, a low degree of adaptivity, and a low degree learner control. On the other hand, the Adaptive Virtual Learning Environments (AVLEs) correspond to a high degree of collaboration, a high degree of adaptivity, and a high degree of learner control. The higher level of collaboration provides better knowledge management processes in terms of knowledge creation, storage, and transfer. Higher levels of the adaptive learning process also have greater impact on the knowledge management process, and higher learner control gives the learner more power to engage in knowledge creation and sharing. Therefore, with the evolution of knowledge management integrated into e-learning environments, AVLE illustrates the future trend of e-learning, which provides adaptive components to personalize learning instruction and match with each learner's individual cognitive capability in order for knowledge construction to occur.

Table 3 presents the integration relationship among knowledge management processes in e-learning within eight scenarios of e-learning environments. It has been clearly identified

Table 3. The integration relationships between KM processes and e-learning systems

		Hypertext Book	CAI	ITS & IEL	AIS	CMC & GS	ICAI	VLE	AVLE
Knowledge Management Process in E-Learning	Knowledge Creation	–	–	+	+	+	+	+	++
	Knowledge Storage	–	+	+	+	–	+	+	+
	Knowledge Retrieval	–	+	+	+	–	+	+	+
	Knowledge Transfer	–	–	+	+	+	+	+	+
	Application	–	+	+	+	+	+	+	++

Note: - less related; + correlated; ++ highly correlated.

that Hypertext Book systems involve very few knowledge management processes. In contrast, the knowledge management processes are well integrated in Adaptive Virtual Learning Environments. Firstly, the knowledge creation process is highly integrated with the AVLEs. Most AVLEs have a "Just-In-Time" e-learning facility, which is an important IT enabler in the knowledge creation process. Some advanced AVLEs have data mining and reasoning capabilities, which are used to help learners analyze their learning performance. Also, the knowledge retrieval process plays an important role in AVLEs, where the contents are retrieved adaptively, based on different individual learners' dynamic situations. Another important knowledge process in AVLEs is knowledge transfer. The communication channels in AVLEs allow learners to publish their opinions and ideas, to access knowledge resources, and to discuss their opinions. For this reason, AVLEs have been attracting more and more attention from educational professionals and development professionals due to their advanced knowledge management facilities and its e-learning effectiveness. In general, the more an e-learning system is integrated with knowledge management processes, the better the learning effectiveness is that can be achieved.

CONCLUSION

E-learning and knowledge management are of increasing importance in this "knowledge economy," and lifelong learning issues will be of continuing significance. Although the integration of e-learning and knowledge management is in its early stage, there are numerous signs of the coming integration that will provide online learners with adaptive e-learning environments. This article has addressed the integration of knowledge management and e-learning to improve the capture, organization, and delivery of corporate knowledge in e-learning. Based on the analysis of knowledge management enablers and knowledge management processes in e-learning, the relationships of these two dimensions are shown in Table 2.

Furthermore, the evolution of e-learning systems has been examined, and eight scenarios have been identified, as shown in Figure 1. Analysis of these eight scenarios helps us to better understand the integration of knowledge management, and to predict the future trends of e-learning systems.

Finally, the integration relationship between knowledge management processes in e-learning and the eight scenarios of e-learning environments is presented in Table 3. The conclusion may be drawn that an e-learning system designed to have a higher level of collaboration, adaptive learning processes, and learner control should better integrate the knowledge management processes. With a higher level of knowledge management integration,, e-learning systems will have more opportunities to achieve e-learning effectiveness.

The proposed relationships in this article between knowledge management enablers and knowledge management processes in e-learning, and between knowledge management processes and e-learning systems, can be viewed as a framework for the integration between knowledge management and e-learning. Such a framework could be very useful for further research, as well as for practitioners in real-world application development.

Chapter 5.23
The Political Economy of Knowledge Management in Higher Education

Amy Scott Metcalfe
The University of British Columbia, Canada

ABSTRACT

In this chapter, I discuss the economic and political implications of knowledge management in higher education. First, I examine the linkages between KM and capitalism, with the help of theoretical frameworks that connect increasing managerialism in higher education with the promises of profit-making in the New (Knowledge) Economy. Next, I discuss the politics of information and the ways in which knowledge is stratified in postsecondary institutions. Third, the social dynamics of information and communications technologies (ICT) are explored in the context of higher education institutions. These perspectives provide a counter-balance to the decidedly functionalist views of much of the knowledge management literature. The intent of the chapter is to provide a foundation for the rest of the volume and the more specific studies of KM in higher education to follow.

INTRODUCTION

As the external environment increased pressure upon institutions of higher education to become more productive and business-like, it is not surprising that business management techniques are promoted as the best vehicles for change (Ewell, 1999). In the Information Age, the management techniques that have been the most popular in the private sector pertain to e-business, the art of combining the marketplace with high technology and opportunities provided by the Internet. E-business initiatives are also becoming common in higher education, with Web-based portals linking academic units to shared databases and common business rules (Katz et al., 2000). Distance education courses are hosted on the World Wide Web, and "e-learning" has become standard jargon in the field. Academic managers have embraced information technology since the age of the mainframe computer, which has resulted in the development of techno-centric institutional infrastructures, electronically-driver business cores, and wired classrooms in colleges and universities throughout the industrialized world.

Ushered into academe on the heels of information technology and institutional restructuring, knowledge management promises to lead to better decision-making capabilities, improve academic services, and reduce costs (Kidwell, Vander Linde, & Johnson, 2001). KM is often loosely defined, but its central purpose is the action of "transforming information and intellectual assets into enduring value" (Kidwell et al., 2001, p. 3). Founded on the notion that "intellectual capital" is a hidden asset of many businesses, KM seeks to bring this essential knowledge to light in order to make organizations more competitive. In the arena of higher education, KM is being touted as a method that will increase institutional innovation (Lyman, 2000). Getz, Siegfried, and Anderson have stated that, "higher education occupies a strategic role in productivity growth, not only because it is an industry itself, but also because it is a source of new ideas and trains the managers that affect productivity throughout the economy" (Getz, Siegfried, & Anderson, 1997, p. 605). It is in this context that KM proponents have noted that the absence of KM principles in higher education is a striking oversight (Serban & Luan, 2002).

Colleges and universities are obvious sites to explore the implementation of knowledge management (KM) principles in the public sector, given the historic connections between academe and the production of knowledge. While the creation and dissemination of knowledge has long been the social role of colleges and universities, recent neoliberal shifts in the political climate have led to legislative and private sector demands for evidence of a return on investment for public expenditures to higher education. As state support for postsecondary education dwindles, more attention is paid to "productivity" measures and ways in which institutions are maximizing public and private investments. Institutional research offices have been at the core of the data collection efforts. An increase in the use of information technology has provided more opportunities to measure and codify the production capacities of higher education institutions, from the learning mission to research output. Data points such as graduation rates, expenditures per student, faculty/student ratios, the cost to raise a dollar, grant revenues received, patents granted, and other factoids are collected, contextualized, and distributed by academic institutions to their public and private constituents. Thus, the information gathered and evaluated is used to determine financial aid formulas, institutional rankings, state appropriations, and other important "knowledge-based" decisions that affect higher education.

Recently the principles of KM have been applied to academic settings to help in these efforts. As an outgrowth of the data-gathering opportunities afforded by the widespread adoption of information technology (IT), KM is wedded to the technological infrastructures of modern organizations. Therefore, issues of access to and control over IT systems and the social power differential between those who are the "monitored", those who are the "users", and those who are the "managers" of technology are inherent to KM implementation, regardless of the size and type of organization where it occurs. Academic labor and its products have been traditionally shaped by professional norms and peer-review, but a shift toward technocratic decision-making in an environment marked by academic capitalism (Slaughter & Leslie, 1997; Slaughter & Rhoades, 2004) has permitted new value systems to prevail. In such an organizational climate, the intellectual capital that was previously considered a public good is now a "knowledge asset" that has the potential to increase institutional legitimacy and to provide new revenue streams. Knowledge management, as it has been defined and shaped by the private sector, is thus being employed in the public sphere in order to "capture" these assets and codify them into tangible objects with market value. However, academic managers who employ KM techniques do not have to adopt business values that promote the commoditization of knowledge for profit. This book offers an alternative expression of ideas and case study evidence to encourage a more thorough exploration of the uses of KM in higher education.

In this chapter, I discuss the economic, political, and social implications of knowledge management in higher education. First, I examine the linkages between KM and capitalism, with the help of theoretical frameworks that connect increasing managerialism in higher education with the promises of profit-making in the New (Knowledge) Economy. Next, I discuss the politics of information and the ways in which knowledge is stratified in postsecondary institutions. Third, the social dynamics of information and communications technologies (ICT) are explored in the context of higher education institutions.These perspectives (economic, political, and social) provide a counter-balance to the decidedly functionalist views of much of the knowledge management literature. The intent of the chapter is to provide a foundation for the rest of the volume and the more specific studies of KM in higher education to follow.

THE ECONOMICS OF KNOWLEDGE MANAGEMENT

The ability to produce and consume information and knowledge products situates the field of knowledge management in a capitalist cycle, and therefore dimensions of power and inequality are inherent in the application of this (or any) managerial schema. From an economic standpoint, information and knowledge are commodities, either exchanged for free in the gift economy market (Lessig, 2001) or for a price in the consumer market. Thus, even when KM is used in non-profit settings, the ability to profit from the capture and diffusion of information and knowledge is embedded in the best-practices and technical infrastructures that were created for the business context. Further, as colleges and universities move closer to private-sector behaviors and values as described by acadmic capitalism theory (Slaughter & Leslie, 1997; Slaughter & Rhoades, 2004), opportunities for the influx of business strategies into higher education institutions increase. For these reasons, we must begin to understand how market principles affect the implementation of knowledge management in the public arena. In addition, I will introduce the theory or academic capitalism, describe the increase in managerialsim in academe, and explore the ways in which higher education institutions are intertwined with digital capitalism.

Academic Capitalism

Academic capitalism is a term used by Slaughter and Leslie (1997) to describe the market-like behaviors of higher education organizations. They noted that the production of human capital is one of the more important functions of higher education in modern society. They stated that:

Universities are the repositories of much of the most scarce and valuable human capital that nations possess, capital that is valuable because it is essential to the development of the high technology and technoscience necessary for competing successfully in the global economy. The human capital possessed by universities, of course, is vested in their academic staffs. Thus the specific commodity is academic capital, which is not more than the particular human capital possessed by academics. This final step in the logic is to say that when faculty implement their academic capital through engagement in production, they are engaging in academic capitalism. Their scarce and specialized knowledge and skills are being applied to productive work that yields a benefit to the individual academic, to the public university *they serve, to the corporations with which they work, and to the larger society. It is indeed academic capitalism that is involved, both technically and practically. (pp. 10-11)*

Central to their analysis was the use of resource dependency theory, as outlined by Pfeffer and Salancik (1978). Resource dependency theory describes the ways in which organizations become dependent upon other organizations through resource allocation. Pfeffer and Salancik list three factors used to determine the extent of dependence: the importance of the resource and its criticality to organizational survival, organizational discretion over the allocation of the resources in question, and the presence or absence of alternative resources (Pfeffer & Salancik, 1978, pp. 45-46). Slaughter and Leslie noted that "national and state/provincial restriction of discretionary resources created increased resource dependence at the institutional level, causing institutions and professors to look to alternative revenue sources to maintain institutional income" (Slaughter & Leslie, 1997, p. 64). While resource dependence largely defines organizational behavior as reactive to external forces, it has also been applied to help understand intraorganizational power relationships (Salancik & Pfeffer, 1974).

The theory of academic capitalism was further developed by Slaughter and Rhoades (2004), who posited that the shift toward market-like behaviors in academe is an outgrowth of the New Economy. Slaughter and Rhoades noted the linkages created among individuals working in academic settings and in industry, realizing that these relationships are far more complex and mutually supportive than resource dependency is able to describe. They conceptualized that:

The theory of academic capitalism focuses on networks—new circuits of knowledge, interstitial organizational emergence, networks that intermediate between public and private sectors, extended managerial capacity—that link institutions as well as faculty, administrators, academic professionals and students to the new economy. Together these mechanisms and behaviors constitute an academic capitalist knowledge/learning regime. (p. 15)

Interestingly, the interpersonal and interorganizational networks noted by Slaughter and Rhoades are enhanced by information and communications technologies. These ICT networks, which form the basis for the academic capitalist knowledge/learning regime, are sources of data for knowledge management. When the human capital of faculty, administrators, academic professionals, or students is transferred to a digital environment, it can be measured and commodified by the organization through the use of KM principles in order to achieve competitive advantage and increased revenue at the institutional level.

Academic Managerialism

While academic capitalism theory provides a lens through which to understand the changing relationship between academe and the marketplace, other perspectives can be utilized to better comprehend the shifts in the internal division of labor within higher education institutions. The changes brought about by the New Economy affect more than the production process, according to Castells. He stated:

…the economy is informational, not just information-based, because the cultural-institutional attributes of the whole social system must be included in the diffusion and implementation of the new technological paradigm, as the industrial economy was not merely based on the use of new sources of energy for manufacturing but on the emergence of an industrial culture, characterized by a new social and technical division of labor. (Castells, 2000, p. 100)

In the academic arena, the new social and technical division of labor described by Castells can be seen most readily in the instructional function, where information and communications technologies have had a profound impact on the cycle of production. This new social and technical division of academic labor is described by Rhoades (1998). He utilizes "enskilling" and "deskilling" labor theories to comment on the changing roles of faculty in relation to the instructional function of higher education. As the instructional paradigm has changed due to the use of ICTs in teaching and the massification of postsecondary education, the role of faculty is in flux. Faculty may either be retrained to utilize instructional technologies or be side-lined by technical experts who can perform the function for them. The decision to "opt out" of using instructional technologies poses career risks for faculty, especially those who are untenured and those who teach large undergraduate courses. Rhoades posited that when faculty shift their teaching to a digital environment they are subjected to increased managerial control and loss of autonomy. He stated that, "new technologies can pose a threat to that freedom, enabling detailed monitoring and/or surveillance of workers' activities" (Rhoades, 1998, p. 199).

Indeed, the instructional purview of faculty is undermined by the increase in the numbers of "managerial professionals," described by Rhoades and Sporn as "neither professors nor administrators," but individuals with "professional associations, conferences, journals and bodies of knowledge that inform their practice" (Rhoades & Sporn, 2002, p. 16). Rhoades and Sporn commented on the impact of managerial professionals on the instructional function of higher education by stating that, "most [universities] now have teaching centres and professional development centres staffed by full-time managerial professionals who directly and indirectly impact instructional delivery—for example, encouraging the use of instructional technology in classrooms" (Rhoades & Sporn, 2002, p. 16). The increase of managerial professionals creates a "matrix mode of production," meaning that the division of labor within academe is more distributed among various employment categories (Rhoades & Sporn, 2002). In other words, whereas the instructional function was previously performed by the lone faculty member with perhaps the aid of graduate teaching assistants, laboratory technicians, and secretaries, today faculty share the instructional function with instructional designers, multimedia specialists, courseware support analysts, library information specialists, and classroom technicians.

Although KM is seen as a rational (impartial) approach to asset valuation and strategic planning, it is critical for academic employees to recognize the ways in which professional self-preservation might affect the adoption and implementation of KM in the postsecondary environment. Knowledge management intersects this new production cycle often at the level of the managerial professional or upper-level administrator. As "management" is at the core of KM, it follows that those who manage will be the first to consider the use of KM in their workplaces, and the "problem-definition" phase of KM will be informed by their perspectives. Yet it is important for academic managers to fully comprehend the changes that have occurred in higher education with regard to the division of labor and production functions. For example, if one of the goals of KM is to optimize the quality/cost ratio, the increased expense of additional administrators and managerial professionals must be taken into account (Leslie & Rhoades, 1995). The cost of additional academic staff is particularly significant with regard to the instructional function, where expenditures for the technologies themselves are not likely to be fully recovered through increases in efficiency or by the implementation of new fees. Therefore, instructional expenditures per student must include the associated costs of instructional support staff and the technological infrastructure, not just faculty/student ratios.

Digital Capitalism

Digital capitalism frames the growth of the IT sector as an extension of the previous industrial economic cycle, with concessions to the thought that an observed "amplification" of capitalism might be a signal of the New Economy (or at least, a new economy). In Digital Capitalism: Networking the Global Market System (1999), Dan Schiller described the neoliberal transformation of electronic networks into a profit-generating system, where communications and data processing would eventually be deregulated in the United States. From military use to a federally funded inter-university research tool, what would become the Internet developed as a shared network using open-source software (Hafner, 1996). As the use of networks grew in U.S. business and finance, investment in computer equipment outpaced all other forms of capital from the late 1970s through the 1990s (Schiller, 1999). Schiller stated that "information technology investment, finally, and network applications in particular, comprised the pivot of a restructuring of big capital—both industrial and financial" (p. 17). The commercialization of the Internet led to a new production cycle, centered on the need for hardware and software to serve the growing number of (primarily American) business clients seeking to perform network transactions.

Although research universities were central to the early stages of the Internet, the role of such institutions since the 1970s is not fully explained by Schiller. Higher education's ties to digital capitalism are discussed in three ways in his book: the commoditization of education (through distance learning and electronic courseware), as a site of consumption of information technology, and as a partner with industry in research alliances. Schiller described the role of universities in research centers with strong ties to business, but only mentioned the use of information technology or production of software at these facilities in passing (Schiller, 1999, p. 164). Although listed by name as corporations with a large impact on worldwide markets for information technology throughout the book, Schiller provided just one sentence to say that "Netscape, Sun Microsystems, and Cisco comprise three leading Internet companies that were each direct spin-offs from academe" (p. 162). Instead of focusing on the development of information technologies on college campuses, Schiller centered on the consumption of technology in higher education, noting the speed at which schools were outfitted with high-speed networks, computers, and high-tech classrooms (p. 190). Yet, Schiller mentioned the for-profit provision of educational services through distance education and courseware production as a contribution to knowledge capital (pp. 185-202). Absent from his discussion of digital capitalism in academe is the growth of revenue-generating courseware and other instructional materials in the public education system, which Melissa Anderson describes as a form of "instructional capitalism" (Anderson, 2001). Further, it must be understood that information technology companies are active in the higher education sector and are becoming closely aligned with the business core of academic services (Metcalfe, 2004).

Thus, colleges and universities are closely tied to both production and consumption through their utilization and creation of information technology products. The framework of digital capitalism, also explored by McChesney, Wood, and Foster (1998), reminds us that the ubiquity of IT in our modern lives rivals that of ever-present capitalism. Not since the creation of the plastics industry have we been so transformed by a particular corporate sector, and just as we rarely object to the use of extruded petroleum byproducts in our lives these days, we rarely mind the ways in which IT has become a fixture of our work and leisure hours. Indeed it could be said that higher education is an environment that is at the forefront of the digital age, and that our campuses are places where it is difficult to labor or learn without high-technology. We might be lured, however, into the belief that academe is a hallowed grove more informed by the agrarian age than a post-industrial one, especially if we find ourselves in liberal arts institutions. Yet, Castells pointed us to the crux of working in a knowledge factory in a knowledge age when he stated that "in the new, informational mode of development the source of productivity lies in the technology of knowledge generation, information processing, and symbol communication" (Castells, 2000, p. 17). He further clarified this notion by stating that "what is specific to the informational mode of development is the action of knowledge upon knowledge itself as the main source of productivity" (Castells, 2000, p. 17).

THE POLITICS OF KNOWLEDGE MANAGEMENT

Although computer systems may seem inherently apolitical, the opposite is true as the digital environment is able to be shaped by nearly any political system or method of control (Loader, 1997). While most peope understand that organizations are rife with internecine struggles, few comprehend how these "turf battles" affect the informational culture and IT landscape. While power and control are at the heart of much of organizational strife, these battles may become most evident in political discussions of jurisdiction and territory. In this section, I discuss the connections between knowledge management and notions of digital democracy and the changes that globalization brings to the electronic environment in academe.

Digital Democracy

Since its introduction to society at large, networked computing has been considered in political terms. Jordan (2001) described early computer culture as anarchist and libertarian, citing organizations such as the Electronic Frontier Foundation and the Center for Democracy and Technology as influential in the formation of basic political values of the Internet and computing (see also Borsook, 2000). Jordan also noted the dominance of Anglo-American norms in cyberspace, including language preference (English) and the desire for self-governance. Other early proponents of the Internet imagined it to be an "electronic agora" (Rheingold, 1993), referencing the notions of egalitarianism and democracy thought to exist in ancient Greek marketplaces. This perspective saw the ancient agora as a place where free exchange of ideas and goods took place, and where equality was common. However, in the same manner that Jeffersonian Neoclassicists championed the characteristics of Greek society that best suited them (such as political representation solely for landowning male gentry), while ignoring considerable social injustices (slavery and the disenfranchisement of women, to name two examples), the application of false notions of ancient "democracy" to the Internet and computing environments only served to obfuscate the existence of digital power and inequality.

In fact, rather than having its roots in democratic ideals, the term "cyberspace" derives from another classical reference, the Greek word kubernetes, meaning helmsman or governor. Thus, at its very core, the digital environment is framed by administrative issues and governance structures (hence the job title "systems administrator"). Knowledge management, then, from a political perspective is as much about jurisdiction as it is about jurisprudence. This is readily understood when one considers the power of information and misinformation within a polarized or politicized organizational environment. Information technology networks are not just conduits for the flow of binary bits and bytes; computer systems are pathways between knowledge territories (Herbert, 2000).

In higher education institutions, this can be seen in the networked domains of separate colleges and departments, each with their own servers. Thus it can be said that higher education institutions exhibit characteristics of both provincial and federal systems of control. The languange of computing reinforces these territories by using words like "domain" to describe areas of administrative control. Knowledge management efforts rarely acknowledge these multi-layered organizational jurisdictions in a way that satisfies both the proponents of decentralization and the champions of central managerialism.

Campus environments can be both decentralized in their computing networks as well as bound together by a single "enterprise" system that serves as the business core of the organization. These campus-wide systems are today more often than not commercial products, sold to institutions by companies such as Sungard SCT, Datatel, and Campus Management. The enterprise software allows for integration of various campus units, such as student admissions, course registration, financial aid, and business services. In many cases, these units previously had their own computing systems and only minimal data sharing with other academic departments. As these units are linked by shared enterprise software and common datasets, information administration becomes more centralized. In circumstances where such campus-wide software is purchased, some degree of control over academic information management is ceded to the private sector. In fact, there are campuses where IT management is performed by employees of the vendors of enterprise software, with these "Outsourced CIOs" sitting on the president's cabinet (Metcalfe, 2004). The mix of public and private managers in these situations complicates the flow of information in higher education organizations, as work-processes themselves are seen as proprietary information and therefore subject to classification as "trade secrets" rather than open systems where anyone in the organization can track the flow of information from individual to individual.

Globalization

The term "globalization" is difficult to define, and even more difficult to determine where and if it exists. However complicated it may be to describe, most scholars agree that a restructuring is occurring on a global scale, affecting capital systems and social structures. In higher education, evidence of these changes are seen in the migration patterns of students and faculty, the development of cross-national education programs such as distance learning initiatives, and increasing internationalization of colleges and universities. Vaira (2004) noted the shifts in postsecondary education by stating:

> *…higher education is witnessing a process of deep institutional change that involves the deinstitutionalization of its rooted policy and values frameworks and the parallel institutionalization of new ones. These processes entail more or less strong resistances, conflicts, [and] tensions but also efforts to conciliate, adapt, translate, assemble the new with the old, the national features of higher education system with the new globalizing pressures, the single institutions structural and cultural features with the new imperatives and demands. (p. 485)*

The institutionalization of new policy and values frameworks, as informed by a globalized economic, social, and political reality, may be seen in the information systems of modern campuses. For knowledge management practitioners, it is important to note that as higher education is becoming more tied to global markets, the value of knowledge assets will be increasingly determined on a global stage. For example, if a university has an International Memorandum of Agreement with another university in a different country, intellectual capital built between the partners could be considered a shared commodity with different value for each contributing agency. What might have the most value to one of the partners might have the least value to the other partner, but the value is still there to be understood and recognized by both. This will be most important in terms of intellectual property policies and copyright laws, which may differ from institution to institution, country to country.

Furthermore, globalization affects the learning environment of higher education in such a way that KM practices should consider the various cultural and language systems embedded within information technology, especially courseware. In a multi-ethnic, multi-lingual learning environment, what values are conveyed by the course management systems given that many have been created in North America (e.g., WebCT and Blackboard)? Are there cultural forms of expression that cannot be conveyed online? Does this have a negative impact on teaching and learning? Perhaps most importantly, does the exportation of courseware reinforce economic, social, and political structures? For example, if Mexican higher education institutions purchase courseware developed in Canada or the United States, does this perpetuate the political and economic dominance that has already made North America an unbalanced trade region? What are the effects of the commercialization of academic IT on national identity? What forces prevent Mexican institutions from developing their own courseware, in Spanish? As globalization continues to become evident in higher education, questions such as these should guide information technology managers in the academic setting.

THE SOCIOLOGY OF KNOWLEDGE MANAGEMENT

The field of knowledge management can benefit from sociological perspectives for several reasons. First, the social study of science, including computer science, has led to a rich body of literature detailing the ways in which patterns of communication and interpersonal relations affect organizational systems. The scholarship, often under the heading of society, technology and society (STS) studies, provides much food for thought for those who attempt to shape "irrational" organizations through seemingly "rational" means. Also, sociological perspectives are important to knowledge management as it is people who are the most important assets of an organization. Understanding the motivations and influences of individual actors is critical to successful KM implementation. In addition, it is important for KM practitioners to understand that technology is not "neutral;" that it is instead created from a particular world-view, and as such performs as a proxy for specific individuals within an organization. In this section I briefly describe the social construction of technology.

Social Construction of Technology

The term "technological determinism" can be defined as the impact of technology on society and the way in which social processes and progress are fixed by the development of particular technological innovations (see Winner, 1977, 2001). While it is not impossible to imagine a world without computers, for example, it is difficult to conceptualize what our contemporary lives would be like without such a technological development. Yet it is more challenging to parse out how computers have determined particular social structures, functions or layers of social contact that would not exist without them. Ultimately, it is first a human that sets the technological "wheel" in motion, and the consequences of that action are either beneficial or harmful to society at large (Tenner, 1996).

A conceptual framework for research on the relationship between technology and society was presented by Pinch and Bijker in a chapter titled, "The Social Construction of Facts and Artifacts: Or How The Sociology of Science and The Sociology of Technology Might Benefit Each Other" (1987). They discussed the empirical approach to the social construction of technology (SCOT) as a three-stage process. First, they stated that the "interpretive flexibility" of the technology or technological artifact must be acknowledged. They elaborated by saying that, "By this we mean not only that there is flexibility in how people think of or interpret artifacts but also that there is flexibility in how artifacts are designed" (p. 40). In other words, technological artifacts are shaped by the inventor as much as they are shaped by the subsequent users. Second, they discuss a period of "stabilization and closure" that occurs with the development of technologies, where the artifact in question has "solved" a particular problem or the problem for which the artifact was originally intended is no longer relevant. This stage is an interesting one in that it highlights the ways that technology is used and repurposed by relevant social groups, rather than just the outcomes that were intended by the developer. Their final stage of analysis involves the "wider context" and how a particular technological innovation has affected the "sociopolitical milieu" (p. 46). This stage involves the development of values and social meanings around objects and their function. While this particular research method has its critics (see Klein and Kleinman, 2002), it nonetheless is an important process from which to consider the mutual shaping of technological artifacts and social systems.

For the field of KM, the research techniques outlined by Pinch and Bijker can be useful ways to understand how information and communications technologies are both created and utilized in an organizational setting. Pertinent questions can be asked by following the SCOT approach, including "What is the problem that is to be solved," and "Who is involved in the process of developing the system (the relevant social groups) to solve this problem?" Furthermore, the SCOT approach acknowledges that there are many possible solutions to any given problem, and the final product will be constructed by the "technological frames" or viewpoints and value-systems held by the developers.

Complimentary approaches to understanding the impact of technological innovations on society include Thomas's "power-process" model. In What Machines Can't Do: Politics and Technology in the Industrial Enterprise (1994), Thomas discussed his "power-process" model, which offers a new perspective on the forces behind the development and implementation of new technologies. Thomas argued that too often the study of technology focuses only on the implementation stage of technological change, and infrequently considers the social and political factors present within an organization that affect the choices made during the entire process. Thomas identifies three stages of change: (1) the identification of the problem that requires attention and the proposal for technological change, (2) the selection between presented technological alternatives, and (3) the implementation of the chosen innovation. Thomas also presented a set of methodological guidelines to use while studying the process of technological change. He promotes taking account of the organizational and decision-making history, paying greater attention to how dissimilar logics are coupled (e.g., technological determinism and social change theory), focusing on the process of choice, and assessing the role of power and worldview of the decision-makers and other organizational members.

Like the SCOT approach, the power-process model contextualized technological change within a social or organizational environment. It recognizes that many individuals are involved in the development of technological solutions, and also highlights the consequences of leaving key players out of the development process. A central element of the model that is critical for those who want to utilize KM techniques is the understanding of the role of power and authority within an organization. Who makes the final decisions in an organization is often more important than the many hours of preparation and planning that might occur around technological change.

Finally, it must be understood that the technology itself bears the imprint of the values and attitudes of its designers. This is made very clear in Forsythe's research as presented in her article, "New Bottles, Old Wine: Hidden Cultural Assumptions in a Computerized Explanation System for Migraine Sufferers" (1996). Forsythe describes the development and implementation of a digital solution to the problem of the tedium of taking patient histories during a doctor's visit in a medical office. Due to the exclusion of migraine sufferers from the design phase, the computerized system that was finally developed was "designed to persuade the patients that the physician's diagnosis of their headaches is correct" rather than truly discover the root causes of the patients' headaches (p. 566). Forsythe found the development of the system as an example of a "technological imperative." She stated that:

practitioners in medical informatics take for granted the benefits of automation, including computerizing the doctor-patient communication that might otherwise take place face to face. In medical informatics, intelligent systems technology is treated as a solution in search of a problem. (p. 570)

Forsythe's work reminds us that "innovation" is often in the eye of the beholder. For KM practitioners, it is important to recognize that personal zeal or affinity for a technological solution may not be in the best interest of the community that the solution is intended to serve.

CONCLUSION

In the Information Age, technological infrastructure is an instrument of power, "whether transparent or opaque." Star (1995, 1999) noted that "the ecology of the distributed high-tech workplace, home, or school is profoundly impacted by the relatively unstudied infrastructure that permeates all its functions" (p. 379). As such it is important for us to recognize the economic, political, and social motivations behind the development of technological "solutions" in organizational settings. In higher education in particular, the knowledge-intensive environment would seem especially ready for the variety of changes that can be brought by way of information technologies, but the "technological imperative" must not sway developers and users of these systems. The "build it and they will come" approach may result in costly development of an underutilized system if in fact the people involved in the implementation are not keen on the project or its intended effects.

Thus, the use of knowledge management principles should proceed only with the careful examination of the economic, political, and social implications of knowledge codification in higher education. Aspects of market-value, political power, and social stratification will impact the development of any technological solution. To counteract the potentially negative effects of technological change in higher education, critical questions must be asked. We must ask why the products of higher education are to be evaluated relative to market value rather than the social good. We should ask who will gain access to our common and individual intellectual property. Furthermore, we should insist that we are made aware of the ways in which our work will be monitored and by whom. Finally, we need to know exactly who will reap the reward when our knowledge is "captured."

Chapter 5.24
Learning in Organizations

Irena Ali

University of Canberra, Australia

INTRODUCTION

In work life, socially based learning occurs all the time. We learn from interactions between peers, genders, functional groups, and across hierarchies, and it happens in ways not normally recognized as learning (Jordan, 1993). Therefore, use of the term "social" learning reflects that organizations, organizational units, and work groups are social clusters, as are study groups and task groups, and thus learning occurs in a social context.

In this situation, social learning is defined as learning occurring within or by a group, an organization, or any cultural cluster and it includes:

- The procedures by which knowledge and practice are transmitted across posting cycles, across different work situations and across time;
- The procedures that facilitate generative learning—learning that enhances the enterprise's ability to adjust to dynamic and unexpected situations and to react creatively to them.

Social learning represents important processes that contribute to individuals' abilities to understand information, create knowledge from that information, and share what they know. Social learning is therefore intrinsic to knowledge management.

This article is based on research conducted by the Enterprise Social Learning Architectures (ESLA) team. The ESLA team was created in

1998 to carry out a research study into "social learning" and the organizational culture that supports such learning. The study, spanning a period of four years, took place in a number of different settings within the Australian Defence Organisation (ADO).

The findings of this research are of importance because the ADO, like other organizations, faces the problem that much of the organization's memory and knowledge is "walking out the door" in terms of the skills, experience, and the corporate knowledge of its ex-employees. In the current climate, the competitive edge lies in gaining the knowledge edge, and to do so requires an understanding of how new knowledge is generated within groups, what motivates people to share what they know, how it is shared between and managed amongst members of an organization, and to what extent organizational culture influences social learning. In this article, we explore some of the organizational factors that enhance social learning and as such, are instrinsically related to knowledge management, as there is a symbiotic relationship between the two concepts.

BACKGROUND

A key assumption underlying the study was that research aimed at explicating social learning requires a socio-technical approach. Many organizations invest heavily in implementing information technology in the hope of providing a seamless solution to managing information resources and organizational knowledge. Unfortunately, these initiatives are often implemented without much regard to how people in organizations go about creating, acquiring, sharing, and making use of information (Bednar, 2000; Davenport, 1994; Vandeville, 2000). The greatest knowledge base in the company does not reside in a computer database somewhere but in the heads of the individuals associated with that organization. These individual knowledge bases are continually changing and adapting to the real world in front of them. Therefore, these individual knowledge bases need to be connected together so that they can do whatever they do best in the shortest possible time. New communication technology will certainly support information sharing where physical proximity is not a possibility. However, the technology alone will not create the trust and interpersonal context necessary to achieve a true network. It is, therefore, necessary to prepare the cultural ground. Values cannot be shared electronically or via bits of paper. Organizations are not based on electronic networks, rather, relationships must be initially constructed through face-to-face interactions (Davenport, 1994). Thus, knowledge sharing will depend on the quality of conversations, formal or informal, that people have (Davenport & Prusak, 1998).

Research on the cultural aspects of those organizations that foster new knowledge and generative learning suggests that employee trust and open communication play an integral role. Higher levels of trust between managers and employees are correlated with more open communication (Ruppel & Harrington, 2000). Schein (1993) and Phillips (1997) suggest that information sharing promotes common identity, mutual trust, and organizational learning and is directly related to organizational cultures that foster generative learning. Schein (1993) also claims that opening up and sharing encourages integration between organizational subcultures and, in turn, organizational adaptation to change. Organizations have a responsibility to create a culture in which learning occurs and that culture will determine the quality of learning that takes place. Such a culture provides the opportunity for personal contact so that tacit knowledge, which cannot effectively be captured in procedures or represented in documents and databases, can be transferred (Davenport & Prusack, 1998; Webber, 1993). For this to occur, the focus has to be on increasing the ability of the individual, as it would be the collective result of many individual actions that would produce a result for the whole of the organization. In a culture that values knowledge, managers recognize not just that knowledge generation is important for business success but also that it should be nurtured.

The methodology of the study evolved over time and included qualitative and quantitative aspects. The research team used ethnographic techniques in the form of fieldwork, which entailed observing the work taking place in different settings, and using directed questioning to clarify issues. In addition to ethnographic observations, the ESLA team undertook extensive, semi-structured interviews with a stratified sample of staff to ensure that an adequate representation was achieved. More than 60 interviews were conducted, and all interviews and field notes were transcribed, coded, and analyzed using the qualitative software package N'Vivo.

The quantitative method involved a questionnaire consisting of Likert scale questions, some open-ended questions, as well as questions ranking listed attributes. In addition, the questionnaires were designed to collect some demographic data about study participants. The response rate for the questionnaires was more than 90%.

The combination of methods offered complementary perspectives of each of the settings. The observations and interviews provided data that offered the insiders' points of view and also shed light on unique aspects of the various social settings that were studied, adding richness to the data. On the other hand, the quantitative surveys enabled generalizations across the settings and answered "what if" types of questions.

SOCIAL LEARNING ENABLERS

A set of overarching organizational values will determine what type of learning culture and organizational communication climate prevails within any company. The ESLA research findings indicate that in organizational cultures characterized by trust, transparency of decision-making, empowerment and forgiveness of mistakes, sharing of information is widespread. It is difficult to determine whether the organizational cultural values are an organizational "property" adopted by its staff or whether these values are influenced by individuals and their belief system. However, within the same organization, different units were operating according to a different "cultural code". This seems to indicate that each individual staff member can mold their organizational culture within the spheres of their responsibility or influence and, as stated earlier, it is the collective sum of individual actions that results in learning at the organizational level.

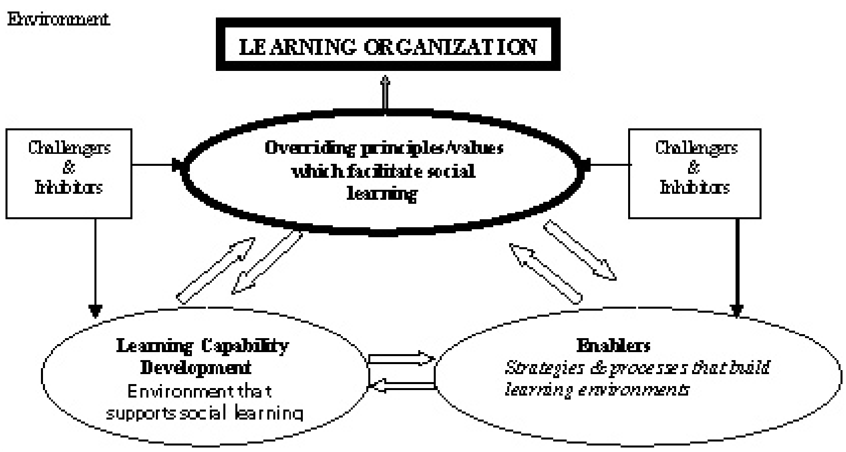
In addition to the overarching values, the research identified an additional set of factors that supports and enables effective social learning. These factors fall into two categories. The first, Learning Capability Development, refers to characteristics in the environment and provides a context in which the second category operates, such as organizational infrastructure. This second category is referred to as Enablers and represents processes and strategies that, if present and effectively applied in an enterprise, can facilitate social learning, such as Common Identity, Team Building, Access to Information, Development of Individual Expertise, and Induction and Enculturation.

As depicted in Figure 1, all of these social learning factors can, from time to time, be either inhibited or challenged by issues such as political and economic vagaries, budget uncertainty, organizational restructures, retrenchments, and so forth.

A graphical representation of the structured social learning architecture is shown in Figure 2.

A common finding through all the settings studied was the impact of trust and open communication on the enablers of generative and social learning. This is because of trust's impact on willingness to share knowledge and to voice ideas.

Figure 1. Factors impacting on social learning in organizations



Higher levels of risk-taking behavior have been found to result from increased trust in co-worker relationships (Mayer, Davis, & Schoorman, 1995) and from supervisors showing concern for employees' ideas and feelings (Oldham & Cummings, 1996). Additionally, greater risk-taking can result from increased trust for supervisors, in that co-workers' preparedness to act in innovative ways is a form of risk-taking, and it can be encouraged by supervisors' acceptance of mistakes as learning tools, which is a form of trust (Costigan, Itler, & Breman, 1998). Moreover, employees see themselves as more motivated and more likely to take initiative in professional development activities when they have higher levels of trust for their supervisors (Costigan et al., 1998).

The ESLA research findings point to a recursive relationship between trust and employees' sense of empowerment and self-esteem. Employees who are feeling good about themselves and their value to the organization are likely to be motivated, reliable, and have loyalty to the organization. This loyalty will precipitate higher productivity, higher staff retention rates, and the willingness to share knowledge and ideas with others, thus contributing to the knowledge base of the organization. These relationships are depicted in Figure 3.

The literature supports the findings that trust is pivotal in climates of organizational change and when environments are uncertain (Kramer & Tyler, 1995). The results of the ESLA quantitative surveys indicate that trust in leaders and their decision-making played an important part, with just over half (53%) of respondents saying that they trust decisions made by their leaders. It is interesting to note that the higher up the hierarchical chain, the greater the level of agreement with this statement. Nevertheless, the need for more transparency of organizational decision-making was often repeated. One of the interviewees put it very succinctly:

We need a far more open information network that actually allows us to see how the organization works.

Figure 2. Structured social learning architecture

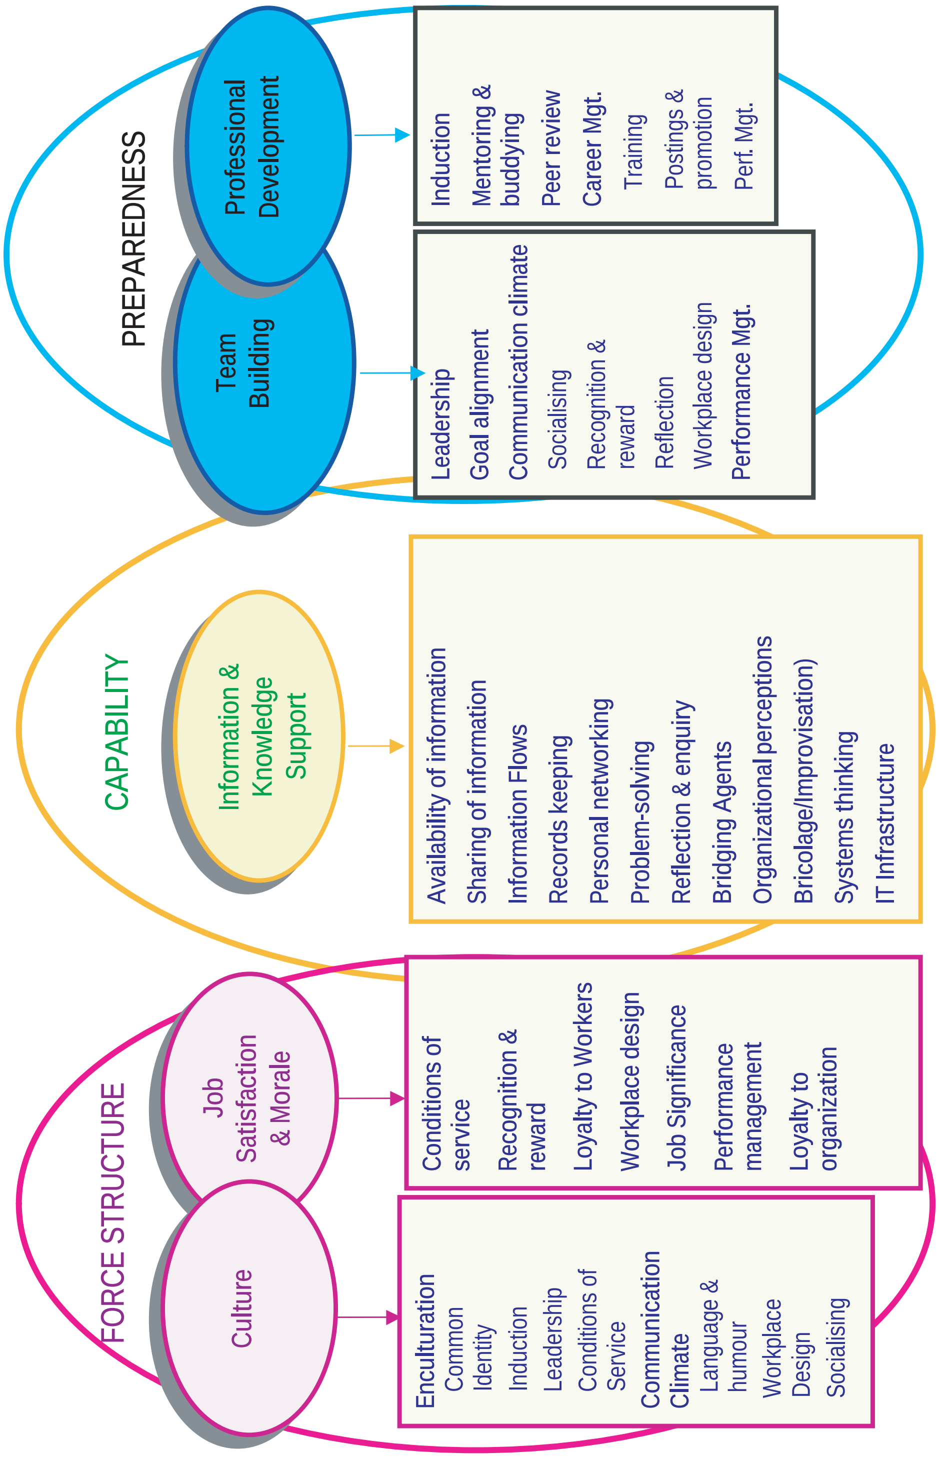


Figure 3. The role of trust in organizations

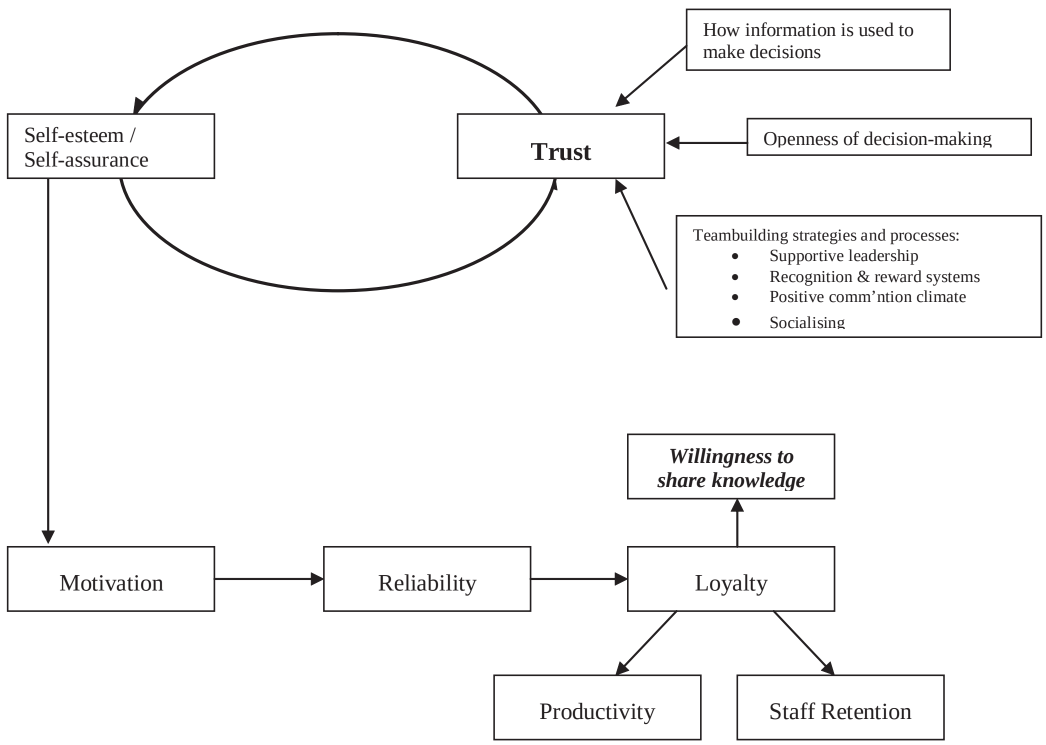

The ESLA research data clearly points out that the qualities of certain leaders and the team cultures these leaders create are associated with high levels of trust within those teams, and a generally positive attitude toward collaboration and teamwork. For instance, in teams characterized by cohesiveness and strong team spirit, leaders took on the role of a facilitator, rather than a traditional command-control role, thus allowing people to shape their work themselves. These leaders empowered people to go and seek out their own solutions rather than mandating actions, and they positioned people in ways so as to leverage their unique strengths, to make their own decisions, and have their own responsibilities. They encouraged a wide span of communication so that the individuals in need of information were able and free to consult not only their immediate work group but also the entire organization and beyond and any network that they needed to go to for information. This way these individuals were able to solve their problems quickly and to provide a rapid response to the customer. Moreover, these leaders used frequent two-way feedback to convey their expectations, as well as asking the staff to provide feedback on their own performance. The ESLA team was told that this type of leadership also gave the staff a tremendous opportunity to explore, improvise, and learn.

The ESLA researchers also were given examples of team leaders who motivated people and built trust by providing every opportunity for their personal and professional development. These leaders were able to motivate people in order to bring the best out of team members and to achieve results. Additional methods of team motivation that were observed included celebrating individual and team achievements, and always looking for something positive to say about each team member.

Leaders of successful teams were able to set realistic expectations of their team. Numerous staff interviewed said that knowing what their leaders are expecting of them is one of the most important factors for successful teamwork because it allowed the team to have achievable goals. Furthermore, staff were constantly kept informed and in the loop by e-mails, drop-ins, and meetings. In many cases, at the onset of a new posting, leaders were forthcoming with their vision and expectations of the team, as is indicated by the following:

…the first day he started, he sat us all down in a big meeting for about two and a half hours and he said this is what I expect of you and he had the white-board out and then we could let him know what we expected of him and it was a good way to start.

However, this practice was not prevalent throughout all the settings under study. The survey data points out that 58% of respondents in one of the settings felt that their supervisors did not communicate their expectations of day-to-day work requirements well. This breakdown in communications, along with a lack of transparency in decision-making processes, became a fertile breeding ground for organizational politics and low morale and subsequently diminished opportunities for social learning.

The interview data and the survey data clearly indicated that good communication skills were considered to be one of the most valued factors of effective leadership, as stated by one of the informants:

…if I pick on three things, I'd say communication skills, observation skills, you know your ability to observe and to take in data, and then also a bit of a brain on your head so you can make sensible decisions, on the basis of that.

In most instances, staff spoke very highly about their leaders, and 83% felt that in their team good leadership enhanced teamwork; however, the ESLA team was made aware that:

…some of the people we have in positions of authority don't have a schmick about manpower management, they really don't. Some are good, I mean it's not a manual skill, it's an emotional skill.

The power of positive feedback, recognition, and reward cannot be overemphasized, not only for building a team's performance but also for the building of trust. This recognition must apply not only to big tough jobs but equally to quiet, unassuming day-to-day tasks. Mitchell (2000) points out that making employees feel appreciated, focusing attention on their good ideas, inviting them to extend themselves, and saying "thank you, we know that you are a good employee, we value you and your work," is a big factor in motivation. A positive self-image and self-confidence is one of the early steps toward effective motivation. A person who feels motivated and feels good about himself or herself acts with confidence. Individuals empower themselves by receiving positive feedback and add to the empowerment of others when recognition is given freely (Katzenback & Smith, 1993).

A lack of day-to-day recognition of one's work came through very strongly as an issue. The research data indicated that recognition of one's achievements and good work was well established in some teams; however, this practice was not widespread throughout all the settings studied. In some units, the managers used recognition and praise as an empowering tool within their teams; however, the same managers were often not recognized themselves, by their own superiors.

[Recognition] it's something that your boss says to you each day, saying, 'Jeez, that piece of writing was really good, mate. You did a great job there.' It's that sort of mentality that we have to get through to our senior managers...

Most of the respondents (86%) indicated that recognition comes foremost from their immediate team members and 62% said that their supervisors always acknowledge their positive contributions at work. The researchers were told that in some teams there are special celebrations once an important piece of work is satisfactorily completed or milestones are reached. Such celebrations reinforce for workers that their efforts are valuable to the team's functions and products. It is clear that the benefits of recognition and reward flow in two directions, on one side there is a benefit for the individual and their willingness to share knowledge, and on the other, the supervisors are gaining respect and trust from their staff. The following quote depicts this:

…the flow on effect of that [recognition] is that the rest of the group say, 'Hey gees, you know, yeah she has done a good job. Yes and she's been recognized for it. Yeah. It's not such a bad group that we were working for.' And the flow on to me is they see that I care, as a supervisor, and I'm prepared to recognize good work. But culturally—culturally we don't put the importance on this, I think, that we should…

The research data strongly indicates that socializing plays an important role in trust building and social learning. The aspect of "feeling good" about work colleagues is an important motivating factor and a factor contributing to building trust amongst employees and, again, their willingness to share knowledge. Maslow's theory of motivation identifies a sense of belonging to a group and getting to know each other as a vital step in the life of a team and in achieving set goals. As they get to know each other, the team members derive satisfaction from belonging to a cohesive team, but more importantly, they become aware of each other's strengths and weaknesses, what they can or cannot do, their expertise and experience. This knowledge facilitates utilizing each team member to their full potential.

The respondents indicated that work-related social activities led to a greater sense of team spirit (85%). These social activities were not just frivolous functions; they were core activities that were ultimately task oriented. As one of the respondents put it:

…it is important and we do, we have time out where we go for coffee and to chat, it's team building and getting to know each other, and I think that's really important because you need to get to know the personalities on your team….We talk about work things when we're having coffee, but it's joking and fun.

Scholars use the term social capital to refer to human relationships that make organizations work effectively. Healthy social relationships in organizations build trust, make people learn faster and be more productive and creative (Prusak & Cohen, 2001). However, building successful social relationships in organizations during times of constant change, staff shortages, and pressure to deliver with fewer resources is extremely difficult.

...People in the headquarters need to let off steam, so if everybody was just working constantly five days a week with no let-up, you know, you'd start to get cracks in the organization. So people do appreciate it, [socializing] you know, when it happens...

The ESLA research data indicates that social activities lead to greater team cohesion and enhanced team morale. Informal social gatherings allow people to get to know each other, build trust and stronger relationships, and (more importantly) share knowledge. Many interviewees stated that during such informal social gatherings they learn more about what is happening in other units in the organization than through formal channels.

CONCLUSION

Social learning requires individuals to be willing to share their knowledge and to be willing to voice their ideas. In this way, shared knowledge empowers not only the individual, but also the team and the organization as a whole.

The ELSA research findings indicate that the requisite cohesion and commitment arises from effective leadership, transparency in decision-making and communication, appropriate reward and recognition, socializing, and commitment to a common goal. However, trust appears to be an overriding requirement, one that provides the glue that binds these processes and strategies for effective social learning and building of corporate knowledge. Knowledge sharing cannot be mandated, it must occur willingly. It is for this reason that trust must underpin the team building behaviors and attitudes that result in the confidence and cohesion needed to openly share knowledge, construct new knowledge, and build stronger organizations.

The implications of the research are that organizations seeking to improve information sharing and knowledge generation need to develop a greater awareness of the processes and strategies of organizational learning. Organizational knowledge is distributed across functional groups and its generation and continual existence is dependent on the overall organizational culture. This study indicates that information sharing and subsequent knowledge generation would be successful when interactive environments are cultivated before other solutions are implemented, particularly those based on technology alone.

Chapter 5.25
Mapping Group Knowledge

Duncan Shaw
Aston University, UK

INTRODUCTION

During group meetings it is often difficult for participants to effectively: share their knowledge to inform the outcome; acquire new knowledge from others to broaden and/or deepen their understanding; utilise all available knowledge to design an outcome; and record (to retain) the rationale behind the outcome to inform future activities. These are difficult because, for example: only one person can share knowledge at once which challenges effective sharing; information overload makes acquisition problematic and can marginalize important knowledge; and intense dialog of conflicting views makes recording more complex.

This article reports on the social process of mapping group knowledge which aims to better support the processes of sharing, acquiring, utilising and retaining, knowledge during group meetings. Mind mapping, causal mapping (Eden, forthcoming), concept maps (Gaines & Shaw, 1995a), and various mapping techniques reported in Huff and Jenkins (2002) have been used to structure and represent individual thinking and knowledge about an issue. Software now exist to support these mind-mappers (e.g., MindMap®, KMap, Decision Explorer). However, often individuals cannot solve problems themselves and instead need insight from a range of people who can collectively address the problem. For example, groups are often used where issues are so complex that they require the involvement of a number of diverse knowledge holders. Also groups are often used where political considerations suggest that the involvement of various key people would facilitate the implementation of actions.

Thus, the principles of mapping individual knowledge have been applied to small groups of people to support their collective structuring and thinking about an issue. Approaches such as Dialog Mapping (Conklin, 2003), concept mapping (Gaines & Shaw, 1995a), and Journey Making (Eden & Ackermann, 1998a) can all support the process of mapping group knowledge during meetings. While it is possible to deploy these approaches using flipchart paper and pens, software have been developed to support these particular approaches (i.e., Compendium, KMap, and Group Explorer, respectively). These software aim to capture, represent, and model the participants' knowledge in a more versatile manner than is possible on paper, enabling more effective navigation and consideration of the breadth and depth of issues.

This article begins with an introduction to the research on mapping knowledge. Then it reviews the benefits for knowledge management of engaging groups in mapping their collective knowledge. An example of a computer-based mapping methodology is briefly introduced—the Journey Making approach. Future research directions and implications for knowledge management conclude the article.

BACKGROUND TO RESEARCH ON MAPPING

Much work has been performed on the applications of cognitive and causal mapping, for example mapping for: negotiation (Bonham, 1993), strategic management (Carlsson & Walden, 1996), strategy (Fletcher & Huff, 1994; Bougon & Komocar, 1994), communication (Te'eni, Schwartz, & Boland, 1997), litigation (Ackermann, Eden, & Williams, 1997), IS requirements planning (McKay, 1998), consumer branding (Henderson, Iacobucci, & Calder, 1998), and knowledge management (Shaw, Edwards, Baker, & Collier, 2003b).

Also work has been conducted on other types of mapping, for example: knowledge networks, which represent the knowledge around a process (Gordon, 2000); mapping knowledge contained on an intranet (Eppler, 2001); and integrating concept maps with other applications to build the knowledge base (Gaines & Shaw, 1995b). With the exception of knowledge networks, that work differs to cognitive/causal mapping which concentrates more on the social process of generating knowledge through personal reflection and/or collaboration.

This article focuses on maps built by groups of knowledge holders during facilitated workshops. This body of literature is smaller, but includes: exploring how to facilitate the process of capturing knowledge from groups using mapping (Johnson & Johnson, 2002), group mapping using computers (Eden & Ackermann, 1998a; Shaw, 2003), using group mapping in a research study (Casu, Thanassoulis, & Shaw, 2002; Edwards, Collier, & Shaw, 2004), and using group mapping for knowledge management (Gaines, 2002). These studies tend to focus on improving the process of conducting a group mapping session and building group maps.

In terms of analysing the content of maps, research has focused on analysing the nature of individual cognitive maps, for example, analysing the themes in the maps (Jenkins & Johnson, 1997), and the number of concepts in the maps and the number of in/out arrows linking concepts (Eden, forthcoming). Some exploration of the properties of group maps (albeit sometimes group maps which have been generated by merging the cognitive maps of individuals) has also been performed (e.g., McKay, 1998; Eden & Ackermann, 1998b; Shaw, 2003). Shaw, Ackermann, and Eden (2003a) offer a typology for how managers access and share knowledge during group mapping activities.

The research on mapping concentrates on the deployment, evaluation, and improvement of the methods often leading to practical and theoretical advances of mapping techniques.

We now review the general benefits of mapping group knowledge.

MAPPING KNOWLEDGE FOR KNOWLEDGE MANAGEMENT

To structure the following discussion, we return to the sharing, acquisition, utilisation, and retention of knowledge to explore how mapping supports each of these. Below we assume that there are 5-12 people (participants) in a group who are mapping their knowledge. The knowledge is being captured in a map, and the process of mapping is being supported by a facilitator. This map is publicly displayed for all participants to see. This arrangement is characteristic of Dialog Mapping, concept mapping, and Journey Making (see Figure 1).

Sharing Knowledge

Sharing knowledge in a group meeting is not a straightforward activity. The group decision support systems experimental literature (see Fjermestad & Hiltz, 1998, for a review) has identified a range of factors which inhibit the sharing of knowledge, for example: "production blocking" when people cannot generate new ideas because they are trying to remember the ideas they want to share, and "evaluation apprehension" that your contributions will be negatively evaluated by the group.

When group mapping, one way of partially avoiding these inhibitors is through participants sharing knowledge by either writing it onto cards or typing it into a networked computer which is running a brainstorming software. These bring the advantage that many participants can share their knowledge simultaneously as they are not constrained to waiting for others to finish speaking before they can share their own opinion. Consequently lots of knowledge can be shared very quickly to the map, enabling the group to focus on discussing the knowledge that has been shared rather then trying to access the knowledge that each member holds. Furthermore, anonymity of who contributed the knowledge gives participants the freedom to share knowledge which they are not too sure of (or which is controversial)—allowing the group to evaluate its legitimacy.

Mapping also encourages creativity by providing stimuli (on the public display of knowledge) in the form of other peoples' ideas from which to gain inspiration. Also, facilitators can offer participants different types of sessions in which to share their knowledge, whether they share their knowledge whilst knowing/without knowing/partially knowing what other participants have shared (see Shaw, 2003, for more details). Finally, sharing knowledge directly into the map enables the participants to select/craft their own wording of contributions, without their knowledge being interpreted and reworded by a facilitator. For more details on these points, see Gaines and Shaw (1995c), Eden and Ackermann (1998a), and Shaw (2003).

Acquiring New Knowledge

Acquiring knowledge in group meetings can be problematic, as often the knowledge is poorly shared and poorly managed when shared, making identification of the key issues difficult. Information overload can also hinder the acquisition of new knowledge (Grise & Gallupe, 1999).

Through mapping, the facilitator will aim to capture the knowledge in a format where individuals can engage in a structured discussion of, what emerges through discussion to be, the key points. By communicating perspectives in only a few words, the public screen can display the breadth of issues. Through discussion, detail can be added to those issues, ensuring the requisite depth of knowledge is acquired and integrated into the group's consideration of the issues. Participating in this discussion is a key source of new information (acquiring knowledge) where people come to appreciate the legitimacy of competing perspectives—but not necessarily agree with that perspective.

Through mapping the participants share and discuss knowledge about the relationships between the issues. This enables them to enrich their appreciation of the issues with new knowledge about their causes and consequences. This is in contrast to a brainstorm where the issues are discussed, but not necessarily the relationship between the issues in a systematic, structured fashion.

In mapping, the acquisition of knowledge is a catalyst for synthesising knowledge across participants. The aim is often for the participants to build a shared understanding of what are the critical pieces of knowledge that must be incorporated into any decision or action plan. This shared understanding often does not extend to consensus on what should be done. Instead, the action plan should contain enough of what the different participants are interested in that they are willing to accept actions which they are less interested in.

Utilising Knowledge

Due to the problems of sharing and acquiring knowledge in group workshops, it is often difficult to gather appropriate knowledge to utilise. Furthermore, bounded rationality, decision-making heuristics, group thinking, and information overload can make the effective usage of shared and acquired knowledge problematic. However, in mapping workshops process support aims to take the group through the issues in a structured and transparent way, to overcome these problems and effectively utilise the knowledge in the group.

Mapping aims to support the utilisation of knowledge, primarily through helping participants to cope with the complexity of multiple perspectives that have been shared. By modelling the knowledge on a public screen, the participants do not need to retain the knowledge in their head or try themselves to integrate different pieces of knowledge from different people. The facilitator, using the model/map, will display the knowledge on the public screen and provide structure to reduce the cognitive demands on the recipients (i.e., manage its complexity). Thus the effects of information overload might be reduced, allowing participants to concentrate on utilising the knowledge for the purposes of the workshop.

For example, in strategy development workshops, the knowledge is utilised to identify and agree on a portfolio of actions which will progress the organisation/group in the required direction. Knowledge will be used to design appropriate actions by understanding drivers and pre-requisites for action, exploring consequences of action, identifying incompatibilities across actions, and appreciating issues of action implementation.

Retaining Knowledge

Knowledge retention can be problematic over the short and long term. At one extreme, people can forget what they heard less than 10 minutes ago as they are overwhelmed with a spiralling conversation that is continuous, offering them new knowledge. At the other extreme, organisations want to retain knowledge for future use, perhaps over years.

Mapping in group workshops assists in the short-term 'retention' of knowledge by publicly displaying the knowledge either on a flip-chart or via a projector. The display is used as a shared device through which the group communicates—that is, participants make reference to the publicly displayed model as they illustrate their reasoning for holding particular opinions. This prevents group members from having to retain the argument in their heads.

The maps can also act as a long-term record of what was agreed and the rationale behind this agreement. These can be circulated around the organisation, but might be difficult to interpret for those not in the workshop. Progress against actions can be logged with reference to the maps (Shaw et al., 2003b).

We now review one particular workshop approach that maps group knowledge—the Journey Making approach.

THE JOURNEY MAKING APPROACH

Journey Making has been selected for further description because it is supported by a mapping software that, like KMap, offers a group the functionality to share their knowledge through a networked computer directly into an electronic map.

Journey Making stands for the JOint Understanding, Reflection, and NEgotiation of strategY (Eden & Ackermann, 1998a). This facilitator-led approach arose from a need to support groups in their strategy making endeavours. Through jointly understanding the range of pertinent issues in a problem, it is believed that a group is in a better position to tackle that problem. Reflection on the range of potential causes of the problem, and consequences of taking action to address the problem, engage the whole group (individually and collectively) in critical thinking and discussion. The range of potential actions to address the problem are rigorously considered with the aim of participants accepting the legitimacy of competing actions (or rejecting actions) through social negotiation. The outcome is typically an action plan that contains a portfolio of strategic actions that when implemented, the group believes, will tackle the problem.

Underpinning Journey Making is an aim of providing participants with a process through which they:

- Surface their own views in a group as other people do the same, and then…
- Collectively explore (not just get told about) the commonality/differentiation between those views, in order to…
- Learn about the connections across these multiple views (i.e., identify how the issues affect/are affected by each other), enabling them to…
- Build their knowledge through developing a richer appreciation of these connections (i.e., thinking through the causes and consequences of issues), to…
- Expand their individual and collective knowledge of the topic beyond that which they held prior to the workshop, enabling them to…
- Select an appropriate combination of actions which are thought to have the desired impact when implemented.

Mapping is central to this process as the following discussion will show.

MAPPING KNOWLEDGE IN JOURNEY MAKING WORKSHOPS

In a computer-supported Journey Making workshop, computer technology assists in the sharing, capturing, and displaying of views, and the voting on options. Walking into a typical Journey Making room (Figure 1), the participant would often see: 8-10 laptop computers sitting in a horseshoe running a group decision support software (Group Explorer); a projector displaying causal mapping software (Decision Explorer) on a very large projection screen; and a facilitator facing the group with computers in front of him/her.

In a Journey Making workshop, normally between 5-16 participants share their knowledge to the causal map through computers. During the brainstorm (or ‘gathering’ in Journey Making terminology, as the process is designed to gather occupational views, not purely lateral thoughts), the participants type their knowledge, views, and opinions (in the form of ‘contributions’ of 4-10 words in length) into their own networked computer which is running Group Explorer software. All contributions are made anonymously, in that issues are not identified to the individuals who made them. For example, in response to a question about how to encourage learning and sharing of knowledge in the workplace, one manager might type: “utilise the existing expertise of existing people”; another might suggest that the company should address the issue that “individuals experience outside of the business is not capitalised.”

Figure 1. Participants in a journey making mapping workshop

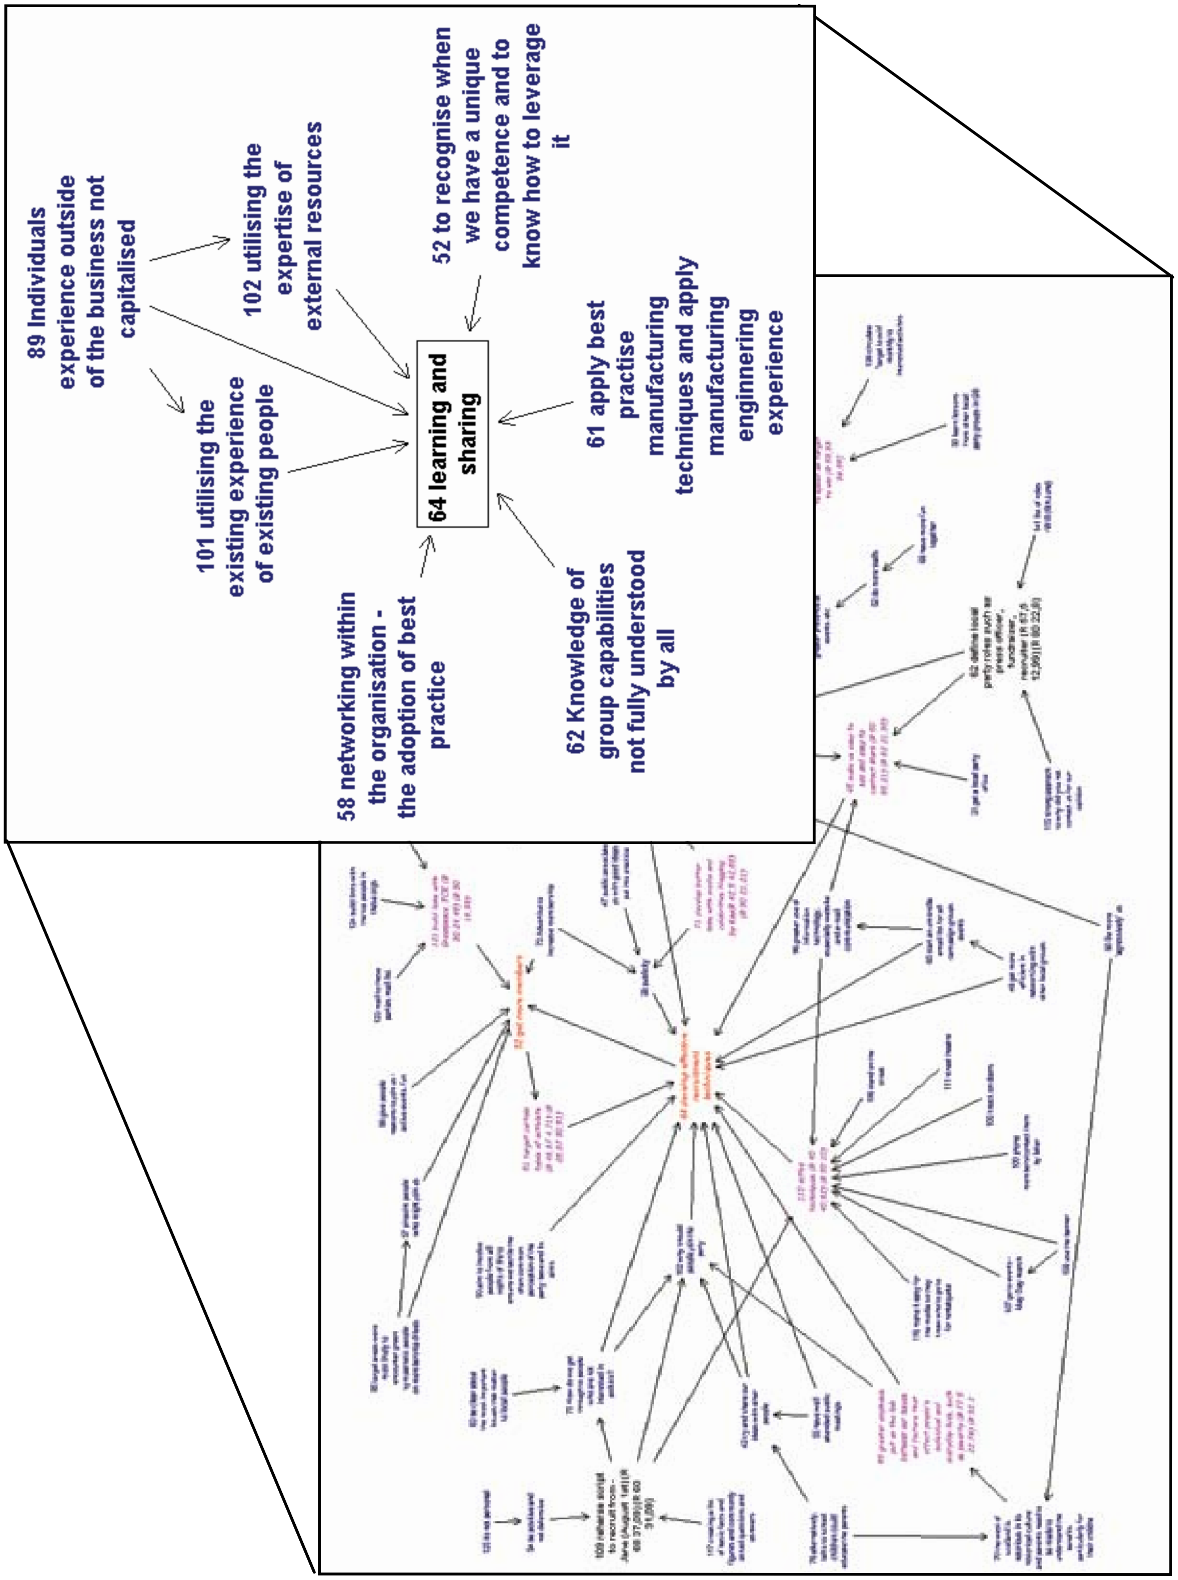
These would then be displayed on the map (see Figure 2).

The facilitator, on his/her own computer screen, will move all the participants' contributions into content-related clusters and display those clusters on a public screen (using a projector) for all the participants to read and be stimulated by. Participants can then type in more contributions in response to either the stimulus 'question' or after reading what others have contributed on the public screen.

Also, participants can share knowledge of the relationship between different contributions. When building group maps, these relationships (represented in the map as an arrow) are usually causal as the group is exploring the causes of problems and drivers that will cause/bring change. For example, the participants building the map in Figure 2 thought that "individuals' experience outside of the business is not capitalised," but if addressed, could be one way of "utilis[ing] the existing expertise of existing people."

Following the gathering, the facilitator will encourage a group discussion around the issues represented on the map. This discussion will aim to surface more contributions to be added to the

Figure 2. An extract from a group map



map, as well as further structure the contributions by identifying more causal relationships/links.

The product of this work will be a structured causal map which reflects the participants' knowledge of the situation and on which the participants can begin to consider which actions should be implemented in the organisation, and exploring the effects these actions might have if implemented. Through exerting effort in building and negotiating a feasible action plan (and understanding the benefits from implementing it), the facilitator will aim for group members to build commitment to implementing the actions. This commitment will help ensure that the implementation of actions is followed through to completion.

FUTURE TRENDS

As evident from earlier discussions, researchers are using the principles of mapping to gather and structure knowledge in a range of ways. For mapping in group workshops, much of this attention aims to evaluate the existing methods as a catalyst for their improvement. In terms of improving the mapping aspect of these workshops, researchers are continually reflecting on practice of mapping in groups (Johnson & Johnson, 2002), offering new ways of conducting workshops to collect knowledge with more breadth and/or depth (Shaw, 2003), offering methods for interrogating maps during workshops (Eden, forthcoming), and developing new software to support different types of group mapping.

In the Operational Research community, researchers are examining how the results from mapping activities can feed into other methods of analysis, for example, multi-criteria decision models (Belton, Ackermann, & Shepherd, 1997) and data envelopment analysis models (Casu et al., 2002). In this way mapping can be effective for multi-methodology applications (as shown in Mingers & Gill, 1998) where a combination of different methods are combined to better address the issues.

The use of computer technology gives new access to the way in which participants contribute knowledge to group maps during workshops. Being able to log the knowledge shared by participants in a computer database enables post-workshop analyses of what each person shared when, and how that was used by the group to inform the final outcome. Complementing this data with video recordings of group discussion and social negotiation would enable the entire workshop to be amenable to post-workshop analyses. A fruitful direction for research would be to use these data to better understand the way in which knowledge is shared and used during these meetings.

Another direction for research would be to explore the impact of a workshop on the organisation—taking a longitudinal perspective through to the implementation of actions and the role of mapping in this.

CONCLUSION

During meetings, the structured collection and representation of knowledge can support the participants' acquisition, utilisation, and retention of available knowledge. We suggest that mapping is able to support the participants when they share, reflect upon, synthesise, expand, record, and creatively employ knowledge to better achieve the aims of the meeting. Through formal mapping methodologies such as Dialog Mapping, concept mapping, and Journey Making, facilitators can better support groups in these endeavours. However, more research to evaluate mapping approaches is needed to inform the continuous development of the techniques and of the software that supports them.

Chapter 5.26
Some Implementation Challenges of Knowledge Management Systems:
A CRM Case Study

Bendik Bygstad
The Norwegian School of Information Technology, Norway

ABSTRACT

The promise of knowledge management systems is challenged by implementation problems. This CRM case illustrates that technology-driven approaches are not likely to succeed. It also indicates some limitations of top-down managerial interventions, arguing that we need a deeper understanding of learning processes to be able to implement KM systems successfully. A more experimental implementation strategy is suggested.

INTRODUCTION

The great expectations for knowledge management systems illustrate a phenomenon long acknowledged by IS research: A strong socio-economic trend (the growth of knowledge workers) fuses with a technological trend (knowledge supporting technologies like Lotus Notes and World Wide Web). In a global economy, knowledge may be the greatest competitive advantage for a company (Davenport, Prusak, 1998), with the support of KM technology to structure the knowledge and make it available in the company's learning process.

On the other hand there are continuing reports of disappointments, due to poor alignment between business and technology (Applegate et al., 1999) or the mismatches between the socio-technical potential and the old management practices (Ciborra, 1996). Implementing information systems has proved to be difficult (Markus, Benjamin, 1997), and the main challenge with KM systems also seems to be implementation (Ericsson, Avdic, 2002).

Implementation is mostly seen as an acceptance challenge (Kwon, Zmud, 1987). This view is probably valid also in the area of KM systems (Ericsson, Avdic, 2002), but there are two aspects which may deserve a closer examination. First, Leonard-Barton observed (1988) that company adoption does not necessarily imply user adaptation. The spread of the knowledge-based, less hierarchical organizations with both more powerful and knowledgable users (Nambisan et al., 1999) has accelerated this development: The knowledge user decides whether he or she will use the system, and in what way.

Secondly, the use of knowledge systems is quite different from the use of transaction systems. Since KM systems usually are set up to support organizational learning, they constitute part of a much more complex process. Argyris and Schön (1996) defines organizational learning in these terms:

Organizational learning occurs when individuals within an organization experience a problematic situation and inquire into it on the organization's behalf (..) In order to become organizational, the learning that results from the organizational enquiry must become embedded in the images of the organization held in its members' minds and/or in the epistemological artefacts (the maps, memories, and programs) embedded in the organizational environment (p. 16).

This process is coined organizational learning II or double-loop learning, in contrast to single-loop learning, i.e., problem-solving. Organizational learning concerns changing the theory-in-use, the underlying assumptions of how things are working, which heavily influence the patterns of actions. Argyris and Schön observe that there often is a mismatch between the official espoused theory and the theory-in-use. An important implication from this is that only real double-loop learning can change the theory-in-use.

Thus, the question posed in this chapter is the following: How should we implement KM systems in a way that supports organizational learning? To illustrate this we shall tell a story of a six-year CRM project - an important goal being knowledge synergies - trying to describe in some detail how a knowledge-based organization addressed the challenge.

The chapter is structured as follows: first, the chapter describes the case methodology. There is followed with a brief outline of the promise of CRM systems. Next, the chapter discusses two process perspectives on implementation are presented, and the case is described in some detail, focusing on the implementation process and actor behavior, told by the practitioner. The chapter then discusses solutions and recommendations, focusing on the interaction between learning and management. Finally, it briefly outlines future trends and finishes with a summary of the conclusions.

METHODOLOGY: A CASE STUDY

This chapter tells the story of a Norwegian knowledge-based organization, the Oslo-based National Institute of Technology (TI) that started implementing a CRM system in 1993. The focus is on the implementation process that lasted six years. The author was the IT manager at the institute during this period.

Using a qualitative and interpretive approach (Miles, Huberman, 1994), the study focuses on behavior as a practitioner experienced the project, using only very simple theoretical concepts. These concepts are part of the narrative, illustrating what we conceived was our methodological options at the time. The empirical evidence also includes company and project documents and user satisfaction surveys.

Being a single case study, there is no claim of validity for the KM systems field in general. Rather, the aim is to ask relevant questions, and discuss them in the light of existing theories.

THE PROMISE OF CRM SYSTEMS

Theories on relationship marketing were developed at the end of the 1980s, under the motto "from transaction to relation." Researchers showed that companies have both economic and social relations: In addition to economic transactions there is, usually, a development of trust. These relations may give benefits to both sides and among them are a higher degree of customer loyalty, lower marketing costs, mutual learning and other forms of strategic cooperation. Developing long-term customer relations is a part of the company's strategy development, and should involve every level of the company (Hakansson, 1995).

Since relationship marketing is heavily dependent on rich customer information, and also dependent on frequent communications with the customers, the pioneers were early aware of the IT potential. Today, CRM systems represent a large and growing part of the software industry (Tafti, 2002).

Ciborra and Failla describe CRM as an information infrastructure, consisting of processes, people and technology (Ciborra, Failla, 2000). CRM is linked to the BPR thinking, in the way that CRM is also process oriented and focused on dramatic and fundamental change. CRM structures and supports all activities that support a business transaction, from the first lead to fulfillment.

Assumptions about the effect of CRM system are simplified in Figure 1.

As Figure 1 illustrates, CRM is a long-term business strategy, where the CRM system is an important component. The reason for the high expectations is that the CRM systems seem to connect the two central resources of the modern, "flat" and decentralized company: The core competence of the knowledge workers, and the company's relations with its most important customers (Kay, 1993).

CRM systems have three promises:

- It gives each worker a tool to manage her personal contacts, activities, documents, etc. As Drucker has stated, "managing oneself" has become the management challenge for the knowledge worker (Drucker, 1999).
- It provides a tool for dialogue marketing, making the company able to individualize the marketing activities: The customer gets only the information he wants and needs (Hakansson, 1995).

Figure 1. The basic assumption of the effect of CRM systems

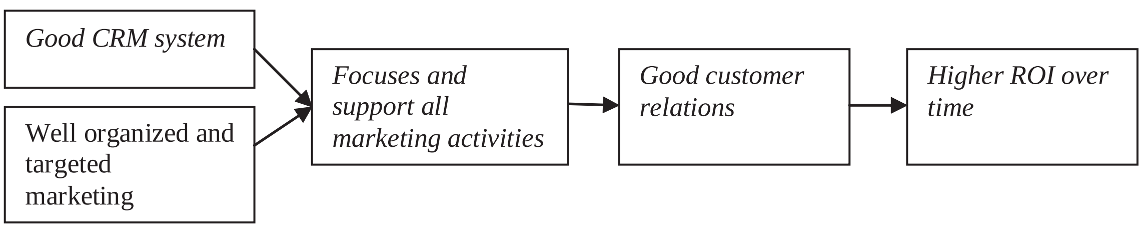

Figure 2. Features of Norwegian CRM system salesmaker

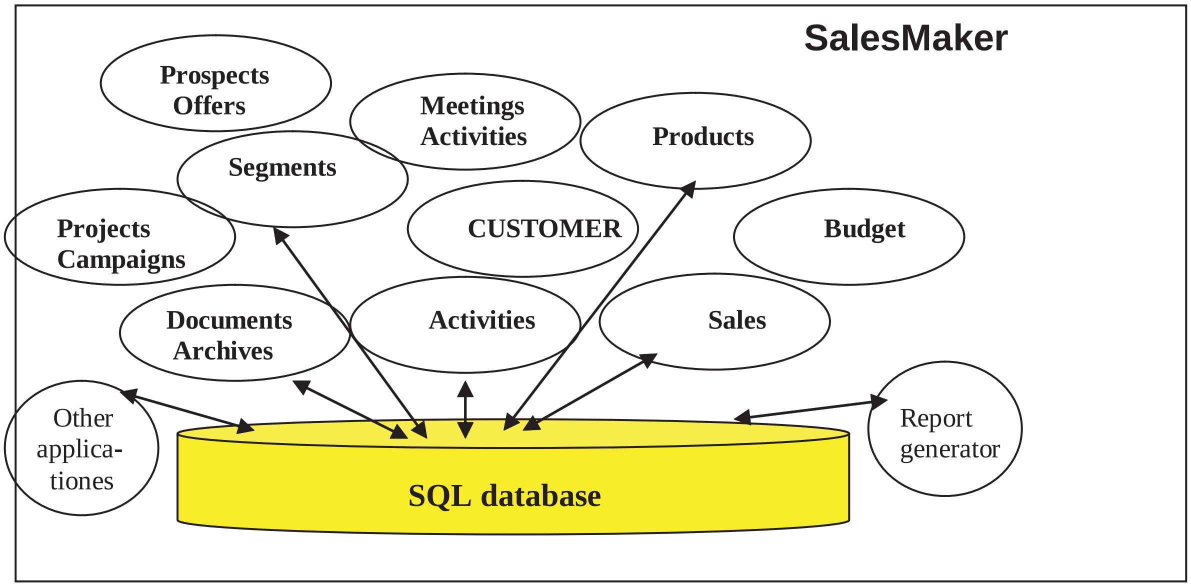


- It represents a synergic potential for the company: If all this information could be utilized in analysis and concept development, it might be a basis for new products and markets, transcending the barriers of business functions and locations.

This is not trivial. If successfully implemented, this implies that the CRM systems could be an important technology for the non-hierarchical, knowledge-based organization of the 21st century.

Figure 2 shows the rich functionality of a medium-sized Norwegian CRM system, SalesMaker, used in the TI case.

THE CASE: COULD A FORMER GOVERNMENTAL INSTITUTE BECOME A FLEXIBLE AND MARKET-DRIVEN COMPANY WITH THE HELP OF CRM?

The National Institute of Technology (TI) was made a private foundation in 1989. The main market was the small and medium-sized companies in Norway (being 95% of all the Norwegian companies) that are too small to do their own technology development and transfer. The services provided were technical consulting, practical courses in disciplines like welding, testing and calibration, and also ISO certification. There were branch offices in other cities in Norway, and an international component, the Norwegian Technology Attachés.

As a private organization TI had to earn its own income, and the governmental support was gradually reduced during the 1990s from 50% to 25%, while the total income increased from 125 mill NOK to 185 mill NOK.

The 260 employees were not used to marketing and selling services. After privatization all the managers were recruited from the private sector, while the technical consultants survived from the old organization. They were largely technically inclined, and regarded marketing as a, maybe necessary, but unwanted activity. The culture in the technical departments was practical and rather practical. The manager of the furniture department, with a lifelong experience with electrical sawing tools was proud to say about job applicants: "Well, it's OK that he has a Ph.D., but then at least he shouldn't have more than nine fingers left!"

TI's only real competitive advantage was the 8,000 small and medium sized customer companies, and thousands of personal contacts. Could this asset be capitalized and thus develop TI into a modern and market-driven company? And could CRM play an important role in this transformation? The director thought so, and in 1992 she commissioned a major project called, The Customer Project. The objectives were:

1994: Better financial control of the consulting projects (about 4,000 each year).
1995: More effective and efficient marketing by systematic dialogue marketing.
1996: Develop long-term relations with the most important customers.

It was easier said than done. In 1992 the institute did not even have a LAN, and the workforce was unfamiliar to the concept of CRM. How was this to be accomplished?

Methodology: Software Engineering — or Organization Development?

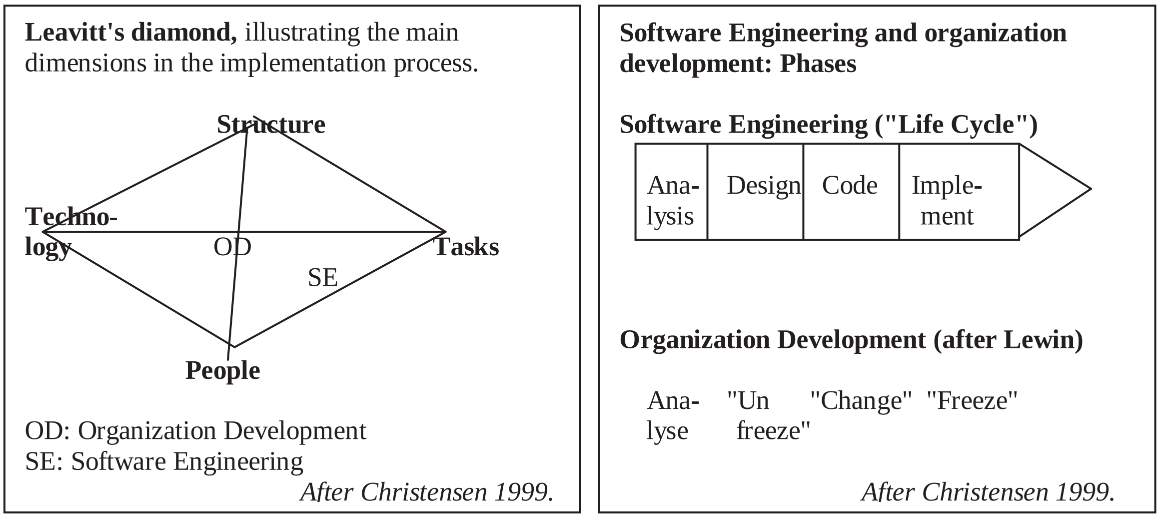
Around 1990 IS projects were usually analyzed in terms of success factors (Kwon, Zmud, 1987). The critical success factors (CSF) for the Customer System were assumed to be strategic alignment, cross-functional synergies (BPR inspired), workforce participation (Scandinavian school), technically competent implementers and a sound technical solution. This was rather by the books, and also the teaching of the TI staff.

The CSFs, however, do not give much guidance on how IS should be implemented. In practice there was a choice of two models, the Software Engineering model or the Organization Development model. The SE approach takes as a point of departure that an information system is developed and implemented into an organization (Sommerville, 2001). The mainstream of the IT industry - like Microsoft - has traditionally focused on the functional attributes of the system (advanced, user friendly, etc.). The Scandinavian school has focused more on the user participation and acceptance. For both schools, however, the starting point is the technology and the emphasis is on structure and rationality.

The Organization Development model comes from the behavioral sciences, and the point of departure is that organizations are stable organisms that change slowly and reluctantly (Argyris, Schön, 1996). To succeed, the organization should prepare for the change, then change slowly, and lastly institutionalize the changes ("freeze"). The OD discipline has traditionally not been very interested in IS, and has focused on the irrational aspects of change processes, and that a normal outcome is a gap between intentions and results. The reason for this is resistance to change.

Both traditions, the SE and the OD, should ideally be combined. Christensen (1999) makes an interesting attempt, where Leavitt's diamond

Figure 3. Two non-congruent frameworks: The organization development model and the software engineering model



is used to illustrate how the two perspectives could be integrated.

Figure 3 illustrates both the elegance and the problem in Christensen's synthesis (Christensen, 1999). Leavitt's diamond illustrates the need for an integrated approach, because the 4 variables are very integrated. The phases, however, show how incongruent these schools are. The main problem is not to gain acceptance for the integrated approach, but to implement it in real projects. The practitioner communities, being the IT consultants on one hand and the OD consultants on the other, represent different cultures, with different tools and terms, for different contexts.

At TI we chose the software engineering approach, following the recommendations of the vendor of the CRM system. This did not imply that the Customer Project was seen as a purely technical project. On the contrary, great effort was made to ensure user participation and organizational alignment. One of several measures was to merge the IT and marketing departments into one unit, with the responsibility for the CRM implementation.

The First Attempt in 1993/94: Crises

Chronology

Autumn 1991.
: IT strategy, concluding with the Customer Project, is approved.

Winter 1992.
: A projects group and a steering group are established. Requirements document is made after interviewing all departments.

Spring 1992.
: Agreement with Software Innovation purchasing SalesMaker (first customer) Analysis and design: A consultant firm produces a business model in DFD and E/R-diagrams. Central users participate.

Rest of 1992.

Database is implemented and prototyping in a 4GL is done in close cooperation with different user groups. Installation of LAN, WAN and servers.

Autumn 1992.

User training with in-house instructors. Managers were sent to take courses to learn to use the report facilities.

January 1, 1993.

System set into production.

Spring 1993.

System in production, but technical problems in client/server technology.

Autumn 1993.

Data quality problems.

Spring 1994.

Data quality problems attacked, but not solved. Confidence in system declining.

The Customer System was based on Sales-Maker from the small Norwegian company Software Innovation, extended with a module developed in-house. The system was, at the time, very modern: Windows based, integrated with both the financial system and with office software like MS Word. For an organization not used to CRM systems, it appeared complex, with many screens and a new terminology including words like "contacts," "relations" and "campaigns." All users were trained, concentrating on screens and terms.

The first problem was technical: The client/server technology at this time was not stable, and created a continuous demand for support. Also, the quality of the in-house developed module was not satisfying, and demanded more support.

A larger problem was the fact that the core of the system, the customer information, had quality problems. The reason was trivial: When registering a new customer, the user should check if the company was already registered. If you don't, the result may be a double or a triple registration of the customer (spelled a little bit differently), which in short time creates chaos in the system.

This was the origin of a vicious circle: The existence of double and triple customers very quickly threatened the confidence in the system: "One cannot trust the new system - it is useless" became a common comment. The positive users became reserved in their use, and the negative ones had lots of arguments in the company canteen.

The result of these problems was that the system was not used as intended. In spite of several activities to increase the quality of information, parts of the organization lost faith in the concept. The system did not give the expected benefits because of incorrect information and lack of trust. It also became evident that the user participation strategy had produced little effect: One reason why the data quality problem persisted was that the system was not considered important enough to spend the necessary time to learn properly. It was not integrated in the day-to-day working routines.

The investment was still financially sound, because the dialogue marketing, as a tool for the marketing department, was beginning to work. But the implementation had failed on important points, and we were looking for another way of doing it.

The Second Attempt from 1995-98: Elephants and Giraffes

Chronology

Autumn 1994.

The "Elephant Method" was developed: A step-by-step method to use the Customer System in dialogue marketing: Define your market, find the potential customers in the system, produce the brochure, mail it to the potentials, follow-up by telephone, register the response, correct any wrong information, summarize the learning. Easy, when assisted by marketing staff.

1995.

The Elephant Method was a success in most departments.

1996-98.

The Giraffe Project: Aimed at changing organization and culture:

- Marketing teams established.
- Each team had a marketing plan, with clear objectives.
- All customers segmented into groups, according to profitability. Main responsibility for each customer is assigned.
- Marketing activities are focused on "A" customers, aiming at creating partnerships.
- A number of motivating and learning activities are initiated by the IT/Marketing depts.

1998.

Project is evaluated partly successful, but local (department) culture is stronger than central push.

In the autumn of 1994 the steering group initiated a task force to help a troubled department perform their marketing activities more systematically. This attempt was gradually developed into the "Elephant Method" (after the how-to-eat-an-elephant joke), which was a step-wise method for market segmentation and Direct Marketing.

This method was gradually implemented in most departments during 1995, and led to more sales of TI's course portfolio, while the volume of DM was cut by half. Together this was the first visible success of the system, and this was also acknowledged.

The experience showed us two things: Firstly, the departments needed hands-on guidance in using the CRM system in a way that gave a commercial effect. Secondly, it showed that only very specific results could change the attitudes in the departments. Traditional user training and general information had very little effect.

In 1996 the perspective was broadened. Under the motto "stretching a little further," the Giraffe project was started. The aim was to concentrate the marketing activities on the most important customers ("A" customers) to increase the profitability of the institute, that is, to make it less dependent on government money.

All managers, secretaries and key consultants were taken to kick-offs and follow-ups, listening to national "relationship gurus" and discussing the concept. All departments were organized into marketing teams, and systematic reporting to the top management group every month was instigated.

For the following two years the Giraffe-1 and Giraffe-2 were run continuously, with a focus on changing the culture from focusing on technical disciplines to focusing on the customer. The whole bag of OD tricks was used, like image and brand building, team building, leadership development, skills development, parties and prizes.

The results were on the positive side, but progress was slow. Some departments worked very systematically, and achieved good results. Others were more half-hearted, and gave priority to other activities. A few were ignoring the whole project, and worked with other concepts. The attitude of the manager and the most senior consultants seemed to determine the culture. Also important was the fact that the CRM system did not support all kinds of products, and that two departments lacked loyal customers altogether, and were working in a spot market.

Summing up, in 1998 the CRM strategy had worked for five years. While having a partial success, the process was not self-sustained. It was still dominated by central staff pushing reluctant technicians into the market. The local cultures were stronger than the central push, and only when the commercial perspective was very short, there was a real commitment to the project. Thus, while the DM activities continued to be rather successful, the more long-term approach of using the customer relations more strategically was much harder to achieve. The Giraffe ambition of changing the culture was, therefore, mainly a failure.

We scratched our heads again, now wondering if the whole concept was wrong, not only the implementation. Our concept was built on releasing the potential synergies in cross-functional coordination. Did such a potential really exist - or is it, at the end of the day, only within the individual projects there are synergies? Is the modern knowledge organization too culturally complex, and immune to this kind of standardization? Should the focus be changed to satisfy the more immediate needs of the knowledge worker?

Third Attempt 1998-99 and Summing-up the Case

A new version of the Customer System was introduced at the start of 1999. The emphasis was now changed to the consultant users, and focused on calendar, document support and personal contacts. This was well received, but also signified a lower ambition on the organizational level.

Of the three original goals of the system, the first two goals, financial control of projects, and more efficient direct marketing, were achieved. The DM activities were concentrated in a new unit, and the "A customers" concept was implemented in the whole organization.

The third and most important goal, to establish partnerships with the "A customers," in a cross-functional cooperation, and to use this partnership systematically in changing the organization, had mainly failed. This goal was more or less abandoned, and the departments were left to develop their customer relationships individually.

The planned three-year implementation became a six-year continuing effort. Is there something to learn from the story?

SOLUTIONS AND RECOMMENDATIONS

Interpreting the case, it is obvious that the system was a success regarding the management goals (cost control, Direct Marketing), and a failure in the area of knowledge management.

The implementation of KM is directly affected by what Argyris has termed the "learning paradox" (Argyris, 1991). Studying professionals, he found (as expected) that they were good at single-loop learning, but surprisingly bad at double-loop learning. The explanation: These knowledge specialists seldom experienced failure, and, therefore, are not used to learning from failure. Thus, instead of double-loop learning, the response is defensive, often including blaming something or somebody else.

Returning to the initial question, how should we implement KM systems in a way that supports organizational learning, we may conclude with two perspectives: What is not working, and what may - in some cases - work?

What Does Not Work

The case illustrates that a technology-driven approach is not working. Implementing CRM is hard, and successful implementation requires a different strategy than systems development. This is a problem, because many CRM vendors still use a systems development implementation framework. Also Davenport and Prusak warn against the unrealistic expectations towards KM software: "Unfortunately, it is usually much harder to get organizational consensus for behaviour change and new roles than it is for technology - and if you start with the technology, the other necessary factors may never materialize" (p. 166).

More controversial, perhaps, is our view that traditional organization development may work well in the logistics and marketing area (for example within Direct Marketing), but not in knowledge management. Why not? One answer may be that the first type of project had support in pre-existing capability in the organization's formative context - the institutional arrangements and cognitive frames (Argyris, 1996), while the Giraffe project was a foreign and abstract concept in the language of management. The system and the concepts - espoused theory, in Argyris' terms- could not be translated into a departmental culture which had a very practical problem-solving way of working. The technical teams at TI were small and tightly knit, and the members preferred, vastly, projects to formal cross-functional coordination meetings. The most important learning was in the projects, and it was shared with the other members by the irregular coffee break. Such teams have, seen from within, no need for a CRM system.

Their response to the CRM challenge was defensive, and indeed not beneficial for a learning process. Moreover, the "management push," insisting on espoused theory, prohibited a more creative approach.

What May — In Some Cases — Work?

These are some elements in an alternative implementation strategy.

Could the teams at TI convert to double-loop learning, where they really attempted to achieve the cross-departmental synergies, and use the CRM system as a vehicle of support? Argyris and Schön (1996) suggest a strategy where members of the organization try to "learn strategically," where designers and implementers develop more open and non-determined communication, using failures as input to change their mind-sets. They also advocate developing managers with more "artistic sense" (p. 259).

Evidently this is not easy- and what does it mean to the actual case? We think it means to stage a more innovative process, to experiment with the following:

- Be honest about implementation problems. (This is harder than you may think, because the project has usually been "sold" with glossy promises.)
- Use the problem as a source of innovation. For example, if the system is used in a "wrong" way - explore if there is a potential in this direction.
- Bring in new people, especially critical ones.
- Reorganize teams which are not productive or creative.
- Do not play political games. Focus on business issues.
- Accept that technical problems are not always "trivial," and that systems in one sense are actors. They should be dealt with, not blamed.

We also think one should accept that implementation is inherently context sensitive. What works in one company, or one department, may not work in another. This seems a paradox, because the synergy expectation of KM systems usually implicates that knowledge should be standardized. We agree that this is an important aspect of KM, but that great care is necessary to distinguish between infrastructure information (like names, addresses) and specific domain knowledge. An infrastructure is clearly important, and should be developed early. On the other hand, standardizing domain knowledge is very challenging, and one may run the risk of jeopardizing the whole KM project if this is done insensitively.

CONCLUSION

This CRM case has been used to illustrate some challenges in KM implementation, and to suggest some possible solutions.

The main challenge is that top-down organization development, focusing on control and change management, is not necessarily a successful implementation strategy for knowledge management systems. Often this will appear as an uphill struggle, against defensive knowledge workers.

The solutions do not come easy. They involve staging a learning process, in which the KM system becomes an integrated part. The hardest part may be to leave the glossy image of KM systems behind, replacing it with promises of hard work.

Solutions may also require a partial loss of management control, because what is recommended is more of an innovation process. Managing such processes is rather different from goal-oriented change management, and should allow for more experimentation, and in particular for learning from failures.

Chapter 5.27
Measuring Organizational Learning as a Multidimensional Construct

Juan C. Real
Pablo de Olavide University, Spain

Antonio Leal
University of Seville, Spain

Jose L. Roldan
University of Seville, Spain

INTRODUCTION

The traditional way of measuring learning as a result has been through the so-called learning and experience curves. The learning curves, developed within the production framework (Levitt & March, 1988), relate the manufacturing cost of a product to the accumulated experience in its production. This establishes that its cost decreases as the number of units made increases. At first, although this relationship was limited to the direct labour cost, it later extends to the total production cost.

In the 70s, the Boston Consulting Group applied this idea to the manufacturing sectors with experience curves. These curves expand the learning effect to activities other than those typical of production (Albernathy & Wayne, 1974). They describe the influence that experience acquired through the repetition of a specific activity has on the variable cost and/or price.

Another form of learning evaluation is the half-life curves that measure the time taken in obtaining an improvement of 50% in a determined measurement performance: The greater slope curves indicate a faster learning (Garvin, 1993).

These systems of evaluation are, nevertheless, incomplete for a learning organization. The cognitive level, changes in conduct, and its influence on performance improvement must be taken into account in assessing a company's learning. Surveys, questionnaires, and interviews are, in this case, more useful (Garvin, 1993).

The research has, however, advanced with great slowness due to two matters: first, as a result of the complexity and multidimensional nature of the object of study; second, the absence of a solid common starting-point, caused by the theoretical disagreement that exists concerning the very definition of the concept and its dimensions. In this line, organization learning (OL), as multidimensional construct, has been analyzed through the dimensions related to the OL capability, according to a series of phases that define a sequential time process, or by means of a knowledge-creation process.

BACKGROUND

In spite of the extensive existing literature on OL, there are very few attempts to operate this construct (Chaston, Badger, & Sadler-Smith, 1999), especially case studies that try to induce theory from practice (Easterby-Smith & Araujo, 1999).

OL, as a result, has been treated as a unidimensional construct (Levitt & March, 1988), whereas its analysis as a lasting process connected with knowledge acquisition and performance improvement has allowed us to go further into its complex and multidimensional character.

Easterby-Smith, Crossan, and Nicolini (2000, p. 789) consider the question of the OL measurement to be lacking in methodological and epistemological debate. In most cases, a contingent vision prevails in which the methods used are appropriate for different kinds of research problems. In general, the studies in this field reveal three perspectives:

a. A macro/positivist perspective that uses quantitative methods—its unit of analysis being the organization or its significant subunits.
b. A micro/interpretative perspective, where the researchers are interested in the phenomenon known as "communities of practice." They collect qualitative data via formal interviews or informal conversations and they use the individual as their unit of analysis.
c. Intermediate perspective typically focusing on case studies. This assumes a combination of the previous methodologies. The studies follow the interpretative tradition to the extent that the researchers gather data mainly from interviews and observation. They differ in the sense that the focus is in on the complete case, or on comparisons between similar cases.

As Easterby-Smith et al. (2000) indicate, the different methods are appropriate for different kinds of research problems. Although the European works mainly use the interpretative methods, North American works place more emphasis on the quantitative empirical investigation. We will take this latter approach in this work to analyze the OL measurement, since this will allow its complex and multidimensional nature to be perceived via a quantitative analysis of its dimensions (Slater & Narver, 1995).

ORGANIZATIONAL LEARNING AS A MULTIDIMENSIONAL CONSTRUCT

The academic field has, in the last decade, shown an increasing interest in the development of a measurement scale that allows the valuing of the OL as a multidimensional construct, made up of a set of attributes or related dimensions. Thus, following a prescriptive approach (Vera & Crossan, 2003), there is a first workgroup referring to how organizations should really learn. In this way, an organization should show a high degree of learning in each and every one of the dimensions defined for its learning capability to be considered as high. In the line of the same prescriptive approach, a second workgroup is centred on how the organizations should manage their knowledge following a series of stages or phases. A third workgroup gathers a set of proposals considering OL to be a process of knowledge creation (Vera & Crossan, 2003).

Table 1. The measurement of the organizational learning capability

Author(s)	OL dimensions (items)	Unit of analysis	Research objective
Goh (2003)	• Clarity of mission and vision (4) • Leadership commitment and empowerment (5) • Experimentation and rewards (5) • Effective transfer of knowledge (4) • Teamwork and group problem-solving (3)	Individual: A longitudinal study with two samples formed by individuals of two companies	To describe a tool to measure an organization's learning capability
Goh & Richards (1997)	• Clarity of purpose and mission (4) • Leadership commitment and empowerment (5) • Experimentation and rewards (5) • Transfer of knowledge (4) • Teamwork and group problem-solving (3)	Individual: 632 people from four organizations, two from the public sector and two from the private sector	To measure the managerial practices that facilitate organizational learning or the conditions and enablers that can help an organization become a learning organization
Hult (1998)	• Team orientation (5) • Systems orientation (4) • Learning orientation (4) • Memory orientation (4)	International strategic business unit (SBU): A sample of 179 domestic and 167 international SBUs	To examine the role of organizational learning in the strategic sourcing process of a multinational service corporation
Hult & Ferrell (1997)	• Team orientation (5) • Systems orientation (4) • Learning orientation (4) • Memory orientation (4)	International strategic business unit (SBU): A sample of 179 domestic and 167 international SBUs	To develop and test a measurement of learning capability (OLC) using the purchaising process of a multinational corporation
Jerez-Gómez et al. (2004)	• Management commitment (5) • System perspective (3) • Openness and experimentation (4) • Knowledge transfer and integration (4)	Organization: 111 firms from the chemical industry	To develop a measurement scale for organizational learning capability
Yeung et al. (1999)	• Generate and generalize ideas with impact (24) • Incompetencies for learning (34)	Strategic business unit (SBU): 268 SBUs from large size and a wide variety of industries	To establish how variables of context (industry, business strategy and organizational culture) can influence how and why an organization learns, and how the organizational learning capability will affect business performance

Within the first workgroup, we find authors, such as Goh (2003), Goh, and Richards (1997), Hult (1998), Hult and Ferrell (1997), Jerez-Gómez, Céspedes-Lorente and Valle-Cabrera (2004), and Yeung, Ulrich, Nason, and von Glinow (1999). They identify as OL dimensions the critical components for the learning organization or intelligent organization, so described initially by Senge (1990). These are shown in Table 1.

OL is defined as the "to learn to learn" capability or "meta-learning": the organization follows a continuous change model, permanently challenging its basic assumptions and theories in use (Swiering & Wiersma, 1992). This idea of learning capability presents a clear link to the learning orientation concept or propensity of the company toward learning in connection with different elements that have to be present for OL to occur (Day, 1994; Galer & van der Heijden, 1992; Sinkula, Baker, & Noordewier, 1997). In order to build an organization with learning capacity, Senge (1990) considers as fundamental the implementation of a series of principles or management practices, that he calls "learning disciplines." Table 2 shows the relationship between these disciplines and the key dimensions of the works that use a learning capability measurement.

Personal mastery discipline means individuals clarify and rethink their personal vision, thus guiding future creation. This proposal implies experimentation and the search of innovative and flexible solutions to current and future problems allowing for the creation of ideas.

Mental models refer to assumptions or thinking schemes that conform the acts of the organization's members. For the organization, it is vitally important to be able to modify behavior lines set out in its organizational memory, offering a space for new knowledge creation. This is especially useful when such behavior lines do not correspond to the facts and continue to prevail and guide organizational activity.

Table 2. Basic aspects of learning organization and their relationship with the learning capability dimensions

Learning capability dimensions	Related factors according to authors revised
Personal mastery	• Team orientation (Hult, 1998; Hult & Ferrell, 1997) • Experimentation (Goh, 2003; Goh & Richards, 1997) • Generate and generalize ideas with impact (Yeung et al., 1999) • Openness and experimentation (Jerez-Gómez et al., 2004)
Mental models	• Learning orientation, systems orientation (Hult, 1998; Hult & Ferrell, 1997) • Incompetencies for learning (Yeung et al., 1999) • System perspective (Jerez-Gómez et al., 2004)
Shared vision	• Leadership commitment and empowerment (Goh & Richards, 1997) • Learning orientation, systems orientation (Hult, 1998; Hult & Ferrell, 1997) • Clarity of mission and vision (Goh, 2003; Goh & Richards, 1997) • System perspective (Jerez-Gómez et al., 2004)
Team learning	• Learning orientation, team orientation (Hult, 1998; Hult & Ferrell, 1997) • Transfer of knowledge (Goh, 2003; Goh & Richards, 1997) • Teamwork and group problem-solving (Goh, 2003; Goh & Richards, 1997) • Knowledge transfer and integration (Jerez-Gómez et al., 2004)
Systems thinking	• System perspective (Jerez-Gómez et al., 2004)

Building a shared vision is the shared ideal that agglutinates individual energies of organizational members and guides them in a common direction, generating a tension that leads to learning. This thought is supported by the managerial commitment, which implies that the management acknowledges the relevance of learning in the organization and supports it, promoting the development of a culture that fosters a learning atmosphere as a key value.

With reference to team learning, such learning can only be carried out via experience interchanges among individuals. This means generalizing ideas, that is, sharing ideas in the organization. Following this principle, there is the organizational ability to transfer knowledge both externally and internally. Teamwork allows an organization's members to be able to share knowledge and increase their understanding about needs and the ways in which other colleagues, in other parts of the organization, work.

Systems thinking allows the bringing together of learning results from previous disciplines and allows its extension to the rest of the organization.

Concerning OL definitions, most academics agree that OL is a process which starts from acquisition and creation of knowledge on behalf of individuals, and continues with its interchange and integration until reaching a body of collective knowledge. This idea, represented in Table 3, is proposed by the second group of works, such as Pérez López, Montes Peón, and Vázquez Ordás (2004), Templeton, Lewis, and Snyder (2002), and

Table 3. The measurement of OL as a process

Author(s)	OL dimensions (items)	Unit of analysis	Research objective
Pérez et al. (2004)	• Knowledge external acquisition (10) • Knowledge internal acquisition (7) • Knowledge distribution (7) • Knowledge interpretation (9) • Organizational memory (11)	Organization: 195 firms from the industrial and service sector	To analyze the relationship between organizational culture, OL and business performance
Templeton et al. (2002)	• Awareness (5) • Communications (3) • Performance assessment (4) • Intellectual cultivation (4) • Environmental adaptability(4) • Social learning (3) • Intellectual capital management (3) • Organizational grafting (2)	Organization: 119 knowledge-based firms	To develop a measure for the organizational learning construct
Tippins & Sohi (2003)	• Information acquisition (6) • Information dissemination (6) • Share interpretation (5) • Declarative memory (7) • Procedural memory (5)	Organization: 271 manufacturing firms	To examine the mediating role of OL in the linkage between information technology competency and firm performance

Tippins and Sohi (2003). These authors consider OL as a dynamic process that, according to Huber (1991), develops in time via several stages.

Table 4 sums up these phases of subprocesses with the dimensions identified in several works. These will be discussed subsequently.

Knowledge acquisition is defined as a process followed by organizations in order to actively search for information and knowledge from both internal and external sources. Such knowledge can have its origin in a firm's founders, intellectual capital management, learned from other organizations, embodiment of new members in the firm who have previously unavailable knowledge, and environmental scanning and observation (Huber, 1991).

Information distribution represents the stage at which information obtained in the previous step is delivered intentionally or not among units and members of the organization, promoting learning of new knowledge or its understanding (Garvin, 1993).

Information interpretation implies that one or more meanings could be given to this information (Daft & Weick, 1984). This requires the existence of a consensus among organizational members concerning information meaning. They learn about organizational matters via social channels.

Organizational memory is the last stage of learning. It refers to the group of systems and structures implemented in an organization to store knowledge created in the entity for this knowledge to be able to be used later (Walsh & Ungson, 1991).

Finally, with a different approach (as shown in Table 5), there is a group of authors which presents a scale for measuring the organizational learning

Table 4. Basic aspects of organizational learning processes and their relationship with the organizational learning dimensions

Organizational learning process dimensions	Related factors according to authors revised
Knowledge acquisition	• Social learning, awareness, intellectual cultivation, performance assessment, intellectual capital management, organizational grafting (Templeton et al., 2002) • Knowledge external/internal acquisition (Pérez et al., 2004) • Information acquisition (Tippins & Sohi, 2003)
Information distribution	• Environmental adaptability, social learning, awareness, intellectual cultivation (Templeton et al., 2002) • Knowledge distribution (Pérez et al., 2004) • Information dissemination (Tippins & Sohi, 2003)
Information interpretation	• Environmental adaptability, social learning, communications, performance assessment (Templeton et al., 2002) • Knowledge interpretation (Pérez et al., 2004) • Share interpretation (Tippins & Sohi, 2003)
Organizational memory	• Environmental adaptability, communications, intellectual cultivation, performance assessment, intellectual capital management (Templeton et al., 2002) • Organizational memory (Pérez et al., 2004) • Declarative and procedural memory (Tippins & Sohi, 2003)

Table 5. The measurement of OL and its integration within the knowledge-based view

Author(s)	OL dimensions (items)	Unit of analysis	Research objective
Bontis et al. (2002)	• Individual level learning (10) • Group level learning (10) • Organization level learning (10) • Feedforward learning (10) • Feedback learning (10)	Individual: A survey instrument based on the strategic learning assessment map (SLAM) was administered to 15 individuals from 32 organizations	To analyze the relationship between the stocks and flows of learning and business performance
Nonaka et al. (1994)	Knowledge conversion phases (SECI): • Socialization (10) • Externalization (9) • Combination(10) • Interiorization (9)	Organization: 105 firms	To validate a scale for measuring the knowledge creation process

as a knowledge creation process in organizations. In this sense, Nonaka, Byosiere, Borucki, and Konno (1994) consider that the dimensions of the knowledge creation are the four modes of knowledge conversion (SECI) in the theoretical model defined by Nonaka (1994).

Bontis, Crossan, and Hulland (2002) present a macro perspective of OL in which it relates to the phenomenon of strategic renewal. These authors describe OL as a process through which stocks and flows of learning are managed to increase a firm's performance. In this way, according to Crossan Lane, and White (1999), OL is a dynamic process, via levels, producing a tension between the incremental or amplified logic that involves the scanning or new assimilation of knowledge (feed-forward), and the reductive logic that implies the exploitation or use of learnt knowledge (feedback). Through a feed-forward process, new ideas and actions flow from the individual to the group and from them to the organization. While learning, a feedback process from the organization to the group takes place, and from the group to the individual level, thus affecting the way people think and act. According to this social approach of OL, learning happens and knowledge is created by social interaction developed among the different levels proposed by the ontological dimension of knowledge (i.e., individual, group, and organization).

FUTURE TRENDS

Future works are needed that consider the necessity of carrying out longitudinal studies using the intermediate perspective that complete the existing cross-sectional studies, especially if we consider the continuous nature of OL. This is an accumulative process in time, implying that the amount of knowledge reached at a specific moment in time is the result of learning accumulated up to this moment. In any case, the existence of a measurement method of OL will allow us to go further in the comprehension of mechanisms that facilitate the transformation process of OL into an increase of business performance. In this sense, in the future, it would be interesting to develop works in line with the micro/interpretative perspective that allows us to obtain objective indicators via case studies.

The measurement of the OL can help to reveal different areas in which the managers act to develop this capability. Also, it can allow the establishment of standard values with which to initiate processes of benchmarking between organizations. Those that score above these standards may be considered as learning organizations. Without a doubt, the existence of OL measures will be useful for evaluating more complex models in which different connections with antecedent and consequent variables can be analyzed (Jerez-Gómez et al., 2004). All this is going to contribute to eliminating part of the existing controversy in significant questions, such as its impact on business performance.

CONCLUSION

This article has shown how the limited consensus on OL meaning has led to a confusion regarding its measurement. This issue has not been considered enough by the literature developed during decades of organizational thought. This has produced a lack of empirical works on the matter and, in particular, the almost absence of an elaboration of multi-item scales.

We have, despite this, focused on analyzing different scales from a macro/positivist approach that allows the undertaking of the measurement of OL as a multidimensional latent construct. Via this approach, a first group of analyzed works measures the organizational learning ability through a set of attributes that defines a learning organization. A second group establishes the learning measurement throughout several stages or phases in time, producing a collective knowledge. Finally, we have presented the OL measurement by the concept of learning stock and flow, aiming to show that OL and organizational knowledge represent both one and the same organizational reality.

Chapter 5.28
Knowledge Management in Higher Education and Professional Development in the Construction Industry

Fung Fai Ng
The University of Hong Kong, Hong Kong

ABSTRACT

Development of a 'knowledge society' affects not only enterprises and organisations, but also individuals. Lifelong learning and continuing professional development are essential for graduates and workers to remain competent and competitive. Hence, knowledge management is not only important in business processes, but also in education. As the importance of knowledge management in the construction industry is growing, competence in knowledge management is essential for graduates of curricula related to the construction industry. Design and implementation of such curricula should take into account methods for enriching the knowledge management competences of students in higher education. This chapter reports on lessons learned from the design and implementation of a particular module where principles of knowledge management are integrated into the learning activities.

INTRODUCTION

Since the early eighties, knowledge management has become a 'hot' issue. Modern organisations consider knowledge as an important resource and a source of competitive advantage. Our society is evolving from an 'information society' to a 'knowledge society'. Advances in information technology and the accessibility to huge amounts of information on the Internet have made everyone aware of the potential for using and creating information and knowledge. The impact is not only on enterprises and organisations, but also on individuals. Lifelong learning and continuing professional development are essential for graduates and other workers to remain competent and competitive. Hence, knowledge management is not only important in business activities, but also in education.

The impact of knowledge management in higher education is multi-levelled. Educational administrators and teachers have begun to look at how they might use information systems to assist in creating effective learning environments. Knowledge management can also be used to support both educational administration and the teaching and learning environment. As the importance of knowledge management in the construction industry is growing, competence in knowledge management is essential for graduates of curricula related to the construction industry. Design and implementation of such curricula should take into account methods for enriching the knowledge management competencies of students in higher education. This chapter reports on lessons learned from the design and implementation of a particular module where principles of knowledge management are integrated into the learning activities. The module is Surveying Studio in the BSc (Surveying) curriculum of the Department of Real Estate and Construction at The University of Hong Kong.

Processes in knowledge management are not new. However, the knowledge management approach provides a more systematic way in which to design and facilitate learning activities. Students working in a team environment to solve problems are exposed to issues related to knowledge management such as communication, knowledge creation, knowledge acquisition, knowledge sharing, and collaborative work. Students are introduced to various tools to support knowledge management, including dialog mapping software, collaborative authoring, and concept mapping. The goal is to integrate principles of knowledge management into a constructivist learning environment so as to enhance students' competence in knowledge management.

LEARNING OBJECTIVES

1. Appreciate the relationship between learning, professional development, and knowledge management.
2. Integrate the principles of knowledge management in designing a course.
3. Design a course with a constructivist learning environment to promote self-learning and to develop skills of knowledge management.
4. Develop and implement learning activities that make use of knowledge sharing tools.

BACKGROUND

In an 'information society', competency in information literacy is an important requirement in business and in education. According to the Information Literacy Competency Standards for Higher Education (American Library Association, 2000), an information-literate individual is able to:

- Determine the extent of information needed
- Access the needed information effectively and efficiently
- Evaluate information and its sources critically
- Incorporate selected information into one's knowledge base
- Use information effectively to accomplish a specific purpose
- Understand the economic, legal, and social issues surrounding the use of information, and access and use information ethically and legally

The emergence of the 'knowledge society' and the knowledge-based economy signify a new era for knowledge workers. Globalisation has led to ever-increasing competition and shortening of the life cycles of products and services. New information and communication technologies continue to transform workplaces and work practices. There is a requirement from industry for continuous professional development and lifelong learning. Based on the report of the Careers Education and Placement Centre (2001), employers today expect undergraduates to have core competencies in:

- Communication skills
- Analytical reasoning
- Lateral thinking
- Interpersonal sensitivity
- Practical orientation
- Information technology proficiency
- Work attitude
- Emotional stability

The growing complexity and dynamics of professional work increasingly require teamwork. The above requirements call for a new paradigm for education and training which goes beyond information literacy. It encompasses creative and critical thinking, problem solving and communication skills, as well as the ability to interact with others in a collaborative manner. The requirements are evolving from competency in information literacy to competency in knowledge management.

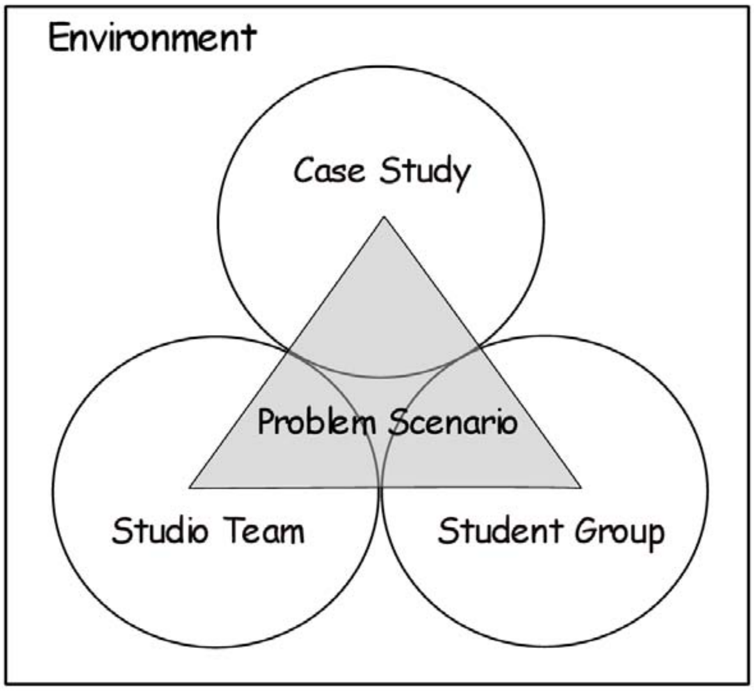
The trend of lifelong learning and learner-centred approaches to education actually reinforce the need for knowledge management competency. In the curriculum design of the BSc (Surveying) course, in addition to core subjects, is a module called Surveying Studio. The aim of Surveying Studio is to allow students to undertake work under their own initiative, and to test their abilities and understanding of professional skills and techniques. Surveying Studio originally started with a task-oriented approach. Feedback from both staff and students was collected and the design was revised. Other successful ideas from courses related to problem-based learning and peer learning were incorporated. The common feature of all these approaches is constructivism. Theories of constructivism suggest that for learning to be useful, the learner needs to be actively involved in constructing new knowledge within meaningful contexts, not merely absorbing it (Duffy, Lowyck, & Jonassen, 1993). Jonassen (1999) lists a number of design principles that can be used to develop what he calls the "constructivist learning environment." These design principles are:

- Create real-world environments that employ the context in which learning is relevant.
- Focus on realistic approaches to solving real-world problems.
- The instructor is a coach and analyser of the strategies used to solve these problems.
- Stress conceptual interrelatedness, providing multiple representations or perspectives on the content.
- Instructional goals and objectives should be negotiated and not imposed.
- Evaluation should serve as a self-analysis tool.
- Provide tools and environments that help learners interpret the multiple perspectives of the world.
- Learning should be internally controlled and mediated by the learner.

The outcome is a change from a transmission model of learning to a constructivist learning paradigm. In a student-centred approach to education, students are responsible for their own self-directed learning. Based on a student-centred framework, a conceptual model of Surveying Studio is shown in Figure 1.

There are four major components in the conceptual model: case study, studio team, student group, and the problem scenario. The case study is a real-life project in the field of real estate and

Figure 1. Conceptual model of Surveying Studio



construction. Information and documentation for the case study are collected from various organisations involved in the project. The case study is intended to set Surveying Studio in an authentic context or theme. The studio team is composed of four or five members of staff including the studio coordinator. The studio coordinator is responsible for planning, scheduling, and coordinating all studio activities. The studio team works together to develop problem scenarios with respect to the selected case study. A problem scenario is an open-ended and ill-structured problem in an authentic context. It allows students to explore the problem from different viewpoints, different pathways, with different learning styles, and to arrive at different solutions. The pathways are complex enough for a variety of investigation approaches by different ability levels. Students are divided into groups with four to six members. Group members remain the same for the whole academic year. Student learning groups work through the problem scenarios to achieve desired learning outcomes.

Studio space and furniture are provided within the department. Students have their own desks, which are usually grouped together according to their learning groups. Network connection points and a wireless network are available to enable the students to connect laptop computers to the Internet from their desks. The studio space is an environment in which students are able to work on their own and conduct informal group meetings. A weekly meeting between the facilitator and student learning group is conducted in a small meeting room. The problem scenario is delivered to the students. The student learning group discusses and defines the problem, distributes workload among group members, continues to explore the issues, and shares the findings and learning experiences with each other. At the conclusion of each problem scenario, the group produces the final learning outcome and deliverable(s). Also, students keep a learning journal to document and reflect on their learning experience and progress. As continuous assessment is employed, there is no written examination for Surveying Studio.

The above description is from the point of view of the module designer. As it is a student-centred learning framework, looking from the student's perspective would show the learning environment as a knowledge management system.

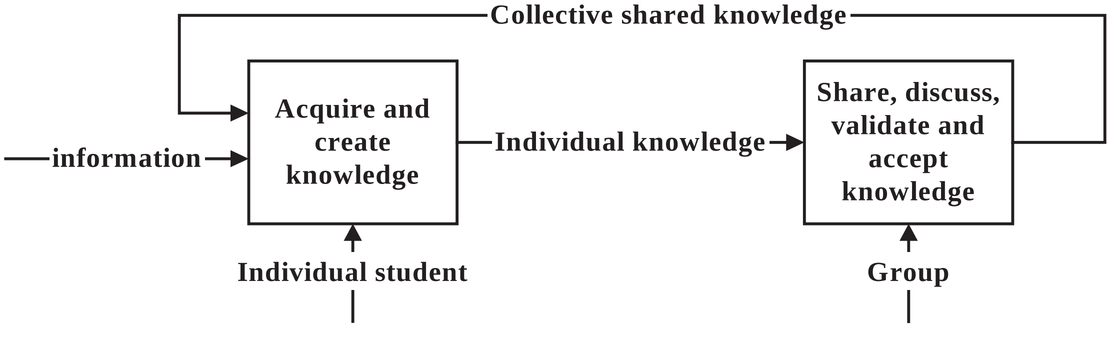
CONSTRUCTIVIST LEARNING ENVIRONMENT AS A KNOWLEDGE MANAGEMENT SYSTEM

Marshall and Rossett (2000) noted that knowledge management systems "are composed of two complimentary parts: one technical, the other social" (p. 26). The technical component seeks to "capture, package, and distribute tangible, documented products," while the social side "enables collaboration, connection, and reflection among system users." To adopt the student-centred learning paradigm, a constructivist learning environment should be created as a knowledge management system for the students. The technical components of the system include the infrastructure and resources to support the knowledge management processes carried out by students. The social components include the time, space, and culture to support collaborative work and peer learning.

Davenport (1998) indicates that knowledge is created invisibly in the human brain, and only the right organisational climate can persuade people to create, reveal, share, and use it. Learning is a process of creating knowledge. Learning how to learn is the spirit of knowledge management. Thinking in processes stresses the dynamic nature of knowledge management. Basically, there are two main categories of knowledge management processes:

- Acquire and create knowledge: When students search, read, organize, and understand information, they acquire and create knowledge in their minds and integrate the new knowledge with their existing knowl-

Figure 2. IDEF01 diagram of knowledge sharing



edge. Hence individual learning is about individual knowledge development and enhancing competences.

- Share and use knowledge: Facing a problem, students apply and use their knowledge to solve the problem. Working in a team environment, students share their knowledge to develop new knowledge, and apply knowledge for problem solving. Sharing knowledge is a way to use knowledge. Knowledge sharing is also the basis of organisational learning.

The relationship between individual learning and collaborative learning is shown in Figure 2.

In both education and business, it is important to create a culture and an environment to maximize individual knowledge development, as well as knowledge sharing, through collaborative work.

LEARNING ENVIRONMENT TO SUPPORT KNOWLEDGE SHARING

Individual students are responsible for their own self-directed learning to acquire and create knowledge. The learning environment should provide access to various information sources, including libraries and resources on the Internet. It should also facilitate the articulation and exchange of knowledge. Effective knowledge creation depends on an enabling context, which can foster ideas and facilitate the articulation, creation, and evaluation of experiences and knowledge. Creating a 'right context' is crucial to student-centred learning.

In Surveying Studio, a problem scenario is designed to stimulate the students' need for more knowledge to solve the problem. When the problem scenario is presented to a student group, the students brainstorm and clarify the issues during their first meeting with their facilitator. Individual students contribute ideas based on their existing knowledge. They need to identify the nature of the problem and the knowledge required for solving the problem. At the same time, they identify gaps in their existing knowledge, and the measures and actions required to fill the gaps.

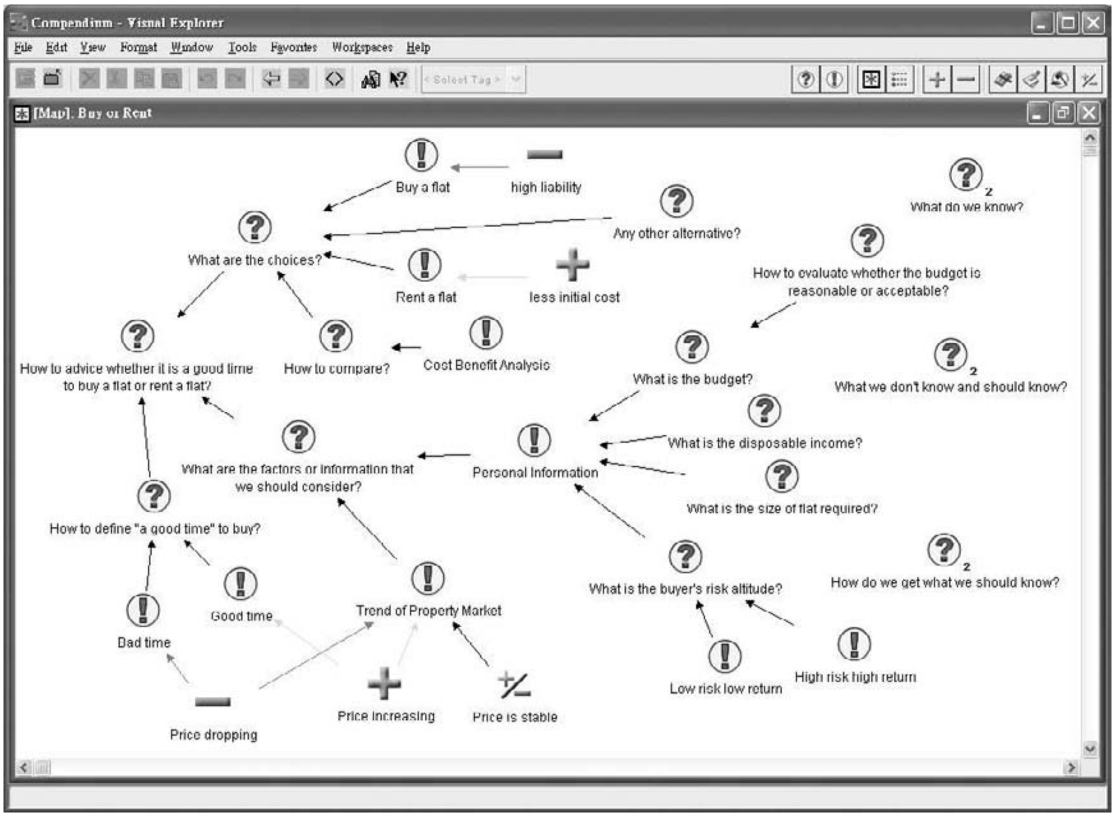
Knowledge Sharing: A Technical Perspective

Although students discuss the problem scenario in a face-to-face meeting, communication and knowledge sharing are not necessarily effective. A learning environment should enable the group to share their thinking and reformulate their assumptions as they expand their understanding. A dialog mapping software tool2 is used to facilitate discussion in a group meeting. The tool provides a visual presentation for tracking and visualizing the argument process. A laptop computer running the dialog mapping software is connected to a data projector. The projected dialog map consists of questions, ideas, and arguments generated from the discussion process (Figure 3). During the meeting, students raise issues, questions, ideas, and arguments. One student, acting as the group scribe, records the issues, ideas, and so forth, using the dialog mapping software on the laptop computer. The projected dialog map serves as a group memory, encouraging students to make their assumptions visible, while helping to clarify their thinking and improve on other students' ideas. The combination of information on the dialog map and visual thinking leads to a rich discussion. The following verbatim passage is part of a group discussion after the facilitator has delivered the problem scenario to the group. Student A is the chairperson and Student B the scribe.

Student A: Today, our task is to advise Janis whether she should buy or rent a flat. In my opinion, I would suggest her to rent a flat.

Student C: If Janis buys her own flat, she'll feel more secure. I think she should buy instead of rent a flat.

Figure 3. Using dialog mapping to augment discussion



Student B: Me too. How about we simply vote to determine our recommendation?

Student D: I don't think so. We should not only tell Janis about our recommendation. We need to advise and explain our suggestion to her.

Student E: In that case, we should compare the pros and cons of the two choices to see which one is better. I think timing is one of Janis's concerns also.

Facilitator: Good. How about establishing a focus question first to guide our discussion?

Student A: So, our question is whether it is a good time to buy or rent a flat.

Student D: Besides buy or rent, are there any other options?

Student B: I don't know. Anyway we'll put this down as a question.

Student C: How are we going to compare the two options?

Student A: We should find out the factors affecting the choice.

Student D: I think the decision may be a personal preference.

Student C: That means we have to consider some personal factors such as monthly income, family size, etc….

Student C: Don't forget that we have to judge whether it is a good time to buy a flat or not.
Student D: It depends on the current status of the property market. I think buying a flat is a big investment.
Student A: Do you know what are the costs involved in buying a property?
Student D: I don't know the details, but I know that there is legal fee, agent fee, and the buyer needs to arrange a mortgage loan with the bank….

Student A: So, in the coming week, (Student C) and I would find out more information about the status and trend of the property market.
Student B: I'll work with (Student D) to find out all the costs involved in renting a flat and buying a flat.
Student E: May be we should ask our parents, as they had made that choice already?...

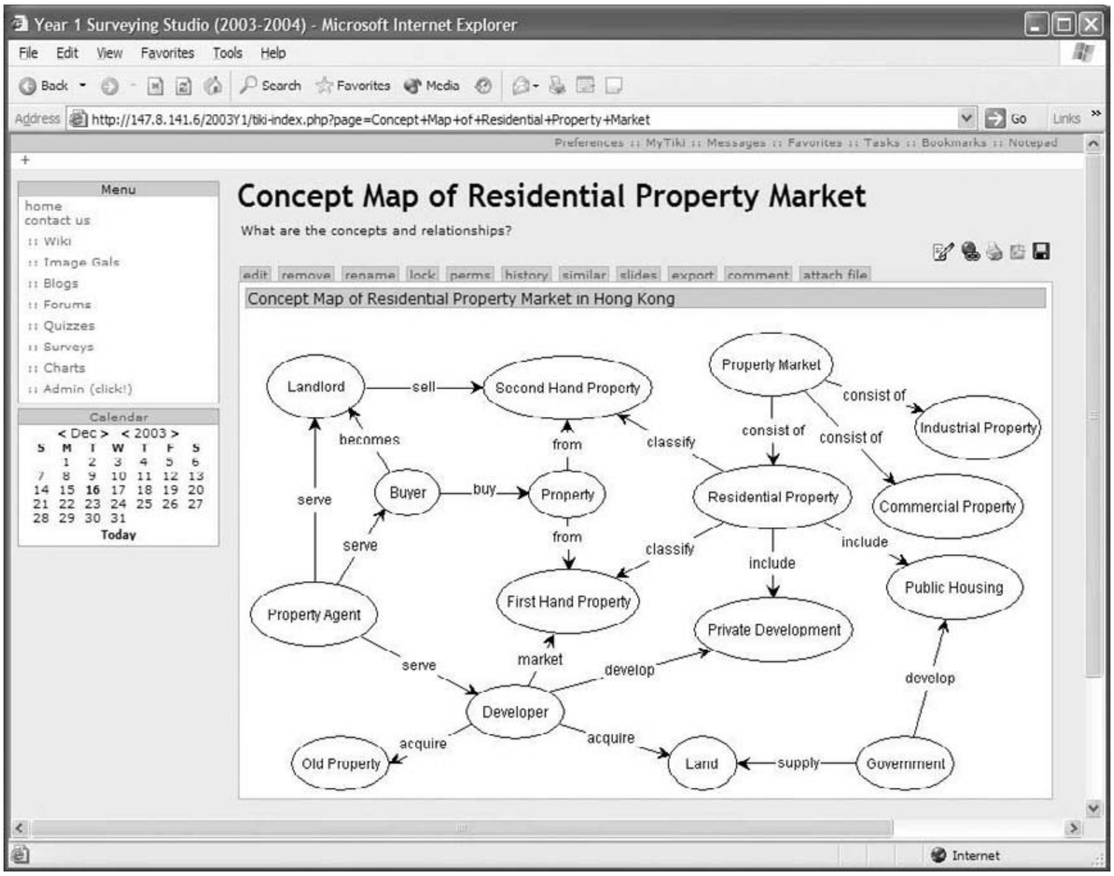
At the end of the meeting, the group has a road map to solve the issue and an action plan to guide the work of individual members. Each student then acquires further knowledge from various sources and shares the knowledge through other channels before the next meeting. The initial design intended to create a discussion forum on the Internet for students to share their findings and ideas in an asynchronous mode after the meeting. The result was not satisfactory. The outcome was a long list of threaded discussion postings. Some messages were subjective, without supporting arguments or follow up. Others were similar or simply repeating other member's ideas. The problem was that the collection of postings in a discussion forum was not consolidated to represent the shared-group knowledge. In fact, students preferred to use their usual channels, for example, ICQ for chatting and discussion rather, than using the prescribed discussion forum.

From the initial experience, we found that students are smart enough to find their own way to communicate and share ideas. What was missing was a repository to capture the collective shared group knowledge generated from the discussion process. Therefore, a knowledge repository was established on the Internet using a Wiki server.3 Instead of posting individual messages, students create and edit Wiki pages in a collaborative authoring environment. Students continue to use their preferred channels for discussion, but they are also required to create Wiki pages to consolidate their findings and ideas generated from discussions. Every member can edit the Wiki page to modify exiting information or add more information using a standard Web browser. The collective shared-group knowledge is represented as a set of linked Wiki pages. Students read the Wiki pages to acquire and create their own individual knowledge. However, students are not just passive receptacles of information, they are also creators. The system allows students to post and share documents. It also allows them to edit documents, to view the history of changes to a document, and to create and contribute documents.

To support meaningful learning from the shared-group knowledge, the technique of concept mapping is also introduced. Meaningful learning is a process in which new information is related to an existing relevant aspect of an individual's knowledge structure (Novak, 1998). A simple graphic editing tool4 is used for the students to create their own concept map. The tool also allows real-time collaborative editing of concept maps, as well as asynchronous editing integrated with the Wiki server (Figure 4).

To reflect and learn from one's own experience is an essential element in knowledge management. Students are required to write and post their learning journal on the Wiki server. A learning journal promotes self-assessment and evaluation which is critical in acquiring and creating individual knowledge. Both positive and negative learning experiences are found in the students' learning journal, for example:

Figure 4. Concept map integrated with Wiki page



Student V: I enjoy searching and exploring new knowledge.

Student W: I feel extremely stressful. I always don't know what to do at the beginning.

Student X: I learn how to work effectively within limited time and how to cooperate with other group members.

Student Y: Group members cannot compromise on issues. Lack of communication between group members is obvious.

Student Z: We learn how to think, how to organize working schedule, and how to solve problem as a group.

As students reflect on their learning experiences, they identify the way to improve or to solve the problem.

To summarize, the tools and technologies that support the constructivist learning environment include laptop computers, data projector, Internet connections, dialog mapping software, Wiki server, and a concept mapping tool. Technology helps to connect students so they can think and work together. However, to achieve effective knowledge sharing, the social and cultural context is also important.

Knowledge Sharing: A Social Perspective

Students learn on their own and together as a group. They see each other's thinking as they solve problems together, in peer reviews, or in arguing with each other. A critical factor to support effective knowledge creation and sharing is the necessity for students to be physically close to each other in space and time. The sense of "nearness" is crucial in stimulating the exchange of ideas, tacit knowledge, and experiences. Therefore, a studio space where students have their permanent working place is desirable. It establishes a stimulating social environment, and generates social pressure and a sense of mutual responsibility. In their studio, students usually group their desks together according to their group memberships (Figure 5).

The design of a constructivist learning environment faces challenges from various aspects. The social challenge is to develop communities

Figure 5. Studio space to augment knowledge sharing

that share knowledge and still maintain enough diversity of thought to encourage thinking rather than copying. The management challenge is to create an environment that truly values sharing of knowledge with trust and reward. The personal challenge is to be open to the ideas of others, to be willing to share ideas, and maintain a thirst for new knowledge.

Before the commencement of Surveying Studio, an orientation and explanation of the student-centred learning approach is delivered to all students. It is important to make sure that all students understand that assessment of their performance is criterion based and not norm referenced. Assessment is based on group performance and individual contribution to the group. Hence, there will be less competition between students. Competition between groups to achieve higher grades may exist, but group members are willing to share and help each other so as to perform effectively as a team.

In addition to the formal meeting to discuss the problem scenario in the presence of the facilitator, the main portion of learning takes place as peer learning in informal meetings among students. Students continually learn from each other on a daily basis. They learn a great deal by explaining their ideas to others and by participating in activities in which they can learn from their peers. They develop skills in organizing and planning learning activities, working collaboratively with others, giving and receiving feedback, and evaluating their own performance. Much peer learning occurs informally without staff involvement.

The design of a problem scenario focuses on the setting of open-ended issues for students, working as a group, to solve the issues. Students engage in exploration of ideas and knowledge, and learn to learn. A member of staff, acting as a facilitator, hands over more control to the students. The student group determines individual roles within the group and it is the personal sense of learning that signifies collaborative learning. Critical thinking, problem solving, making sense of complex issues and personal transformation, the social construction of knowledge—exploration, discussion, debate, criticism of ideas—are the essence of collaborative learning. Bruffee (1999) names this approach 'constructive conversation'—an educative experience in which students learn by constructing knowledge as they talk together and reach consensus or dissent. Dissent, questioning each other's views within a group, is a necessary part of learning.

CURRENT RESULTS

The design and development of Surveying Studio is an ongoing process. There have been both success and failure scenarios. Feedback and lessons learned are used to improve ongoing design and development. Preliminary observations indicate positive results in enhancing students' knowledge management competence in the following aspects:

- Working with others: A student group is a learning community. Students develop a sense of responsibility for their own and others' learning. They also develop confidence and self-esteem. They learn to acknowledge the backgrounds and contributions of other students they are working with to develop collaborative skills.
- Critical enquiry and reflection: A challenge to existing ways of thinking arises from more detailed interchanges between students in which points of view are argued and positions justified. Opportunities are present for formulating questions rather than simply responding to those posed by others. Students are able to articulate what they understand and to be more open to critique by peers, as well as learning from listening to and criticizing others.
- Articulation of knowledge: Concept development often occurs through the testing of ideas

on others and the rehearsing of positions that enable students to express their understanding of ideas and concepts. It is often only when they are expressed and challenged that students appreciate whether they have a good grasp of what they are studying.

- Learning how to learn: The learning activities in Surveying Studio require students to develop self-management skills and management of others. Students take collective responsibility for identifying their own learning needs and planning how these might be addressed. Learning to cooperate with others to reach mutual goals is a prerequisite for working in a complex society.
- Self- and peer-assessment: The learning activities require students to identify criteria to assess their own learning and to practice self- and peer assessment. This is a key element of sustainable assessment needed for lifelong learning.

Surveying Studio enhances students' experience of learning, and enables them to engage in the learning processes that reflect the working practices in which they will be expected to participate later, when they are in the workplace.

FUTURE TRENDS

Information and communications technologies are changing the nature of instructional design. Technology and the use of the Internet and World Wide Web have allowed major changes both in teaching practice and learning, and consequently, in the management of information and knowledge. Since the inception of the World Wide Web in the early 1990s, increasing numbers of educators have used this medium to make information, relevant to their courses, available to students. The ability to use the Internet to place information online for others to access, as well as to collaborate with others, creates a new way of thinking about the management of knowledge, information, and documents.

The challenge faced by both business and education is not only how to best manage the volume of information so that it is easily accessible to search and retrieve materials, but also how to provide people with the ability to post information and to enhance collaboration. It is important to create a culture where instructors and students are willing to share their information and knowledge, as well as contributing to the generation of new knowledge. The application of knowledge management principles and the desire to deliver documents to learners has opened the door for creating a more effective learning environment in higher education and professional development.

The rapidly changing knowledge economy has led to an increased interest in lifelong learning. Workplaces are in need of employees who can learn new skills and adapt quickly to social and technological changes. Educational institutions are faced with the challenge of providing students with the knowledge and skills to enable them to adapt successfully to job-related changes after completing their formal education.

The growing complexity and dynamics of professional work increasingly requires teamwork. Professionals piece information together, reflect on their experience, generate insights, and use those insights to solve problems. Continuous learning while working is obligatory to meet the performance requirements of the workplace. In the above context, there are many questions regarding new ways of working and learning still to be resolved.

CONCLUSION

In the developed world, the basis of the economy has changed from manufacturing products to creating and managing knowledge. In addition to the possession of professional knowledge, the ability to continue learning has become more and more important. Education is of increasing importance in its form as a lifelong and continuous learning process, both in business and in the individual context. The significance of lifelong learning and continuous learning raises the need for new teaching and learning paradigms. For example, lifelong learners typically plan their own learning, apply existing knowledge and skills effectively, evaluate their own learning, locate information from different sources, use different learning strategies in different situations, and resolve complex problems with multiple or uncertain solutions. These requirements need to be considered in both curriculum design and course delivery.

Although knowledge management has been developed within a business context, it can be applied to education. Knowledge management is not only essential at an organisational level. It should be a key competence at an individual level. Knowledge management should be integrated into higher education and professional development programs related to construction industry. The design and development of Surveying Studio is a step forward in the trend of integrating knowledge management principles to create a constructivist learning environment in higher education. This learning environment promotes students working as a team and augments knowledge sharing in both a technical and socio context. Various tools to support knowledge management are introduced to students, including dialog mapping, collaborative authoring, and concept mapping tools. Problem scenarios and learning activities are designed to integrate the use of knowledge sharing tools and knowledge management strategies. The primary objective is to enhance students' competence in knowledge management so that, after graduation, they are able to cope with the knowledge-based working environment.

The design and development of Surveying Studio is an ongoing process. We are learning from our experience by acquiring and creating our own knowledge. We are using our knowledge to improve, and also sharing our knowledge through this publication.

PRACTICAL TIPS AND LESSONS LEARNED

- Competence in knowledge management is important for graduates and professionals working in a knowledge-intensive industry.
- Learning how to learn is an essential skill of knowledge management.
- Learning to cooperate with others to reach mutual goals is a prerequisite for working in a knowledge society.
- Encourage the use of all possible types of communication channels (formal and informal, physical and virtual) to support knowledge sharing. The community will find the most effective way to share knowledge.

ENDNOTES

1. IDEF0 is a method designed to model the decisions, actions, and activities of an organisation or system. It is a public domain modelling system, and in fact it is an American standard (FIPS 183).
2. The dialog mapping software used is called Compendium, available at Compendium Institute, www.compendiuminstitute.org.
3. The Wiki server is established using TikiWiki, freely available at tikiwiki.org.
4. The graphic editing program is called JGraphPad, freely available at jgraph.sourceforge.net.

Chapter 5.29
Legal Knowledge Management

John Zeleznikow
Victoria University, Australia

INTRODUCTION

Legal practice is primarily concerned with the transfer of legal knowledge from practitioners or clients. Whilst lawyers may draft contracts and make representations on behalf of their clients, their primary task is to advise their clients on appropriate remedies and courses of action. Rodríguez Morcón, Pérez García, and Sigüenza Pizarro Rodriguez (2002) claim that a lawyer sells what he knows, often in the form of a document (a contract, an opinion, a report) and much more often in a trial before a court or in a negotiation with a counterpart. Khandelwal and Gottschalk (2003) claim that lawyers can be defined as knowledge workers. They are professionals who have gained knowledge through formal education (explicit) and through learning on the job (tacit).

To carry out their daily work, lawyers also have to manage a great many sources of information. It is important for them to be aware of current changes in legislation and jurisprudence, and to consult books and articles. But it is also necessary to manage the information that is generated from within the practice in the course of lawyers' relationships with their clients. In a law firm's day-to-day work, a mass of information and knowledge is generated which has to be managed efficiently, so that it is easily, quickly. and intuitively accessible whenever it is needed by any of the firm's offices. Rusanow (2003) defines legal knowledge management as the leveraging of the firm's collective wisdom by using systems and processes to support and facilitate the identification, capture, dissemination, and use of the firm's knowledge to meet its business objectives.

We commence by emphasising the difficulty of developing generic legal knowledge management approaches given the multiplicity of different legal systems. We next focus on maintaining legal knowledge using an argumentation-based approach and building legal knowledge-based systems for World Wide Web. Since the goal of the legal process is to avoid litigation, we conclude by discussing how knowledge can be managed to provide Online Dispute Resolution.

BACKGROUND

One of the major difficulties in providing generic legal knowledge management tools is the fact that legal practice is very context dependent. Whilst the laws of gravity are fairly uniform throughout our earth, this is definitely not the case with legal norms. Even within Western Europe, Canada, and the United States, there are distinct legal traditions—namely Common Law and Civil Law.

David and Brierly (1985) note that common law and civil law legal traditions share similar social objectives (individualism, liberalism, and personal rights), and they have in fact been joined in one single family, the Western law family, because of this functional similarity. Other countries may have a code of law based upon tribal practice or religious principles.

Even within one country, there may be various modes of legal practice or major regional differences in the way law is practised. For example, in the United States, a state court determines Family Law. Because of the varying legislation between states, lawyers often engage in forum shopping to obtain an advantage for their client.

As well as regional differences, the different courts in the same region may rely upon distinct burdens of proof—the necessity or duty of affirmatively proving a fact or facts in dispute on an issue raised between the parties in a cause (Black, 1990). Except as otherwise provided by the common law, the burden of proof requires proof by a preponderance of the evidence (or the balance of probabilities). In a criminal case, the government must prove all the elements of the crime beyond a reasonable doubt. Except in cases of tax fraud, the burden of proof in a tax case is generally on the taxpayer.

Hence law is very domain specific. An ontology is an explicit conceptualization of a domain (Gruber, 1995). Legal ontologies represent legal norms and are very significant for developing legal knowledge-based systems on the World Wide Web.

Building generic legal ontologies is not possible. Breuker, Elhag, Petkov, and Winkels (2002) claim that unlike engineering, medicine, or psychology, law is not ontologically founded. They claim law is concerned with constraining and controlling social activities using documented norms. Zeleznikow (2004) conducts an overview of legal ontologies.

CLIME, e-COURT, and FFPOIROT are all legal ontology projects funded by the European Union. Because of the plethora of legal systems in Europe, there is a great need to develop legal ontologies that are applicable across the European Union.

Given the domain specific nature of legal knowledge, and the fact that law firms exploit their legal knowledge for commercial gain, legal knowledge management has often been conducted in-house. Perhaps the one exception to this rule has been legal aid organisations, which provide advice to a large number of indigent clients.

LEGAL KNOWLEDGE MANAGEMENT, DECISION SUPPORT, AND THE WORLD WIDE WEB

Gottschalk (1999) states that the use of advanced technologies enables the law firm to take advantage of the most appropriate tools to improve efficiency, increase effectiveness, streamline communication, and reduce costs for their clients. A law firm is a collection of fiefdoms—each lawyer has his or her own clients and keeps the information about them private. One of the greatest objectives of knowledge management in law firms seems to be consistency of work output in an increasingly global market. Knowledge management support systems in law firms are concerned with capturing and codifying knowledge, creating knowledge, distributing knowledge, and sharing knowledge (Edwards & Mahling, 1997).

Russanow (2003) claims that information technology creates an expectation of faster and alternative legal services. In the age of instantaneous communication, lawyers have been forced to find quicker ways to deliver traditional legal services. Knowledge management systems and processes enable lawyers to work more efficiently and provide legal services quicker than ever before.

The Internet has also opened a whole new market for lawyers to sell their services. Lawyers must examine how they will use technology to deliver services to their clients. Online advisory and drafting tools, developed and managed by law firms, are becoming commonplace. Knowledge management systems and processes provide the foundation of online services.

Ross (1980) states that the principal institution of the law in action is not trial: it is settlement out of court. Alternative dispute resolution involves alternatives to the traditional legal methods of solving disputes. It is difficult to construct a concise definition of alternative dispute resolution (to litigation) for resolving disputes. Online dispute resolution, the application of information communication technology in alternative dispute resolution, has become a new and enhanced technique for dispute resolution.

Russanow (2003) further claims that a large firm may find that there is little sharing of knowledge across practice groups and offices. There are a number of cultural reasons for this. Where the partner compensation model rewards the individual rather than the firm, practice groups tend to operate as separate business units, focused only on growing their own practices. There is no incentive to share work with others, since there may be no reward for referring work to colleagues. Indeed, there may be overlap in areas of practice between lawyers in different practice groups. These groups may be competing with each other in the market. Lawyers may also believe that their knowledge base is their power base, and that sharing that knowledge would dilute their value.

This lack of knowledge sharing between individuals and practice groups means that the firm is not leveraging its multi-practice, multi-office infrastructure. Practice groups are not looking at cross-selling opportunities with other practice groups. These inefficiencies and lost business opportunities may directly impact the firm's revenue. In some instances, the lack of cross-referrals to other, more appropriate practice groups may even affect the firm's risk exposure.

Carine (2003) claims key elements of knowledge management are collaboration, content management, and information sharing. These elements can occur concurrently.

Collaboration refers to colleagues exchanging ideas and generating new knowledge. Common terms used to describe collaboration include knowledge creation, generation, production, development, use, and organisational learning

Content management refers to the management of an organisation's internal and external knowledge using information management skills and information technology tools. Terms associated with content management include information classification, codification, storage and access, organisation, and coordination.

Information sharing refers to ways and means to distribute information and encourage colleagues to share and reuse knowledge in the firm. These activities may be described as knowledge distribution, transfer, or sharing.

Effective information technology (IT) support for knowledge management can serve as a competitive advantage and as a professional aid to law firms. To examine IT support for knowledge management in Norwegian law firms, Gottschalk (1999) conducted a study that involved two phases of data collection and analysis. The first phase was an initial field study of the largest law firm in Norway to identify issues and attitudes towards IT and knowledge management in a law firm as a basis for the survey approach in the second phase. The semi-structured interviews conducted in the initial field study documented a strong belief in the potential benefits from knowledge management. The second phase was a survey of Norwegian law firms. Firm culture, firm knowledge, and use of information technology were identified as potential predictors of information technology support for knowledge management in law firms in Norway. The extent to which law firms in Norway use information technology to support knowledge management is significantly influenced by the extent firms generally use information technology.

FUTURE TRENDS: LEGAL DECISION SUPPORT ON THE WORLD WIDE WEB

Susskind (2000) indicates that until recently, there was only limited use of IT by legal professionals. While the use of word processing, office automation, case management tools, client and case databases, electronic data/document interchange tools, and fax machines is now standard, for example, only recently have law firms commenced using IT for knowledge management purposes. He claims that the use of knowledge-based legal knowledge management tools will become common in large firms by 2007 and in all legal firms by 2012.

But how will such systems be constructed?

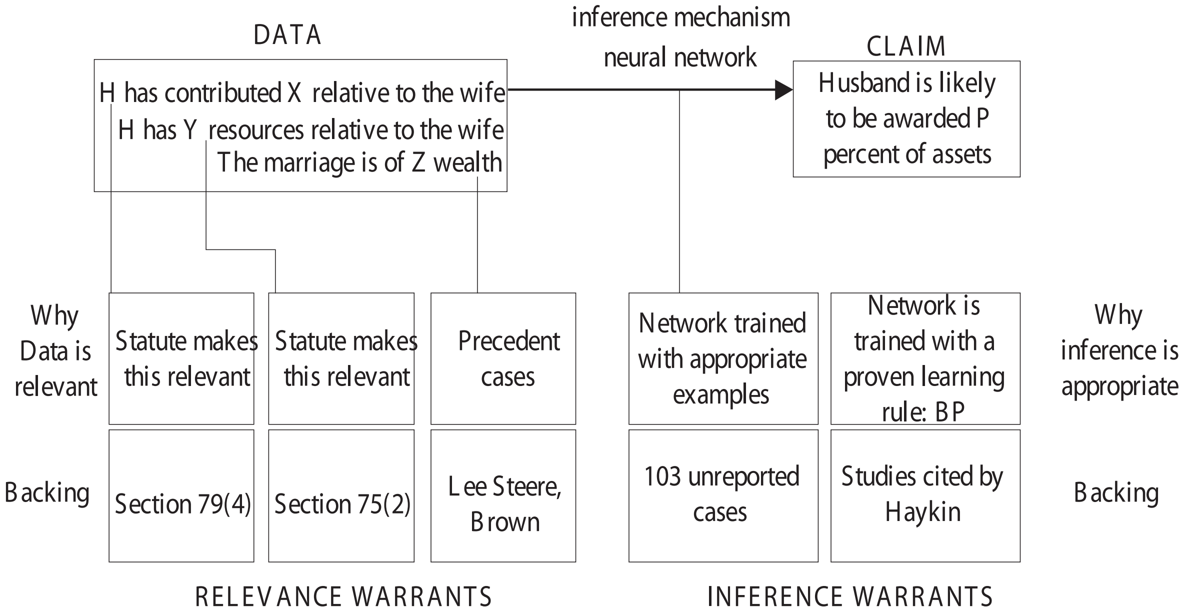
Argumentation has been used in knowledge engineering in two distinct ways: to structure knowledge and to model discourse (Stranieri & Zeleznikow, 2004). Stranieri, Zeleznikow, and Yearwood (2001) have used Toulmin's theory of argumentation to manage legal knowledge. Toulmin (1958) concluded that all arguments, regardless of the domain, have a structure that consists of six basic invariants: claim, data, modality, rebuttal, warrant, and backing. Every argument makes an assertion based on some data. The assertion of an argument stands as the claim of the argument. Knowing the data and the claim does not necessarily convince us that the claim follows from the data. A mechanism is required to act as a justification for the claim. This justification is known as the warrant. The backing supports the warrant and in a legal argument is typically a reference to a statute or a precedent case. The rebuttal component specifies an exception or condition that obviates the claim.

A system they constructed called Split-Up (Stranieri, Zeleznikow, Gawler, & Lewis, 1999) provides advice upon how Australian Family Court judges distribute marital property following divorce. Figure 1 illustrates one argument from the Split-Up system. We can see from that figure that there are three data items. Each of these is the claim item of other arguments, leading to a tree of arguments where the ultimate claim of the system is the root of the tree. In the argument in Figure 1, the inference mechanism is a neural network. The network, once trained with appropriate past cases, will output a claim value (percentage split of assets) given values of the three data items.

Figure 1 illustrates one argument from the Split-Up system. In 20 of the 35 arguments in Split-Up, claim values were inferred from data items with the use of neural networks, whereas heuristics were used to infer claim values in the remaining arguments. The Split-Up system produces an inference by the invocation of inference mechanisms stored in each argument. However, an explanation for an inference is generated after the event, in legal realist traditions by first invoking the data items that led to the claim. Additional explanatory text is supplied by reasons for relevance and backings. If the user questions either data item value, she is taken to the argument that generated that value as its claim.

The Split-Up system performed favourably on evaluation. Currently, the tree of arguments is being modified in conjunction with domain experts from Victoria Legal Aid (VLA) to accommodate recent changes in legislation. The argument-based representation facilitates the localization of changes and makes maintenance feasible. The use of the argument-based representation of knowledge enables machine-learning techniques to be

Figure 1. Argument for percentage split of assets to the husband



applied to model a field of law widely regarded as discretionary. JUSTREASON, developed by JUSTSYS (www.justsys.com.au) is a knowledge management shell that integrates a rule-based reasoning approach with argumentation structures similar to those used in the Split-Up system. To date the argument structure has been trialed in systems in family law (35 arguments), refugee law (200 arguments), sentencing (23 arguments), copyright law (50 arguments), evaluation of eyewitness evidence (23 arguments), and eligibility for legal aid (8 arguments).

The argument structure is also being used to support online dispute resolution. Lodder and Zeleznikow (2005) argue that an online dispute resolution environment can be appropriately designed through the use of dialogue tools and negotiation systems in a three-step model. Their proposal involves the use of collaboration and information sharing. The model involves: (a) determining the BATNA (according to Fisher and Ury, a BATNA—Best Alternative to a Negotiated Agreement—is what would occur if the issue were not resolved), which is a form of information sharing; (b) attempting to resolve the existing issues in conflict using argumentation techniques—a collaborative approach to resolving the dispute; (c) for those issues not resolved in (b), we use compensation/trade-off strategies to advise on a possible sequencing and resolution of a dispute—a further attempt at sharing information given the disputants' preferences. If the advice suggested in (c) is not acceptable to the parties, return to (b) and repeat the process recursively until either the dispute is resolved or a stalemate occurs.

We are currently using the JustReason Shell as a tool for building our online dispute resolution environment. It allows for the development of decision support systems to advise upon BATNAs, provides support for the disputants to conduct discussions and negotiations (argumentation), and allows for the use of game theory techniques to advise upon trade-offs. Our online dispute environment has been tested in the domain of property distribution in Australian Family Law.

CONCLUSION

In this article, we have noted that generic legal knowledge management is difficult, since legal knowledge is very domain and region dependent. Recently, there has been an increased focus on providing legal knowledge through the World Wide Web. We argue that future legal knowledge management systems that provide support for dispute resolution will become available on the World Wide Web. We introduce one approach for building such systems.

Chapter 5.30
Operational Knowledge Management in the Military

Gil Ariely
University of Westminster, UK, & Interdisciplinary Center Herzliya, Israel

INTRODUCTION

This article intends to cover operational-knowledge management (KM) as implemented in the military. In particular, it is based on experience and published examples from the U.S. Army and the IDF (Israeli Defense Forces). It concentrates on the characteristics of operational knowledge as the core type of interest for the military due to the nature of the mission. The proxy of human lives and mission success are used vs. the more common currencies in the business industry.

The article covers common vehicles in KM through examples implemented in the military (such as communities of practice in the U.S. Navy, storytelling, and scenario planning), with special attention given to a detailed description of the AAR (after-action review). This is a military-originated KM process now widely adopted by industry. Although all these are familiar KM methods and concepts in industry, their value and uniqueness for military applicability are illustrated.

In the current and future battlefield, knowledge and information are critical resources (both of the enemy and of our forces). Through innovative and dispersed IT systems, KM has transformed the modern battlefield situational awareness, both for the individual soldier and the very core of command and control.

A section is devoted to KM in low-intensity conflicts (LICs) that emphasizes learning throughout fighting due to the unique and asymmetric nature of LIC as the contemporary and most common modern form of warfare. In LIC, the learning cycles are short as opposed to those of classic wars where the main learning is done before and after conflicts. In LIC, as a prolonged process (of varying intensities), learning must be conducted throughout the fighting.

BACKGROUND

Liddell Hart (1991) stressed that throughout history, militaries that should have been organizations of the highest adaptability capabilities (due to the nature of their mission) have been the least flexible, harming their own functioning. This has promoted the adoption, for more than a decade in the military, of the learning-organization concept aimed at transforming the military into a dynamic organization that continuously implements organizational learning. Indeed the learning-organization concept (Senge, 1990) is closely entwined with, and is one of the drivers of, the KM movement.

The concentration of knowledge management is derived from the military's mission and vision. The U.S. Army, in its "knowledge vision" (2004), defines "a transformed Army, with agile capabilities and adaptive processes, powered by world class network-centric access to knowledge, systems and services, interoperable with joint environment." Indeed, a continuum strategy to such vision transforms the Army into "a network-centric, knowledge-based force."

Why Operational-Knowledge Management?

Operational has two different meanings in the military context: a knowledge type, and a level of fighting forces and warfare. This article refers to the first.

As a knowledge type, operational knowledge has meaning in industry as well. Although operational research (OR) started in the British Military during WWII, it evolved as a discipline into industry and different domains and areas (Keys, 1995).

However, operations are entwined in most organizations on their way to achieve organizational goals. In the military, the operations (in the sense of military operations) are the very core and essence of the organization. A military organization is established and trained toward operations, be it peacekeeping, defense preparedness, or wartime operations. Hence, operational knowledge is a salient.

The characteristics of operational knowledge demand exploration as the core type of interest for the military (due to the nature of the mission). Indeed, this supports the usage of proxy indicators, such as human lives and mission success vs. the more common currencies in industry.

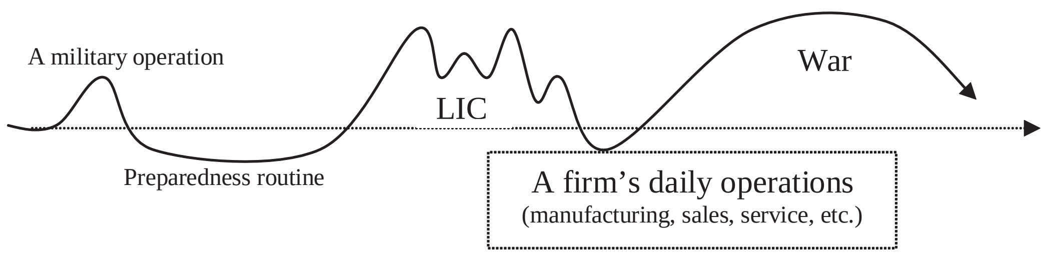
Although various knowledge types exist in the military (e.g., professional or procedural knowledge in different domains), most of these may be differentiated in their connection to operations, hence to operational knowledge. Whether knowledge is entwined with the conduct of military operations, or indirectly connected merely due to the eventual goals of a military, makes a difference in the way it is referred to.

The military is a competencies-based, mission-oriented organization, which is operational in nature. Hence, operational knowledge is the very essence of the military. So, we need to focus on managing it first, for more reasons than one.

- It is the best testing ground for KM in the military, rendering the fastest ROI.
- Every operational KM implementation is principally applicable toward other knowledge types in the military (once the methodologies are familiar).
- Since commanders' and sponsors' attention are scarce (as are other resources), it is aimed at the operational goals of the military.

Since operational in this context refers to knowledge type, the discrimination from the analogous military term for a level must be determined. Operational refers in the army command also to levels of forces and warfare (i.e., strategic, operational, tactical levels). However, KM can be implemented at all these levels, aimed at operational goals.

Figure 1. A simplification of a firm's operations compared to the nature of military operations



Although presumably KM is more applicable at organizational levels, tactical implementation yields a higher mission success rate. Exploring new operational paradigms is especially crucial for special-operations success (Gagnon 2002), where a clear delineation between essentially tactical missions and possible operational or strategic effects does not exist.

FIRST FOCUS: ADAPTING KM VEHICLES FROM (AND TO) INDUSTRY

Most common KM vehicles implemented in industry are applicable to the military with appropriate adaptation. Furthermore, some KM practices that originated from the military have been adopted by industry. However, the military might have called it by a different name, or did not consider it a KM process. The scope of this article allows a sample of only a few such prominent vehicles, but many more exist, entwined in the daily operations of the military. Even regular officers' gatherings, from the battalion level to divisions, account for such KM processes that aim to create a knowledge-sharing culture as well as sharing specific knowledge.

Since even the titles of these KM processes may differ from those familiar in industry, it is essential to describe their military reembodiment and value. Furthermore, KM in the military context requires adaptations to operational settings, for instance, to "match the pace of operations" (McIntyre, Gauvin, & Waruszynski, 2003, p. 38): "Knowledge management and the knowledge cycle within the context of military operational environments, therefore, require emphasis on these additional requirements of robustness, content and speed."

The current synergy of the military, the academic community, and industry practitioners and researchers promises to benefit the military from the progress of KM.

The After-Action Review

One of the fundamental tools of KM in the Army is the after-action review process. It was developed by the U.S. Army, although it is in use by other militaries as well, sometimes under different titles and a slightly different process (e.g., debriefing). Due to the intense nature of events in the Army, it allows for almost real-time learning in a brief session.

There are four distinct phases in the after-action review.

1. What was supposed to happen? What was the action plan, and what did we aim to do?
2. What actually happened? There is a reviewing and establishing of the facts of the events.
3. What was the gap? What went wrong, causing the gap between 1 and 2?
4. What can we learn? What are the lessons learned that could be implemented in future circumstances (vs. just erroneous judgments)?

Furthermore, a fifth phase may be added.

5. How can we disseminate the lessons learned and to whom should we communicate them?

Higher resolution AAR requires a more detailed prescription, but the principal phases are kept, and so are some cultural principles.

- The AAR is a learning event and not an inquiry aimed at blaming.
- The AAR should be conducted as soon as possible after the action or event, when facts are clear and memory is fresh. In some cases, it can also be conducted throughout events.
- The action itself may be a mission, a training exercise, a project phase, or any clearly defined event.
- Participants should be inclusive of all those in the action reviewed.
- The climate should be open and nonhierarchical, contrary to military culture.

The product of the after-action review is an after-action report detailing the lessons learned. The terms might differ slightly; for example, the Australian Army refers to PAR and POR (post-action review and post-operation report) templates for similar purposes.

Since the U.S. Army's after-action reviews are "probably the best known example of leveraging knowledge within a team" (Dixon Nancy, 2000, p. 37), they are widely adopted by industry. For instance, "British Petroleum has made it the middle step of its three-part knowledge management process" (p. 38) since the AAR is so intuitive and appropriate to the "serial transfer" of knowledge and of lessons learned in the organization.

Sullivan and Harper (1997) observed the direct, immediate personal benefits and usefulness to participants in action and in AAR as its success rationale. Indeed, AARs produce local value: knowledge to be used at the decision-making point (Sullivan & Harper). What the basic AAR process lacks is a system to transform and disseminate it beyond local knowledge and value to the organizational level, and to permeate it throughout the Army. That system is the Center for Army Lessons Learned (CALL).

The CALL

Since the disadvantage of AAR is that it is conducted locally and produces local value, the CALL aims to disseminate AARs and lessons learned organizationally throughout the Army while validating their content in a wider context.

Military knowledge management is far from secretive (although the knowledge itself might be). Voluminous unclassified material exists (methodological and core) on the Web site of the CALL(http://call.army.mil/).

Similar examples are the Australian Army's CAL (http://www.defence.gov.au/army/cal/) and the IDF Central-Command Operational-KM Site on the internal intranet.

The CALL may also assign learning observers to specific units or training exercises. Their role is to accompany a unit on its duties, bring lessons learned through AARs back to the CALL, and disseminate them to the forces. An excellent example of such conduct was with the U.S. Army's 10th

Mountain Division on the naval aircraft carrier Eisenhower during the 1994 Haitian peacekeeping efforts (Baird & Henderson, 2001).

Organizational Knowledge Portal

One of the first steps to the implementation of a dispersed IT-enabled organization like the Army is the creation of accessible knowledge centers containing codified, explicit knowledge and information. An effective infrastructure vehicle for such knowledge centers are organizational portals, which the military as a whole (or specific units) implement extensively on internally accessible networks.

The collaborative IT infrastructure is the foundation for many KM and knowledge-sharing vehicles, especially for a geographically dispersed organization. Some (like CoPs [communities of practice]) are elaborated upon in this article.

The U.S. Army Knowledge Online (AKO) is the Army's intranet portal, which "features content-management software, e-mail, instant messaging, chat rooms, knowledge centers, a people locator and white pages" (U.S. Army, 2004, p. 374). "AKO, the army's knowledge portal has grown to over one million soldier and civilian registered users."

Communities of Practice

IT collaboration tools and environments, like organizational portals, are crucial for the establishment of geographically dispersed communities of practice, a common vehicle in KM.

Indeed, the Army has long acknowledged the role of communities of practice in the creation, sharing, and leveraging of tacit knowledge. CoPs cross units and domains since they may share a professional interest or practice, or rather an operational one. They may be active (as is usually the case) during routine times, but should aim at maintaining, and if possible, implementing, the support networks of relationships and knowledge where and when needed operationally in real time.

An example of implementation guidelines can be found in the U.S. Navy's CoPs manual (http://www. hq.usace.army.mil/cecc/PG/Starter-Kit.doc).

Indeed, CoPs are implemented widely in the military and yield high operational results: "Communities of Practice (CoPs) are the cornerstone of NAVSEA's strategy for evolving a knowledge enterprise. CoPs offer a collaboration structure that facilitates the creation and transfer of knowledge" (Department of the Navy's Knowledge-Centric Organization).

The ultimate implementation goal of CoPs in a network-centric military should be operational (due to the nature of the mission). It is improved operational ability resulting from real-time support amongst combating units (geographically or task tangential). Such collaboration is based on acquaintance and common language, values, and knowledge nurtured in routine times in these communities of practice.

Storytelling

Nothing is more common and familiar in the Army than war stories. However, besides being just good stories, they also act as a key learning vehicle. They are perhaps even the most ancient and intuitive learning vehicle to human nature as recent research of narration and storytelling proves and promotes.

From the minute a unit returns from mission activity, even before formal AAR or debriefing, storytelling takes form at all levels: from a personal level to a group. This ontological re-creation of events in memory allows for the screening of events through learning binoculars on different levels, formal or nonformal.

Once researched and made explicit through KM processes such as AAR, stories become a formal military learning apparatus—as battle stories are taught not only in military colleges, but are also communicated in other surroundings many times as heritage and history.

KM supports the transition of such processes toward the organizationally cognitive by entwining storytelling beyond heritage: the dissemination of currently relevant or emphasized lessons learned from past occurrences.

For example, a history quiz prepared in the Counter-Terrorism School of IDF was aimed to disseminate contemporarily validated lessons learned from past hostage-rescue events to instructors.

Scenario Planning, War Games, and Simulations

Scenarios are of instrumental core use in the military. They detail contingency plans for a range of eventualities from which the action plan is chosen and formed.

In a similar manner, throughout the process of intelligence analysis, the enemy's possible scenarios are created and analyzed in light of probability and perilousness to our forces. This is done not merely as a risk analysis, but is entwined into the force's own scenarios.

In industry, scenarios are used in different contexts. Ringland (2002, p. 2) says, "In the creative media, it may mean a storyline…strategists, policy makers and planners use scenarios in a 'future-oriented' sense." Indeed, in the field of knowledge management, the usage of scenarios has been researched and promoted as a vehicle for the creation and dissemination of common knowledge and vision through the creation of common future scenarios. This allows for the creation of a unified organizational paradigm. According to Ringland, "Scenarios have been in use at Royal Dutch Shell since the 1960s," and they "help us to understand today better by imagining tomorrow, increasing the breadth of vision and enabling us to spot change earlier" (http://www.shell.com).

The synergy between the KM scenarios approach and the common one in the military allows for a step further in other knowledge and KM military implementations—when using simulations for training.

In the '70s, an experiment with two groups of flight controllers showed that the learning of one group a priori was much less effective than the other group, which was in control towers in a real-life context. Indeed, critical-incidents professions emphasize this notion, which I refer to as context-dependent learning, most applicable in the Army.

Context-dependent learning uses familiar methodologies in the Army like war games and simulations that are implemented for various tasks and enhances them.

The U.S. Army prairie-warrior simulation, for instance, tested the effects of digitizing the battlefield, allowing the consideration of possible changes before actual combat deployment (Baird and Henderson, 2001).

Such war games and simulations are also the most effective learning vehicle for soldiers and commanders at all levels of the systems they operate in (social or technological). Furthermore, they allow participants to learn about themselves in a unique context, and they trigger the most inherent level of learning that comes only from doing.

War games were always used by military organizations on strategic and operational levels. However, recent research shows (Ariely, 2004) that even the learning of a terrain cell becomes more effective through context-dependent learning when taken to tactical levels (e.g., a tactical war game played on that terrain cell).

Further goals of scenarios, war games, and simulations include the following (Ariely & Fighel, 2004).

- Testing different scenarios as they develop, including accordance with enemy scenarios

- Testing of specific subjects (e.g., battlefield digitization in the prairie-warrior simulation)
- Context-dependent learning for new commanders and decision makers
- Rehearsal and repetitive knowledge aimed at testing and maintaining readiness
- Dissemination of lessons learned (either through other simulations or AARs)

As illustrated, the blend of KM methods and concepts used in industry are of critical value when adapted and implemented in the military. Experience from KM in industry promoted the cognitive and explicit implementation of KM and KM managerial education, which leads to the appointment of KM-related roles to leverage knowledge as a resource. Hence, it is requisite in a modern military. According to Kaplinski (2004), in the IDF's Central Command, for instance, operational CKOs were appointed up to battalion level (as cited in Lubetzki, 2004).

It is the duty of operational knowledge officers to disseminate methodologically and to implement the KM vehicles proven to be so effective operationally (such as the AAR, which leverages local knowledge, and the lessons-learned repositories that complement it organizationally). The ability of a unit arriving at a unique terrain cell to learn from the past experience of other units operating in the same place before is crucial for maintaining human life and mission success.

SECOND FOCUS: KM AND MODERN WARFARE

KM Transforming the Modern Battlefield

Information technology and the network-centric approach are transforming the nature of the modern battlefield. It is not the existence of voluminous, immediate information from multiple sources that makes the transformation the application in fighting. Tactical knowledge has become a major resource for fighting from the individual level to command and control at all levels. Anyone with combat experience is familiar with the battlefield "information fog" during chaotic events.

Combat KM and IT systems aim at minimizing this fog while not overloading with unnecessary information. Such an example is the Blue Force Tracker system, which Col. Mike Linnington of the 101st Airborne's Third Brigade in Iraq described, dealing with one of the biggest problems of "situational awareness and the ability to battle track blue force, or friendly units" (as cited in Chilcote, 2003). It allows locating units (through GPS [Global Positioning System]) and friend or foe identification that prevent friendly fire (or "blue-on-blue") incidents. Other systems allow intelligence to be transmitted to the battlefield in real time, for example, visual digital aerial imagery of enemy locations and status.

Today, the field commander manages a battle picture loaded with information and knowledge through a variety of supporting measures. These measures are supportive in managing and integrating (mainly technologically) the knowledge and information both of our forces and of the enemy. However, they demand a cultural adaptation of command and control as strategic commanders must reject the temptation to micromanage the battlefield.

Furthermore, knowledge and information that were conveyed to field commanders (and back) are now dispersed to the individual level, allowing a whole new concept of the "knowledge warrior."

KM and Information Warfare

Information warfare stands as a military domain of its own. Clearly, where the ammunitions are information and knowledge, managing both becomes a core military competency, both offensively and defensively (protecting information, infrastructure, and knowledge risk analysis). The scope of this article does not allow full coverage of the relationship between KM and information warfare (e.g., Hall, 2003), however, it suffices to posture knowledge warfare as the next evolutionary phase in information warfare. The fight is not only for information superiority, but rather the way it is implemented toward action and the widening effect of knowledge (e.g., on public opinion and consciousness in low-intensity conflicts, directly affecting military stakeholders).

Learning throughout Fighting: KM in Low-Intensity Conflicts

In his book Low Intensity Operations (1971), Frank Kitson claimed that during the quarter of the century since WWII, the British Army participated in only four conflicts classified as "limited war," while at the same time it was active in about 30 other low-intensity operations, not confronting regular forces of enemy nations.

The elusive nature of such warfare (even more than other forms of modern urban warfare that is fought amongst civilians) is asymmetric by definition. The advantages of conventional military force cannot be expressed vs. the full implementation of the opponent's advantages. The LIC is a very demanding form of warfare for the Army (challenging Clausewitz's focus on decisive battle (Clausewitz, 1956)) since it is a prolonged process of varying intensities. It demands the extraction of resources including knowledge, and managing them skillfully.

In the LIC, learning cycles are short, and contrary to classic wars when the main learning is done before and after, the learning must be conducted throughout the fighting. It can be compared to two learning sinus waves adapting one to the other, where every event obliges the opponent to quickly adapt through a short learning cycle and vise versa (Nir, Or, Bareket, & Ariely, 2002). Such an example is the IRA vs. the British detonation-devices learning cycles, or the equivalent learning cycles relating to detonation devices between Hizbulla and the IDF in Lebanon (Gordon, 2002). Hence, in LIC, operational KM is crucial not only amongst the Army's forces, but also in learning from the enemy's activities. Confronting the asymmetric nature of the LIC is achieved through the replication of the opponent's advantages (e.g., through special forces), only implementing that knowledge better. Such an example is the replication of guerilla warfare tactics from Hizbulla in Lebanon to the EGOZ IDF unit (Gordon).

One of the main tasks of the military today is the global war on terrorism. In the current global era of state-sponsored and postmodern terrorism, no clear delineation can be drawn between LIC involving terrorist organizations or guerilla forces and other forms of global terrorism. This is greatly due to the lack of an agreed-on definition of terrorism (Ganor, 2001). Hence, further attention is needed on the synergy between military KM in LIC and other organizations countering terrorism.

Brig. Gen. Kochavi of the IDF referred to the main insight from LIC as the need for having a learning mechanism: "Victory in a changing reality = the ability to learn" (as cited in Yair, et al., 2004).

The Transformation of KM toward Intellectual Capital

Intellectual capital (IC) is briefly defined as intangible assets, and since there is no clear delineation between IC and KM, the relationship clearly deserves further attention (see in this publication "Intellectual Capital and its Relationship with KM" by the same author).

In fact, much of the resources used in the military are intangible: Within the soldiers exist their knowledge and training, there are the weapon systems required for implementation and planning, and so forth. For all these, the IC paradigm developed in the last decade is useful.

The U.S. Army (2004, p. 367) KM strategy defines intellectual capital as "[i]ndividual, team, and enterprise knowledge, systems, and services, and workforce strategies that are necessary to improve operations and decision making."

What forms does IC take in the military? As opposed to the more common currencies in industry (that transform to "hard capital"), proxies in the military for IC differ.

Human casualties within the military and between civilians seems to be the ultimate cost, both the trivial and the critical one when considering the mission of the Army.

However, in the current economically oriented militaries, we may find interesting examples of how military KM becomes through intellectual capital hard currency. In a recent example, the Israeli Army chief of staff offered training knowledge and facilities (part of IDF's intellectual capital) to be marketed to foreign armies (Shapiro, 2003). Some of that intellectual capital relates directly to KM since the Army's tactical training center includes sophisticated debriefing and AAR technological systems that allow 3D images of the conducted training.

Recent research in the military (Ariely, 2004) proposes that internal stakeholders perceive operational KM as a core competency in itself, and that various proxy indicators exist to common industry financial indicators for valuing IC and knowledge assets. In many cases, these may be achieving the mission objectives or minimizing casualties (e.g., reducing cases of friendly fire on soldiers' own forces). Nevertheless, a particular unit's IC is perceived as its ability to be assigned the mission vs. other competing units being assigned. Hence, many concepts relevant to competitive edge and the intellectual-capital paradigm may be very relevant indeed for the military (internally or amongst units).

FUTURE TRENDS

KM is prominent for the future of the military. In the short and medium run, KM promises to continue revolutionizing the battlefield, not just technologically but culturally (as seen in the past and in the present with embedded reporters in fighting). Every soldier and vehicle should arrive at full real-time knowledge autonomy, free to engage in fighting. The network-centric approach requires new operational paradigms to be revisited at all levels.

In the long run, the combination of technology, IT, and the human factor (the soldier as a knowledge worker) is of consequences beyond any imagination.

Forecasts predict unmanned vehicles and even possibly (with progress in research) brain-machine interfaces (BMIs; Shran, Hauptman, & Marcus-Kalish, 2003). Parallel progress in the research of knowledge management, cognitive science, and artificial intelligence may bring a whole new era of knowledge-based warfare aiming at a lower rate of casualties. The U.S. DARPA (Defense Advanced Research Projects Agency) predicts the future warrior to wear clothing that will include processors and sensors, allowing more information to be available at the individual level and thus requiring less (scarce) attention.

Since knowledge is humane and knowledge management is societal, the real transformation is expected in the essence of modern warfare through trends like transparency to the public, casualty sensitivity, and wider global trends.

The result is only greater dependencies on knowledge, and hence, on managing it best.

Subsequently, the explicit understanding of knowledge as a resource renders it vulnerable and as such a target in itself. KM might support further development in the field of information warfare toward a whole new concept of knowledge warfare.

CONCLUSION

Nowhere is the transformation from the industrial age to the information age more evident than in the modern battlefield. Knowledge has become a major resource for fighting from the individual level to strategic command. The skills of managing and implementing methodologies relating to knowledge (like learning throughout fighting) are now critical fighting skills. Thus, knowledge management may become not only a mission-improving and life-saving vehicle, but the very difference between defeat and victory.

Chapter 5.31
Military Knowledge Management

R. William Maule
Naval Postgraduate School, USA

INTRODUCTION

Knowledge is a critical component of military operations, and the military has been an early adopter of knowledge management (KM) technologies. Significant events include a strategic use of tools to filter information into knowledge, the designation of knowledge officers in high-level strategic positions, and the implementation of knowledge systems as a means to support situational awareness and understanding. Following is a brief overview of knowledge management within the military and a review of knowledge theory and practice pertinent to military knowledge management.

MILITARY KNOWLEDGE MANAGEMENT

The military is extremely diverse in its knowledge systems and practices. In the collective, the military would be the equivalent of many large corporate conglomerates, each with multiple research and development (R & D) branches. Adding to the complexity is the secrecy of many of the systems. To attempt to summarize military knowledge management in its entirety would be presumptuous, if not impossible. Rather, this discussion will focus on some representative systems and approaches being advanced in military-sponsored KM research and practice. Included are comparisons to knowledge-management initiatives in the private sector. The discussion begins with an overview of private-sector and academic-research practices that have carried forward into the military.

Relevant Research

The importance of knowledge management has been equated to the importance of natural resources in previous generations wherein strategies that companies once devoted to optimizing capital and labor are now being applied to maximize the productivity of knowledge resources (Silver, 2001). A means to maximize productivity in the military is to integrate systems, technologies, and information resources. Such aggregations are increasingly under the umbrella of knowledge management.

At a technical level, military knowledge management is addressed within enterprise-systems engineering initiatives, with a current initiative force transformation through network-centric systems (MIT, 2002). Knowledge systems may be an adjunct to specialized computing systems or an umbrella under which information and communications technologies can be grouped. Similar to the private sector, military KM integrates disciplines addressing computer and communications technology, cognitive science and artificial intelligence (AI), and human-computer and human-systems integration. There is additional research addressing information synthesis or fusion, with XML (extensible markup language) as a categorization schema and ontology structure in support of semantic understanding. In addition are military-specific KM initiatives such as command and control, military intelligence, and sensors.

Common to both the military and private sector is research into mechanisms to consolidate data and information into knowledge, and once integrated, to understand strategic options and cause-effect relationships (Primix Solutions, 2000). The desired result is improved decision making, interorganizational communications, cooperation, and interaction (Schwartz, Divitini, & Brasethvik, 1999). An example at the macrolevel is Army knowledge management with its transformation mission toward a knowledge-based organization that integrates best practices into professional duties through active involvement with the knowledge infostructure (MIT, 2003).

At a microlevel are issues in knowledge design that address navigation and search mechanisms (Sherman, 2000), and knowledge structures to help achieve a goal or objective (Saward, 2000). In the military, a current focus is on context to help document knowledge flows (Nissen, 2001). Metrics are important for the assessment of knowledge initiatives, and means have been advanced to address the value of specific knowledge units (Gao & Sterling, 2000), to include relevance weightings for context-integration points, and to allow the knowledge value added (KVA) methodology to ascertain return on knowledge investments (Housel & Bell, 2001).

Both the military and private sector have an interest in cognitive understanding and research to encode process, procedural, and expert knowledge into software (Storey, Goldstein, & Ullrich, 2002); to find techniques to capture common-sense knowledge in a context-sensitive manner and extract expert-level specifics (Storey & Day, 2002); to derive metacognitive attributes to help define relationships between user cognitive needs and knowledge metadata (Maule, 1998, 2000, 2001); and to implement reasoning tools to identify patterns of behavior to resolve problems or identify opportunities (Fensel & Motta, 2001). All of these approaches are active in military research as a means to structure or derive knowledge for decision-support applications.

A next step is to make this processed knowledge readily available. Portals with collaborative tools are mechanisms to establish relevance (Silver, 2001); to personalize, sort, and filter information (Moore, 2001); and to enhance business intelligence with decision support (Ruber, 2000). A portal with real-time chat and messaging empowers users with collaborative abilities (Loria, 2001). In the Navy, portals have become a primary means for information, communications, collaboration, work-flow coordination, and decision support (Maule, Gallup, & Schacher, 2003).

Also notable is the trend toward communities of practice as a means to build knowledge expertise. Communities increase social capital or the economic value of relationships within an organization and therein lower the cost of knowledge. Workers find information more quickly and realize overall information efficiencies as a life cycle of involvement forms around the knowledge community (DoN CIO, 2000). In the military, knowledge communities support work-group collaboration around specific knowledge concepts or initiatives. They help extend and expedite the traditional reach of individuals to colleagues who can share knowledge in a just-in-time manner (Tate, 2001). For example, the Air Force Materiel Command is fielding an Air Force-wide knowledge management initiative using the community-of-practice methodology to support collaboration among a widely dispersed workforce to enable teamwork, communication, and sharing within a virtual environment (AFMC, 2003).

Warriors need specific data in a timely manner. As in the private sector, semantics, ontology, and XML are emerging techniques to support transparent, automated knowledge exchange. Research in semantics has established that (a) content can be embedded with meaning, (b) relationships between meanings are delineated, and (c) access methods are coordinated around those meanings (Grimes, 2002). Semantics can additionally characterize participant roles in an interaction to establish relationships between entities, context, and knowledge bases (Storey et al., 2002). XML provides the syntax and structure, and ontology provides the means to define terms and relationships (Berners-Lee, Hendler, & Lassila, 2001). Value is added through classification and metadata (Chandrasekaran, Josephson, & Benjamins, 1999).

Military-specific ontology has been developed to aid in experimentation analysis and to contextualize problem scenarios in support of detailed situational assessment and understanding (Maule, Schacher, Gallup, Marachi, & McClain, 2000; Schacher, Maule, & Gallup, 2001). Military-specific ontology is being developed by agencies including DARPA (Defense Advanced Research Projects Agency) with its DAML (DARPA agent markup language), and the North Atlantic Treaty Organization (NATO) with its LC2IEDM (Land C2 information exchange data model; NATO, 2000).

MILITARY KNOWLEDGE SYSTEMS

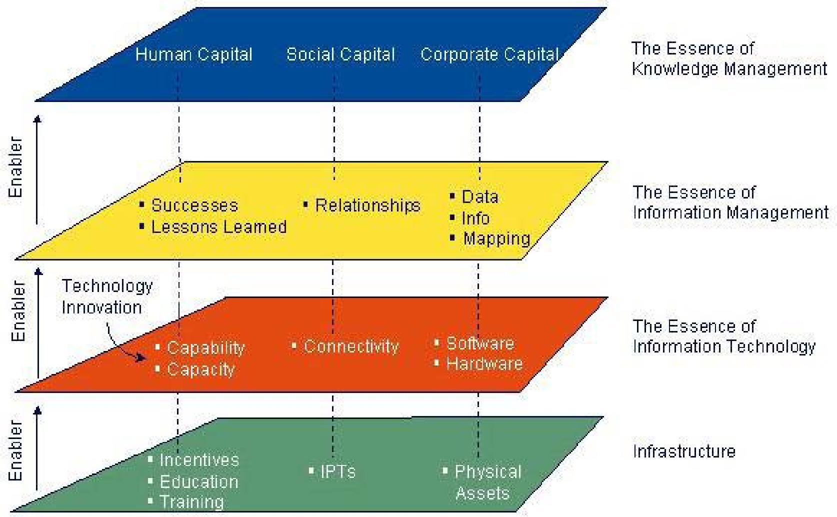
Similar to KM private-sector research, there are many approaches to knowledge management in the military, each with its own set of tools, techniques, and methodologies. These range from AI-based techniques, to the statistical analysis of content, to ontology and metadata for categorization, to structural methodologies for cognitive profiling and user personalization, and to data mining for content pattern recognition. In complex environments, such as the military, an effective approach might involve several techniques, multiple tool sets in various combinations, and the integration of knowledge outputs with current situational data to help form an understanding for decision makers.

The services have taken somewhat different routes to KM. The Navy has its wide-reaching $6.9 billion Navy-Marine Corps intranet program that is converting 200 networks into the world's largest intranet while simultaneously consolidating date, information, and knowledge resources. The Army is using knowledge management as a way to centralize systems management at major commands under the CIO's (chief information officer's) office, and the Air Force portal will consolidate hundreds of disparate legacy data systems into a single decentralized point of access (Onley, 2001).

Current Practices

Joint-forces operations and cross-service integration is a current focus in the military. With this comes the challenge of data, information, and knowledge integration across the services. In response to such challenges are new techniques to evolve data into information, and informa-

Figure 1. Evolution from information to knowledge (DoN CIO, 2000)



tion into knowledge and understanding. Figure 1 provides a Navy perspective to illustrate how knowledge is evolved from learning and training to address technology, connectivity, and access. Then, information management is where data and information are mapped, relationships are explored, and lessons are derived. Finally, knowledge management is where human, social, and corporate capital are integrated.

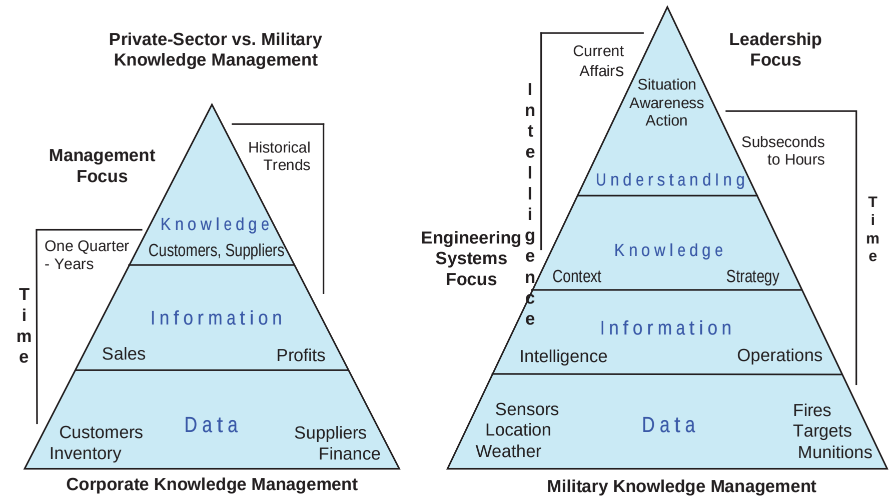
Knowledge management in the military is often used in the broadest sense to include such variables as the management of numerical values obtained from automated collection systems, qualitative data from human subjective opinions, synthetic results from both human and machine simulation, and systems output or result sets tailored to address specific long-range plans or objectives (Maule, Schacher, & Gallup, 2002). Military knowledge applications are often designed to support specific strategic, operational, or tactical decision-making processes and related questions.

Many knowledge tools are adopted from the commercial sector, but there are some notable differences in application, especially for warfare. Of course, there are unique demands placed upon the military for just-in-time knowledge for the warriors.

For example, in corporate knowledge management, a dynamic situational assessment for a real-time attack is not a typical company objective. In the military, knowledge systems for such an objective would need to help convey understanding. The concept is modeled in Figure 2.

Military knowledge systems may be called upon to integrate information and knowledge output with current situational data to form an understanding in the mind of the decision maker. Understanding requires a real-time context. The idea is to develop real-time understanding faster

Figure 2. Corporate vs. military knowledge management



than the enemy, and this cannot be achieved if decision makers are overloaded with too much information. Knowledge should enable a commander to develop an understanding of the situation, make good decisions, and implement them faster than the enemy (Harrigan, Jenkins, Winters, Mohs, & Hay, 2001). The Army is attacking information overload by developing knowledge ontology and infrastructure, evaluating existing knowledge-fusion algorithms, and developing computational models to address specific knowledge-management needs (MIT, 2002).

Collaborative tools are important in military knowledge systems because they can integrate resources to enhance situational awareness and understanding. Chat, instant messaging, online meetings, and shared application technologies are hallmarks of current knowledge-management initiatives (Donnelly, 2003). The integration of traditional knowledge technologies with collaborative capabilities has increased overall complexity, and knowledge officers have been assigned to monitor information flow, encourage the use of collaborative planning tools, and assist with knowledge-based communications. An example is the global war games in which the "knowledge warrior" has emerged as a facilitator of information for the Commander Joint Task Force with responsibilities for shaping knowledge in response to information requirements and therein speeding decision times within multitiered collaborative environments (Harrigan et al., 2001).

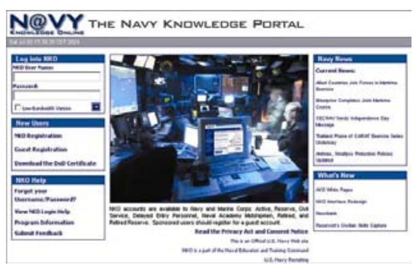
Portals are a popular means to provide access to information and knowledge repositories. Military portal initiatives focus on the aggregation of Web services, information sites, collaboration tools, and decision-support applications into centralized portals (Tate, 2001). Portals are often supported through communities of practice to ensure active participation by key decision makers. Portals additionally offer a means to implement system-wide security policies through single sign-on and common-directory services for the authentication of specific information items on a need-to-know basis (MIT, 2003). Portals are often implemented to provide warriors with access to tacit or know-how knowledge from communities of practice and collaborative access to subject-matter experts (Donnelley, 2003).

Some examples include Army Knowledge Online and Navy Knowledge Online that, in addition to current events and operations, integrate e-mail, chat, personal Web portals, and communities (Onley, 2004; Figure 3). The Air Force portal gives people the ability to view information needed to do their job without regard to the system which manages that information such that a soldier anywhere in the world can log on to a computer, check e-mail, and get the status of an order or review a schedule.

The Army Knowledge Awards Program acknowledges initiatives, programs, and concepts that exploit knowledge-management tools and principles. The program recognizes KM-based reengineering enterprise initiatives that focus on major commands, functional areas, and process transformation (DOIM, 2004). The Center for Army Lessons Learned (CALL) (a) transforms raw data into knowledge that can be acted upon, (b) sends the knowledge out to the whole organization, and (c) produces rapid behavioral change based on the knowledge. Teams of experts observe missions firsthand, collect and analyze information, ask experts to validate it, and once the information is validated, produce lessons learned that are delivered as written reports, videos, or simulations to the troops (CALL, 2004).

The Knowledge-Centric Organization (KCO) is a Navy initiative wherein personnel organize virtually around knowledge needs such that the virtual organization becomes an overlay to existing command structures (Millward, 2000). Focus areas include preparation and issues of culture, leadership, relationships, and communications; knowledge-centric systems and the development of strategy, performance measures, and incentives; knowledge-centric organizations and the measurement of performance, assessment, validation, and strategy revision; knowledge creation and brokering to address learning styles and knowledge facilitation and instruction; and knowledge communities to aid in knowledge design, mobilization, and connection (DoN CIO, 2000). Sailors reporting to a new command would previously spend days acclimating to new processes and procedures, while with a KCO, learning time has been reduced up to 80% as sailors, marines, and civilians can immediately access lessons learned and command knowledge stored in the knowledge systems (Millward).

Figure 3. Army knowledge online and navy knowledge online knowledge portals



Knowledge Metrics

Metrics are an important component of military knowledge-management initiatives. In the private sector, requirements and specifications typically lead to product evaluations, demonstrations from vendors, selection, and implementation. The process is somewhat more complicated in the military where production selection often involves a rigorous test and evaluation cycle in live operational experiments, with a focus on systems interoperability and knowledge integration at both technical and organizational levels. It is in this context that metrics provide the basis for evaluation. A few prominent themes and categories of metrics are identified in Table 1. The metrics are largely extracted from the research presented above, so the references will not be repeated. This categorization of knowledge metrics pertinent to the military will hopefully aid future researchers in military knowledge management.

Metrics addressing cognition consider knowledge needs of classes of decision makers. Initiatives may consider metadata and perception,

Table 1. Military knowledge functions and metric categories

KM Function	Metric Categories
Discovery	Acquisition, query optimization, indexing, filtering, link analysis, ontology, agents, semantics, concurrency, domains, interfaces, visualization, AI tools, sequences, streams, temporal, spatial, clustering, mining, pattern matching
Management	Logs, interviews, surveys, observers, coverage, evolution, sustenance, reuse, domains, requirements, documentation, value added, scalability, planning, scheduling, agents, organization, cleansing, unification, maintenance, safety, migration
Performance	System, process, communications, events, flows, status, readiness, integration, latency, behavior, interoperability, optimization, maintenance, survivability, fault tolerance
Decision Support	Effectiveness, efficiency, prediction, integration, representation, reaction, concurrency, agents, optimization, disambiguation, categorization, summarization, filters, mining, pattern matching, cleansing, unification
Work Flow	Planning, scheduling, domains, interfaces, concurrency, agents, sequences, streams, constraints, optimization, organization, clustering, unification
Collaboration	Synergism, domains, media, interfaces, behavior, agents, temporal, spatial, constraints, organization, clustering, pattern matching, unification
Assurance	Security, privacy, trustworthiness, authentication, aggregation, nonrepudiation, reliability, survivability, validation, consistency, documentation, verification, concurrency, interoperability, constraints, maintenance, safety, survivability, fault tolerance
Metadata	Schemas, XML structures, objects, inheritance, temporal, spatial, optimization, organization, categorization, profiles, clustering, unification, migration
Fusion	Algorithms, inference, relationships, uncertainty, ambiguity, ambience, value added, incompleteness, concurrency, sequences, streams, temporal, spatial, constraints, optimization, organization, categorization, summarization, filters, clustering, pattern matching, cleansing, unification, maintenance, migration, ubiquity
Reasoning	Integration, multimodal, inconsistency, uncertainty, incompleteness, behavior, agents, AI tools, sequences, streams, temporal, spatial, constraints, optimization, organization, disambiguation, filters

visualization, or interpretation. Reasoning models specific to a given situation may assess concept formation and evolution, collaborative behavior, inference, case-based reasoning, problem solving, or adaptation and learning. The decomposition of interactions, and cause-effect relationships based on knowledge and resultant decisions help in reasoning about information flows. Artificial-intelligence tools may be tested as aids in the information-synthesis and -extraction process.

Knowledge fusion is a related area providing a basis for the integration of content, often addressing semantics and ontology as the knowledge infrastructure. Fusion research generally considers the processes involved in combining data and information to produce knowledge to make estimates and predictions. As previously discussed, in the military, the focus is on situation assessment and impact (threat) analysis. Other fusion areas address metadata, information interaction and integration, knowledge discovery and visualization, and knowledge and information flow. Process models are means to capture organizational and system processes. Metrics may consider the impact of knowledge injects or fusions into specific processes.

Collaboration metrics address the results of human-human interchanges concerning generated information, and the impact of new variables introduced during the course of any given flow of events (ad hoc alliances, changed positions or objectives, etc.). Work-flow technologies in the military are increasingly grouped under collaborative technologies, which are in turn a driving force in military knowledge management. Metrics would stress integration between supporting technologies, systems, and organizational processes.

FUTURE TRENDS

Predicting new developments in knowledge management in the military is challenging given the size of the organizations and the complexity of the operations. Some trends that do seem certain involve the increase in interoperability of knowledge across the branches, likely occurring under joint-forces initiatives. Web services will continue to expand, integrate operations, and provide a means for knowledge sharing to increase situational awareness and understanding.

Of special interest are emerging opportunities to synthesize or fuse knowledge, and then supplement the collective with visualization or reasoning. This may be considered an area of research akin to artificial intelligence in the previous decade, but today it crosses into real-world military operations, with concerns in performance and decision support.

Virtualization and distributed knowledge through the Global Information Grid and grid computing architectures will offer many possibilities for the cross-pollination of knowledge and the integration of previously disparate knowledge operations and applications. The impact of peer-to-peer technologies for knowledge sharing will be an interesting area for future research. Experimentation is currently underway with many peer-peer technologies, however, security concerns are evident.

CONCLUSION

Knowledge management is a serious area of inquiry in the military. Given the life-threatening situations modern warriors confront and the new types of behaviors exhibited in conflict, knowledge systems have become a priority area. Many knowledge technologies and research approaches have come from the commercial sector, while many others remain proprietary and classified. This discussion has attempted to provide a bridge between public KM technologies and research in current military R & D, highlighting common areas in each. Examples of military knowledge portals and management practices provide some insight on current thinking, and the areas synthesized in the metrics and future-trends sections above hopefully provide visibility in some of the areas in which the military seeks active research and development.

Chapter 5.32
Challenges in Developing a Knowledge Management Strategy for the Air Force Material Command

Summer E. Bartczak
Air Force Institute of Technology, USA

Ellen C. England
Air Force Institute of Technology, USA

EXECUTIVE SUMMARY

It is widely acknowledged that an organizational knowledge management strategy is a desired precursor to the development of specific knowledge management (KM) initiatives. The development of such a strategy is often difficult in the face of a lack of organizational understanding about KM and other organizational constraints. This case study describes the issues involved in developing a new KM strategy for the Air Force Material Command (AFMC). It centers around the AFMC KM program manager, Randy Adkins, and his challenges in developing the future KM strategy direction for the AFMC enterprise. The case study begins with a description of the history of the AFMC KM program and the existing KM system, but then focuses primarily on issues to be considered in future strategy development, such as maintaining top leadership support and understanding, conflict with the IT organization, funding cuts, future KM system configuration needs, and outsourcing of KM. The intent of this case study is to demonstrate, using Randy Adkins and AFMC as an example, many common issues that can be encountered as leaders struggle to develop viable KM strategies.

BACKGROUND

The Air Force Material Command

The Air Force Material Command (AFMC) is one of the Air Force's nine major commands (Figure 1). It is headquartered at Wright-Patterson Air Force Base in Dayton, Ohio, and employs 85,000 military and civilian employees across the globe. The primary mission of AFMC is to "develop, acquire, and sustain the aerospace power needed to defend the United States and its interests . . . today and tomorrow" (HQ AFMC PA, 2001a). As such, it has cradle-to-grave oversight for the Air Force's aircraft, missiles, and munitions (HQ AFMC PA, 2001a). Key mission essential tasks

Figure 1. U.S. Air Force major commands

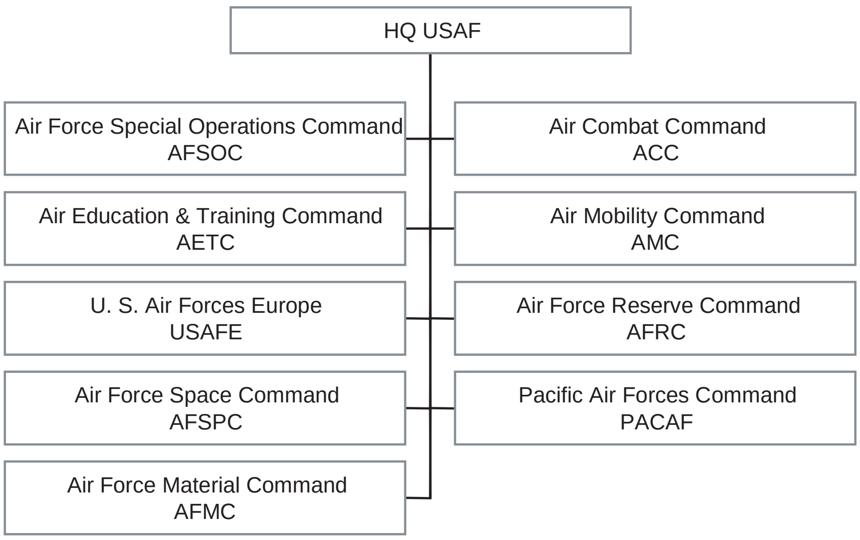

Figure 2. Air Force Material Command organization

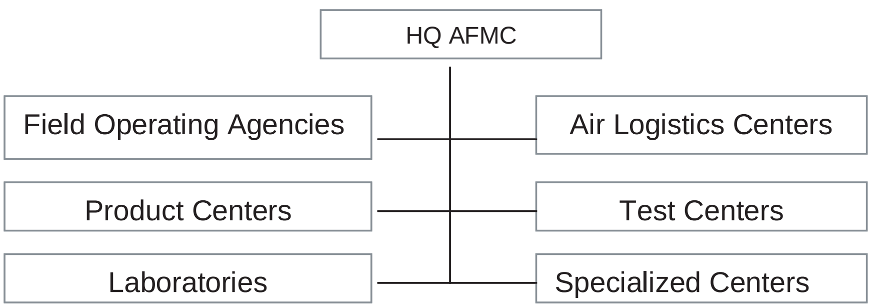


supported by AFMC include product support, supply management, and depot maintenance (see Appendix 1 for a further breakdown).

According to the AFMC Public Affairs Fact Sheet (HQ AFMC PA, 2001a), AFMC fulfills its responsibilities through organizations that serve as product centers, research laboratories, test centers, air logistic centers for maintenance, and specialized centers (Figure 2). Weapon systems, such as aircraft and missiles, are developed and acquired through four product centers, using science and technology from the research laboratories. These weapon systems are then tested at AFMC's two test centers and are serviced and repaired at its three air logistics maintenance depots. The command's specialized centers perform various other development and logistics functions. Eventually, aircraft and missiles are "retired" to its Aircraft Maintenance and Regeneration Center in Tucson, Arizona.

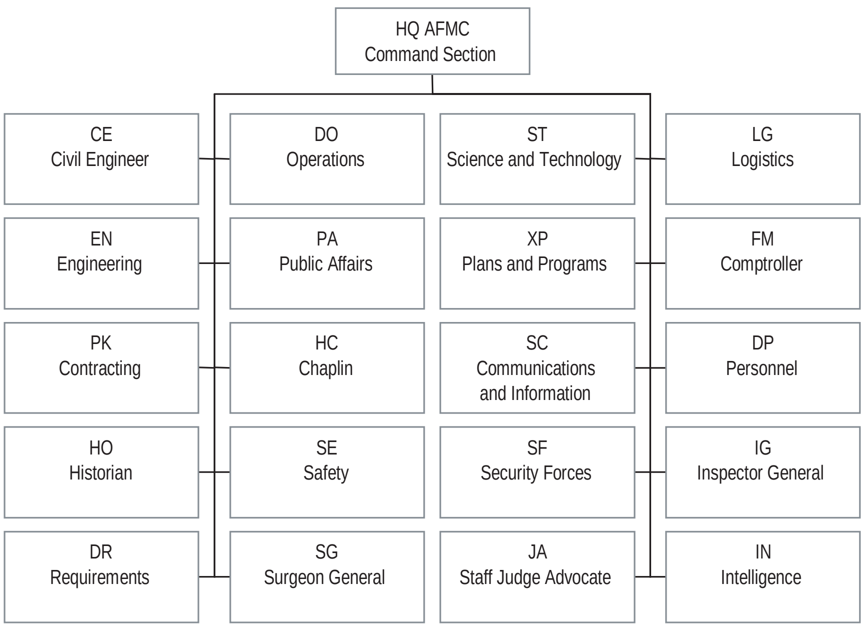
AFMC's central governing organization, Headquarters (HQ) AFMC (Figure 3), consists of all the functional areas that provide support for command organizations. The Directorate of Requirements (DR)—the focus of this case study—is the command's focal point for policies, processes, and resources that support the product and information services mission (HQ AFMC PA, 2001b) and is the home of AFMC's Knowledge Management program which has the official name, Air Force Knowledge Management (AFKM).

SETTING THE STAGE

Evolution of KM in AFMC

In the early 1990s, the U.S. Department of Defense (DoD) recognized the need to streamline its acquisition process. As a result, the Air Force

Figure 3. HQ AFMC organization and directorates



(AF) created a System Program Office (SPO) to develop technology solutions to help achieve that end. One such technology solution was called the AF Acquisition Model. Initially, this information system included an online repository of all acquisition regulations, step-by-step processes for conducting acquisitions, and miscellaneous help information such as points of contact and lessons learned. Although the technology used was immature, this digital repository was a first of its kind in the military and an idea quickly copied by the other services.

After its initial success, the SPO proposed the same idea to the Office of the Under Secretary of Defense for Acquisition Technology for possible implementation across the DoD. The proposal was approved in 1998 and the resulting effort became known as the Defense Acquisition Deskbook program. Now, as a DoD-level project, the program (and the accompanying information system) was to be managed and developed by an interservice Joint Program Office. As such, major Deskbook activities were transferred to the Joint Program Office and AFMC/DR personnel were assigned the remaining task of keeping the AF's Deskbook documents that resided on the system updated and current. Although the Joint Program Office retained oversight responsibility for the Deskbook program, a yearly funding stream of $1.5 million remained to support AFMC/DR's portion of the effort. Of this $1.5 million budget, only $500,000 was committed to maintenance of the Deskbook program. As such, AFMC/DR found itself asking, "What can we do with an extra million dollars?"

The answer came quickly in the form of an AF Inspection Agency study that identified a need for an overarching "lessons learned" program for the AF. While the need was AF-wide, the AFMC/DR Deskbook Team decided to use its own expertise and excess funding from the Deskbook program to address the problem for the AF. As a result, it produced a formal requirement to develop an information system-based AF Lessons Learned pilot program. Using the AFMC Deskbook system design as a foundation, the Deskbook Team added additional capabilities that allowed the capture and dissemination of "lessons learned" information.

While researching and developing the Lessons Learned pilot program, the Deskbook Team decided that the new business concept touted as "KM" captured the essence of what they were doing. The Team's understanding of KM was that it should be used to enhance organizational performance by explicitly designing and implementing tools, processes, systems, structures, and cultures to improve the creation, sharing, and use of knowledge that was critical for decision making. With this understanding, the Team felt that the goals of KM and the goals of the Deskbook and Lessons Learned projects were consistent. The Team also strategized that if it labeled its efforts as KM, it was possible the Team could receive more leadership support and funding. From that point forward, AFMC/DR Deskbook Team approached its projects and proposals from a KM perspective.

In addition to the Deskbook and Lessons Learned projects, the AFMC/DR Deskbook Team had also developed Web-based acquisition training to educate the acquisition workforce in lieu of sending them to classroom training. Randy Adkins, a civil service employee with 20 years of experience in various positions at Headquarters AFMC, was in charge of the development of this Web-based training program. At the same time, Robert Mulcahy, the deputy director of AFMC/DR, expressed concern with the impending retirement-driven talent drain that was soon to affect his organization as well as all of the AFMC enterprise. Previous studies both inside and outside the AF indicated that more than 50% of the AF's civilian acquisition personnel would be eligible to retire by 2005 (Cho, Jerrell, & Landay, 2000). Unless this issue was immediately addressed, Mulcahy knew that the acquisition workforce would lack the talent, leadership, and diversity needed to succeed in the new millennium. In searching for a solution, he recognized the value of KM concepts as they applied to his organization. He soon became a KM champion and pushed for a merger of the Deskbook, Lessons Learned, and Web-based training programs. He felt these programs, and the information systems that comprised their foundation, were synergistic and could be used in tandem to help capture and disseminate the knowledge of the rapidly retiring civilian workforce. In early 1999, Mulcahy turned to Adkins to spearhead the consolidation which would result in a new combined effort called the AF Knowledge Management (AFKM) program. Together, he believed they could bring KM to AFMC.

Developing the AFKM Program

Randy Adkins worked tirelessly to educate himself on KM and to develop an overarching strategic direction for the many existing elements of the AFKM program and AFKM system. His initial efforts in developing the AFKM program were aimed primarily at applying commercial KM processes and technologies to solve specific business problems. In doing so, his focus was on identifying, capturing, and leveraging knowledge and expertise within the organization. The ultimate goal of the AFKM program was to design information system solutions so that AFMC users could share information and knowledge and, at the same time, create a supportive, collaborative, and information- and knowledge-sharing culture (HQ AFMC/DRI, 2001).

The AFKM "System"

Under Adkins' direction, the Deskbook Team, deemed the AFKM System Development Team 1999, continued to grow the Web-based system beyond its original three components (Lessons Learned database, DoD Acquisition Deskbook, and Web-based training). The AFKM System Development Team structure is shown in Appendix 2. By mid 2000, the AFKM system was comprised of five basic components (Figure 4) — the Lessons Learned database, the AFMC portion of the DoD Acquisition Deskbook, the AFMC Virtual Schoolhouse (Web-based training), the AFMC

Figure 4. AFKM system components

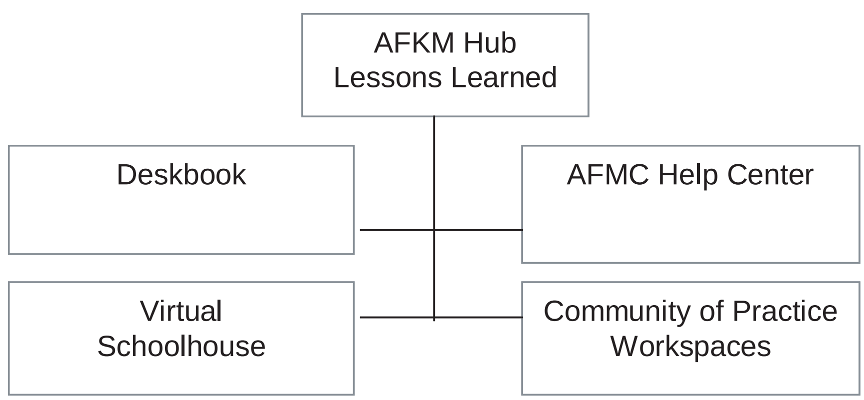


Figure 5. AFKM home page

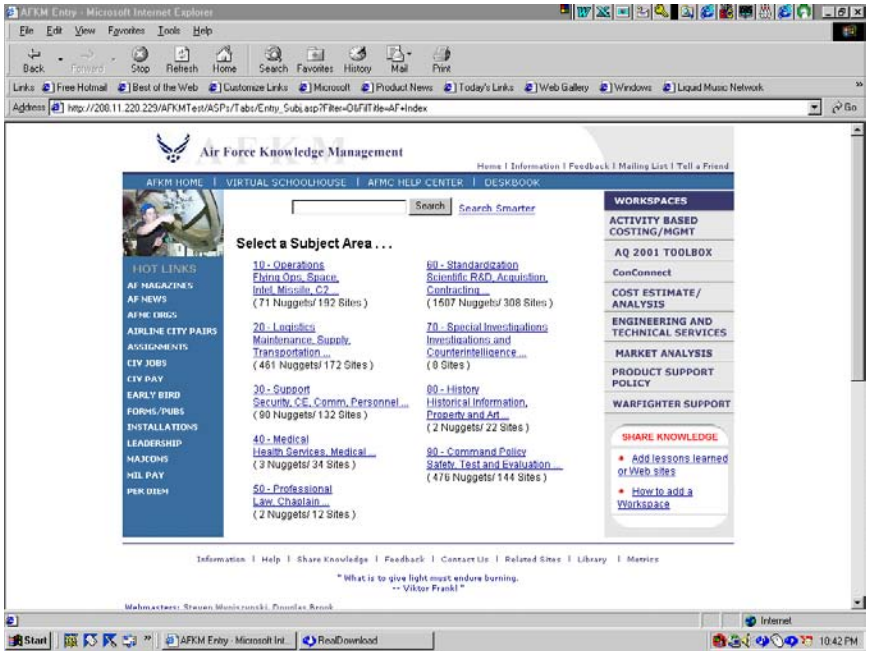


Help Center module, and a Community of Practice (CoP) collaboration workspace module.

The AFKM home page (Figure 5) described the functionality of the AFKM system as follows:

Air Force Knowledge Management is the place to go to find out what you need and to share what you know. . . . [It] applies commercial knowledge management concepts and technologies to address AF business problems. It includes: collaborative workspaces for communities of practice, high-value Internet links, Internet-based learning technology to provide training via the Web, and a repository of lessons learned, best practices, and other bits of usable knowledge. The objective is to make our jobs easier and to enhance job performance by integrating organizational lessons learned, community wisdom, training and collaborative technology to support current and future projects. (AFKM Home Page, 2001)

The AFKM system was designed to be used as a portal. The main portal entry point is the AFKM Hub (or AFKM home page) which includes access to Lessons Learned, DoD Acquisition Deskbook, AFMC Help Center, Virtual Schoolhouse, and CoP workspaces. The AFKM Hub evolved from the original Lessons Learned Web site and now serves as the access point to a range of knowledge and information resources. The DoD Acquisition Deskbook provides a variety of documents describing the laws, directives, policies, and regulations related to DoD acquisitions. The AFMC Help Center provides an English-language search engine for both AFMC and other customers to find information or documents that may reside on any of the many AFMC Web sites. The Virtual Schoolhouse delivers over 20 online courses for AF acquisition training. And finally, the CoP workspaces allow for information exchange, collaboration, and problem solving. The specific functions of each of these portal components is further described in Appendix 3.

CASE DESCRIPTION

It wasn't long after Adkins had taken charge of the AFKM program that he realized it was approaching a crossroads. Specifically, a strategic vision and plan for the future of the program and underlying system was lacking. With strong leadership support and sufficient funding, the AFKM program and system had grown; however, there were now a variety of emerging issues that had to be considered in any future KM strategy development. Some of these key issues are discussed.

Leadership Support

As the deputy director of AFMC/DR, Robert Mulcahy had been a staunch supporter and champion of AFMC's KM efforts. It was his vision that had brought the program together under Adkins. He knew the value of creating the AFKM program and understood the benefits it could bring to AFMC, the AF, and the DoD. Mulcahy had protected and given support to the AFKM System Development Team so that it could expand and explore new opportunities. He believed all of AFMC, not just the headquarters organization, could benefit from KM. Mulcahy was a key reason the AFKM program was successful.

Upon Mulcahy's departure to a new job in early 2000, David Franke was appointed as his replacement. Major General Michael Wiedemer had also become the new Director of Requirements. Both were very open to KM concepts and the AFKM program, but neither was as educated or enthused about KM as Mulcahy had been. Franke, to whom Adkins primarily reported, was not sure that KM should be a centerpiece of AFMC strategy. Franke saw the primary benefits of KM as coming from the building "of" and participation "in" communities of practice. While encouraging Adkins and the AFKM Team to continue their pursuits, he did not have a firm vision for KM or the AFKM program in the future. He was also not sure that AFKM could compete with other programs for additional resources given all the other AFMC priorities. All in all, it was Adkins' assessment that Franke simply didn't see KM as needing emphasis above and beyond other programs. As a result, Adkins predicted that he might have increased difficulty getting the backing and exposure for AFKM that it needed to compete with other AFMC programs for scarce resources.

Conflict with AFMC's IT Organization

Dealing with the headquarters' information technology (IT) organization, referred to as the Directorate of Communications and Information, was a continual challenge. This organization saw many conflicts between its responsibilities and the direction being pursued by the AFKM System Development Team. The Directorate saw its role as providing technology solutions; AFKM was also providing technology solutions. Although the conflict had not escalated to an intolerable level, Adkins noted that his Team and the IT folks "just didn't talk anymore."

Within HQ AFMC, the Directorate of Communications and Information had primary responsibility for command, control, communications, computer, and information (C4I) issues and execution. As such, it possessed sole authority for policy, procedures, and standards with respect to

C4I systems and programs. As the AFKM System Development Team expanded its efforts, a conflict had arisen regarding collaboration software tools. The IT organization had mandated and implemented LiveLink® software as the only authorized collaboration tool. This action not only conflicted with the AFKM System Development Team's work on CoP workspaces, but appeared to be, in the Team's estimation, a much more sophisticated collaboration tool than was needed by the average customer. Based on the AFKM Team's in-depth experience, Adkins had tried to convince the IT folks that an AFMC-wide LiveLink® implementation would be a waste of money at this point. Although Adkins had hoped to work with the IT organization on KM issues, this "disagreement" had driven them farther apart. Adkins stated:

We've had numerous discussions, but we have never been able to partner. So they're off getting everybody to do LiveLink®, trying to force everybody to do LiveLink®. I'm off trying just to get people stuff to help them do their jobs better.

Knowledge of the conflict with the IT organization was not limited to the HQ either. When asked by Adkins about his experience with LiveLink®, one of his CoP customers had remarked, "I will tell you . . . you are on the radar warning receiver. They know you're out there and you are a huge threat to them."

Although Adkins had been able to continue the AFKM efforts, he knew the conflict with the IT organization, regarding LiveLink® and other information system issues, was not going away. Since both organizations claimed a role in providing and establishing KM systems, disputes would be ongoing. While Adkins and his Team had a wealth of KM knowledge and system development expertise, the IT organization was still the authorized policy maker. If conflicts continued, the AFKM program and system risked being changed, dismantled, or simply "taken over." This, too, was something that weighed heavily on Adkins' mind.

Funding Cuts

It was Adkins' understanding that a $600,000 budget cut was in the offing for 2001. Such a cut would force him to make hard choices that would affect the AFKM program's future. In practical terms, the budget cut would require Adkins to let go of six AFKM System Development Team contractor personnel. If cuts did come to pass, he knew he would have to reassess, reprioritize, and reorganize the current AFKM system development workload distribution.

Adkins was also worried about the impact on AFKM system customers. From its inception, the AFKM program had attempted to serve a wide range of customers. Whether it was supporting DoD-wide efforts such as Deskbook, AFMC internal efforts such as the Help Center, or outside command efforts such as the Engineering and Technical Services CoP for Air Combat Command, the AFKM System Development Team had eagerly built new applications. While some of the projects had been fully funded by the requesting customers, many had been accomplished on an as-can-pay basis or without funding support at all. Adkins knew that without AFKM program funding assistance, some customers would never be able to get their KM efforts off the ground. With the budget cuts looming, customer support practices would have to be reevaluated as well.

AFKM System Usage Concerns

Despite rave reviews about the usefulness of the AFKM system from customers, Adkins was disturbed by low use, or "hit" rates. Simple system access metrics showed that, although use continued to rise, it was only a small portion of what it could or should be. To counter this phenomenon, Adkins and the AFKM System Development Team attempted to improve awareness with a series of road shows. They traveled to many AFMC bases to market the AFKM system's many capabilities. While this effort had increased usage somewhat, overall AFKM usage was still low. From a macro view, Adkins understood that KM and the AFKM system tools were still in their infancy. However, the low usage statistics did not help the AFKM System Development Team justify the benefit or the budget. Adkins was glad that his superiors had supported the Team's efforts on intuition and common sense; however, he also understood that he could be asked at any time to measure the true impact and return on investment. Remarking about the necessity of good metrics, Adkins said, "we had a budget drill not too long ago where I lost a little bit of money and some people . . . that reinforced the fact that I needed better metrics." In preparation of such requests, Adkins needed to seriously consider how he could improve results.

Lack of Understanding about KM

Adkins constantly encountered a lack of knowledge about KM. Few individuals, at any level across AFMC, had much idea of what KM was all about. Adding to the confusion was the fact that there seemed to be no accepted standard definition for KM. While it was easy to communicate the importance of individual KM applications, such as lessons learned databases, document repositories, and electronic yellow pages for experts, it was much more difficult to explain the more comprehensive KM concepts. This made it hard to get people interested in the purpose and goals of the AFKM program. Adkins realized that "learning about KM" took time, but also understood that ignorance by those whom he relied on for support could threaten the AFKM program's survival before it really had a chance to prove itself on a large scale. Again, any strategy for the future of AFKM had to address an education element.

Technological Challenges

The AFKM System Development Team was facing technological challenges even though it was very skilled in responding to the fast-paced changes in technology. In the past, it had Web enabled all of its products, making extensive use of technologies such as HTML, java script, active server pages, and so forth. After the Deskbook, Lessons Learned, and Help Center products achieved stability, the Team continued development efforts and had found a niche in developing CoP workspaces for customers. The Team became so efficient in developing workspaces that it could hand over a "CoP in a box" with a few minor customer-specific tweaks in only a few days' time. Instead of providing content, as it had done with Deskbook and Lessons Learned systems, the Team now simply provided the software framework and the customer became responsible for adding the information and knowledge. Actually, the CoP workspace component had been an important addition to the AFKM system as it had resulted in immediate benefits to various customers and helped to spread the word about the AFMC KM efforts. Adkins believed that continued development of CoPs might, in time, provide a central focus for the AFKM System Development Team's development efforts.

Along with this development, however, another technological challenge had arisen with the development of the AF portal. The new AF portal was to be, by decree, the de facto "single access point" for all AF information and knowledge. This raised a key question of how to design future AFKM system applications. Adkins acknowledged that his team was still heavily involved in the "technology piece" of building CoPs, but saw that the capabilities of the AF portal might eventually change that. Because the AF portal offered some "community" features, he saw the technical nature of the AFKM Team's work on CoPs possibly changing. As such, he now had to consider yet another host of issues such as how should AFKM products tie in to the AF portal? How could the AFKM Team take advantage of AF portal capabilities? Would the AFMC-centered KM system lose its identity and mission with the establishment of the AF portal? Would the AF Portal provide new collaboration tools that would conflict or supersede those developed by the team at AFMC? These questions, again, made a clear future strategy very difficult for Adkins to envision.

The AFKM Name

Another issue for consideration in AFKM strategy development involved the AFKM name. When the AFKM Team began the Deskbook and Lessons Learned initiatives, there were no other known KM programs in the AF. This situation, combined with the fact that the Lessons Learned tool was originally designed to serve the entire AF, gave cause for the Team to label the program "AF" KM instead of "AFMC" KM. As time passed, however, KM initiatives began popping up across the service and the "AF" KM label seemed suddenly inappropriate. A representative from the AF chief information officer's office, who was heading the AF-wide KM movement, had even called Adkins to insist that his program's name be changed to avoid confusion with what would become the real AF-wide KM program.

Adkins realized this was not a simple name change from "AFKM" to "AFMC KM" — it had significant implications for his organization. On the positive side, Adkins thought a name change might actually be a good thing. With other KM initiatives surfacing throughout the AF and with the advent of the AF portal, he had found that the title "AFKM" was no longer descriptive of what his Team was providing. His thoughts were that the specific AFMC KM system and products had to be identifiable, especially now that they would be "buried" behind the AF portal. He used the following example:

And so, if I was Joe Blow out there at Ogden Air Logistics Center and I open the [AF] Portal and I happen to see this link [AFKM Hub], I wouldn't click on it . . . because I don't have any idea [of what it is] unless I happened to have that wonderful briefing we gave them.

On the negative side, Adkins knew a name change wasn't that simple. In addition to generating confusion among existing customers, a name change could signal a reduction in program scope and applicability, which might ultimately impact leadership support at the highest levels and funding.

Outsourcing AFKM Strategy

Since the initial collection of programs and systems (e.g., Deskbook and Lessons Learned) had been brought under the AFKM umbrella, Adkins had lacked a coherent strategy to guide future developments. Although most of the previous work of the AFKM Team had been technology-oriented, Adkins realized that a more comprehensive KM strategy that also addressed people and cultural issues was needed. So far, most AFKM program and system development priorities had been opportunistically selected depending on funding source and visibility potential, but were not consistent with an overall objective or strategy. However, with so many issues developing that could ultimately impact AFKM's existence, Adkins realized that a strategic vision, and ultimately an implementation road map, were needed to guide future AFKM developments and to help him make "hard decisions."

Not confident that he or the existing AFKM System Development Team had the expertise or time to develop a comprehensive strategic plan and roadmap on their own, Adkins contracted to AeroCorp[2] to lead the development. Although AeroCorp contractor personnel had composed a portion of the AFKM System Development Team all along, Adkins had only recently selected them as the primary contractor due to their growing KM expertise. To their credit, AeroCorp, with more than 5,000 employees nationwide, had successfully completed other government KM projects since 1997. In outsourcing to AeroCorp, Adkins justified his decision by saying,

We find AeroCorp provides unique benefits to the government and is the best value for the technical services required. AeroCorp rates are competitive with the other contractors reviewed; AeroCorp is a highly regarded supporter of KM at the OSD [Office of the Secretary of Defense] level; AeroCorp is the developer of the AFKM Virtual Schoolhouse; and AeroCorp has proven integration expertise. In addition, AeroCorp rated extremely high in the area of customer service and past performance.

Although the final statement of work for the AeroCorp contract reflected a number of specific deliverables (see Appendix 4) that ranged from strategic visioning to deployment plan and execution, Adkins' foremost concern was the development of the AFKM strategic vision and plan (or roadmap). These documents would be key in helping him to decide the future direction of AFKM. With a strategic vision and road map, he would have at least a starting point for decision making.

CURRENT CHALLENGES/ PROBLEMS FACING THE ORGANIZATION

Randy Adkins had hoped that by outsourcing the AFKM strategy development to AeroCorp that resolution of major issues associated with the evolution of the AFKM program and system would be addressed. The statement of work outlined that it was AeroCorp's job to do the following (HQ AFMC/DRI, 2000):

1. Help AFMC management define a strategic vision for KM to support the AF acquisition community mission.
2. Integrate the AFKM Lessons Learned database, AFMC Help Center, and the Virtual Schoolhouse into a single dynamic system based on this strategic vision.
3. Provide support to these existing systems throughout the integration effort and ultimately for the integrated AFKM system.

AeroCorp's initial deliverable was to build an AFKM strategic vision and plan within 60 days. According to the statement of work, this plan should incorporate both the cultural and technical aspects of the acquisition environment. The resultant document was to include a road map of how to proceed from the current business environment to the envisioned environment (HQAFMC/DRI, 2000).

Consequences of Outsourcing KM Strategy Development

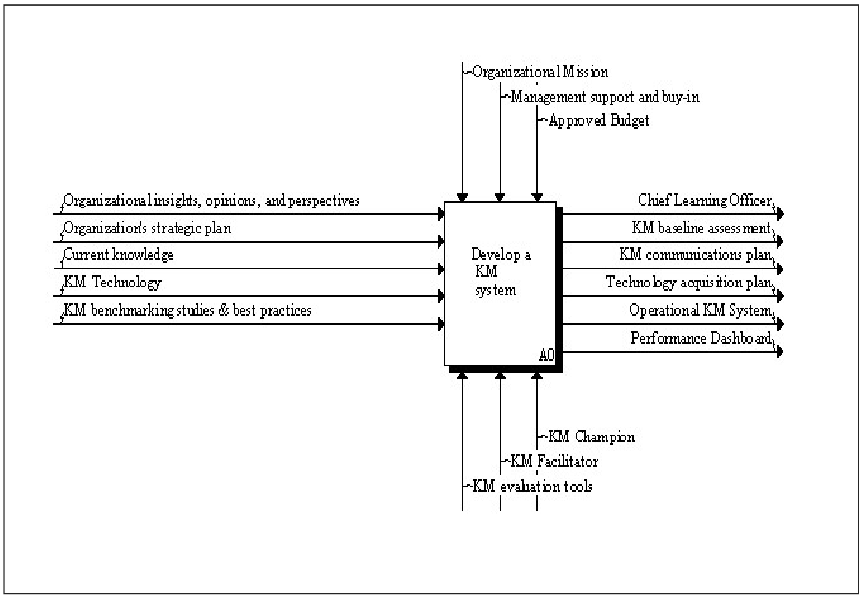
The first action taken by AeroCorp under the new contract was to conduct both a cultural and technical needs assessment "snapshot" of AFMC with respect to KM. These needs assessments were to provide the "as is" picture of AFMC's environment while providing recommendations for the "to be" vision and the necessary supporting policies and processes. Actual completion of the needs assessments went rather quickly and were presented to Adkins in early 2001. Each report included both specific, one-liner recommendations for transitioning from the "as is" state to the "to be" state, and an additional section provided an even more in-depth description of recommendations of what needed to be done to achieve the "to be" state. These assessments with the final recommendation descriptions are detailed in Appendix 5. On the whole, the assessments were comprehensive and surfaced many technical and cultural issues that had to be addressed if AFMC was to transform itself into a true knowledge-sharing organization. These final reports, however, were not what Adkins had expected the strategic vision and plan document to be. The recommendations captured the complicated nature of the current AFMC environment yet, while providing a good road map for the future, were so broad and involved that it was difficult to determine a starting point. To further compound his disappointment, Adkins also learned that AeroCorp considered completion of the assessment reports as having not only fulfilled deliverable #1, the AFKM Strategic Vision and Plan, but also deliverable #2, the AFKM Integration Recommendations Document. He was baffled.

Although Adkins had not gotten exactly what he expected from AeroCorp, the company was allowed to continue work on the remaining deliverables. Adkins hoped that the subsequent documents would make things clearer. Deliverable #3, the AFKM Integration Blueprint, which AeroCorp referred to as a KM methodology, took much longer to produce than the assessments. Delays resulted, first of all, from the turnover of two AeroCorp program managers during early 2001. The current program manager, Mike Lipka, though very knowledgeable about KM, was relatively new to AeroCorp and had to get up to speed on the AFKM project. The key delay, however, stemmed from the fact that AeroCorp had difficulty developing a concise KM methodology or "blueprint" that could address the enormity of what AFMC needed to do to develop a comprehensive KM program that would help it evolve into a true knowledge-sharing organization.

Although the initial assessment and recommendations documents had stated that a systems engineering approach would be used to design the "integration blueprint," the use of integrated definition (IDEF) process modeling methodology surprised Adkins and Lipka. Neither Adkins, nor his superiors, were familiar with this methodology. Lipka, having not been the program manager when the decision to use IDEF was made, had not seen it applied to KM before. Developed for use in systems engineering, IDEF modeling had been around for quite a few years. Its primary users had been the DoD and other large organizations. IDEF had originated with the AF's Integrated Computer Aided Manufacturing (ICAM) program in the mid 1970s, but had evolved over the past six or seven years to also address modeling enterprise and business areas. As such, it was used for modeling "as is" enterprise processes and defining information requirements for improved planning. On the whole, there were 14 separate methods being developed within the IDEF family for use in business process engineering and reengineering, software process definition and improvement, and software development and maintenance areas. It provided a multitude of viewpoints required to describe business area processes and software life-cycle processes and activities. As such, it stood that IDEF could be appropriate for modeling an enterprise approach to KM and subsequent KM systems development, but it did not appear to be a really usable methodology for the average customer. After seeing the initial draft of the high-level IDEF model (Figure 6), neither Adkins nor Lipka were satisfied. Lipka expressed his opinion thus: "I think we have too much methodology for what we need . . . I think it's [been] a little overengineered."

No one was more frustrated, however, than Adkins. After almost a year of working with AeroCorp and waiting patiently for a strategic vision and plan he could really use to press forward, what he had now was a cultural and technical needs assessment, some recommendations for transitioning AFMC into a knowledge-sharing organization, and a road map (or methodology) for doing so that was too unfamiliar and complicated for him or others to practically implement. And faced with the impending budget cut, it did not appear that AeroCorp would have the opportunity to make needed changes. Adkins knew, however, as the AFKM program lead he was still responsible for the strategic direction and success of the

Figure 6. AeroCorp's proposed KM blueprint (IDEF model)



AFKM program. He was unsure exactly what to do next, but he knew the responsibility for a solution was his alone. He began to ponder the facts and options. Would he ever get a document from AeroCorp that would provide a KM strategy and vision for AFMC? Had he made a mistake in outsourcing AFKM strategy development? If not, would there be time and money for AeroCorp to prepare something that was more practical? What parts of the needs assessments and strategic plan were usable? In absence of a clear KM strategy for AFMC, what was the right direction for his AFKM Team to take? How did the AFKM effort now fit (technically and conceptually) into the evolving AF-level KM approach? Would his AFKM program and Team survive? At this point, Adkins had no good answers. The only thing he knew for sure was that there had been and would continue to be many challenges in bringing KM to AFMC, but it was he, if anyone, who still had the opportunity to make it a reality.

APPENDIX 1

Air Force Material Command

Mission Essential Tasks and Objectives

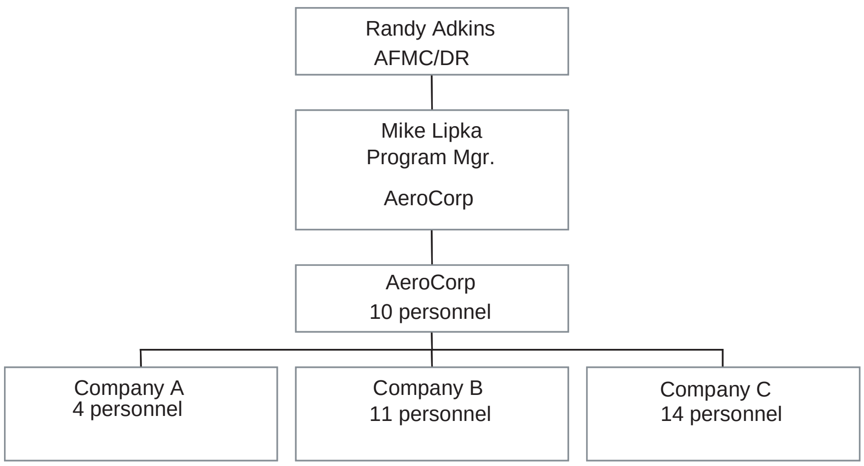
Tasks	Objectives
Product Support	To provide world class products and services, delivering dominant aerospace systems and superior life cycle management.
Information Services	To develop, acquire, integrate, implement, protect and sustain combat support information systems for the USAF and DoD customers.
Supply Management	To provide and deliver repairable and consumable items (right product -- right place -- right time -- right price).
Depot Maintenance	To repair systems and spare parts that ensure readiness in peacetime and provide sustainment to combat forces in wartime.
Science and Technology	To develop, demonstrate and transition affordable advanced technologies to achieve AF Core Competencies.
Test and Evaluation	To provide timely, accurate and affordable knowledge and resources to support weapons and systems research, development and employment.
Information Management	To provide secure, reliable, interoperable communication and information services/access anytime, anywhere, to AFMC customers, partners and employees.
Installations and Support	To provide base support services, property management and environmental protection at AFMC installations.
Combat Support	To provide the trained and equipped expeditionary combat support forces and capabilities to meet worldwide taskings.

APPENDIX 2

AFKM Team and Structure

Throughout the history of the AFKM program, contractors played a key role. Although final authority was always vested in a military officer or civil service employee assigned to AFMC/DR, most programming and technology for the AFKM System came from contractors. The primary contractor for the DoD Acquisition Deskbook development had been Company A.[2] With additional projects, Company B[2] and Company C[2] joined the team. The specific responsibilities and tasks varied from year to year as projects evolved and as the contracts were renewed and renegotiated. The resulting AFKM program organization is shown in Figure 1. AeroCorp was charged with establishing the basic AFKM program by bringing together the existing AFKM Lessons Learned database, AFMC Help Center, and Virtual Schoolhouse. Most of the AFKM System Development Team's work was split between maintaining and updating existing functions and developing new applications. The majority of the new applications focused on building workspaces for CoPs. Each contractor used a number of personnel to work on projects—some personnel worked on AFKM projects exclusively while others came in and out of the projects as necessary. Prior to the 2001 budget cuts, with AeroCorp acting as the lead contractor, 41 personnel had been assigned to the AFKM Team.

Appendix 2 – Figure 1. AFKM Team structure



APPENDIX 3

Explanation of AFKM System Components

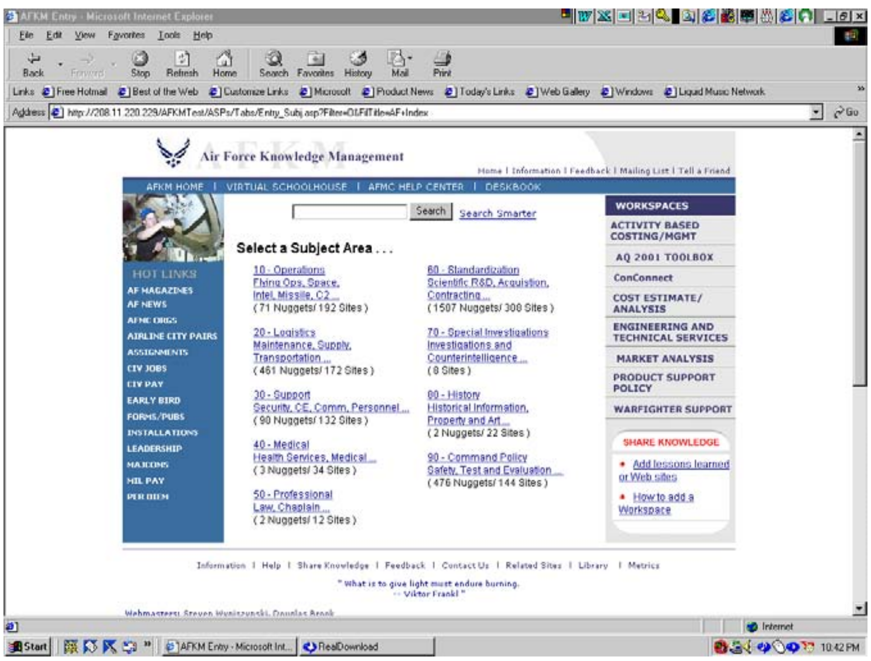
AFKM Hub. What is now the AFKM Hub was originally the primary Web site for the AF Lessons Learned utility. Although the Web site has evolved, the Lessons Learned are still the centerpiece of the Hub (Figure 1). Lessons Learned have been captured and categorized by subject area and provide valuable knowledge about past processes and events. The AFKM Hub also acts as a portal for all other AFKM components and, as such, it also serves as the default AFKM home page. The AFKM Hub provides a conduit to select relevant information and knowledge resources and provides an avenue for creating a knowledge-sharing organization.

Deskbook. The DoD Acquisition Deskbook (Figure 2) is an automated reference tool that provides the most current acquisition information for all DoD services and agencies. Deskbook simplifies the acquisition process by maintaining a single source of up-to-date reference material on acquisition policy and practices.

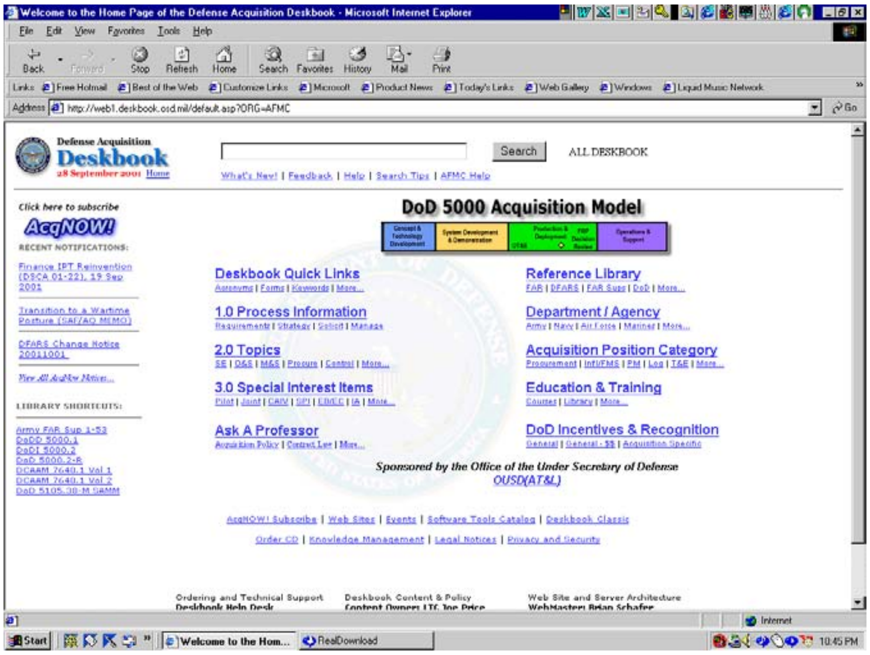
AFMC Help Center. The AFMC Help Center (Figure 3) allows AFMC customers to perform a natural language or keyword search of over 130 AFMC Web sites and selected databases. It connects AFMC customers throughout the AF and DoD with the appropriate AFMC information source or point of contact. The search engine used dynamically creates a unique results page separated into four categories:

- ranked list of related Web documents and links

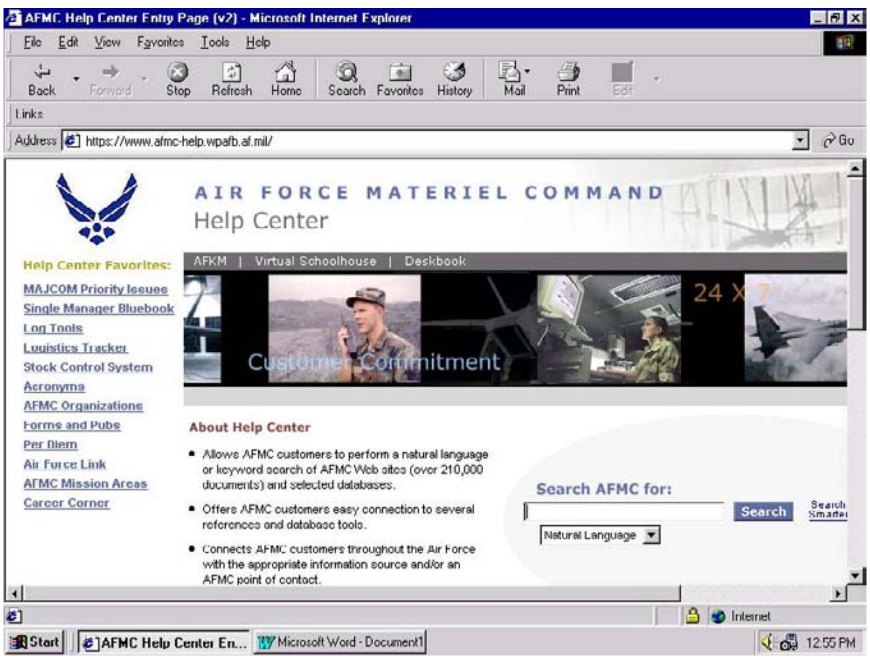
Appendix 3 – Figure 1. AFKM Hub



Appendix 3 – Figure 2. DoD Acquisition Deskbook



Appendix 3 – Figure 3. AFMC Help Center

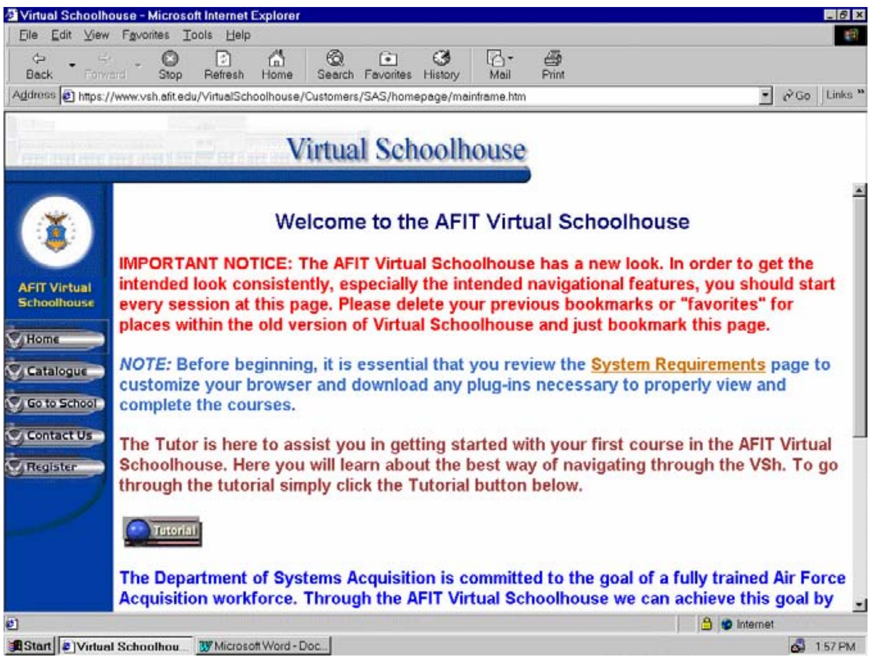


- top-priority major command issues
- bulletin board discussion entries
- contact information for the AFMC command liaisons and topic area points of contact

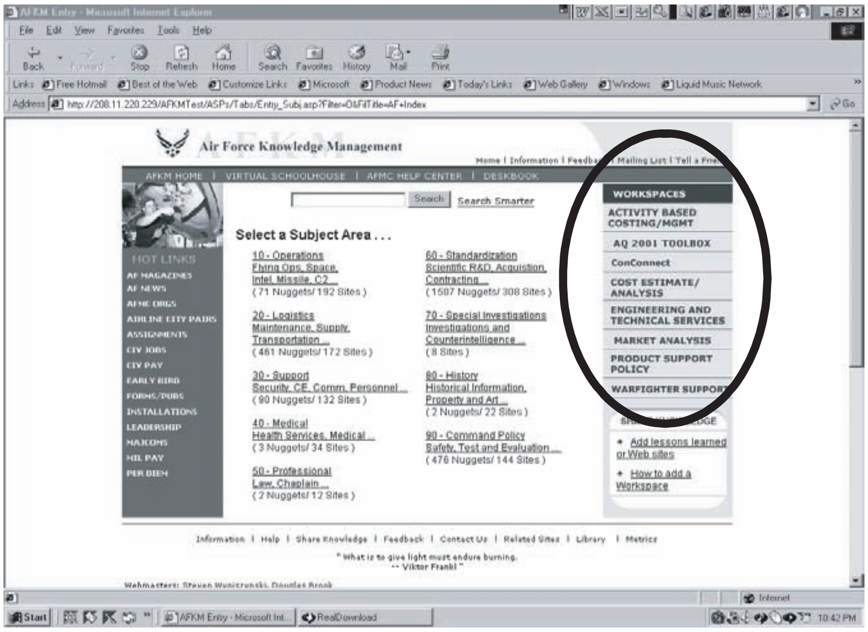
Virtual Schoolhouse. The Virtual Schoolhouse (Figure 4) is a cooperative effort between AFMC/DR and the AF Institute of Technology (AFIT). The Virtual Schoolhouse provides an integrated Web-based learning management system with over 20 online courses. Its purpose is to support the goal of a fully trained AF acquisition workforce.

CoP Workspaces. A CoP is a network of people who share a common goal. CoP workspaces are virtual environments where members of these CoPs can exchange information to complete work tasks and solve problems. Each CoP serves a specific customer set. The AFKM Hub provides workspaces (Figure 5) for a variety of CoPs.

Appendix 3 – Figure 4. Virtual Schoolhouse component



Appendix 3 – Figure 5. CoP Workspaces



APPENDIX 4

AeroCorp's Contract Deliverables

1. Deliverable 60 days: AF Knowledge Management Strategic Vision and Plan. Description: A document that should incorporate both the cultural and technical aspects of the acquisition environment and include a "road map" from the current business environment to the envisioned environment.
2. Deliverable 120 days: AFKM Integration Recommendations Document. Description: An integration plan that should define user operational requirements with detailed cultural and technical consequences as well as time and material requirements to implement the recommendations.
3. Deliverable: AFKM Integration Blueprint. Description: Based on the approved integration plan, the blueprint document should show how the three existing knowledge management systems will operate in the new integrated environment.
4. Deliverable: AFKM Integrated Products. Description: The result of the contractor integrating the three AFKM systems using a phased approach. Each integration effort should provide a working product that can be accessed by the acquisition users in the organizational environment.
5. Deliverable: AFKM Deployment Plan and Execution. Description: The plan should support the deployment of the AFKM system. It should identify user support, and release change management support, including training, communications, and measurement, as well as time and material requirements.
6. Deliverable: Ongoing AFKM Sustainment Support. Description: Sustainment support should be provided for all AFKM elements. The contractor should provide all the functional and technical support necessary for the maintenance and upkeep of the Lessons Learned, Help Center, and Virtual Schoolhouse components.
7. Deliverable: Contractor's Progress, Status, and Management Report. Description: The contractor should use a management and cost-tracking system to support the AFKM effort and ensure technical and funding requirements are accomplished on time and on budget. The contractor should also maintain a continuing dialogue with the government program manager to ensure that schedule and budgetary requirements are met and potential problems are proactively addressed. The contractor will prepare and submit monthly progress and financial reports summarizing the technical accomplishments and expenditures for each task.
8. Deliverable: Weekly/Monthly Functional Analysis Support Analysis Reports. Description: The contractor should provide fielded system product support analysis and readiness assessments as directed by HQ AFMC/DR based upon immediate supportability concerns of the command.
9. Deliverable: 180 Days After Receipt of Order (ARO), Market Research Decision Support Tool. Description: The contractor should provide a Web-based decision support tool integrated within the Market Research Post Tool.

APPENDIX 5

AeroCorp Cultural and Technical Needs Assessment and Recommendations

Cultural Needs Assessment—Recommendation Descriptions

1. Design a KM Action Plan that combines the results of the Cultural Needs Assessment with the results of the Technical Needs Assessment. Data from both assessments will be used to design a "track to action" plan that includes:
   - Methodology and systems engineering
   - Project management procedures
   - Top business technical process needs to streamline for efficiency
2. Create a KM communications plan with a centralized formulation strategy. Establish a clear road map so that the big picture can be articulated to all groups; this includes leadership support of the decisions communicated. The communications plan should clearly define why a project is being done and the benefits to the employees. This should support the mission/vision of AFMC in regards to process improvement. Document the strategy and create a plan to achieve the strategy and explain how each project supports the mission/vision. Establish a clear vocabulary for communication of ideas across teams; standardization of vocabulary for communication of ideas across groups is essential. Initiate team-building/communication activities to foster relationships across the organization (dialogue, inquiry vs. advocacy). Balance being a visionary against execution of jobs.
3. Perform an Organizational Cultural Inventory (OCI) across AFMC. The OCI expands the point-in-time picture of the AFMC culture collected in this report to include a broader pool. The OCI pinpoints 12 specific types of behavioral norms which focus on behavioral patterns that members believe are required to accommodate the expectations of the organization. Norms are organized into three general clusters that distinguish between constructive cultures, passive/defensive cultures, and aggressive/defensive cultures. In addition to measuring shared behavioral norms, the OCI will also identify the ideal operating culture within an organization, providing an opportunity for quantitative data collection on information about the organization's culture at multiple levels, and add additional confirmation to this qualitative Cultural Needs Assessment. This cultural alignment tool will determine the cultural issues prevalent within AFMC.
4. Develop a KM transition plan from current practices to the new KM system. Create a plan of action identifying those items that are helping and hindering AFMC from moving toward their business direction; determine the present state of organization, the desired state, and what must occur during the transition from one to the other. This transition plan should include both internal and external changes within the organization and do the following:
   - Create or incorporate a change management plan that focuses on cultural (and technical) issues within AFMC. A great deal of disillusionment, discouragement, and resistance may need to be overcome. Include a cohesive story of where the group is going and what it is doing. Consider projects that empower people more with authority and accountability for measurable results.

- Establish clear documentation, which defines roles, responsibilities, and boundaries within AFMC. Create a detailed corporate plan on how business is to be conducted in AFMC and with its customers.
- Establish priorities with specifics that provide needed direction to be executed effectively. Have project contacts to call as subject matter experts. Establish clear transition points of projects between groups. Require that decisions be discussed at the appropriate leadership level prior to being evaluated to upper levels of leadership.
- Identify and change business processes that need to be changed so that business can be run more effectively and efficiently.
- Provide extensive training for all aspects of developed KM protocols.

5. Create an AFMC knowledge market. The AFMC knowledge market concept has knowledge "buyers" (seekers of specific knowledge) and "sellers" (suppliers of specific knowledge) who negotiate to reach a mutually satisfactory price for the knowledge exchange. Knowledge "brokers" (people who know who in the organization possesses the information sought) would make connections between buyers and the sellers. Knowledge transactions occur because people expect that knowledge helps them solve problems and succeed in their work. The knowledge market design puts into perspective the sharing culture and provides a framework for formulating actionable steps for building each category within AFMC.

   In addition, the knowledge market will work more efficiently if places are created where people can meet to buy and sell knowledge. Establish "talk rooms" where researchers are expected to spend 20 to 30 minutes casually discussing each other's work. Several organizations have held "knowledge fairs" at which sellers display their expertise for others in the organization. Intranet discussion groups provide an electronic gathering place for people to share knowledge.

6. Establish a multidisciplined AFMC KM integration team. This team will work on organizational and KM technical and continuous improvement teams. The initial tasks assigned to the team will be to do the following:
   - Organize in such a way that all AFMC interests and disciplines are represented.
   - Determine clear and measurable business and technical processes.
   - Identify areas where activities overlap and create a business plan which includes management and technical requirements, with metrics to measure the success or failure of the effort. The metric system will be aligned directly with the business case issues and the KM requirements such that it will access and demonstrate incremental progress being made across the AFMC organization.
   - Develop a reporting mechanism for continuous improvement item tracking to keep record of items that have been successfully identified (based on data collections) and resolved. Report the findings to AFMC management. Establishment of a clearly defined measurement process will provide the momentum and sustainment of the KM program.
   - Foster a workplace that lends itself toward continuous improvement versus policing or auditing of organization in-

formation. The ideal workplace would be where peoples' growth and participation occur within the framework of open teamwork, collaboration, and open flow of new ideas. This way, a link exists between the bottom and top of the organization. Address leadership styles and determine which leadership style is appropriate for which situation (situational leadership).

7. Create a KM Executive Board to oversee KM implementation activities. The KM Executive Board will include community-wide members whose major role is to define the AFMC KM requirements. Create a KM Executive Board Charter. Start a focused pilot (business case development, lessons learned deployment, strategy, etc.). AFMC leadership needs to know and participate on the Board, chaired by the Deputy AFMC Commander. The AFMC Chief Learning Officer (CLO) should serve as the liaison between the integration team and the KM Executive Board. The responsibilities of the Board should include:

   Endorsing mechanisms for transferring knowledge within the organization, including creating a knowledge map, providing mentoring programs, encouraging job transfers, and holding knowledge fairs.

7A. Approving the use of Rapid Improvement Teams (RITs) to work complex issues that the community is either unable to agree on a remedy or for which attempted remedies have not worked. The integration team should recommend RIT campaigns as a part of its activities. The CLO would serve as the RIT sponsor and bring RIT recommendations to the KM Executive Board for approval.

8. Launch a reshaping mission by the AFMC Commander that links the KM strategy to the AFMC Acquisition and Sustainment Strategic Vision and Plan. The architecture for the KM capability must be explicitly linked to the business processes that are required to implement the AFMC KM Strategic Plan. Without this linkage, one of these two planning elements becomes irrelevant as a guide for achieving AFMC's long-term interests. Establish a task force consisting of representatives from SAF/AQ, AFMC, and each center that will report to the Executive Board. The task force would rely on the collective ideas of many people throughout the AF community, using a number of approaches to obtain input from industry, academia, other federal agencies, members of the acquisition workforce, and employee unions. The task force deliverable should outline initiatives to make it easier and more efficient to manage, reshape the acquisition workforce, and advance the current AFMC program to share best practices within the AFMC acquisition workforce. By documenting the deficiencies in the availability of core knowledge; the effectiveness of knowledge capture, storage, and retrieval systems; and the adequacy of personnel skills and attitudes, AFMC will be able to establish tailored remedies that will provide the most efficient knowledge management capability to its members, partners, and customers. The task force should work in concert with the AFMC internal KM team's objectives.

9. Establish a rewards and incentive policy for sharing knowledge. To ensure that such people will share their expertise, AFMC management must make sharing more lucrative than hoarding knowledge. To establish value, evaluation criteria should be established, written, and eventually incorporated in the Human Resources evaluation process so as to provide direct evidence of AFMC employees being rewarded for sharing knowledge. The reward policies should

be valuable, such as substantial monetary awards, high recognition, salary increases, or promotions. Such incentives promote a shift in behavior toward nurturing a sharing culture.

Technical Needs Assessment: Recommendation Descriptions

1. Develop a technology evaluation and approval mechanism that explicitly links requirements for new information technology to process improvements that impact mission accomplishment and customer satisfaction. As organizations have begun to recognize the value of KM to their future well-being, technology providers have been scrambling to recast their data warehousing, intranet, document management, workflow, and so forth, products and the ultimate KM solution. All of these providers fall short in that KM solutions are not "one size fits all" but, rather, organization specific. Without a business strategy, there is no rational basis to evaluate the various technology solutions and craft a KM toolkit that delivers value to the organization and its customers. Organizational evaluation, then, needs to start with an assessment of the mission and business strategy. Value chain activities (research, develop, test, acquire, deliver, and support) should be used as the first level of indenture for evaluating AFMC's KM system.
2. Review AFMC Web sites and identify improvements to increase their effectiveness in making knowledge available to the users. When Web technology was new and viewed as a supplement to accomplishing work, efficiency did not seem very important. Web engineers were more concerned with the eye appeal and user friendliness of the site than whether it provided valuable information. Users readily accepted the fact that they would be directed through several Web sites before accessing any meaningful information. Today, however, the Web is becoming a key work tool for many of AFMC's personnel. For this reason, reduction in search and retrieval time and one-click access to information is no longer an option but a necessity. All AFMC Web sites should be reviewed for their ability to provide value-added knowledge to the workforce.
3. Establish a working group to reduce redundancy in transactional databases. Much of the KM literature is focused on collaboration and the extraction of tacit knowledge. However, the foundation of an organization's knowledge and the source of many of its business metrics are found in its rather mundane workhorse transactional data systems. Several of the interviewees for this assessment commented on their inability to trust the data without independent validation. They reported that the same data element could be found in multiple sources with different values. Technology in and of itself cannot fix this problem, but enforcing the rules of good data management can go a long way to establishing trust in the data. Among these rules is assigning responsibility for ensuring the validity of each data element to the maximum possible extent. Each AFMC CoP should form a working group comprised of its database managers to address issues of data accuracy, replication transparency, and report validity.
4. Establish a task force to improve the capture of tacit knowledge from CoP designated experts. Each CoP has its own set of expert and tacit knowledge that should be captured and put in the organization's knowledge repositories. The pervasive dilemma is that expert knowledge is the most difficult to obtain because it is often ill-defined (knowledge holders do not know what they should be contributing) and difficult to provide (experts are usually too busy to provide this

knowledge). Every CoP has its novices, apprentices, masters, and gurus. Each of these experience levels has an expectation for the knowledge that is required to perform work. An effective KM system should capture knowledge from the top of the experience pyramid and pass that knowledge down and across the CoP. Learning tools, such as the Virtual Schoolhouse, could provide training to knowledge workers on how to determine what constitutes value-added knowledge. The second important aspect of this recommendation is how to influence the collection of this kind of subjective knowledge. It is important that this not be viewed as an additional duty but as a routine and fundamental part of the job. Performance metrics should include contributions to the knowledge base. Technical equipment (e.g., electronic notes and journals) or personal whiteboards may make it easier to contribute.

5. Develop a plan for reducing restricted access to data and data repositories. An effective KM system is open to all participants. Though we are all familiar with the phrase "knowledge is power," many organizations have cultures that treat knowledge as political capital—something to be hoarded and shared only when it is deemed advantageous. If KM is to flourish, that cultural value needs to change from "having knowledge" to "sharing knowledge." Therefore, AFMC should review internally imposed firewalls and password protections to determine those that are needed for security or sensitive data reasons. AFMC should also consider using software that reduces the need for blanket restrictions.
6. Create a metadata-tagging plan to improve AFMC's ability to search and retrieve stored knowledge. AFMC currently uses user profile metadata to improve ease of access to Web-enabled search engines. However, user profiles are limited if the desired data files are not also tagged. It is relatively easy to issue a policy that requires all new data files to be appropriately marked. The real question is, "How much of the legacy data can AFMC afford to retroactively tag?" This raises the economic questions of return on investment. AFMC should create a plan that provides the necessary guidelines for tagging data files.
7. Require each AFMC CoP to develop a collaboration plan. Knowledge-based activities related to innovation and responsiveness are highly collaborative. The attention that AFMC pays to collaboration can be attributed to its role in leveraging the expertise that is often distributed throughout the organization. Frequently, a CoP—the epitome of a collaborative body—cuts across formal organizational boundaries. A CoP often extends across departments and into other organizations, including customers, allies, partners, and sometimes competitors. The range of collaboration-enabling technology can present a daunting task to the people responsible for selecting the best solution for their organizations. Additionally, collaboration needs might vary from one CoP to another. AFMC should require each of its formally recognized CoPs to develop a collaboration plan that describes how that community intends to foster collaborative activity and the recommended technology to enable that collaboration.

Chapter 5.33
Reserve Bank of New Zealand: Journey Toward Knowledge Management

Yogesh Anand
Reserve Bank of New Zealand, New Zealand

David J. Pauleen
Victoria University of Wellington, New Zealand

Sally Dexter
Victoria University of Wellington, New Zealand

EXECUTIVE SUMMARY

This chapter outlines the adoption and implementation of knowledge management within the New Zealand Reserve Bank. In 1999, the Bank recognised that it had a very high exposure to loss of knowledge on departure of key staff. This was mainly due to two factors: recruitment of staff from a limited global pool of specifically skilled labour, and an average length of service of more than nine years during which time staff members accumulated an extensive knowledge of the Bank and its operations. In response to this and other challenges, the Bank embarked on an ongoing knowledge management program. The Bank invested significant resources into the program and from an initial corporate vision developed a knowledge management framework that led to the identification of potential areas of improvement within the organisation. The resulting knowledge strategy encompassed several key initiatives, the most significant of which was the goal of changing the organisational culture. Other initiatives included the consolidation of the Bank's contact management into a single system, a review of the existing document management system, and information mapping. To date, while some initiatives have been achieved, others remain to be done. The challenge for the Bank now is to move from structured to unstructured processes for knowl-

edge management and maintain the knowledge management focus while balancing available resources. The Bank must also consider how best to progress initiatives without necessarily attaching a specific knowledge management label, and identify ways to move ongoing development of knowledge management strategies to the next level.

BACKGROUND

The Reserve Bank is the central bank of New Zealand and a unique entity. Due to its exclusive status, it is not therefore afforded the recruitment opportunities available to organisations in more prolific industries. In addition, the average lifetime of staff members is more than nine years, resulting in a significant potential loss of knowledge on departure. Consequently, the Bank has identified knowledge loss as a high risk within the organisation. In response to this risk, an extensive knowledge management program has been initiated that now spans a five-year period.

This paper presents a background to the case study organisation, and details the steps taken to implement knowledge management through the organisation.

Organization Background

The Reserve Bank of New Zealand (RBNZ) is wholly owned by the New Zealand Government and serves as the nation's central bank. The Bank has the mission of building national and international confidence in the stability and integrity of New Zealand's currency and the country's monetary system. The Bank has three main functions:

- Operating monetary policy to maintain price stability;
- Promoting the maintenance of a sound and efficient financial system; and
- Meeting the currency needs of the public.

More specifically, the Bank is charged with:

- the registration and prudential supervision of banks, and the promotion of a sound and efficient financial system;
- the provision of interbank settlement facilities and related payment services to New Zealand banks;
- advising the New Zealand Government on the operation of the financial system;
- the provision of cash and debt management services to the Government as well as secretariat services to the Overseas Investment Commission; and
- the issue of New Zealand currency and management of foreign exchange reserves.

The Bank's core functions also include the management of NZ $4+ billion of foreign reserves and the management of relationships with international bodies such as the World Bank and the International Monetary Fund (IMF) in order to ensure that the interests of New Zealand are promoted.

Management Structure

The governor leads the Reserve Bank. The minister of finance, on the recommendation of the board, appoints the governor for a five-year term. In accordance with the RBNZ legislative framework (RBNZ Act of 1989), the governor is the single decision maker for the organization and accountable for all activities of the bank.

The minister of finance is responsible for appointing the board of directors. It is the task of the board to regularly review both the performance of the governor and the bank, and provide feedback to the minister of finance. The board must comprise not less than seven, but not more than 10 non-executive members, and does not have any decision-making authority, although they do make recommendations to the minister regarding the appointment of the Reserve Bank governor.

The governor is provided advice from a number of internal committees, including the following:

- the Governor's Committee;
- the Monetary Policy Committee;
- the Official Cash Rate Advisory Group;
- the Financial System Oversight Committee;
- the Risk Management Committee;
- the Reserves Oversight Committee; and
- the Communications Committee.

The Bank is structured into nine departments including the Knowledge Services Group. The senior management team consists of the governor, a deputy governor, and the heads of the various departments as detailed in Figure 1.

Financial Status

The Reserve Bank income is mainly derived from investing the proceeds that the Reserve Bank receives from issuing currency. The Bank spends some of the money to pay its operating costs, the extent of which are fixed in a five-year funding agreement with the Government. The remaining earnings are passed directly to the Government. The balance sheet of the Reserve Bank is shown in Table 1. Further financial information is included in Appendix 1.

Organizational Climate

The Reserve Bank employs approximately 220 staff, a figure which has been much reduced from the mid 1980s, mainly as a result of a "rightsizing" program.

The Bank works to ensure that it has the right people, systems, and structures in place. In keeping with this policy, in 2002, the Bank carried out a review of its human resource and corporate policies with the aim of ensuring flexibility in responding to changing priorities. The Bank has a commitment to a process of staff consultation and involvement when making changes and believes that the presence of a very flat organizational structure provides greater integration, flexibility, and cooperation across departments.

More recently, the results of a staff survey focused the Bank on the need to develop leadership and communication programs for its staff. The purpose of the survey was to identify areas that would improve the overall organisational environment to make the Bank a more effective and better place of work. The results identified several opportunities for the Bank including the following:

- Changes to the management practices;
- Improvement in communication within the Bank;
- Better tools and information; and
- Recognition for work done.

The Bank is an advanced and proactive user of technology, comprising predominantly technology-literate, highly skilled specialist staff. Due to the nature of policy development, there is a requirement for collaboration across business units and this has been primarily facilitated through either face-to-face meetings or through the use of e-mail. The Bank was an early adopter of a document management solution as a way of encouraging collaboration and the sharing of unstructured information across business units.

At an early stage, management identified issues related to collaboration and investment in both human and technology capital. However, business case justification of any major investments in technology has been challenging, given the size of the organization, particularly in the last five years. This has been countered by a management philosophy that accepts that some initiatives are strategic and, as such, may not always stand to business case justification in the traditional sense. The management also had the foresight to recognise the risks related to management of

Figure 1. Reserve Bank management structure (adapted from Reserve Bank, 2002)

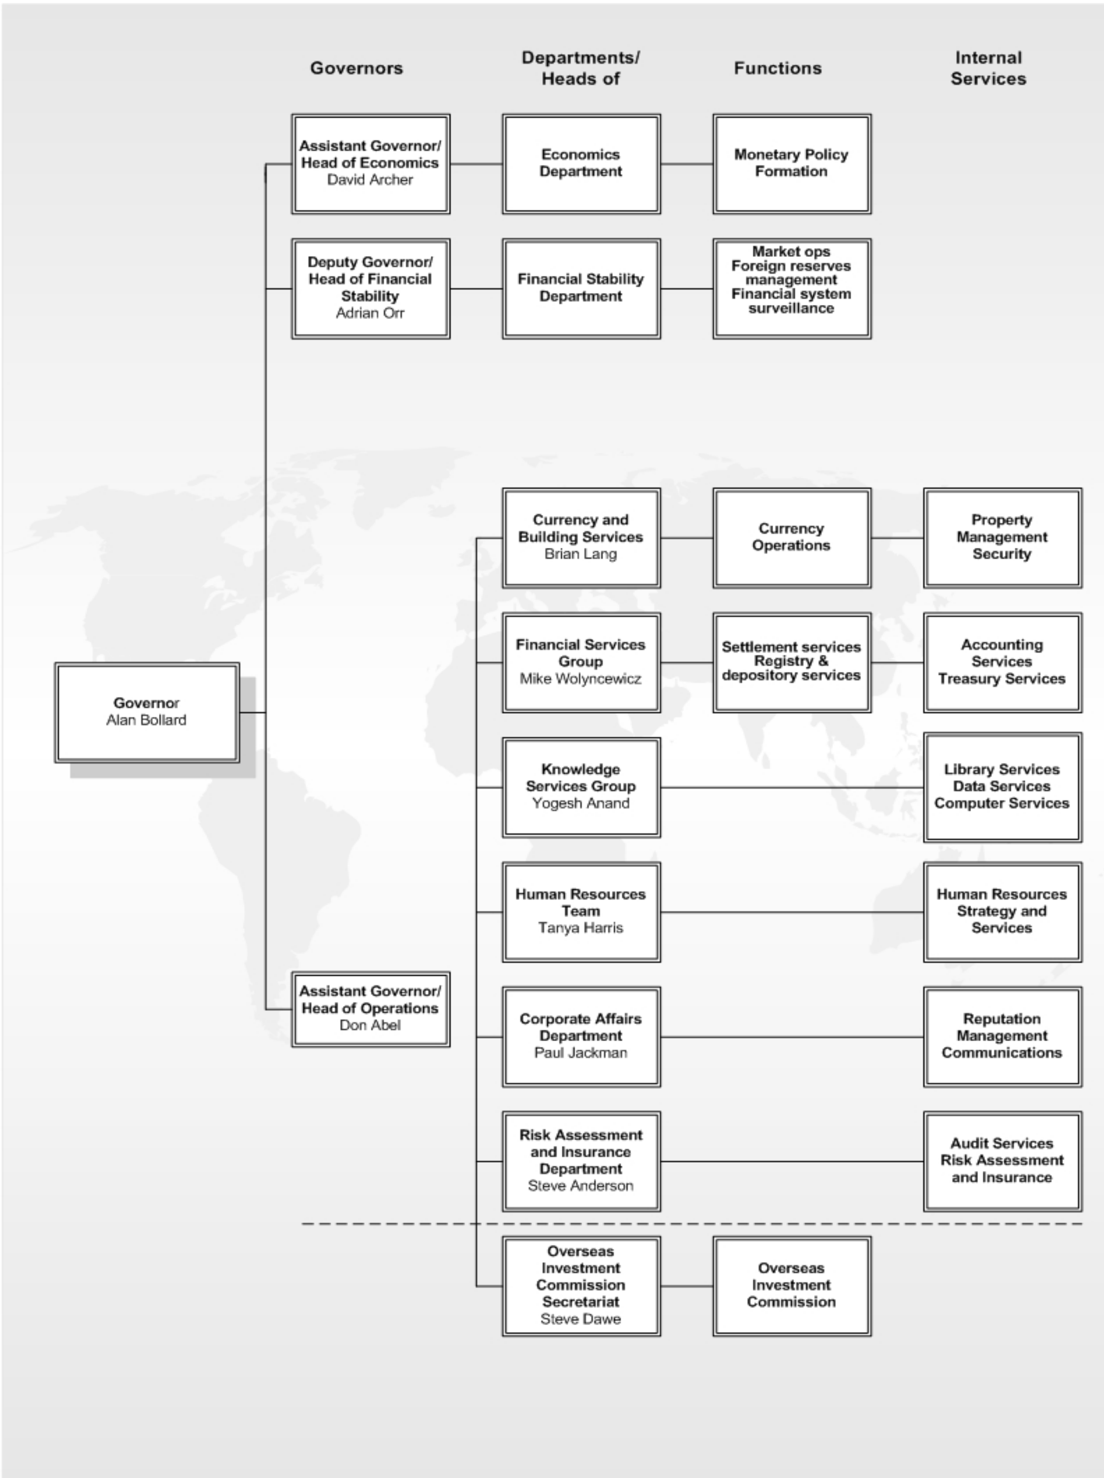

Table 1. The Reserve Bank's balance sheet (adapted from Reserve Bank, 2002)

Assets	2002/03	Liabilities
Foreign Reserves.	$5.1 billion	Debt to fund the purchase of foreign reserves.
Assets arising from managing the Crown's cash operations.	$3.4 billion	Obligation to repay the Crown's and others' deposits with the Reserve Bank.
Government bonds purchased with monies received from issuing currency.	$2.8 billion	Obligation to replace bank notes and coins already in circulation.
		Equity
Assets, including the Reserve Bank building in Wellington etc, and government stock, bought with equity.	$0.4 billion	The Government's net investment in the Reserve Bank.
	Total **$11.7 billion**	

intellectual capital and embarked on initiatives to mitigate these risks.

SETTING THE STAGE

In the early 1990s, the Bank employed approximately 800 staff, many of whom had been with the organization for a considerable period of time. In one instance, a staff member had been with the Bank for over 40 years. In another, a governor of the Bank recently left after 33 years of service. The length of service, combined with the specialist skill set required by Bank staff, resulted in a high percentage of knowledge workers. Consequently, there was a significant risk of potential loss of knowledge as a result of a staff member leaving.

Towards the end of the 1990s, with the rapid advances in technology and the accompanying shift to a global community, the Bank began to experience a slight rise in the level of staff departures. Initially, staff were leaving from predominantly operational areas where the loss of knowledge was not as critical. In these areas, much knowledge had been captured through documented processes and procedures. However, when staff concerned with policy started leaving, it became critical to consider how to deal with this potential loss of knowledge.

As a policy-making organization, the Bank had always been reasonably good at sharing information. When any development was taking place, it was normal practice for information to be readily exchanged with problems arising only where previous actions had been forgotten about, or staff members had left the organisation and, as a result, the information was not readily accessible. However, despite this seemingly strong knowledge-sharing practice, there was still a culture of structural silos within the organisation, with little boundary crossing between departments. This was emphasized in the policy areas where staff members were closeted in offices and were rarely seen to leave other than at lunchtime or at the end of the day.

Concurrent to the increasing level of staff turnover and problems arising from structural silos, the Bank was going through an organisational "rightsizing" program. There was also growing interest in knowledge management within the wider environment at a national level from the government and public sector as well as within commercial and academic circles.

Knowledge management, as it is currently understood, has been around for more than a decade. The term has, however, spawned a proliferation of definitions. Snowden defines it succinctly (1999) as:

The identification, optimisation, and active management of intellectual assets, either in the form of explicit knowledge held in artefacts or as tacit knowledge possessed by individuals or communities (p. 63).

The predominant focus of organisations embracing knowledge management has been the potential for higher levels of profitability, greater market share, and increased innovation. However, there are wider potential benefits for organisations that successfully manage their knowledge, including a flexible approach to change and better workplace morale (Scherer, 2001). In the public sector, Wiig (2002) contends that knowledge management can enhance decision making, assist public participation in decision making, build competitive societal intellectual capital capabilities, and assist in the development of a knowledge-intensive workforce. It can also bring much needed assistance in the area of knowledge sharing, which has historically been an area of difficulty for the public sector (OECD, 2003).

Much academic research pertaining to knowledge management has been predominantly published in the information science/information technology (IS/IT) literature (Newell et al., 2002) and has led to information systems and technology becoming synonymous with knowledge management. More recently, the field has undergone a change in focus from a predominantly technological approach to a more integrated approach (Gold, Malhotra, & Segars, 2001), which has encouraged organisations to bring a more holistic approach to their knowledge management efforts.

Implementation of knowledge management has proved a problem for many organisations. Despite recognition of the potential benefits that knowledge management may offer, many organisations simply did not know where to start (Earl, 2001). Knowledge management best practice has been well documented (Davenport, De Long, & Beers, 1998; Chourides, Longbottom, & Murphy, 2003; Mertins, Heisig, & Vorbeck, 2001) and is often an approach advocated by knowledge management consultants. The downside of best practice is that while it provides examples of implementation approaches that organisations may adopt, it does not take into account the individual factors of the organisation, including the external environment, the internal environment, technology, culture, and infrastructure. Knowledge management is not a "one size fits all" solution, but must be carefully tailored to meet the unique organisational characteristics. By contrast, Snowden's principles of "organic knowledge management" and interest in complex adaptive theory support the view that knowledge management solutions are unique to the organisational context in which they are created (Lelic, 2002).

As a quasi-government department, the Reserve Bank was able to leverage public sector interest in knowledge management in support of its knowledge management journey.

CASE DESCRIPTION

The nature of the work of the Reserve Bank was such that it required a range of specialist skill sets that were not readily available within New Zealand. This was mainly due to the fact that each country has only one central bank, and therefore does not have a large pool of individuals with the specialist skill sets, such as macro-economics and

Table 2. Human resource statistics (adapted from Reserve Bank, 2002)

	1994/ 1995	1995/ 1996	1996/ 1997	1997/ 1998	1998/ 1999	1999/ 2000	2000/ 2001	2001/ 2002	**2002/ 2003**

banking supervision, that are required. Consequently, recruitment of staff was effectively limited to a global pool of specifically skilled labour drawn from central banks around the world.

In addition to the scarcity of skill sets, the average length of service at the Reserve Bank was more than nine years, as shown in Table 2.

During this time, staff members accumulated an extensive knowledge of the Bank and its operations, resulting in a very high exposure to loss of knowledge on the departure of key staff. As a consequence of this exposure and of the "rightsizing" program that the Bank was then undergoing, the Bank recognised that it needed to take action to minimise the risk of knowledge loss. Although the NZRB was one of the first to recognise the significance of these issues, other central banks such as the Bank of Canada have also expanded their research programs to include the issues of talent and knowledge sharing (Bank of Canada, 2002).

In 1999, the Bank was not alone in recognising the growing importance of knowledge management. At the same time, the Information Technology Advisory Group (ITAG), comprising academics and representatives from the business community and public sector, presented a report to the New Zealand Government, titled "The Knowledge Economy." The report focussed on the need for New Zealand to change its economic mix and warned that if the nation failed to make the transition from a pastoral to a knowledge economy, then it was destined to become nothing more than a holiday destination for visitors from countries where the knowledge economy had been embraced (ITAG, 1999). As a result of this report, the New Zealand Government developed a vision of New Zealand as a world leader in e-government, with the Internet being the dominant means of access to government information, services, and processes. In addition, it was their intention that public sector innovation should support a wider knowledge based society. Hearn and Rooney (2002) posit that it is the role of governments to facilitate the technical, cultural, and social aspects of waves of innovation. This role is widely supported throughout the Organisation for Economic Co-operation and Development (OECD), where the majority of central government organisations regard knowledge management as a priority and have knowledge management strategies in place (OECD, 2003).

It was at this point, and with the combination of national and local drivers, that the Bank developed a corporate vision that focussed on knowledge management as a key component. The vision was led by the then deputy governor, whose involvement signified the high level of importance that the Bank attributed to knowledge management. This was an important first step and allowed the Bank's vision to permeate the organisation, providing staff with a needed sense of purpose that transcended everyday activities (Gold, Malhotra, & Segars, 2001). The Bank's new corporate vision prompted the required changes within the organisation (Kanter, Stein, & Jick, 1992). In this case, the vision encapsulated the contribution that knowledge-based value creation can make (Earl, 2001).

The first step after development of the corporate vision was for the Bank to develop a business case to move forward in developing a knowledge management program. Development of a business case for knowledge management is difficult given the seemingly intangible benefits and difficulty in quantifying or measuring the potential outcomes of initiatives. Although the Government vision and the national drivers arising from this were a key source of support for the Reserve Bank vision, they did not assist in the development of a direct business case for the undertaking of a knowledge management program. However, the Bank's status as a quasi-government department enabled it to leverage government interest in building the knowledge economy and positioning the public sector as the driver of the knowledge economy was of particular importance to the Bank. The Bank also emphasised its view that government departments should be showing leadership. By emphasising the importance of leadership from the public sector, the Bank was able to add significant weight to its own business case.

One of the most significant steps in the Bank's journey to knowledge management was the establishment of the Knowledge Services Group. This group, comprising staff from across the organisation, was charged with identifying the importance of knowledge management for the Bank and, subsequent to this, implementation and maintenance of organisational knowledge management practices. The Bank appointed Yogesh Anand to the role of chief information officer (CIO). His role was to head the Knowledge Services Group and take overall responsibility for the Group's combined areas of knowledge management, information management, and technology. A critical part of Anand's role was to take the knowledge management vision and understand what it meant for the Bank, to refine it, to elaborate it, and finally to replace theory with action.

From the outset, involvement in the knowledge management initiative came from all levels. The Bank's governor directly sponsored the initiative, and this top-level support was particularly helpful in communicating the importance of the initiative to all staff. A clear corporate vision (Kanter, Stein, & Jick, 1992; Nonaka & Takeuchi, 1995) and top-level support (Blackler, 1995; Nonaka & Konno, 1998) are widely acknowledged as fundamental to the development of a strong knowledge culture. At the same time, staff from the library and records management area as well as other parts of the Bank came together to form an informal, grassroots network. This network followed the growth of thinking on knowledge management theory and could be categorised as an early community of practice, defined as one of three key critical components of knowledge management (Cohen & Prusak, 2001). Other critical components were identified as the trust of the organisation's staff and the presence of appropriate social norms and organizational culture, both of which were confirmed by the experience of the Bank. Communities of practice have an important role to play in sharing learning and knowledge across an organisation (DiBella & Nevis, 1998), as evidenced within the Bank, where this informal network initiated brown-bag lunchtime sessions, where those interested in finding out more about knowledge management and how it would work in the Bank could meet and discuss the various issues. This group also helped to identify the barriers that existed in terms of knowledge sharing.

Building a KM Framework/Strategy

Thus far, the Bank had developed a vision and seen the formation of both the Knowledge Services Group and more informal knowledge management-friendly networks. However, although knowledge management was much discussed, very few organisations were actually implementing knowledge management programs. Despite recognition that knowledge management could be beneficial to an organisation, many organisations simply did not know where to start (Earl, 2001). The Bank found itself in a similar position and determined that the most logical starting point was to gain an understanding of knowledge management, to investigate global best-practice thinking, and to identify a preferred development process or framework that would be most appropriate to the Bank. Development of knowledge management frameworks can assist organisations to understand the sorts of knowledge management initiatives that are possible and to identify those that are most suitable to the context of the organisation (Earl, 2001).

To enable this development, the Bank sought to develop its own local framework with the help of an outside individual who could bring in best practice and knowledge in terms of what was happening in other parts of the world. However, a critical concern for the Bank was loss of control of ownership of the process. In order to maximise potential of the appointment, the Bank secured the services of an individual through whom it could gain access to established networks and the individual's organisation. By doing this, the Bank was able to harness significant information on what other organisations were doing in relation to knowledge management, and assessment of this information would assist the Bank to develop its own knowledge management strategy. The aim of a strategic approach to knowledge management is "to build, nurture, and fully exploit knowledge assets through systems, processes, and people and convert them into value as knowledge-based products and services" (Earl, 2001, p. 228). This was the Bank's objective.

The Bank then undertook a 12-week program that effectively developed the framework into a workable strategy.

Strategy Development

Developing the Bank's knowledge management strategy involved all areas of the organisation, and contained four main phases as shown in Figure 2. As part of this work, examination was made of the organisational culture, structure, and infrastructure to determine what changes would be needed.

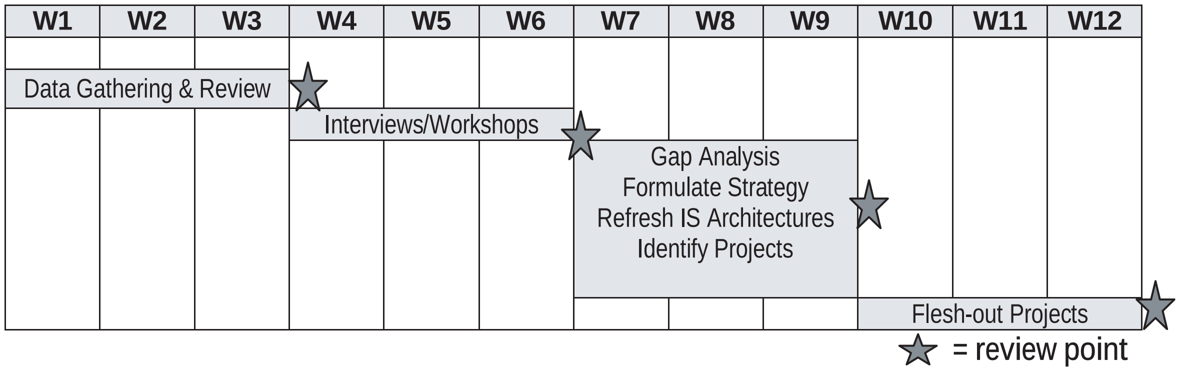
In the initial three-week phase, the Knowledge Services Group worked with the external consultant to gather and review the knowledge management data and best practice from around the world.

The second phase focussed on internal data gathering during which a number of structured interviews and workshops were carried out throughout the organisation to investigate the knowledge required by each function and to understand what individuals saw as being the opportunities (see Appendix 3). Additional input was sought from the members of the informal brown-bag network who had been meeting prior to the onset of the strategy development. This group had valuable information regarding knowledge management thinking at the grassroots level and had helped to identify some of the existing barriers to knowledge sharing within the Bank.

One area of the strategy development that posed particular difficulty was the identification of specific knowledge that would have to be managed in each function. In order to overcome this difficulty, three separate categories were identified for classification purposes:

1. Structured data (S)
2. Unstructured and semistructured information (U)

Figure 2. Knowledge management strategy development process (adapted from Anand, 2003)



3. Experience/knowledge (E)

The information gathered through the interviews and workshops was then structured into these three categories as denoted in Figure 3. For example, one workshop focussed on experience and information into the development of monetary policy. Feeding into the process was structured (data) and unstructured information (reports, etc.) along with experience from external and internal organizations. This was then used to identify where the exposures may be in terms of risks or barriers.

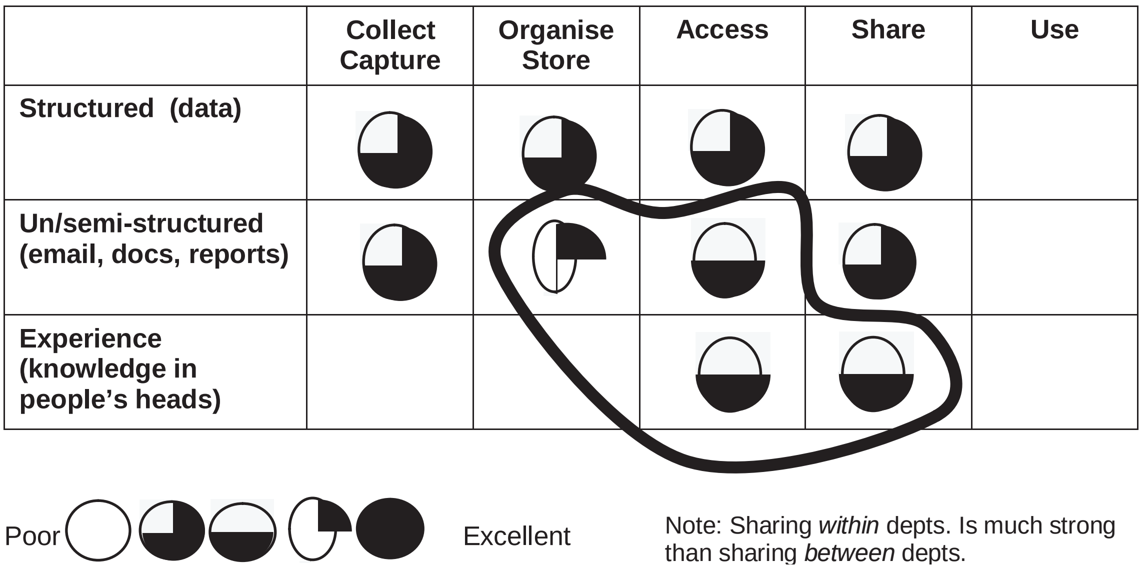
The three categories were also analysed in terms of their collection, storage, access, sharing, and use as shown in Figure 3.

This outcome of this process indicated that, as expected, the Bank was reasonably good at managing the structured information (data) in terms of sharing it and providing access to it. With unstructured or semistructured information, the Bank considered it was good at its collection, but not so good at organising and storing it. For example, although a document management system was in place, it did not integrate well with the e-mail system and so e-mails tended to be held personally. The same thing was found with experience — while the Bank considered it was good at recruiting both graduates and globally experienced staff, its view of their experience then tended to become limited to their specific role rather than their entire experience, which was often far wider. The Bank also found that sharing of information within departments was far better than the sharing between departments.

Armed with this knowledge, the Bank then carried out phase three of the program, which included a gap analysis that would be used to formulate the strategy. The gap analysis identified four threads:

- People to Information. This category consisted of infrastructure-type activities aimed at improving knowledge repositories as well as making them easier to access. This ensured that individuals had timely, secure, and accurate data and information to be able to carry out their work. These infrastructure-type activities operated at two levels: management of information coming into the organization, and handling the dissemination of captured information. To carry out

Figure 3. Categorisation of information (adapted from Anand, 2003)



the activities required an understanding of what information was needed, or at least, anticipation of the broader requirements. To achieve this, staff in the Bank's information centre worked closely with the different departments to ensure that they knew all that was available within the organisation.

- People to People. This category was identified primarily as a culture issue and focussed on sharing the experience and knowledge of staff and making it easily accessible through maintaining and developing contact networks. In this instance, an environment was required, for example, "coffee machine discussions," which enabled and encouraged the exchange of ideas, and which ensured that staff were aware of who knew what within the organisation, as well as allowing new experiences to be shared.
- Institutionalise Knowledge. While the Bank was good at capturing decisions, it was not always as efficient in its responses to them. For example, the thinking that went into its decisions, the alternatives discussed, and market reactions were not always captured. Consequently, there was little learning captured for reuse. The challenge here was to turn individual knowledge into an institutional repository, so that it became part of the corporate memory.
- Collaborative Culture. The intent of this was to change the culture so that sharing became second nature within the organisation, and as a consequence, moved away from the view that "knowledge is power" to one of "knowledge sharing is power." From an organisational perspective, this meant ensuring that the organisation allowed shar-

ing to happen, with executives leading by example to develop and actively reinforce the organizational culture (Schein, 1992).

An example of facilitating opportunities to share is the recognition of the importance of staff mixing in the cafeteria. When the existence of the cafeteria came under review, the Bank decided to keep it as its benefits in this regard had been recognised. Activities in this area were focussed on creating a collaborative culture in order to make the most of the resources that the Bank had, and a collaborative working environment in which sharing is active and deliberate.

The completion of the gap analysis allowed the Knowledge Services Group to identify a number of specific initiatives that would enhance knowledge management within the Bank. These initiatives were developed and categorised in terms of cost and importance as shown in Figure 4.

In general, the initiatives were aimed at improving the accessibility to structured and unstructured data and to the knowledge held by people, improving the corporate memory, and developing the right culture. In particular, they focussed on infrastructure issues such as the tools required. These issues could be regarded as the low-hanging fruit since they were more easily understood by people and provided a catalyst for a change in culture. However, they also included more difficult cultural and leadership issues. In keeping with the complex nature of knowledge management, these initiatives presented a multifaceted approach that included cultural, technological, and organisational infrastructures as identified by Gold, Malhotra, and Segars (2001).

During the strategy development process the general feeling amongst many within the organisation, apart from the knowledge management enthusiasts, seemed to be one of nonchalance. In many respects, it was recognised that the concept of knowledge management was not new, and there was an underlying feeling of a new label being placed on an old problem. The Knowledge Services Group countered this by talking not about knowledge management, but about the specific issues that were being identified and how these might be resolved. While the term "knowledge strategy" or "knowledge framework" was found to be useful in terms of discussions with the senior management team and in the development of individual business cases, at the grassroots level, people wanted issues to be resolved. In removing the "knowledge management" label, more credibility was able to be added to the initiative.

Specific Initiatives

The most significant knowledge management initiative to be undertaken at the Bank was aimed at changing the organisational culture. The Bank recognised that although this change had the mandate of the senior management group, it would require much more than this. To facilitate the change, three key areas were identified. First, it was understood that it required leadership by example. Shaping culture is critical to an organisation's ability to manage its knowledge more effectively (Gold, Malhotra, & Segars, 2001), and an important aspect of culture is the vision that is presented from top-level management (Davenport, DeLong, & Beers, 1998). The initial vision had been shaped by the then deputy governor, and mandated by the governor, it was important that this high-level support was seen to be continued. Unlike many organisations embarking on knowledge management initiatives, the relatively small size of the Bank was to prove advantageous, as it was possible to sustain strong lines of communication. As the CIO points out:

There are about 215 people located in this building. If I can't walk to everyone of them and tell them something, there is a problem. In this way, it could be seen that the initiative was being supported at the highest levels in the organization (Anand, 2004).

Figure 4. Reserve Bank knowledge management strategies (adapted from Anand, 2003)

	Low cost	High cost
A (highly recommended)	❑ Develop policies/standards & training programs for document management and email usage ❑ Work with departments to review file classification and handling of records/physical files ❑ Scan selected incoming correspondence ➢ Document lessons learned in formal manner ➢ Make corporate history more visible using timelines o Implement the Learning and Development Project and evaluate outcomes o Assess job rotation, multi-department projects and committees as part of development plans for all staff o Develop communications strategy to support culture change o Continue with Leadership Project & evaluate outcomes o Job evaluation, rewards and motivation initiatives ● Grow info publishing and data analysis with DU	❑ Work toward integrated KM system. Start by reviewing document management system and using this as an opportunity to review KM solutions available in marketplace. 1 Web enable applicationsGoveStatistics NZ 2 dBoaBanks *manageme* *t dat* ❖ base *Data warehou* ● e pilot
B (should do)	● Review data acquisition ● XML enable external data feeds ➢ Build knowledge into standard operating procedures and systems	● Standardise data storage ● Develop data warehouse
C (could do)	● Develop high level data map ❖ Implement e-collaboration tools (project & chat rooms) ❖ Develop a who's who directory within the Bank ❑ Review Bank's document scanning/OCR requirement	

LEGEND

- ● Make structured data more accessible
- ❑ Make unstructured information more accessible
- ❖ Make knowledge held by people more accessible
- ➢ Develop corporate memory
- o Develop the right culture

To further enhance the leadership role and embed knowledge management into the organisational psyche, the Bank identified knowledge management as being a core competency for all managers, and a key element of the appraisal process. Within the performance appraisal, knowledge sharing was broken into multiple statements and the employees measure themselves as to where they think they are at on a scale of one to five, with one being "needs lots of development" and five being "walking on water." The manager then carries out the same assessment. The idea being that once both parties have completed the assessment, they then sit down and look at any gaps or discrepancies in the assessment. This method of assessment has been received well and has prompted staff to look at how they are sharing knowledge in terms of documentation and both internal and external networking. The appraisal is not linked to pay, therefore there is no disincentive attached.

Knowledge management also became an integral part of the Bank's recruitment program, and was used during the recruitment process to capture candidates' thinking on knowledge management and determine their likely approach.

The second key area of priority in terms of changing the organisational culture was to increase opportunities for collaboration. Prior to the onset of the initiative, the Bank had begun to move to open-plan offices for the whole organisation. Only the chief executive and the deputy chief executive retained their own offices. The driver for the change had not been an overt attempt at increasing knowledge sharing. Rather, it was the initiative of a new head of department in the policy area. One of his first observations was that the current environment, comprising individual offices, was not conducive to facilitating policy making, and did little to promote communication between staff. This initiative initially met with strong resistance principally because staff equated offices to status. By removing the offices, individuals felt that they no longer had particular status within the organisation. Having observed the resentment toward the plan, the head of department first took the time to explain the reasons behind the change. However, there continued to be resistance within the workforce, with some staff feeling so strongly that they threatened to leave. This did not eventuate and the change was made. Ironically, three years later, with the Bank still located across a number of floors, the staff requested that the Bank relocates to a single floor location to remove barriers to communication. Another of the key concerns put forward by the staff prior to the change, was that an open-plan layout would be noisy and interfere with their ability to concentrate. In the initial stages, the open-plan approach was found to be noisier; however, complaints about this soon died away and people were now talking far more than when there had been the physical barrier of the offices.

The third area identified as a potential contributor to facilitating a change in organisational culture was the provision of incentives for knowledge sharing. This area has generated much thought within the knowledge management literature and the Bank was not convinced that the introduction of incentives, particularly in terms of financial rewards, was necessarily a positive step. Through careful research, the Bank found that although this approach had appeared to work in other organisations, some problems had occurred. These problems included determining the value of the knowledge and the need for increased payments for greater amounts of knowledge to avoid some being held back. The literature in this area is also divided. While some posit that that productivity and quality occur within corporate cultures that systematically recognise and reward individuals, both symbolically and materially (Willmott, 1993), others argue that extrinsic rewards, such as monetary awards, will have a negative impact on intrinsic motivation (Deci & Ryan, 1985). The Bank decided that while it would continue to monitor developments in this area, the incentive approach was counter to what it was trying to achieve in terms of its culture.

The gaps analysis also made apparent difficulties in the availability of information in terms of access and integrity. A good example of this was the proliferation of contact databases operating within the Bank. It was common for each database to contain the same or similar information as that contained elsewhere and there was no common system for updating or deleting material. As a consequence, there were significant overlaps, data redundancy, and integrity-type issues. In addition, access was not available to everyone and some staff were still operating using business cards. The approach to this problem was to consolidate the databases in order to bring the contact information into one location.

On the surface, consolidation of the various contact databases appeared to be a very low-level issue. In reality, it was one of the most difficult and time-consuming projects that was undertaken. The main difficulties arose from the reluctance of individuals to move from their own contact database, which in some cases had been used for over 15 years, to a database that would be maintained centrally and where access would be available to all.

A large project team was formed to work through the issues that the changeover presented. The project team consisted of three working groups each consisting of 12 people. With the participation of the working groups, a new intranet solution was identified, and the changeover commenced. In order to ensure that the changeover ran as smoothly as possible, the Bank ran multiple training seminars and carried out a great deal of one-on-one hand-holding. Today, the intranet is the primary contact source within the Bank and has been extended to include a contracts link so that all the contracts held within the bank are also held centrally. However, as the CIO states:

> *I know that probably some people have still got business cards. You can't force people to give them, but now if you spot an anomaly you can fix it, and that updated information is available to everyone (Anand, 2004).*

In total, this process took 18 months, which was longer than expected, and was mainly due to the reaction to the change and the feelings of loss of direct control.

The Bank also undertook a review of all of its electronic records and document management activities. The Bank had been an early adopter of document management and had a system in place since 1993. The gaps analysis had shown there were several areas in which the Bank could improve its document management activities, including better management of all external and internal information resources such as the integration of e-mail. Although the current system captured a significant amount of external documentation, the aim was to now electronically capture internal documentation as well. Successful capture of both internal and external documentation would result in staff having a wide and ready access to a range of information.

In contrast to many organisations, the Bank operated as a totally open organisation, which meant that there was no security on any documents, including the discussions of the senior management group. The culture within the senior management group was to discuss why such documents would not be shared in the organisation, as opposed to shared. The only exceptions to this policy were around market-sensitive information on monetary policy where information remained private to protect staff from the results of any leakage, and the staff understood and accepted this. Mintzberg (1979) sees this form of semiadhocracy as one that facilitates knowledge sharing and an intensity of knowledge work, and is particularly appropriate in a knowledge-based organisation comprised of professional knowledge workers.

The review of the document management system was initially considered in terms of a data warehousing issue; however, as the review progressed, it became clear that the issues were more about providing a single point of access to information. As a result, data warehousing was removed from the agenda.

The review is ongoing, with the project team about to introduce the potential new solution to the wider organisation. With the experience gained from the integration of the contact databases, it is at this point that the CIO believes the document review program may encounter possible resistance as the current solution has been in place for 10 years. To counter this, the Bank has in place an extensive change management strategy, which includes "fun parts," strong messages, as well as heads of departments taking an active role in promoting and selling the messages to their respective departments.

There were also a number of smaller initiatives, including increased use of information mapping techniques, as well as use of scanning with a pilot on how best to enable access to documents that were not currently available online.

As well as improving the Bank's infrastructure tools, some of these initiatives are also intended to reinforce the values of the organisation, for example, in support of providing a family-friendly environment.

CURRENT CHALLENGES/ PROBLEMS FACING THE ORGANIZATION

The Bank has committed sizeable resources to the initial development and subsequent implementation of knowledge management strategies. These have resulted in significant benefits to the organisation, the most important of which was to mitigate the risk of loss of knowledge through staff departure. There are several other subjective benefits that the Bank attributes to knowledge management, including the culture of the organisation, the extent of current knowledge-sharing practice, and the accessibility of a wider range of documentation of all staff. Despite the difficulty in quantifying the potential benefits of knowledge management, the Bank was, from the outset, comfortable with the idea that the potential benefits were not easily measurable.

The Bank's journey to knowledge management has been a holistic one, and has focussed on culture, structure, and infrastructure. In some ways, the CIO regards technology as the easy part and believes that the greater challenge is in bringing about the change, especially when benefits are more intangible. Change is easier to enact when it can be hooked to something rather than change for the sake of change; therefore, technology is often used as the hook. However, he stresses, that from the Bank's viewpoint, knowledge management is not all about technology. It is not the technologists but the information manager who has responsibility for the Bank's knowledge management strategy. He said:

They're the ones who are used to thinking about unstructured information, whereas if I was to give it to a technology person, they'd be trying to put a structure round it. When you do that, you're going to lose a lot of value from it (Anand, 2004).

There are still several strategies that have not yet been put into place. Although the review of the document management system is partially completed, the introduction of a potential solution is seen to be one that will potentially meet some resistance. The Bank will approach this with the insight gained from previous initiatives and with the experience of knowing that while the road may at times be difficult, the view from the other side is generally better.

There has certainly been progress made in terms of recording past decisions. This has mainly been achieved by targeting individuals developing an e-mail-centric organisation whereby the majority of discussions and debate are captured in threads within e-mails. This has proved successful to date, but moving forward, there may be less use of e-mail and so the Bank will need to initiate alternative approaches to formalise some of the processes.

There are also a number of legacy systems operating within parts of the organisation, such as Human Resources. The integration of these is being addressed in the single point of access activity. At this point, the project is still largely in the stages of trying to understand exactly what is the boundary and scope of the project.

The Bank is also investigating the idea of "yellow pages," a system of identifying those within the organisation with specific expertise. The context of the system will be somewhat wider than other systems in operation in that the extent of the experience will relate not just to that of the person's job but in terms of their wider experience. A good example of this is a staff member who survived the Kobe earthquake in 1995. He has talked to many groups within the Bank about preparedness and issues such as business continuity. Although that experience may not relate directly to his position at the Bank, it is invaluable in the wider context and makes him an excellent knowledge source for a yellow pages system.

An ongoing challenge for the Bank, like several other organisations, is that of continuing to meet the ongoing business demands with the level of available resources. In that environment, keeping knowledge management in the forefront is a challenge and needs to be achieved through practical initiatives that can demonstrably provide tangible and/or strategic benefits. This requires commitment from within the organisation as well as ongoing communication. In the Bank's case, it looked on knowledge management as a sunk investment and focussed on getting acceptance to the framework. Once this was completed, it provided a reference point for the specific initiatives that could be looked at in terms of how well they delivered against the framework.

Culturally, the Bank is at an interesting crossroads. The organisation is becoming wary of what might be termed as "consulting labels." As the organisation's awareness of knowledge management concepts has increased, the term "knowledge management" has become a less favoured label. As a result, one of the challenges for the Bank is to progress the knowledge management initiatives but package them differently.

There is also a need to move the Bank's ongoing development of knowledge management strategies to the next level. To date, a best-practice-based approach has provided a good framework for the Bank. However, one school of thought for ongoing evolution is to explore the more unstructured process for developing knowledge management strategies. Embracing complex adaptive systems theory, this approach can be used to create a sense-making model that utilises self-organising capabilities to identify a natural flow model of knowledge creation, disruption, and utilisation (Snowden, 2002). Snowden concludes that the enabling of such descriptive self-awareness within an organisation will provide a new simplicity that can facilitate new meaning through the interaction of the formal and informal in a complex ecology of knowledge (Snowden, 2002).

EPILOGUE AND LESSONS LEARNED

Epilogue

This case illustrates the challenges inherent in implementing knowledge management initiatives into knowledge-intensive organisations. With no tried-and-true frameworks or models to follow, organisations, such as the Reserve Bank, must grapple with devising and implementing strategies appropriate to their own needs and circumstances. Although it is unlikely that prescribed knowledge management implementation strategies will ever be off the shelf in the sense of providing an easy and effective solution for any given organisation, it is possible to foresee a time when a great enough body of research and practice has been accumulated to offer an organisation such as the Bank enough successful models of knowledge management implementation to pick and choose strategies that might be appropriate to at least begin working with. This case helps point the way forward for others by detailing the journey of one organisation that is seriously pursuing a comprehensive programme.

Lessons Learned

Knowledge management is not a project; it is a continuum

At the outset, the Bank viewed knowledge management in terms of a project, with a distinct time frame and process. In broad terms, knowledge management was viewed as a problem that required fixing. In retrospect, the Bank considers that knowledge management is not a distinct task, but rather as the way you work, encompassing all aspects of the organisation. Essentially, it is an intrinsic part of an individual's approach to work, as well as intrinsic to the Bank's culture.

Committing to a framework that will evolve in a more organic way

In keeping with the view of knowledge management as a continuum, commitment to an organically evolving framework retains a close alignment to the individual nature and requirements of the particular business environment. This avoids the need to put a tight structure around things, which is likely to constrain thinking and result in a less-than-optimum result. While best practice can work well, essentially it is transferring someone else's idea to your individual business circumstance, and can stifle innovation because you are constraining yourself to what others have done. Rather than applying scope and boundaries from others, the challenge is to say, "let us just throw everything up in the air and see where it lands."

It is not exclusively about technology or business process or culture; it is a combination of culture-change initiatives with technology as an enabler.

The combination of technology and business process were important components of the Bank's knowledge management initiative, but neither was considered in isolation. The Bank's knowledge management program necessitated changes to the way things had previously been done. Change is often easier to enact when it has a hook. Often, technology is used as the hook for facilitating change.

High level of commitment from within the organisation

The Bank's knowledge management program was sponsored from the highest level, the governor. If this top-level support had not been apparent, it is believed that the Bank would not have made as much progress as it did. Although it could have been pushed, to a certain extent, by the CIO, there were a number of business cases where the projected benefits were intangible and not able to quantified. Without high-level support, it would have been difficult to secure funding for these business cases in the absence of a tangible return on investment.

The intangible nature of benefits

The benefits derived from knowledge management initiatives are often intangible and hard to quantify. Most organisations require a strong business case to be in place before committing funds to an initiative or project. The Bank found it difficult to identify and measure benefits in terms of financial return and was therefore unable to present these as part of its business cases. The Bank took the approach that by addressing the problems that existed, this would result in intangible benefits, such as a happier workforce, thus leading to increased productivity. The investment was, therefore, more a strategic investment in the business in the long term. Success of earlier business cases has also added support for future business cases.

Learning about the Organization via Knowledge Management:
The Case of JPL 101

ABSTRACT

This article describes the development and operation of a knowledge system to support learning of organizational knowledge at the Jet Propulsion Laboratory (JPL), a U.S. national research laboratory whose mission is planetary exploration and to "do what no one has done before". JPL 101 is a Web-accessible database of general organizational knowledge, captured in a series of quizzes. The heart of JPL 101 is the content that is encoded as questions and annotated answers with connections to related information and resources. This article describes the requirements generation process, implementation, and roll-out of the JPL 101 system. Data collected over 19 weeks of operation were used to assess system performance with respect to design considerations, participation, effectiveness of communication mechanisms, and individual-based learning. These results are

discussed in the context of organizational learning research and implications for practice.

BACKGROUND

The Jet Propulsion Laboratory (JPL) is a United States Federally Funded Research and Development Center (FFRDC) operated for the National Aeronautics and Space Administration (NASA) by the California Institute of Technology (Caltech). JPL's primary mission is to explore our own and neighboring planetary systems. In pursuit of this mission, JPL has a rich program of technology development, science, and mission development (the three "value adding" processes of the Laboratory), as well as an extensive infrastructure to support Research and Development.

SETTING THE STAGE

The JPL 101 system described in this article is a Web-accessible database of general organizational knowledge, which is encoded as questions and annotated answers with connections to related information and resources, and captured in a series of quizzes. The Knowledge Capture (KC) team, a subset of JPL's Knowledge Management (KM) Project, conceived of JPL 101. This four-person team consisted of a librarian, two Web and database system designers, and an engineer who alternated between KM-related projects and working on Mars missions.

The motivation for the system was two-fold. First, there was a growing concern by KC team members that the KM project in general was isolated from the value-adding processes that formed the mainstream work of the Laboratory. This isolation was believed to lead to products and services that did not fully address user needs.

The second motivation was a desire to share valuable knowledge gained through a previous knowledge capture task. Prior to his retirement in the fall of 2001, the Deputy Director of the Laboratory agreed to do a series of retrospective interviews. During his tenure, JPL went through a decade of sweeping changes that fundamentally altered the way JPL did business. The primary purpose of the interviews was to collect information for the incoming Deputy Director, who was new to the organization. However, it was felt that the insights gained during the interviews were of potential value to the greater Laboratory population. In particular, discussion about stakeholder relations and the interplay between NASA, Caltech, and JPL served to make sense of the changes that occurred throughout the 1990s.

This combination of motives led to the concept for "JPL 101". It was felt that by calling attention to work related to the value-adding processes, the system could help improve the connection of the KM team to the rest of the Laboratory. In addition, by incorporating information gained through the interviews with the Deputy Director, valuable insights on stakeholder issues and basic operations could be shared with the Laboratory population.

Although inspired by events local to the KC team, the circumstances correspond to a broader organizational issue. To perform the planetary exploration mission and "do what no one has done before," large numbers of technical and professional disciplines must be integrated to support innovation (the value-adding process). In addition, infrastructure and support services are required to perform routine organizational functions (the enabling processes). While cross-functional project teams have become a common approach to integrating multi-disciplinary knowledge in support of product development (Brown & Eisenhardt, 1995), less attention has been paid to bridging gaps between value-adding and enabling processes.

In established firms, emergent knowledge processes (EKPs) (Markus, Majchrzak & Gasser, 2002) such as product development take place within the context of the organization's bureaucracy. The clash between those tasked with operating the bureaucracy and those who must work within it can be viewed as another flavor of "thought world". Dougherty (1992) describes thought world differences between members from the marketing, engineering, and manufacturing functions in new product development teams. Areas such as human resources, contracting, accounting, and information technology also draw from different professional disciplines, focus on different critical issues, and use different approaches to define and solve problems. While cross-functional teams serve to bridge thought worlds by creating a shared vision of a successful, marketable product, there are few resources (e.g., mission statements) that are effective at providing the same sort of actionable focus for the organization as a whole.

Thought-world related problems, such as conflict and miscommunication, can be mitigated by helping people to learn about other domains and to recognize and exploit differences (Dougherty, 1992). Knowledge management systems (KMS) have the potential to support this type of learning. Knowledge-based approaches have been used to support transfer of best practices (Markus, 2001), knowledge reuse for innovation (Majchrzak, Cooper & Neece, 2004), identifying experts, and a variety of business processes (Davenport, Jarvenpaa & Beers, 1996).

Therefore, JPL 101 was envisioned as an educational resource for Laboratory personnel, and a way to assist them in exploring the abundance of electronic and other resources available to them. The orienting question that guided development was "how do you help people to make sense of the 'big picture' given that direct work-related exposure may be minimal (or non-existent)?"

CASE DESCRIPTION

This case describes the 11-month evolution of JPL 101 from initial concept to fully operational system. There were three distinct stages: (1) beta test of initial concept, (2) feasibility analysis for use as a contest, and (3) implementation. Each of these phases is addressed in the following sections.

Beta Test

The goal of the beta test phase was to quickly assess whether it was worth pursuing implementation. Due to the structure of the KM project there was flexibility to explore interesting concepts, but implementation required explicit approval and sponsorship by the KM project. From the very beginning, JPL 101 was conceived of as a quiz. The name was chosen as a tongue-in-cheek reference to beginners' classes in college to emphasize the educational nature of the resource, and to convey that much of the content is basic material that employees should know. The "quiz" metaphor seemed like a natural approach in an organization that values education as highly as JPL does.

The beta test version consisted of a paper prototype. Over the course of one week, the team brainstormed questions, experimented with different formats, difficulty and wording of questions, and had a lot of fun creating wrong answers. The resulting list of 81 questions was divided up into three roughly equal groups. Participants were given the three sets of questions, in different orders to make sure that all the test questions would have at least a subset of the group looking at them. Timed tests were then conducted where people worked their way through the quizzes. As expected there were the occasional chuckles as people viewed the more humorous entries.

Reaction to the quiz from the KM Project team was generally positive but skeptical as to the potential value of the system. While this beta testing did not garner enthusiastic support from the KM Project, it did provide feedback used to determine the rough size of the quiz, appropriate mix of questions, and what constituted a reasonable level of difficulty for the questions.

Beta testing of content provided insight into the types of questions that had the potential to be controversial — primarily those that asked about absolutes such as "firsts," "only," or "bests". This led to standards for structuring a "good" question and guidelines for a reasonable amount of material to include in the answer.

Following the internal beta test, organizations within JPL that were perceived as potential stakeholders of the eventual system were contacted: Internal Communications, Human Resources, and the Ethics Office. Additionally, a shortened, improved set of questions was tested as a demonstration model on actual work groups from the team's home organizations. The response was overwhelmingly enthusiastic. People were anxious to share the information with their colleagues, contribute questions and answers, and considered it both valuable and fun. Everyone, including people who had been with the organization for multiple decades, indicated that they learned something either through the questions or the supporting information given in the answers. In addition to encouraging proceeding with development, people also began suggesting questions that they thought would be good to include.

The beta test phase ended in a surprising way with the serendipitous opportunity to show one of the Laboratory's highest ranking executives the paper prototype. He was instantly interested in the concept, brought his staff members in to have them take the quiz, and formulated the idea of using the JPL 101 concept as a Lab-wide contest as part of the 40th anniversary of planetary exploration being celebrated that year. Given this level of advocacy, the go-ahead from the KM Project was granted and the second phase of development, the feasibility analysis of using JPL 101 for a contest, began immediately.

By the end of the beta test phase the following was achieved:

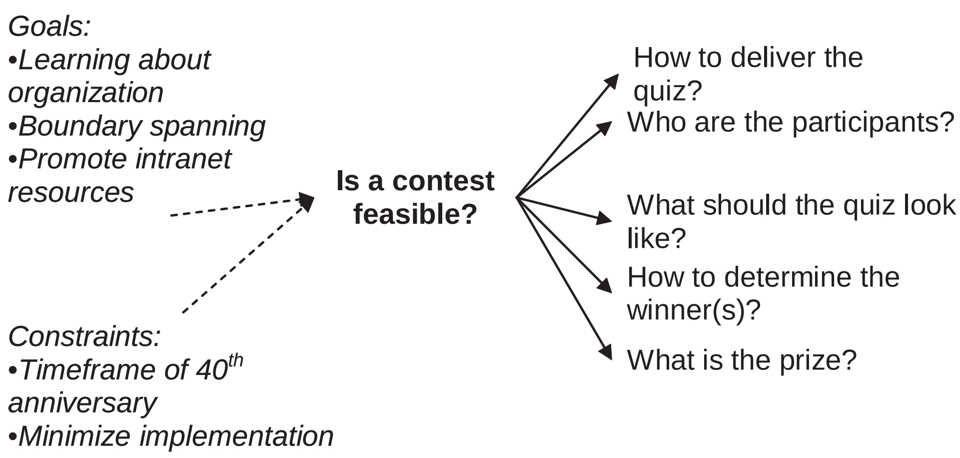
- Confirmation that the basic concept was sound, and likely to be positively received by the Laboratory population.
- A cadre of stakeholders interested in seeing the system implemented.
- A clear understanding of what constituted a well-formulated question: clear, concise, simple structure, cautious use of absolutes, and humorous wording.
- A practical approach to ensure correctness of the question by either triangulating an answer (two-sources to confirm) or verification through an unimpeachable source.
- A requirement from the Knowledge Management Project that the system encourage employees to explore the JPL intranet.

Feasibility Assessment

The direction to evaluate if and how JPL 101 could be used to support a Lab-wide contest led to a detailed requirements analysis and the design decisions described in the following. At the same time, the team was also involved in a separate effort investigating how to capture decision rationale. It was decided to test some of the ideas from that effort internally using informal decision-mapping techniques to capture the requirements generation process. These decision maps form the basis for the following discussion.

Answering the question "Is a contest feasible?" first required answering a set of key questions (Figure 1). An assessment was conducted by methodically working through each of these questions, identifying additional constraints, and incorporating stakeholder concerns. The decision maps were used to track open issues, options, assumptions, information sources, and resulting requirements and design decisions. Even for a simple system such as JPL 101, the decision map quickly became a tangled web of interactions and information that did not easily fit into single

Figure 1. High-level decision map



categories. The decision maps presented in the following sections are simplified for illustration purposes.

How Do You Deliver the Quiz?

This turned out to be the easiest question to answer. Two potential methods were considered as shown in Figure 2. The first was to use a paper system, by sending a hard copy to all participants. This option was quickly eliminated as too burdensome due to the need for hand scoring of the quizzes, no ability to time-tag responses, and the reproduction and mailing costs. This option also was contrary to the KM requirement to promote exploration of the intranet.

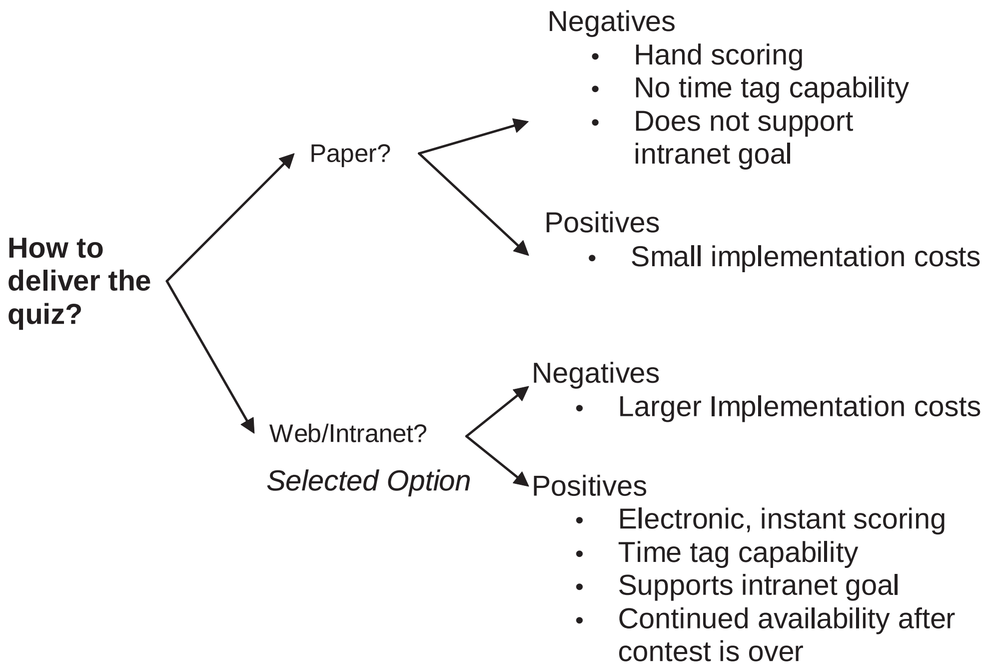
The second option was to use a Web-based delivery mechanism via the JPL internal intranet. In addition to being the area of expertise for our team members, this option eliminated the negatives from the first option and contributed to a reasonable definition of our participants. After making this decision, the team immediately began prototyping activities so we would have a system to experiment on during the rest of the assessment period.

Who are the Participants?

The delivery mechanism decision effectively limited participation to those people who had legitimate access to the JPL intranet. Four categories of potential participants were identified based on the derived requirement that participants have a JPL badge and identification number: current JPL employees, current JPL contractors, retirees, and others resident at JPL but not falling into the previous categories. From within these categories several issues were identified.

1. Timekeeping constraints: How much time could people in the individual categories commit to participating before we needed to provide them with an account code? This was resolved through the ethics office and resulted in a requirement that each individual

Figure 2. Delivery mechanism decision map



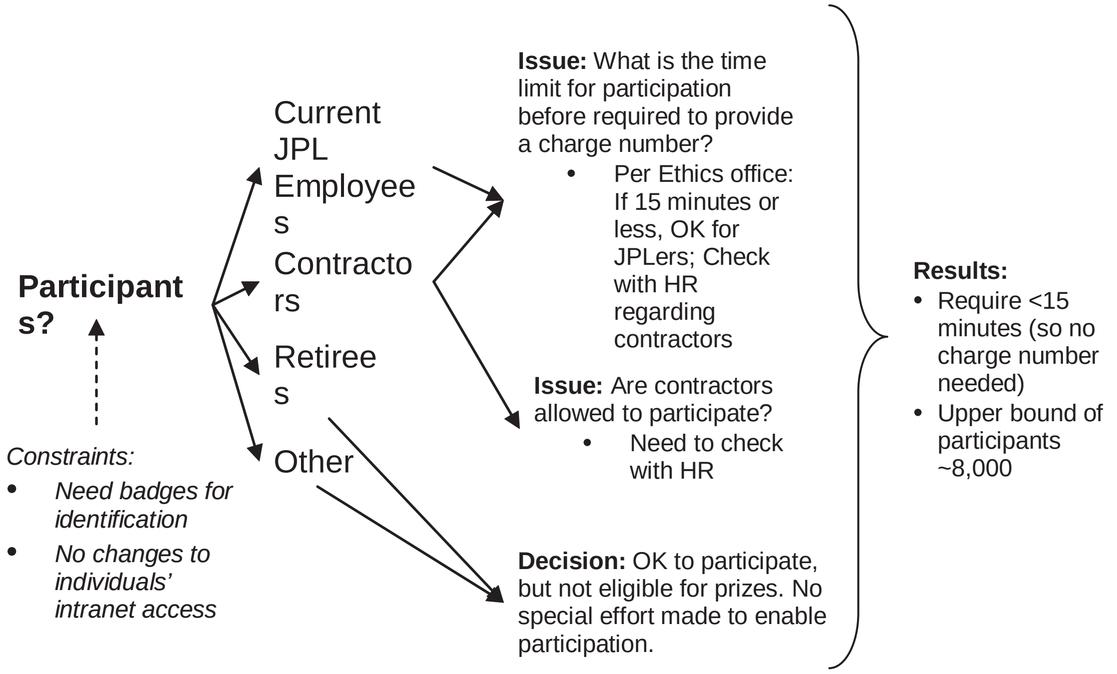
quiz take 15 minutes or less. Also, our Ethics Office confirmed that JPL personnel could participate, but that the Human Resources department would have to make a determination on whether contractors could participate.

2. Contractor constraints: Could contractors participate, and if so, were there any time-keeping constraints, and were they eligible for prizes? These issues remained open during the feasibility analysis.
3. Retiree participation: Would we actively work to enable retiree participation, and if so, were they eligible for prizes? It was decided that our system should not preclude participation from retirees as long as they had intranet access (we would not provide external access) and they had a JPL badge. However, they would not be eligible for prizes.

As shown in Figure 3, these decisions led to the following:

- System must be capable of supporting an upper bound of 8,000 participants.
- The individual quizzes must be sized to keep participation under 15 minutes.
- Participants must have a current JPL badge and intranet access.
- Only JPL current employees are eligible for prizes.

Figure 3. Participation decision map



What Should the Quiz Look Like?

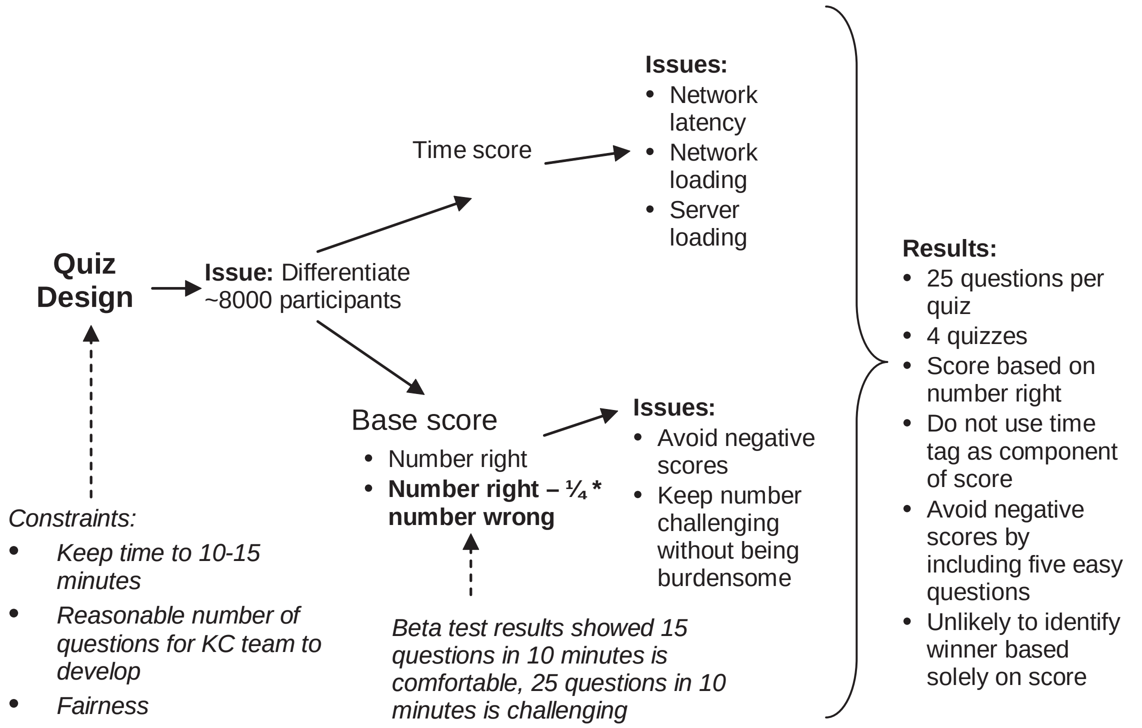
Beta testing determined how to construct good individual questions. The next set of decisions addressed how to construct the quizzes. Figure 4 shows the decision map for the quiz design. In addition to requirements to keep participation under 15 minutes and able to differentiate 8,000 participants, specific goals that we set for the system were:

1. Make the quizzes challenging, but not burdensome.
2. Keep the number of questions required to a reasonable amount.
3. Have a broad mix of questions that include some aspect from all areas of the Laboratory community.

The driving factor in the quiz design was the need to differentiate 8,000 participants to determine the winner(s). We knew there was limited project support for this effort and therefore felt that we would have resources to reliably develop only 100 to 120 questions. This is too small a number of questions to be able to distinguish the number of potential participants solely based on score, so we determined that a time component was also needed.

Several options were considered for incorporating a time-based component to the score. Our executive advocate had suggested a "fastest finger" approach where whoever got the most right in the shortest time would win. This approach, however, brought to bear issues of network latency (which is a function of the number of users) and would

Figure 4. Quiz design decision map



require that the system time-tag all quizzes, leading to concerns about server load.

A technically feasible approach to the quiz design was not possible until we answered the question of how to determine the winner. However, it was determined that we were looking at a four-week contest, consisting of four quizzes at 25 questions each, and that it was highly unlikely that we would be able to identify a single winner based on this design.

Summary

Additional analyses investigated how to determine contest winner(s) and potential prizes. Despite the relatively simple nature of JPL 101, the decision space quickly became complicated with multiple interacting requirements and constraints. Management was presented the following options:

Option 1: Use the JPL 101 quiz for a Lab-wide contest. Winners in each category would be chosen based on best score over the four weeks of the contest. Token prizes, as permitted, would be given to the finalists, with the ultimate grand prize winner(s) chosen from a random drawing of the finalists. This option required additional software development and coordination across multiple departments, but had the potential to generate significant interest and participation. Additional details would be worked out with the internal contest sponsor.

Option 2: Proceed with JPL 101 as originally conceived without the contest element. This option required minimal software development, kept the focus on the content and therefore the goals of the KM project to promote intranet capabilities, and was considered less risk. However, it would not benefit from the executive level attention and did not have prize incentives as a way of gaining interest.

After several months of debate, cost considerations won out, and we went with Option 2.

Implementation

JPL 101 is a Web-accessible database of general organizational knowledge. Knowledge is encoded as questions, answers, and connections to related information and resources (see Cooper, 2003a for a detailed discussion of the use of the "quiz" interface). The system is organized into quizzes containing five to 10 multiple choice and matching questions each. The deployment of the system took place over 12 weeks, after which it entered steady-state operation. During each of the first 12 weeks a new quiz was added. Following the 12-week initial deployment of the content, the system provided access to the full set of past quizzes.

The implementation of JPL 101 was relatively simple, with a minimal amount of user functions. Due to rapidly dwindling support from the KM project, low maintenance costs were essential and the questions and answers needed to be robust with regard to obsolescence. In addition to question and answer fields, the JPL 101 database also included administrative fields for identifying the category, originator, quiz, and validation date for each question.

During the initial 12-week deployment, the entry page for JPL 101 featured a direct link to the current week's quiz. Access to previous quizzes, background information, and feedback mechanisms were provided through pull-down menus. Following the 12-week deployment period and continuing on, the entry page provided a direct link to the list of previous quizzes as well as the menu-accessible items.

Design Considerations

JPL 101 was designed based on the assumptions that the general JPL population had access to a computer, was able to effectively use a Web interface, and would find the use of a quiz-based model for the knowledge acceptable. The first two are reasonable given the proliferation of Web-based institutional applications for general exchange of information, support of business and administrative functions, and organizational communications. The third assumption was validated during preliminary beta testing of the concept.

Based on the assessment of the organization and with guidance from ethics, human resources, and internal communications offices, several constraints were incorporated into the design process. First, the overall set of quizzes were made representative of concerns across the wide range of disciplines on Lab so that no group would feel "ignored" in the process and to ensure that the thought-world issues were addressed. Second, in order to avoid potential problems with time-keeping rules the quizzes were kept short. Third was ensuring that people could participate at their convenience, and that pragmatics, such as individuals being on travel, would not limit participation. Fourth, since participation would be voluntary, there had to be motivations to use the system. Fifth, the goal of the system was learning, and therefore it was critical that there were mechanisms for assessing whether people actually benefited from the system. Finally, it was important that people not feel that they were being graded or assessed in any way. Therefore, it was necessary to ensure that participants could take the quizzes without fear of violating their privacy. This limited the type of performance and participation data that could be collected.

Content

The heart of JPL 101 is the content. The content categories were carefully chosen to emphasize areas important to the laboratory; essentially representing the different thought worlds. Table 1

Table 1. JPL 101 question categories

Area	Description	Rationale	Example
Basics (n=22)	General knowledge about how JPL operates at and below the level of published procedures	Make it easier for employees to learn about things that make it easier to get their job done (and correct misconceptions)	What is the number to call if you're having computer hardware or software-related problems? (A: x4-HELP)
History (n=6)	Knowledge of key accomplishments and of individuals who contributed greatly to the Lab	Establish a connection to the past and share accomplishments that contribute to a sense of pride. Share the excitement of space exploration, which is the reason for existence for the Lab.	Who was the director of GALCIT, and co-founder of JPL? (A: Theodore von Karman)
Missions (n=10)	Knowledge about missions, which are the primary product of the Laboratory and the focus of our work		What is the name of the rover that explored the surface of Mars in 1997? (A: Sojourner)
Product Development (n=9)	Knowledge about how the Laboratory builds and operates space missions and instruments	The three JPL core processes represent the reason the Lab exists: our mission of space exploration. All work at the Laboratory contributes either directly to one of these three areas, or is responsible for supporting these processes.	Where could you go at JPL to evaluate your spacecraft under environmental conditions that are similar to those found in space? (A: 25-foot Space Simulator)
Science (n=5)	Knowledge about key scientific principles of importance in space exploration		What is the most active volcanic body currently known in the solar system? (A: Jupiter's moon, Io)
Technology (n=4)	Knowledge about the development of technology of importance in space exploration		What is the name of the substance nicknamed "frozen smoke"? (A: Aerogel)
Stakeholders (n=10)	Knowledge about external entities that impact or are impacted by JPL	JPL is answerable to multiple constituencies and is often highly constrained in the way it can operate. It is critical for JPL personnel to understand these factors and how they impact their work.	Who is the President of Caltech? (A: Dr. David Baltimore)

provides a description of the different categories, the rationale for including them, and an example of each.

Over the course of the 12 weeks, a total of 66 questions were presented. Each question went through a rigorous quality check to ensure accuracy and that it met the standards for a well-formulated question. The distribution of questions across categories is also provided in Table 1.

Two areas received special attention in developing the questions: JPL Basics and Stakeholders. The 21 questions in the Basics category covered material ranging from how to get help with computer problems to knowledge on new institutional resources and local restaurants available after hours. This is the type of knowledge that generally does not get high visibility, but contributes to the overall work environment. The Stakeholder category consisted of 10 questions that covered the multiple constituencies to which JPL is responsible. Because JPL is a National Laboratory operated for NASA by the California Institute of Technology, there is a wide spectrum of stakeholders who influence the operations of the Laboratory. Understanding the nature of these stakeholder relationships and the various legal, contractual and public trust concerns of the Laboratory is important for efficient operation.

DATA COLLECTION

Two primary methods were used for collecting performance, participation, and user data: background collection of usage statistics and quiz answers, and user participation in the form of e-mail feedback, an online survey, and an online form to submit comments. The background data collection was performed using a commercial monitoring package associated with the Web server. It provided information such as hit rates, IP addresses, number of unique visitors, amount of time spent on site, and time distributions of users. In addition, the quiz database recorded the answers submitted each time someone took a quiz.

The online survey was used to collect basic organizational demographics (tenure, organizational unit, job category, and whether a manager or not) and responses to two questions: “Did you learn anything from the questions?” and “Did you learn anything from the answers?” Taking the survey was voluntary, as was responding to the demographic questions. The second anonymous response method was an online feedback form. Users could submit comments, problems, feedback, and candidate questions for the system. While most users decided to remain anonymous, some made the effort to include their names and contact information. Finally, the e-mail based feedback form was available to contact the development team directly. This was not anonymous and was the least used form of feedback.

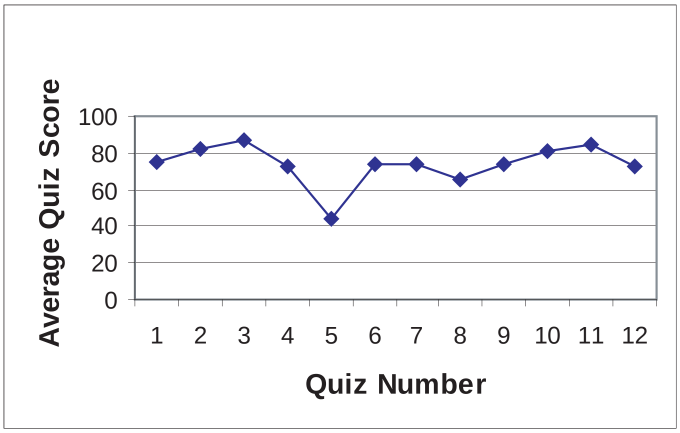
RESULTS

JPL 101 premiered on January 13, 2003 and ran for 12 weeks, ending its initial deployment on April 6. It remains in operation, although new content is not currently being developed. Results are presented based on analysis of the data collected during the initial 12 weeks, and extending through week 19 of operations relative to the following: design considerations, usage, motivation for use, learning results, and general reaction.

Design Considerations

Background usage and database data were analyzed to assess how well the design considerations were met. Background usage data indicated success in meeting the participation time goals of the system. The average time spent in the system each workday ranged from 2:01 minutes to 8:21 minutes, with the mean being 3:53, which are within the limits recommended by JPL Ethics and Human Resources offices.

Figure 5. Average quiz score per quiz



A second consideration was that the quizzes needed to be challenging but not too hard. Figure 5 shows the average quiz scores for the 12 quizzes, based on data from the entire operational period. With the exceptions of weeks five and eight, the average quiz scores stayed between 70-90%, meeting the goal.

Additionally, there was a concern with question quality. Because the JPL culture is such that participants would readily point out any errors in the questions, evaluation of question quality was based on the number of corrections required. Two inputs regarding the accuracy of questions were received, one of which resulted in a minor change (attributing an additional source for information in an answer). Given the volume of material in 66 questions plus all the associated ancillary information, two minor comments were well within the range for acceptable performance.

Participation

Ultimately, a measure of success for a system is the number of people who use it (DeLone & McLean, 1992). Given that this is a voluntary-use resource, and not required for anyone's job, participation statistics are critical for gauging overall success. Background usage statistics were collected, including hit rates and unique visitors based on IP addresses, modified to filter out members of the development team and automated Web crawlers. During the 19 weeks of operation covered in this study, a total of 2,144 employees participated, roughly 40% of the Laboratory population. Figure 6 shows the usage statistics over time for the 19 weeks.

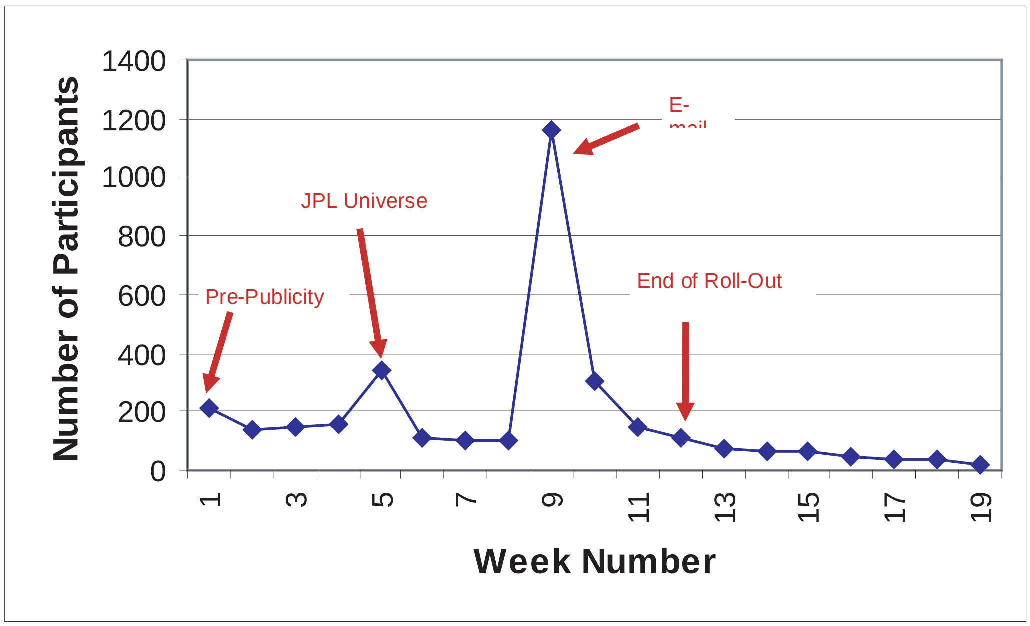
In addition to reaching a large audience, the goal was to reach a broad audience. Although privacy and user-burden concerns prevented automatic collection of organizational demographics on general participants, a voluntary survey instrument was used to collect some data. Five hundred and fifty surveys have been received to date (the response rate during operations was 25%). The organizational tenure for participants ranged from brand new (0 years) to a maximum of 47 years, with an average of 15.1 years and a standard deviation of 10.5 years. Users spanned the entire Laboratory, with participation concentrated most heavily in the Technical and Administrative divisions, where the majority of Laboratory personnel are assigned. Participants were distributed across technical, administrative, and science disciplines, and included both managers and non-managers. Taken in total, the data collected via the online survey indicate a broad and substantial audience.

Impact of Communication Mechanisms

Because JPL 101 is a voluntary-use system, providing general rather than job-specific knowledge, a number of institutional communication mechanisms were employed to let people know this resource existed. These mechanisms were:

- JPL Universe: a traditional, bi-weekly organizational "newspaper" distributed to personnel through interoffice mail. There was a multi-column story about JPL 101 plus a sample quiz the week before rollout.
- Cafeteria Monitors: closed circuit television screens in the cafeterias that broadcast announcements. Consisted of "teaser" questions — shorter versions of quiz questions, plus the URL for the site, for three days prior to rollout.
- Daily Planet: electronic daily "newspaper" for JPL personnel. Accessible via intranet. Publicity was via a small graphic posted on the sidebar of the page that linked to JPL 101, starting the first day of rollout and continuing through the 12-week rollout period. In addition, a short informational article was

Figure 6. Participation by week, annotated to show key communication activities



placed in the center column "news item" area during Week 5 of rollout.
- Inside JPL Portal: Web portal that provides central access to JPL Webspace for internal users. A link to JPL 101 was included in sections for new employees and institutional knowledge management during the first week.
- This Week: electronically distributed (e-mail announcement with link to Web page) weekly newsletter that highlights personnel announcements, organizational changes, upcoming talks and events. A one-paragraph blurb about JPL 101 plus access information was included several times throughout the 12-week rollout.
- All.Personnel e-mail: a tightly controlled list that sends e-mail to entire Laboratory population. A single all.personnel e-mail was sent during Week 9.

Publicity for JPL 101 began one week prior to its rollout. Pre-release publicity included an article in the JPL Universe and announcements on the JPL monitors. In partnership with the Internal Communications office, the primary entry point for JPL 101 was the Daily Planet. Unfortunately, higher priority events limited entry to a single sidebar icon during the initial weeks. This icon remained until the end of the initial 12-week run. Later during the first week, access was added via the Inside JPL portal. These links continued throughout the entire period.

The impact of each of these devices can be seen in the usage statistics shown in Figure 6. The first spike in the graph occurs during Week 5 and corresponds to the publication of the Daily Planet article. Additionally, a smaller increase, not visible in the weekly statistics, but present in the daily statistics, occurred when links were added to the Inside JPL portal. The most prominent feature of the graph, however, is the gigantic spike that occurs during Week 9. This corresponds to the sending of the all.personnel e-mail publicizing JPL 101. This spike is due almost entirely to the day that the e-mail was sent.

Learning Results

The primary goal of the system was individual learning. Success was assessed in attaining this goal in two ways. The first, and most direct way was to use the survey to simply ask participants if they learned anything. Over 90% of the survey respondents indicated that they had learned something from either the questions, the answers, or both. No significant correlations were found between learning, tenure, or job category (Table 2).

The second approach to evaluating learning was to look at the quiz response data. Figure 1 shows the average scores for each of the 12 quizzes. These data indicate that on average, people missed one to two questions per quiz, indicating a learning opportunity existed. Detailed analysis of individual questions shows that the number of respondents getting a specific question right varied from a low of 33% to one question where everyone who answered got it right.

There was also interest in how well people performed across the different categories of questions and in what questions were skipped. Table 3 provides a summary of the performance in each of the categories. Inspection of Table 3 data indicates that JPLers performed well on questions relating to the three value-adding processes, slightly below average on Basics, History, and Missions, and significantly below average on Stakeholder questions. While JPL 101 is not intended as a diagnostic system for organizational knowledge, these results suggest a gap in knowledge about stakeholders that should be remedied. Inspection of the data on questions that were skipped clearly showed that matching-type questions were skipped more often than multiple choices, with all five matching questions placing within the bottom six-response rates. We believe this was due to the extra effort required to answer these questions.

Table 2. Correlation data

	N	(1)	(2)	(3)	(4)	(5)	(6)
(1) Years	550	1.0					
(2) Learned	550	-.083	1.0				
(3) Technical	285	.035	-.054				
(4) Administrative	143	.002	.068				
(5) Scientist	26	.059	-.047				
(6) Other	51	-.104*	.041				
(7) Manager	77	.373**	-.056	.251**	-.229**	.040	-.105
(8) Non-Manager	104	-.373**	.056	-.251**	.229**	-.040	.105

** p < .05, **p < .01, Note Items (3) – (6) and (7)-(8) represent categorical data; therefore intra-correlations are not shown*

Table 3. Summary of performance across question categories

	Basics	History	Missions	Prod Dev	Science	Stake holders	Technology	Total/ Avg
Number of Qs	22	6	10	9	5	10	4	66
Avg%Skipped	2.1	1.7	1.4	0.8	0.8	1.5	0.6	1.3
Avg%Right	73.2	70.9	75.6	83.5	85.2	66.0	85.1	77.1

Feedback via e-mail and through the online form was overwhelmingly positive. (The sole negative comment received via any of the feedback mechanisms was a complaint about the use of the all.personnel e-mail.) For example, one respondent wrote, “This is great and I love it! I learned more about JPL in the past few weeks just by taking these quizzes then the three years I have been here. Thank you.” Several constructive comments were made about how to improve the system. Respondents were pleased with the quiz-type presentation and one suggested that “JPL 101 is the paradigm that should be used for all training and knowledge dissemination at JPL”.

One area of disappointment was the lack of suggestions for questions. During beta testing for JPL 101, one of the most surprising results was the level of excitement individuals had over the idea of the quiz, and their desire to contribute questions and make suggestions for material. Because of this response the feedback form in the system included a field specifically for submitting potential questions. Only three suggestions were received, resulting in two new questions.

Summary

In summary, the variety of data collected during the 19 weeks of operation for JPL 101 provided valuable information that can hopefully be applied to future efforts. Although unable to collect all the data as originally planned, sufficient data were collected for a pragmatic approach that is reasonable for practitioner analysis. The following section discusses these results and the potential learning to be gained from them.

CURRENT CHALLENGES FACING THE ORGANIZATION

JPL 101 was a small effort created to share special information and promote intra-organizational appreciation for the different areas that need to work together to accomplish the JPL mission. When JPL controls spacecraft en route to other planets, small forces applied in the right direction at the right time are the difference between reaching the destination and missing by hundreds of kilometers. These efforts are viewed in a similar light.

As with many KM systems, the effects of the knowledge conveyed through JPL 101 cannot be measured directly (Cooper, 2003b). Conditions before and after remain virtually indistinguishable. The differences, if any, were small and below the surface, for example: less frustration when following a policy, a little more respect for others doing their jobs, a greater sense of community. By having a positive individual impact, we expect to have a positive organizational impact, as suggested by Jennex and Olfman (2002). While we cannot measure it, the net effect of JPL 101 was that nearly half the employees learned something new that is relevant to the organization. And that should be a good thing.

As noted by Kuchinke (1995), "organizations have in fact little control over whether learning takes place, but they do have potentially substantial amounts of control over the kind of learning that occurs within their bounds" (p. 309). In this respect, JPL 101 provides a learning opportunity where the content, by its mere presence, indicates a degree of organizational importance and the system serves as an intervention aimed at reducing thought world differences between personnel.

Insights

There are a number of valuable lessons for the organization to be gained from JPL 101. First, fun works. The use of humor and clever construction of questions and answers did not diminish the fundamental value of the content, but instead contributed to user satisfaction.

Second, there were remarkable differences in the effectiveness of different institutional communications channels, as evidenced by the usage data. While one must be cautious about extrapolating from a small number of experiences, the data for JPL 101 imply that specific channels are more effective in motivating participation than others. In this case, the all.personnel e-mail (which was short and clearly indicated that participation would take a small time investment with high potential for payoff) resulted in orders of magnitude increases in participation. The e-mail message differed from the other mechanisms because it was initiated by the team and sent directly to the users, rather than requiring the users to initiate contact by, for example, visiting the InsideJPL Web portal. It essentially caught their attention without requiring any effort on their part at a time (when they were logged on to the intranet and reading their e-mail) when it was easy to access the system.

Third, the differences in successful response rates for different question categories do provide a level of diagnostic information regarding gaps in individual knowledge about the organization. The particularly low scores in the stakeholder category reinforced the concern about general awareness of stakeholder issues. This information could be used to modify communication and training activities to place special emphasis on areas with sub-par performance.

Fourth, the feedback responses were overwhelmingly positive, particularly with respect to the quiz interface. Given the JPL culture, it was felt that this was a good approach (Cooper, 2003a), but there was surprise at the level of enthusiasm, and with the degree of frustration expressed regarding other online training interfaces. This result indicates that modifications to existing training approaches may be warranted.

Finally, the future value of a KMS is dependent upon continued support. Management support (e.g., funding) for JPL 101 stopped immediately after the initial 12-week deployment. While JPL 101 continues to remain in operation, no new content has been developed and updating of the current content is on a volunteer basis. This was anticipated and the questions were designed to minimize obsolescence and the system incorporated mechanisms to make content maintenance easy (e.g., on the order of minutes to update questions or answer content). It is the sense of ownership felt by the development team coupled with the intentionally low maintenance design that keeps this system operational.

Individual Learning & Organizational Learning

JPL 101 is first and foremost a system for individual learning. If one adopts the perspective of Huber (1991) that an organization learns if "any of its units acquires knowledge that it recognizes as potentially useful to the organization" (p. 89), then JPL 101 can also be seen as supporting organizational learning. Using the framework of Senge et al. (1994), JPL 101 supports organizational learning by:

1. Mental Models: Contributing to the development and maintenance of mental models of how the organization operates and why it operates that way. For JPL, the natures of the work and of the institution both drive and constrain the work environment in many different ways. Mental models that accurately predict the behavior of this complex environment will contribute to improvements in the people's ability to work more effectively. JPL 101 attempted to contribute to mental model development, for example, by providing information about how JPL's special status as an FFRDC affects operations. A number of policies that might not make sense under a for-profit business model appear much more logical with a fuller understanding of FFRDC status.
2. Personal mastery: JPL 101 provides a mechanism for both validating the personal knowledge of individuals who are well-informed about how the Lab operates, and for guiding less experienced personnel to important material. The privacy afforded by the quiz interface allows individuals to assess their own knowledge in a non-threatening environment. There are no penalties for getting answers wrong. By structuring JPL 101 for self-learning, and by keeping the general tone light and fun, individuals were encouraged to "test themselves" strictly for their own knowledge.
3. Shared vision: JPL 101 served to provide insights into the culture as shaped by past accomplishments and an understanding of important components of current projects. Simply asking a question in a given area sends the message that this area is important. JPL 101 was intended to help bridge boundaries between different groups at the Laboratory. By highlighting critical issues associated with different disciplines, JPL 101 served to expose participants to areas outside of their normal working environment.
4. Team Learning: JPL 101 is an individual learning tool that can also be used in a shared

mode. For example, there were instances where versions of the quizzes were used as an activity during group meetings. One common approach was to print out a quiz and complete it as an exercise at a group meeting. Members would share their own insights to the answers presented in the quiz with each other, debate answers, and describe their personal experiences relative to a topic covered in the quiz. Several requests were received to generate longer versions of the quizzes with special groupings of questions to support larger organizational meetings.

5. Systems thinking: JPL 101 contributes to systems thinking by providing insights into the internal structure, processes, and players, as well as external influences. All of the areas covered in the quiz contribute to JPL's overall mission. A better understanding of the competing constraints, differing perspectives, and the coupling between different functions leads to a better ability to make sense of the organization.

Questions for Future Research

The work reported in this article raises several questions regarding both knowledge management and organizational learning:

1. JPL 101 was designed to support boundary spanning between different technical and administrative disciplines, and to promote sharing of cultural information. While the literature on cross-functional teams has looked at the benefits of integrating technical disciplines for new product development, the cross-organizational integration of knowledge attempted by JPL 101 represents an under-explored boundary.
2. The relationship between individual and organizational learning is the subject of debate in the organizational learning literature (Argyris, 1999). How does learning about the organization, as supported by JPL 101, relate to organizational learning?
3. There are obvious connections between learning and knowledge management systems. JPL 101 is a KMS explicitly created to provide a learning opportunity. It collects knowledge and codifies it in a way to make it appealing to a broad audience. It also provides a starting point for deeper exploration of the topics presented in the quizzes. Based on the JPL 101 experience, the use of a quiz interface provides a mechanism to transform a KMS into a tool for learning. While this proved true at JPL, additional research is needed to identify general approaches to merging KMSs with learning support.
4. The JPL 101 experience clearly demonstrated that different communication media have different results with respect to increasing participation. The huge increase in participation following the all.personnel e-mail indicates that, at JPL, this is a powerful tool for instigating initial attention. However, in this environment, broadcast e-mail could only be used once during the 12 weeks of primary operations due to internal communications policies. Questions remain regarding how effective e-mail would be if employed on subsequent occasions, how to increase long-term participation (i.e., as compared to the significant fall-off in participation in weeks after the e-mail "blip"), and theories for how to predict which communication mechanism would be most effective in general.
5. The categories of questions included in JPL 101 were chosen specifically for this organization and weighted toward topics (i.e., Basics and Stakeholders) where it was felt there was both unique information to share and a special need to do so. The generalizability of these categories, however, remains an open question. From a process-based

perspective, all organizations have a reason to exist that represents value to external customers and need internal processes to enable the organization to function. In addition, most organizations develop a culture that influences how work gets done. From this perspective four general categories can be identified as common across organizations: value-adding processes, enabling processes, external interfaces, and culture. From within these broader categories, organizations can focus on areas of particular importance to them.

6. Finally, the question of whether organizational learning actually occurred is unanswered. While there is clearly evidence that individuals learned — and considered what they learned to be valuable — organizational learning could not be assessed. For example, it is not known if or how knowledge conveyed by JPL 101 may have changed attitudes or work behavior. It also is not known if there was a sufficient enough change (e.g., by many individuals) to have a measurable impact on the organization.

CONCLUSIONS

This case contributes to the on-going discussion of knowledge management and organizational learning by providing a detailed description of the deployment and operation of an organizational knowledge-based resource specifically targeted to support general learning. A clear goal for knowledge management systems is to expand the knowledge base of the organization — in other words, learning. The work presented in this article describes one instance of the deployment of such a knowledge management system and provides some lessons learned that can be applied to future systems.

ACKNOWLEDGMENTS

The work described in this article was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration. We would like to acknowledge the contributions of Eric Ramirez in the implementation and administration of JPL 101, and offer special thanks to Barbara Amago, Winston Gin, Cara Cheung, Sanjoy Moorthy and Angela McGahan for their contributions.

Chapter 5.35
Knowledge Management and Social Learning

Irena Ali
Department of Defence, Australia

Leoni Warne
Department of Defence, Australia

INTRODUCTION

There are probably as many variations of knowledge management definitions as there are practitioners and researchers in the discipline. Complete consensus in such a group would be a surprising finding. This is because the two words are loaded with pre-existing meanings that do not always sit comfortably in juxtaposition, so what it means to "manage knowledge" is difficult to ascertain, and hence comes to mean different things to different people.

We do know, however, that knowledge exists in the minds of individuals and is generated and shaped through interaction with others. In an organizational setting, knowledge management must, at the very least, be about how knowledge is acquired, constructed, transferred, and otherwise shared with other members of the organization, in a way that seeks to achieve the organization's objectives. Put another way, knowledge management seeks to harness the power of individuals by supporting them with information technologies and other tools, with the broad aim of enhancing the learning capability of individuals, groups, and, in turn, organizations.

BACKGROUND

In this article, we examine both theoretical and practical socio-cultural aspects of knowledge management based on years of research by the authors in a large and diverse organization. The study involved numerous functional settings of the organization and the researchers used qualitative and quantitative methodology to gather data. Elements required to build an organizational culture that supports knowledge management are discussed. Unless otherwise specified, words in double quotes in the text are direct quotes from personnel in research settings.

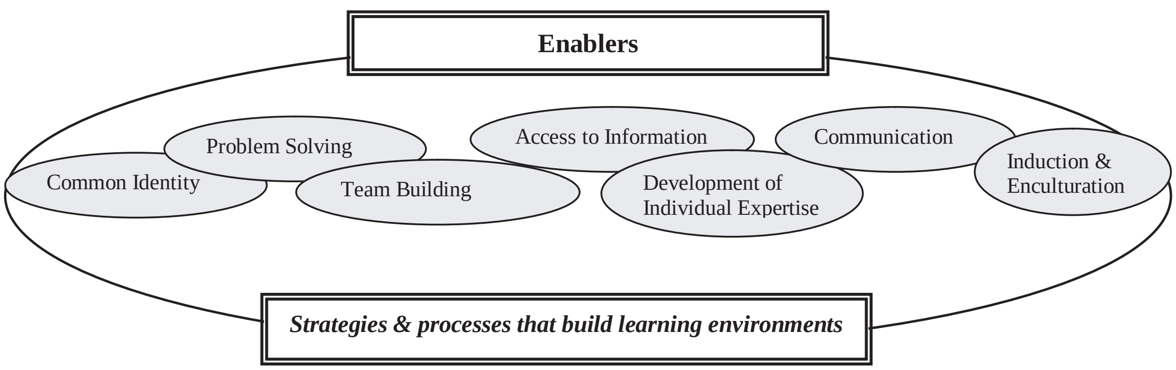
MAIN THRUST OF THE ARTICLE

The research team identified seven basic categories that constitute enabling processes and strategies to facilitate social learning: common identity; problem solving; team building; access to information; development of individual expertise; communication; and induction and enculturation (see Figure 1).

Common identity: a common ground/understanding to which many people/groups can subscribe, and requires a shift from seeing oneself as separate to seeing oneself as connected to and part of an organization unit. Based on our research, motivators impacting on common identity are: goal alignment, cultural identity, gendered identity, language, morale, and workplace design (spatial and physical design).

- Doney, Cannon et al. (1998) discuss the relationship between goal alignment and group cohesiveness, claiming that the extent of group cohesiveness relies on the extent to which a team's goals are clear and accepted and also on the degree to which all members adopt team behaviors.
- The term cultural identity refers to a member's sense of self in relation to the specific "tribe" and "tradition" to which they belong and how this distinctiveness applies in their workplace. Cultural identity is another important motivator for social learning because, like common identity, it impacts on the extent to which staff feels that they are part of the system or alienated from it.
- Gendered identity relates specifically to one's sense of self, which is imbued with the social, cultural and historical constructions surrounding femininity and masculinity. Gender identity, because of its relationship with common identity, was also seen to impact on social learning.
- Language is another important factor fundamental to the overall social learning processes. By reflecting the social and politi-

Figure 1. Constructs enabling social learning



cal relationship between various members, language can impact on common identity. Language is also important in terms of creating a shared understanding among workers and their relationship to the wider organization. "Words are bullets. Never, never use imprecise language." Thus learning the specific work-related language is of central importance to broader social learning development, and is an important outcome of the enculturation process.

- Morale has been a significant focus in the overall study because the research team found evidence of low morale being coupled with higher levels of alienation towards senior management. Such alienation has obvious implications for the broader understanding of a common identity and thus for social learning.
- Workplace design and proximity also threatens common identity when staff are not working in the same location. "[Building X] and us. We don't see them. There is not any spirit that we are belonging to one branch. I have more to do with [a specific area] than anything else and I've made some good contacts in there,... who I sit around with."

Problem solving: a core activity. It fosters social learning, because each problem represents an opportunity to generate knowledge. Motivators associated with this enabler are: networking, perceptions of the organization, systemic understanding, and time for inquiry and reflection.

- An individual's personal and social networks are an important means of acquiring, propagating, and sharing knowledge. As Davenport and Prusack (1998) claim, when those who are in a position of "know-how" share their expertise they contribute to problem solving. Personal networks were seen to function as channels supporting both "information pull" and "information push".
- Individual and shared perceptions of the organization, and how they operate, provide an essential backdrop to problem solving within an organizational context. These perceptions may consist of deeply ingrained assumptions, generalizations, or even pictures or images that influence how people understand their organizational world and how they should act within it (Senge, 1992). The importance of these perceptions cannot be stressed enough, because they directly influence the construction of individuals' knowledge and understandings that they draw upon in their day-to-day-activities.
- Effective problem solving often requires a systemic understanding of organizational and inter-organizational issues. Systemic understanding requires a holistic view of an organization and its interrelationships, an understanding of the fabric of relationships and the likely effect of interrelated actions (Senge, 1992).
- Inquiry and reflection together are a powerful means of enhancing social learning and knowledge creation. Inquiries, or questions, are triggered by problems that require solutions or explanation. Reflection allows time for examination, contemplation and, often, resolution of the inquiries. To use a common metaphor, it is perhaps the best means for distinguishing between the forests and the trees of everyday working life.

Team building: working together and understanding what each member is trying to do. Team building was seen to be essential for effective social learning and problem solving. Motivators associated are: leadership, team-based morale, performance management, public recognition and reward systems, use of humour, and workplace design.

- In general, the caliber of leadership within the settings studied was to be admired. The leaders and managers were innovative and they motivated and developed their staff, mainly by demonstrating that staff are highly valued and by acknowledging expertise and knowledge regardless of their pay or position. Another team building issue that emerged was that people were appreciative of informal "drop-ins" by senior managers inquiring how they were doing. This "roving management" was said to contribute to better cohesion of teams, to promote system thinking, to help focus on overall goals, and to facilitate communication and feedback.
- "Team spirit" and "team cohesiveness" are both important values within the work culture and work ethic; nonetheless, there was nothing uniform about this in the settings studied. Some teams did not see the significance of their particular tasks to the overall goals of the organization. However, good examples of teamwork and team spirit were also evident. There were instances where teamwork was well integrated into daily work and where people worked collaboratively. Such teams were goal-oriented and were not only teams in structure but in spirit and were led by a leader who saw his/her role as serving team members rather than just having the position of a leader.
- For many employees, the performance cycle is annual and the outcome of a performance report often determines the prospects of one's career progression. Some felt somewhat uneasy as their performance evaluation was due relatively early into their posting cycle. A well-planned performance appraisal system should help to make equitable and unbiased decisions regarding staff selection, placement, development and training (Wood, 1989). Researchers were told that there was often a lack of clear communication about performance expectations. Also, an annual performance appraisal appears to be too long to wait for recognition of good work and too late to correct a performance problem. Morgan (1989) and Wood (1989) explain that to maximize positive results, the appraisal process should be two ways: it should facilitate and coach staff in doing their jobs effectively; and it should be frequent and informal.
- It was observed that humor was used for smoothing discussions that were becoming heated and to stop the conflict from escalating while also enabling the conflicting subordinates to save face. At meetings, humor was used to assist in uniting people around common themes and to make criticism palatable.
- One way of increasing team and individual morale is to publicly acknowledge outstanding work. Making employees feel appreciated, and saying, "Thank you, we know that you are a good employee, we value you and your work", is a big factor in motivation (Mitchell, 2000). Key informants stated that public recognition of good work was scarce and that a written or verbal word of praise, a pat on the back often means more, for example, than a pay raise – "praise is better than money" and praise is needed at all levels.
- Workplace design was seen to have impact on social learning. Staff located at small isolated outposts were at risk of feeling isolated and did not identify strongly with the parent organization. As stated earlier, out-posted staff identified more with the workplace with which they were based than their branch where they affiliated. This was further exacerbated by the fact that they often felt excluded by their colleagues.

Access to information: the easy availability of corporate information in whatever format was observed to effect knowledge acquisition and generation of new knowledge and social learning. Motivators associated are: record keeping, networking, meetings, and information technology (IT) infrastructure.

- The researchers observed that general familiarity with records keeping procedures was quite poor. Some people have developed their own personal records keeping systems but there was little uniformity in these and no adherence to file naming conventions and standards. As some informants stated: "I believe that physical files in the … are no longer managed well because their management has been farmed out to outside bodies." Or "I think we have problems with passing on information in the organization as a whole. We just don't do it very well." The issue of electronic records, particularly e-mail messages containing evidence of business transactions, posed problems not only in the setting studied but also in the whole of organization.
- Personal networks from previous postings as well as newly acquired contacts in the new environment play a vital role in knowledge construction and acquisition. New knowledge often begins with the individual and through conversations people discover what they know, what others know and in the process of sharing, new knowledge is created. Knowledge sharing depends on the quality of conversations, formal or informal, that people have. Webber (1993) aptly describes it: "Conversations – not rank, title, or the trappings of power – determine who is literally and figuratively 'in the loop' and who is not."
- Meetings are another means of accessing information and those that were observed varied significantly in format and the protocols in place. At the tactical headquarters, meetings that were mission-related provided excellent opportunities for learning. Strict protocols were observed at these briefings, for example, allowing participants to discuss errors or problems encountered during missions without assigning blame or shame to individuals. There were few equivalent meetings at the strategic headquarters, other than some induction sessions and briefings, and it appeared that learning how to do one's job was not given quite the same priority.
- The researchers observed that information access due to failings in the IT infrastructure inhibited access to information within the strategic settings. Another issue that caused problems was the difficulty in finding information on the shared drive. Since there was no specific person responsible for maintaining the shared drive and for naming folders, it was left to the discretion of the document originator where information would be stored.

Development of individual expertise: the acquisition and development of expertise was seen as an integral part of social learning. Motivators associated with this enabler are: career trajectories, professional currency, professional training, postings and promotion, and mentoring.

- A career trajectory describes the positions, roles and experience that individuals have accumulated, up to and including the position they currently hold. While not excluding personal experiences outside of a work or training context, a well-designed career trajectory generally equips an individual with the skills, experience, maturity and personal networks needed to successfully fill a particular posting.
- The term professional currency has a somewhat different meaning within different environments. However, professional currency promotes social learning in the same way that appropriate career trajectories do so "

by providing a foundation for the generation of new knowledge.
- Appropriate professional training is a significant component of the development of individual expertise and, therefore, a fundamental for generating new knowledge. Training courses are important for furthering individuals' expertise, as well as for forming the personal networks that subsequently develop. However, in times of budgetary constraints, training money is often the first to go, with damaging consequences for the organization's ability to learn and manage their knowledge.
- Mentoring is regarded as an effective method of assisting the development of individual expertise; especially for junior staff, a degree of informal mentoring was seen to be built into elements of the training program in some of the settings studied. In terms of developing a career trajectory, the knowledge acquired through mentoring may also be important when individuals want to prepare themselves for specific roles in the future.

Communication: essential to effective learning within an organization and to effective social learning. Motivators associated with this enabler are: overall communication climate, formal and informal information flows, time for inquiry and reflection, use of humor, language, and workplace design.

- Supportive communication climates are being positively linked to open and free exchange of information and constructive conflict management. Characteristics of a supportive communication climate include a culture of sharing knowledge, treating each other with respect, and generally behaving in a cooperative manner. Research has established the link between supportive organizational communication climates and generative learning (Bokeno, 2000; Ruppel, 2000) and with higher levels of organizational commitment (Guzley, 1992).
- An important element of generative learning is for organizational members to be able to engage in dialogue which is open and is based on inquiry and reflection. A supportive communication climate is a prerequisite for such dialogue, and it requires learning how to recognize defensive patterns of interaction that undermine learning (Senge, 1992).
- The issue of workplace design and its impact on teams, network building, and on accessing information arose repeatedly during the study. Physical location and proximity to each other had the potential to promote the transfer of pertinent knowledge. The point was made that in addition to more quickly obtaining answers to questions about particular tasks, an open plan workplace enabled one to tap into pertinent knowledge by overhearing others' conversations. Hutchins (1996) uses the term "horizon of observation" to describe the area of the task environment which can be seen, and is therefore available as a context for learning by team members.

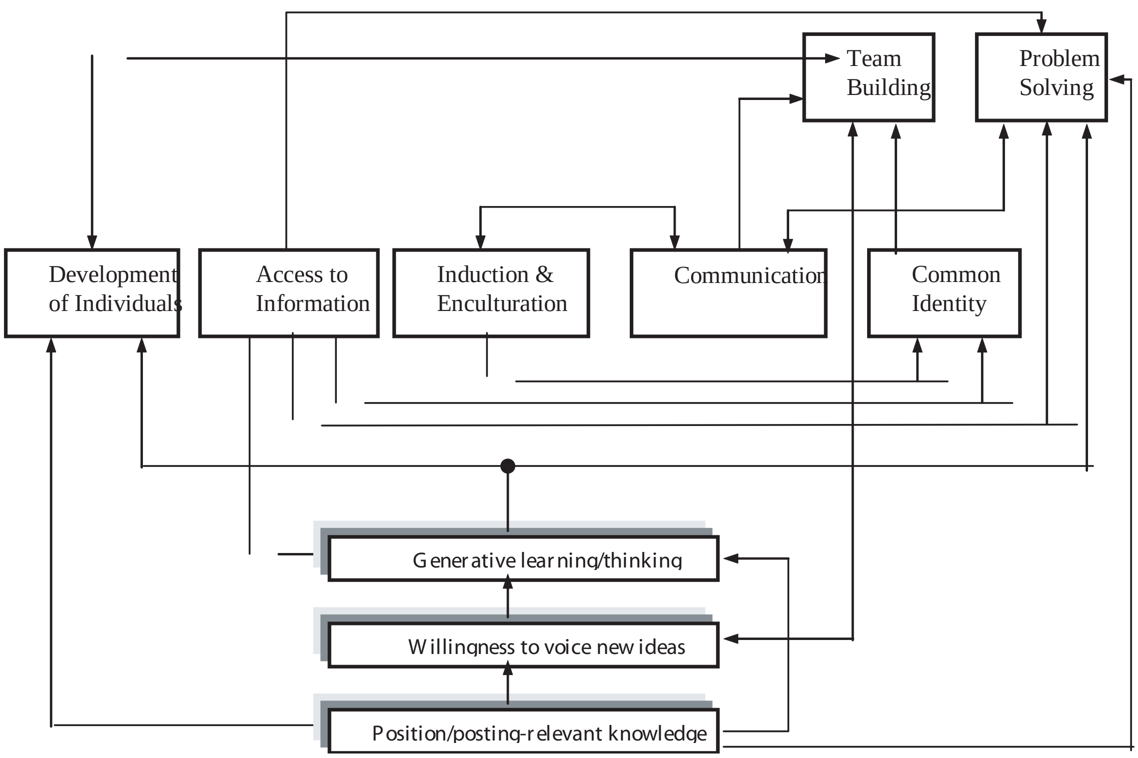
Induction and enculturation: facilitates social learning by providing a foundation upon which an individual can become fully productive. Issues associated with this enabler are: timeliness and comprehensiveness of the process, buddy/mentoring system, handovers and information packages, and training.

- Good induction is more than just an introduction to a new job and workmates; it is a way of helping people find their feet. Attitudes and expectations are shaped during the early days of new employment, and work satisfaction is linked to well-timed and conducted work orientation (Dunford, 1992; George & Cole, 1992). The interviews clearly indicated a relationship between meaningful and timely induction and subsequent job satisfaction. An interesting finding was that those who were not properly inducted or enculturated into the organization saw no need and responsibility to actually prepare any form of handover for anyone who may take over their position in the future.

- Although highly desirable, it was not always feasible to conduct an induction program at the beginning of a new posting cycle. In the interim, a "buddy" or "mentoring" system could fill in the gap. A "buddy" would be an experienced workmate who could be available to answer questions and assist the orientation of new members during the initial few weeks. Some interviewees said that having a buddy when they started was invaluable to settling into a new job and to effective learning.
- The researchers were repeatedly told that early training is an important part of effective induction and enculturation. It is an opportunity to learn the explicit knowledge that is taught as part of formal training. It is also an opportunity to be exposed to the attitude and cultural perceptions of colleagues and peers.

These factors enabling social learning identified from our data are by no means exhaustive, however, based on the available data, the research team could see a relationship between these enablers and social and generative learning. Figure 2 depicts these relationships and their impact on social learning.

Figure 2. Enabling processes and their impact on social learning



CONCLUSION

Therefore, organizations seeking to improve information sharing and knowledge generation need to develop a greater awareness of the processes and strategies of organizational learning. Organizational knowledge is distributed across functional groups, and its generation and continual existence is dependant on the overall communication climate which is embedded in the organizational culture. This study indicates that information sharing and subsequent knowledge generation would be successful when interactive environments are cultivated before other, for example, technology-based solutions are implemented.

Chapter 5.36
Knowledge Management Trends:
Challenges and Opportunities for Educational Institutions

Lisa A. Petrides
Institute for the Study of Knowledge Management in Education, USA

Lilly Nguyen
Institute for the Study of Knowledge Management in Education, USA

ABSTRACT

While the pressure of public accountability has placed increasing pressure on higher education institutions to provide information regarding critical outcomes, this chapter describes how knowledge management (KM) can be used by educational institutions to gain a more comprehensive, integrative, and reflexive understanding of the impact of information on their organizations. The practice of KM, initially derived from theory and practice in the business sector, has typically been used to address isolated data and information transfer, rather than actual systemwide change. However, higher education institutions should not simply appropriate KM strategies and practices as they have appeared in the business sector. Instead, higher education institutions should use KM to focus on long-term, organization-wide strategies.

INTRODUCTION

Knowledge management (KM) can be used by educational institutions to gain a more comprehensive, integrative, and reflexive understanding of the impact of information on their organizations. Specifically, the practice of KM, initially derived from theory and practice in the business sector as described in the previous chapter, provides a framework to illuminate and address organizational obstacles around issues of information use and access (Davenport, 1997; Friedman & Hoffman, 2001). Yet introducing the concept of KM into the educational arena from the business sector has been a slow and often underutilized process. This is partially due to the fact that KM is a multi-layered and systems-oriented process that requires organizations to rethink what they do and how they do it (Brown & Duguid, 2000; Senge, 1990). Additionally, educational institutions are traditionally hierarchical with silo-like functions, making cross-functional initiatives difficult to implement (Friedman & Hoffman, 2001; Petrides, McClelland, & Nodine, 2004).

However, educational institutions can perhaps learn from KM efforts in the business sector, in terms of the limitations and drawbacks associated with KM. In fact, there are several compelling reasons why educational institutions have not, and perhaps should not, simply re-appropriate KM, as popularized by the business sector, into their own organizations. For example, in the business sector, there has been an appeal to focus on information technology and systems as solutions to problems of knowledge transfer and knowledge sharing (Hovland, 2003; Huysman & de Wit, 2004). Coupled with a profit motive, KM as it exists in the business sector is often limited in its ability to create far-reaching organizational change (Hammer, Leonard, & Davenport 2004). Furthermore, recent trends in the field also fail to fully distinguish between data, information, and knowledge (Huysman & de Wit, 2002). Consequently, organizations merely address singular and isolated data and information transfer, rather than actual systemwide and organization-wide change.

These particular limitations are especially salient now as higher-education institutions face an increasing number of challenges that have forced them to rethink how they are accountable to external demands, as well as how to improve internal accountability. Rather than focus on micro-level information-sharing activities, implementing KM strategies and practices requires these educational institutions to examine the larger context of information sharing within the organization, specifically how their people, processes, and technology function within it. As such, neither data-sharing activities nor technological implementation should be viewed as the ultimate objective and final stage of a KM strategy. Instead, KM practices necessitate strategies that build upon current practice, leading to more comprehensive and organization-wide changes in knowledge practices and actions.

How then can educational institutions translate isolated sharing activities into long-term learning? This chapter illustrates how KM strategies and practices enable higher-education institutions to distinguish between data, information, knowledge, and action and how this iterative cycle can help organizations assess their available resources—that is, their people and processes along with their technology. In turn, this chapter demonstrates how KM can help educational institutions place themselves on the path toward continuous learning and organizational reflexivity.

CONCEPTS AND THEORIES

An overview of KM practices in the business sector demonstrates an overwhelming focus on simplified solutions, specific applications, and singular information-transfer activities. Recent accounts suggest that KM has seen limited impacts in the private sector due to overemphasis on technological hardware and software (Hammer et al., 2004; Hovland, 2003; Huysman & de Wit, 2004). This may be due in part to the fact that it is often easier to persuade organizations to acquire new technology tools than to modify or redesign existing organizational processes (Coate, 1996).

However, these particular approaches to KM are less likely to embrace a systematic approach to how organizations function. By focusing too narrowly on isolated information-sharing activities, organizations are prematurely confined and prevented from engaging in a more integrative approach to KM. These information-sharing activities, which some might argue are wrongly classified as KM, may include electronic search and retrieval, document management, and data warehousing systems. These examples demonstrate important yet isolated occurrences of information activities and practices. However, these practices are often implemented disassociated from a larger organization-wide strategy. Secondly, and perhaps more importantly, the interpretation of these as KM does not acknowledge a vital distinction between information and knowledge. It is this delineation that pinpoints the incremental process behind the implementation of KM strategies and practices: Information is data with contextual meaning, data that has been categorized, or subjected to a process of sense-making and interpretation. Knowledge is information that is put into action through the process of problem-solving, decision-making, feedback processes, and so on (Davenport, 1997).

Therefore, developing policies and processes that fundamentally support and organizationally align information-sharing activities to each other is one of the first steps an organization must take to embrace and develop successful KM strategies. Often, an organization will try, yet fail, to implement an entire host of activities related to data collection and information access, only to find that the necessary organizational conduits for information sharing and new knowledge creation are not in place. How an organization shares information, along with the incentives and rewards to do so, and a culture that supports information-based decision-making are all key components that need to be in place before KM can be successfully implemented.

People, Processes, and Technology

KM strategies and practices come to embody the interactions between people, processes, and technology. These three—people, processes, and technology—all function as an integral part of the ongoing dynamics as organizations struggle to meet their information needs. First, it is people, not systems or technology, who "know." Thus, it is people who manage the policies, priorities, and processes that support the use of data, information, and knowledge. KM strategies and practices seek to engage different groups of people across various levels of an organization in the process of collective sense-making and decision-making. Whether these groups are formal or informal, a KM strategy includes supporting individuals in coming together to share information to address their collective needs.

Likewise, self-evident processes or embedded, day-to-day work practices can greatly affect the exchange and sharing of information within any organization. For example, it may be common practice within an organization for decision-making authority to be exercised only at the most senior level. These kinds of decision-making processes can create barriers to ownership, in which individuals are not provided with the appropriate incentives to make their own decisions and changes, let alone use data and share information. By uncovering these processes, KM strategies and practices can help identify knowledge gaps, and thus enable people to obtain the information they need and encourage them to share it with others, sometimes creating new knowledge and improved decisions. In highlighting patterns of information use that might not be evident otherwise, KM practices encourage a certain level of organizational reflexivity, which allows organizations to better understand themselves, in turn leading to more informed decision-making.

Rather than situating technology as the focal point, KM practices approach technology as an essential resource that is necessary for changes in organizational process to occur, but not sufficient. Recent trends in KM may grant technology disproportionate authority in how organizations share information. However, technology and information systems are neither the driver of information sharing, nor are they tangential to the process. Instead, technology is of equal importance in its ability to impact how information flows throughout an organization. Therefore, KM is the combination of people, processes, and technology that come together to promote a robust system of information sharing, while guiding organizations toward ongoing reflexivity and learning.

In summary, recent KM trends in the business sector often do not explicitly address all of the organizational resources necessary to implement KM, namely, the people and processes as well as the technology. To some, KM is used as a phrase to describe the technology that is used to manage an organization's data, such as data on monthly sales figures or a database of successful sales strategies. However, the way that these information systems are used is fully contingent on the strategies and policies employed by the organization, and does not constitute KM on its own. It is not uncommon to hear a claim that a vendor has developed "knowledge management software," rather than "developing software that could be used to help an organization implement KM strategies and practices." Although this distinction may appear to split semantical hairs, we argue that these types of technology present only one part of a larger whole within organizations, but they often do not address the necessary steps to become an organization that uses information and knowledge to develop continuous learning throughout.

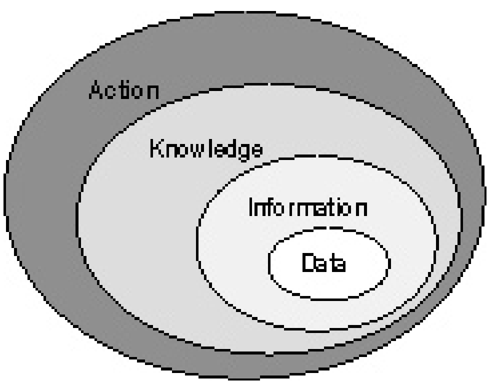
Data–Information–Knowledge–Action

KM strategies and practices are predicated on the distinction between information and knowledge. Other research in KM makes this distinction to highlight that information undergoes a series of processes that transform it into knowledge as it flows and is exchanged among individuals within an organization (Davenport & Prusack, 1997; Drucker, 1998; Wilson, 2002). To further refine this notion, we assert that information and knowledge need to be further delineated. As such, we propose four stages that comprise the KM cycle: data, information, knowledge, and action. Data are the facts and quantitative measures that are available within any organization. When groups or individuals take data and contribute their own interpretation and categorization, data can be transformed into information. In turn, knowledge is the resulting understanding that allows people to share and use this information that is now available to them. Once this knowledge is applied to make specific decisions or address problems, it is transformed into an action. Each component of the cycle builds upon the preceding element, feeding back and connecting actions and decisions and new learning, which eventually translates back to new questions that are informed by data once again.

There is a certain set of activities and practices that typically takes place in each part of the cycle, where each component builds upon the one before it, making it an iterative process of change or improvement. Data activities in the KM cycle can include accessing data by departmental request, or retrieving data directly from information systems and placing them within personalized spreadsheets. Information activities may include analyzing data to find patterns, problems, and discrepancies, or aggregating and disaggregating data, writing reports, or discussing findings from the data with colleagues. Knowledge activities entail formal and informal discussion and collaboration to address issues and problems in the context of the data and information. It is important to note that the knowledge stage of the KM cycle encompasses a process of collective sense-making, which includes ongoing discussion, collaboration, and feedback, thus shifting individual data and information practices into the organizational environment. The last stage of the cycle is then implementation of changes and action that result from the iterative process.

Therefore, organizations that simply engage in the collection and distribution of data are engaged in data management activities only. However, knowledge management is more than the mere aggregation of data management practices. KM practices include the management of the infrastructure that supports the data–information–knowledge–action cycle, as well as the implementation of the process. In these examples, we see then that KM activities and practices bring together all four components of the cycle: data, as well as information, knowledge, and action. In turn, KM strategies embrace practices at every stage of this cycle, and integrate the people, processes, and technology within the organization. It is important to note that each stage of the KM cycle is not mutually exclusive. An organization that fully adopts KM strategies and practices also demonstrates activities within each component of the KM cycle simultaneously. Engaging in the knowledge stage of the KM cycle also includes individuals engaging in data and information activities. In fact, KM practices necessitate that individuals simultaneously engage all three stages of practice, data, information, and knowledge as they implement changes and action (see Figure 1).

Figure 1. The data-information-knowledge-action cycle



Thus, the KM cycle demonstrates the dynamic qualities of KM strategies and practices. Their simultaneous, ongoing, and cyclical nature further highlights the necessary feedback and iterations that serve as the foundations for ongoing reflexivity and learning. As such, KM practices demonstrate how knowledge is most valuable not when stored in static repositories, but when exchanged across groups of people, used and applied to inform actions and change. KM strategies and practices can help organizations better identify their information-sharing and knowledge-generating activities, which, in turn, can help organizations capitalize on the iterative nature of knowledge-sharing activities.

CURRENT CHALLENGES FOR KM IN HIGHER EDUCATION

Increasing pressures and demands for data on student success have translated into an increased call for reliable information regarding critical outcomes in higher education. Due to rising public accountability pressures and strains on fiscal resources, many legislators have begun to demand information that can be directly linked to academic outcomes. As a result, these institutions are faced with requirements to provide accurate data and information around a growing number of issues and outcomes. In order to do so, the institutions are now re-evaluating their own knowledge strategies and practices.

However, these processes of re-evaluation have proven to be challenging. To begin with, the information technology infrastructure at many higher-education institutions is problematic. Rather than having one robust and integrated system, educational institutions more often maintain several information systems that support various functions throughout the organization, some of which are antiquated legacy systems. In addition to this fragmented information technology infrastructure, there are often inconsistent priorities around data collection, which can result in inaccessible or unreliable data. These characteristics translate into disparate data silos throughout the organization, redundant data gathering, and information hoarding, the cost of which is an impaired ability to sustain knowledge development, growth, and effective decision-making (Petrides et al., 2004). In an increasingly performance-driven climate, this only exacerbates these already problematic and costly practices.

Furthermore, cultural issues associated with information hoarding and overall disincentives for sharing and cross-functional cooperation can undermine KM implementation strategies in educational institutions. In a climate of accountability, data and information can appear threatening as well as politically charged, particularly when programs or other initiatives are under fiscal strain. Nevertheless, educational institutions can minimize these potentially negative consequences by developing KM strategies under a set of policies that explicitly encourage change and progress rather than penalize mistakes. A culture that is intolerant of mistakes can severely impede KM initiatives (Davenport & Prusack, 1997). The psychological instability that can arise is a very real challenge that can curtail any change initiative. As such, when implementing a KM strategy, educational institutions are better served by fostering an environment that reduces the sense of fear and retribution that individuals within the organization may face, for example, as they uncover data and information that may support unpopular opinions.

KM practices also require long-term strategies and commitments in order to fully realize their benefits. While educational institutions have tentatively begun to incorporate KM strategies, they will benefit from gaining a better understanding of the current limitations of these recent approaches to KM in the business sector, such as the narrow focus on seemingly easier-to-address solutions—for example, creating a data warehouse from which to extract student data. In microscopically fixating on specific information solutions, many current trends in KM do not help these institutions build the capacity to sustain long-term organization-wide change, but instead limit the potential that information and knowledge sharing can have.

While KM researchers may recognize the importance of distinguishing between data, information, and knowledge, KM practitioners in the private sector have not necessarily taken into account these distinctions. In this particular conception of KM, knowledge is then simply used as an overarching term for all three—data, information, and knowledge. Subsequently, many of the products, repositories, and exchange activities that are currently termed KM prove to merely support data and information, rather than actual knowledge. Doing so runs the risk of prematurely curtailing the necessary feedback mechanisms for continuous organizational learning.

However, it becomes much more difficult to address systemic barriers to knowledge sharing. The desire to find narrow and short-reaching solutions is often rooted in a compartmentalized understanding of the nature of organizational barriers to information sharing, even though these problems are more than technological. These problems include people's prevailing attitudes, beliefs around knowledge sharing, and systematic and structural disincentives to share and exchange. For example, the politics of information are often heavily embedded in organizational culture and structure, which complicates efforts to change processes that could be used to potentially support and drive knowledge sharing and creation. Recent evolutions of KM do not necessarily take into account the organizational cultures and structures that serve as barriers to data sharing, information sharing, and eventually knowledge sharing. Furthermore, these recent developments in KM fail to acknowledge the evolving and iterative qualities of knowledge. Knowledge is only useful when it is shared, transmitted, or acted on in some capacity. During these exchanges, knowledge undergoes an ongoing and continual cycle of change from data, information, knowledge, and action. However, these distinctions are lost as KM practitioners attempt to find solitary solutions to problems of data and information.

If these attempts at KM remain truncated and narrowly focused on simplified solutions, specific applications, and singular knowledge-transfer activities, these tools can only marginally improve an organization's use of information and knowledge and do not address the deep-rooted processes and strategies necessary to overcome these barriers. Information technologies and applications only incrementally improve an organization's ability to facilitate data sharing and information exchange. As such, these approaches demonstrate a bounded set of limitations that ultimately prevent organizations from overcoming their current obstacles and diminish their ability to build a self-sustaining and long-term organization-wide system, thus undermining the very benefits KM practices have to offer.

Therefore, we suggest that educational institutions should not simply appropriate KM strategies from the business sector and apply them to their organizations. If KM is being implemented poorly, does that mean it should be done away with completely? Or does it hold its own as a concept worth striving for? The current limitations and drawbacks of KM in the private sector should serve as a warning for educational institutions. These organizations should be careful not to prematurely fragment their KM practices and focus on narrow applications and solutions. Instead, higher-education institutions stand to benefit from an approach that incorporates a more long-term and inclusive strategy to their knowledge activities. As such, improved methods of data and information sharing need to be coupled with embedded and long-term KM strategies in order to address the organization-wide factors that can either impede or promote an ongoing culture of research, reflexivity, and long-term organizational learning. If the evolutionary qualities of knowledge management—as it evolves from data, information, and knowledge—cross through multiple groups of people within an organization, as well as traverse the three key organizational resources available—that is, people, processes, and technology—then the dynamic process that guides successful KM strategies and practices is more readily supported and maintained.

OPPORTUNITIES FOR KM IN EDUCATION

Educational institutions demonstrate a great need for improved knowledge-based systems. We already find that there are many formal and informal administrative processes, information-sharing patterns, work incentives, information silos, and other work practices that have flourished over time, yet these can also critically impede organizational and systematic information flow and knowledge exchange. KM strategies and practices can begin to integrate these disjointed systems. For example, the use of information maps and audits can initially be used to obtain a bird's-eye view of the current processes and practices, and their corresponding strengths and weaknesses. This type of initial diagnosis proves to be important for implementing KM in order to identify the most appropriate entry point for change. The cyclical quality of KM encourages organizations to take an honest and reflexive stance on what is already going on in their organization. KM requires that educational institutions candidly address their current patterns and processes, and only from this position begin to capitalize on the opportunities that KM strategies and practices can offer. This process of organizational re-evaluation and reflexivity proves to be the most difficult challenge for educational institutions. At the same time, the process offers the ideal opportunity for these institutions to integrate KM to promote sustainable learning within their organizations in order to meet these external demands as well as improve organization-wide effectiveness.

Higher-education institutions can begin to translate these strategies into action by identifying their information shortages and needs, including finding out where people are already requesting more data and information. These institutions can also start by identifying groups of people who already maintain synergistic relationships of collaboration and sharing within the institution. In fact, educational settings already demonstrate many information-sharing activities in effect, such as existing formal or informal communities of practice. However, to sustain ongoing inquiry and continuous learning, educational institutions need to strategize as to how they will systemically embed these activities and practices within the very fabric of the organization. Taken individually, information-sharing activities can be used toward incremental improvement; however, when KM is adopted and executed as an organization-wide strategy, improved methods of data and information sharing can be used to continually promote the development of KM-based practices. This can help educational institutions become more informed in their decision-making as a whole. All of this helps to lay the foundation for a robust culture of inquiry and reflexivity, thus establishing the mechanisms for sustainable, long-term organizational learning.

Perhaps more importantly, student access and success are the likely benefactors of these KM practices. KM practices can promote organizational reflexivity in such a way that educational institutions better understand their own weaknesses and strengths, and can then allocate their resources to where they are most needed. As demands for accountability rise, educational institutions need to become much more adept at assessing students' needs along with their own institutional capabilities. KM practices can help bring these two together, that is, aligning institutional capabilities and resources to better address students' needs and thus student success. Subsequently, educational institutions that engage in KM practices for continuous learning at the organizational level also engage in promoting continuous learning for their students.

OPPORTUNITIES FOR CONTINUOUS LEARNING

In conclusion, to fully realize the potential of KM, educational institutions will need to change the focus of KM from isolated knowledge-sharing activities to long-term, organization-wide strategies. Thus, KM practices can help educational institutions meet their goal of improved decision-making to advance student learning, allowing these institutions to begin to identify the value of programs and services that contribute to student access and success. This requires not only addressing information policies, but also taking a closer look at the institution's own processes and current practices to stimulate ongoing and constructive data use. Therefore, KM practices can be used to help educational institutions develop a sense of reflexivity across all levels of the organization, thereby providing these institutions with the means for a sustainable culture of inquiry and continuous learning.

Chapter 5.37
Wise Organizations?

Chauncey Bell
Bell & Associates, Business Design for Innovation (BABDI), California, USA

ABSTRACT

In seeking wisdom, the first step is silence; the second, listening; the third, remembering; the fourth, practicing; the fifth teaching others. Solomon Ibn Gabirol, Jewish Poet and Philosopher (c. 1021-1058)

"There is no use trying," said Alice; "one can't believe impossible things." "I dare say you haven't had much practice," said the Queen. "When I was your age, I always did it for half an hour a day. Why, sometimes I've believed as many as six impossible things before breakfast." Lewis Carroll, Alice in Wonderland

This chapter explores the ways that wisdom and wise action appear in the work of organizations and asks how systems can be designed to support that. Building on C. West Churchman's thought experiment with five philosophers about how to improve the design of systems, the author asks and brings fresh answers to the questions, "What is wisdom?" and "What is wisdom in organizations?" The author offers a series of six brief reflections about foundations that he believes can make the design of systems that support people in acting wisely far easier to do. The chapter concludes with a case example of a system illustrating many of the chapter's themes and specific recommendations for IT designers about how to think from the chapter's suggestions. The author hopes to build a richer background for IT designers, leading to systems that do a better job of supporting people in the wise exercise of their responsibilities in all kinds of organizations.

INTRODUCTION

In this chapter, I want to help put a richer background in place to support the work of IT designers. I hope that an examination of wisdom may inform those who have the ambition, or are charged with, designing and building software systems, and lead to the development of systems that do a better job of supporting people in the wise exercise of their responsibilities in all kinds of organizations. The subject is too big for a chapter in a book, but perhaps with the following I can inspire, suggest some foundations, suggest directions for exploration, and, at the same time, point out some goofy interpretations that may be adjusted or altered.

In his exploration of the idea of designing inquiring systems, C. West Churchman (1968) challenged himself to invent a basis for building systems that support human action more effectively:

"Instead of just asking the traditional questions of how human minds come to learn from experience, [I] asked how one could design a system that would learn from its experience in some 'optimal fashion.' My plan was to translate some of the historical texts in the theory of knowledge into modern systems terminology, by assuming that the authors were discussing the components of a system design…I was struck again [while studying Leibniz] by the fact that in his approach to the inquiring system he was insisting that a concept of the whole system was essential in understanding how each 'part' worked…Now in these days of rather intense study of systems and their management, few seem in the least concerned about…the characteristics of the whole system in any but a very narrow sense. If Leibniz was right, then modern theories of system design and managerial control are sadly lacking in their reasoning." (pp. v-vi)

I am a designer of business habits. I design ways that human beings— in explicit or tacit collaboration with others—do things to shape their futures by adjusting or changing their habits. Mostly, I work in large institutions. In the process of building new working habits in a number of industries over the years, I have designed and led the development of several complex software systems.

We human beings are creatures of habit, and habits are deeply relevant to the question of wisdom. Even before we notice we are doing it, we act out of structures in which we are predisposed to act in particular ways—ways that are shaped by habits of thought, word, and deed. Most of the time, people pay little attention to the way that acting in habitual and unexamined ways shapes our world. I have for many years been interested in ways of thinking and acting that allow me and my clients to look beneath the world's neatly ordered stories about why and how people do the things they do. Further, because the construction of new habits always involves breaking or reshaping old habits, I also study how to intervene in old habits. As the reader will see, these matters are deeply relevant to the subject of designing and building systems that support wise action in organizations.

The chapter is organized into five parts followed by a short conclusion.

1. In What is Wisdom? we begin by exploring what we mean by that word and the implications of setting out in pursuit of it.
2. In What About Wisdom in an Organization? we do the same with organizations, asking questions about what happens to people when they work together in organizations.
3. In Churchman's Gathering of Philosophers, I turn to a series of reflections on the philosophical traditions in which C. West Churchman gathered five philosophers to help him in his work and open an exploration of what those traditions tell us that could be important for the job of IT designers.
4. Preparing the Way for Wisdom in Organizations offers a set of reflections about underpinnings, or conditions, in which wisdom can be cultivated and exercised in organizational settings.
5. A Well-Tooled Investment Management Process sketches a case example of design, implementation, the underlying logic of a set of practices and supporting tools for investment management in large organizations, and makes a series of specific recommendations for systems designers.

WHAT IS WISDOM?

For Churchman, knowledge bespoke an accumulation of the capacity to act wisely. His interpretation of what would need to be examined in order to develop systems that engender wise action was remarkable. Courtney (2001) tells us that Churchman saw knowledge as at once collection, activity, and potential:

1. Deeply connected to action, "a vital force, which makes an enormous difference in the world," in the midst of action, or as "potential for action";
2. Dynamic, as one of knowledge is able "to learn as circumstances change";
3. Somehow deeply connected to ethics and morality; and
4. In some way requiring the actor to break with rationalist scientific traditions and become entangled in one's own feelings and thought processes. (p. 22)

In this chapter, we want to interpret wisdom as the substrate of what Churchman was observing—the base metal if you will. We will explore the construction of wisdom and its appearance in enterprises so that when it comes time to cultivate or accumulate wise action, we have explored what that is and where it comes from.

Looking in http://www.dictionary.com, we find wise defined as "Having the ability to discern or judge what is true, right, or lasting; sagacious: a wise leader."2 The behavior of organizations,3 and of people working in organizations, seems at first glance to be a good place to observe everything but wise behaviors. Something about the notion of a wise organization is oxymoronic, like a deafening silence. Why are organizations not automatically bastions of wisdom? After all, a whole lot of people should be smarter than any one of us, right? Our experience with the behavior of people in organizations tells us that this logic doesn't work reliably.

Let us first turn our attention more to the question of what we mean when we say wise or wisdom. Think back to an interaction you had at some moment in your life with someone you consider wise. Think about what happened before, during, and after your saying to yourself, or to another, "That is wise," or the equivalent. Here are three examples of my own, the first personal and the second and third institutional. See how your example is similar to and different from these examples:

1. During our teens, 20s, and into our 30s, my younger brother and I were not close. He is two and a half years younger and on coming into adulthood, he concluded that I was not interested in listening to him or learning from him. For my part, I carried forward one of those standard older brother irritations with the too-full-of-himself younger brother. As a result, when we were together at family affairs, we would be found at opposite ends of the room, and we did not speak between such events. Unbeknownst to me, as he came into his thirties, my brother had shared with our mother his yearning for a relationship with me. In the spring of 1984, my wife suddenly became very ill, lost the child with whom she was nearly at term in her pregnancy, and found herself at death's door. In that moment, my mother called my brother and said to him, "I know that you have wanted a relationship with your brother. He is in trouble and he needs you. If you want that relationship, figure out how to drop everything and go and be beside him immediately, where he is sitting in the hospital praying and waiting to see what will happen with his wife." He followed her suggestion, and, in the ensuing weeks, our relationship transformed.
2. Perhaps some of you reading this are familiar with the "Iron Ring" that Canadian Engineers wear on the fifth finger of their

right hands. The ceremony in which the ring is delivered to a young engineer about to graduate from engineering school, called the "Ritual of the Calling of an Engineer" was invented early in the 1900s by the engineering professors Herbert Haultain and Rudyard Kipling after a railway bridge to link Winnipeg, Manitoba, and Moncton, New Brunswick twice collapsed while under construction, over the course of 10 years, at a human cost of 85 lives and untold other damage. An inquiry revealed that the collapses resulted from errors in judgment by the bridge's engineers. Haultain and Kipling invented the ritual to alter Canadian engineers' sense of their responsibilities and their experience of the realities of their profession. Graduating new engineers are told, "The ring itself symbolizes the pride we have in our profession while, at the same time, reminds us of our humility." The humility is cemented into the memories of those engineers by the fact that the rings were originally crafted from the iron of the bridge that collapsed.4

3. A decade ago, I was working on the management practices at one of the world's largest copper mines, operating more than two miles up, and at the end of one day, a colleague of mine arrived back from the smelter in a terrible mood. A young man he had met and formed a small friendship with had died during the day when a huge oven belched a cloud of toxic gas while he was walking across the top of it. I asked my colleague many questions about the accident, and here is what we pieced together. This had happened before. I don't remember the numbers, but let us say there had been three deaths over the previous four or five years. The conditions in which the belching occurred were understood by the engineers but could not be predicted or stopped in any way that the engineers could figure out. The engineers involved were skillful, well-educated, and dedicated. All of the deaths recorded under these circumstances were of young workers. I suggested to my colleague that he discuss with the responsible engineers and managers the advisability of a new work practice to the effect that young workers would not go onto the top of this oven without being accompanied by an older worker. In the discussion, some older workers acknowledged that they sometimes had a weird sense about when not to be on top of the oven, a sense that they obeyed, although they did not even know how to describe it. The new work practice was instituted immediately and without further discussion.

Using only these few examples as a point of departure, what can we begin to say about wisdom? Here are some of the elements that I think are essential:

1. When we enter into a conversation about wisdom and wise action, one of our central concerns is to intervene in some set of current behaviors, to bring about possible futures that will not otherwise happen, and to lead people away from other futures that would be better avoided. I am grateful to James Gosling (Sun Microsystems, inventor of Java) for introducing me to the use of the word goofy for pointing to situations in which sincere, otherwise intelligent people behave in ways that are wildly inconsistent with their ambitions, declarations, and/or capabilities. A whole lot of behavior in organizations, including much of what we call bureaucratic behavior, is goofy.
2. Wisdom is born in a concern for action to take care of things that matter to people, and it is fundamentally connected to human bodies and language. Wisdom is something that we ascribe after some actions are taken in response to some set of circumstances

that we find in our world. The actions can be of word or deed, but they are not purely cognitive actions.

3. Some change, or learning, or new adaptation is possible in the moment of such actions. Wise people have their attention on different things than those who are primarily absorbed in everyday activities. Before the actions, there was a continuity of circumstances, but in the moment of action, the whole world changes. Deep caring and solidarity is evidenced in the way that the wise party acts to take care of things that matter to the futures of the other party.
4. Wisdom happens in the right kinds of conversations and practices and in the right kinds of communities. It is not a solitary occupation. Buddhist monks who spend years or even decades apparently alone and silent are participating in conversations that have been going on for generations.
5. The wise party in an event of wisdom is using the moment of change to illuminate, emphasize, and expand some human ethical values. Wisdom is about getting the best out of individuals and communities of people and inventing futures and relationships from a new expanded point of departure. To be wise is to be able to observe deep and abiding stabilities and regularities in the world. We are each born unable to care for ourselves; the sun comes up every morning and goes down every night; each of us will die, and we do not know or control the moment of our death. At the same time, to be wise in action is more about changes than it is about these regularities that are the foundations of wisdom.
6. At the moment of the intervention (about which we will subsequently say, "That was wise"), it is not clear that the intended beneficiary of the wisdom actually has the qualities, virtues, or skills that are called forth by the wise action. The wise speaker or actor is, in effect, making a bet that the other parties have those qualities, virtues, or skills as possibilities, is inviting those parties to commit themselves to learn and grow, and is inventing a future out of that invention and invitation.

Now, for a moment, before we go on in our exploration of wisdom and wisdom in organizations, let us consider the alternative. Not all opportunities for wise action produce reinvented relationships, transformed professions, or lives saved. We have all spent countless hours observing and participating in conversations in which people were communicating with each other, but the actions that bring the moment of wise action were missing:

- Someone declares responsibility for a matter of concern.
- Someone proposes, offers, or requests new actions.
- Someone criticizes the results of our historic actions as being below what we are capable of.

What do we observe instead of wisdom? People immobilized in the moment of possible action; people repeating standard actions from the past; people in private conversations of intentions, but not in action.

The moment of a possibility of wisdom is a moment in which people are called to respond to some situation with integrity and authenticity, stepping outside of traditional ways of observing the situation, entering a domain in which they put themselves at risk of being ridiculed or assessed negatively by the community of their peers. In this regard, my colleague Guillermo Wechsler reminds me that this conversation about wisdom is also a conversation about a human tragedy—about the enormous numbers of intelligent caring people who are coupled together in the wrong ways—having organized themselves to continue their lives along paths of behavior that are recurrently unproductive, self-defeating, or, worse, that literally produce damage to the lives involved.

Finally along these lines, a deep look into the question of wisdom will also show us that sometimes it is better to be silent. Sometimes we call someone wise after we see that they have "smelled" a tragedy coming, and then let it happen, thereby bringing hidden emotions to the fore, unfreezing the situation, accepting the consequences, and building out of that with relentless intention. Sometimes it is wiser to be patient and wait, let things happen, and deal with the ensuing mess.

Then we need to conclude that wisdom is paradoxical, contradictory, controversial, and sometimes vexing. It does not follow the kinds of rules under which we build stable recurrent practices or systems. Think about how we understand the roles of managers and leaders in enterprises today. Professor John Kotter5 (1990), Harvard Business School Professor and expert on leadership, tells us that:

"... the pioneers who invented modern management… were trying to produce consistent results on key dimensions expected by customers, stockholders, employees, and other organizational constituencies, despite the complexity caused by large size, modern technologies, and geographic dispersion.… Leadership is very different. It does not produce consistency and order, as the word itself implies. It produces movement. Throughout the ages, individuals who have been seen as leaders have created change, sometimes for the better, and sometimes not." (p. 4)

Building on top of the claim that we should understand wisdom as associated with actions responding to circumstances we encounter, we can add one more distinction at the beginning of this exploration. I propose we distinguish three levels or orders of wisdom to observe from:

1. Level One Wisdom has to do with learning from mistakes, finding ways to eliminate waste, inventing shortcuts, the like. Continuous improvement programs set up the conditions for this level. Finding ways of doing more with less is an example of the kind of result of this level of wisdom.
2. Level Two Wisdom is what is needed for producing discontinuous changes. Instead of learning from your mistakes or eliminating waste, you invent circumstances in which particular mistakes or wastes cannot happen. Poka-yoke is a Japanese expression that originated in the Toyota Production System that means a way of eliminating mistakes by design. Simple mechanical examples are the throttles on railway trains that stop the train if continuous pressure is not placed on them or switches for dangerous equipment that stop the equipment if the operator's hand leaves the switch before a hand can come into contact with the equipment.
3. Level Three Wisdom is where I will speak about philosophical breakthroughs and reinvention of social realities. Such wisdom creates alternative interpretations of what is possible and builds new discourses in which to observe changes. The Toyota Production System, an example, creates a kind of mass production in which each car is customizable as it moves down the production line. It is less expensive to put quality into a production line than it is to leave it out, the absence of inventories helps, rather than hindering the process of producing, and in which the place to put the final authority for determining when the production line needs to stop for process repairs is in the hands of the lowest employees on the totem pole.

Wisdom is not something that lands on the planet automatically like moonlight; it belongs to the world of intentional human action, not to accident, and it has been the subject of intense attention for millennia.6 To call someone or something wise is to make an historical assessment 7 that we ascribe to particular behaviors within specific traditions and structures at particular moments of time. We cultivate the capacity to make that assessment within the communities that ascribe wisdom to particular behaviors. Human beings live uncertain existences. We live with historical possibilities, facts, courage, and to navigate in our worlds we make judgments and interpretations to underpin our actions. As we invent meaning and actions for ourselves, we invent assessments like wise (and standards for judging what we mean by them) when we need them for preparing a space of action. Whom shall we turn to in the moment of a particular difficulty? Why, someone wise in the matters at hand, of course!

What About Wisdom in an Organization?

Now let us turn our attention to wisdom in organizations, per se. The first thing that we will do is to introduce several questions and foundations that we will employ for thinking with you about wisdom, mostly without resolving them.

Do you admire the way that the bank handles your questions, the supermarket manages your experience, the dealer handles the maintenance of your car, or manufacturers of things you buy handle your questions and suggestions? We may admire the wisdom of someone in dealing with his children, spouse, or even colleagues or employees in his company, but a wise organization? Can you remember a real sustained experience with an organization that learns from its mistakes, as Churchman dreamed?

Even those small community and fraternal organizations over which we might think we have the greatest control are often sources of epic frustration. I listen to my neighbor: "You will not believe what just happened at the neighborhood association meeting." (Yes, I will.) Does anyone admire the way our governments interact with us? Take a deep breath and prepare yourself to stand patiently in line and wait. When, as does occasionally happen, we have the experience of someone in an organization listening carefully and acting with alacrity in response to our request, this is an occasion for a celebration. "A miracle happened!" My wife will begin a report of that rare event: an organization acting wisely.

Some institutions produce disproportionately large numbers of people adjudged wise in their communities. Consider, for example, the histories of the great religious institutions of the East and West, the institution of science itself, and the institution of medicine down through the ages. These are not the only examples by any means. Can you think of other examples of your own? Why does this happen? And why are these histories so uneven? Why great wisdom at some moments and behaviors that we would call stupid, self-serving, or even criminal at others?

Churchman (1968) speaks particularly of his admiration for the institution of science and points directly at the revolutionary nature of the life of that institution:

"The inspiration of Singer's story was his account of the history of science, one episode after another in which complacency was shattered, by Copernicus, by Newton, by Einstein, by Heisenberg. One 'ideal' of progress is to create the 'optimal' shatterer of old tablets, a shatterer that does not simultaneously shatter all chance of further progress in the cooperative ideals. Mood plays its part in all this process: The mood of the cooperative ideals is sanguine, phlegmatic, comic; the mood of the shattering ideal is filled with despair and joy, is tragic." (p. 215)

Sometimes organizations exhibit behaviors we call wise, and sometimes they do that over long periods of time. We can find examples of moments in which leaders set organizations on paths that produced luminous results for the people in and served by those organizations. Consider, for a big example, the founding of the United States of America. This country also provides ample examples of goofy behaviors, for example, in a long history of supporting oppressive dictatorships around the world while we have simultaneously kept our borders open to new citizens and espoused freedom, equal opportunity, and governance under the rule of law.

The point of organizations has to do with what we can do together that we cannot do alone. Working in organizations, people can do things the scope and scale of which is not possible for individual people or even for people gathered together in other assembly. It is in what we call organizations that we human beings constitute the capacity to deliver products and services of an extraordinary variety on local and global scales. Effective organizations create value for their clients and customers, focus on expanding possibilities for them, and demonstrate commitments to cultivating authentic styles. When those characteristics appear together, we create space for people to be wise in that culture.

Here is one source of confusion in the matter. Organizations are not human unities; they are unities constituted of and by human beings. Frequently, we describe the behavior of organizations with analogies, metaphors, and assessments that are more properly applied to human beings. I will do that in this chapter. For example, we can, with validity and to good effect, characterize organizations as existing in or having emotional states or moods.

Nevertheless, I insist that humans and organizations are different kinds of beings. The temptation to anthropomorphize organizations—to speak of them as collective human beings—is not valid and will mislead us in this conversation. Organizations, per se, are not capable of being wise. We need to look to human beings, not the organizations in which they work, for wisdom. The central reason for this is that wisdom comes from a capacity made up of other capacities that are dependent on the existence of human will and intellect, the emotions, and other structures, all of which require the presence of a human body.8 People sometimes are wise; organizations are not.

Churchman pursued the question of how an organization could learn from its experience. What does this mean? I propose that it means, for a start, that people in such an organization would continuously adjust the organization to the concerns of client/constituents and to changes in the world. The organization will be continuously reinvented in ways that encourage people to listen to each other, bring people together to be responsible for things that matter in the world, and so forth.

If we look closely at any moment of organizational reinvention, we will see that one or more people are speaking, guiding the institution into a new future. We may call these phenomena one of the attributes of wisdom in organizations. When this happens repeatedly over time, if we look closely, we will see that the institution has organized itself around a set of rules and practices (sometimes set out explicitly in documents of its governance and more often embodied in a common sense shared by those responsible for the organization) that govern its operation by (1) specifying who will occupy certain roles of responsibility in which they promise to take care of the future of the organization and (2) specifying who will declare those roles obsolete over time and see that they are changed. I think that families often are more reliable than traditional business organizations for taking care of these particularly important roles over long periods.

We speak about wisdom in many contexts, especially in ethical and spiritual domains, in spiritual, religious, and community leaders, in the arts and the helping professions, in commerce, and even in politics. We also find people speaking of wise executives, salespeople, or even sometimes criminals —people in roles in which the purpose of their actions is the economic, political, or social benefit they derive from their actions.

When we ascribe wise behavior to those in such instrumental roles, we have crossed a line. We can ascribe wisdom to players in instrumental roles, but we should be careful when we do so. Is the experienced salesman wise in recommending to us options on a vehicle when he will sell it to us and then take a profit from the sale? Remember that the slang name for members of certain criminal gangs is wise guys. Wisdom is deeply connected to ethics; we will explore this more carefully later in the chapter.

I will not deal with the kind of wisdom that is merely synonymous with smart or intelligent. Significantly, organizations that are structured or managed in ways that do not encourage (or permit) relationships among its people that are more than exclusively instrumental (e.g., relationships that are not connected to the purposes of the business) will be unable to produce any but the shallowest kinds of wisdom, or being wise in such organizations will simply not be relevant.

Inevitable Goofiness

Over time, all organizations become rigid, fall out of touch with the worlds they were constituted to serve, and behave in goofy or sometimes even criminal fashions. As time passes, every organization accumulates rigidities and practices that lead, inexorably, to these kinds of behaviors. How does this happen? (If we look closely, we will see that organizations that are successful over long periods are periodically reconstructed, sometimes violently, sometimes quietly.)

One of the central mechanisms for accumulating rigidity has this remarkably simple and apparently benign structure of action:

1. Something goes wrong.
2. Those responsible act to repair the situation.
3. At the same time, those responsible put in place mechanisms to prevent the same error from happening again.
4. They do this with rules, new procedures, changes in roles, and so forth.

Ronald Heifetz (1996) points well to the heart of the matter in Leadership Without Easy Answers:

“Living systems seek equilibrium. They respond to stress by working to regain balance. If the human body becomes infected by bacteria, the system responds to fight off the infection and restore health…These responses to disequilibrium are the product of evolutionary adaptations that transformed into routine problems what were once nearly overwhelming threats. Looking backward in time, we marvel at the abundant success of these adaptations and the breadth of exploited opportunities. Yet we tend to notice the successes and innovations more than the failures. By definition, the successes survive while the failures disappear. The roads of evolution are strewn with the bones of creatures that could not thrive in the next environment.” (p. 28)

We are saying that organizations accumulate rigidities as a consequence of the same thing that underlies their faculty as a place for generating wise behavior—they are made up of human beings. What happens in an organization is a lot like what happens when a patient of modern Western medicine has a bunch of prescriptions: the remedies begin to interact badly with each other and produce second and third-order side effects. In organizational life, if we look carefully over time, we will see that as time passes the majority of our prescriptions are dealing with the unintentional side effects of other previously applied prescriptions.

The general situation in human organizations is the same as the case of medicine. The behaviors of the people in the organization are habitual. When we install repairs and modifications to avert future occurrences of an error, if we look carefully, we will see that the conditions that led to the error are often preserved so that the difficulty will arise again but next time in new clothing so that we will not recognize it. Over time, the accumulation of a propensity to goofiness in organizations is inevitable, and periodic reconstruction is required.

ORGANIZATIONS AND AUTHENTIC WAYS OF BEING

One of Churchman's central questions, repeated often in his work, concerned the interplay of the parts of a system and the whole system, understood as a unity. Let me start a new approach to this question. In this chapter, we will come back to this question repeatedly, asking first the question, "who is observing the unity, and on what basis does a person interpret that as a unity?" At this moment, I want to start this process by introducing the notion of authenticity, which I take principally from the philosopher Martin Heidegger.9 Heidegger was convinced that it is impossible for human beings to make good sense of our lives except in the context of a process of continuous reinterpretation of our entire situatedness in the worlds in which we dwell. I think this is more than analogy to the question that Churchman posed; it is a foundational distinction. The question, as I said a moment ago, is this: who is observing the unity? Those who are considering a system and its relationship to ourselves, our work, and our worlds—that is, ourselves—cannot make sense of who we are as observers and speakers unless we have a very specific kind of understanding ourselves. In the process of constructing that understanding, we must have avoided exactly the same trap that Churchman fears—the decontextualization of ourselves—not at the level of the system but at the level of the individual human beings who are conceiving the system and of the individual human beings who will be the beneficiaries of the system.

We understand ourselves well, Heidegger tells us, only in the midst of our worlds, and not abstractly (Dreyfus, 1991, p. 10ff). As we conduct ourselves in our worlds, we are thrown (taken, or swept away, by our normal ways of being) to inauthentic ways of being. Ironically, those inauthentic ways of being provide us with signals inviting us to construct ourselves authentically.

There are two principal inauthentic ways of being. The first is falling into normal everyday busyness—coping with our anxieties and problems by throwing ourselves into activities that are familiar to us from our histories and experience, activities that we hope will suppress or tranquilize our anxieties because we remember that they have worked for us in the past. The second is becoming frozen in fearful patterns of conforming to accepted everyday behavioral norms. Can you see that organizations—with all of the kinds of pressures that we tend to find there to follow rules, not rock boats, not offend people, and so forth, are very often effective places for producing inauthentic ways of being? In contrast, authentic being confronts, in a public way, its anxieties and concerns, and invents new ways of being and acting in the midst of the messes of everyday life. You can see examples of this characteristic in each of the wisdom examples I gave at the beginning of this chapter. Can you think of examples from your own life?

Heidegger (1962) characterized humans as having a way of being the central focus of which is the issue of being:

"... to work out the question of Being adequately, we must make an entity — the inquirer (sic) —transparent in his own being. The very asking of this question is an entity's mode of Being; and as such it gets its essential character from what is inquired about—namely, Being. This entity which each of us is himself and which includes inquiring as one of the possibilities of being, we shall denote by the term 'Dasein.'" (p. 27)

Working in modern organizations may not be a healthy practice for building the kind of observer who can help Churchman with his inquiry. Most of us cannot avoid working in organizations of some size; none of us can avoid interacting with organizations. John Kotter (1990) concludes that training as a manager or executive in a (Western) corporation is not good for building wisdom. (He speaks of leadership, but if you listen carefully, you will see that what he calls leadership is a kind of wisdom-on-the-hoof.)

"For the vast majority of people today, including most of those with leadership potential, on-the-job experiences actually seem to undermine the development of attributes needed for leadership.… managerial careers in many corporations produce individuals who are remarkably narrow in focus and understanding, moderately risk averse, weak in communications skills, and relatively blind to the values of others. They produce people who know little about competitive business strategies, who have limited credibility, and who know more about how to play games with a budget than how to celebrate the real achievements of their people. Four characteristics of managerial careers seem to be particularly important in producing these [negative] results. First, these careers usually begin in centralized and specialized hierarchies and, as such, in jobs that are narrow in scope and tactical in focus.…[Second,] promotions in many firms are almost entirely up a narrow, vertical hierarchy.… [T]he knowledge and relationship base of successful people is often extremely narrow; they understand only one aspect of the business and only one group of people in their corporation.…[Third,] moving through jobs every twelve to eighteen months, these people rarely have an opportunity to learn anything in depth, and never see the longer-term consequences of their actions.… [Fourth, and] perhaps most damaging of all… all too often, people are rewarded almost exclusively for short-term results. As a result, most individuals focus on the process that produces those results-- management. This is especially true for ambitious young people. Because of this, they learn little about leadership. Since developing the leadership potential of others is also not a short-term activity, senior executives are strongly encouraged by such reward systems not to invest time in such an activity. The overall result can be devastating." (p. 119ff)

The question and reflection that I would like to bring to the reader at this moment in the conversation is this. While on the one hand there are obvious reasons that someone could be interested in knowledge or the cultivation of wisdom as Churchman was, on the other hand, the cultivation of wisdom and knowledge is not a mainstream concern in organizational life today. What was it about Churchman's interests that took him in this direction?

CHURCHMAN'S GATHERING OF PHILOSOPHERS

Churchman gathered five philosophers to help him in his work. What was he doing when he did that? What can an exploration of those traditions tell us about what could be important from the work of philosophers for the job of IT designers? Many computer scientists and IT professionals read at least some philosophy; few study it broadly, and few write about it. Churchman put five philosophers into a thought exercise, in which he asked and answered questions—inquired— about how systems might participate in the creation of knowledge.10

Here is my next question: What was Churchman doing with his five philosophers? Why did he bring them to the conversation? Why these five—Gottfried Wilhelm von Leibniz, John Locke, Immanuel Kant, Georg Wilhelm Friedrich Hegel, and Edgar A. Singer, Jr.—and not others? What did he intend we understand in the conversation? How did he intend to alter us, his readers, and students with this thought experiment of his?

There are various ways that we can interpret what he was doing with his five philosophers. I propose the following interpretations for the reader's consideration. I warn in advance that I am not going to claim that any one is right. The point here is to go beyond the standard conversation about using each as emblematic of a member of taxonomy of organizational types. I invite an exploration in which readers get their own answers.

1. Perhaps each philosopher is symbolic of a particular style of inquiry that we can see was important in that philosopher's work and life. Churchman, the argument goes, saw certain virtues and vices of each of the styles he characterized with the help of the philosophers, and he uses their names to compare and contrast these styles. In this sense, the name of each is iconic, representing that style. Leibniz stands for analytic deduction, Locke for consensual induction, and so forth.
2. Perhaps the first four are foils for Singer, Churchman's teacher, whose answers Churchman may have preferred for the questions of how to productively inquire. The role of each of the first four, in this sense, is to help Churchman show dimensions of Singer's propositions that would otherwise be cumbersome to show. In this sense, the name of each of the four stands for an era of incomplete thinking about how to constitute human enterprise, and Singer, though no wiser necessarily than the others, stands on their shoulders, just as Churchman stands on Singers'.
3. Perhaps, as a trained philosopher himself, Churchman gathered around him a gaggle of philosophers to provide a space of conversation through the implicit dialogue, in which certain deep questions could be revealed more richly than they might have been in a straight textual description. In this sense, the entire sensibility of the work of each philosopher is important, and their names point us to the concerns of each in the times in which they worked on those concerns.
4. Perhaps Churchman used the device of introducing an argument among the five philosophers as a way of inviting his students into a richer investigation of the philosophical literature as a foundation for thinking about the design of systems.
5. Finally, perhaps Churchman—not fully resolved himself about the place of inquiry in the operation of organizations—was using the five philosophers' work to inquire into the nature of inquiry in purposeful social interchange.

Churchman chose five philosophers to bring to the party, introduced them and certain aspects of their work to us, and then, through his writings, invited us to go on in conversation with him and with them for as long as the questions he was asking yielded fruit. He did not invite other philosophers whose work we can guess he knew. Why did he do these things? I propose that insufficient attention has been given to this question and invite conversation about it. I do not find in the literature much in the way of additional exploration along the lines that Churchman was exploring.

Let us ask now about a series of themes we can discern in the work of those philosophers Churchman gathered around him. I think that these same themes appear in his questions about knowledge and systems. In the following, I invite you to explore with me three concerns that all six philosophers (I include Churchman himself) grappled with. I will call these concerns (1) the ambitions of philosophy; (2) the problem of what a thing is, objectivity, and the problem of the observer; and (3) the problems of ethics, morality, and value. Obviously, in the limits of this chapter, I will only touch on these questions, but I do so in the spirit of offering a provocation—an invitation to the reader to consider more deeply what Churchman may have intended with his gathering of philosophers. The reader will notice that in order to do this, I have assembled my own group of philosophers with the help of Anthony Kenny,11 and that my group includes some new faces.

The Ambitions of Philosophy

Churchman, a trained philosopher, did not attempt to avoid standing in the middle of traditional philosophical ambitions as he worked in his adopted country—the field of computer systems. My impression is that we can appreciate some of Churchman's thinking by looking at the ambitions of the field of philosophy as a whole. Werner Ulrich, a student of Churchman who is now a professor in his own right, quotes his teacher in "An Appreciation of C. West Churchman," talking about Churchman's (1968) concern with the ignorance of the investigator in critical matters, and the centrality of the unity of the system as a whole: "How can we design improvement in large systems without understanding the whole system, and if the answer is that we cannot, how is it possible to understand the whole system?" (p. 3).

Ulrich (1999) explores Churchman's conviction:

"The systems idea, provided we take it seriously, urges us to recognize our constant failure to think and act rationally in a comprehensive sense. Mainstream systems literature somehow always manages to have us forget the fact that a lack of comprehensive rationality is inevitably part of the conditio humana. Most authors seek to demonstrate how and why their systems approaches extend the bounds of rational explanation or design accepted in their fields. West Churchman never does. To him, the systems idea poses a challenge to critical self-reflection. It compels him to raise fundamental epistemological and ethical issues concerning the systems planner's claim to rationality. He never pretends to have the answers; instead, he asks himself and his readers a lot of thoroughly puzzling questions."

Now we turn to Anthony Kenny (1997), who tells us that this struggle of Churchman's implicitly belongs to philosophy:

"The ambition of philosophy is to achieve truth of a kind which transcends what is merely local and temporal; but not even the greatest of philosophers have come near to achieving that goal in any comprehensive manner. There is a constant temptation to minimize the difficulty of philosophy by redefining the subject in such a way that its goal seems more attainable …even the greatest philosophers of the past propounded doctrines which we can see—through hindsight of the other great philosophers who stand between them and ourselves—to be profoundly mistaken. This should be taken not as reflecting on the genius of our great predecessors, but as an indication of the extreme difficulty of the discipline…But we philosophers must resist [the] temptation [to understate the difficulty]; we should combine unashamed pride in the loftiness of our goal with undeluded modesty about the poverty of our achievement." (p. 368)

Thus, this central question of Churchman's and something important about the form in which he held the question, he shared, in important ways, with philosophy as a tradition. He knew it was a central question to be confronted by any who would dare to think how to think in the domain in which he had chosen to work, and he knew that it would not be easily answered.

What is a Thing, Objectivity, and the Observer

Churchman and his five philosophers were profoundly aware of the danger of assuming the validity of prevailing common senses about the nature of things, objectivity, and the role and capacity of any observer to observe objectively. Philosophers' concerns over these questions have never abated over the last two millennia. To speak in a way that transcends the local about the interplay of designers, organizations, and systems of things supporting people working in organizations, philosophy teaches us that we need to stand on good interpretations about what these things are—people, things, and gatherings of people. To address the question of how organizations might better learn from experience, Churchman was looking for answers to these questions.

Churchman gave center stage to something he called inquiring. What did he mean by this? Who inquires? About what? He was particularly interested in the how part of the question. I take it that he was not calling primarily for a process composed of questions and answers, nor for a narrow questioning style, but instead was looking for something broader—particularly, I suspect, inquiring as a style of openness to different interpretations about the world and the actions we are taking in it. And, he was surfacing the problem of the observer and objectivity. On the other hand, he was calling for the invention of processes, rather than questioning the nature and role of the human being in the center of the puzzle, as we saw Heidegger doing earlier in this chapter. My opinion is that the absence of this element in his questioning marks a serious weakness in his overall project of inquiry.

Churchman speaks of constructing effective powers of observation through the application of diversity: "To deal with such connectedness … Singerian organizations must deploy UST to go well beyond the bounds of the other four organizational styles, by bringing in multiple perspectives or worldviews, and employing a holistic systems approach in their thinking and decision-making processes" (Courtney, 2001, p. 20).

Courtney goes on to show elements of the richness of what Churchman had in mind—ethics, spirituality, and aesthetics—and to show Churchman's dissatisfaction with a strictly scientific orientation:

"The multiple perspectives approach does not end with the technical, organizational, and personal perspectives. It also explicitly brings ethics and aesthetics into play. Many factors in the Industrial Age, the machine metaphor, the desire for "objectivity" and "rigor" in academic work, modeling social science research on "hard science" approaches, and the study of "rational man" to the neglect of our "spiritual" being, have all led to the demise of ethics, morality and aesthetics in decision making today. As we move into the Information Age, or perhaps the Knowledge Age, we seem to be stuck with this legacy of neglecting the factors that make us human." (p. 29)

More than 200 years ago, Kant concluded that the nature of things is inescapably unknown to us: " 'If we take away the subject space and time disappear; these as phenomena cannot exist in themselves but only in us.' The nature of things in themselves is unknown to us" (Kenny, 1997, p. 171).

Arthur Schopenhauer, who followed Kant by a few decades, shifted the place of the observer in the conversation and put the observer under the microscope in a new way:

"The empirical world exists, for the subject, only as representation: 'every object, whatever its origin, is, as object, already conditioned by the subject, and thus is essentially only the subject's representation'... The search for the thing-in-itself behind the representation is futile, so long as we turn our thoughts towards the natural world. Every argument and every experience leads only to the same final point: the system of representations, standing like a veil between subject and thing-in-itself. No scientific investigation can penetrate the veil; and yet it is only a veil, Schopenhauer affirms, a tissue of illusions which we can, if we choose, penetrate by another means."

We are not merely the knowing subject, but that we ourselves are also among those entities we require to know, that we ourselves are the thing-in-itself. Consequently, a way from within stands open to us to that real inner nature of things to which we cannot penetrate from without. [Kenny's emphasis] (Kenny, 1997, p. 212)

At about the same time, others, including Hegel, were moving in the same direction, asking new questions about the observer and how to understand the observer in ways that allow us to responsibly make sense of what he observes.

Churchman, Courtney tells us, puts the Singerian inquirer at a level of extreme abstraction, "above teleological, a grand teleology with an ethical base" (Courtney, 2001, p. 28). We need to give full credit to Churchman for his ambition and the validity of the concerns he brings us, but I am not happy with Churchman's thinking in this regard. Perhaps from his commitment that the observer needs to be looking at systems as a whole, he does something that I regard as a serious mistake and attempts to raise the observer to a lofty position of omniscience. He does not confront the real difficulty at the center of this dilemma.

Singer's better known contemporary Martin Heidegger made important contributions to this discussion that do not appear in Churchman's thought experiment. Following the tradition from Kant, Heidegger distinguished between persons and things and then distinguished further between the ways of being that things are for people when those things are held conceptually and when they are held practically in action. He distinguished between the way of being of things when they are ready-to-hand—having a way of being that is experienced in the middle of their use (as in hammering a nail)—and when they are present-at-hand—experienced as conceptual or abstract objects as when knowledge is contained in a database [my emphasis]. I think this is important when we are considering how to think in regards to building systems.

In Churchman's conversation with his five philosophers, I have the impression that he never escapes the grip of pre-Heideggerian Western analytic philosophy and, under the influence of Singer, moves to ever-more abstract ways of interpreting knowledge, leaving the role of the observer largely unresolved. His worthy ambitions demand more.

The Problem of Ethics, Morality, and Values

Churchman exhorts his readers to put the concerns of ethics, morality, and values in the front rank of their attention, at least alongside rational logic. Courtney (2001) sums up Churchman's understanding of the interplay of knowledge, acting, learning, and moral and ethical values as: "Thus, one might say that knowledge involves the ability to act intelligently and to learn. Wisdom guides knowledgeable actions on the basis of moral and ethical values" (p. 23).

It should be clear from the first and second sections of this chapter that I agree fully with Churchman that the exercise of wisdom and learning are ethical occupations and that architects and designers should put these questions in the center of their concerns. I'll say more about this in the next section of the chapter.

As a provocation, however, I would say that I understand the way that these matters interrelate with each other in a radically different way than does Churchman. Here is how I will put my version of the proposition that Courtney articulates for Churchman just above: People ascribe wisdom and knowledge to actions enacted from embodied structures of ethical behaviors, and learning ensues from repetition of the action together with reflection on those actions and the consequences of the actions.

I will spell out why I say this in the next section of the chapter.

PREPARING THE WAY FOR WISDOM IN ORGANIZATIONS

In this section, I will offer a set of six tiny essays that invite reflection about the construction of the conditions and situations in which wisdom can be cultivated and exercised in organizational settings. The essays are:

- Taking Language and Listening Seriously
- Language-Action and the Constitution of Organizations
- Preparing for Ethical Action
- Learning and Competence
- "Inventing" Waste
- Pain-Free Wisdom?

Taking Language and Listening Seriously

Language, including the misconceptions and confusion that abide in it, underlies everything we understand and know and all our actions. We encounter and invent ourselves in language. What we find desirable and fearsome, our ambitions, doubts, and resignations, the identities in which we make sense of ourselves, those we live and work with, and our worlds, all these live in language. Our problems with things, observers, and ethics all arrive escorted by and clothed in language, and we encounter them only in their clothing, as Schopenhauer pointed out. Heidegger called language "the house of being."

The warp and woof of the tapestry of organizations and the threads that reveal the patterns of that tapestry belong to language. Cars, to take an example, move down assembly lines in the wake of a network of conversations in which an extraordinarily complex set of conversations has set every part of the stage of action, and they move because people are making commitments, to shape, build, sell, and buy. Long before any parts move, design engineers speak instructions telling all concerned how the actors, instruments, and parts will come together into a set of unities that will make sense to all concerned. In operation, production managers lay plans, workers come to work as asked, suppliers deliver materials as promised, and salesmen make offers and customers accept those offers.

All the joys and all the miseries, all the services and all the destruction and waste laid by people working together in organizations begins and is shaped in language. Ethics and values are created, understood or not, passed on, and acted on in language. We speak to each other, and we listen. And, we underestimate, continuously and vastly, the role that language plays in our affairs.

The serious student of wisdom and organizations, I suggest, must put language in the center of his inquiry.

Listening, I propose, is the first prerequisite of wisdom. By the word listening, I point to the biolinguistic process through which we attune ourselves to situations, the concerns of others, our own concerns, and prepare ourselves for action. I distinguish listening from hearing. I use the latter word to point to the mechanics of receiving and decoding disturbances in airwaves, signs, and signals in our worlds—receiving data—what most people refer to as listening. The two are related, but the deaf who were not born deaf listen, just as the blind who were not born blind see. What I call to our attention with the term listening is exemplified by what happens to us when we read poetry or attend a great performance and are touched by it. We are altered by the experience of listening. Listening is partially an automatic process that is out of our control, going on continuously in life, while we are awake and asleep, and the process of listening can be affected, as when "we take a walk" "to collect ourselves" before undertaking a difficult conversation to be responsible for the emotional state in which we will be listening to our conversant. Listening happens all the time and not just when we are listening to spoken language. Here is a partial list of situations in which we can observe listening happening:

- Language spoken and written in our native tongues;
- Distinctions in other languages ranging, for example, from moods and music to finance and marketing;
- Gestures and silence, absorbed and interpreted; and
- Brands, icons, images, art, machinery, offices, and other features of our worlds.

To encounter wisdom in a fresh way, that can give grounding for the work of people preparing tools for working in organizations, we need first to prepare ourselves to get closer to language—to observe some things that happen as we speak and listen to each other.

Listen carefully to the following pair of passages by Gemma Corradi Fiumara (1990) in her book The Other Side of Language, in which she wrestles with the poverty of listening in our time. Neither she, nor Martin Heidegger, whom she quotes, is easy to read. You may have to read each short passage a few times to catch the heart of what she is saying.

"One is often tempted to maintain that the 'richness' of our inner world possesses a guarantee of existence in itself, and that the 'problem' merely consists in knowing how to select the words which are best suited to expressing and representing it in a context of consensus. In this way, we may be tempted to believe that words are 'like a grasp that fastens upon the things already in being and held to be in being' (Heidegger, 1971, p. 68)—a grasp which seizes and compresses. In fact, however, the situation is far more complex, demanding and enigmatic than that. The organization of our innerness seems to exist on condition that it is heard, brought out—in effect brought to be born. It is not just a matter of entities lying there waiting to be linguistically seized and organized in the most diversified expressions." (p. 148)

"To pay heed to what the words say is particularly difficult for us moderns, because we find it hard to detach ourselves from the 'at first' of what is common (e.g., from the common sense that strikes us immediately from what is said); and if we succeed for once (in detaching ourselves from the common sense), we relapse all too easily." (p. 130)

Language-Action and the Constitution of Organizations

For the vast majority of the moments of our lives, including in a great proportion of our sleeping hours, we are doing things in language with each other, and language is doing things to us. The opportunity of this topic is that language-action offers a radically improved path to knowing what we are doing as we are speaking. When we speak, we create new interpretations, moods, possibilities, and futures in the bodies and minds of those with whom we are speaking. Therefore, one of the distinctions that will be essential for us is language-action, observing language as communicative acts.

The English philosopher John L. Austin (1962) was the first to notice the existence of a class of verbs that he called performatives (p. 148)—verbs that, rather than describing actions, perform actions. When someone says "I promise to …," he is performing the action of promising, not reporting that he will, did, or might promise. It turns out that all human languages contain performatives. For the purpose of designing work in organizations, I distinguish six classes of performatives: declarations, offers, requests, promises, assessments, and assertions. The most important and interesting thing about these verbs is that, when we look carefully, we can see that it is with these acts that we human beings invent our futures. Very often we don't actually use the words; people make promises all the time without saying "I promise" and make requests even more often without saying "I request" (for example, "The soup needs salt" and "Don't you think that it is cold in here?"). The roles that the major classes of language-acts play in our invention of our futures?

- With declarations, we create new distinctions—identities, products, roles, services, companies, names, and so forth—with which to take care of our concerns.
- With offers, requests, and promises, we orchestrate new spaces in which we can take action, and we elicit mutual commitment and coordinated action.
- With assessments, we take stock of our world, evaluate our progress, assure that we are prepared for action, and navigate in our projects and worlds.
- With assertions, we build confidence in our judgments and consistent reliable coordination.

Each language action has standard elements which, when recognized, can help guide designers in their specification of systems: speakers, listeners, conditions of satisfaction, time of speaking, time of expected response, time of committed action, and so forth. The implications of Austin's discovery are vast and substantially unrecognized.12 For example, ask the question, "What makes something be an organization?" Within every culture there are a variety of standard modes of business operation that can be observed (sales activities, billing, and so forth) but underneath all of the variety is a more fundamental core. Whether a business is as simple as an individual sitting on the ground with a pile of fruit for sale or it is a multinational conglomerate, and whether it produces tangible goods in factories, provides janitorial services, or operates entirely "on paper," as in many financial businesses,

"A business is created when a person or group of people declares that they will recurrently make certain classes of offers to some population of customers and that they will satisfy the conditions of those offers (deliver what they promised) in exchange for some offer the customer makes in return, or the fulfillment of some request they may make to the customer."

This definition shows several key aspects of how an enterprise is constructed.

- First, it says that the business is created by a declaration. In order to be in business, you have to declare to the appropriate people that you are entering a domain of potential business transactions.
- Second, it says that the business is constituted by classes of offers. If you are in the automobile business, you offer to provide automobiles. If you are in the doctor business, you offer to see and treat patients. A single business may have a variety of different classes of offers but without some public declaration of what they are, the business is not defined.
- Third, to be in business, you must be prepared to satisfy the conditions of the whole transaction: to make offers, recognize acceptance of those offers by customers, complete the conditions of the offers (by providing goods, services, etc.) and recognize that the customer declares the transaction completed to satisfaction.
- Finally and centrally, a business is distinguished from other kinds of enterprises (e.g., charities and governments) by the fact that there is an explicit offer in return from the customer (some form of payment, whether in money or other actions), which is linked to successful completion of the offer made by the business entity.

We can identify these common elements in every business activity we see around the world. Moreover, these structural features of a business belong to how human beings take care of things with each other. The deep structures that we are observing in this conversation have existed since people have been exchanging goods and services, and it is impossible to conceptualize businesses that do not have these underlying structures. In the simplest case, a single individual in verbal communication does them all with customers. In large organizations, each aspect is supported by organizational structures and business processes that have evolved in the ambition to make sure the conditions can be met regularly with a minimum of breakdowns.

Let us take "wise" as an example and look at what it is from the perspective of language-action. Wise, as I said earlier, is an assessment—a judgment or evaluation made by an observer with a particular background, experience, and concerns that shape that judgment. (Examples of assessments: I am late. The cat is sick. The car is behaving strangely. Your hair is getting long. The project is expensive. The new president is not doing well.) Assessments are never true or false; they are effective or not. Assessments help us make sense of our worlds, our place and progress in it, and, most important, they prepare us to take action in those worlds. Judgments about the state of affairs in my world or yours invite us to consider actions to take advantage of opportunities or avoid dangers.

To ascribe wisdom to someone or to some action is to make an evaluation, and that evaluation originally comes from the mouth (or fingers, gestures, silence, written words, etc.) of a particular individual.

Not only is wise an assessment, but it is difficult to be wise (perhaps impossible) without skill at distinguishing assessments from assertions—the class of language action that we call facts—and without the corollary capacity to test assessments by grounding them with facts. (Examples of assertions: The project is late; 60% of the project deliverables are still incomplete one month before its scheduled end.) We may make an assessment shared by many others, even in very large populations. However, even if a measured majority of the French people of France think that Americans have no judgment or taste, it is still an assessment and not a fact. People can ground their interpretations by citing facts that defend the judgment. The evaluation—an assessment—and the facts brought forth to ground it, which are assertions, are two different kinds of language actions, and they have different purposes.

Assertions—facts that can be observed by a universal witness—are true or false. However, the act of making an assertion—stating a fact—does not invite action, except when for the speaker or a listener, the fact elicits a judgment (assessment) of a shift in the expected future and sets up a condition inviting action. (Just look at those black clouds! Implied: The clouds are forbidding. It looks like rain is coming. Let's get under cover.)

Different observers have different assessments about the same phenomena; the source of the difference is that they do not have the same concerns. (One man's meat is another man's poison. A flat tire for a driver is business for a garage.)

Turning to the implications of language-action for the design of systems, Fernando Flores and Terry Winograd (1986) outline a three point theory of management and conversation in their book, Understanding Computers and Cognition, that shows well many of the features of how software designs could embody the insights we are exploring here:

1. Organizations exist as networks of directives and commissives.13 Directives include orders, requests, consultations, and offers; commissives include promises, acceptances, and rejections.
2. Breakdowns will inevitably occur, and the organization needs to be prepared. In coping with breakdowns, further networks of directives and commissives are generated.
3. People in an organization (including, but not limited to managers) issue utterances, by speaking or writing, to develop the conversations required in the organizational network. They participate in the creation and maintenance of a process of communication. At the core of this process is the performance of linguistic acts that bring forth different kinds of commitments. (p. 157)

Flores and Winograd (1986) further claim, and I am convinced that they are right, that the classical idea of decision making is not well supported phenomenologically, and we can usefully substitute a notion of "dealing with irresolution" and supporting people in coming to resolution (p. 144ff).

Preparing for Ethical Action

The concern for action is central to the question of wisdom. Even the extraordinarily rigorous contemplative activities frequently found in the practices of wisdom traditions, when carefully examined, will be found to have to do with getting prepared for taking action.

At the same time that wisdom has more to do with action and less to do with dry abstraction than many traditions would have us believe, as I said before, Churchman is right about the relationship of wisdom and ethics. Here is Heifetz (1996), again putting the case beautifully in the context of effective (i.e., wise) leaders:

Understandably, scholars who have studied "leadership" have tended to side with the value-free connotation of the term because it lends itself more easily to analytic reasoning and empirical examination. But this will not do for them any more than it will do for practitioners of leadership who intervene in organizations and communities everyday.

"We have to take sides. When we teach, write about, and model the exercise of leadership, we inevitably support or challenge people's conceptions of themselves, their roles, and most importantly their ideas about how social systems make progress on problems. Leadership is a normative concept because implicit in people's notions of leadership are images of a social contract. Imagine the differences in behavior when people operate with the idea that 'leadership means influencing the community to follow the leader's vision' versus "leadership means influencing the community to face its problems." (p. 14)

"If a leader personally wants to turn away from the difficulty of problems, and so do his constituents, does he exercise leadership by coming up with a fake remedy? … socially useful goals not only have to meet the needs of followers, they also should elevate followers to a higher moral level." (p. 21)

Similarly, in The Reflective Practitioner, Donald Schon (1983) reported that he found that the most effective professionals' skills are not built on rational structures learned in school but instead result from intuitions and improvisations built through a process of observing themselves in the midst of their practices.14

The reader may be tempted to discard aspects of this discussion as philosophizing or a matter of semantics. I urge you to be patient and follow the thread of this part of the inquiry. This is not a minor theoretical part of the conversation. Recent discoveries in neurophysiology show clearly that the traditional ways of understanding wisdom as a matter of distilling action from abstract conceptions is wrong.

The cognitive scientist Francisco Varela (1999), trained as a neurobiologist, gave a series of three short lectures in 1994 on conclusions about the construction of wisdom in human beings, which he bases on the intersection of recent developments in the science of mind and the teachings of Eastern wisdom traditions. The lectures have been published as a little jewel of a book entitled Ethical Know-How: Action, Wisdom, and Cognition. "As a first approximation," he says, "let me say that a wise (or virtuous) person is one who knows what is good and spontaneously does it" [Varela's emphasis] (p. 4). Quoting the philosopher Charles Taylor, Varela (1999) says:

"Ethics is closer to wisdom than to reason, closer to understanding what is good than to correctly adjudicating particular situations. … the focus [of the current examination of these questions]

has moved away from meta-ethical issues to a much sharper debate between those who demand a detached, critical morality based on prescriptive principles and those who pursue an active and engaged ethics based on a tradition that identifies the good." (p. 3)

Varela (1999) builds his arguments upon current scientific research regarding the functioning of the brain and the human nervous system. Here are three conclusions that bear on our concerns in this chapter:

1. Truly ethical behavior does not arise from mere habit or from obedience to patterns or rules. Truly expert people act from extended inclinations, not from precepts, and thus transcend the limitations inherent in a repertoire of purely habitual responses. This is why truly ethical behavior15 may sometimes seem unfathomable to the untrained eye, why it can be what is called in the Vajrayana tradition "crazy wisdom." (p. 31)
2. We acquire our ethical behavior in much the same way we acquire all other modes of behavior: they become transparent to us as we grow up in society. This is because learning is, as we know, circular: we learn what we are supposed to be in order to be accepted as learners. (p. 24)
3. Contrary to what seems to be the case from a cursory introspection, cognition does not flow seamlessly from one "state" to another, but rather consists in a punctuated succession of behavioral patterns that arise and subside in measurable time. This insight of recent neuroscience—and of cognitive science in general—is fundamental, for it relieves us from the tyranny of searching for a centralized homuncular quality to account for a cognitive agent's normal behavior. (p. 49)

In a passage that sounds as if Varela were right in the middle of the conversation we are having with Churchman and his five philosophers, Varela (1999) says:

"Were we to entertain the idea that there is no hard and fast distinction between science and philosophy, philosophers such as Descartes, Locke, Leibniz, Hume, Kant, and Husserl would take on a new significance: they could be seen as, among other things, proto-cognitive scientists." (p. 25)

In this background, I propose that in the pursuit of systems that support wise organizational action, architects and designers must take careful note of recent developments in some apparently distant parts of the field of cognitive sciences. Along the way, I propose that some treasured wisdoms of the IT and DSS field should be rethought, including for example, the notions that at the heart of the process is a mental model that decision processes begin with the recognition that problems exist and decisions need to be made.

Learning and Competence

When people set out to increase their competence in some domain, they begin by revealing themselves as having a certain level of competence and also incompetence. Our ability to learn depends first upon our acceptance of our incompetence in the domain in which we will learn. In all great wisdom traditions, there are famous stories about masters laughing at what they do not understand and are incompetent for doing (Dreyfus & Dreyfus, 2000, p. 16).

When we speak of a master, we refer to a person of historical excellence, set apart from peers by participation in the ongoing invention of a domain of practices. A master is not only able to act in that domain; a master can produce important innovations in the standard practices of the domain, revolutionizing the history of the domain. Richard Warren Sears of Sears Roebuck invented catalog sales. Sam Walton of Wal-Mart invented another kind of merchandising. Each changed the face of their industry.

Masters do not differ from the competent or virtuoso practitioners in some domain so much by the character of their performance, as by the concerns they bring to the practice. While a competent person attends to the business of the day and a virtuoso explores the limits of invention inside the domain, the master lives in a larger conversation about the meaning of the practice and its place in the larger culture. By focusing on anomalies (situations in which something appears not quite right or violates the expectations the master has built up from long experience), masters find ways to transform the practice of their skill to take on a different meaning in the culture. While a proficient person or even a virtuoso might pass over an anomaly as an exceptional circumstance, a master may become obsessed with an anomaly. Accidental discoveries, such as the discovery of penicillin or the vulcanization of rubber, offer vivid examples of this phenomenon.

"Inventing" Waste

Historic inventions are often built from historic difficulties, and they always involve the invention of new distinctions. At the end of the Second World War, the people of Japan were in terrible trouble, their morale, productive capacity, and international relations demolished. An engineer named Taiichi Ohno, in the enterprise today known as Toyota, began the task of building a new capacity for Japanese production on top of Henry Ford's designs with some important additions. Ford incorporated everything into one plant; Ohno designed for operation in a network. The operational heart of Ford's designs were the way the engineers designed the coordination of the work; Ohno's design was centered in processes that built the capacity of each person on the production floor to take responsibility for the quality and coordination of their work. His invention became the foundation of the quality movement that swept the world starting in the 1970s and 1980s.

To keep the workers thinking, Ohno invented a new collection of wastes for them to observe and eliminate. Waste, like wisdom, is an assessment, an interpretation. For example, inventories, he said, were waste, as was time that workers spent waiting—for parts, others to complete work, and so forth. By inventing these new interpretations, Ohno was able to trigger important revisions in the way the people of Toyota thought and acted. What we in the West now call just-in-time logistics and many other innovations of the last 30 years were born in these inventions.

The organizational wastes with which we have orchestrated our interpretations of work for the last 50 years—wasted movement, wasted time, wasted resources, and so forth—were invented in the traditions of the industrial revolution. I am convinced that they will not be the most important organizational wastes of the next 50 years. Here is my own list of what will be the five most important new waste generators:

1. Not Listening: Tolerating working together in conditions in which people cannot effectively listen to each other in the midst of mistrust, resignation, resentment, and simple incompetence.
2. Bureaucratic Styles: Interacting with each other as if people were machines doing tasks—sequences of movements and activities—in which our concerns, moods, and emotions show up at best only briefly before and after the work but not during it.
3. Worship of Information: Tolerating the illusion that the essential matters of work can be invented, managed, and sustained through the creation, storage, retrieval, display, and publication of information.
4. Suppressing Innovation: Tolerating ways of working in that which is different, unusual,

or new is feared, rejected, or avoided so that it becomes all but impossible to develop flexibility and evolve practices for dealing with a changing world.

5. Work as Toil: Tolerating the interpretation that work consists fundamentally of sequences of things to do. In this interpretation, most people appear to be victims trapped by their needs to make a living, prepare for retirement, support families, and so forth. We ignore, diminish, or distort the ways that most work can bring meaning to people's lives and take care of features of the world for which people care.

Pain-Free Wisdom?

Finally, the kind of wisdom that is involved in historic innovations and longstanding successful leadership of organizations and even that which is required for important reconstructions of organizations does not come from mechanical, procedural, or algorithmic structures. Recently, the Harvard Business Review published a letter that colleagues and I wrote to the editors about an article by Gary Hamel and Liisa Välikangas ("The Quest for Resilience," September 2003), in which we strongly criticized the authors' proposal of what we called "a utopian corporate capacity that adapts to strategic failure without the traumatic wake-up calls of lost market share, protracted earnings slumps, the need for wrenching turnarounds" (Bell et al., 2004). We said to the authors:

"A recipe for pain-free learning could work only if learning were solely about developing valuable new ideas."
"The strategically important innovations that give companies resilience do not come from experiments, less still from multiple bet-hedging experiments—and least of all from people whose careers are protected from the consequences of failed experiments. Instead senior managers need to develop the commitment to risking their careers to develop new ideas. The value of new ideas only becomes real in the midst of failed pilots, funding losses, and heartbreaking rejiggerings."
"Likewise, corporate resilience generally does not come from training senior managers to apply resources, like markets, to a hundred different well-hedged futures. Companies learn to spot difficulties early, invent opportunities in the midst of breakdowns, and fundamentally change how they interact with suppliers and customers by taking a single-minded stand on the core customer concerns they serve. Disconnection from these concerns occurs when managers begin to seek pain-free solutions—such as focusing on one well-understood set of products or segments. Resilience requires reigniting managers' passion and commitment to taking chances and working through them, not pain free experimentation." (Bell et al., 2004)

I agree with Churchman (1968) in his ambition to "create the 'optimal' shatterer of old tablets, a shatterer that does not simultaneously shatter all chance of further progress in the cooperative ideals." (p. 215)

WELL-TOOLED INVESTMENT MANAGEMENT PROCESS

The next several pages recount the process of designing, building, and deploying a software-supported system to help a large institution with the integration of its processes for strategic planning, capital expenditures, and a number of important functions adjacent to those. The reader will see many of the concerns and topics we have discussed in this chapter appearing in the way that the design was done. Here are some of those that I think most relevant and graspable from the written story of what we invented:

1. The example illustrates an important aspect of Churchman's concern with the unity of the system we are designing. The design does not merely integrate many functions, as some software brochure might tout; it would not be possible to do what it does as a function of integration. It is able to do what it does because the design invents a new unity—here called investment management— that did not exist in the language or explicit concerns of the people of the company before we went to work with them.
2. In the example, investment management conversations are managed as interactions among people, paying attention to the interpretations they are making with a system helping keep their attention there, and the articulation of what is handled in the system—the investments—is always held in that context.
3. The design assumes that the participants in the process are ethical actors and does not attempt to police their actions. On the other hand, the system makes their actions visible to other actors and prompts them to act in ways that are coherent with the promises for which they are responsible in the organization (for example, at a high level, for directing operations or for advising others as they direct operations). The system also records everyone's actions for auditors, regulators, and posterity, and it does all that in a way that encourages authentic action.
4. The interpretation of the enterprise that underlies the design of the application is that of a network of commitments, constructed in language-actions, and invented, articulated, and enacted by human beings speaking and listening to each other. All data in the system gets there in that way—by people speaking and listening—and to the extent that a new future is shaped in the process we designed, it is shaped by the human beings and not the data, formulae, and so forth.
5. The design of the system allows the human beings involved to improvise as they invent ways to define their futures under many different kinds of situations and to design structures of coordination that can be adapted to wildly different circumstances that may be encountered. One important effect is to make it possible for new things to emerge rather than only old ones.
6. The way that the system puts a spotlight on the behavior of each participant in the process has the effect of helping the people involved to see their own strengths and weaknesses and thereby encourages and supports learning.

The Situation

During the 1990s, one of my clients was a large and very successful electric utility company (primarily operating coal-fired power plants and a distribution network) that was attempting to shift itself from a style of management suitable to a regulated monopoly in a bounded geographical region to one suited to competition in an open market on a continental or, even eventually, global scale. In the course of several years of work together, we examined and rebuilt many of the company's pivotal processes and ways of working. One of the most important we called their Investment Management process.

Like any modern industrial firm, the company had standard ways of doing a whole variety of things to responsibly prepare to take care of the fact that the future coming to them was not exactly the same as the present, including:

1. Strategic planning,
2. Forecasting demand,
3. Proposing and approving capital budgets,
4. Managing the process of committing to capital expenditures,
5. Managing the actual flows of cash to make capital investments,

6. Managing the execution of capital projects,
7. Accounting for capital expenditures, and
8. Measuring overall returns on capital invested.

As is normally the case with most large firms, these eight processes were related to each other because they all involved money. Indicators of each appeared in the company's accounting system. Also as is normally the case, they had no standard practices for tracking particular investments, nor for measuring the return on any one particular investment, unless a special project was set up to do that. New capital investments once implemented and accepted went into the company's general asset accounts, and their returns were measured along with all other assets.

Anyone with experience in the workings of large enterprises has seen examples of similar collections of processes and can follow as I give a quick critique of them.

- They were slow, expensive, bureaucratic, and generated a lot of paper.
- Most importantly, the processes had the effect of diffusing responsibility, authority, and accountability for one of the most important aspects of the management of an organization's future.
- As a result, the management of the conversation about investing in the company's future moved into a set of essentially unmanageable, highly politicized, back-corridor conversations.
- When proposal packages moved through the organization with their signature lists on the cover, you would hear executives complain, "If all these other people are approving this, of course I am going to go along," "The approval happens in another conversation; this is irrelevant," "This is <so and so's> pet project, and if I don't approve this he'll go after my projects," and the like.
- The processes actually slowed down the speed at which the company's managers were able to think and design how the company moved into the future and pitted people against each other in political contests in the background.

Diagnosis and Design Criteria

In conversation with the company's executives, I characterized their processes as more or less consistent with the processes that I called allowance when dealing with my children. At my request, the children make up stories about what they will need money for in the future, we discuss the stories and arrive at a figure that fits our family finances, fits my wife's and my idea about how much money our children should have access to, and then announce a final number. After that, the children nag us each week for their allowance. We have general anecdotal conversations about what they spend their money on, and at the end of the year when we review the family finances, we discuss how much we spent on allowances.

The difference, as you might guess, was that the allowance process works relatively smoothly, and the collection of eight processes I mentioned above broke, or failed to deliver, the kinds of results that my client's company needed in an agonizingly large proportion of the most important cases. Those processes did not work:

- When the company needed to make a new investment in a hurry.
- When the making of an investment stretched over a long period of time.
- When an unconventional investment was being considered.
- When new ideas were being brought.

In short, they did not work in a lot of the most important investment opportunities.

To cite just one example, in the middle of a scheduled maintenance event, engineers would discover that a turbine blade costing a million dollars needed replacement. The standard processes would all be put aside, as over a period of a few hours a few executives would approve all parts of the purchase, and then people would "fill in the blanks" on the process forms after the fact. The consequence of not acting was far too great to allow action to be constrained by the bureaucratic processes.

In thinking carefully about the diagnosis we would make, I proposed and the client agreed that the support of the intelligence of the people in the company—i.e., wise action—was the critical matter, along with supporting discipline in conversation. We concluded with the client's team that an algorithmic approach (i.e., a fully defined procedure or protocol, possibly supported by mathematical modeling or artificial intelligence tools), which they had been attempting to do for some time, would actually make the situation worse, no matter how sophisticated an approach was taken. For an analogy to understand the claim, think about what is involved in managing the conversation between the pilot and the tower during takeoffs and landings at a major airport. This conversation cannot--nay, must not--be automated. On the other hand, the capacity to have that conversation can be supported with multiple redundant communications channels to mitigate against interruption with radar that allows both to have second opinions about what they observe with their own eyes (or what they cannot see) and other tools.

I proposed criteria for judging a new design:

1. The process should help them manage a unity called "managing our investment in the future of the company" rather than attempting to manage the components that had previously been considered unities.
2. The process should work across a wide spectrum of investment situations, as for example, spanning from an investment where a commitment had to be made in a hurry to investment conversations stretching over a period of years.
3. The process should be organized so that it reveals to managers and executives things going wrong within it as they occur.
4. The roles of participants in the process should be organized in ways that are consistent with the participants' roles in the organization as a whole. For example, senior strategic, operational, and financial managers should have control over the pacing of the process, and senior technical advisors should be able to force their assessments to be heard by all who should listen to them but should not control the pace of the process.
5. The process should automatically generate all the records that will be needed by regulators as a by-product of the participants' work and not require additional processes to complete.

We designed a new process to span all eight component processes, along with a tool implementing the process. The process defined who speaks at which points in the process, whose commitments move the process forward or slow it down, how records are kept, assures that what is happening in the process is transparently visible to all participants, and makes records of everything that happens in the process accessible to all participants. The process could be followed for an investment conversation that lasts only a few hours or for one that lasts years.

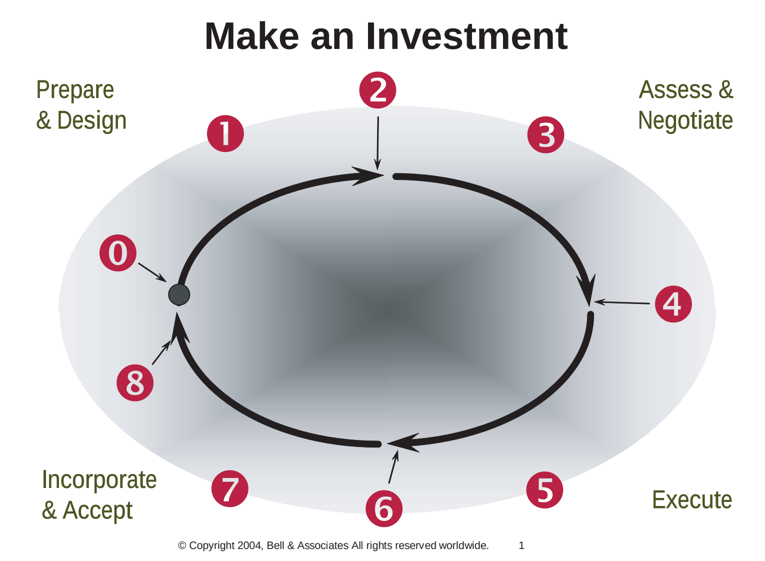
We prototyped and tested the process and tool in the utility company and then implemented it across the company. A year later, we repeated the whole process for the investment management processes of a six billion dollar multinational cement company.

The Design

The process and tool at the center of the design are remarkably simple but also subtle and not intuitive for most system designers. Key elements embodied in the final design are:

1. Participants in the process are assigned to roles during the first phase of the process. Three line roles are defined: Investor, Proposer (who must be a line operational manager), and Manager (the person who implements the investment). An unlimited number of staff roles are defined, covering whatever technical, financial, social, political, or other issues that may need to be topics of conversation for the investment to be properly vetted and designed.
2. The process as a whole is organized, conducted, and recorded as sets of conversations, each set covering a single investment. Each set begins when a potential investment, indicated by the assessment that something important is missing, broken, or in the way, is proposed by a proposer speaking to an investor. After the investor has agreed to make an investment, a manager (who may be the same person as the proposer), promises to implement the investment, does so, and then comes back to the investor to get the latter's declaration of satisfaction. After an investment has been implemented, additional conversations are initiated and managed covering the assessment of its contribution to the enterprise.
3. Every action (transaction) in the process and the system that supports it is structured as a performative. Line roles make requests, offers, promises, and declare investments complete and satisfactory. Staff roles make assessments and recommendations about the investments, including for example, the desirability of a particular investment, conditions for its successful execution, likely costs and returns on investment, assessments of progress, and of the value produced. In this way, each role is being asked to do what "they are paid to do"—line managers for

Figure 1. Make an investment



producing results and staff for providing counsel.

4. Each "investment conversation set" is invoked, conducted, and recorded through four phases of the process: preparation and design; assessment and negotiation; execution; and incorporation and assessment. This process is diagrammed in the figure below.16 The four arcs headed with arrows correspond to the four phases of the process, and the arrowheads correspond to the four critical language-actions that brace the action when an investment is successfully proposed, constructed, and implemented. In the figure, I have numbered the critical moments in each investment conversation. The table explains these moments.
5. Prospective and completed investments are organized into a hierarchy of portfolios matching the current organization chart, with each manager responsible for a portfolio corresponding to his or her role. The senior executives of the company define which investments will be located in each portfolio. Managers can review the progress and performance of all portfolios located below them in the hierarchy through online tools.
6. Schedule objectives are set out at the beginning of each investment process, and requests, offers and promises carry fulfillment dates, which then allow the status of the work in each part of the process to be color-coded.
7. Displays of the progress of each investment show hierarchies of conversations under each phase of the investment process. These displays show in a transparent way the progress of the investment conversation, arguments and difficulties in the process, and so forth. The next figure illustrates what these look like. Entries in the displays are active; clicking on them brings records of the language actions (communications) to the screen.
8. Files and databases supporting the process are organized by the logic of the sets of conversations and integrated with the organization's standard accounting tools.

We built our first prototype of the supporting system (rapidly) with Lotus Notes and later built with more robust platforms.

Benefits

Here are a few of the results that came out of this invention:

- Radical improvement in the organization's capacity to oversee its capital investments, with consequential improvements in the speed of all processes, reduction in the cost of operating all the processes, reduction in the actual risks of investments, increased rates of success in investments, and many other benefits.
- Capacity to couple strategy, capital budgeting, and capital expenditures in ways never before possible.
- Greatly improved and earlier identification of ineffective investments, investment managers, and early warning of investments in trouble.
- A new capacity to cut cycle times for investment decisions and implementation almost at will.
- The approach is tremendously helpful in training young managers and detecting opportunities to improve the skills of senior managers.

CONCLUSION

Having come to the end of this brief inquiry into a question to which some of the best minds in the history of humankind have devoted much, or

Table 1. Critical moments

Step	Action
0	An investment process begins when someone notices an anomaly, or something missing, broken, or in the way and declares an investment opportunity (or the necessity of an investment). Individuals or groups are named to three roles for operational managers ("line") and any number of "staff" roles. A timetable is declared for the conversation, including the moments in which each of the critical actions must be taken.
1	Under the direction of people in the key roles work begins to prepare an investment offer. Conversations among them are conducted through electronic media, in a public space, where people in all roles defined for this particular investment are able to read and observe the conversations.
2	The ***Proposer*** role offers a specific investment to ***Investor*** with ***Manager*** and staff roles observing. Additional staff roles are named at this point for giving assessments in technical, environmental, economic, and other domains as appropriate for the particular investment. In addition, the main operational roles can at this point define process elements in which particular staff roles are compelled to make assessments at particular moments in the process.
3	A very flexible and yet also formal, choreographed conversation now ensues among the key roles, guided by requests from the operational managers. In the conversation the participants answer questions about the value that will be contributed by the investment to the organization, its clients, and others, the costs it will produce, and how it will be evaluated once completed. The governing assumptions (assessments) behind the investment are spelled out in this conversation, in context.
4	The ***Investor*** commits the organization to go ahead with the investment. This commitment is understood by all to have these dimensions: the ***Investor*** is committing the organization (a) to make a specified investment, (b) under specified assumptions, (c) to produce a particular result. At any point in the execution of this investment that any of these "get sideways," the parties understand that the commitment as a whole is in trouble and those responsible at the moment (usually the ***Manager***) must go back to the ***Investor*** and revisit the commitment.
5	The ***Manager*** manages the implementation of the investment, using whatever resources were spelled out in the assumptions at stage 3 above. The other roles are informed about progress and ask questions during the implementation, and those conversations are preserved as part of the record, along with the records of costs during the implementation.
6	The ***Manager*** reports the successful implementation of the investment to the ***Investor*.**
7	Under the direction of the ***Investor,*** the participants in the process evaluate the investment's results, including defining future benchmarks of review and evaluation as appropriate along with accounting standards that will be followed for tracking the investment's results.
8	The ***Investor*** declares him/herself satisfied with the investment on behalf of the organization.

Table 2. Example of the display of the index to an investment management conversation

Date	Who	Act		Subject
Replace blade 110 in Winn Dixie Turbine A				
20040510	Wiseman	OPEN		Trouble with blade 110, no spare available
20040510	Blanquette		Assess	Cost of delays will be $650k/day
20040512	Demasio		Assess	Vendor promises to find replacement
20040512	Wiseman	OFFER		Acquire replacement blade by 5/22
20040512	Demasio		Assess	Vendor wants $12k
20040513	Blanquette		Assess	Bargain! Grab it.
20040513	Demasio		Assess	Committed - in our hands 5/24
20040513	McMaster	COMMIT		Acquisition authorized
20040526	Wiseman	COMPLET		Blade installed
20040528	Wiseman		Assess	Tests passed
20040528	McMaster	SATISF		Thanks, Dwight. Well done all.

sometimes all of their adult working lives, what shall we say?

First, I conclude that to care about wisdom, to ask what it is and how to cultivate it, is, itself, to take an ethical stand. To set the possibility of wise action as a standard for judging the way that we develop management and leadership practices in organizations and as a standard for the design of systems to support action in enterprises, is, itself, to take an ethical stand. To set out to produce the capacity for wisdom is no less than to commit to act in a way that is designed to bring out, make available, the very best that people have to offer. In big and little circumstances that call for wise action, where someone who is in a position to act has not before that moment been prepared to address what is happening, wisdom is possible. In that moment, someone prepared to act with wisdom does not flee or turn away from those circumstances. Instead, they themselves take an ethical stand and use the moment to discover something heretofore undiscovered about themselves, others, and/or the circumstances, as the foundation for building something new. And then they act in a way that is not merely following the rules or repeating what others before them have done.

Then, as a last question, let us ask, "Where, after all, does wisdom come from?" I propose that whatever we may conclude are the essential structures of wisdom, we may be clear that when we say someone is wise, or say that some action was wise, that what we observed is rooted in at least these four places:

1. In the fact that human beings are historical beings, able to remember and continuously reinterpret our experiences, and possessed of practices that allow us to record, read about, and interpret the experience of others.
2. In our capacity to learn from our interactions in our worlds.
3. In our capacity to speak and act from that background.

4. In the biology that gives us the wherewithal for all of the above--cognition, memory, intellect, and language itself, as well as our emotional reactions and predispositions with which we orient ourselves to each other, our experience, and our worlds.

Curiously, in each of these areas, a great deal of new current research is yielding remarkable new insights into what it is that human beings do. I propose these give us a good point of departure and can give us a whole series of places in which to continue Churchman's inquiry and to draw inspiration and ideas for improving the quality of our work on the design and construction of organizational practices and systems to support them.

wise
\Wise\, a. [Compar. Wiser; superl. Wisest.] [OE. wis, AS. w[=i]s; akin to OS. & OFries. w[=i]s, D. wijs, G. weise, OHG. w[=i]s, w[=i]si, Icel. v[=i]ss, Sw. vis, Dan. viis, Goth. weis; akin to wit, v. i. See Wit, v., and cf. Righteous, Wisdom.] 1. Having knowledge; knowing; enlightened; of extensive information; erudite; learned.They are wise to do evil, but to do good they have no knowledge. --Jer. iv. 22. 2. Hence, especially, making due use of knowledge; discerning and judging soundly concerning what is true or false, proper or improper; choosing the best ends and the best means for accomplishing them; sagacious.When clouds appear, wise men put their cloaks. --Shak.From a child thou hast known the holy scriptures, which are able to make thee wise unto salvation. --2 Tim. iii. 15. 3. Versed in art or science; skillful; dexterous; specifically, skilled in divination.Fal. There was, mine host, an old fat woman even now with me; but she's gone. Sim. Pray you, sir, was't not the wise woman of Brentford? — Shak.4. Hence, prudent; calculating; shrewd; wary; subtle; crafty. [R.] "Thou art . . . no novice, but a governor wily and wise." --Chaucer. Nor, on the other side, Will I be penuriously

wise As to make money, that's my slave, my idol. --Beau. & Fl. Lords do not care for me: I am too wise to die yet. --Ford.5. Dictated or guided by wisdom; containing or exhibiting wisdom; well adapted to produce good effects; judicious; discreet; as, a wise saying; a wise scheme or plan; wise conduct or management; a wise determination. "Eminent in wise deport." --Milton.To make it wise, to make it a matter of deliberation. [Obs.] " We thought it was not worth to make it wise."--Chaucer. Wise in years, old enough to be wise; wise from age and experience; hence, aged; old. [Obs.]A very grave, state bachelor, my dainty one; He's wise in years, and of a temperate warmth. --Ford. You are too wise in years, too full of counsel, For my green experience. --Ford.Source: Webster's Revised Unabridged Dictionary, © 1996, 1998 MICRA, Inc.

wise

\Wise\, a. [OE. wise, AS. w[=i]se; akin to OS. w[=i]sa, OFries. w[=i]s, D. wijs, wijze, OHG. w[=i]sa, G. weise, Sw. vis, Dan. viis, Icel. ["o]?ruv[=i]s otherwise; from the root of E. wit; hence, originally, knowledge, skill. See Wit, v., and cf. Guise.] Wayof being or acting; manner; ode; fashion. ``All armed in complete wise.'' --Spenser.To love her in my beste wyse. --Chaucer. This song she sings in most commanding wise. --Sir P. Sidney. Let not these blessings then, sent from above, Abused be, or spilt in profane wise. --Fairfax.Note: This word is nearly obsolete, except in such phrases as in any wise, in no wise, on this wise, etc. " Fret not thyself in any wise to do evil."--Ps. xxxvii. 8. "He shall in no wise lose his reward." --Matt. x. 42. " On this wise ye shall bless the children of Israel." --Num. vi. 23.Note: Wise is often used as a suffix in composition, as in likewise, nowise, lengthwise, etc., in which words -ways is often substituted with the same sense; as, noways, lengthways, etc.Source: Webster's Revised Unabridged Dictionary, © 1996, 1998 MICRA, Inc.

wise

adj 1: having or prompted by wisdom or discernment; "a wise leader"; "a wise and perceptive comment" [ant: foolish] 2: marked by the exercise of good judgment or common sense in practical matters; "judicious use of one's money"; "a sensible manager"; "a wise decision" [syn: judicious, sensible] 3: evidencing the possession of inside information [syn: knowing, wise(p), wise to(p)] 4: able to take a broad view of negotiations between states [syn: diplomatic] 5: carefully considered; "a considered opinion" [syn: considered] n : a way of doing or being: "in no wise"; "in this wise" [syn: method]Source: WordNet ® 1.6, © 1997 Princeton University

3 I understand organizations as a broad range of human enterprise, including what we construct within the institutions of families, communities, societies, governments, as well as businesses of all sizes and types.

4 http://traditions.skule.ca/articles/ironring/ironringinfo/ironringinfo.html

5 In October 2001, Business Week magazine rated Kotter the #1 "leadership guru" in America based on a survey they conducted of 504 enterprises.

6 The development of wisdom has been a central theme in a number of ancient traditions for millennia. I am thinking of traditions that come to us principally from India, China, Japan, Asian countries, and from Judaism, Christianity, and Islam. These traditions share principles about wisdom, "paths to enlightenment," and styles of learning. I cite a few below. They are relevant to our ambi-

tion for improving systems, but beyond our grasp in such a short work. The names that I give in the following are not universally accepted labels but rather the nomenclature I have given to a short list of topics that can be found in the great books of many traditions.

Transcendence: the principle that meaning, satisfaction, and the organizing principles in life are rarely found first in the phenomenal world of things.

Transformation: the principle that life is far more mutable than any of us is given to suspect in the day-to-day living of it. Our understanding of our lives, our situations, and what we are doing are subject to change rather suddenly. Through our behavior, we can influence how that happens.

Tension: the principle that in life many important things are born in the middle of tensions and that tension, as a result, sometimes needs to be cultivated in order to support invention.

Temporal Structures: the principle that calls for close attention to the temporal horizons in which we conceive and understand life. "Be here now," living in the present, planning and envisioning the future, and care with the processes of recording and accounting for the past are part of this.

The Unity of Existence: John Donne pointed to the center of the question with his Meditation XVII: "All mankind is of one author, and is one volume; when one man dies, one chapter is not torn out of the book, but translated into a better language; and every chapter must be so translated...As therefore the bell that rings to a sermon, calls not upon the preacher only, but upon the congregation to come: so this bell calls us all: but how much more me, who am brought so near the door by this sickness....No man is an island, entire of itself... any man's death diminishes me, because I am involved in mankind; and therefore never send to know for whom the bell tolls; it tolls for thee."

7 I'll say more formally later about assessments. For this moment, take the word in its conventional sense of an interpretation or a judgment.

8 See for example the following from Anthony Kenny, (1992). The Metaphysics of Mind, Oxford: Oxford University Press, p. 17ff, 20.

"To say that I have an intellect is to say that I have the capacity to acquire and exercise intellectual abilities of various kinds, such as the mastery of language and the possession of objective information. To say that I have a will is to say that I have the capacity for the free pursuit of goals formulated by the intellect. My intellect and my will are in essence capacities. What are they capacities of ? Of the living human being, the body you would see if you were here in the room where I write.

"The most important intellectual skill is the mastery of language. Others, such as the knowledge of mathematics, are acquired by human beings through the languages they have mastered. So the study of the acquisition and exercise of language is the way par excellence to study the nature of the human mind. To study knowledge of language you have to consider what the exercise of linguistic knowledge is… for instance, reciting a poem to myself in my head imperceptibly will count as an instance of linguistic behavior."

9 I build a substantial portion of my interpretations about the behaviors of humans and organizations on the work of Kierkegaard, Heidegger, Wittgenstein, and Anthony Kenny. Heidegger is particularly difficult. I use Hubert Dreyfus' Being-in-the-World (see next footnote) as my guide to the Heidegger of Being and Time. I have found Lawrence Vogel's The Fragile "We": Ethical Implica-

tions of Heidegger's "Being and Time" particularly useful in picking my way through the ethical thicket presented by Heidegger's interactions with National Socialism during the time of Hitler. This controversial 20th century philosopher is rapidly becoming, by the measures philosophers use to assess each other's importance, the most important philosopher of all time.

10 The creation of knowledge as a capacity for taking action - I normally speak of it as different kinds of capital that enable one to act skillfully, act in ways that convoke action on the parts of others, and produce satisfaction to those served--is a central issue in my interpretation of what we do with each other in organizations. On the other hand, most speaking in the IT, DSS, and adjacent traditions give the central role in the activities of those leading and managing organizations to what is called decision making. I do not. I think it is important that I note that I have an alternative view of how people in an organization conclude that new actions are possible or called for, come to resolution about how to take those actions, and then put themselves into action. I do not address this difference in this chapter.

11 Anthony Kenny is Warden of Rhodes House, Oxford, and Chairman of the British Library. Until recently, he was Master of Balliol College, Oxford, and President of the British Academy. In The Oxford Illustrated History of Western Philosophy he brought together essays by a series of philosophers covering the epochs of the five Churchman philosophers.

12 Dr. Fernando Flores Labra, currently a Senator in the Chilean government and candidate for President of his country, was the first to point out the importance of performatives for understanding and shaping the behaviors of people in organizations as an underpinning of design in organizations. Flores originally assembled the traditions and many of the thinkers on which I rely in this chapter.

13 Directives and commissives refer to a different categorization of performative verbs than the one I employ in my own work.

Section 6
Managerial Impact of Knowledge Management

This section presents contemporary coverage of the social implications of knowledge management, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Core ideas such as training and continuing education of human resources in modern organizations are discussed through these more than 35 chapters. Also discussed is strategic planning related to the organizational elements and knowledge sharing program requirements that are necessary to build a framework in order to institutionalize and sustain knowledge management systems as a core business process. Equally as crucial, are the chapters which address the gap between theory and practical implementation within the knowledge sharing community. Directing the reader's focus forward, the final chapters found within this section help to establish a basis for assessing the value of knowledge management while evaluating its results within business enterprises.

Chapter 6.1
Knowledge Management Systems

Petter Gottschalk
Norwegian School of Management BI, Norway

INTRODUCTION

As we trace the evolution of computing technologies in business, we can observe their changing level of organizational impact. The first level of impact was at the point work got done and transactions (e.g., orders, deposits and reservations) took place. The inflexible, centralized mainframe allowed for little more than massive number crunching, commonly known as electronic *data* processing. Organizations became data heavy at the bottom and data management systems were used to keep the data in check. Later, the management *information* systems were used to aggregate data into useful information reports, often prescheduled, for the control level of the organization — people who were making sure that organizational resources like personnel, money and physical goods were being deployed efficiently. As information technology (IT) and information systems (IS) started to facilitate data and information overflow, and corporate attention became a scarce resource, the concept of *knowledge* emerged as a particularly high-value form of information (Grover & Davenport, 2001).

Information technology can play an important role in successful knowledge management initiatives. However, the concept of coding and transmitting knowledge in organizations is not new: training and employee development programs, organizational policies, routines, procedures, reports and manuals have served this function for many years. What is new and exciting in the knowledge management area is the potential for using modern information technology (e.g., the Internet, intranets, extranets, browsers, data warehouses, data filters, software agents and expert systems) to support knowledge creation, sharing and exchange in an organization and between organizations. Modern information technology can collect, systematize, structure, store, combine, distribute and present information of value to knowledge workers (Nahapiet & Ghoshal, 1998).

According to Davenport and Prusak (1998), more and more companies have instituted knowledge repositories, supporting such diverse types of knowledge as best practices, lessons learned, product development knowledge, customer knowledge, human resource management knowledge and methods-based knowledge. Groupware and intranet-based technologies have become standard knowledge infrastructures. A new set of professional job titles — the knowledge manager, the chief knowledge officer (CKO), the knowledge coordinator and the knowledge-network facilitator — affirms the widespread legitimacy that knowledge management has earned in the corporate world.

The low cost of computers and networks has created a potential infrastructure for knowledge sharing and opened up important knowledge management opportunities. The computational power, as such, has little relevance to knowledge work, but the communication and storage capabilities of networked computers make computational power an important enabler of effective knowledge work. Through e-mail, groupware, the Internet and intranets, computers and networks can point to people with knowledge and connect those who need to share knowledge independent of time and place.

For example, electronic networks of practice are computer-mediated discussion forums focused on problems of practice that enable individuals to exchange advice and ideas with others based on common interests. Electronic networks make it possible to share information quickly, globally and with large numbers of individuals. Electronic networks that focus on knowledge exchange frequently emerge in fields where the pace of technological change requires access to knowledge unavailable within any single organization (Wasko & Faraj, 2005).

In the knowledge-based view of the firm, knowledge is the foundation of a firm's competitive advantage and, ultimately, the primary driver of a firm's value. Inherently, however, knowledge resides within individuals and, more specifically, in the employees who create, recognize, archive, access and apply knowledge in carrying out their tasks. Consequently, the movement of knowledge across individual and organizational boundaries, into and from repositories and into organizational routines and practices is ultimately dependent on employees' knowledge-sharing behaviors (Bock, et al., 2005).

According to Grover and Davenport (2001), most knowledge management projects in organizations involve the use of information technology. Such projects fall into relatively few categories and types, each of which has a key objective. Although it is possible, and even desirable, to combine multiple objectives in a single project, this was not normally observed in a study of 31 knowledge management projects in 1997 (Davenport & Prusak, 1998). Since that time, it is possible that projects have matured and taken on more ambitious collections of objectives.

Regardless of the definition of knowledge as the highest value of content in a continuum starting at data, encompassing information and ending at knowledge itself, knowledge managers often take a highly inclusive approach to the content with which they deal. In practice, what companies actually manage under the banner of knowledge management is a mix of knowledge, information and unrefined data — in short, whatever anyone finds that is useful and easy to store in an electronic repository. In the case of data and information, however, there are often attempts to add more value and create knowledge. This transformation might involve the addition of insight, experience, context, interpretation or a myriad of other activities in which human brains specialize (Grover & Davenport, 2001).

Identifying, nurturing and harvesting knowledge is a principal concern in the information society and the knowledge age. Effective use of knowledge-facilitating tools and techniques is critical, and a number of computational tools have been developed. While numerous techniques are available, it remains difficult to analyze or compare specific tools. In part, this is because knowledge management is a young discipline. The arena is evolving rapidly as more people enter the fray and encounter new problems (Housel & Bell, 2001).

In addition, new technologies support applications that were impossible before. Moreover, the multidisciplinary character of knowledge management combines several disciplines, including business and management, computer science, cybernetics and philosophy. Each of these fields may lay claim to the study of knowledge management, and the field is frequently defined so broadly that anything can be incorporated. Finally, it is difficult to make sense of the many knowledge management tools available; it is not difficult to perform a search to produce a list of more than one hundred software providers. Each of the software packages employ unique visions and aims to capture its share of the market (Housel & Bell, 2001).

Ward and Peppard (2002) find that there are two dominant and contrasting views of IS/IT in knowledge management: the engineering perspective and the social process perspective. The engineering perspective views knowledge management as a technology process. Many organizations have taken this approach in managing knowledge, believing that it is concerned with managing pieces of intellectual capital. Driving this view is the belief that knowledge can be codified and stored; in essence that knowledge is explicit and therefore is little more than information.

The alternative view is that knowledge is a social process. As such, it asserts that knowledge resides in people's heads and that it is tacit. As such, it cannot be easily codified and only revealed through its application. As tacit knowledge cannot be directly transferred from person to person, its acquisition occurs only through practice. Consequently, its transfer between people is slow, costly and uncertain. Technology, within this perspective, can only support the context of knowledge work. It has been argued that IT-based systems used to support knowledge management can only be of benefit if used to support the development and communication of human meaning. One reason for the failure of IT in some knowledge management initiatives is that the designers of the knowledge management systems fail to understand the situation and work practices of the users and the complex human processes involved in their work.

While technology can be used with knowledge management initiatives, Ward and Peppard (2002) argue that it should never be the first step. Knowledge management is to them primarily a human and process issue. Once these two aspects have been addressed, then the created processes are usually very amenable to being supported and enhanced by the use of technology.

What, then, is knowledge management technology? According to Davenport and Prusak (1998), the concept of knowledge management technology is not only broad but also a bit slippery to define. Some infrastructure technology that we don't ordinarily think of in this category can be useful in facilitating knowledge management. Examples are video conferencing and the telephone. Both of these technologies don't capture or distribute structured knowledge, but they are quite effective at enabling people to transfer tacit knowledge.

Our focus here, however, is on technology that captures, stores and distributes structured knowledge for use by people. The goal of these technologies is to take knowledge that exists in human heads, and partly in paper documents, and make it widely available throughout an organization. Similarly, Alavi and Leidner (2001) argue that information systems designed to support knowledge in organizations may not appear radically different from other forms of IT support, but will be geared toward enabling users to assign meaning to information and to capture some of their knowledge in information. Therefore, the concept of knowledge management technology in this book is less concerned with any degree of technology sophistication and more concerned with the usefulness in performing knowledge work in and between organizations.

Moffett and McAdam (2003) illustrate the variety of knowledge management technology tools by distinguishing between collaborative tools, content management and business intelligence. Collaborative tools include groupware technology, meeting support systems, knowledge directories and intranets / extranets. Content management includes the Internet, agents and filters, electronic publishing systems, document management systems and office automation systems. Business intelligence includes data warehousing, decision support systems, knowledge-based systems and workflow systems. In addition to technologies, we also present techniques in this book. The term technique is defined as a set of precisely described procedures for achieving a standard task (Kettinger, et al., 1997).

KNOWLEDGE MANAGEMENT PROCESSES

Alavi and Leidner (2001) have developed a systematic framework that will be used to analyze and discuss the potential role of information technology in knowledge management. According to this framework, organizations consist of four sets of socially enacted knowledge processes: (1) creation (also referred to as construction), (2) storage and retrieval, (3) transfer and (4) application. The knowledge-based view of the firm represents here both the cognitive and social nature of organizational knowledge and the embodiment of this knowledge in the individual's cognition and practices as well as the collective (i.e., organizational) practices and culture. These processes do not represent a monolithic set of activities, but an interconnected and intertwined set of activities.

Knowledge Creation

Organizational knowledge creation involves developing new content or replacing existing content within the organization's tacit and explicit knowledge. Through social and collaborative processes, as well as individual's cognitive processes (e.g., reflection), knowledge is created. The model developed by Nonaka, et al. (2000) involving SECI, ba and knowledge assets, views organizational knowledge creation as involving a continual interplay between the tacit and explicit dimensions of knowledge, and a growing spiral flow as knowledge moves through individual, group and organizational levels. Four modes of knowledge creation have been identified: socialization, externalization, internalization and combination (SECI), and these modes occur at "ba," which means place.

Nonaka, et al. (2000) suggest that the essential question of knowledge creation is establishing an organization's ba, defined as a common place or space for creating knowledge. Four types of ba corresponding to the four modes of knowledge creation are identified: (1) originating; (2) interacting; (3) cyber; and (4) exercising ba. Originating ba entails the socialization mode of knowledge creation and is the ba from which the organizational knowledge creation process begins. Originating ba is a common place in which individuals share experiences primarily through faceto- face interactions and by being at the same place at the same time. Interacting ba is associated with the externalization mode of knowledge creation and refers to a space where tacit knowledge is converted to explicit knowledge and shared among individuals through the process of dialogue and collaboration. Cyber ba refers to a virtual space of interaction and corresponds to the combination mode of knowledge creation. Finally, exercising ba involves the conversion of explicit to tacit knowledge through the internalization process. Thus, exercising ba involves the conversion of explicit to tacit knowledge through the internalization process.

Understanding the characteristics of various ba and the relationship with the modes of knowledge creation is important to enhancing organizational knowledge creation. For example, the use of IT capabilities in cyber ba is advocated to enhance the efficiency of the combination mode of knowledge creation. Data warehousing and data mining, document management systems, software agents and intranets may be of great value in cyber ba. Considering the flexibility of modern IT, other forms of organizational ba and the corresponding modes of knowledge creation can be enhanced through the use of various forms of information systems. For example, information systems designed for support or collaboration, coordination and communication processes as a component of the interacting ba, can facilitate teamwork and thereby increase an individual's contact with others.

Electronic mail and group support systems have the potential of increasing the number of weak ties in organizations. This, in turn, can accelerate the growth of knowledge creation. Intranets enable exposure to greater amounts of online organizational information, both horizontally and vertically, than may previously have been the case. As the level of information exposure increases, the internalization mode of knowledge creation, wherein individuals make observations and interpretations of information that result in new individual tacit knowledge, may increase. In this role, an intranet can support individual learning (conversion of explicit knowledge to personal tacit knowledge) through provision of capabilities such as computer simulation (to support learning-by-doing) and smart software tutors.

Computer-mediated communication may increase the quality of knowledge creation by enabling a forum for constructing and sharing beliefs, for confirming consensual interpretation and for allowing expression of new ideas. By providing an extended field of interaction among organizational members for sharing ideas and perspectives, and for establishing dialogue, information systems may enable individuals to arrive at new insights and/or more accurate interpretations than if left to decipher information on their own.

Although most information repositories serve a single function, it is increasingly common for companies to construct an internal "portal" so that employees can access multiple repositories and sources from one screen. It is also possible, and increasingly popular, for repositories to contain not only information, but also pointers to experts within the organization on key knowledge topics. It is also feasible to combine stored information with lists of the individuals who contributed the knowledge and could provide more detail or background on it (Grover & Davenport, 2001).

According to Grover and Davenport (2001), firms increasingly view attempts to transform raw data into usable knowledge as part of their knowledge management initiatives. These approaches typically involve isolating data in a separate "warehouse" for easier access, and the use of statistical analysis or data mining and visualization tools. Since their goal is to create data-derived knowledge, the initiatives are increasingly addressed as a part of knowledge management. Some vendors have already begun to introduce e-commerce tools in this area. They serve to customize the menu of available knowledge to individual customers, allowing sampling of information before buying and carrying out sales transactions for knowledge purchases. Online legal services are typical examples where clients can sample legal information before buying a lawyer's time.

For knowledge creation there is the current emergence of *idea-generation software*. Idea-generation software is designed to help stimulate a single user or a group to produce new ideas, options and choices. The user does all the work, but the software encourages and pushes, something like a personal trainer. Although idea-generation software is relatively new, there are several packages on the market. IdeaFisher, for example, has an associative lexicon of the English language that cross-references words and phrases. These associative links, based on analogies and metaphors, make it easy for the user to be fed words related to a given theme. Some software packages use questions to prompt the user toward new, unexplored patterns of thought. This helps users to break out of cyclical thinking patterns and conquer mental blocks.

Knowledge Storage and Retrieval

According to Alavi and Leidner (2001), empirical studies have shown that while organizations create knowledge and learn, they also forget (i.e., do not remember or lose track of the acquired knowledge). Thus, the storage, organization and retrieval of organizational knowledge, also referred to as organizational memory, constitute an important aspect of effective organizational knowledge management. Organizational memory includes knowledge residing in various component forms, including written documentation, structured information stored in electronic databases, codified human knowledge stored in expert systems, documented organizational procedures and processes and tacit knowledge acquired by individuals and networks of individuals.

Advanced computer storage technology and sophisticated retrieval techniques, such as query languages, multimedia databases and database management systems, can be effective tools in enhancing organizational memory. These tools increase the speed at which organizational memory can be accessed.

Groupware enables organizations to create intra-organizational memory in the form of both structured and unstructured information and to share this memory across time and space. IT can play an important role in the enhancement and expansion of both semantic and episodic organizational memory. Semantic memory refers to general, explicit and articulated knowledge, whereas episodic memory refers to context-specific and situated knowledge. Document management technology allows knowledge of an organization's past, often dispersed among a variety of retention facilities, to be effectively stored and made accessible. Drawing on these technologies, most consulting firms have created semantic memories by developing vast repositories of knowledge about customers, projects, competition and the industries they serve.

Grover and Davenport (2001) found that by far the most common objective of knowledge management projects in Western organizations involves some sort of knowledge repository. The objective of this type of project is to capture knowledge for later and broader access by others within the same organization. Common repository technologies include Lotus Notes, web-based intranets and Microsoft's Exchange, supplemented by search engines, document management tools and other tools that allow editing and access. The repositories typically contain a specific type of information to represent knowledge for a particular business function or process, such as:

- "Best practices" information within a quality or business process management function;
- Information for sales purposes involving products, markets and customers;
- Lessons learned in projects or product development efforts;
- Information around the implementation of information systems;
- Competitive intelligence for strategy and planning functions; and
- "Learning histories" or records of experience with a new corporate direction or approach.

The mechanical generation of databases, Web sites and systems that process data are good and have the potential to take us to a higher plane in the organization, help us understand workflows better and aid in dealing with organizational pathologies and problems. The data-to-information transition often involves a low level mechanical process that is well within the domain of contemporary information technologies, though humans are helpful in this transition as well. This information could exist in different forms throughout the organization and could even form the basis of competitive advantage or information products. For example, provision of information to customers about their order or shipment status is something that companies like Baxter and FedEx have been doing for years. But unlike knowledge, mechanically supplied information cannot be the source of sustained competitive advantage, particularly when the architectures on which it is based are becoming more open and omnipresent.

IT in knowledge management can be used to store various kinds of information. For example, information about processes, procedures, forecasts, cases and patents in the form of working documents, descriptions and reports can be stored in knowledge management systems. TietoEnator, a Scandinavian consulting firm, has a knowledge base where they store methods, techniques, notes, concepts, best practices, presentations, components, references, guidelines, quality instructions, process descriptions, routines, strategies and CVs for all consultants in the firm (Halvorsen & Nguyen, 1999).

Knowledge retrieval can find support in content management and information extraction technology, which represent a group of techniques for managing and extracting knowledge from documents, ultimately delivering a semantic meaning for decision makers and learners alike. These types of computer applications are targeted at capturing and extracting the content of free-text documents. There are several tasks that fall within the scope of content management and information extraction (Wang, et al., 2001):

- *Abstracting and summarizing*. This task aims at delivering shorter, informative representations of larger (sets of) documents.
- *Visualization*. Documents can often be visualized according to the concepts and relationships that they play a role among. Visualization can be either in an introspective manner, or using some reference model / view of a specific topic.
- *Comparison and search*. This task finds semantically similar pieces of information.
- *Indexing and classification*. This considers (partial) texts, usually according to certain categories.
- *Translation*. Context-driven translation of texts from one language into another. Language translation has proven to be highly context specific, even among closely related languages. Some kind of semantic representation of meaning is needed in order to be able to make good translations.
- *Question formulation and query answering*. This is a task in human-computer interaction systems.
- *Extraction of information*. This refers to the generation of additional information that is not explicit in the original text. This information can be more or less elaborate.

A group of computational techniques are available to alleviate the burden of these tasks. They include fuzzy technology, neural networks and expert systems. On a more application-oriented level, there are several approaches that apply one or more of the general techniques. The field is currently dynamic, and new advances are made continuously. One novel approach is the CORPORUM system, presented in the section on expert systems.

Knowledge Transfer

Knowledge transfer can be defined as the communication of knowledge from a source so that it is learned and applied by a recipient (Ko, et al., 2005). Knowledge transfer occurs at various levels in an organization: transfer of knowledge between individuals, from individuals to explicit sources, from individuals to groups, between groups, across groups and from the group to the organization. Considering the distributed nature of organizational cognition, an important process of knowledge management in organizational settings is the transfer of knowledge to locations where it is needed and can be used. However, this is not a simple process, in that organizations often do not know what they know and have weak systems for locating and retrieving knowledge that resides in them. Communication processes and information flows drive knowledge transfer in organizations.

Depending on the completeness or incompleteness of the sender and the receiver's information sets, there are four representative types of information structure in knowledge transfer according to Lin, et al. (2005): symmetric complete information, sender-advantage asymmetric information, symmetric incomplete information and receiver-advantage asymmetric information. Lin, et al. (2005) found that because of asymmetry and incompleteness, parties seeking knowledge may not be able to identify qualified knowledge providers, and the appropriate experts may fail to be motivated to engage in knowledge transfer.

Knowledge transfer channels can be informal or formal, personal or impersonal. IT can support all four forms of knowledge transfer, but has mostly been applied to informal, impersonal means (such as discussion databases) and formal, impersonal means (such as corporate directories). An innovative use of technology for transfer is use of intelligent agent software to develop interest profiles of organizational members in order to determine which members might be interested recipients of point-to-point electronic messages exchanged among other members. Employing video technologies can also enhance transfer.

IT can increase knowledge transfer by extending the individual's reach beyond the formal communication lines. The search for knowledge sources is usually limited to immediate coworkers in regular and routine contact with the individual. However, individuals are unlikely to encounter new knowledge through their close-knit work networks because individuals in the same clique tend to possess similar information. Moreover, individuals are often unaware of what their cohorts are doing. Thus, expanding the individual's network to more extended — although perhaps weakerconnections is central to the knowledge diffusion process because such networks expose individuals to more new ideas.

Computer networks and electronic bulletin boards and discussion groups create a forum that facilitates contact between the person seeking knowledge and those who may have access to the knowledge. Corporate directories may enable individuals to rapidly locate the individual who has the knowledge that might help them solve a current problem. For example, the primary content of such a system can be a set of expert profiles containing information about the backgrounds, skills and expertise of individuals who are knowledgeable in various topics. Often such metadata (knowledge about where knowledge resides) proves to be as important as the original knowledge itself. The provision of taxonomies or organizational knowledge maps enables individuals to rapidly locate either the knowledge, or the individual who has the needed knowledge, more rapidly than would be possible without such ITbased support.

Communication is important in knowledge management, because technology provides support for both intra-organizational as well as inter-organizational knowledge networks. Knowledge networks need technology in the form of technical infrastructure, communication networks and a set of information services. Knowledge networks enable knowledge workers to share information from various sources.

Traditional information systems have been of importance to vertical integration for a long time. Both customers and suppliers have been linked to the company through information systems. Only recently has horizontal integration occurred. Knowledge workers in similar businesses cooperate to find optimal solutions for customers. IT has become an important vertical and horizontal interorganizational coordination mechanism. This is not only because of the availability of broadband and standardized protocols. It is also caused by falling prices for communication services and by software programs' abilities to coordinate functions between firms.

One way to reduce problems stemming from paper workflow is to employ document-imaging systems. Document imaging systems are systems that convert paper documents and images into digital form so they can be stored and accessed by a computer. Once the document has been stored electronically, it can be immediately retrieved and shared with others. An imaging system requires indexes that allow users to identify and retrieve a document when needed (Laudon & Laudon, 2005).

Knowledge Application

An important aspect of the knowledge-based view of the firm is that the source of competitive advantage resides in the application of the knowledge rather than in the knowledge itself. Information technology can support knowledge application by embedding knowledge into organizational routines. Procedures that are culturebound can be embedded into IT so that the systems themselves become examples of organizational norms. An example according to Alavi and Leidner (2001) is Mrs. Field's use of systems designed to assist in every decision from hiring personnel to when to put free samples of cookies out on the table. The system transmits the norms and beliefs held by the head of the company to organizational members.

Technology enforced knowledge application raises a concern that knowledge will continue to be applied after its real usefulness has declined. While the institutionalization of best practices by embedding them into IT might facilitate efficient handling of routine, linear and predictable situations during stable or incrementally changing environments, when change is radical and discontinuous, there is a persistent need for continual renewal of the basic premises underlying the practices archived in the knowledge repositories. This underscores the need for organizational members to remain attuned to contextual factors and explicitly consider the specific circumstances of the current environment.

Although there are challenges with applying existing knowledge, IT can have a positive influence on knowledge application. IT can enhance knowledge integration and application by facilitating the capture, updating and accessibility of organizational directives. For example, many organizations are enhancing the ease of access and maintenance of their directives (repair manuals, policies and standards) by making them available on corporate intranets. This increases the speed at which changes can be applied. Also, organizational units can follow a faster learning curve by accessing the knowledge of other units having gone through similar experiences. Moreover, by increasing the size of individuals' internal social networks and by increasing the amount of organizational memory available, information technologies allow for organizational knowledge to be applied across time and space.

IT can also enhance the speed of knowledge integration and application by codifying and automating organizational routines. Workflow automation systems are examples of IT applications that reduce the need for communication and coordination and enable more efficient use of organizational routines through timely and automatic routing of work-related documents, information, rules and activities. Rule based expert systems are another means of capturing and enforcing well-specified organizational procedures.

To summarize, Alavi and Leidner (2001) have developed a framework to understand IS/IT in knowledge management processes through the knowledge-based view of the firm. One important implication of this framework is that each of the four knowledge processes of creation, storage and retrieval, transfer and application can be facilitated by IT:

- *Knowledge creation*: Examples of supporting information technologies are data mining and learning tools, which enable combining new sources of knowledge and just-in-time learning.
- *Knowledge storage and retrieval*: Examples of supporting information technologies are electronic bulletin boards, knowledge repositories and databases, which provide support of individual and organizational memory as well as inter-group knowledge access.
- *Knowledge transfer*: Examples of supporting information technologies are electronic bulletin boards, discussion forums and knowledge directories, which enable a more extensive internal network, more available communication channels and faster access to knowledge sources.
- *Knowledge application*: Examples of supporting information technologies are expert and workflow systems, which enable knowledge application in many locations and more rapid application of new knowledge through workflow automation.

KNOWLEDGE MANAGEMENT SYSTEMS

There is no single information system that is able to cover all knowledge management needs in a firm. This is evident from the widespread potential of IT in knowledge management processes. Rather, knowledge management systems (KMS) refer to a class of information systems applied to managing organizational knowledge for use at the individual, group and organizational level. These systems are IT applications to support and enhance the organizational processes of knowledge creation, storage and retrieval, transfer and application.

Knowledge management systems can be classified as illustrated in Figure 1. Systems are exemplified along the axis of internal support versus external support and along the axis of technology support versus content support for knowledge workers. As an example of a knowledge management system, we find customer relationship management (CRM) systems in the upper left quadrant. CRM systems support knowledge exchange between the firm and its customers.

Figure 1. Classification of knowledge management systems

Tools	**Information**	
Tools for external communications such as customer relationship management services	Information for external electronic cooperation such as Web-based	External
Tools for internal work by knowledge workers	Information for internal work by knowledge workers	Internal

Despite widespread belief that information technology enables knowledge management, and knowledge management improves firm performance, researchers have only recently found empirical evidence of these relationships. For example, Tanriverdi (2005) used data from 250 Fortune 1000 firms to provide empirical support for these relationships.

Knowledge management systems are becoming ubiquitous in today's organizations. Knowledge management systems facilitate the efficient and effective sharing of an organization's intellectual resources. To ensure effective usage, a knowledge management system must be designed such that knowledge workers can readily find high-quality content without feeling overwhelmed (Poston & Speier, 2005).

Requirements from Knowledge Management

The critical role of information technology and information systems lies in the ability to support communication, collaboration and those searching for knowledge, and the ability to enable collaborative learning (Ryu, et al., 2005). We have already touched on important implications for information systems:

1. *Interaction between information and knowledge.* Information becomes knowledge when it is combined with experience, interpretation and reflection. Knowledge becomes information when assigned an explicit representation. Sometimes information exists before knowledge, sometimes knowledge exists before information. One important implication of this two-way direction between knowledge and information is that information systems designed to support knowledge in organizations may not appear radically different from other forms of IT support, but will be geared toward enabling users to assign meaning to information and to capture some of their knowledge in information (Alavi & Leidner, 2001).
2. *Interaction between tacit and explicit knowledge.* Tacit and explicit knowledge depend on each other, and they influence each other. The linkage of tacit and explicit knowledge suggests that only individuals with a requisite level of shared knowledge are able to exchange knowledge. They suggest the existence of a shared knowledge space that is required in order for individual A to understand individual B's knowledge. The knowledge space is the underlying overlap in the knowledge bases of A and B. This overlap is typically tacit knowledge. It may be argued that the greater the shared knowledge space, the less the context needed for individuals to share knowledge within the group and, hence, the higher the value of explicit knowledge. IT is both dependent on the shared knowledge space and is itself an important part of the shared knowledge space. IT is dependent on the shared knowledge space because knowledge workers need to have a common understanding of available information contained in information systems in the organization. If common understanding is missing, then knowledge workers are unable to make use of information. IT is an important part of the shared knowledge space because information systems make common information available to all knowledge workers in the organization. One important implication of this two-way relationship between knowledge space and information systems is that a minimum knowledge space has to be present; IT can contribute to growth in the knowledge space (Alavi & Leidner, 2001).
3. *Knowledge management strategy.* Efficiency-driven businesses may apply the stock strategy where databases and information systems are important; effectiveness-driven businesses may apply the flow strategy where

information networks are important; and Expert-driven businesses may apply the growth strategy where networks of experts, work processes and learning environments are important (Hansen, et al., 1999).

4. *Combination in SECI process.* The SECI process consists of four knowledge conversion modes. These modes are not equally suited for IT support. Socialization is the process of converting new tacit knowledge to tacit knowledge. This takes place in the human brain. Externalization is the process of converting tacit knowledge to explicit knowledge. The successful conversion of tacit knowledge into explicit knowledge depends on the sequential use of metaphors, analogy and model. Combination is the process of converting explicit knowledge into more complex and systematic sets of explicit knowledge. Explicit knowledge is collected from inside and outside the organization and then combined, edited and processed to form new knowledge. The new explicit knowledge is then disseminated among the members of the organization. According to Nonaka, et al. (2000), creative use of computerized communication networks and largescale databases can facilitate this mode of knowledge conversion. When the financial controller collects information from all parts of the organization and puts it together to show the financial health of the enterprise, that report is new knowledge in the sense that it synthesizes explicit knowledge from many different sources in one context. Finally, internalization in the SECI process converts explicit knowledge into tacit knowledge. Through internalization, the explicit knowledge created is shared throughout an organization and converted into tacit knowledge by individuals.

5. *Explicit transfer of common knowledge*. If management decides to focus on common knowledge as defined by Dixon (2000), knowledge management should focus on the sharing of common knowledge. Common knowledge is shared in the organization using five mechanisms: serial transfer, explicit transfer, tacit transfer, strategic transfer and expert transfer. Management has to emphasize all five mechanisms for successful sharing and creation of common knowledge. For serial transfer, management has to stimulate meetings and contacts between group members. For explicit transfer, management has to stimulate documentation of work by the previous group. For tacit transfer, management has to stimulate contacts between the two groups. For strategic transfer, management has to identify strategic knowledge and knowledge gaps. For expert transfer, management has to create networks where experts can transfer their knowledge. These five mechanisms are not equally suited for IT support. Explicit transfer seems very well suited for IT support as the knowledge from the other group is transferred explicitly as explicit knowledge in words and numbers and shared in the form of data, scientific formulae, specifications, manuals and the like. Expert transfer also seems suited for IT support when generic knowledge is transferred from one individual to another person to enable the person to solve new problems with new methods.

6. *Link knowledge to its uses.* One of the mistakes in knowledge management presented by Fahey and Prusak (1998) was disentangling knowledge from its uses. A major manifestation of this error is that knowledge management initiatives become ends in themselves. For example, data warehousing can easily degenerate into technological challenges. The relevance of a data warehouse for decisions and actions gets lost in the turmoil spawned by debates about appropriate data structures.

7. *Treat knowledge as an intellectual asset in the economic school.* If management decides to follow the economic school of knowledge management, then intellectual capital accounting should be part of the knowledge management system. The knowledge management system should support knowledge markets where knowledge buyers, knowledge sellers and knowledge brokers can use the system.
8. *Treat knowledge as a mutual resource in the organizational school.* The potential contribution of IT is linked to the combination of intranets and groupware to connect members and pool their knowledge, both explicit and tacit.
9. *Treat knowledge as a strategy in the strategy school.* The potential contribution of IT is manifold once knowledge as strategy is the impetus behind knowledge management initiatives. One can expect quite an eclectic mix of networks, systems, tools and knowledge repositories in this scenario.
10. *Value configuration determines knowledge needs in primary activities.* Knowledge needs can be structured according to primary and secondary activities in the value configuration. Depending on the firm being a value chain, a value shop or a value network, the knowledge management system must support more efficient production in the value chain, adding value to the knowledge work in the value shop, and more value by use of IT infrastructure in the value network.
11. *Incentive Alignment.* The first dimension of information systems design is concerned with software engineering (error-free software, documentation, portability, modularity and architecture, development cost, maintenance cost, speed and robustness). The second dimension is concerned with technology acceptance (user friendliness, user acceptance, perceived ease-of-use, perceived usefulness, cognitive fit and task-technology fit). The third dimension that is particularly important to knowledge management systems is concerned with incentive alignment. Incentive alignment includes incentives influencing user behavior and the user's interaction with the system, deterrence of use for personal gain, use consistent with organizational goals and robustness against information misrepresentation (Ba, et al., 2001).

EXPERT SYSTEMS

Expert systems can be seen as extreme knowledge management systems on a continuum representing the extent to which a system possesses reasoning capabilities. Expert systems are designed to be used by decision makers who do not possess expertise in the problem domain. The human expert's representation of the task domain provides the template for expert system design. The knowledge base and heuristic rules, which are used to systematically search a problem space, reflect the decision processes of the expert. A viable expert system is expected to perform this search as effectively and efficiently as a human expert. An expert system incorporates the reasoning capabilities of a domain expert and applies them in arriving at a decision. The system user needs little domain specific knowledge in order for a decision or judgment to be made. The user's main decision is whether to accept the system's result (Dillard & Yuthas, 2001).

Decisions or judgments made by an expert system can be an intermediate component in a larger decision context. For example, an audit expert system may provide a judgment as to the adequacy of loan loss reserves that an auditor would use as input for making an audit opinion decision. The fact that the output supports or provides input for another decision does not make the system any less an expert system, according to Dillard and Yuthas (2001). The distinguishing feature of an expert system lies in its ability to arrive at a non-algorithmic solution using processes consistent with those of a domain expert.

Curtis and Cobham (2002) define an expert system as a computerized system that performs the role of an expert or carries out a task that requires expertise. In order to understand what an expert system is, then, it is worth paying attention to the role of an expert and the nature of expertise. It is then important to ascertain what types of expert and expertise there are in business and what benefits will accrue to an organization when it develops an expert system.

For example, a doctor having a knowledge of diseases arrives at a diagnosis of an illness by reasoning from information given by the patient's symptoms and then prescribes medication on the basis of known characteristics of available drugs together with the patient's history. The lawyer advises the client on the likely outcome of litigation based on the facts of the particular case, an expert understanding of the law and knowledge of the way the courts work and interpret this law in practice. The accountant looks at various characteristics of a company's performance and makes a judgment as to the likely state of health of that company.

All of these tasks involve some of the features for which computers traditionally have been noted — performing text and numeric processing quickly and efficiently — but they also involve one more ability: reasoning. Reasoning is the movement from details of a particular case and knowledge of the general subject area surrounding that case to the derivation of conclusions. Expert systems incorporate this reasoning by applying general rules in an information base to aspects of a particular case under consideration (Curtis & Cobham, 2002).Expert systems are computer systems designed to make expert level decisions within complex domains. The business applications of this advanced information technology have been varied and broad reaching, directed toward making operational, management and strategic decisions. Audit expert systems are such systems applied in the auditing environment within the public accounting domain. Major public accounting firms have been quite active in developing such systems, and some argue that these tools and technologies will be increasingly important for survival as the firms strive to enhance their competitive position and to reduce their legal and business risk.

Dillard and Yuthas (2001) find that the implementation and use of these powerful systems raise a variety of significant ethical questions. As public accounting firms continue to devote substantial resources to the development of audit expert systems, dealing with the ethical risks and potential consequences to stakeholders takes on increasing significance. For example, when responsible behavior of an auditor is transferred to an audit expert system, then the system is incapable of being held accountable for the consequences of decisions.

Expert systems can be used in all knowledge management processes described earlier. For knowledge retrieval, content management and information extraction technology represent a useful group of techniques. An example of an expert system for knowledge retrieval is the CORPORUM system. There are three essential aspects of this system (Wang, et al., 2001).

First, the CORPORUM system interprets text in the sense that it builds ontologies. Ontologies describe concepts and relationships between them. Ontologies can be seen as the building blocks of knowledge. The system captures ontologies that reflect world concepts as the user of the system sees and expresses them. The ontology produced constitutes a model of a person's interest or concern. Second, the interest model is applied as a knowledge base in order to determine contextual and thematic correspondence with documents available in the system. Finally, the interest model and the text interpretation process drive an information search and extraction process that characterizes hits in terms of both relevance and content. This new information can be stored in a database for future reference.

The CORPORUM software consists of a linguistic component, taking care of tasks such as lexical analysis and analysis at the syntactical level. At the semantic level the software performs word sense disambiguation by describing the context in which a particular word is being used. This is naturally closely related to knowledge representation issues. The system is able to augment meaning structures with concepts that are invented from the text. The core of the system is also able to extract information most pertinent to a specific text for summary creation, extract the so-called core concept area from a text and represent results according to ranking which is based on specified interest for a specific contextual theme set by the user. In addition, the system generates explanations, which will allow the user to make an informed guess about which documents to look at and which to ignore. The system can point to exactly those parts of targeted documents that are most pertinent to a specific user's interest (Wang, et al., 2001).

Like all software, CORPORUM is continuously improved and revised. The Content Management Support (CMS) was introduced in 2005 (www.cognit.no). It is based on technology that applies linguistics to characterize and index document content. The ontology based approach focuses on semantics rather than shallow text patterns. The software can be applied for intelligent search and indexing, structure content in portals, annotation of documents according to content, summary and compression of information and extraction of names and relations from text.

Another software introduced in 2005, CORPORUM Best Practice, enables organizations to structure their business and work processes and improve value creation. It is a software tool and associated methodology to build organization-wide Best Practice. In operation, the Web part of the system is a work portal. It embraces an ontology based set of templates that helps to publish work-related documentation. Company resources like check lists, control plans, MS Word templates, images and e-learning material that is relevant for any process or activity described can be linked in where it is useful and intuitive (www.cognit.no).

A final software to be mentioned is CORPORUM Intranet Search & Navigation (SLATEWeb), which indexes and categorizes corporate information sources. Featuring language detection and find-related concept search, this tool lets companies find documents that would otherwise be hard to locate. Categories are available to dynamically classify documents into a taxonomy or group structure (www.cognit.no).

Analysis and design necessary for building an expert system differ from those needed for a traditional data processing or information system. There are three major points of distinction that prevent expert systems development being subsumed under general frameworks of systems development (Curtis & Cobham, 2002):

1. *The subject matter is knowledge and reasoning as contrasted with data and processing.* Knowledge has both form and content, which need investigation. Form is connected with the mode of representation chosen — for instance, rules, semantic networks or logic. Content needs careful attention, as once the form is selected it is still a difficult task to translate the knowledge into the chosen representation form.
2. *Expert systems are expert / expertise orientated whereas information systems are decision / function / organization directed.* The expert system encapsulates the abilities of an expert or expertise and the aim is to provide a computerized replica of these facilities.

3. *Obtaining information for expert systems design presents different problems from those in traditional information systems design.* Many expert systems rely, partly at least, on incorporating expertise obtained from an expert. Few rely solely on the representation of textbook or rulebook knowledge. It is difficult generally to elicit this knowledge from an expert. In contrast, in designing an information system, the analyst relies heavily on existing documentation as a guide to the amount, type and content of formal information being passed around the system. In the development of an expert system the experts are regarded as repositories of knowledge.

Expert systems and traditional information systems have many significant differences. While processing in a traditional information system is primarily algorithmic, processing in an expert system includes symbolic conceptualizations. Input must be complete in a traditional system, while input can be incomplete in an expert system. Search approach in a traditional system is frequently based on algorithms, while search approach in an expert system is frequently based on heuristics. Explanations are usually not provided in a traditional system. Data and information is the focus of a traditional system, while knowledge is the focus of an expert system.

Expert systems can deliver the right information to the right person at the right time if it is known in advance what the right information is, who the right person to use or apply that information would be, and, what would be the right time when that specific information would be needed. Detection of non-routine and unstructured change in business environment will, however, depend upon sense-making capabilities of knowledge workers for correcting the computational logic of the business and the data it processes (Malhotra, 2002).

QUESTIONS FOR DISCUSSION

1. What kind of knowledge is created in each primary activity of the value shop?
2. How can expert systems support each primary activity of the value shop?
3. Why is efficient and effective interaction between information and knowledge so important for successful knowledge management systems?

Chapter 6.2
Business Processes and Knowledge Management

John S. Edwards
Aston Business School, UK

INTRODUCTION

Knowledge has been a subject of interest and enquiry for thousands of years, since at least the time of the ancient Greeks, and no doubt even before that. "What is knowledge" continues to be an important topic of discussion in philosophy.

More recently, interest in managing knowledge has grown in step with the perception that increasingly we live in a knowledge-based economy. Drucker is usually credited as being the first to popularize the knowledge-based economy concept, for example, by linking the importance of knowledge with rapid technological change in Drucker (1969). Karl Wiig coined the term knowledge management (hereafter KM) for a NATO seminar in 1986, and its popularity took off following the publication of Nonaka and Takeuchi's book "The Knowledge Creating Company" (Nonaka & Takeuchi, 1995). Knowledge creation is in fact just one of many activities involved in KM. Others include sharing, retaining, refining, and using knowledge. There are many such lists of activities (Holsapple & Joshi, 2000; Probst, Raub, & Romhardt, 1999; Skyrme, 1999; Wiig, De Hoog, & Van der Spek, 1997). Both academic and practical interest in KM has continued to increase throughout the last decade.

In this article, first the different types of knowledge are outlined, then comes a discussion of various routes by which knowledge management can be implemented, advocating a process-based route. An explanation follows of how people, processes and technology need to fit together, and some examples of this route in use are given. Finally there is a look towards the future.

BACKGROUND

Types of Knowledge: Tacit and Explicit

Nonaka and Takeuchi's book (1995) popularized the concepts of tacit and explicit knowledge, as well as KM more generally. They based their thinking on that of Michael Polanyi (1966), expressed most memorably in his phrase "we know more than we can tell".

It is, however, most important to realize that tacit and explicit knowledge are not mutually exclusive concepts. Rather, any piece of knowledge has both tacit and explicit elements, as shown in Figure 1. The size of the inner circle represents the proportion of tacit knowledge: the "tacit core" at the heart of the knowledge that we "cannot tell". Figure 1(a) shows a case where the knowledge is almost entirely tacit, as in riding a bicycle. Figure 1(b) shows mainly explicit knowledge, where the tacit core is very small, for example, how to process a claim for travel expenses in an organization. Figure 1(c) shows an intermediate case, such as making a piece of furniture, where substantial amounts of both tacit and explicit knowledge are involved.

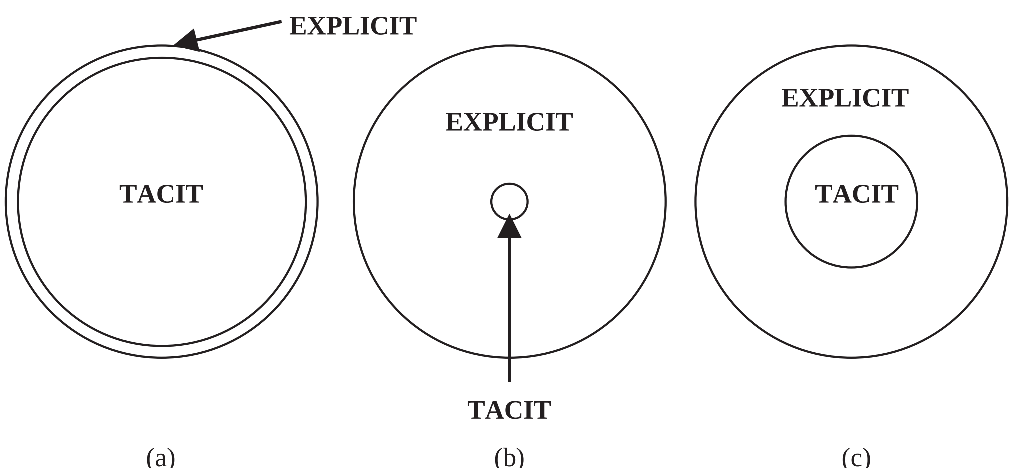
The Role of KM Systems

KM systems represent a deliberate, conscious attempt to manage knowledge, usually in an organization. Hansen, Nohria, and Tierney (1999) identified that there are two fundamental KM strategies, codification and personalization. Codification concentrates more on explicit knowledge (often relying very heavily on information technology), personalization more on tacit knowledge. Again, it is important to realize that these are not mutually exclusive, and that a strategy combining elements of both is likely to be the most successful.

ROUTES TO IMPLEMENTING KM

Many organizations have found it difficult to implement knowledge management systems successfully. Identifying "who", "what", and "why" – who is involved in knowledge manage-

Figure 1. The relationship between tacit and explicit knowledge



ment, what knowledge is being managed, and why is it being managed – can be problematic. The routes they have attempted to follow can be put into five generic categories, which will now be described.

Knowledge World Route

A substantial amount of the literature on knowledge management addresses knowledge at the level of the whole organization, or in a "world of knowledge" that is not specifically linked to the activities that a particular organization carries out. On an abstract level, such discussion of knowledge management can be extremely valuable. However, it has weaknesses in terms of practical implementation. For example, it is necessary not only to understand how individuals learn, but also how they learn in a given organization, and how the organizational systems may help or hinder the individual's learning process. The same issue applies even more forcefully to group learning, since the organization provides a crucial element of the group's context.

The practical focus in Nonaka and Takeuchi (1995) was very much on knowledge creation. As a result, organizations attempting to follow their principles for other aspects of KM, such as sharing or retaining knowledge, have sometimes found it difficult to make a specific connection from abstract ideas about knowledge to what the organization actually does, or could do, or should do. Often only the "why" is present, not the "who" or even the "what". Something more concrete is needed.

IT-Driven Route

This route assumes that the fundamental requirement is for the codification of as much knowledge as possible. Advocates of this approach sometimes refer to this as "extracting" the knowledge from the people who possess it; see for example Johannsen and Alty (1991). This is an inadvisable term to use, for two reasons. First, it is logically incorrect; their knowledge is being shared, not extracted. The people still have the knowledge after the "operation" has taken place. Second, it gives the people the wrong impression – that their knowledge is being taken away. This is not a recipe to encourage their co-operation. For an organization of any size, such a codification task evidently requires IT support, and the thrust of this route is that once the "correct" form of IT support for managing knowledge has been chosen, it is simply a matter of a great deal of hard work.

This technology-driven route only works well in a limited range of situations where the "what" questions are most important, for example, where the main KM task is managing the knowledge held by a company in the form of patents. In other circumstances, it may not achieve any improvement in knowledge management at all. One example of this from the author's experience is of a heavy manufacturing firm. Knowledge management in this organization was seen solely as an information systems issue; the KM group was part of the information systems department. The "solution" was seen in terms of the implementation of a knowledge sharing system based on Lotus Notes™. However, there was no real consideration as to who would share what knowledge or for what specific purpose. Consequently, the eventual use of the installed IT was poor; the only really successful use was by the knowledge management project team itself, where the "who" and "why" questions had been properly addressed, as well as the "what" questions.

Functional Route

An alternative route that has the potential to address the "who", "what" and "why" questions is to organize the implementation around the existing organizational structure. The most commonly found structural elements intended to facilitate learning and knowledge sharing in organizations are departmental groupings based on functions. These have clear advantages in terms of what might be termed professional development and allegiance. Davenport and Prusak (1998) report examples of successful knowledge transfer between groups of surgeons, and groups of tunneling engineers, among others. However, this functional route also has the disadvantage that it encourages the compartmentalization of knowledge. This problem can only worsen over time, as specialisations multiply and sub-divide. In addition, professional divisions can actively prevent sharing of knowledge. It has, for example, taken decades for hospital doctors in the UK National Health Service to allow other professionals such as pharmacists and physiotherapists to participate in decision-making about treatment of individual patients on an equal footing. On a wider scale, modern Western medical science has come to separate "diet" and "drugs", at least until the very recent past, in a way that Chinese medicine, for example, never has done. The problems of running an organization in this manner, and the "functional silos" mentality that tends to result, were recognized by authors such as Hammer (1990) as part of the business process re-engineering movement, when KM was in its infancy.

Therefore, although the functional route to implementation will allow some improvement in KM, progress may be limited by the characteristics of the existing structure, and in the worst cases (for example, where transferring knowledge between functions is the greatest KM issue in the organization) this route may be counter-productive.

People-Centric Route

A people-centric route to KM is the essence of the Hansen et al. (1999) personalization strategy. By definition, such an approach, appropriately implemented, will answer all the "who" questions that might be involved in KM. Thus in organizations where there is general consensus on "what" knowledge is important and "why" it needs to be managed, such a route should prove effective.

However, as was mentioned in the previous sub-section, organizations have become increasingly diverse in their activities, and in the range of specialized knowledge that they need to access. This means that consensus even on what knowledge the organization has, never mind what is important, may be difficult to achieve. On the one hand, it may not be easy for a particular specialist to fully appreciate "what the organization does". Equally, even the most conscientious senior manager will find it literally impossible to understand all the expertise and knowledge possessed by the specialists in his or her organization. To repeat the quotation from Hewlett Packard CEO Lew Platt (Davenport & Prusak, 1998, p. xii), "If HP knew what HP knows, we would be three times as profitable."

Business Processes Route

The managers in an organization have to translate the goals of any strategic program or initiative – whether on knowledge management or something else – into practical, implementable reality. In other words, to connect with "what the organization does". Various management thinkers have presented models of this, for example:

- Porter's (1985) value chain,
- Earl's (1994) view of core processes, the ones that are done directly for external customers,
- Beer's (1985) "System Ones", the systems that make the organization what it is,
- Core competences/competencies as espoused by Hamel and Prahalad (1994).

Although there are some significant differences between them, their common theme is that the effectiveness – indeed, the competitive advantage

– of organizations depends not on how they are structured, or on what resources they have, but on what they do. In the terminology of this article, this means their underlying business processes. Note that the term business processes is used throughout, but such processes exist equally in not-for-profit organizations.

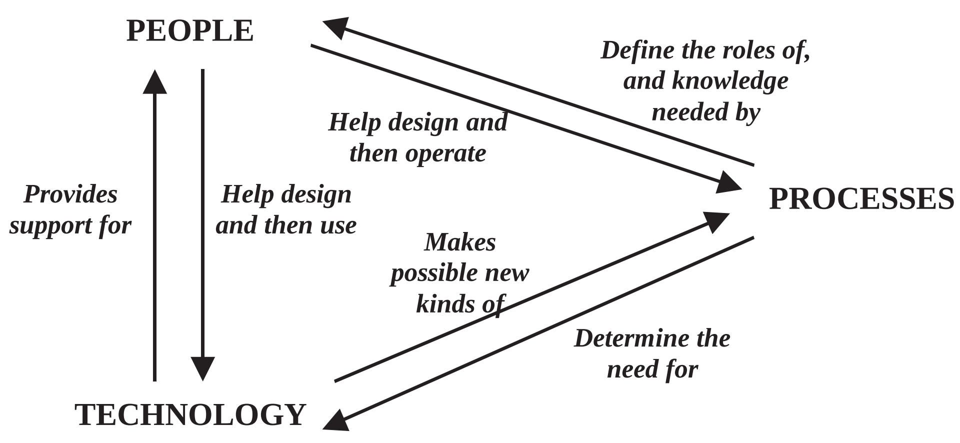
Business processes possess five characteristics that justify their use as a foundation for knowledge management in organizations.

1. Business processes have identifiable customers, whether internal or external. Knowledge is of little relevance unless put to use for a customer of some kind.
2. Business processes cut across organizational boundaries. Knowledge does not need to, and does not, obey the artificial boundaries within an organization.
3. Business processes consist of a structured set of activities. Choosing the appropriate way to structure activities is an important part of the knowledge.
4. Business processes need to be measured. Without some form of measurement as a comparison, knowledge cannot be validated.
5. While the parts of a business process are important, the overriding requirement is that the overall process works. Valid knowledge in an organizational context must take a holistic view.

An additional argument (Braganza, 2001) is that viewing knowledge management in terms of an organization's processes gives a much-needed demand-side view of knowledge. This is complementary to the supply-side view of knowledge that stems, for example, from considerations "of data leading to information leading to knowledge". Beer and Earl particularly concentrate on this demand-side perspective. Beer indeed goes even further, to include the informal processes and activities of the organization as well as the more formalized ones.

Completing this argument for a greater use of the business processes route, the knowledge that an organization requires must, logically, be related not just to what that organization does, but also to how it does it. Thus, people in organizations

Figure 2. People, processes and technology in a KM system



should think about this knowledge, and how to manage it, by reference to that organization's business processes.

PEOPLE, PROCESSES AND TECHNOLOGY

From the earlier discussion, it may be seen that, whichever route is chosen, effective KM requires the consideration of both tacit and explicit knowledge. The need is to coordinate people, processes and technology successfully. The interaction of these three elements is shown in Figure 2.

Not only does a knowledge management system consist of more than technology, it is important to realize that the technology used to support KM does not have to be "KM software". Recent studies have found that generic software such as e-mail or an Intranet may be at least as important as specific software (Edwards, Shaw, & Collier, 2004 (to appear); Zhou & Fink, 2003).

KM BY A BUSINESS PROCESSES ROUTE

As it has so far been less frequently attempted than the other routes, some examples of organizations that have implemented KM by a business processes route will now be given.

Unisys (Wizdo, 2001) have embarked upon a company-wide knowledge management initiative with an explicit process focus. Its objectives include:

- Accelerating the speed and scope of organisational learning,
- Decreasing the time it takes to reach critical mass in new markets,
- Uniting cross-boundary groups,
- Increasing innovation in product and process.

Wizdo identifies three increasingly ambitious categories of "transformation" in business: efficiency, innovation and re-invention. The Unisys knowledge management program regards a focus on processes as essential in achieving the two "higher" categories.

Objective Corporation (Fisher, 2001) changed most of their processes over a period of some five years. They found that such an emphasis not only improved knowledge management within the business, but also had a significant impact on the performance of the business itself. In this case, it was most likely the effect of a coherent training programme, with an emphasis on understanding, increasing the overall organisational performance through the people involved operating more effectively.

Both of these examples involved substantial use of information technology. However, that does not have to be the case. The author's group has been working with a component manufacturer in the aerospace industry, whose KM initiative also has an explicit process focus. Typically, their manufacturing processes use a machine operated by one person. The operators' choice of the best way to retain and share knowledge does not use IT at all (except for a word processor). The agreed best operating procedure, with illustrations, is put on a laminated sheet of paper mounted near the machine, which includes the names of the people who had contributed to designing the procedure. A suitable pen is provided to annotate the laminated sheet. At regular intervals, office staff come round to produce a revised version of any of the "Standard Operating Sheets" that have been annotated.

FUTURE TRENDS

A further justification for the use of business processes as the foundation for implementing knowledge management is that they are now becoming part of the mainstream of management thought. For example, the latest version of the ISO9000 family of standards for Quality Management Systems, including ISO9001: 2000, is constructed on the basis of a "process approach". The ISO9000 term realisation process is equivalent to Earl's core process or Beer's primary activity as discussed earlier. Significantly, the latest editions of strategic management textbooks (Johnson & Scholes, 2001) typically discuss the business process view of organizations, whereas earlier ones did not.

It seems clear, therefore, that the business processes route to implementing knowledge management is likely to become more common in future, and that this will encourage the development of ever more appropriate information technology for supporting it. Equally, new information technologies will enable new types of process. Intelligent agents, smart cards and "picture phones", for example, all offer different possibilities for supporting KM which have only just begun to be considered.

CONCLUSION

This article has considered the implementation of knowledge management systems by looking at five different generic routes towards achieving it: knowledge world, IT-driven, functional, people-centric and business processes. While each of these routes has some merits, it has been argued that the business processes route offers potential for the greatest integration between knowledge management and "what the organization does". It is, thus, likely to be increasingly common in the future.

Chapter 6.3
Creating Knowledge for Business Decision Making

Shiraj Khan
University of South Florida (USF), USA

Auroop R. Ganguly
Oak Ridge National Laboratory, USA

Amar Gupta
University of Arizona, Tucson, USA

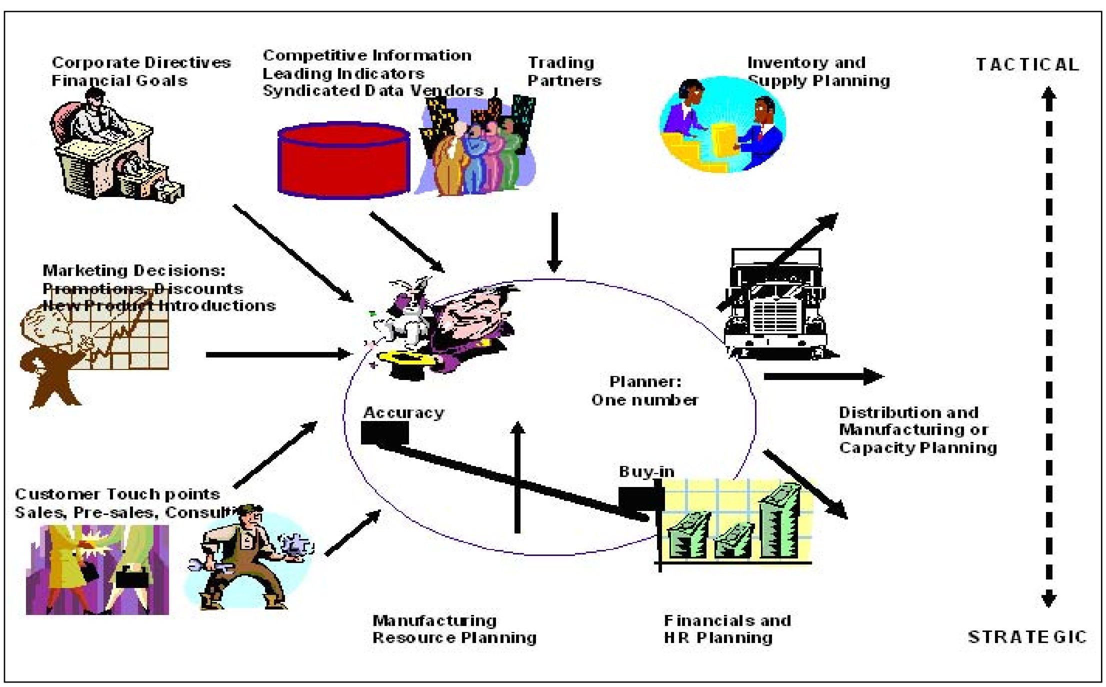
INTRODUCTION

Business forecasts and predictive models are rarely perfect. A paraphrase of the Nobel winning physicist Neils Bohr is apt in this context: Prediction is difficult, especially if it is of the future. However, executives and managers in enterprises ranging from retail and consumer packaged goods to high tech and semiconductors have to resort to forecasting and planning about the future. Phenomenal growth and spectacular failures are associated with organizations depending on their ability to understand market directions and respond quickly to change. Relatively minor improvements in forecast accuracy and predictive modeling at detailed levels can translate to significant gains for the enterprise through better strategic decisions, continuous performance management, and rapid translation to tactical decisions. The key to these processes is the knowledge-based enterprise, which can effectively utilize information from multiple sources as well as the expertise of skilled human resources, to develop strategies and processes for creating, preserving, and utilizing knowledge. These efforts, spanning revenue-generation endeavors like promotion management or new product launch, to cost-cutting operations like inventory planning or demand management, have significant impacts on the top and bottom lines of an enterprise.

Advances in scalable mathematical model-building, ranging from advanced statistical approaches and data mining (DM) to operations research (OR) and data assimilation, can extract meaningful insights and predictions from large volumes of data. Information technologies and e-business applications can enable a degree of process automation and collaboration within and among enterprises. Enterprises of the new millennium can truly take advantage of scalable but cutting-edge data-dictated approaches to understand the past and predict the future, and then focus valuable planner resources on key value drivers or exceptional situations through human-computer interaction, which in turn utilizes tools like online analytical processing (OLAP) and automated or planner-driven decision support systems (DSSs).

Analytic information technologies enable managers of the knowledge-based enterprise to choose the path to new revenues, new markets, good customer service, and competitive advantage over their rivals. The ability to produce "one-number forecasts" that reconcile information from multiple sources and blend disparate points of view is a critical first step for enterprise-scale strategic, operational, and tactical planning (see Figure 1). However, this is a challenging process, especially in recent years owing to short product lifecycles, mass customizations, and dynamic markets, combined with the ever-increasing service expectations of consumers and trading partners on the one hand, versus the need to reduce operating and inventory costs on the other. The need to manage product lifecycles and promotions or pricing decisions, factor in market signals or competitive intelligence, analyze consumer behavior, and achieve buy-in from multiple participants within and across enterprises has fundamentally changed the way the forecast

Figure 1. "One-number forecasting" for an enterprise

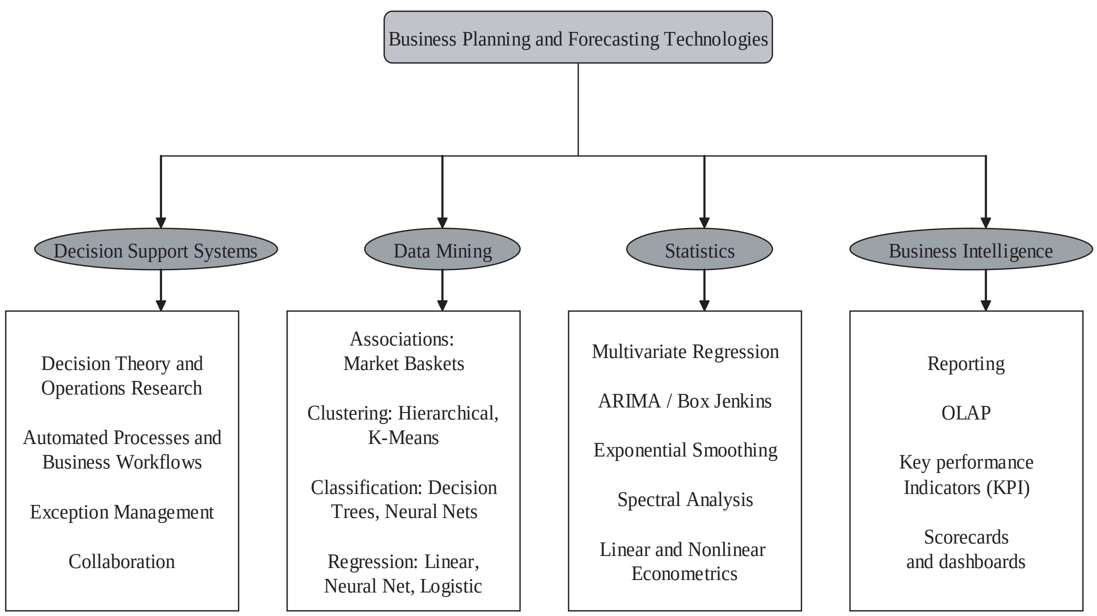


generation process is perceived. Corporate data repositories, collaborative information technologies and processes, syndicated data vendors, and the Internet provide large volumes of historical and real-time information. The challenge is to acquire, manage, analyze, and reconcile the information for knowledge extraction and predictive purposes in an optimal fashion.

BACKGROUND

Data-derived knowledge adds value to a business through products, processes, and better decision making. Davis and Botkin (1994) describe six features of knowledge-based businesses. Manual analysis, evaluation, and interpretation are the most common approaches of creating knowledge from digital data. Volumes of information can grow rapidly, as every communication, interaction, and transaction produces new data. Thus, manual data analysis quickly becomes slow and inexpensive, and is becoming obsolete in applications like retail, telecommunication, health care, marketing, the natural sciences, and engineering. With the advent of analytical information technologies, researchers and engineers have been exploring the possibility of constructing data-dictated models by mining large-scale corporate or scientific data repositories. These approaches combine data management technologies and innovative computational or visualization methods with analytical techniques drawn from the diverse fields of statistics, machine learning, and artificial intelligence (Fayyad & Uthurusamy, 2002; Hand, Mannila, & Smyth, 2001). Many organizations have invested in automated analysis techniques (Ganguly, Gupta & Khan, 2005) to unearth meaningful patters and structures from millions of records with hundreds of attributes. Automated analytical approaches like data mining (DM) and statistics are combined with planner-driven

Figure 2. Examples of technologies used for business planning and forecasting



analytic systems like decision support systems (DSSs) and business intelligence (BI) (see Figure 2). These are being integrated with transactions systems, producing insights into how effectively a company does business, responds to or forecasts trends, understands and reacts to market conditions, and develops customer-focused products and services. The knowledge mined from objective data and generated by human experts is encapsulated through adaptive information systems. This knowledge becomes an asset in current business conditions where supply-driven "push" of products and services has yielded to demand-driven "pull" as well as one-on-one or mass customizations. Management scientists (Aviv, 2001; Cachon & Lariviere, 2001; Chen, Drezner, Ryan, & Simchi-Levi, 2000; Lee & Whang, 1998) have theoretically demonstrated the value of collaborative forecasting on the supply chain and modeled the impact of information sharing among trading partners as well propagation of uncertainty (Gilbert, 2005). A research report by the analyst firm Gartner (Peterson, Geishecker, & Eisenfeld, 2003) indicated the opportunity, need, and confusions surrounding the generation of "one-number forecasts," and highlighted the "opportunity for intra-enterprise forecast improvement."

MAIN FOCUS OF THE ARTICLE: TOOLS AND PROCESSES FOR CREATING KNOWLEDGE FOR BUSINESS DECISION MAKING

Data Management

Data warehousing provides an infrastructure to process vast amounts of data, as well as discover and explore important business trends used for knowledge creation and decision making. Inmon (1992) and Kimball (1996) suggested a data warehouse that integrates data from diverse operational databases to aid in the process of decision making. A data warehouse is the first component of a knowledge system where all available information is acquired from online transactional processing (OLTP) sources, cleansed, stored and processed, and made available for use by knowledge creation systems like business planning and forecasting. The information might range from point of sales (POS) data for the retail industry, to income, marital status, location, demographics, and credit history for a financial or a phone company. A few key data warehousing activities include data cleaning or scrubbing, data transformation, data condensation, data aggregation, data refreshing, data reporting, and metadata synchronization.

Planning and Forecasting Tools

Businesses need to react quickly to evolving market conditions, especially in these days of mass customizations, global competitions, and corporate consolidations. As early as 1999, Forrester Research and Meta Group reported that 30% of firms' data warehouses contained over one trillion characters of data worldwide (Bransten, 1999), and the total sum of data is increasing every hour. Creation of knowledge from this data efficiently through analytical information technologies, and utilizing the knowledge for driving business decisions quickly, is a key requirement.

Data mining (DM) refers to diverse technologies suited for extracting knowledge and insights from vast quantities of data in an efficient manner. Most DM tools use traditional statistical techniques coupled with highly efficient pattern recognition and machine learning algorithms (Breiman, Friedman, Olshen, & Stone, 1984; Ganguly, 2002; Quinlan, 1992). DM methods are used in conjunction with database-centric approaches for knowledge discovery in databases (KDD) (Fayyad, Shapiro, & Smyth, 1996). The type of knowledge created by DM and KDD tasks determines the categories into which these tasks are grouped together (Table 1). Heinrichs and Lim (2003) gave an insight into integrating Web-based DM tools with business models to

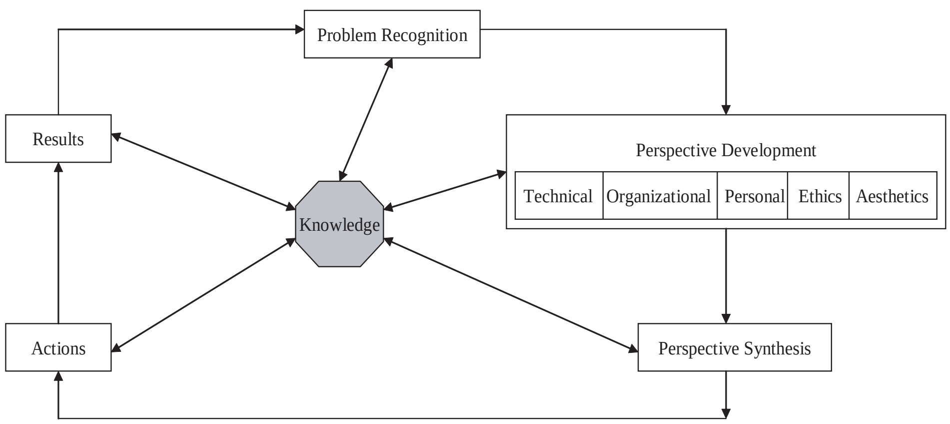
Table 1. A taxonomy of data mining tasks (Shaw, Subramaniam, Tan, & Welge, 2001)

Dependency Analysis • Associations • Sequences *Class Identification* • Mathematical taxonomy • Concept clustering *Deviation Detection* • Anomalies • Changes	*Concept Description* • Summarization • Discrimination • Comparison *Data Visualization* • Pixel oriented • Geometric projection • Graph based

understand changing customer requirements, monitor product performance, uncover market opportunity, and manage customer relationships in real-time. Web-based software tools help skilled knowledge workers identify and understand their competitors' strategy, thus preparing them to respond to potential competitive threat quickly (Lim, Heinrichs, & Hudspeth, 1999).

The ability to anticipate, react, and adapt to market trends and changes, through appropriate business strategies and implementation, are the characteristics of a successful company. Given the uncertainties inherent in the forecasting planners, some companies rely on the "gut feel" of senior decision makers and executives. However, as business conditions are getting more dynamic, it

Figure 3. A new decision paradigm for DSS (Courtney, 2001)



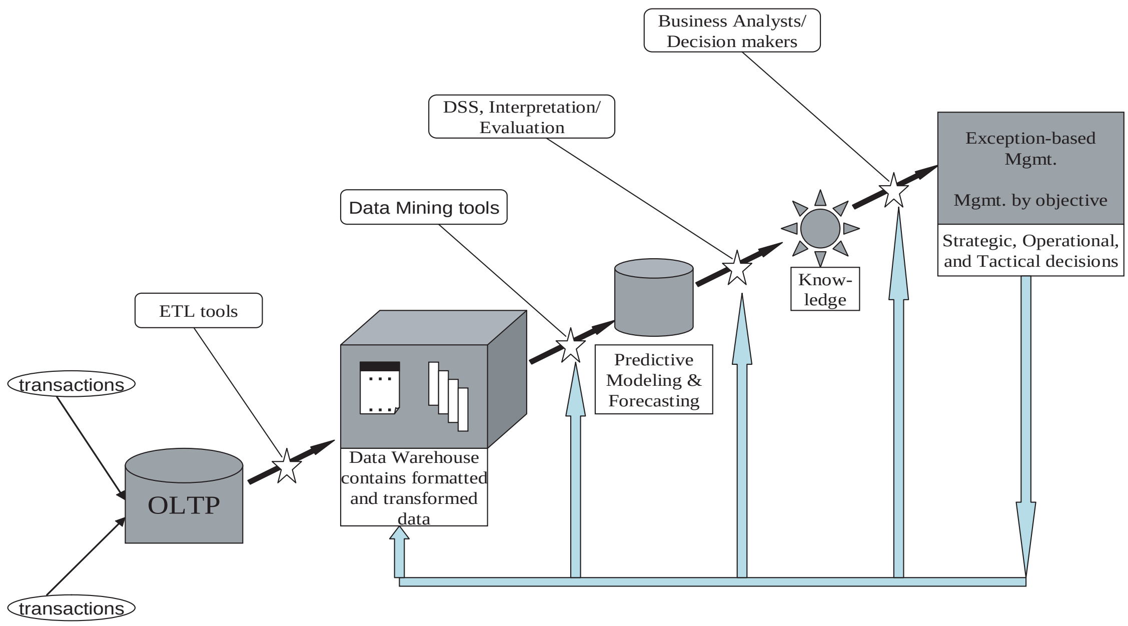
is becoming more and more important to continuously visualize and monitor the state of business through tools like DSS and BI, and to develop predictive modeling capabilities through tools like DM and KDD, for creating knowledge and insights about the future. Originally, the concept of DSS was provided by Gorry and Mortan (1971), who integrated Simon's description of decision types like unstructured, semi-structured, and structured (Simon, 1960) and Anthony's categories of management activities like strategic planning, management control, and operational control (Anthony, 1960). Courtney (2001) described a new paradigm for DSS where a centralized knowledge model is influenced by every step of the process. The model recognizes the problem, creates perspectives to gain insight into the nature of the problem, finds its possible solutions, and continually updates itself. Today, a number of fields like database technologies, management science, operations research, cognitive science, AI, and expert systems (Bonczek, Holsapple, & Whinston, 1981), in addition to software engineering, assist in the design of DSSs. Management science and operations research tools like linear and nonlinear programming, optimization, Monte Carlo simulation, and dynamic programming help to develop mathematical models for use in model-driven DSSs. The use of the Internet and communication technology in DSSs allows organizations to become global and connects suppliers, producers, and customers through collaborative planning, forecasting, and replenishment (CPFR) processes. This helps to achieve full collaboration, develop and share "one-number forecasts" through the extended ("n-tier") supply chain, thus helping in the sales and operations planning (S&OP) process, improving forecasting accuracy, reducing inventory levels, improving customer service levels, designing effective promotions, and maximizing profits through revenue generation and cost cutting.

BI tools like querying or reporting are used to pull information from data stores and present it to end users in the language and structure of a specific business. Key performance indicators (KPIs) are used to monitor critical factors within the business on an ongoing basis. OLAP tools specify fast, consistent, and interactive ways of analyzing multidimensional enterprise data and providing end users analytical navigational activities to gain insights into the knowledge contained in large databases. Drill-down, slice-dice, reach-through, and rotation are the activities of OLAP used for many business applications, including product performance and profitability, effectiveness of a sales program or a marketing campaign, and sales forecasting.

Planning and Forecasting Processes

Extract, transform, and load (ETL) tools extract data from heterogeneous sources like OLTP systems, syndicated data vendors, public domain sources like the Internet, legacy systems, real-time data repositories maintained by business analysts, decision makers, internal or external collaborators, consultants, and executives for business planning and forecasting (see Figure 4) applications (Gung, Leung, Lin, & Tsai, 2002; Peterson et al., 2003; Wang & Jain, 2003; Yurkiewicz, 2003). The data is crunched and transformed into a standard or desired format and then loaded into a data warehouse or a data mart. The data is further processed inside the data warehouse to make them available for online analysis and decision support. DM and KDD tools access the data from the data warehouse to discover new patterns and fit models to predict future behavior. The results of predictive models are presented and utilized in the form of structured business workflows, interactive formatted data models for visualization, graphic models (Pearl, 1988; Whittaker, 1990), planning cycles, and automated predictive and forecasting outputs which can be used as baselines by business planners and decision makers. DSS and BI tools like OLAP (Hammer, 2003) are utilized to interpret and evaluate predictive and forecasting

Figure 4. An overview of the steps involved in business planning and forecasting



models for creating knowledge about the future, which in turn helps analysts and decision makers to make strategic and tactical decisions.

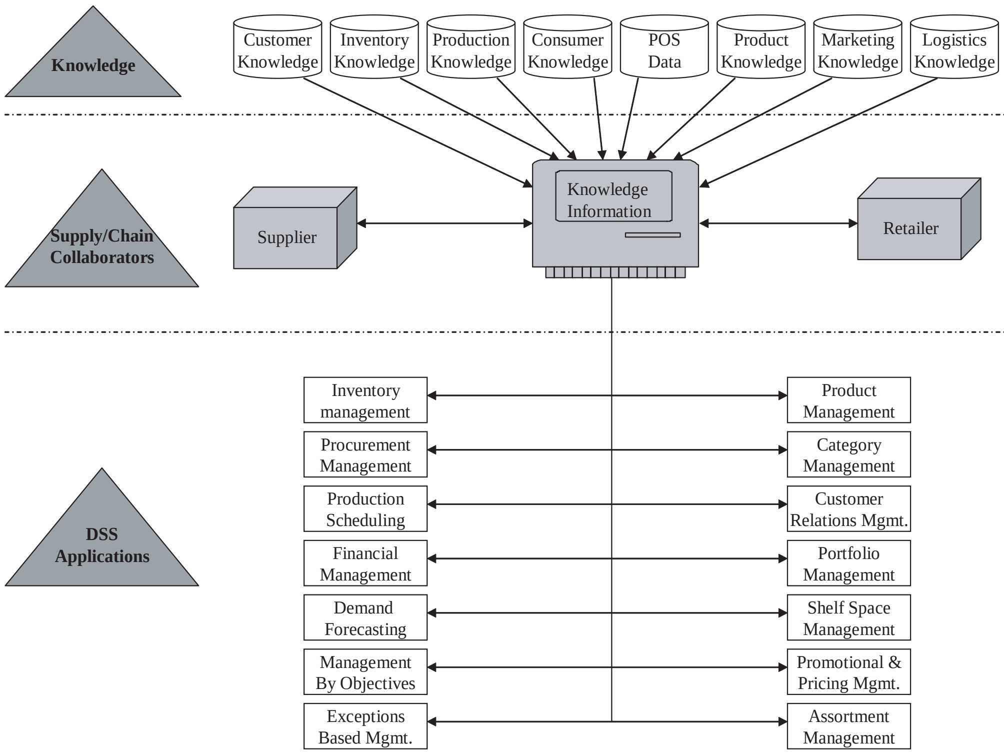
Data Mining Technologies and Decision Support Systems

Managers and business planners use DMT to extract meaningful patterns about their business and customers which can be interpreted as useful or interesting knowledge. Machine learning and pattern recognition algorithms, along with statistical methods like classification, clustering, and regression, are used to fit a model to data, to find structure from data, and derive high-level knowledge from the voluminous data present in the data warehouse.

Predictive and forecasting models generated by DM or KDD tools are interpreted and analyzed by business analysts, planners, and executives using DSS and BI tools to understand trends, manage metrics, align organizations against common goals, develop future strategy, and drive action. In this highly competitive world where different manufacturers offer the same category of products, trade promotions and advertisements can result in larger return on investment (ROI) from the perspective of a CPG company if the marginal increase in promotional sales is caused by increase in brand share. There is a need to distinguish these from natural variability in demand (e.g., seasonal, weather, economic, demographic, or other effects), as well as ancillary effects like cannibalization, drag, or pre- and post-sales dips.

A process described in Figure 5 involves a knowledge information system where all partners can access, view, and modify the same data and knowledge to come up with “one number,” demand forecasts or a common plan that is shared through the extended enterprise, thus resulting

Figure 5. Inter-enterprise DSS in supply chain management

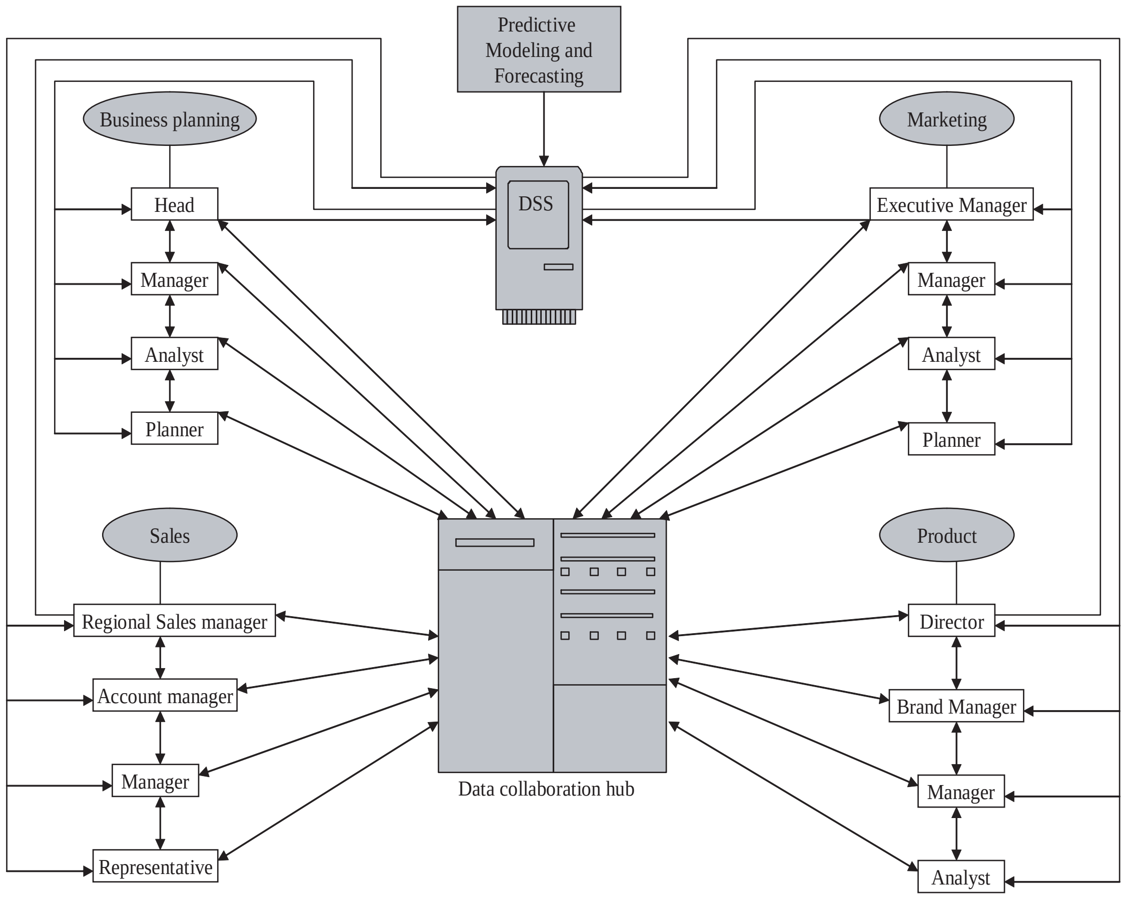


in improvements in forecasting accuracy, shorter lead times, good customer service levels, reduction of inventory levels, and maximum profits.

An intra-enterprise process described in Figure 6 having DSSs used by sales people to understand sales patterns, product people for product lifecycle management, marketing people for managing promotions or introducing new products, and business people for making strategic, operational, and tactical decisions. Each department analyzes and evaluates the information stored in the DSS for creating knowledge about the future and stores this knowledge in the system. A centralized data "collaboration hub" collects every kind of information from business, marketing, product, and sales so that every department can also access other department's information for its own use. The following activities are performed by different departments to create knowledge about the future:

- Marketing: Marketing people want to know: (1) which products need to be promoted, where, when and at what price; (2) which existing products need to be phased out and when; and (3) when and where new products need to be introduced. They might want to interact with sales people to know about historical sales or customer behaviors, product people to know the stage of the product lifecycle, and business people to decide if the promotions would be effective and result

Figure 6. Intra-enterprise DSS in the CPG company



in larger ROI or whether to launch a new product. They perform simulations, 'what if' analysis, and scenario planning to ensure the effectiveness of promotions or advertisements. They can create knowledge in terms of the effectiveness of promotions or advertisements on the sales, and determining the best time to phase out existing products and introduce new products.

- Sales: The sales people might want to interact with product people to understand the behavior of products, marketing people to know about promotions, and business people to understand the impact on sales based on their decisions. The knowledge created by them can be sales variability due to seasonality, customer behaviors, and change of sales patterns due to promotions or advertisements.
- Product: The product people might need to get POS data from sales to know the stage of the product lifecycle, or interact with marketing and business people to know about promotions and new products. They

can create knowledge in terms of the product behaviors at different stages of the product lifecycle.

- Business: Business planners and executives (e.g., in a CPG company) analyze the results of predictive models for promotional and baseline demand forecasts to design promotional strategies that maximize profits and ROI. The definition of maximized profits can differ, depending on whether the promotions are designed from longer-term considerations like brand acceptance or shorter-term considerations like the need to sell excess inventory. They get historical sales data or information about new opportunities from the sales department, product information from the product department, and information about market conditions as well as corporate policies like promotions or advertisements from the marketing department to develop future promotional strategy. They need to know if the promotions would result in lifts (e.g., increased demand due to a promotion on a specified product), drag effects (e.g., increase in sales driving the sales of associated product), and cannibalization (e.g., increase in sales reducing the sales of other products). They need to blend the natural variability of demand (e.g., seasonal and cyclical trends) with market information (e.g., competitive landscape, economic drivers, customer forecasts, demography) with direct and indirect promotional impacts. They use BI tools like querying and reporting for pulling and presenting the data relevant for planning, like past sales patterns, seasonal and cyclic patterns, economic indicators, weather patterns, demographics, and sales patterns of competitive products (and competitive promotions, if such information is available), as well as OLAP for viewing multidimensional data to get a better understanding of the information. OLAP-related activities have been described by the OLAP council (1997). Broadly, OLAP tools are well suited for management by objectives and management by exceptions.

The analysis and evaluation of information through mathematical models and by business analysts and planners produce a wealth of knowledge which can be stored in the system for future use. For example, waterfall accuracy charts can be used to compare forecasts with actual values, as they become available, for continuous evaluation and improvement. Similarly, audit trails and comments entered by planners during manual adjustments can be preserved and mined for evaluation and use in forecasting. The results of prior forecasts and the previous insights of knowledge workers are key building blocks in the process of knowledge creation about the future.

FUTURE TRENDS

The pace of rapid industry consolidations suggests that marketplaces of the future may well be characterized by a few leaders in each vertical, and laggards who run the risk of eventually fading into oblivion. In verticals like retail and CPG where the leaders have probably achieved long-term sustainability, one of the key differentiators between the leaders and the laggards has been the ability to create, retain, and utilize knowledge about the future through forecasting, predictive modeling, and planning efforts. Giants in retail and CPG are known to be superior to their peers in areas like demand forecasting, inventory management, promotion planning, pricing strategies, store and factory placements, as well as product allocations or placement. These leaders have developed the best analytical models, as well as planning and execution systems, in the business, and strive to maintain their superiority. This is indicated by the strong analytical and planning groups in these enterprises, as well as by developments like the use of radio frequency ID (RFID) tags on each product mandated by large retailers. Similar developments are expected in the high-tech industry in the longer term. While innovative newcomers are probably more likely to emerge in these areas even during relatively mature stages, the industry is expected to consolidate around leaders who are not necessarily (or only) the active pioneers and state-of-the-art researchers, but who (also) have the best processes for knowledge creation, retention, and utilization. The advent of globalization will enhance this trend of consolidation around a few large multinationals, who will strive to maintain their superiority by creating knowledge about the future. Mathematical models for extraction of knowledge from vast quantities of information, as well as efficient processes that enable interaction among planners and computers within and among organizations and enterprises, are expected to be ubiquitous in this business scenario. The competition among multinationals to maintain their edge over rivals and innovative challengers may well spawn the age of ubiquitous analytical information technologies, which encapsulates data mining, knowledge discovery, predictive modeling, and decision support.

CONCLUSION

The ability to create, preserve, and utilize knowledge about the future for efficient decision making is a key to competitiveness and survival for a business in this age of globalization, Internet commerce, and rapidly fluctuating economies. Forecasting and predictive modeling is a challenging process and is never perfect. However, even minor improvements can lead to significantly better tactical and strategic decisions, and improve the ability of an enterprise to react quickly to change. The tools, technologies, and processes that enable knowledge creation about the future have been presented in this article. The ability to create knowledge by meaningfully blending data-dictated predictive modeling with the expertise of business planners and executives, as well as retaining and utilizing this knowledge effectively, remains a key requirement for efficient business processes and better decision making, which in turn can make the difference between the leaders and laggards of an industry vertical.

Chapter 6.4
Integrated Modeling

Thomas Hädrich

Ronald Maier
Martin-Luther-University Halle-Wittenberg, Germany

INTRODUCTION

Modeling is a key task in order to analyze, understand, and improve business processes and organizational structures, and to support the design, implementation, and management of information and communication technologies in general and knowledge management systems (KMSs) in particular. Process-oriented knowledge management (Maier, 2004; Maier & Remus, 2003) is a promising approach to provide the missing link between knowledge management (KM) and business strategy, and to bridge the gap between the human-oriented and technology-oriented views (e.g., Hansen, Nohria, & Tierney, 1999; Zack, 1999). However, existing modeling approaches for business processes, including their extensions for KM, still lack concepts to support knowledge work, which is often unstructured, creative, and learning and communication intensive. Recently, the activity theory has been proposed to provide concepts to analyze knowledge work (e.g., Blackler, 1995), but it has not yet been integrated with business process modeling for designing KM initiatives and KMSs. The following sections analyze the characteristics of knowledge work, distinguish important perspectives for modeling in KM, and discuss extensions of process modeling approaches including activity modeling. Then, the process-oriented and the activity-oriented perspectives on knowledge work are compared and connected by means of the concept of knowledge stance.

BACKGROUND

Knowledge work can be characterized by a high degree of variety and exceptions, strong communication needs, weakly structured processes, an increasing importance on teamwork in the form of project teams, networks, and communities, and it requires a high level of skill and expertise. Inputs and outputs of knowledge work are primarily data, information, or knowledge. Knowledge comprises observations that have been meaningfully organized and embedded in a context through experience, communication, or inference that an actor uses to interpret situations and to accomplish tasks (based on Maier, 2004). Knowledge work consists of a number of specific practices, for example, expressing or extracting experiences, monitoring, translating, and networking (Schulze, 2003).

From an ICT perspective, the main changes in the requirements posed by knowledge work occur due to the considerably higher complexity of data and the focus on organization-wide and interorganizational communication, cooperation, and mobility of knowledge workers. The storage, handling, and sharing of semistructured data require additional ICT systems, such as document , content, and knowledge management systems. Modeling has focused largely on data (entity relationship modeling), objects and classes (object-oriented modeling), and business processes (business process modeling). Knowledge work requires content-, user-, and communication-oriented modeling techniques that show what persons, communities, topics, tools, rules, and other activities and processes are involved, and thus demands concepts and modeling techniques that extend business process modeling to cover these aspects.

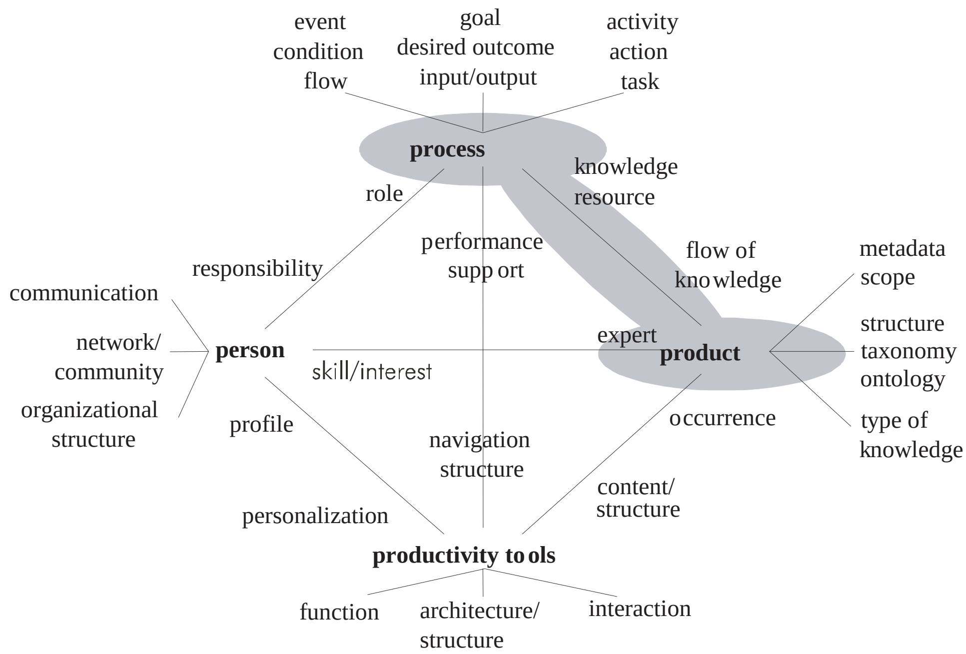
PERSPECTIVES FOR MODELING IN KM

Models are representations of a selected portion of the perceived reality of an individual or a group of observers. The design of KM initiatives requires modeling concepts for (a) processes that describe the organizational design, that is, knowledge tasks, flows, roles, and resources, (b) persons by capturing facts about people, that is, their skills, communication, and cooperation in networks and communities, (c) products, that is, the type of knowledge, structures, taxonomies, ontologies, and metadata, and (d) productivity tools, that is, the architecture, functions, and interaction of ICT tools in support of KM (see Figure 1).

A large number of modeling approaches, methods, and techniques have been developed in the literature (e.g., Balzert, 2001). Each of these approaches predominantly focuses on one of the dimensions in Figure 1. For process-oriented KM, concepts are needed that combine process modeling with the other perspectives, especially with knowledge products and the knowledge-intensive tasks being part of knowledge work.

In recent years, many organizations have applied concepts of business process reengineering (e.g., Davenport, 1993; Hammer & Champy, 1993), and a number of methods and techniques to support business process modeling have been proposed in the literature. Approaches for process modeling distinguish between three levels of granularity that are interconnected: (a) Value chains (Porter, 1985) arrange value-adding activities, (b) business processes connect functions, and (c) work flows orchestrate tasks. As process modeling is a complex task that requires computer support in order to be an economically feasible approach, most methods are applied with the help of a corresponding tool. Examples are ADONIS (Junginger, Kühn, Strobl, & Karagiannis, 2000), ARIS (Scheer, 2001), IEM (Heisig, 2002; Spur, Mertins, & Jochem, 1996), MEMO (Frank, 2002), PROMET (Österle, 1995), SOM (Ferstl & Sinz, 1994), UML-based process modeling (Oestereich, Weiss, Schröder, Weilkiens, & Lenhard, 2003), and the IDEF family of modeling methods (http://www.idef.com). Moreover, there is a number of frameworks and reference models for the definition of work flows that implement business

Figure 1. Perspectives for modeling in knowledge management (based on Maier, 2004)



processes (see, e.g., Kumar & Zhao, 1999; WfMC, 2001). The methods differ in formality, semantic richness, and understandability.

Recently, a number of authors have proposed extensions that model (some of) the specifics of KM. Examples are the extensions to ARIS (Allweyer, 1998), PROMET®I-NET (Bach & Österle, 2000; Kaiser & Vogler, 1999), GPO-WM (Heisig, 2002), KMDL (Gronau, 2003), Knowledge MEMO (Schauer, 2004), and PROMOTE (Hinkelmann, Karagiannis, & Telesko, 2002; Karagiannis & Woitsch, 2003). The main extensions are the introduction of additional object types like knowledge objects, that is, topics of interest, documented knowledge, individual employees, and skills, as well as the introduction of model types like knowledge structure diagrams, communication diagrams, and knowledge maps. More detailed aspects of knowledge-intensive tasks have been implemented in tools for flexible workflow management (Goesmann, 2002). Examples are Bramble (Blumenthal & Nutt, 1995), KnowMore (Abecker, Bernardi, Hinkelmann, Kühn, & Sintek, 1998), MILOS (Maurer & Dellen, 1998, Work-Brain (Wargitsch, Wewers, & Theisinger, 1998), and Workware (Carlsen & Jorgensen, 1998).

The extensions can be classified according to whether they target the abstract level of KM-related organizational design, for example, ARIS and GPO-WM, or whether they target the detailed level of KM-related work flows, for example, PROMOTE and tools for flexible workflow management. None of the extensions provides concepts to model all four perspectives of persons, process, product, and productivity tools, and particularly their relationships. The added concepts describe a portion of the context of knowledge work, but they are not suited to model the often unstructured and creative learning and knowledge practices and their links to business processes.

For example, in the case of ARIS, the added object types “documented knowledge” and “knowledge category,” as well as the model types “knowledge structure diagram,” “knowledge map,” and “communication diagram,” give a rough impression of the knowledge needed and produced in each step of a business process, the general knowledge structure, the required skills of the roles, as well as their communication. However, neither of these concepts indicates which knowledge-related actions are possible or required in the process step, with which communities and other processes or activities. Thus, the concepts only describe a fragment of knowledge work, and it remains unclear when and how knowledge is created and applied, and specifically in what occasions and in what context knowledge-oriented actions should be supported, for example, by KMS functions.

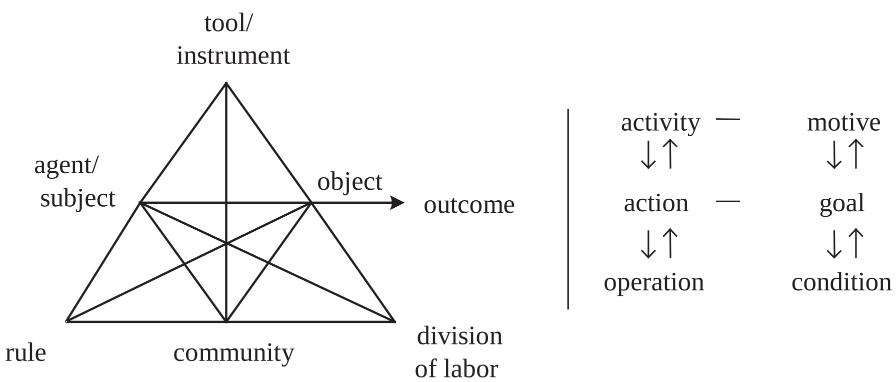
The activity theory has been proposed to guide the analysis of knowledge work (see, e.g., Blackler, 1995) and to design information systems, especially group support systems and KMS (see, e.g., Clases & Wehner, 2002; Collins, Shukla, & Redmiles, 2002; Hasan & Gould, 2003; Kuutti, 1997; Sachs, 1995). It places the focus on activities, not to be confused with activities in Porter’s (1985) value chain and activities in UML.

The core idea of the activity theory is that human activity is a dialectic relationship between individuals (called agents or subjects) and objects (the purpose of human activity) that is mediated by tools and instruments like cultural signs, language, and technologies in so-called activity systems (see Figure 2, left side). The subject is a part of communities and its connection to them is determined by implicit or explicit social rules. A division of labor (e.g., role system) defines the relation of these communities to the object of the activity system (Engeström, 1987). Intended or unintended results are the outcome of the activities’ transformation process.

This is a significant contribution to KM (Hasan & Gould, 2003) since the acquisition of knowledge in modern learning theories is not a simple matter of taking in knowledge, but a complex cultural or social phenomenon (see, e.g., Blackler, 1995).

Activities have a hierarchical structure (see Figure 2, right side). First, the activity is driven by a common motive that reflects a collective need and the reason why the activity exists (Engeström, 1999). Second, an activity is accomplished by

Figure 2. Model and levels of the socially-distributed activity system (Blackler, 1995; Kuutti, 1997)



actions directed to goals coupled with the motive of the activity. Actions consist of an orientation and an execution phase: The first comprises the planning for action, and the latter is its execution by a chain of operations (Kuutti, 1997). Repeated exercise leads to better planning of the action that then can be conducted more successfully. With enough practice, the separate planning phase becomes obsolete, and actions collapse into operations due to learning and routinization. Third, operations are executed under certain conditions. They are the most structured part that is easiest to automate. An important feature of the activity theory is the dynamic relationship between the three levels. Elements of higher levels collapse to constructs of lower levels if learning takes place. They unfold to higher levels if changes occur and learning is necessary.

An example is the activity of learning to drive a car (Leontiev as cited in Hasan & Gould, 2003). The object is being able to drive. For an unaccomplished driver, the handling of the gearbox happens on the action level. A separate planning and execution phase is necessary for changing gears. For an accomplished driver, driving a car merely is an action with the goal to get somewhere in the context of a broader activity. For him or her, the handling of the gearbox happens nearly unconsciously on the level of operations. If he or she has to drive a different car model with a distinctively designed gearbox, these operations can again unfold into actions.

Activity modeling comprises the identification of activity systems and emphasizes the analysis of the mediating relationships and tensions between its constituting components. Compared to process modeling, the contributions of the activity theory are the consideration of individual or group motives, the notion of communities, a way to conceptualize learning by routinization, and the concept of mediation.

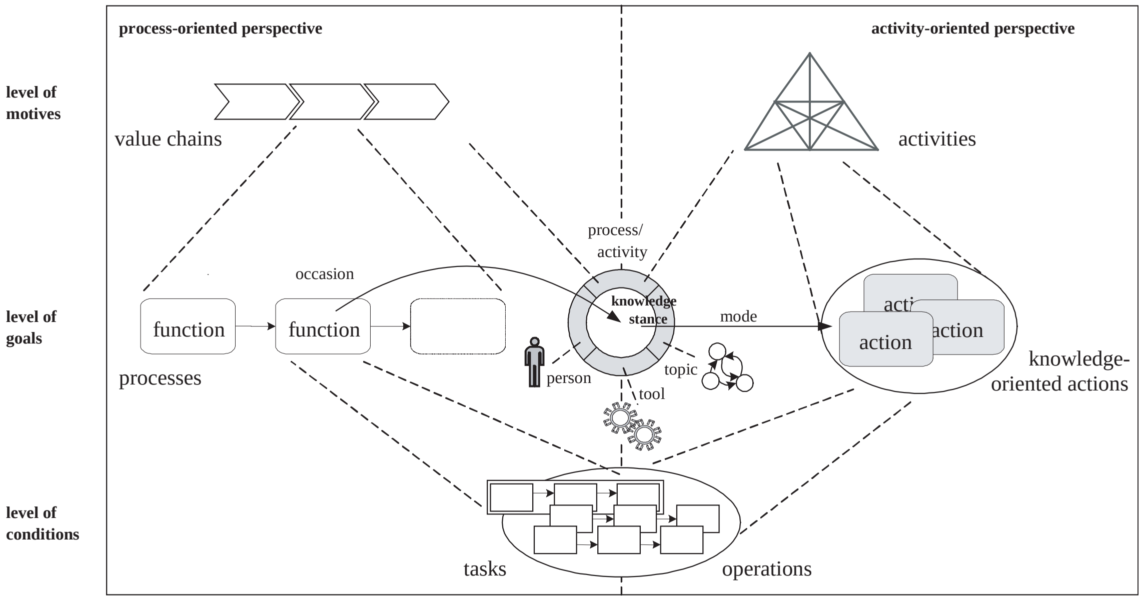
MODELING KNOWLEDGE WORK IN BUSINESS PROCESSES

The concepts provided by the activity theory are well suited to analyze the creative, unstructured, and learning-oriented practices of knowledge work. However, activities primarily aim at the joint creation of knowledge (exploration). Activities lack integration with the value chain and it is not ensured that activities are oriented toward creating customer value (exploitation of knowledge). Therefore, concepts of process and of activity modeling have to be combined in order to get a more comprehensive picture of knowledge work in a business context. This is the aim of the concept of knowledge stance.

A knowledge stance is a class of recurring situations in knowledge work defined by occasion, context, and mode resulting in knowledge-oriented actions (Hädrich & Maier, 2004). It describes a situation in which a knowledge worker can, should, or must switch from a business-oriented function to a knowledge-oriented action (see Figure 3). In a process-oriented perspective, an employee accomplishes functions on the level of goals that belong to a value chain on the level of motives by fulfilling a sequence of tasks on the level of conditions. Simultaneously, he or she can be involved in an activity framing knowledge-oriented actions and corresponding operations. An activity and its corresponding actions and operations can (a) be focused on the business process or (b) pursue a motive not related to the business process (e.g., an effort to build competencies) and thus may make a direct or a more indirect contribution to the process goal.

A business process offers several occasions to learn and to generate knowledge related to the core competencies of the organization. Occasions trigger knowledge stances and are associated with the functions of the business process by offering the opportunity or the need for knowledge-related

Figure 3. Concept of knowledge stance



actions. A knowledge stance is not limited to the generation of knowledge, but may also include the translation and application of knowledge created outside the knowledge stance.

The context comprises all relevant dimensions suitable to describe the actual situation of the worker. It can be structured according to the perspectives for modeling in KM: the process, person, product, and productivity tool. It comprises data about the current process like other subjects involved, desired outcomes, formal rules, or other process steps as well as data about the involved activity like the related community, their objectives, and social rules. Person-related data comprises the level of expertise (e.g., Dreyfus & Dreyfus, 1986), skills, interests, relations to other persons, and position in the organizational structure. The context includes information about what knowledge products and topics are needed, used, or created. Finally, available functions and systems are defined together with privileges to access them.

The mode classifies what actions can be performed and refers to four informing practices (see Schultze, 2000, 2003): (a) Expressing is the practice of the self-reflexive conversion of individual knowledge and subjective insights into informational objects that are independent of the person, (b) monitoring describes continuous, nonfocused scanning of the environment and the gathering of useful just-in-case information, (c) translating involves the creation of information by ferrying it across different contexts until a coherent meaning emerges, and (d) networking is the practice of building and maintaining relationships with people inside and outside the organization.

Context, mode, and occasion are means to specify the set of available, allowed, or required knowledge-oriented actions. Examples for ac-

Table 1. Components of knowledge stances

component	description
occasion	is a type of opportunity to learn and to generate knowledge related to the (core) competencies of the organization within the function of a business process
context	describes the actual work situation, i.e., the process/activity context, personal characteristics, as well as topics and tools
mode	classifies knowledge-oriented actions into expressing, monitoring, translating, and networking
action	refers to an unstructured, knowledge-oriented action and is specified by occasion, context, and mode

tions are (Eppler, 2003) to summarize, prioritize contents, evaluate sources, indicate levels of certitude, compare sources, link content, relate to prior information, add meta-information, notify and alert, ask questions, and offer interaction. In contrast to the clearly defined sequences of functions in the process-oriented perspective, there is no predetermined flow of actions. Table 1 summarizes the components of knowledge stances.

Depending on occasion, context, and mode, it can be decided which KM instruments are suited to support knowledge-oriented actions.

Table 2. Example of a knowledge stance

element	description
function	regular check of gas pipes, to alert and cooperate with service technicians if necessary (in Process 1)
context	**process/activity:** • Process 1 (maintenance of gas pipes): technical and geographical specifics of the gas pipe, problem type, urgency • Process 2 (negotiation with outsourcing partners): regulations and guidelines to formulate a contract, possible cooperation partners • Activity (cooperation with strategic partners): rules like communication patterns, motives, & objectives of the cooperation partners **person:** experience and internal role of maintenance engineer, other people with relevant technical knowledge **tool:** geographical information system, communication systems, access privileges of the worker **topic:** checklists, documented good/best practices
occasion	Damage on a gas pipe or a related component is identified within Process 1 and can only be repaired by a specialist of a company not yet under contract. Process 1 and Process 2 are connected through actions within the scope of the activity.
mode	The worker builds relationships with persons of another company and thus is in the mode of networking.
actions	search for the right partner, negotiate the specifics of the contract, validate the contract, check the skills of the company's workers

When designing KMSs, those knowledge stances are of primary interest that can be supported by ICT. A straightforward approach would be to suggest adequate KMS functions to the user or to automate corresponding operations. This could be accomplished, for example, by offering work flows or user agents known from office applications. The large set of KMS functions available can consequently be tailored to the needs in a stance and thus must obtain information from the context variables as well as the mode and occasion. The context should be derived with as little user effort as possible. The elements and their relation can be represented by a standardized or shared ontology. That way, inference techniques can be applied and the context can be communicated to and translated for other applications.

The following table shows an example of a knowledge stance for a worker consigned with the maintenance of gas pipes within a specific geographic area (see Table 2). The service is fulfilled by specialized companies under contracts that are renegotiated regularly by the purchasing department of the company.

FUTURE TRENDS

The design of KM instruments and of supporting ICT need structured representations of knowledge work in the context of business processes. It is necessary to integrate both process-oriented and activity-oriented elements for the exploration as well as exploitation of knowledge. The concept of knowledge stance, its integration into a modeling method for KM, and the subsequent design and implementation of ICT-supported KM initiatives promise substantial increases in the productivity of knowledge work.

CONCLUSION

This article discussed characteristics of knowledge work and gave an overview of perspectives and approaches for modeling in the context of process-oriented KM. We studied the activity theory as a means to include the dynamic, creative, and often less structured aspects of knowledge work, and proposed the concept of knowledge stance with the following contributions. First, a knowledge stance integrates the process-oriented and the activity-oriented perspectives. The latter is necessary to extend modeling to knowledge-oriented actions. Second, they are a means to design KM instruments and KMSs. The latter could be accomplished, for example, by portals or work spaces that bundle KMS functions and filter contents for knowledge stances, by user agents that guide through an action, and by workflows that routinize parts of actions. To clearly translate into KMS, the concept of knowledge stance needs to be detailed. Overall, the concept seems to be an important step in the quest for adequate extensions of business process modeling to cover aspects of knowledge work.

Chapter 6.5
Networks of People as an Emerging Business Model

Lesley Robinson
Lesley Robinson Company, UK

INTRODUCTION

Networking as a skill is becoming more and more important as traditional ways of doing business continue to change. Many organisations are moving from the industrial model of culture to a more "knowledge"-based culture, changing from having structured hierarchies to flatter structures with distributed responsibility. This has vast implications for how things get done. Instead of receiving instructions or being expected to work to a strict process, the knowledge-based organisations are giving people looser frameworks, and expect them to take responsibility for contributing ideas and sharing their knowledge.

EFFECTIVENESS THROUGH NETWORKING

The most effective way to work in these organisations is to build a network of contacts, colleagues, and teams. This networking approach is different from communities of practice where a group of people come together, formally or informally, to solve particular problems or discuss specific issues. Building a network is wider than just one specific focus; it is a new way of working and indeed a new way of thinking. This will give rise to many questions for organisations including structure, leadership, decision making, and much more. Many are not familiar in working in such an unstructured way.

Traditional communication techniques such as e-mail are also failing to deliver, as they dramatically overload people who have fallen into bad usage habits, thus restricting the techniques' effective use. The preferred way to communicate in the new 'networked organisations' is by using instant messaging and blogs, providing immediate business interactivity and truly engaging people.

Along with these developments, many organisations are downsizing and encouraging more virtual working scenarios. This means that individuals are having to become more self-reliant and build up their networks for support and development purposes. The number of small businesses, independent workers, and those with portfolio careers is also growing, and they are starting to join and form their own online communities to share work, develop business ideas, and to gain profile. With this trend, the skills of networking become critical.

These new online businesses are becoming the 'new corporates', and moving from being efficient networkers to providing infrastructure and benefits to members of the network. An example of this is eBay, which has provided a very successful online world where you can make a living from buying and selling on the company's Web site; but eBay has also developed a huge amount of infrastructure around building a community. eBay promotes its community values as:

- We believe people are basically good.
- We believe everyone has something to contribute.
- We believe that an honest, open environment can bring out the best in people.
- We recognise and respect everyone as a unique individual.
- We encourage you to treat others the way you want to be treated.

Perhaps some of the remaining large corporates could learn from these values. eBay also runs workshops for members of its community, offers a forum facility, and even offers insurance to regular users.

THE FUTURE

Another example of a growing network is Ecademy. This is a business exchange that connects people to knowledge, contacts, support, and business. It is free to join Ecademy, and you can create a profile of yourself, read what is happening within Ecademy, search the site, and receive e-mail newsletters and updates. The idea of Ecademy is to build up a wide range of business contacts. For a small fee, £25 per annum, you can access and contribute to all areas of the site and build a network of up to 20 contacts. At this level you can also generate more awareness of yourself and your business through submitting content onto the Ecademy homepage. There are also a range of specific networking clubs you can join. For £120 per annum, you can have access to a growing list of premium Web site tools, but the ultimate level is the BlackStar level, which costs £2,500 per annum and is available to a limited audience. Benefits include personal introductions, mentoring and promotional opportunities, personal branding, networking tuition, online system training, and much more.

This is a huge support network backed up by regular events where it is not just a case of business cards flying around but real business gets done. They also publish a "Citizens Guide" on how to get the best out of the Ecademy community.

CONCLUSION

Examples like eBay and Ecademy are the beginning of many structured networks that set out to truly help people to do business, as well as provide a support network of value. All this without the company politics, but having true respect for the individual.

These trends are a serious challenge to the traditional corporate environment.

Chapter 6.6
Bridging the Gap from the General to the Specific by Linking Knowledge Management to Business Processes

John S. Edwards
Aston Business School, UK

John B. Kidd
Aston Business School, UK

ABSTRACT

A phenomenon common to almost all fields is that there is a gap between theory and practical implementation. However, this is a particular problem in knowledge management, where much of the literature consists of general principles written in the context of a 'knowledge world' that has few, if any, references to how to carry out knowledge management in organisations. In this chapter, we put forward the view that the best way to bridge this gap between general principles and the specific issues facing a given organisation is to link knowledge management to the organisation's business processes. After briefly reviewing, and rejecting alternative ways in which this gap might be bridged, the chapter goes on to explain the justification for, and the potential benefits and snags of, linking knowledge management to business processes. Successful and unsuccessful examples are presented. We concentrate especially on the issues of establishing what knowledge is relevant to an organisation at present, the need for organisational learning to cope with the inevitable

change, and the additional problems posed by the growing internationalisation of operations. We conclude that linking knowledge management in terms of business processes is the best route for organisations to follow, but that it is not the answer to all knowledge management problems, especially where different cultures and/or cultural change are involved.

INTRODUCTION

The main topic of this chapter is the implementation or the application of knowledge management. By this, we mean how the ideas and theories of knowledge management can be made applicable in an organisation. Too often we hear or read the rhetoric of knowledge management without there being any route mentioned to turn these ideas into practical applications. As Americans might say, what happens when "the rubber meets the road?"

We begin by explaining why we believe the application of knowledge management in a specific organisation is problematic. We then propose that the concept of business processes is the most suitable way to help resolve this problem, and go on to review some of the consequences (actual and potential) of rooting knowledge management in an organisation's business processes. We believe that this is the most appropriate way to make the theories of knowledge management applicable. However, the approach is not without its difficulties.

We discuss both the justification and some of the potential snags in the main body of this chapter, with a special emphasis on problems of internationalisation. Our conclusions, however, given the current state of knowledge about knowledge management, are as much in the way of a question as an answer. However, it is clear that while a process orientation may be necessary for successful knowledge management in an organisation, it is not sufficient on its own. For example, an appreciation of cultures and cultural distance is also essential, given that we now live and work in a "global village."

CAN KNOWLEDGE BE MANAGED?

Baseline Definitions

Despite the surge of interest in knowledge management over the past few years, there is no general agreement as to whether knowledge can be "managed" in any meaningful sense. Three views on this topic are apparent to us (others may suggest more):

1. Meaningful knowledge resides only in people's heads, and therefore managing organisational knowledge is an oxymoron (Weick & Westley, 1996).
2. All knowledge can be managed; the principal challenge is to "extract" it from its current location, whether that is a human mind or somewhere else.
3. The statement that "knowledge resides in people's heads" is literally true, but there are knowledge processes in organisations (and elsewhere), and these processes can be managed, even if it is not possible to manage the knowledge itself directly.

View number 1 implies that not only this chapter, but indeed the entire book is a waste of time, and thus need not be discussed further here. Many software vendors may be found advocating view number 2, which has its ancestry, at least in part, in the more mechanistic aspects of the expert/knowledge-based systems field. In our view, the history of that field demonstrates that this view is unlikely to be valid in most domains of knowledge (see for example Gill, 1995). Even the oft-cited Huber has modified his thoughts over a 10-year period to accept that knowledge can be "sticky" and thus difficult to "extract" even from a willing donor (Huber, 1991, 2000).

Most of the literature specifically on knowledge management, not surprisingly, adopts view number 3. This literature often refers to "knowledge processes" or "knowledge management processes." However, the meaning of these phrases is usually only weakly specified, if at all. It is implicitly assumed that "something to do with knowledge" is taking place in organisations.

TOWARDS THE IMPLEMENTATION OF KNOWLEDGE MANAGEMENT

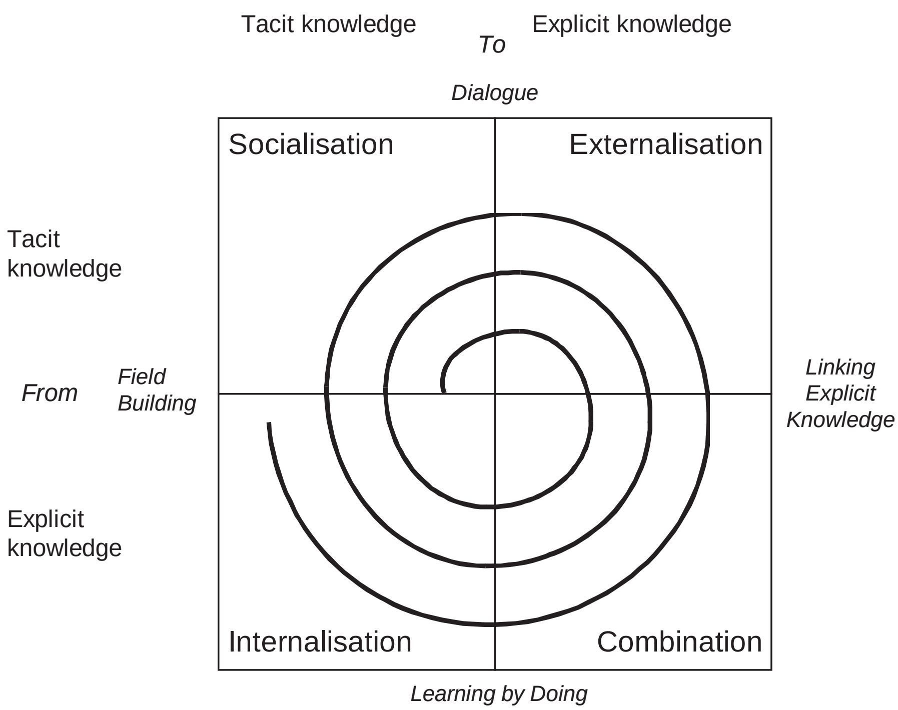
In this section, we consider four routes to the implementation of knowledge management in an organisation. We identify these as follows:

- The "knowledge world" route
- The IT-driven route
- The functional route
- The business processes route

The "Knowledge World" Route

The discussion of the knowledge processes mentioned under view 3 in the previous section is most often considered at the level of the whole organisation, or in a "world of knowledge" that is not specifically linked to the activities that a particular organisation carries out. These features may be seen in the most commonly cited generic model of knowledge processes, that of Nonaka and Takeuchi (1995), as shown in Figure 1. We should make it clear at this point that Nonaka and Takeuchi do go on to consider the practical realities of managing and encouraging these knowledge

Figure 1. Nonaka and Takeuchi's (1995) model of knowledge transfer processes



processes in organisations. However, many of those who cite Nonaka and Takeuchi's models seem to have lost the practical implementation aspects somewhere.

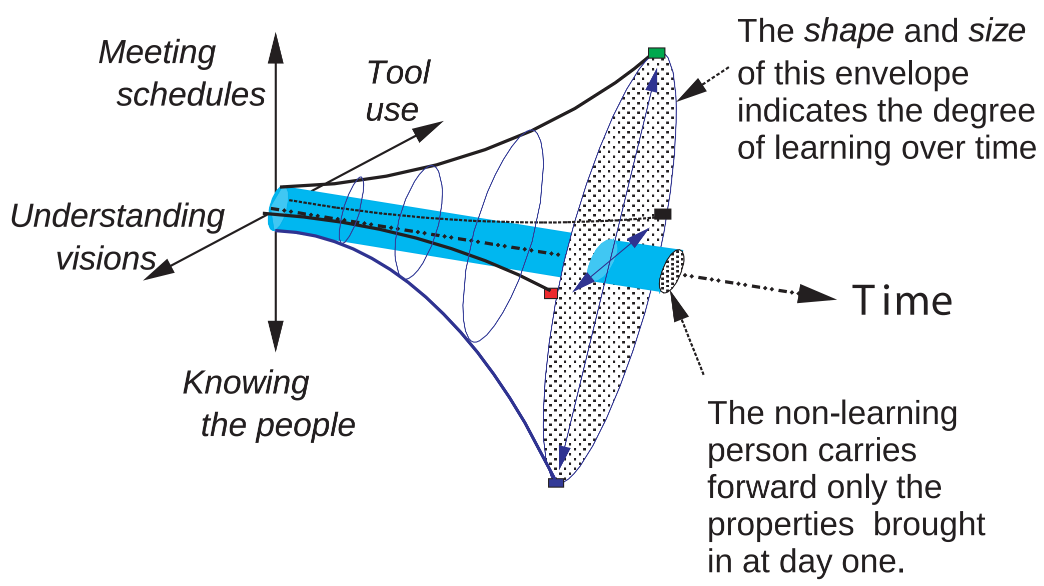
On an abstract level such discussion of knowledge management can be extremely valuable. However, in order for knowledge management to be implemented in an organisation, we believe that such a model has to be "attached" somehow to what the organisation actually does. It is necessary not only to understand how individuals learn, but also how they learn in a given organisation. In other words, we have to understand the processes by which individuals learn to "use their tools, to do what, why and with whom" — and how the organisational systems may help or hinder the individual's learning process. The same issue applies even more forcefully to group learning, since the organisation provides a crucial element of the group's context, whether that group is formal or informal, entirely internal or partly external.

We emphasise these points further in Figure 2. The figure is intended to indicate that a new individual in a firm will initially understand little of his/her new firm and its mores — but we trust he/she has some potential to learn.

As time progresses, they will learn to use the best tools for the job (these might be a telephone or the ubiquitous PC). They will learn that management has provided the best tools possible so they can meet the schedules demanded by the managers, and imposed by customers. They will learn to integrate with the CEO's visions so that all 'do their part and pull together.' Lastly they will learn to commune with others over many business issues. Figure 2 is in part an echo of the schema presented by Nonaka and Takeuchi, though here the focus is on what the individual is doing, whereas Figure 1 focuses on what is happening to the knowledge.

However, none of these ideas, however expressed, provides a specific connection from

Figure 2. The 4-knows of individual/group learning



the abstract ideas about knowledge to what the organisation actually does, or could do, or should do. Something more concrete is needed.

The IT-Driven Route

One possible route that has been adopted by some organisations is a natural progression from "view 2" on whether knowledge can be managed, as set out earlier. This route assumes that the fundamental requirement is for extraction and codification of as much knowledge as possible. For an organisation of any size, such a task evidently requires IT support, and the thrust of this route is that once the "correct" form of IT support for managing knowledge has been chosen, it is simply a matter of a great deal of hard work.

In our opinion, this technology-driven route is unlikely to work well, and may not achieve any improvement in knowledge management at all. One example of this from our own experience is of a heavy manufacturing firm. Knowledge management in this organisation was seen solely as an information systems issue; the knowledge management group was part of the information systems department. The "solution" was seen in terms of the implementation of a knowledge-sharing system based on Lotus Notes. However, there was no real consideration as to who would share what knowledge or for what specific purpose. Matters were not helped by the absence of a prior culture of knowledge sharing in the organisation. Consequently, the eventual use of the installed IT was poor; the only really successful use was by the knowledge management project team itself, where the "who, what and why" questions had been properly addressed!

The Functional Route

An alternative route to the implementation of knowledge management that at least has the potential to address the "who, what and why" questions is to organise the implementation around the existing organisational structure. The most commonly found structural elements intended to facilitate learning and knowledge sharing in organisations are departmental groupings based on functions. These have clear advantages in terms of what we might term professional development and allegiance. Davenport and Prusak (1998) report examples of successful knowledge transfer between groups of surgeons, and groups of tunnelling engineers, among others. However, this functional route also has the disadvantage that it encourages the compartmentalisation of knowledge. This problem can only worsen over time, as specialisations multiply and sub-divide. In addition, the professional divisions can actively prevent sharing of knowledge. It has, for example, taken decades for hospital doctors in the UK National Health Service to allow other professionals such as pharmacists and physiotherapists to participate in decision making about treatment of individual patients on an equal footing. On a wider scale, modern Western medical science has come to separate "diet" and "drugs," at least until the very recent past, in a way that Chinese medicine, for example, never has done.

We believe, therefore, that although the functional route to implementation will allow some management of knowledge to take place, progress may be limited, and in the worst cases this route may be counter-productive.

The Business Processes Route

It is clear that the managers in an organisation have to translate the goals of any strategic programme or initiative — whether on knowledge management or something else — into practical, implementable reality; in other words, to connect with "what the organisation does." Various management thinkers have presented models of this, for example:

- Porter's (1985) value chain;
- Earl's (1994) view of core processes, the ones

that are done directly for external customers;
- Beer's "System Ones" (1985), the systems that make the organisation what it is,
- core competences/competencies as espoused by Hamel and Prahalad (1994).

There are some significant differences in detail between these perspectives. For example, Beer and Porter have substantially different views as to what constitute the primary activities of an organisation. In Beer's view, the primary activities are those that distinguish this organisation from one in a different line of business. Porter, by contrast, sees the activities of all organisations as fundamentally similar. Nevertheless, what these views have in common is that all of their definitions are consistent with looking at the organisation in terms of what it does, rather than how it is structured. From our perspective, this means looking at knowledge learning and exchange in terms of its underlying business processes. Note that we use the term business processes throughout this chapter, but such processes exist equally in not-for-profit organisations, and we believe the concepts discussed here are equally applicable in that context.

Defining 'Business Processes'

There are many definitions of a business process. We prefer that of Davenport:

"A structured, measured set of activities designed to produce a specified output for a particular customer or market." (Davenport, 1993, p.5)

Among the characteristics of business processes that in our opinion justify their use as a foundation for knowledge management in organisations are the following.

1. Business processes have identifiable customers, whether internal or external. Knowledge is of little relevance unless put to use for a customer of some kind.
2. Business processes cut across organisational boundaries. Knowledge does not need to, and does not obey the artificial boundaries within an organisation.
3. Business processes consist of a structured set of activities. Choosing the appropriate way to structure activities is an important part of the knowledge.
4. Business processes need to be measured. Without some form of measurement as a comparison, knowledge cannot be validated.
5. While the parts of a business process are important, the overriding requirement is that the overall process works. True knowledge of the organisation must take a holistic view.

An additional argument, presented by Braganza (2001), is that viewing knowledge management in terms of an organisation's processes gives a much-needed supply-side view of knowledge. This is complementary to the demand-side view of knowledge that stems, for example, from considerations 'of data leading to information leading to knowledge.' Again, this links with our earlier argument; Beer and Earl particularly concentrate on this supply-side perspective. Beer indeed goes even further, to include the informal processes and activities of the organisation as well as the more formalised ones.

A further though indirect justification for the use of business processes in this role is that they are now becoming part of the mainstream of management thought. The new version of the ISO9000 family of standards for Quality Management Systems, including ISO9001: 2000, is constructed on the basis of a "process approach." The ISO9000 term realisation process is equivalent to Earl's core process or Beer's primary activity.

Completing our argument, the knowledge that an organisation requires must, logically, be related not just to what that organisation does, but also to how it does it. Thus we must think about this knowledge, and how to manage it, by reference to that organisation's business processes. But should we be focusing on the current processes, or future, changed processes? Clearly good knowledge management must include both, but this does raise difficulties.

CHANGE AND THE NEED FOR FLEXIBILITY

Types of Change

In looking at how the organisation moves from the present into the future, it is possible to distinguish three fundamentally different sets of circumstances:

- Continuing status quo operation.
- Incremental change or improvement (also called evolutionary change or continuous improvement).
- Radical change or improvement (also called revolutionary, discontinuous or step change).

Note the use of "improvement" as synonymous with "change" here. We do recognise the possibility that change occurs which worsens a particular situation, but in this chapter we take the optimistic view that in a competent organisation such reverses will be only temporary.

Each of these circumstances has different implications for the knowledge the organisation needs, but conversely knowledge drift is itself one of the key drivers for change. One of the main reasons for process change cited in the business process re-engineering (BPR) literature (Hammer, 1990; Hammer & Champy, 1993), is that: "the old ways no longer seem to be effective." In our terms, if old ways are ineffective, this must mean that the knowledge needed to accomplish the activity has changed. Work on knowledge management from an organisational behaviour perspective confirms this view of knowledge as being dynamic. Scarbrough et al. (1999), for example, describe knowledge as relatively transient, in other words changing at different times, even in the same organisation.

The Organisation as a Learning Entity

The requirements for organisational learning are similarly affected by whatever changes the organisation is undergoing. These effects may well permeate through all the human resource management activities of the organisation, right down to recruitment. Elsewhere we have discussed how top-down knowledge management and bottom-up organisational learning must be complementary to each other — changing together to meet the changing circumstances in which the organisation finds itself (Kidd & Edwards, 2000). Again, as most learning relates to the how of the organisation's activities rather than the what, a focus on business processes will be helpful, if not essential.

Knowledge management, organisational learning and business processes are all inextricably linked. Together they require an appropriate combination of human, organisational and IT support. We now go on to consider the issue of change in more detail.

CHANGE AND KNOWLEDGE MANAGEMENT

In considering knowledge, learning and change, we start from the perspective that all those who work in an organisation are thinking beings, capable of reflecting on what they are doing. The principal implication of this is that the "obvious" three-category view of change in the future, as presented in the previous section, is in fact misleading. It may be a valid depiction of change, but it is not the most useful way to consider future needs for knowledge and knowledge management.

In our opinion, there are three scenarios of change to be distinguished:

1. Status quo/continuous improvement: the same processes with perhaps minor changes to the activities.
2. Radical change to one process, with the customers and the organisational boundaries remaining the same.
3. Radical change across the whole organisation, where anything may change, even the nature of the organisation itself. Indeed, as we shall see later, such change may extend well beyond a single organisation, to a sector, region or country.

We argue that the requirements of continuing status quo operation and incremental improvement are effectively the same in terms of knowledge management and organisational learning. It is hard to conceive of a status quo that is enforced so solidly that no improvement ever takes place at all. We will admit that we are aware of some organisations — or at least parts of them — where the type of thinking mentioned at the start of this section is not encouraged, or even positively discouraged. Brief examples are given below.

Examples Within Scenario 1

In the first of these scenarios, we suggest that any learning that takes place must be related to the current process, and will probably be done in the first instance by the actors currently involved in carrying out that process. Thus the management of learning and/or knowledge also involves only incremental change. This does not necessarily mean that it is easy.

We have experience of a situation where even transferring knowledge from workers on one shift to workers on the same equipment on another shift presented serious obstacles. One shift team had developed a clearly superior operating practice, but the other two shifts working on the same production activities refused to adopt their proposed practices. Each shift had its own operational management, and the organisation's middle management were therefore the main communication channel between shift teams. However, this middle layer of managers tended to work "normal office hours," and so had very little involvement with the two of the three shift teams who worked "abnormal" hours. Partly as a consequence of this, the people concerned hardly ever met informally either. The official channels for communicating to and from the non-day shifts were therefore the only ones that could be used. As a result, nothing much happened. Only when a conscious effort was made to exchange management personnel between shifts did matters begin to improve. Changing this management process enabled knowledge sharing about the related business process to take place.

Even in an organisation where development is discouraged, like the archetypal 1930s-style production line environment satirised by Charlie Chaplin in the film Modern Times, change does still occur. Although there may be little scope for an individual to modify the way that they perform their current task while they are performing it, even these organisations would allow "off line" incremental improvement. In the 1950s production line, this might have taken place via work-study investigations, or (in more enlightened cases) a suggestion box scheme.

As a further example of discouraging development, we recall Fred Olsen, the boss of Digital (DEC), who banned conversations about PCs in the 1980s since he believed they were trivia that 'would go away.' As history shows, they did not go away — Olsen left, and eventually Digital was bought by successful PC manufacturer Compaq! Digital's business vision was based on the principle of tailoring the product to fit the customer's needs. This worked very successfully for their main mini-computer market in the 1980s. By the time

Digital (after Olsen) began to produce PCs, their learning curve was at odds with that of their more successful competitors, who had realised that PCs were now commodity items that required being cheaply mass-produced.

Examples Within Scenarios 2 and 3

The remaining two scenarios differ in whether the radical re-engineering is of one process, or of the whole business. Note that it might well be possible to re-engineer most of the processes in a business one after another without really changing the nature of the business overall. There are several examples of organisations that have recently taken a process-based approach to knowledge management with the intention of improving the processes, but not radically changing the business: here we offer three examples — the Unisys Corporation, the Objective Corporation and General Electric.

Unisys (Wizdo, 2001) has embarked upon a company-wide knowledge management initiative, whose objectives include:

- accelerating the speed and scope of organisational learning,
- decreasing the time it takes to reach critical mass in new markets,
- uniting cross-boundary groups,
- increasing innovation in product and process.

Wizdo identifies three increasingly ambitious categories of "transformation" in business: efficiency, innovation and re-invention. The Unisys knowledge management program regards a focus on processes as essential in achieving the two 'higher' categories, although at present the emphasis is on innovation. From our perspective they are re-engineering one process at a time.

Objective Corporation (Fisher, 2001) has adopted a similar process orientation over the past five years. They have found that such an emphasis has not only improved knowledge management within the business, but has had significant impact on the performance of the business itself. Indeed we can refer the reader back to Figure 2 and its discussion. A coherent training programme, with an emphasis on understanding, would be likely to increase the overall organisational performance through the betterment of its constituent personnel.

Probably the largest process-based change initiative, which with the benefit of hindsight can be seen to have had substantial knowledge management aspects as well, is that which has taken place at General Electric (GE) over the last 20 years. Jack Welch, until recently the CEO, completely transformed the company through his strong leadership and by using the knowledge of all its employees — especially those on the shop floor (Lucier & Torsilieri, 2001). GE's "corporate university" at Crotonville has proven to be central to this approach, making the link between Welch's strategy from the top down and the employees' knowledge and learning from the bottom up. They all would seem to understand the rationale of "what, how, who…."

Two Cautionary Tales

It might be easy to conclude from these examples that a process focus always leads to success in knowledge management, or indeed business in general. Unfortunately, this is by no means always the case. Here we present two cautionary tales.

One of the original "success stories" in process re-engineering concerned the application process at Mutual Benefit Life Insurance (Hammer, 1990). The changes to that process were undoubtedly successful, with results such as a reduction in processing time from 5-25 days to 2-5 days. Flow of new business (and funds) in was greatly improved on the basis of an innovative programme including such features as IS professionals and line managers changing roles for a year. However, this did not stop Mutual Benefit Life from first having to file for protection against bankruptcy and then going into administration. They had re-engineered the wrong process; a key one, but not the one that was most problematic for their business. In parallel with all these beneficial changes, the (unchanged) process of investment in real estate and mortgages was making a series of imprudent choices that brought the company to its knees. This was a failure of knowledge management at the management level. Just possibly, company-wide implementation of the change programme would have averted this, but a process focus by itself did not.

Timing of knowledge availability can also be a problem. Robinson et al. (2001) report on the organising of unplanned maintenance (i.e., responding to equipment failures) in an automobile manufacturing facility. Although a process perspective has been taken, the facility being studied is a relatively new one, and therefore has not yet experienced the full range of unplanned maintenance issues. Clearly this gives rise to potential knowledge management problems: how can they know what to do in a situation that has not previously arisen? The transferability of knowledge from other, older, facilities is being investigated as a possible way to overcome the problems. In general, the half-life of knowledge is problematic; however, since there are no easily applicable rules as to what to discard, what data and learning will be unwanted in the new situation, and conversely what will still be valid.

A further potential problem with a process focus is that of over-formalisation, whether of the business processes themselves or the forms of knowledge management in use. There is a risk that too much formalisation will lose the benefits of such means of knowledge sharing and transfer as storytelling and informal communities of practice. A process route to implementing knowledge management will certainly not lessen these risks, and may even increase them compared to the functional route.

INTERNATIONALISATION

One of the most radical changes that an organisation can undertake is to move from a national market and operations to operate on an international scale. Initially, in order to derive cost-cutting benefits, an organisation might venture overseas to access lower cost raw materials or lower cost labour markets to assemble components which are brought back home to satisfy home customers who do not perceive any changes to the vendor's organisational boundaries. Internally the organisation may have grave difficulties in achieving effective learning within the new supply chain. A process view is, in our view, essential to have any chance of success in this, but it is not sufficient and of course the firm must eventually pass beyond these Scenario 1 changes (in our terminology). We now discuss these issues further.

The Concept of 'Distance' and its Effect Within Scenario 2

Space does not permit a deep theoretical development here, but we would argue that 'distance' is a pervasive concept reaching deep into our everyday life. We have our own feelings about "what should be," and when these are broken for whatever reason, we may react at any level — from being mildly puzzled to grossly affronted. Often however we are inconstant in our reactions, and this happens more often in situations where there are cross-cultural issues that leave us bewildered or where there are strong power brokers who distort our ability to cope and react, as is our habit, under normal circumstances.

Research proposes that internationalisation should also be studied as a process (Aharoni, 1966). In consequence a number of different models of the internationalisation process have been developed. One of the most commonly cited models is the "Uppsala model" based on the Nordic studies of Johanson and Wiedersheim-Paul (1975) and Johanson and Vahlne (1977). This suggests that organisations will internationalise in stages as they overcome "psychic distance" (factors which inhibit the flow of information between markets). Johanson and Wiedersheim-Paul (1975) also suggest that organisations will enter countries with successively higher psychic distance. While it is not validated for some industries and markets (Turnbull, 1987; Forsgren, 1989; Erramilli, 1990), the Uppsala model is still put forward as a likely description of the internationalisation process of small, internationally inexperienced organisations (Forsgren, 1989; Johanson and Vahlne, 1990; Buckley et al., 1988). This is important since we note that in all countries the vast majority of firms may be classified as SMEs (Small & Medium Enterprises). In the UK for instance, in 2000, 99% of firms were defined as 'small' although they created 38% of the nations' turnover (DTI Statistical News Release — P/2000/561— 7th August 2000). It follows that some of these firms will venture abroad, and probably will follow the Uppsala model.

Informal support for this 'thesis' was given by Efurth (2001) while discussing aspects of the work of Dzever et al. (2001). The gist of the argument was that the Swedes offer a view of human resource management and entrepreneurship that is clearly distinguished from the Anglo-U.S. or the Asian models. This would correspondingly affect the requirements for knowledge management. Such confirmation is important as process models similar to those above are surfacing in research: such as Brouthers and Brouthers (2001) who review again the cultural distance paradox in joint ventures and mode of entry to another country by single or multi-national organisations; by Larsson et al. (1998) who propose a matrix framework to categorise the issues that 'joint' venture organisations may encounter; and by Kumar and Nti (1998) who note the discrepancies between processes and outcomes. Thus within organisational cultures we may suggest that training be given to help make the intangible more clear in the eyes (and concepts) of the other — and once more we may refer to the subtlety of concepts carried through the learning cycle in Figures 1 and 2. Yet we know from work in knowledge-based systems that knowledge domains have to be well defined and quite restricted, and that effective knowledge management systems need to include links to human knowledge that continues to remain tacit. Thus if the cultural distance (a measure akin to the 'psychic distance') between the parties is too large (Kogut & Singh, 1988), the partners will not achieve (even) a slight congruency.

Although we can envisage organisations moving from Scenario 1 change into Scenario 2 change, and perhaps finally Scenario 3 change, most of this work refers essentially to Scenario 2, that of radical change to one process, with the customers and the organisational boundaries remaining the same. A development of the Larsson matrix by Edwards and Kidd (2001) implies that when a willingness to 'work with the other' goes wrong, there is potential to descend into anomic states rather than cooperate or at least work in a cooperative mode. Equally, when an organisation ventures into a region grossly culturally different (e.g., Anglo-Americans in Asia) they may see the local host organisations employing staff using 'rules' derived from what they see as cronyism, nepotism or simple favouritism, and using working practices they see as somewhat corrupt (Kidd & Li, 2001). Here an understanding of the processes will not be sufficient on its own. The enjoining of radically different cultures may prove too great a threat to the morale of the merging organisation's work force as they fight to retain knowledge. This may mean, for example, that they will not cooperate in any way with those whom they view as 'the enemy.'

It must be conceded that this may be seen to be quite correct historically, at least on some occasions. Entering organisations have taken-over and dissolved indigenous industries; the cotton trade in Manchester, UK, or the UK motorcycle industry after the Japanese 'invasion' are just two cases. Not all foreign direct investment (FDI) is good FDI — Cantwell and Janne (1999), and Driffield and Munday (2000) show that there are benefits accruing from investments which stimulate indigenous organisations; but all is not rosy — they also suggest that local adverse effects can occur, namely that inefficient organisations may be bankrupted under the new competition. The knowledge needed to be successful will have changed, but the organisations do not know about it until too late.

The Problematic Scenario 3

Taking this further, especially in this era of globalisation, brings us back to Scenario 3: radical change across the whole organisation, where anything may change, even the nature of the organisation itself.

Looking back at our five reasons for "thinking of process" in knowledge management, all of them may become problematic.

1. The customer may change in subtle ways, even for the same product or service in a different country.
2. Existing knowledge applied overseas may not be sufficient.
3. Organisational structures — real or virtual — will differ in different countries. Actual and perceived boundaries will multiply when alliances are involved, yet from the point of view of knowledge, all remain artificial.
4. Even transparent measurement can be problematic, especially if the two partners in a joint venture have radically different objectives (perhaps technology transfer for one partner, and access to a new market for the other).
5. Finally, even holism may be interpreted differently in different cultures, although further discussion is beyond our scope here.

We close this section by offering an increasingly important example from international human resources management — the consideration of demographic and economic migrants. Ronås and Ramaurthy (2001) present a powerful description of international labour migration linked to globalisation. Often (they say) there is contract migration when a migrant's sojourn is linked to a specific job and for a specific time. However, there are also many instances where there is an escalator of people from poor countries moving to relatively better developed countries, while that nation's people move onwards to even better developed nations. Sometimes, as in the case of Japan (and soon in Italy), there will be the need to import labour to maintain the local economy. Ronås and Ramaurthy also cite the case of Germany, where even they, over the period from 2000 through 2005, anticipate a need to allow 6,000 migrants annually per million inhabitants simply to maintain the size of the working population. Under these circumstances there may be great cultural distances observed even within one organisation, notwithstanding errors in perception by staff from country A of the workforce of an alliance firm in country B who may in fact be employing many workers from country C.

Radical changes will therefore need to take place across the whole organisation, as nothing in the knowledge exchange and learning systems may be taken for granted. For example, working practices due to local legislation or religious tolerance will have to be observed and absorbed. To overcome some of this effect, we may suggest that the continuing development of and greater familiarity with Information and Communications Technology will facilitate outsourcing and/or teleworking, thereby reducing the need for migration. But this demands earlier infrastructure investment at a national level that just has not taken place in most newly developing regions. This mode will still demand human tolerance, compromise and understanding of "the other" in order to make the processes work well.

CONCLUSIONS

We have explained why we believe that considering knowledge management in terms of business processes is the best route for organisations to follow. We have cited some good examples, but also some indications that a process focus is not the answer to all knowledge management problems, especially where different cultures and/or cultural change are involved.

We conclude with an unanswered question concerning change and knowledge management. In terms of organisational performance, greater potential benefit comes from greater change. But when great change occurs, some of the organisation's existing knowledge, whether it be in stories or systems (or even people) will be less valid in that new context. How does the organisation know, before the change occurs, which of the knowledge that will be?

Returning to the Digital example: in today's purchasing climate, some customers look deeply into an organisation's supply chain to ascertain the ethical and ecological properties of the product's origin, even questioning the origins of its components (Dzever et al., 2001). Thus, ironically enough, Digital, 20 years on, might have been able to retain its marketplace and its original stakeholders' confidence through a continued use of its U.S. design and production chain, and by being perceived to not unethically milk the labour market of developing countries. But hindsight is a wonderful thing!

The key medium- and long-term knowledge challenge is thus "what to keep, and what to throw away." We believe that relating the knowledge to business processes will help, but there will always be an element of, yes, luck, in such matters. Greater change does, after all, involve greater risk. Innovation implies change; change implies lessening the dependence on history as a predictor of the future. Except, that is, in finding those who are adaptable and receptive to change. But will they be forever thus? Who can tell? In the end, as is appropriate, knowledge management is a "people thing" — manageable with care!

Chapter 6.7
Knowledge Management: The Missing Element in Business Continuity Planning

Denise Johnson McManus
Wake Forest University, USA

Charles A. Snyder
Auburn University, USA

ABSTRACT

This chapter provides a new perspective for Knowledge Management applications within organizations. The relevance of knowledge management components in disaster planning has been underscored by the large-scale terror attacks of September 11, 2001. The objective of the chapter is to provide a different perspective on the risk management category of business continuity planning or disaster recovery. Specifically, the authors show how most plans ignore or downplay the essential requirement for the organization to preserve its critical knowledge resources in the event the possessors of that knowledge are killed. Most proponents of Knowledge Management have neglected this important facet of the field. At the same time, the risk management and disaster recovery fields have ignored the important contributions of Knowledge Management to a viable business continuity plan.

INTRODUCTION

As the horrific events of September 11, 2001 in New York City, Washington, DC, and rural Pennsylvania unfolded, the first thoughts of most were likely for the victims of terror on such a huge scale. In the aftermath of the tragedy and destruction, many survivors had to turn to restoring businesses. Much was written about disaster recovery and business continuity planning as people struggled to regain the essential systems that underlie the modern organization. One aspect of this restoration that has typically been ignored is that of organizational memory management—a crucial part of Knowledge Management (KM). The importance of knowledge as a critical resource continues to gain recognition in the business world. This chapter discusses the need for KM programs in order to cope with large scale disasters such as the World Trade Center attacks.

BACKGROUND

This is really a dual topic as it contains the topics of both KM and risk management. The major focus is on the need for the addition of corporate memory management to complete any business continuity plan. The terrorist attacks of 9/11 have forced many to re-examine their disaster recovery plans.

For the first time, organizations have had to confront the massive loss of intellectual capital. Even if disaster recovery plans had provisions for software, equipment and networking, the plans could not be executed without knowledgeable people. Terrorist attacks have underscored the importance of adding knowledge management or corporate memory management components to make a comprehensive business continuity plan. In order to understand the domains of business continuity planning and KM, it is necessary for us to provide some definitions of the concepts. In the following section, we begin by defining KM.

KNOWLEDGE MANAGEMENT

Unfortunately, KM has a variety of meanings both in the literature and in practice. Some definitions are provided here. Knowledge management is the utilization of "the collective knowledge, experience and competencies available internally and externally to the organization whenever and wherever they are required" (Fearnley, Horder, 1997, p. 25). They have considered KM to be a supportive process comparable to the management of people. It includes the systematic generation, capture and transfer of knowledge and learning for the application and benefit of the whole organization. We believe that knowledge is similar to potential energy in providing the basic competence to perform. A manager's major concern should be centered on the knowledge required to perform the organization's critical processes and tasks. Knowledge Management is the discipline that focuses on capturing, organizing, filtering, sharing and retaining key corporate knowledge as an asset. "KM is the sharing of information and wisdom between global business units and their support organizations" (Griffiths, 1997, p. 62). Dorothy Yu, a global consulting partner at PricewaterhouseCoopers, defines KM as "the art of transforming intellectual assets into business value" (Zerega, 1998, p. 61). Knowledge management is the ability to realize increased returns from business competencies," according to Kirk Klasson, director of knowledge-management solutions at Cambridge Technology Partners (Zerega, 1998, p. 61). The lack of effective management of knowledge could be because most organizations are still struggling to comprehend the KM concept (Holsapple, Joshi, 1997).

To make knowledge work productive will be the greatest management task of this century just as to make manual work productive was the greatest management task of the last century. The gap between knowledge work that is left unmanaged is probably a great deal wider than was the tremendous difference between manual work before and after the introduction of scientific management (Drucker, 1969, p. 272).

Thus, our focus is on the management of the corporate memory that is required for superior performance of those critical processes. This becomes even more important as the world's forces engage in war activities and human knowledge bases leave the organization.

BUSINESS CONTINUITY PLANNING

Business continuity planning is often equated with external forces, such as natural disasters, that present the risk of power disruption, building destruction or worse (McManus, Carr, 2000). Less obvious is the risk inherent with a terrorist attack as devastating as the horrific events experienced by the United States on September 11, 2001. Risk is inherent in any organization, in any operation, in any situation where the goal is continuity.

There are expected situations that cause downtime. However, there are disastrous events that are much more difficult to plan for that can cause total disruption in business. Examples of these interruptions of business are shown in Table 1.

The cost of downtime, whether the result of disastrous or normal situations, has a widely varying impact on the organization depending upon the industry. According to Kelly (2002), the Energy and Telecommunications groups are exceptionally vulnerable to downtime—with revenue at risk of 2.17 million dollars per hour for energy and 2.066 million dollars per hour for telecom companies as displayed in Table 2.

An essential component of any sound Information Resources Management program is that of Business Continuity Planning or, in a more limited sense, Disaster Recovery Planning. These programs are emplaced to ensure that a business can continue to operate after a disaster. From an information technology perspective, the plans deal with restoring capability so that essential IT supported functions can be carried out. An important part of the recovery planning should be on the KM aspects that enable the systems to function. What are these aspects? What are the specific tasks that managers need to perform? How should managers address the KM tasks?

As stated by Dickerson (2001), "In the coming days and weeks, businesses that lost employees in the attack are faced with realities of rebuilding business infrastructure to serve their customers amid the bottomless grieving for their colleagues. The loss of so many people means a catastrophic loss of intellectual capital." Therefore, even companies that have a good disaster recovery plan are struggling to implement that plan. While the total cost of damage to a company's equipment and facilities can easily be determined, intangible

Table 1. A categorization of disasters (Source: Adapted from Aberdeen Group in Kelly, 2002)

	Normal Situation	Disaster Recovery Situation
Time Down	* Minutes per year	* Hours of day per event
Infrastructure Threat	* Disk failure * Network congestion * Application performance	* Earthquake * Blizzard * Fire * Flood
Willful Threat	* Computer viruses * Hacking	* Disgruntled employee * Terrorist attack

Table 2. High cost of downtime (Source: Adapted from Meta Group in Kelly, 2002)

Industry	Revenue/hour	Revenue/employee-hour
Energy	$2,817,000	$589
Telecomm	$2,066,000	$187
Manufacturing	$1,610,000	$134
Finance	$1,495,000	$1,079
Info Tech	$1,344,000	$184
Insurance	$1,202,000	$370
Retail	$1,107,000	$244
Pharmaceutical	$1,082,000	$167
Chemicals	$704,000	$194
Transport	$668,000	$107
Utilities	$643,000	$142
Health Care	$636,000	$142
Media	$340,432	$119
Retail	$1,107,000	$244

damage, such as the cost of downtime and the loss of intellectual capital, are difficult to measure. Not only are companies faced with the loss of employees and loss of the business infrastructure, but also they are struggling with the rebuilding efforts due to a lack of available company employees that can implement the plan. This solidifies the necessity to capture relevant knowledge that can be engaged during such catastrophic disasters as experienced on September 11, 2001.

KM ASPECTS OF CONTINUITY PLANNING

Information technology managers have long advocated certain practices that make a business capable of restoring IT-based aspects of the business in disaster situations. Some of the most basic practices are backup, especially of critical applications. However, most disaster recovery plans that rely on conventional backup, outdated testing, narrow redundancy, etc., are woefully inadequate to comprehensively cover enterprise needs (Grygo et al., 2001). With catastrophic disasters such as massive terrorist attacks, there is a huge human dimension in addition to the technical one. In some cases, the majority of the human resource may be lost in addition to the destruction of IT and facilities. As Kearns (2001) stated, "it is not pleasant to contemplate, but what would your company do in the event that you and your entire department were wiped out?"

One rather recent aspect of KM could be considered the idea of an alumni network for a company. Because talented people do not stay in one organization forever, the alumni network helps to maintain contact with them even when they are gone. The alumni network is designed to engender lifelong affiliation. Eventually, some of the alumni that possess critical organizational knowledge may want to return or may be in the position of being advisors. Therefore, there is a new movement to build alumni networks. Even if the people do not return to the company, the company may be able to bring their knowledge back (Canabou, 2002).

In an interview (Scannell, 2001), the head of IBM's disaster recovery center, Ted Gordon, stated that the basic disaster recovery plan was insufficient when the whole fabric of how the business operated was disrupted, rather than just getting computers back up and running. He said that, "Every company has to take stock of exactly how they do business, where it is most critical for them to keep that part of the business running, and what the processes are that support that…technology is not as big a risk as is the way we use technology to do business—it is the emphasis on the people, and our dependency on them, and how we choose to operate."

Companies must conduct risk assessment and manage the risk potential from all aspects of the company, i.e., personnel, technology. In the traditional disaster recovery plan, it was the responsibility of management to determine where unexpected and undesired consequences were likely to occur. The assessment was often focused on the interruption of technology, process, or procedures. "The technological inability to communicate with customers and suppliers is devastating, which can prevent the company from staying in business. By detecting and recognizing risks, the result of adverse consequences will be less catastrophic" (McManus, Carr, 2000, p. 3).

Johnson (2002) has pointed out that traditional disaster recovery plans are unable to keep up with the speed of doing business today. He advocates continuous processing architecture (CPA). CPA is a complete, high availability concept that allows instant failure recovery as well as storage. Provided adequate separation of the required redundant systems, the systems, applications and data should survive. However, a CPA may be just another piecemeal solution when a comprehensive, complete strategy is needed.

Comprehensive plans are designed to eliminate unnecessary decision-making immediately following the disaster. This plan is only effective if the appropriate personnel are available to invoke the actions necessary to continue the business. The companies in the World Trade Center experienced immediate problems from the terrorist attack and will continue to experience difficulty for months, even years, and potentially may never recovery, because of the tremendous loss of intellectual capital.

Few firms have been so deeply and irrevocably devastated by the World Trade Center attack as KBW. In all, 67 of the firm's 172 New York-based employees died or are still missing. They accounted for nearly a third of KBW's 224 employees. In a stroke, the firm lost more than 400 years of professional experience and much of its leadership. Gone are five of nine board members, including KBW's directors of equity trading, bonds, and research, along with its most prominent and influential financial analysts. Those missing or dead were responsible for 40% of KBW's annual revenues, which reached $125 million last year. In addition to the human loss, the firm lost its headquarters and every shred of paper documentation that existed there (Byrne, 2001).

Many companies in the World Trade Center may have the ability to recover their technological losses quickly, however, not their intellectual losses. In an interview with Howard W. Lutnick, a Cantor Fitzgerald Securities executive, he indicated that 68% of the intellectual assets of the company were lost in the tragedy. "The government bond trader had almost its entire New York staff wiped out on September 11" (Powell, 2001, p. 68). The company did not lose the critical data of the company, however, they did lose customer contact personnel, which will ultimately affect their supply chain management and CRM capabilities. It is apparent that the knowledge of the personnel of Cantor Fitzgerald Securities is a necessity to stay in business.

"Nothing can compare to the enormity of our loss of life," said Mr. Lutnick. "This tragic event has taken from us over one third of our employees (approximately 700), including half of our senior leadership. However, what we have learned from this horrendous act is that it is impossible, to destroy the spirit of our family and together we are forging ahead. We will remain the market leader with the foremost electronic trading platform in the world and in doing so honor the integrity of those employees, executives, family and friends we have lost" (Business Wire, 2001).

Although valuable data was stored in various applications, the employees with the knowledge of creating and using this information were killed in the attack and their knowledge died with them. Therefore, these examples indicate the necessity to store the data in a data warehouse and manage the knowledge for future use. In an effort to replace the personnel, the company will encounter tremendous risk that includes the inability of the new employees to perform at the appropriate level, as well as the risk of a start-up company stealing the business.

"Risk International's Mr. Wellman advised employers to spread staffers around and to 'minimize decision-making' to protect against catastrophes. Businesses that had all or most of their workforce in a single location violated a fundamental risk management principle, 'concentration of risk'" (Bradford, 2001, p. 21). How can survivors restore the firm's presence and ability to do business? "In a disaster, companies may be able to get the IT side up, but what about the rest of the company? What about management and production?" (Kovar, 2001, p. 71). One measure that managers need to address is that of harvesting the crucial knowledge of their best performers and preserving it. This should be a priority undertaking, as it may prove vital for survival in an era where terrorism poses new risks.

KNOWLEDGE MANAGEMENT TASKS

Knowledge management has been a popular concept for several years; however, there are many definitions and controversies about the scope, content, and implementations still clouding the issues. In this regard, we believe that the scope and content may be clarified by delineation of KM tasks that are important for business continuity planning. Consequently, we list tasks that are relevant within this context.

Since managers are interested in capturing relevant knowledge about the key processes of their firms, it is now apparent that this should be part of the strategic goals of the company (Snyder, Wilson, McManus, 2000). An organization's knowledge base and continuity plan needs to contain relevant (expert) knowledge that can be made available during a disaster. Peter Drucker (1993) stated in his book Post Capitalist Society, "The basic economic resource is no longer capital, nor natural resources. It is and will be knowledge." Managers are trying to understand what this means as they move their companies and information technology departments from strategies of data management, to information management, to knowledge management. Organizations are now striving to establish knowledge management systems to assist in the dynamic business environment.

To appreciate the problem with expertise retention, consider the dilemma that suddenly arises when highly valued employees leave the organization unexpectedly, as experienced by many companies on September 11. You want to retain that person's expertise, generally viewed as his or her knowledge (Snyder, Wilson, McManus, 2000).

Corporate Memory Management is an integrated set of processes whereby the hidden insights from top performers are converted into specific, actionable know-how that is able to be transferred to thousands of employees via software (Snyder, Wilson, 1997). The process follows a sort of life-cycle approach (Snyder, Wilson, McManus, 2000). The parts of the process are:

Focus

The first step is to determine the existing explicit knowledge and implicit knowledge that is needed for the focal process. What are the know-how content priorities for this process? Then a formal project plan must be created to capture the information. This capturing process maintains the brain of the organization regardless of downsizing, attrition or resignation of employees.

Find

Another one of the initiating steps involves finding top performing people and their critical activities. The top performers will be identified as a way to determine the source of critical actions. The nature of the person that is being sought and the output of that person's activities create knowledge as opposed to a simple action.

Elicit

Once identified, an understanding of these activities will be elicited from the key individuals. The activities of the top performers are educed and logically mapped in the knowledge harvesting process. KM must uncover the rules of decision within the activities of key performers.

Organize

The knowledge must be arranged in a coherent or systematic form. This procedure of structuring the knowledge into orderly and functional processes allows anyone in the organization to retrieve the necessary information quickly and efficiently. It is this inherent method that allows the organization's knowledge to be carried forward for future use of various applications within the company.

Package

The determination of how to properly package the knowledge so that it can be available when and where needed is a necessity. We must assess the best packaging form, e.g., an Electronic Performance Support System (EPSS). This process collects and preserves information or data on a particular subject within the organization. This is a non-trivial process because the application will have to be expertly structured to glean knowledge from the action of the user and ignore everyday data and information. These knowledge processes are recorded in a database that is accessible through a software package. Software can be used by anyone, increasing the organization's ability to make effective use of all harvested know-how.

Share

Sharing brings different aspects to the value and use of knowledge and will likely lead to the seeking and capturing of other knowledge and uses of previous and new knowledge not formerly considered. This captured knowledge can be distributed throughout the organization to individuals or groups that may require this relevant information. Throughout this sharing process, a corporate repository is developed where tangible “intellectual capital” of an organization can be captured and exchanged. This sharing phase allows individuals to track activities while significantly increasing efficiency and effectiveness of existing groupware for any organization.

Apply

The purpose of a KM system is to allow people other than the key players to use the same decision rules. Once these decision rules have been elicited and captured, they are only of value if we have a way to apply the newly-gained knowledge. It is the employees of the firm that may request or seek assistance, employment or admission of a specific task. By creating these applications through the knowledge harvesting process, these employees can seek that assistance from the database of knowledge that has be gained and stored from the experts of the organization.

Evaluate

Evaluation must be performed in order to determine the effectiveness of the applications. Appraisal of the resulting captured knowledge will occur during its application and sharing. In sharing the knowledge, it will be evaluated—a process that should be continuous so that the total database can be kept up-to-date, relevant and as small as possible. The organization needs to evaluate its learning systems and their contribution to useful knowledge. At the most basic level, learning should be evaluated by assessing the impact on individual performance.

Adapt

The KM system must incorporate the ability to adapt to new knowledge so that it can be refreshed. To maintain this core asset, knowledge, software is utilized to record the knowledge and activities of the company experts. By instantly recording all input information generated during the learning sessions, these processes increase the organization’s ability to make effective use of all harvested know-how. Therefore, when a crisis occurs, the organization’s knowledge can be shared with others. This sharing process allows for a quick recovery. The combination of these harvesting processes can significantly reduce time and result in improved thinking and decision-making when a company is faced with a disaster.

A few case studies were used by Wilson and Frappaolo (2000) to illustrate the application of the approach. One case is of particular interest in the present context. This case is titled “Before A Key Employee Walks Out the Door.” In this case, the firm was forewarned of the imminent departure of one of its key individuals. The firm recognized the importance of capturing his intimate knowledge of a critical process and proceeded to work through the parts of the Knowledge Harvesting process cited above. This is the sort of procedure that all firms need to go through before there is a known loss of knowledge if they are to build survival capabilities.

A MANAGER’S KM CHECKLIST

Companies are already thinking about IT lessons. They “will most likely reconsider centralizing key personnel at a single office—one company lost its entire disaster recovery team of nine people in the attack" (Wagner, 2001, p. 15). Using some of the steps of Knowledge Harvesting, Inc., model as a basis, we have a series of actions for managers. One of the first tasks involves simply identifying the organization's key or critical processes. We would suggest that these processes be evaluated and ranked along a criticality scale in order to determine the areas for priority focus. A checklist can provide a normative model for managers.

1. Identify Key Organizational Processes
2. Rank-Order with Most Critical Processes First
3. Assess Organizational Readiness (From: Assessing Readiness, 1999)
    a. Determine Knowledge Orientation
    b. Assess Climate for KM
    c. Assess Culture
    d. Determine the Degree to Which Daily Operations Support Change
    e. Assess Information Architecture Ability to Support Change
    f. Determine Leadership Support for Change
    g. Determine the Scope and Magnitude of Change
4. Develop KM Plan
5. Select a Proof-of-Concept Process Project
    a. Employ a Proven Methodology
    b. Select a Doable Project
6. Implement Proof-of-Concept Project
7. Evaluate Proof-of-Concept Project
8. Extend KM Implementation to Priority Processes
9. Ensure Integration and Update is Ongoing

These steps can assist managers in their efforts to harvest and preserve essential knowledge surrounding the organization's key processes. The checklist is a suggested model for managers to follow in adding an essential KM element in their business continuity plans. Only by doing this, can firms ensure that they can recover from unexpected disasters such as large-scale terrorism.

FUTURE TRENDS

There are parallel trends that impact this topic. First, the events of September 11, 2001 have caused many firms to reevaluate their business continuity planning because of the scale of disaster caused by terrorists. Firms have had to rethink their total disaster planning and business continuity planning to face the possibility of massive loss of intellectual capital, even if their computing facilities were able to be restored rapidly. The second impact has been the very fact that the loss of intellectual capital can mean that even if all other aspects of computing and telecommunications are backed up, these efforts are futile if firms are without skilled or knowledgeable personnel.

Future research might include building a profile of business continuity plans. An examination of those plans that are executed could determine the impact of inclusion or exclusion of KM facets. Future research would include a study of the knowledge components that should be included in business continuity planning.

CONCLUSIONS

The disastrous effects of the events that occurred on September 11, 2001 will drive companies not only to consider the importance of traditional disaster recovery plans, but also to incorporate a knowledge management component that may have been overlooked in the past. The loss of intellectual capital has virtually crippled some companies, with no recovery possible. In the last ten years, a major disaster has been reported somewhere in the United States as well as the world, every year. The size of the disaster is not the determining factor of staying in business; it is a comprehensive business continuity plan that will determine the success of most companies. Firms must go farther than building a disaster recovery plan in the face of new threats. They need a comprehensive business continuity plan that includes the possibility of massive loss of knowledge. This plan must address organizational memory management. The technology infrastructure can be replaced, the physical facilities can be rebuilt, but it may be impossible to recover the loss of expertise unless there has been a concerted effort to harvest that knowledge and have it packaged so that the essence of the experts' implicit knowledge is preserved.

Chapter 6.8
Workflow Systems and Knowledge Management

Alfs T. Berztiss
University of Pittsburgh, USA

INTRODUCTION

The business reengineering movement has left two lasting benefits: One is the identification of an organization as a set of processes (Davenport, 1993); the other is an emphasis on knowledge management (Davenport, 1997). The process orientation finds an expression in workflow systems. Processes have to be supported by knowledge management. Our purpose here is to provide an outline of how knowledge management relates to workflow systems.

The main source of information on workflow systems is the Workflow Management Coalition (WfMC). In 1994, the coalition published a 55-page Workflow Reference Model (available from its Web site www.wfmc.org), which establishes a common vocabulary, a description of key software components of a workflow management system, and interfaces between these components. The WfMC has been publishing an annual workflow handbook, an example being Fischer (2004). This volume contains an evaluation of the Workflow Reference Model (Hollingsworth, 2004). For a textbook with exercises refer to van der Aalst and van Hee (2002). Important pioneering work in this area was done by Schael (1998). A somewhat dated bibliography has been compiled by the ISYS group of the University of Klagenfurt (ISYS, 2000).

We start with a few definitions, based in part on the 65-page WfMC Terminology and Glossary document (also available from the WfMC Web site www.wfmc.org), and on van der Aalst and van Hee (2002). A business process is a set of linked activities that collectively realize a business objective or policy goal, and workflow is the result of automation of this process, in whole or part. A workflow comprises cases and resources. Cases are instances of the business process, and resources support the process. For example, the set of resources of an automated process that provides information about flight arrivals has to include a constantly updated database of flight data and a set of telephones. Every enquiry submitted to this system is a case.

A workflow system (WfS) manages the routing of cases through a workflow: A case "flows" from one station to another, and at each a task is performed on it. The task can be manual, automatic, or semiautomatic, but the definition of workflow as given suggests that the tasks of an ideal WfS should be automatic. It is important to realize that the ideal will not be achieved in the foreseeable future. Most WfSs of today are semiautomatic because they have to deal with unanticipated situations that only a human operator can handle. Moreover, software, the platforms on which it is implemented, and communication links can break down, requiring transfer of control to people. It is therefore important that the skills of these people be maintained by occasionally switching to a totally manual mode of operation.

The term "workflow," which we take to be a way of writing "flow of work," is appropriate because the cases move between workstations connected in a network. Indeed, implementation of workflows would have been difficult before computer networks became commonplace. A workflow management system (WMS) is a software package for the implementation of a WfS; adaptation of the generic WMS to the needs of a specific application turns it into a WfS for this application. This means that the WfS is also a software package. A distinction has to be made between the movement of cases between stations and the tasks performed at the stations. The movement, which is what the WfS controls, is normally fully automated: After a case has arrived at a station, the task is started automatically, or the system prompts a person to start the task; the task is then started at once, or after a delay. The delay may be due to a backup of cases or because the task is to be performed within a specified time window.

In the next section, we present a background survey, namely a discussion of processes that relate to workflows, and a discussion of information and knowledge. Then, we consider the management of knowledge in the context of workflow systems. We look to the future and offer a conclusion.

BACKGROUND SURVEY

Software Processes

In our view, the key concept of workflows is the use of software. With any software system, one has to consider: (a) the processes that create the software; (b) the software being created, which also defines a process; (c) the capabilities needed to implement and manage these processes; and (d) the knowledge resources involved throughout. As regards (a), the software development process can be regarded as a workflow system—this follows from the insight that the software development process is itself software (Osterweil, 1987).

Having established that a WfS is essentially a software system, we need to take a closer look at software development. The software process is made up of people, tools, and procedures. The people have to possess a set of capabilities that are to allow them to understand and make full use of the tools and procedures. For software development, such capabilities are defined by the Capability Maturity Model (CMM-SW) of the Software Engineering Institute (1995), and the more recent CMMI-SW (CMMI Product Team, 2002).

Under CMM-SW there are three types of processes: (1) a generic software development process; (2) processes derived from the generic process for the development of specific applications; and (3) these application processes. In addition, there is a process that assists in the conversion of process (1) into an instance of processes (2). In our context, the WMS would correspond to type (2): a process adapted from a generic software process that takes into account the specialized needs of WfSs. However, the workflow community has been understandably more concerned with business processes than with principles of software development. As a result, WMS is an abstraction of the features of application processes. Nevertheless, the capabilities of the CMM-SW can be of great value in the determination of how best to allocate the resources of an organization in the setting up of a workflow system, and how to modify the system to deal with changing business conditions.

We should also note that an application software system may in principle be developed by a WfS, which is itself an application software system. Rus and Lindvall (2002) and Dingsøyr and Conradi (2002) discuss knowledge management in this context, but software engineering shows that it is difficult to automate all tasks. Although some business processes have been fully automated (e.g., responses to enquiries by telephone), in the software development process not much more can be automated than the transfer of the software system under development from one work group to the next, help with extraction of components from a software reuse library, and prompts that tell developers what they should be doing next.

Information and Knowledge

Three kinds of knowledge are associated with a WfS. The first assists in the setting up of the system. The second is to be accessed by the system in its regular mode of operation. The third allows the system to be adapted in response to changing business conditions. In other words, the first and third kinds relate, respectively, to the implementation and maintenance of the WfS. Since the WfS is a software system, these components are in fact knowledge about the software process. The second kind is specific to a WfS. Its management is to be our primary concern. Note that Davenport (1997) prefers the term information management. In his view, knowledge exists in the human mind and is very difficult to embed in machines. This view is shared by Nonaka and Takeuchi (1995). Based on the seminal work of Polanyi (1958), they distinguish between tacit knowledge, which is personal and hard to formalize, and explicit knowledge that can be expressed in a formal language. We agree in principle. However, the driving force for workflows is the automation of business processes. Hence, we prefer to make the following distinction between information and knowledge: Information for our purposes is embedded in machines and is interpreted (i.e., it is data provided with meaning), and knowledge is information that is being put to use. This implies that we shall refer to information bases rather than knowledge bases, but what is extracted from an information base will be referred to as knowledge. According to Levesque and Lakemeyer (2000), a knowledge base is a collection of symbolic structures representing what a knowledge-based system believes and reasons with during the operation of the system. This view strengthens our distinction between information and knowledge. For Nonaka and Takeuchi (1995), "information is a flow of messages, while knowledge is created by that very flow of information, anchored in the beliefs and commitment of its holder." Fernandes (2000) makes this distinction: Information is obtained by deduction, knowledge by induction. As these examples show, it is difficult to make a clear distinction between information and knowledge, and sometimes we will use the terms interchangeably.

The knowledge that is to support the operation of a WfS can be grouped into five classes: databases, data warehouses, business rules, libraries of cases for case-based reasoning, and external sources. Databases have been extensively studied, and they are well understood. Data warehouses are repositories of archival data. Data mining (Hand, Mannila, & Smyth, 2001) looks for interesting relationships between these data, particularly for cause-effect relationships, with the aim of using these relationships for the improvement of business practices, which in our context means improvement of WfSs. Some WfSs operate on data streams. Thus, data from points of sale in a supermarket can determine policy. Research on mining from data streams is an active research area. A bibliography on this topic (Gaber, 2004) has 63 entries.

Business rules are of the form "if condition, then action." An example: "If the credit rating of the customer is of grade C or below, then demand payment before the order is shipped." Such uncertainty can be intrinsic to any WfS. For example, if the customer is of very long standing, we would be justified to assume some risk, and ship the order even though the credit worthiness may be questionable. To take a broader view, a rule is a trigger for a decision to be made, as it is in our example, or it is an operational definition, for example, "an age is obtained from date-of-birth by applying procedure get-age," or it is a terminological definition, such as "the grandfather of x is the male parent of a parent of x," or it is explanatory as in "the countries that have the euro for their currency are …" We are now in a position to define capability more precisely: It is the potential that an organization or an individual possesses for collecting and making effective use of information, rules, and process definitions.

Case-based reasoning (CBR) allows a system to respond to a situation by modifying a response made to a similar situation in the past (for surveys, see Watson, 1997; Shiu & Pal, 2004). In any software system the most difficult design problem is the treatment of exceptions. Consider a WfS that implements a loan approval process. Most applications can be handled routinely, but in borderline cases, approval or rejection could depend on some exceptional condition that is normally not taken into account. The information base of CBR is a case library of past decisions with the reasons for the decisions. By extracting loan applications similar to the application under consideration, the decisions made in those cases allow a decision to be made for the case being considered, and this decision will be reasonably consistent with the earlier decisions. Note that British law has been for centuries grounded in CBR.

FOCUS: KNOWLEDGE MANAGEMENT AND WORKFLOW SYSTEMS

Information has to be put to use in the operation of a WfS. The structure of the information base is to facilitate access to information, and this is a pragmatic concern. Pragmatics relate signs to their users. These are the people who gather, organize, manipulate, and use the information base. In terms of the distinction between information and knowledge that we made earlier, they convert information into knowledge. A WfS implements a process in a particular domain, and for the implementation to succeed, there has to be adequate knowledge about the domain. Ontologies and design patterns are pragmatic tools for managing domain knowledge.

A widely accepted definition of an ontology is that it is an explicit specification of a conceptualization of a domain. It is important to note that concepts are the basis for the interpretation of data. An ontology makes explicit the set of concepts that characterize a domain. It also indicates how the concepts are related. For example, an ontology for banking would include the concepts of account, account owner, and balance, and would tell that an account has an account owner and that balance is an attribute of an account. Kalfoglou (2001) surveys ontologies and includes a useful list of Web sites.

Software patterns represent general solutions to recurring problems. A pattern has five main components: the problem addressed, the context in which it arises, the solution, several known uses, and related patterns. The known-uses component indicates that patterns are not invented, but are the codification of experience with real projects. Devedzic (2002) surveys software patterns and provides a very useful list of Web addresses to libraries of patterns. There is a similarity to CBR. Under CBR, a search is made in a library of cases for a solution to a similar problem, and this solution is modified to suit present conditions. A pattern is an abstraction that has to be refined to make it correspond to the new situation. This means that a library of cases could be reduced to a limited number of patterns by merging similar cases. However, the advantage of CBR is precisely the details that would be lost in a pattern: The details help to achieve consistency in decision-making.

Most of the patterns to be found in libraries of patterns are very general, for example, requirements gathering, finding and defining domain objects, and user interface requirements. At this level of abstraction workflow itself is a pattern. What we need is a set of templates for the tasks of a WfS. This is investigated in Berztiss (1997) for the general class of rentals. Rentals relate to cars, formal wear, and library books. Even restaurant visits and airline flights have the characteristics of rentals: You "rent" a restaurant table or a seat on a flight. The rental processes for different types of rentals differ, and the different varieties of the process are obtained by refinement of the templates. Some of the templates for rentals include reservation, cancellation, handover, return, damage assessment, overdue item, payment, and inventory management. As a first step, each task is described as natural language text. Our example is the reservation template:

- Reservation: A customer makes a reservation of a rental object for a length of time starting at an indicated date and/or time. Variants of the basic task include (a) group reservations, (b) indication of just the starting point and not the duration, (c) no indication of a starting time, as in the case of a library book currently out on loan, (d) confirming of the reservation, (e) overbooking in anticipation of cancellations, (f) return site differs from rental site.

The description of a task of a specific rental WfS has to follow a definite format, but it is still expressed in natural language. From these refinement templates a decision can be reached regarding what is to be automated, and what is to be done by people. The format of the specialization templates includes:

- "Triggered by" establishes how the task is initiated.
- "Activities" gives an outline of all the activities that are part of the task, an indication under what conditions an activity is to be performed, and the order in which they are to be performed.
- "Information base changes" indicates those parts of the information base supporting the WfS that are to be affected.
- "Affects" identifies all tasks that can be affected by this task and states the conditions under which this task would interact with other tasks. This establishes flow patterns for a WfS.
- "Notes" contains any information thought to be relevant by the author of the template, for example, an explicit indication of what is not to be part of this task.

The Triggered by and Affects components define the flowlines of a workflow. Thus, specialization templates define both the tasks and the flow structure of a WfS.

A LOOK TO THE FUTURE

The biggest challenge to the manager of a WfS is keeping the system up-to-date. The business world of today is very volatile, and managers of

WfSs that are interacting with the world have to adapt their systems in response to changes taking place in this world. It is not enough merely to react to changes that have already taken place. There also has to be proactive adaptation of a WfS in response to analysis of business process data, such as the extrapolation of trends. We regard the determination of what existing and anticipated changes should lead to a modification of a WfS, what form the modification should take, and how the modification is to be implemented as very important research topics in knowledge management as it relates to WfSs. Totally new knowledge management problems arise when a workflow spans more than one organization (Schmidt, 2004).

The updating of a WfS is to be triggered by information that can come in various guises. But this creates a problem: How reliable is a particular item of information? Techniques such as data quality control (Tayi & Ballou, 1998), computing with words (Wang, 2001), and fuzzy techniques (Klir & Yuan, 1995) can be used to deal with data that are not crisp or reliable; Berztiss (2002) is a general survey. Methods have to be found for the determination of the level of unreliability of knowledge used in the estimation of business risks, and for the configuring a WfS in a way that reduces the risk associated with business process changes based on such knowledge.

A fairly recent development is the view that knowledge management can be purchased as a service (Woitsch, 2003). Workflow systems have become products, marketed by companies such as SAP. It remains to be seen to what extent the knowledge required to support these systems can become a service.

CONCLUSION

Workflow is a representation of a business process as software, but with the understanding that exceptional situations, and even some normal ones, require human intervention. Both the software system and human operators base their decisions on knowledge. Our main focus has been on the use of templates for the representation of this knowledge.

Chapter 6.9
Integrating Knowledge Management with Programme Management

Jill Owen
Monash University, Australia

ABSTRACT

Knowledge reuse has long been an issue for organisations. The management, reuse and transfer of knowledge can improve project management capabilities (i.e., learning, memory, cycle time) resulting in continuous learning. Although knowledge management has been recognised as a critical success factor in programme management very little research has been conducted to date (Lycett, Rassau, & Danson, 2004; Soderlund, 2004). A framework is discussed that demonstrates how knowledge is created, transferred, captured and reused within project and programme management, resulting in improved project management maturity. The framework utilises a task based approach to knowledge management and assumes that knowledge is created, transferred and reused as a result of an individual performing a specific task, which in this context is a project at the project level and a programme at the programme level.

INTRODUCTION

Organisations use projects to implement their strategy and change (Cleland, 1999). To achieve this, organisations need to utilise knowledge gained from earlier projects or project phases and not reinvent the wheel. One method of achieving this is for an organisation to develop a knowledge management strategy. A knowledge management strategy articulates how the organisation creates, values, preserves and transfers knowledge critical to its operations. As a way of ensuring that knowledge is effectively reused across projects they are often allocated to programmes. A programme is a group of projects managed together allowing added benefit and control that would not normally be achieved from managing projects individually (Project Management Institute, 2004; Turner, 1999).

Although knowledge management has been recognised as a critical success factor in programme management very little research has been conducted to date (Lycett et al., 2004; Soderlund, 2004). The focus of current research covers knowledge management in project management from intra- and inter-project learning (Kotnour, 1999) where it is important to capture knowledge as lessons learned where a full description of the project is captured allowing it to be used on other projects (Disterer, 2002). There has been a lack of formal knowledge exploitation in project management organisations.

A framework has been developed to demonstrate how knowledge is created, transferred, captured and reused within project and programme management. The framework utilises a task based approach to knowledge management and assumes that knowledge is situated within a specific context. Knowledge is created, transferred and reused as a result of an individual performing a specific task, in this context the task is a project at the project level and a programme at the programme level (Burstein & Linger, 2003). The framework shows how knowledge management can be integrated with project management.

The paper is structured as follows, a background to knowledge management within project and programme management grounded in relevant literature is provided, including actor network theory (ANT). ANT describes the way that a project team can be viewed (Parkin, 1996) in terms of comprising both humans and nonhumans (machines, procedures, processes and documents) and how knowledge can be created, transferred and reused (Latour, 1987, 1999). The next section provides a framework for how knowledge is developed at the task level and is embedded into the project methodology of an organisation allowing knowledge to be linked and reused in future projects and programmes. A description of a case study and a discussion of how knowledge management issues in the case study relate to the framework are then provided.

THE IMPORTANCE OF INTEGRATING KNOWLEDGE MANAGEMENT INTO PROJECT MANAGEMENT

The Project Management Institute (2000) defines a project as:

…a temporary endeavour undertaken to create a unique product or service. Temporary means that every project has a definite beginning and a definite end. Unique means that the product or services is different in some distinguishing way from all other products or services. (p. 4)

This definition offered by the Project Management Institute and widely used in both industry and academia focuses on project management as a tool rather than including project objectives, business performance (portfolio and programme management) that are fundamentally linked to project success (Morris, 2003). Morris (2003) offers an alternative definition:

Project management has to be about delivering business benefits through projects, and this necessarily involves managing the project definition as well as the downstream implementation. (p. 3)

Project success involves project management taking into account the traditional areas of project control and organisation, as well as the softer issues of stakeholder success, portfolio and programme management, project strategy, technology, and communication management (Morris, 2003). To achieve this, there needs to be a greater understanding of the integration of knowledge management into project management.

Different forms of knowledge exist in the project management environment — predominantly procedural (including tools) and contextual. While procedural knowledge is important, in larger or more complex projects contextual knowledge plays a key role both in learning and project success (Morris, 2003). Conversely if this procedural and contextual knowledge is not fully exploited the cost to an organisation could potentially be large in terms of time and dollars, reinventing the wheel and not reusing existing knowledge.

As project teams are temporary organisations need to ensure that knowledge from one project is available for use on future projects to reduce rework. Damm and Schindler (2002) argue that knowledge needs to be captured and indexed for future retrieval, however while it is important to capture explicit knowledge in a usable form it is also important to ensure that tacit knowledge can be tapped into (either personal knowledge or via a network)

Snowden (2002) argues that context is important in knowledge transfer because at one level people exchange knowledge personally based on trust and experience, while at the other level knowledge is coded for an unknown audience whose specific experience is unknown.

A knowledge management strategy is developed by organisations, including project organisations, for improving the way it develops, stores, and uses its corporate knowledge. Both tacit and explicit knowledge are important in the creation and reuse of knowledge. Organisational memory forms the basis of intellectual capital that is held in an organisation. Intellectual capital is the knowledge and capability to develop that knowledge in an organisation (Nahapiet & Ghoshal, 1998).

If an effective knowledge management strategy is not developed and managed by an organisation valuable intellectual capital can be lost, causing rework and lost opportunities. Better identification, transfer and management of knowledge allows intellectual capital to be effectively retained within the organisation, allowing it to be reused on other projects, reducing the time staff spend recreating what has already been learned.

For a project management organisation to be competitive Project Managers need to build knowledge and improve project performance (Cooper, Lyneis, & Bryant, 2002). In a structured organisation the learning process is important as it helps Project Managers to build on their experience by delivering not just one but a succession of successful projects, and to develop the right sorts of capabilities, that is, the project management process, the product development process and the knowledge management process (Kotnour, 1999).

In a project management organisation learning is important as it helps project managers deliver not just one but a succession of successful projects, and to develop the right sorts of capabilities, that is, the project management process, the product development process, and the knowledge management process. Learning within (intra-project) and between (inter-project) projects is required for this (Kotnour, 1999). Knowledge needs to be developed within a project, where it is used and tested, before it can be transferred to other projects. The challenge within some projects, particularly long-term, is to look at the process for the capture and reuse of knowledge in future projects (or phases of the same project) and to ascertain how intra and inter project learning occur (McLoughlin, Alderman, Ivory, Thwaites, & Vaughan, 2000).

Four key factors are critical to a project organisations capacity to learn, and these in turn are influenced by:

- A culture that encourages learning,
- A strategy that allows learning,
- An organisational structure that promotes innovative development, and
- The environment (Fiol & Lyles, 1985).

These factors contribute to individuals creating, transferring and reusing knowledge leading to organisational learning (Argyris & Schon, 1978). For a project organisation to continually learn and develop organisational learning needs to occur. Organisational learning is the capacity or process within an organisation to maintain or improve performance based on experience (Nevis, DiBella, & Gould, 1995). Organisational learning is dependent on individuals improving mental models (representing a person's view of the world). To develop new mental models the existing models need to be captured allowing organisational learning to occur independently of any specific individual (Kim, 1993). Organisational learning occurs when:

… members of the organization act as learning agents for the organization, responding to changes in the internal and external environments of the organization by detecting and correcting errors in organizational theory in use and embedding the results of their inquiry in private images and shared maps of organization. (Argyris & Schon, 1978, p. 29)

A key component of this mapping process is the recording of organisational memory. Organisational memory comprises the sum of participating individual's knowledge (Argyris & Schon, 1978). Organisational memory is distributed across an organisation rather than in one central area. There are six repositories, five internal and one external: individuals, culture, transformations, structures, ecology, and external archives. Once this body of knowledge is created new people can use it and it survives people leaving the organisation (Walsh & Ungson, 1991). The sum of an organisation's knowledge exceeds the sum of the individuals (Nelson & Winter, 1982).

At a project level knowledge is created by individuals and groups building on existing knowledge and creating new knowledge (adapting McElroy's [2003] definition of knowledge production at an organisational level). This knowledge can either be coded in project documentation or is stored with the project member.

PROGRAMME KNOWLEDGE

Knowledge Management is an important aspect of programme management. Programmes are the central point for the capture of knowledge such as project management policies, procedures and templates (Kerzner, 2003; Project Management Institute, 2004). Effective programme management allows for an enterprise or programme view of projects to be obtained via reporting and communication (Lycett et al., 2004) allowing for the more effective and efficient utilisation of schedules, resourcing, interface management, prioritisation, risk identification, mitigation, and management and forecasting (Lycett et al., 2004; Kerzner, 2003; Turner 1999).

At the programme level knowledge is shared, reused and created via training, mentoring, benchmarking, and capturing of lessons learned (Kerzner, 2003; Project Management Institute, 2004). In addition knowledge from previous projects can be stored and shared in a knowledge management system allowing for contextual searches for items such as lessons learned, financial data, processes, and procedures (Project Management Institute, 2004).

Project team members are often under pressure to move onto the next project rather than having time to reflect or transfer learning. Organisations need to develop a culture that allows knowledge to be captured and transferred (Lycett et al., 2004). It is suggested that it is a key role for programme management to foster this culture.

Knowledge management at the enterprise or programme level contributes to a learning organisation approach (Szymczak & Walker, 2003). Learning loops occur at regular review periods throughout a programme allowing benefits to be achieved (Thiry, 2002). These learning loops are a key point in knowledge creation, reuse, and transfer.

Successful organisations continually respond to change and reinvent themselves to maintain their competitiveness. Learning and knowledge management are key elements of the transformation and success (Thiry, 2002). Extending this it could be argued that learning and knowledge are embedded into the organisation (people, policies, and procedures).

ACTOR NETWORK THEORY

Project teams are temporary in nature with project team members moving back into operational roles, or onto another project, at the completion of a project or project phase (Cross, Nohria, & Parker, 2002; Blackburn 2002). Project management is associated with human and nonhuman machines, tools, and artefacts) in temporary organisations, as in actor network theory (ANT) (Blackburn, 2002). ANT comprises heterogeneous actors comprising both humans and nonhumans, for example, machines, procedures, processes, and documents (Latour, 1987, 1999a). The creation of knowledge occurs within a network. Within a network, sucha as a project team, a situation is framed and structured according to the actors existing knowledge, skill sets and competencies, and the nonhuman actors present in the network. It is a dynamic situation and changes as actors come and go within the network (Callon, 1998). Knowledge is gained by interacting with actors within a network and in understanding how and why they have behaved in a particular way (Latour, 1993, 1999a). Programme and project teams are networks based on the concept of ANT. Knowledge within a project is unstable as knowledge is continuously built on and created as new situations emerge and project team members enter and leave the network (Callon, 1998).

An important element of a given network is the boundary of the network that is set and the links within the network. These links have properties via which actors can collaborate within the network (Law & Hassard, 1999). Both the actor and the network rely on the other (Callon & Latour, 1981). Networks are constantly redefined as situations change and actors enter and leave the network (Latour, 1999b).

Actors (both human and nonhuman) within ANT are linked to the external environment (including networks), which is constantly changing and existing knowledge is constantly being built on and created (Callon, 1998). Based on Callon's (1998) work it is argued that a programme or project has a network of connections with the outside world, usually with resources or actors (human and nonhuman) both within and outside the organisation. Overflows occur when an actor enters or leaves the network. Actors continually reconfigure their networks as they change and adapt.

The changing nature of the networks allows knowledge to be reused as the "black box" concept (Callon & Latour, 1981). Decisions that are made/adopted within networks utilise the concept of the "black box", allowing people to take known, accepted and established work of others as a resource and build on this work rather than reproducing and questioning it (Callon & Latour, 1981; Latour, 1987). Within a programme this is most likely artefacts such as processes, methodologies, and documentation.

THEORETICAL FRAMEWORK

Project Management

Projects typically have subject matter experts or application area specialists who are required to manage a project or input specialist knowledge into a project to ensure that it runs effectively and efficiently (Dinsmore, 1999; Project Management Institute, 2004). Activities are the specific tasks that must be performed to produce the various project deliverables (Project Management Institute, 2004). Deliverables are any measurable, tangible, verifiable outcome in a project that must be produced to complete a project or a phase of a project (Project Management Institute, 2004). These outputs (usually in explicit form) are organisational process assets that are embedded into the corporate knowledge base (Project Management Institute, 2004). As a number of different project team members may be involved in completing the same task tacit knowledge is created, transferred and reused at each deliverable (Owen et al., 2005).

As an individual conceptualizes the task and reuses and reapplies past knowledge and experiences it can be argued that organizational memory is accessed and built on at the work breakdown structure/activity level. Also, knowledge is created, transferred and reused as a result of performing a specific task (Burstein & Linger, 2003).

An output of a project, that is often required at regular review points throughout the project, is performance reporting. Performance reporting involves progress and status reporting and forecasting. This reporting provides details of actual performance/progress against projected progress. Measures cover scope, project schedule and quality. At these review points the method of reporting varies depending on the organisation (including industry and methodology used) and the type of project. Knowledge is captured and transferred at these performance reports at the explicit level through reporting and at the tacit level in the form of project review meetings (Project Management Institute, 2004).

Organisations have formal or informal methodologies in place (depending on the type of organisation and their level of project maturity) to allow a project to be managed on time and budget and develop appropriate risk mitigation strategies (Kerzner, 2001b; Project Management Institute, 2000). These methods are often linked to other processes within the organisation (Kerzner, 2001b). Knowledge is embedded and captured within the methodology (Project Management Institute, 2004). As identified earlier regular review points identified within the methodology allow knowledge to be captured and reused at the tacit and explicit level.

As a project moves into latter phases, past the initial scoping, the project can be planned in greater detail (including risks) it can be understood what resources in terms of manpower, facilities, proprietary knowledge, special expertise, and knowledge of the business and financials are required. People provide the knowledge, skills, capabilities, and talents of the firm's employees in terms of knowledge of the business, special expertise, and proprietary knowledge (Kerzner, 2001a). This progress inputs into an organisation's capability.

In order to sustain a competitive edge an organisation needs to continually develop capability, that is the ability to achieve a desired effect or outcome in a specific operating environment and be in a constant state of readiness (applying the military definition) (Hinge, 2000). Lessons learned need to be embedded into the way a firm does its work. Within the project environment improving capability is to deliver successful projects and develop a competitive edge. This could be extended to knowledge creation where knowledge is embedded and made available for reuse and sharing thereby developing capabilities. To be competitive or retain competitiveness an organisation needs to continually develop its capabilities. In order to be competitive, an organisation needs to improve its level of project management maturity (Kerzner, 2001a). As capability improves, the appropriate resources can be supplied improving project maturity (Kerzner, 2001a). Project Management capabilities can only improve if continuous learning occurs. Learning occurs via knowledge creation, transfer, and reuse. If knowledge is lost, an organisation's project management maturity can decline (Kerzner, 2001a).

Where issues cannot be resolved within the normal project environment and intervention is required, an escalation process is used identifying when, how and the issue will be resolved (Project Management Institute 2004). As well as resolving the issue in the short term a decision needs to be made if the project methodology should be improved. To develop and maintain a competitive advantage an organisation needs to embrace continuous improvement rather than becoming complacent allowing competitors to catch up or overtake (Kerzner 2001a).

Knowledge is embedded throughout the project lifecycle at both the tacit and explicit level. Tacit knowledge is captured and reused at the project level in the form of personal knowledge (utilisation of knowledge from earlier projects), networks (informal to obtain specialist knowledge), and informal lessons learned. At the performance reporting level tacit knowledge is captured via mentoring (formal mentoring at regular review points). At the capability level, tacit knowledge is transferred and reused via mentoring. Explicit knowledge is reused at the explicit level in terms of documentation, while at the performance reporting level it is captured in the form of action and issues (Owen et al., 2005). Project templates and the project methodology allow for consistent reporting and for lessons learned to be captured (Project Management Institute, 2004). Knowledge creation, capture, transfer, and reuse occur throughout different phases of the model, learning occurs at all of these points. Based on Beer's (1981) concept of sympathetic and parasympathetic flows where knowledge is created at the sympathetic flow, it is reused in the parasympathetic flow (Owen 2004).

Programme Management

Following Beer's (1981) concept of recursiveness this model can be linked to the programme level. Related projects are aligned to a programme to allow benefits to be gained that would not be achieved if the project was managed individually (Lycett et al., 2004).

Programmes of work focus on effectiveness and efficiency goals and business goals (Lycett et al., 2004). Key common areas for programme management are typically planning and resource management, monitoring and control, configuration management and change control, risk and issue management, benefits management, and stakeholder management. Programme management allows for consistent reporting and communication (Lycett et al., 2004). Knowledge is reused, created, and transferred via consistent reporting and communication.

Interfaces amongst projects are managed and aligned at the programme level. Alignment allows for a more efficient and effective use of resources, especially scarce and limited resources (Turner, 1999). In addition managing the interdependencies between projects can reduce the amount of rework between projects therefore reducing project delays and eliminating risks that arise between the interfaces of projects (Lycett et al., 2004).

Monitoring of the programme usually occurs within a project or programme management office (PMO). The PMO oversees the management of projects within a programme. Resources are shared and coordinated and a common set of tools and techniques are used allowing knowledge to be embedded within the PMO (Kerzner, 2003). As well as standardising processes, the PMO allows for an improvement in resource allocation and a more realistic prioritisation of work (Kerzner, 2003). The PMO is responsible for ensuring that knowledge is maintained and disseminated throughout the programme. Relevant tools and processes need to be available for the capturing of and dissemination of knowledge including: risk data, lessons learned, project plans, team meeting minutes, and subject matter experts (Kerzner, 2003). Organisational process assets allow knowledge to be embedded within the methodology. Organisational process assets can vary depending on the type of industry and application area but are often templates, processes, guidelines, standards, communication requirements, and change control procedures (Project Management Institute, 2004). A challenge is to ensure that the knowledge is distributed in a timely manner (Kerzner, 2003). In addition, knowledge can be transferred to Project Managers via programme management meetings.

One output of programme monitoring (and the PMO) is prioritised projects. Prioritisation of projects can be based around resource requirements, the length of the project, interdependencies of projects and the strategic and business initiatives (Turner, 1999). As a programme of work progresses and more knowledge about the programme (and projects within the programme) is gained, a greater level of project prioritisation can occur. The prioritisation of projects inputs into a programme's capability.

Within the programme environment improving programme capability is to deliver a successful programme of work. This could be extended to knowledge creation where knowledge is embedded and made available for reuse and sharing thereby developing capabilities. To be competitive or retain competitiveness, an organisation needs to continually develop its programme capabilities. In order to be competitive, an organisation needs to improve its level of project management maturity (Kerzner, 2001a). Capabilities must be improved over time allowing repeatable successes in programme management.

As capabilities are improved effective resource utilisation can occur (Lycett et al., 2004). There is an improvement in the effectiveness and efficiency of resources, including justification for allocating specialist and scarce resources to particular projects. Resources would be allocated based on project prioritisation (Lycett et al., 2004).

Improved monitoring of the programme leads to effective benefits realisation, including benefits associated with the delivery of key organisational capabilities and the associated outcomes over time (Thorp, 1998). Benefits can be the elimination of risks arising from effective interface management, successful completion of projects and effective resource utilisation (Turner, 1999).

Effective capabilities of the programme lead to improved project and scope definition (Lycett et al., 2004). Where issues cannot be resolved within the normal programme environment a programme escalation is used identifying when, and how the issue will be resolved (Project Management Institute, 2004).

Framework

The theoretical framework provides a structure for linking programme management to knowledge management and mutually exploiting it (see Figure 1). The framework is a theoretical construct that represents the link between knowledge management and programme management.

As highlighted earlier, I choose to look at knowledge management using a bottom-up approach where knowledge is created, transferred, and reused as a result of a knowledge worker completing a task. Knowledge work is created, transferred and reused within a community of practice supported by a knowledge management system (Burstein & Linger, 2003).

A task is defined as:

…a substantially invariant activity with outcomes that include tangible output, central to the organization's viability and internal outcomes that are potential drivers of change. (Burstein & Linger, 2003, p. 290)

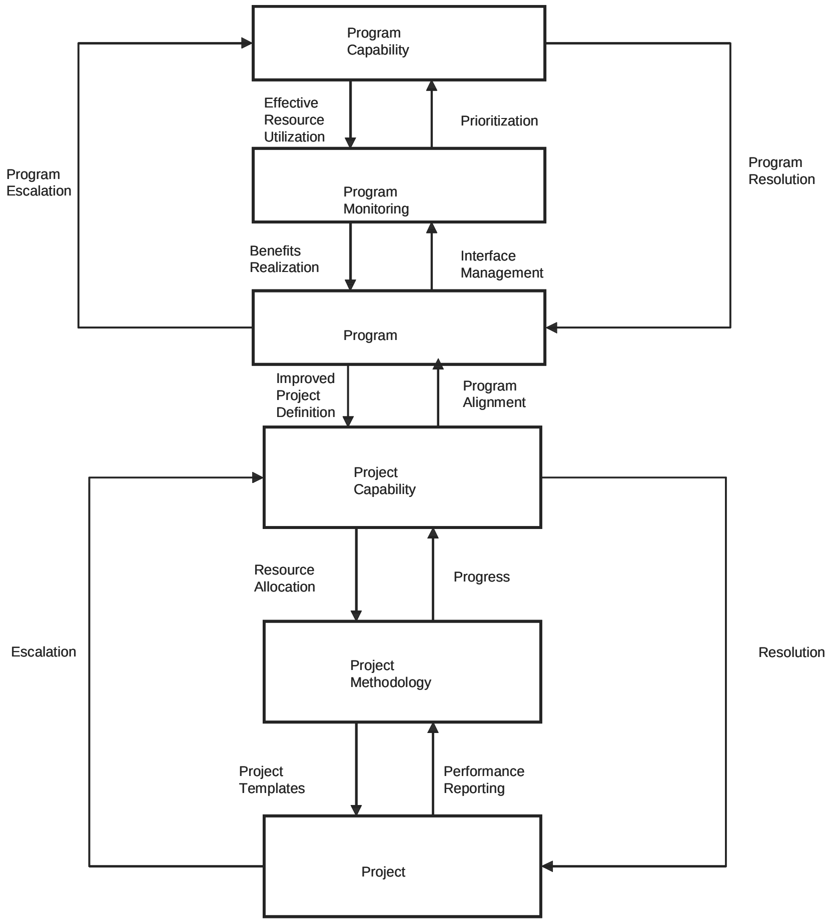
A project can be defined as a task where knowledge is created as the result of the activities that are carried out in a project by project teams and project team members (Owen et al., 2005).

Project team members create, transfer, and reuse knowledge in a community of practice (in this case it is most likely the project team) supported by a knowledge management system.

This framework (Owen et al., 2005) caters for the fact that when completing the task project team members will be able to conceptualise the task, reuse and apply past knowledge and experiences. Their knowledge work is supported via a knowledge management system (Burstein & Linger, 2003). The framework shows how knowledge is developed at the task level, is embedded into the project methodology, and improves the capability of an organisation.

This framework has alternative channels — sympathetic and parasympathetic flows. In order to maintain a stable environment where there is an input channel (sympathetic), there is an alternative channel (parasympathetic) which reports different information (Beer, 1981). The framework utilises the concept of recursiveness and as such is extended from the project to the programme level (refer to Figure 1) (Beer, 1981).

Figure 1. Knowledge management and project/programme management linked



CASE STUDY

Methodology

To initially test the project management component of the theoretical framework comprehensively within an organisation an exploratory case study, methodology was used allowing an insight to be gained into how knowledge was created, reused and transferred within and between projects (Owen et al., 2005). Data was analysed to look at emerging patterns to the research questions. Two analytical techniques were used in the research: document analysis, and unstructured interviews, with project team members, from both projects were conducted; both providing different perspectives and enabling crosschecking (Sabherwal et al., 2001).

A framework was developed for recording and analysing the relevant project documentation. In addition an interview guide was developed for conducting in-depth interviews. Both instruments were mapped to the theoretical framework.

Relevant project documentation was studied, assessed, and analysed during the case study research. Nine in-depth interviews, each taking approximately one hour, were conducted from a random sample of project team members across both projects. Project team members were interviewed from all work streams, seniority levels, and permanent versus contract staff.

The theoretical framework provides a structure for showing how knowledge management can be applied to project management. This model identifies four main areas of research:

1. Intra-project/programme learning and knowledge creation;
2. Knowledge transfer and reuse across projects and programmes;
3. Whether project and programme knowledge becomes part of organisational memory or is retained as individual knowledge; and
4. Management of project and programme knowledge.

The Case Study Site

A case study was conducted in an engineering project management consulting organisation. Two linked projects from planning to implementation and closure were chosen in conjunction with the organisation and studied. The organisation treated the projects as two separate projects with separate deliverables and have been analysed as such. The projects were analysed at the completion of the projects with no intervention from the researcher.

The organisation studied for the project management component is a global consulting company and is recognised as a leader in the market place. The organisation is employee owned and has grown organically and via strategic mergers with organisations with similar cultures and values. Their mission is to focus on valued client relationships to achieve remarkable success for them. The firm has a commitment to service, quality, and high standards of safety and business ethics. Management of the organisation follows a global management structure. The management structure reflects the regional, business and functional unit structure. A wide range of knowledge workers including project managers, engineers and scientists are employed by the organisation.

The corporate vision is to deliver solutions to clients which create exceptional value. The strategy is a global approach through our local offices. The projects analysed for this research supported the strategy to deliver exceptional service for and create an ongoing relationship and reputation with key clients. A key strategy of the organisation is to invest in the future of the business; knowledge management has been recognised as a key contributor to the future of the business. To assist with this strategy there has been the appointment of a

Knowledge Manager and the implementation of a knowledge management system. The knowledge management strategy is people centric rather than technology driven.

FINDINGS

Project

At the project level there is a reliance on both the existing network and actors in other networks (overflows). Documentation is usually in the form of a "black box", that is documentation that has been developed by others and is accepted as a resource, the documentation is built on rather than reinventing the wheel (Callon & Latour, 1981).

You use information that other people have worked on, particularly if you are running a project which is not like what you've done before. You ask around to find out who has the knowledge for that type of project and perhaps use their assistance.

Documents are stored on a server via job number, making it impossible to search contextually for documents (the organisation is in the process of implementing a knowledge management system) so explicit knowledge is often obtained from earlier projects that a person has worked on or obtaining the information from an expert. Documents are used as a starting point while more complex and detailed knowledge (such as financials and methodology) are obtained via tacit means, usually via human networks, that is, asking someone for the information.

It's a lot more efficient if you know who produced the file last time and you can go and ask them where it is…

Project Templates and Project Methodology

The organisation has a robust project management methodology with strong links to the methodology developed by the Project Management Institute (2000, 2004) Project Management Body of Knowledge (PMBOK). Each project follows a methodology based on: initiation, planning, execution, and closing phases. Business processes and project management systems also support the project and are aligned with the PMBOK methodology.

The project methodology has regular review points embedded into it allowing for performance to be reported against plan and allows for forecasting. The templates used cover scope, risk management and mitigation, project schedule, and quality. There is a reliance on existing templates and project methodology.

The critical steps in the process are signed off by the project manager and project director … we register them with a budget … and we monitor progress on a monthly basis we calculate earned value on the project online.

Performance Review and Reporting

Performance reporting occurs at regular review points of the project, using project templates; the performance of the project is measured against the project plan. Project templates that are used for performance reporting cover risk management, quality assurance, progress, performance against plan, and change management requests. The review points are identified by the project methodology.

As part of the reporting there is a review process (between the project director and project manager or an external reviewer and project manager/project team member), linked to the project methodology, where knowledge gained from one phase is incorporated into the next phase of the process. In this instance I would argue that the external reviewer, usually a quality assurance manager, is part of the external environment (including networks), which is constantly changing as they bring new knowledge into the project network during the review (Callon 1998).

Quality Assurance requirements are set up at the start of a project. Documents tend go through informal reviews to begin with, and then after changes are made, go back to the original reviewer for a formal review and sign off.

Capability

Mentoring is a key way of improving project capability, and is used within the existing network and via external networks (see Table 1). A Project director is appointed to mentor a project manager during the project. Mentoring occurs via regular review points.

The system of having a project director and project manager is one way that we reuse knowledge, because generally the director has more experience than the project manager. It's partly a mentoring system where the project director passes on knowledge to the project manager.

In addition more senior people (in terms of hierarchy and experience) external to the project mentor more junior project managers.

We've got a good mix of very senior guys and we try and get our junior guys to run projects and the senior guys feed the knowledge into the project…

Table 1. Knowledge use in project management

Phase of Model	Artefact	Actor
Project	• Informal lessons learned • Documentation • Informal networks	• Project team • "Black box" documentation and experience • Specialists (informal and formal)
Performance Reporting	• Project review process • Mentoring • Review points	• Programme manager/ project director • Project director • QA manager
Project Templates	• Project plans • Scope documents • Review documents	• "Black box" documentation
Project Methodology	• Methodology/ documentation	• Project team utilise "Black box" methodology
Progress	• Monitoring/mentoring	• Project director/project manager monitoring and mentoring at regular review points
Project Capability	• Mentoring	• Project director/project manager • Knowledge transfer from experienced employees to junior project managers
Resolution/Escalation	• Alliance project meetings	• Project director and project manager alliance meetings with their alliance counterparts

Escalation/Resolution

Typically issues that cannot be resolved within the project are resolved by external networks. The project director and project manager meet with their alliance counterparts, and the client issues that cannot be resolved by the project team or the project manager/project director can be resolved.

There's an alliance leadership team (ALT) and an alliance management team (AMT). The ALT meeting is at a higher level than the AMT and takes a broad overview of issues. If the project team cannot resolve an issue, there is a process whereby the issue gets escalated for a decision up to the AMT or ALT. It's a case of using the experience of senior alliance members to resolve issues using a best for project approach.

DISCUSSION

Knowledge is embedded and reused throughout the model. Knowledge creation, capture, transfer, and reuse, as stages of the implementation of a knowledge management strategy, occur throughout different phases of the model, learning occurs

Table 2. Project phases—How knowledge is managed and used

Knowledge Element	Type of Artefact	Existing Network/ Overflow (Based on Callon, 1998)	Phase of Project Component of Framework
Knowledge Creation	• Personal tacit knowledge • Collaborative tacit knowledge within project network • Tender/technical documentation • Tacit/explicit knowledge via external networks (informal/formal)	• Network • Network • Network • Overflow	• Project • Performance reporting • Progress • Project capability • Escalation • Resolution
Knowledge Capture	• Lessons learned (formal/ informal • Meeting minutes • Files • Project documentation	• Network/ overflow • Network • Network • Network	• Project • Performance reporting • Project methodology • Progress • Project capability • Escalation
Knowledge Transfer	• Collaborative tacit knowledge within project network • Project documentation – Explicit • Tacit/explicit knowledge via external networks (informal/formal)	• Network • Network • Overflow	• Project • Project templates • Project methodology • Resource allocation • Resolution
Knowledge Reuse	• Project review documentation • Earlier project documentation/ methodology/ templates • Personal experience • Subject matter experts – informal/formal	• Network – black box • Network – black box • Network/overflow • Overflow	• Project • Project templates • Resource allocation • Project capability • Resolution

at all of these points. Based on Beer's (1981) concept of sympathetic and parasympathetic flows where knowledge was created at the sympathetic flow it was reused in the parasympathetic flow (see Table 2).

Networks

Networks, based on the concept of ANT, play a crucial role in the creation, capture, transfer and reuse of knowledge. The project manager and senior project team members initially relied on personal knowledge and then "overflowed" into their informal external networks throughout the project when external expertise was required (Callon, 1998). Formal networks (e.g., as established in the corporate e-mail system) were only tapped into if the relevant knowledge could not be obtained from the other sources. In most cases as well as utilising tacit knowledge people utilised informal networks when seeking explicit knowledge, that is, black box documentation that was accepted and established of others (Callon & Latour, 1981). People interviewed said it was quicker to ask the person who knew where the relevant documentation was rather than searching for it on the server or in folders.

Knowledge Creation

While there is a reliance on personal knowledge, explicit knowledge and collaboration within the projects external networks play a crucial role in terms of knowledge creation. These networks tend to be the informal networks of project team members and "overflow" (Callon, 1998) into the network when external knowledge or expertise is required.

Build up relationships with people over a period of time. You work with them and find out who the specialists are in areas of the company. You talk to a specialist call that person and ask questions on how they have approached something a relationship is established. As you build personal relationships you know who to call.

Knowledge Capture

Knowledge capture predominantly occurs within the project team, both formally and informally, usually at regular review points during the methodology. Formal lessons learned are stored by project (each project is allocated a project number) on the network server, or in individual paper-based files. While this network server can be accessed by more than one office it does not allow for contextual searches. As a result there has tended to be a reliance on informal knowledge capture and reuse.

Knowledge Reuse

Knowledge is embedded and reused throughout the model. Knowledge is informally reused or re-created from one project to another as the culture and system is not in place to formalise it. Several project team members have worked with the organisation for a number of years, and given the length of time that they have been with the organisation they have created informal networks (usually people that they have worked with on previous projects).

The project team manager and senior project team members initially relied on personal knowledge and then their informal networks. Formal networks (e.g., as established in the corporate e-mail system) were only tapped into if the relevant knowledge could not be obtained from the other sources. In most cases, as well as utilising tacit knowledge people sought out explicit knowledge, that is, people interviewed said it was quicker to ask the person who knew where the relevant documentation was rather than searching for it on the server or in folders.

At the more senior levels of the organisation formal networks (across the distributed enterprise) also played a crucial role. In addition there was one exception where one team member relied predominantly on informal knowledge transfer but also documented everything so that if he was not in the organisation any longer another person could access the information, the only issue is that as everything (including all e-mails) were stored in hardcopy it would be difficult to find the most appropriate knowledge.

During project implementation a key reason that knowledge is reused, from documented lessons learned (explicit knowledge) and informal lessons learned (obtained from informal networks), is to deliver a solution where any potential pitfalls are known in advance allowing them to be overcome.

You remember the projects you've worked on the most, so you are more inclined towards them. But a lot of the time you pick up cost estimates and specifications and use information from projects other people have worked on, particularly if you are running a project which is not like what you've done before. You ask around to find out who has the knowledge for that type of project and perhaps use their assistance.

The knowledge derived from the formal lessons learned can form content for a knowledge-management system. An immature knowledge management system had been implemented within the case study site, however as project documentation was stored on a network server, a key question for the future is as the

knowledge management system is utilized within the organisation will there still be the same reliance on informal lessons learned or will people start to rely on formal lessons learned that are stored in the system.

Knowledge Transfer

Knowledge is transferred from the project level to business unit and organisational levels contributing to the creation of organizational memory. Mentoring played a key role in knowledge transfer from the project director to the project manager at regular reviews/meetings throughout the project. In addition as part of the development of more junior project managers and in recognition that a lot of experience and knowledge was held by more senior people one business unit developed a system whereby a senior staff member of retirement age mentored and transferred knowledge to more junior project managers.

CONCLUSION

This paper has established a theoretical framework for knowledge reuse based on a review of relevant literature. The literature is mainly concerned with how knowledge is integrated at both the programme and project level. Networks (both human and nonhuman) play a key role in knowledge creation, reuse, and transfer.

At both the project and programme level knowledge plays a crucial role in delivering successful projects and programmes of work. The paper builds on Burstein and Linger's (2003) concept of task based management where the project is the task and knowledge is created as a result of project team members completing a task within the project team environment. The model shows that in order for an organisation to deliver successful projects, develop its project management maturity, and improve its capability continuous learning needs to occur.

This research is grounded by the principles of task based management where knowledge is created in a project by the project team member or project team completing the task. This article contributes to the overall body of knowledge by exploring the contribution of learning and knowledge to a project organisation's development in terms of capability. The framework will also make a substantial practical contribution in terms of developing guidelines for creating, sharing, and reusing knowledge in a project management environment.

ACKNOWLEDGMENTS

This research is partly funded by Monash University, I am grateful to my supervisors Associate Professor Frada Burstein and Dr. Henry Linger for their support and constructive comments. I am also grateful to the support from the case study site. I acknowledge the reviewers and associate editors for the constructive comments that they made when reviewing this paper.

Chapter 6.10
Alignment of Business and Knowledge Management Strategies

El-Sayed Abou-Zeid
Concordia University, Canada

INTRODUCTION

The role of knowledge as a crucial asset for an enterprise's survival and advancement has been recognized by several researchers (e.g., von Krogh, Ichijo & Nonaka, 2000). Moreover, by having knowledge (intellectual resources), an organization can understand how to exploit and develop its traditional resources better than its competitors can, even if some or all of those traditional resources are not unique (Zack, 1999).

However, realizing the importance of organizational knowledge and its management in creating value and in gaining competitive advantage is only the first and the easiest step in any knowledge management (KM) initiative. The second and almost as important step is to answer how and where to begin questioning (Earl, 2001). In fact, "many executives are struggling to articulate the relationship between their organization's competitive strategy and its intellectual resources and capabilities (knowledge)" (Zack, 1999). As Zack (1999) argued, they need pragmatic yet theoretically sound model. It has been highly accepted that a pragmatic and theoretically sound model should meet at least two criteria. First, it should explicitly include the external domains (opportunities/threat) and internal domains (capabilities/arrangements) of both business (B-) and knowledge (K-) strategies and the relationships between them. Second, it should provide alternative strategic choices.

In order address this issue a KM strategic alignment model (KMSAM) is presented. It stems from the premise that the realization of business value gained from KM investment requires alignment between the business (B-) and knowledge (K-) strategies of the firm and is based on the Henderson-Venkatraman SAM for IT (Henderson & Venkatraman, 1993).

Overview of the Henderson-Venkatraman Strategic Alignment Model

The KM strategic alignment model is based on the theoretical construct developed by Henderson and Venkatraman (1993). In their model business success is viewed as the result of the synergy between four domains. The first two, the external domains, are business strategy and information technology (IT) strategy. The strategy domains are described in terms of (business/technology) scope, (distinctive business/IT systemic) competencies and (business/IT) governance. The second two, the internal domains, are organizational infrastructure and processes and IT infrastructure and processes. Both internal domains are described in terms of (administrative/IT) infrastructure, (business/IT) processes and (business/IT) skills. This synergy is achieved through two types of relationship:

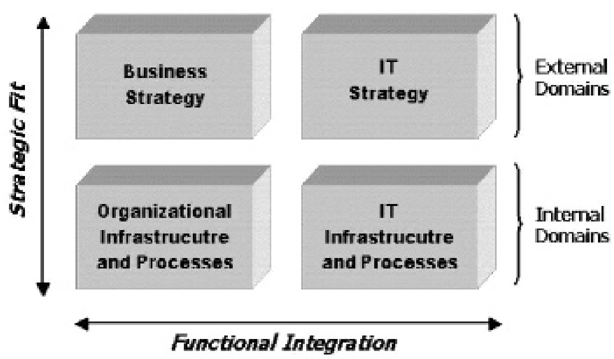
- Strategic fit emphasizes the need for consistency between strategy (external domain) and its implementation (internal domain).
- Functional integration, which has two modes, extends the strategic fit across functional domains. The first mode, strategic integration, deals with the capability of IT functionality both to shape and to support business strategy. The second mode, operation integration, focuses on the criticality of ensuring internal coherence between organizational infrastructure and processes and IT infrastructure and processes.

Figure 1 shows the elements of the IT strategic alignment model (ITSAM).

KM Strategic Alignment Model (KMSAM)

The premise of the original ITSAM is that ”the effective and efficient utilization of IT requires the alignment of IT strategies with business strategies” (Henderson & Venkatraman, 1993). In parallel way, the premise of KMSAM, in which knowledge strategy replaces IT strategy, is that “the effective and efficient use of organizational

Figure 1. IT strategic alignment model (Henderson & Venkatraman, 1993)



knowledge requires the alignment of knowledge strategies with business strategies". Since strategy, whether business (B)-strategy or knowledge (K)-strategy, can be seen as a balancing act between the external domain (opportunities/threats) and the internal domain (capabilities/arrangements) of the firm (strengths and weaknesses) (Henderson & Venkatraman, 1993; Zack, 1999), the external and internal domains of K strategy have first to be defined.

K-Strategy External Domain

In the case of K-strategy, the external domain involves three dimensions: K-scope (what the firm must know), K-systemic competencies (what are the critical characteristics of the required knowledge) and K-governance (how to obtain the required K-competencies). The first dimension, K-scope, deals with the specific domains of knowledge that are critical to the firm's survival and advancement strategies. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability (von Krogh et al., 2000).

Determining the K-scope can be achieved by constructing a business (B-) domain/ Knowledge (K-) thing matrix that documents the current and required state of organizational knowledge concerning some or all business domains. The first group of elements that constitute this matrix includes the list of B-domains (Bi). The second group of elements includes the K-things (Kj) that describe the current state of knowledge associated with each of the relevant B-domains. To relate this knowledge to enterprise business strategies, K-things are further classified according to the roles they play in such strategies. Von Krogh et al. (2000) have suggested that there are two types of strategies: survival and advancement. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability. Therefore, organizational knowledge, and consequently K-things, is classified into two categories: survival (KS) and advancement (KA). Figure (2) shows the generic form of this matrix.

The second dimension of the K-strategy external domain is K-systemic competencies. The focus of this dimension is the set of utilization-oriented characteristics of knowledge that could contribute positively to the creation of new business strategy or better support of existing business strategy. This set includes characteristics such as:

- Accessibility, the extent to which organizational knowledge is made available to its members regardless of time or location (Buckman, 1998);

Figure 2. Generic form of B-things/K-things matrix (Abou-Zeid, 2002)

Survival Knowledge				**Advancement Knowledge**		
B_1	K_{S11} (Current/ Required States)	….	K_{S1n} (Current/ Required States)	K_{A11} (Current/ Required States)	….	K_{A1m} (Current/ Required States)
B_2	K_{S21} (Current/ Required States)	….	K_{S2k} (Current/ Required States)	K_{A21} (Current/ Required States)	….	K_{A2l} (Current/Required States)
….	….	….	….	….	….	….
B_N	K_{SN1} (Current/ Required States)	….	K_{SNk} (Current/ Required States)	K_{AN1} (Current/ Required States)	….	K_{ANl} (Current/ Required States)

- Transferability, the extent to which the newly acquired knowledge can be applied in other contexts, for example organizational, cultural (Grant, 1996);
- Appropriability, the extent to which knowledge can be imitated. Things are said to have "strong" appropriability if they are difficult to reproduce by another organization. The converse is "weak" appropriability. A related concept is that of "sticky/slippery"; that is, sticky knowledge is such an integral part of a regime that it cannot be extracted in a meaningful whole (Grant, 1996; Narasimha, 2000);
- Depth and breadth (Narasimha, 2000);
- Compositionality, the amenability of knowledge to be synthesized from existing knowledge; and
- Integrateability, the extent to which the newly acquired knowledge can be integrated with existing knowledge.

Finally, K-governance dimension deals with the selection and use of mechanisms for obtaining the required K-competencies. The following are examples of some "acquisition mechanisms" (Probst, Raub & Romhardt, 2000):

- Bringing experts to the firm by recruiting specialists as full-time or temporary staff. Temporary hiring is becoming an increasingly interesting alternative.
- Tapping knowledge held by other firms through different inter-organizational co-operation forms such as joint ventures or strategic alliances.
- Utilizing the knowledge of stakeholders, for example, customers, suppliers, employees and owners. For example, involving customers early in the product-development process could generate valuable information about their needs.
- Acquiring knowledge products such as software, patents, and CD-ROMs.

K-Strategy Internal Domain

In the case of K-strategy, the internal domain involves three dimensions: knowledge (K)-processes, knowledge (K)-infrastructures, and knowledge (K)-skills.

Knowledge (K)-processes, the first dimension of the K-strategy internal domain, can be classified into two main categories: K-manipulating processes and K-enabling processes. The first category, K-manipulating processes, includes all the organizational processes needed to change the state of organizational knowledge such as K-generation, K-mobilization and K-application (Abou-Zeid, 2003). The second category, K-enabling processes, includes organizational processes that support K-manipulating processes such as managing conversation, mobilizing knowledge activists, creating the right context, and globalizing local knowledge (von Krogh et al., 2000).

Organizational knowledge processes are socially interaction-intensive. They involve social interactions and direct communication and contact among individuals and among members of "communities of practice". Therefore, they require the presence of social capital. Social capital is "the sum of actual and potential resources embedded within, available through, and derived from the network of relationships possessed by a social unit" (Nahapier & Ghoshal, 1998). Recognizing the importance of social capital, Gold et al. (2001) have identified three key K-infrastructures, the second dimension of the K-strategy internal domain, that is, technical, structural and cultural, that enable social capital. The K-technical infrastructure includes IT-enabled technologies that support KM activities such as business intelligence, collaboration and distributed learning, K-discovery, K-mapping, opportunity generation and security. The K-structural infrastructure refers to the presence of enabling formal organization structures and the organization's system of rewards and incentives. Finally, the K-cultural infrastructure involves elements such as corporate vision and the organization's system of values (Gold et al., 2001).

The last dimension of the K-strategy internal domain is K-skills. KM processes are by their very nature multifaceted. They involve many dimensions such as technical, organizational and human. This characteristic of KM processes reflects on the nature of skills required to perform them. For example, Malhotra (1997) defines a senior knowledge executive, such as a chief knowledge officer (CKO) or an organizational knowledge architect, as the person who should have the combined capabilities of a business strategist, technology analyst, and a human resource professional. The ability to facilitate the ongoing process of knowledge sharing and knowledge renewal, the ability to develop the human and cultural infrastructure that facilitates information sharing, and the ability to utilize the available technologies for serving the creation, sharing and documentation of knowledge are some examples of the required skills.

The Dynamics of KM Strategic Alignment Model (KMSAM)

Effecting a change in any single domain may require the use of three out of the four domains to assure that both strategic fit and functional integration are properly addressed. Therefore, applying KMSAM requires the identification of three domains: pivot, anchor and impacted (Luftman, 1996). The pivot domain is the weakest and offers the greatest opportunity for improvement. The anchor domain is the strongest and will be the driver of change. Finally, the impacted domain is the area affected by a change to the pivot domain. Figure 3 shows the dynamics of the strategic alignment process.

Based on this distinction, different perspectives of strategic alignment can be identified. Each perspective represents a pattern of linkages between at least three elements of the four elements of KMSAM, that is, the two external domains (business strategy and knowledge strategy) and the two internal domains (organizational infrastructure and processes and knowledge infrastructure and processes). By identifying the strongest (anchor) domain and the adjacent weakest (pivot) domain, it becomes possible to identify the area that will be affected by the changes (the impacted domain). The direction the perspective flows is based on which domain is the strongest and which is the weakest.

For example, Figure 4 shows knowledge potential perspective in which business strategy, the strongest domain, derives changes to the adjacent

Figure 3. The dynamics of the strategic alignment process

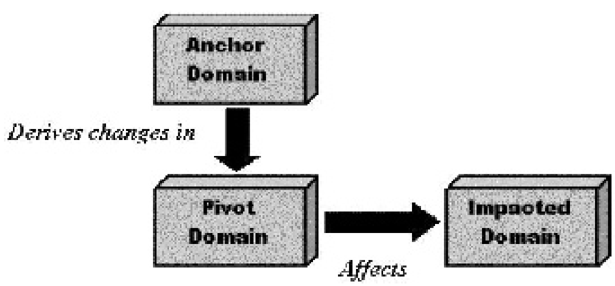


Figure 4. Knowledge potential perspective

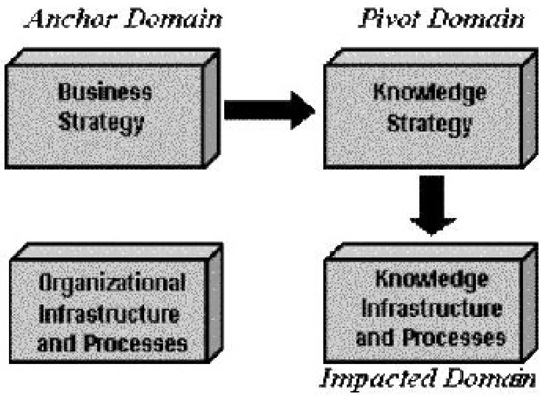

Figure 5. K-infrastructure fusion perspective

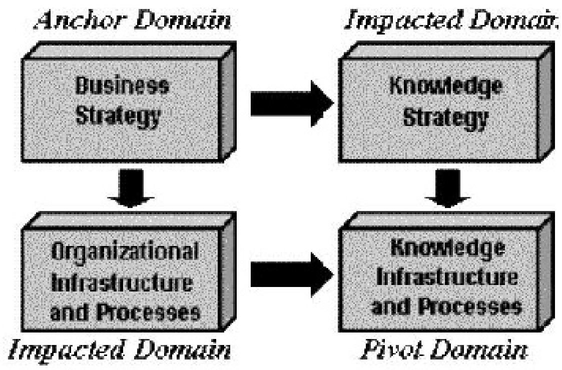

weakest domain, knowledge strategy, and these changes will impact knowledge infrastructure and processes. In general, each alignment perspective has to include two types of relationships. The first is between external and internal domains of its business and knowledge components, that is, strategic fit. The second is the functional integration between business and knowledge domains. Eight single-path alignment perspectives can be then identified, namely: from anchor domain to adjacent pivot domain to impacted domain.

When the pivot and the anchor domains are not adjacent to one another, but rather across from each other on the diagonal, there will be two possible "paths" from the anchor domain to the pivot domain. This yields four fusion perspectives that result from fusing two of the eight single-path perspectives (Luftman, 1996). For example, Figure 5 shows K-infrastructure fusion perspective in which business strategy derives changes to the K-infrastructure and processes domain through organizational infrastructure and processes, and K- strategy domains.

Table 1 summarizes the 12 alignment perspectives.

CONCLUSION

Based on the premise that the realization of business value from KM investments requires alignment between the business and knowledge strategies and on the IT strategic alignment model (SAM) developed by Henderson and Venkatraman (1993), a KM strategic alignment model (KMSAM) is developed. Moreover, it provides executives with a logical framework for analyzing and assessing alternative strategic choices with regard to aligning K-strategy and B-strategy.

Extension of this work would move in two directions. The first would be to use KMSAM in cross-sectional study of KM initiatives in order to identify the dominant patterns of K-strategy and B-strategy alignment. As "strategic alignment is not an event but a process of continuous adaptation and change" (Henderson & Venkatraman, 1993), the second direction would be a longitudinal study of each enterprise cycle around the alignment perspectives and how the adopted perspective is related to the degree of maturity of the KM initiative.

Table 1. KM strategic alignment perspectives

	Domain / Strategic Perspective	Anchor Domain	Pivot Domain	Impacted Domain
1	**Strategy Execution**	Business Strategy	Organizational Infrastructure and processes	K-Infrastructure and processes
2	**Knowledge Potential**	Business Strategy	K-Strategy	K-Infrastructure and processes
3	**Competitive Potential**	K-Strategy	Business Strategy	Organizational Infrastructure and processes
4	**Service Level**	K-Strategy	K-Infrastructure and processes	Organizational Infrastructure and processes
5	**K-/Organizational Infrastructure**	K-Infrastructure and processes	Organizational Infrastructure and processes	Business Strategy
6	**K-Infrastructure/ K-Strategy**	K-Infrastructure and processes	K-Strategy	Business Strategy
7	**Organizational/ K-Infrastructure**	Organizational Infrastructure and processes	K-Infrastructure	K-Strategy
8	**Organizational Infrastructure/ Business Strategy**	Organizational Infrastructure and processes	Business Strategy	K-Strategy
9	**K-Infrastructure Fusion** (Perspectives 4 + 7)	Business Strategy	K-Infrastructure and processes	• Organizational Infrastructure and processes • K-Strategy
10	**Organizational Infrastructure Fusion** (Perspectives 1 + 5)	K-Strategy	Organizational Infrastructure and processes	• Business Strategy • K-Infrastructure and processes
11	**Business Strategy Fusion** (Perspectives 3 + 8)	K-Infrastructure and processes	Business Strategy	• Organizational Infrastructure • K-Strategy
12	**K-Strategy Fusion** (Perspectives 2 + 6)	Organizational Infrastructure and processes	K-Strategy	• Business Strategy • K-Infrastructure and processes

Chapter 6.11
Developing Business Aligned Knowledge Management Strategy

El-Sayed Abou-Zeid
Concordia University, Canada

ABSTRACT

With the growing awareness of the crucial role that knowledge can play in gaining competitive advantage, several issues with regard to knowledge management (KM) initiatives have challenged executives. The articulation of the relationship between an organization's competitive strategy and its knowledge strategy is the most eminent. This chapter addresses the issue of how to align knowledge strategy with enterprise business strategy. Based on the premise that the realization of business value from KM investments requires alignment between business and knowledge strategies, the issue is addressed by developing a strategic alignment model for KM. This model, which is based on the Henderson-Venkatraman strategic alignment model, includes the external domains (opportunities/threat) and internal domains (capabilities/arrangements) of both business (B-) and knowledge (K-) strategies and the relationships between them. Furthermore, it provides alternative strategic choices. The model is used to study a KM initiative at Buckman Laboratories.

INTRODUCTION

The role of knowledge as a crucial asset for an enterprise's survival and advancement has been recognized by several researchers (e.g., Von Krogh, Ichijo, Nonaka, 2000). Moreover, by having knowledge (intellectual resources), an organization can understand how to exploit and develop its traditional resources better than its competitors can, even if some or all of those traditional resources are not unique (Zack, 1999a).

However, realizing the importance of organizational knowledge and its management in creating value and in gaining competitive advantage is only the first and the easiest step in any knowledge management (KM) initiative. The second, and almost as important, step is to answer how and where to begin questioning (Earl, 2001). In fact "many executives are struggling to articulate the relationship between their organization's competitive strategy and its intellectual resources and capabilities (knowledge)" (Zack, 1999a). As Zack (1999a) argued, they need a pragmatic, yet theoretically sound, model. The required model has to meet at least two criteria. First, it must explicitly include the external domains (opportunities/threat) and internal domains (capabilities/arrangements) of both business (B-) and knowledge (K-) strategies and the relationships between them. Second, it must provide alternative strategic choices.

This chapter stems from the premise that the realization of business value gained from KM investment requires alignment between the business (B-) and knowledge (K-) strategies of the firm. Therefore, it addresses the aforementioned issues by developing a "strategic alignment model (SAM)" for KM initiatives. It is based on the Henderson-Venkatraman SAM for IT (Henderson & Venkatraman, 1993).

The remainder of this chapter is organized as follows: The Henderson-Venkatraman SAM for IT (ITSAM) is first presented. Next, the KM Strategic Alignment Model (KMSAM) is developed and used to study the KM initiative at Buckman Laboratories. The paper then concludes by discussing the implications of the proposed metamodel and future research.

OVERVIEW OF THE HENDERSON-VENKARTAMAN STRATEGIC ALIGNMENT MODEL

The strategic alignment model (SAM), the framework for this study, is based on the theoretical construct developed by Henderson and Venkatraman (1993). In this model, business success is viewed as the result of the synergy between four domains. The first two, the external domains, are business strategy and information technology (IT) strategy. The strategy domains are described in terms of (business/technology) scope, (distinctive business/IT systemic) competencies and (business/IT) governance. The second two, the internal domains, are organizational infrastructure and processes and IT infrastructure and processes. Both internal domains are described in terms of (administrative/IT) infrastructure, (business/IT) processes and (business/IT) skills. This synergy is achieved through two types of relationship:

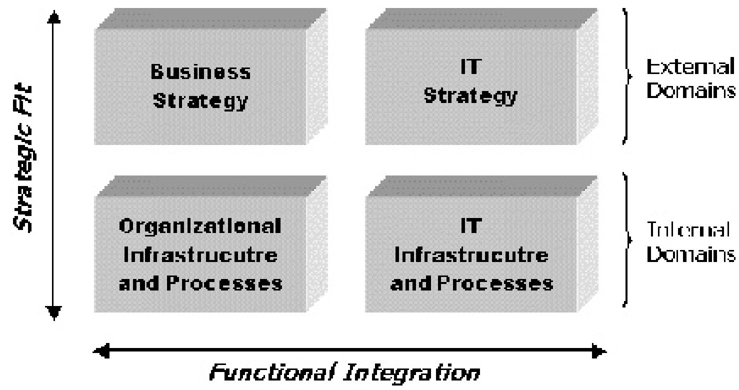
- Strategic fit emphasizes the need for consistency between strategy (external domain) and its implementation (internal domain).
- Functional integration, which has two modes, extends the strategic fit across functional domains. The first mode, strategic integration, deals with the capability of IT functionality both to shape and to support business strategy. The second mode, operation integration, focuses on the criticality of ensuring internal coherence between organizational infrastructure and processes and IT infrastructure and processes.

Figure (1) shows the elements of the IT Strategic Alignment Model (ITSAM).

KM Strategic Alignment Model

Whereas the premise of the original ITSAM is that, "the effective and efficient utilization of IT requires the alignment of IT strategies with business strategies" (Henderson & Venkatraman, 1993), the premise of knowledge management SAM (KMSAM), in which knowledge strategy replaces IT strategy, is that, "the effective and efficient use of organizational knowledge requires the alignment of knowledge strategies with business

Figure 1. IT strategic alignment model (Henderson & Venkatraman, 1993)



strategies." Since strategy, whether business (B)-strategy or knowledge (K)-strategy, can be seen as a balancing act between the external domain (opportunities/threats) and the internal domain (capabilities/arrangements) of the firm (strengths and weaknesses) (Henderson & Venkatraman, 1993; Zack, 1999a), the external and internal domains of K-strategy first have to be defined.

K-Strategy External Domain

In the case of K-strategy, the external domain involves three dimensions: K-Scope (what the firm must know), K-Systemic Competencies (what are the critical characteristics of the required knowledge) and K-Governance (how to obtain the required K-competencies). The first dimension, K-Scope, deals with the specific domains of knowledge that are critical to the firm's survival and advancement strategies. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability (Von Krogh et al., 2000).

In order to identify the required knowledge, two concepts are introduced. First, is the concept of the enterprise's cognitive domain, which is composed of all relevant things, together with the set of possible relationships between them, toward which thought or action is directed or is communicated by the members of the enterprise, i.e., business (B-) things. Examples of B-things include: business outcomes, business processes, resources, business rules (Davenport, Sbort, 1990; Eriksson, Penker, 2000; McDavid, 1999), consumer, supplier, competitors, and partners (e.g., distributors, vendors, banks, …).

Second, is the concept of knowledge (K-) thing. A K-thing describes the knowledge about the knowledge associated with a B-thing, i.e., the meta-knowledge. Each B-thing in the enterprise's cognitive domain is associated with certain knowledge that is needed to deal with it or to act upon it (Grant, Baden-Fuller, 1995). For example, STEP (The Standard for the Exchange of Product Model Data) data architecture recognized three categories of knowledge to be associated with a product, i.e., classification, marketing and technical (Fowler, Boyle, 1997). Classification knowledge is concerned with how the product is classified or categorized. Marketing knowledge is concerned with how the product is presented to the market. Finally, technical knowledge is the technical description of the product for the purpose of design, engineering, manufacturing, operations, maintenance, etc. This knowledge is characterized in terms of one or more knowledge thing (K-thing). Such a distinction between B-things and K-things is important, since the knowledge associated with a B-thing is in constant change and is context-dependent. For example, the knowledge required to manufacture certain product may change because of the introduction of new technology or the emergence of new marketing demands. Table (1) shows examples of a K-thing's attributes that characterize the knowledge associated with a B-thing.

Based on the concepts of B-thing and K-thing, determining the K-scope can be achieved by constructing a B-things/K-things matrix that documents the current and required state of organizational knowledge concerning some or all of the constituents of the enterprise cognitive domain. The first group of elements that constitute this matrix includes the list of B-things in the enterprise cognitive domain. The second group of elements includes the K-things that describe the current state of knowledge associated with each of the relevant B-things. To relate this knowledge to enterprise business strategies, K-things are further classified according to the roles they play in such strategies. Von Krogh et al. (2000) have suggested that there are two types of strategies: survival and advancement. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability. Therefore, organizational knowledge, and consequently K-things, are classified into two categories: survival (KS) and advancement (KA). Figure (2) shows the generic form of this matrix.

The second dimension of the K-strategy external domain is K-systemic competencies. The focus of this dimension is the set of utilization-oriented characteristics of knowledge that could contribute positively to the creation of new business strategy or to better support of existing business strategy. This set includes characteristics such as:

- Accessibility, the extent to which organizational knowledge is made available to

Table 1. Examples of the attributes of a k-thing

Attribute	Description
Actualization	The list of products, services, or processes in which the available or the required knowledge is/will be used.
Convertibility	The ability and the feasibility of converting knowledge from one form to another.
Compositionality	The amenability of knowledge to be synthesized from existing knowledge.
Currency	The recentness of knowledge.
Form	The form of the available/required knowledge: tacit, explicit.
Mode of Generation	The way by which the new knowledge is generated, i.e., acquisition, externalization, discovery, synthesis, creation.
Mode of Mobilization	The way in which the organizational knowledge, whether explicit or tacit, is distributed or shared.
Mode of Preservation	The way in which the organizational knowledge, whether explicit or tacit, is preserved.
Ownership	The bearers or the sources of available or required knowledge.
Value	The business value of actualized knowledge.
Visibility	The list of individuals and collectives who can access the knowledge.

Figure 2. The generic form of b-things/k-things matrix (Abou-Zeid, 2002)

Survival Knowledge				**Advancement Knowledge**		
B_1	K_{S11} (Current/Required States)	….	K_{S1n} (Current/ Required States)	K_{A11} (Current/Required States)	….	K_{A1m} (Current/Required States)
B_2	K_{S21} (Current/Required States)	….	K_{S2k} (Current/ Required States)	K_{A21} (Current/Required States)	….	K_{A2l} (Current/Required States)
….	….	….	….	….	….	….
B_N	K_{SN1} (Current/ Required States)	….	K_{SNk} (Current/ Required States)	K_{AN1} (Current/ Required States)	….	K_{ANl} (Current/Required States)

its members, regardless of time or location (Buckman, 1998);

- Transferability, the extent to which the newly acquired knowledge can be applied in other contexts, e.g., organizational, cultural (Grant, 1996);
- Appropriability, the extent to which knowledge can be imitated. Things are said to have "strong" appropriability if they are difficult to reproduce by another organization. The converse is "weak" appropriability. A related concept is that of "sticky/slippery", i.e., sticky knowledge is such an integral part of a regime that it cannot be extracted in a meaningful whole (Grant, 1996; Narasimha, 2000);
- Depth and breadth (Narasimha, 2000);
- Compositionality, the amenability of knowledge to be synthesized from existing knowledge; and
- Integrateability, the extent to which the newly acquired knowledge can be integrated with existing knowledge.

Finally, the K-governance dimension deals with the selection and use of mechanisms for obtaining the required K-competencies. The following are examples of some "acquisition mechanisms" (Probst, Raub, Romhardt, 2000):

- Bringing experts to the firm by recruiting specialists as full-time or temporary staff. Temporary hiring is becoming an increasingly interesting alternative.
- Tapping knowledge held by other firms through different inter-organizational co-operation forms, such as joint ventures or strategic alliances.
- Utilizing the knowledge of stakeholders, e.g., customers, suppliers, employees and owners. For example, involving customers early in the product-development process could generate valuable information about their needs.
- Acquiring knowledge products, such as software, patents, and CD-ROMs.

K-Strategy Internal Domain

In the case of K-strategy, the internal domain involves three dimensions: Knowledge (K)-infrastructures, Knowledge (K)-processes and Knowledge (K)-skills. Organizational knowledge processes are socially interaction-intensive. They involve social interactions and direct communication and contact among individuals and among members of "communities of practice." Therefore, they require the presence of social capital. Social capital is "the sum of actual and potential resources embedded within, available through, and derived from the network of relationships possessed by a social unit" (Nahapier, Ghoshal, 1998). Recognizing the importance of social capital, Gold et al. (2001) have identified three key K-infrastructures, i.e., technical, structural and cultural, that enable social capital. The K-technical infrastructure includes IT-enabled technologies that support KM activities, such as business intelligence, collaboration and distributed learning, K-discovery, K-mapping, opportunity generation and security. The K-structural infrastructure refers to the presence of enabling formal organization structures and the organization's system of rewards and incentives. Finally, the K-cultural infrastructure involves elements, such as corporate vision and the organization's system of values (Gold et al., 2001).

The second dimension of the K-strategy internal domain, Knowledge (K)-processes, deals with the processes that change the states of K-things. While things in the cognitive domains of the enterprise (B-things) are relatively stable, the associated K-things are in a state of continual change. For example, during its life cycle K-things can exist in different states that correspond to the states of the knowledge associated with B-things. The life cycle of a K-thing starts with the "Being identified" state. This state occurs whenever the necessity of having certain knowledge relevant to a B-thing becomes obvious, and the form of the required knowledge, together with its owner/bearer, is identified. After being identified the K-thing may have many states, such as "Being created," "Being acquired," "Being discovered," "Being synthesized," "Being externalized," "Being preserved," "Being actualized," "Being justified," "Being updated," "To be evaluated," "Being evaluated," "Being mobilized," and "Being visible." Some of these states are composite; for example, the state "Being justified" contains nested states such as "Being conceptually justified" and "Being commercially justified" (Abou-Zeid, 2002). The state transitions of a K-thing are caused by performing one or more K-manipulating processes. Based on the literature review (e.g., Firestone, 1999; Nissen, Kamel, Sengupta, 2000; Nonaka, 1994; Probst et al., 2000; Zack, 1999b) and on analysis of several KM initiatives (e.g., Davenport, 1998; Elliott, 1997, 1998), K-manipulation processes can be classified into three main categories, i.e., K-generation, K-mobilization and K-application.

K-Generation Processes

The knowledge generation process includes all activities by which new knowledge is generated within the organization. There are several types of knowledge generation, namely:

- Acquisition, where the new knowledge is acquired from external sources;
- Externalization, where the convertible tacit knowledge of the members of the organization is conceptualized and articulated;
- Discovery, where the knowledge hidden in the data sources of the organization (e.g., databases, data warehouses) is discovered (O'Leary, 1998);
- Synthesis, where the new knowledge is generated either by integrating the newly generated and validated knowledge with the existing knowledge or by combing the existing knowledge;
- Production (creation), where the new knowledge is produced by interacting with the things in the cognitive domains of the enterprise (Cook, Brown, 1999).

K-Mobilization Processes

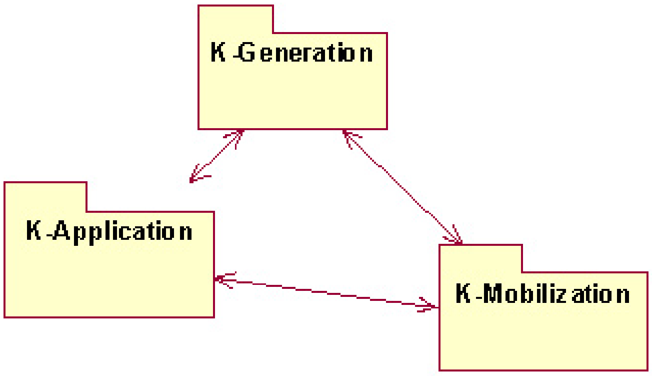
Knowledge mobilization means increasing the visibility of knowledge by sharing it or transferring it from one bearer (the knowledge provider, owner or source) to another (the knowledge seeker or target) through space or time. The knowledge bearer could be an artifact, such as technical documents or best practice databases, or human, such as experts in a certain domain. Based on the nature of the provider/source and seeker/target, four K-mobilization types can be distinguished, i.e., human-human, human-artifact, artifact-human and artifact-artifact.

- Human-human: Mobilizing knowledge among individuals depends on its form. In the case of tacit knowledge, this mode can be realized through activities such as socialization, which results in the creation of common perspectives and shared experience (Nonaka, 1994) or informal and semi-formal learning, e.g., mentorship and apprenticeship. In the case of explicit knowledge, it can be realized through activities such as formal learning, i.e., professional training. Moreover, through these activities individual knowledge will be preserved by extending its ownership range.
- Human-artifact: Two processes are needed in order to transfer the explicit knowledge and store it in physical media, i.e., knowledge (K-) refinement and knowledge (K-) preservation processes. K-refinement process consists of all the knowledge activities intended to refine existing or newly generated explicit knowledge, e.g., testing, labeling, indexing, abstracting, restructuring, and to maintain (update) the existing explicit knowledge (Zack, 1999b). The refined knowledge is then preserved. The K-preservation process includes activities, such as formalizing, codifying, organizing, and storing in different media.
- Artifact-human: This type of K-mobilization includes the processes that aim at increasing the visibility of the preserved explicit knowledge that is stored in physical media, i.e., K-delivery and K-presentation. An example of such processes is K-delivery process, which includes activities such as pushing/pulling, searching/retrieving. However, as knowledge and knowledge use are context-dependent, whether this context is related to the individual user or to the business process in which it will be used, the effective use/re-use of knowledge depends upon the degree to which the presented knowledge matches its context-of-use. From this perspective, the K-presentation process aims to develop the capabilities for presenting explicit knowledge "with sufficient flexibility to render it meaningful and applicable across multiple contexts of use" (Zack, 1999b).
- Artifact-artifact: The main purpose of the processes of this type of K-mobilization is to develop and implement machine-processable representations of the semantics of the preserved knowledge. For example, the Resource Description Framework (RDF) specifications provide a lightweight ontology system to support the exchange of knowledge on the Web. It provides interoperability between applications that exchange machine-understandable information on the Web (Harmelen, Fensel, 1999; W3C, 1999).

K-Application Processes

During K-application processes, knowledge is embodied in various forms. Knowledge can be used to develop new product/service/business processes or to improve existing ones. Associated with the processes of K-application are the processes of K-evaluation, which includes all the activities that aim at justifying and measuring the business value of the knowledge. Von Krogh et al. (2000) have identified three types of knowledge justification. The first type, strategic justification, includes justifying the newly generated knowledge against the advancement and survival strategies of the company. The second type, stakeholders' justification, focuses on evaluating the stakeholders' attitudes towards the newly generated knowledge. The final type, emotional justification, concerns the aesthetic value of the newly generated knowl-

Figure 3. K-manipulating processes



edge (Von Krogh et al., 2000). The K-evaluation process may initiate a K-identification process, which includes all the activities that develop the awareness of the need to create new K-things or to update existing ones. It also includes activities that determine the form, the convertibility, and the owner(s) of the required knowledge. The following are examples of such activities:

- Determining the knowledge gap by comparing knowledge needs with the existing knowledge.
- Identifying the form and convertibility of the required knowledge.
- Identifying the possible internal and external sources of the required knowledge.

Figure (3) shows the cyclical nature of K-manipulating processes.

However, knowledge processes are characterized by their dual nature. On the one hand, there are K-manipulating processes, i.e., processes such as acquiring knowledge, converting it into a useful form, applying it, and protecting it. On the other hand, it has been identified that cultural and organizational issues are crucial in the successful deployment of KMS (Alavi, Leider, 1999; Von Krogh et al., 2000). Therefore, each K-manipulating process should be associated with one or more K-enabling process. The following are examples of K-enabling processes (Von Krogh et al., 2000):

Managing Conversation

This process includes setting the guiding principles for holding fruitful conversations with respect to encouraging active participation, establishing conversational etiquette, editing, and fostering innovative language.

Mobilizing Knowledge Activists

The principal activities of this process consist of triggering K-manipulating activities throughout the different parts of an enterprise, coordinating them, and providing overall directions for them. These activities are performed by the "knowledge activist," which could be an individual, group or function.

Creating the Right Context

As K-manipulating activities are crucially dependent on social interactions among the organizational members, this process aims at setting "shared spaces" - physical, cyber, and mental - that enhance existing interactions and foster new ones. This involves creating the organizational structures that foster solid and effective collaboration.

Globalizing Local Knowledge

This process aims at supporting the creative approach to knowledge mobilization. Since knowledge is context-sensitive, it cannot be treated as a "commodity" that can be packaged and shipped to another location, within or outside the organization, to be readily re-used. Rather, to be effective, it must be reshaped by local experience and expectations, and justified by local values. In other words, it must be re-created.

Table (2) is an extension of the von Krogh et al. (2000) knowledge enabling grid. It shows the links between K-manipulating processes and K-enabling processes, and to what degree each K-enabling process affects the related K-manipulating process.

The last dimension of the K-strategy internal domain is K-skills. KM processes are by their very nature multifaceted. They involve many dimensions, such as technical, organizational

and human. This characteristic of KM processes reflects on the nature of skills required to perform them. For example, Malhotra (1997) defines a senior Knowledge Executive, such as a Chief Knowledge Officer (CKO) or an Organizational Knowledge Architect, as the person who should have the combined capabilities of a business strategist, technology analyst, and a human resource professional. The ability to facilitate the ongoing process of knowledge sharing and knowledge renewal, the ability to develop the human and cultural infrastructure that facilitates information sharing, and the ability to utilize the available technologies for serving the creation, sharing and documentation of knowledge are some examples of the required skills.

The Dynamics of KMSAM

Affecting a change in any single domain requires the use of three out of the four domains to assure that both strategic fit and functional integration are properly addressed. Therefore, applying KMSAM requires the identification of three domains: pivot, anchor and impacted (Luftman, 1996). The pivot domain is the weakest and offers the greatest opportunity for improvement. The anchor domain is the strongest and will be the driver of change. Finally, the impacted domain is the area affected by a change to the pivot domain. Figure (4) shows the dynamics of the strategic alignment process. Based on this distinction, 12 perspectives of strategic alignment can be identified (see Table (3)). Among the 12 perspectives, the last four are fusion perspectives that result from fusing two of the eight single-path perspectives. In the fusion perspectives, the pivot domain is not directly adjacent to the anchor domain (Luftman, 1996).

KMSAM AT BUCKMAN LABORATORIES

In order to illustrate its interpretive power, KMSAM it will be used to study one of the KM initiatives at Buckman Laboratories (Buckman, 1998; Fulmer, 1999; Pan, Scarbrough, 1999; Rifkin, 1996). The first KM initiative, global knowledge sharing, was introduced when Robert Buckman, who became the new chairman and CEO in 1978, was convinced that the company was too "product driven" and not sufficiently

Figure 4. The dynamics of the strategic alignment process

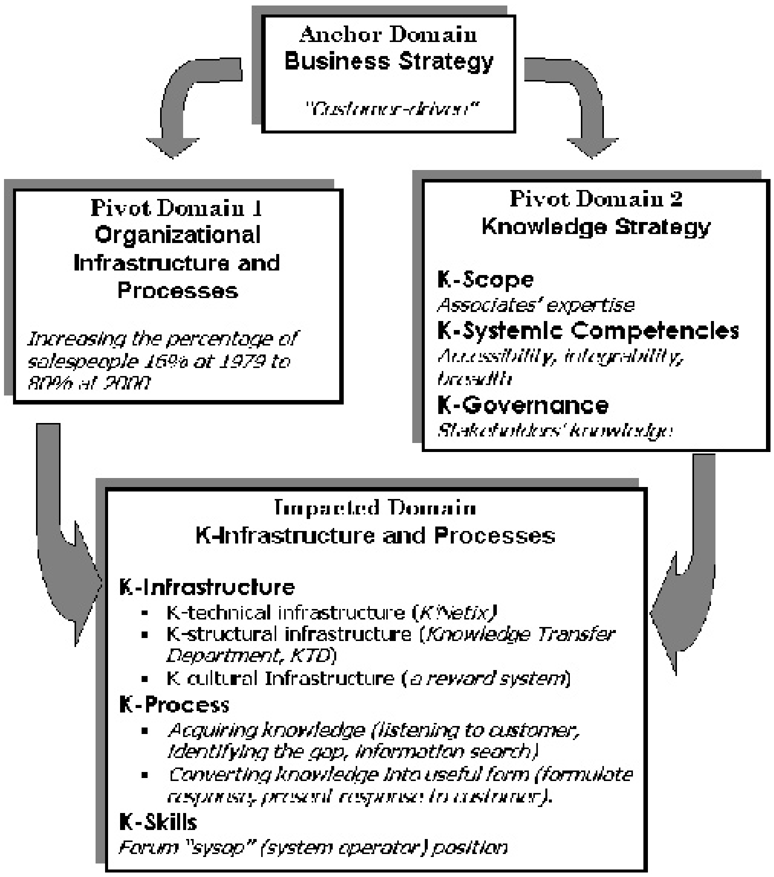
9	**K-Infrastructure Fusion** (Perspectives 1 + 2)	Business Strategy	• Organizational Infrastructure • K- Strategy	K-Infrastructure
10	**Organizational Infrastructure Fusion** (Perspectives 3+ 4)	K-Strategy	• Business Strategy • K-Infrastructure	Organizational Infrastructure
11	**Business Strategy Fusion** (Perspectives 5+ 6)	K-Infrastructure	• Organizational Infrastructure • K- Strategy	Business Strategy
12	**K-Strategy Fusion** (Perspectives 7+ 8)	Organizational Infrastructure	• Business Strategy • K-Infrastructure	K-Strategy

"customer driven." This shift reflected Buckman's belief that "cash flow is generated on the front line with customers, by associates…who have built relationships of continuity and trust, face-to-face with the customer" (Fulmer, 1999). To realize such a strategic shift, the percentage of salespeople, i.e., those employees "effectively engaged with the customer," was increased from 16% in 1979 to 80% by 2000 (Rifkin, 1996). Moreover, salespeople must provide fast and correct answers to customers by deploying the company's tacit knowledge, carried in the heads of the company's associates, at the points of sale. The new K-strategy that emerged from this strategic business shift was characterized by its emphasis on associates' expertise (K-scope), accessibility, integrateability and breadth of knowledge - "replace the depth of knowledge offered in a multi-tiered hierarchy with the breadth of knowledge that is the sum of the collective experience of employees" (Fulmer, 1999) - (K-systemic competencies) and "utilizing stakeholders' knowledge" as the main mechanism for acquiring knowledge (K-governance).

Figure 5. "K-infrastructure fusion" perspective at Buckman Laboratories



The implementation of this new K-strategy was accomplished by developing K-infrastructures, K-processes and K-skills. The first component of K-infrastructures, K-technical infrastructure, is K'Netix, a global corporate intranet consisting of e-mail, seven forums, files of company knowledge and databases of 'fluid' knowledge. K'Netix's forums are "open spaces" where anyone can post a message, question, and/or request for help. The second component, K-structural infrastructure, is the Knowledge Transfer Department (KTD) which is formed by merging three departments: IS, Telecommunication and Technical Information Center. The last component, K-cultural Infrastructure, includes a reward system, "the most powerful people are those who become a source of knowledge by sharing what they know" (Rifkin, 1996) and Buckman's Code of Ethics that "provides the basis for the respect and trust that are necessary in a knowledge sharing environment" (Fulmer, 1999). As both Buckman's B-strategy and K-strategy are customer driven, the K-sharing flow includes processes such as K-acquisition (listening to customer), K-externalization (formulating response), and K-presentation (presenting response to customer). Finally, the K-skills at Buckman Laboratories are exemplified by the forum "sysop" (system operator) position, which has been established to facilitate discussion, promote usage, track requests and make sure that they were fulfilled and to assist users.

From the previous discussion, one can identify the "K-infrastructure fusion" strategic alignment perspective adopted by Buckman Laboratories. In this perspective, B-strategy is the anchor domain that drives the change, K-strategy and organizational infrastructure are pivot domains and K-infrastructure and processes are the impacted domain. Figure (5) shows the "K-infrastructure fusion" perspective at Buckman Laboratories.

CONCLUSION

Based on the premise that the realization of business value from KM investments requires alignment between the business and knowledge strategies and on the IT strategic alignment model (SAM) developed by Henderson and Venkatraman (1993), a KM strategic alignment model (KMSAM) is developed. The interpretive power of KMSAM is illustrated by studying the KM initiative at Buckman Laboratories. Moreover, it provides executives with a logical framework for analyzing and assessing alternative strategic choices with regard to aligning K-strategy and B-strategy.

Extension of this work would move in two directions. The first would be to use KMSAM in a cross-sectional study of KM initiatives in order to identify the dominant patterns of K-strategy and B-strategy alignment. As "strategic alignment is not an event, but a process of continuous adaptation and change" (Henderson, Venkatraman, 1993), the second direction would be a longitudinal study of each enterprise cycle around the alignment perspectives and how the adopted perspective is related to the degree of maturity of the KM initiative.

Chapter 6.12
Competitive Advantage of Knowledge Management

Gabriel Cepeda-Carrión
University of Sevilla, Spain

INTRODUCTION

Knowledge management has been proposed as a fundamental strategic process and the only sustainable competitive advantage for firms (Grant, 1996; Davenport, 1998). A key to understanding the success and failure of knowledge management efforts within organizations is the ability to identify the relevant knowledge to manage and to extract value out of this knowledge. In the last decade past research has focused heavily on defining what knowledge is and on using different typologies (e.g., tacit vs. explicit knowledge, individual vs. collective) to characterize the different types of knowledge available to firms (e.g., Polanyi, 1967; Spender, 1996). In addition, researchers have described the processes through which knowledge is created, developed, retained, and transferred in firms (e.g., Argote, 1999; Nonaka & Takeuchi, 1995), and the role played by leadership (Bryant, 2003; Vera & Crossan, 2004) and decision-making styles (Kalling, 2003) in influencing these processes. Unfortunately, despite the growing interest in knowledge management, little specific has been said about the mechanisms firms use to identify key knowledge areas and to gain competitive advantage out of knowledge management investments. The recognition of the important knowledge resources for a firm is critical, because the effectiveness of knowledge and learning can only be assessed on the basis of its utility in guiding behavior relative to the firm's relevant domain (Crossan, Lane, & White, 1999; Cepeda, Galán, & Leal, 2004; Zack, 1999). Knowledge for the sake of knowledge is not useful to firms.

We define knowledge management as the formalized, integrated approach of managing an enterprise's articulated and tacit knowledge assets. Knowledge assets include systems, documents, policies, and procedures, as well as unarticulated expertise and experience across the individuals, groups, organizational, and inter-organizational domains. We discuss how a knowledge management infrastructure enables the generation, acquisition, use, and transfer of knowledge, and most importantly, the identification of the critical knowledge areas for a firm. Moreover, we argue that competitive advantage consists of two dimensions: the value created to the customer and the ability to differentiate (through cost, innovation, or both) from competitors. The framework describes specific mechanisms through which knowledge management contributes to these two processes. Building on a resource-based view of the firm (Barney, 1991, 1995, 2001) and the knowledge management and organizational learning literatures (Grant, 1996; Hall, 1992, 1993; Spender, 1996), we develop a framework to address how critical knowledge areas can enable competitive advantage sources through customer approach and competitor approach.

This article integrates knowledge management and strategic management fields by taking a fine-grained look at the connection between knowledge resources and competitive advantage. We are explicit about how firms can identify key knowledge areas that impact competitive advantage, and how they can implement market (value creation) and competitor (differential capabilities) mechanisms that are instrumental in obtaining competitive advantage. Our integrative approach provides a fresh perspective on knowledge management from which we generate important insights for management practice. Only relevant and available knowledge impacts competitive advantage, thus top management needs to proactively engage in identifying this knowledge and extracting value out of it.

BACKGROUND

The relevance and importance of knowledge is becoming increasingly critical in business as we transition from an industrial era into an information and knowledge era.

With the arrival of the knowledge and information age as well as the service economy, the importance of effective knowledge and management has been emphasized by several scholars and industry analysts (Quinn, 1992; Toffler, 1990; Nonaka, 1991; Glazer, 1991; Leonard-Barton, 1992; Bohn, 1994; Klein & Prusak, 1994; Winslow & Bramer, 1994; Davis & Botkin, 1994; Peters, 1992). Drucker (1994) argues that the world is witnessing a great transformation, which he calls the "post-capitalist society," in which the basic economic resources will no longer be the traditional production input factors, but that the primary resource for both organizations and the economy will be knowledge.

Organizational knowledge management (KM) as a source of competitive advantage is now widely recognized (Nonaka, 1991; Bohn, 1994; Davis & Botkin, 1994). KM holds key implications for virtually all industries. Research indicates that knowledge and knowledge work has infiltrated deep into the value chain of most businesses (Quinn, 1992). Some of the reasons for this infiltration, such as product differentiation, creating "best in class" capabilities, and setting high entry barriers, provide important insights in the area of organizational knowledge and its impact on core business processes and functions. According to Quinn (1992) the majority of all public and private organizations are rapidly shifting to become repositories and coordinators of knowledge-based activities.

As we transition from an industrial/manufacturing economy to a more service-driven economy, we see the emergence of knowledge-intensive service organizations emerging alongside the more traditional capital-intensive and labor-intensive organizations (Bonora & Revang, 1993). Examples of knowledge-intensive service organizations include consulting, software engineering, law firms, and health care.

Actually, the challenge posed to contemporary businesses, particularly knowledge-intensive firms, is to remain competitive in a highly volatile and competitive knowledge environment in which markets quickly shift, technologies rapidly proliferate, competitors multiply, and products and services become obsolete almost overnight. Increasing customer needs and demands for immediate high value at low cost mandates the harnessing of knowledge coupled with the flexibility to meet changing needs. Achieving this goal in the information age requires the implementation of different strategies from those that were effective in the industrial age. For traditional organizations, it is no longer adequate to only achieve production and manufacturing efficiency. Knowledge-intensive firms, as well as traditional organizations, now increasingly compete because of knowledge and information. As a result, the issue of ownership and control of knowledge as a source of power in business has also become increasingly important. Both industry and academia are looking for approaches and methods to capture, organize, and leverage knowledge for increased competitiveness.

A set of publications (Stewart, 1994; Sveiby & Risling, 1987; Sveiby, 1990; Starbuck, 1990) indicates that several organizations are learning how to capture, manage, store, and leverage knowledge, and are making significant investments in KM. In this way, increasingly, firms are implementing KM, which is not surprising, since several types of firms, such as consulting and law firms, have the primary business of the application of their knowledge. Some authors include the idea of demonstrating accrued knowledge and experience in their area of service to customers, thereby retaining current customers and gaining new business by quickly delivering high-value solutions at low cost (faster, better, cheaper than their competitors). To leverage knowledge and intellectual capital in a more cost- and time-efficient manner, the firms develop employee competencies by sharing leading practices in their service areas, and capture and preserve knowledge that may be lost as a result of individuals leaving the firm.

A review of literature in the area of knowledge and information management reveals that many scholars have highlighted the importance of knowledge and information management.

MAIN FOCUS OF THE ARTICLE

An Organizing Framework Linking KM and Sustainable Competitive Advantage

Knowledge and Competitive Advantage

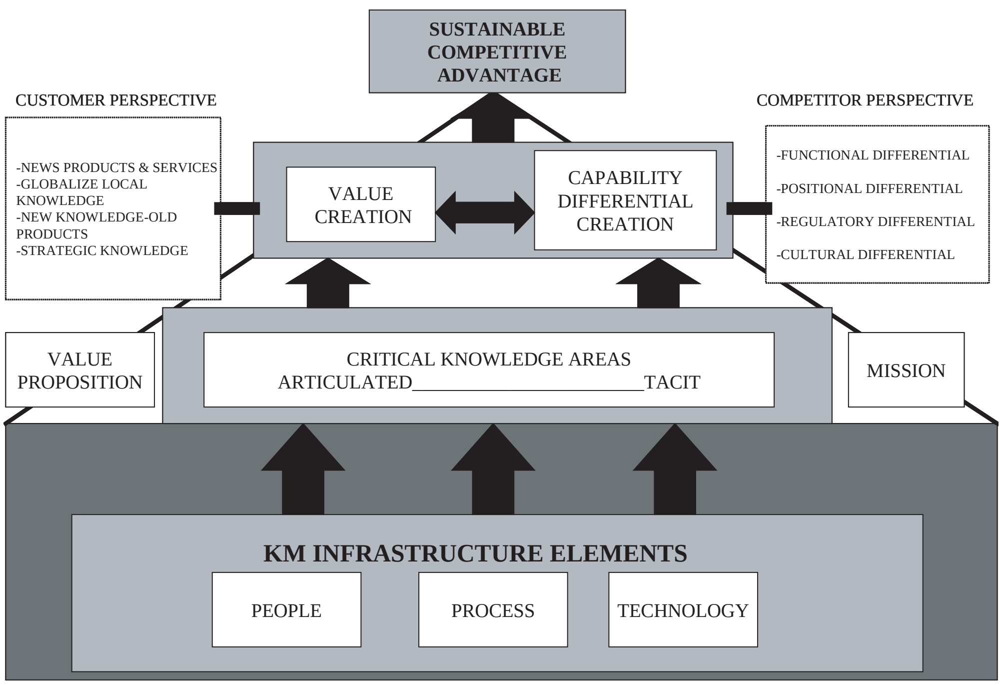
Knowledge activities in organizations have increased in significance over the past few years (Davenport & Klahr, 1998). In fact, knowledge has been proposed as the primary source of wealth creation (Cole, 1998), and knowledge protection has been suggested as critical to generate and preserve competitive advantage (Porter-Liebeskind, 1996). Davenport and Prusak (1998) also note that the only sustainable competitive advantage a firm has comes from what it collectively knows, how efficiently it uses what it knows, and how readily it acquires new knowledge.

Our conceptual development builds on the resource-based view (RBV) of the firm, an influential theoretical framework for understanding the creation and sustainability of competitive advantage (Barney, 1991; Nelson, 1991; Peteraf, 1993; Teece, Pisano, & Shuen, 1997). In this perspective, firms are conceptualized as bundles of resources. Resources are heterogeneously distributed across firms; resource differences might persist over time (Amit & Schoemaker, 1993). Resources are defined as all assets, capabilities, organizational processes, or firm attributes which are controlled by a firm, and which enable it to conceive of and implement strategies that improve its efficiency and effectiveness (Barney, 1991; Daft, 1983). When the resources are valuable, rare, inimitable, and non-substitutable (VRIS), firms can achieve sustainable competitive advantage by implementing strategies that leverage their resources in unique ways (Dierickx & Cool, 1989; Barney, 1991; Grant, 1996; Amit & Schoemaker, 1993).

One of the few resources that can pass the VRIS test is knowledge. Consequently, several authors have argued for a knowledge-based view (KBV) of the firm as a specialized case of RBV (Conner, 1991; Conner & Prahalad, 1996; Ghoshal & Moran, 1996; Grant, 1996b). KBV presents firms as social communities (Kogut & Zander, 1992) with the primary role of integrating the specialist knowledge resident in individuals into goods and services, so that organizational capabilities are the manifestation of this knowledge integration (Grant, 1996). Knowledge is embedded in multiple entities within the firm, such as the organizational culture, routines, policies, systems, and documents, as well as individuals and teams (Crossan et al., 1999; Nelson & Winter, 1982; Grant, 1996; Spender, 1996). Knowledge shapes the firm's core competences (Prahalad &Hamel, 1990) and therefore determines value creation (Grant, 1996). Furthermore, tacit knowledge, social knowledge, and complex knowledge are difficult to imitate (Leonard & Sensiper, 1998; Helfat & Raubitschek, 2000; McEvily & Chakravarthy, 2002). Hence, competences based on these types of knowledge cannot be easily duplicated by competitors, and strategies based on these competences are likely to lead to sustainable competitive advantage.

A contentious aspect of knowledge is its definitional domain. Researchers have engaged in a

Figure 1. Critical knowledge areas, value creation, capability differentials, sustainable competitive advantage, and infrastructure elements (people, process, technology)



passionate debate about what knowledge is and what forms or types of it are available (Collins, 1993; Drucker, 1994). Knowledge has been defined as information whose validity is established through test of proof (Porter-Liebskind, 1996), and as relevant and actionable information based at least partially on experience (Leonard & Sensiper, 1998). While the positivist view ("knowledge as justified true belief") is the predominant one in Western culture and a generally accepted assumption in organizational theory (Nonaka & Takeuchi, 1995), it has been increasingly complemented by authors arguing that knowledge cannot be conceived independently from action (Blackler, 1995; Cook & Brown, 1999; Polanyi, 1967). These views shift the notion of knowledge as a commodity that people acquire to the study of knowing as something that they do.

For the purpose of this article, we define knowledge as familiarity with or understanding of a phenomenon. Knowledge can be contained in subjects such as individuals, groups, and organizations, and in objects such as systems, products, and processes. We view knowledge as a higher form of information, which is elevated by the specific nature and purpose of the organization to provide an opportunity that the firm can exploit for its advantage (Beckett, Wainwright, & Bance, 2000). Hence, the challenge for many firms is to identify that knowledge, which is relevant to their goals and strategies.

Figure 1 shows interrelationships between knowledge management infrastructure, critical knowledge areas, and various elements leading to sustainable competitive advantage. These relationships between these elements ensure the leading and enhancing sustainable competitive advantage. In the next sections, we discuss the factors that influence the identification of critical knowledge areas and the mechanisms through which critical knowledge areas have an impact on competitive advantage.

Identifying Critical Knowledge Areas

Critical knowledge areas are specific bodies of knowledge or key resource capabilities that are unique to an enterprise and reside at the core of their business (Thompsen, Ibarra, & Center, 1997). Given that "the most important context for guiding knowledge management is the firm's strategy" (Zack, 1999, p. 125), every strategic position is linked to some set of intellectual resources and capabilities. In order to implement knowledge management processes (e.g., data analysis and information communication) that support a firm's strategy, managers need to consider several issues. First, they need to assess what the firm must do to compete and what the firm can actually do (strategic gap) (Zack, 1999). Second, they should establish what the firm must know to compete and what the firm actually knows (knowledge gap) (Zack, 1999). Third, organizations need to recognize what their knowledge management infrastructure needs to be and what it currently is. While the first two issues focus on linking knowledge management efforts to strategic goals, the third point acknowledges that knowledge is a path-dependent resource (Teece et al., 1997) and that future knowledge configurations will be constrained by previous investments in a knowledge infrastructure. In the next sections we describe in further detail the role of two tangible components of a firm's strategy—its mission and value proposition—and that of the existing knowledge management infrastructure in helping organizational members to identify the firm's critical knowledge areas.

- Business mission: The starting point for business strategy is some underlying idea of why the business exists; this is typically comprised in a firm's mission, which includes a statement of the company's purpose and overarching goal (Grant, 2002). Some mission statements, such as that of Skandia, are explicit about the role of knowledge. For example, "Skandia creates unique skills around the world that allow us to provide the best financial solutions for our customers and enduring value for our shareholders. We build special relationships, engage the energy of our employees, and transfer knowledge with pride." If a statement of corporate purpose embodies or embraces knowledge, it becomes a "knowledge business vision" (Earl, 2001). Otherwise, when a business mission, such as that of America Online ("To build a global medium as central to people's lives as the telephone or television…and even more valuable") is not explicit about knowledge, the question firms need to answer is, what is the contribution that knowledge can make to the attainment of the firm's purpose?

Because a mission defines the basic functions the firm has decided to perform in society, it provides organizational members with initial strategic guidelines about the knowledge they require (Bailey & Clark, 2000; Beckett et al., 2000). The firm's goals and purpose create a roadmap that helps the company to define its core activities and the knowledge creation and knowledge sharing processes that will support those activities. For example, in an in-depth case study at a European Innovation and Technology Center, Cepeda et al. (2004) showed that the preparation of a mission statement—one that emphasized the promotion of innovation and research activities among companies in the industry—helped the firm to guide its knowledge management efforts. Given that their mission was the promotion of innovation efforts, organizational members identified knowledge areas such as training and development and industry social networks as critical for their success.

- Value proposition: A business' value proposition is a statement of the fundamental benefits it has chosen to offer in the marketplace; it answers the question: How does the business intend to attract customers? (Crossan, Fry, & Killing, 2002). A value proposition communicates to employees what the business is trying to do for its customers and, by inference, the requirements of their particular role. It represents the attributes that firms provide, through their products and services, to achieve satisfaction and build loyalty with their targeted customers (Thompsen, 1999). The choice of a value proposition is perhaps the most obvious way in which a business attempts to differentiate itself from competition (Crossan et al., 2002). For example, Microsoft and Harley-Davidson have a product-leadership value proposition; they offer one-of-a-kind products and services, state-of-the-art features, and innovative solutions that customers often cannot get anywhere else. In contrast, firms such as IBM and Nordstrom have a customer-relationship value proposition, choosing to focus on the quality of their relationships with clients and offering them "complete solutions." A third case is that of Wal-Mart and Southwest Airlines, which have an operational-excellence value proposition. These firms opt to excel at attributes such as price, quality, on-time delivery, selection, and availability that their rivals cannot match.

  To deliver a value proposition, a business needs to make choices about the core activities it intends to perform and the knowledge needed to perform those activities (Furlong, 2000). Furthermore, by comparing the value proposition to the current performance of the company, performance gaps can be detected (Earl, 2001). There could be quality problems, customer service issues, or a deficit in product innovation efforts. Analyzing the gap between the current and the desired value proposition is a way of discovering the critical knowledge needed. From this perspective, knowledge management supports strategy when it enables the firm to implement solutions based on the unique needs of the client.

- Knowledge management infrastructure: To implement knowledge management successfully, it is important to understand the infrastructure required to support the acquisition, generation, transfer, and storage of tacit and explicit knowledge resources. Knowledge management involves the coordination and integration of multiple knowledge-based activities, structures, systems, processes, and individuals with diverse roles in the organization. These elements are frequently grouped into three categories—people, processes, and technology—and constitute what scholars call a knowledge management infrastructure (Gold, 2001; Muzumdar, 1997).

  While knowledge management solutions are a rising phenomenon, many firms manage knowledge in an implicit way and have elements of a knowledge infrastructure without calling it so. For example, Volvo has extensive databases and core experts in lifecycle analysis; Sony has training cells on product disassembly and ensures knowledge sharing with designers; BMW design teams have permanent members from the recycling function to ensure lessons from previous experiences be incorporated into product design. The existence of implicit or explicit knowledge management elements (people, processes, and technology) creates awareness about the importance of knowledge and facilitates the identification of critical knowledge areas (Thompsen, 1999; Muzumdar, 1997; Cepeda et al., 2004).

  Furthermore, an existing knowledge infrastructure affects the identification of critical knowledge areas because knowledge resources are path dependent, which is to say that "a firm's previous investments and its repertoire of routines (its 'history') constrain its future behavior" (Teece et al., 1997, p. 522). Resources are specific to a firm, embedded in their routines or assets, and accumulated over time (Dierickx & Cool, 1989). Consequently, an existing knowledge infrastructure (people, processes, and technology) may constraint the process of identifying critical knowledge areas. Independent of the firm's strategy, the current infrastructure elements might create boundaries and mental models within which managers will evaluate their knowledge needs. In this circumstance, it may appear faster and easier to develop a new strategy that leverages the current knowledge management infrastructure than it would be to create a new knowledge infrastructure to leverage the desired strategy.

Relationship Between Critical Knowledge Area and Competitive Advantage

Having discussed factors that facilitate the identification of the critical knowledge areas that support a firm's strategy, we now discuss two processes that mediate the impact of critical knowledge areas on competitive advantage: value-creation ways and capability differentials. Value-creation ways address how knowledge contributes to competitive advantage through the satisfaction of customer needs (customer perspective). In contrast, capability differentials address how knowledge contributes to competitive advantage through differentiation from competitors (competitor perspective).

- Value-creation ways: An emphasis on customer value and value creation is an intangible asset that has been posited to positively influence business performance and competitive advantage (Narver & Slater, 1990; Deshpandé et al., 1993; McNaughton, Osborne, & Imrie, 2002). The ultimate test of value creation is whether customers are willing to pay for a firm's products and services under conditions of wide competitive choices available to them (Rastogi, 2003). Knowledge is at the origin of most improvements in customer value (Novo, 2001; Rowley, 2002). Companies create value by instilling knowledge in products and services (Rastogi, 2003), by applying new knowledge to old problems (and in the process displacing existing knowledge), and by synthesizing discrete kinds of existing knowledge (Hamel, 2000). Another way to create value to customers is by globalizing deeply embedded local knowledge (Hamel, 2000). This implies transferring knowledge in the form of products that are easily moved worldwide, but also the more subtle effort of transferring knowledge in the form of services. In addition, firms create value by converting knowledge to strategic knowledge and enhancing shareholder wealth (Hamel, 1996, 2000). Because organizations grow or decline as their value-creation possibilities expand or contract, the richer, wider, and more varied the knowledge resources, the larger the value-creation opportunities open to the enterprise (Rastogi, 2003). Thus, a firm's capacity for sustained and superior value-creating ability may lie in the richness of its knowledge.

- Capability differentials: Coyne (1986) identifies the sources of sustainable competitive advantage as being four types of capability differentials, which Hall (1992, 1993) labels functional capabilities, cultural capabilities, positional capabilities, and regulatory capabilities. While functional and cultural capabilities involve competences and processes such as advertising and manufacturing, positional and regulatory capabilities refer to assets that the firm owns such as brands and reputation. By including assets and processes, the notion of capability differentials encompasses the concepts of resources and capabilities as described by RBV (Barney, 1991) and the dynamic capabilities perspectives (Teece et al, 1997; Eisenhardt & Martin, 2000). Because knowledge is the cornerstone of resources and capabilities, competitive advantage depends on the speed at which organizations can generate, capture, and disseminate knowledge, and use it to develop new resources and capabilities that competitors cannot easily imitate (Sharkie, 2003).
  Zack (1999) stresses the importance of concentrating on the development of unique and valuable capabilities, rather than exclusively focusing attention on the production of products and services. A concentration of products and services can provide, at best, short-term advantages because, as Schumpeter (1934) argues, organizations that engage in invention, innovation, and imitation in a continual basis render current products and services obsolete. Long and Vickers-Koch (1995) also argue that organizations that wish to improve their performance need to develop underlying skills and expertise, and channel them into process improvements. These skills and expertise include capability differentials such as know-how of employees, suppliers, and distributors (functional); learning ability and quality perception (cultural); reputation and networks (positional); and contracts, licenses, and trade secrets (regulatory). The building up of these internal capabilities results in sustainable competitive advantage because of the difficulty in imitating competences that are based on knowledge,

skills, and attitudes; built into processes; and developed over time in a particular organizational context (Long & Vickers-Koch, 1995; Quinn, 1992).

FUTURE TRENDS

On the basis of the issues in this article, specific recommendations are made for further research.

- Multiple case studies are recommended to establish the basis for cross-case analysis and the potential for even more compelling evidence and conclusions. Multiple case studies also provide greater probabilities for external validity and generalizability of the theory.
- A quantitative study is also recommended. Such a study could be designed to establish baseline strategic decisions, measures, and competitive comparisons. Other procedures could be designed to isolate specific decisions that incorporate deliberation of the critical knowledge area and to track the relative measurable impact upon the business results and competitive position of an enterprise.
- Additional research is recommended to establish financial valuation measures for a critical knowledge area and the creation of a theoretical foundation for a business formula to identify a measurable return on critical knowledge.

To summarize, the results of these recommendations would be expected to build upon the theoretical foundation. This additional research would extend and enrich this framework.

CONCLUSION

Several conclusions are derived from the description of this framework. These are presented as follows.

The eventual isolation of a unique body of knowledge, the identity of a critical knowledge area can create a new perspective on the enterprise and how it contributes value to its customers. The framework can support management's intent in creating and using a business planning framework of competitive analysis, strategy formation, and identification of critical success factors for decision making and measurement. Such a business framework is designed to create a managerial mindset that is predisposed to focus upon certain factors. The practitioners could find this predisposition as a source of difficulty in reframing their perspective of the organization. These conclusions align with the research of Penrose (1959), Mahoney (1995), Leonard (1998), and Thompsen (1999) on the impact of mental models on the identification and selection of key resource-capabilities that can serve in the best interest of the firm.

A critical knowledge area can be considered as another critical success factor and important for management decision making and the formation of competitive strategy. By examining the connections between the critical knowledge area and the points of competitive differentiation (differential capabilities and value creation ways), specific actions can be identified to leverage those points and enhance competitive advantage. A critical knowledge area can be a unifying factor in the development of an integrated strategy for enhancing competitive advantage. It can also be used to align infrastructure, policies, practices, systems, and processes to achieve fulfillment of competitive strategies.

Consistent deployment of a critical knowledge area is expected to produce positive impact on business results and relative competitive position. The development of benchmarking data and subsequent measurement are required to confirm such results. These findings and conclusions build on the research of Hall (1993) and Kamoche (1996), which concluded that resource-capabilities have important implications in management practice.

To summarize, the described framework could be aligned with the theoretical proposition that the identification of key resource-capabilities, or critical knowledge areas, in a firm can serve as an important and practical foundation for management decision making and enhancing competitive advantage.

The identification of key resource-capabilities or a critical knowledge area is an essential step in defining competitive forces and determining strategy. A critical knowledge area is another critical success factor that can be used in conducting situational and competitive analysis, formulating differentiating strategies, making strategic decisions, and aligning the organization infrastructure for strategy fulfillment.

The consideration of a critical knowledge area in management deliberations in a variety of scenarios can enhance competitive advantage and the potential for positive business results. The structure of an organization, its processes, systems, policies, and practices can be examined and adjusted to achieve greater leverage with the critical knowledge area. Some of these processes and systems include: acquisition/generation, store/retrieval, transfer, application, and protection.

A critical knowledge area can also used as a benchmarking measure for comparison of practices. Asset valuation and ownership policies can be more intentionally applied to the critical knowledge area. All of these are examples that demonstrate ways in which the identification and measurement of a critical knowledge area can impact management decision making and contribute to the economic value of a firm.

Chapter 6.13
An Exploratory Analysis of Information and Knowledge Management Enablers in Business Contexts

Karen Nelson
Queensland University of Technology, Australia

Michael Middleton
Queensland University of Technology, Australia

ABSTRACT

This chapter explores the factors limiting organizational information and knowledge management (IKM) through the perceptions of IKM practitioners. The authors propose that a number of organisational factors – which for them are enablers – have the ability to influence IKM project outcomes. It follows that explication of these enablers in an integrated framework could, therefore, be beneficial for practitioners. This chapter itemises 10 candidate enablers identified from a review of the literature and explored in previous research work. The authors discuss the findings of two exploratory surveys, which indicated that all ten enablers were perceived as important to the performance of IKM. However, the amount of management attention required by each enabler appears to be IKM project specific.

INTRODUCTION

Information systems, business professionals and academics have become increasingly fascinated with a seemingly new phenomenon1, knowledge management. While some authors believe KM to be merely a reinterpretation of information management (IM), and others believe it to be just another management fad2, independent writers with a business focus, such as Senge (1990), Peters and Waterman (1992) and Drucker (1993), and the IT research organisation – Gartner – have articulated sensible reasons to explain why organisations should embark on knowledge management (KM) projects. The reasons given for these projects are based on a premise that knowledge and the capability to manage it are the most crucial elements in sustaining or improving organisational performance.

Regard for knowledge as a strategic resource is well documented (for example, von Krogh, Roos, Kleine, 1998) and corroborates Nonaka and Takeuchi's 1995 theoretical framework, which as Magalhaes (1998, 101-102) puts it, is based on an understanding that business advantage arises from the ability of an organisation to create new knowledge. Several case studies have been reported that show support for this idea, [for example, the Skandia AFS case (Marchand, 1998) and Nonaka, Umenoto and Sasaki (1998)]. Although the overall number of empirical studies in KM is low, recent quantitative evidence has further substantiated these cases by showing a direct relationship between effective information and knowledge management (IKM) practices and corporate performance (Marchand, Kettinger, Rollins, 2000). Furthermore, well-organised IM and KM are seen to be complementary (Blumentritt, Johnston, 1999; Marchand, 1998) with both required to operate effectively to ensure adequate supply of both "old and new knowledge" (Stephens, 2000).

The purpose of this chapter is to present the results of some exploratory research that aimed to understand which organisational factors IKM practitioners believe are enablers for IK activities. This work is part of a larger research project, which aims to develop a multidimensional integrated framework for IM and KM, and to test the application of this framework within business contexts.

BACKGROUND

Integrated Information and Knowledge Processes

The relationship between data, information and knowledge existing at various points along a continuum (leading to wisdom) has been discussed and debated for some time. Although there is some confusion in the use of these terms, most authors agree that knowledge is the ultimate result of the capture of raw facts (data), applying specific context and purpose to it to produce information, and finally applying one's own terms of reference to produce knowledge within the minds of individuals. Tuomi (1999) challenges this view, and proposes that knowledge comes first and is used to create data. His view is that individual knowledge is represented in the design of databases and, as such, information is derived from the data contained within these repositories.

Some authors find that making a distinction between the three information stages is unwarranted and does not provide any benefit. Others, although they agree that making a distinction is largely unnecessary, create boundaries for their work in a specific area by providing definitions. Still others (including the authors of this paper) believe that effective IM and KM activities rely on a sound understanding of these stages and what they mean. We have, therefore, adopted definitions from Marchand (1998) for this paper:

- Data are context free and can always be shared because the receiver cannot or does not interpret them (e-mail is data to those who do not share the context for its interpretation).
- Information includes all documents and verbal messages that make sense or can be interpreted by organisational members and is never context or value-free. Information always encompasses an act of transfer or sharing among people and involves inter-

preting representations of our own or others knowledge and is context specific for use and application.

- Knowledge is always personal – it resides inside peoples' heads. Knowing means not only to understand or believe, but also to use or apply that knowledge. In an organisational context, knowledge conversion processes depend on human-to-human or human-to-technology interactions (Nonaka, Takeuchi, 1995). Knowledge use emphasizes personal interpretation and understanding and is context specific for expressing beliefs and commitments.

According to Marchand (1998), knowledge is converted to information for communication and transfer, which means the two are inextricably linked in a complementary and co-dependent relationship. Therefore, in practice, it is not enough to talk about KM as an isolated construct, but that effective management of knowledge should be based on sound information management and knowledge management processes, as well as addressing elements of the information environment, such as culture, behaviour, information politics and technology. Therefore, information management focuses on the acquisition, capture, sharing and use of essentially tangible information, while knowledge management focuses on the creation and identification of intangible information so it can be shared with others, or for conversion to tangible information. The approach used for managing knowledge in organisations reflects a focus on either sharing or conversion, and these approaches are known respectively as personalisation or codification strategies (Hansen, Nohria, Tierney, 1999; Davenport, Grover, 2001).

Issues, Controversies, Problems

Information, knowledge and their application within organisational or enterprise contexts are the subject of a large (and ever-increasing) number of publications (Davenport, Prusak 1998; Dixon 2000; Housel, Bell, 2001; Marchand, Kettinger, Rollins, 2001). A recurring theme is that a number of "factors" are critical for successful implementation of IM and KM initiatives. A review of literature in both the IM and KM areas revealed the range of elements that are regarded by academics and practitioners as constituent parts (our candidate enablers) of IM and KM frameworks3. These candidate enablers often include, but are not limited to: information and information technology architectures (McGee, Prusak, 1993), individual behaviours (Bonner, Casey, Greenwood et al., 1998) organisational culture, policy and strategy and information politics (Davenport, Eccles, Prusak, 1992; Davenport, 1997; Norton, 1994; Orna, 1999; Strassman, 1995), people management (including roles and responsibilities) (Ichijo, von Krogh, Nonaka, 1998; Broadbent, 1997; Standards Australia, 1999), and processes (Marchand, Kettinger, Rollins 2000). Some authors have addressed various groupings of enablers because it is believed to be "unlikely that the adoption of new titles, procedures or technology alone will produce sustainable competitive advantage" (Nonaka, Umenoto, Sasaki, 1998). Davenport (1997) presented a holistic view of organisational information environments in his model of an information ecology, which incorporated many, but not all, of the enablers mentioned above.

These candidate enablers, each with a scope statement and examples of the sources in which they were identified, are provided in Table 1. The scope statements in this table derived to set boundaries for the purpose of defining the categories in the practitioner surveys. These statements are not intended to limit the interaction and co-dependencies that may exist between many of the enablers.

Ideally, each key enabler in an information environment would be designed and operate optimally to facilitate effective IKM, but this aim is difficult and impractical to achieve. Not only

Table 1. Candidate IM and KM enablers from the literature

Candidate IM & KM Enabler (& Code)	Scope	Examples of Reference to Enabler in Literature
Information Architecture (IA)	Elements that define what information the organisation has, what it needs to achieve its goals, and what should be done with information and / or knowledge. (Tools include: information maps, directories, yellow pages etc.)	McGee and Prusak 1993, Orna 1999; Davenport 1997.
Information Behaviour (IB)	How individuals behave and are encouraged to behave in respect to information, for example how information sharing, exchange, use and communication occurs between individuals.	Davenport 1997; Bonner, Casey and Greenwood et al 1998; Orna 1999
Organisational Culture (OC)	How "the way things are done" effects IM and KM.	Brooking 1999, 112; Bertels and Savage 1998; Davenport 1997; Ichijo, von Krogh and Nonaka 1998; Orna 1999; Standards Australia 2000; Norton 1994
IM Processes (IMP)	Activities focussed on managing tangible information.	Orna 1999; Marchand et al 2000; Davenport 1997; Standards Australia 2000
IT Practices (ITP)	Management of IT to support IM and KM.	Marchand et al 2000; Brooking 1999; Orna 1999; Standards Australia 2000
KM Processes (KMP)	Activities focussed on the capture and sharing of knowledge held within the minds of individuals.	Marchand et al 2000; Standards Australia 2000; Ichijo, von Krogh and Nonaka 1998
People Management (PM)	Interventions to create environments that enable and encourage people to create, share and use knowledge, for example dynamic teams, role rotation, reward and recognition programs, training and education.	Broadbent 1997; Brooking 1999; Ichijo, von Krogh and Nonaka 1998; Standards Australia 2000
Information Policy and Strategy (IP&S)	High-level formal statements that explicitly assert the organisation's intent for information and or knowledge and provide guidance about the overall approach to information and or knowledge.	Strassman 1995; Davenport 1997; Orna 1999; Standards Australia 2000
Information Politics (IP)	Organisational activities and behaviours specifically related to the power information instils and how these are managed to ensure effective information and knowledge use.	Marchand et al 2000; Strassman 1995; Davenport, Eccles and Prusak 1992, Davenport 1994, 1997
Organisational Structures (OS)	Formal roles, responsibilities and authority for IM and KM.	Bertels and Savage 1998; Blacker, Crump and McDonald 1998; Ichijo, von Krogh and Nonaka 1998; Davenport 1997; Orna 1999;

do these enablers constitute a substantial portion of the fabric of organisations but, also, the ubiquitous nature of IK means that their management need permeates all business processes. This ideal position is further complicated by potential co-dependencies between the enablers (for example, strategy, politics, organisational structure and people management) and the need to manage resistance to change when attempting to transform enablers, such as culture and behaviour. Yet, the need to address some of these enablers seems inherent in any IKM initiative.

Solutions and Recommendations

Firstly, an understanding of the emphasis IKM practitioners place on each of the candidate enablers would assist refinement of a proposed IKM framework. Secondly, a comparison of management attention required for these enablers and the situation in a sample of organisations would be informative regarding awareness and progress towards the ideal situation described above.

Two exploratory surveys were used in this study to explore practitioners' perceptions of the candidate IKM enablers. Both surveys required qualitative and quantitative responses and were pre-tested, piloted and administered by e-mail to a group of individuals unknown to the authors, but who were members of an active KM forum.

Survey 1 consisted of nine questions. Questions 1-7 requested qualitative information such as occupation, professional affiliation, employer type, and some demographics (age and gender). Question 8 contained a series of 50 principle statements, which the respondents were asked to rate on a 5-point Likert scale to indicate their perceived importance to IKM. The 50 items were made up of five descriptive statements for each enabler. These statements were derived from the literature and were seen as adequately describing each enabler in the pre-test and pilot stages. The participants were not aware of the list of candidate enablers at this stage and, as such, the links between the statements and enablers were not made visible in the survey. In addition, the five statements for each enabler were distributed throughout the question. Question 9 invited respondents to include additional principles that they thought were important and had not been addressed in Question 8.

Survey 2 consisted of seven questions. Question 1 presented the list of ten candidate enablers (accompanied by scope statements) and required respondents to indicate their significance to IM and KM effectiveness (using a 7-point Likert scale). Question 2 asked respondents to rank the relative importance of the enablers from 10 (most important) to 1 (least important), while Question 3 requested additional enablers. In Question 4, the set of 50 principles used in Survey 1 was reused and this time respondents were asked to indicate (again, using a 7-point Likert scale) how well the statement reflected the situation in their organisation. Questions 5 and 6 focused on position titles and organisational size, while Question 7 asked for descriptions of IM and KM projects.

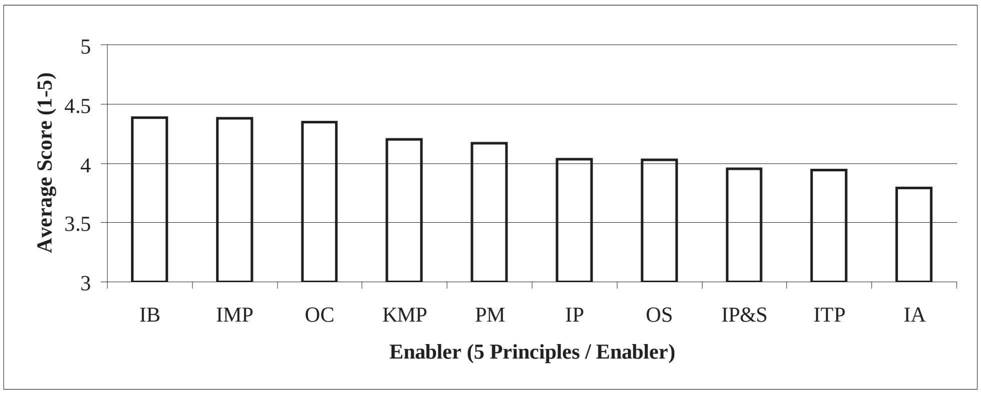
These exploratory surveys did not attempt to derive factor interrelationships. Rather, questions were associated with the perceptions of specific enablers. Copies of the survey forms are available from the authors.

Survey 1 Results

There were six respondents in the pilot group (100% response rate) and 20 respondents in the sample group (21% response rate), which was a low response rate, but, for the purposes of this exploratory work, we felt adequate. The pilot and sample group were assessed separately and as no differences were found, the results were pooled (26% response). The ten most important principles, their average score (out of five) and the enabler that they represent are listed below.

- Sharing information (4.77) - IB.
- Identifying the information needed to meet business objectives (4.73) - IMP.
- Demonstrating appropriate information behaviours at senior levels (4.69) - IB.
- Making key business information accessible throughout the enterprise (4.65) - IP.
- Open communication between people (4.58) - OC.

Figure 1. Enabler importance by principle statement



- A strong affinity between the espoused and experienced culture (4.58) - OC.
- Meeting the information needs of core processes (4.54) - IMP.
- Capturing learning from past experiences (4.50) - KM.
- Investing in employee training, skill enhancement or education (4.50) - PM.
- Making decisions that support the firm's mission or goals / Encouraging collaboration between IT, content and HR managers (4.46) – OC/OS.

The data collected about the importance of principles allowed us to extrapolate the enabler rankings from this initial survey. The values in this figure were calculated by averaging all the statement scores for each of the enablers. Figure 1 illustrates that the aggregated average for all enablers was over 3.5 on the 5-point scale used, with the scores ranging from 4.39 for information behaviour to 3.79 for information architecture.

Survey 2 Findings

The second survey was pre-tested for accuracy and then piloted with the survey one pilot group before being distributed to the 21 respondents from the previous survey. Fifteen responses were obtained (71% response rate).

The importance ranking of the enablers is shown in Figure 2. The most highly ranked enablers were information behaviour, organisational culture and people management. The least highly ranked enablers were information technology practices, information policy and strategy, and organisational structure.

Two sets of data are shown in Figure 3, significance and organisational alignment. Firstly, the respondents saw that nine of the 10 enablers were seen as significant to the ultimate success of IKM, and that these organisational aspects required some type of planned attention to ensure IKM initiative success. It was only seen necessary to pay attention to organisational structures when problems arose. Secondly, Figure 3 shows

Figure 2. Ranking of IM and KM enablers

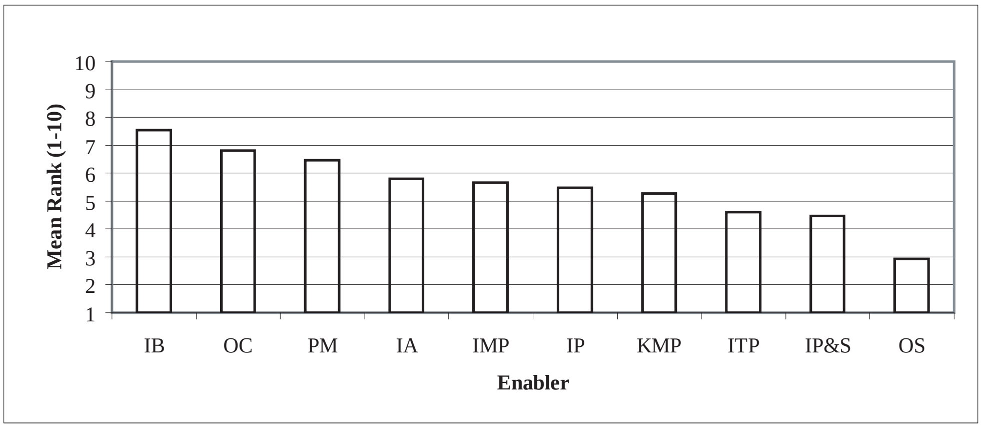


Figure 3. Comparison of enabler significance and organisational "state of practice"

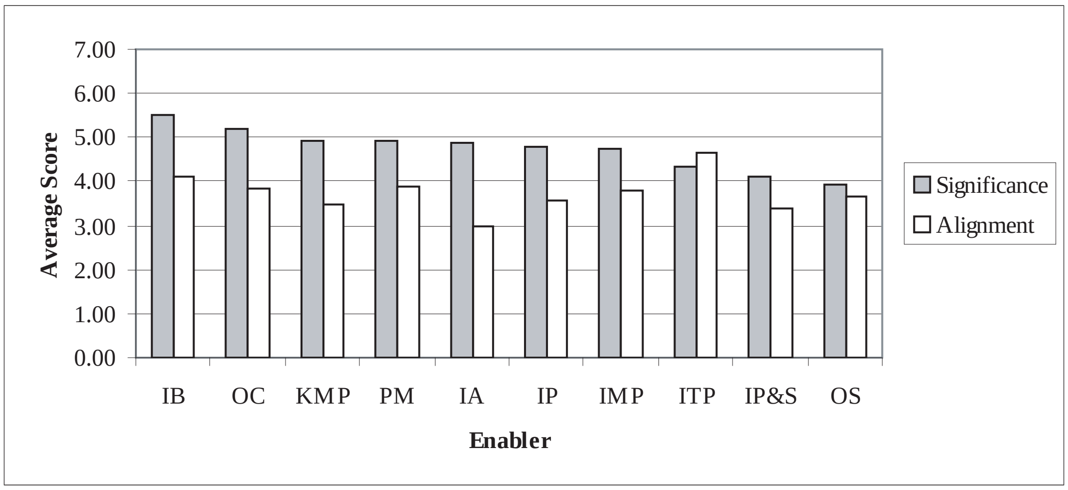

the degree of alignment between the IM and KM enablers and the actual situation in the sample group of organisations. Alignment was assessed using a seven-point Likert scale where a seven meant that the principle statement was highly aligned with the organisation's circumstances and one indicated no alignment between the organisation and the statement. Responses from

14 organisations were used to provide the alignment score for each enabler (no data was received from one organisation for this question). For the organisations surveyed, an average score of close to five indicates good alignment with the enabler, while scores nearer to three indicate some degree of alignment between the organisation and the enabler.

Figure 3 allows a visual comparison between (1) the significance of each enabler and (2) the organisational "state of practice" for that enabler.

DISCUSSION

The results of Survey 1 indicated that practitioners recognised the relevance of 50 principles seen to be important to IKM. The data, when aggregated for each enabler, shows a ranking of enablers from most to least important in terms of IKM; however, the small number of responses precludes any statistical inference. Another limitation of this first survey is that the statements used to gauge the importance of each enabler were derived from the literature and, as such, were contrived to correspond to a single candidate enabler. Despite these limitations, we believe this data indicates that all ten candidate enablers were seen as important for the facilitation of sound IKM, and this initial exploratory assessment provided us with a foundation on which to base further research activities.
