In the study of Bonini, Jackson, and McDonald (2001), three dimensions of trust were found of importance: belief, dependence, and experience. If you have to trust the information coming from others, you have to be confident in the other and the information provided, you are dependent because you need the information, and you rely on the experience you have with this person and the information. In design processes, the designer is regularly in a dependent position, because preliminary versions are shared between group members and designs of other, related systems are often also in a not yet stable version (participatory design).

Especially in the design of safety-critical systems, one has to make sure that the knowledge that is shared is correct and can be trusted. For this reason extensive validation and document version management is in place in industries. One should avoid the risk of basing one's design on information that has not been verified, and designers should be aware what the latest version of a document is in order to use it.

DESIGN IS WRITING, AND WRITING IS DESIGN

Knowledge management for safety-critical systems mostly deals with documentation since everything should be traceable and formally validated. Consequently, the way things are written is crucial. However, writing is not always perceived as a key issue in engineering and design. Engineers are not scientists who base their careers on the number and quality of the papers they produce. A technical document may be generated the day before delivery just because it was planned to do so. Engineering culture is based on creativity and efficiency, based on very specific languages, often in the form of drawings and schematics that cannot be understood by an outsider. Engineers do not perceive the writing-for-all philosophy as relevant.

Two Separate Worlds: Engineering and Literature

The distinct worlds of engineering and literature barely met during the last century. The human-computer interaction (HCI) community has nicely introduced design "into the picture" since user interfaces require a subtle combination amount of technique and graphical art. There, science and arts met. In knowledge management, a deeper step is required. Designers need to step into literature. They need to write technical documents describing requirements, specifications, job orders, evaluation rationale, training and performance support, experience feedback, and a large variety of official documents. It has been observed that people who are already in senior positions in an organization know the benefit of good documentation, and tend to write more than younger employees who do not have as much experience. Document content should satisfy the objectives, thus answering the question: Why and for whom are we writing this document?

In addition, in international environments such as contemporary European multi-national companies, writing in English may be a difficult task for non-native English-speaking personnel. The result is that produced English-written documents may be difficult to understand

The Time-for-Writing Issue

Project deadlines are always very short and do not allow enough time for decent writing. In an engineering organization, the real job is design, not writing. People are usually awarded on design performance issues, not on documentation issues. Writing time should be clearly planned in a project schedule and given the same priority as other activities, so that when there is an extension in the duration of the project, writing is not the last item on the agenda when there is little time left to perform it, as is often the case.

What is Obvious for Someone (Expert) is Not Necessarily for Someone Else

There is no consensus whether writing has improved over the years, for example, in the aeronautics domain. However, some people think that most aerospace technical documents generated during the 1960s are remarkably precise. They were not ambiguous. Work was very well done. People had time and resources to write properly. Other people think that current engineers do not capitalized the necessary technical background to produce appropriate and sufficiently detailed technical documents. It is very important that a selected group of readers reviews all documents. If someone does not understand a technical document, then it should be modified and improved towards a better comprehension. We should apply to documents the same kind of usability testing and user-centered design procedures as for systems. Human factors principles are very similar. Sometimes we say "writing is design, and design is writing."

Redefining Prose Rules Using Multimedia

This statement claims that the quality of technical documentation contributes to the quality of design. We usually write for potential readers. In the same way, we design for potential users. Researchers know that several persons must review papers before being delivered outside. We also know that several persons must test artifacts before being delivered outside. The reader of a multimedia document has become a user of a software application. From this viewpoint, reading a physical note, report, or book has evolved towards interacting with a computer. Writing has also evolved towards design of interactive software. Writing words, phrases, paragraphs, and chapters has become designing objects and software agents. Static paper documents have become (inter)active documents.

The active part of a book (system) is the reader (user). In addition, the organization of the book (system), the way phrases (objects) are written (designed), style, and lexicon used suggest reader (user) activity. Sometimes, the reader (user) hardly understands what the author (designer) wanted to express. Instead of mobilizing the cognition of the reader (user) on interaction problems, the most important part of the cognitive activity of the reader (user) should be centered on the understanding and interpretation of (active) document content.

Toward Simplicity

Design documents are not only outputs of design processes, but also inputs—that is, formulating design rationale contributes to improving the design itself. There are two issues of simplicity: documenting to improve the simplicity of use of a system being developed, and reducing the difficulty of generating technical documents—that is, making it simpler. Simplest systems are best used. In most cases, when systems are too complicated, they are not used at all. This is true both for the system being developed and for its documentation.

Writing from Bottom-Up (Annotations) vs. Top-Down (Requirements)

People tend to write little notes either by using Post-Its, personal notebooks, page marks, and so on. They annotate what they do and use these notes in order to improve the capacities of their own short-term and long-term memories. If this kind of practice is very useful to people themselves, for a short term, interoperability becomes a problem when such knowledge needs to be exchanged with others or reused by the same person after a longer period of time. Annotations can be considered as pragmatic knowledge that needs to be structured if it is to be used by others. People cannot structure such knowledge in the first place because it is intrinsically situated—that is, it is captured in context to keep its full sense. This is why a mechanism that would support annotation generation and why structuring can be a powerful tool.

APPROPRIATE TOOLS AND ORGANIZATIONAL SETUPS

In industries that develop safety-critical systems, a variety of knowledge management tools are available. Also in R&D projects (including projects in the European Frameworks), many KM tools have been developed. It is clear that tools cannot be designed and used without appropriate organizational setups. People adapt to technology and groups, whether they are teams, organizations, or communities. However, adaptation can be limited by the constraints imposed by tools and socio-cultural habits of the people involved.

Active Notifications of Changes in Design

Designers of safety-critical systems are expected to be proactive people who manage information using available tools in their organizational setups. However, information technology is capable of augmenting their initial skills. Software agents may provide assistance in a variety of tasks that require routine, and usually boring, actions. Safety-critical technology always incrementally changes due to accidents and incidents, customer requirements and needs that continuously evolve, and refinement of the technology itself. There is always a discrepancy between these effective changes of technology and its related operational documentation. People need to be notified about changes in order to operate such technology in a safe way. When such notification is timely, it is usually passive and left to the expertise or intuition of the user; it may not be noticed. This is why a system that would provide proactive notification of changes would be tremendously useful. In the WISE environment, people can subscribe to documentation, indicating about which changes (updates, deletion, status changes, etc.) they want to be notified, by e-mail or in the active work environment.

Supporting the Writing Process

Above we have emphasized the importance of writing for the design process. Tools are available that can support engineers in documenting their work, and capture annotations during the design work, not just after the design is finished. An example of such a tool is the Computer Integrated Documentation (CID) system developed at NASA (Boy, 1991). Another example can be found in the IMAT (Integrating Manuals and Training) system developed for designing learning material (de Hoog et al., 2002). Also in the WISE workspace, the engineer is enabled to make annotations to all different kinds of knowledge objects and to choose whether to share them with team members or others.

Crisp and clearly understood design rationale is a good indicator of maturity in design. Formalisms have been developed to describe design rationale such as gIBIS (graphical Issue-Based Information System) (Conklin & Begeman, 1989) or QOC (Questions Options Criteria) (MacLean, Young, Bellotti, & Moran, 1991). They support the elicitation of design rationale and enable the documentation of design decisions, development plans, and systems that are effectively developed.

Organization of Personal and Team Workspaces

In current communication and cooperation software, very efficient search engines are available; bottlenecks are elsewhere. They are in the way people categorize incoming information with respect to what is already available on their desktop. This categorization is a strong condition for further retrieval and traceability. People organize their workspace in order to perform their tasks efficiently and manage time and content accordingly. They use Post-Its, bookmarks, document piles, proximity for urgent or frequent access, and so on. In any case, people do not stop to fine-tune their initial categorization to better fit their everyday needs. In the WISE project we have developed a environment in which users have a personal workspace in which they can organize the knowledge they need for their task, as well as a workspace for groups in which knowledge can be pre-structured and shared. The environment consists of a portal that gives access to the companies' documentations, databases, and tools, including search facilities on all knowledge objects thus available, of whatever format or location.

Active Design Documents

The concept of active design document (ADD) (Boy, 1997) was developed to support designers of safety-critical systems in knowledge management. Active documentation may take various forms and involve different kinds of content. An ADD is defined by four categories that organize a designer's workspace: interface objects, interaction descriptions, contextual links, and design rationale.

Interface objects (IOs) provide appropriate, useful, and natural illusions of designed artifacts. IOs have their own behavior reflecting the behavior of related artifacts. They enable users to test usefulness and usability of related artifacts. They provide concrete feeling and grasp of the use of an artifact, its learning requirements, its purpose hands-on, and so forth. Their progressive integration leads to a series of prototypes and, in the end, the final product.

Interaction descriptions (IDs) provide the specification of user-artifact dialogue. IDs may be expressed in either natural language, or a domain-specific technical language ranging from textual descriptions in simplified English (operational procedures for example) to a knowledge representation like the interaction blocks (Boy, 1998). A main advantage of using interaction blocks is to enable formal testing of interaction complexity, and expressing contexts and abnormal conditions of use explicitly.

A test user either follows IDs and produces an activity by using appropriate related IOs, or interacts directly with IOs and verifies the validity of related IDs. In both cases, he or she tests the links between IOs and IDs in context (i.e., in the context of the task being performed). The corresponding category is called contextual links (CLs). This is where usefulness and usability evaluations (sometimes annotations) are stored in the form of either free text or specific preformatted forms.

Design rationale (DR) provides the reasons why the IOs and IDs of an artifact have been designed the way they are, and design alternatives that were not chosen. DR is commonly implemented by using semi-formal languages such as gIBIS or QOC already mentioned.

ADDs are tools that support not only communication and mediation, but also prototyping and evaluation. They enable their users to store design knowledge according to a concrete and systematic formalism. Creation and maintenance of such ADDs enable an entire organization to maintain awareness of their design processes and products.

Interoperable Documents and the Portal Concept

Documents should be interoperable. This requirement induces two kinds of issues: standards and integrated environments. When people exchange documents across teams, organizations, and communities, they expect the others to be able to process what they provide. This is commonly a matter of standards. In a closed world where an organization can cope with an integrated environment in the form of intranet for example, people do not have to worry about standards. Nevertheless, standards progressively emerge from the extensive use of specific types of documents.

Designers require KM environments that are user-centered (easy to use and avoid overload) and integrated within their current tasks. They should have easy access to KM services at each design step. For example, in a safety assessment process, there should be information provided for performing safety analysis and related documents. In other words, the designer workspace should be (re)designed in such a way that he or she has easy access to experience feedback (e.g., not only a list of what is necessary to do and forbidden (checklists), but providing deep knowledge to foster preventive design actions and avoid later corrective actions) at any time. Having this knowledge available at the designer's desktop at all times can be realized by a KM portal. A portal means that it provides access to knowledge, wherever it is located, but does not contain this knowledge itself. In the KM portal developed in WISE, designers have access to knowledge available in, for example, databases with experience feedback, lessons learned, and best practices, to all kinds of relevant documents, and to people who can bring interesting knowledge and experience. Access to all these sources is provided in the same manner and with a single search facility.

CONCLUSION

The way knowledge is exchanged during the design and the further lifecycle of a safety-critical system induces several factors related to systems (complexity, completeness, maturity, traceability) and people (expertise, writing, simplicity, drafts, information credibility, uncertainty, and awareness).

Several actual developments influence the design processes of safety-critical systems: more people from different organizations (within the company or (sub)contractors) get involved, more procedures are in place (such as certification procedures, involving human factors in particular), and product development needs to be faster than before. These evolutions have a direct impact on the increase of both the number and content of documents. Information technology provides new means to generate, maintain, and use such documents. A main issue is to improve the use of such means.

Important questions remain to be answered: Does this technology change the job of engineers? Does it free up engineers from boring tasks? Or does it create new ones? Answers to these questions are complex. However, this article contributes by providing categories of KM solutions such as the organization of personal and team workspaces, active design documents, and knowledge portals. Usefulness and usability of such solutions need to be tested carefully in a real-world environment with a critical mass of people involved. This is very difficult to do since experts and specialists (e.g., designers of safety-critical systems) are always occupied, busy, and constrained into an already existing KM system, often very far from the solutions proposed. Transformations should be incremental, accepted by the people involved. Implementing a new KM system is also redefining a new philosophy of work, a new culture. This is hard to do and hard to implement! This is the main reason why the design of new KM systems must be human-centered—that is, team-centered, organization-centered, and community-centered. Each of these types of group has its own motivations, requirements, and constraints.

Chapter 3.24
Metadata Management:
A Requirement for Web Warehousing and Knowledge Management

Gilbert W. Laware
Purdue University, USA

ABSTRACT

This chapter introduces the need for the World Wide Web to provide a standard mechanism so individuals can readily obtain data, reports, research and knowledge about any topic posted to it. Individuals have been frustrated by this process since they are not able to access relevant data and current information. Much of the reason for this lies with metadata, the data about the data that are used in support of Web content. These metadata are non-existent, ill-defined, erroneously labeled, or, if well-defined, continue to be marked by other disparate metadata. With the ever-increasing demand for Web-enabled data mining, warehousing and management of knowledge, an organization has to address the multiple facets of process, standards, technology, data mining, and warehousing management. This requires approaches to provide an integrated interchange of quality metadata that enables individuals to access Web content with the most relevant, contemporary data, information, and knowledge that are both content-rich and practical for decision-making situations.

INTRODUCTION

Today, many of us use computers and the World Wide Web to communicate. We enter a Website name or address (www.informationbydesign.biz, www.ibm.com, www.tech.purdue.edu) into a browser on our desktop computer, where a unique numerical number replaces the words representing the Website name or address. It is analogous to a telephone number. We then are connected immediately to another computer assigned a numerical address somewhere on the World Wide Web. This allows us to access any document (Web page) on that computer. The Internet is capable of connecting us with any computer anywhere in the world. This computer sends the Web page we have requested from its Internet address to our desktop computer, where it is displayed using our browser. In most cases, the returned Web page is written in English and we are able to understand its content. But, if the Web page is written in another language, we would need an interpreter to understand its content. In a telephone analogy — if a person who responds to our telephone call speaks another language, then what is said may not have any meaning to the caller. If the information that describes the currency, content, and location of the Web page or telephone number is erroneous, it is of little value.

Now, in a different way, let's consider the reason why it is difficult for computer systems to communicate and to share data. First, the data often have been structured differently in one system than in another. This is particularly true with older application systems. Second, the data may not be stored in the same format (i.e., they are in a numerical format rather than in text format). Third, the name for the data may be different, causing a problem in identification or recognition of what they represent between systems. Last, the values of the data stored may be inconsistent between the systems. Technically, the programs in each system can be interconnected if they are designed, defined, and structured logically and physically for that purpose. But, each of the above items has to be evaluated for possible integration and sharing of the data between the systems if that is not the case.

One of the most common problems is that identical data are named differently in different systems. All too often, different names or terms refer to the same data that need to be shared. For example, a human resources system may use the term employee or candidate to refer to a person. An ordering system may refer to a person or an organization as a customer. In a sales system, the term may be prospect, client, or customer. Each system may use different terminology — a different language in a sense — to refer to similar or identical data. But if they use the wrong language, again, the systems cannot share the data to provide required information.

The problem can be even worse. Consider terms used in different parts of a business. Accountants use jargon — a technical language — that is difficult for non-accountants to understand. Similar terms used by individuals in engineering, production, sales, or in marketing may have different meanings. Likewise, managers may use another vocabulary. Each speaks a slightly different language and uses the same words in different ways. What is said may have no meaning without a common definition and so they cannot easily share common information. Each organization has its own internal language and jargon that becomes part of the subculture that evolves over time and is a key part of the way individuals communicate. In fact, in some organizations it is a miracle that people manage to communicate meaning at all!

As we saw above, there can be more than one language used in an organization. Metadata, the data about the data, identifies and uses their organization's own language. Where different terms refer to the same thing, a common term is agreed upon by all to use. Then people can communicate clearly. The same is true in the use of systems. Systems and programs intercommunicate when there is understanding and meaning between them. But without a clear definition and without common use of an organization's metadata, information cannot be shared effectively throughout the enterprise.

Previously we discussed how each part of an organization maintains its own version of customer, client, or prospect data. Each defines processes (a series of actions) — and assigns staff (persons) — to add new customers, clients or prospects to their own files and databases. When common details about customers, clients or prospects change, each redundant version of that data also has to be changed, requiring staff to make these changes. But, wait a minute, how about the metadata? They are also a consideration. Both the organizational and technical metadata may be affected and may also be redundant. This is the same rationale for reusable programs! These are all redundant processes that make use of redundant data and metadata. This is enormously expensive in both time and people — all quite unnecessary.

So, as metadata gains prominence, the process of managing metadata becomes critical since it becomes the common language used within an organization for people, systems and programs to communicate precisely. Confusion disappears. Common data are shared. Enormous cost savings can be made since it means that redundant processes (used to keep up-to-date redundant data) are eliminated as redundant data versions are integrated into a common version for all to share.

BACKGROUND

The mission statement of the Data Administration Management Association is to deliver the right data to the right person at the right time. This is a concept that has been around Information Resource Management (IRM) for years (Burk & Horton, Jr., 1988). Data are proclaimed to be an enterprise asset but little management of that asset has occurred. As a result, the world is made up of much disparate data and metadata, resulting in erroneous information being used in decision-making.

From a computing systems perspective, disparate data and metadata have also been around for years. It started with the early development of computing systems. Much of the data about data (their format and structure) was packaged within programming languages and their supporting technology. With the development of database management systems, these same technical metadata were incorporated into the database management system's catalog or dictionary. This content became known as metadata. They are needed by all systems.

Metadata is more than just a means for technological implementation. It is much broader in scope. Metadata embraces the fundamental data that are needed to define requirements. It is the information (metadata) that is used to design a product, understand business processes, provide information access, obtain data understanding, outline the rules applying to actions and data, and ultimately, make business decisions. In this context, metadata encompasses many aspects of an organization: its processes, organizational structure, technologies, motivations and, certainly, the format, structure, and context of data required to meet informational needs.

So, What are Metadata?

Let us examine the definition of metadata. This requires us to examine the meaning of data, information, and knowledge. These three terms need to be defined for the purpose of this discussion because of their key role in today's organizational environment.

- Data. Discrete facts that are represented in some symbolic way and are recorded in many different formats. By themselves, data may have little meaning or use.
- Information. Data being used and interpreted by a person. The data are relevant and have a purpose in influencing or altering a person's decisions or behavior.
- Knowledge. Personal or organizational experience, value and insight gained from an applied use of information. It is actionable information that is relevant information available in the right place, time, and context to the person using it in a decision-making situation.

Together, these terms (DIKs) are fundamental to every organization's daily existence. They work closely together to build the foundation for knowledge management (KM) and the use of Web mining.

So, what is metadata and where do they fit? There are definitional differences of metadata among authors (e.g., Devlin, 1997; Inmon, 1992; Kimball, 1998; Loshin, 2001; Marco, 2003; Tannenbaum, 2002). These definitions differ either in basic purpose (administrative, structural or descriptive), depth and richness, or in specificity for a particular situation. As such, metadata is our knowledge of data that we have interpreted as information in a particular decision-making situation. Therefore, it is a continuum between data (facts) and knowledge (experience) used in a personal or organizational context.

Where does metadata fit? Without naming, defining, structuring, categorizing, standardizing, and storing both the data and metadata, the utility of Web mining, warehousing and KM is suspect. Why? Because it is the semantic bridging mechanism (requirements and specification for semantic data models) that enables effective information access and exchange to occur both internally and externally for organizations. It requires management.

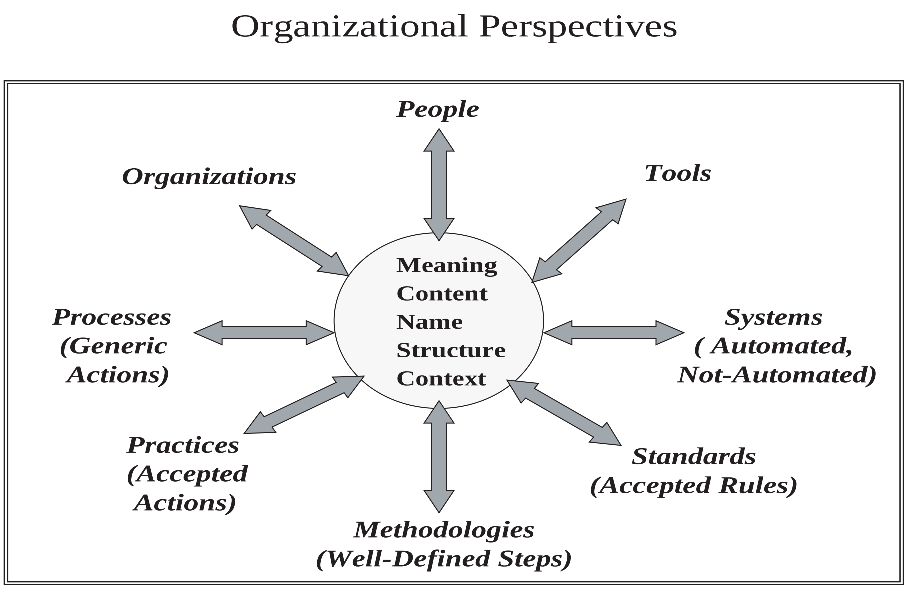
There is Management

In a sense, management takes action to produce a certain effect. Management is the activity that embodies four major functions: planning, organizing, leading, and controlling. Planning function is the selection and prioritization of goals and the ways to obtain them. Organizing function assigns the responsibilities to individuals to perform work or actions to produce something (product or service). Leading uses influence to effectively motivate individuals to attain the goals desired. In controlling, work activities or actions are monitored and corrected as required to meet stated goals. By focusing on doing the right things, the organization chooses the right goals to be effective, and by doing things right the organization is making the best use of its resources, including data.

Management is the art of getting things done by taking action and using people to achieve the goals of the organization. These goals are clearly communicated to all the individuals who are involved in their implementation by providing the reasons the actions are performed in an organizational context. Peter Drucker made the point of how management has changed with the use of information technology. He states: "So far, for 50 years, Information Technology has centered on DATA — their collection, storage, transmission, and presentation. It has focused on the 'T' in 'IT'. The new information revolutions focus on the 'I'. They ask, 'What is the MEANING of information and its PURPOSE?' And this is leading rapidly to redefining the tasks to be done with the help of information and, with it, to redefining the institutions that do these tasks" (Drucker, 1999, p. 82). The process of making a choice and taking action is a decision.

Management uses business processes that combine information technologies and people in attaining the goals of the organization. As they become more knowledge-based, individuals must take more personal responsibility for contributing to the whole organization by understanding the objectives, the values, the measurements, and the performance required. They must communicate effectively and efficiently with their peers and the other professional knowledge workers with whom they interact. The outcome is that "Every knowledge worker in modern organization is an executive [italics added] if, by virtue of his position or knowledge, he is responsible for a contribution that materially affects the capacity of the organization to perform and to obtain results" (Drucker, 1989, p. 44). Drucker (1999a) stated that the most valuable assets of the 21st century company are its knowledge and its knowledge workers. Knowledge workers face interesting challenges to use data,

Figure 1. Organizational perspectives cause different metadata to be captured



information, and knowledge more effectively and efficiently. The executives and leaders who manage have different organizational perspectives. Each piece of metadata has core elements of a name, meaning, descriptive content, structure and overall context. All of theses elements are essential to create metadata that are universally acceptable.

Each organizational perspective must ensure that effective communication of DIKs occurs. Each dimension provides different management perspectives and implications. People have different skills, talents, and needs. They are organized in a way to achieve some goal in a business process. Each process has a set of business practices that are executed in well-defined steps in accordance with internally or externally accepted rules or conventions. Many of these practices, steps, and tasks are part of organizational systems and in many instances may be automated in computerized software applications. In other cases, the basic tools (i.e., hardware or software) become instrumental parts of our daily work activities. An important implication of this environment is that each individual should have an understanding of the meaning, context, naming, structure, and content of data, information, and knowledge that are represented in each organizational situation.

The Purpose of Decision-Making

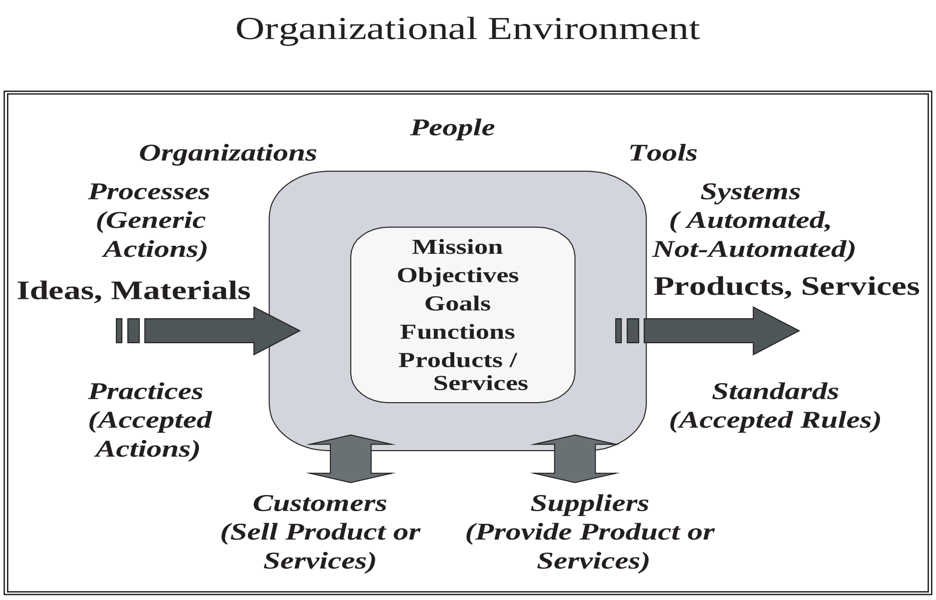
The purpose of delivering information and knowledge content through the Web is for one critical purpose: to help an individual gather DIKs for making a decision. Therefore, one has to question the various assumptions used in decision-making. What business are we in? What should it be? What changes are necessary to get it to the next level? These questions are contextually meaningful for decision-making. They set the stage for determining excellence and the priorities of processes, practices, and methods needed to implement the desired strategy to achieve the goals. Decision-making involves making choices in taking action and is an important ingredient in the overall process. Today's knowledge workers understand their contribution to achieving a result and must concentrate on opportunities that provide a competitive advantage in a systematic, purposeful, and organized manner for the welfare of the overall organization within its environment.

From an organizational perspective, an organization creates capital by combining ideas, materials or both and transforming them into some product(s) or service(s) that are marketed or sold to its customers, as shown in Figure 2.

The organization uses explicit or implicit mission statements, sets objectives, and outlines goals for the benefit of the owners of the organization. It structures itself along the lines of traditional business functions: accounting, finance, development, manufacturing, marketing, sales, and distribution of its final product(s) or services(s).

An assumption that underlies decision-making situations in any organizational environment is that data, information, and knowledge applicable to a particular situation provide a factual representation of the environment used by the decision-maker(s) in assessing the options available. Unfortunately, this premise does not hold true, as evidenced by documented studies about the low quality of data (English, 1999; see also Brackett, 1996, 2000; Loshin, 2001). Inaccurate data can be found in 1-5% of the time while impacting costs from 8-12% of revenue (Redman, 1998). Others have stated that data quality contributed to reducing the GNP by .5% in the year 2000 (Mandel, 1998). Thomas Redman described 15 ideal characteristics for data quality (Redman, 1992) and suggested groupings of these attributes into three areas: conceptual (level of detail, view consistency, composition, robustness and flexibility), data value (accuracy, completeness, currency, and value-consistency), and data representation

Figure 2. Transforming inputs into product(s) or services(s) in an organization

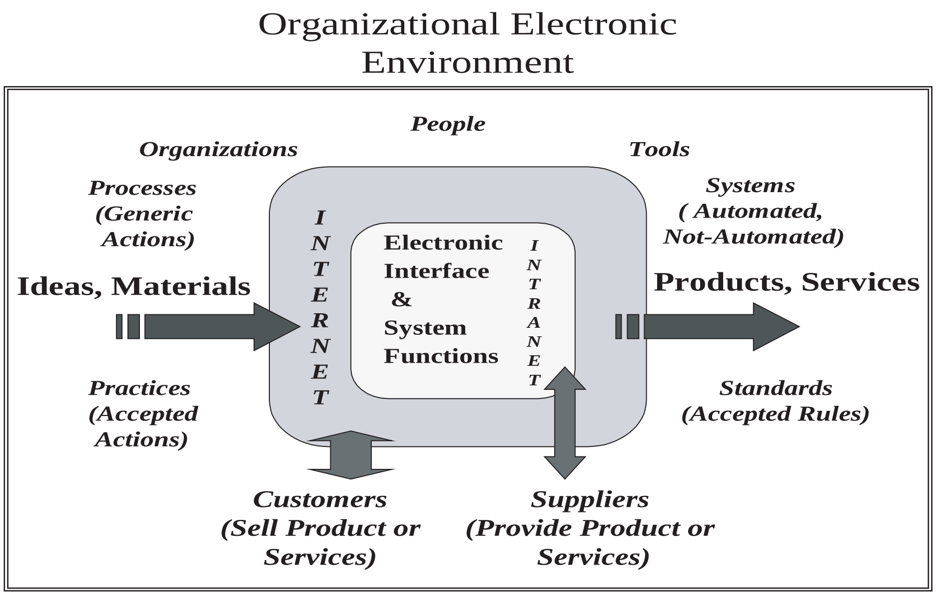


(appropriateness, interpretability, and portability) (Redman, 1996). By substituting the term metadata for data, the same characteristics are applicable in decision-making situations.

A human activity that is part of any leader or managerial role is decision-making. Henry Mintzberg (1971) described the characteristics of decision-making in a managerial role as an entrepreneur, disturbance handler, resource allocator, and negotiator. In each role, the use and quality of data, information, and knowledge are critical to understanding the problem, examining the options, and taking action. We use a decision rule or policy embedded in the world that we perceive from the data, information and knowledge that we have experienced. From a different perspective, Herbert Simon (1957) has best articulated the limits of human decision-making ability in his principle of bounded rationality, stating: "The capacity of the human mind for formulating and solving complex problems is very small compared with the size of the problem whose solution is required for objectively rational behavior in the real world or even for a reasonable approximation to such objective rationality" (p. 198). Faced with complexity in the real world and time pressures to make decisions, we fall back to habits, heuristics (rules of thumb), procedures or simple mental models to make a decision. This drives a critical requirement for quality data and information because it is paramount to producing the best possible results under the most stringent of time constraints and the critical need for high quality metadata. It has a tremendous impact on the processes used to collect, analyze, classify, standardize, translate, select, and distribute DIKs in a timely fashion to the organization and its collaborative parties.

With the introduction of the Internet and the World Wide Web, organizational boundaries have been significantly altered. This technology has enabled a global economy to develop in which

Figure 3. Organizational electronic environment increases scope of communications with Internet technologies



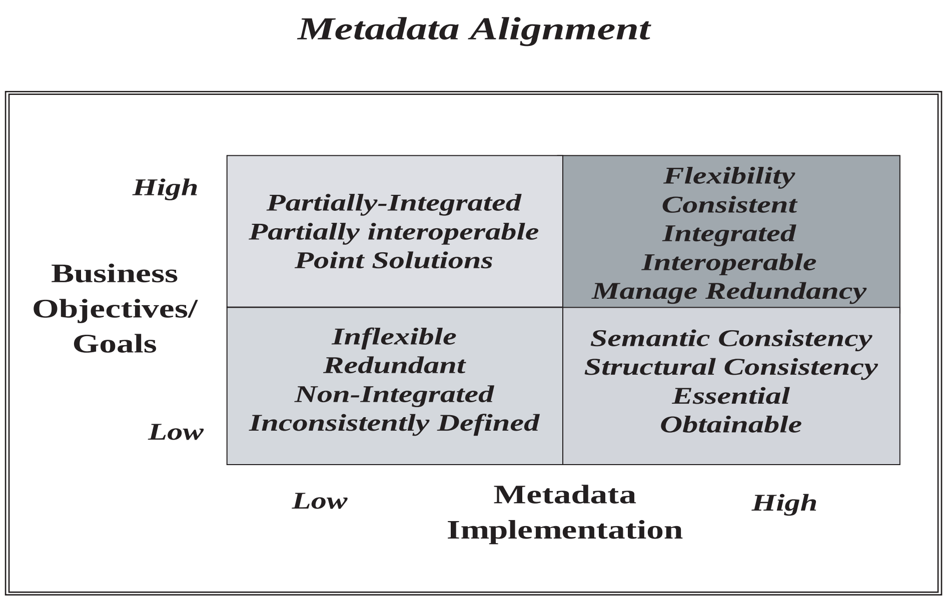
any organization with its accountants, distributors, financiers, customers, manufacturers, or suppliers can operate without regard to physical and geographical boundaries. In this environment, the digital transmission of all types of data, information, and knowledge, regardless of their form (numbers, words, graphs, photos, voice, video, etc.) is electronically moved throughout the world, as in Figure 3.

Within an organization, the application of the Internet's protocol (TCP/IP) is called an intranet. This is where an organization maintains proprietary, confidential, or intellectual property-based DIKs. Using both intra/Internet technologies can provide an immediate access to internal and external data, information and knowledge. This makes the management of the metadata critical for the decision-making process since knowledge workers can have access to too much information that may or may not be relevant to the decision-making situation. In cases in which various collaborative partnerships exist between organizations, electronic transactions exist between customers (B2C) and between other privileged organizations (B2B) that can access your DIKs. This further emphasizes the need for a mentality within an organization that data, information, and knowledge are an asset.

The Need for Asset Mentality

Realizing that data, information, and knowledge are so critical to an organization's overall success, why have we not seen a more strategic approach to managing DIKs in an organization? Should data and metadata be considered an asset? An asset is defined as "a useful desirable thing or quality" (Braham, 1998, p. 26). An intangible asset is something valuable which a company possesses which is not material, such as a good reputation or a patent (Merriam-Webster, 2003). Both definitions describe some factor or circum-

Figure 4. Impact of metadata alignment with business objectives



stance that benefits the possessor (advantage) or is considered a resource (source of information or expertise).

Dow Chemical Corporation in 1993 (Davenport, p. 85) started to manage data and metadata as an intangible asset and turned them into an asset by managing their company's patent database. Dow claims that they saved more than $1 million in patent maintenance fees within the first 18 months. This example also illustrates the concept of intellectual capital (such as documented patents in databases) tied to knowledge available in a managed environment.

Historically, organizations have set up programs, policies, and procedures to support managing data and information as an asset, but for the most part, "information and data are identified assets without an associated management process" (Metcalfe, 1988. p. 19). This is due largely to the diversity of technologies, differing organizational and management directives, incompatibility of data development and their implementations, lack of integrated solutions, and evolutionary standards. Figure 4 shows the implications of missed organizational opportunities from a business perspective since the relationships between business objectives/goals and metadata have to be aligned.

Metadata is a mediator in the DIKs environment. A higher degree of alignment between metadata and business objectives/goals results in a more flexible, consistent, integrated, interoperable environment for an organization. The tremendous payoff for Dow Chemical illustrates this point.

Need for Web Warehousing and Knowledge Management

Since data, information, and knowledge are so critical to an organization's overall operational success, Web mining, warehousing and KM are logical extensions of existing operational activities. In the quest for timely, accurate decisions, an essential element is to obtain the best DIKs possible to produce appropriate and effective courses of action.

The concept of Web warehousing originated with the development of data warehousing. W.H. Inmon (1992) defined data warehousing as a "subject-oriented, integrated, non-volatile, time variant collection of data in support of management's decisions" (p. 29). The only difference between data and Web warehousing is that in the latter, the underlying database is the entire World Wide Web. As a readily accessible resource, the Web is a huge data warehouse that contains volatile information that is gathered and extracted into something valuable for use in the organization situation. Using traditional data mining methodologies and techniques (TechReference, 2003), the Web mining is the process of extracting data from the Web and sorting them into identifiable patterns and relationships. Various data techniques of analysis determine:

- Association. A pattern exists in which one event is connected to another event
- Sequence or path analysis. A pattern exists in which one event leads to another later event
- Classification. A totally new pattern exists (develops a new structure)
- Clustering. Relates facts previously not known by finding and visually inspecting new groupings of data
- Forecasting. Predicting future conditions based on existing patterns in data

Given this sense of what Web mining is and warehousing is, what, then, is knowledge management (KM)?

Like metadata, knowledge management has multiple interpretations (Davenport, 1998; Firestone, 2003; Gates, 1999; Malhotra, 1998; Tiwana, 2001). Firestone (2003) provides a discussion of additional authors' treatment in the context of his definitions.

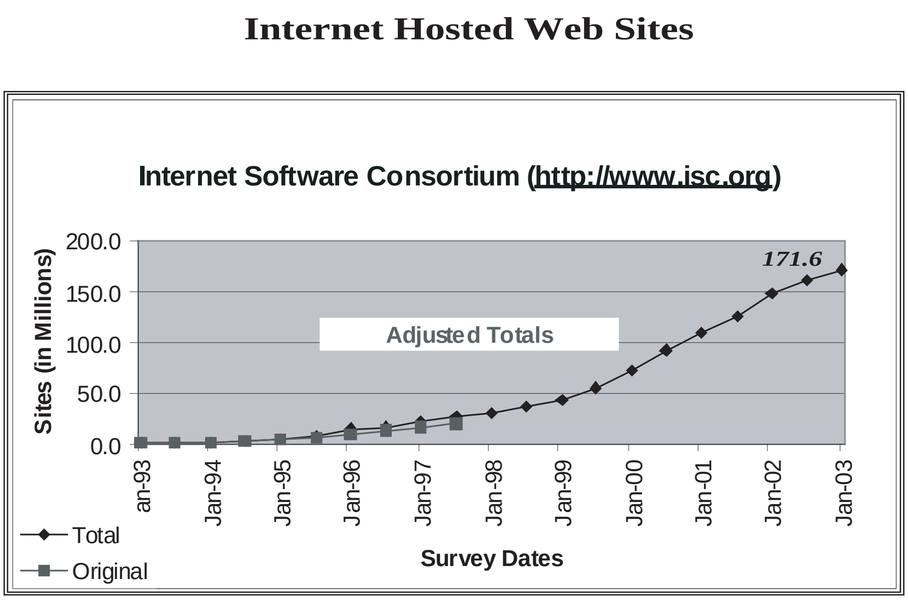
In this discussion, KM is the embodiment of all management activities (in the handling, directing, governing, controlling, coordinating, planning, organizing, disseminating of data, metadata, information, and knowledge) in a planned, directed, unified whole for the purpose of producing, maintaining, enhancing, acquiring, and transmitting the enterprise's DIKs assets to meet organizational objectives and goals. This definition is slightly different from Firestone's in that it encompasses data, metadata, information, and knowledge elements. The rationale for this distinction is the criticality of timely, accurate, quality-based information needed for organizational decision-making. In today's global market, maintaining an organization's knowledge base not only gives a competitive advantage, but is also necessary for its own survival. It is from this perspective that today's implementation of Web mining, warehousing and KM activities have to be closely aligned with management perspectives to ensure its success and the ultimate achievement of their goal.

With this New Environment

Without question, the development of Web technologies has been a great enabler to access data from worldwide sources. The growth of Internet hosted Websites continues to rise exponentially (Figure 5).

The Information and Research Division of InterGOV International indicated that online Web users in 2002 numbered 625 million, with an estimate that there will be 700 million in 2003 (InterGov, 2003). Currently hosted sites provide 3 billion Web pages (Sargent, 2003) with content. The Internet and its infrastructure can deliver a glut of information and data to a user. A million Web pages are added to the World Wide Web each day. If we also consider the volume of Intranet publications that occur each day, which

Figure 5. Internet hosted sites survey: An historical profile



is difficult to estimate, the Internet/intranet is a wonderful resource of useful DIKs to anyone accessing the Web.

ISSUES, CONTROVERSIES, PROBLEMS

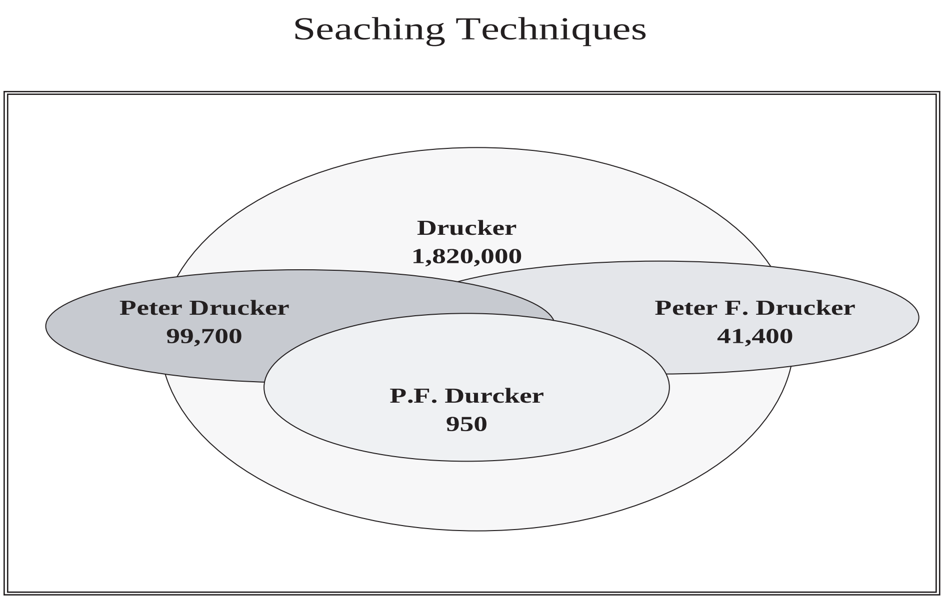
Internet/intranet Web page publications present some interesting issues, concerns and problems.

Ever-Increasing Proliferation of Redundant Data and their Disparate Metadata

Twenty years ago, if you needed certain information, you would drive to an excellent resource library. For example, you might ask the assistance of a highly skilled librarian for information on Peter F. Drucker's conclusions in his book: Managing for Results. Perhaps, in a couple of hours, you would receive the required information.

Today, using one of the Internet's most successful search engines, Google, you might formulate a search for information on "Peter Drucker". It returns a result with 99,700 possible Web pages to examine. If you refine your search to "Peter F. Drucker," the search gives 41,400 choices. Again, you might refine your search to "P.F. Drucker," resulting in 950 choices. If you just chose "Drucker," 1,820,000 referenced Web pages are returned. This illustrates the difficulty one has in assessing potential overlaps; currency of the content; material source generated whether from commercial, private, or foreign; or the possibility of mislabeled content. If you were interested in specific information from one of his books, Managing for Results, your next search would yield 20,700 possible references. This result allows you to get closer to your objective but still may not be sufficient since you might be interested in his

Figure 6. Search technique to access details on managing results by P.F. Drucker



chapter The Commitment (7,670 references) or finally, to his conclusion (2,870). The issue is the quality of the metadata that describe accurately the characteristics of the Web page. Even using a refined search process, it would take time and computing resources to get the required information sought. Much of the results from these searches might not contain what you require. This searching technique is illustrated in Figure 6.

Without standardized metadata, an ever-increasing proliferation of redundant data and their disparate metadata is a key inhibitor to successful data, information, and knowledge integration.

This brings up the next point.

Management of Metadata has not been a Key Part of Data Management Implementations

In a review of the implementation of Information Resource Management (IRM) or Data Administration (DA) organizations and practices, the predecessors of Web warehousing and KM, there is little external evidence that corporations have valued these practices. Very few public success stories have documented the value of data administration or data management in organizations, since these activities are not considered part of the value chain that directly contributes to the profit or bottom line of the organization. Only recently at an Information Quality conference was there a claim by attendees of savings of over one-half (1/2) a billion dollars (English, 2003). The U.S. government, however, through the Clinger-Cohen Act of 1996, has driven governmental organizations to be much more proactive in setting up and adopting IRM-based programs in the public sector.

In an attempt to standardize metadata, a meeting hosted by the Online Computer Library Center, Inc. (OCLC), in Dublin, Ohio set up standards for Web page metadata documentation elements. This is similar to a library's catalog card: title, subject, author, publisher, other agent, data, object type, form, identifier, language, relation and coverage. But this is only an initial step in the evolution of Web standards for metadata delivery. Will these developing standards be successful in the management of metadata and the software tools to manage them?

Software Solutions do not Address the Management of Metadata

Commercialization of software to support various business applications has increased dramatically. But the commercialization of software to assist in developing, cleaning, and relationship standardization of data has not been a key market item or a commercial success. What is the reason? Is it the quality of the software or is it the organization's lack of recognition for the need to manage the metadata? Why should there be thousands of ways to collect personal contact information? Likewise, why have software standards not addressed the uniformity and interchange of data? We are just beginning to see commercialization of this type of software.

Lack of Support to Manage Data and Metadata Inhibits Successful Implementation Efforts

By far, the profit motive drives most commercial organizations to focus on maximizing revenue while minimizing costs. In the service sector, generating a profit requires maximizing the services while minimizing the cost of resources to produce that service. The implication of this heuristic is that anything not directly related to the actual production of the product or service is non-essential. Thus, any resource (data, metadata, etc.) that is consumed in the process that does not directly contribute to the end product or service has little or no added value. This references a mentality that leads to redundant processes, redundant data and metadata that actually inhibit long-term solutions.

SOLUTIONS AND RECOMMENDATIONS

Explicit Recognition that Data and Metadata are Assets

Until an accepted norm for evaluating the value of data in the world of accounting and finance is established, the recognition and management of data and metadata will continue to be difficult. Although many engineering practices are accounted for in the manufacturing of a product, the same accounting practices (GAAP, taxes, etc.) have to be applied to data, metadata, information, and knowledge. The concept of intellectual capital has to encompass all activities used in the development of DIKs. This would mean a shift in the management of data and metadata, allowing for the adoption of a framework to manage these assets.

Adaptation of a Framework for Managing Data, Information and Knowledge

Using a Web-enabled metadata data warehouse with an Organization Search Assistant System (Scime, 2000) begins to provide a framework to access current, relevant DIKs and serves as a foundation for expanding enterprise KM. In order to become an effective enterprise resource, these metadata need to be managed with the same vigor and enthusiasm as data. The information glut must be overcome with contextual information and management practices that provide competitive advantage to those who are decisive about its practice. Two essential items have to be addressed from a communication perspective:

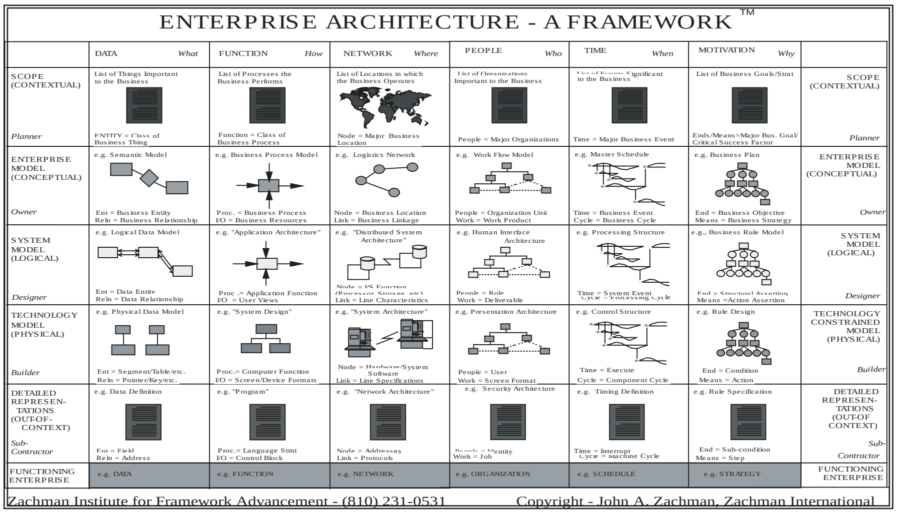
- Collaboration. A willingness to share, to cooperate, and to enhance subject DIKs
- Communities of Practice. A sociological grouping of people whose interests and experience complement the KM process

Foremost in the enterprise environment is a concerted effort to ensure that collaborating is rewarded. In a sense, declarative knowledge has much in common with explicit knowledge in that it consists of descriptions of what tasks, methods and procedures are used. Procedural knowledge describes how to do something, and strategic knowledge is knowing-when and knowing-why. Collaboration and communities of practice need all three forms of knowledge. An absence of organizational support, encouragement, and rewards often hinders the development of this practice. This inhibits the successful development of a process and practice, preventing it from becoming one of the basic beliefs of the organization. These values and beliefs need to be an integral part of development that requires declarative, procedural, and strategic knowledge.

Management provides an organization with a unifying framework for operating the organization. Much like Zachman's 1987 article, Framework for Information Systems Architecture, management needs a framework for DIKs. His framework contains 36 cells that represent the possible intersections of design perspectives and their aspects, from generic descriptions to specific details, in a consistent manner, as a way to support the organization's information systems requirement (O'Rouke, 2003). In a sense, these aspects provide the variety of perspectives needed to define requirements to implement an organization's need for an information-based solution (i.e., Web mining and KM). This framework requires one to address several key perspectives in answering the "why, who, when, where, what and how" to provide an insight into the motivations, initiatives, and expectations desired from Web mining, warehousing, and KM activities. Supporting processes address the following: knowledge cycle, program and project management, policies and procedures, methods and techniques, controls, and best practices. This framework is shown in Figure 7.

Figure 7. A framework for information systems architecture

Zachman Framework for Enterprise Architecture



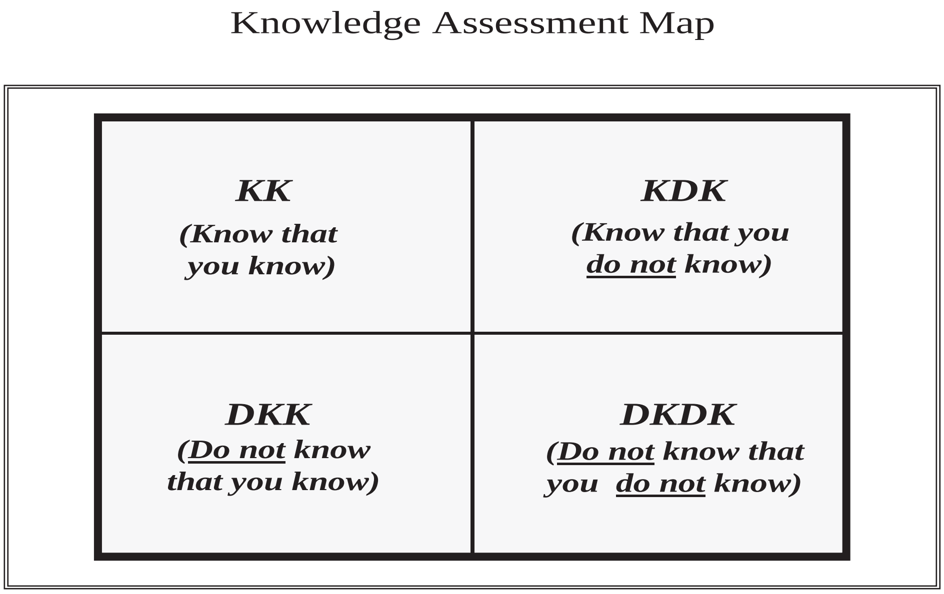
These processes provide the foundation for identifying, naming, defining, storing, documenting, authorizing, changing, securing, distributing, and deleting DIKs. They become the roadmap to successful implementation. From a different perspective, the underlying metadata supporting this taxonomy help to map the relationships to navigate across the 36 discrete cells of the Zachman Framework. Jeff Angus and Jeetu Patel in their InformationWeek article (1998, March 16) described the key KM processes to be gathering, organizing, refining, and disseminating DIKs. There is a significant need to develop tools and standards to ensure consistent semantic integrity of Web-delivered data to anyone who needs the DIKs.

Development of Web-Based Warehouse to House Consistent Data Definitions and Taxonomy to Ensure Semantic Consistency and Effective Communications

In the development of Web mining and warehousing, consistency of terminology becomes increasingly important in decision-making. Figure 8 shows a traditional matrix used to assess one's understanding in determining the current state of knowledge.

From the perspective of one who is accessing DIKs, each grid has different search criteria and different levels of DIKs that constrain the search requirements and impact the tools needed to support that request.

Figure 8. A knowledge assessment map



- In the KK quadrant, the requestor knows what he or she is looking for and where to get it. No additional investment is required in time or resources.
- In the KDK quadrant, the person realizes the DIK exists but does not have a means to access it. In this case, the person would use time and consume resources to determine how to access a DIK that exists.
- In the DKK quadrant, the DIKs are available but the person is not knowledgeable of the availability of the DIKs. In this case, the person would spend time and resources to determine if the DIK exists and later to determine how to access it if it does exist.
- In the final quadrant-DKDK, a person is totally unaware of the DIKs and any means to access them. In this case, the person may not even spend time and resources to determine if the DIK exists, since he or she is not aware of the possibility.

Consider the searching strategies we use on the Web and you can probably relate to the different scenarios above. How much time do we consume in search of quality information on the Web? Are the metadata critical to success or frustration with the Web's ability to retrieve something about which we are inquiring?

Metadata and basic terminology are critical to the access and use of DIKs. It is clear from the prior discussion that without metadata, it would be difficult to move from one grid to another. From that perspective, let's discuss the development of a data warehouse. The team that develops the data warehousing application has to understand all the required data from a business perspective. They must determine the best source of those data from various information systems and must inventory their associated technical (IT) metadata. This provides a profile of the data's current implementations. Design of the target data for implementation is required and becomes the basis for developing the Extraction-Translation-Load (ETL) rules; an automated process is set up to build the data warehouse. In implementing a data warehouse, the metadata that are collected and delivered as a part of this application are a critical part of the delivery of the warehouse for the organization's knowledge workers. The reason knowledge workers and information systems professionals develop a data warehouse together is that neither have the requisite knowledge to build the application independently. The knowledge workers (seekers of knowledge) understand the context of the required information required but do not have the insight and depth to organize it effectively. On the other hand, the information systems analyst has the knowledge of the DIKs and possible classification and structuring of the required DIKs, but does not have the contextual knowledge of its use from inside the organization.

Develop a Measurement to Assess Quality, Timeliness, and Accuracy of Web Content to Start to Minimize the Amount of Disparate Metadata

Given the acceptance of a financial recognition of the economic value of "intellectual capital," the assessment of the quality, timeliness, and accuracy of data, metadata and ultimately, Web content, has to be measured. Redman's grouping of characteristics, conceptual, data value and data representation would be an excellent starting point for measurement. Work currently being done to address data quality by MIT's Total Data Quality Management program is starting to address this issue from different perspectives (see Aerve, 2001; Kahn, 2002; Segev, 2001; Wang, 2003).

Management of Metadata has not been a Key Part of Data Management Implementations

Whenever information systems organizations design something new (i.e., applications, data, functions, systems, networks, or other key artifacts) for operating an organization, models are used. Models are descriptive or mathematical representations supporting a new design. It is significantly better to design models to communicate new requirements than it is to implement solutions without them. Because of the complexity in many of today's organizations, analysts develop various models (business model, business process, etc.) to portray a new design's requirements. In this process, an analyst gathers DIKs to build contextual representations of the new design requirements with his/her associated knowledge workers. The gathering of these DIKs is the metadata necessary to complete the modeling activity. Figure 9 shows one view of models that could be used in the process.

We perform various types of metamodel implementations in the development of information technology-based systems. Typical types of analysis associated with models include: clustering (combine, intersect, select), comparing (similar, different), inferring (seeing relationships between objects), ordering (by grouping or special sequence) and ranking (subjective evaluations) to provide recommendations.

With the implementation of repository (database) systems, we have an opportunity to perform some of the above analysis by modeling different relationships. The example in Figure 10 illustrates a transition in thinking which may require us to re-think the way we have done this process in the past.

Teaming concepts are critical to operational activities in delivering new ideas, concepts, approaches, and results. Organization dynamics often necessitate internal and external participation in cooperative efforts, so organizational objectives and goals need to be clearly understood by all. This process involves time and judgment in assessing the right content, experience, and knowledge that is applicable to the organization's requirement and operational activity. Supporting DIKs are involved in this process and are checked

Figure 9. Metamodel of models: A structure of models for relating metadata

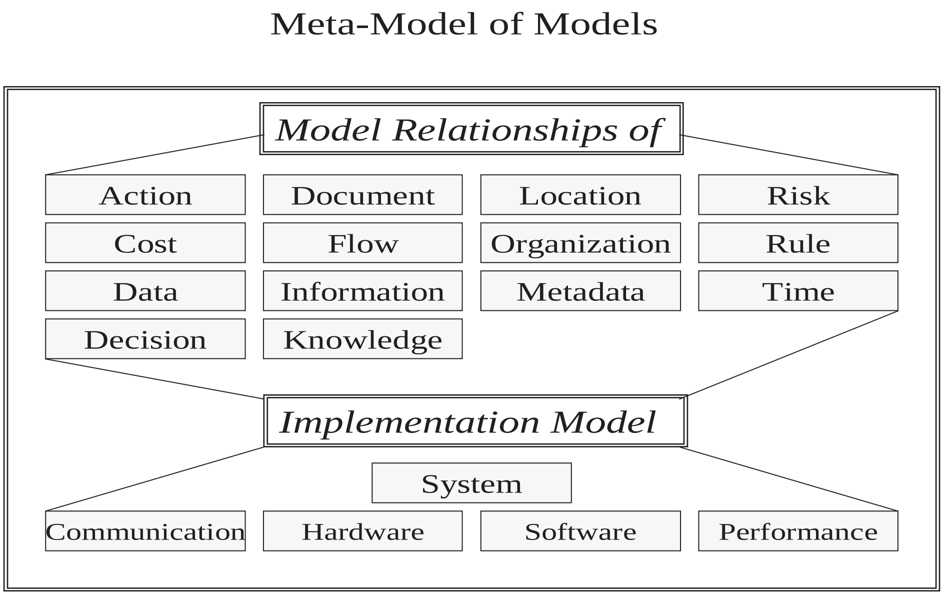


Figure 10. Transitional thinking: A repository structure for relating metadata

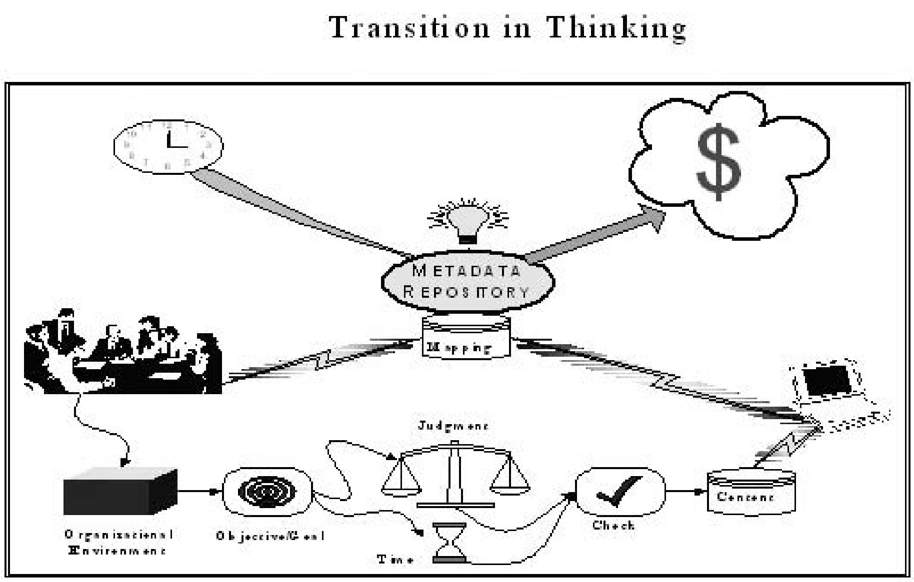


against the assumptions made and implemented in various systems. To assess the success of the decision, measurements are taken as part of the implementation of the system. Today, the critical factor is the necessity of timely decisions with sufficient return on investments in terms of implementation.

How does Web mining and KM fit into the picture? A central theme is that a metadata repository (database) provides the semantic mechanism and transitions necessary to deliver effective interchange of content appropriate to the operational activities. This is the beginning of the era of ever-increasing demand for automated DIKs. John F. Rockart and James Short (1989, p. 16) describe an increasing spiral of demand for information systems and technology in the business world, stating, Accessible, well-defined and a transparent network are, therefore, the keys to effective integration in the coming years. Developing these resources, however, is not easy. Excellence at investing in and deploying IT isn't sufficient to achieve superior business performance: companies must also excel at collecting, organizing and maintaining information, and at getting their people to embrace the right behaviors and values for working with information. In today's environment, it means that Web mining and KM are a large part of building and managing a new type of culture and infrastructure. Thus, organizations and their IT units must develop an architecture, establish standards, communicate the value of the infrastructure, and operate the increasingly complex infrastructure to deliver the content supporting this transition in thinking.

In an unpublished book in the 1990s, Ron Shelby wrote, "Senior management is sponsoring high-visibility initiatives to build common systems and databases to support their organization in the future. Increasingly, information resource management (IRM) organizations are asked to architect, integrate, and manage shared-data environments that will support the core of tomorrow's enterprise." In 1999, Shelby was cited in an InformationWeek article about data warehouses:

"One of the early reasons for data warehousing was to optimize your own business," says Ron Shelby, acting chief technology officer of General Motors Corp. "Sharing data with suppliers is an extension of that. To be more agile, we have to have a supplier base that's equally agile." The automotive giant is starting to use Internet technologies and data-analysis tools so it can share its data warehouse with suppliers and, in effect, treat them like other divisions. (Davis, 1999, June 28)

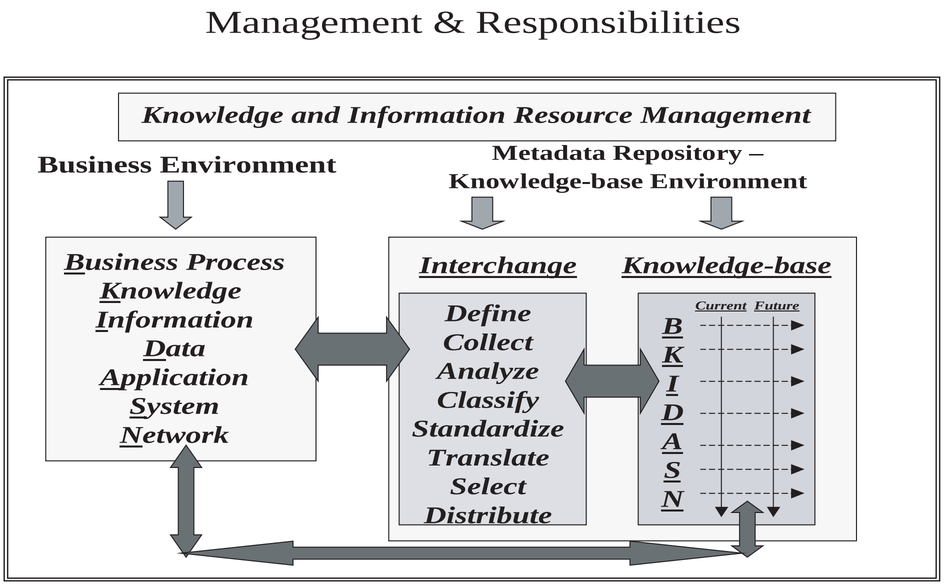
Since the 1999 articles, the likes of GM, GE and others have successfully implemented Internet technologies and data mining techniques, with significant dollar savings in supply chain logistics and marketing. For example, GM's Buy Power Website operates in 40 countries and, with other efficiencies, is saving the company $1.5 billion annually, with 9,900 GM suppliers linked in real time to the company (Riftin, 2002). A large part of the success of these implementations is based upon the management of data and metadata, a key proposition stated by Shelby and highlighted by Rockhart and Short.

Development of Software Standards and Measurements to Address Metadata Management Functionality

Given an organizational environment that addresses the objectives/goals, leadership is required to cultivate, motivate, and manage a knowledge and IRM initiative. Metadata, in combination with real-time data, provides immediate information for decision-making purposes in business systems. This is a valuable lesson since using metadata as an active participant in the management and control of this decision support system make the human-system interaction far more valued, flexible, and operationally successful as a knowledge-based information resource.

The premise of this 1986 integrated Business Information and Data (iBID) (Shields, 1986)

Figure 11. Management of an integrated business information architecture



architecture work, as shown in Figure 11, was to deliver a mechanism for a business to develop integrated, flexible, adaptive, and predictive information-based products and services.

This author included knowledge as a dimension in the business environment since it was an assumed element in the development of this architecture. A key part of this architecture was the collection, resolution, and dissemination of the business rules (Ross, 2003) that the organization currently operates, plans to operate, and analysis of gaps prior to their implementation. This type of simulation and forecasting of current business dynamics (Sherman, 2003) seeks to project the future environment prior to its implementation. This architectural representation provides a clear analogy to today's operating environment. Each organization or business environment has business models, business process management, data models, and data semantics. The organization performs a series of actions (broadly categorized as business processes) that effectively utilize data (internal or external) that have been created, updated, or deleted either by a business system (manual/semi-manual) or by an application of an information system. These business systems are networked internally, externally, or some combination of both to locations by some type of communications network.

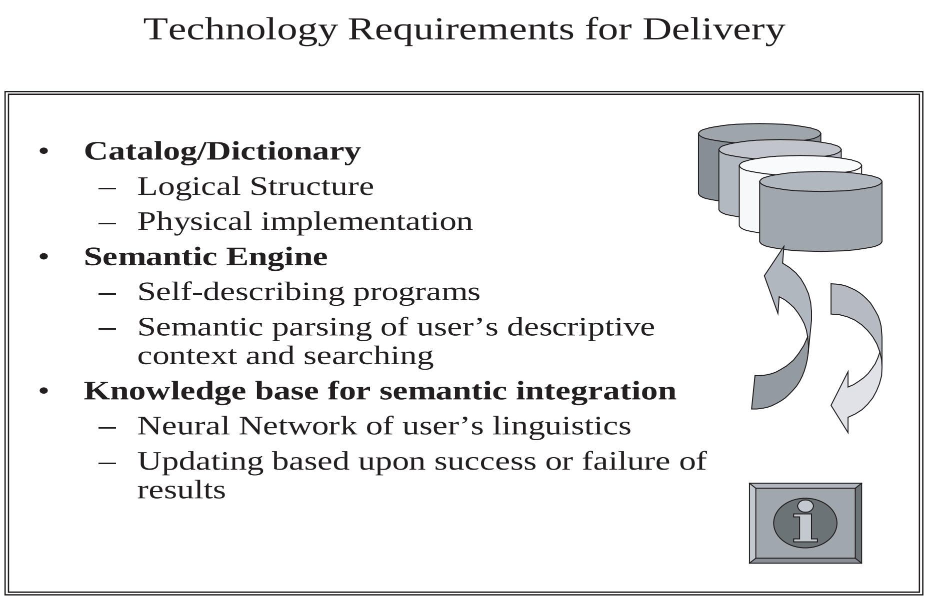
Within the knowledge base, two aspects are highlighted: the current (as-is) or the future state (to-be) across each dimension and is comparable to Zackman's use of interrogatives (who, what, where, when, how, and why) within each dimension. The main purpose is to understand current and future states to ensure transitional planning between the states so that they work. This transition between states is done effectively and efficiently because understanding the many interrelationships avoids errors in implementation.

The interchange mechanism enables and facilitates some of the services required (define, collect, analyze, classify, standardize, translate, select, distribute). Each service uses appropriate metadata that require management with a support system or tool in the delivery of repository services. Finally, the bi-direction arrows represent the system capability to access the knowledge-information resource repository from anywhere at any time, and for any purpose. Today, our mechanism to accomplish this is the intranet/Internet.

This knowledge base environment cannot be achieved without some critical considerations for the technology components that are required of such an environment. The focal point is the delivery of quality DIKs. Three essential components are required to be integrated, as shown in Figure 12 below.

The catalog/dictionary/thesaurus/repository system component is needed to provide the translation mechanism to bridge to various semantic questions that arise in the implementation of languages. A dictionary also would include relationships to other synonyms to ensure that content would be delivered properly to the requestor. Both logical and physical implementations should be available through the public domain. The semantic engine component provides a series of self-describing programs that hone in on the knowledge worker's descriptive model of context and searching needs. With a type of semantic matching (Rahm, 2003) and profile technique, this component would understand some of the context of the knowledge worker's characteristics to use as a means to extract and mine more meaningful results from the knowledge base. Based upon the overall experience in the knowledge base, it would develop fuzzy-set solutions. The semantic integrity component provides an artificial intelligence engine that dynamically adjusts a neural network of the results achieved from the knowledge worker's inquiries. This would improve the quality of the results from the inquiries based upon the various states from which the person may operate.

Figure 12. Technology requirements for delivery of KM environment



FUTURE TRENDS

Increasing Importance for an Organization to Adopt a Framework for Managing Information and Data

Because data and metadata will become an "asset" as part of the KM function, organizational leaders will be faced with competitive situations that will dictate their need for it. With distributed Web warehousing activities, the key role of DIKs is to become a new resource in an organization's environment. A centralized logical approach to develop and manage metadata content databases may be necessary. With centralized logical metadata that is indexed, searched, and processed by tools, it becomes an enabler for organizations to assess and use its knowledge. This IRM metadata repository and knowledge-based environment supports the overall mission and goals of the organization.

The implication of this change is that more robust analytical tools will be required. They will need to support automatic indexing, validation, searching, mapping of casual relationships, adaptive modeling, and fuzzy-set logic technologies to measure the metadata's utility in the context of organizational delivery and adaptation to their environment. Tools in many forms will develop: glossaries, dictionaries, subject taxonomies (generic-to-specific hierarchies), semantic maps (term/definition-to-homonym(s)-synonym(s)), visualization techniques to build relationship maps and new languages to support relationship structures.

This implies that managing metadata, data and information is clearly and explicitly linked to the organization's strategy with a real understanding of its knowledge advantage.

Assessing Organizational Context in a Systematic Approach for Adopting a Knowledge Management Practice

Because data and metadata are essential in the delivery of a robust Web mining and knowledge management solution, a systematic approach is needed to develop the organization's mission and requirements. Basic principles are the foundation for success in providing a systematic approach. They are: (1) to capture, codify, and share both information and knowledge; (2) to focus on the collaborative efforts among people and communities with an emphasis on learning and training; and (3) to prioritize the knowledge and expertise used in the everyday workplace. Remember, in the initial assessment of an organization's needs, one KM best practice may not work in another situation due to organizational culture and context (Glick, 2002). A plan can be put in place using this systematic approach and analysis, specific project goals, requirements, resources, and metrics. The essential design elements of the approach address several areas: content management, the knowledge chain and its dissemination, the infrastructure needs, and its components. In assessing the implementation of the knowledge chain, understanding the organizational context plays a significant part in delivering solutions that emphasize context, interaction and flows, the knowledge base with its content, and the acquisition strategy to be deployed. Knowledge delivery, services, and technology are a key part of the organization's infrastructural practices and culture. The evolution of an organization's knowledge management practice can move from short-term to longer-term projects to full acceptance based upon the success of each knowledge initiative within its proper context. This implies a compelling vision and architecture for your organization's KM mission and goal.

Emerging Standards to Address the Redundancy and Quality of Web-Based Content

The mapping of relationships between different objects in the meta-model of models is starting to play a key role in both organizational and industry standards. The development of various industry-based taxonomies (a class of objects and relationships that exist between them in a generic-to-specific structure) has started. The mapping of synonyms, homonyms, and data with definitional clarity becomes an essential ingredient to the interchange of DIKs. Ontologies (databases that contains the mapped relationships of one object to one or more objects) will be frequently used to provide the capability to infer new facts and observations. Concepts discussed in the InfoMap (Burk, 1988), especially those that focus on measuring cost and the retention practices for DIKs, will be of critical importance to the utility of the metadata knowledge base repository.

Information systems vendors and consultant organizations will support efforts to build these taxonomies and ontologies to provide hardware, software and consulting services that support their use. The implication is that if software products are developed to support these activities, the products may be proprietary in nature.

The American National Standards Institute (ANSI) is one of a number of member bodies that propose U.S. standards be accepted by the International Standards Organization (ISO). Each standards organization is made up of volunteers who develop, assess, and submit a standard for formal approval. There can be competing standards that are developed and some have to be reconciled. Due to the length of time, the level of detail and cost of participating in these standards, delays in the standards process often occur. This delay results in de facto standards being used and implemented prior to full acceptance as a standard. This could impact the development and transitional efforts needed to build robust taxonomies and ontologies. This implies a systematic approach for capturing explicit and implicit knowledge into a well-developed knowledge infrastructure.

Development of Tools and Standards to Assess Semantic Integrity of Web Delivered Pages

The efforts to develop a semantic Web by the W3C group will be key in development of standards. This effort from diverse participants will address a large opportunity to increase the utility of the Web. Various tools (agents) will be generated to assist in the functional services needed by the interchange architecture previously (define, collect, analyze, classify, standardize, translate, select, distribute). The most difficult service will be the semantic translation between a Web user's request and utility of the results. Products being developed for natural language, conversational, and parametric searching (Abrams, 2003) will be vital to their successful implementations.

Increasing Use of Intelligent Software to Enable Delivery of New Content to be Delivered into a Knowledge Base Under Users' Metadata Requirements

The efforts supporting the development of DARPA's Agent Markup Language (DAML) and Resource Definition Framework (RDF) are focused on the semantic integration, retrieval and utility of the Web's resources. A key effort is to have a unifying meta-model to store the metadata effectively in its knowledge-base repository for effective and efficient use in the organization. The success of the knowledge-based environment is predicated on linking multiple technologies and practices with critical focus on the quality of the data, information, and maintaining knowledge. This will be one of the biggest organizational challenges!

CONCLUSIONS

To create solutions for today's marketplace needs, the opportunity to build a quality knowledge base depends upon the following:

- The metadata management of DIKs as the major vehicle for the successful implementation of Web mining, warehousing and KM.
- The requirement that organizations adopt new methods/processes, organizational roles, standards and tooling.
- Addressing emerging standards in terms of redundancy and quality of DIKs being delivered through the Web warehousing of content and metadata.

Because of today's global marketplace, a KM system becomes necessary for economic survival. It enables an organization to assess internal and external content via World Wide Web resources and its own internal content-rich knowledgebase. To successfully develop that system, the enterprise has to establish an environment in which the system can succeed. This means integrating many processes and technologies in orchestrating a different environment. A significant hindrance has been the inability to access current, relevant DIKs. Much of the reason lies in the fact that the metadata used in support of the collection of DIKs' knowledge have been limited, or nonexistent, ill-defined, erroneously labeled, and disparate. With the ever-increasing demand for Web-enabled mining, the KM environment has to address multiple facets of process, technology, metadata Web mining and warehousing management approaches to provide an integrated content-rich and practical enterprise solution to assist in the delivery of Web warehousing and knowledge management.

Chapter 3.25
Multimedia Capture, Collaboration, and Knowledge Management

Subramanyam Vdaygiri
Siemens Corporate Research Inc., USA

Stuart Goose
Siemens Corporate Research Inc., USA

ABSTRACT

This chapter presents methods and technologies from Siemens Corporate Research that can assist in the process of creating multimedia collaborative knowledge bases: capture, querying, visualization, archiving, and reusability of multimedia knowledge bases. A selection of Siemens products in the healthcare and communication domains are introduced, above which novel multimedia collaboration and knowledge management technologies have been developed by the authors. With examples, it is explained how in concert these technologies can contribute to streamlining the processes within healthcare enterprises, telemedicine environments and home healthcare practices.

INTRODUCTION AND MOTIVATION

The networked healthcare enterprise is providing unprecedented opportunities for healthcare workers to collaborate and make clinical decisions in an efficient manner. Significant progress has been made to enable healthcare personnel to obtain answers to simple clinical questions by using medical databases of evidence-based answers. This approach allows reuse and sharing of knowledge to help healthcare professionals to save time and effort and help patients in an efficient manner. For situations where healthcare workers have simple questions with simple answers, this approach is perhaps overkill. However, when the questions are of a more complex nature, by capturing and archiving complex answers in a rich multimedia form they can be exploited multiple in the future to explain solutions in a manner that can be easily digested by healthcare workers.

A contemporary healthcare enterprise involves complex media elements (images, videos, documents, etc.) and volumes of documentation both digital and on paper. The healthcare knowledge base should incorporate these media elements and easily allow users to search, extract, and reuse. Some of the modern knowledge management systems allow building of communities of practice around documents. But there is a need to move beyond regular office documents to address rich media and encompass specialized medical and clinical data.

The networked enterprise is also enabling a plethora of ways for healthcare personnel to communicate and collaborate. The next generation of communication technologies will bring converged voice and data solutions on a single network. This is helping integrate the healthcare IT (Information Technology) systems with Web-based communications. In recent years we have witnessed a proliferation of communication and data devices like GPRS cellular phones and PDAs, thus providing an opportunity for accessing clinical information anywhere/anytime and allowing users to collaborate over clinical information to reach decisions quickly.

The concept of presence and availability offered by various instant messaging tools is changing the manner in which people are communicating with each other. Presence enables a user to know who in their contact or buddy list is available or not at any given point in time. Availability options allow a user to signal whether they are available to be contacted and which form of communication they favor. Presence and availability information allow users to interact in various ways in offline, real-time or in near-real time modes. Mobile communication technologies are being developed that enables mobile location and presence. The integration of the healthcare enterprise content repository with a Web-based infrastructure and presence and availability represent the three pillars of modern unified, or converged, communication.

Although the potential for a rich communications and IT infrastructure is high, there remains a need to streamline the communications and collaborations between healthcare personnel to ensure that valuable knowledge gained from daily interactions between healthcare personnel is not lost. This chapter presents methods and technologies from Siemens Corporate Research that can assist in the process of creating multimedia collaborative knowledge bases: capture, querying, visualization, archiving, and reusability of multimedia knowledge bases. Throughout the chapter, a number of Web-based technologies are introduced that enable healthcare personnel to interact in a variety of modes regardless of whether they are mobile or sedentary.

BACKGROUND: STREAMLINING HEALTHCARE AND TELEHEALTH

Since the advent of Web-based workflows, there has been a growing emphasis in healthcare enterprises on methods to increase organizational efficiencies, reduce errors and focus on patient care. One such platform is Soarian (Siemens Soarian) from Siemens Medical (Siemens Medical) that offers an integrated workflow technology that can streamline the operational processes of healthcare. Soarian's infrastructure has been engineered based on clinical processes that enable physicians to focus less on administrative duties and more care by providing them with access to all clinical data in a single view. The goals being to offer actionable guidelines to clinicians based on best practices and to support them in reaching accurate, evidence-based decisions promptly.

A nascent area for which technology can be a significant enabler is that of telemedicine (Hibbert, Mair, May, Boland, O'Connor, Capewell, & Angus, 2004), where clinical needs are extended beyond the boundary of the hospital. A key requirement to facilitate a telehealth consultation is to have medical personnel in remote locations to communicate and collaborate with each other in a quick, efficient, and effective manner.

Some of the issues that an integrated communications and healthcare medical IT infrastructure can help address are:

- Reducing time and effort wasted in daily communications (paging, phone calls) between clinicians, nurses, and patients
- Reducing the communication pathways by a combined infrastructure can streamline how users can be reached at a given point in time
- Complex solutions to questions can be assembled in multimedia fashion to succinctly convey the message
- Knowledge exchanged and gained from daily interactions between people can captured and archived with high granularity
- Reuse, by querying and retrieving relevant segments from past collaborative activities, can avoid recreating the wheel when a recurrent problem reappears
- Reduce paper work by having one consolidated IT-communications infrastructure
- Reduce cost by managing a single converged voice and data network

Remote communications in contemporary telehealth systems allows users to collaborate in two different modes: store & forward and in real time. The asynchronous mode, or store & forward method, allows for the sharing of medical information in an offline mode, but the absence of human interactivity prevents healthcare personnel from augmenting this with personal comments, insight and knowledge. The real time collaboration mode requires the session to be scheduled in advance, and all participants must be dedicated to the collaboration session for the duration.

The current mode of document/data sharing involves all users within telehealth WAN (Wide Area Network) cluster to upload documents, data and code to a central repository from where other users can extract materials of interest. This mode of collaboration among users is not sufficient for many users to exchange complex ideas and viewpoints regarding various images and other documents in intricate detail. For example, medical researchers frequently need to locate and reference information that is not only physically distributed across the sites of their collaborators, but also in an array of formats (images, reports generated based on experiments, or code execution).

Often users collaborate by exchanging e-mail messages along with data/documents downloaded from a central Web server. Although this allows individuals to participate at their own pace, users invest much time typing descriptive text to discuss a particular topic, especially when expressing complex thoughts within context of a document or image. The problem becomes particularly acute when users are collaborating using document attachments. This mode leads to large documents being exchanged as attachments back and forth between users, with the potential for inconsistencies to arise between successive versions. Moreover, with clinicians collaborating across time zones on documents or images, a need has been observed for conveying complex information via rich multimedia.

To anticipate and streamline the future communication and IT needs of healthcare enterprises and burgeoning telehealth market, the various requirements were distilled:

- Communication: It is clear that there exists a need to combine communications within the healthcare processes to optimize the clinicians' time to manage better the inexorable stream of phone calls, paging, exchange of paper and digital documents. Presence-based communications enables the healthcare personnel to communicate in a very effective manner.

- Collaboration: The tools should provide a consistent manner to collaborate irrespective of the mode, all online in a real time conference, or a single user making her analysis and comments on an image in offline mode. By allowing users to collaborate in different modes within a browser-based environment on diverse medical data can facilitate a seamless collaboration workflow. These technologies can enhance typical telemedicine scenarios and also extend conventional doctor-patient interactions to include web-based interactions such as chronic care or follow-ups.
- Knowledge Management: There should also be a consistent way to archive the multimedia annotations made on such documents. This would not only allow researchers to collaborate based on their time and schedule, but also to search, retrieve and filter all comments and analysis made previously by collaborators on any multimedia document.

The remaining sections describe ongoing efforts at Siemens Corporate Research to develop technological solutions driven by these anticipated future needs.

TECHNOLOGICAL BUILDING BLOCKS

OpenScape (Siemens OpenScape) from Siemens Communications Networks (Siemens Information and Communications Networks) is a suite of communication applications designed to increase the productivity of information workers. It aims to control the panoply of communication applications and devices, on both fixed and wireless networks, connected via local and wide area networks. OpenScape addresses the fragmented nature of communication modalities and their separation and provides a unifying framework for integrating, managing and streamlining communication in the enterprise.

It obviates redundant communication sessions, where a person calls multiple phone numbers and/or leaves duplicate voice, email, and instant messages in an effort to communicate urgent issues. Hence, it is possible to avoid:

- Unnecessary cell phone intrusions into client meetings, work sessions or personal time;
- Wasted time setting up conference calls, communicating call-in information, sending and synchronizing documents, and establishing separate sessions for voice, Web and video collaboration; and
- The difficulty of mobilizing all key colleagues that may be equipped with different applications, or because setting up a collaborative session is too complex and time consuming.

It provides healthcare personnel the experience of a single, synchronized set of communication resources, sharing common controls and shared communication rules and intelligence. These capabilities can be accessed via a wide range of devices and interfaces to serve the constantly changing needs of mobile employees. OpenScape provides personal and workgroup communications portals for multiple healthcare domains. OpenScape makes extensive use of presence-based communication. There are different ways of showing presence and the user's status:

Device Presence: indicates the presence of an application or communications device. The user could be online or off-line. For example:

- Off hook/on hook status of an IP desk phone or mobile phone
- Instant Messaging (IM) application presence
- Collaboration application presence indicating whether an individual has signed on to the application or not

- On which terminal can the user be reached

User Presence: associates presence with an individual rather than the user's device

- The willingness of the user to be reached
- The activity that the user is currently engaged
- The location of the user—working remotely, out of office, and so on.
- Mood—happy, good or bad tempered or even annoyed

Device presence or terminal status will become less important as terminals become more advanced and intelligent, with the ability to handle a multitude of multimedia content adaptively. A mobile phone or PDA, for instance will be able to negotiate with the remote communication party the type of information it can support, for instance video, audio, and so on.

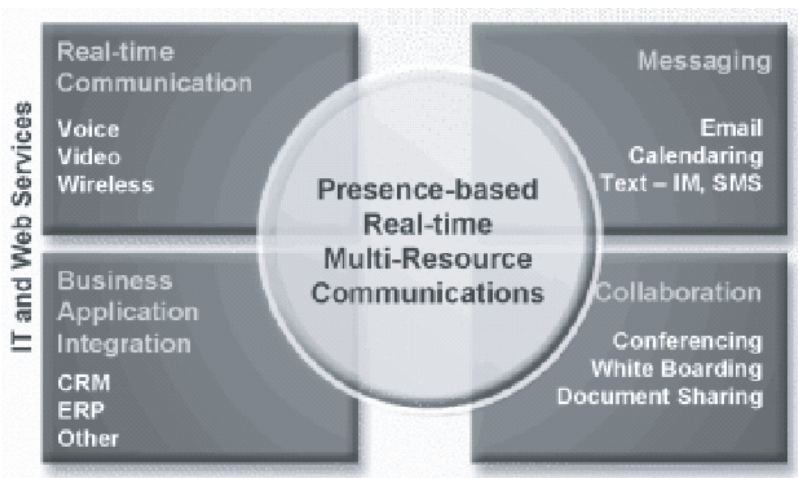
IMS (Siemens IMS) from Siemens Communications Mobile (http://www.siemens-mobile.com) provides new presence and communications platform for mobile devices and networks. The IMS platform was standardized for new multimedia applications and services that could be rapidly deployed by mobile network operators, such as audio/video conferencing, chat, and presence services over new mobile devices. Moreover, IMS is positioned to voice and multimedia communication. Different from the legacy circuit-switched voice/data communication in regular phone calls, IMS is based on IP technology that can control real-time and non-real-time services on the same IP network.

Together OpenScape, IMS and Soarian provide the core technological building blocks that enable the integration of the healthcare enterprise content repository with a Web-based infrastructure and presence and availability. Our research work is layered above these three pillars and the following sections illustrate the benefits of a converged communication healthcare enterprise.

ENRICHING COLLABORATIVE CONSULTATIONS

During a telehealth consultation between patient and clinician various medical documents might be

Figure 1. OpenScape: A way of communication



used including laboratory reports, photos of injury/skin lesions, x-rays, pathology slides, EKGs, MR/CT images, medical claim forms, prescriptions, clinical results, case reports, and other documents. Some of the documents like photos and images might have been captured using camera during patient visits, while other clinical (lab reports) or financial information (insurance claim) were gleaned from other information systems. Face-to-face video conferencing is commonly used in telemedicine not only for personalized remote communications, but also for regulatory reasons as evidence of a consultation the costs for which can subsequently be reimbursed.

It would be convenient if a clinician could combine, interface, convert, and extract disparate medical information such as those listed above from peripheral devices like photo cameras, video conferencing session, content management systems, PACS, and regular office documents into a Web-based composite document. Thereafter, it would be convenient if this composite document could be used as the basis for browser-based collaboration (whether it is offline or real time) between various participants. Such a composite document generated should combine all relevant information needed for a particular collaboration session into one seamless document so that effective offline or real time collaboration can occur.

Let us now look at some of the details involved in realizing our solution. A user could choose specific pages from document(s) stored locally and automatically have the selected pages converted to HTML format and hyperlinked with each other to form a composite document. Then, he or she could highlight important parts of the document and add personal comments with the help of voice and graphic annotations using our multimedia presentation software, called ShowMe (Sastry, Lewis, & Pizano, 1999). The multimedia annotation technology developed is unique as it not only captures the spatial nature but also the temporal aspects. For instance, the multimedia annotation on a document would capture a synchronized temporal voice, graphic and mouse pointer annotations. Finally, the user could save the composite document along with the annotations on the local web server, and this document is referred to as the collaboration document. Associated with this collaboration document is some metadata in the form of an XML schema that describes this document. This metadata is finally uploaded to the central server and its URL on this central server can then be sent to other participants.

Participants can view the collaboration document via the URL of the metadata stored on the central Web server using a lightweight Web-browser player. As the collaboration documents are stored locally, they are amenable to document management tasks, including deleting, moving, and so on. However, any such document management task must be accompanied by making an appropriate change in the metadata located at the central Web server. The above process allows various users to collaborate over documents quickly and easily by only sharing information relevant to the topic in question. In addition, there is increase in productivity as users can quickly exchange information without having to exchange e-mail to explain problem/solution.

Figures 2, 3, and 4 show a particular workflow implemented to demonstrate the spectrum of modes of browser-based collaboration using office documents and Web content. The components can be re-used in several other collaboration workflows and processes. As only specific parts of different documents might be needed for a particular collaborative session, participants are able to combine, on the fly, specific pages from several documents with different formats into one seamless Web-based composite document. Using synchronous voice and graphic annotations along with mouse as a pointer, a clinician can continuously narrate a patient's case history across the entire composite document while using the mouse to gesture or annotate on different parts of the aggregated document.

Figure 2. Multimedia Enhanced Store & Forward Collaboration: A clinician can quickly create one seamless web-based composite multimedia document by combining various medical information segments like images, photos, EKGs together. Synchronous voice, graphic and mouse annotations can then be easily added on top of the composite document before sending it via regular e-mail. The recipient needs only a web browser to view the composite document along with the voice and graphic annotations.

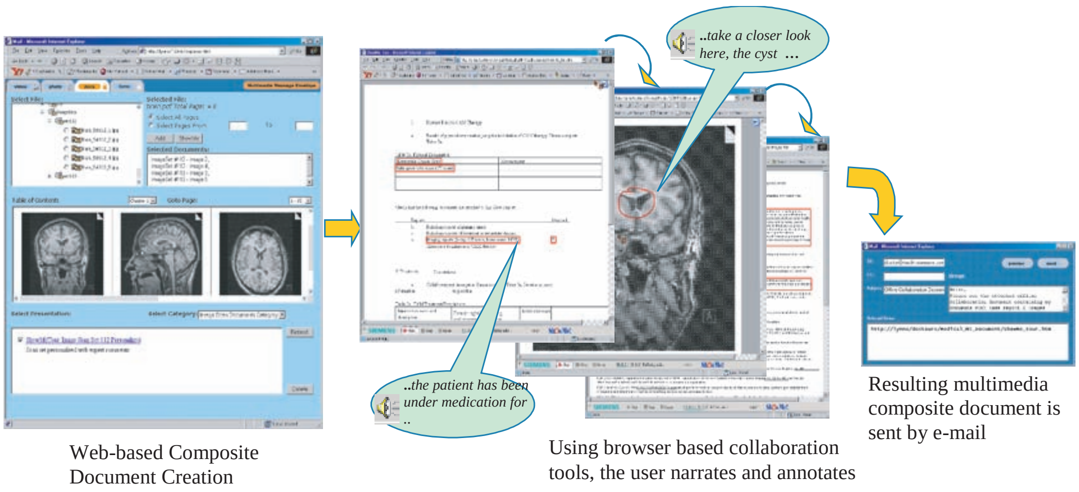


Figure 3. Instant Messaging Based Document Collaboration: This uses presence and availability of different participants to setup collaboration. Also, this allows asynchronous messaging of voice and graphic annotations within a real-time collaboration session. This enables users to exchange information at one's own pace and yet participate in a near real-time collaboration session.

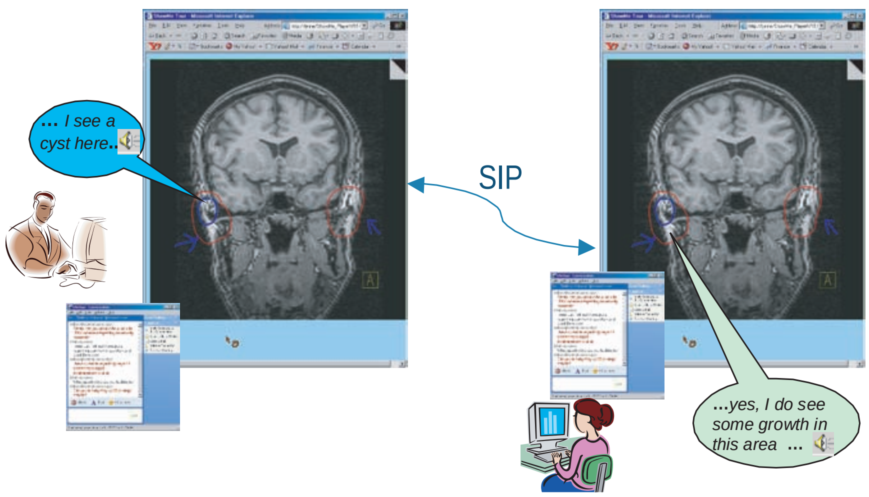

Figure 4. Multi-participant Real-Time Collaboration: Several remote participants using their web browser can collaborate on the generated composite medical document. The collaboration is accompanied by a voice conference.

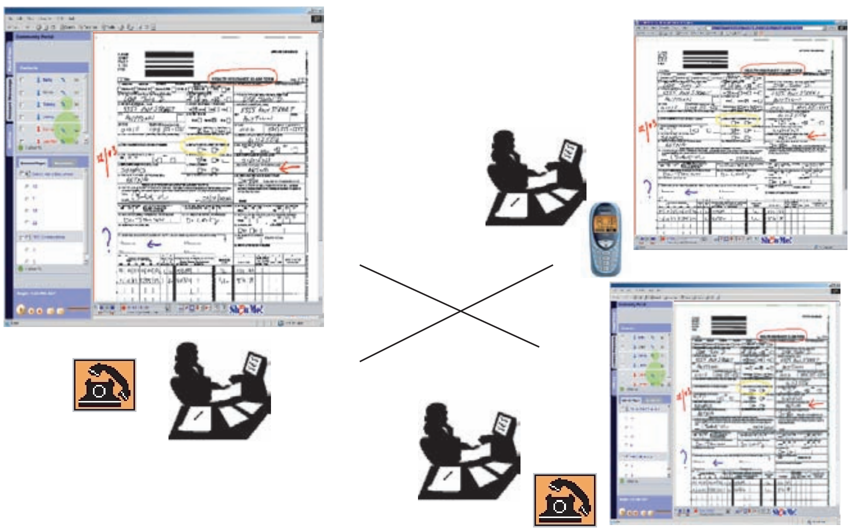


These modes of collaboration—whether off-line, IM-based, or real-time—take place using a regular web browser with the requisite collaboration plug-ins. This allows the participants to collaborate within the familiar environment of a Web browser. The annotations by various participants during a collaboration session on composite medical documents can be archived into a database in a very lightweight manner. The voice and graphic annotations along with the composite document can be archived with high granularity along with meta-data describing the various annotations. This would allow for searching and retrieval of not only medical information/documents exchanged during collaboration sessions, but also to obtain information regarding comments, interactions and dialogue between various participants. For instance, one can query and retrieve specific comments/annotations made by particular participant from a past collaboration session on a specific medical document. In addition, one can easily follow the changes in the medical condition of the patient by comparing the medical documents and associated annotations made during successive patient visits.

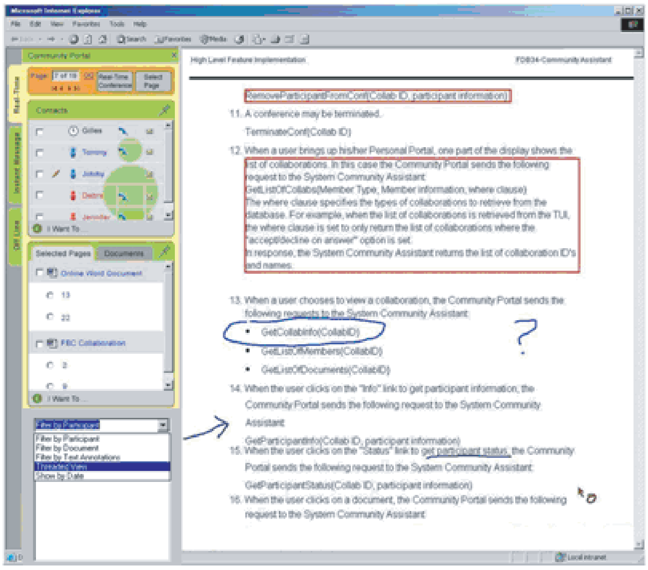
COLLABORATION KNOWLEDGE ACCESS AND MANAGEMENT

Access to and the management of the knowledge contained within the collaboration documents introduced above is reviewed in this section.

Filtering Collaboration Annotations

The ability to save annotations from a real time, offline or IM based document collaboration enables participants to filter and view a conference in several different ways. The figure below illustrates

Figure 5. The clinician can filter and quickly access specific segments from past collaborative sessions and reuse to address the current problem.



how an archived conference may be viewed in different ways by applying different filters. For example, the filters can be to show the conference view by participants, by documents collaborated on, by threaded view, by type of annotations, by session, and so on. New filters can be easily created based on the use case scenario.

Navigation, Access and Reusability of Knowledge Documents

The ability to archive annotations (both temporal and spatial) allows the users to retrieve and reuse segments of existing annotated documents from any mode of collaboration. For example, during a real time conference, several participants collaborated on different composite pages (where the composite pages might have come from different original documents). A user can select a particular page from an existing collaboration document, filter annotations based on any criteria (as described above), add any more composite pages, add more temporal/spatial annotations and collaborate in off-line, IM, or real time mode. This allows the enterprise to preserve the knowledge gathered during several collaboration sessions performed in any mode, while still enabling users to select parts of annotated documents from previous sessions for further reuse in future collaboration sessions.

Multimedia Response and Discussion Boards

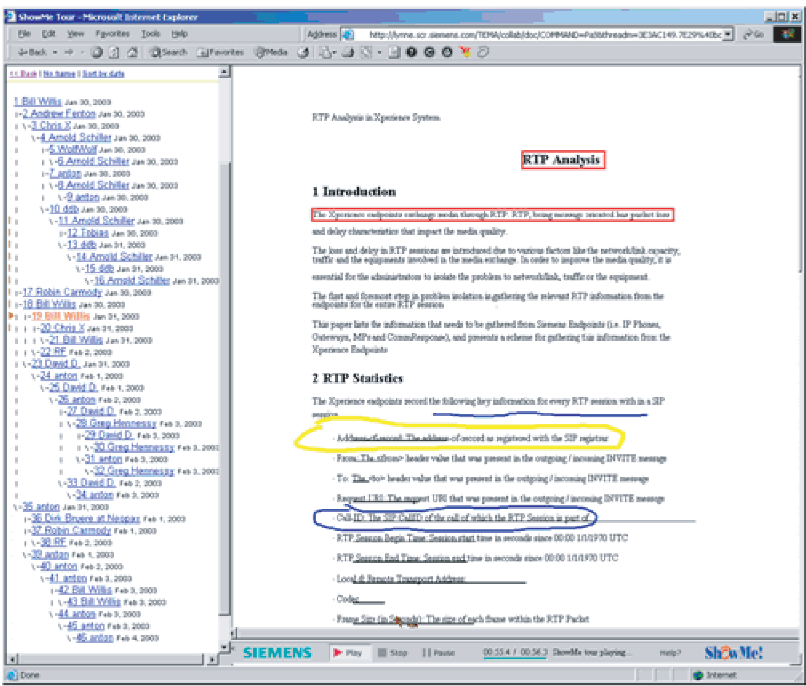
The structure of the collaboration archive allows one user to respond to any particular comment or annotation made by another user. The response could be in the form of a temporal or spatial annotation, or both. One scenario is that a sender can compose a composite document, make his or her annotations and send to the recipient(s). The annotated document could be sent as an attachment, or accessed from a central server. In the latter case, the annotated document is sent as a URL link. The recipient(s) can overlay their replies (annotations) and send back the annotated document, or the annotated document can be further annotated by other users (forwarding via e-mail.) By quickly overlaying temporal or spatial annotations it allows users to imbue information and temporal context to their responses.

Figure 6 shows document(s) being collaborated upon by several users in different collaboration modes using a threaded approach. These annotations could have been made in offline mode by different users or some of the annotations could have happened in a real time or IM conference and then imported into the discussion thread. For example, a user creates a composite document, adds various annotations in offline mode and sends it to her workgroup. The workgroup meets later and discusses in real time conference mode where annotations are captured as temporally with high granularity. During the real-time conference, they add more composite pages and perform collaborations above them. When finished, one user adds the resulting composite document with the temporal and spatial annotations to the discussion group. Subsequently, participants can add/edit/delete more comments (or annotations), or respond to any particular comment—hence a rich threaded discussion is facilitated. This scenario illustrates how group of users can work in a newsgroup discussion manner and leverage rich multimedia to express their thoughts.

Query and Retrieval of Multimedia Knowledge Base

As reported in the previous sections, the collaboration archive of interactions—voice, graphic, text, or mouse pointer annotations—between

Figure 6. A multimedia threaded discussion board



participants over several documents in different collaboration modes being captured and archived in a structured manner over time. As knowledge in the form of annotations is captured and reused in high granularity, there is a need for a simple search mechanism to locate appropriate segments of annotated documents from a large archive of annotated composite documents.

Queries to the knowledge base can be based on various criteria, for example, using metadata captured during collaboration session, the annotations using voice, text and the document content, and also by using feature relative annotations one can get the textual content of the document on which annotations were overlaid.

Representation, Visualization and Browsing of Collaborations

To leverage the knowledge contained within archived collaboration sessions, we have also explored various approaches for representing,

Figure 7. A visual overview of a session that conveys structure, documents used, and action items assigned

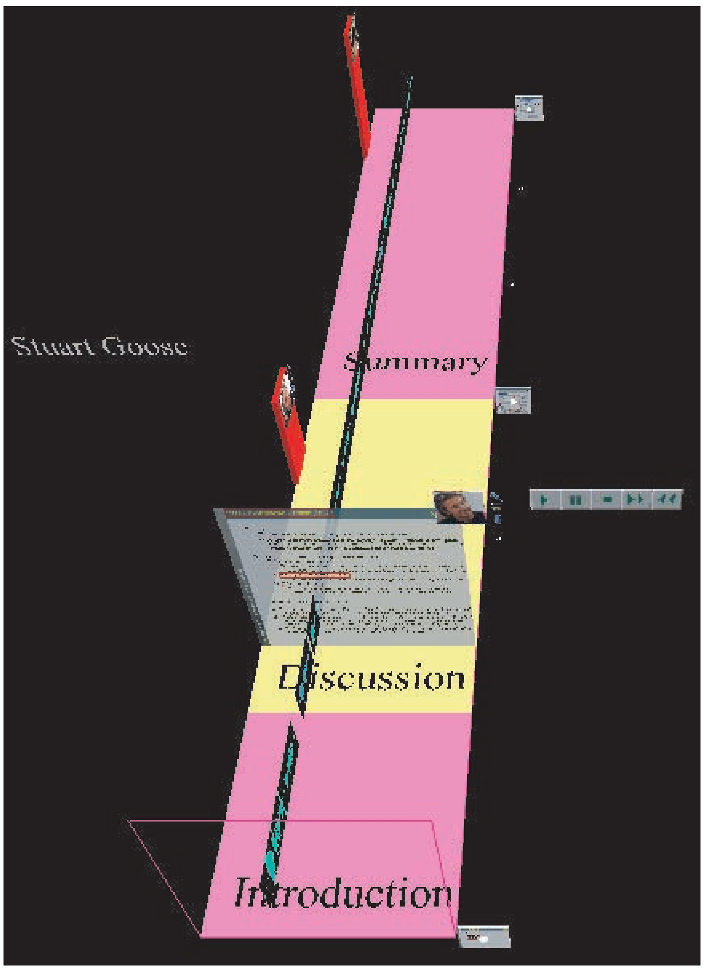


Figure 8. The detail view of a session

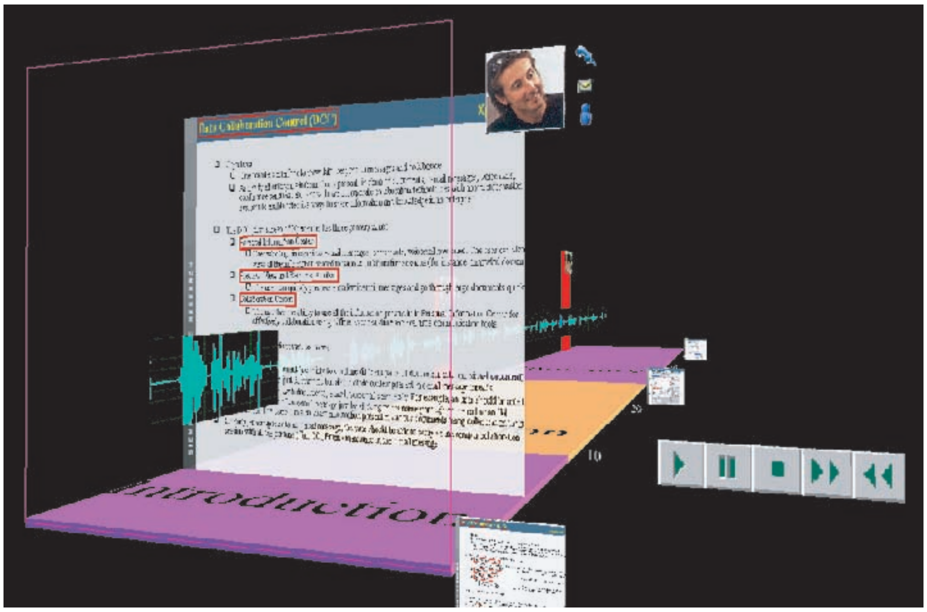

visualizing and browsing archived collaboration sessions. As collaborations often involve two dimensional documents and are by nature temporal, we are investigating representing the structure and content of collaborations in a three dimensional space. Arguably the most prevalent standard in the 3D graphics arena is VRML: a high-level textual language for describing the geometry and behavior of 3D scenes. Fortunately, a plethora of browser plug-ins are readily available. Following an iterative design/evaluation cycle, we converged on the design of a single VRML model with an interface that embodied and combined many of the characteristics that we sought:

- A viewpoint providing a visual overview/summary of the session
- A viewpoint providing a detail view of the session
- Interactivity and browsing capabilities at both overview and detail levels

Figures 7 and 8 show two viewpoints on the same VRML model, with each viewpoint having a distinct purpose.

The viewpoint shown in Figure 8 conveys the structure of the session (three topics were discussed), the documents used in the course of the discussion (indicated by the thumbnail icons on the right of the timeline), and that two action items were assigned (the red columns on the right of the timeline).

The viewpoint shown in Figure 8 exposes more detail regarding the content of the session. An audio waveform running along the timeline illustrates the presence of noise and is also color-indexed to the participants. An exploded view of the current document under discussion is show in the middle of the visualization. A small portrait image of the current speaker is shown in the corner of the current document, along with an icon that can be clicked on to initiate a phone call, e-mail, or instant message to that person. In addition, red columns along the left side of the timeline indicate assigned action items with a portrait image of the person responsible.

A VCR metaphor is provided to assist with navigation, and a VCR control panel can be seen at the right of the interface. When the play button is activated, the exploded view of the current document begins to glide backwards through time in synchrony with the audio stream played at normal speed. The forward and rewind buttons move the current position to the beginning of the respective session topic.

IN SUPPORT OF HOME HEALTH: NOMADIC NURSE

Home healthcare nursing is an increasingly widespread type of healthcare that typically involves a nurse driving to a patient's place of residence to provide the necessary monitoring and treatment. There are a wide variety of cases in which home healthcare is recommended by physicians, and recent years have seen a steady increase in the need for this type of care (Giles, 1996). While many industry observers believe home healthcare will increase in the future, many current home healthcare providers are either non-profit agencies or operate with conservative profit margins. In addition, as nurses' time is a scarce resource and IT spending limited, any new technologies that are not economically priced or that require nurses to increase the time spent with patients have a high probability of being passed over or abandoned.

Home healthcare nursing is by nature a peripatetic profession, and as such nurses need to transport their equipment from one home to the next. From our studies described previously, it was observed that the preponderance of nurses used paper and pencil notes augmented by their memory to record the interactions with their patients throughout their working day. The written and memorized notes were entered into the computer-based system upon their return home or to the office. There were a plethora of reasons as to why some nurses chose to operate in this mode. For example, some asserted that anything that breaks the contact between the clinician and the patient breaks the treatment involved in the visit. "There is a healing involved in the physical touch between the nurse and the patient" was the expression used. To avoid breaking this important connection, the application would need to use less obtrusive techniques that still provide for sterile-hands operation. In addition, the application would need to integrate well with the nurses' workflow and their frequent need for non-linear information access.

Hardware and Software Selection

The hardware selection was influenced by the following factors:

- Laptops were identified as the device of choice for the majority of home healthcare clinicians interviewed during the study. Lowering costs of laptops make them relatively affordable even for low-budget agencies; lightweight of the devices is appropriate in context of patient visits.
- The study revealed that clinicians were open to the idea of using a PDA for reasons of size, weight, and no boot-up latency. However, concern was expressed as to whether the screen size would be adequate for their needs.
- New government regulations (HIPPA) place significant emphasis on ensuring secure access to sensitive patient information in order to preserve patient privacy. Towards satisfying the HIPPA regulations, a Siemens biometric mouse was incorporated (Siemens Biometric Mouse).
- To reduce the impact of the interaction upon the nursing tasks, a discreet wireless Bluetooth earpiece was incorporated. This

enables the nurse to issue spoken commands, but also to receive spoken feedback without the patient hearing. The absence of wires was crucial so as not to inhibit the nursing duties.

The software technology selection was influenced by the following factors:

- Clinicians may access the application from a variety of different locations, including the office, their homes, patient homes, from the car while driving, etc.
- Administering clinical care requires sterile conditions, which makes traditional input devices unsuitable. This requirement indicates a multimodal interface (Multimodal Interaction Working Group), which, if necessary, can be controlled entirely by voice.
- Home healthcare practitioners would prefer continuous access to the patient database, however the existing wireless coverage of rural areas remains too fragmented to be reliable. The application needs to be able to work in either offline or online modes of connectivity.

Collectively, these requirements led us to conclude that a WWW-based solution was feasible, and that recent advances in multimodal technologies provide support on various devices. As such, the user interface was developed using a combination of HTML, Java and Javascript.

Notebook Design: Capturing Patient Vital Signs

The goal of our prototype is to show how cost-effective technology can be integrated into the workflow of a nurse to prove that patient vital signs can be captured unobtrusively. If successful, this could obviate the need for the nurse to enter this data into a computer system upon returning to the office.

In order to address the majority of agencies that expressed interest in notebook and PDA platforms, our design sought to offer a similar user experience while attempting to leverage the respective advantages of each. To provide hands-free operation, the nurse's notebook computer is equipped with a Bluetooth (Bluetooth) capability. Bluetooth wireless headset (Bluetooth headset from Siemens) supports mobile speech interaction with the application within an adequate radius. The initial implementation was developed for a notebook, as seen in Figure 9.

As can be seen from Figures 10 and 11, a multimodal interface allows the nurse to use the keyboard/mouse and/or speech to navigate and enter values into the visualization. For the laptop, SALT (SALT Forum) was selected as the technology used to develop the multimodal interface. In the classical SALT paradigm, speech recognition is initiated using either a keyboard or a mouse, but to offer truly hands-free operations we introduced some novel approaches to support continuous recognition and pause/resume functionality. This enables nurses to use verbal commands to indicate to the application that they are about to start dictating commands, or whether they are engaged in the conversation with a patient. Additionally, after temporarily deactivating the

Figure 9. Nurse's laptop, Bluetooth PCMCIA card and Bluetooth enabled headset

Figure 10. While taking measurements from the patient, the nurse can speak the clinical measurements via the Bluetooth enabled headset directly into the HTML form

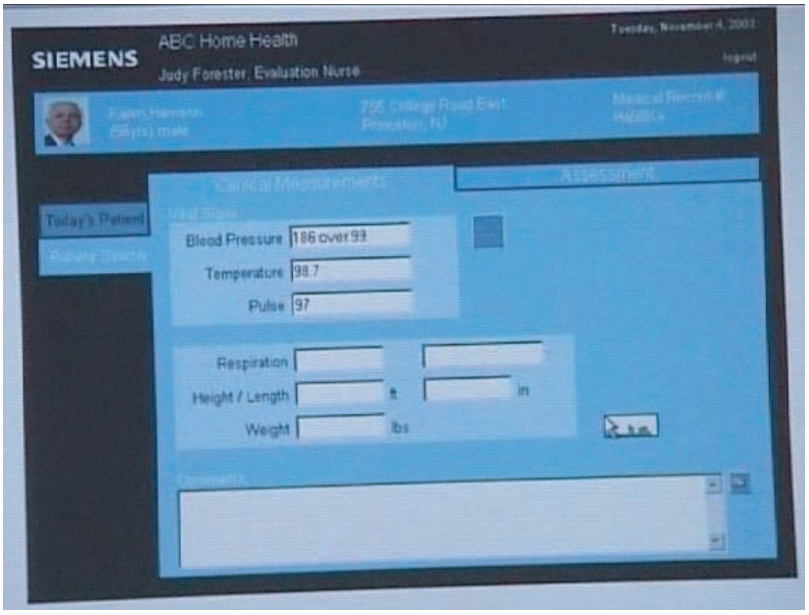

Figure 11. While interviewing the patient, the nurse can speak the diagnosis and functional assessment data via the Bluetooth enabled headset directly into the HTML form

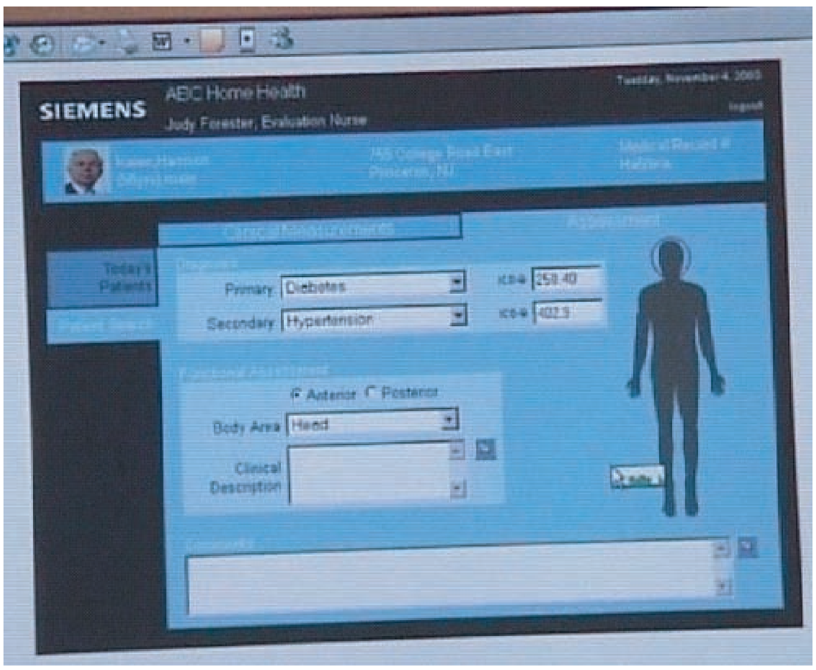


speech recognition, the nurse can resume working by simply issuing a voice command.

PDA Design: Less is More

The notebook implementation was heavily leveraged for the subsequent implementation for the Pocket PC PDA. While the functionality was preserved, the HTML was simplified and modified for appropriate consumption and interaction on the PDA form factor, as can be seen in Figure 12.

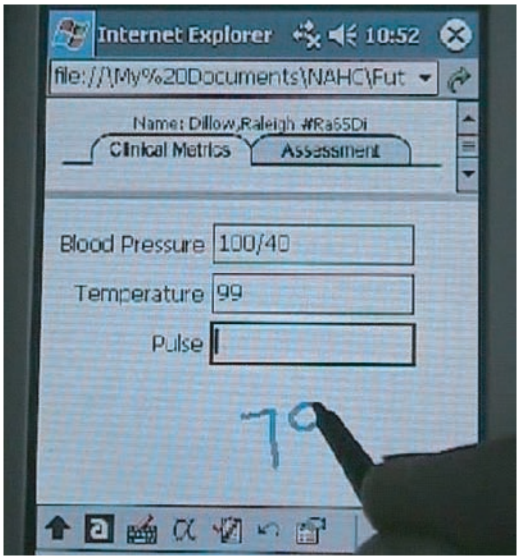
Although SALT technology can be demonstrated using a Pocket PC PDA, the speech processing is not performed locally on the mobile device but redirected to a server machine on the LAN. While this is not practical for deployment, it enabled us to experiment with the approach. It is anticipated that speech processing on the PDA will become available in the near future.

Speech is not the most appropriate input mechanism for every occasion, but one tool in the palette of a multimodal interface designer. As many of the nurses that we studied rely on paper and pencil to record patient notes, we sought to exploit handwriting recognition technology as a means to harness this activity and increase nurses' productivity by capturing this text and entering in directly into HTML form fields. This approach can be seen in Figure 12.

In our interviews we found that the old adage of a picture capturing a thousand words is not lost on nurses. Hence, we sought to offer in our prototype the seamless support for capturing images and integrating them directly into the patient information. A small and inexpensive digital camera peripheral connected via the SDIO port can be used for this purpose. The process of capture, abstraction through a thumbnail representation, and the viewing of the image can be seen in Figures 13 and 14.

In addition to capturing an image, it is often desirable to be able to augment an image with a synchronized audio commentary and associated pen markings to describe specific aspects

Figure 12. Leveraging handwriting recognition to capture vital signs into an HTML form



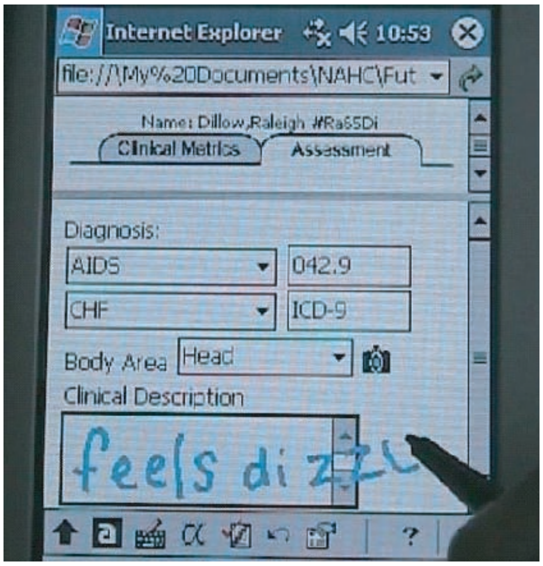


Figure 13. Convenient image capture is seamlessly integrated into the patient record

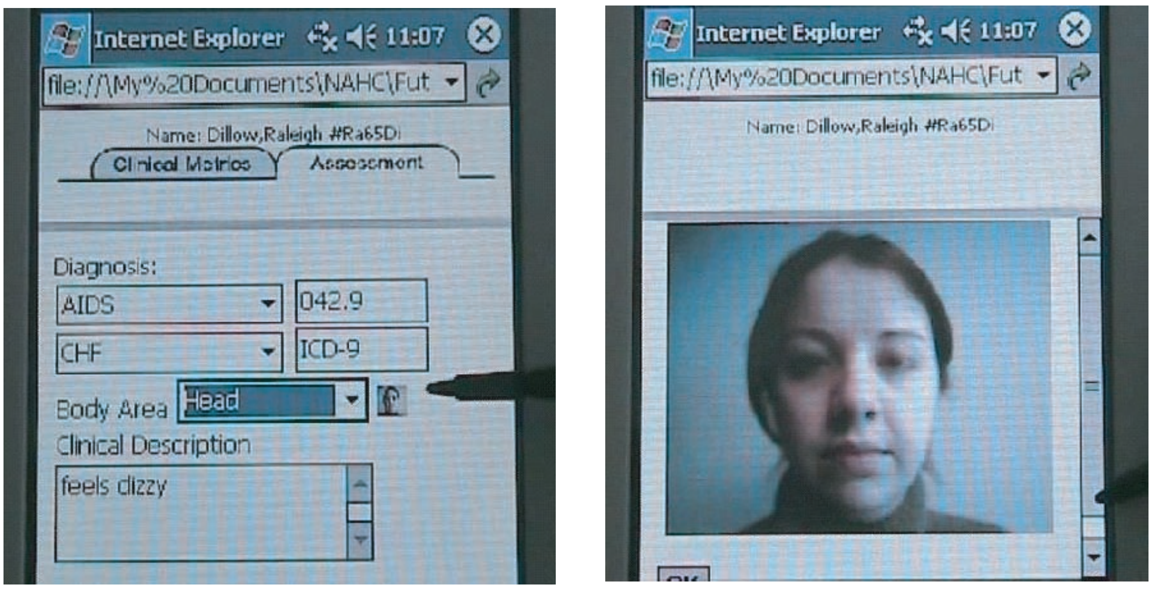
Figure 14. A thumbnail icon of the captured image can simply be clicked-on for closer inspection



of the patient's condition. Hence, a multimedia annotation capability is offered that can support this requirement and be stored along with the patient record.

Current and future work includes conducting formal user studies with nursing practitioners from two home healthcare agencies to evaluate the usability and efficacy of the devices and approaches described above to inform the subsequent iteration of the prototype design.

CONCLUSIONS

The manner in which a networked enterprise can facilitate a plethora of ways for healthcare personnel to communicate and collaborate was explored within this chapter. The next generation of communication technologies augurs well for converged voice and data solutions on a single network. We anticipate a closer union between healthcare IT systems and web-based communications. Technology innovation has spawned a proliferation of communication and data devices, such as GPRS cellular phones and PDAs, and with it a significant opportunity for accessing clinical information anywhere, anytime, allowing healthcare practitioners to collaborate upon clinical information and reach conclusions more effectively.

Throughout the chapter a selection of technologies has been presented that can enable healthcare personnel to interact in a variety of styles. These approaches demonstrated how multimedia technologies can be harnessed to capture information and enable users to collaborate in range of modes in an effective manner. It was also described how the knowledge captured during collaboration interactions can be saved and archived for future search, reference and reusability. In addition, technology support for home healthcare nurses is presented that shows potential for streamlining the capture and entry of information into the patient record.

ACKNOWLEDGMENTS

The authors would like to thank our team members at Siemens Corporate Research for their contributions to the technologies described.

Chapter 3.26
Storage and Access Control Policies for XML Documents

George Pallis
Aristotle University of Thessaloniki, Greece

Konstantina Stoupa
Aristotle University of Thessaloniki, Greece

Athena Vakali
Aristotle University of Thessaloniki, Greece

INTRODUCTION

The Internet (and networks overall) are currently the core media for data and knowledge exchange. XML is currently the most popular standardization for Web document representation and is rapidly becoming a standard for data representation and exchange over the Internet. One of the main issues is XML documents and in particular, storage and accessing. Among data management issues, storage and security techniques have a particular importance, since the performance of the overall XML-based Web information system relies on them. Storage issues mainly rely on the usage of typical database management systems (DBMSs), whereas XML documents can also be stored in other storage environments (such as file systems and LDAP directories) (Amer-Yahia & Fernandez, 2002; Kanne & Moerkotte, 2000; Silberschatz, Korth & Sudarshan, 2002). Additionally, in order to guarantee the security of the XML data, which are located in a variety of the above storage topologies, the majority of implementations also provide an appropriate access control. Most storage systems cooperate with access control modules implementing various models (Joshi, Aref, Ghafoor & Spafford, 2001), whereas there are few commercial access control products available. However, there are some standardized XML-based access control languages that can be adopted by most tools.

This article focuses on presenting an overview related to both storing and securing XML documents. Such an overview will contribute to identifying the most important policies for storage and access in Web-based information systems (which extensively use the XML as the data representation format). In addition, the most well-known related implementations are presented. A more integrated survey on these issues is presented in Pallis, Stoupa, and Vakali (2004).

BACKGROUND

Storage Policies

Several solutions for storing XML data have been proposed both in the scientific literature and in commercial products. In particular, storage approaches can be classified with respect to the type of system on which they rely and on the used XML document representation model. In this framework, they can be categorized as follows:

- Relational DBMS: Uses a collection of tables to represent both data and relationships among these data. More specifically, in order to represent XML data by using tables, it is necessary to break down the XML documents into rows and columns. The tree-like structure of XML facilitates both their decomposition and storage in relational tables. However, this process is expected to cause some performance overhead mainly due to the continuous translation of trees to tables (and vice versa). Due to its popularity, several models have been proposed to store XML documents in relational DBMSs (e.g., Bohannon, Freire, Roy & Simeon, 2002; Khan & Rao, 2001; Schmidt, Kersten, Windhouwer & Waas, 2000; Tian, DeWitt, Chen & Zhang, 2000; Zhu & Lu, 2001).
- Object-Oriented (O-O) DBMS: XML documents are stored as collections of object instances, using relationships based on the O-O idea (McHugh, Abiteboul, Goldman, Quass & Widom, 1997). O-O DBMSs have been designed to work well with object programming languages such as C++, C#, and Java. Inheritance and object-identity are their basic characteristics. However, O-O DBMSs cannot easily handle data with a dynamic structure since a new class definition for a new XML document is needed, and the use of O-O DBMSs for XML document storage is not as efficient and flexible.
- Object-Relational (O-R) DBMS: The XML documents are stored in a nested table, in which each tag name in DTD (or XML schema) corresponds to an attribute name in the nested table. Currently, researchers have showed a steadily increasing interest in O-R DBMSs, since they combine both the benefit of the relational maturity and the richness of O-O modeling (Pardede, Rahayu & Taniar, 2004). In O-R DBMSs, the procedure for storing XML data to relation mapping is modeled by an O-R model. In this context, a number of transformation steps from the XML schema to an O-R model are presented (Widjaya, Taniar & Rahayu, 2004). More specifically, each nested XML element is mapped into an object reference of the appropriate type. Then, several mapping rules are indirectly embedded in the underlying model.
- Native XML DBMS: In this case, the XML document is the fundamental unit of storage (Kanne & Moerkotte, 2000). Therefore, a native XML database defines a (logical) model for an XML document, and stores and retrieves documents according to that model. In particular, two basic steps are involved for storing the XML documents on a native XML DBMS: (1) the data are described by its structure (DTD or XML schema), and (2) a native database XML schema (or a data map) is defined. However, the native XML DBMSs have not yet become very popular, since these systems must be built from scratch.
- LDAP Directories: XML documents are stored in LDAP directories which can be

considered as a specialized database (Marron & Lausen, 2001). Therefore, the internal storage model of this database system is defined in terms of LDAP classes and attributes. More details about the architecture of the LDAP model and protocol are discussed by Howes, Smith, and Good (1999). Comparing the LDAP directories with the typical DBMSs, they are more widely distributed, more easily extended, and replicated on a higher scale.
- File Systems: Since an XML document is a file, a typical storage approach is to store it simply as a flat file. In particular, this approach uses a typical file-processing system, supported by a conventional operating system (as a basis for database applications). The wide availability of XML tools for data files results in a relatively easy accessing and querying of XML data (which are stored in files). By using a flat file for XML data, we have faster storing (or retrieving) of whole documents. However, this storage format has many disadvantages, such as difficulty in accessing and updating data, since the only way to accomplish this is to overwrite the whole file (Silberschatz et al., 2002).

Access Control Policies

In order to protect XML files, we need to design authorizations defining which client (subject) can access which protected resource (object) and under which mode. Since XML files are organized according to DTDs or XML schemas, protected resources can be both XML files, DTDs, or schemas, or parts of them, such as a specific element or even attribute.

The basic access control models are:

- Discretionary Access Control (DAC): Every subject and object is enumerated, and there are authorizations connecting each subject and object. The owner is responsible for defining policies in order to protect his/her resources, and (s)he can also define who is going to be assigned some access privileges. It is the most flexible and simple access control model. However, it does not provide high levels of protection, and it cannot be used in case multiple security levels are required.
- Mandatory Access Control (MAC): This is based on the existence of one central administrator responsible for the definition of policies and authorizations. It is expressed with the use of security labels associated with both subjects and objects. Every object has a classification label defining its sensitivity, and each subject is assigned a clearance label defining its trustworthiness. This model is more secure than DAC, but it cannot be used in wide distributed Internet-based environments. Therefore, their usage is gradually decreased.
- Role-Based Access Control (RBAC): The most widely used access control model in modern environments (Sandhu, Coyne & Feinstein, 1996). Subjects are assigned roles that are categorizations of subjects according to their duties in an organization. Thus, every subject is assigned roles that in their part have some authorizations. Therefore, the number of the needed policies is highly decreased. RBAC model is a super set, since it can also express DAC and MAC policies. It is appropriate for distributed heterogeneous networks offering Internet access. Moreover, it is recommended to protect hypertext documents (HTML or XML files). Lately, a generalized RBAC model has been proposed where objects and environmental conditions are assigned roles (Moyer & Ahamad, 2001).

FUTURE TRENDS

Implementations

Some of the most popular database vendors (like IBM, Microsoft, and Oracle) have developed (mainly) database tools for the storage of XML documents, and several storage techniques have been adopted in order to maximize functionality and performance. Furthermore, for reasons of integrity, the majority of the DBMSs are supported by access control mechanisms.

In general, the most well-known software tools that employ XML document storage and access control can be categorized in the following types of databases:

- XML-Enabled DBMSs: These provide various interfaces for extracting structured data from XML documents and then to be stored in DBMSs (according to their model). Table 1 presents the basic products of such an approach.
- Native XML DBMSs: XML documents are stored in XML internally in the database. Table 2 shows some of the most popular DBMSs.

Currently, the most widely adopted technology to enforce the security guarantees of the XML-based databases is the Microsoft (MS) .NET platform. MS .NET has been recently proposed and has been adjusted to support XML Web Services. Its security mechanism is adopted by MS SQL Server 2000 (Rys, 2001), Oracle 9i, and DB2, which have been designed to cooperate with Microsoft .NET technology.

All of the above storage systems can be supported by access control modules. Most of them support the Microsoft .NET access control framework. The idea of protecting XML files is quite new, and therefore most of the implemented systems still belong to the scientific literature and they have not stepped into the market.

The core of every access control mechanism is a language used for expressing all of the various components of access control policies, such as subjects, objects, constraints, and so forth. To date several languages have been proposed. Since XML is a structured language, it can be used in the definition of access control issues, such as roles, policies, and authorizations. Therefore, the most well-known general-purpose XML-based access control languages are:

Table 1. Storage in XML-enabled databases

Product	DBMS Model	Storage
Oracle 9i *technet.oracle.com*	Object-Relational	XML documents are stored as relational tables.
MS SQL Server 2000 *www.microsoft.com*	Object-Relational	Each XML document is stored as a relational table, and an element is created for each row.
IBM's DB2 *www-4.ibm.com*	Object-Relational	XML documents are stored as relational tables.
XIS *www.exceloncorp.com/xis/*	Object-Oriented	XML documents are stored in a B-tree-like structure.
Lore (McHugh et. al., 1997)	Object-Oriented	XML documents are stored using an Object Exchange Model (OEM).
SHORE (Hess, Schulz & Brossler, 2000)	Object-Oriented	This stores information extracted from XML documents using a variant of R-trees and B-trees structure.

Table 2. Storage in native XML databases

Product	**Storage Model**
NATIX (Kanne & Moerkotte, 2000)	Tree structure: XML documents are split into sub-trees (basic storage and query units) based on certain criteria.
SODA *www.cse.unsw.edu.au/~soda/*	Tree structure: XML documents are stored in a single tree, which preserves all XML information.
Xyleme *www.xyleme.com*	Tree structure: XML documents are stored as trees until a certain depth where byte streams are used.
Ipedo *www.ipedo.com/html/products.html*	Collection structure: XML documents are organized into collections (like directories), which can be typed or un-typed.
eXist *exist.sourceforge.net*	Collection structure: XML documents are stored using a DOM-tree (built from SAX-events) and are organized into hierarchical collections, similar to storing files in a file system.
Tamino (Schoning, 2001)	Collection structure: Each XML document is stored in exactly one collection.
Xindice *www.dbxml.org*	Collection structure: Each XML document is stored in at least one collection (a collection can be created either consisting of documents of the same type, or a single collection can be created to store all documents together).

- XACML (eXtensible Access Control Markup Language): This is an OASIS standard that defines both a policy language and an access control decision request/response language (both written in XML) (www.oasis-open.org/committees/xacml/repository). The policy language is used to describe general access control requirements, and has standard extension points for defining new functions, data types, combining logic, and so forth. The request/response language permits forming a query in order to ask whether a given action should be allowed (or not), and to interpret the result that defines the response.
- XrML (eXtensible rights Markup Language): This is a language for digital rights management (Wang et al.). By using XrML, the owner of a digital resource can specify who can use the resource (principal) and under what circumstances (constraints). The owner thus produces licenses containing such information that are then given to the appropriate principal. Since XrML is mainly used for protecting digital media, it contains schemas defining the metadata of such resources, such as audio or video files. Of course, it can be easily extended for controlling access to any other type of resource.
- ODRL (Open Digital Rights Management): This is a language used for Digital Rights Management (DRM) in open environments (odrl.net/1.1/). It can express rights for protecting any digital content, like electronic publications, digital images, audio and movies, learning objects, computer software, and so forth.

Except for the languages, research has to present several access control tools protecting XML files. Those can be categorized into non XML-based and XML-based. Table 3 contains some of the tools belonging to both categories.1 The only

Table 3. Examples of access control tools

Product	Type	Access Control
XENA (Tan & Zhao, 2000)	Non XML-Based	Centralized tool protecting XML repositories using relational database technology.
Author-X (Bertino, Castano & Ferrari, 2001)	XML-Based	Java-implemented tool, supporting varying security granularity levels. PULL and PUSH dissemination technology.
ACP (Access Control Processor) (Damiani, De Capitani di Vimercati, Paraboschi & Samarati, 2000)	XML-Based	Decentralized system supporting distributed XML repositories by using both local and global authorizations.
ProvAuth (Kudo & Hada, 2000)	XML-Based	Access control environment where access is allowed with some provisions. It uses XACL.

tool using a standardized access control language is ProvAuth (Provisional Authorizations) (Kudo & Hada, 2000). As its name suggests, access is allowed to users only after (or before) the execution of some provisional actions, like logging the session, encrypting the view of a protected document, and so forth. To support such functionality, a specific-scope XML access control language (XACL) has been introduced which is part of the IBM XML Security Suite. Due to its extensibility and flexibility, the model can be integrated into a conventional Web application consisting of clients and servers.

CONCLUSION

This article has presented an overview for storage and access control of XML documents. It is important to indicate that no definite guidelines have yet been proposed for selecting an optimal solution when storing and securing XML documents. In order to improve the management of XML documents, some issues should require further research. In particular, the storage of XML documents may be improved by using some data mining techniques (e.g., specific clustering algorithms). Furthermore, the XML management techniques should further extend existing access control policies, in order to improve the security in XML documents accessing. Finally, the commercial DBMSs should be extended to support more sophisticated storage and access control techniques such as integrated methods for locating and accessing dynamic XML documents.

Chapter 3.27
Technology and Knowledge Management

Helen Mitchell
Unitec, Auckland, New Zealand

INTRODUCTION

Rapid and extensive advances in technology, particularly in the area of communications, have had a considerable impact on the way organizations operate and opened pathways to access vast amounts of information. Information, however, is static unless knowledge is applied to translate it into something meaningful and with the potential to be actionable. From the time organizations commence business, they accumulate information about the markets in which they operate, yet often, knowledge is not applied in a way that it can be exploited to bring benefit. The ability to share knowledge, to develop ideas, and to become more innovative is increasingly important for businesses, and the range of technologies now available provides a conduit for knowledge to flow through the organization to enable sharing to occur. Technology is frequently referred to as "just an enabler," but it can also be identified as a value-adder.

INFORMATION AND KNOWLEDGE

In their paper, Evans and Wurster (1997, p. 71) referred to changes that had taken place over the previous 10 years as organizations adapted their "operating processes" to "information technologies," recognizing that accessing information was going to have an important bearing on where industries would be going in the future. During this period, technology was moving forward at a rapid rate, and organizations were investing huge sums of money in information technology.

Information is defined as facts and data organized to describe a particular situation or problem. The definition used for knowledge is that by Davenport and Prusak (1998):

Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded *not only in documents or repositories but also in organizational routines, processes, practices, and norms. (p. 5)*

Connectivity, it is suggested by Evans and Wurster (1997), provided the most important change in the information revolution: "What is truly revolutionary about the explosion in connectivity is the possibility it offers to unbundle information from its physical carrier" (p. 73). Amidon (1997) referred to the major change from information processing to knowledge processing that has taken place, "which includes the concepts of learning tools, intelligent electronic coaching, decision-making systems, and more" (p. 87). The availability of such tools, and their ongoing development, add considerable value to an organization by providing a means through which more efficient and effective management techniques can be introduced. This evolving of expectations indicates that organizations are not only anticipating more from technology but are also becoming more reliant upon it.

As interest grows beyond information per se, organizations are looking to technology to progress toward the development of knowledge management systems. Bhatt (2001) referred to business managers who believe computers and communication technologies provide an avenue for the harvesting of knowledge from data repositories of organizations, while other managers say knowledge "resides in human minds, and therefore, employee training and motivation are the key factors to knowledge management" (p. 68). The development of technology has taken the drudgery out of searching, analyzing, and converting data into information to which knowledge can be applied.

Technology and knowledge, however, do not stand in isolation. There are many interacting factors, not least of which is the environment in which the organisation operates. According to Bhatt (2001), the "…pattern of interaction between technologies, techniques and people is unique to an organization" (p. 69). Such uniqueness is important, because it is not easy to replicate. The organisation that promotes the value of the knowledge, skills, and competencies of its people, and recognizes the importance of technology, is providing well for its future (Carneiro, 2000; Bhatt, 2001).

From a productivity perspective, Grant (2000) indicated the value of digital technology. He referred to knowledge no longer being held exclusively by people. Codification and use of technology provides the opportunity for knowledge replication. While costly to create, replication and distribution can be reduced to almost "zero marginal cost" (Grant, 2000, p. 32). In the long term, and with the arrival of new technologies, the rate of productivity growth is likely to accelerate (Grant, 2000). People have skills and knowledge, but it is technology that enables them to access in a timely manner huge amounts of data available both internally and externally to the organization. While technology enables people to access data, the added value comes in its ability to allow the data to be assembled in a meaningful way for the purpose of decision making.

SHARING KNOWLEDGE

An environment in which knowledge sharing is encouraged leads to the creation of new knowledge, but as Marshall, Prusak, and Shpilberg (1996) indicated, it is not easy to encourage voluntary sharing of knowledge by employees. An organisation that develops a knowledge-sharing environment increases opportunities for the creation of new ideas that have the potential to add value to it.

Barriers to sharing knowledge exist, and for managers advocating knowledge sharing, they should examine the existing practices within the organization. It is possible that somewhere in the organization, the "knowledge is power" syndrome exists, and if so, it does not auger well for knowledge sharing. There may also be concern over job security, "if I share my knowledge, I am no longer of value to the organization, and therefore, my job will be in jeopardy." A barrier to knowledge sharing may simply rest on the premise that a person may not realize that knowledge acquired in another situation could be of value to the organization. Managers may need to look to changing the organizational culture to one that recognizes, and acknowledges, the value of shared knowledge.

Bhatt (2001), referring to the need for the distribution and sharing of knowledge throughout the organisation, suggested that interactions among technologies, techniques, and people have a direct bearing on the effectiveness of the distribution of knowledge.

RANGE OF TECHNOLOGIES

According to Frappaola and Capshaw (1999): "Knowledge management refers to the practices and technologies that facilitate the efficient creation and exchange of knowledge on an organizational level" (p. 44).

From the literature, it appears that there are a number of applications specifically designed for sharing knowledge (Davenport, 1997; LaPlante, 1997; Fahey & Prusak, 1998). The benefits of applications, such as groupware, data warehousing, knowledge maps, client server systems, and chat rooms, are recognized as providing the means through which knowledge can be shared. A useful aspect of such applications is that they allow for interaction and sharing of information that is highly unstructured in nature (Shani, Sena, & Stebbins, 2000). Research carried out by Mitchell in 1999 indicated that people are finding groupware applications useful mechanisms for sharing knowledge.

A number of writers, Allee (1997), Amidon (1997), Marshall (1997), Watt (1997), and Davenport and Prusak (1998), refer to the intranet as providing channels through which organizational knowledge can flow. E-mail is now well accepted as a useful and valuable medium of communication, and for knowledge to flow through an organization (Bontis, Fearon, & Hishon, 2003). The advent of electronic conferencing provides an avenue through which people geographically dispersed can interact without the time and cost involved in traveling. Networking, bulletin boards, and the establishment of virtual teams also provide opportunities for people to interact over distances and to share knowledge.

Reference is made by Beckett (2000) to the "Data warehousing knowledge set" containing reference data, defined as market trends, operational data, and customer performance needs. From this knowledge set, actions can be taken that ultimately benefit stakeholders and customers. While the knowledge set may be considerable, ideally, its value only becomes realistic when there is in place the means to allow for the "free" flow of knowledge throughout the organisation and when there are people who can recognize that value can be gained from it. It is most unlikely that organizations allow for a free flow of knowledge, because issues such as privacy and confidentiality, "need to know," and other constraints restrict access to knowledge. However, providing access to knowledge that can be made available should be the aim of organizations wanting to encourage a knowledge-sharing environment.

Technology has opened avenues to the customer to search for opportunities and products that may better serve their needs. The opportunity, however, is also open to the organization to exploit the potential of technology to create greater value for its customers.

KNOWLEDGE MANAGEMENT STRATEGY

Hansen, Nohria, and Tierney (1999) identified management consultants as being among the first to recognize the potential of information technology for the capture and dissemination of knowledge. It was found that organizations tend to employ two very different strategies for the management of knowledge. One is the "codification strategy," where maximizing the use of technology shows a strong focus on codifying knowledge and storing it in databases for access by anyone in the company. The second approach viewing knowledge being shared through person-to-person contacts is identified as the "personalization strategy" (Hansen, Nohria, & Tierney, 1999, p. 107).

From their research, Hansen et al. (1999) found that organizations pursuing "an assemble-to-order product or service strategy emphasized the codification and reuse of knowledge. Those that pursued highly customized service offerings, or a product innovation strategy, invested mainly in person-to person knowledge sharing" (p.112). Whichever strategy is used, there is inevitably the inclusion, as a support mechanism, of an element of the other strategy. Hansen et al. suggest an 80:20 split, that is, "80% of their knowledge sharing following one strategy, 20% the other." They go on to say that "Executives who try to excel at both strategies risk failing at both" (p. 112).

In his article, Beckett (2000) referred to the fastest knowledge-transfer vehicles, relating them to the work of Nonaka and Takeuchi (1995). The tacit/tacit transfer is fast, "because people use multiple sensors in working together in teams" (p. 317). Using electronic media for the transfer of explicit/explicit transfer can also be fast. However, there is evidence that "tacit/explicit transfers are slow, as specialist skills are needed to draw out and carefully enunciate tacit knowledge" (p. 317). Becket indicated that explicit/tacit transfers are similarly positioned, and provides the example of formal education.

Giving consideration to the perspectives of Hansen et al. (1999) and Beckett (2000), and others, such as Ericsson and Avdic (2003), Mockler and Dologite (2002), Jentzsch and Prekop (2002), and Frappaolo and Capshaw (1999), determining a knowledge management strategy needs careful thought if it is to meet the requirements of the organization.

TECHNOLOGY: ENABLER OR VALUE-ADDER?

Lloyd (1996) referred to the use by organizations of worldwide networks and said that new technology is "the catalyst which is forcing all organizations to re-evaluate what they know, what they do with that knowledge, and how they continually add value (or not) to that knowledge in meeting changing customer needs" (p. 576). Technology has advanced considerably since Lloyd made this comment, and it will continue to evolve in the years ahead, providing for greater enrichment of organizational operations. While the cost of "keeping up" with technological developments has always been a problem for organizations that have made a strong commitment to technology, others recognize that they need to work smarter with what they have.

If technology is just an enabler, what is it that adds value to the organisation? Binney (2001, p. 33) addressed the question of knowledge-management (KM) investments. What has emerged is the KM spectrum, in which he identifies KM applications and places them into "six common categories to establish the elements of the KM spectrum" (p. 34). Binney identified from the literature six categories to provide the elements of the KM spectrum: transactional, analytical, asset management, process, developmental, and innovation and creation. He then mapped KM applications to the elements:

1. Transactional—Order entry applications; help desk applications
2. Analytical—Data warehousing, customer relationship management, DSS, MIS

3. Asset management—Document management, intellectual property
4. Process—TQM, process automation, benchmarking
5. Developmental—Skills development, training
6. Innovation and creation—Communities, virtual teams, networking

The next stage of the process added to the various elements, enabling technologies:

1. Transactional—Expert systems, probability networks
2. Analytical—Intelligent agents, data analysis and reporting tools
3. Asset management—Document management tools, knowledge maps
4. Process—Workflow management, process-modeling tools
5. Developmental—Computer-based training, online training
6. Innovation and creation—Search engines, voice mail, groupware

The KM spectrum provides organizations with the means to identify their present positions and to make use of the framework to map their future investments in knowledge management. The examples given above illustrate the wide range of applications available to organizations, and their potential and value emerges through maximizing their use for the purpose of effective decision-making in an increasingly competitive environment.

Technology has provided the impetus for the growth of the information age, but it should not be regarded as a dominant partner. As Pemberton (1998) commented, "The IT exponents of KM tend to downplay the central role of human factors in KM…IT doesn't itself create knowledge any more than does a library, an office, or a classroom" (p.60). But, as Carneiro (2000) indicated, the combining of knowledge and information technology is a major success factor in strategic planning formulation. The future will bring ever more sophisticated advancements in technology providing new avenues of exploration for seeking, creating, and sharing knowledge.

CONCLUSION

Is technology just an enabler, or is it also a value-adder? From the literature, technology, while recognized as being important, tends to be regarded as an enabler rather than a value-adder. Yet the continual movement in technological progress, as shown in Binney's KM spectrum, clearly identifies the developments that have taken place in technology to enhance the operation of business. People provide value through the application of their knowledge, but their ability to do so is considerably enhanced by the availability of technology. Technology enriches opportunities for disseminating and sharing knowledge, and through providing the means to access information for decision making. While the role of technology may be seen as that of enabler to access information, value is added through the ability to assemble data, put it into meaningful information, and manipulate it into various scenarios before determining the best decision. Technology is adding value by allowing organizations to do this. Without the range of technology available to organizations, they would be considerably restricted in their ability to effectively manage their business. Therefore, technology should be identified as an adder of value.

Section 4
Utilization and Application of Knowledge Management

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective knowledge management programs and processes. This section includes more than 50 chapters, some of which review knowledge management literature published in top-tier journals, offering findings on the most popular trends researched within the academic community. Other chapters discuss the utilization of knowledge management within the governmental realm. Also considered in this section are the challenges faced when utilizing knowledge management with healthcare systems. The adaptability of governmental agencies in response to disasters is given consideration as well through research which investigates major hurdles faced in knowledge sharing in the face of disasters, spanning the globe. Contributions included in this section provide excellent coverage of today's global community and how knowledge management research is impacting the social fabric of our present-day global village.

Chapter 4.1
A Hierarchical Model for Knowledge Management

Nicolas Prat
ESSEC Business School, France

INTRODUCTION

Knowledge management (KM) is a multidisciplinary subject, with contributions from such disciplines as information systems (IS) and information technology (IT), strategic management, organizational theory, human-resource management, education science, psychology, cognitive science, and artificial intelligence. In order to take full advantage of these various contributions, the necessity of a multidisciplinary approach to KM is currently widely acknowledged, particularly in the IS and IT, management, and artificial-intelligence communities (Alavi & Leidner, 2001; Dieng-Kuntz et al., 2001; Grover & Davenport, 2001; Nonaka & Konno, 1998; O'Leary & Studer, 2001; Zacklad & Grundstein, 2001).

Several KM models have been proposed in the literature. These models reflect the diversity of disciplines contributing to KM. By describing KM concepts and investigating their relationships, they provide a useful conceptual tool for KM research and practice. However, they suffer from three major limitations.

- They are often incomplete. This may be intentional (in the case of models focusing on a specific aspect of KM) or reflect disproportionate emphasis on one of the disciplines contributing to KM, for example, IS and IT.
- They are inappropriate for navigating between abstraction levels of KM topics ("drill down" or "drill up").
- They do not provide a structure for the quantitative assessment of KM research and/or practice (e.g., for auditing KM practice in a specific company).

This article presents a KM model that aims at providing a solution to these three problems. The model is formalized and structured as a hierarchy, which enables navigation between the abstraction levels of KM topics. Furthermore, by combining this hierarchical structure with the analytic hierarchy process (Saaty, 1980), the KM model may be applied to quantitatively assess KM practice and/or research. The model is organized into three components: knowledge types, KM processes, and KM context. It integrates the contribution of previous models and reflects the multidisciplinary aspect of KM.

The article is structured as follows. The next section provides an overview of extant KM models, that is, the background of our work. Then the article presents our hierarchical KM model, develops its three components, and discusses and illustrates how the model may be applied to KM research and practice. Before concluding, we present our view of future trends and research opportunities regarding KM models.

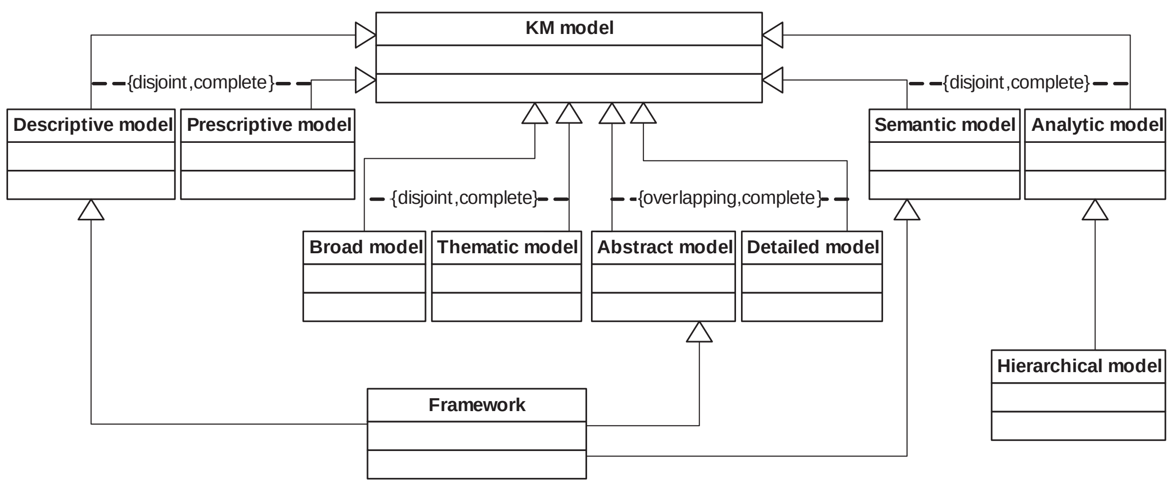
KM MODELS

ISO (2004) defines a model as a "limited representation of something suitable for some purpose." This definition applies to KM models. In broad terms, the purpose of these models is to provide conceptual tools for KM research and/or practice.

Figure 1 proposes a classification of KM models. This classification elaborates on and refines the classification criteria proposed by Holsapple and Joshi (1999) for KM frameworks. Figure 1 uses the UML (unified modeling language) formalism (OMG, 2003) for representing classes, generalizations, and generalization constraints. We classify KM models according to four complementary criteria (the first two criteria are those defined in Holsapple and Joshi).

- A KM model is either descriptive (i.e., describing the nature of KM phenomena) or prescriptive (i.e., proposing methodologies for performing KM).
- KM models are either broad or thematic. Broad models attempt to cover the whole of KM, while thematic models focus on a specific topic.
- A KM model may be abstract, detailed, or both (as indicated by the generalization constraint in Figure 1). This classification complements the distinction between broad and thematic models. For example, a broad model may be both abstract (providing a global view of KM concepts or topics) and detailed (enabling navigation into the details of a topic).

Figure 1. A classification of KM models



- The last classification distinguishes between semantic and analytic models. Semantic models describe the meaning of KM concepts and their interrelationships. Analytic models adopt a deductive approach, progressively detailing KM topics by decomposing them into subtopics.

In addition to these four classifications, Figure 1 represents two specific types of KM models: frameworks (defined as KM models that are at the same time descriptive, abstract, and semantic) and hierarchical models (a special kind of analytic model).

Several KM models have been proposed in the literature (Alavi & Leidner, 2001; Davenport & Prusak, 2000; Despres & Chauvel, 2000; Fowler, 2000; Grover & Davenport, 2001; Handzic, 2001; Holsapple & Joshi, 2004; Newman & Conrad, 2000; Nissen, 2002; Nonaka, 1994). A comparative analysis is presented later in this article. If we consider the above-presented classifications, we notice that existing KM models are often descriptive, abstract, and semantic models, that is, frameworks. All the models are semantic. Consequently, elaborating on the contribution of these models, our objective is to define an integrated, analytic KM model. This broad, analytic model will facilitate navigation into the details of KM topics and enable the quantitative assessment of KM research and/or practice.

A HIERARCHICAL KM MODEL

In this section, we present our KM model and compare it with previous models; we discuss and illustrate how it may be applied to KM research and practice.

Introduction

KM comprises a set of processes. These processes concern knowledge (e.g., knowledge transfer) and are influenced by context (e.g., the organizational culture). Consequently, KM models are often structured around the concepts of KM processes, knowledge, and/or context (Alavi & Leidner, 2001; Despres & Chauvel, 2000; Grover & Davenport, 2001; Handzic, 2001; Holsapple & Joshi, 2004). These concepts form the three basic components of our model.

- The knowledge types component characterizes knowledge according to several complementary classifications.
- The KM processes component is dedicated to KM activities.
- Finally, the KM context component comprises the factors that influence (positively or negatively) the conduct of KM. Depending or their nature, these factors may (more or less easily) be controlled to improve KM.

The components of our KM model are organized into a hierarchy. The concepts of the model are represented as nodes. The parent-child relationships between nodes are abstraction relationships: A parent node is detailed by its children nodes (or conversely, a child is abstracted into its parent). There are no generally applicable structural criteria indicating when decomposition should stop. This is guided by semantic and practical considerations (e.g., the decomposition of a concept stops when the concept is easy enough to measure in practice or when further decomposition would be meaningless).

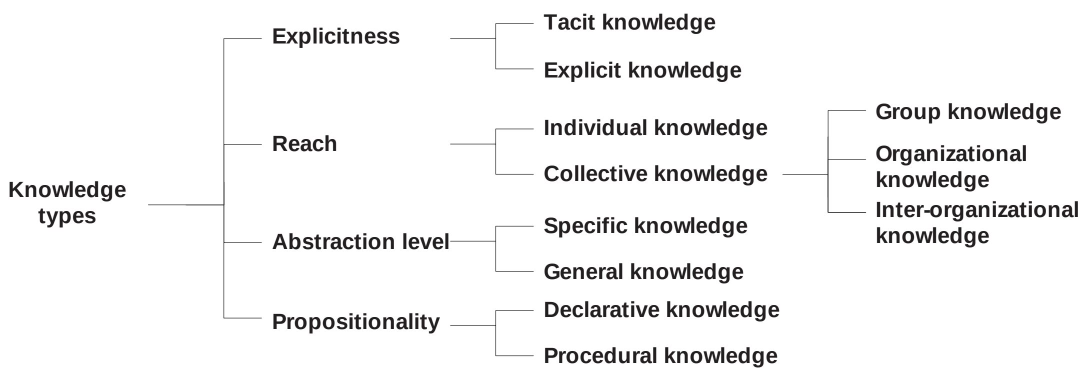
We describe the three components of the KM model.

Knowledge Types

The part of the KM model pertaining to knowledge types is represented in Figure 2. Elaborating on previous work, we propose four complementary classifications for characterizing knowledge.

The first classification, which is almost universally adopted in previous KM models,

Figure 2. Knowledge types



distinguishes between tacit and explicit knowledge. Similarly to Nissen (2002), we use the term explicitness to name this classification. The distinction between tacit and explicit knowledge was first applied to KM by Nonaka (1994). Tacit knowledge is deeply rooted in the individual's mind and may not be easily codified as opposed to explicit knowledge.

The reach classification makes the distinction between individual and collective knowledge. Collective knowledge is further decomposed into group, organizational, and interorganizational knowledge. In general terms, the concept of organizational knowledge may designate knowledge at the organization or at the group level. The reach classification appears in many KM models (e.g., the model of Nissen, 2002, has a reach dimension).

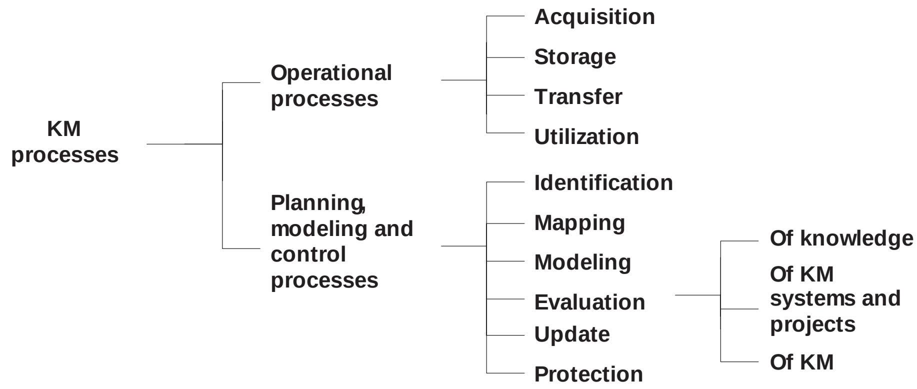
The abstraction-level classification distinguishes between specific and general (abstract) knowledge. This distinction appears explicitly in the model of Fowler (2000). The distinction is relevant to KM since knowledge is often more easily transmitted when it is in a specific form (examples). This principle is applied in such methods as case-based reasoning (Kolodner, 1993; Prat, 2001a) and narratives (Soulier, 2000).

The last classification distinguishes between declarative knowledge ("know-what") and procedural knowledge ("know-how"). Since declarative knowledge is made of propositions, this classification is called propositionality. Procedural and declarative knowledge are often assimilated to tacit and explicit knowledge respectively. However, the two classifications are not equivalent (For example, the sequence of steps necessary to make a coffee with a coffee machine is procedural knowledge that may easily be made explicit). Procedural knowledge is richer than declarative knowledge. In particular, procedural knowledge comprises the various choice alternatives considered: and the choice criteria (Rolland, Souveyet, & Moreno, 1995). In this respect, the traceability of design processes and decisions is a key research direction for KM (Karsenty, 2001; Prat, 2001b; Zamfiroiu & Prat, 2001).

KM Processes

Figure 3 represents the KM processes component. In contrast with previous KM models, which often focus on the basic processes (knowledge creation, storage, transfer, and utilization) and/or consider all the processes to be at the same level, we dis-

Figure 3. KM processes



tinguish between an operational level comprising the basic processes and a strategic or tactical level (planning, modeling, and control).

Operational processes are the basic processes of KM. Even if the number and names of operational processes may vary, the majority of KM models comprise the same fundamental processes. The typology we use in our model draws heavily from Prat (2001a).

- Knowledge acquisition comprises all activities that increase the global stock of knowledge potentially useful to the organization.
- Knowledge storage consists in retaining knowledge in individual or collective memory. Knowledge is indexed to facilitate future retrieval.
- Knowledge transfer is the sharing of knowledge between individuals, groups, and organizations.
- Knowledge utilization is the application of knowledge to business processes.

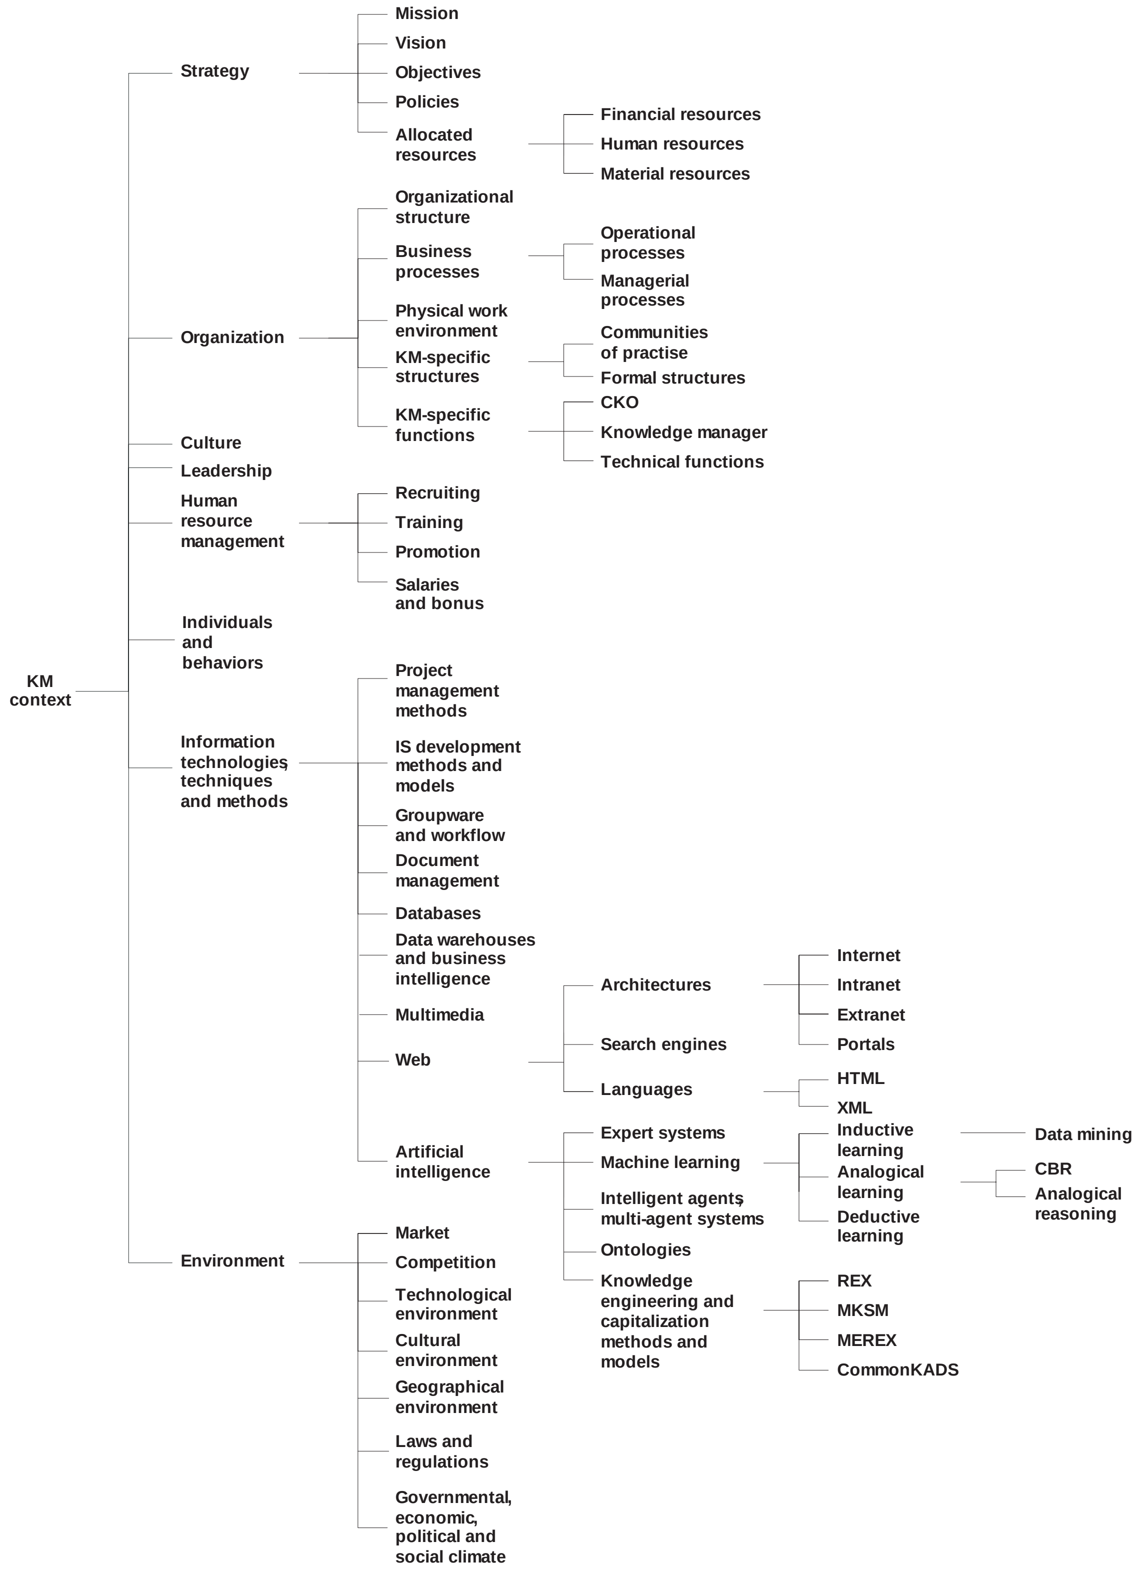
The planning, modeling, and control processes encompass the following processes.

- The identification, mapping, and modeling of current knowledge or of knowledge necessary to achieve previously defined objectives.
- Evaluation, which may be operated at various levels: the evaluation of knowledge, the evaluation of KM projects and/or of KM systems (KMSs) resulting from these projects, and the evaluation of KM.
- Knowledge update. This process includes unlearning (forgetting). Although unlearning is often neglected by the IS and IT community, the organizational-theory and strategic-management literature often emphasise this key process, which is often a condition for the acquisition of new knowledge (Huber, 1991; Tarondeau, 2002; Walsh & Ungson, 1991).
- The protection of knowledge through various means (patents, firewalls, etc.).

KM Context

This last component of the KM model comprises the factors that may positively or negatively influ-

Figure 4. KM context



ence KM (Figure 4). Whenever possible, these factors should be used to leverage KM efforts.

Strategy is refined into mission, vision, objectives, policies (rules), and allocated resources. The latter may be financial, human, or material resources.

The organization comprises the following subtopics:

- Organizational structure.
- Business processes, into which the KM processes should ideally be incorporated. Following Davenport and Short (1990), we distinguish between operational and managerial processes, the latter being often more knowledge based.
- The physical work environment.
- KM-specific structures, that is, communities of practice or formal structures.
- KM-specific functions: chief knowledge officer (CKO), knowledge manager, technical functions.

The culture of an organization is crucial to the success of KM (Grover & Davenport, 2001).

Leadership is mentioned in several KM models, underlying the role of senior management support in the success of KM.

Human-resource management influences individuals and their behaviors.

Information technologies, techniques, and methods are a key KM enabler and facilitator, although it is generally admitted that technology should not represent more than one third of a KM project (Davenport & Prusak, 2000; Smith & Farquhar, 2000).

Information technologies, techniques, and methods include project management methods, IS development methods and models, groupware and workflow, document management, databases, data warehouses and business intelligence, multimedia, the Web, and artificial intelligence. The latter two are discussed in detail below.

The Web comprises architectures (Internet, intranet, extranet, and portals), search engines, and languages (primarily HTML [hypertext markup language] and XML [extensible markup language]).

Artificial intelligence includes the following topics.

- Expert systems apply to the representation and utilization of explicit knowledge.
- Machine learning permits the generation of new knowledge. Following Michalski (1993), we distinguish three types of learning: inductive learning (from specific to general), analogical learning (specific to specific, or general to general), and deductive learning (general to specific).
- Intelligent agents and multiagent systems apply to knowledge searching on the Web.
- Ontologies also permit the improvement of knowledge searching on the Web in conjunction with XML (semantic Web).
- The methods and models of knowledge engineering and capitalization include REX (Eichenbaum, Malvache, & Prieur, 1994), MKSM (Ermine, 2001), MEREX (Corbel, 1997), and CommonKADS (Breuker & van de Welde, 1994).

Finally, KM is influenced by the environment. Drawing from Holsapple and Joshi (2004) and Reix (2000), we decompose the environment into the market; the competition; the technological, cultural, and geographical environments; laws and regulations; and the governmental, economic, political, and social climates.

Comparison with Previous Models

Table 1 illustrates which topics of our KM model are covered by previous work. For the sake of readability, we only consider the first two detail levels of our model. Table 1 shows that while previ-

Table 1. Topics covered by KM models

	Alavi & Leidner (2001)	Davenport & Prusak (2000); Grover & Davenport (2001)	Despres & Chauvel (2000)	Fowler (2000)	Handzic (2001)	Holsapple & Joshi (2004)	Newman & Conrad (2000)	Nissen (2002)	Nonaka (1994)

ous KM models are complementary and thereby contribute to the definition of our model, none of these models covers the whole range of topics covered by ours (this would have been made even more visible if we had considered the more detailed levels of our hierarchy). The most complete model that we have found is the ontology developed by Holsapple and Joshi (2004). However, this ontology, like the other models, is a semantic model, which is inappropriate for navigating between abstraction levels of KM topics and for quantitatively assessing KM research and practice. On the contrary, navigation and quantitative assessment are facilitated by our hierarchical KM model. This opens the way to different applications both in research and practice.

Application to KM Research and Practice

Navigation Between Abstraction Levels of KM Topics

KM models (more specifically, broad models) should enable researchers and practitioners to examine KM concepts at various levels of detail, and to navigate from abstract levels to detailed levels (drill down) or from detailed levels to abstract levels (drill up). However, even if semantic KM models may comprise concepts of various levels of detail, they do not allow easy navigation between these levels. On the contrary, hierarchies provide a natural mechanism for organizing information of various detail levels, and for navigating between these levels (Saaty, 1999). Consequently, our KM model, by its very hierarchical structure, enables KM practitioners and researchers to master the complexity of KM phenomena.

Quantitative Assessment of KM Research and Practice

Based on the hierarchical structure of the KM model, the analytic hierarchy process (Saaty, 1980) may be applied to the quantitative assessment of KM by taking the following steps.

1. A subhierarchy of the hierarchical KM model is selected depending on what needs to be assessed and for what purpose.
2. Weights are determined for the nodes of the subhierarchy.
3. The weighed subhierarchy is used for performing evaluations. For each evaluated item, scores are entered for the end nodes of the subhierarchy. Aggregated scores, including the global score of the item, are calculated based on the previously defined weights.

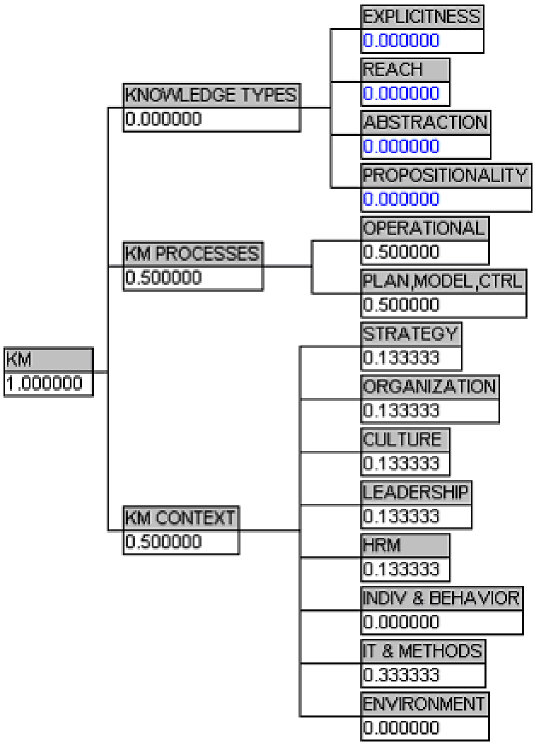
Assessment of KM Practice

In practice, the KM model can be applied to evaluate (audit) the KM maturity of a given organization. The analytic hierarchy process is perfectly adapted to auditing, as illustrated by the INFAUDITOR system (Akoka, Comyn-Wattiau, & Prat, 1993). The subhierarchy of the KM model chosen for KM auditing typically includes the KM processes and KM context. Weights assigned to the nodes of the subhierarchy reflect the relative priorities of the audited organization with respect to KM (e.g., information technologies, techniques, and methods are more important than leadership, etc.).

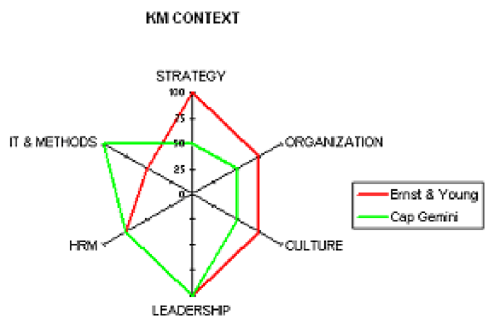
We illustrate this application of the KM model with the Cap Gemini and Ernst & Young case (Figure 5). This is simply an illustrating example and by no means a judgment on the way these two companies have handled KM. Information was gathered from secondary sources (Davenport, 1997; Hjertzén & Toll, 1999; Lara, Andreu, & Sieber, 2002). The example was treated using the Descriptor® tool, which supports the analytic hierarchy process (Adexys, 2004).

We consider KM at Ernst & Young and Cap Gemini respectively, before Cap Gemini acquired Ernst & Young in 2000. Our KM model is applied to evaluate and compare KM practices in these two companies. We assume that two levels of detail (not counting the root) are sufficient for getting a first impression of KM practices in the two companies. We exclude the KM types component. Moreover, in the KM context, we exclude the factors environment, and individuals and behaviors (the companies supposedly have limited control on the environment and can

Figure 5. Applying the KM model



Scores %	Ernst & Young	Cap Gemini
KM	**67,9**	**63,3**
KM PROCESSES	62,5	50
KM CONTEXT	73,3	76,7
OPERATIONAL	75	50
PLAN,MODEL,CTRL	50	50
STRATEGY	100	50
ORGANIZATION	75	50
CULTURE	75	50
LEADERSHIP	100	100
HRM	75	75
IT & METHODS	50	100



control individuals and behaviors only indirectly). We assign weights to the remaining nodes of the subhierarchy. We obtain the weighed subhierarchy represented in the left part of Figure 5 (e.g., information technologies, techniques, and methods count as one third of the KM context). We then use this weighed subhierarchy to assess KM for the two companies, entering scores for the end nodes. The final and intermediary KM scores for the two companies are computed and shown in the table of Figure 5. The final results illustrate the predominant KM orientation for the two companies (IT for Cap Gemini and strategy, organization, and culture for Ernst & Young). Based on these results, we may decide to investigate more precisely one aspect of the KM process or context (e.g., the topic of planning, modeling, and control processes). To this end, we would need to change the selection of the subhierarchy and the definition of the weights; however, the approach would remain the same.

Assessment of KM Research

In research, the KM model can be used to compare, contrast, and combine the contributions of different disciplines to KM. Thanks to the hierarchical structure, the commonalities, differences, and profiles of different disciplines can be represented and analyzed at various levels of detail. For example, the score of a given discipline for the tacit-knowledge end node of the KM model can be computed as the frequency in which the word tacit appears in a sample of publications of this discipline relating to KM.

FUTURE TRENDS

By their very structure, hierarchical KM models support navigation between the levels of detail of KM topics. Furthermore, coupled with the analytic hierarchy process, they permit the quantitative evaluation of KM practice and research at various levels of detail. Due to these advantages, we predict a growing interest for such models.

Despite the advantages of hierarchical KM models, they can not replace semantic models for describing and defining KM concepts and explicitly representing the complexity of their relationships. Therefore, since the two types of models do not serve the same purposes, we suggest that they be used complementarily.

Our future research plans concern (a) further applications of our hierarchical KM model to the quantitative assessment of KM research and practice, and (b) ways of combining in practice our KM model with one or several semantic models.

CONCLUSION

In this article, we have presented a hierarchical model for KM research and practice. The model integrates the contributions of previous works. Furthermore, its hierarchical structure eases the navigation between the detail levels of KM topics, and permits quantitative evaluations of KM research and practice.

To the best of our knowledge, no hierarchical KM model had been defined so far. Marchand, Kettinger, and Rollins (2000) present a model to assess the information orientation of a firm. However, this model has few levels of detail and concerns information rather than knowledge management. Van den Hooff, Vijvers, and de Ridder (2003) present an instrument that companies can use to assess their KM maturity. However, for the most part, this instrument is informal and therefore may not appropriately be called a model.

We do not contend that our KM model is completely stable. However, the hierarchical structure of the model makes it easy to update.

It is our hope that this article will incite more research on hierarchical KM models and on their application to KM-research and practice quantitative assessment.

Chapter 4.2
Applications of Agent-Based Technologies in Smart Organizations

László Zsolt Varga
Hungarian Academy of Sciences, Hungary

ABSTRACT

This chapter introduces agent technology as a means of creating dynamic software systems for the changing needs of smart organizations. The notion of agency is introduced, and individual and collective agent architectures are described. Agent interaction methods and agent system design techniques are discussed. Application areas of agent technology are overviewed. The chapter argues that the autonomous and proactive nature of agent systems make them suitable as the new information infrastructure for the networked components of dynamically changing smart organizations.

INTRODUCTION

Nowadays the whole world is networked into the Internet and if an organization is not connected to the Internet, then it has serious competitive drawbacks. Private persons are using the Internet more and more as well, so organizations keep contact with their clients through e-mail and give them information on their products and services on information portals. Customers can do the shopping in electronic shops and get all the information they want from the portal server; they can even configure the product they want to order. In order to satisfy individual needs, smart organizations must feed online information from the Internet into their internal information system and then further to their internal production control, accounting, design, resource planning, and several other components. The organization can adapt to these requirements only if it requires the same type of information management from its suppliers, so the interorganizational communication must become part of this networked environment as well.

In this environment, we can less and less talk about individual software products, because software components are interconnected and sooner or later almost every software component must be capable to interoperate with other software systems. This way, the information system of smart organizations becomes part of the worldwide Internet, so individual solutions cannot be applied. The software technology of smart organizations means less and less the design and implementation of individual software systems; rather, we can talk about the development of the design and implementation of a single distributed worldwide information system. In this context, the designers of subsystems cannot apply individual solutions, they have to adapt to global practice and standards. At the time of the design of such a global information system, the designer does not have enough information and resources to make a complete solution, so the designed system must integrate into the worldwide system with the ability to adapt to unforeseen changes and requirements using incomplete information at run-time.

Satisfying these requirements is among the goals of several technologies, including the Web services technology characterized by SOAP1, WSDL2, UDDI3 abbreviations (Web Services, 2004; UDDI, 2004), the semantic Web technology (Berners-Lee, Hendler, & Lassila, 2001), the grid (Foster & Kesselman, 1999) and maybe the most complete approach, which is agent-based computing (Wooldridge, 2002).

This chapter presents the most important elements of agent technology and how they can be applied in smart organizations. First, we define what agents and agent systems are, then we overview the history of agent developments. We discuss the internal structures of agents, then how these agents can form smart organizations, then the methods of agent system analysis and design. Finally, we discuss the applications of agent systems and the conditions of their wide adoption.

THE AGENT METAPHOR

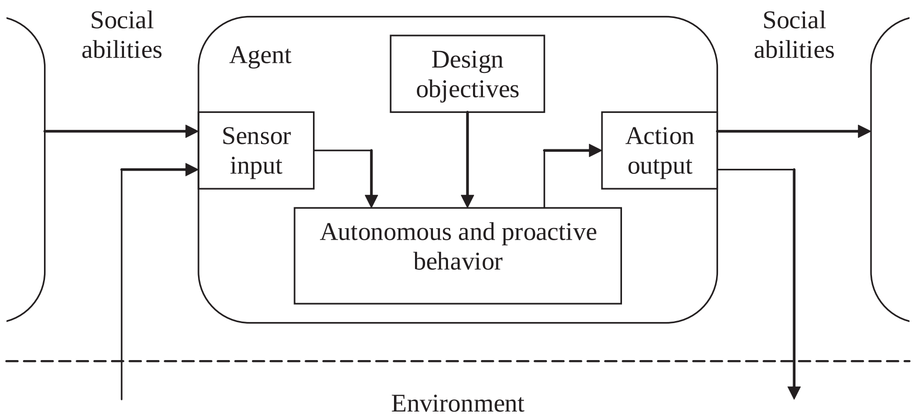
The word "agent" has different meanings in different contexts, so computer scientists working in the agent field may have somewhat different definitions of agency. There is agreement on the main characteristics, but some researchers consider other characteristics important as well, while some researchers think that these are not important, depending on their background.

Intelligent Agents

The notion of agent emerged from many different fields, including economics, game theory, philosophy, logic, ecology, social sciences, computer science, artificial intelligence, and later distributed artificial intelligence. In all these fields, an agent is an active component that behaves intelligently in a complex environment to achieve some kind of goal. Artificial intelligence is the branch of computer science which investigates how to implement in computer systems intelligence comparable to human intelligence. While the goal of artificial intelligence focuses mainly on intelligent performance comparable to an individual person, distributed artificial intelligence investigates how a group of software components called agents can achieve intelligent behavior comparable to a group of persons.

From a software technology point of view, agent technology promises to enable system designers to handle more complex systems than before. As systems become more and more complex, software development processes need higher and higher abstractions. In the beginning, functional and modular programming techniques provided enough level of abstraction, then object-oriented systems became the most commonly used technique to model complex systems. Agent technology promises to handle systems that object-oriented techniques cannot adequately model, like

Figure 1. The most important characteristics of intelligent agents



large, distributed organizations with incomplete information and distributed responsibility, where individual components must dynamically adapt to unforeseen changes.

Experts from the different fields tend to agree that the most important characteristics of agents are those which are defined by Wooldridge and Jennings (1995) and shown in Figure 1. First of all, an agent is a computer system situated in some environment. The agent is reactive, which means that it is capable of sensing its environment and acting on it. The agent can autonomously act in its environment and make decisions itself. The agent has design objectives and can decide itself how to achieve them. While taking the decisions the agent is not just passive, but can take initiatives towards its goals. The agent has social abilities and can interact with the actors in its environment.

Agents as Building Blocks in Smart Organizations

The above-mentioned characteristics make the agent concept an important element in modeling systems needed for smart organizations. First of all, multi-agent systems are distributed cooperative computing systems, therefore they themselves form an intelligent organization. The reactive, autonomous, and proactive features of agents require that they are knowledge-driven, dynamically adaptive, agile, and learning computing elements. The social abilities of agents mean that they are usually internetworked, as well as dynamically adaptive to new organizational forms and practices. Since these features are necessary for smart organizations, we can expect that software systems built with agent technology will play an important role in smart organizations. A multi-agent system itself can be regarded as a smart organization, because the above-mentioned characteristics are in line with the definition of smart organizations. The term "smart organization" is used for organizations that are knowledge-driven, internetworked, dynamically adaptive to new organizational forms and practices, learning, as well as agile in their ability to create and exploit the opportunities offered by the new economy (Filos & Banahan, 2000).

In the following sections, we will discuss agent systems in order to be able to understand their importance for smart organizations. Agent technology offers new techniques for smart organizations, but it cannot solve everything. Several design techniques and software tools have been developed to support and implement agent oriented systems. Although these techniques and tools allow the designer to think in the way an agent system needs, the major challenge in implementing agent systems is related to the intelligence of the agents.

HISTORY AND STANDARDS

Current interest in autonomous agents emerged mainly from artificial intelligence research, but object-oriented programming and human-computer interface design also contributed among the many other fields mentioned earlier. Although we could think that agency is central to artificial intelligence (AI), because AI is about building intelligent systems, artificial intelligence researchers did not intensively study intelligent agents until the 1980s. The focus of AI research was on the different components of intelligent behavior, like learning, reasoning, problem solving, and so forth. Among these independent investigations, AI planning was most closely related to agents, because AI planning is related to what and how to do, and agents also have to plan what they are going to perform autonomously in their environment. AI planning first used a symbolic reasoning approach, but when the ultimate viability of this approach was questioned, the attention of researchers turned toward behavioral or reactive AI. According to this approach, theorem provers cannot produce intelligent behavior; rather, intelligence is a product of the interaction between the intelligent system and its environment. In this approach, intelligence emerges from the interaction of several simpler behaviors and competing behaviors can suppress each other. However, emergence is purely reactive, so in the early 1990s researchers started to combine reactive behavior with the deliberative approach of symbolic reasoning. The combination of reactive and deliberative approaches was later replaced with the practical reasoning approach, where reasoning is influenced by a kind of mental state with three components: Beliefs, desires, and intentions, where beliefs represent the information that the agent has about its environment, desires represent the different possible states the agent may choose to commit to, and intentions represent the states the agent has chosen and committed resources to.

The Beginnings

Agent research became a separate branch of AI in 1980 at the first Distributed Artificial Intelligence (DAI) workshop at the Massachusetts Institute of Technology, where participants decided that there is need to investigate issues of how intelligent problem solvers can coordinate their activities to solve common problems, and these issues are on a higher level than the parallelism issues of how to distribute processing over machines and parallelize centralized algorithms. The first multi-agent model was the actors model, in which self-contained, interactive components communicate by asynchronous message passing. Task allocation then became an important topic, and the Contract Net Protocol was defined to allocate tasks from the contractor to bidders through an announcement—bidding—allocation process. The early applications were related to the coordination of physically moving vehicles. Later, the research focused on teams working toward a common goal, and theoretical foundations of cooperation were investigated, including notions of commitment and joint intention. A group of agents jointly intends a team action if all of them are committed to completing the team action and they mutually believe that they are doing it. In this case, the joint commitment is a joint persistent goal. Agents enter into a joint commitment by establishing appropriate mutual beliefs and commitments through an exchange of request and confirm speech acts.

The investigation of how to achieve joint commitment centered on the notion of negotiation. It turned out that negotiation was a good method for coordination, conflict resolution, communication of plan changes, task allocation, and resolution of constraints violations as well. The common characteristics of these are that agents have to resolve some conflict in a distributed way by exchanging proposals and counter proposals, the agents have their own goals, they have bounded rationality and incomplete information.

At this time, agent architectures focused on the internal modules of agents and how the above-mentioned concepts can be handled with software engineering methods. Agents usually had five components: the communication layer, the agent acquaintance module, the self module, the inference engine, and the knowledge base. The communication layer was responsible for performing the necessary transformations on the messages the agent wanted to send and receive to and from its environment, in order that these messages conform to the external and the internal world of the agent. The agent acquaintance module contained information about the environment of the agent and modeled the capabilities of the agents to interact with. The self module contained information about the capabilities of the agent itself. The inference engine was responsible for executing the actions of the agent based on the knowledge of the agent stored in the knowledge base.

Networked Agents

In the 1990s, the Internet and hypertext protocol was spreading rapidly, and more and more applications were deployed on the Internet. This open environment gave way to the wide-spread application of software agents communicating over Internet protocols. Previously, multi-agent systems were designed and implemented usually by a single team, but now multi-agent systems from different backgrounds and design approaches had to communicate and interact. The most important issues in this environment are discovery and interoperability. Discovery is the problem of how agents can find each other even when they do not know anything about the other agent. Interoperability is the problem of understanding the syntax and semantics of the language of other agents, which means that agents have to be able to parse the message of other agents and find out the meaning of the elements of the messages.

To solve the discovery issue in open environments, the notion of middle agents has been introduced. Agents can advertise their capabilities to some kind of middle agent. Different types of middle agents have been identified, including yellow page middle agents that match advertisements with requested capabilities, blackboard middle agents that collect requests, and broker middle agents that do both. Of course, this middle agent approach works only if agents know how to find the appropriate middle agent. In practice, this can be solved by having a few well-known middle agents, which preferably even talk with each other so that if there is no match at a specific middle agent, then the request can be forwarded to another one. These well-known middle agents form the basis of the infrastructure of an open agent environment. The first attempt for a world wide agent infrastructure was the Agentcities network (Willmott, Dale, Burg, Charlton, & O'Brien,2001).

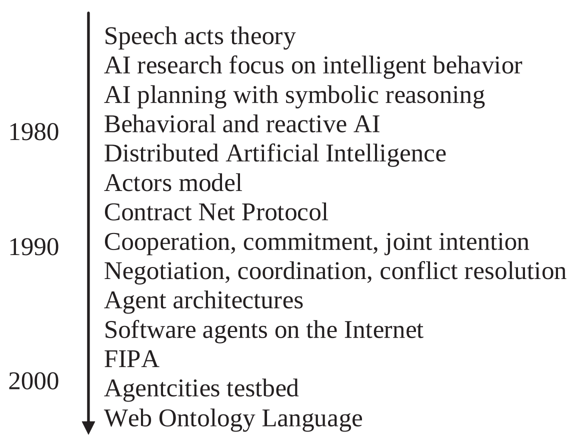
Solving agent interoperability is approached on two levels: on the agent communication language level and the agent content language level. The agent communication language defines the types and the format of the messages between agents. Agent communication languages provide a set of performatives, like "request" and "inform," based on the speech acts theory (Searle, 1969), where communications are modeled as actions that change the mental state of communication participants. Using the agent communication language, an agent can send to another one a request for "something," or can inform the other agent about "something," where the "something" is the content of the message. The schema for the agent content language is the ontology which formally describes a domain of discourse. Agents can understand the content of the messages if they share their content language ontologies, preferably by publishing them on ontology servers. Ontology servers are also an important part of an open agent infrastructure like the Agentcities network (Willmott et al., 2001)

Standards and FIPA

The need for interoperable agent communication created the standardization body of agent systems, which is called Foundation for Intelligent Physical Agents (FIPA). FIPA was founded in 1996 and registered in Geneva, Switzerland as an international nonprofit organization. The aim of FIPA is to develop software standards for heterogeneous and interoperating agents and agent systems, in order to enable the interworking of agents and agent systems operating on platforms of different vendors in industrial and commercial environments. As a result of the FIPA standardization activity, many research labs and industrial organizations started to develop competing agent platforms independently all over the world. FIPA standard agent platforms provide an environment where agents can be deployed, and with the help of the agent platform services they can interact with other agents on any FIPA standard agent platform in a FIPA conformant way, achieving agent communication level interoperability. Agent platforms from more than 15 vendors show interoperability in the Agentcities testbed. More than half of the Agentcities nodes use the Jade agent platform from Telecom Italia Laboratories (Balboni, 2003).

The most important agent standardization activities are done in FIPA, but significant activity was also carried out in the Object Management Group (OMG) and agent standards are starting to become highly relevant to bodies such as the World Wide Web Consortium (W3C) and the Global Grid Forum (GGF), because developments such as Web Services (Web Services, 2004) and

Figure 2. Trends in agent research



Semantic Web Services (DAML Services Coalition, 2002; Bussler, Maedche, & Fensel, 2002) also investigate many of the issues agent technologies have already addressed.

Figure 2 summarizes the history and trends in agent research as discussed in this section.

AGENT ARCHITECTURES

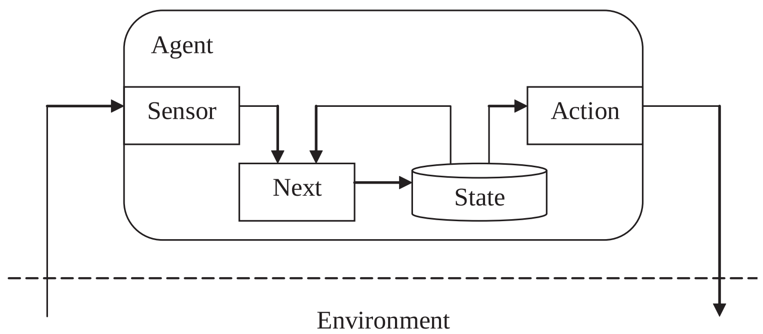
As we have seen in the previous section, the agent concept evolved over time. Different aspects of agency were discovered and in the end merged into the currently applied agent architectures. Nowadays, agents that show traits of only one aspect are not considered real intelligent agents. For example, a stock exchange trading agent in charge of a stop-loss order is a purely reactive agent, but does not satisfy the current notion of intelligent agency. In this section, we are going to elaborate on the different aspects of agency.

Reactive Agents and Agents with State

One of the first aspects is that agents are reactive. A purely reactive agent decides what to do without reference to its history. The behavior of a purely reactive agent is the function of the state of its environment. This type of agent architecture has two main subsystems: perception and action. The perception subsystem contains the agent's ability to observe its environment. In the case of agents in the physical world, like robots, this may be a video camera, and in the case of an agent in the software world this may be system or network routines like finger, ping, or network messages. The output of the perception module is a percept, or the internal representation of the environment. The action subsystem of the agent contains the agent's ability to act on its environment. In the case of a physical agent this may be a robot arm, and in the case of a software agent this may be system commands. The action subsystem maps the sequences of percepts into actions. The perception subsystem of the agent grabs those features of the environment which are relevant for the goals of the agent. For example, in the case of the stock exchange trading agent in charge of a stop-loss order, the whole range of the stock price is mapped into two values: hold and sell. If the price falls below a certain value, then the agent has to issue a sell order.

Purely reactive agents often compose a fine-grained multi-agent system. A fine-grained multi-agent system consists of many simple agents,

Figure 3. Agent with state



and the intelligent behavior of the fine-grained multi-agent system emerges from the interaction of the simple agents. Coarse-grained multi-agent systems consist of fewer, but more intelligent, agents. Agents in a coarse-grained multi-agent system usually have one of the architectures discussed below.

Purely reactive agents do not remember the history of their environment. Agents with state, shown in Figure 3, can do so by having additional components in their architecture: a state and a next function. The state represents the current mental status of the agent, while the next function maps the percept of the agent and the current state of the agent to the next state of the agent. The action subsystem of agents with state maps the current state of the agent into actions. Agents with state have the full power of agency; they are behaviorally equivalent to agent architectures discussed later in this section, but the other architectures grab more of intelligent behavior and help better understand the notion of agency.

Agent Reasoning

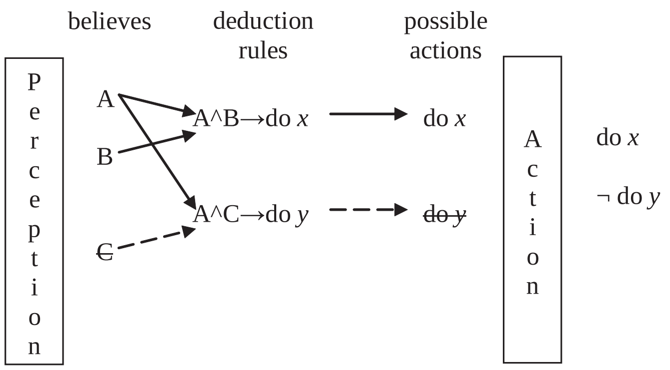
Agents usually have to act in a dynamically changing environment, therefore it is better not to tell the agent exactly how to carry out the tasks. It is better to tell the agent what to do without telling how to do it. This can be done by defining tasks indirectly with some kind of performance measure.

One way of defining tasks indirectly is by associating utilities with states of the environment. The utility function maps the environment states to real numbers and tells how good the state is: the higher the value, the better the state. A disadvantage of the utility function is that it assigns utilities to local states and does not take into account long term values. However, we can use overall utility; for example, by defining the worst state that might be encountered by the agent or as the average utility of all states encountered. Although this model is useful to understanding agent behavior, in practice sometimes it is very difficult or even impossible to implement the desired utility function.

Another way of indirect task specification is predicate task specification. Predicates are utility functions that have either true or false values. A predicate task specification maps the set of all possible runs of the agent to true or false value, and the agent achieves the desired goal if the predicate function results in true value either for all runs, or at least for one run or for a given percentage of runs of the agent, depending on how pessimistic or optimistic the definition of success is. Some common forms of predicate task specifications are the achievement tasks and the maintenance tasks. In the achievement task the goal of the agent is to achieve a state, while in the maintenance task the goal of the agent is to maintain a state. In the achievement task, the agent is successful if it can force its environment into one of the goal states, while in the maintenance task the goal of the agent can be characterized as to avoid some state. Complex tasks can be specified as combinations of achievement and maintenance tasks.

Deductive reasoning agents originate from symbolic AI, which says that intelligent behavior can be generated using logical deduction or theorem proving from symbolic representation of the world. In this approach there are two key problems: the transduction and the reasoning problem. The transduction problem is how to translate the real world into an accurate and adequate symbolic representation. This may be very hard; for example, in the case when a photo has to be converted into a set of declarative statements representing that photo. The reasoning problem is how to manipulate symbolic information to be useful in time. Since the computational complexity of theorem proving may require long computation, theorem provers may not always operate effectively in time-constrained environments. A deductive reasoning agent (shown in Figure 4) is an agent with state and its perception module translates external information into symbolic representa-

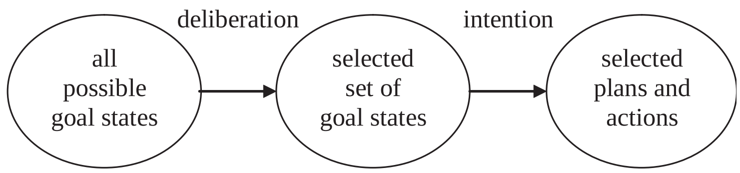
Figure 4. Deductive reasoning agent



tion. Once there is a symbolic representation of a fact in the database of an agent, then the agent believes this fact, although in the real world this might not be the case. The next function of the deductive reasoning agent maps the agent database and a perception into a new database. The action subsystem of deductive reasoning agents use deductive reasoning to deduce the action of the agent. The deduction rules of the agent are defined in a way that if a formula "do action A" can be derived from the fact database using the rule database, then the action of the agent will be action "A." The reasoning engine of the action subsystem takes each of the possible actions "x" of the agent and tries to prove "do action x." If there is no action for which this formula can be proved, then the reasoning engine tries to find an action "x" for which "do not do action x" cannot be derived. If there is such action "x," then this action is consistent with the rules, so the agent can execute this action. If this also fails, then the agent does nothing.

Practical reasoning agents try to improve the deductive reasoning agent architecture by reducing the search space of deductive reasoning. One of the main problems of deductive reasoning agents is that deducing all possible logical consequences takes too much time and sometimes is even impossible. In practical human reasoning, the logical reasoning is influenced by the current state of the mind. Human practical reasoning first tries to reduce the search space by deciding what state we want to achieve. This is called deliberation. Once deliberation is done, the reasoning concentrates on how to achieve the selected state. This is called means-ends reasoning. There must be a good balance between deliberation and means-ends reasoning, or else practical reasoning agents do not perform well or even do nothing. Deliberation cannot go on forever—some goal state has to be chosen and the process of achieving this state has to be started even if the selected goal state is not optimal. The process of achieving the selected goal state is called intention. Intention involves the process of creating a plan to achieve the selected goal state and actions taken according to the created plan. Deliberation and intention are shown in Figure 5. Intentions drive the means-end reasoning and if one plan creation fails, then another is tried. An intention must persist typically until it is believed that it is successfully achieved, or it is believed

Figure 5. Steps of practical reasoning



that it cannot be achieved, or it is believed that the reason for the intention no longer exists. Intentions constrain deliberation, and options which are not consistent with the current intentions are dropped. Intentions restrict the beliefs on which practical reasoning is based, and beliefs that are not consistent with the intention are dropped.

The deliberation process of practical reasoning agents has two parts: the option generation function and the filtering function. The option generation function produces a set of options, called desires. The filter function selects the best one(s) from the set of desires based on the current beliefs, desires, and intentions.

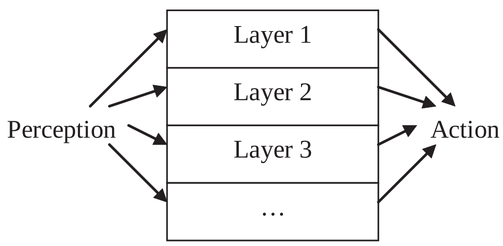
Once a desire passes the filter function and becomes part of the set of currently selected intentions of the agent, then we say that the agent has made a commitment to that intention. The commitment strategy of the agent is the mechanism used to determine how long a commitment must persist. Blind commitment strategy is to keep the intention as long as the agent believes that the intention has been achieved. Single-minded commitment strategy is to keep the intention as long as the agent believes that either the intention has been achieved, or the agent currently has no plans to achieve the goals of the intention. Open-minded commitment strategy is to keep the intention as long as the agent believes that the goals of the intention are possible. The agent has to reconsider its commitments from time to time to check if they still have to be kept. There must be a good balance, because if the agent reconsiders its commitments very often, then it does not have enough computing resources to achieve them; on the other hand, if the agent does not reconsider its commitments often enough, then it may continue to pursue them for a long time after it is obvious that they cannot be achieved.

Means-ends reasoning produces a plan to achieve the selected goal state based on the current intentions, the current beliefs (i.e., the state of the environment), and the actions available to the agent. In many implementations, the planning function does not create a plan from scratch; rather, the agent has a set of plans given by the agent designer, and the agent searches through the set of plans to find one that has the needed intention as a post condition and is in accordance with the current beliefs and available actions.

Layered Agent Architectures

An alternative to the reasoning agent architecture is the hybrid agent architecture, or layered agent architecture, in which there are layers responsible for different agent-like behaviors. In the horizontally layered hybrid architecture, each layer is directly connected to the perception and the activation modules, as shown in Figure 6. In horizontal layering, each layer produces competing suggestions as to what to do, and a control subsystem must decide which layer actually takes control over the agent. Some of the layers are responsible for low-level actions; for example, in a financial organization, to avoid

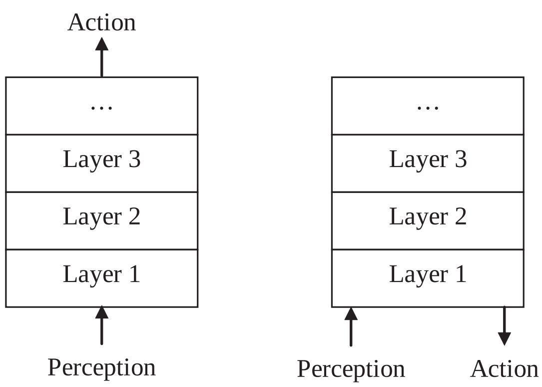
Figure 6. Horizontally layered agent architecture



bankruptcy some of the other layers are responsible for higher-level actions like deciding where to invest. The control subsystem gives priority to low-level actions in urgency and gives way to higher levels otherwise.

In vertically layered hybrid architectures, perception and activation are connected to at most one layer, as shown in Figure 7. Layers make processing and pass information to each other. In two pass vertical layering information flaws up the architecture to higher and higher level processing. Decision is made at the upper-most level where action is generated, which then flaws down to lower levels.

Figure 7. Vertically layered agent architectures



Not long ago, a popular agent model was the mobile agent architecture. In this model, agents are seen as programs roaming the network to collect business-related data. This approach had a lot of problems related to authorization policies; that is, hosts and agents had to be protected against each other. Since network bandwidth is usually available, mobile agents did not have much advantage over nonmobile agents except in a few cases—for example, in auctions when different network latencies were not allowed for fairness. Because of the difficulties, mobile agents have not yet been taken up by the mainstream; however, mobility issues may be investigated again when agents running on mobile devices become widespread.

AGENT ORGANIZATIONS

Up to now, we have been discussing how agents can organize and plan their activity on their own, but agents have to act in a networked environment; for example, as part of a smart organization. In this environment, they act on the real world, and sometimes the real world imposes restrictions on their activities; for example, because two agents want to use the same resource at the same time. In this case, it is obvious that the agents have to coordinate their plans. Even if there is no conflict in the real world, the agents want to distribute the task allocations among themselves, and there must be some kind of interaction between the agents. The interactions are even more complex when the conflict in the real world arises between the activities of two groups of agents. In this case, the groups of agents have to coordinate among themselves as how to interact with the other group.

In order to model the interactions among agents, the utility function is used. The utility function of an agent assigns to each state a real value. If the utility function gives higher value for a state s1 than for another state s2, then the agent has preference for s1 compared to s2. Many times the utility function is linear, but nonlinear utility function models that situation when the agent achieved most of its goals and is satisfied with the state, therefore its utility function does not give much higher values when the state improves somewhat. Similarly, if the agent has not achieved any goal, then a small improvement in the state gives higher increase in its utility function than in a more or less satisfied status.

Properties of Agent Organizations

When several agents act on the environment, their actions may depend on the actions of the other agents. If one agent makes a choice, then the other agent is already restricted and has to make a choice depending on the choice of the other agent. In an ideal situation, the different agents have preference for the same state and all other states are less preferable for all of the agents. A somewhat less ideal but still very good situation is when agents can still find a state which is most preferable for all the agents, but there are other states which give the same utility value for all the agents. In this case, agents can select one of these preferable states, but they must agree which one, because if an agent deviates from this state toward another more preferable state, then none of the agents achieve the most preferred state. It is also possible that there are more than one state with which agents are all satisfied and do not want to deviate from it if the others do not deviate; however, one of these preferable states may be better than the other one. All the situations in this paragraph are called Nash equilibrium, because no agent has the incentive to unilaterally deviate from the preferable state.

The efficiency of the agent system can be measured as a combination of the utility functions of all of the agents. A simple efficiency measure is the sum of the utilities of all the agents, and according to this measure an agent system is in sum optimal state if the sum of the utilities is maximal. An agent system is in a Hicks optimal state if the utility is maximized for all of the agents in the agent system. An agent system is in Pareto optimal state if it satisfies, more or less, all of the agents, and in all other states at least one agent's utility function gives smaller value if at least another agent's utility function gives higher value. Note that Hicks optimal state cannot always be achieved. Also note that sum optimal and Pareto optimal state may not be equilibrium state, if at least one agent might achieve better utility by deviating from the optimal state. An example of this is the prisoner's dilemma, in which the equilibrium is not optimal.

Agreement in Agent Organizations

Now that we have seen the different types of states multiple agents can achieve, let us turn our attention to how they can reach agreement to get to the desired state. Agents coordinate their actions by exchanging messages. The messages are exchanged similarly to usual network communication protocols, which are governed by protocol rules so that the participating partners can get to some useful result and are not locked in, for example, a deadlock. Agent interaction protocols build on communication protocols and strive to ensure, for example, community level results (Sandholm, 1999). It is expected that an agent interaction protocol guarantees that agents eventually get to some agreement and this agreement leads to either sum, Hicks, or Pareto optimal state. Participating in agent interaction protocols must be Nash equilibrium behavior for the participating agents, that is, all of the agents must be interested in keeping to the protocol rules, which must be simple enough so that agents can easily determine the optimal strategy. Multi-agent systems are usually distributed and there is no centralized node, and this must be the case for agent interaction protocols as well.

Although agents may interact in many different ways, there are three types of interaction protocols which are the most used and studied. These are the auction, the negotiation, and the argumentation interaction protocols.

The auction protocol can be used to allocate a given resource to one of the agents from a group. The resource can be a good or a task to be executed; in the latter case the auction protocol is also called a contract net protocol. The roles in the auction protocol are the auctioneer and the bidder. The auctioneer agent has the resource to be allocated and wants to maximize the price for it. The bidders are the agents to which the resource is to be allocated and want to minimize its price. In many cases the exact value of the resource is not known or is not unambiguous. The agents may value the price of the resource differently according to their different interests in the resource and different knowledge about the current and future value of the resource. The auction protocol helps the agents agree on a price and allocation which is most acceptable for them. According to the different rules, the auction interaction protocol can be one shot, if there is only a single round of bids, or it can be ascending or descending sequential, if there are several rounds with the necessity of ascending or descending bids. The auction interaction protocol can be open cry, if every agent sees the bid of every other agent, or can be sealed bid, if they do not see each other's bid. The auction protocol is first price if the winner is the one with the best bid and pays its own bid, or it can be second price if the winner is the one with the best bid, but pays the second best bid.

Auction is a special form of negotiation which is a somewhat more general form of agent interaction. The negotiation interaction protocol is defined with the negotiation set, the proposal order, a set of strategies, and an agreement criterion. The negotiation set contains all the possible proposals the agents can make. In the simplest case, the proposal contains one issue to be negotiated, like the price in auction protocols, or can contain multiple issues which may be interrelated. The proposal order defines the set of allowed proposals as a function of the negotiation history and the timing of proposal making. Typically, agents make the proposals at the same time or one after the other, and they are not allowed to repeat previous proposals. Each agent has a negotiation strategy which defines the proposal selection method from its allowed proposals. Negotiation strategies are not public and are related to how the agent is going to achieve its goal. The agreement criterion defines when the negotiation stops and what the accepted proposal is.

The most complex form of agent interaction protocol is argumentation, which most resembles human negotiation and allows dynamic negotiation and the justification of the negotiated deal. Argumentation is based on formal logic. In formal logic there are statements and logic rules. Using the logic rules other statements can be derived from a set of statements. In the beginning of the argumentation interaction protocol, the agents have in their knowledge base different sets of statements which represent their beliefs about the state of affairs. During the argumentation process agents can send each other the statements they have, the derivation rules they are capable of, and concrete derivation instances in order to get to a status when all the agents have the same statement about the issue to be agreed in their knowledge base.

Communication in Agent Organizations

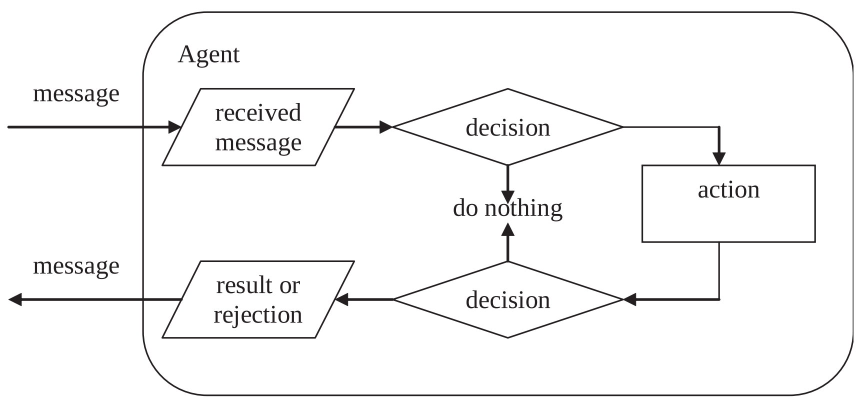
We have seen how agents can get to agreements by exchanging messages; now let us see how they communicate these messages. In usual-distributed computing environments, like in object-oriented systems, one object can call the method of another remote object. In this kind of communication, the calling object causes the execution of the procedure in the remote object. This may happen synchronously if the thread of control returns to the calling object only after the execution of the remote procedure, or asynchronously if the thread of control immediately returns to the calling object and the remote procedure is executed in parallel. In both cases the calling object executes the remote procedure. However, agents are autonomous and their communication is even less coupled, as in the asynchronous remote procedure call.

Agents are autonomous, and when agents send messages to each other, they do not force the execution of a remote procedure, or write data into the internal data representation of the remote agent. When a sending agent sends a message to a remote agent, the sending agent performs an action to influence the behavior or the beliefs of the remote agent. This kind of communication is based on the speech act theory, which treats communication as action (Austin, 1962; Searle, 1969). When a fact is sent from the sending agent as an information to the remote agent, the sending agent intends the remote agent to believe the fact, but it is up to the remote agent whether it trusts the sending agent and builds the belief into its knowledge base or not, as shown in Figure 8.

Based on the speech act theory, the Knowledge Query and Manipulation Language (KQML) was developed (Finin, McKay, Fritzson, & McEntire, 1993) in the framework of the DARPA funded Knowledge Sharing Effort. The KQML language defines the envelope format for agent messages, and the content of the message is described in the Knowledge Interchange Format (KIF) (Genesereth & Fikes, 1992). The KQML envelope contains what the intention of the sending agent is with the information contained in the content part. The KQML part of the message has slots for the type of the message (inform, request, reply, etc.), the sender, the receiver, the language of the content (e.g., KIF), the ontology the content is related to (e.g., electronic products), the content itself, and possibly other features.

We should say a few words about the content language and the ontology. The content language is the format of the description of the content. However, the content cannot be anything, it belongs to a specific domain of discourse that both agents understand. The ontology specifies the notions of the allowed content, the possible properties of the notions, and relations between the notions of the domain. Roughly we could say that the content is the data and the ontology is the schema of the content, but the ontology defines not only the syntax of the allowed content, but the semantic dependencies as well. An ontology describes the common understanding of a specific domain of discourse; it is described in an ontology

Figure 8. Autonomous communication



description language, and it is usually published so that everybody can use it to understand the same. KIF itself is an ontology language, but the most recent ontology language used on the Web is the Web Ontology Language (OWL) defined and standardized by the World Wide Web Consortium (Dean & Schreiber, 2004).

Although KQML defined a framework for agent communication, it was never precisely defined, therefore many versions of KQML were implemented and when agents started to inhabit the Internet, they could not interoperate. Based on the KQML efforts, FIPA standardized agent communication with the specification of the FIPA Agent Communication Language (ACL), interaction protocols, and architecture. As a result of the standardization effort, many vendors implemented agent platforms interoperable on the communication language level.

Trust and Security

In industrial and business environments, special attention has to be made to trust and security aspects, especially in the open and dynamically changing society of agents forming smart organizations. In the open and dynamic environment, agents interact with each other on an occasional basis without having reliable information on each other and the organization they represent. As identified by Wong and Sycara (1999), the most important security threats in agent systems are the corrupted naming and directory services, the insecure communication channels, the insecure delegation, and the lack of accountability.

A naming service in a distributed environment maps names of components to their addresses. A directory service maps services and capabilities to their providers. These services are not part of agent architectures; rather, they are part of the infrastructure of an agent society. However, the agent society cannot function if the members cannot find each other and their services. A naming service or a directory service is corrupted if some entries are missing or contain a wrong value. A wrong value may be entered, for example, by a misbehaving agent.

The communication channels are secure if authentication, integrity, confidentiality, and nonrepudiation are guaranteed. Authentication means that agents know that they talk to agents they think they are talking to. Integrity of messages is guaranteed if the message is not modified or falsely inserted in the communication channel. The message is confidential if other agents cannot intercept the message. Nonrepudiation is guaranteed if nobody can deny having sent a message which was sent.

Insecure delegation occurs if an agent impersonates itself as a delegate of someone who did not entrust to it. Lack of accountability occurs if agents cannot be held accountable for what they are doing and their services cannot be trusted.

As proposed by Wong and Sycara (1999), several measures have to be taken in an agent society to give protection against the above-mentioned trust and security threats. The naming and directory services must service only valid requests coming from a rightful requester and the request is valid. The naming and directory service databases must be kept consistent. The agents and their delegators must have unique identity which can safely be proved. The communication channels must be protected. Agents can be deployed only if there is someone who can be made liable for their actions.

Theoretical models have been developed to guarantee these protective elements, and agent architectures implement more and more of them.

AGENT-ORIENTED SOFTWARE ENGINEERING

In the previous sections, we wrote about how agent systems work, but if we want to write about how such agent systems can be designed and implemented, then we have to select from several approaches. Many agent systems have been implemented and now there are dominant standards, tools, and platforms to operate them, but there is no unique methodology for their design. As we have seen, agent systems propose solutions to problems which the traditional software products do not cover; therefore, we cannot expect that traditional software engineering techniques provide solution to agent-oriented software engineering. Of course, when a specific component of an agent system has to be implemented, then traditional software engineering methods can be applied and traditional software components can be used in the implementation. However, we need new methodology until we get to the point at which we can apply traditional techniques.

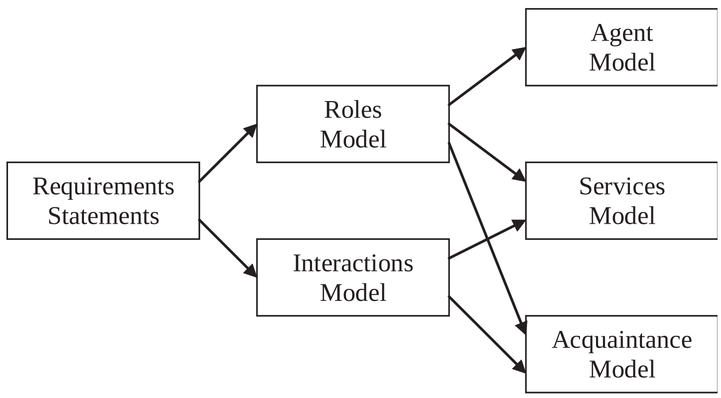
Usually an analysis and design method provides techniques to understand the problem domain and how to handle the complexity of the system so that it can be designed. This is usually done by creating models of the system at different levels, and then transforming higher level models to models closer to the implementation using formal guidelines. What are needed for agent-oriented software engineering are those high-level models that are above the traditional software engineering methods.

There are many agent-oriented software engineering approaches (Giorgini, Müller, & Odell, 2002) among which probably the agent extensions of UML (Odell, Parunak, & Bauer, 2001) and the Gaia methods (Wooldridge, Jennings, & Kinny, 2000) are the most well known. We are going to write about the latter one here, because this method focuses mainly on the agent levels of agent-oriented software engineering and is based on the organizational view of the system, which is important for smart organizations.

The Gaia methodology starts from the requirements statements, which are the textual and formal descriptions of what the system is supposed to do. The requirements capture phase is independent of the paradigm used for the analysis and design, so traditional methods can be used. The Gaia methodology uses the roles and the interactions models for analysis, and the agent, services, and acquaintance models for design. These models and their dependency, as shown in Figure 9, are discussed in the following paragraphs.

The roles model identifies the key roles in the system. The role is an abstract description of the expected function of an entity. The roles are similar to offices in organizations. The role is characterized by the responsibilities and the permissions

Figure 9. Gaia models



of the role. The responsibilities are the functions to be performed by the role. A responsibility can either be liveness or safety responsibility. A liveness responsibility says what the role is supposed to do, while safety responsibility is an invariant that the role must keep. Invariants are described as predicates. The permissions associated with the role either identify the resources that can be used to carry out the responsibilities of the role, or define the resource limits within which the execution of the responsibilities can be carried out.

The interaction model captures the interaction links between the various roles in a smart organization. The interaction model consists of a set of protocol definitions for each type of interrole interaction. In this model, a protocol is abstracted away from the concrete execution steps and is described by a brief textual description of the protocol, the roles responsible for starting the interaction, the roles with which the initiator interacts, the information used by the initiator while executing the protocol, the information supplied by the initiator and responder roles, and a brief textual description of the processing activities during the protocol execution.

The agent model consists of a set of agent types used in the system under development. The agent types are marked with information on how many instances of them will be implemented in the actual system (zero, one or more, n to m, etc.). The agent type is defined as a set of agent roles to be fulfilled by an agent of the given type. Agent types are organized into an agent type tree, where the leaf nodes correspond to roles and the upper-level nodes correspond to agent types. An agent type is composed of the roles of its children agent types in the tree. The agent type tree is derived from the roles model.

The service model specifies the functions associated with each agent role. A service is a single coherent block of activity to be carried out by the given agent type. A service is specified with the inputs, outputs, pre-conditions, and post-conditions of the service. The inputs and outputs are derived from the protocol definitions of the interaction model, while the pre- and post-conditions are derived from the safety responsibilities of the roles model.

The acquaintance model defines the communication links between agent types. The agent acquaintance model is a directed graph in which each graph node corresponds to agent types and arcs correspond to communication links. Arcs are directed and indicate that an agent of one type will send messages to an agent of the other type. The acquaintance model does not specify what messages are sent or when messages are sent, the goal of the acquaintance model is to identify potential communication bottlenecks.

Using these models the designer can specify most of the agent features of the system under development. Further design and implementation can use any traditional design techniques to implement the agent instances.

AGENT APPLICATIONS

In the previous sections, we discussed what agents are, what their internal structure can be, how agents behave in organizations, and how agent systems can be designed. Now we are going to discuss the applications of agent systems in smart organizations. Basically, agent applications in smart organizations can be classified into three categories: distributed agent systems (or multi-agent systems), assistant agents, and multi-agent simulation systems. In the first two types of applications, agents become part of the smart organization, while in the third type of applications agents are used to evaluate and design the structure of the organization. In the first type of applications, several agents make collective decisions and actions within the organization to improve the operation of the organization. In the second type of applications there may be several agents deployed within the organization, and these agents may even interact with each other, but the main function of each agent is to assist its individual user in autonomous and proactive decision-making.

In distributed agent system applications the agent system becomes an integral part of the organization and agents assist the distributed intelligent operation of the organization. Typical areas where distributed agent systems can be applied are business process management, distributed sensing, distributed resource management, process control, trading and purchasing networks. Distributed agent systems can outperform centralized business process management systems, because they are more responsive and are able to cope with unpredictable events. In an agent-based business process management system, the organizational structure and the roles in the organization are mapped to agents, which are responsible for the given role and embody the knowledge needed for the role. These agents can then autonomously and proactively execute most of the automatic processes of the organization with minimal user intervention and approval. Distributed agent systems help distributed sensing by allowing cooperation between the sensors and predicting future trends in the area of one sensor from the data of another sensor. Distributed resource management can benefit from the proactive behavior of agent systems. For example, agents can monitor the network load in telecommunication networks and jointly make predictions on trends and future needs to reallocate resources. Agents can coordinate the workload and the schedule of the field engineers—for example, of electricity provider or telecommunication companies—by taking into account the location and capabilities of the field engineers. Agents can execute the job of automatically negotiating and trading with the suppliers of an organization. Since agents are dynamic, they can adapt to the changing needs of virtual organizations and supply chains.

Assistant agents help their users in gathering and filtering information, or executing some task on behalf of their users. Information retrieval agents can gather information and categorize it according to predefined conditions. This helps the user overview huge amounts of information. More advanced assistant agents learn from the activities of their users; for example, by recording the activities and decisions of the user and deriving rules with knowledge discovery and data mining techniques.

Organizations can also benefit from multi-agent simulation systems, which can simulate real-world environments with a high degree of complexity and dynamism. In a multi-agent simulation system, many individual behaviors can be encoded, thus giving a more complex and real picture of what might happen. The organization can make decisions regarding future products and product features based on a multi-agent simulation of the market where the product is to be sold.

AGENTS SUPPORTING SMART ORGANIZATIONS

As we can see, agent technology discussed in this section has a lot of features that support smart organizations. Smart organizations act in a globally distributed system in which software applications must appear in a new way. A software application in this distributed system is just a component with possible utilizations not completely known at design time. The designer implements some functionalities into the component, but the component may be dynamically included in different temporary compositions in the globally distributed environment. The software component provides services to other software components and it may invoke services of other components. This architecture is in line with the dynamically changing organizations of the economy. Software components advertise their services and other software components can search for the desired services. In order to achieve the goals, software components can select and invoke the desired software services based on the service descriptions, the trust and reputation information available from different sources. In this environment, software components are formed into temporary alliances and their services are dynamically combined. The experiences learned in one temporary alliance are reused in another composition dynamically created later. This way, any software component available on the Web may become part of a Web application.

Agent-based computing provides a new software technology for this new changing environment of smart organizations. Agent technology allows that the creation of the complete functionality of the software system can be postponed beyond design, implementation, and deployment time to operation time, when the software components themselves compose their relation to other software components. This new way of software composition requires that the software components have dynamic and autonomous features.

It is also important that agent technology standards provide the glue for tightening the software components together. Agent technology standards provide machine processable, formal descriptions for the functionality, accessibility, and quality properties of the software components, the data used by the software components, as well as how they can be composed in a workflow. Agent technology also provides standards for registering and searching agents and their services in registries.

Agent technology also takes software components considerably closer to semantic interoperability, which is crucial to smart organizations. Semantics is the relation between the formal notation systems used by the computers and the real objects and notions used by humans. Although simple bit sequences may have semantic meaning, it is better to have the computer representation closer to the human representation, because this way computer interaction on a higher semantic level can be implemented more easily.

SUMMARY

In this chapter, we discussed how agent-based technologies can contribute to smart organizations. Agent technology forms the base of knowledge-driven, internetworked, dynamically changing systems like smart organizations. The most important characteristics of agents are that they are reactive, autonomous, have design objectives, can take initiatives towards their goals, have social abilities, and can interact with the actors in their environment. Agent technology emerged from artificial intelligence by dealing with distributed aspects, and lead to the semantic interoperability technologies of the current Internet. Agent architectures provide means for agents to organize and plan their activity on their own. The types of states multiple agents can achieve can be classified from stability, efficiency, and optimality aspects. Agents reach agreement to get to the desired state by exchanging messages. Agent interaction protocols build on communication protocols and strive to ensure community level results. Agent technology can also be viewed as a software engineering approach to design large, open, networked, dynamic software systems. Agent technology applications can be classified into three categories: distributed agent systems (or multi-agent systems), assistant agents, and multi-agent simulation systems. The methods and approaches discussed in this chapter show that agent technology is fundamental to smart organizations.

Chapter 4.3
IT-Based Project Knowledge Management

Michel J. Leseure
Al Akhawayn University, Morocco

Naomi J. Brookes
Loughborough University, UK

ABSTRACT

This chapter presents IT solutions supporting knowledge management initiatives within project organizations. The first section describes the background of the problem, that is the difficulty of managing knowledge in project-based organizations. The second section presents a model of knowledge management as the activity of managing compromises on a number of dimensions, and uses this model to present IT solutions for project knowledge management. The last section discusses future trends and key challenges and focuses on knowledge representation.

INTRODUCTION

This chapter primarily deals with project management and more especially the increasing tendency of modern organizations to use project organizations to carry out a range of vital operations or innovative activities. The use of project organizations is to be expected in industries for which this operating system is a necessity, e.g., the construction industry. The use of project management in these industries actually originated in the 1950s. However, the use of projects can now be observed across all industries, for new product development or for business performance improvement. This means that in today's economy the leverage of project performance on overall business performance keeps intensifying.

This chapter discusses project management from a knowledge management perspective. The concept of knowledge management, initially popularized by Nonaka (1991), has been quickly adopted by the business and communities at large; see Despres and Chauvel (1999) for a discussion of the rising popularity of the topic. This suggests that knowledge management is also a managerial approach which is here to stay.

The goal of this paper is to discuss IT applications, present and future, designed for project knowledge management. Capitalizing on existing knowledge for greater profitability is nothing novel: It has been implemented through management science since the dawn of the industrial revolution. This approach has only been possible in business sectors where operations can be highly routinized and can be improved in small steps. In the volatile and uncertain environment of project organizations, complexity has blocked such an effective management of knowledge.

BACKGROUND

Micro-Scale Knowledge Management

This chapter deals with the management of knowledge within and across project teams. The research approach used by the authors was to analyze the problem of project knowledge management at the operational level. In other words, this chapter does not discuss how to design a knowledge strategy and what kind of top commitment is necessary from top management. This is consistent with the school of micro knowledge management (μKM) as defined by Vergison (2000):

- Micro-scale knowledge management focuses on the capture, structuring and use of knowledge at a local level and does not necessarily require strong management support. It is not very sensitive to strategic plan variations.
- Macro-scale knowledge management is very sensitive to company strategic plans and it deals with knowledge flows within a large business entity. It definitely requires strong top management support and commitment.

As described by Vergison (2000) the micro-scale approach is based on the assumption that a top-down approach to knowledge management is rather ambitious and exposed to implementation problems. Thus, the goal of this chapter is to identify generic micro knowledge management problems faced by project teams and to describe what type of IT solutions have been or may be developed. This is not to say that any μKM problem can be solved with IT: In this chapter, many of the problems evoked can only be dealt with by using organizational design techniques. The goal of this paper is show how IT solutions can either solve some problems or facilitate the process of solving them.

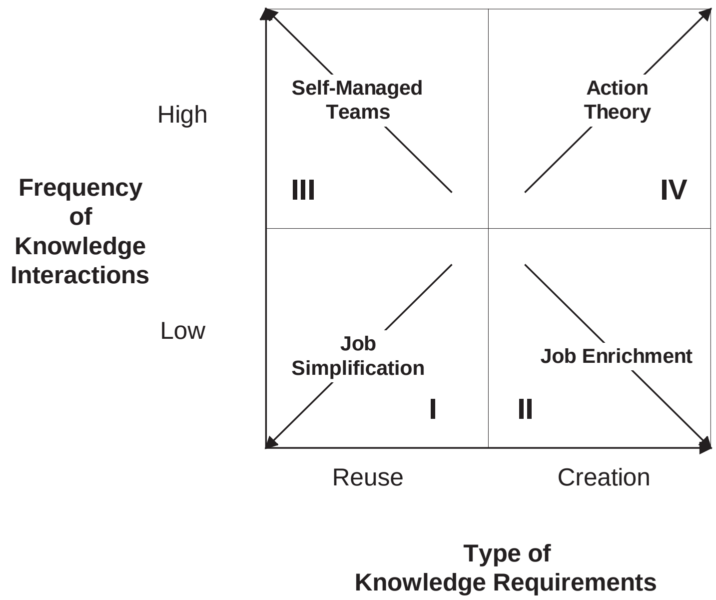
Job Context and Complexity of Managing Knowledge

Since its inception, knowledge management has already gone a long way and many models have been formulated. However most models, solutions, and techniques in knowledge management are either presented at the macro-scale level or in job contexts that are different from those encountered by project teams.

The typology of job design systems proposed by Leseure and Brookes (2000a) illustrates the criticality of the second point. Figure 1 indicates which job design theories are most appropriate when the context of knowledge usage is changing. The arrows indicate which job design practices are likely to be appropriate when one moves in a specific direction.

In this model, the technical interdependence of tasks and the environmental uncertainty of the task environment are combined to define the vertical contextual variable: the required frequency of knowledge interactions. Technical interdependency creates the background for knowledge interaction. Environmental uncertainty adds a time (frequency) dimension and controls how often these interactions need to take place.

Figure 1. Job design framework



Technical uncertainty is the second dimension of the context of micro-knowledge management. A low uncertainty describes a system that is primarily based on the reuse of routine knowledge. A high uncertainty occurs in systems where problems and products vary too broadly to be handled simply through reuse of knowledge. In high technical uncertainty environments, new knowledge needs to be created.

It is important to stress that the model in Figure 1 does not present four archetypes: Instead it presents a continuous space of systems. Hence, the horizontal axis origin reads as "0% innovation – 100% reuse" and its extreme point as "100% innovation – 0% reuse," and a system can be observed in any state within these two limits.

The point of focus in this chapter is the fourth quadrant, where the requirements of knowledge creation and collective work are merged together. The problem in this quadrant is to find how to smoothly combine the independence of the specialist and the requirement of frequent, extensive interaction.

Action theory is a relatively unknown school of job design which was originally developed by German researchers (Frese & Zapf, 1994). Work is defined as being action oriented, i.e., as being a collection of elementary activities. There are two important features of actions:

- An action encompasses a number of activities: defining a goal for the action, translating it into plans, executing these plans, and finally, receiving feedback from the action.
- Any action is subject to an individual cognitive regulation. Some actions become highly routinized (e.g., an assembly line worker's task) whilst some can never follow a rigid, identical structure (i.e., a commercial engineer's sales tactic).

The golden rule of action theory is that the active involvement of an employee is only possible if this employee is dealing with the entire action and not part of it. Second, action theory is probably less prescriptive than any other school in terms of practical recommendations. The tasks and context of executions of these tasks are the determinant of the final job design to implement. For this reason, action theory has been coined as a dynamic form of job design (for more information on these schools of job design, see Leseure & Brookes, 2000a).

Newman (1999) reports that lean production (a concept that relies extensively on teamwork and that lies in Quadrant III) improves productivity at the cost of innovative capability. This confirms the opposite, diverging directions of job enrichment and self-managed teams, and the fact that the task of seeking the benefits of both types of job design systems is not trivial. This is why Quadrant IV is in management terms the most difficult of all regions. It is the environment where innovation needs to take place on a daily basis and in parallel with design reuse. Knowledge interactions need to be frequent and efficient. This chapter draws the specifications of an IT-based knowledge management system for organizations operating in Quadrant IV.

Literature Review

A number of research studies, all from the UK, have recently targeted the improvement of project knowledge management. Gilbert and

Table 1. Data sources

Company	Industry	Interviewees	Size of Organizational Unit Being Discussed	Project Strategy
1	Aerospace	Project Manager	More than 1000	One-off
2	Aerospace	Business Development Manager	Less than 100	Focused Innovation
3	Aerospace	Program Manager	Less than 100	Focused Innovation
4	Aerospace	Engineering Manager	Less than 100	Focused Innovation
5	Aerospace	Program Manager	Between 100 and 500	One-off
6	Utilities	Project Manager	More than 1000	One-off
7	Capital Goods	Vice President	More than 1000	Both
8	Utilities	Director	More than 1000	Both
9	Capital Goods	Director Chief Engineer	Less than 100	One-off
10	Capital Goods	Director	Less than 100	Focused Innovation
11	Construction	Division Director Foreman Project Manager Construction Planner Estimator	Between 100 and 500	One-off
12	Service	Division Director	More than 1000	One-off
13	R&D, Engineering	Division Director	More than 1000	One-off
14	R&D, Engineering	Project Manager	More than 1000	One-off

Holder (2000) take an organizational stance on the problem of project knowledge management and propose organizational consulting services to address these problems. Braiden and Hicks (2000) study the management of knowledge in the engineered-to-order industry and adopt primarily a process-oriented approach to managing project knowledge. The IKON project studies the management of knowledge in conjunction with innovation processes (Hislop, Newell, Scarbourgh & Swan, 2000). In the IKON project, the term innovation is used in its broadest possible meaning—change of practices—and the objectives are to formulate best practices in knowledge management terms when a company is innovating. Finally, the B-Hive project formulated a Cross Organizational Learning Approach system, labeled COLA. COLA consists of innovative processes supported by information systems for the review, evaluation, feedback and organizational learning linked to project work (Orange, Cushman & Burke, 1999). The COLA system will be mentioned later in this chapter as an example of an IT solution.

Data Sources

The research and model presented in this paper are the outcomes of a multi-disciplinary research project at the University of Loughborough (UK). The data was collected through semi-structured interviews focusing on knowledge management problems and practices. Table 1 displays some general information about the interviews.

PROJECT KNOWLEDGE MANAGEMENT

Knowledge Management as Managing Compromises in System Configuration

Since the goal of this paper is to present which IT solutions have been or should be developed to support project knowledge management, it is necessary to benchmark the various problems observed in the companies surveyed against a generic model of an effective knowledge management system.

The model of knowledge management as compromise management of Leseure and Brookes (2000b) will be used to this end. This model is based on the premise that what is being questioned through the recent focus on knowledge management is the notion that work groups, teams, and organizations are systematically effective at managing collective knowledge. A more realistic model of collective work is to acknowledge that there are a number of dimensions which constrain, limit, or block an effective and timely exchange of knowledge between the different members of a project team.

The following list of compromise dimensions is used:

- Reuse/Innovation: Is a work unit achieving a productive compromise between the reuse of knowledge and innovation? Or does it have a tendency to reinvent the wheel? Or does it have a tendency to be a poor innovator?
- Collaboration/Competition: Is a work unit achieving a productive compromise between collaboration and competition (1) in its internal, interpersonal and intergroup interactions and (2) in its interaction with external parties?
- Tacit/Explicit: Is an organization achieving a compromise between the tacit and explicit forms of knowledge that it is manipulating in the course of operations? Or does is suffer from the predominance of tacit forms of knowledge? Or a predominance of explicit forms of knowledge?
- Informality/Formality: Does an organization achieve a productive compromise between informality and formality? Or does procedural compliance block spontaneity in the workplace? Or does spontaneity and

informality lead to chaos and anarchy?

- Internal/External: Does a work unit manage effectively its compromise of internal and external knowledge? Or does it tend to take unnecessary risk by reinventing or taking the responsibility for elements of knowledge that should be brought in by third parties? Or has a work unit lost its core competencies?
- Individual/Group: Does an organization distribute roles and responsibilities to individuals and group in a productive manner? Or does it suffer from knowledge bottlenecks attached to individuals? Or does it suffer from groups being unable to manage knowledge efficiently?
- Private/Public: Does an organization manage effectively the commercial sensitivity attached to knowledge? Does it suffer from an overly secretive corporate culture? Or does it suffer from diffusing its knowledge too broadly?

According to this model, a knowledge management problem can be explained by one (or several) imbalance along these dimensions.

Reuse vs. Innovation

Common Problems

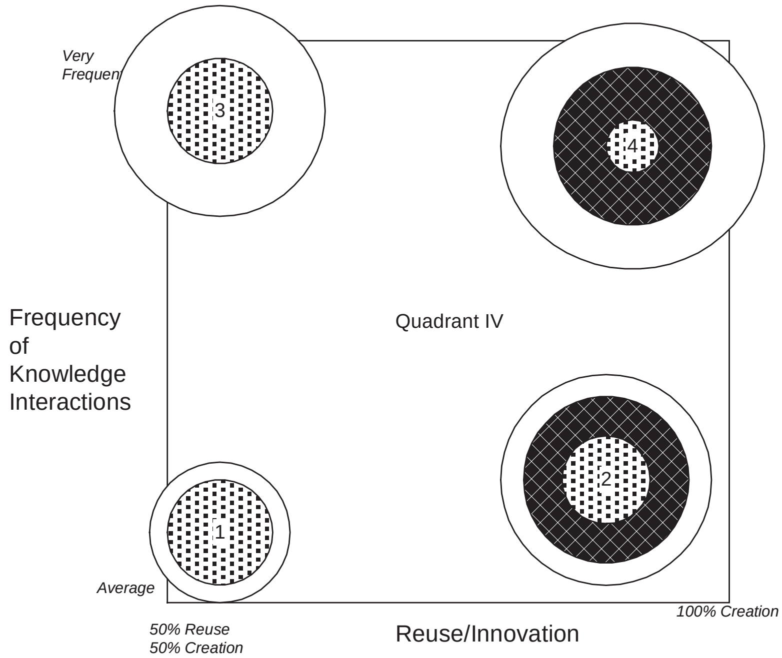
In the course of the research interviews, most interviewees stressed that they had difficulty with reusing knowledge. To be more precise, they indicated that they had problems re-creating previously used knowledge without making new mistakes and in many cases, without making exactly the same mistakes that they did in the past. This can be analyzed as an indication of a double problem:

1. Knowledge reuse capabilities are poor in project teams. This is not surprising if one considers that project organizations are structured for knowledge creation, i.e., to formulate solutions to new problems. As the organization of a project team targets knowledge creation capabilities, a side effect could be to naturally create a tendency to “reinvent” the wheel.
2. Despite the advantages of being organized as a project team, knowledge creation and innovation remain delicate tasks, and without clear guidelines, project teams are likely to reproduce past mistakes.

Some of the interviewed companies declared having solved these problems by adopting a focused innovation strategy as defined by Sivaloganthan and Shahin (1999): A company merges an existing design with other independent designs to develop a common core design, which can then be built in a variety of products. With this strategy, knowledge reuse is linked to the core design and easily managed and controlled. Innovation is limited to product variations and therefore is also easier to manage. However, it should be clear that this focused innovation strategy consists in moving away from Quadrant IV, as reuse increases and innovation diminishes. By generalizing this idea, one is at risk of transforming the upper right-hand corner of Quadrant IV into a “no-man’s-land” where activity is deemed impossible. Many companies, those selling engineered-to-order products and services (“one-off” projects), operate in this zone of Quadrant IV and are in crucial need of better knowledge management: Their problem is to improve innovative capabilities whilst reusing any relevant knowledge. This is illustrated in Figure 2, where a distinction is introduced between generic project knowledge and project-specific knowledge.

This section addresses how all the companies displayed in Figure 2 can improve their knowledge reuse capabilities. The issue of dealing with dealing with knowledge appropriation (a problem faced especially by Companies 2 and 4) is discussed in the Internal vs. External subsection.

Figure 2. Relative importance of reuse and creation in Quadrant IV



In this graph, dealing with project-specific knowledge (outer white circles) is a knowledge appropriation task which is different than knowledge creation. At the origin of the quadrant, Company 1 deals with a limited knowledge stock composed of a reusable core (dotted inner circle) and of some project-specific knowledge which requires integration. Company 2 deals with a limited amount of project-specific knowledge but has to create of lot of knowledge linked to its technical core (black circle). Company 1 primarily reuses knowledge in its technical core whereas Company 2's technical core is about innovation. Company 3 requires a lot more project-specific knowledge than creating new core knowledge: It is a problem of appropriation rather than creation. Company 4 combines the challenges faced by Companies 2 and 3.

Improving Knowledge Reuse

Matta, Ribière, Corby, Lewkowicz and Zaclad (2000) define project memory as "lessons and experiences from given projects" or as "project definition, activities, history and results." Although the model proposed by Matta and his colleagues deals exclusively with design projects, it can be generalized to other projects. Project memory is structured in two components:

- Project characteristic memory: This part of the memory includes all the information about the context, the organization and the results of the project. For instance, one may recall what the objectives of the project were, specific instructions received, the environment in which the project took place, who was part of the project team, what was each participant's respective responsibilities, etc.

- Project rationale memory: Project rationale memory covers the problem solving stage, that is, a description of which methodology was used and why, a list of the actors and their roles and views about solving the problem. This may include the memory of dissenting views within the project team. This may also include the memory of alternative solutions considered but rejected and of the rationale for doing so. Finally, project rationale memory includes all decisions made, from arguments about the decision to the analysis of each pro and con about the decision.

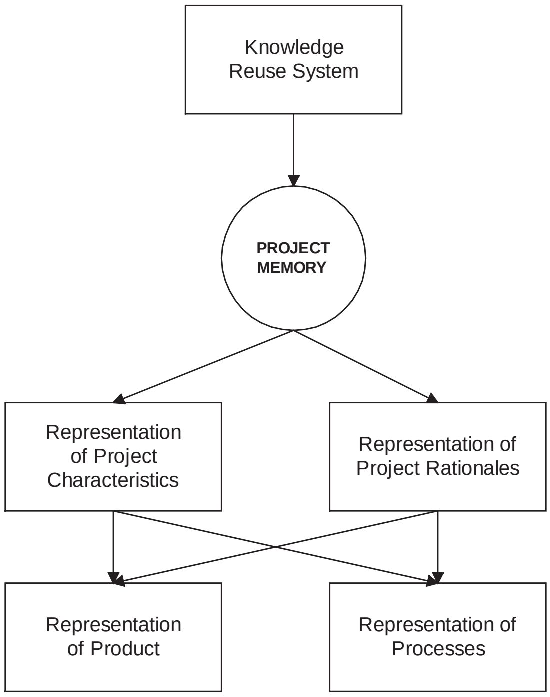
During the research interviews, most interviewees were aware of the possibility of using knowledge intranets to "memorize" knowledge. One of the interviewed companies in particular had developed internally a state-of-the-art knowledge intranet system including a bought-in search engine. However, after a review of what this intranet system could do, it became clear that it only dealt with project characteristic memory. At best, the system could memorize a problem with simple specifications (i.e., reasons for interrupting work on a site) and who solved that problem in the past in the company. This is consistent with the technical assessment of Matta et al. (2000), who report that as project characteristics are usually described in textual documents, tools that index textual documents such as LEXTER and FX-Nomino combined with database management tools are sufficient to implement a system for project characteristic memory.

Thus, the real challenge in terms of improving reuse of knowledge is to find a tool to memorize project rationales. This is a difficult issue given the evasive and fuzzy form of project rationale knowledge. Matta et al. present a review of existing models (2000):

- The tool IBIS is a process-oriented approach to support complex problem solving by structuring a problem as "issue, positions and arguments."
- QOC is a decision-oriented approach which structures rationales as "questions, options and criteria."
- The Drama system uses goals, options, criteria and choices to build a decision table representative of a decision made.
- DCRS is a system based on three sub-models. An intent model describes the problem at stake and its context. A version model represents the different options in terms of solutions, and the argumentation model describes how the decision is made.
- DIPA is a model attempting to model cognitive processes in terms of design rationales. It structures a rationale formulation situation as a problem, facts, interpretations, abstract and actual constraints, proposition and arguments. An interesting feature of DIPA is the capability of differentiating the processes of analysis and synthesis and memorizing both.

During the research interviews, many project managers or senior managers agreed that their organization would benefit from more knowledge reuse. Although they did not have an IT system which would capture project memory, it was clear that they themselves had memorized projects' characteristics and rationales. Despite this fact, they were still unable to generalize knowledge reuse within their company. This means that project memory is a necessary but not a sufficient condition for knowledge reuse. The other component that is needed is a reuse management system that provides a systematic method to specify when to store, retrieve, and update project memory. Shahin, Sivaloganathan, and Gilliver (1997) provide an

Figure 3. Project knowledge reuse system



example of such a reuse system in the case of a design project.

Figure 3 displays the full structure of a knowledge reuse system as discussed in this section. As shown in Figure 3, one should bear in mind that a project memory model relies on two other systems: one representing the product (or service) and the second representing processes.

Collaboration vs. Competition

The collaboration/competition compromise dimension is concerned with the environment of a project task. Whereas a competitive spirit can be a powerful driver of productivity, too much competition can be unproductive. The actual balance between competition and collaboration is a function of the context of the project. In the research interviews, managers all agreed that their organizations could benefit for more collaboration at several levels:

- Across ongoing projects: Project managers' performance is assessed on their ability to complete a project on time, within budget, and according to specifications. Project managers consider (legitimately) that time spent visiting another site to help a peer and sending another team member to another site would only endanger their own performance. This blocks any type of cross-project collaboration, and hence blocks knowledge sharing.
- Across hierarchical levels or fields of specialization: During the interviews, a lot of problems were identified with people refusing to collaborate because "it was not their job." In these cases, individuals had job descriptions and although they had the knowledge to solve a problem, they would not do so because they felt this violated the instructions that they had received. This is clearly a confusion of Quadrant I and Quadrant IV. This observation is confirmed by experts in work design, who report that the job simplification school tends to often be a "default model" (Parker & Wall, 1998).
- Along the supply chain: Subcontractors often perceive their relationship with their customer as adversarial. Their customer will require tasks not laid out in the contract whilst the supplier will try to provide less. This leads to a form of relationship management based on strict contract management and leaves little room and incentive for knowledge sharing along the supply chain.

It is necessary to distinguish the two reasons explaining why collaborative behavior is difficult in project teams. The first reason is cultural: Through involvement in projects, individuals have developed a certain distrust of suppliers and dislike the project schedule not being respected. The lessons learned are reinforced by senior managers' stance on these problems and by the guidelines they issue. These are internalized and become a way of thinking. When cultural habits turn out to be unproductive, they need to be changed. This task is addressed by the management and organization design disciplines and is beyond the scope of this chapter.

The second reason is infrastructural: Individuals do not collaborate because they feel that doing so would violate a written procedure and would go against orders; they cannot collaborate because they do not know who to collaborate with, or if they know, they are not able to collaborate because their counterpart is located elsewhere.

The IT solutions discussed in this section attempt to overcome infrastructural barriers. Although cultural barriers are not discussed here, they should not be overlooked. As stated by Davies (2000), using IT to facilitate knowledge sharing gives an opportunity to discover cultural resistance and to overcome it. In other words, IT can be used in this case as a technology driver to improve collaboration.

Know-who databases are the simplest IT tools that address the problems described above. Simply put, they allow a user to know who to contact to find the answer to a specific problem. It is noteworthy that a know-who database is a subsystem of the project memory system described in an earlier section.

Walström and Lindgren (2000) discuss the problems observed with five stand-alone know-who databases systems in seven companies through 24 semi-structured interviews. They identified five problems areas:

- Knowledge mapping: There is an ambiguity regarding what competencies are and how to provide an organizational structure for them.
- Knowledge evolution: Know-who knowledge is a volatile entity as both competencies and people change with time. This issue is complicated by the fact that individuals may also voluntarily omit some information when they fill in forms or prepare CVs.
- Knowledge isolation: The system may point to the individual who holds the knowledge sought, but hierarchy and/or procedures may prevent actual access to this individual or to the knowledge held.
- Knowledge interaction: Once a contact person is identified, there are often no corporate mechanisms to initiate the dialogue and for knowledge sharing to take place.
- Operative knowledge management: Know-who databases are unable to handle the logistical aspect of knowledge sharing. For instance, the system cannot express if an individual is free to collaborate when queried.

The conclusion of Walström and Lindgren (2000) is that know-who database systems often do not differ significantly from traditional personnel files as they only name individuals.

As stated in the section on the reuse/innovation compromise dimension, the concept of project memory needs, in order to be implemented on an IT system, an effective representation scheme of both product and process. Therefore, the concept of project memory as defined previously provides a solution to the knowledge mapping problem mentioned by Walström and Lindgren.

The issues of knowledge evolution, isolation and interaction are addressed by virtual communities of practice. A community of practice is a group of people who have similar functions or duties in a corporation, without necessarily knowing each other. There is nothing formal about communities of practice: They are an informal network of individuals connected by mutual interest and they get involved in the community on their own accord. Their corporation provides for them the platform and the infrastructure for knowledge sharing. An example of such a system is BT's

Jasper system, which is a WWW-based designed for knowledge sharing within BT. Jasper holds a list of registered users details and uses intelligent software agents to organize news, users' interests and users' documents (Davies, 2000). Although it is clear how such systems address the issues of knowledge evolution (as they are designed to evolve as users and their interests change) and knowledge isolation (as content is available from the system), it does not address the operative issue.

The operative component is a challenge left for IT solutions developers. The challenge is to go beyond connecting the people and helping them to actually collaborate. For example, BT has begun to develop interesting job trading systems where BT maintenance fleet employees can trade jobs whilst on the road. The objective is to optimize the productivity of the maintenance fleet by constantly revising its schedule according to the problems faced earlier in the day. This idea can be generalized to a "project trading system." The scope of such a system would be to support information sharing (or information trading), job trading (exchanging two workers between two project teams), and job sharing (temporarily sending a team member to another team). The difficulty in implementing such a system is to integrate it fully with the corporate planning system and to verify that trading/sharing activities do result in increased productivity.

Tacit vs. Explicit

During the research interviews, the following common problems were identified:

- Many companies suffered from knowledge being held in a tacit form. This, however, was not a universal problem. Some companies held tacit knowledge and had no problems working with it, whilst others need to go through the internalization process suggested by Nonaka (1991), that is, to transform tacit knowledge into explicit knowledge.
- In some cases, some companies indicated that although they may have an explicit source of knowledge, for instance, documents about a past project characteristic, they did not feel confident applying this knowledge, as they were unsure about the rationale aspect of this explicit knowledge.

In this section, we discussed IT issues in three cases:

1. The case of a company which has problems transferring tacit knowledge but which believes that the tacit/explicit balance is respected. In other words, it does not want to internalize knowledge, just to transfer it in a tacit form.
2. The case of a company which has concluded that it suffers from the tacit character of its knowledge and which has decided to internalize it. In others words, this company wants to use IT to reposition itself on the tacit/explicit dimension.
3. The case of a company which is satisfied with its tacit/explicit balance but its explicit knowledge base lacks scope and quality.

In the first case, the problem is to facilitate the transfer of tacit knowledge between different parties. The problem here is not the tacit nature of knowledge but the difficulty of transferring it. Nonaka (1991) describes this transfer as being based on a socialization process, for instance, between a master and an apprentice. This is a knowledge sharing problem and can be addressed by virtual communities of practice or project trading systems, as discussed in the collaboration/competition section.

In the second case, knowledge engineering and knowledge-based systems (KBS) provide the solution to internalization of tacit knowledge.

KBS are IT systems specialized in problem solving and decision making from the application of a substantial body of knowledge. With knowledge engineering, the knowledge of experts is analyzed, modeled and documented (i.e., made explicit). Once implemented in a knowledge-based system, the application of knowledge is automated. As there is an extensive literature available about KBS, the characteristics of these systems are not discussed further in this chapter.

In the third case, it is necessary to consider two different scenarios:

1. The poor quality of explicit knowledge is linked to the internalization process. For example, Carter (2000) gives the example of a utility company where a large body of engineers was replaced by a rule-based engineering system. When asked to comment about the knowledge engineering process, one of the engineers declared that since the rule-based engineering program was not a viable idea, he was purposefully giving wrong information to the knowledge engineers. In this scenario the problem is linked to the solution and not to knowledge itself. This is often an issue as verification and validation of KBS are issues that tend to be overlooked (Preece, 2000). Verification means checking that the specifications are matched (building the system right) whereas validation means checking that the system actually works (building the right system). The development of effective verification and validation procedures is a challenge for IT.
2. The second scenario takes place when the company has internalized some knowledge, but the nature of the knowledge itself is such that there is an unavoidable loss of content when converting it from a tacit form to an explicit form. The integration of a KBS with a project memory system addresses this problem as the project memory concept includes object attributes such as options, perspectives, opinions, etc. However, it is more realistic to acknowledge that there are limits to what explicit knowledge can convey. In this case, as stated by one of the interviewees, what needs to be in place is a system of "holding hands," i.e., a system where an individual can validate his or her assimilation of explicit knowledge by comparing it to the tacit knowledge of another individual. Communities of practice provide a platform for this.

Informal vs. Formal

It is more difficult to identify generic problems along this compromise dimension as the interviewed companies exhibited several types of problems:

- In some companies, knowledge was not accessed by some parties because of problems of compatibility between software, versions and formats. This is a case of lack of formality in the structure of information.
- In other companies, the opposite problem was observed. The structuring of information would be so formal that it would actually constrain the content of the message. For example, one interviewee reported that a memo from a project manager to a senior manager could only be written in a specific style and tone. Likewise, the answer from the senior manager would follow specific guidelines. Such a "bureaucracy of knowledge" prevents certain concepts (emotions, opinions, etc.) to be carried in a message. This level of formalism was seen as unproductive.
- Some companies relied heavily on procedures and a mechanistic organization of operations. This formalism can block

knowledge sharing, collaboration, innovation and any other activities based on informal relationships.
- In stark contrast, other companies preferred a more organic organizational approach and did not stress formalism and strict compliance to written operating procedures. These companies suffered from too much anarchy in operations.

As in the case of the collaboration/competition dimension, most of the problems faced in informal/formal dimension are either cultural or infrastructural. This section discusses how to address the latter and how to use IT as a technological driver to tackle the former.

First is the case of the company aware of the fact that it suffers from the fact that it is too formal. In this case virtual communities of practice provide the platform for informal exchanges as they are precisely designed as communities escaping the rules and structure of the formal organization.

In the second case, a company may be aware that it faces problems along the informal/formal dimension and may decide to improve its knowledge management capabilities by repositioning itself on this spectrum. This calls for a critical analysis of the relationship between project knowledge and project processes to identify when and why knowledge is not passed on, is lost, or is wrongly applied. What is needed in this case is a tool targeting the improvement of project knowledge management through process modeling. Modeling workshops are computerized integrated systems designed with this task in mind. Modeling workshops permit simulation of working practices under different scenarios of activity/role matrices within a working group and can help diagnose where knowledge management is inefficient. For an overview of MAMOSACO as an example of a Modeling workshop, see Vergison (2000). Another example is the COLA review process (Orange et al., 1999). Whereas MAMOSACO provides an example of a system that can be used for simulation (and improvement) purposes, the COLA review process is an example of a system able to trigger reflection and the formulation of lessons learned. COLA was developed in the construction industry to address the problem stated by Fisher (1998): "The construction industry struggles with its ability to capture the lessons learned from its projects and activities for the benefit of future, similar work." According to the designers of COLA, what lacks in the construction industry is reflective practice. Thus, COLA was designed to provide a review process forum for the social construction of knowledge.

Internal vs. External

In the case of project knowledge management, reaching a balance along this dimension means that all forms of generic project knowledge are internal to the company and are passed on to the different generations of project teams. It also means that project teams are able to assimilate project-specific knowledge without developing a full expertise about this external knowledge.

Common problems along these dimensions quoted by the interviewees were:

- A project team has to solve a very specific problem. Although there are sources both within and outside the company that could contribute to the supply of knowledge relevant to this problem, these sources are too dispersed (in space, time, objectives and values) for the project team to assimilate and aggregate their inputs. Instead, they prefer to engage in the risky and costly exercise of creating the missing knowledge themselves with limited resources. This often results in wrong decisions.
- A company has lost its internal competencies as people have moved on. In this case, internal knowledge has become external.

In the second case, project memorization and KBS are two IT solutions that provide the benefits of making sure that core knowledge remains within the company, as it has been internalized and embedded in IT systems. One of the interviewees gave the example of a key competency related to product testing. His company had a significant competitive advantage in terms of verifying that a product would match their industry regulations. Although this knowledge could have easily been applied from a manual, the company preferred to use a computerized system. Any modifications of the system are subject to extensive documentation requirements so that the company can trace (and revert when necessary) the evolution of the system. The interviewee stressed that the advantage of this procedure was to provide full management control about key internal knowledge.

A second interviewee provided the IT solution to the problem of assimilating quickly and in a cost effective manner external knowledge. One of his project teams had to work on a construction project where local conditions (weather, topology, nature of soil) were such that it was not clear how to apply regulations. In more standard projects, how to interpret and apply regulations was part of the experience of the company. In this specific project, conditions were such that the project team had to consider constraints and issues not dealt with previously in the company. However, there were a number of individuals from the project team, the company, and outside the company that had some ideas and experiences in some aspects of the problem faced by the interviewee. The problem was to find a tool that allowed the interviewee to tap into this dispersed source of knowledge and to aggregate the collected information into a whole. The interviewee decided to use a groupware system (in this case, Lotus Notes) to facilitate this acquisition and assimilation process. In his opinion, the project was a success thanks to the use of the groupware system.

In addition to groupware systems, knowledge intranets are useful in the acquisition and assimilation of external knowledge, provided that they are enriched with knowledge discovery and data mining capabilities. This constitutes an automation of the processes supported by groupware systems, but it is doubtful that the complex problems handled by project teams can all be solved by knowledge discovery applications, at least at the time of writing this chapter.

Individual vs. Group

The interviewed companies mentioned the following problems along this dimension:

- Knowledge retention, extinction and dominance: In an organizational process, an individual becomes a knowledge bottleneck when he or she retains some knowledge useful at the group level. A first major risk associated with knowledge retention is that of knowledge extinction when the individual or group at stake leaves the company. A typical example of knowledge extinction is the retirement problem: When an individual retires he or she takes with him or her product and process knowledge. The company often has to find a last-minute "quick-fix" solution to cope with this event. Downsizing operations were also blamed by interviewees as a factor weakening a group's knowledge stock. A second risk of knowledge retention is to use individually held knowledge to build authority and/or bargaining power. In this case, dysfunctional processes leading to delays, low innovation and poor performance can be observed.
- Knowledge dispersion: Knowledge is dispersed in and outside the organization but its application can only take place at the group/team level. This is a problem commonly encountered by project managers

installing IT systems or change programs. Knowledge exists dispersed in individuals but it is difficult to create group awareness.

- Knowledge factions: Knowledge may exist in different (conflicting) versions in different individuals or groups within the company. When different knowledge factions meet in a project team, a number of disputes and political issues arise. In the worst-case scenario, several people work in a project team with different objectives and specifications, as they refuse to exchange their information and experiences.

The basic challenge behind the individual/group compromise dimension is the management of ownership rights. In other words, it is to decide who has precedence and ownership of different classes of knowledge.

Knowledge retention is a problem solved by knowledge engineering as they force the expertise of an individual into a project memorization system. Another approach is to detect when knowledge retention is unproductive with a modeling workshop system. This would allow the company to reposition itself on the individual/group scale after it has decided if a specific class of knowledge is better owned by a single individual or by a group of individuals.

The knowledge faction problem is addressed by intranets and communities of practice. The knowledge dispersion problem is addressed by groupware systems.

All these modules (project memorization, modeling workshops, knowledge intranets, communities of practice and groupware systems) may all include their internal ownership rights specifications. However, as they all share the same needs, an optimal knowledge project management system should include a unique ownership rights module.

Private vs. Public

Whereas the individual/group dimension addressed who should own an element of knowledge, i.e., has the right to create and modify it, the private/public dimension defines who has the right to access and apply this knowledge.

The research interviews revealed the following generic problems:

- Too much corporate secrecy results in individuals needing some knowledge not being granted access to it. Such a corporate policy is motivated (1) by the fear that if too public, knowledge could get to the competitors and (2) by the fear that individuals may not be able to apply the knowledge properly.
- Too much leniency in protecting information does result in the problems quoted above and can also create anarchy and unproductive speculation about strategy, product and processes, as individuals feel free to voice their different perspectives, be they aligned or not with corporate objectives. For example, there is nothing more unproductive than the analysis of a quality problem about a cutting tool degenerating into a debate about the roles of project managers. Although the debate about project management may be relevant (by the parties allowed to do so), the debate about cutting tool quality should be addressed with the relevant actors focused on relevant knowledge.

The management of access rights to information is in fact easier to manage through IT than human systems. In the example of the product testing computerized system quoted above, the interviewee stressed that only accredited individuals were allowed to access the content of the software along specific rules. For normal team members, they interacted with the system through queries and answers.

FUTURE TRENDS

This section is divided in two parts. Throughout this chapter it is clear that knowledge representation is a fundamental issue in project knowledge management, especially with the concept of project memory. Project memory and representations about product and process are the link between each of the IT systems discussed in this chapter. Therefore, a unique and universal knowledge representation scheme is a sine qua non condition of an integrated project knowledge management system.

Challenges in Knowledge Representation

The key challenge in terms of knowledge representation is to develop a scheme which is universal enough to be queried and updated by all the other components of a project knowledge management system. To illustrate this challenge, consider the case of one of the interviewed companies which tried to design an expert system for the pricing of its project. The product is engineered to order production machines. The pricing is done by top management of the company (only three senior managers know how to formulate a price quote). Needless to say, this pricing knowledge is entirely tacit and unstructured. After a few knowledge engineering sessions it appears that the experts used three key pricing schemes:

- Technical pricing: The experts decompose a component of the machine in material, component and working hours. Then, they add all of the elements up and take into account margins and overhead expenses.
- Case-based reasoning: The experts see that a subset of the machine is similar to a subset previously designed on another machine. As they have some first-hand experience on what this previous subset cost, they can formulate a price estimate directly. It is noteworthy that the accounting department did not have any cost accounting capability and did not formulate what the costs of subsets were; in fact as far as accounting was concerned there were no subsets. The price estimate of the experts was based on the initial quote corrected for the problems encountered when the subset was designed and built.
- Function pricing: Experts have also devised rules of thumbs that are based on classification of functions. For instance, experts were able to give a price for the "grasping" function provided that they were specified the weight of the element to grasp, the speed of the machine, the dimension of the object, and the degree of precision required when grasping.

The problem is that when pricing, experts use these three approaches simultaneously. Although this may be perceived as a methodological flaw, this price assessment flexibility is what allows experts to give the price of a machine before it is designed solely from its specifications.

The accounting department of this company was particularly interested in this pricing project and wanted to develop a cost accounting system that would provide direct feedback on the original project. The problem was that although a pricing expert system was developed, it added apples and oranges, as it used the three approaches. It was a question-driven system, rather difficult to use, which did not integrate a concept of "machine" that could be tested for consistency and completeness. The accounting department implemented a cost accounting system based on subsets, but there was never any integration between the two systems.

This example illustrates the challenge faced by IT in terms of knowledge representation. It is easy to develop a knowledge representation or a set of representation schemes for one application but much more difficult to have a universal and flexible representation scheme for a variety of applications.

Other Key Challenges in Project Knowledge Management

The other key challenges are the development of modeling workshop systems and project trading systems. Modeling workshops are critical to project knowledge management as they address the performance assessment of how knowledge is managed within projects as well as how projects are organized in relation to the use of knowledge. It is through the modeling workshops that improvement in methods and practice for knowledge management comes from. Project trading systems can also contribute to a new generation of project management techniques as they allow project teams to move away from planning and scheduling rigidity toward a more flexible and dynamic approach to organizing projects.

CONCLUSION

In this chapter, a number of IT systems were presented to address project knowledge management issues. Amongst the most important are project memorization systems, knowledge intranets, know-who databases, communities of practices, knowledge-based systems, modeling workshops, etc. As stressed in the first part of this chapter, each of these systems can be easily developed at an operational level. It is possible to envision a large, integrated computer system including all the different systems discussed in this chapter. However, one should realize that such a system would definitely escape the micro-scale knowledge management approach used here: Such an integrated system would require considerable resources and top management support. Moreover, as stressed in the section discussing the issue of knowledge representation, a large integrated system could require such a level of formality in its specification that it could fail to capture the flexible methods through which knowledge can effectively be transferred between project teams. Although there is a cost to develop non-interfaced, isolated IT applications within a company, the research interviews showed that companies and project teams seldom have a crucial need in all these systems at once. For instance, "one-off" project organizations had a need for knowledge reuse and reflection process, IT project implementation teams had a more crucial need for communities of practice, large R&D department for knowledge intranets, and large project sites for groupware systems. These companies confirmed that once identified, simple and cost-effective IT tools could be built and adopted.

Chapter 4.4
Domain Ontologies

Matteo Cristani
University of Verona, Italy

Roberta Cuel
University of Verona, Italy

INTRODUCTION

In conceptual modeling we need to consider a general level of abstraction where the domain of interest is formalized in an independent way with respect to the specific application for which the conceptual modeling process is performed. This leads to an integrated approach that takes into account knowledge about a domain and metaknowledge about a methodology. Indeed, knowledge about a domain is represented by a system of concepts and instances that reify the knowledge that is managed within a domain, and the metaknowledge about a methodology is the description of the knowledge deriving from the method used. For instance, when a technology is used to unveil ontologies within a specific domain, the knowledge about the domain is the resulting ontology, and the metaknowledge about a methodology is the description of the method used to construct the ontology. In this article, a novel method for the creation of both upper level and specific domain ontologies, called the bidirectional method for developing ontologies, is described. In particular, it will guide the developer to obtain ontologies resulting from the combination of both top-down and bottom-up approaches. The first one focuses on conceptual modeling through "armchair" research (philosophical, psychological, sociological aspects) and figures out a formal draft schema. The second approach employs an automatic (or semiautomatic) extraction of categories, taxonomies, partonomies, and dependency graphs in particular from linguistic corpora of documents related to the topics of the domain.

BACKGROUND

Formal ontologies are a popular research topic in several communities, such as knowledge management, knowledge engineering, natural language processing, artificial intelligence (AI), and others (Fensel, 2000). Formal ontology can be defined as the systematic, formal, axiomatic development of the logic of all forms and modes of being (Cocchiarella, 1991). More generally, we employ the term formal ontology to designate an explicit specification of a shared conceptualization that holds in a particular context. In other words, an ontology provides an explicit conceptualization that describes semantics of data, providing a shared and common understanding of a domain (from an AI perspective, see the definitions of Gruber, 1998, and Jasper & Ushold, 1999). Ontologies are used to manage knowledge within and among communities, to manage and organize corporate knowledge bases, and to negotiate meanings among individuals. Moreover, ontologies are used to share knowledge among people, and heterogeneous and widely spread application systems, such as semantic-Web applications (Schwartz, 2003). They are implied in projects, as conceptual models, to enable content-based access on corporate knowledge memories, knowledge bases, or data warehouses. They are employed to allow agents to understand each other when they need to interact, communicate, and negotiate meanings. Finally, they refer to common information and share a common understanding of their structure.

In computer science, knowledge management, knowledge representation, and other fields, several languages and tools exist for helping final users and system developers in creating good and effective ontologies. In particular, various tools help people in manually or semiautomatically creating categories, partonomies, taxonomies, and other organization levels of ontologies. The generally accepted term to designate these tools is ontology editors. Some of them are open source such as Protégé-2000, KAON, and SWOOP, and others are commercial suites for knowledge management based on ontology development, such as tools provided by the onto-Knowledge Project (for an in-depth description, see http://protege.stanford.edu, http://kaon.semantic web.org/, http://www.mindswap.org/2004/SWOOP/, http://www.ontoknowledge.org/index.shtml).

Some Important Methodologies

Behind these tools and techniques, different (domain-independent) approaches and methods are used to develop numerous heterogeneous ontologies. In particular, Ushold's (2000; who proposed codification in a formal language) methodology and methontology, which constructs an ontology in a sequence of intermediate representations finally translated into the actual object (Fernández, Gòmez-Pérez, & Juristo, 1997), are the most representative. Here are short descriptions of some important methodologies:

- One of the first modules of the foundational ontologies library is the descriptive ontology for linguistic cognitive engineering (DOLCE). DOLCE is an ontology of particulars and refers to cognitive artefacts that depend on human perception, cultural imprints, and social conventions. This ontology derives from armchair research in particular, referring to enduring and durable entities from philosophical literature. The main authors' idea is to develop not a monolithic module, but a library of ontologies (WonderWeb Foundation Ontologies Library) that allows agents to understand one another despite enforcing them to interoperate by the adoption of a single ontology (Masolo, Borgo, Gangemi, Guarino, & Oltramari, 2002). Finally, basic functions and relations (according to the methodology introduced by Gangemi, Pisanelli, & Steve, 1998) should be general enough to be applied to multiple domains, be sufficiently intuitive and well studied in the philosophical literature, and hold as soon as their relations are given without mediating additional entities.
- In Gatius and Rodríguez (1996), the authors developed a three-step process (natural-lan-

guage interface generator [GISE]) to build a domain ontology: the building and maintenance of general linguistic knowledge, a definition of the application in terms of the conceptual ontology, and a definition of the control structure. It includes the metarules for mapping objects in the domain ontology with those in the task ontology, the metarules for mapping the conceptual ontology onto the linguistic ontology, and those for allowing the generation of the specific interface knowledge sources, mainly the grammar and the lexicon.

- One of the most famous ontology-design environments is methontology. It tries to define the necessary activities that people carry out when building an ontology (Fernández et al., 1997). In other words, it is a flow of ontology development for three different processes: management, technology, and support. The ontology-development process is composed of the following steps: project-management activities that include planning, control, and quality assurance; development-oriented activities that include specification, conceptualization, formalization, and implementation; and activities that include knowledge acquisition, evaluation, integration, and documentation.
- The authors Lauser, Wildemann, Poulos, Fisseha, Keizer, and Katz (2002) use the multilingual methontology methodology defined by Fernández et al. (1997), and enrich this one by stressing on specific actions for supporting the creation process for ontology-driven conceptual analysis. The domain ontology is built by using two different knowledge-acquisition approaches: the creation of the core ontology and the derivation of the domain ontology from a thesaurus. The first one is basically comprised of the first three steps of methontology-development activities defining a list of frequent terms and a list of domain-specific documents to analyze. The second one consists of descriptive keywords linked by a basic set of relationships. The goal of this step is to refine an RDFS ontology model to develop a pruned ontology and a list of frequent terms.
- Toronto Virtual Enterprise (TOVE) is a methodology for ontological engineering that allows the developer to build ontology following these steps: scenarios motivation, ontology requirements definitions, terminology specification, formal description requirements, axiom specification, and completeness theorems (Fox & Gruninger, 1994, 1998).
- Ontology Development 101 has been developed by authors involved in these ontology-editing environments: Protégé-2000, Ontolingua, and Chimaera (Noy & McGuinnes, 2001). They propose a very simple guide, based on iterative design, that helps developers to create an ontology using these tools. The sequence of the steps to develop an ontology are to determine the domain and scope of the ontology, consider reusing existing ontologies (e.g., Ontolingua ontology library, DAML ontology library, UNSPSC, RosettaNet, and DMOZ), enumerate important terms in the ontology, define the classes and the class hierarchy, define the properties of class slots, define the facets of the slots, and create instances.
- Ushold's (2000) methodology uses formal language for building ontologies via a purely manual process, identifying purpose and scope, capturing (the identification of key concepts and relationships, and the provision of definitions), and finally coding ontology (committing to the basic terms for ontology), integrating existing ontologies, evaluating, and documenting the ontology processes.
- The On-to-Knowledge (OTK) methodology focuses on application-driven development of ontology during the introduction of

ontology-based knowledge-management systems (Fensel, van Harmelen, Klein, & Akkermans, 2000; Lau & Sure, 2002; Sure, Erdmann, Angele, Staab, Studer, & Wenke, 2002). It is based on the following steps: a feasibility study, an impacts and improvements study for the selected target solution, a kickoff phase, a refinement phase, a formalization phase, an evaluation phase, and an application and evolution phase. This methodology stresses the need for ensuring organizational acceptance and the integration of knowledge systems. Then it is based on bottom-up strategies, and gathering insights into the interrelationships between the business task, actors involved, and the use of knowledge for successful performance.

- The authors Izumy and Yamaguchi (2002) have used the business-object ontology to develop an ontology for business coordination. They constructed the business-activity thesaurus by employing WordNet as a general lexical repository. They have constructed the business-object ontology in the following way: by concentrating on the case-study models of e-business and extracting the taxonomy, counting the number of the appearances of each noun concept, comparing the noun hierarchy of WordNet and the taxonomy obtained and adding the number counted for the similar concepts, choosing the main concept with high scores as upper concepts and building upper ontologies by giving all the nouns the formal is-a relation, and merging all the noun hierarchies extracted from the whole process.

Comparing these Methodologies

Although there are relevant differences among the methodologies described above, a number of common points clearly emerge. Many of the methodologies take the domain definition as a starting-point task. From one point of view, it focuses on the acquisition, provides the potential for evaluation, and provides a useful description of the capabilities of the ontology, expressed as the ability to answer well-defined competency questions. On the other side, it seems to provide limitations to the reuse of the ontology and to the possible interactions among ontologies. Besides this, there are two different types of methodology models: the stage-based models (represented, for example, by TOVE) and evolving prototype models (represented by methontology). Both approaches have benefits and drawbacks: The first one seems more appropriate when the purposes and requirements of the ontology are clear, and the second one is more useful when the environment is dynamic and difficult to understand. Finally, both the informal description of the ontology and the formal embodiment in an ontology language are often developed in separate stages, and this separation increases the gap between real-world models and executable systems. There is no one correct way to model a domain; there are always viable alternatives. Most of the time, the best solution depends on the application that the developer has in mind, and the tools that he or she uses to develop the ontology. In particular, we can notice that the need for correspondence between existing methodologies and environments for building ontologies causes these consequences: Conceptual models are implicit in the implementation codes and a reengineering process is usually required to make the conceptual models explicit, ontological commitments and design criteria are implicit in the ontology code, and ontology developer preferences in a given language condition the implementation of the acquired knowledge.

MAIN FOCUS OF THE ARTICLE

In this article, the focus is the necessity for a tenable trade-off between a stable corporate model of knowledge and the dynamism of the very same knowledge in the history of real-world organizations. What is not sufficiently studied in the current literature of ontology methodology, which we believe to be the crucial aspect of this type of investigation from the knowledge-management viewpoint, is the nature of the knowledge of the methodology itself (the metaknowledge of the domain), which is very important for the choices we make in the deployment process of any ontology.

Our discussion focuses on how an explicit representation of the metaknowledge is helpful in knowledge-management practice. To demonstrate this, an analysis of the basic assumptions about ontology creation is provided, the bidirectional method for developing ontologies is described, and finally a knowledge-management viewpoint on ontology creation is presented.

Basic Assumptions on Ontology Creation

As explained above, one of the first steps in ontology creation is the choice of domains and categories that represent, in a neutral way, the real world. In fact, in the real world or in practical applications (e.g., information systems, knowledge-management systems, portals, and other ICT applications), general and universal categories are not widely being used. This is also due to the difficulties in implementing a general ontology within specific domains. Moreover, general and universal categories are very abstract and can lead to heterogeneous interpretations and different conceptualizations. For instance, everyone has a different interpretation and conceptualization of love, trust, or spatial-temporal regions. Besides this, the more a concept is abstract, the more it is difficult to define it. Then, workers very stressed by their daily activities might find it difficult or useless to make their daily used concepts more abstract and decontextualized. Namely, they might prefer to achieve, in short time, an effective agreement on shared spaces in their office than stay days and days talking about space regions.

More often, it is simply too expensive to create complex, complete, and general ontologies. Another important justification of the above-mentioned lack of general and supposedly complete ontologies in real-world applications is that, in the same project or domain, people might use different ontologies composed by several combinations of categories. Indeed, different ontologies might use different categories or systems of categories to describe the same kinds of entities. Even worse, two ontologies may use the same names or systems of categories for different kinds of entities. In fact, when trying to measure the similarity between two ontologies, it is necessary to pursue at both the lexical layer and the conceptual layer (Maedche & Staab, 2002). Therefore, it might be that two entities with different definitions are intended to be the same, but the task of proving that they are indeed the same may be difficult, if not impossible (see Sowa, 2000).

The basic reason for these behaviours is that what we know cannot be viewed simply as a unique picture of the world since it always presupposes some degree of interpretation. Indeed, depending on different interpretation schemas, people (with different perspectives, aims, and world interpretations) may use the same categories with different meanings, or different words to mean the same thing. For example, two groups of people may observe the same phenomenon, but still see different problems, different opportunities, and different challenges. This essential feature of knowledge was studied from different perspectives, and the interpretation schemas have been given various names, for example, paradigms in Kuhn (1979), frames in Goffman (1974), thought worlds in Dougherty (1992), contexts in Ghidini and Giunchiglia (2001), mental spaces in Fauconnier (1985), and cognitive paths in Weick (1979). This view, in which the explicit part of what we know gets its meaning from an (typically implicit, or taken for granted) interpretation schema, leads to some important consequences regarding the adoption and the use of categories and ontologies. An ontology is not a neutral organization of categories, but it is the emergence of some interpretation schema according to which it makes sense to organize and define things. In summary, an ontology is always the result of a sense-making process (conceptual modeling) and represents the point of view (the knowledge representation) of those who took part in that process (see Benerecetti, Bouquet, & Ghidini, 2000, for an in-depth discussion of the dimensions along which any representation, including an ontology, can vary depending on contextual factors).

Moreover, according to a structuration approach (for an in-depth discussion, see, for example, Giddens, 1984; Orlikowski, 1992; Orlikowski & Gash, 1994), technology cannot be considered as a neutral matter with respect to organizational structures and the managing of knowledge. Ontologies can shape knowledge sharing and managing processes, and organizational behaviours can affect the concrete appropriation of technology. Therefore, there is no one correct way to model a domain; there are always viable alternatives. Mainly, the best solution depends on the application that the developer has in mind, the system of artefacts that she or he wants to integrate with the ontology, and the tools that she or he uses to develop the ontology. Indeed, most of the tools only give support for designing and implementing the ontologies, but they do not support all the activities of the ontology life cycle. Besides this, most of the existing methodologies for building ontologies depend on their environments. Therefore, conceptual models are implicit in the implementation codes and a reengineering process is usually required to make the conceptual models explicit. Ontological commitments and design criteria are implicit in the ontology code, and ontology developer preferences, in a given language, condition the implementation of the acquired knowledge (Gruber, 1998).

The Bidirectional Method for Developing Ontologies

The bidirectional method for developing ontologies provides guidelines to assist the ontological engineer in making choices at different levels, from the high-level structure of the ontology to the fine details of whether or not to include distinctions. The bidirectional method for developing ontologies aims at satisfying all the developer needs and merging two different needs: a more adequate representation of the local domain and the very effective development of a top-level ontology. Taking into consideration these aspects, it seems useful to consider that manually constructed ontologies are time consuming, labour intensive, and error prone (Ding & Foo, 2002), but they are necessary to define a domain in which the quality and the general comprehension of the ontology are good. For example, experts might provide the system with a small number of seed words that represent high-level concepts. These concepts can emerge from theoretical ideas and knowledge or from the practice and the experiences of specialized workers. The steps defined by the bidirectional method for developing ontologies shortly are the following:

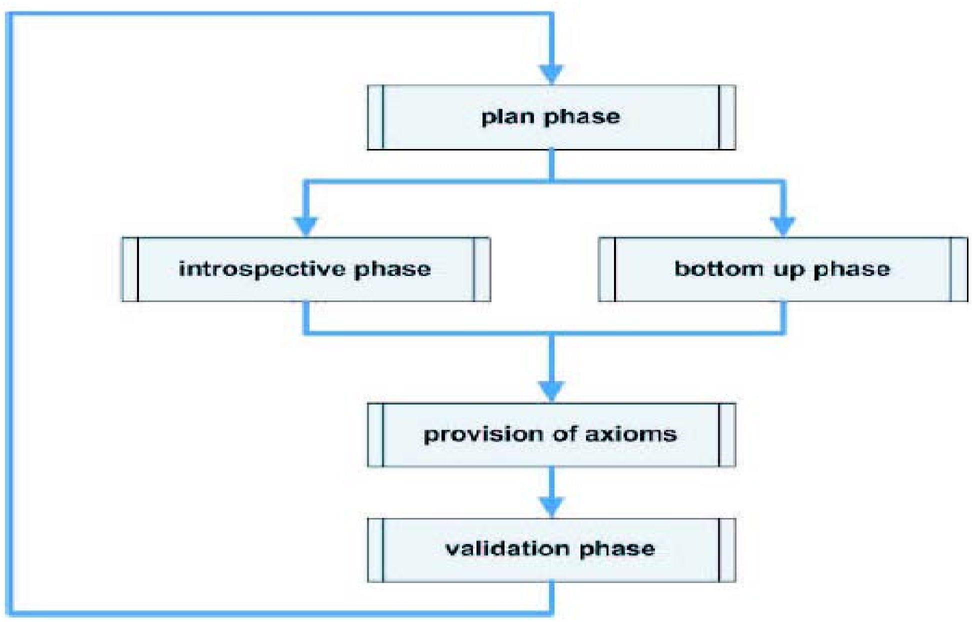
- Plan phase: The goals, amount of resources needed for the ontology development, and bonds (e.g., languages, timing, computational power, type of software used to describe the ontology) are defined. It is important to notice that there is a trade-off between the computational complexity (which is domain independent) and the expressive potential defined by the language.
- Introspective phase: The draft schema, such as the general specifications, categories, and relations; its formalization into the chosen formal language; and its demonstration are defined. It is important to notice that this phase is based on references to literature (philosophical, linguistic, psychological,

sociological literature) and on armchair research.

- Bottom-up phase: The draft terminology is automatically or semiautomatically generated, the description of relations among terms is extracted, and the refinement of draft terminology is handled. The lexical analysis is developed partly in an automated way (through the extraction of phrases containing seed words in documents, archives, and so on) and partly experienced (through expert discussion; domain experts can help the developer to refine the draft terminology). Notice that this phase is based on a very neat domain knowledge and on semiautomatic ontology generation, which depends, in particular, on data-mining processes, syntax systems of analysis, and so on.
- Provision of basic axioms: A set of ontology definitions is obtained through domain-expert interviews or participation.
- Validation phase: The set of definitions is tested, validated, and used.

The above-deployed analysis gives to the bidirectional method for developing ontologies the meaning of a metamethodology, namely, a methodology for operating the right choice among different possible methodologies. This is practically useful in ontology constructions within complex organizations. In fact, within big organizations, knowledge is managed according to different perspectives, and specialized knowledge is managed in the way that better suits specific needs. The presented bidirectional method for developing ontologies sustains the creation of very specialized, specific, and different domain ontologies, allowing a high level of flexibility in ontology-construction processes. Moreover, it allows one to manage a complicated ontology commitment that in practice is routed in dynamic contents and in specific methods. Contents and

Figure 1. A representation of the bidirectional method for developing ontologies



metaknowledge for ontology constructions can be managed and modified only at execution time, namely, at the moment in which the ontology is created. In Figure 1, a schematic analysis of the phases is described. Each phase is related in terms of the direct dependency on previous phases. The metaknowledge included in the ontology methodology adopted is rendered explicit by the definition of these dependencies. Note that the resulting phase set is minimal with respect to the possible phases in existing methodologies, and that the execution of the phase sequence is cyclic in order to provide a model for reusability.

A Knowledge Management Perspective on Ontology Creation

An ontology is a tool for knowledge management whenever it is used for meaning negotiation. However, a coherent perspective on ontology construction from the knowledge-management point of view is not well defined within the current literature of both artificial intelligence and organizational studies.

The perspective defined here is focused on three fundamental aspects of ontology creation: the widely recognized need for tools to be used in the generation of a shared conceptualization for corporate knowledge management; the generally acknowledged need for methodologies that developers of ontologies can follow in a coherent, systematic, and easy-to-implement way; and the economic value of ontologies as artefacts in the practice of knowledge management.

In particular, using the structuration-theory approach (Giddens, 1984; Orlikowski, 1992; Orlikowski & Gash, 1994), the main features of the bidirectional method should be analyzed, and the most important consequences generated by using a special methodology (the bidirectional method) should be unveiled. In particular, the method facilitates the management of some activities such as controlling the development of knowledge repositories in a corporate knowledge-management system, which may include a data warehouse, a corporate Web portal, and intranet tools for accessing distributed data.

The major value of a systematic definition of these aspects is the opportunity for measuring the quality of an ontology from a social and organizational point of view. Though the aim of this investigation is not so far to obtain metrics and evaluation methods for ontologies, we maintain that such a result is going to be shortly available once the methods for building ontologies have been defined.

An important observation is that we have three different situations for ontology development at different levels of difficulty: development from scratch, development as a completion of an existing ontology, and development as a merge (or coordination or alignment) of several ontologies. The three cases require different methodologies, and the methodology we have deployed in this article is valid only for the first case. The other two cases are also interesting extensions of the perspectives of knowledge management we consider as the focus of the article, and they deserve deep analysis. However, we believe that this is possible only when using a flexible methodology for the case from scratch.

FUTURE TRENDS

This article discusses a methodology for building a domain ontology from scratch. The intention of the investigation is to prove that extracting an ontology from a corpus (or from many corpora) is a tenable solution for certain paths, and the opposite way based upon a deep thinking on the topics of the domain is acceptable in other cases. The methodology we propose here is able to help the developer in discriminating between the two cases and provides a general schema for the mentioned purpose.

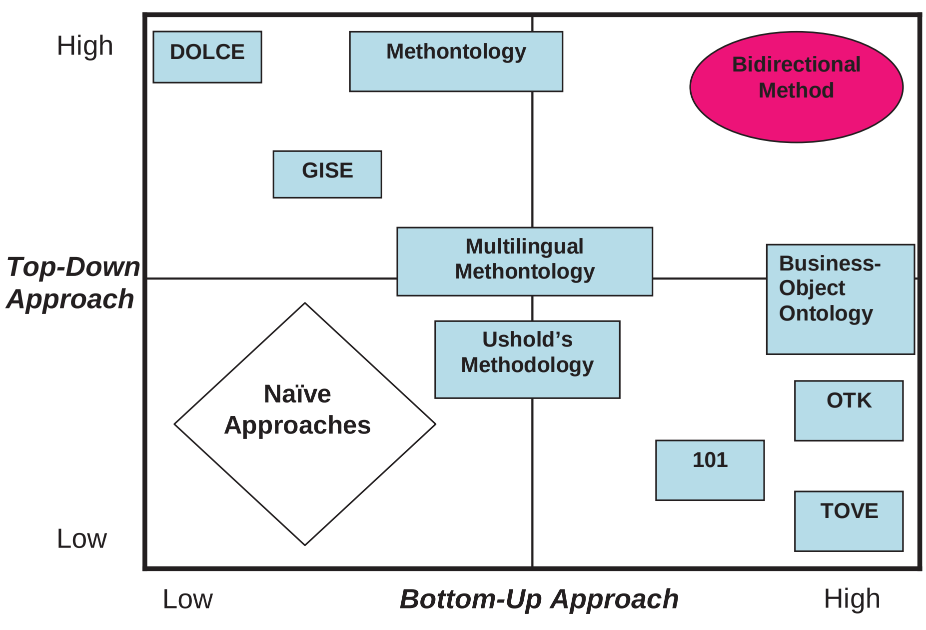
The investigation on the cases of the development of ontologies as an integration of existing models and as a merge has to be deepened. The other aspects that have to be covered are how this methodology can affect the updating processes, and how it can allow the integration of domain ontologies into an upper level ontology. Finally, the evaluation and measure of ontologies seem interesting issues in order to quantify how much an ontology costs and how one can improve the daily activities of workers. In particular, taking into account organizational and management studies, an ontology should be evaluated in terms of its ability to satisfy and its effectiveness.

The above-discussed needs and solutions can be deployed in technologies for knowledge management both as CASE (computer-aided software engineering) in the context of ontology creation, where the tool helps the developer in doing the right thing at the right moment, and as knowledge-sharing and -meaning negotiation tools, especially in network systems.

CONCLUSION

The major claim of this article is that an explicit representation of the methodological knowledge employed to provide conceptual analysis and express the model of knowledge by means of formal ontologies is a valuable plus for knowledge management. In the article, the existing major methodologies are described, and it is shown that everyone provides a framework for making tenable decisions upon the correct case to be used in each specific case, depending both upon the knowledge type and the domain. Although a lot of different methodologies for ontology creation are used in different domains, a good methodological approach should not change depending on the domain in which it is applied and on the type of technology that is used (see Figure 2). A metamethodology is needed, which allows the developer to use the same metamethodology even

Figure 2. A description of ontology-creation methodologies



if the domain, the tool for ontology creation, the needs, and so on change during the time.

In particular, both bottom-up and top-down approaches are very important and are both used in different stages of ontology creation. The bidirectional method for developing ontologies gives an explicit answer to the need of merging both approaches, accounting for the need of tenable, if not optimal, trade-offs between the stability of the model of knowledge and the dynamism of the knowledge itself, which is the actual reason for which an explicit methodology is invented.

Chapter 4.5
Knowledge Reuse

Ilan Oshri
Erasmus University Rotterdam, The Netherlands

INTRODUCTION

Knowledge reuse is the process through which knowledge is captured, validated, stored, and retrieved. Through the reuse of knowledge, organizations may exploit internal capabilities and improve the effectiveness of their exploration activities (March, 1999). Knowledge reuse processes emphasize the centrality of knowledge within an organization by aligning information systems and communication technologies with human activity and organizational mechanisms, such as learning processes and organizational structures. The process of knowledge reuse can be systematic and planned; however, it can also be carried out in an informal manner through social networks and interpersonal ties (Newell, 2004). While knowledge reuse is explored from an entitative perspective, in which knowledge is generic, accessible, and codifiable, other views, such as social construction (Lave & Wenger, 1991), are also considered in this article. Furthermore, various contexts are considered in this article; however, the emphasis in this article is on knowledge reuse activities in product development and project management contexts.

In this article, the concept of knowledge reuse will be explored. First, a review of recent discussions in the academic and practical literature will be presented. Following this, a discussion about the processes, contexts, mechanisms, and challenges involved in reusing knowledge will be developed. Lastly, future research in this area and conclusions will be offered.

BACKGROUND

The study of knowledge reuse has evolved from the field of software development through object-oriented software development practices (Banker & Kauffman, 1991) to more strategic management concepts such as modularization and product design (Sanchez & Mahoney, 1996). Several authors (e.g., Markus, 2001) introduced knowledge reuse as an important concept in knowledge management. The practical relevance of knowledge reuse was considered from software and hardware engineering perspectives (Sanderson & Uzumeri, 1994), the management of multi-project environments (Cusumano & Nobeoka, 1998), and as a phase in the evolution of a firm (Victor & Boynton, 1998). More recently, research has explored additional scenarios for knowledge reuse providing further insight about the reuse of project-specific knowledge (Newell, 2004), templates, information about bids, components, and platforms (Nightingale, 2000).

Various mechanisms and processes have been associated with knowledge reuse. First and foremost, knowledge reuse has been perceived as a process that is based on documenting, verifying, indexing, and retrieving information from repositories (Markus, 2001). Indeed, the information systems approach to knowledge reuse is vital. Nonetheless, knowledge reuse is also an outcome of an informal, people-based activity (Newell, 2004), which can also be complementary to the information system approach. In this respect, the challenges organizations face when attempting to reuse knowledge involve aspects associated with both information systems and human behavior. On the one hand, knowledge re-users face challenges in properly storing, indexing, filtering, verifying, and retrieving information from repositories. On the other hand, these challenges intimately relate to motivational factors to share knowledge, which are human-related factors. The above topics will be discussed in detail in the following sections.

MAIN FOCUS OF THE ARTICLE

The Concept of Knowledge Reuse: Some Examples

Knowledge reuse is defined as the process through which knowledge is captured, verified, filtered, stored, and retrieved (Markus, 2001). There are at least three actors involved in this activity: the knowledge creator who creates the knowledge, the knowledge broker or intermediary who prepares the knowledge for reuse by synthesizing and documenting the knowledge, and the knowledge re-user who retrieves the knowledge and re-applies it in different contexts (Markus, 2001). Knowledge reuse activities are arguably related to organizational effectiveness through the exploitation of existing knowledge and resources (Dixon, 2000).

There are several knowledge processes related to the reuse of knowledge. In particular, knowledge sharing and transfer are two knowledge processes that were often associated with knowledge reuse. Unlike knowledge sharing and transfer, reusing knowledge is an activity in which specific knowledge or design is transferred from a knowledge holder to a knowledge seeker in order to make use and re-apply the knowledge or the design in different contexts. Some car models made by Toyota, for example, share the same components. This was achieved through the transfer of these components between different project teams. In such an activity, a knowledge base will be populated with information about designs and components; and through a knowledge search mechanism, a re-user will be able to verify, retrieve, and reapply a particular component. In this reuse activity, a modification of the reused design may take place in order to adjust the reused design to the requirements and specifications of the new product.

Advantages and Disadvantages in Reusing Knowledge

The advantages associated with the reuse of knowledge are many. By reusing knowledge, organizations may also avoid “reinventing the wheel” in terms of products, components, templates, and processes, thus freeing up resources to other core activities, be these customer responsiveness or innovation. In the context of product development, some more specific contributions were associated with the reuse of knowledge such as lower risk in new product development and a robust design (Nightingale, 2000), shorter time to market, reduced R&D costs, and higher responsiveness to customer needs (Datar, Clark, Sunder, Surendra, & Kannan, 1997; Nayak, Chen, & Simpson, 2000).

However, reusing knowledge may also bring stress to organizations. Excessive exploitation, in particular, may lead to a trap in which organizations that operate in "sub-optimal stable equilibriums" and enjoy the cost effectiveness associated with the reuse of knowledge may suffer from a lack of explorative activities that are crucial for the future development of organizations (March, 1999). Furthermore, information distortion, in the form of missing information or false information, could possibly negatively affect the reuse process and outcome (Carley & Lin, 1997). Therefore, to avoid these pitfalls, organizations require an understanding of the various aspects involved in knowledge reuse, and may design their internal processes and systems to respond to such challenges.

The Process of Knowledge Reuse

Several processes are involved in the reuse of knowledge. From an information systems perspective (Markus, 2001), the reuse of knowledge is based on the use of repositories and may involve four processes: First, knowledge is captured through documentation, something that can be a by-product of the work process or as an intentional activity using information systems. Capturing knowledge can also include filtering knowledge and preparing the knowledge for future reuse. Second, knowledge is classified and formatted by relating the content to existing and new classification schemes, and through the contextualization and de-contextualization of the content. Third is distributing the knowledge by either pull or push mechanisms. Populating a repository is an example of a pull mechanism, while an automatic e-mail that informs knowledge workers about project management templates available to reuse is a push mechanism. The reuse activity is the last stage in which the re-user is (re)applying the knowledge and updates the knowledge source with contextual context that may serve future re-users.

From a learning perspective (Prencipe & Tell, 2001), the reuse of knowledge can take place at three levels of the organization—individual, group or team, and organizational—through mechanisms that relate to experience accumulation, knowledge articulation, and knowledge codification. Knowledge reuse is more systematic and exploitative in nature when the learning is based on knowledge codification at the three levels of the organization, and tends to be more explorative in nature when the learning is based on accumulative experience at the individual level.

From a strategic management perspective (Victor & Boynton, 1998), knowledge reuse is a step towards building sustainable and dynamic capabilities. A full renewal lifecycle of a product from a knowledge-based perspective may consist of the creation of knowledge, the transformation of new knowledge into modular products and components, and the reuse of these modules, according to market needs, by reconfiguring and re-applying knowledge.

Achieving successful knowledge reuse requires the involvement of each of the aspects mentioned above. Information systems aspects are important for the storage and retrieval of the knowledge, while the learning aspects are key for the improvement of reuse activities. The following section will address the contexts within which knowledge reuse may occur.

The Context of Knowledge Reuse

Knowledge reuse may take place in different contexts, such as between organizations (interfirm knowledge reuse) or within an organization (intra-firm knowledge reuse). Sharing knowledge and designs between firms is not free of challenges. Issues pertaining to trust between suppliers of a supply chain may impede the sharing of knowledge. Furthermore, proprietary issues may restrict the reuse of designs across firms. Nonetheless, in recent years, research and development have seen an improvement in the level of knowledge sharing between firms. In particular, examples from the automobile industry provide an insight into the systems and processes that support product delivery through information sharing within a supply chain (Childerhouse, Hermiz, Mason-Jones, Popp, & Towill, 2003).

In the context of intra-firm knowledge reuse, firms put the emphasis on making generic and specific knowledge available for reuse through repositories, social networks, and interpersonal connections. Recent years have seen a growing interest in reusing project-specific knowledge (Newell, 2004). Projects have become a central vehicle through which companies learn—hence, requiring a systematic method to capture the learning and experiences and reusing them over time. The reuse of project-specific knowledge and the broad firm context will be discussed below.

Mechanisms Involved in Knowledge Reuse

Various mechanisms are mentioned in the context of knowledge reuse. These can be divided into three areas: information systems, managerial practices, and social networks mechanisms.

Information systems support knowledge reuse through the use of repositories (Markus, 2001). These repositories store and make available various types of information such as internal and external knowledge, data or documents, specific or generic information, or as a pointer to experts.

Managerial practices may include several mechanisms through which knowledge reuse is supported. Sharing work procedures is one important mechanism for knowledge reuse. In this respect, commonality across tools and technical procedures is important and may include, for example, the use of identical development tools (e.g., C++ or Microsoft Office) across several software development projects. Furthermore, shared work procedures may also include the involvement of different stakeholders in a decision-making process to ensure that past learning, from various perspectives, will be included in the process. Sharing past experiences, for example, is achieved when a multi-functional product development team meets every week to assess progress and suggest solutions, based on their individual and shared learning.

Furthermore, the organization of experts and expertise within the firm may have an impact on the possibilities of reusing knowledge. In this respect, two modes of organizing were considered. First is the functional structure in which experts and expertise are centered within the functional department and contribute to the project objectives from their departments. Second is the project-centered structure in which experts and expertise from different departments work as a project team towards common project goals. While the functional structure offers more possibilities to reuse knowledge within the department, mainly with regard to technologies and product concepts, the project-centered structure presents opportunities to reuse lessons learned between multi-functional teams with regard to product development process. The matrix structure, which combines functional with project-centered structures, includes the possibilities to reuse expert technical knowledge within the functional structure with the learning from past projects about the process of product development within project teams.

Another managerial practice that gained attention in recent years is project management practices (Cusumano & Nobeoka, 1998). Through a careful coordination of projects, the reuse of knowledge between projects can be improved. In this context, the emphasis has been on the reuse of components and platforms from a source project to other projects that are carried out concurrently.

Reward schemes were also considered as a driver to encourage knowledge reuse. Reward systems were designed to remunerate knowledge workers who documented and indexed valuable knowledge, as well as knowledge workers who made a useful (re)use of existing knowledge by reapplying concepts and solutions to new product and process introductions.

While technology and managerial practices dominated the discussion about knowledge reuse, social networks and interpersonal connections contributing to knowledge reuse are no less important to the exploitation of internal capabilities (Newell, 2004). Person-to-person communications, informal encounters, and social rituals within communities of practice are among the various activities that drive knowledge reuse through social interactions (Prencipe & Tell, 2001; Wenger, 1998).

There are several scenarios in which the mechanisms involved in knowledge reuse may play a role. Managerial practices, in particular project management practices, will enhance the reuse of knowledge between projects in a project environment. In this scenario, the use of information systems may further assist in documenting, screening, and retrieving knowledge to be re-configured and re-applied by another project team. Social interaction as a vehicle for knowledge reuse is more an explorative activity which drives knowledge exchanges between knowledge creators and re-users; however, it may enjoy the planning and discipline introduced by project management practices.

Challenges in Knowledge Reuse

The reuse of knowledge may face a number of challenges. From an information system perspective, there are several challenges at the individual, group, and organizational levels. Knowledge can be either tacit or explicit (Polanyi, 1966). Articulating tacit knowledge is a difficult task, let alone capturing, storing, and retrieving it. This is perhaps the most challenging task that a knowledge re-user is facing.

Secondly, properly creating and indexing knowledge may generate mistakes or confusion about the "true" meaning of the information stored or retrieved (Markus, 2001). A common problem, for example, is to search for specific information. The common system of indexing generates problems for knowledge seekers because of a misplacement of the information within the indexing system.

Thirdly, the costs involved in creating repositories by carefully documenting and indexing knowledge for future reuse are very high. Furthermore, data entries are long and can hardly be justified as a central activity within product development.

Lastly, the "stickiness" of knowledge presents additional barriers to transfer and reuse knowledge. The recipient's lacks of absorptive capacity is one example of the recipient's inability to value, assimilate, and apply new knowledge (Szulanski, 1996, p. 31).

From a managerial perspective, the process of knowledge reuse may face challenges in the area of the organizational structure, project management coordination, and planning and reward systems. In terms of the organizational structure, while adopting either a functional or project-centered structure would present advantages for knowledge reuse within and across projects respectively, each structure still cannot support the reuse of knowledge across the organization. The matrix organization combines functional departments and cross-functional teams in the form of projects. Under this structure, projects usually succeed in integrating knowledge across functional areas, therefore increasing the possibilities to reuse knowledge and designs (Cusumano & Nobeoka, 1998).

Rewarding knowledge re-users has also posed challenges in terms of the criteria that define what a valuable knowledge reuse process is. Some of the criteria suggested in this context are at the project level. Criteria assessing the exploitation of resources, for example, included: man/month software development saved following the reuse process, total reduction in project costs, and a shorter product lead-time. Both the number of hits per index in a repository and the number of times an existing solution was reapplied in different contexts were considered as criteria for the value and quality of a reuse process. Because a reuse process can also be based on social interactions, a process that is often unplanned and undocumented, rewarding those involved can be a difficult task.

Lastly, planning a reuse process through project management practices may not always be possible (Cusumano & Nobeoka, 1998). Indeed, in companies that can plan product introductions in advance, the possibilities to design and monitor the reuse of knowledge between projects are feasible. This is mainly the case in mass-producing companies such as Toyota and Sony. On the other hand, many organizations cannot rely on the project planning approach. Suppliers of complex systems and products (CoPS), for example, may not be able to plan in advance the reuse of knowledge by solely relying on project management practices. This is because of contractual arrangements between the supplier and the client that define the production time interval, the design, and the number of units to be produced (Hobday, 2000). For this reason, suppliers of CoPS are more likely to rely on information systems and social interactions as the drivers for knowledge reuse (Prencipe & Tell, 2001). In summary, the challenges involved in achieving a successful reuse process are many, bringing together aspects from the social, information system, and human behavior perspectives.

FUTURE TRENDS

Two main future trends can be considered: practical and research themes.

From a practical viewpoint, potential developments are in three areas: defining the role of knowledge facilitator in knowledge reuse activities, motivating individuals and teams to engage in knowledge reuse activities, and balancing between exploitation (reuse) and exploration (innovation) activities.

Firms face major challenges in building and successfully maintaining knowledge systems. Several studies confirmed that it takes more than information systems to reuse knowledge (Markus, 2001; Newell, 2004). It has been suggested that knowledge facilitators (also known as knowledge brokers and knowledge managers) can improve the capture and filtering of knowledge for reuse (Markus, 2001). Instead of relying on project teams to carry out the storage of knowledge in a repository, firms should follow some recent successful examples, such as Booz-Allen, in which knowledge managers accompanied the project team making sure that knowledge generated during the project is captured, indexed, and prepared for reuse (Markus, 2001). In addition to the need to continuously improve technology-based indexing and searching mechanisms, the development of transactive memory, a concept which emphasizes the idea of "who knows what," can be enhanced through the involvement of knowledge facilitators, acting as knowledge brokers.

While the rationale for reusing knowledge is well grounded in the economies of efficiencies, in practice empirical evidence suggests that many organizations do not pursue this activity. In many cases the reason for this behavior is a lack of awareness and incentives that would encourage individuals and teams to seek solutions in-house prior to launching an explorative activity which may well be a "reinvention of the wheel." Managers should consider developing educational programs relating to the many aspects involved in reusing knowledge, including methodologies that fit their organization and incentive schemes that link reuse activities to individual, team, and organizational performance.

Lastly, while this article represents a call to undertake knowledge reuse activities, organizations should still consider achieving a balance between exploitative and explorative activities. When launching a new product, for example, an assessment of the costs involved in reconfiguring an existing design for reuse versus developing a design from scratch should be undertaken.

From a theoretical viewpoint, future research trends may consider understanding the process and context of reuse activities in the following scenarios: (i) reuse of intangible products such as financial products, (ii) reuse of processes, and (iii) reuse between firms also coined here as inter-firm reuse process.

The study of processes and innovation of intangible products, in particular in the financial services, is very limited. More specifically, little is known about the reuse of knowledge of intangible products as opposed to tangible products (e.g., the broad research on reuse in the context of the automobile industry or the aircraft industry).

The study of knowledge reuse has traditionally focused on the potential to reuse products or sub-systems within products. More research is needed into the potential to reuse processes and templates of operations in the broad context of the firm, and more specifically within and between projects.

Lastly, knowledge reuse is perceived as an intra-firm activity. Little is known about the process through which inter-firm knowledge reuse can be achieved, the mechanisms involved in the reuse that may support it, and the challenges involved in the process.

CONCLUSION

This article explored the concept of knowledge reuse. Aspects associated with knowledge reuse were reviewed from information system, social, and strategic management perspectives. While research and practice has traditionally focused on information systems to support the reuse of knowledge, other tools and practices, such as managerial practices and social networks, were reviewed as complementary vehicles. While research and practice has made significant progress in understanding knowledge reuse contexts and processes, far more investment in methodologies, tools, and processes is still needed in order to exploit the potential offered by this practice.

Chapter 4.6
Direction and Trends in Knowledge Management Research:
Results from an Empirical Analysis of European Projects

George M. Giaglis
University of the Aegean, Greece

ABSTRACT

Knowledge and Information Management (KIM) has existed as a separate field of scientific research for almost a decade. It is therefore surprising that very few studies to date have been concerned with the identification of the scope and boundaries of the field, as well as the sub-topics and research themes that constitute it. This chapter reports on the results of an empirical analysis of more than 200 research projects in Knowledge and Information Management. Using an inductive methodology of pattern matching analysis, a more accurate definition of knowledge management is attempted, and an innovative taxonomy of research sub-themes within the 'umbrella' area of Knowledge and Information Management is proposed. Furthermore, a trend towards a gradual maturation of the presently prevailing research paradigm is identified, indicating a need for a 'paradigm shift' that will provide a new direction and vision for future research in the area. We suggest that targeted future research efforts in the area of knowledge technologies will contribute to the development of the 'next generation' knowledge management systems that will transform the existing 'passive' knowledge repositories into 'active' learning environments.

THE FIELD OF KNOWLEDGE AND INFORMATION MANAGEMENT

In a world of dynamic and discontinuous change, organisations are constantly seeking ways to adapt themselves to new conditions so that they are prepared to survive and flourish in an increasingly competitive environment. The proliferation of the knowledge economy (Castells, 1996), emphasizing the value of information as an enabler of competitive advantage, is naturally driving many companies to re-examine the ways they have treated their knowledge assets in the past and to identify ways in which they can exploit them more effectively in the future (Argyris, 1994; Albert, 1997).

In such a landscape, it is not surprising that Knowledge and Information Management (KIM) has emerged as one of the most popular strategic change management approaches in the dawn of the 21st century (Davenport and Prusak, 1997; Currie, 1999; Spiegler, 2000). Its supporters argue that organisations may achieve significant competitive advantages by analysing the data and information that often remain unexploited in organisational systems and by transforming them into useful and actionable knowledge. KIM has attracted significant attention in the spheres of both academic research and industrial practice in recent years (Davenport et al., 1998). This is hardly surprising: knowledge is long known to be one of the primary enablers of sustainable competitive advantage in periods of economic turbulence (Nonaka and Takeuchi, 1995). At the same time, the increasing capabilities of contemporary information systems to store, process, and disseminate information and to contribute to its transformation into knowledge, have also served to enhance the role of KIM in organisations.

Despite the wide attention being paid to KIM, the definition of the field (both as an academic discipline and as a managerial application area), together with a clear description of its scope and boundaries, is still a subject of intense debate. A small sample of definitions found both in academic textbooks and business-oriented sources serve to demonstrate the sources of disagreements usually encountered. For example, Starr (1999) defines knowledge management as "information or data management with the additional practice of capturing the tacit experience of the individual," while O'Brien (1999) defines it as "a tool of enterprise collaboration that facilitates the organisation, management, and sharing of the diverse forms of business information created by individuals and teams in organisations." Laudon and Laudon (1998) claim that knowledge management is "the process of systematically and actively managing and leveraging the stores of knowledge in an organisation," while Malhotra (1997) maintains that knowledge management "embodies organisational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings."

Even from this small sample of definitions, the epistemological and ontological basis of KIM as an independent and distinguishable field of research and practice is rather unclear. Some authors see it as an extension of traditional information management, while others view it as the synergistic outcome of combining information management and human creativity. Moreover, some definitions seem to adopt a primarily soft organisational stance and view KIM as a 'process,' while others follow a more technologically oriented hard approach and view KIM as a 'tool.'

Perhaps some of this confusion may be attributable to the fact that the terms 'knowledge' and 'information,' while not necessarily meaning the same thing to everybody, are explicitly or implicitly treated as synonymous in many definitions. Another source of confusion may be the fact that different types of knowledge seem to exist, each with potentially different management requirements by organisations and individuals. For example, the distinction between explicit and tacit knowledge may prove to be ultimately misleading (Marshall and Brady, 2000), as it tends to split the co-existent and inter-twined types of knowledge into mutually exclusive categories. Finally, a main source of disagreement seems to stem from the use of different analytical lenses to view KIM depending on one's background:

researchers from the computer science and information systems fields tend to view KIM as a tool and speak about knowledge management systems, while researchers from a management science background usually focus on the knowledge management process.

As usual in such cases, the truth is somewhere in the middle: knowledge and information management is an inherently interdisciplinary research field inasmuch as its implementation depends on technological systems and its application depends on user acceptance and embracement (managerial and employee alike). The interdisciplinary nature of the field renders its detailed epistemological study more difficult, albeit at the same time also more important. This chapter sets out on a roadmap to answering these questions through a combination of theoretical and empirical research. The next section identifies the boundaries of KIM by drawing on the relevant literature of the computer science and the management science reference disciplines. Following that, we present the results of an empirical investigation into more than 200 research projects in Knowledge and Information Management that were funded by the Commission of the European Communities during the years 1998-2001. These projects, most of them still ongoing, amount to a total cost of nearly one billion euro (€1bn), thus representing the largest coherent group of research efforts in the area. Therefore, their analysis can yield extremely interesting findings regarding the major research sub-topics within the 'umbrella' area of KIM as well as indicators of trends and future research directions. These findings are then encapsulated in a novel taxonomy of knowledge management research sub-fields that can serve as an analytical framework when assessing the usefulness and potential contribution of a given area of study within the overall field of knowledge management (including related aspects of information management as well). In turn, this understanding can assist towards formulating policy suggestions for effectively supporting and promoting coordinated knowledge management research for the future.

THEORETICAL ANALYSIS: 'HARD' AND 'SOFT' KIM RESEARCH

As argued earlier, research within the 'umbrella' field of Knowledge and Information Management can generally fall under two broad categories depending on the departing point of the research questions. On the one hand, one research stream draws predominantly on findings from the fields of computer science and information systems, and sees knowledge management as an application area that extends the traditional realm of databases and information management into so-called knowledge bases and knowledge management systems. In other words, this 'sub-area' of KIM is mostly concerned with investigating ways in which technological capabilities can be exploited by organisations in their pursuit of knowledge-driven competitiveness. On the other hand, a separate research stream is approaching the same kinds of problems from a complementary perspective and attempts to tackle the managerial, organisational, and human issues surrounding the successful introduction of knowledge management within organisations. Research under this 'sub-area' of KIM is mostly concerned with investigating ways in which the process of knowledge creation, assimilation, communication, and enactment can be managed by organisations. Table 1 summarises the characteristics and differences between these research perspectives.

'Hard' Research

Knowledge management systems can be thought of as computer-supported tools that address one or more of the following problems related to

Table 1. Different research approaches on knowledge and information management (KIM)

	'Hard' KIM Research	'Soft' KIM Research
Driven by	Technological Developments	Organisational Problems
Focus on	Information	Process
Reference Disciplines	Computer Science, Information Systems, Artificial Intelligence	Management Science, Cognitive Sciences, Psychology, Linguistics
Exemplary Outcomes	Knowledge Management Systems, Knowledge Ontologies	Collaborative Work Processes, Employee Empowerment Mechanisms

knowledge and information management (Ruggles, 1997): Knowledge Generation, Knowledge Codification, and Knowledge Transfer.

Knowledge Generation refers to the transformation of raw data or summarised information into actionable knowledge. A number of research problems can be thought of as belonging within this area. The first is the problem of pattern recognition (Brash, 2000), which is concerned with identifying useful patterns in data so that knowledge may be extracted from them. Questions related to data mining are relevant here, as is research in the field of artificial intelligence and knowledge-based systems. However, other research questions may also be relevant, such as real-time knowledge capture and computer-supported groupware.

Knowledge Codification is concerned with the process of codifying, categorising, and storing knowledge in an information system. One important research question here is indexing (Delesie and Croes, 2000), that is the appropriate data structuring schema to support knowledge discovery. Other relevant questions deal with problems of knowledge acquisition and knowledge representation (for example, knowledge ontologies).

Finally, Knowledge Transfer deals with the exchange of knowledge between individuals and organisations (O'Dell and Grayson, 1998). User interfaces in knowledge systems, technology-based learning, and knowledge assessment (Guns and Valikangas, 1998) are research issues that may be classified under this category.

'Soft' Research

The introduction of a knowledge tool may be a necessary, but it is definitely not an adequate condition of the successful implementation of knowledge management in an organisation (Gill, 1995). To this end, firms need to implement a surrounding knowledge environment (Irani and Sharp, 1997) that deals effectively with individual and organisation-wide aspects of managing knowledge as a corporate resource. Collective learning (Rzevski and Prasad, 1998), collaboration and trust (Constant et al., 1994), and change management (Burrows, 1994) are only some of the areas where 'soft' research issues related to KIM may become of importance.

Towards a More Accurate Definition of KIM

The aforementioned differences in departing points, scope, and expected outcomes in much of extant research in Knowledge and Information Management may serve, at least partially, to explain our difficulties when trying to define the area as a scientific field and portray its constituent elements. The differences between 'hard' and 'soft' approaches to KIM research may further mean that a single identifiable research field may simply just not exist. Instead, what we usually term as 'KIM research' may in reality hide two (or even more) separate research fields that, although intertwined and complementary, can be thought of as independent and distinguishable, even if only for analytical purposes.

However, such a hypothesis needs to be backed up by appropriate empirical evidence. To this end, a complementary analysis of empirical nature is needed to identify the pragmatics of ongoing KIM research and contribute towards enhancing our understanding of what the main research problems that constitute what we term as 'KIM research' are. The results of such an empirical analysis of more than 200 ongoing research projects in KIM are presented in the following section.

EMPIRICAL ANALYSIS: KIM RESEARCH PROJECTS

The discussion that follows is based on the results of the so-called Integrated Programme Portfolio Analysis (IPPA), which is organised by the European Commission at regular intervals in order to provide a strategic overview on the response to calls for research proposals in the area of the 'Information Society Technologies' (IST) programme. The last IPPA exercise, on which this analysis is based, was carried out in July 2001. IPPA is conducted by a group of independent experts and examines the project characteristics from the technical perspective, the time to market, the risk profile of projects related to market dynamics, and so on. In this chapter, the analysis is limited on the part of IPPA dealing with research into Knowledge and Information Management (KIM).

Global Picture

Out of the 1,725 proposals funded by the European Commission in the first six calls of the IST Programme (1998-2001), 316 (more than 18% of the total) were marked as addressing the technological area of 'Knowledge and Information Management' (KIM). Since this renders KIM the most popular of the technological areas addressed by the programme, it was decided to pursue a more detailed investigation of these projects to identify:

a) The major research sub-topics and themes that can be grouped under the general heading 'Knowledge and Information Management.'
b) The trends in KIM-oriented research, as well as the characteristics and directions of promising future research efforts.
c) Suggestions and recommendations for the effective management of this large-scale research portfolio at the European level.

The KIM projects represent a total funding on behalf of the European Commission of 440 million euro (€440m), while the project participants themselves commit an equivalent amount of money in self-financing the research efforts, thus resulting in a breathtaking amount of nearly one billion euro (€1bn) devoted to European-wide research in Knowledge and Information Management. The sheer magnitude of this amount makes a more detailed analysis of the research outcomes a worthwhile endeavour.

Out of the 316 KIM projects, 235 (or 74.4%) are classified as Research and Technology Development (RTD) projects. This sample of 235 projects was used as a basis for all the analyses presented herein.

Analysing these projects regarding their distribution of projects per Key Action Line (KALs represent the smallest classification unit of research areas in the IST programme) reveals a rather fragmented picture. KIM research projects can be found under no less than 55 different Key Action Lines. The most popular of those is naturally KAL 2.1.2 (Knowledge Management) with 24 projects, followed by KAL 2.2.2/2.2.3 (Smart Organisations) with 17 projects, and KAL 6.1.1 (Future and Emerging Technologies) with 13 projects.

Given the great diversity and dissimilar nature of Key Action Lines that seem to attract Knowledge and Information Management projects, it was felt that the projects might belong to more than one coherent research theme, thus providing an initial indication that our theoretically driven hypothesis discussed in the previous section may prove to be true. It was therefore decided, apart from the overall statistical analysis discussed in the next section, to pursue a more in-depth investigation of the individual projects submitted under the most popular Key Action Lines to identify pertinent research themes and future research directions in KIM.

Project Profiles

The first type of analyses performed on the KIM projects were of the single-variable type, aimed at identifying the project profiles based on a number of characteristics. The KIM projects, as expected, are quite interdisciplinary in nature in terms of the technologies addressed. Figure 1 illustrates the most popular technologies addressed by KIM projects. These include Visualisation, Virtual Environments, and Image Processing (14% of projects), followed by Optimisation Tools and Decision Support Systems (13%), Content Authoring Tools (12%), and Agent Technologies (11%). Other technologies that seem to form the underlying basis for research and development in KIM include: Mobile and Wireless Communications, Middleware and Distributed Systems, and Internet Technologies.

Most of the KIM projects are horizontal in nature, addressing the Cross Sector/Generic category, as illustrated in Figure 2. Of the remainder,

Figure 1. Technologies addressed in KIM research

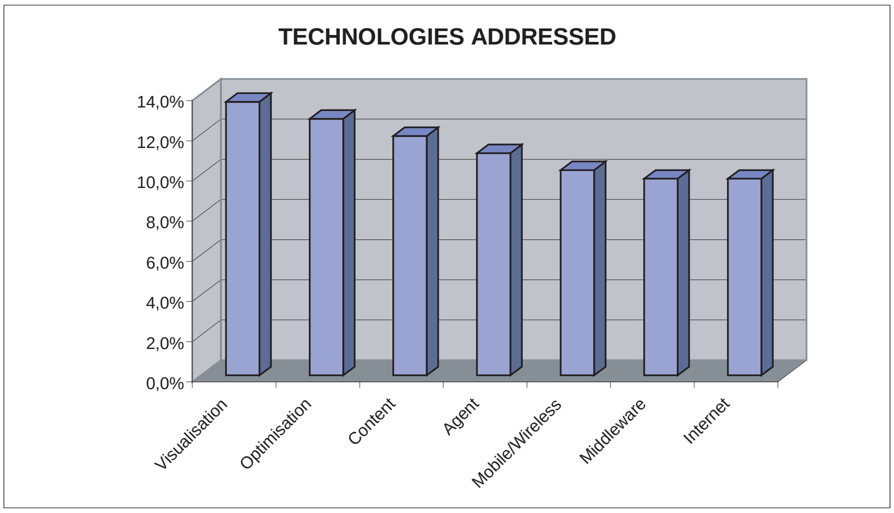

Figure 2. Industrial sectors addressed in KIM research

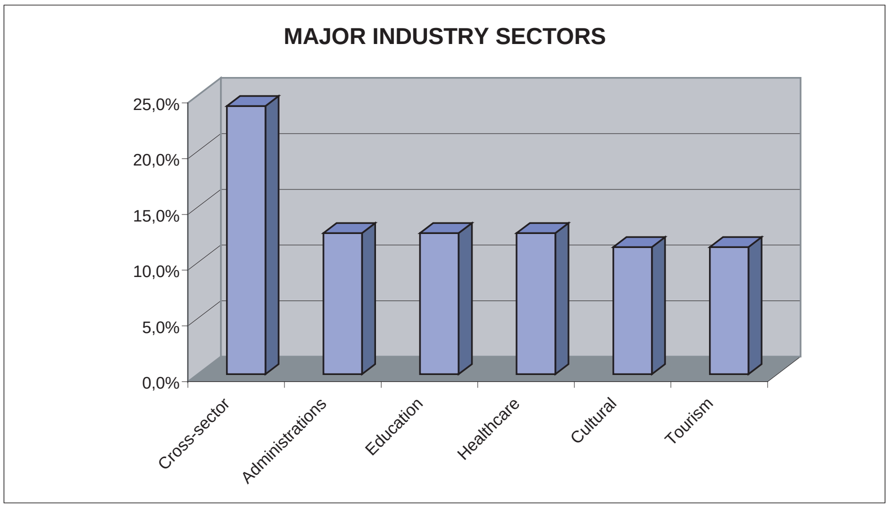

the interest seems to be almost evenly spread between Administrations (13%), Education and Training (13%), Healthcare (13%), Cultural (11%), and Tourism (11%).

Identifying The Trends

A second-level analysis was then performed to identify major differences between earlier Knowledge and Information Management projects (submitted within 1998 and 1999) and more recent ones (submitted within 2000 and 2001). This comparative analysis yielded interesting results regarding the trends of KIM research through time. Firstly, there is a marked decrease in the number of Research and Technology Development projects, from 84% to 60% of the total, as shown in Figure 3. Non-RTD work in the context of the IST programme refers mainly to demonstration projects, dissemination and technology transfer actions, studies, and so on.

As the non-RTD work refers mostly to projects that aim at demonstrating the commercial potential of already developed technological solutions, the aforementioned decrease in the number of RTD projects may imply a gradual maturation of KIM as a research field, coupled with a corresponding uptake of more industrial practice-oriented work. This assumption is also supported by other analyses. More specifically, there is a clear shift from more 'revolutionary' project outputs (including proof-of-concepts, improved methods, increased know-how) to rather 'evolutionary' outcomes that are closer to the market (new products and services), as illustrated in Figure 4.

The above might suggest that the area of Knowledge and Information Management is moving towards a gradual assimilation of the prevailing paradigm, as indicated by the fall in research being done. If this is true, a new 'vision' might be required to indicate new research orientations for the future. However, to substantiate

Figure 3. RTD vs. non-RTD knowledge and information management projects

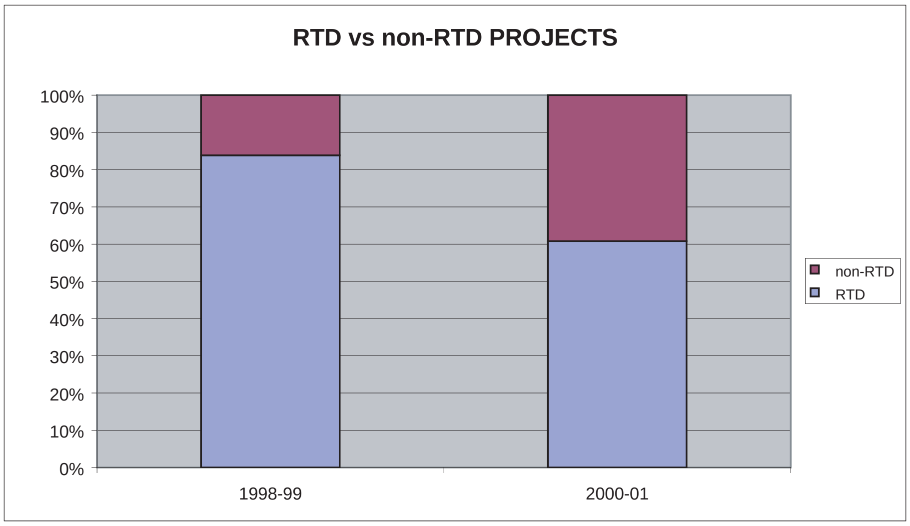

Figure 4. Expected output of KIM research projects

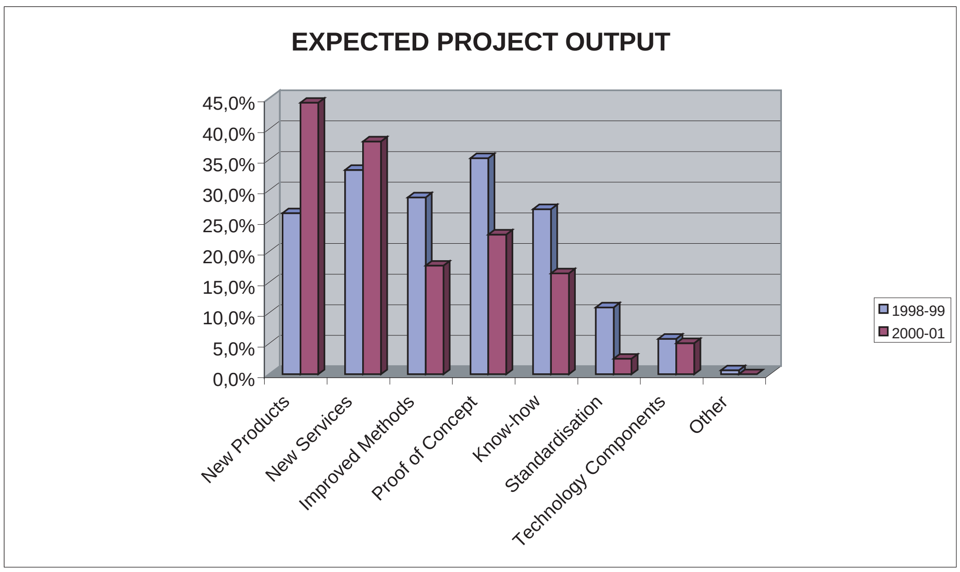


this finding and elaborate on what the new vision might be, the next section discusses the results of a detailed analysis of research themes as identified by an analysis of individual KIM projects. This analysis leads us to suggest a novel taxonomy of knowledge management and information management research.

TOWARDS A TAXONOMY OF KNOWLEDGE MANAGEMENT RESEARCH

The aforementioned empirical analysis suggests that a large and rather diverse number of research sub-themes are classified under the KIM research area. For example, in line with the theoretical analysis, a number of projects address corporate knowledge management applications, while some projects address primarily knowledge technologies (for example, technologies for knowledge representation and visualisation). This finding is also consistent with the preliminary results of the theoretical analysis of the literature and suggests that there might be an opportunity for drawing a list of sub-areas within the overall field of Knowledge and Information Management in the form of a taxonomy. It was therefore decided to pursue an exploratory analysis of individual projects to identify the most pertinent research themes and propose a more detailed classification of the KIM category.

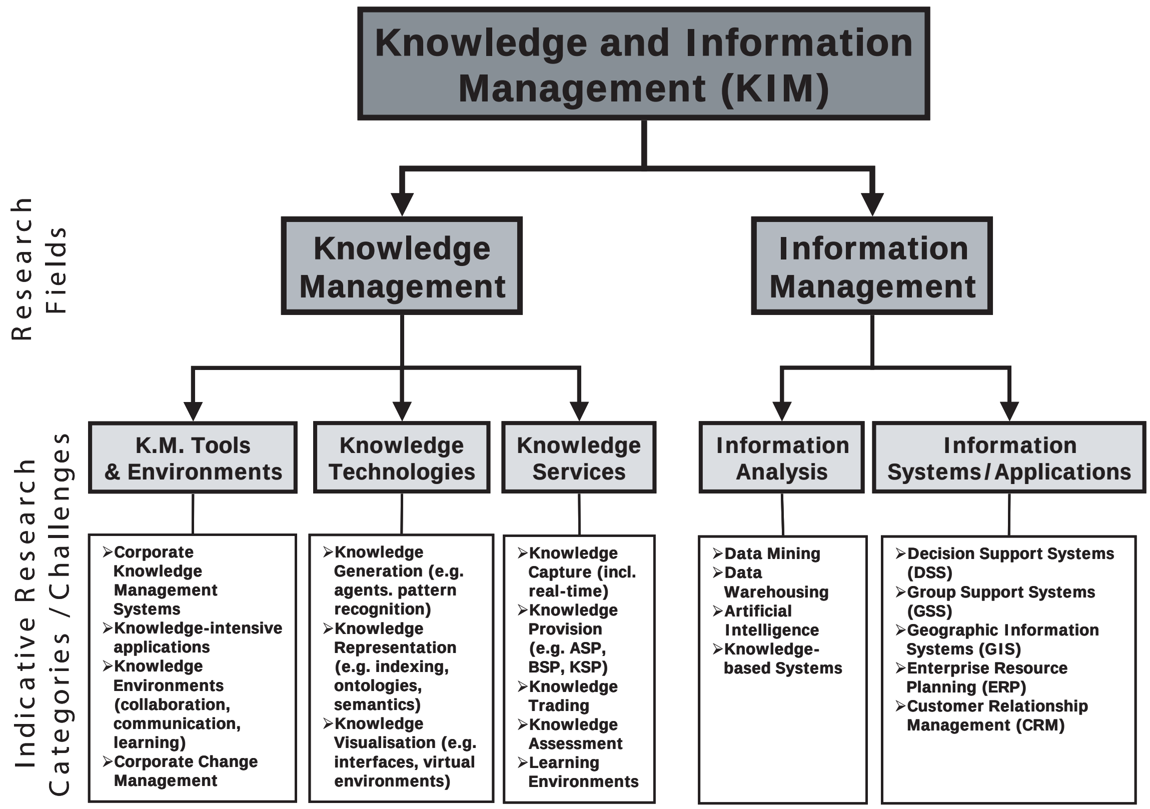
To this end, a more detailed analysis was conducted on the KIM research projects. This analysis was based on examining the project scope and objectives as provided by the researchers themselves in the description of each research project. This analysis produced the following outcomes:

- The majority of projects submitted in the Knowledge Management Key Action Line address either the provision of Knowledge Management Services (66%) or the development of Knowledge Management Systems (31%). However, more than half of these projects (55%) do not directly contribute to research and technology development, while some address issues such as ontologies (24%), knowledge visualisation (17%), and semantics (14%).
- The projects submitted in the Smart Organisations Key Action Line address primarily the provision of Knowledge Services (such as knowledge trading) (47%), Application Service Provision (12%), with limited research on knowledge technologies (12%).
- In the Open FET Domain Key Action Line that deals with high-risk long-term research, things are expectedly very different. No common research themes can be easily identified as projects deal with issues ranging from algorithms and data management to neurocomputing and learning (either for humans or machines).
- Finally, the projects submitted under the other Key Action Lines address somewhat different research themes. The majority deals with Information Analysis Methods & Indicators (33%), while some address data mining and data warehousing research problems. Finally, a minority of projects deals with organisational information systems, either in the form of decision support tools or geographic information systems.

Based on an inductive pattern matching analysis on the above findings, a novel classification for Knowledge and Information Management research is proposed (illustrated in Figure 5). According to this, the KIM area consists of two domains that present different characteristics and research roadmaps: Knowledge Management and Information Management. Each of these two main research areas can be further divided into a number of more detailed research sub-themes and challenges as shown in the figure.

It must be noted that neither the list of research sub-themes nor the list of research problems and challenges identified in Figure 5 are meant to be exhaustive. Both the fields of knowledge management and information management are very lively research areas, and any attempt to provide anything but an indicative list of current research problems would be fruitless. Instead, the taxonomy aims to suggest that the portfolio of research issues commonly placed under the

Figure 5. Taxonomy for research in knowledge and information management



KIM 'umbrella' is so complicated and diverse that it deprives KIM of the coherency that should be identifiable in any distinct research field.

At the same time, however, the fact that research in Knowledge Management presents problems and issues that are identifiable from those typically associated with the more 'traditional' field of Information Management does not mean that talking about KIM in general makes no sense. There is a clear need, identified earlier in this chapter, for an interdisciplinary approach to the overall problem of managing information and knowledge as organisational assets. However, we contend that, due to the complexity of this problem, only by a careful analytical decomposition and focused research effort may the research community address the entirety of this overall problem effectively.

CONCLUSIONS

Following a combination of theoretical and empirical research, this chapter has suggested that the research fields of Knowledge Management and Information Management are analytically separable and present distinct research challenges and issues, despite the fact that they are quite commonly treated as synonymous in much academic research and organisational practice.

Furthermore, we have shown that the overall domain of Knowledge and Information Management seems to be at a stage where the prevailing research paradigm has started to present signals of potential weaknesses, since the research community seems to be less focused on research work in recent years. Based on this observation, we may arrive at a conclusion that a paradigm shift may be required. From a research policy perspective, this would present the challenge of identifying the next paradigm, and providing the research community with support to address the research themes necessary to realise this paradigm in the near future.

However, this conclusion should be treated cautiously as significant further research is needed to substantiate it beyond reasonable doubt. Indeed, we have based our observation by examining only research projects being funded by the Commission of the European Communities. Further to the restriction of our sample within the confines of Europe only, this choice presents us with an additional potential bias. The European Commission has a certain viewpoint as to what constitutes 'research,' which is heavily oriented towards applied research and near-commercial tool development. This may explain, at least in part, the bias we have identified towards the lack of basic research and the alleged trend towards less research work being carried lately.

However, the policy implications of our findings remain significant. The challenges associated with the research categories shown in the taxonomy we have suggested are quite different from each other, and some research issues have received much less attention by policy makers (including the European Commission itself) than others. For example, we believe that the Knowledge Technologies area has been rather overlooked in comparison with other sub-fields of Knowledge Management. This includes research work in a number of frontier domains such as knowledge representation (including ontological developments and semantics), knowledge visualisation (including interfaces for knowledge presentation and understanding), and knowledge analysis (including agent-based and data mining-based knowledge analyses). Furthermore, in the Knowledge Management Tools and Environments domain, an identifiable research challenge exists to drive the development of the so-called 'next generation' Knowledge Management systems that will transform the existing 'passive' knowledge repositories into 'active' learning environments. Further research efforts may address this issue in more detail by explicating the current research challenges within the field of Knowledge Management, and devising research and policy programmes that would address this unbalanced rate of development, which, if left unsupported, will undoubtedly hinder the likelihood of successful Knowledge Management application in organisations.

Chapter 4.7
Knowledge Management and the Leading Information Systems Journals:
An Analysis of Trends and Gaps in Published Research

Todd Peachey
Auburn University, USA

Dianne J. Hall
Auburn University, USA

Casey Cegielski
Auburn University, USA

ABSTRACT

Knowledge management (KM) is maturing as a research topic, although there is still debate among researchers over what constructs form its basis. Because the topic has received increasing attention in academic journals, it is important for researchers to be aware of the research streams associated with KM. Accordingly, this paper reviews KM literature published in top-tier journals from 2000 to 2004. These articles are then classified into five constructs from two knowledge management frameworks. The results indicate that the majority of KM research has examined the construct of knowledge transfer. This conclusion holds whether examining academic or practitioner journals. Trends of published KM research, gaps, and imbalances in the examined literature and areas of potential research are presented.

INTRODUCTION

Academics and practitioners have stressed the significance of managing knowledge in today's competitive environment (Desouza, 2003). From the mid-1990s though 2004, KM has become one of the most dynamic research topics. Despite this increased attention and effort, several issues remain. Dissention exists by both academia and practitioners over the true definition of KM; there are also questions about the relevant constructs that comprise KM and where our collective research has taken us in our efforts to discover the underlying constructs. This paper examines current research in KM to determine which constructs are the most extensively researched and published in leading information systems (IS) journals.

Research in knowledge management has increased dramatically in recent years. From 1990 to 1995, a search of the ABI/Inform database using the key phrase knowledge management returned 43 articles. From 1995 to 2000, the number of articles increased to more than 700, and from 2000 to 2004, the number of articles increased yet again to more than 2,000. This research is published to varying degrees in a wide variety of disciplines, including management, hospitality, economics, health care and, of course, IS. If we examine the sample of published research in this study with consideration for the total number of articles published, we see that approximately 7% of this research is published in what are considered by many to be the leading IS journals. This is interesting in that some of those that are considered to be leading IS journals are cross-discipline journals, such as Decision Sciences and Management Science; other journals, such as Harvard Business Review and the Communications of the Association for Computing Machinery, are widely considered to be practitioner journals. These four journals alone account for more than 40% of our sample. From this we can infer that not only is there research in KM that originates from outside the IS arena, but that KM research appeals to a variety of journals with differing readership.

We propose that understanding the future direction of research in KM requires that we first know what constructs in KM have received the most attention from researchers and where there currently are gaps in the published literature. Given the quantity of current literature, there is an adequate sample size to determine the coverage of our collective research efforts. Our research indicates that the majority of KM research articles published in the leading IS journals cover the topic of knowledge transfer; this finding holds true for both academic and practitioner journals.

The first step in this research was to identify a framework or frameworks that would allow us to place published articles into a small range of categories. This review identified several frameworks for classifying KM. Our goal was to find frameworks that contained well-defined constructs suitable for categorization; we found that the Alavi and Leidner (2001) framework, in conjunction with Davenport and Prusak (1998) framework, provided a sound basis for our categorization scheme. These two works are respectively the fourth- and second-most cited KM manuscripts (Jennex & Croasdell, 2005). The second step of this study was to identify, classify and measure the quantity of research in each construct within the framework. By doing so, we will be able to provide a foundational understanding of published KM research, along with the constructs being addressed. This allows us to identify whether there is an imbalance of research in any particular area of KM within the constraints of our classification scheme.

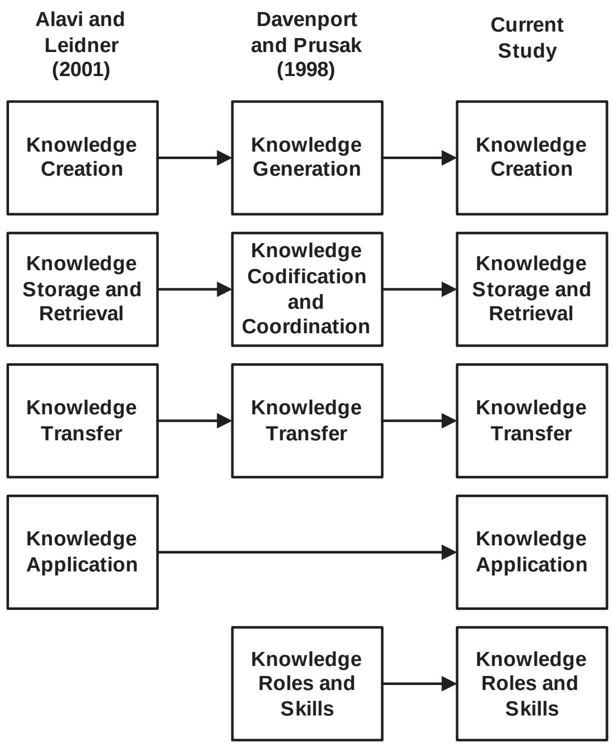
FRAMEWORK CONSTRUCTION

A coherent review emerges only from a coherent conceptual structuring of the topic itself (Bem, 1995). A number of frameworks are available for classifying KM research; one literature review identified 26 different frameworks from both practitioners and academics (Rubenstein-Montano, Liebowitz, Buchwalter, McCaw, Newman, Rebeck, The Knowledge Management Methodology Team, 2001). Some frameworks address specific concepts within the overall discipline of KM. For example, Griffith, Sawyer and Neale (2003) developed a framework to better facilitate understanding of knowledge transfer among groups and teams. Holsapple and Joshi (2001) proposed a framework to better understand an organization's knowledge resource hierarchy. These frameworks are significant contributions to the literature in their focused area. However, because a goal of this study is to identify trends prevalent to the overall concept of KM, the authors determined that the Alavi and Leidner (2001) and Davenport and Prusak (1998) frameworks are most appropriately aligned with that goal. Both of these frameworks are parsimonious in their structure and relevant to academics and practitioners alike.

The Alavi and Leidner (2001) framework separates KM research into four constructs: creation, storage and retrieval, transfer, and application. Alavi and Leidner (2001) provide extensive definitions of the four areas of KM used in this study to categorize research articles into construct categories. In addition to the articles reviewed for this study, source articles described in the Alavi and Leidner (2001) framework were also reviewed for consistency of categorization. Some of those source articles are described below in relation to specific definitions of the constructs used by Alavi and Leidner.

The Alavi and Leidner (2001) framework is formed around four constructs in the organizational knowledge management process. They state that, "organizations as knowledge systems consist of four sets of data: (1) creation (also referred to

Figure 1. Five construct categorization framework



as construction), (2) storage/retrieval, (3) transfer, and (4) application. The four constructs of this model are essential to effective organizational knowledge management" (p. 115).

Davenport and Prusak's (1998) research suggests another set of constructs: knowledge generation, knowledge codification and coordination, knowledge transfer, and knowledge roles and skills. They provide extensive definitions and examples of the different constructs. Knowledge generation, knowledge codification and coordination, and knowledge transfer are the key processes of KM; these processes are critical for an organization's successful management of knowledge (Davenport & Prusak, 1998). Knowledge roles and skills, along with technology, are enablers of KM (Davenport & Prusak, 1998). Because we cannot reasonably separate the people or the technology from the overall process of KM, combined with the fact that of the 26 frameworks identified by Rubenstein-Montano et al. (2001), none identified the supporting roles and skills necessary to make a KM initiative successful, the Davenport and Prusak framework was chosen as the second reference framework. Based on the definitions provided by the authors of both frameworks, we were able to develop a five-construct model for categorization (see Figure 1).

In the following section, the constructs are defined. These definitions are used for the classification of the papers that are the subject of this research. The definitions were developed from the material in the two reference frameworks. When noted, the original citation was reviewed to ensure the authors of this research correctly grasped the intent of the frameworks' authors.

Knowledge Creation

A significant amount has been written about the importance of knowledge to management, but little research appears to address how knowledge is created or managed (Nonaka, 1994). Alavi and Leidner's (2001) framework views organizational knowledge creation as involving a continual interplay between the tacit and explicit dimensions of knowledge (Nonaka, 1994) and a growing spiral flow as knowledge moves through individual, group and organizational levels. Nonaka (1994) stated that one dimension of the knowledge creation process can be drawn from the distinction between tacit and explicit knowledge. Explicit knowledge is knowledge that can be transmitted by formal, semantic means, while tacit knowledge has a personal quality that makes it difficult to formalize and communicate (Nonaka, 1994).

Davenport and Prusak focus on the conscious and intentional generation of knowledge. They posed five modes of knowledge generation: acquisition, dedicated resources, fusion, adaptation and networking (Davenport & Prusak, 1998). Knowledge can be acquired by an organization as well as developed from within it. Additionally, knowledge can be rented in the form of research grants and consulting contracts. Many organizations have dedicated staff to focus on knowledge generation in the form of research and development departments or other organizational think tanks. An organization that uses fusion for knowledge generation intentionally introduces conflict and complexity into the process to develop synergies. An organization's ability to adapt is critical to its long-term survival. The most important adaptive resources are employees who can easily acquire new knowledge and skills. Davenport and Prusak (1998) also refer to informal, self-organizing networks within organizations that may remain informal or eventually develop into a formal structure for knowledge generation.

Knowledge Storage and Retrieval

The process of storing, organizing and retrieving organizational knowledge is also referred to as organizational memory (Stein & Zwass, 1995; Walsh & Ungson, 1991). Two supporting technologies of knowledge storage and retrieval are data mining and learning tools. Data mining and advancing computer storage technology can be effective tools for enhancing organizational memory. One learning tool that has gained popularity in recent years is groupware. Groupware enables organizations to create intra-organizational memory in the form of both structured and unstructured information and to share this information across time and space (Walsh & Ungson, 1991). According to Stein and Zwass (1995), organizational memory is the means by which knowledge from the past is brought to bear on present activities, thus resulting in higher or lower levels of organizational effectiveness, depending on application. They proposed an Organizational Memory Information System (OMIS) that is composed of two layers: the first layer contains integrative, adaptive, goal attainment and pattern maintenance subsystems, and the second layer controls the mnemonic functions of knowledge acquisition, retention, maintenance, search and retrieval.

The aim of codification is to put organizational knowledge into a form that makes it accessible to those who need it (Davenport & Prusak, 1998). This knowledge is coded (although not necessarily computer coded) into a form that is organized, explicit, portable and easy to understand (Davenport & Prusak, 1998). The importance of mapping knowledge to the codification process was also noted. The principal purpose and clearest benefit of a knowledge map is to show people in the organization where they need to go when they need expertise (Davenport & Prusak, 1998).

Knowledge Transfer

The ability to transfer knowledge is key for an organization. Knowledge transfer occurs at many levels. Knowledge can be transferred between individuals, from individuals to explicit sources, from individuals to groups, between different groups, and between groups and the organization (Alavi & Leidner, 2001). Knowledge transfer between organizations is also gaining popularity. As organizations become more integrated, there is more transfer of knowledge between organizations through integrated supply chains and other cooperative systems. Knowledge flows within an organization are affected by five major elements: (a) the value of the source unit's knowledge stock, (b) motivational disposition of the source unit, (c) existence and richness of the transmission channels, (d) motivational disposition of the receiving unit, and (e) absorptive capacity of the target unit (Gupta & Govindarajan, 2000). Alavi and Leidner (2001) note that of these five elements of knowledge transfer, the majority of research in knowledge transfer focused on the third element, existence and richness of the transmission channels. However, in a majority of articles reviewed for this research, the respective authors noted that the channel is only part of the process of knowledge transfer.

Knowledge is transferred in organizations whether the process is managed at all (Davenport & Prusak, 1998). Davenport and Prusak extensively discuss knowledge transfer in both formal and informal intrapersonal exchange. Technology came into play as a threat to knowledge transfer by way of virtual offices and groupware (Davenport & Prusak, 1998). Research in KM asserts that technology can both increase and decrease knowledge transfer through its effects on the interpersonal contact between workers.

Knowledge transfer is the first area where the two frameworks diverge. While Alavi and Leidner (2001) separate transfer and application, Davenport and Prusak (1998) combine the constructs through the following equation: Transfer = transmission + absorption (and use).

For the purposes of our classification, we use the separate constructs as proposed by Alavi and Leidner (2001). This allows us a slightly more concise classification of the knowledge transfer concept.

Knowledge Application

The importance of knowledge application is that the source of competitive advantage lies in the application of the knowledge rather than in the knowledge itself (Grant, 1996). There are four mechanisms for integrating specialized knowledge: (a) rules and directives, (b) sequencing, (c) routines, and (d) group problem solving and decision-making (Grant, 1996). Technology can support knowledge application by embedding knowledge into organizational routines (Alavi & Leidner, 2001). Both the concepts pertinent to knowledge application and the relevant technology are important to ensure the most effective use of organizational knowledge.

Knowledge Roles and Skills

If KM is to thrive, organizations must create a set of roles and skills to do the work of capturing, distributing and using knowledge. Knowledge-oriented personnel, KM workers and chief knowledge officers all are important for successful organizational KM. Four levels of KM roles are: (a) line workers who must manage knowledge within their own jobs, (b) KM workers, (c) knowledge project managers, and (d) senior knowledge executives (Davenport & Prusak, 1998).

METHODOLOGY

Data Gathering

Major contributions in any domain are more likely to be represented in leading journals of that field (Webster & Watson, 2002). KM research has been published in a wide variety of journals in many disciplines; however, our focus is specifically that increasing amounts of research in a specific topic that is accepted into leading IS journals is generally a signal of a topic's increasing maturity and acceptance within mainstream academia. To determine which journals are generally considered to be leaders, we used two recently published articles that ranked IS journals to determine the list of publications to search for the relevant literature. The first is a recent article by Peffers and Ya (2003), and the second is an article by Mylonopoulos and Theoharakis (2001). Using two ranking schemes allowed us to increase the probability that the journals chosen for this study research did, in fact, represent the leading IS journals.

The Peffers and Ya (2003) article in the Journal of Information Technology Theory and Application (JITTA) identified 10 top-rated journals as: Information Systems Research, MIS Quarterly, Journal of Management Information Systems, European Journal of Information Systems, Decision Support Systems, Information and Management, Information Systems Journal, Journal of the Association for Information Systems, International Journal of Electronic Commerce and Information Systems. In this article, Peffers and Ya used several ranking schemes. For our purposes, we chose the ranking scheme that used the average weighted perceived value rating of journals as outlets for information systems research. In this scheme, Peffers and Ya (2003) used only rankings for journals that were rated by at least 10% of their respondents. This avoided the problem of artificially inflating a journal's ranking by a small number of researchers (Peffers & Ya, 2003).

Five of the journals in the Peffers and Ya (2003) study were also included in the article by Mylonopoulos and Theoharakis (2001). These were Information Systems Research, MIS Quarterly, Journal of MIS, Information and Management, and Decision Support Systems. Rounding out their top 10 were the Communications of the ACM, Management Science, IEEE Transactions, Harvard Business Review and Decision Sciences.

The journals chosen to represent IS also cross other disciplines and represent practitioners. For instance, both Communications of the ACM

and Harvard Business Review are considered practitioner-oriented. Decision Sciences and Management Science are leading journals in the production and operations management disciplines as well as IS. Journals outside the IS discipline are beyond the scope of the current investigation. Table 1 summarizes the journals chosen for this study from the list of journals in the articles mentioned in this section.

The current study examines a four-year window. The ABI/Inform database was used to search the journals listed in Table 1 from January 1, 2000 through December 31, 2004. Each journal was searched using the advanced search option that allowed the authors to restrict the search dates and publication source. All of the journals listed in Table 1 were searched; however, there were no applicable articles that appeared in the International Journal of E-Commerce, and therefore this journal will not appear in the discussion to follow.

After applying date and publication constraints, the authors further restricted the search to the key phrase knowledge management. This key phrase was chosen because we were specifically searching for articles where the authors explicitly stated they were researching "knowledge management." We found that this term allowed us to find articles specific to individual constructs (for instance, knowledge transfer) as well as articles that may or may not represent constructs but are published under the general KM umbrella. We also found that many articles whose authors specifically used "knowledge management" as a key phrase were not in the mainstream of KM research. For example, one article focused on the effects of animation on information seeking on the World Wide Web (Zhang, 2000). Had we chosen only to search on specific construct terms, these more general articles may have been missed. The process outlined above presented a sample of 132 articles.

The identified articles were reviewed to determine which framework construct or constructs were represented in the research, and each was coded according to the number of constructs represented in the article, with a maximum sum of one. For example, an article describing research in knowledge creation was coded as a one. We expected, and found, that many articles represented more than one construct. When this was the case, the value was divided by the number of constructs addressed in the article. For example, if an article contained research in both knowledge creation and transfer, each construct was coded with .5, giving the total for the article a sum of 1. For a construct to receive credit from a specific article, the process had to have more than cursory coverage. Several articles briefly described one of the other functions without including it in the research or conceptual development. This coding process was conducted individually by our research team based on the collective understanding of the construct definitions and the example articles from our two frameworks. Cross-checking was conducted to identify inconsistencies in coding; although few were found, each was addressed and a consensus reached as to the correct coding scheme.

Results

The number of articles in the publications ranged from a high of 27 to a low of one. Knowledge transfer was the most frequently researched topic, with knowledge storage and retrieval the second most frequently researched topic. The constructs of creation, application and roles/skills were represented about equally across the publications.

Decision Support Systems and Management Science published the most articles on KM, with 23 and 27 articles respectively. However, each of these journals published a special KM issue. Decision Support Systems published nine articles in its knowledge management issue in May 2001; Management Science published 13 articles in its "Special Issue on Managing Knowledge in Organizations: Creating, Retaining, and Transferring Knowledge" in April 2003. Removing these special issue articles indicates that these journals have published about the same number of articles on KM as the next highest journals, European Journal of Information Systems, Journal of Management Information Systems and Harvard Business Review. Information Systems, Information Systems Journal and IEEE Transactions each published three articles. JAIS published the least number of articles on KM, with only one article each in the time period. Table 2 shows the complete distribution of the relevant articles published in the journals reviewed. The Number of Articles column contains the total number of articles published in the specific journal over the period in our study. The number in each of the other five columns reflects how many of the articles were coded into a specific knowledge management construct from each journal. Fractions may occur depending on the number of articles included that represent more than one construct.

Several articles described research in more than one of the construct areas. Twenty-seven articles were coded as research covering two constructs. One article was coded as research covering three constructs, and four articles were coded as containing research on four constructs. Nine articles that researched other areas of KM did not fit into any of the processes in the chosen frameworks; several of these articles proposed research agendas. Other articles identified in the search did not involve KM as the primary area of research, but were identified by the search engine, which often returns "information" as an alternative to knowledge.

Much of the research published in the top journals was based in the construct of knowledge transfer. Approximately 42% of all articles focused all or in part on knowledge transfer. Storage and retrieval was the second most-researched construct, with 21% of all the articles conducting research in this construct. Knowledge creation and knowledge application accounted for 13% and 14%, respectively, of the published articles. Knowledge roles and skills was the least-researched topic, accounting for 10% of the published articles. Previous research by Davenport et al. (1996) showed that

Table 2. Leading IS journals and KM articles

Journal	Number of Articles in each journal	Creation	Storage & Retrieval	Transfer	Application	Roles and Skills
Communications of the ACM	10	1	3.5	4.5	0	1

** this journal published an entire issue on Knowledge Management						

there was a lack of research in knowledge generation. The results described in Table 2 show that researchers might have addressed Davenport's initial concerns. From 2000 through 2004, it appears that creation (generation) was researched at approximately the same frequency as application constructs, although still well behind either transfer or storage and retrieval. Table 3 shows the breakdown of the research by percentage of each of the constructs in KM.

Two of the journals from which articles were chosen are well-known practitioner journals. Both of these journals were ranked by Mylonopoulos and Theoharakis (2001) as leading places to publish IS research. An interesting question is whether the practitioner journals have a different focus than the other journals in this study. If we examine the articles only from Harvard Business Review and Communications of the ACM, we can see another interesting trend. Although the sample size is very small, n=21, knowledge transfer is researched significantly more than the other constructs. Storage and retrieval is still the second most-frequently-published construct, but

Table 3. Topic coverage in all journals

Knowledge Management Topic	%
Creation	12.75
Storage and Retrieval	21.08
Transfer	42.30
Application	14.02
Roles and Skills	9.85

Table 4. Topic coverage in practitioner journals

Knowledge Management Topic	%
Creation	9.52
Storage and Retrieval	16.67
Transfer	59.53
Application	2.38
Roles and Skills	11.90

Table 5. Topic coverage in academic journals

Knowledge Management Topic	%
Creation	13.36
Storage and Retrieval	21.92
Transfer	39.04
Application	16.22
Roles and Skills	9.46

there is marked difference between it and transfer. Further, unlike the complete journal set, these practitioner journals emphasize rolls and skills over either creation or application. In fact, application received only minimal coverage in the practitioner journals. Table 4 shows a summary of the articles published in practitioner journals.

Separating the practitioner journals from the other journals shows another interesting result. When the practitioner journals are removed from the sample, knowledge transfer is still the most heavily researched topic, but storage/retrieval and application increase. This, in conjunction with the decrease in the percentage of transfer articles, shows a narrowing of the gap between these constructs in academic journals. Table 5 summarizes these results.

We also investigated the result of removing the special issues from the the numbers above. We removed a total of 22 articles: nine from the

May 2001 issue of Decision Support Systems, and 13 from the April 2003 issue of Management Science. In doing so, we found that the percentage of storage and retrieval articles increased by approximately 3% and the percentage of application articles decreased by approximately 3%. The other constructs moved by less than 1%. This indicates that the constructs in the special issues were as broadly covered as those in the rest of the publications.

While trend data is of interest and shows, in general, that two of the constructs (transfer and storage/retrieval) are more frequently addressed in published work than the others, it is often insightful to apply statistics to determine whether the viewed differences also have statistical difference. Using the entire sample population, means differences were calculated to determine whether one or more constructs is significantly over or under represented.

We expected that research addressing the constructs used in our framework would be relatively evenly disbursed; that is, that each construct would be represented in about 20% of the sampled articles. With the exception of storage and retrieval, all constructs' expected values were significantly different than .2. The construct of transfer was significantly higher than the expected value, while the other constructs — creation, application, and roles and skills — were lower. When completing a means comparison between constructs, we found a significant difference between the coverage of knowledge transfer and all other constructs, at p=.000. Additionally, there was a significant difference between the roles and skills construct and the storage and retrieval construct, at p=.012. Finally, there was an arguably significant difference between creation and storage and retrieval, at p=.067. From the information above, it appears that only storage and retrieval is published at about the level we would expect. Transfer is published more than twice as often as the other constructs; the remaining constructs are under-published.

DISCUSSION

This research raised almost as many questions as it answered. Why is knowledge transfer the dominant construct within KM? Is knowledge transfer more interesting to researchers than the other constructs? Is it easier to operationalize and examine? One explanation may be that information technology supports the knowledge transfer construct; thus, many IS researchers choose to investigate the medium rather than the process of transfer. However, as noted earlier from both Alavi and Leidner (2001) and Davenport and Prusak (1998), knowledge transfer is more than just the channel, medium or technology. In fact, it is estimated that much, if not most, knowledge transfer happens during informal communication (e.g., the "water cooler" theory) and is separate from technology. Further, most researchers suggest that tacit to explicit knowledge conversion is difficult, if not impossible, despite advances in research in communication technology. Channel and media richness is researched, as have been collaborative systems, but less research has been done in the realm of learning behaviors. Given the results of this study, it documents that IS researchers are looking at KM through a "technical" lens and, thus, that research is published in IS-oriented journals.

However, while answers to these types of questions may explain the trend in academic journals, we still don't know why practitioner journals focus so heavily on knowledge transfer. Is it because many organizations believe that KM is appropriate use of technology, rather than a new process? That is, when the technology field leveled, and other avenues of competitive advantage were sought, did use of technology as a KM tool rise to the surface? Is it that we, as IS researchers, are able to inform the practitioners with best practices for technology management more easily than best practices for people management?

Another question this study begets is whether the balance of the academic and practitioner literature would still lean toward knowledge transfer if other journals that publish KM articles but were not included in the scope of this research were included in the study. To answer that question, we examined articles in top management journals as ranked by Johnson and Podsakoff (1994). The journals identified by this ranking were: Administrative Science Quarterly, Research in Organizational Behavior, Academy of Management Review, Academy of Management Journal, Journal of Applied Psychology, Strategic Management Journal, Organizational Behavior and Human Decision Processes, Industrial and Labor Relations Review, Harvard Business Review and American Sociological Review. Using the same constraints and key phrase search done for IS journals, we found approximately 20 articles in these 10 journals that referenced KM. The articles from Harvard Business Review were not included, as they were already classified in the original search; of the remaining articles, approximately 75% addressed the issue of knowledge transfer. The May 2003 issue of Organization Behavior and Human Decision Processes was almost exclusively composed of articles that addressed knowledge transfer in one form or another; however, if we remove this issue from the sample, knowledge transfer is the topic of almost half of the remaining articles. Apparently, knowledge transfer is the most commonly researched construct from a management viewpoint also, albeit in a less technical vein than within the IS community.

We believe that transfer, as well as storage and retrieval, remain topics of interest in the IS community because of their obvious tie with information technology. It is telling that academic journals publish articles on knowledge roles/skills least often, whereas practitioner journals published that construct as often as both creation and application. While both creation and application also have direct ties to information technology (e.g., data mining, discovery, expert systems), roles and skills are less directly associated. Nonetheless, IS are constructed to support people; skills necessary to succeed with new technology and roles designed to shepherd the process are necessary and should be included in research done by the IS community.

FUTURE RESEARCH

Webster and Watson (2002) stated that a review should identify critical knowledge gaps and thus motivate researchers to close this breach. With this in mind, the authors make the following recommendations. First, researchers should look to expand this study by extending this research to more KM-focused journals to determine if the conclusions still hold. The research could be expanded to see if the trends identified in this article are consistent among KM-focused publications. Specifically, journals that focus on KM, such as the International Journal of Knowledge Management, Journal of Knowledge Management and Journal and Knowledge Management Research and Practice, should be reviewed with a similar methodology and framework to determine if it is truly the research that is focused on knowledge transfer or if the leading IS journals tend to publish knowledge transfer articles more frequently than other topics in KM.

Second, other frameworks are available that would be appropriate for this methodology. Applying one of these frameworks may provide a differing view of the state of research in KM. A different framework may view the topic in a manner that sheds new light on the collective research efforts of the community. For example, Argote, McEvily and Reagans (2003) propose a matrix framework for organizing the literature in KM. Their framework proposes viewing KM outcomes of creation, retention and transfer vs. KM contexts of properties of units, properties of relationships between units and properties of knowledge. Given the two-dimensional nature of this framework, the results would be extremely useful for the discipline.

Researchers should try to expand the coverage of the constructs that are currently under-researched. As shown earlier, knowledge transfer has been the object of a disproportionate amount of effort relative to the other constructs. Given the current depth of theories and frameworks, there should be an adequate foundation to perform more research in the areas of creation, storage and retrieval, and application. If the conclusions of this research remain consistent after studying other KM publications, future research in KM should start to address the relative shortage of research in creation, application, and storage and retrieval. These areas have significantly less research than the construct of knowledge transfer. For the field to continue to grow, researchers must provide more even coverage to all the relevant constructs in KM.

An additional benefit of increased research of the other constructs within KM would be an increased precision in the respective definitions of the constructs. First, there is not universal acceptance that these constructs form KM. Next, as research coverage of the other constructs increases, there may likely be a natural selection of the most appropriate definitions. Finally, further research may influence researchers to determine the most appropriate framework to define KM and increase the precision of future research.

CONCLUSION

This study found that current research has investigated the construct of knowledge transfer more frequently than the other constructs in KM as developed from the Alavi and Leidner (2001) and Davenport and Prusak (1998) frameworks. This conclusion remains consistent whether examining academic research journals or practitioner-focused journals. While this is currently not a significant problem, it could be in the future. For KM to continue to grow as a respected topic within the IS research discipline, we must present well-rounded and parsimonious yet diverse research to the rest of the IS community. If one of the constructs within KM is researched extensively while the others are less developed, the topic as a whole will suffer from an imbalance. As a community of researchers, we know that KM is more than just knowledge transfer. For practitioners to deploy effective KM systems, the other constructs must be more fully developed. The Davenport and Prusak construct of knowledge roles and skills adds a critical area to the topic of KM. For KM to be truly effective, few could argue against the need for appropriate supporting skills. Researchers should more fully investigate the other constructs that form the foundation of KM.

This research raised a number of interesting questions about the research effort apparent in published work. A number of excellent articles are identified in this paper as well as many others that were not described in detail because of space constraints. Many of these articles proposed concepts that form an excellent foundation for further investigation. As a community of researchers, we know that KM is more than regeneration or integration of other, more mature topics such as expert systems or decision support systems. Additional research in the other core constructs while framed under the topic of KM will serve to enhance the understanding of the breadth of KM and ensure it remains a significant research topic in the future.

A list of the articles reviewed for classification may be obtained from the authors.

An earlier version of this paper was presented at HICSS-38 on January 4, 2005.

Chapter 4.8
Document Search Practices

Karen L. Corral

INTRODUCTION

A large portion of the knowledge of most organizations is contained in electronic documents. For users to get pertinent information from the accumulation of stored documents, they need effective document retrieval systems. Unfortunately, electronic document management has fallen into the same trap that electronic data processing fell into: simply automating what previously was done manually. Paper documents were stored in folders in drawers in file cabinets. Electronic documents are stored in folders in directories on disk drives.

The ability to find a document depends on the logic of the filing system, how familiar the individual is with the filing system, and how familiar the individual is with the problem domain of the item being sought. Some persons (e.g., research librarians) are much better than others at organizing and retrieving documents. Rarely, however, is a manager an expert at either storing or retrieving documents. Unfortunately, many electronic filing systems are set up by managers with little or no training on how to organize a filing system, and few tools, other than the Windows Search command, are available to help managers find documents that have been filed.

The filing systems for libraries and knowledge management systems are more sophisticated than the filing systems of most small offices or individual managers. But even libraries and knowledge management systems predominately rely on keyword searching for retrieval. For example, if one visits the Web site for the Journal of Management Information Systems at http://jmis.bentley.edu/keywords/, one notes that the only option available for searching (other than browsing the entire collection) is a keyword search.

Keyword searching has improved over the years. Knowledge seekers have benefited enormously from the ability to search remotely, the increased speed with which searches are conducted, and the ability of the search mechanism to identify variations of the keywords. Nevertheless, keyword searches have significant limitations. In particular, keyword searches cannot return all relevant documents nor can they filter out irrelevant documents. This article briefly reviews the difficulties associated with keyword searches, especially as the number of documents increases, and proposes a way to overcome those limitations.

BACKGROUND

In his 1990 seminal article on business process engineering, Hammer (1990) argues that organizations should use computers to redesign—not just automate—existing business processes. With document management systems, the opposite has been done. Documents were stored in file cabinets in offices or on shelves in libraries, and electronic document storage systems adopted the same basic principles.

Paper documents such as memos, white papers, reports, and so forth were filed based on the value of some specific field (e.g., project name). To retrieve a document, a user needed to know the value of the field which was used to organize the documents. Because of the shear mass of paper that quickly accumulated in any office, duplication for the purpose of access through multiple fields was not encouraged. In highly organized filing systems, cross-references were filed for important documents, resulting in the capacity to find some documents from two or three different fields. However, this was done infrequently, was quite time-consuming when it was done, and was difficult to maintain.

The logic of the paper filing system usually was determined by a secretary or office assistant, who also was the person primarily responsible for retrieving the documents. This person generally had significant knowledge of the content of the documents, and therefore the system worked quite well for that individual. Unfortunately, the system did not work as well for others.

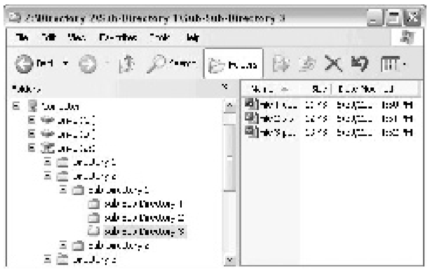
Today, most individuals organize their computer directories in the same manner in which their file cabinets were organized, or even more poorly because they have had little or no training on filing and tend to store all of their folders in the hard drive root directory. While this may be an acceptable strategy for a small set of documents, it is unacceptable when dealing with a large number of documents.

Figure 1 shows the similarity between paper filing systems and simple computerized filing systems. To find a file in the paper system, an individual needs to know which file cabinet to search, which drawer to select, and which folder contains the sought after file. To find a file in the computerized system, an individual follows a very similar strategy. The individual first selects the disk drive to examine, then searches the directory, sub-directory, sub-sub-directory, and so forth, until the file is located. The only advances made to this point are the amount of physical space saved and the ability to use the “find” command.

At the organizational/library level, document management systems require more structure. Generally, documents are organized by hierarchical levels of categories. For example, with the Dewey Decimal system, documents associated with “technology (applied sciences)” are grouped together. Within that category, “management” is separate from “manufacturing” and so on. A major benefit of this method of organization is that once the individual arrives at one document on the topic of interest, other potentially relevant documents are located in close proximity and are easily browsed for relevance. Everyone who has visited a library has located additional relevant books by browsing the library’s physical stacks.

Indexes make cross-referencing of materials possible. Though not physically stored together on

Figure 1. Filing cabinet vs. simple computerized system



shelves, documents that are similar with respect to some characteristic (other than the one used to physically store the document) can be referenced together in a card catalogue. Cross-referencing is very important for libraries. An article that describes how regression analysis is used to conduct mass appraisals, for example, should be locatable both by someone who is interested in applications of regression analysis and by someone who wants to understand how the county assessor determines the assessed value of a home using regression analysis. This only can be done with cross-referencing.

Even with cross-referencing, however, the problem remains of needing an entry point for retrieving relevant documents. Not knowing applicable keywords makes a library little more than a jumble of documents. Given the sheer number of documents that are stored, it no longer is possible for one, or a few individuals, to know the content of each document. Librarians are experts at the storage system, but to be useful to the individual they need to understand the subject matter (e.g., a chemical librarian vs. a general librarian). The ability of librarians to keep up with the content of documents is limited by the capacity of human cognition. As the volume of documents increases, the ability of librarians to help individuals diminishes. Further, librarians are limited in their capacity to identify documents from a different area that might be pertinent to the individual. The limitations on human memory prevent any single individual from retaining adequate information to be able to answer questions on a wide variety of subjects.

Current State

Today, more and more documents are being stored electronically. Several factors have contributed to the shift from paper to electronic documents, including the low cost of mass storage devices, the ease with which documents can be scanned and stored, government recognition of electronic signatures, the replacement of desktop computers with notebook computers, and ubiquitous access to the Internet. After more than 30 years of being just around the corner, the paperless office finally is moving from myth to reality. Many organizations provide their employees with notebook computers, and strongly encourage the use of digital documents for sharing information. Unfortunately, those same organizations provide little guidance on how to store or retrieve digital documents, and the ability to effectively retrieve documents has fallen far behind the capability to store documents.

The introduction of electronic document retrieval systems offered an opportunity to address three significant problems associated with the storage of paper documents. First, a large number of documents could be stored in very little space. Second, retrieval time after a document is located became almost zero. And third, anytime, anywhere, access enormously simplified retrieval. Unfortunately, increasing the speed and convenience with which a large number of documents can be retrieved does not help the individual to locate the documents that he or she needs. In fact, it produces a new problem: information overload.

Most document retrieval systems rely on keyword searching as their primary retrieval mechanism. Keyword searches have problems with respect to both locating all of the relevant documents and locating only relevant documents. The problems with respect to locating relevant materials are well documented (Blair, 2002a, 2002b; Gorla & Walker, 1998; LaBrie & St. Louis, 2003). Gorla and Walker (1998) group the problems into the following categories:

- Errors in spelling
- Inconsistencies of abbreviations
- Improper combining of dissimilar terms
- Inconsistent spelling of words
- Inconsistent compounding of words
- Redundant keywords

LaBrie (2004, p. 92) shows that because of these problems keyword searches find only 10% to 30% of the relevant documents in organizational holdings. This is a low percentage as compared to alternative retrieval mechanisms such as visual hierarchies.

Keyword searches also can overwhelm the individual with irrelevant articles. If a keyword insufficiently defines the search scope, many documents will be returned that are not relevant. For example, if a user needs information on the systems development life cycle (SDLC), selecting all documents with the keyword "system" will result in a large number of documents unrelated to the SDLC. This problem is annoying but manageable for small holdings. If 20 documents are returned and only 10% are pertinent, it does not take long to look through the 20 documents to find the two useful ones. However, if the result set size is 5,000 documents, the user will not be able to look through all 5,000 documents.

The scalability of retrieval systems is a serious problem. The Zipf distribution has been shown to apply to natural languages (Blair, 2002). Briefly, the Zipf distribution shows that as the number of documents increases, the number of documents in which a specific term occurs also increases. Further, as the library increases in size, the likelihood of a term being used with different meanings also increases. So not only does the result set size increase, but the percentage of irrelevant documents in the result set also increases.

Increased processing speed makes it possible to scan the full document for a keyword, as opposed to scanning just the keyword field, title, or abstract. This article uses the term "causal modeling" in Figure 2 and its associated text. With full document scanning, a search for documents dealing with causal modeling would return this article, although the content of this article has nothing to do with causal modeling. Blair (2002) labels this phenomenon as "over-description," and defines it as a situation where "some, or many, of the terms that are used to describe the document may misrepresent the intellectual content of the document" (p. 280). Though it is technically possible to perform full document scanning, or have a large set of keywords describing a document, doing so may be counterproductive to the objective of retrieving pertinent documents. Increasing the speed of search mechanisms does not solve the information overload problem.

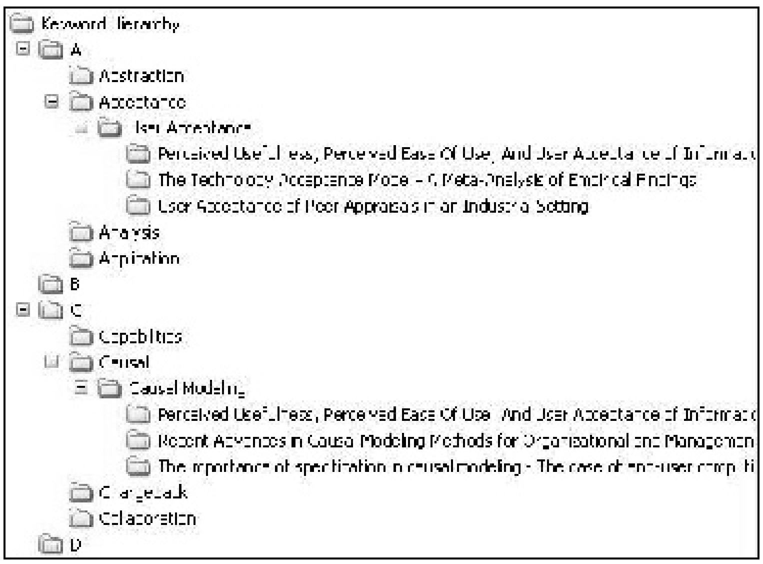
Cognitive psychologists have been studying human memory capacity for well over 100 years (Ebbinghaus, 1913) and have identified two predominant forms of retrieving information from memory: recall and recognition. Trying to remember the name of someone you met at a conference is recall. Recognition is remembering that person's name when looking at a list of conference attendees. Recognition routinely outperforms recall in retrieval accuracy, especially when context is added by organizing the information hierarchically (Anderson, 1995; Bower, Clark, Lesgold, & Winzenz, 1969; Clark, 1999; Simon, 1962).

Figure 2 is an example of a hierarchical arrangement of keywords. The hierarchy is based on the alphabet and has a four level structure. The root node, or highest level of the hierarchy, is the first letter of any word that has been used in any keyword phrase. The next level represents a unique word that was used in a keyword phrase. The third level identifies the actual keyword phrase provided by the author(s). The fourth and lowest level of this hierarchy is the title of the document that contains the keyword phrase. In an electronic document management system this title would contain a link to the actual document.

In Figure 2, note that all articles with the keyword phrase "user acceptance" are grouped together. Similarly, all articles with the keyword phrase "causal modeling" are grouped together. Although the documents themselves are stored in one location (eliminating duplicate copies which wastes disk space), links to the articles can be stored in multiple locations. This makes electronic browsing much more effective than physical browsing. As an example, suppose Davis' (1989) article on the technology acceptance model used as its keywords user acceptance and causal modeling. An individual who is interested in applications of causal modeling, easily finds Davis' article on "Perceived Usefulness, Perceived Ease of Use, and User Acceptance of Information Technology" even though he or she may never have thought to look under "User Acceptance," which is where the article may have been physically stored based on subject.

With existing low cost and pervasive technologies any individual or small office can create the search mechanism shown in Figure 2 (LaBrie & St. Louis, in press). The process to develop such a visual keyword hierarchy is quite simple. Keyword phrases are taken from an article's keywords list when the article is entered into the

Figure 2. Visual keyword hierarchy



system. The keyword phrases are broken down into individual words. Trivial words such as "a," "the," and "and," are removed. Individual words are linked to their original keyword phrase and the article with which the keyword is associated. The result is a hierarchy similar to Figure 2 that allows a user to search via any of the words within the keyword phrase. If someone were looking for articles on the "Technology Acceptance Model," they could find them in three different areas of the hierarchy: (1) Under A, Acceptance, Technology Acceptance Model; (2) Under T, Technology, Technology Acceptance Model; or (3) Under M, Model, Technology Acceptance Model.

Hierarchies built on keywords are easily maintained. As new articles with new keywords are added to the holdings, trigger mechanisms can be implemented to dynamically update the hierarchies (LaBrie & St. Louis, in press). These dynamic hierarchies are easily searched because both individual keywords and keyword phrases appear in them. This means the individual does not have to spell the keyword correctly nor recall the exact keyword phrase. The only requirements are that the individual recall the first letter of a relevant keyword (where to enter the hierarchy) and recognize relevant keywords or keyword phrases that appear in the article (browse the hierarchy). This overcomes many of the disadvantages of keyword searches and allows individuals to retrieve documents from their notebook computers or organizational servers as effectively (or more) than documents can be retrieved from a library.

FUTURE TRENDS

The number of stored documents is increasing at an astronomical pace (Ball, 2002). The advances that have occurred with respect to the ease and speed of searching have been equally dramatic. But as the collection of documents grows, the scalability of retrieval systems is adversely affected. As a consequence, both the number of articles and the percent of irrelevant articles in the result set increases. The real challenge now is to filter out the irrelevant documents. A promising approach is to filter articles on the basis of both context and keywords.

To capture the intellectual context of a document requires more than picking out words or phrases from the document. For example, a document that includes the results from a regression analysis that was performed using the SPSS statistical package on data from the assessor's rolls to create mass appraisal values for individual homeowners may be very useful to someone wanting to see an application of regression analysis, but may not be useful to someone wanting to understand how conditional means are calculated by software that enables regression analyses. Using keywords alone, there is no way to distinguish between documents that focus on applying regression analysis and documents that focus on explaining regression analysis. Yet regression analysis is a legitimate keyword for both searches.

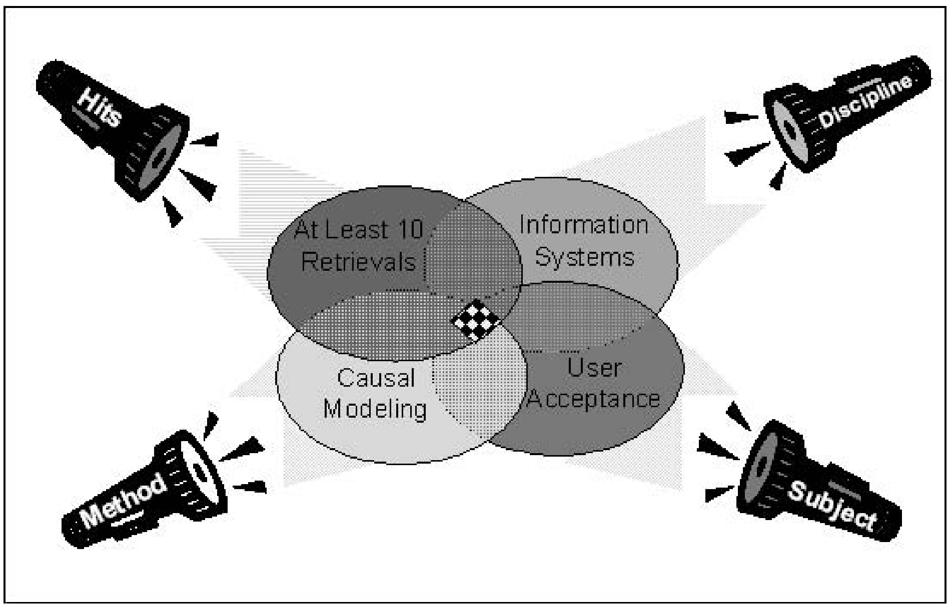
One role that the librarian fills is that of a domain expert. The librarian can distinguish between articles that apply regression analysis and articles that explain regression analysis, or even much finer distinctions of word use. Document retrieval systems need a context filtering mechanism that can substitute for the librarian. One reason why librarians are so effective at finding relevant articles is that they understand both the Library of Congress Subject Headings and the Dewey Decimal System. Categorization provides context. If electronic document retrieval systems are going to become as effective as librarians at filtering out irrelevant documents, then they need to use categorization schemes. Presenting the categorization scheme as a visual hierarchy contributes even more to effectiveness because the user can recognize the categories which are appropriate.

Continuing with the example of an article that applies regression analysis vs. an article that explains regression analysis, one lens through which to filter the articles might be "subject of document." The individual, when presented with the initial list of search lenses, would select "subject of document" and then be presented with a list of possible subjects which might include, among others, the subjects "residential property appraisals" and "regression analysis." The individual wanting an explanation of regression analysis would select the "regression analysis" subject and not the "residential property appraisals" subject. Another lens could be "most frequently retrieved," which is similar to one used by Google and other search engines. This presumes that the most useful documents will be retrieved most often. With electronic documents, it is easy to record the number of times a document has been retrieved for a particular subject category.

Applying lenses is different than applying an "and" search on keywords. It is cross-indexing documents by both keywords and the lens categories that are selected. Visual classification hierarchies enable the individual to use recognition-based rather than recall-based search mechanisms to select criteria, and thus enable the individual to see the context of the keyword. This greatly enhances the individual's ability to screen out irrelevant articles. It is important to note that the set of lenses does not have to be the same for every electronic document management system. Rather, a set of search lenses can be designed to fit the needs of the organization. A research lab's document management system, for example, might include a "methodology" lens, while a law office's document management system might not.

Knowledge workers spend a tremendous amount of time culling irrelevant documents. A keyword search can return thousands of documents with only a small fraction of those being relevant to the individual's needs. By adding multiple visual hierarchies as lenses, many of those irrelevant documents can be removed. It takes some time and effort to create and maintain the

Figure 3. Examples of lenses



classification schemes required to add the needed context. However, the amount of time and effort is not Herculean. Allowing users to specify subject headings, and arranging them into visual subject hierarchies using the same technique that is used to construct visual keyword hierarchies (LaBrie & St. Louis, in press), does not require a great deal of effort. Moreover, once established, these new visual classification schemes will greatly facilitate knowledge management. Figure 3 illustrates a situation where four lenses are used: discipline, subject, methodology, and number of hits. In this example, an article would be retrieved only if it were categorized as being in the information systems discipline, had a subject of "user acceptance," used causal modeling as its methodology, and had been retrieved at least 10 times.

CONCLUSION

There is a disconnect between the ability to store documents and the ability to retrieve them. It is extremely easy to save documents. In fact, it is so easy to save documents, and storage space is so inexpensive, that many individuals save all documents that are sent to them, rather than determining which ones might be needed later. Unfortunately, when it comes time to find a document, they frequently fail to do so, or take a long time to do so. The ease with which documents can be stored stands in stark contrast to the difficulty of finding a sought-after document that one knows is stored somewhere in a personal or organizational file.

A solution to this information overload is to add context to the keywords through the application of various classification schemes (subject, author, methodology, etc.). These classification schemes can be maintained and presented to the user in the form of multiple dynamic, visual hierarchies. This approach to document retrieval significantly reduces the numbers of irrelevant articles and therefore reduces information overload. Surprisingly, to combat information overload, "rather than needing less information, we actually may need lots more, specifically information about information, or metadata" (Farhoomand & Drury, 2002). The disconnect between the ability to store documents and the ability to retrieve documents can be resolved. This article explains how simply automating what was done with paper documents created that problem, and how reengineering the process to capture context can resolve the problem.

Chapter 4.9
On the Design of Knowledge Management System for R&D Organization:
Integration of Process Management and Contents Management

Yongtae Park
Seoul National University, Korea

Yeongho Kim
Seoul National University, Korea

Intae Kang
Seoul National University, Korea

ABSTRACT

This chapter proposes a framework for designing knowledge management system (KMS) for R&D organization. Broadly, KMS comprises two principal modules: a process management module to administer knowledge activities to generate and utilize knowledge, and a contents management module to deal with knowledge contents, input and output of knowledge activities. The two modules are then materialized through two operational systems: workflow management system (WFMS) for R&D process and R&D knowledge management system (RKMS) for R&D contents. As a building block to integrate the two systems, workflow-based knowledge map is suggested. The authors admit that the research is an exploratory proposal that suggests merely a conceptual scheme. Therefore, it is required to elaborate detailed procedure and materialize real system.

INTRODUCTION

Recently, knowledge management (KM) has attracted increasing recognition from academicians and practitioners alike. In a corporate setting, the functional spectrum of KM is so ample, ranging from procurement of raw material to the marketing of end products. Amongst others, R&D organization serves as the primary actor of knowledge management (KM), since it is the major source of knowledge generation and dissemination. Furthermore, R&D organization may be a challenging test bed for KM in that it needs to coordinate collaborative work among knowledge workers and ill-defined workflows across knowledge nodes. Despite the importance, however, little attention has been paid to development and implementation of KM for R&D organization. In this regard, the main purpose of this chapter is to propose a framework for designing KM system (KMS) of R&D organization.

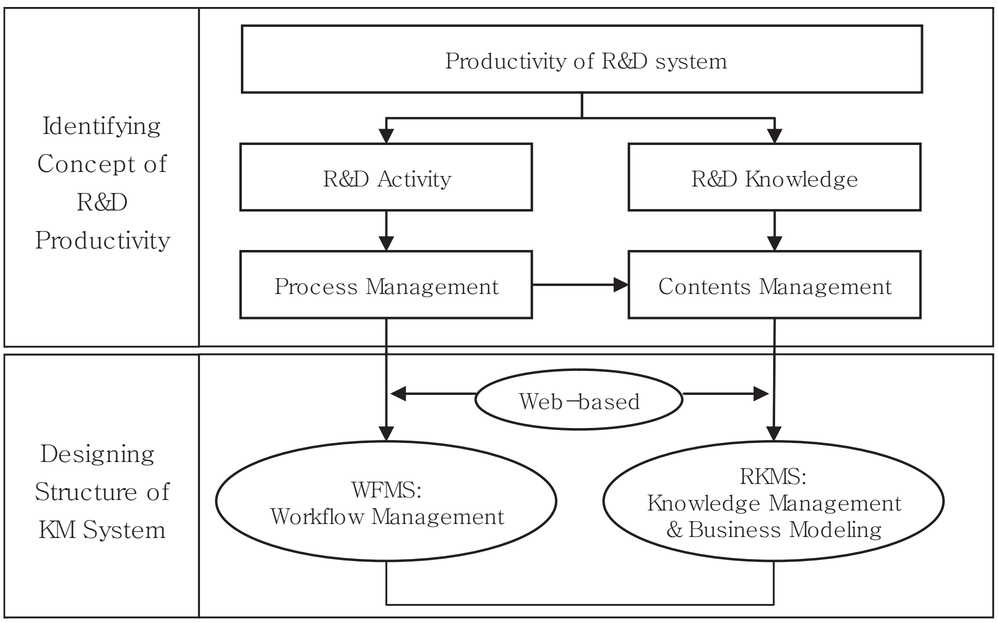
Broadly, KMS is composed of a process management module to administer knowledge activities to generate and utilize knowledge and a contents management module to deal with knowledge contents, input and output of knowledge activities. Accordingly, the framework is composed of two major pillars, process management for R&D activity and contents management for R&D knowledge. Then, we propose two operational systems: a workflow management system (WFMS) for R&D process and an R&D knowledge management system (RKMS) for R&D contents. The overall architectures of WFMS and RKMS are briefly described and the procedure to integrate RKMS and WFMS is explained. The proposed system is web-based in that it is designed and developed on the web environment.

OVERALL FRAMEWORK

Matching WFMS and RKMS

As explained before, KMS for R&D organization comprises two major components, R&D activities and knowledge contents. R&D activities are associated with processes to generate and utilize

Figure 1. Overall framework of KMS to integrate WFMS and RKMS



knowledge, and knowledge contents are related with input and output of knowledge activities. Therefore, the overall framework of KMS is constructed by matching process management to administer knowledge activities and contents management to deal with knowledge contents, as portrayed in Figure 1.

Matching R&D Organization Types and KMS Domains

KMS of R&D organization encompasses heterogeneous and multi-disciplinary knowledge that is hard to formalize and R&D activities comprise complicated and unstable processes that are hard to standardize (Polanyi, 1966; Saren, 1984; Cooper, 1983; Clark, 1985). In particular, the notion of a sectoral pattern of innovation highlights differences across industrial sectors in terms of knowledge management (Pavitt, 1984). Therefore, it is impossible to propose a general structure of KMS that is applicable to all the forms of R&D organizations. The design of KMS, thus, needs to be customized by matching characteristics of individual R&D units and characteristics of KMS domains. To this end, it is necessary to classify

Figure 2. Matching of R&D organization and KMS domain

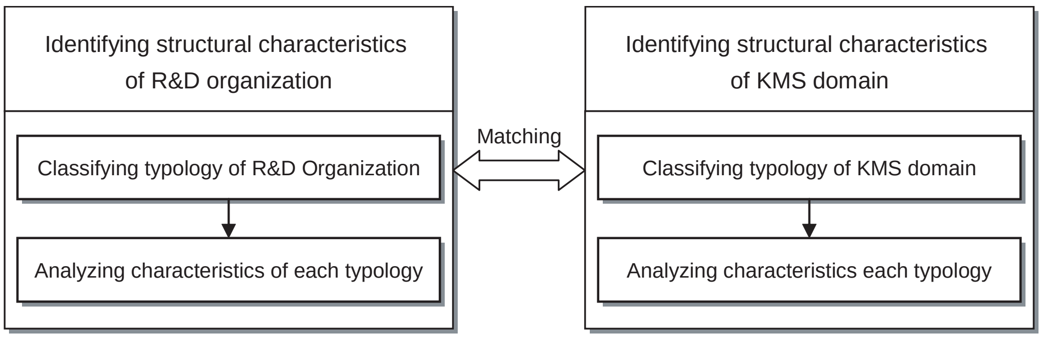


Table 1. Typology of R&D organizations

Typology of R&D organizations	Description
Product-oriented Organization	R&D organization comprise separate units, each takes charge of Development of individual product
Process-oriented Organization	R&D organization comprise separate units, each is related to different process of research and/or manufacturing
Technology-oriented Organization	R&D organization comprise separate units, each takes charge of development of component technology
Function-oriented Organization	R&D organization comprise separate units, each takes charge of management of different function
Matrix(hybrid) Organization	R&D organization comprise separate units, each is a combination of multiple features

R&D units into several types and to identify the best-practice form of KMS for each type of R&D units. The conceptual scheme of customization is depicted in Figure 2.

To illustrate, as presented in Table 1, it may be possible to classify R&D units into five types and develop customized KMS domains according to the characteristics of each type (Park, 2001).

DESIGN OF RKMS

Once the correspondence between R&D organization type and KMS domain is established, the blueprint of RKMS is developed. In this chapter, we suggest a comprehensive system that covers the whole cycle of R&D activities, from initial research to ultimate commercialization. To this end, RKMS is composed of a main system and several supporting tools. The main system includes a management module to create, store, secure, distribute and retrieve knowledge and a utilization module to structure knowledge map, evaluate knowledge asset and commercialize knowledge to business model. To support the main system, several supportive tools such as classification, visualization, agent, navigation and decision-making criteria are also included in the framework. Figure 3 describes the overall architecture of RKMS.

DESIGN OF WFMS

Broadly, workflow is a tool to define and administer business processes automatically and, in turn, becomes the core engine of WFMS that electronically operates and controls the R&D

Figure 3. Overall architecture of RKMS

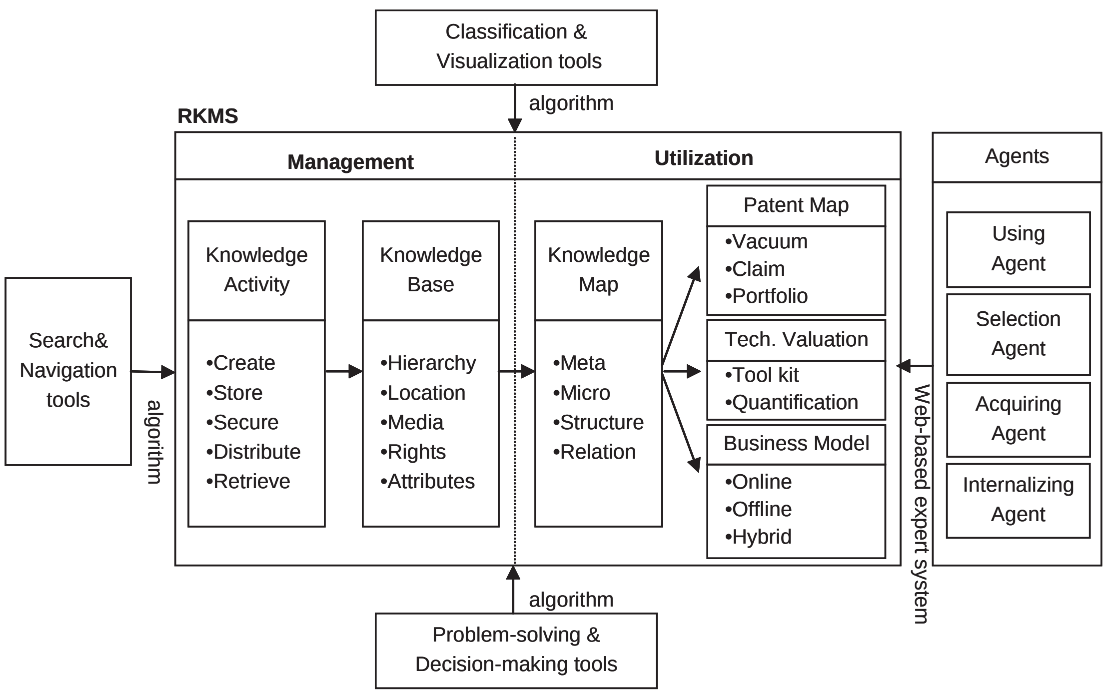

Figure 4. Overall architecture of WFMS

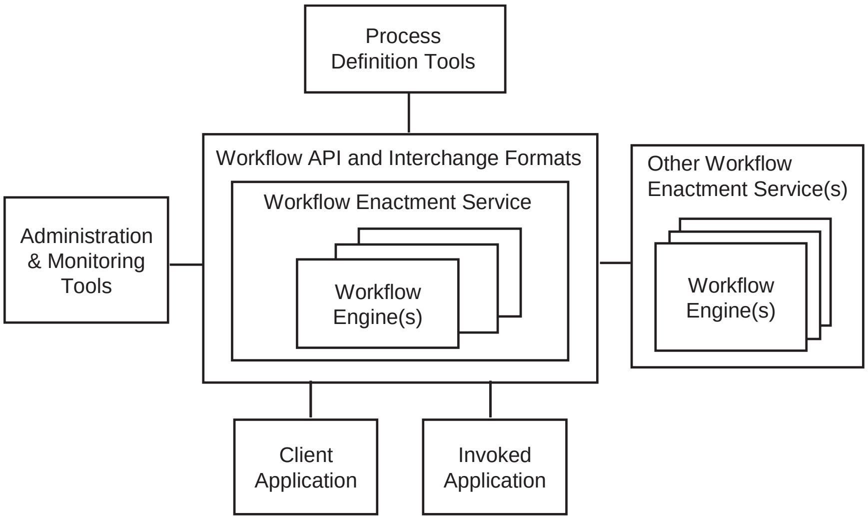


process. The usefulness of WFMS is highlighted as the amount of knowledge becomes intractably large, the business units are geographically decentralized but more closely networked and the importance of collaboration among individual workers is emphasized (WFMC, 2001; Kumar, Zhao, 1999; Kim et al., 2000).

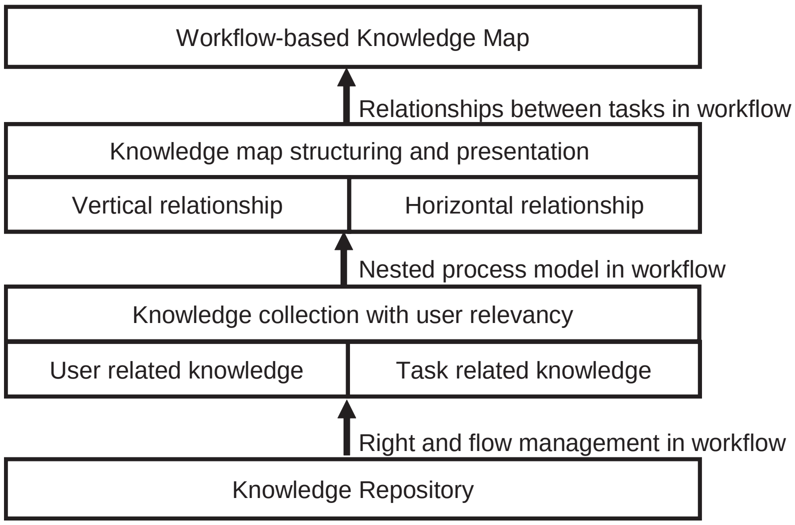
In this chapter, WFMS is composed of two main modules: a definition module to identify and design R&D processes and an execution module to monitor the progress of processes, control and carry out tasks and manage application programs. These modules are basically developed and implemented on the workflow engine. The overall architecture of WFMS is exhibited in Figure 4.

INTEGRATION OF WFMS AND RKMS

Finally, RKMS and WFMS need to be integrated. The integration of RKMS and WFMS is accomplished by developing a workflow-based knowledge map. The notion of knowledge map, defined as a visual architecture of knowledge domain, may be developed in diverse forms (Eppler, 1999), but a workflow-based map is suggested here. Since workflow is the backbone of process management and the knowledge map is the building block of contents management, the integration represents an exploratory effort to combine process management and contents management. Basically, the construction of a knowledge map of RKMS consists of two steps: knowledge collection and knowledge structuring. As depicted in Figure 5 and as explained below, these two steps of RKMS necessitate information from WFMS.

First, in the knowledge collection step, knowledge in the knowledge repository is filtered in accordance with knowledge users and related tasks. In building a knowledge map, it is critical to provide the right knowledge to the right user. For the relevancy in terms of knowledge contents and knowledge users, we need information on user

Figure 5. Integration of WFMS and RKMS



and task attributes. This information is obtained from the process definition in WFMS. By doing so, the knowledge collection takes the relationship of user-task and task-knowledge into account.

In the second step, the filtered knowledge is structured and presented based on the vertical relationship and horizontal relationship of knowledge. The term vertical relationship means the hierarchical linkage of knowledge artifacts, whereas horizontal relationship indicates the input-output relationship of knowledge artifacts. The information on the vertical and horizontal relationship among knowledge artifacts is also obtained the workflow definition of WFMS. The proposed system is web-based in that it is designed and developed on the web environment.

CONCLUSIONS AND FUTURE WORK

In this chapter, we proposed a framework for designing workflow-based KMS of R&D organization. The framework consists of two major components: WFMS for process management and RKMS for contents management, whereby RKMS derives necessary information from WFMS. In doing that, it was emphasized that the design of KMS needs to be customized by matching characteristics of R&D units and KMS domains.

This research in nature is an exploratory proposal that suggests merely a conceptual scheme. Therefore, it is required to elaborate detailed procedure and materialize real system. Specifically, the notion of workflow-based knowledge map needs to be put in a definite shape. The definition module of WFMS is another source of difficulty, since the workflow of the R&D process is hard to generalize. Finally, the identification and determination of the relationship among knowledge necessitates that more practical efforts should be made from the perspective of the knowledge user, rather than the system developer.

Chapter 4.10
Knowledge Management: Analysis and Some Consequences

Petros A. M. Gelepithis
Kingston University, UK

Nicole Parillon
Kingston University, UK

ABSTRACT

Although the debate on the nature of 'knowledge' and 'information' is far from settled, it is now taken for granted throughout the academic world that the two notions are related but fundamentally distinct. This result, and its significant consequences, still need to be realised and understood by the great majority of the business world. In the first section of this chapter, we briefly comment on some characteristic views of 'knowledge' and 'knowledge management,' and subsequently we analyse in-depth the core constituent notion of the latter, that is, knowledge. In section two, we outline three major consequences of our analysis. The first concerns the limits of management for a certain class of activities involving knowledge. The second concerns the scope and limits of technology for the same class of activities. The third concerns the issue of knowledge market. The thesis we develop is that knowledge cannot be taken as a commodity; in other words, the notion of a knowledge market is not implementable.

WHAT IS KNOWLEDGE MANAGEMENT?

Attitudes towards 'knowledge management' (KM) have fluctuated widely since the term first appeared. At first, it was highly and sharply inflated, then a deep, albeit less sharp, disillusionment trough followed until recently. Now, a slightly upward leading slope has started to take form. This should not come as a surprise given the wide disagreements, in both the academic and business worlds, concerning both the term 'knowledge management' and its central constituent notion: 'knowledge.'

To start with compare the following three conceptions of KM that appeared in the Financial Times in November 1999.

"The systematic management of the knowledge processes by which knowledge is created, identified, gathered, shared and applied." (Newing, 1999).

"[Knowledge management] Is about spreading information throughout a corporate body." (Dempsey, 1999).

"The management of commercially valuable information." (Vernon, 1999).

What these conceptions exemplify is that KM is perceived in two substantially different senses: a) as synonymous to information management; and b) as distinct from it.

The former sense is the case, knowingly or unknowingly, in the majority of firms dealing with knowledge management. This mistaken identification is what Malhotra (2000) terms the information-processing paradigm to knowledge management. The business world needs to realise that the notions of 'knowledge' and 'information' are substantially different from each other. It follows that firms also need to realise that certain activities cannot be just renamed and expect successful resolution by the application of old techniques and approaches. As Gupta and Govindarjan (2000, p. 71) remark:

"A gap exists between the rhetoric of knowledge management and how knowledge is actually managed in organizations."

To be precise, the gap that exists is between the rhetoric of knowledge management and what is actually managed in organizations. And what is actually managed in the vast majority of companies is anything but 'knowledge'.

The latter of the two senses introduced above is now taken for granted throughout the academic world and by some major pioneering organisations like Slumberger and Nucor Steel. Such acceptance though has not led to a much-needed clarification of their foundations, that is, of the core constituent notions of 'knowledge' and 'information'. The rest of this section aims to contribute to the foundational clarification of the notion of 'knowledge'. For a summary presentation of the major views on information as well as a rudimentary theory of information and some of its consequences, see Gelepithis (1997).

Before proceeding with our task, we should stress that epistemology (i.e., the study of knowledge) is a vast area that has been studied for 2,500 years by the greatest minds in philosophy and, increasingly, by scientists in disciplines like psychology, neuroscience, and Artificial Intelligence (AI). This fact is ignored by or unknown to the great majority of books and papers on knowledge management, creating a distorted picture of the issues involved and hence of the appropriate solutions. To illustrate our point we present the following four viewpoints.

The easiest way out of the nexus of problems surrounding knowledge, without really addressing any, is exemplified by Newing's (1999) definition above in which knowledge is taken as something self-explainable or something we all know about and therefore is in need of no explanation at all. I would avoid commenting on such an approach. Let us concentrate on three views by, more or less, well-known workers in knowledge management who do accept not only the importance of the distinction between information and knowledge but also the need to explain what knowledge is.

Borghoff and Pareschi (1998, p. v) write:

"Information consists largely of data organised, grouped, and categorized into patterns to create meaning; knowledge is information put to productive use, enabling correct action. Knowledge is quite different from information, and managing knowledge is therefore decisively and qualitatively different from managing information. Information is converted into knowledge through a social,

human process of shared understanding and sense-making at both the personal level and the organizational level."

This viewpoint, however unintentionally, gives the impression that there are no problems in an area beset with significant issues. For instance, what about all that information that is not put to productive use? Is knowledge creation, however viewed, a manageable process? Why yes or no? Could human knowledge be shared through the use of information and communication technologies (ICT) or even of AI techniques? How information is actually converted into knowledge is a big, significant, and wide open issue.

Consider now a different viewpoint as exemplified by Davenport and Prusak (1998, p. 5):

"Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organisations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms."

This view restricts knowledge to informal expertise and assumes the incorporation of values. However valuable tacit knowledge is, it is definitely not the full story. The reader may juxtapose this view with the following two classification schemes attempting to specify what types of knowledge are most important for an organisation.

First according to Savage as quoted in Skyrme (1999):

- Know-how — a skill, procedures.
- Know-who — who can help me with this question or task.
- Know-what — structural knowledge, patterns.
- Know-why — a deeper kind of knowledge understanding the wider context.
- Know-when — a sense of timing, and rhythm.
- Know-where — a sense of place, where is it best to do something.

The second classification, due to Quinn, Baruch, and Zien (1997, pp. 2-3), structures the knowledge of an enterprise into the following five levels of increasing importance:

- Cognitive knowledge (or know what) — the rules and facts of a discipline.
- Advanced skills (know how) — the capacity to perform a task sufficiently well to compete effectively.
- System understanding (know why) — understanding the interrelationship and pacing rates of influences among key variables.
- Motivated creativity, discovery, or invention (care why) — the capacity to interrelate two or more disciplines to create totally new effects.
- Synthesis and trained intuition (perceptive how and why) — the capacity to understand or predict relationships that are not directly measurable.

It is interesting to note that both schemes accept the importance of the notions of understanding and sense (i.e., meaning) in, at least, some cases, but choose not to address the foundational issues involved.

We come now to our preliminary analysis of the nature of 'knowledge.' First, a couple of remarks and a disclaimer. The debate on the nature of 'knowledge' is far from settled and it is well beyond the scope of this chapter to review it. Equally, our analysis is only intended as a first draft outline contribution rather than a fully fledged theory of knowledge. For a philosophical and AI perspective on 'knowledge,' the reader is referred to Pollock (1986) and Newell (1990) respectively.

All theories (more accurately conceptions or schools of thought) of knowledge are based on the notion of belief. Where they differ is their stance on the justifiability of a belief.

We part with this tradition. Our basic building blocks are: a) the notion of meaning; and b) the process of understanding. Specifically, our thesis is that knowledge is the end result of the communication and understanding processes. The previous sentence seems to contradict the one immediately preceding it. It does not; it is coded for brevity and needs to be expanded in order to be clarified. First, both understanding and communication involve meaning. Second, there are two kinds of knowledge: individual and collective. As a first cut, individual knowledge is the end result of the understanding process; and collective knowledge is the end result of all communication processes among the members of a community. We now need to provide appropriate definitions of the related processes of understanding and communication so that proper definitions of individual and collective knowledge can also be given.

Although there had been general agreement that 'communication' involves sharing and 'understanding' (see, for example, Cherry, 1957; Ogden and Richards, 1923; Rogers 1983, 1986), no one had, axiomatically, defined them until Gelepithis (see 1984 for the overall framework and detailed argument, 1991 for a summary and a major key consequence). In what follows, we repeat those definitions and proceed with our analysis.

Definition of communication:

- H1 communicates with H2 on a topic T if, and only if: (i) H1 understands T {Symbol: U(H1 T)}; (ii) H2 understands T {Symbol: U(H2 T)}; (iii) U(H1 T) is describable to and understood by H2; and (iv) U(H2 T) is describable to and understood by H1.

Definition of understanding:

- An entity E has understood something, S, if and only if, E can describe S in terms of a system of own primitives (i.e., self-explainable notions).

Let us now develop a rudimentary theory of knowledge by clarifying and expanding some of the basic notions of our axiomatic system.

First, one's own primitives may refer to any idea, expression, belief or whatever someone may use to think. Second, primitives are of two kinds: linguistic and non-linguistic. It follows that such primitives may be either formal or informal. Usually, they are informal. Primitives may also be implicitly referred to. It is obvious that what may be a primitive for one person may not be a primitive for another. Even more to the point, what may be a primitive for one may be a complex idea for another. For example, 'water' was a primitive for my grandmother but it is not a primitive for those knowing that 'water' is really H2O. It follows that since one's understanding depends on one's own primitives, it may well vary very significantly from person to person depending on the system of primitives reached by each person on a particular topic by a certain time. Also, since one's primitives may change with time, one's understanding may change as well. Compare, for example, a toddler's primitives with those of a quantum physicist with respect to the notion of electricity (for a discussion, see Gelepithis 1995). In summary, one's understanding depends both on time and on one's primitives. Or, more accurately, it depends on one's own primitives, which in turn depend on time. With these remarks we move on to our definition of individual knowledge:

Knowledge of a topic T for an entity E at time t, is the end result of E's understanding at time t.

It follows that:

Knowledge of E at time t is the system of understandings that E has reached by that time.

This we call E's knowledge system at time t or equivalently, E's individual knowledge at time t (symbol, Ke,t). Obviously, Ke,t is a subsystem of E's semantic system at time t (symbol Se,t). Where, Se,t is the system of all meanings that E has acquired, or has produced, by that time.

Let us see now some further important characteristics of one's individual knowledge, which follow from our analysis so far. First, individual knowledge is both structured and extremely rich. Second, there is a single most important characteristic of both individual human knowledge and of human semantic systems: they both change and, crucially, their changes are unpredictable.

So far we considered only individual human knowledge. There is of course collective human knowledge, which may take two forms: shared (e.g., common beliefs); and shareable (e.g., books, databases). This distinction may be seen better when considering organisational knowledge (sometimes known as organisational memory). Organisational knowledge may refer to two fundamentally different types. First, it may refer to employed individuals and their individual knowledge. This is the most valuable type and the one that the company has no real power over it. Second it may refer to an organisation's databases (whether electronic or paper-based); as such it should better be termed organisational archives. The characteristic of the second type is its static nature. This is in sharp contrast to the claim of writers like Davenport and Prusak (1998, p. 25) that: "[i]n contrast to individual knowledge, organizational knowledge is highly dynamic: it is moved by a variety of forces."

Although extremely interesting, a discussion of collective human knowledge would take us far beyond the scope of this chapter; we, therefore, just make explicit a point we shall use later on. Namely, given the relation between understanding and communication, one easily deduces that individual and collective knowledge necessarily both overlap and they are fundamentally distinct. As a result, both types of human knowledge have both formal and informal elements.

The above definitions and remarks provide a rudimentary but useful body of knowledge. Let us see what consequences do follow from this.

OUTLINE OF CONSEQUENCES

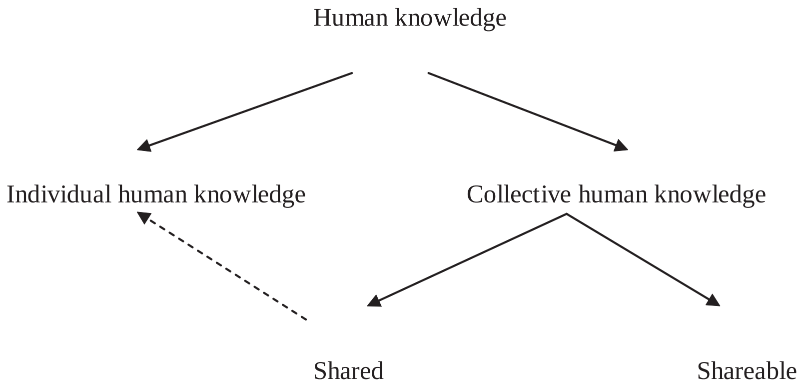
We present three major consequences of our rudimentary theory concerning:

a) The limits of management for a certain class of activities involving knowledge.
b) The scope and limits of technology for the same class of activities.
c) The issue of knowledge market.

The first consequence is both obvious and unlikely to be pleasing. The expression 'knowledge management', when it is not misleadingly used to refer to the management of information, is a misnomer since no-one can manage something that takes place inside another one's mind. Let us clarify this point. As we have seen in the previous section, human knowledge may be partitioned in the way (illustrated in Figure 1).

Where the hyphenated arrow stands for the fact that shared human knowledge is essentially individual human knowledge that is common to more than one human. Furthemore, individual human knowledge is the result of one's complex, internal process of understanding. As such it is not manageable. What we are left with then is shareable human knowledge. Such knowledge in a variety of media (e.g., electronic, paper-based) is fundamentally static and, as it stands, meaningless. In other words, information. It needs to be interpreted by a human to be useful in any way. Such interpreted information becomes inter-

Figure 1. Major partitionings of human knowledge (see text for the meeting of the hyphenated arrow)



nalised and subsequently may provide part of the constituents for further knowledge creation (e.g., innovation). There it is where the management of a company — not knowledge management — can help. It can facilitate the creation and mobilisation of the available intellectual capital (that is, human resources) required for any knowledge-creation activities. Equally, it can create, sustain, or, even better, develop further the appropriate environment that would nurture such activities. This can be extremely valuable but it has nothing to do with managing knowledge.

It is worth noting that those widely accepted as pioneers in what is now called 'knowledge management' (e.g., Itani, 1987; Nonaka 1991) did not talk of knowledge management. Their emphasis was on human resources and how they could be best nurtured so that they can be mobilised and innovate. Nonaka, for instance, talked about the knowledge-creating company and how it could be managed, not about KM. It follows that a more appropriate name for the field would be knowledge nurturing. But that would be, probably, too much to be expected from those managers whose professional behaviour is still, exclusively, hard-science based.

Talking about mobilisation of invisible assets and the knowledge-creating company, Itani and Nonaka identified the key issues needed to be addressed. For our purposes we shall focus our attention to the Identification, Creation, Acquisition, and Sharing of Knowledge or KICAS for short. Their solution is far from clear. Actually, we believe that there cannot be a solution in the traditional sense of the word since they refer to the ongoing, dynamic, and creative processes necessary for the solution of any kind of humanly solvable problem rather than to problems themselves. As such, and taking into account the key characteristics of knowledge as outlined earlier, managers need to become themselves the 'couriers' and, most importantly, the communicators of knowledge within their company. This is, in essence, the major new activity of what Hansen and Oetinger (2001) call T-shaped managers.

The first consequence referred to the limits of management for a certain class of activities, namely, the KICAS nexus of issues and the need for managers to refocus their activities. The second consequence concerns the scope and limits of technology in dealing with the KICAS issues. Without loss of force for our argument, we shall focus on two of the four issues, namely, the creation and sharing of human knowledge. These are the issues emphasised by organisational and management scientists like Nonaka and Takeuchi (1995), Quinn et al. (1997) — under the name diffusion for knowledge sharing — and Skyrme (1999) — under the name knowledge networking for the same issue.

Our second point may best be seen if we start with some historical remarks. The earliest, but neither easy nor permanent, way to solve the KICAS nexus of problems has been to attract the appropriate human(s). This practice, of all organisations, individuals, and states, is still the best prerequisite to the solution of the KICAS nexus of problems. Slowly, the development of networks of knowledgeable people started — sometimes in the form of schools of thought like the Platonic Academy and the Aristotelian Lyceum — and gradually were turned into what we now call Universities or Learned Societies. More recently, companies with sufficient resources started developing their own dedicated resources in the form of R&D departments. Usually, the objective of such divisions is the development of appropriate technology for the benefit of the company. Sometimes the objective was more general, such as developing aids to innovation. Instances are the Myers-Briggs type indicator and the Herrmann Brain dominance instrument (see Leonard and Straus, 1997, for discussion and references).

Most recently, the use of ICT and increasingly AI is at the forefront of developments facilitating innovation and providing solutions to aspects of the KICAS set of problems. Books and edited collections describing models or technological tools for enhancing human interaction or a human's ability to deal with the exponential explosion in exploring one's semantic structure abound (e.g., Quinn et al., 1997; Borghoff and Pareschi, 1998; Skyrme, 1999). What is common in all these developments is that despite the increasing use of artificial aids, the human remains in the loop. We cannot do without her too (see, for instance, Cross and Baird, 2000; Senge and Carstedt, 2001). Let us take a closer look.

In principle, AI/ICT can provide solutions to the following three types of problems:

- Overall integration of information and knowledge sources and tools.
- Identification of appropriately specified information through the use of Search Engines.
- Formalisation of certain aspects of Human Knowledge through R&D in Knowledge representation, and reasoning.

AI/ICT systems though, cannot, on their own, either create or share knowledge. This is a point that is very often overlooked with serious negative consequences. Let us briefly see the reason for these intrinsic limits of the AI/ICT systems.

Such systems may be distinguished into two categories (Gelepithis, 2001). The first category is characterised by tools employing representational systems, which are eventually human-based. Human-based AI systems, whether creative or not, are, at best, axiomatic systems with in-built procedures for the handling of the system's premises. At worst, they are ad hoc systems capable of providing a cost-effective and, quite often, enhanced solution with respect to their human counterparts. A better solution, nevertheless, does not constitute creation of new knowledge. In the best-case scenario, they are capable of producing consequences some of which are bound to be new. Such a capability is of course very desirable but it is ultimately checked and evaluated by humans. In other words, novel human knowledge could only be created by humans; creative AI systems, even in principle, can only create new consequences of existing knowledge. Creation of novel human knowledge is species-specific.

It should be noted that although humans are the only creators of novel human knowledge, ICT and in particular AI can facilitate the creation of such knowledge through the development of tools enabling: (a) increased connectivity within the semantic system of humans; and (b) increased and enhanced human-human communication. I believe the latter is what Skyrme (1999) calls knowledge networking.

The second category — say R — not yet developed but feasible, will be characterised by systems possessing their own representational systems, that is, by representational systems independent of the language of another kind of system —say human. Such systems will be able to create novel knowledge, but such knowledge will not be necessarily understood by humans. To be precise such knowledge will be understandable by humans only to the extent that it will be formalised. This is a point that need not concern us here though and we shall not expand on it (for more information on the two fundamental categories of representational systems, the reader is referred to Gelepithis (1995)).

We come now to our third consequence: a knowledge market is not implementable. The first thing that any knowledge market would need is a system that would measure knowledge. This is a requirement that, probably, the great majority would agree on but nobody has, so far, proposed a solution to it. Of course, no solution yet does not imply no solution ever. In what follows we first present two claims and one argument for the implementability of a 'knowledge market', and subsequently we briefly outline our argument against.

The first viewpoint may be termed the 'blind faith to market forces' approach. According to this, the situation in trying to create a knowledge market is problematic but: "Given time, market forces will undoubtedly take care of the situation" (Burton-Jones, 1999, p. 221). The second viewpoint may be termed the 'shifting the goalposts' approach. Its extreme form is illustrated by Gamble and Blackwell (2001, p. 185). They remark: "It is almost axiomatic in management that what you cannot measure you cannot manage." Unfortunately, the next step they go to is to create a metric for a "knowledge management initiative." No comments.

An almost acceptable 'shifting the goalposts' viewpoint has been put forward by Davenport and Prusak (1998). They first introduce the elements of a 'knowledge market' and subsequently they discuss its inefficiencies and pathologies as well as ways to overcome them. For the purpose of this chapter, we focus our attention on their presentation of the characteristic elements of a 'knowledge market'. Their starting point is that knowledge markets exist although not as "pure" markets (i.e., markets that operate solely in economic terms). On that basis they try to establish the elements for a good knowledge market. They see three:

"first of all, to recognize that market forces exist; second, to try to understand how it functions; and third, to make it more efficient" (ibid, p. 26).

On market forces they distinguish three players: buyers, sellers, and brokers. The problem is that the object of their transactions although named to be knowledge is, essentially, information. The two notions are related, but as we know, they are fundamentally distinct. Their next step is the mechanism of the knowledge market, that is, its price system. They claim that a price system for a knowledge market revolves around the notions of: money, reciprocity, reputation, altruism, and trust. In a nutshell they recognise that money is far from adequate and believe that reciprocity, reputation, and altruism (these three in diminishing degree), as well as their combinations, constitute the substitute for money. Since transactions involving reciprocity, reputation, and altruism do not constitute payment in the traditional monetary sense of the term, they are forced to introduce the notion of trust as the necessary factor for the workings of such a market. But trust is one of the goods (the other two are loyalty, and truth-telling), cited by Nobel Laureate Arrow (1974, p. 22), which "cannot, in principle, be taken as commodities in the market sense."

Linking knowledge to truth or truth-telling is an avenue worth taking and fully exploring but it is well beyond the scope of this chapter. Instead, we briefly outline here why a 'compromised' knowledge market of the sort that Davenport and Prusak have considered cannot really function by commenting on the first two elements of their methodology. In other words, we assume that markets require two elements for their existence. First, an object to be transacted among their players. Second, a price system as its mechanism for the transactions. Let us see why these two requirements are not applicable in the case of knowledge.

Attaining knowledge is a process whereby the start and end points are difficult if not impossible to define. The expert is knowledgeable in his particular field because of an integration of a number of factors such as factual information, experience and intuition. This process is ongoing, and even when a knowledgeable state is achieved the learning process still continues. Therefore knowledge is a special state or process which cannot be seen as a commodity. Davenport and Prusak's (1998) buyers, sellers, and traders cannot trade in knowledge but only in information.

When an expert gives some advice or judgment, we are gaining information that is based on his or her knowledge. We may say that the more knowledgeable the expert, the more valuable the information gleaned. Therefore what companies should be aiming to do is create the environment that allows the knowledge process and state to be achieved. The information resulting from such environments can be marketed. It is important to make the distinction between the two. Information can be treated as a commodity but the knowledge environment that produces the information is not subject to market forces.

Some may argue that 'knowledge' markets have existed, at least since humans started exchanging goods they produced themselves, for any good produced was bound to involve the use of some 'knowledge' at some point in the production process. Nevertheless, what was traded was the good produced, not the 'knowledge' involved in its production. The reason is simple. The 'knowledge' involved in the production of goods was but one element of a complex internal process. In those earlier times, that process was simply beyond any sort of measure. It is still today, and it will be tomorrow, because it involves too many tacit elements. The formal-informal boundary will keep shifting, creating ever larger areas of formalised knowledge and, at the same time, revealing larger areas of informal knowledge. Again a full discussion of this point exceeds the confines of this chapter.

Goods are there to be checked, compared against similar ones, and eventually assigned a price. Goods are objective entities persisting, more or less invariably, through considerable time intervals. Human knowledge, both individual and collective, changes. What is more, it changes unpredictably. No manager would wish to purchase a car that could be turned into a 10-meter boa constrictor. Seriously now, what should be the value of the 21st century equivalent of Newton's laws? How much should one pay for that imperceptible, yet consciously made, grimace that reveals a no-purchase of company-X? Human knowledge is not a rose, a cup, or a massage.

ACKNOWLEDGMENT

We would like to thank the anonymous reviewer for his or her constructive comments. Taking them into account was a useful exercise and resulted in a better chapter.

Chapter 4.11
Knowledge Sharing Barriers

Keith L. Lindsey
Trinity University, USA

INTRODUCTION

To ensure continued existence, an organization must develop ways to share the knowledge that is possessed within that organization with the people who need, or who will need, that knowledge. This critical organizational task transcends departmental boundaries and is a necessary element for the maintenance of every organizational function. Improving the efficiency of knowledge sharing is a highly desirable goal because it offers a promise of compounded returns as the organization works harder and smarter. As business practices have developed over the last few decades, knowledge workers have developed a variety of mechanisms and routines to share knowledge, but these have not yet been well studied. Specifically, the barriers to knowledge sharing remain somewhat elusive.

A better understanding of the knowledge-sharing process may provide managers with a set of tools that could be used to identify and combat barriers to knowledge sharing, which could lead to much more efficient organizational routines. In this article, the process of knowledge sharing will be examined by framing the knowledge-sharing transaction as a form of communication in order to identify and isolate the barriers to that type of communication. Once the barriers are isolated, they can be overcome.

BACKGROUND

In order to manage knowledge, researchers must first develop an understanding of the way that knowledge flows through an organization. The flow of knowledge is reflected in the most basic construct of this article: knowledge sharing. Opposing that flow of knowledge, barriers to knowledge sharing present a challenge to every organization. However, when the managers of an organization embark on a journey to improve knowledge sharing within that organization, they are met by a host of confusing issues. If they review the literature, they find a wide variety of issues that are thought to prevent knowledge sharing, each of which is typically deemed the most critical by the researcher who is promoting it. If they hire outside consultants, they may be offered solutions to problems that they do not even have. Until the managers are able to objectively measure how the specific barriers to knowledge sharing are perceived to exist within their organization, they will be unsure of the optimum method of overcoming those barriers. The first step to objectively measuring knowledge workers' perceptions of barriers to knowledge sharing in an organizational environment is the identification of the many barriers to knowledge sharing that exist within the organization.

It is proposed that barriers to knowledge sharing should actually be measured in terms of knowledge workers' perceptions of barriers to knowledge sharing. Though the difference is subtle, it acknowledges the fact that many decisions are made on a subconscious level, and that there is no surety that knowledge workers are cognizant of the particular barriers that they face, or even if they are, they will not always act rationally to promote the organizational good. In addition, even when knowledge workers understand why they act, they may not be able to explain their actions to researchers, and thus their perceptions must be used as a proxy to measure the effect of a barrier to knowledge sharing.

The concept of knowledge sharing is best illustrated by Foy (1999, p. 15.2): "facilitating learning, through sharing, into usable ideas, products and processes." This definition implies that the focus should be on sharing knowledge within an organization for a specific purpose. Thus, this concept diverges somewhat from the field of learning (because learning may or may not have an organizational imperative or objective) but may still draw from that field because learning is an artifact from the knowledge-sharing process.

UNMASKING BARRIERS TO KNOWLEDGE SHARING

The Knowledge-Sharing Process

A common tendency in knowledge management (KM) research has been to build on the work to understand knowledge that was begun in the 1960s. Polanyi (1962, 1967), who introduced the concepts of tacit and explicit knowledge, is widely cited. Nonaka's (1994) and Nonaka and Takeuchi's (1995) further research into the way that knowledge is created in organizations has also been of significant influence. Perhaps because of these three great contributors, most of the constructs that have been researched as possible barriers to knowledge sharing are cognitive or behavioral based. From the factors-for-success literature (Bennett & Gabriel, 1999; Broadbent, Weill, & St. Clair, 1999; Davenport & Prusak, 1998; Purvis, Sambamurthy, & Zmud, 2001), an emphasis has been placed on determining the factors that enable KM systems. The globalization research (Chow, Deng, & Ho, 2000; Gupta & Govindarajan, 2000; Hofstede, 1980; Hofstede, Neijen, Ohayv, & Sanders, 1990; Okunoye, 2002) emphasizes culture, including both the national and the organizational culture. McDermott and O'Dell (2001) found that organizational culture was more important to knowledge sharing than the approach or commitment to KM.

Barriers to Knowledge Sharing

The KM literature yields several articles that describe knowledge sharing as it occurs in sample organizations. KM researchers have identified a host of barriers to knowledge sharing, but generally focus on a single knowledge-sharing context. The issues that could potentially constitute barriers to knowledge sharing that have been identified in the KM literature are summarized in Table 1.

Table 1. Summary of potential barriers to knowledge sharing

Study	Issues
APQC (1996)	culture, technology, measurement
Buckman Model (1998)	simplicity, access, usability, motivation to participate
Okunoye (2002)	operating environmental factors, national culture and beliefs, local orientation
Bock & Kim (2002)	associations, contribution, (but not reward)
Fraser, Marcella & Middleton (2000)	lack of a *knowledge-sharing facility*
Weiss (1999)	time limitations, lack of rewards, common practices in professional services, lack of recognition, lack of reciprocity
Ellis (2001)	contribution, accuracy, recognition
Dixon (2002)	absorptive capacity, understanding of the context, perception that gaining knowledge will be of worth, confidence in the knowledge, feeling that the knowledge fits into current context
Hall (2001)	user friendliness
Levina (2001)	low trust, lack of contextual clues, memory loss, discontinuity in progress toward goals, inability to voice relevant knowledge, unwillingness to listen, and differences in unit: subculture, unit goals, local problem constraints, professional cultures, professional goals, specialized languages and methodologies, national cultures, languages
Dyer & Nobeoka (2000)	network that motivates participation, prevention of free riders, and reduction of the costs of knowledge search
McDermott & Odell (2001)	obvious link between knowledge sharing and business problems, tools and structures for knowledge sharing consistent with the overall style of the organization, reward and recognition systems that support knowledge sharing, availability of time
Barson, et al. (2000)	Personal - internal resistance, self-interest, trust, risk, fear of exploitation, fear of contamination, proprietary thinking, skepticism toward sharing, lack of common ground, and fear – of exploitation, contamination, penalty, becoming redundant, losing power, losing resources, losing confidentiality Organizational - targeting, costs, proprietary knowledge, distance, and technological - available technology, legacy systems, efficiency and effectiveness of system, compatibility of system Multidimensional - culture, rewards, and existing resources
Cabrera & Cabrera (2002)	payoffs for contributing, enhanced efficacy perceptions, strengthened group identity and personal responsibility

Note that there are some conflicting factors, such as expected rewards. Barson et al. (2000) and Weiss (1999) determined that rewards were important factors for encouraging knowledge sharing, while Bock and Kim (2002) found rewards were not significant. This conflict is disturbing, however, these researchers examined differing sets of barriers and used different knowledge-sharing contexts, and these differences could account for the differing results.

Communications

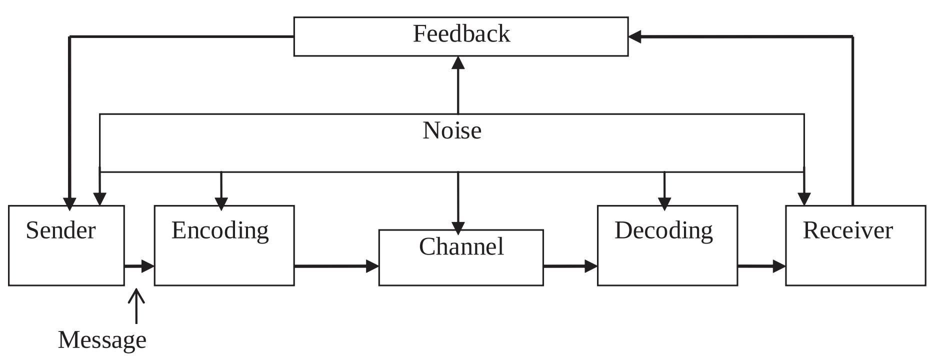
In just over 50 years, a great deal of communications research has been conducted, and this research has the potential to contribute some rigor to the field of KM. Though communications research initially ignored context, some recent results have noted the potential importance of context when the message to be communicated is complex. The work of Tucker, Meyer, and Westerman (1996) indicated that communication processes that enhance shared experiences (context) could result in improved organizational performance. The issue of context and the way that context emerges was further addressed by Augier, Shariq, and Vendelo (2001). They investigated the ways that context might emerge and be transformed, and the relationship between context and knowledge sharing. Consistent with Tucker et al., they found that context emerges as a result of the experiences that an individual brings to a situation. They also determined that context may subsequently transform over time as an individual's experiences change. Their final finding constitutes an important rationale to pursue the current research. They found that, for complex, unstructured problems, knowledge sharing will not occur unless there is a shared context. This research supports the conclusions drawn from the KM research that context is a variable that should be explicitly manipulated.

The Communication Process

This section will develop the communication model that will form the communication framework for evaluating knowledge sharing. The communication model employed in this research is presented in Figure 1. This model will be used to facilitate the identification of a complete set of barriers to knowledge sharing by providing a framework that suggests that barriers could be encountered in each area of the model.

This model is based upon the Shannon and Weaver (1949) transmission model of communication, a model suggested by Szulanski (2003) to be fundamental to most research on knowledge transfer. The Shannon and Weaver model has been adapted by Schramm (1965) to model human communication. Schramm made the model somewhat more generic by substituting encoding and decoding for Shannon and Weaver's transmitter and receiver. In addition, since Shannon and Weaver's original model was intended to apply to electronic transmission, noise was only conceptualized to affect the message while it was within the channel. In recognition that human communication is subject to a far wider range of interferences, the model presented in Figure 1 accounts for noise within each step of the communication process. Finally, to acknowledge the importance of meaning and context, a feedback loop is included. The feedback loop is based on the Osgood-Schramm circular model of communication (McQuail & Windahl, 1981), however, while the Osgood-Schramm model conceptualizes communication as an unending circular pattern of messages, this model (with a single feedback

Figure 1. The communications model



loop) acknowledges the directionality of knowledge sharing.

As defined by Jablin (1979), communication is the process used to transfer information and influence from one entity to another. The combination of information and influence could certainly be viewed as knowledge, and thus, the transfer of knowledge from one entity to another could be viewed either as knowledge sharing or communication.

Barriers to Communication

This section reports the result of a literature review to identify potential barriers to knowledge sharing that have been studied from a communications perspective. Table 2 summarizes the barriers to communication that have been addressed in the communications literature. In order to validate the assertion that these barriers are representative of a complete set of barriers to communication, they have been subjectively categorized using the elements of the communication model, and it can be seen that each element is represented. Some barriers are applicable to more than one category, for example, cultural differences apply to both sender and receiver. These barriers are listed only once in the table since only a single entry is necessary for barrier identification.

The communications literature presents a more broad perspective concerning these barriers to communication, and these barriers can clearly be deemed barriers to knowledge sharing. While there is a high degree of duplication, this is only indicative of the close relationship between communication and knowledge sharing.

Summary of Barriers to Communication and Knowledge Sharing

The list of barriers from the KM literature can be supplemented by the list of barriers to communication in order to create a more complete list of barriers to knowledge sharing. It is through this action that the importance of the communication framework is highlighted. After combining both lists, 124 barriers to knowledge sharing are identified. Table 3 presents these barriers, organized in alphabetical order.

Note that there is a significant level of duplication, which was expected since knowledge sharing and communication are similar events. The important issue is that by framing the knowledge-sharing transaction as a communication event, the communication model yielded significantly a larger and richer set of potential barriers to knowledge sharing derived from the communications literature.

FUTURE TRENDS

The most pressing issue is the resolution of conflicting reports, such as the importance of expected rewards. Recall that Barson et al. (2000) and Weiss (1999) determined that rewards were important factors for encouraging knowledge sharing, while Bock and Kim (2002) found rewards were not significant. As these researchers examined differing sets of barriers and used different knowledge-sharing contexts, this conflict is not an indication that some of the research may have been faulty. By analyzing a single, comprehensive set of barriers to knowledge sharing, future researchers may be able to resolve conflicts such as this.

Another important need is to analyze these barriers to knowledge sharing for context dependency. Recent research by Augier et al. (2001) noted that knowledge sharing requires a shared context, so it is possible that when the knowledge-sharing context changes, the barriers to knowledge sharing may change as well. Now that a single broad set of potential barriers to knowledge sharing has been identified, the set may be analyzed over several different knowledge-sharing contexts to determine whether knowledge workers' perceptions of these barriers change with the conditions.

Table 2. Summary of potential barriers to communication

Category	Study	Issues
Sender		
	Blagdon (1973)	power and status relationships, information ownership
	Golen & Boissoneau (1987)	status or position, poor organization of ideas
	Gupta & Govindarajan (2000)	motivational disposition of source (willingness to share), perceived value of source unit's knowledge
	Johlke, Duhan,	ambiguity regarding ethical situations, peers, or rewards
	Lewis (2000)	communicating goal achievements
Encoding		
	Blagdon (1973)	specialization of jobs
	Bennett & Olney (1986)	poor communication skills (lack of clarity and conciseness)
	Golen & Boissoneau (1987)	know-it-all attitude
	Hulbert (1994)	cultural differences play a significant role in encoding/decoding messages
	Buckman (1998)	global constraints including culture
Channel		
	Westmeyer, DiCioccio, & Rubin (1998)	appropriateness of a channel, effectiveness of a channel
	Weiss (1999)	use of static channels, use of dynamic channels
	Gupta & Govindarajan (2000)	existence and richness of transmission channels
	Johlke et al. (2000)	communication mode
Feedback		
	Golen & Boissoneau (1987), Messmer (1998)	improper feedback
	Lewis (2000)	sense making and feedback
Message		
	Johlke et al. (2000)	communication content, communication direction, communication frequency
Decoding		
	Golen (1980)	tendency not to listen
	Golen, Burns, & Gentry (1984)	information overload
	Rogers & Roethlisberger (1991)	tendency of the receiver to evaluate
	Golen & Boissoneau (1987)	defensiveness, differences in perceptions, emotional reactions, inability to understand nonverbal communication, prematurely jumping to conclusions, information overload, tendency not to listen
	Messmer (1998)	state of mind, preoccupation with an ongoing task, passive listening
Receiver		
	Golen (1980)	communicator's lack of credibility, hostile attitude
	Golen et al. (1984)	personality conflicts
	Golen & Boissoneau (1987)	lack of credibility, lack of interest in the subject matter, lack of subject-matter knowledge, lack of trust, lack of understanding of technical language, personality conflicts, prejudice or bias, resistance to change, hostile attitude, overly competitive attitude, either-or thinking
	Golen, Catanach, & Moeckel (1997)	credibility/background, conflict
	Gupta & Govindarajan (2000)	absorptive capacity of receiving unit, motivational disposition of receiving unit
	Lewis (2000)	establishing legitimacy
Noise		
	Blagdon (1973)	physical distance between members of an organization
	Golen & Boissoneau (1987)	inappropriate physical appearance, speaking too loudly, fear of distortion or omission of information, informal social groups or cliques, too many gatekeepers, physical distance between members of an organization, poor spatial arrangements, physical noise and distractions, use of profanity
	Buckman (1998)	structural barriers associated with hierarchical organizations
	Messmer (1998)	ambiguity regarding the knowledge-sharing task or procedures
	Johlke et al. (2000)	ambiguity regarding customers, ambiguity regarding supervisor support
	Lewis (2000)	creating and communicating vision
	McPhee, Corman, & Dooley (2002)	employees know what the knowledge is
	Lehr & Rice (2002)	use of measures

Table 3. Combined list of barriers to knowledge sharing

absorptive capacity of receiving unit
access to the knowledge
ambiguity regarding:
  ethical situations
  knowledge seekers
  peers
  reward
  supervisor support
  the knowledge-sharing task
  professional goals
appropriate communication mode
appropriateness of the sharing channel
availability of:
  dynamic channels to share knowledge
  knowledge-sharing technology
  static channels to share knowledge
  time to dedicate to knowledge sharing
communication direction
communication frequency
communication of organizational vision
communicator's lack of credibility
compatibility of legacy systems
sharing systems
confidence in the knowledge
cultural differences
defensiveness for gaining knowledge
desire to retain information ownership
differences in perceptions of workers
discontinuity in progress toward goals
effectiveness of sharing channel
effectiveness of the sharing system
efficiency of the sharing system
either-or thinking
emotional reactions to sharing
employees can identify the knowledge
richness of transmission channels
existing resources sufficient to share
expected:
  associations with other sharers
  contribution to the organization
  recognition for sharing knowledge
  rewards for sharing knowledge
obvious link between sharing and
  the business' problems
operating environmental factors
org. communicates goal achievements
overly competitive attitude
passive listening
perceived value of source's knowledge
perception that knowledge will be of worth
personality conflicts
physical distance between workers
physical noise and distractions
poor communication skills (lack of)
poor organization of ideas
poor spatial arrangements
power and status relationships
prejudice or bias
prematurely jumping to conclusions
preoccupation with an ongoing task
prevention of free riders
professional cultures
proprietary knowledge
proprietary thinking
questionable accuracy of information
receiver perceives enhanced efficacy
feeling that the knowledge fits current context
fear of:
  becoming redundant
  distortion or omission of information
  exploitation once knowledge is shared
  losing confidentiality
  losing power once knowledge is shared
  losing resources once knowledge is shared
  penalty if knowledge is shared
  risk
global constraints including culture
high costs of knowledge search
hostile attitude toward knowledge sharing
improper feedback
inability to understand nonverbal cues
inability to voice relevant knowledge
inappropriate physical appearance
informal social groups or cliques
information overload
internal resistance to knowledge sharing
know-it-all attitude
knowledge-sharing structures match compatibility of
  the organization's style
knowledge-sharing system simplicity
knowledge workers have a local orientation
lack of:
  a knowledge-sharing facility
  clarity and conciseness
  common ground
  contextual clues
  interest in the subject matter
  motivation to participate
  reciprocity
  subject-matter knowledge
  trust
  understanding of technical language
  willingness to share
local problem constraints
measurement of knowledge transfer
memory loss
motivational disposition of source
multiple languages used by knowledge workers
resistance to change
satisfactory content of the sharing transaction
self-interest
sender must establish legitimacy
sense making
skepticism toward sharing
specialization of jobs
specialized languages and methodologies
state of mind
status or position
strengthened group identity
strengthened personal responsibility
structural barriers in hierarchical organizations
tendency of the receiver to evaluate
time limitations
too many gatekeepers
understanding of the context
unit goals
unit subculture
unwillingness to listen
usability of the knowledge
use of a network that motivates participation
user friendliness of knowledge-sharing system

An important prerequisite for measuring context dependency is the development of an instrument to measure knowledge workers' perceptions of which barriers pertain to their specific knowledge-sharing task. Once a valid, reliable tool for identifying which barriers are important within an organization is made available, future researchers may then study a large number of organizations in order to draw general conclusions about knowledge workers.

After common barriers to knowledge sharing are identified, researchers can then work to develop ways to manage and improve the knowledge-sharing process in order to lessen (or even eliminate) the greatest barriers. This action could unlock vast organizational potential by improving the efficiency of knowledge sharing within an organization.

CONCLUSION

The exhaustive list of barriers to knowledge sharing presented in Table 3 begs reduction through further analysis. The Delphi method could be used to do this and to rank the factors accordingly; alternatively, factor analysis could be employed to reduce the data and detect structure in the relationships between them. A third alternative, which may be more difficult to accomplish but is of greater value to the development of management practices, would be to devise a field experiment to observe how knowledge workers perceive each of these barriers. By adopting a communications framework, this comprehensive set of potential barriers to knowledge workers was derived, and now this set can provide a structure for the objective analysis of all barriers simultaneously. Researchers can analyze these barriers in an organizational environment to determine which, if any, are most important, or at least which are perceived to be most important to knowledge workers. By sampling a large number of individuals, a pattern may be seen to emerge indicating areas that are worthy of management attention.

Knowledge sharing is a field that, as of yet, has not received a great deal of researcher attention. Rigorous research, based in theory, concerning knowledge sharing and the barriers to knowledge sharing can help frame this field as a legitimate academic pursuit and provide a basis for the discovery of fundamental truths that may be of real use to managers as the need for knowledge sharing becomes more important.

Chapter 4.12
Institutional Research (IR) Meets Knowledge Management (KM)

José L. Santos
University of California–Los Angeles, USA

ABSTRACT

In this study, a selected university's capacity to provide necessary and meaningful information under a KM framework in order to guide it through its current and new and sweeping initiatives was examined. Specifically, information generated from a university-created Study Committee charged with studying the IR function and key units that perform this function were analyzed. A critical analysis of the committee, its methodological approach to studying the IR function, the IR units, and the findings of the committee was conducted. It was found that KM principles were employed in a limited fashion, and that no knowledge creation was taking place. Another key finding was that the primary focus of the committee and a key unit in the IR function were much more concerned about the decision support systems and their ability to provide good data that, in turn, they believed would lead to excellent decision-making.

INTRODUCTION

Universities and colleges across the United States have an inherent desire and need to establish data/information systems in order to support and, purportedly, to optimize decision-making. In a changing higher education marketplace, this could not be any more central to universities' ability to compete and self-direct in ways that afford them comparative advantages in such a competitive marketplace. As a result of increasing competition and the creation of the field of knowledge management (KM) in the early 1990s, universities have moved in a direction that captures the cumulative endowment of knowledge that universities hold. In order to remain competitive and strategically contend with market forces, universities are engaged in this fast-moving field of knowledge management in several areas: human resources, organizational development, change management, information technology, brand and reputation management, performance measurement, and evaluation (Bukowitz & Williams, 1999). As the young and popular field of knowledge management continues to emerge, some universities will succeed in aligning their organizational activities with KM principles while others will not; others will only adopt parts of a KM framework. For example, some universities may only develop a capacity for data/information systems but fail to develop capacities in other critical areas that are necessary to interpret information that is created from such systems. That is, they will spend large sums of money building system-wide database warehouses and investing in the people that support such systems but will fail to invest in a commensurate fashion in the human capital needed to interpret the information generated from these systems in order to advise decision makers. Such is the case of Western University, a research extensive university and the subject of analysis for this chapter.

LITERATURE REVIEW

Knowledge Management (KM), a term and movement that was coined by the corporate world (Serban & Luan, 2002), is a fairly young field, yet it has gained momentum in both the public and private sectors. In fact, it is becoming a standard in universities whereby they can harness their cumulative knowledge in order to make informed decision-making by taking data in its raw form and create knowledge for decision-making consumption. KM principles are usually found in institutional research offices at universities, the function of which are explored in the following review of the literature.

Institutional Research (IR)

According to Saupe (1990), "Institutional research is conducted within an institution of higher education to provide information which supports institutional planning, policy formation and decision making" (p. 211). These activities include strategic planning, academic program reviews, environmental scans, enrollment management, faculty productivity analyses, budget analyses, and others. The IR function is a decision support model that is structured around applied and basic research—an approach that involves evaluation, problem identification, action research, and policy analysis.

Typical questions asked in an applied approach may involve questions such as: (1) How many sections of a specific course should be offered? (2) By what amount should tuition rates be increased to produce a target amount of tuition income? (3) What impact would increasing tuition have on access for low-income students? (4) Is attrition a problem at our institution? (5) Are our faculty salaries competitive with those paid by peer institutions? and (6) Are there statistically significant differences in salary between men and women or non-minorities and minorities?

As an evaluation function IR addresses the following areas: (1) information on cost and productivity that underlie judgments about efficiency; (2) information on other characteristics of programs, units, and outcomes that lead to judgments about effectiveness or quality; and (3) information on program purposes, on programs offered by other institutions, on the labor market and on potential demand that produce judgments about the need for academic programs.

Problem identification may surface when looking at results from routine queries or tabulations. For example, in the course of querying data for a routine retention report it might be found that certain racial/ethnic groups experience lower rates of persistence from year to year and overall retention during a six-year time period. An action research approach in IR, perhaps, holds the greatest promise for addressing complex questions such as this. IR offices are where the researcher and client (anyone in the organization) work closely throughout the problem definition, research design, data collection, analysis, interpretation, and implementation phases of the project. That is, the institutional researchers work with units throughout the organization in a consultative manner.

KM Overview

According to Serban and Luan (2002), "KM is the systematic and organized approach of organizations to manipulate and take advantage of both explicit and tacit knowledge, which in turn leads to the creation of new knowledge" (p. 8). On the one hand, Crowley (2000) argues that explicit knowledge is easily codified and transmittable in systematic language. On the other hand, Kidwell, Vander Linde, and Johnson (2000) suggest that tacit knowledge is personal, context-specific, difficult to articulate, and often poorly documented. However, Firestone and McElroy (2003) suggest that the dichotomy between explicit and tacit knowledge does not go far enough. In fact, he suggests that tacit knowledge can be made explicit. However, this goal is difficult to achieve in complex organizations such as higher education institutions. One of the greatest ironies in higher education is that such organizations' core business is to create, transform, and transmit knowledge, yet, they tend to lack organized knowledge management systems that may allow them to optimize institutional decision-making (Kidwell, Vander Linde, & Johnson, 2000; Laudon & Laudon, 1999).

IR Meets KM

Serban & Luan, (2002) present a careful overview of KM in the context of Institutional Research (IR). IR and strategic planning have multiple functions in colleges and universities. Joe Saupe (1990), perhaps, provides us with one of the best descriptions of the nature of institutional research, of its role in institutional governance and of the contributions it can make to the function of post-secondary institutions. J. Fredericks Volkwein (1999) provides us with a comprehensive volume about institutional research. Andrea M. Serban (2002) contributed to our understanding of IR by providing us with a look at the contemporary IR person in the knowledge management context. These foundations of IR literature reveal that, theoretically, IR should use and integrate knowledge management principles in order to provide key decision-making support. Moreover, in order for the IR person to be successful, this person must successfully navigate institutional database systems while providing analytical products to decision-makers.

According to J. Fredericks Volkwein (1999), the IR profession is described as having four faces, wholly based on the people served and the culture of the organization where IR is being executed. The four faces he described center around the notion that IR serves as information authority, spin doctor, policy analyst, and scholar and researcher. Andrea M. Serban (2002) adds a fifth face of IR: knowledge management. She contends that "in a knowledge management environment, these four facets continue to exist; however, they converge into a broader, more integrated dimension—the fifth face of institutional research—IR as knowledge manager" (Serban, 2002, p. 105) (see Table 1).

This fifth face of IR requires different training than that referred to by Saupe and Volkwein. In fact, knowledge management requires people with interpersonal skills that can negotiate an organization's culture and still have strong skills in business processes and technology.

IR in a KM framework has its benefits and challenges, and, therefore, it is best to understand them. According to Serban (2002), "there are clear advantages of implementing knowledge management frameworks and processes" (p. 108), which are summarized in Table 2.

The benefits to KM clearly outweigh the challenges associated with employing such principles.

Table 1. Purposes and roles of institutional research

	Purposes and Audiences	
	Formative and Internal (for Improvement)	*Summative and External (for Accountability)*
Organizational Role and Culture		
Administrative and Institutional	To describe the institution *IR as information authority*	To present the best case *IR as spin doctor*
Academic and Professional	To analyze alternatives *IR as policy analyst*	To supply impartial evidence of effectiveness *IR as scholar & researcher*
Knowledge Management	To gather and transform data into information and knowledge; to collaborate in the creation and maintenance of an institutional official repository of data, information, and knowledge (i.e., portals); to facilitate the process of knowledge creation, capturing, and sharing. *IR as knowledge manager*	

Adapted from Serban (2002, p. 106) and Volkwein (1999, p. 17)

Table 2. Benefits and challenges of KM

Benefits	**Challenges**
Access to and sharing of knowledge	Strategy—developing a clear sense of direction
Customer responsiveness	Tacit knowledge and organizational cultures
Better understanding of the organization and its customers	Skills and expertise—developing highly technical skills
Operational efficiencies and decentralization of functions	Cost—human and financial

For example, if an organization has a need to somehow leverage its endowed knowledge base in order to be competitive in the marketplace, this can be accomplished by providing its users access to institutional information so that knowledge creation can occur, thereby, adding to the effectiveness and efficiencies in decision-making. However, when information asymmetry exists, the rewards to this KM benefit fail to materialize. The main challenge arises when the organizational culture is not responsive to sharing information and to knowledge creation. Arguably, organizational culture can be an impediment instead of an enabler and can lead to a lack of clear institutional sense of purpose and direction. Culture as an impediment can be symptomatic of a much greater problem such as leadership void in IR, the IR function, and senior management. As an enabler, culture can be the key ingredient in a recipe that gives rise to competitive and innovative behavior in the higher education marketplace.

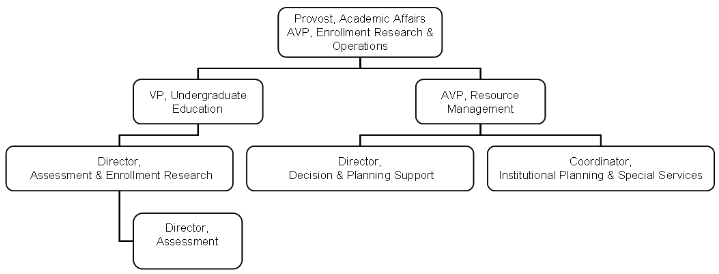
METHODS

The purpose of this study is to examine whether or not KM principles as described in the knowledge management field were evident and employed at Western University. This analysis uniquely explores deeply seeded beliefs about what the three departments that make up the IR function believed were their strengths. The analysis is a case study using various qualitative techniques. This approach adds depth of understanding as to how IR and strategic planning departments make use of or do not employ KM principles. We should be cognizant however, that this approach is not absent of its limitations, but it is a powerful approach to provide a fuller picture of how KM is used in practice.

Western University (a pseudonym) was selected for this study because it demonstrated a need to take raw data and move it efficiently and effectively through a continuum, beginning with raw facts and numbers and ending with decision-making and planning decisions. Having such a seamless process would be vital to the institution's ability to compete effectively in the marketplace. Further, an effective flow of data toward knowledge creation would help the university.

Western is a public research extensive university with an approximate student body enrollment of 37,000. This university was selected because its IR and strategic planning function has undergone a transformation with respect to its organizational hierarchy. Prior to the reorganization, the IR function within the organization was spread across three separate units. That is, the three units that make up the IR function at Western were: (1) decision & planning support; (2) institutional planning & special services; and (3) assessment and enrollment research. The decision support unit reported to a director, who in turn reported to a senior administrator that oversaw resources

Figure 1. Organizational chart pre-reorganization



in the academic affairs area. The planning unit was managed by a coordinator who also reported to the senior administrator in the academic affairs area. The assessment and enrollment research unit reported to a different senior administrator in academic affairs, a vice president for undergraduate education (see Figure 1).

Memoranda and various forms of correspondence from a study committee that was formed to examine the various IR functions and its committee members were analyzed. The author placed himself as a participant observer in some of the data gathering and analysis, providing valuable access to information.

FINDINGS

IR as a Fragmented University Function

In December 2002, a senior and powerful dean at Western sent a letter to the provost expressing concerns about duplication of efforts, resource efficiency, data accuracy, and ambiguity of roles between the decision support, planning, and assessment and enrollment research units. In the dean's letter, strong concerns were expressed about what appeared to be three "organizations doing many of the same things with little coordination."1 The dean conveyed that "the bottom line that we [the dean speaking on behalf of his college] face at the college level is the lack of accurate information upon which administrators can make informed decisions." Moreover, the dean made a specific recommendation in order to address the concerns expressed by suggesting that the senior administrators who directed these units meet with the academic council in order to address and remedy the dean's concerns. The concerns were never addressed at the venue requested by the dean; however, a team to study these concerns under the backdrop of a new and sweeping university reorganization initiative was formed. This letter would later serve as a significant trigger for the forming of a university-wide study team that came to be known as the "Data, Analysis, and Planning Study Team" (DAPST).

In June 2003, the president of the university and the provost created the new DAPST and charged the newly appointed chief information officer (CIO) to chair the team. According to the chair's invitation letter to prospective DAPST members, "the underlying goal behind this study is to improve the University's ability to bring data and analysis to bear on management decisions." In the same document it was expressed that the "administration is increasingly tied to assessment and projection, both of which are completely dependent on the quality of the data we collect and the analyses we conduct on the data." The chair also found it necessary to illustrate a significant example where IR failure had occurred. The chair stated that the "effort to set future priorities should have involved data-based assessment of academic and support units against a specific set of criteria, and reorganization plans should have been informed by analytic models projecting outcomes and costs for various possible lines of action. The Reorganization Initiative exercises were instead supported largely by such noncomparative narrative records as Academic Program Reviews and constituent testimonials." Clearly, the chair was suggesting that one of the units, if not all, did not successfully coordinate this effort in order to provide the best information possible to inform decision-making for such a high level management initiative.

The DAPST membership was "balanced between academic administration and the various offices that provide support for management through data collection, data warehousing, data analysis, or report generation."2 Although the DAPST membership did, in fact, comprise a decent balance of academic administrators and various offices of special interest, the attendance of the membership quickly and sharply decreased to just those offices that had a vested interest in the outcome of the “findings” as it pertained to their organizational units.

The Proceedings

At its inception, the chair of the DAPST conveyed a message to its membership that the team would address issues that hindered Western University’s ability to respond to sweeping institutional initiatives. It appeared that the problem identification rested in the notion that there was a broken IR function—a function that was unable to mine data elements, resulting in a lack of knowledge creation for tactical and strategic decision-making. The findings from the proceedings and behavior inferred from various membership correspondences suggest that some members agreed with the perceived problem definition and wanted to effectively address it while others dug in, circled the IR wagons and went to great lengths to preserve the status quo.

Digging In

Examining public electronic e-mails, facsimiles, and other documents such as correspondence between the DAPST membership itself, between membership and the chair, and the like suggests that there was a clear struggle among the members who believed that creating data through an existing decision support system known as the Integrated Information Warehouse (IIW) is knowledge creation whereas others believed that such processes are a good starting point for knowledge creation by fully integrating the analysis of such data.

The IIW is a data warehouse that contains Western University’s related historical, census, and start-of-business-current-week data, and it is maintained by the decision and planning support department’s servers from which internal and external reports can be generated. Census data comes from snapshots taken of operational data at the same time each year. Historical and Census data are used for viewing trends and the state of the institution at the same time each year. The Census data are taken from Western’s University Information System (UIS). The UIS is a university-wide data warehouse with start-of-business-current-day data from Western’s financial, personnel, space, sponsored project, student, and other operational systems. The UIS is maintained by Western University’s computing center that reports to the CIO.

Before the first meeting of the DAPST, there were questions from the three units being examined. For example, the senior executive who oversaw the decision support unit and the planning unit suggested that the provost was interested in hiring an external consultant to review the roles of the three units, a suggestion that was at odds with the articulated function of DAPST. In fact, language was used that appeared to undermine the DAPST chair, the charge of the study team, and the team’s eventual findings. When employees of those units raised questions, the executive withdrew from the desire to hire an outside consultant. The question remains as to what problem this executive and/or the provost was trying to address that was either different from or similar to that of DAPST. Moreover, it is possible that this interest had nothing to do with knowledge management and how to effectively deliver quality information and quality analysis of the information. Rather it can be construed as an exercise to signal to staff in the decision support and planning departments that this executive retained control of these two units and the likely outcome of any reviewing committee.

A member of the decision support unit and a member of the DAPST raised questions and introduced information that might have been helpful to the direction of the study team. This person suggested that to effectively address IR needs there needed to be a focus on “what we should be doing.” Moreover, through an electronic correspondence with the chair, this member asked the chair if the team could benefit from viewing the IR function through a systems and integrated approach. This person believed that "the lack of understanding, coordination, and cooperation on data, analysis, and planning from a systems view is a key piece of the puzzle on our suboptimal performance in these critical areas. Can we gain from taking a systems view and creating integrated, holistic, data, analysis, and planning function for our institution?" This was a powerful set of statements not only because the chair responded favorably to the suggestion but also because the DAPST had not previously considered an institutional information systems paradigm.

The decision support unit director highlighted his unit's most significant accomplishment—the Integrated Information Warehouse (IIW). The goals listed by this unit are consistent with KM principles as the unit sought to provide timely and accurate information and tried to be the central repository of institutional data for decision-making. This unit saw itself as playing a role in university "perception management." That is, the unit engaged in the IR role Volkwein (1999) called "spin doctor." Also, this unit, through its direction, seemed to focus much of its energies on data inputting, data editing for the sake of accuracy, and internal and external reporting. It expended its resources around the IIW, as the IIW was the perceived data creation generator and the means for better decision-making. The assumption was that the IIW, with its five gigabytes (GB) plus of data added annually, would somehow yield better decision-making. That is, great data equals great decision-making. The projected public discourse that the director of this unit propagated for DAPST can be summarized in three areas: goals, functions, and systematic information (see Table 3). However, in actuality, the unit diverged from its publicly stated rhetoric in a number of significant ways. For example, although the unit expressed the goal to "help the university understand and interpret its environment, self, and options on critical information," no evidence is found that administrators with decision-making authority on critical issues used any information from the IIW that strengthened their decision-making ability. As a result, the fact that this unit had been relatively absent in its provision of key university information also suggests that it had failed in

Table 3. Decision support goals, functions and systematic information

Goals	Functions	Systematic Information
Provide accessible information Provide accurate, timely, and comprehensive information for varied users Help the University understand and interpret its environment, self, and options on critical information	Collect missing information Address key university questions Improve perceptions of the university—"perception management" Provide valid and external reports	IIW—10 plus years of consistent data; 36 GB, add 5 GB more a year Clean, code, and compile system data for ease of use Census and other standard information for most university-wide, non-accounting reporting Flexible web answers to campus questions—X pages a year

one of its major functions of "address[ing] key university questions." The question does remain as to why this unit was not approached on key university questions on something as central as the university-wide reorganization plan that took place before the formation of DAPST.

Another example rests in the assertion that this unit through its IIW provides "flexible Web answers to campus questions …" This is referring to its ability to provide Web portals for various users (i.e., administrators, university community, and external community). The unit provided Web portals and for the most part one could retrieve information quickly. However, power users found it impossible to access the source codes. That is, in most cases a power user at Western was using Oracle-based SQL or a relational database application such as ACCESS or BrioQuery. These users tried to access the data through the Web portal, the IIW returned data in HTML format and downloadable EXCEL files, but the user was unable to identify the tables and table elements that were used. In other words, one would have to call the unit to request the source code in SQL. For an administrator, this may not be as important but for a support systems analyst that is supporting an administrator at the college level this is extremely important because, in most cases, the source code needs to be modified to fit the specific use.

So how did the assessment and enrollment research unit engage in pubic discourse and assert its projected domain of expertise? The director of the assessment and enrollment research put together a list of activities that were being performed on campus, attempting to make a clear demarcation of some of the questions that were going to be addressed by the DAPST. It was a list of different IR activities that were being performed throughout Western but made no attempt to affix any units to the activities. More importantly, this list took the form of a process-related exercise rather than an outcomes approach that would suggest a rational assignment of activities within domains and the units that would carry out such activities. Moreover, with respect to the assessment and enrollment research unit, examination of this list suggests that this director was not going to overtly project the unit's role within the IR function. Instead, it appears that this director placed the enrollment activity in his purview, in the analysis/planning domain. This is important because it suggests that this director appears to have valued this domain or may have had some reason to believe that administrators valued this domain for knowledge creation and enhanced decision-making. The list of activities is summarized in Table 4.

By the time the planning unit made its case, it had become clear that the discussions in the study team were about data, quality, and the ability to inform decision-making—and, not much about using or not using KM principles in the IR function. The planning department introduced a list of activities that it felt were in its domain and in the course of generating the list aggressively projected the capacity for certain domains. This unit went to great lengths to suggest that in addition to coordinating a university strategic plan, it performed activities designed to inform management. In other words, the unit, through its coordinator, tried to convey that it was central to management decision-making and, thereby, they created knowledge pursuant to KM principles.

In actuality, this unit indicated that it provided certain types of products, but these were not delivered. For example, this unit indicated that it provided quantitative and qualitative analysis. When the products that have been created by this unit were examined no products would fit those criteria. Instead, the five-year strategic plan, summaries of colleges' annual reports, and other similar products were created without any qualitative and/or quantitative techniques. This unit also listed a "departmental profile" as a key accomplishment. Indeed, this product was used for key decision-making as it contained information valuable to the discussion of departmental eliminations and/or mergers. However, it is im-

Table 4. The domain of analysis, planning, and assessment

Data Collection	Data Administration/ Management	Reporting/Basic Data	Analysis/ Planning	Assessment/ Evaluation
Admissions	Loading Databases (university database, integrated information warehouse[IIW] maintained by the decision support unit)	IPEDS	Enrollment	General Education Program
Curriculum & Registration	Edit Checks	Governing Board	Budget/Costs	Academic Programs
Financial Aid	Database Maintenance	State Planning Office	Faculty/Staff	Student Development
Bursar	Hardware/ Software	State Legislative Budget Committee	Space	Teaching Evaluation
College & Academic Departments	Documentation	AAUDE	Capital Projects	General Program Evaluation
HR	Software Training	Campus (APRs, Deans, Departments)	IT	Personnel Evaluation
Budget Office	Training on use of data	Ad hoc service requests	College & Academic Departments	Accountability for Governing Board & Accreditation Board
VP Research	Integration w/Subordinate and Shadow Systems	Fact Book/ websites	University Planning Advisory Group Support	Test Scoring & Analysis
Facilities Mgmt	Web (IIW) queries	Public Records	Operating Plan for State Legislative Budget Committee	N/A

portant to note that this departmental profile is the same report that attracted criticism from and was referred to by the influential dean that triggered the formation of the DAPST in the first place. The dean had indicated that the departmental profile was flawed. The activities of the planning unit can be summarized in Table 5 in the following way by their respective general function.

The findings suggest that the vested units were signaling within the organization how they wanted

Table 5. Planning activities

Institutional	Planning	Analysis	Ad hoc
Summarize college annual reports Consult & review units' academic program reviews Coordinate accreditation activities & reports	Staff the University Planning Advisory Group Prepare the five-year strategic plan	Quantitative/ qualitative	Departmental Profile

to be perceived, and what capacities they believed they possessed. This institutional maneuvering resulted in a carefully orchestrated dialogue that would, basically, preserve existing domains and spheres of influence. Interestingly, no final report was generated by the DAPST and none of the committee's findings were disseminated to the university community as promised by the provost and president. Instead, the chair of the DAPST electronically circulated a draft of the final report3 to its membership soliciting input. The question remains as to why such a high-level review team was charged with studying a generally understood and important function of the university and why the findings were not disseminated as is normally expected when a task force study team is assembled at a public university. Perhaps the report regarding the process and products of information management was considered too divisive for general review.

The Elusive Final Report

The draft of the final report revealed some very important social aspects. The report was organized into six key thematic groups: trust, culture, awareness, access, questions, and resources. Culture and awareness are the central themes of interest as these were the two areas where most of the conversations centered; whereas the other four themes were given cursory consideration. In the report much space was dedicated to these themes and not much was given to the delivery of services from an IR function in order to take data, create knowledge, and manage knowledge as Serban (2002) suggests is the fifth face of IR. The culture theme revealed:

The organizational culture does not include consensus on the importance of data or acceptance of shared responsibility for data quality. Complaints about errors in data breed cynicism *without feeding back into improved practice. We not only lack shared definitions and standardized metric; we also seem to lack an interest in developing them.*

Even when discussing culture it appeared that the focus immediately gravitated toward inputs in knowledge creation—data and data quality. The awareness theme revealed:

Data providers must be aware of the data needs of the colleges, and the colleges must be aware of what is available—what data sources, what tools, and what expertise. Everyone must understand what numbers in datasets mean and how they are meant to be used. We need heightened awareness of the "unintended consequences" of measurement and a more thoughtful approach to choice of metrics.

The report focused on one aspect of the battery of skill sets required of a modern day institutional researcher—advanced technical skills centered on data, data definitions, and a heightened awareness in decision rules when querying datasets. Unfortunately, this theme overlooks the other important prerequisite skills required of today's institutional researcher—institutional consultant, policy analyst, and knowledge contributor and creator.

Noticeably absent from the report was any analysis of any data that examined the veracity of the products that the respective IR units under study indicated they provided and, moreover, the quality of such products. The report made some references to the original charge of the DAPST with an astonishing shift in language, stating that "excellence in administration depends on the quality of our decision-making, including the quality of our decision support systems." In other words, the chair conflated good data support systems with quality decision-making. This is a significant finding because it suggests that data support systems such as the IIW are a means to and end rather than a foundational starting point for knowledge creation. Perhaps Patrick Terenzini (1993) put it best when he described three tiers of intelligence—defining the nature of institutional research and its prerequisite skills, whereby technological skills is the lowest of the three tiers. According to Terenzini, "this form of intelligence is foundational: by itself, however, it is of little value." (p. 9). What is more, the report made no recommendations for reorganization of the units that were studied. Notwithstanding, the units were reorganized approximately six months after the report was drafted. Remarkably, in the absence of a public dissemination of the DAPST findings, the reorganization further contributed to an organizational culture of misinformation.

Study Team & Its Findings: Do KM Principles and Practices Emerge?

There is no conclusive evidence from the data that was analyzed that KM principles were being employed in a thoughtful manner at Western University. To the contrary there is ample evidence to suggest that the IR function is fixed in data and data systems and has yet to make the necessary transformation along the KM continuum to knowledge creation. In short, at Western, technology is viewed as the panacea for good decision-making. Moreover, from the draft report itself there are no acknowledgments or recommendations addressing policy analysis and knowledge driven activities for better decision-making. However, arguably, the most significant finding is the units that made up the IR function and were under review underwent major reorganization six months after the report was drafted. This was unexpected given that the report was neither publicly disseminated nor was anyone seemingly following through on any set of recommendations that would have been advanced from the draft version of the report. The question still remains as to why these units were reorganized. Certainly, there must be other private reasoning that is not captured in the data analyzed.

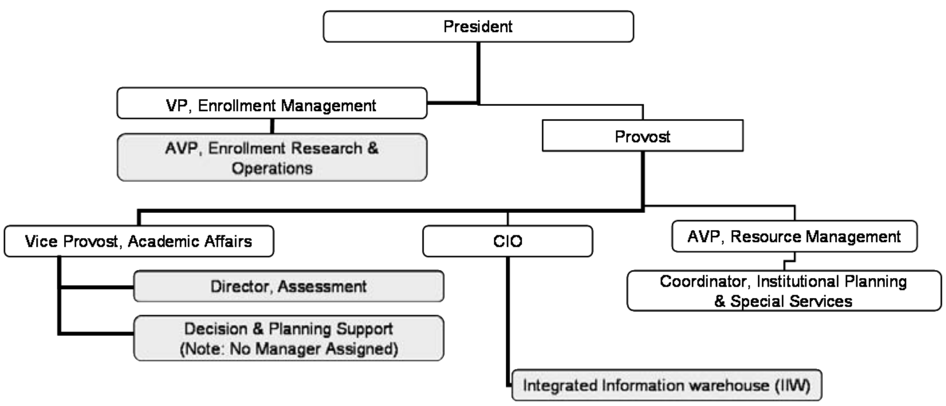
As a result of the reorganization, decision and planning support, institutional planning, analysis and special services, and assessment and enrollment research were separated into four distinct units reporting to three different senior administrators. The new units are as follows: decision and planning support, institutional planning, analysis and special services, assessment, and enrollment research and operations. They all remained in the academic affairs (provost's office) except for enrollment research and operations who now reported to a newly created area called enrollment management (president's office) (see Figure 2). Remarkably, in this reorganization, not a single person that was part of the original IR units under review was fired. However, two key individuals resigned and the director along with two other technical staff of the decision and planning support unit along with the IIW responsibilities were transferred out of that unit and into the CIOs area. One individual was a key architect of the IIW in the decision and planning support unit and the other was the administrator of the UIS. In addition, the former director and two systems support individuals of the decision and planning unit were reassigned to work with the IIW. In short, there was a shuffle in the organizational hierarchy with two key resignations and the transferring of a key director and other staff, none of which would be expected given the DAPST findings.

CONCLUSION

Western University is an example of an organization that only adopted parts of KM principles by developing the capacity for data/information systems through its IIW but failed to develop capacities in other critical areas necessary to interpret and create knowledge. That is, Western spent much of its energy discussing how to improve upon its data, data quality, and data access and invested in the people that support such systems but failed to invest in a commensurate fashion in the human capital needed to transform the information generated from these systems into knowledge in order to advise decision makers.

The DAPST and its draft report illustrate that KM principles were not at the core of its values. Its myopic focus on such a small part of KM rendered

Figure 2. Organizational chart post-reorganization



its team's report meaningless in helping to advance knowledge creation for enhanced decision-making, especially during a time when Western needed critical IR to help senior management navigate through its new and sweeping objectives and a changing higher education marketplace.

Recommendations

The DAPST team would had been better served if they focused their attention on: (1) developing a critical perspective of university colleges and departments performance and plans that are informed by a deep understanding of each unit's strategic objectives and overall operating environment; (2) executing consultative projects in close collaboration with various units to help address administrative and financial management questions and/or opportunities; (3) examining important university-wide academic/financial/physical planning issues and/or opportunities by working closely with units as well as by drawing on external data as appropriate and necessary to inform internal review processes; (4) collecting critical academic/financial/physical information from across the university for the purposes of not only supporting internal decisions-making but also to ensure timely and accessible responses to requests for data from regulatory agencies, peer institutions, and other interested parties; and (5) moving the IR function beyond information authority and into the realm of IR as policy analysis.

Chapter 4.13

A Knowledge Management Case Study in Developing, Documenting, and Distributing Learning

Brigette McGregor-MacDonald
Marsh Inc., UK

EXECUTIVE SUMMARY

This case study reflects the work of a global organization in its knowledge management efforts to sustain and transfer learning from a global leadership development curriculum. It focuses on the Knowledge Management (KM) solution developed to support employees to sustain their learning, to enable them to share their insights and experiences with others, and thus increase organizational capability. The paper is written to illustrate an example of a large organization's efforts to engage employees to share their learning from a management programme across geographical and cultural boundaries.

INTRODUCTION

This case study reflects the work of a global organization in its knowledge management efforts to sustain and transfer learning from a global leadership development curriculum. It focuses on the Knowledge Management (KM) solution developed to support employees to sustain their learning, to enable them to share their insights and experiences with others, and thus increase organizational capability. The paper is written to illustrate an example of a large organization's efforts to engage employees to share their learning from a management programme across geographical and cultural boundaries.

Georgensen (1982) estimates that learners retain approximately 10% of material covered in a tutor-led workshop when back at the workplace. The KM strategy in this project was to support high-performing, high-potential employees to retain a greater proportion of the tutor-led learning and experience. This in turn increases organizational capability by transferring the learning to colleagues and delivers a greater return on investment to the business.

A key challenge of the KM strategy was to effectively manipulate existing KM platforms within the business and research and propose the use of additional ones.

The issue was to make best use of the current multiple resources in the organization, acknowledging that not one of them was totally suited to meet the needs across the globe. The Learning and Development team worked to find a solution with either a range of existing platforms or, as a result of research and testing of new technologies, a new KM platform to support the strategy.

There are a number of cultural challenges associated with implementing effective KM across a global organization with presence in over 100 countries, with different levels of technology sophistication, language, and experience. Revenue-generating business demands mean implementing an effective KM strategy with "learning" content as another challenge entirely. For example, time spent documenting personal reflections from learning and on-the-job experiences, and reading others' reflections from learning and on-the-job experiences struggles to compete with business opportunities that deliver an immediate bottom-line return.

The nature of the insurance industry is relationship based. Interaction has historically been, and still is, predominantly face-to-face or over the telephone. As Nixon (2000) confirms, many other industries have found implementing effective technology-based KM solutions with only face-to-PC interaction is a cultural and pragmatic challenge. In their everyday role, brokers prefer to pick up the phone and talk to someone or go to see them versus logging on to a computer, entering a password they need to have remembered and change regularly to maintain security protocols. The Lloyds of London broking environment, established in 1688, reinforces the face-to-face relationship-based culture. Experience of working with an internal client group to support employees to use the system suggests that if the Internet connection is slow or a password is typed incorrectly thus denying access, users will pick up the phone before trying again, or worse, will avoid the system in future.

BACKGROUND

The Organisation

Marsh Inc. is the world's leading risk and insurance services firm. Its aim is "[t]o create and deliver risk solutions and services that make our clients more successful." Founded in 1871, it has grown into a global enterprise with 400 owned-and-operated offices and 42,000 colleagues, who serve clients in more than 100 countries. Marsh's annual revenues are $6.9 billion, and the company meets client needs in two principal categories:

- Risk Management, insurance-broking, and programme-management services are provided for businesses, public entities, professional services organisations, private clients, and associations under the Marsh name.
- Reinsurance-broking, risk and financing modeling, and associated advisory services are provided to insurance and reinsurance companies, principally under the Guy Carpenter name.

The organisation is made up of distinct divisions with specialist knowledge. One of the key business drivers for the future is to maintain and develop the specific knowledge within each of these divisions, while sharing more learning and experiences across the business, particularly to reduce "reinvention of the wheel" comments across divisions and geographies.

SETTING THE STAGE

Knowledge Management Platforms in Learning

Newman (1991) defines KM as "the collection of processes that govern the creation, dissemination, and utilization of knowledge." The cascade and consistent communication of corporate goals and performance management is pivotal to business success, learning interventions, and employees' personal development. In 2000, Marsh made a fundamental shift in the mechanism used to cascade company strategy across the globe. Local performance management tools, processes, and procedures were replaced with one common approach to aligning goals and consistently measuring performance with the Balanced Scorecard.1

At the beginning of 2001, there was no common, pan-European technology platform specifically targeting learning and the consistent documentation of learning in Marsh. E-mail provision was the one common tool and platform across the globe. The company had a variety of software to support the creation and application of databases and had the capability to share databases across geographies, through shared network drives, Internet-based secure "filing" programmes, Microsoft Access and Lotus Notes programmes. Few employees were aware of the range of these capabilities and even fewer were aware of how to manipulate such tools.

In 2001, the firm implemented a global learning management system with specific, pan-European capabilities including e-learning, registration for tutor-led learning, and an online lending library with books, CDs, tapes, videos, and computer-based training (CBT). The system also provided the capability to record for each learner what learning they had accessed and to allow an "approver" path for line manager involvement and alignment to learning. Usage statistics have increased from 11% of the total European population in 2001 to more than 28% in 2004.

In 2002, the organisation launched a company-wide portal, an interactive client and colleague platform to source information about Marsh to both external and internal requestors. The portal is intended to ultimately replace local country-specific intranet sites. The learning management system is now operating effectively from this medium. Local intranets are still in operation across Europe providing more specific local information to employees with the portal offering a platform that spans the entire region and links to colleagues and learning in the United States.

The business is using a number of communication tools to promote cost-effective knowledge sharing, the most common being an interactive, Internet-based tool WebexTM, used alongside the telephone for conference calls to share presentations, documents, and access to specialised software. This tool allows Internet dialogue over the course of a meeting and has "ownership" rights for a person or persons to own a presentation document and to be able to make adjustments online in real time with feedback from the conference call participants. This tool can also be used with external clients and has been particularly useful in sharing across boundaries as all colleagues have a desktop computer and access to a phone.

CASE DESCRIPTION

This paper will specifically focus on the KM strategy implemented for the European implementation of a global leadership programme. The programme is one of three core programmes in a Global Leadership Development Curriculum and targets high-performing, high-potential colleagues with people management responsibility. It is a three-day off-site event. Titled "Managing

Essentials," it was launched in the spring of 2002. The business used an external provider to deliver across the globe with a core team of dynamic and experienced facilitators. This strategic decision enabled consistency of message, delivery, language, and experience.

The audience for the programme is diverse in years within the organisation and in the industry, time in a management role, geography, and first language. In Europe alone, the target population of colleagues to attend the programme in the first 18 months was close to 500 (50% from the United Kingdom and 50% from continental Europe). Results from employee surveys and dialogue on the programme demonstrated the need to create ownership and responsibility for change at this level. The Learning and Development (L&D) network of colleagues managing the programme at the local level across the globe is also diverse. Technology has played a key role in communicating across geographies with both the delegate and the L&D communities by way of the telephone, Internet, e-mail, various global software platforms, and even camera.

The ultimate KM strategy for Managing Essentials is to improve organisational capability and capacity.2 Underpinning this are four main goals:

1. For delegates of the programme to sustain their learning of best-practice management tools and techniques
2. For delegates to sustain the pan-European colleague network from the programme
3. For delegates to share their learning and lessons learned from implementation with other colleagues
4. To demonstrate a measurable return on investment against the learning intervention

Next is an account of what actions have been taken to address each element of the strategy and the observed outcomes to date. Georgensen's (1982) hypothesis of learning retention was a key factor in the design of the strategy with pre- and postcontact with delegates at progressive intervals to reinforce the learning. For this reason, the material that follows identifies the cycle stage of the actions taken to the programme (pre, during, or post).

Sustaining the Learning

Pre Event

High-performing, high-potential colleagues were the target audience for Managing Essentials because this population was generally known to be more capable and willing to cascade learning, lead by example, and to therefore impact the majority of colleagues as a result of their experience on the event. To ensure appropriate employees with this skill set were exposed to the learning, employees could not self-register for the programme but had to be nominated by a senior colleague in their business.

To combat cultural issues that historically reinforced silos within the business and across geographies, Managing Essentials is delivered at a pan-European level as opposed to local country level. Nominations are managed by the Programme Manager through the database to ensure a 50/50 split of participants from the UK and continental Europe. The deliberate mix of delegates on each event, sharing and cascading knowledge and breaking down business segment and geographical boundaries, has been recognised by delegates as a core strength of the programme.

During the Event

Every delegate received a hard copy binder of materials covering the learning models and references from the three-day event and supplementary reading materials and references. The facilitators referred delegates to their binders throughout the programme and ensured key action points were documented in the binder to encourage participants to refer back to it and use it when back at the office.

On approximately 60% of the conference calls held with delegates post event, at least one employee referred to his/her frequently returning to the binder to remind him/her of his/her learning. Many claimed to keep their binder on their desk where it could be easily referred to.

Post Event

The Marsh internal Learning and Development team developed a sustainability timetable post programme using a variety of KM tools. A summary of activity is noted in Table 1.

Months three, six, and 12 of the postprogramme plan were proposed in first quarter 2003, but have not yet been fully implemented. Europe has consistently implemented up to the three-week stage in this timeline and has sporadically implemented the six-week and onwards activities.

Each of the KM tools and practices used in the above timeline has its pros and cons. The objective of using this range of tools and methods is to provide an overall synergy to all the learners involved, appreciating different learning styles. The feedback the team has had is that the facilitated conference call is useful for reminding delegates of their learning and bringing the "community" back together again. The conference call does not, however, lend itself to support those colleagues

Table 1.

Within a fortnight	Take time to reflect and think Receive group photo of delegates Commence 3-6 month challenge
Two weeks	Receive the following information by email: • Email distribution list along with ideas on how to use it, i.e. 'What I've learnt this month' • Copy of the APT[2] (see *Transferring Learning Across the Organisation*) model previously completed on-site • Copy of Excel spreadsheet with all delegates' Background pre-work • Excel spreadsheet with names of all participants on the programme across Europe since Spring of 2002 Receive an additional email directing delegates to specific e-learning materials to reinforce key learning points, accessible through the global learning management system Attend conference call with other delegates (recorded and transcribed for later reference)
Three weeks	Receive an A5 colour laminate for their desk with key models and messages from the 3-day event
6 weeks	Receive notification of bi-monthly Webex™ calls to share feedback on 3-6 month challenges
3 months	Line managers of participants receive on-line questionnaire to complete on noticeable changes in participants' performance since attendance on the programme
6 months	Attend video conference with delegates to reinforce the network
Annually	Attend a central conference of delegates to review content and lessons learned on implementation, and facilitated discussions around transfer of learning and knowledge management.

who speak English as a second language and the transcript of the call, while a valuable record of verbatim comments and stories, is detailed and time consuming to analyse at a later date.

As the networking opportunity of the event holds such great wealth for the participants and lends itself to the transfer of knowledge both to the network after the event and to their colleagues back in the office, a digital photo is now taken on site on the last day of the programme and circulated to the delegates approximately two weeks afterwards via e-mail. For those people who learn more effectively in a group and through visual stimulus (as opposed to audio or kinesthetic), the photo provides a reminder of the experience and the learning.

The A5 laminate needs no translation, it's colourful, and delegates do not need to actually "do" anything with it other than hang it somewhere prominent on their desk as a reminder. When walking around the offices, these laminates are becoming more and more visible with the numbers of colleagues attending the programme. This is a simple way to cascade the message as yet other colleagues ask questions about the laminate on the desk and the explanation cascades the learning.

The central conference would provide value to the delegates and the organisation, but taking more than 250 colleagues out of the business for a day and bringing them to a central location has financial and work flow implications. A compromise suggested by the participants has been to hold local country conferences. This is something the team considered implementing in fourth quarter, 2004.

Three years after implementation, the learning management system the business has implemented globally is becoming a powerful tool. European colleagues are beginning to embrace the tool although they are just scratching the surface to use it to its full functionality. Employees have been forced to become familiar with the system and to register for learning events through this medium where previously they called through to a learning team to manually register for events. Many, however, are not using the personal learning history, assigning a mentor, or reporting functionality of the system. The second e-mail sent at the two-week stage post programme (above) targeting the high-performing, high-potential employees, enforces strategic organisational goals of employing more blended learning, promoting the learning management system, e-learning, sustained learning, and the use of technology as a learning tool.

Transferring the Learning Across the Organisation

During the Event

Key learning from best-practice networks of learning professionals in the United Kingdom led to the discovery of Unilever's3 Transfer of Learning tool known as APT2 (Acquire, Practice, Transfer to Job and Transfer to Colleagues). This tool has been consistently utilized at the end of each of the three days in the Managing Essentials programme. Delegates identify and publicly document what learning they have acquired, how they will practice that learning (in a safe environment where they can afford to make mistakes), how they will transfer the learning to the job, and how they will transfer the learning to colleagues. At the end of each day, this is recorded by each participant on post-it notes and posted on flip charts, where it stays over the duration of the programme. Delegates can add to it as required over the three days. After the event, the data are recorded electronically by the programme management team for redistribution to delegates by e-mail, primarily providing an aid to sustain the learning but also to remind and share with the group how everyone committed to transfer the learning. Feedback on this process has been that it is a useful reminder of the programme content as everyone records what key learning they have acquired each day, and a generator of ideas of how to implement the learning. This record is also used as a tool to describe to senior leaders what key learning the participants are taking away from the programme and what they are committing to do back in the office on their return.

One of the richest sources of knowledge transfer and sustainability is storytelling. The power of the true story, the real experience of someone in the room or someone the participants know as a colleague has an impact few, if any, other mediums can match. Participants in the programme, like many others in the financial services industry, are rarely satisfied with theories. They need proof, not simply of how something has worked but of how something has worked in their environment under the same pressures they work under. The external providers Marsh work with to deliver the learning are insightful in the way they share their stories and experiences to emphasise and reinforce learning points. A key aspect of the KM strategy has become to collect, collate, and share participant stories across the relevant geographies, where a colleague can be named for their success at making a difference — not only for the what, but also the how — after attending the programme. The KM strategy reflects this as participants are asked to attend conference calls post programme and to share a story of their learning and implementation back at the office.

The stories from the conference calls are cascaded (with employee permission) back to the external providers who facilitate the programme. The external facilitators also elicit stories from participants over each three-day event, record the story and the source, and then use these stories at future events. For delegates experiencing later programmes, this makes the experience tailored when they hear the external facilitators referencing known employees and their real experiences with the material. One example of such a story was that of a woman who consistently used four key questions with her team in monthly one-to-one meetings. She had read a number of texts and had experimented with a variety of tools to develop her people to be proactive, show initiative, and involve her when appropriate. She shared these four questions on the programme and her experiences in asking them of her team; how they first reacted, how they reacted over the short term, and how they react today. As a result of her story and the reaction of the group on the programme, her story and the questions are now included as part of the learning event. A testament to the KM efforts is the fact that on recent programmes in Europe, delegates have brought this story to the workshop, having heard it from other colleagues or seen it practiced.

Demonstrating Return on Investment

Pre Event

At the launch of the first programme, all nominations were collected through e-mail. The team relied on e-mail to communicate the new programme and to connect with the target population. Lists of nominators, nominees, and delegate information were initially collated by a central team on a programme-by-programme basis on spreadsheets. Over time, as management information reporting was required, a more functional database was developed allowing easy access to all details of attendees from across Europe by country, business unit, programme attended, and nominator. The ease, speed, and flexibility of reporting available in this database has increased efficiency and accuracy in the information reported. For example, one leader in the business asked for a report of all the colleagues in his/her business unit who had attended the programme over a given time period. The leader used the list to ask all those colleagues who had attended to make a formal presentation in a full office meeting to share their knowledge. The learning management system has now been successfully implemented throughout the majority of Europe and options are currently being generated to maximise this facility in the nomination of participants, ensuring cross-business unit and cross-geography participants on each programme.

A three to six month Business Challenge is a key part of the prework for participants. The Business Challenge was devised together with the external provider delivering the workshop and the global Learning Team. The Challenge is agreed upon with the local line manager and brought to the event to share, discuss, and create an action plan. The Challenge meets a number of the KM strategy criteria in that it aligns the individual and his/her manager to a business output of his/her learning and demonstrating a return on investment measurement (subject to the goal being specific, measurable, achievable, realistic, and timed).

The Business Challenges are one example of thread being sewn between many of the delegates as discussion is generated when delegates realize many have the same or a very similar Challenge, albeit in a different business unit or geography. Connecting cross-function and cross-geographical border issues and people continues to be a focus for discussion around the return on investment for the event. The postprogramme conference calls have begun to identify business opportunities across divisions in the organization and direct revenue-generating projects as a result of the network established and promoted at the event. It is hoped that in time these trends and successes will be recorded by delegates on an Internet-based platform for any employee to see, learn from, and follow.

The networking and quick understanding of the knowledge and business representation in the room is a fundamental quick win of the curriculum and the platform on which further learning will be maintained and shared. Feedback after the first few programmes in 2002 alluded to the struggle to get to know everyone and how they contributed over the three-day event. As a result, Europe implemented an additional prework assignment named Background Information. Each participant was asked to complete a brief electronic proforma prior to the event documenting his/her name, office location, business unit, three to six month Business Challenge, time of service with the company, greatest achievement while at Marsh, and what they do on a Sunday afternoon. These data are e-mailed to the Programme Manager to be collated into a simple spreadsheet and circulated to delegates at the beginning of Day 1 of the event to help people know and remember colleagues they meet and learn from. This document is also circulated after the workshop by e-mail, along with an e-mail distribution list to encourage the network to sustain and grow.

Post Event

Marsh Europe invested in a questionnaire distributed to a random selection of colleagues who had attended the programme. These questionnaires were sent out to delegates six to eight months post event through an online Web-based interview tool allowing the results to be recorded electronically and transferred into a database for future reference. The outcome of the questionnaires was verbatim comments leading to a number of conclusions about the event itself, the impact of efforts to sustain learning, and the needs for KM tools.

The feedback identifies that while colleagues felt that the programme gave them much material to enrich their personal effectiveness, few were able to make the connection to how the learning had impacted the organisation. The Business Challenge template has been revised in the third year of delivery of the programme to include a specific question to the delegate of the hard-dollar value of the business challenge they hope to complete as a result of their learning. These documents are signed before each delegate leaves the event and sent to a central global team to collate. The next step proposed in this process, with a high-man-hour intervention, is to go back to each delegate three to six months after the programme to reconcile proposed dollar return with actual return to clearly demonstrate a tangible bottom-line impact. One particular Business Challenge has estimated a return equal to the financial value of delivering one Managing Essentials event for 30 employees.

It has been agreed to investigate the development of a leadership "portal" which would also enable colleagues across Europe to interact, share learning and lessons learned to a greater proportion of delegates with the tool targeting all those who have attended Managing Essentials, rather than those who attend each individual programme.

KM Across the Learning and Development Community

The global Learning and Development network has been investigating KM opportunities to enhance and ensure consistency in the role of colleagues increasingly involved in managing this programme around the globe. Through the programme's life of just more than two years, colleagues in different geographies have approached its implementation in slightly different ways, all sharing their experiences with the global Programme Manager based in New York. The global Learning network is now looking to use a specific database functionality through the cross-company e-mail system to communicate with each other, store documentation, and to share tasks.

The decision to use this particular database came after consideration of a number of internal options, including a Microsoft® Access database, use of an intranet, and use of technology known as E-Room. None of the above media allowed an economical, easy global access and storage of documents along with online interactive communication through electronic discussion boards. The Access database would be difficult to share and update across the globe on each regional internal network. Ensuring secure access to the intranet site to restrict access to only L&D colleagues would come with comparatively high expense on a direct cost basis and the "one more log-on and password" toll to colleagues in using it. The E-Room facility offered the closest match as a type of online filing cabinet where information could be stored, e-mails could be sent and access levels could be dictated; unfortunately, this option was prohibitively expensive for the number of users anticipated over the foreseeable future.

While the chosen database is not the most visually stimulating platform, the challenges of the other options make it the most practical and economical solution.

CONCLUSIONS

The KM strategy for a core Leadership Development programme in Europe is to sustain learning for colleagues who attend, cascade learning to others, and demonstrate return on investment from the event. While the organization had a number of KM tools available in various geographies, these were mainly used to manage day-to-day business knowledge. Sharing of learning materials and experiences was a relatively new concept in the organization. The existing tools have been flexed to implement a structured programme of interventions to increase organizational capacity through this sharing of knowledge. There is now a set of tools and practices in place to reinforce and cascade the learning across Europe aligned to the organizational culture using a variety of mediums including, but not limited to, the PC. These tools and practices are being shared in the internal learning community across the globe. The foundations of the strategy are in place and are being executed. It is too early to confirm the long-term success of this solution, but feedback to date suggests the strategy is supporting sustainable KM and breaking down geographical and business silos to improve organizational capacity.

Epilogue and Lessons Learned

The same external partners continue to deliver the three-day learning event across the globe. The challenge over recent months has been to maintain the organisations' commitment and energy to the KM strategy. Priorities in the business are regularly reviewed to ensure effective investment is appropriately placed where it can maximize return. The KM strategy has provided a measurement tool in the Business Challenges, although the financial implication of the Challenges has only recently been recorded and realized. Attendance on postprogramme conference calls is lower over the last eight months than what it was 12 months ago. In Europe, the number of colleagues comfortable with a three-day learning event in English outside of the United Kingdom is diminishing. Over this time, the organization has developed a more pan-European business, uniting colleagues from across Europe in an increasing number of projects. Delegates and learning professionals in the business are now pushing the KM strategy to deliver a global, Web-based interactive tool to share stories, post documents, and caretake the learning community. Lessons learned include:

- KM across a large organization with diversity across geographies, languages, and regional, local, and office cultures requires persistence, creativity, and ownership from the audience. Knowledge must be easy to access, relevant to the day job, and seen as an added value to individuals personally and professionally, and to individual and team performance.
- This programme benefited from transparent senior leader involvement and commitment. Senior leaders gave their time to be present at the three-day event and their endorsement to the KM strategy post event. Without this support, which included a time and a direct financial cost, the learning and therefore KM strategy would not be implemented.
- Stories from colleagues, peers, and senior leaders are rich, credible, and effective tools in transferring and sustaining learning, both for the storyteller and for the listener.
- Upon implementation of the Managing Essentials programme, the KM was necessarily owned by the L&D team. This meant a small number of people brainstorming on ideas to develop the strategy. Now that the programme is embedded, known and branded as a success, the L&D team can now hand this responsibility over to the end users who have already attended the programme. This will generate a wealth of more ideas immediately relevant to the business, hand in hand with ownership of those KM processes.
- Blend the KM activity with a variety of media to match learning styles in the audience. After a learning event, keep any KM intervention 60 minutes or less for two reasons: the delegate is more likely to clear time to attend in his/her diary, and the facilitator is more likely to retain the attention span of all attendees.
- Keep the key messages short and simple to allow easy, quick, and frequent reinforcement. The Managing Essentials learning event has approximately 10 key, high-level statements. While each delegate usually chooses between one and three of these messages to focus on first when back at the office, the programme manager refers to a variety of the 10 whenever communicating to the group.
- In this case, the external delivery partners' style, delivery method, and connection with the delegates have a significant impact on the effectiveness of the KM. On conference calls after the programme, delegates make consistent reference to the humor and personal teaching "stories" of the facilitators when reflecting on the event. The three-day event is, however, a relatively short interven-

tion in the overall strategy. Coupled with the dynamic facilitation, the role of the programme manager is important in reinforcing the key messages. Over the life of this case, the programme manager's job was to know and reinforce the relevant stories to share with delegates and to be a central source of connection between delegates to encourage the learning networks to continue.

- KM projects require significant resources. Organizations looking to build KM as an organizational capability need to expect it to take time. As this case demonstrates, KM is evolving from a technology-based field to one of business efficiency through the effective communication of common key messages. After working on the sustainability and KM for this single learning event for two years, this company has introduced a number of tools and processes that have impacted success. There is still, however, much to do to achieve behavioral change in managers across the business as a result of the learning event.

INTRODUCTION

While there are many aspects to managing corporate knowledge, one key issue is how to disseminate corporate documents with appropriate context. Upon finding an article on a certain subject, for example the material properties of titanium, a reader is likely to be interested in related articles such as applications of titanium or manufacturing methods for titanium parts. Each related article has the potential to increase the reader's knowledge of the subject. Therefore, organizing documents into categories of interest plays an essential role in discovering and interpreting information. Furthermore, categories can be expected to provide historical context, describing how titanium was used in early designs or initial practices used for the repair of titanium parts.

While most large companies make a practice of cataloging and controlling well-established documents, there is a vast set of explicit information that has not traditionally been effectively disseminated. This class of information is less formal and may be exchanged, updated, and otherwise managed at the local level. Such information is usually not controlled at the corporate level or governed by the same organizations established to handle more stable information. Processes to disseminate such information tend to be ad hoc or nonexistent. In this article, we discuss the elements necessary to effectively disseminate informal and explicit information not controlled at the enterprise level. While the main emphasis of the article is to promote a general process for the dissemination of this type of material in large corporations, we will use a specific implementation of this process at the Boeing Company as an illustrative example.

BACKGROUND

Traditionally, the dissemination of corporate knowledge has taken a number of different forms. First, there are the methods of classic library science often as implemented by a formal corporate library staffed by trained librarians (Taylor, 2000). This is used for things that are well established such as textbooks, established how-to knowledge on a subject, published papers on a subject, and so on. Second, it has long been necessary to disseminate official policy and procedure through "Command and Control" processes and associated media. In addition, certain industries also require configuration control processes for special classes of information such as product data, drawings, and manufacturing rejection and acceptance documentation. These are all subject to an authentication process, flowing top-down to intended users. A third, extremely important approach to knowledge maintenance and dissemination has been through mentoring and establishment of departments aligned to technical specialties and communities of interest. These approaches are particularly well suited for tacit knowledge. A fourth category of knowledge sharing applies to the communication of explicit knowledge among peers but also includes dissemination to management and other reference groups. This method applies to information that is less formal and frequently ephemeral.

This fourth method is of an entirely more fluid nature and, in some cases, represents the majority of a corporation's explicit knowledge. While it is appropriate for the enterprise to disseminate formal information using traditional, formal means, there is a need to disseminate less formal information as well. This informal knowledge often includes the most current information within a company and without adequate dissemination, corporate decision-making is likely to fall short. In summary, stable and formal information is well handled by existing library or document release systems. Ephemeral, less formal, and generally less controlled content, while important, is currently only shared across the enterprise by a variety of ad hoc means, if at all.

MAIN FOCUS OF THE ARTICLE

This article focuses on how to systematically share this fourth category of informal and uncontrolled knowledge. The ideal for knowledge dissemination is to make sure information of this type can be well integrated into existing formal content, taking advantage of the context that has been created over time by librarians and other formal content management systems. To achieve this, it is necessary to organize this knowledge in a way that is consonant with the information categories of multiple existing systems. This is made possible by using an enterprise ontology or some form of controlled system of keywords which can be mapped to existing vocabularies. Portals, and other tools which allow content aggregation and term mapping, enable sharing of this knowledge at a physical level. It provides search and simple navigation across sources, as well as security services to restrict access as needed. A central ontology combined with an interactive text classification tool make dissemination of this knowledge possible at a content level.

In the matter of assigning documents to categories, we emphasize the importance of involving subject matter experts. Traditionally, this is done by librarians who are trained to catalog (categorize) content. However, in the case when authors are widely distributed throughout a complex corporate enterprise, we suggest that text classification software be used by these subject matter experts to facilitate broad knowledge dissemination. The challenge is to provide text classification services which can be used to produce high quality results by users who are not trained in library science.

The essential elements of a distributed dissemination scheme for this type of explicit but informal knowledge are a portal, an ontology, a text classification system, and a publication process. In combination, these four elements allow autonomous subgroups of a corporate entity to interact with common resources and tools to publish their local work in a way that places it within a context comprehensible to an enterprise audience.

Knowledge dissemination, as used here, applies specifically to explicit knowledge captured in documents from many sources. There are a number of frameworks that address the life cycle of explicit knowledge (Bock, 1997; O'Dell, 1998), but here we will follow the steps outlined by Mack (2001). In this framework, the basic tasks in knowledge work are Capture/Extract, Analyze/Organize, Find, Create/Synthesize, and Distribute/Share. In particular, text classification has direct benefit to the Analyze/Organize and Find stages and portal services will be the basis of the Distribute/Share stage. As discussed here, knowledge dissemination applies to the Analyze/Organize, Find, and Distribute/Share stages.

Portals

A portal is used to collect content from many different sources, resulting in a virtual collection available through a single point of access. This aggregation of content is perhaps the key characteristic of all portal products. In addition, a portal provides some capability for metadata management whereby tags and values can be directly replicated from source documents or harmonized within the virtual collection by mapping them to a centralized schema. In addition, a portal may permit the addition of metadata based on characteristics of the source system or based on the decisions made by the group about how ontology terms will be attached to documents. The documents themselves remain in their source system, maintained, refreshed, or deleted by the groups that own them.

Other kinds of information systems besides portals can be useful for knowledge dissemination. However portals, in one form or another, are well suited for publishing a distributed collection based on the intellectual products of many subgroups. Further, because of their flexibility in combining a variety of tools and services, portals can be customized to create a rich knowledge-sharing environment. For example, portals can readily support search and navigation. In addition, they can be extended to support personalization services, which would allow even more focused dissemination.

Thus, portals are a natural element to aid in knowledge dissemination. They can be used to achieve the key goal of achieving awareness (Alavi, 1999; Prusak, 1997). Indeed, creating awareness is a goal of dissemination and is a prerequisite to collaboration or further synthesis.

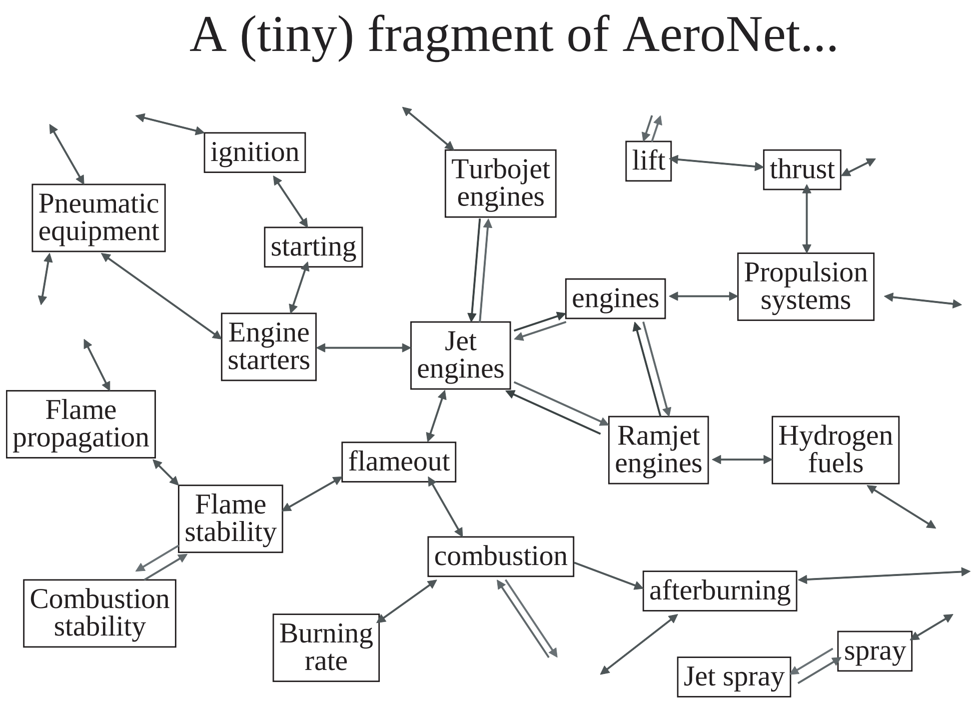
Ontologies

To produce an organization of corporate documents that can be readily shared, it is essential to have some standard in the form either of a corporate taxonomy, a corporate thesaurus, or both. What is minimally necessary is simply a list of controlled keywords expressing the topics that are important to the enterprise. We refer to the concepts expressed by these keywords as knowledge categories. Ideally, there is some kind of structure or organization to the knowledge categories, for example, a generalization-specialization hierarchy. Such a specification of the things that can be talked about and their relationships is referred to in artificial intelligence as an ontology. There is a strong advantage to organizing documents this way, because it enables much easier and better quality search, and greater use of the knowledge in those documents. In the Boeing case, there were about 60,000 knowledge categories as well as generalization-specialization relationships, synonymy relationships, and more general "is-related-to" relationships, so that the ontology is somewhat richer than a hierarchy (see Figure 1) (Clark, 2000).

This approach benefits most when it can build on an existing cataloging scheme, such as one maintained by an enterprise library system or a professional organization (e.g., the IEEE, Institute of Electrical and Electronics Engineers), or a taxonomy provided by an industrial consortium (e.g., the ATA, or Air Transport Association). The ontology used in the Boeing realization of the approach derives from the corporate thesaurus, a list of controlled keywords sanctioned by the Boeing technical library system, together with the relationships among them. By using a set of controlled keywords created by corporate librarians, not only was an immense amount of time saved in constructing the taxonomy, but the system also was able to leverage off of their collective and accumulated expertise.

However, with some additional effort, categories can be established and applied even when such a resource is not available or is not sufficiently complete. In this case, one approach

Figure 1. The AeroNet ontology contains more than 60,000 concepts used as categories for text classification and subsequent knowledge dissemination. This figure shows a small fragment of the total ontology.



is to use text clustering and automatic summarization (Kao, 2004). Text clustering serves to group documents together based on the words they contain. The words with the greatest frequency or strength either throughout or near the center of each cluster can summarize the documents in that cluster. Using this summary, domain experts, knowledge administrators or managers, or librarians can decide which clusters represent important categories to the enterprise and supply standard names for those categories. If desired, they can further subdivide or group the resulting categories giving generalization-specialization relationships, and shared summary words may suggest other relationships. Of course, while this approach will provide more consistency within the enterprise, it will lose the historical context provided by leveraging off of existing ontologies.

Once an ontology is available, the concepts must be attached to documents and used to retrieve those documents. We do not assume that those who are involved in knowledge dissemination, whether as knowledge provider or consumer, have either the training or perspective of librarians. Nevertheless, by allowing participants to interact with a controlled vocabulary in the context of their subject matter of interest and giving them a means to do so easily, the process can improve dissemination of knowledge by grouping topically similar documents together regardless of their original local vocabulary usage. What is required is a tool to aid the author or searcher in finding the appropriate categories, and that is the function of an automatic text classifier.

Text Classifier

An automatic text classifier takes a piece of text (e.g., a memo, an abstract, or a longer document), and based on its features (typically the words it contains) determines automatically which of a set of predetermined categories should be assigned to it. There are a number of different approaches, as summarized in Sebastiani (2002), including naïve Bayes (McCallum, 1998), support vector machines (Joachims, 1998), and logistic regression classifiers (Komarek, 2003).

Whichever approach is used, the first step in creating a classifier is to collect a training sample of texts that are already associated with the appropriate knowledge categories. Again, if the ontology derives from a set of keywords provided by a corporate library, there is likely a set of documents that have already been assigned these keywords or knowledge categories by the librarians (similarly for other sources of the controlled keywords, be it industrial consortia or professional societies or journals). At the Boeing Company, the abstracts for about 500,000 corporate documents in the technical library were used as the training sample.

If the categories are not a pre-existing set created by librarians or another standard professional body but have been developed as described using a text clustering algorithm, there may still be an easy way to create a training set. If the clustering algorithm generates convex clusters, as does K-means (Hartigan, 1975; Hartigan & Wong, 1979), the central members of the chosen clusters could serve as a training sample for those categories.

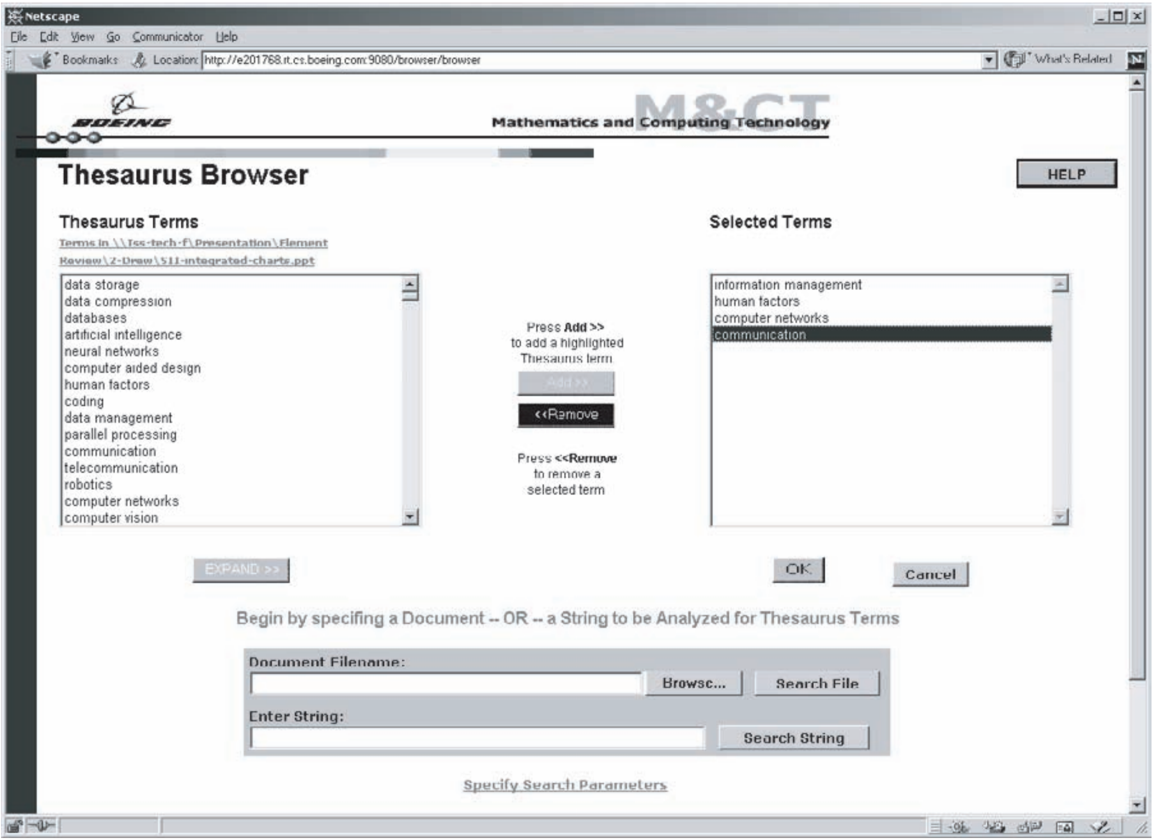
A text classifier is then constructed or trained based on the knowledge categories and the training sample of already categorized documents. The text classifier is then made available to both producers and consumers of the documents.

Authors of new documents to be entered into the system can use the text classifier to automatically propose knowledge categories appropriate to their document. In the Boeing implementation of this process, using the Graphical User Interface (GUI) shown in Figures 2 and 3, they first either type in the name and location of their document or browse to enter it into the classifier. The classifier then proposes the most likely knowledge categories ranked in order of likelihood in the box under the "Thesaurus Terms" label (see Figure 2). The authors can either select these terms or use AeroNet, a semantic network

Figure 2. The Graphical User Interface (GUI) allows users to scan documents and find suggested categories from the AeroNet ontology based on the results of a text classifier.

of thesaurus keywords developed at the Boeing Company (Clark, 2000), to navigate through the relationships among the categories to find more precise or more general knowledge categories to better describe their document. For example, the knowledge category "data management" might have been returned by the classifier (see Figure 3). By highlighting that and clicking on "EXPAND," AeroNet will bring up specializations like "factory data access system" and "data integration" and generalizations like "management" from which the user can select or use as a starting point for further navigation. If a category was selected incorrectly, they can remove it from the list by highlighting the category of interest and then clicking on the "Remove" button. When the list of selected knowledge categories is finalized, they associate it as metadata with the document by clicking on the "OK" button. This leads to not only much faster organization of information but also much more consistent quality in the organization of the information.

Figure 3. Users can use the GUI to expand terms and then select those that represent the best categories for a given document.



During the Find phase, the same text classifier can be used to identify information the user is interested in, without requiring the user to know the controlled vocabulary. Users may search for documents in the knowledge management system by entering a natural language query in a similar GUI and then selecting from the knowledge categories suggested to construct a precise query based on the content metadata. This allows the searcher to take advantage of the controlled vocabulary without memorizing it.

Publication Process

A workgroup needs to have a process that uses the classifier and portal for knowledge to be shared outside the group. Minimally, individuals would be required to add metadata to all documents they wish to publish. In addition, the group could use the text classifier on a representative sample of their documents to produce an initial down-selection of knowledge categories appropriate for most documents they are likely to produce.

FUTURE TRENDS

Effective classification and processes for knowledge dissemination have a positive impact on the evolution of the Semantic Web (Berners-Lee, 2001; Schwartz, 2003). The basic idea of the Semantic Web is to make content on the Web machine-sensible with regards to its semantics (what the content is about) and with regards to machine reasoning over (what the content is related to or implies). In achieving semantics it will be important to classify content in terms of one or more ontologies. Tools involving automatic text classification will probably be essential in making this feasible. Using classification based on existing library practices, as an underpinning, to provide these semantics will have the same advantage as mentioned: the meaning assigned to Web content will be more likely consistent with existing catalogs of knowledge. In knowledge dissemination as discussed here, users are able to traverse the relationships in the ontology when choosing terms. However, in the future Semantic Web, reasoning one or more ontologies is expected to occur automatically, at runtime, whenever a query is activated. One function of the Semantic Web will be to improve knowledge dissemination by using software agents to execute queries selectively, taking advantage of both the context of the content and the matching profiles of end users. The different ways that reasoning, and multiple domain ontologies, can be leveraged in the future Semantic Web should substantially extend what is used in current knowledge classification and dissemination. Nonetheless, the four essential elements discussed here will still be crucial. Without effective text classification, reasoning capabilities cannot be expected to provide significant improvements.

CONCLUSION

There is a broad class of explicit but informal knowledge created within almost any enterprise which is not well disseminated by conventional means. Taking advantage of the Web infrastructure, this knowledge can be effectively disseminated using four essential elements: a portal, an ontology, a text classification system, and a publication process. Perhaps most important is a broad, cost-effective means to classify content according to an ontology. We suggest that text classification tools can provide such a means. Given this, portals can be used to disseminate knowledge, subject to appropriate publication processes, according to consistent categories. This provides context that links each new item of content to the information previously collected in library catalogs and published from other content resources.

Further, text classification helps overcome a substantial obstacle to knowledge dissemination within a large enterprise. Users are notoriously reluctant to assign any kind of metadata to documents that they author or maintain. By providing aids to classification, basic users can accomplish cataloging tasks without much training, time, or effort, and are therefore more likely to do it. In the approach outlined, the list of proposed knowledge categories is essentially consistent with the practice of professional librarians. Overall, the quality of the user-selected categories is likely to be much better compared to categories selected without assistance from a large ontology. Consequently, using these four elements, enterprises have at their disposal a means to disseminate a class of information that is likely to aid corporate decision-making and which should qualitatively increase a company's understanding of itself.

Chapter 4.15
Dynamic Taxonomies

Giovanni M. Sacco
Università di Torino, Italy

INTRODUCTION

End-user interactive access to complex information is one of the key functionalities of knowledge management systems. Traditionally, access paradigms have focused on retrieval of data on the basis of precise specifications: examples of this approach include queries on structured database systems, and information retrieval. However, most search tasks, and notably those typical of a knowledge worker, are exploratory and imprecise in essence: the user needs to explore the information base, find relationships among concepts, and thin alternatives out in a guided way.

Examples of this type of access include the selection of the "right" product to buy, of a candidate for a job, but also finding the likely cause of a malfunction, and so forth. Indeed, exploratory access applies to an extremely wide range of practical situations. Traditional access methods are not helpful in this context, and new access paradigms are needed. Effective end-user access requires a holistic approach, in which modeling, interface, and interaction issues are considered together.

BACKGROUND

Since the vast majority of knowledge is textual and unstructured in nature, information retrieval (IR) techniques (van Rijsbergen, 1979) have been extensively used in the past. IR techniques require almost no editorial work or manual preprocessing of information. However, their limitations have been known for some time: a study on a legal environment reported that only 20% of relevant documents were actually retrieved (Blair & Maron, 1985). Such a significant loss of information is due to the extremely wide semantic gap between the user model (concepts) and the model used by commercial retrieval systems (words). IR systems are also poor from the point of view of user interaction because the user has to formulate his query with no or very little assistance. Finally, results are presented as a flat list with no systematic organization, so that browsing/exploring the knowledge base is impossible.

Hypermedia (see Groenbaek & Trigg, 1994) addresses the problem of browsing/exploration, but it has a number of serious drawbacks: there is no systematic picture of relationships among knowledge base components; exploration is performed one document at a time, which is quite time consuming; and building and maintaining complex hypermedia networks is very expensive.

Traditional taxonomies are used by many systems, such as Yahoo. Here, a hierarchy of concepts can be used to select areas of interest and restrict the portion of the infobase to be retrieved. Taxonomies support abstraction and are easily understood by end-users. However, they are not scalable for large knowledge bases (Sacco, 2002) because they can be used for discrimination just down to terminal concepts, which are no further specialized. As the knowledge base grows, the average number of documents associated to a terminal concept becomes too large for manual inspection.

Solutions based on semantic networks were proposed in the past (e.g., Schmeltz Pedersen, 1993) and are being reconsidered in the current effort on ontologies and Semantic Web. Although more powerful and expressive than plain taxonomies, general semantic schemata are difficult to understand and manipulate by the casual user. They are better suited to programmatic access, and user interaction must be mediated by specialized agents. This increases costs, time to market, and decreases generality and flexibility of user access.

MAIN FOCUS OF THE ARTICLE

Dynamic taxonomies (Sacco, 1987, 2000; also known as faceted classification systems) are a general knowledge management model based on a multidimensional classification of heterogeneous data items and are used to explore/browse complex knowledge bases in a guided yet unconstrained way through a visual interface.

The intension of a dynamic taxonomy is a taxonomy designed by an expert. This taxonomy is a concept hierarchy going from the most general to the most specific concepts. Directed acyclic graph taxonomies modeling multiple inheritance are supported but rarely required. A dynamic taxonomy does not require any other relationships in addition to subsumptions (e.g., IS-A and PART-OF relationships).

In the extension, items can be freely classified under n (n>1) topics at any level of abstraction (i.e., at any level in the conceptual tree). This multidimensional classification is a departure from the monodimensional classification scheme used in conventional taxonomies. Besides being a generalization of a monodimensional classification, a multidimensional classification models common real-life situations. First, items are very often about different concepts: for example a news item on September 11, 2001, can be classified under "terrorism," "airlines," "USA," and so forth. Second, items to be classified usually have different features, "perspectives," or facets (e.g., Time, Location, etc.), each of which can be described by an independent taxonomy.

By taking a "nominalistic" approach—that is, concepts are defined by instances rather than by properties—a concept C is just a label that identifies all the items classified under C. Because of the subsumption relationship between a concept and its descendants, the items classified under C (items (C)) are all those items in the deep extension (Straube & Ozsu, 1990) of C; that is, the set of items identified by C includes the shallow extension of C (i.e., all the items directly classified under C) union the deep extension of C's sons. By construction, the shallow and the deep extension for a terminal concept are the same.

There are two important consequences of this approach. First, since concepts identify sets of items, logical operations on concepts can be performed by the corresponding set operations on their extension. This means that the user is able to restrict the information base (and to create derived concepts) by combining concepts through the normal logical operations (and, or, not).

Second, dynamic taxonomies can find all the concepts related to a given concept C; these concepts represent the conceptual summary of C. Concept relationships other than subsumptions are inferred through the extension only, according to the following extensional inference rule: two concepts A and B are related if there is at least one item d in the knowledge base which is classified at the same time under A or under one of A's descendants and under B or under one of B's descendants. For example, we can infer an unnamed relationship between Michelangelo and Rome, if an item classified under Michelangelo and Rome exists in the knowledge base. At the same time, since Rome is a descendant of Italy, also a relationship between Michelangelo and Italy can be inferred. The extensional inference rule can be seen as a device to infer relationships on the basis of empirical evidence.

The extensional inference rule can be easily extended to cover the relationship between a given concept C and a concept expressed by an arbitrary subset S of the universe: C is related to S if there is at least one item d in S which is also in items (C). Hence, the extensional inference rule can produce conceptual summaries not only for base concepts, but also for any logical combination of concepts. Since it is immaterial how S is produced, dynamic taxonomies can produce summaries for sets of items produced by other retrieval methods such as database queries, shape retrieval, and so forth, and therefore access through dynamic taxonomies can be easily combined with any other retrieval method.

Dynamic taxonomies work on conceptual descriptions of items, so that heterogeneous items of any type and format can be managed in a single, coherent framework. Finally, since concept C is just a label that identifies the set of the items classified under C, concepts are language-invariant, and multilingual access can be easily supported by maintaining different language directories, holding language-specific labels for each concept in the taxonomy. If the metadata descriptors used to describe an item use concepts from the taxonomy, then also the actual description of an item can be translated on the fly to different languages.

Exploration of the Knowledge Base

Dynamic taxonomies can be used to browse and explore the knowledge base in several ways. The preferred implementation follows. The user is initially presented with a tree representation of the initial taxonomy for the entire knowledge base. Each concept label also has a count of all the items classified under it—that is, the cardinality of items(C) for all Cs. The initial user focus F is the universe—all the items in the knowledge base.

In the simplest case, the user can then select a concept C in the taxonomy and zoom on it. The zoom operation changes the current state in two ways. First, concept C is used to refine the current user focus F, which becomes $F \cap$ items(C). Items not in the focus are discarded. Second, the tree representation of the taxonomy is modified in order to summarize the new focus. All and only the concepts related to F are retained, and the count for each retained concept C' is updated to reflect the number of items in the focus F that are classified under C'. The reduced taxonomy is derived from the initial taxonomy by pruning all the concepts not related to F, and it is a conceptual summary of the set of documents identified by F, exactly in the same way as the original taxonomy was a conceptual summary of the universe. In fact, the term dynamic taxonomy is used to indicate that the taxonomy can dynamically adapt to the subset of the universe on which the user is focusing, whereas traditional, static taxonomies can only describe the entire universe.

The retrieval process can be seen as an iterative thinning of the information base: the user selects a focus, which restricts the information base by discarding all the items not in the current focus. Only the concepts used to classify the items in the focus and their ancestors are retained. These concepts, which summarize the current focus, are those and only those concepts that can be used for further refinements. From the human computer interaction point of view, the user is effectively guided to reach his goal by a clear and consistent listing of all possible alternatives. This type of interaction is sometimes called guided thinning or guided navigation.

Dynamic taxonomies can be integrated with other retrieval methods in two basic ways. First, focus restrictions on the dynamic taxonomy can provide a context on which other retrieval methods can be applied, thereby increasing the precision of subsequent searches. Second, the user can start from an external retrieval method, and see a conceptual summary of the concepts that describe the result. Concepts in this summary can be used to set additional foci. These two approaches can be intermixed in different iteration steps during a single exploration.

An Example of Interaction

We show a simple systematic exploration on a multimedia knowledge base containing the works of the most important painters of the Italian Renaissance (Piero della Francesca, Masaccio, Antonello da Messina, Paolo Uccello, and Raffaello). Each work was thoroughly classified according to a number of subjects that are shown in Figure 1. The main difference with traditional methods is that no traditional method is able to taxonomically summarize a set of documents: there is no problem in selecting all the works by Masaccio through a database query, but there is no way of knowing where these works or what their themes are without exhaustively inspecting all the items.

Figure 1. Initial taxonomy: Preparing to zoom on Masaccio

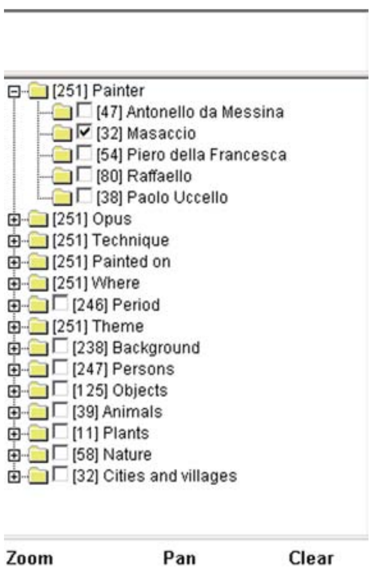

Figure 2. Locations for Masaccio's paintings: Preparing to zoom on USA; candidate items are reduced to 32 from 251

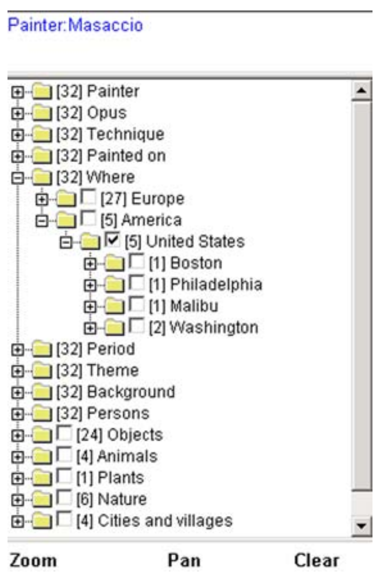

Figure 3. Themes for Masaccio's U.S. paintings: Miracles was clicked; candidate items are reduced from 32 to 5, and then to 1 by selecting the "Miracles" concept

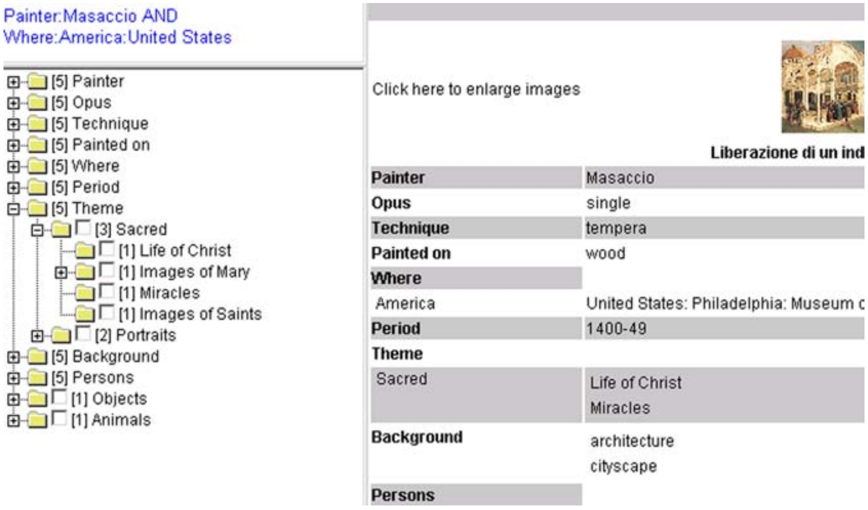

Conventional taxonomies have the same problem: they give a description of the entire collection, but are unable to summarize subsets of it.

A simple interaction that shows the importance of conceptual summaries follows. In Figure 1, we have the initial taxonomy and we are preparing to zoom on Masaccio. In Figure 2, the taxonomy no longer describes the entire knowledge base, but only the subset of it that consists of Masaccio's paintings. In this reduced taxonomy, we have expanded the location branch (Where) and found out that five paintings are in the USA. A single zoom operation thinned our 251 item knowledge base to only five items. Note that we could have expanded any other branch, according to our interests. Finally, Figure 3 summarizes the Themes for Masaccio's U.S. paintings, after a zoom on USA, and further reduces the number of candidate items to be inspected.

Advantages

The advantages of dynamic taxonomies over traditional methods are dramatic in terms of convergence of exploratory patterns and in terms of human factors. The analysis and experimental data by Sacco (2002) show that three zoom operations on terminal concepts are sufficient to reduce a 1,000,000 item information base described by a compact taxonomy with 1,000 concepts to an average 10 items. Experimental data on a real newspaper corpus of over 110,000 articles, classified through a taxonomy of 1,100 concepts, reports an average 1,246 documents to be inspected by the user of a static taxonomy vs. an average 27 documents after a single zoom on a dynamic taxonomy.

Dynamic taxonomies require a very light theoretical background: namely, the concept of a taxonomic organization and the zoom operation, which seems to be very quickly understood by end-users. Hearst et al. (2002) and Yee et al. (2003) conducted usability tests on a corpus of art images. Despite an inefficient implementation that caused slow response times, their tests show that access through a dynamic taxonomy produced a faster overall interaction and a significantly better recall than access through text retrieval. Perhaps more important are the intangibles: the feeling that one has actually considered all the alternatives in reaching a result. Although few usability studies exist, the recent (2004) widespread adoption of systems based on dynamic taxonomies by e-commerce portals, such as Yahoo, Lycos, BizRate, and so forth empirically, in late 2003/early 2004 empirically supports this initial evidence.

The derivation of concept relationships through the extensional inference rule has important implications on conceptual modeling. First, it simplifies taxonomy creation and maintenance. In traditional approaches, only the relationships among concepts explicitly described in the conceptual schema are available to the user for browsing and retrieval. The schema designer must therefore anticipate and describe all possible relationships—a very difficult if not helpless task. In dynamic taxonomies, no relationships in addition to subsumptions are required, because concept relationships are automatically derived from the actual classification. For this reason, dynamic taxonomies easily adapt to new relationships and are able to discover new, unexpected ones. Second, since dynamic taxonomies synthesize compound concepts, these need usually not be represented explicitly. This means that the main cause of the combinatorial growth of traditional taxonomies is removed. Sacco (2000) developed a number of guidelines that produce taxonomies that are compact and easily understood by users. Some of these guidelines are similar to the faceted classification scheme by Ranganathan (1965), at least in its basic form: the taxonomy is organized as a set of independent, "orthogonal" subtaxonomies (facets or perspectives) to be used to describe data.

As an example, consider a compound concept such as "15th century Florentine paintings." First, we can break the compound concept into its facets: in the case at hand, we will have a Location taxonomy (of which Florence is a descendant), a Time taxonomy (of which the fifteenth century is a descendant), and finally an Art taxonomy (of which painting is a descendant). Second, by taking advantage of the multidimensional classification scheme, the items to be classified under "15th century Florentine paintings" will be classified under Location>Florence, Time>15th century, and Art>Painting instead. The extensional inference rule establishes a relationship between Florence, 15th century, and Painting, and the compound concept can be recovered by zooming on Florence, then on 15th century, and finally on Painting, or any permutation of these concepts since concept composition is commutative. In a conventional classification scheme, such as Dewey (1997) indexing, in which every item is classified under a single concept, we will need to explicitly define a number of different concepts equal to the Cartesian product of the terminals in the three taxonomies. Such a combinatorial growth either results in extremely large conceptual taxonomies or in a gross conceptual granularity (Sacco, 2000). In addition, the dynamic taxonomy approach makes it simple to focus on a concept, such as 15th century, and immediately see all related concepts such as literature, painting, politics, and so forth, which are recovered through the extensional inference rule. In the compound concept approach, these correlations are unavailable because they are hidden inside the concept label.

Additional advantages include the uniform management of heterogeneous items of any type and format, easy multilingual access, and easy integration with other retrieval methods.

Related Areas

Dynamic taxonomies directly derive from the work on the Fact Model (Sacco, 1988), the first semantic data model to include standard inference capabilities based on the conceptual schema itself rather than on external Prolog-like rules. In the Fact Model, relationships among entities (facts) are expressed as irreducible relations (Falkenberg, 1976): one of the standard inference rules in the model (called fact subsumption) states that given a fact F on entities E1, …, En, F is subsumed by all the facts defined on a subset of these entities. This means that, for instance, F(E1, E2) is a generalization of F(E1, …, En), in which E3, …, En are treated as 'don't cares'. In addition, F(E1, E2) exists if there exists at least one fact referencing both entities and at least one tuple in which these entities are not null. If the classification of an item in dynamic taxonomies is seen as a tuple in a fact which references all the concepts in the taxonomy, the extensional inference rule is derived immediately.

Dynamic taxonomies have obvious connections with Description Logic (Baader, 2003), especially in the interpretation of concepts as sets of instances. Since the model is able to dynamically reconstruct all the combinations of concepts, it can be seen as a device to interactively build and explore hypercubes, in a way applicable to OLAP techniques for databases (see Chaudhuri & Dayal, 1997).

Some of the guidelines for the construction of the taxonomy are similar to basic faceted classification (Ranganathan, 1965; Hearst, 2002). Although some researchers use the term faceted classification instead of dynamic taxonomies, we believe it to be a misnomer because: (a) faceted classification only addresses conceptual modeling and very basic concept composition—conceptual summaries, reduced taxonomies, and guided navigation are totally absent; and (b) faceted classification is a special case of the more general multidimensional classification on which dynamic taxonomies are built.

Finally, agent-based architectures based on user profiles (see Ardissono, 2002, as an example) are a contender for recommender systems and product selection. However, they suffer for a number of important shortcomings with respect to dynamic taxonomies. First, they usually try to acquire knowledge on the user through lengthy dialogs, which are usually perceived as boring and intrusive, and at the same time, often fail to capture a sufficient amount of information. Second, it is often quite difficult to explain to the user why a certain solution was found and which alternatives exist: in short, the properties of selected candidates are not as transparent as they are in dynamic taxonomies.

Applications

Although dynamic taxonomies have an extremely wide application range, the main industrial application is currently e-commerce. Assisted product selection is a critical step in most large-scale e-commerce systems (Sacco, 2003), and the advantages in interaction are so significant as to justify the restructuring of well-established e-commerce portals: current examples include Yahoo, Lycos, BizRate, and so forth.

An interesting application area is multimedia databases, where dynamic taxonomies can be used to integrate access by conceptual metadata and access by primitive multimedia features (color, texture, etc.) into a single, coherent framework (Sacco, 2004). Among other application areas are news archives, encyclopedias, legal databases, multilingual portals, general-purpose search engines, e-auctions, CRM systems, human resources management, medical guidelines (Wollersheim & Rahayu, 2002), and diagnostic systems. Dynamic taxonomies seem especially important as a tool for accessing laws and regulations, and consequently quite relevant for e-government.

A number of Web-based commercial systems based on dynamic taxonomies exist. These include Knowledge Processors, Endeca, i411, and Siderean Software.

FUTURE TRENDS

Five broad areas need further investigation:

1. Extensions to the Model: Dynamic taxonomies assume a Boolean classification. In some practical cases, a fuzzy (Zadeh, 1965) classification, in which a document can be classified under several concepts with different probabilities, can be more appropriate (Sacco, 2004).
2. Centralized, Distributed, Federated Architectures: Effective systems based on dynamic taxonomies must perform the zoom operation and the subsequent reduction of the corpus taxonomy in real time. A slower execution would severely impair the sense of free exploration that the user of dynamic taxonomy systems experiences. Commercial database systems do not achieve a sufficient speed on large to very large information bases, so that special data structures and evaluation strategies must be used (Sacco, 1998). Distributed and federated architectures need also to be investigated since centralized architectures are not always appropriate, because of organization needs and performance and reliability bottlenecks.
3. Guidelines for Effective Conceptual Schema Design: The design of effective dynamic taxonomies obviously plays a critical role in practical applications. Sacco (2000) indicates a number of general guidelines for the construction of dynamic taxonomies schemata, which take into account the fact that dynamic taxonomies are able to summarize concepts related to the current focus. Further research is needed to determine more stringent and specific guidelines.
4. New Application Areas and Environments: Dynamic taxonomies have an extremely wide application range, and the application areas listed above are but an initial sample. For instance, because of quick convergence, dynamic taxonomies seem the ideal access method for low-resolution wireless devices, especially when a taxonomy design that minimizes breadth is used.
5. Human Factors Both in General and in Connection with Specific Application Areas: A critical human factor issue is the presentation and manipulation of the taxonomy, where several alternatives exist (as an example, see Yee et al., 2003, vs. Sacco, 2000, 2004). With respect to specific application areas, dynamic taxonomies may need adaptation or complementary schemes (Sacco, 2003).

CONCLUSION

Exploratory browsing based on dynamic taxonomies applies to most practical situations and search tasks in knowledge management: an extremely wide application range going from multilingual portals, to general-purpose search engines, e-commerce, e-auctions, CRM systems, human resources management, and so forth. In this context, dynamic taxonomies represent a dramatic improvement over other search and browsing methods, both in terms of convergence and in terms of full feedback on alternatives and complete guidance to reach the user goal. For these reasons, we believe them to be a fundamental complement of traditional search techniques, and in fact, systems and Web sites implementing this paradigm are rapidly growing in number.

Chapter 4.16
Effects of Knowledge Management on Electronic Commerce:
An Exploratory Study in Taiwan

Wen-Jang Kenny Jih

Marilyn M. Helms
Dalton State University, USA

Donna Taylor Mayo
Dalton State University, USA

ABSTRACT

The Internet-enabled e-commerce field provides capabilities for firms in all sectors to reach global buyers and suppliers. Knowledge management provides frameworks to manage intellectual capital as a valuable organizational and strategic resource. Current literature on e-commerce and knowledge management primarily emphasizes the benefit of knowledge management for innovative e-commerce operations. Do knowledge management practices significantly benefit electronic commerce? If so, does the relationship work in the other direction? Does a firm's e-commerce applications significantly benefit knowledge management practices, as well? To test these exploratory propositions, empirical data were collected from companies in a variety of industries in Taiwan, a country emphasizing e-commerce initiatives. The results revealed significant relationships between the way businesses implement electronic commerce projects and how they experiment with knowledge management concepts, as well as interesting benefits and difficulties in implementation. These relationships were found to operate in both directions, offering reinforcing effects as well as connections.

INTRODUCTION

Internationally, Internet technology is an integral component of business strategy. Most firms use electronic commerce to reach customers at home and abroad. E-commerce, when properly linked with business processes and aligned with an organization's culture, aids a firm's strategic growth (Ahadi, 2004; Piris, Fitzgerald & Serrano, 2004). These initiatives can lead to important performance gains (Green & Ryan, 2005). Another global imperative is the widespread recognition of the value of intellectual capital as a major source of sustainable competitive advantage (Marr, Schiuma & Neely, 2004). To avoid basing competitive strategy on price discounting alone, a company continuously must engage in acquiring and updating the knowledge base. According to Porter (2001), intellectual assets embodied in the total business system are then difficult to duplicate.

Thus, these two developments of knowledge management and e-commerce would seem to supplement each other (Bose & Sugumaran, 2003; Fahey, Srivastava, Sharon & Smith, 2001). Knowledge management provides the mechanism for firms to keep up with innovative activities (Bakhru, 2004; Trethewey & Corman, 2001). As e-commerce information flows freely and sites are easy and inexpensive to duplicate, innovations have an increasingly shorter life span. The integration of major business processes brought about by e-commerce provides a wealth of data and information that can fuel knowledge management (Kocharekar, 2001). Yet, most discussions in the literature are largely conceptual in nature (Holsapple & Singh, 2000).

Inquiries that examine these global issues, based on actual data, are needed to obtain more insight into the relationship and directionality between the two management themes. The purpose of this study is to correct this deficiency in the literature by exploring these relationships. Thus, the primary research question is: Do knowledge management practices significantly benefit electronic commerce? If so, does the relationship work in the other direction? Does a firm's e-commerce applications significantly benefit knowledge management practices, as well? To test these exploratory propositions, empirical data were collected from companies in a variety of industries in Taiwan. Taiwan was chosen due to its aggressive emphasis on e-commerce initiatives.

The paper first will briefly review the existing literature on both knowledge management (KM) and electronic commerce (EC) individually and then will present current literature on the linkages or supplementary relationships between the two topic areas. The paper links this literature to the paper's research propositions. Next, the case of Taiwan, a global EC leader, is discussed, along with the questionnaire development and subsequent data collection and analysis. The implications for practice call for future research in other countries in order to validate these exploratory research findings.

LITERATURE REVIEW

Knowledge Management

KM has captured increased attention in today's global business environment, because it views intellectual capital as manageable and suggests frameworks to help companies utilize this valuable strategic resource (Brand, 1998; Child, 2002; Kim & Mauborgne, 1999). KM is a set of business processes through which valuable knowledge is identified, collected/created, organized/stored, distributed, managed, and applied to problems or projects (Child, 2002; Davenport & Prusak, 2000; Grover & Davenport, 2001; Kim & Mauborgne, 1999; Leseure & Brookes, 2004; Pan & Scarbrough, 1998; Zack, 1999a).

Early discussions of KM practices range from a human-oriented to a technology-driven point of view. At one extreme of the continuum is the view of knowledge as completely unmanageable and KM as managing knowledge as human networks (Brand, 1998; Porter, 2001; Savary, 1999; Storck & Hill, 2000). Some researchers, however, view KM as an expansion of traditional data and information management. This latter view suggests a holistic approach (joining social and technological factors) in order to achieve performance expectations (Davenport & Prusak, 2000; Koch, Chae & Guo, 2002; Georgopoulos, Koulouriotis & Emiris, 2004; Soo, Devinney, Midgley, Diakoulakis & Deering, 2002).

Researchers argue that organizational knowledge can be managed without an explicit definition of the knowledge itself. Rather, the focus should be on measuring its business processes (i.e., problem solving and decision making) and the innovative outcomes (Grover & Davenport, 2001; Soo, Devinney, Midgley & Deering, 2002). Various researchers (see Ahn & Chang, 2004; Castanho, 2004; Diakoulakis, Georgopoulou, Koulouriotis & Emiris, 2004; Holsapple & Joshi, 2004; Wang & Ariguzo, 2004) have studied knowledge management and worked toward a better understanding of the topic as well as moved toward model development.

KM is emphasized in the computer information systems community and is continuously gaining interest in industries, enterprises, and government (Ahn & Chang, 2004; Davenport & Prusak, 2000). Data and knowledge are available in various forms, and decision makers combine different types of data and knowledge (Mataxiotis, Ergazakis, Samouilidis & Psarras, 2004; Woods, 2004). While the research cites IT issues, artificial intelligence, and EC, most experts agree that the true goal of KM is to establish a unified, global framework (Stankosky, 2004). Although technology is not a replacement for knowledge, the gap between the two must be bridged (Spiegler, 2003).

There are three major areas of concern characterizing an organization's KM program: (1) the choice of implementation strategy (e.g., system-oriented vs. individual-oriented and top-down vs. bottom-up); (2) the set of objectives expected to be achieved (determined by such factors as top managers' support and involvement, the nature of the industry in which the organization operates, its existing information technology infrastructure, and the organizational culture) (Zack, 1999a, 1999b); and (3) critical successful factors.

Mudambi and Navarra (2004) studied multinational subsidiaries' knowledge flows in the United Kingdom and found support for a more creative role for knowledge intensity. Gerstlberger (2004) studied companies in Upper Austria, Germany, and the Silicon Valley in the U.S. and found that regional innovative systems were important for knowledge sustainability.

Electronic Commerce

E-commerce includes business-to-consumer (B2C), business-to-business (B2B), and internal business via an Intranet (Kalakota & Whinston, 1996a). While the expectation for the commercial value of Internet technologies was widely touted during the end of the last century, the sudden collapse of dot-com companies in the spring of 2000 drove many to the other extreme of the expectation continuum. Recent observations have demonstrated that, when used properly, the Internet can become the technological foundation of an innovative international business strategy. It has been recognized generally that how the Internet is incorporated in the value-creating business strategy, rather than the Internet itself, enhances a company's competitive advantage (Barua, Konanna, Whinston & Yin, 2002; Feeny, 2001; Fingar & Aronica, 2001; Garbi, 2002; Jih, 2002; Lee & Whang, 2001; Prusak & Liam, 1998; Wigand, 1997).

The Internet provides companies of all sizes and in all industries with a convenient, affordable communication infrastructure that is not limited by time and distance. Internet transactions include the purchase of information products (i.e., software, CDs, books) to physical products (i.e., automobiles and groceries) (Child, 2002; Feeny, 2001; Turban, Lee, King & Chung, 2000). Internet technologies have enabled innovative companies, such as Tesco, e-Bay, Rosenbluth International, Dell, and Amazon.com, to outperform their competitors. As companies streamline their internal and external business processes, the distinction between the old economy and the new economy continues to fade.

Researchers have analyzed EC business models from many different perspectives and frameworks (Barua, Konanna, Whinston & Yin, 2002; Hogue, 2000; Kalakota & Whinston, 1996b; Mahadevan, 2000; Turban, Lee, King & Chung, 2000). EC has become important to countries around the globe. Salman (2004), for example, studied EC for competitive advantage in developing countries, concentrating on Bangladesh. In their study of e-tourism in Greece, Buhalis and Deimezi (2004) found EC to have a great potential for the country and confirmed how EC has revolutionized the travel industry, in particular.

Linkages Between EC and KM

EC Supports KM

The way companies implement KM concepts often is facilitated by their capabilities in implementing EC applications. The implementation of their EC applications also can benefit from experience acquired from their KM practices. This reinforcing effect results from the following seven characteristics shared by the two management paradigms. Both (1) use the Internet and their related technologies (Grover & Davenport, 2001); (2) emphasize intangible assets; (3) must be tightly integrated with major business processes; (4) are innovation-minded (Srinivasan, Lilien & Rangaswamy, 2002); (5) lack commonly accepted operational performance indicators and are hard to justify (Soo, Devinney, Midgley & Deering, 2002); (6) have strategic significance (Davenport & Prusak, 2000; Zack, 1999a, 1999b); and (7) govern EC applications and KM implementations, to a certain degree, by the principle of network economies (Brand, 1998; Pan & Scarbrough, 1998; Savary, 1999).

Specifically, EC supports KM in both technology and content. EC applications must be developed with the foundation of an information architecture. Hogue (2000) identified nine functional components of one such EC process architecture: profiling, personalization, search management, content management, workflow management, collaboration and trading, event notification, catalog management, and payment. It is evident that the functional components for EC applications also play an important role in KM practices, as evidenced by the first six of the nine EC components in the Hogue model. In the KM field, Turban, Aronson, and Liang (2005) emphasize the essential role of information technology in KM implementations. In particular, three categories of information technology are instrumental: knowledge discovery (e.g., data warehousing and data mining), knowledge distribution (e.g., collaborative software), and knowledge application (e.g., expert systems and intelligent agent). Most of these technologies, such as expert system and intelligent agent, have helped EC companies to add a wide variety of customization capabilities to EC applications. The supporting role of EC for KM is evident.

EC applications also support KM practices by providing valuable customer knowledge to help better focus the KM program. Focusing on customer knowledge allows a KM program to be effective in accomplishing its mission and efficient in the use of organizational resources. The importance as well as the dimensions of customer knowledge are addressed by Glosch (2000), Bose and Sugumaran (2003), Jarvenpaa and Todd (1997), and Plessis and Boon (2004). EC Web sites constantly collect a massive amount of customer knowledge through daily operations. These knowledge contents represent valuable resource input for KM programs.

Alvesson (2004) found that key knowledge-intensive firms are using EC in their business models and include IT, management consulting, advertising, and life sciences. He further agrees that KM is, indeed, a core competency. The increased sense of urgency for the institutionalization of comprehensive knowledge management programs is driven by EC. A well-designed KM infrastructure facilitates sharing of knowledge and reduces operating cost, improves staff productivity, and increases the knowledge base and expertise sharing (Bose & Sugumaran, 2003). Spiegler (2003) states that the idea of technology is to represent the means and the knowledge to the end as well as to support the EC process. He agrees that methods for generating knowledge are assisted by using technology or EC.

KM Supports EC

Electronic commerce is challenging and is only sustainable for global companies who continue to innovate and strategically use acquired knowledge. Wenger (2004) agrees that if knowledge is a strategic asset, it must be managed. For example, the value-added content in Web site design has been recognized as an important factor in influencing online shoppers' perceptions as well as their behaviors (Jarvenpaa & Todd, 1997; Wolfinbarger & Gilly, 2002).

True value-added content of an EC Web site only can be produced and sustained through a viable knowledge management program. Huosong, Kuanqu, and Shuqin (2003) agree that, while KM has been studied, our understanding of how the design of a KM system affects both its use and definition is still limited. Malhotra (2000) confirms that knowledge creation is relevant to both e-business and EC.

KM Supports EC in Various Forms

Singh, Furrer, and Ostinelli (2004) studied Web standardization in Italy, India, the Netherlands, Spain, and Switzerland, and found that knowledge of local cultural preferences was important for Web customization. In Brazil, Tigre and Dedrick (2004) studied local cultural knowledge for EC adaptation and found that local forces were important for driving EC diffusion. Plessis and Boon (2004) studied e-business in South Africa and found that knowledge management is a prerequisite for e-business and its increasing customer-centric focus and is an integral part of both customer relationship management and e-business.

Synergy in Both Directions

KM-to-EC and EC-to-KM. Gathering and using customer knowledge and feedback serves to link KM and EC (Blosch, 2000; Bose & Sugumaran, 2003). The potential synergy between KM and EC has been noted in both the information systems and the marketing literature along three dimensions: process impact, community and content, and system architecture (Holsapple & Singh, 2000; Salazar, Hackney & Howells, 2003). The process-impact point of view, in particular, stresses the increasing demand for in-depth knowledge in implementations of e-business processes and views KM as playing a vital role in change management. Fahey, Srivastava, Sharon & Smith (2001) suggest that KM is valuable in evaluating the what, how, and why aspects of e-business operations. Through the development of e-business-focused knowledge, organizations can evaluate the type of work performed in the global e-business environment, understand how they are doing it, and determine why certain practices in companies are likely to change in the future.

In the implementation of a KM solution in Greek banks, Samiotis, Poulymenakou, and

Doukidis (2003) found support for KM in the newly employed and strategically important e-banking role, while Bose and Sugumaran (2003) found a U.S. application of KM technology in customer relationship management, particularly for creating, structuring, disseminating, and applying knowledge. Rowley (2002) agrees that such customer knowledge is an important e-business opportunity, since customers in the digital economy depend on knowledge management and the accompanying organization's knowledge management paradigm.

Recent developments in information technology — the Internet, enterprise resources planning systems, and KM — are all necessary for business survival (Soliman & Youssef, 2001). However, the new business models created by e-business are changing operations. But most agree that it has not been integrated well with internal knowledge management initiatives. Fahey, Srivastava, Sharon, and Smith (2001) stress that, with the development of e-business, focused knowledge organizations are needed to enhance customer relationship management, supply chain management, and product development. The authors also emphasize the central role of knowledge management in managing e-business changes occurring in organizations. Warkentin, Bapna, and Sugumaran (2001) studied e-knowledge networks and found them key in inter-organizational collaborative e-business, thus linking KM and EC.

KM plays a role in customer retention with value-added service through product-related knowledge and support of the online community. Faced with a great array of vendor choices, customers often are attracted by the Web sites that contain relevant, well- organized information and knowledge relating to product quality and usage. The rich knowledge information and knowledge content, according to Wolfinbarger and Gilly (2001), represents an important motivating factor by providing online shoppers with freedom, control, and even fun. Williams and Cothrel (2000) argue for the importance of the online community in the Internet-centered business world and highlight the important role of experience sharing in managing the online community. Finally, on the system architectural dimension, Kocharekar (2001) contends that both KM and EC represent the next movement beyond ERP systems and must converge to a commerce characterized by knowledge-intensive activities, which they term knowledge commerce or K-Commerce.

Based on our literature review on KM and EC and their initial linkages, we propose that:

EC facilitates the practices of KM, whereas KM guides and supports EC.

The reasoning behind this proposition is reiterated as follows. Although experience suggests that traditional wisdom should not be ignored in running EC businesses, there is also an abundance of evidence indicating that innovative thinking is critical to conducting business via the Internet. Facing a massive amount of information, customers' attentions will be drawn to the Web sites that offer innovative values. KM supports EC by enabling a company to put its entire organizational knowledge base behind such major business processes as new product development, customer service, and supply chain management. The infrastructure constructed for EC applications also provides valuable mechanisms for the implementation of KM programs.

The literature also shows that successful EC operations must be guided and aligned with business strategy, backed by fully integrated business processes and work flows, and built around a consistent customer-centric system of interactions. This requires a great deal of innovative capability and learning capacity, which only can be achieved with an effective, ongoing knowledge management program. The characteristics shared by EC and KM suggest existence of synergy between the two fields. To test this linkage, we chose to examine the relationship between the two fields in terms of the basic aspects of each, considering B2B and B2C EC applications as well as strategy, objectives, and critical success factors. Thus, the following research propositions were developed:

P1: EC applications do not significantly affect KM practices.
- P1.1: EC applications do not significantly affect the choice of KM implementation strategies.
- P1.2: EC applications do not significantly affect the objectives of KM initiatives.

P2: KM practices do not significantly affect the applications of EC.
- P2.1: The choice of KM implementation strategy does not significantly affect applications of EC.
- H2.2: Critical success factors of KM initiatives do not significantly affect applications of EC.

RESEARCH METHODOLOGY

The first step to validate our research proposition regarding the mutually reinforcing effect between KM and EC is to test the correlation between the two. For this purpose, a cross-sectional survey was administered to business managers.

Taiwan

Taiwan was selected as the site for this exploratory study for several important reasons. Among other major initiatives, EC has been designated by the government of Taiwan as an important area of investment to stimulate national economic vitality and to enhance competitiveness. In the second quarter of 1999, the Ministry of Economic Affairs launched a multi-year project to promote EC applications in 40 industries identified as having the best potential to stimulate long-term national economic development (http://www.ec.org.tw). A primary project objective is to develop Taiwan into an Asia-Pacific regional commercial center. Both B2C and B2B EC applications are included in the promotional campaign. These government-funded promotions include research support, training, systems development, and a national innovative projects contest. In academia, a variety of research projects have been sponsored by the National Science Council, and numerous industrial associations in Taiwan examine various aspects of EC applications. Based on a field survey, Jih (2002) found that a variety of benefits has been realized by companies in Taiwan who have actively adopted EC.

Taiwan recovered more quickly than other Asian nations from the 1997-1998 financial crises that hit Asian markets and experienced only a brief period of slow growth. Currently, Taiwan has a solid economic and financial foundation due to its economic transformation from a labor-intensive environment to a capital and technology-intensive environment. This export-oriented economy has grown at a 5% to 6% yearly rate, and this growth, in part, is due to the continuous development of a knowledge-based economy (Tang, 2000; Wang, Scherban & Bonnici, 2005). Taiwan now exports twice as much to China as to the U.S. after decades of relying only on the American market, largely due to their increase in the production of computer chips, laptop computers, and notebooks (Bradsher, 2004).

Recognizing the importance of continuous innovation in such major areas as new product development, production process streamlining, and quality assurance, many Taiwanese companies have attempted to implement forms of KM programs in their organizations. Many manufacturing firms in Taiwan play an important upstream role in global supply chains. These companies understand that they must continually improve their production cost, quality, delivery, and service. The service industries within the domestic Taiwanese market also face competition from global players with scale advantages (Child, 2002). World Trade

Organization membership means that almost every company in Taiwan will face unprecedented, larger competitors. Taiwan, a small island nation, is a major exporter with little domestic demand. Thus, EC levels the playing field for the nation. Its commerce must be with international partners, and most of these transactions depend on EC as their means of competition.

Survey Instrument

The questionnaire was written in Chinese and contained items designed to address issues related to EC applications, KM practices, the benefits realized, and the difficulties experienced in applying the concepts. The questionnaire was pilot-tested with a convenience sample of managers to ensure validity and reliability. Some questions were revised for clarity and wording, based on the feedback obtained from the pilot test; the companies involved in the pilot testing were excluded from the final results. The data were collected in 2002 and 2003.

In designing the questionnaire, the EC applications in three categories (business-to-business, business-to-consumer, and intra-organizational EC activities) were considered, following the original definition of Kalakota and Whinston (1996b). The following three macro-level aspects of KM practices also were used in the study: KM strategies, KM objectives, and KM critical success factors. Each construct was measured with multiple questions. Except for questions about the respondents' demographic background and company information, all questions used a 7-point Likert-type scale to collect perceptual data, with 7 representing "strongly agree" and 1 representing "strongly disagree." Figure 1 is a graphical depiction of the research proposition and the study's conceptual framework. The EC and KM components, which serve as the basis for the survey items, are summarized in Table 1. The questionnaire consisted of four questions for B2B applications, five questions for B2C applications, and three questions for intranet applications. For KM implementation practices, there were two questions on KM strategies, 13 on KM objectives, and 10 on KM critical success factors. In addition, 15 benefits questions and 11 difficulty items were included to advance understanding of KM implementations.

For KM strategies, companies were asked to identify the relative emphasis (as a percentage) of system-oriented (technology view) vs. personal-oriented (human resource view) and top-down (revolution approach) vs. bottom-up (evolution approach) KM implementation strategies. Examples of survey questions are included in Table 2.

Figure 1. Conceptual framework

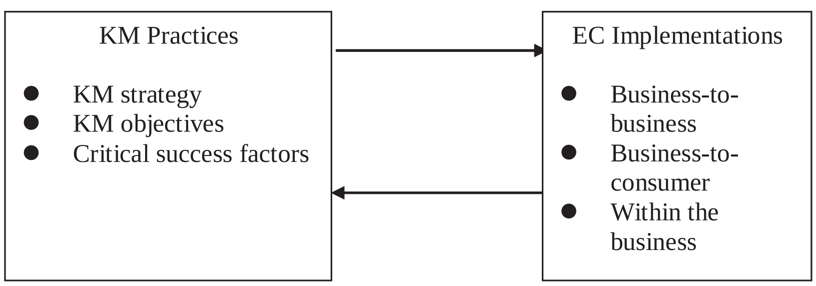

Table 1. Summary of research variables

Research Variables		Definition
EC Activities	Business-to-Business EC Activities	• Electronic financial transaction • Knowledge dissemination and sharing • Workgroup discussion • Workflow integration
	Business-to-Consumer EC Activities	• Organizational information dissemination • Online transaction • Product/Service information inquiry • Customer service • Online advertising
	Intra-organizational EC Activities	• Information dissemination and sharing • Workgroup discussion • Workflow integration
KM Activities	KM Strategies	• Systems approach vs. Individual approach • Top-down vs. bottom-up approach
	KM Objectives	• Increasing organizational knowledge repository and value • Establishing knowledge network • Improving efficiency of knowledge usage • Facilitating organizational innovation • Promoting organizational learning
	Critical Success Factors for KM	• Linkage with overall organizational performance • Technological and organizational infrastructure • Flexible knowledge organization structure • Organizational culture enables knowledge sharing • Clear and specific objectives • Incentive measures • Multiple knowledge transfer channels • Top management support

Data Collection and Analysis

A total of 221 questionnaires were mailed to the chief information officers of a variety of companies in Taiwan. The companies were selected, based on their publicly reported EC and KM activities and their positions as recognized leaders in the application of EC and KM concepts within key industries in Taiwan. They were categorized into financial service institutions, information technology, electronics manufacturing, and other industries (representing pharmaceutical, management consulting, and retail chains). Sixty-three questionnaires were returned, representing an effective response rate of 28.5%. Information technology representatives had the highest re-

Table 2. Sample survey items (All on a 7-point Likert-type scale with 1 as Strongly Disagree to 7 as Strongly Agree)

EC (B2B):
- Our financial transactions with upstream and downstream business partners are all conducted on WWW and/or EDI.
- We exchange information, knowledge, and experience with business partners on WWW and/or EDI.
- We use WWW and/or EDI to communicate and collaborate with our business partners.
- We use computer networks, including the Internet, to integrate with business partners our work flows.

EC (B2C):
- We provide company and products/ services information on our website.
- We conduct product and service transactions online.
- We provide online search capability for customers' information inquiry.
- We offer online customer service and inquiry capabilities.
- We advertise and promote our products and service online.

EC (Intranet):
- We encourage knowledge and experience sharing among employees using computer networks.
- We provide networking capabilities for employees to communicate with one another and to engage in group discussions.
- We attempt to integrate our workflows using Internet technologies.

KM Strategy:
- Please indicate the relative emphasis on the two knowledge management strategies of your company:
  System-driven: _____ %
  Personally oriented: _____%
  (Please note the two numbers should total 100 %.)
- Please indicate the relative emphasis on the following two knowledge management strategies of your company:
  Top-down strategy: _____ %
  Bottom-up strategy: _____%
  (Please note the two numbers should total 100 %.)

KM Objectives:
- Our objective for knowledge management implementation is to create electronic databases, digital knowledge bases, document bases, and other digital media so they are can be conveniently accessed by our employees.
- Our objective for knowledge management implementation is creating valuable knowledge repositories in electronic forms.
- Our objective for knowledge management implementation is to strengthen our innovation
- Our objective for knowledge management implementation is to uncover knowledge owned by our employee so it can be utilized more.

KM Critical Success Factors:
- Our knowledge management initiatives are aligned with our overall business strategy.
- Knowledge management is viewed as a long term organizational effort rather than just a short-term and one-time endeavor.
- A flexible organization structure is employed to promote knowledge management efforts, such as an interdepartmental km team.
- We have a clear definition for knowledge to distinguish it from data and information.

Table 3. Sample distribution

	Financial Service Institutions	Information Technology Industry	Electronics Manufacturing Industry	Other Industries	Total
Questionnaires Mailed	102	19	50	50	221
Questionnaires Received	37	13	17	11	78
Effective Questionnaires	31	10	14	8	63
Effective Questionnaire Return Rate	30.4%	52.6%	28%	16%	28.5%

Table 4. Reliability measures of the research constructs and the questionnaire

	Cronbach's α	**Question Category**	**Number of Questions**	**Cronbach's α**
E-Commerce	0.94	B-B EC	4	0.8682
		B-C EC	5	0.9775
		Intranet	3	0.9380
Knowledge Management	0.9792	KM Objectives	13	0.9832
		KM CSF_	10	0.9762
		Current Implementations	26	0.9592
Entire Questionnaire		0.9795		

sponse rate (52.6%) — an understandable result, given the progressive nature of this industry in Taiwan. A follow-up interview was conducted with a small number of these companies to obtain anecdotal and supplementary information to augment the quantitative data. The distribution of the respondents is summarized in Table 3.

Statistical analysis was used to analyze the collected data. First, descriptive statistics were obtained for each variable. The correlation between EC applications and KM objectives and between EC applications and KM critical success factors then were analyzed using Pearson Product-Moment Correlations. A one-way analysis of variance was conducted to examine the impact of KM implementation strategy on EC applications and the difference of KM implementation strategies among different industries. In addition, the internal consistency of the questionnaire (measured by the Cronbach's alpha coefficient) was examined to ensure survey reliability. Table 4 shows each individual construct has a Cronbach's α coefficient of at least 0.8682, and Cronbach's alpha for the entire questionnaire is 0.9795. The questions for perceived benefits from KM implementations and for the difficulties encountered also were analyzed. Cronbach's alpha for the former is 0.9827, and the latter is 0.9204, both indicating high degrees of reliability.

SURVEY RESULTS

Since the effective respondents all had EC and KM programs, the distribution of their sizes (as measured by the number of employees and annual sales) was examined to determine if size had a significant influence. Although there were 23 companies (36.5%) with 1,000 or more employees, there were also 28 companies (44.4%) with 300 or fewer employees. The largest revenue category was represented by 19 responding companies with annual sales of $800 million USD or more. The second category was represented by the companies with annual sales between $40 million and $134 million USD. Although larger companies had more resource support for applications of EC and KM, smaller companies also were actively engaged in these activities. In fact, follow-up interviews revealed that smaller companies hoped EC and KM applications would help them compete more effectively within their respective industries.

Effects of EC Applications on KM Practices

The possible effects of EC applications on KM strategies were examined by obtaining the Pearson product-moment correlation coefficient between EC applications and KM practices. Each EC application type was used as an independent variable, and each knowledge strategy type as a dependent variable. As summarized in Table 5, the system's approach is positively correlated, and the individual approach is negatively correlated with B2B EC applications. The fact that these are the only

Table 5. Correlations between EC implementations and KM strategies

	B-to-B EC	B-to-C EC	Intranets
Systems Approach	0.461*	0.121	0.178
Individual Approach	-0.461*	-0.121	-0.178
Top-down Approach	-0.101	-0.126	-0.018
Bottom-up Approach	0.101	0.126	0.018

** Level of significance < 0.01*

** Level of significance < 0.05; ** Level of significance < 0.01*

significant correlation coefficients (at the 1% level) may be explained by the experimental nature of EC (especially B2C EC) and KM activities. The system's approach places more emphasis on the use of information technology in implementing KM projects, whereas the individual approach views human interaction as the more important information technology. Both the degree and the direction of the correlation coefficients indicate that key aspects of EC applications and KM implementation strategies (system vs. individual) are significantly correlated.

When EC activities are correlated with KM implementation objectives, the correlation coefficients are significant at the 1% level (See Table 6). The degrees of EC implementations are positively correlated with the importance placed on each KM objective. It appears that these companies have an understanding of the strategic value of KM to their organizations and an expectation that EC applications will facilitate successful implementations of KM. In summary, some EC applications do facilitate KM practices. Therefore, Proposition 1 is rejected.

The data from Taiwan about the effects of EC applications on KM practices indicate that KM practices benefit from EC application. This facilitating effect is especially obvious in fulfilling KM objectives — all EC application types have a significantly positive impact on both the efficiency and effectiveness of KM programs. The technological infrastructure and business processes designed for EC operations, such as the Web-based user interface, product/service customization, and online community, also facilitate important aspects of knowledge management (e.g., knowledge acquisition, knowledge flow, and knowledge application. The facilitation effect is discussed by Alvesson (2004) and Rowley (2002). Buhalis and Deimezi (2004) also reported similar findings in their study about the travel industry in Greece. Kankanhalli, Tanudidjaja, Sutanto, and Tan (2003) shared this observation by attributing part of the KM program's implementation success at British petroleum, Buckman Laboratories, and Shell to the capabilities of their EC-enabled information technologies. As a matter of fact, the majority of technological tools discussed in the KM literature are associated with some types of EC applications (Holsapple, 2004). Although successful KM implementation does not depend solely on EC technology, the technological tool is essential in order to smoothly implement the KM program.

Effects of KM Practices on EC Applications

A one-way analysis of variance (ANOVA analysis) was used to determine the effects of KM practices on EC applications using each EC application as the dependent variable and KM strategies as the independent variables. The B2B EC is the only variable affected significantly by the choice of systems approach vs. individual approach to KM implementation (F-value: 9.257, level of significance < 1%). Thus, the choice of KM implementation strategy does significantly affect some aspect of EC application; namely, B2B EC.

When each type of EC application was used as the dependent variable with critical success factors for KM implementation as the independent variables, the result of Pearson Product-Moment Correlation analysis shows that all correlation coefficients pass the test at either the 1% or 5% level of significance. The highest correlation relationship is found between Intranets and flexible KM organization structures. Thus, the more flexible the organization structure for KM, the more likely that company-owned Intranets would be utilized. It is also worth noting that the degree of Intranet usage has higher correlations (with all but one KM variable) than the other two types of EC applications (B2B and B2C). This is an understandable phenomenon, given the current similar internal orientation of both intranet and KM applications. The second component of Proposition 2 (H2.2: Critical successful factors of KM initiatives do not significantly affect applications of EC) is rejected.

EC is emerging rapidly as a competitive paradigm in today's globalized business environment. The companies in Taiwan understand this trend and actively engage in integrating EC in their business models. The key to succeeding in EC applications is to provide attractive customer value (effectiveness) at affordable cost (efficiency). Both effectiveness and efficiency of EC applications can be enhanced by KM. This finding is shared by Singh, Furrer, and Ostinelli (2004) in their report on Web standardization in several European nations, by Tigre and Dedrick (2004) in their study regarding using local cultural knowledge for EC adaptation in Brazil, and by Plessis and Boon (2004) in the study in South Africa. In addition, stories abound in Fortune 500 companies about how innovative EC applications derive enormous business value from aggressive KM implementation (Holsapple, 2004).

Perceived Benefits from KM Implementations

Qualitative understanding of the future of KM in Taiwan was addressed by 15 items in the questionnaire. The means and the standard deviations, as well as the rankings, are summarized in Table 8. The top five benefit items are (1) improvement of organizational capability in responding to environmental change; (2) improvement of overall productivity; (3) improvement of overall performance; (4) timely monitoring of competition; and (5) enhancement of organizational innovative capability. It is interesting to note the breadth of the top 10 benefit items: capability to respond to change; productivity and performance improvement; relationship improvement (customer, supplier, and employee); and product quality improvement. Companies appear to have a good understanding that successful KM requires a broad view of value assessment. This is a sound beginning, since it requires an extensive period of time for a company to reap the long-term benefits from a KM investment. These findings are consistent with those reported in the KM literature.

Table 8. Benefits realized from KM initiatives

Rank	Benefit from KM Initiatives	Mean	Standard Deviation
1	Improvement of organizational capability in responding to environmental change	4.92	1.35
2	Improvement of overall productivity	4.90	1.52
3	Improvement of overall performance	4.86	1.62
4	Timely monitoring of competition situations	4.83	1.62
5	Enhancement of organizational innovative capability	4.81	1.48
5	Enhancement of customer satisfaction	4.81	1.62
6	Quicker response to market demand variation through production adjustment or marketing planning change	4.79	1.60
7	Improvement of product quality	4.78	1.53
8	Improvement of relationship with suppliers and customers	4.75	1.44
9	Improvement of employee satisfaction	4.73	1.61
10	Increase of sales volumes	4.63	1.37
11	Reduction of operational costs	4.51	1.53
11	Increase of profitability	4.51	1.51
12	Reduction of maintenance costs	4.41	1.42
13	Reduction of product/service development costs	4.38	1.56

PERCEIVED DIFFICULTIES ENCOUNTERED IN KM IMPLEMENTATIONS

On a 7-point Likert-type scale, the six difficulty items with difficulty averages above 4, as reported by respondents are (1) difficulty in knowledge flow due to lack of interdepartmental coordination; (2) lack of top management support; (3) weak consensus on the value of knowledge to the organization; (4) lack of innovative capability and motivation to innovate; (5) lack of incentive to encourage knowledge sharing; and (6) lack of clearly defined communication mechanisms across departments. Organizational and human factors ranked higher than technological factors, a confirmation of the observation reported in KM literature about the importance of organization culture for KM implementation (Brand, 1998; Davenport & Prusak, 2000; Koch, Paradice, Chae & Guo, 2002; Pan & Scarbrough, 1998; Storck & Hill, 2000). The finding suggests that, while companies have a clear understanding of the strategic value of knowledge, it is difficult for them to develop momentum. Nonetheless, the fact that the highest degree of difficulty is only 4.62 indicates that companies do not feel hopeless about coping with these challenges.

SUMMARY AND CONCLUSION

The business environment today requires companies to continually offer new and improved products or services, trim operational costs, shorten delivery time, increase quality, provide

Table 9. Difficulties experienced in KM implementations

Rank	Difficulties Encountered	Mean	Standard Deviation
1	Difficulty in knowledge flow due to lack of inter-departmental coordination	4.62	1.47
2	Lack of top management support	4.44	1.64
3	Weak consensus on the value of knowledge to the organization	4.33	1.51
4	Lack of innovative capability and motivation to innovate	4.30	1.53
5	Lack of incentive to encourage knowledge sharing	4.16	1.45
6	Lack of clearly defined communication mechanisms across departments	4.11	1.48
7	Employee resistance to sharing knowledge	3.94	1.60
8	Lack of clearly defined objectives for KM	3.92	1.51
9	Lack of trust between employee and management	3.76	1.51
10	Lack of hardware equipment to implement KM projects	3.49	1.74
11	Lack of proper software to implement KM projects	3.46	1.68

value-added customer services, and quickly adapt to unexpected changes. To cope effectively with these multi-faceted challenges, companies must engage diligently in activities that are capable of transforming their businesses into intelligent-acting organizations (Wiig, 1994, 1995). EC represents a promising avenue by enabling companies to interact directly with customers and integrate efforts of supply chain members (Keeny, 1999). The improved innovative capacity resulting from a thorough execution of KM strategies helps companies to establish and sustain competitive advantage by providing unique, attractive customer values (Zack, 1999a, 1999b).

The literature reviewed suggests that there is a significant relationship between how companies apply EC and how they practice KM in their operations. Our empirical study confirms this proposition. More specifically, the choice between systems-oriented and individual-oriented KM implementation strategies is affected by the B2B EC and vice versa. Each of the of KM implementation objectives is significantly affected by each of the three types of EC applications, and each of the three types of EC applications is significantly affected by all but one KM critical success factor.

Two important implications for information systems professionals and EC managers can be drawn from the findings of this study. First, although information technology does not guarantee success of either EC applications or KM implementations, it does represent an essential component, since it provides the technological infrastructure. The information technology infrastructure must be aligned properly with business strategy and business processes in order to create synergies. Only with a high degree of synchronized efforts can a company perform competitively in an open environment. Taiwan is not unique in the pressures for global expansion and increased need for market development. Taiwan's recent success in manufacturing computer-related hardware and software is a natural fit to the need for EC applications and KM implementations.

Second, the investments in EC applications and KM implementations are complementary. As noted in the Taiwanese example, the hardware and software tools acquired for EC applications can be useful for the promotion of KM activities. EC applications are guided and supported by an active KM program. The companies in Taiwan, as demonstrated in this study, are similar to companies in other parts of the world with regard to the facilitation effect of EC on KM. The enabling and support effect of KM on EC and the synergistic effect between EC and KM in Taiwan also are evident in companies throughout the world. These findings add to and extend the EC and KM research by providing empirical evidence obtained in Taiwan.

The contributions of this study are largely exploratory. It is the first study to attempt to empirically test the directional linkage or correlation between KM and EC. Other literature has alluded to the relationship but has not attempted to validate its presence. Since the subjects for this research were Taiwanese businesses operating in a global business environment, the study has global relevance. However, it is limited to one country. Other limitations of the research are the questionnaire design, which was limited to subjective judgment, and variable response rates. Future research should work to overcome these limitations.

Three directions for future research are suggested. The first direction extends the scope of coverage by including additional forms of EC application (such as customer-to-business) and other KM practice items (e.g., knowledge acquisition methods). The second direction should examine in-depth relationships between EC and KM. For example, an interesting research issue might be how communities of practice support EC operations. The third direction involves collecting primary data from companies in the U.S. and internationally in order to further validate the research propositions, explore additional relationships, make cross-cultural comparisons, and establish further global linkages between these two important management themes.

Chapter 4.17
Knowledge Intermediation

Enrico Scarso

Matteo Di Biagi
University of Padova, Italy

INTRODUCTION

Since knowledge is increasingly regarded as the central source of competitive advantage, a "cognitive" interpretation of business activities becomes vital. With regard to this, the flourishing field of knowledge management (KM) provides useful insights into approaches to a systematic and explicit management of knowledge. Furthermore, the development of Internet technologies raises expectations of new opportunities to acquire, process, and distribute knowledge. Little research has, however, been done on the new businesses that may originate from a combination of KM practices and the use of new technologies. In particular, since the activities of knowledge creation and sharing are not bound to the single organisation, there is room for the development of innovative services that enable a "knowledge-based use" of network technologies such as the Internet. In fact, an increasing number of examples of innovative "knowledge-intensive" firms based on the Web can be found, but there is the need for better understanding of the contents and issues associated with such emerging ventures.

This article focuses on the business of "knowledge intermediation" via the Web, that is, the provision of technology-based services designed to support knowledge flows between organisations. In detail, the aims are: (1) to explore the development of a new business model that combines the use of information and communication technologies with a KM capability; (2) to suggest preliminary classifications; and (3) to highlight possible economic opportunities and problems as well.

BACKGROUND

As the day-by-day practice shows, it is very unlikely that the single firm can own or internally generate all the knowledge assets required for the business (Quintas, Lefrere, & Jones, 1997; Bolisani & Scarso, 2000). As a consequence, companies are increasingly realising that their knowledge resources derive in significant part from the system of interorganisational relationships established with customers, vendors, business partners, institutions, and even competitors. Such knowledge networks (i.e., formal or informal agreements to share knowledge, explore innovations, and exploit new ideas, Millar, Demaid, & Quintas, 1997; Pyka, 1997, 2002; Warkentin, Sugumaran, & Bapna, 2001; Peña, 2002) constitute a basic and distinctive feature of the current knowledge-based economy.

Until now, most of the literature on KM has focused on knowledge generated, transferred, and used within a single organisation, while little work has been done to understand how to manage knowledge across organisations (Parise & Henderson, 2002; Spring, 2003). Hence, it is necessary to analyse whether and how the principles and approaches elaborated in "traditional" KM have to be reframed to perform knowledge network management (Seufert, von Krogh, & Bach, 1999). This sort of "extended KM" clearly raises more problematic issues than managing knowledge within the single firm. For instance, attempts to communicate meanings may be difficult due to the lack of common goals, languages, values, and mental schemes. As a matter of fact, a cognitive distance or gap may separate knowledge sources and users, which makes the sharing of useful knowledge difficult. Furthermore, reciprocal trust is needed, since a knowledge exchange may be easily exposed to the risk of opportunistic behaviours. Also, the effective "functioning" of a knowledge network involves the subdivision of "cognitive tasks" and KM competencies among the participants. Finally, an adequate technological infrastructure may be required to handle the large amounts of contents scattered in a wide context.

For this reason, new kinds of "mediating services" can be of great use: to fill the cognitive gap between players; to facilitate the flowing of knowledge inside the network (Spring, 2003); to act as "organizational translators" (Teece, 1998) between different interests, values, and culture of interconnecting partners; to implement and manage Internet-based interorganisational KM systems; to build network trust, and so forth. There is already evidence of companies providing such innovative services (see Bolisani, Di Biagi, & Scarso, 2003). The purpose here is to verify whether a "KM viewpoint" can be of help to describe more formally the new businesses of knowledge intermediation that we will name "knowledgemediary" (KMY). In particular, their distinctive features, key competences, and critical managerial issues are illustrated and discussed.

CONCEPT DEFINITION

To better specify the notion of knowledgemediary, it is useful to briefly recall its antecedents.

Knowledge-Intensive Business Services (KIBS)

The term KIBS was introduced to define business service firms providing knowledge-intensive, technology-based services with a high level of supplier-user interaction, generally produced by employing a highly qualified labour force (Nählinder, 2002). KIBS play the crucial role of both creating knowledge for (or together with) their customers, and assisting the circulation of knowledge from one firm to another. This knowledge brokering function is generally a byproduct of their work, that mainly consists in "solving problems for the clients." A growing number of studies about KIBS highlights the relevant contribution given by such services in the present economic systems (OECD, 1997; Roberts, Andersen, & Hull, 2000; Nählinder, 2002), as well as their special features, that is, they are innovative, act as vehicles of innovation, and connect firms, thus performing the function of "cognitive interface" between different business partners. Miles (1996) proposes a useful distinction between "traditional" KIBS (e.g., classical consulting services) and T-KIBS (i.e., services that concern or are based on the use of information and communication technologies, including Internet-based applications). Our notion of KMY has its roots inside the T-KIBS category.

Intermediation and Internet Applications

As mentioned, KMY services imply a mediating capability by their very nature, since they act in the middle of an interorganisational context. It is, however, necessary to specify the particular kind of intermediation that can be of interest here.

First, it is important to note that even the activity of intermediaries in traditional trade (e.g., identification of demand needs; information on products and suppliers; comparisons; market intelligence; distribution of information on products; customer targeting; demand orientation, etc.) involves cognitive contents (Sarkar, Butler, & Steinfield, 1995). In substance, a significant part of the value added by an intermediary consists of "bridging" over the cognitive gap between buyers and sellers, thereby facilitating the exchange of knowledge for settling transactions. Such cognitive implications of the intermediation activity also are underlined by the economic theories. For instance, according to the transaction costs theory, the choice between in-house direct sale and use of external intermediaries is based on the complexity, specificity, and uncertainty of economic exchanges (Rangan, Menezes, & Maier, 1992), that is on the cognitive aspects of a transaction. Also, in the principal-agent theory, agents are delegated to assist principals with their economic counterparts, in order to reduce the decisional complexity produced by knowledge shortages (Pratt & Zeckhauser, 1985). Another important problem concerns the quality of information exchanged by trading partners, and the signalling (transferring) mechanisms employed for this (Choi, Stahl, & Whinston, 1997).

The cognitive connotation of intermediation raises peculiar issues for Internet-based businesses. In fact, although the huge amount of information available on the Web extends the cognitive capabilities of the surfers, the growing size and complexity of the cyberspace and the resulting "information overload" effect makes its exploitation very difficult. In such context there may be the need for "knowledge mediators," capable of assisting the users in the management of online sources. Indeed, theoretical arguments and empirical observations show that the diffusion of Internet applications generally implies the development of new forms of intermediaries (Sarkar, Butler, & Steinfield, 1995), such as infomediaries (online firms specialising in online customer profiling and analysis of navigation traces), cybermediaries (online companies that specialise in electronic transactions such as Web malls, comparison sites, credit card clearing services, etc.), and so on.

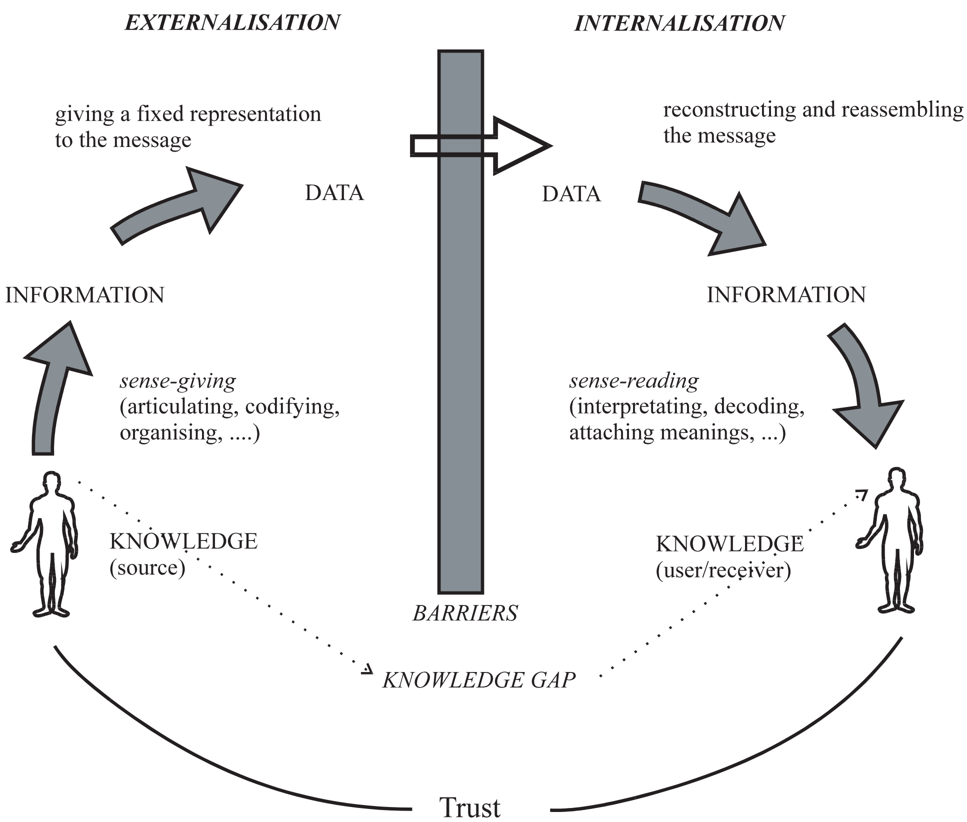
Knowledge Mediators in KM Processes

The notion of "knowledge mediator" is also relevant to the literature of KM. For instance, the resort to "domain experts" is recommended for a corporate Web portal, in order to facilitate the extraction of knowledge from internal sources and its delivery to end users (Mack, Ravin, & Byrd, 2001). The presence of a "knowledge broker" is often suggested for the good functioning of knowledge exchanges (e.g., the concept of "knowledge markets," Davenport & Prusak, 1998; Markus, 2001; Matson, Patiath, & Shavers, 2003; Kafentzis, Mentzas, Apostolou, & Georgolios, 2004). The task here consists of assisting sources and recipients to match their different interpretative contexts, translating meanings and values, and supporting the whole knowledge transfer process.

Knowledge Transfer Process

To better understand the role played by a knowledge mediator, we can refer to a representation of the knowledge transfer process (Hendriks & Vriens, 1999; Tuomi, 2000; Garavelli, Gorgoglione, & Scozzi, 2002). Figure 1 depicts the particular case of knowledge transferred through electronic communication. A piece of knowledge content must be first externalised (i.e., converted in the appropriate format, language, and data), transmitted, and then internalised (i.e., understood and assimilated by the receiver¾cf. Sharratt & Usoro, 2003). The success of this process requires: an "interpretative context" (or background) shared by the interconnecting partners; a mutual interest in transferring knowledge; and established "trust" (i.e., the parties should not doubt the quality of the knowledge transferred and its use). Such conditions can be better satisfied thanks to the action of a knowledge mediator, who can assist

Figure 1. The knowledge transfer process (adapted from Hendriks & Vriens, 1999)



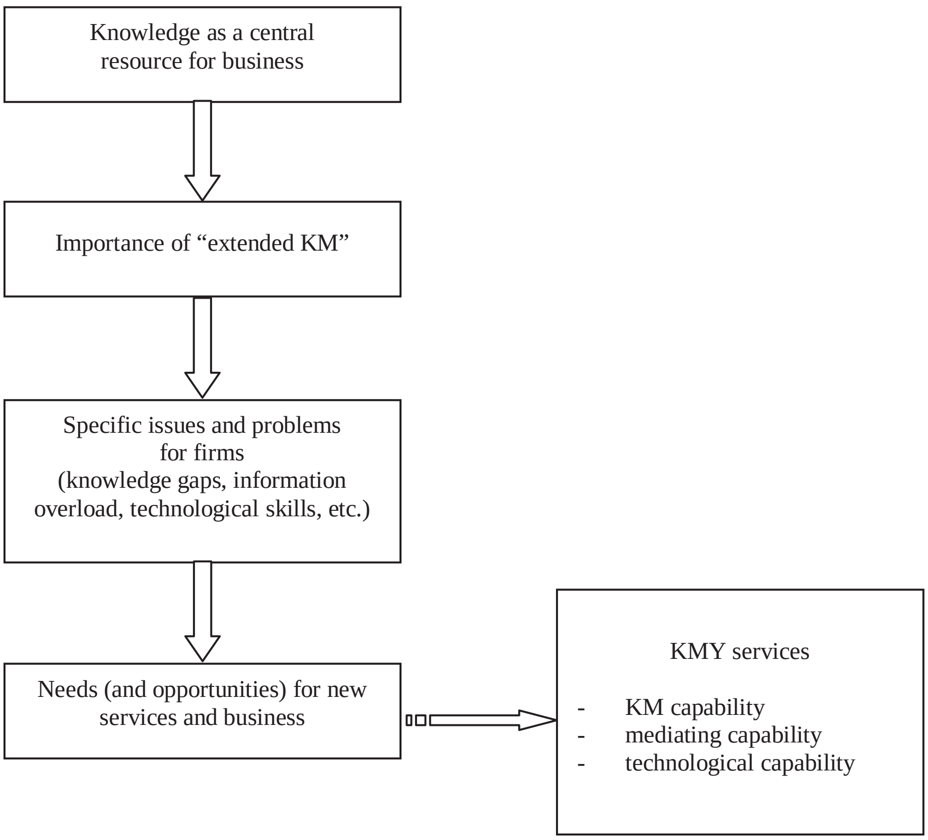
or perform the externalisation/internalisation processes and help generate trust. In addition, the mediator might deal with the development and management of the technical infrastructure that underpins the transfer process.

Conceptual Roots of KMY Services

The following points represent the conceptual roots of the kind of firms that we named KMY (Figure 2). To summarise, the recognition of knowledge as a core resource for business and the increasing resort to external competencies explains the growing importance ascribed to "extended" KM processes. However, since a single firm may encounter several problems in accessing external sources and managing knowledge relations, this may open opportunities for innovative intermediating services that combine different services and capabilities:

- solving knowledge-intensive problems and applying extended KM ("KM capability")
- acting as an interface between knowledge sources and users, thus favouring knowledge exchanges ("mediating capability")
- designing and/or using information and communication technologies as a fundamental support of its activities ("technological capability")

Figure 2. Conceptual roots of KMY services



The practical foundations of the services provided by a KMY can be associated to the following aspects:

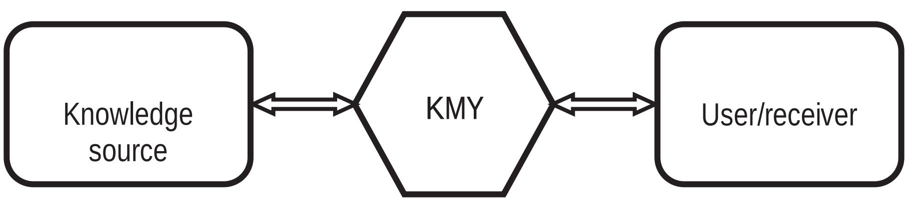
- a basic competence in managing knowledge transfer between firms/organisations, for example, to identify knowledge needs of the users, to research and select sources and knowledge contents, to perform processes of codification/de-codification, and so forth
- the capability of selecting the most adequate solution for settling a knowledge transaction in accordance to the specific circumstances of application (namely, nature of players involved, kind of knowledge exchanged, property rights, legal implications, payments, etc.)
- and, finally, the capability of using and integrating the technology into the KM processes

It is worth noting that such services can be provided by completely new startups but also by existing companies that can create departments specialising in KMY activities. Indeed, the focus of some existing companies (as in the case of consulting firms, or even media groups) is information or knowledge transfer. However, even in this case, the novelty is that KMY services represent the evolution and enrichment of traditional activities, thanks to the organic integration of KM competencies, mediating capabilities, and the advanced use of new technologies.

To specify in more detail the possible features of a KMY service, we outline a framework and propose a reference taxonomy, by considering a typical situation denoted by the presence of: the user (typically a business user: firm, professional, etc.); a source, that provides or sells knowledge (other firms, university departments, research centres, etc.); and a KMY. For this purpose, we also refer to a scheme of a knowledge transaction (Figure 3), that is, a situation where economic players exchange knowledge contents with one another, by means of KMY services. The notion of transaction is essential to analyse the economic value of knowledge exchanges used in business processes.

Similarly to other economic exchanges, a knowledge transaction implies the transfer of a kind of goods (i.e., knowledge) from a source to a receiver, and a flow of payments. Clearly, there are peculiar aspects that should be considered when knowledge is the object of economic exchange. While in a traditional transaction, it is the buyer that makes a payment in favour of the seller (and, in addition, the intermediation service is paid by one or both parts); in the case of a knowledge transaction, it may be less clear who pays for what. For instance, in some cases knowledge sources can be "free," and the user can be asked to pay for the intermediation service (e.g., the research

Figure 3. Knowledge transaction by means of KMY services



activity performed by the KMY). Another important issue regards pricing. Since knowledge is typically an experience good (i.e., its value can be estimated after acquisition and use), it is very difficult to establish a market price, and consequently the pricing of KMY services also is harder. Other special questions concern the property rights protection, namely the attempts to avoid opportunistic behaviour associated with the exchange of knowledge.

All things considered, our analytical framework consists of six dimensions.

a. Knowledge flows:
   - knowledge asked or researched by the users
   - knowledge delivered by the source (not necessarily on demand)
   - knowledge that represents an additional (and original) contribution of the KMY

b. Knowledge forms and contents:
   - tacit vs. explicit knowledge components: referring to the knowledge transfer process, the explicit component can be more easily "de-contextualised" and transferred in formal modes, while the tacit component is tightly connected to the interpretative framework shared by the parties involved in the transfer process
   - range and scope of knowledge, for example, multidisciplinary vs. specialised knowledge
   - object of knowledge, for example, know-about, know-how, know-why, know-who, know-with

c. KM process implied in delivering KMY services:
   - acquisition (identifying and cataloguing sources, analysing nature and formats of knowledge, etc.)
   - selection (choice of the specific knowledge contents to be transferred in relation to the specific uses)
   - internalisation (assistance to users in the assimilation of knowledge)
   - externalisation and distribution (assistance to sources in the delivery of knowledge)

d. Service structure and competencies needed:
   - organisational-managerial component: KM competencies (see point c), knowledge of the sector/market where the KMY operates, capability of managing interorganisational network relations, and intermediation skills
   - technical components: tools used to support interorganisational KM processes in an Internet environment, as well as the skills to select, configure, and use them

e. Management of knowledge transactions: When knowledge is the object of an economic exchange, the transaction raises specific questions in relation to the transfer, protection, and replication of the property rights. It also should be analysed what service of knowledge transfer is paid for. More generally, the issues involved are:
   - mechanisms used for the economic exchange (formats, times, contracts, etc.)
   - mechanisms used for payments
   - duration of the transactional relations (e.g., spot, repetitive, or project-based relation)

f. Model and structure of relations established by the KMY:
   - bilateral relations with a single user or source (i.e., KMY as a sort of "private consultant")
   - relations with multiple and indistinct sources and users, with players belong-

ing to a specific sector, value chain, or business community

EMPIRICAL INVESTIGATIONS

Despite their novelty, various examples of KMYs can be found in the business arena. Here, the features of some emergent categories or models are described, just as they were identified on the basis of an empirical exploration of the current experience in the field (see Bolisani, Di Biagi, & Scarso, 2003).

- Mediator: Its main role is to activate knowledge flows from sources to users. Examples include KMY services for professional consulting. The clients submit queries that are interpreted by the KMY, that also selects the appropriate professional, and takes care of the correct transmission of the answer as well as payment execution, and so forth. Other examples are human-based search engines, that is, services that provide assistance in information retrieval through the Net. In this case, users formulate complex queries interpreted by the KMY operators that also search on the Net and provide possible answers. Thus, the mediator model focuses on the management of "know-who" knowledge (i.e., knowledge of the possible sources and of their "quality" or reliability). Accordingly, the "reputation" that the KMY builds is crucial. Another key issue is the KM process of interpretation/de-contextualization of queries, which is vital especially considering that the entire relation occurs on the Internet with no face-to-face interactions.
- Facilitator: Its key function is to build appropriate environments for knowledge transfer, by identifying the optimal mechanisms or technology (i.e., a database, a document exchange, an online form, etc.), by processing codification/de-codification, and so on. A typical example is that of "job seeking" online services: The KMY performs a collection, selection, and presentation of job ads that are classified in a common format to facilitate retrieval. It is crucial for facilitators to have a "standard" process of collection, de-contextualization, and presentation of knowledge contents from heterogeneous sources to undifferentiated users. All this raises peculiar issues, such as the selection, explication, and standardisation of knowledge contents to be presented through a common interface (e.g., a Web portal). While knowledge coming from sources can be the "know-about" type, the added contribution of the KMY service is essentially a "know-with" component (i.e., how to connect different contents).
- Aggregator: This KMY service performs preliminary recognition and mapping of knowledge sources for a specific business community or market; knowledge contents are then made available to the users on demand. Examples are "vortal" (vertical portal) services, supplying market and technical information for specific business communities. The "aggregator" model refers to a common situation: a multiplicity of heterogeneous sources, and several potential users belonging to the same business community. The highly specific knowledge contents, which also can have heterogeneous formats, must be aggregated and collected for the community. The added service of the aggregator rests on the capability of selecting and reformulating contents that "may be" of interest for the users, which requires high competence of the business sector. In addition, the contents collected have to be

converted and proposed in the appropriate form.

- Manager: This is the most complex model of KMY, since it combines many of the services described. Examples can be the online services for virtual business communities, or for communities of practice. In this case, an Internet-based platform for "knowledge sharing" is provided to all the firms and professionals serviced. This sort of Web portal, reserved to registered users, is based on a "flexible" system for sharing all the documents and contents needed. Since the mediating role of the KMY and the business relations between the users are closely intertwined, the kind of knowledge that the KMY has to manage is highly specific, but at the same time requires extreme flexibility to manage exceptions and innovations.

CONCLUSION AND FUTURE TRENDS

The main point here is that the practical transition toward the knowledge economy implies the implementation of new businesses that combine the explicit management of knowledge with an advanced use of Internet-based technologies. To investigate such issue, we attempted to introduce new approaches to the analysis of online business models by integrating "classical" themes of e-commerce (i.e., the characteristics of online transactions and the role of intermediation) with the emerging discipline of KM. The definition of KMY is strictly functional to this purpose, and is used to analyse new businesses of online intermediation by considering their role in KM processes in an explicit and direct way. Clearly, one limitation is that the empirical evidence is still insufficient to draw a conclusion. Actually, any new study of emerging business models necessarily suffers from scarce empirical confirmations. In any case, our early findings (see Bolisani, Di Biagi, & Scarso, 2003) apparently show that the perspective adopted could be promising.

Although the approach proposed here has descriptive aims, the findings also can provide useful insights into practical managerial aspects of new business implementation. In particular, the classifications of business models previously discussed, and the evaluation of the specific opportunities and problems associated with each specific KMY feature, can be of use for the implementation of new services based explicitly on KM practices and Internet technologies.

Having said that, there is still work to do to transform the analysis into a more complete subject of research. In particular, the transactional nature of KMY services should be investigated more thoroughly, with direct reference of knowledge as the object of economic exchange. As regards managerial guidelines, an important issue concerns the practical implementation of an online strategy for a KMY service. There is especially the need to integrate a descriptive or analytical approach (that can be useful to make classifications or illustrate problems) to more normative prescriptions.

Chapter 4.18
An Investigation to an Enabling Role of Knowledge Management Between Learning Organization and Organizational Learning

Juin-Cherng Lu
Ming Chuan University, Taiwan

Chia-Wen Tsai
Ming Chuan University, Taiwan

ABSTRACT

This chapter is an exploratory investigation of the relationship and interaction between the learning organization and organizational learning in terms of an enabling role of knowledge management. In the severe and dynamic business environment, organizations should respond quickly to their rivals and environment by transforming into a learning organization. A learning organization could provoke innovation and learning through its structure, task and process redesigns, and evermore adapt gradually toward the eventual goal of organizational learning. Therefore, the dynamic process between the learning organization and organizational learning is an important issue of current knowledge management and practice — that is, the enabling role of knowledge management could enhance the interaction between learning organization and organizational learning. Furthermore, the authors will explore the relationship and interaction between the learning organization and organizational learning in terms of knowledge management processes in business. Two cases, TSMC and Winbond, the semiconductor and high-tech firms in Taiwan, will be studied to illustrate the findings and insights for the study and the chapter.

INTRODUCTION

Today a "Third Industrial Revolution" is under way; knowledge will replace land and a firm's resources as important asset (Thurow, 1999). Even Drucker (1993) argues that in the new economy, knowledge is not just another resource alongside the traditional factors of production — labor, capital and land — but is the only meaningful resource today. Tangible assets will be decreased or consumed because of use, but intangible assets — knowledge, information and technology will grow through sharing and application. In many industries, firms could sustain their competitive advantage if their abilities for learning and evolution are faster than their competitors. Thus, organizations should learn to survive in the fast-changing and intensely competitive environment, continually redesigning themselves into learning organizations (Daft, 1998).

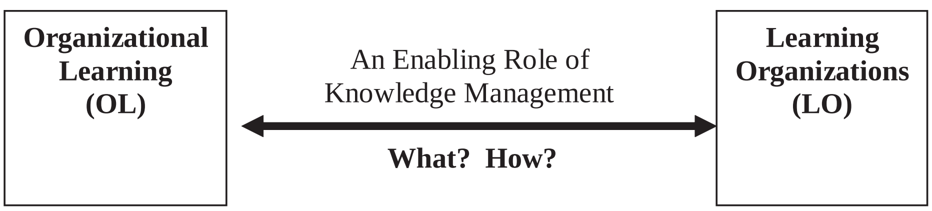
Knowledge is a limitless resource in the knowledge-based economy, therefore, organizations should learn, store, transfer and apply knowledge to add value or gain competitive advantage (Sveiby, 1997). Knowledge management refers to identifying and leveraging the collective knowledge within the organization to help in competing (von Krogh, 1998). But in a severe and dynamic environment, organizations should respond quickly to their rivals and their environment by transforming into a learning organization, an organic and flexible company, to foster knowledge flow and sharing among the departments and task groups. A learning organization could provoke innovation and learning through its structure, task and process redesigns, and adapt gradually toward the eventual goal of organizational learning. Therefore, the dynamic process between the learning organization and organizational learning is an important issue of current knowledge management and practice — that is, an enabling role of knowledge management could change the interaction between the learning organization and organizational learning. But what is and how does knowledge management play this enabling role? The research question can be depicted as shown in Figure 1.

This study will try to find the relationship and interaction between the learning organization and organizational learning in terms of an enabling role of knowledge management. We hope to provide some new insights for firms as they translate their organizations into learning organizations and implement knowledge management practices to provoke organizational learning.

LEARNING ORGANIZATION

Learning organizations can be described as places where people continually expand their capacities to create the results they truly desire,

Figure 1. The dynamic process and interaction between OL and LO



where expansive and new patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together (Senge, 1990). It also can be defined as one in which everyone is engaged in identifying and solving problems, enabling the organization to continuously experiment, change, and improve, thus increasing its capacity to grow, learn, and achieve its purpose (Daft & Marcic, 1998). Most definitions focus on the importance of acquiring, improving, and transferring knowledge, facilitating individual and collective learning, integrating and modifying behaviors and practices of the organization as a result of the learning (Appelbaum & Reichart, 1998; Ellinger, Ellinger, Yang, & Howton, 2002).

Learning organizations are also generally described as being market-oriented; having an entrepreneurial culture as well as a flexible, organic structure; and having facilitative leadership (Lundberg, 1995; Luthans, Rubach, & Marsnik, 1995; Slater & Narver, 1995; Watkins & Marsick, 1996). When the environment is complicated and dynamic, organizations need to create, validate and apply new knowledge into their products, processes and services for eventual value-adding (Bhatt, 2001). Learning organizations take action, reflect and adjust course as they seek to enhance the speed and effectiveness by which they learn how to change (Rowden, 2001).

A learning organization could facilitate the learning of all of its members and continuously transform itself (Hawkins, 1991; Pedler, Boydell, & Burgoyne, 1988). It also improves its knowledge and understanding of the environment over time by facilitating and making use of the learning of individual members (Galer & Kees, 1992). After all, Garvin (1993) argued that a learning organization is an organization skilled in creating, acquiring and transferring knowledge, and modifying its behavior to reflect new knowledge and insights.

ORGANIZATIONAL LEARNING

Nevis, DiBella and Gould (1995) defined organizational learning as the capacity or processes within an organization to maintain or improve performance based on experience. Organizational learning occurs when workers act as learning agents for the organization, responding to changes from the internal and external environments by detecting and correcting errors and embedding the results of their inquiries in private images and shared maps of the organization. Organizational learning is at the heart of continuous improvement today. While companies learn, the crucial and key point is to learn fast enough to sustain the competitive advantage (De Geus, 1988). How effectively an organization learns can dictate whether it will improve, and how fast, or if it is destined to lose ground to competitors who can and do learn (Lynn, 1998). The abilities to continuously learn, adapt and improve on its capabilities are all key elements to gain competitive advantage.

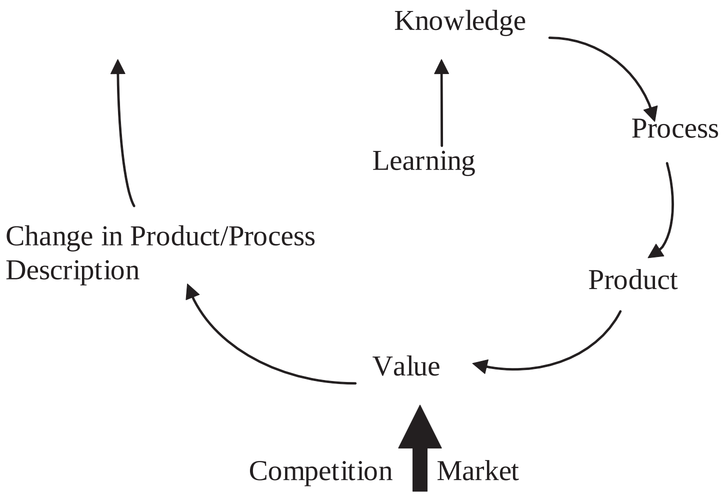
Continuous learning is essential for surviving in dynamic and competitive environments, but the key to gain competitive advantage is the method and speed of learning (De Geus, 1988; Garvin, 1993; Nonaka, 1991; Popper & Lipshitz, 2000; Senge, 1990; Lennon & Wollin, 2001). Argyris and Schon (1978) proposed three processes of organizational learning: (1) Single-loop learning: individuals respond to errors by modifying strategies and assumptions within constant organizational norms, (2) Double-loop learning: the response to detected error takes the form of joint inquiry into organizational norms themselves, so as to resolve their inconsistency and make the new norms more effectively realizable, (3) Deutero-learning: workers learn about previous contexts for learning, and reflect on and inquire into previous contexts for learning. They also reflect on and inquire into previous episodes of organizational learning or failure to learn. They discover what they did that facilitated or inhibited learning and then they invent new strategies for learning.

Kanevsk and Housel (1999) argued that corporate success largely rests on the ability to translate learning from these changes into knowledge that will result in new or modified products. Learning is a critical element ensuring that a corporation makes the necessary adjustments to the new market by continuing to produce valuable products. Hence, the organization must track the effectiveness with which corporations change learning into knowledge that is valuable to customers. A "Learning-Knowledge-Value Spiral" illustrates the process of transforming learning into value (Kanevsk & Housel, 1999), as shown in Figure 2. Any company has to understand that learning from the market must be translated into knowledge that can be applied to its production processes, resulting in changes to its product or service. This "learning to knowledge to new value" cycle must spiral upwards if any company is to flourish, not to mention to survive at all.

An organization can't create knowledge on its own without the initiative of the individual and the interaction that takes place within the group. But, having an insight or a hunch that is highly personal is of little value to the company unless the individual can convert it into explicit knowledge to be shared with others in the company (Nonaka & Takeuchi, 1995). In terms of the process of activity, organizational learning is the social process from individual, group, to the whole organization — that is, organizational learning begins with the individual to affect the groups or departments, and then extends to the organization (Dodgson, 1993). It is not organizational learning if it can't shape any force to affect the organization (Lu, 1996).

But what's the relationship between the learning organization and organizational learning? Organizational learning means activities or processes of learning in organizations, while a learning organization is an ideal form of organization that successfully practices all of these

Figure 2. A learning-knowledge-value spiral



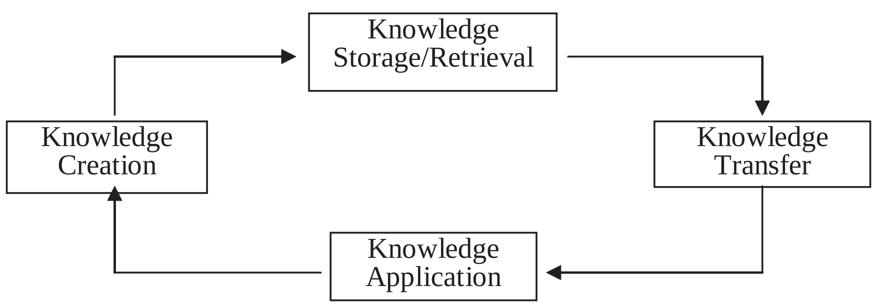
Source: Kanevsk and Housel (1999)

activities (Örtenblad, 2001). Popper and Lipshitz (2000) pointed out that learning organizations are organizations that have embedded institutionalized learning mechanisms into a learning culture. Marquardt (1996) notes that learning organizations focus on the "what" — the characteristics, principles, and systems of an organization that produces and learns collectively, while organizational learning refers to the "how" — the proficiencies and processes of knowledge development. Organizational learning is a concept used to describe certain types of activity that take place in an organization, and the learning organization refers to a particular type of organization in and of itself (Tsang, 1997; DiBella, 1995; Elkjaer, 1999; Finger & Bürgin Brand, 1999; Lundberg, 1995). DeBella and Nevis (1997) argued that a learning organization is a systems-level concept; it has been characterized as having the capability to adapt to changes in its environment and to respond to lessons of experience by altering organizational behavior. In contrast, organizational learning is a term used to describe certain types of activities or processes that may occur at any one of several levels of analysis or as part of an organizational change process. Thus it's something that takes place in all organizations, whereas the learning organization is a particular type or form of organization in and of itself. In summary, learning organizations focus on learning at the organization level, but an organization will learn when the organizational knowledge is out of date, incorrect, or insufficient, and then feedback the learning to the organization. Therefore, we could demonstrate that there exists an interactive relationship between the learning organization and organizational learning.

KNOWLEDGE MANAGEMENT AS AN ENABLING ROLE

Knowledge management is concerned with systematic, effective management and utilization of an organization's knowledge resources (Demarest, 1997). It consists of the creation, storage, arrangement, retrieval and distribution of an organization's knowledge (Demarest, 1997; Saffady, 2000). Alavi and Leidner (2001) classified the processes of knowledge management into four steps: knowledge creation, knowledge storage/retrieval, knowledge transfer and knowledge application, representing a detailed process view of organizational knowledge management with a focus on the role of Information Technology. This systematic framework is shown as Figure 3.

Figure 3. Four processes of knowledge management



Modified from Alavi and Leidner (2001)

Knowledge Creation

Organizational knowledge creation involves developing new content or replacing existing content within the organization's tacit and explicit knowledge (Pentland, 1995). In today's rapidly changing environment, organizations have to focus on the creation of knowledge to prevent existing knowledge from obsolescing quickly. When organizations innovate, they do not simply process information from the outside in, but solve existing problems and adapt to the dynamic environment. They actually create new knowledge and information, from the inside out, in order to redefine both problems and solutions and, in the process, to recreate their environment (Nonaka & Takeuchi, 1995). New knowledge is a necessary raw material for innovation and the creation of knowledge, both are closely tied to new products and services (Hauschild, Licht, & Stein, 2001). When a firm starts to develop new products or services, or when organizational knowledge is antiquated or insufficient, a firm could innovate and create new knowledge by organizational learning activities to face the challenges.

Knowledge Storage/Retrieval

While new knowledge is developed by individuals, organizations play a critical role in articulating and amplifying that knowledge (Nonaka, 1994). The storage, organization, and retrieval of organizational knowledge are referred to as organizational memory (Stein & Zwass, 1995; Malhotra, 2000). Organizational memory includes knowledge residing in various component forms, including structured information stored in electronic databases, written documentation, expert systems, documented organizational procedures and processes and tacit knowledge acquired by individuals and networks of individuals (Tan, Teo, Tan, & Wei, 1999).

The individual's knowledge is not equal to the organizational knowledge. The organizational knowledge is of company-level and it should be identified or shared by the members and correlated to a knowledge system (Lu, 1996). Hence, to translate to a learning organization that is full of knowledge, there should be a mechanism and system to store the knowledge for the further application. The strategy for knowledge management should reflect the firm's competitive strategy: how it creates value for customers, how that value supports a business model, and how the organization's people deliver on the value. Two strategies are being used for storing knowledge (Hansen, Nohria, & Tierney, 1999):

1. Codification: Provide high-quality, reliable, and fast information-systems implementation by reusing codified knowledge;
2. Personalization: Provide creative, analytically rigorous advice on high-level strategic problems by channeling individual expertise.

Knowledge Transfer

The distribution and transfer of knowledge is an important process in knowledge management (Alavi & Leidner, 2001; Huber, 1991). Knowledge should be shared and generalized within the organization. In addition, generalization occurs not only when single ideas are moved, but also when the entire process of moving ideas becomes institutionalized within an organization (Yeung, Ulrich, Nason, & von Glinow, 1999). The institutional process embedded in a firm and the capability of generalizing ideas consistently are important elements to meet the real goal of knowledge management.

Organizations should provide several ways and mechanisms to transfer and distribute knowledge to ensure unrestricted transferring. For example, knowledge that is more or less explicit can be embedded in procedures or represented in documents and databases and then transferred accurately. But, transfer of tacit knowledge generally requires extensive personal contacts (Davenport & Prusak, 1998). Hung (2001) found that two approaches facilitate the efficiency of knowledge transfer among employees:

1. Systematic mechanism: refers to the centralized management that stores the knowledge in the institutional systems built upon information and network technology and disseminating the knowledge through the network.
2. Socialized mechanism: refers to an extensive notion, including many heterogenous ways of social interaction, such as the learning community, virtual community, yellow page (of specialists), institutional community, knowledge intermediary within a company, and a speech or conference outside a company.

Knowledge Application

Knowledge application means making knowledge more active and relevant for firms in creating value, since organizational knowledge needs to be employed into a company's products, processes and services (Bhatt, 2001; Demarest, 1997). The source of competitive advantage resides in the application of the knowledge rather than in the knowledge itself (Alavi & Leidner, 2001). Using knowledge more powerfully than your competitors is a key to battling it out in the global information era (Prokesch, 1997). Employees use all available resources, including the corporate knowledge base, to improve their chances of reaching the goals of the organization (Hauschild et al., 2001). Learning from the experience of others and reusing materials that have been effective elsewhere improves the quality and speed of problem solving (Cross & Baird, 2000). Knowledge should be really used to create value for the company and when it is applied, the company can judge the validity and suitability. Knowledge application is essential when the organization transforms into a learning organization and helps the organization to retain correct and valuable knowledge.

RESEARCH METHOD

Case Selection and Data Collection

This case study is applied to illustrate how high-tech firms implement knowledge management practices to transform themselves into learning organizations. The case selection is very important in this study and should be guided by principles (Yin, 1994). Kofman and Senge (1995) suggested that a learning organization should be grounded in three foundations: a culture based on transcendent human values of love, wonder, humility and compassion; a set of practices for generative conversation and coordinated action; and finally, a capacity to see and work with the flow of life as a system. Two cases, Taiwan Semiconductor Manufacturing Corporation (TSMC) and Winbond, have been selected, because of their reputation for their knowledge management practices, to illustrate the different enabling roles of knowledge management in the interaction between learning organizations and organizational learning. TSMC is the world's largest and most successful dedicated independent semiconductor foundry. Winbond is the largest integrated circuit (IC) supplier in Taiwan's IC industry. In addition, the Chief Knowledge Officer (CKO) of the firms promises to provide case interviews. Also, case data collection from multiple evidence resources, company profiles and internal documents is to control the construct validity of the study, and the chain of evidence is found to keep track of the processes of implementing knowledge management in TSMC and Winbond. Besides, data and content from the firm's web site and knowledge portal is collected and analyzed systematically.

Case Illustration: TSMC and Winbond

TSMC: Company Overview

TSMC, founded in 1987 and located in the Hsin-Chu Science-Based Industrial Park of Taiwan, is listed on the New York Stock Exchange (TSM). As the first "pure play" foundry company, TSMC has experienced strong growth by being a true partner with its customers by designing and manufacturing IC products for them. The evolution of advanced IC technology over the past decade has been so rapid that it has changed the ways that companies do business. Demands for faster time-to-market and design cycle have increased, as well as demands for higher speed and product quality. These are some reasons companies around the world turn to TSMC as their manufacturing partner. TSMC puts more resources into its manufacturing facilities and capacity than nearly anyone else. It continues to be the trusted source for a global collection of innovative and savvy businesses, large and small, who appreciate their steadily increasing manufacturing capacity and consistent volume production levels. TSMC enhances its ability to serve its customers by operating, expanding and developing many new facilities as we enter into the new decade:

- Nine 8-inch wafer Fabs in full operation (Fabs 3, 4, 5, 6, 7A, 7B, 8A, 8B, plus WaferTech).
- One 8-inch wafer Fab facility through our TSMC affiliate-Vanguard International Semiconductor Corporation.
- Ground-breaking for the company's two initial 12-inch wafer fabs took place in late 1999 in Hsin-Chu Science-based Park and Tainan Science-based Industrial Park.
- A joint venture with Philips Semiconductor and with Singapore's EDB Investments (SSMC) will also bring increased capacity in the coming years.

TSMC: Knowledge Management Practices

1. Knowledge Creation: TSMC maintains a stable relationship with their customers, has extended their production, innovated their service in eFoundry via the Internet, owns the most advanced process technologies and leads the market. One of the main reasons for its growth is the investment in the innovation of production technologies and the development of value innovation ability that enables TSMC to be the leader. To be more competitive, TSMC has concentrated its attention on the modification and the coordination of various technologies to decrease production costs, reduce its defect rate, cut down the product cycle time, and improve productivity (Hung, 2001). TSMC is not only devoted to technical innovation but also to the innovation of customer service. Morris Chang, the TSMC chairman, announced that TSMC is a customer-oriented service business and he stressed the importance of service innovation. In July 2000, TSMC proposed the idea of eFoundry that allows their customers to be served via the Internet. The vision of eFoundry is to offer the best services for customers; that they can gain benefits from eFoundry without paying a lot for establishment and management. TSMC offers customers a highly integrated supply chain management system with reliability, security, speed and transparency through strategic use of Information Technology. This innovative strategy has enabled TSMC to maintain its superior position and more competitive edge. TSMC continues to boost its learning capabilities and create new knowledge, such that its organizational

learning occurs not necessarily because of the shortage of knowledge, but out of the desire to maintain its superior market position. As we found, knowledge creation plays a key role as TSMC engages in organizational learning.

2. Knowledge Storage/Retrieval: Dr. Tsai, the President and Chief Operating Officer, drives the knowledge management activities in TSMC and founded eight technical boards that are categorized according to the processes in the semiconductor industry. The workers have to join relevant technical boards to share information and knowledge. The manager of IC Design, Dr. Kao, indicates that TSMC should translate the records of the best machines, equipment and technical processes into know-how that can be shared, and then transfer that knowledge to the new foundry. He said that, "The best knowledge of building foundries in the world was filed in our technical board." Any employee in any foundry can share best techniques and knowledge with others on the technical board. The technical board checks and reviews records in which the experience of work will be encoded, stored and shared. As the evidence shows, TSMC pays much attention to knowledge storage and retrieval.
3. Knowledge Transfer: TSMC promotes two approaches for knowledge transfer (Hung, 2001): (a) Sharing: The experiences of engineers are codified and stored in the knowledge system. As the production process can be scientifically measured, it's easy to translate processes into explicit knowledge and to accumulate it. Besides the technical knowledge, information about decision-making is also stored in the Documentation Center after review by the managers. Then, that information can be shared and referred to by the relevant workers. (b) Collaboration: TSMC builds communities among the departments to help the knowledge demander track the knowledge provider and ask for support. This is a social mechanism in which all workers can seek support from those experienced workers through the TSMC Yellow Pages. The effect of knowledge transfer in such a dynamic sharing mechanism is better than the static knowledge system. Through the combination of an active knowledge network and static knowledge system, working knowledge is shared continuously. Sharing and collaboration improve the knowledge transfer in TSMC and help to create more new knowledge. It also enables the positive cycle of knowledge creation, storage and transfer.
4. Knowledge Application: TSMC's employees are urged to apply knowledge to their work and benefit from doing so. Owing to efficient knowledge management, TSMC grew rapidly in the past 12 years and there are five new factories still in the process of construction. Moreover, factories in Singapore and Boston are now in the planning stage. As for process technology, TSMC developed 0.18 micron logic, copper process technology and the embedded process technology applied in sys-on-a-chip. TSMC provides support to the process technology and design of semiconductor to satisfy customers' needs. The primary process technology is 0.35 micron, but it will increase that technology from 0.25 micron to the advanced 0.18 micron at the same time that it goes into mass production. Now, TMSC has also started to test 0.15 micron and plans 0.13 micron process technology for mass production on its schedule. The advanced process technologies significantly cut down the production costs, so that TSMC has made more profit and gains competitive advantage in the world.

The ability of continuous improvement, learning and innovation leads to high efficiency in integrating and coordinating the varied process technologies, and reduces the production cost, while achieving high product quality, low defect rate and short cycle time. The main reason for TSMC superiority is its concentration on technological evolution and innovation of new knowledge and process technology. In addition, TSMC provides the standard circuit component-base and intellectual property (IP) for customers to strengthen their design service abilities.

Winbond: Company Overview

Winbond Electronics Corporation, established in 1987 in the Hsinchu Science-based Industrial Park, Taiwan, is the largest brand name IC supplier in search of excellence in process technology, worldwide marketing networks and wafer processing. After 14 years of growth and accumulation of bountiful assets in products and technologies, Winbond has started to design, develop and market its own products under its brand name and aims at a broad range of product lines to meet the demands of the information industry and satisfy customers' needs. The products include PC and peripheral ICs, micro-based consumer ICs, Network Access ICs, Memory ICs, etc. Winbond, on the average, invests more than 10% of annual revenues into R&D and has built on its extensive technical knowledge and technological experiences. For the past few years, Winbond investment in R&D has yielded substantial growth in technology and helped it to forge strategic alliances, combining R&D with leading global companies. R&D centers have been set up in China and the United States, both tasked with aggressively absorbing new market trends. Winbond's depth in design IP, combined with skilled production capability, allows the company to effectively leverage its efforts to a number of growing markets.

Winbond: Knowledge Management Practices

1. Knowledge Creation: Since 1991, Winbond has been honored by receiving the R&D Investment Award from the Hsinchu Science-Based Park. The company has a long history of knowledge management and patent production worldwide—already surpassing 1,000 patents. In 1998, the company made the top 300 American Patents list. In 1999, Winbond became the winner of the Gold Medal of National Invention by the Bureau of IP, the Ministry of Economic Affairs. Winbond has been named "Outstanding Electronics Component Supplier" for two years in a row and was also selected as the best performing manufacturing company in Taiwan. Dr. Tauso, the manager of knowledge management, implied that the company does emphasize the storage, transfer and application of knowledge rather than the creation of knowledge. But it does not mean that Winbond ignores the importance of knowledge creation. In fact, Winbond is checking and counting its intangible assets first and foremost. As the knowledge is refined, shared and applied, if the knowledge is incorrect, out of date, or not suitable for use, it might force the company to engage in another wave of organizational learning based on the knowledge creation.
2. Knowledge Storage/Retrieval: With the speedy change in the electronics industry, Winbond tends to collect and check the knowledge, then store it in Winbond's knowledge bank after the investigation and refinement by the technical board. To make the knowledge more accessible to workers, Winbond uploads it to the Intranet, so that workers may obtain the knowledge and experience online easily. As the invention of IC is highly specialized in varied

fields of knowledge, the invention of new products design needs clear standard interfaces and technical definitions within the IC framework. Hence, it's easy to transfer an individual's knowledge to codified knowledge, and accumulate it systematically. This crucial knowledge is standardized and stored in Winbond's knowledge systems for those who would request it.

The knowledge systems comprise patents databases, learning materials and technical information, etc. Technical information is subdivided into debug/design reports, IP code and IP Map. Furthermore, to prevent knowledge from being stolen, there is a security mechanism. Some IP and debug/design contents are designed to be online training courses to reduce the training time for newcomers. Most patent information is classified into company patent and market patent information provided for administrators and executives to reference when making decisions. The evidence shows that Winbond pays much attention to knowledge storage/retrieval.

3. Knowledge Transfer: Winbond's technical information and learning materials are explicit knowledge for workers to obtain knowledge and peers' experience through the Intranet immediately. Moreover, senior engineers' experiences can be also transferred to the new employees through IP Map or Yellow Pages, when they are vague about the knowledge or going to check it out. The knowledge department plays the role of mediating for workers to search for the knowledge source. As to knowledge that is unclear or value undefined, Winbond provides an online forum to facilitate sharing that implicit knowledge. This online forum is divided into two kinds — public and nonpublic with some confidential issues reserved for qualified members only. The main purpose of the Knowledge Management Center is to increase the volume and value of organizational knowledge and to spread knowledge throughout the firm. As the knowledge management practices in Winbond imply, it plays a significant role in knowledge storage/retrieval and knowledge transfer.
4. Knowledge Application: Winbond set up the Knowledge Management Center to advance product technology and improve the performance of service innovation on its core competence by applying the knowledge. But during transformation to a learning organization, Winbond emphasizes more of the practice of knowledge application to gain competitive advantage in the IC battle. According to the statistics in the Knowledge Management Center, most engineers encountered similar problems in their work before, but now engineers need not waste time in solving the same problems or recommitting the same errors due to the functions of the center, which has reduced their products' defect rate to 2~3% and cut the cycle time down to 75%. The evidence implies that Winbond takes advantage of organizational knowledge to improve the quality of products, lower defect rate and decrease cycle time of production, and utilizes organizational knowledge to lead the firm.

Case Reasoning and Discussion

TSMC's technology innovation is the wellspring of its growth and is vital to all sectors from strategic planning to management of technology and production. TSMC regards employees and shareholders as important constituents and its goal is to provide better salary and benefit packages for employees. TSMC has implemented an open-style management system designed to keep all lines of communication free in the working environment, and employees are instructed to treat each other sincerely, honestly and cooperatively.

Winbond's human resource is an important asset for company to go from strengths to high quality. It provides suitable working conditions, munificent salaries and bonuses for its employees. In addition, Winbond provides 1,200 training programs and more than 20 Web-based training courses for employees to pursue further upgrades and learning. The continuous-learning culture in Winbond has been established and, furthermore, it also set up many channels (like IP Map, Expert Yellow Pages) for workers to solve their problems or seek help based on the Knowledge Portal.

TSMC and Winbond, famous high-tech companies in the world, put knowledge management into practice and the way they learn, providing many consultations and references due to making efforts to transform into learning organizations. Such dynamic interaction between the learning organization and organizational learning is an important issue for the academic and in practice. This study would provide practical implications and insights for business and research.

Insights from Case Study

With the stiff global competition, high-tech companies face the challenge of shorter product life cycles, the rapid depreciation of tangible assets and the transience of employees. It is essential for firms to put knowledge management into practice positively and actively. Based on the literature and

Table 1. The comparison of case studies: TSMC vs. Winbond

Item comparison	*TSMC*	*Winbond*
Industry	"pure" foundry company	IC design and manufacturing
Enabling role of KM (Knowledge Management)	Focus more on knowledge creation, comparatively (on knowledge innovation)	Focus more on knowledge storage/retrieval, comparatively (on knowledge checking)
Organizational type toward KM	Foster the organizational learning aggressively	Foster move toward a learning organization gradually
KM Mechanism	8 Technical boards; Sharing and Collaboration	KM department and KM Center / IP code and IP map
The KM Agent	The President (Dr. Tsai)	The KM Manager (Dr. Tauso)
KM Strategy	Facilitate faster design cycle, time-to-market and the high quality of product/service	Facilitate checking and counting the intangible asset of IC know- ledge by refinements
Key success factor (KSF)	Technology innovation based on knowledge innovation	Knowledge refinements based on knowledge storage/retrieval
Competitive Advantage via KM practices	Toward customer-oriented service business via the eFoundry with advanced process technologies	Low defect rate and short cycle time to cut down IC product cost. Reduce training cost and keep experience value-added

cases studies of TSMC and Winbond, the authors offer the following insights for managers or readers seeking to develop the enabling role of knowledge management in their companies. Table 1 shows the comparison of the case studies in terms of an enabling role of knowledge management and the organization.

Insight 1. There exists empirically an interactive and recurring relationship between the learning organization and organizational learning. The former is an organization that fills with knowledge and embeds an institutionalized learning mechanism into the learning culture. This type of organization will continue learning to create new knowledge to gain or sustain its competitive advantage. The learning results and accumulated knowledge will modify the organization itself. This feedback continuously transforms the learning organization.

Insight 2. When organizations transform to learning organizations, the processes of knowledge storage/retrieval, transfer and application play more important roles in the knowledge management process because knowledge must be stored in the organization, and then transferred to people who need to apply that knowledge in productivity. Gradually, as learning organizations continue learning, knowledge creation becomes more important than other factors in the process of knowledge management. This is an interaction between organizational learning, with emphasis on knowledge creation, and the learning organization, with emphasis on knowledge storage/retrieval, transfer and application, in terms of an enabling role of knowledge management.

Insight 3. The strategies for knowledge management and practices differ because of different implementation stages or the nature of the company. For example, Winbond doesn't focus mainly on creating knowledge but on checking and reviewing the existent intangible assets; while TSMC does make much effort to create more technology knowledge in order to safeguard its leading advantage in the world.

Knowledge management for firms should refer to the source of competitive advantage or "dynamic capabilities," emphasizing the dynamic character of the environment and capabilities of appropriately adapting, integrating and reconfiguring internal and external organizational skills, resources and competencies. This study suggests that the competitive advantage of firms lies in their managerial and organizational processes, where processes include the routines and patterns of current practice, learning, the endowments of technology and intellectual property. As the cases show, TSMC and Winbond's timely response and rapid development of product innovation, coupled with the enabling role of knowledge management to effectively coordinate and redeploy internal and external competences of knowledge-based innovation, requires careful analysis of various kinds of knowledge. The results indicate there is an interactive relationship between the learning organization and organizational learning. Organizational learning emphasizes mainly knowledge creation, but the learning organization mainly emphasizes knowledge storage/retrieval, transfer and application, in terms of the enabling role of knowledge management. Therefore, firms should transform themselves into learning organizations to foster organizational learning by implementing knowledge management practices in order to gain or sustain a competitive advantage in the knowledge-based economy.

CONCLUSION AND SUGGESTION

This chapter depicts the relationship and interaction between the learning organization and organizational learning in terms of the enabling role of knowledge management in business, However, the result of this case study is difficult to infer from two cases and the generalization of the findings is limited to these contexts (Yin, 1994). But two cases, TSMC and Winbond, are studied to suggest that the enabling role of knowledge management plays the dynamic relationship between the two constructs — the learning organization and organizational learning. Future research may apply the quantitative methods to study the solid relationships between the learning organization and knowledge management, and organizational learning and knowledge management, respectively.

The practical implication of the chapter would be helpful to certain high-tech industries. For example, an enabling role of knowledge management could provoke the emphases on the importance of knowledge creation for the turbulent environment; otherwise, on the importance of knowledge storage/retrieval, transfer and application for the static environment. Firms would define their organizational status and starting point to foster implementation of knowledge management practice based on their goals. Therefore, the interchange transformation of organizational learning and the learning organization should be dynamic adaptation systematically.

Chapter 4.19
Integrating Knowledge, Performance, and Learning Systems

Scott P. Schaffer
Purdue University, USA

Ian Douglas
Florida State University, USA

INTRODUCTION AND BACKGROUND

Considerable effort has been devoted recently to development of systems or platforms that manage the learning, performance, or knowledge delivered to students and employees. These systems are generically labeled learning management systems (LMS), learning and content management systems (LCMS), performance support systems, and knowledge management systems (Rockley, 2002). Organizations increasingly use content management systems to deliver content objects to employees on a just-in-time basis to support knowledge and performance requirements (Rosenberg, 1999).

While systems are developed that efficiently manage learning, knowledge, or performance, it seems desirable to consider how integration of each of these areas into a single system would benefit organizations. A major challenge to developing such systems has been the degree to which they are interoperable and the components within each are reusable. Reuse of data or information for learning or performance solution development is considered the primary driving force behind the movement toward object-based architectures for such systems (Douglas & Schaffer, 2002; Schaffer & Douglas, 2004).

Ideas for integrating different sources of support for individuals and making its construction more cost effective have begun to take shape. Some efforts have focused on reusable and interchangeable (between different delivery systems) content objects, such as the U.S. Department of Defense Advanced Distributed Learning initiative (http://www.adlnet. org). A big challenge in development of support is the lack of a pedagogical model that takes advantage of object-based architectures while promoting collaboration and knowledge capture and sharing. A significant move in this direction has been outlined by Collis and Strjker (2003) who view the learner as a contributor of knowledge that may be captured and stored for reuse by future learners or course designers. An expansion of this idea, focused on in this article, is the reuse of the contributions of various members of a design and development team. This includes artifacts, decisions, and rationales related to activities such as the analysis of needs, identification of metrics, and identification of causes and possible solutions to workplace problems. This approach essentially attempts to link the analysis and design processes related to initial development of solutions with the ongoing adaptation and evaluation of the solutions in practice.

MOVING FROM E-LEARNING TO E-PERFORMANCE DEVELOPMENT

Advances in technology have made integration of various types of information for the purpose of just-in-time learning and performance development more viable (Greenberg & Dickelman, 2000). The Internet and World Wide Web, along with various authoring tools, have facilitated development of digital materials that are easily accessible by learners and performers. The technology that has lagged is the pedagogy and design thinking and strategies required to make all of this digital information reusable and targeted toward adding value (Clark & Meyer, 2002). Structured training or learning experiences do not always translate into better performance, and, given the fast changing nature of modern organizations, workers need to access critical and specific knowledge and performance support exactly when they need it. The traditional training approach relies on acquisition of knowledge in the hope that it will be useful and be remembered when needed. Unfortunately, much of this knowledge acquisition is explicit and context-specific and does not often transfer well to problem-solving situations (Smith, 2002).

Software development has for a number of years progressed toward embedding knowledge acquisition in context rather than rely up-front on training courses. This is evident through context-sensitive help, task-oriented help, task automation, and task wizards. For example, an LMS will often support a particular task such as entering a new course or adding new students to a course. Furthermore, content management systems are becoming object-based and will allow learners and designers to actively "pull" learning content on an as-needed basis. The development of tools to support the selection of content and to guide this kind of designing "on-the-fly" is also on the rise, as the new wave of user support tools are designed with an object-oriented architecture in mind (Spector, 2001).

Integrating knowledge, performance, and learning within a single system requires thinking of both the whole and the parts. The learners and performers who use the system will interact with an interface that is integrative and allows them to filter and select information most important to them (Gery, 1991). The kinds of information made more readily available to a particular user should be determined by their job role, function, performance objective, and organizational goal. Visual modeling tools are proposed as one way to aid in such integration during problem analysis. Such tools may allow collaborators to construct system models that identify key requirements and subsystems. The veracity of the models is tested as collaborators with multiple perspectives on the system provide feedback and revisions to the model. Subsequent KPL solutions developed from these models would thus more accurately reflect actual workplace situations, constraints, resources, and interactions.

An integrated KPL system would support learners and performers as they (1) access and construct knowledge; (2) perform a specific task; and (3) learn about a topic or objective. Such a system may take many forms. A knowledge management system may essentially be a digital library of artifacts such as manuals, guides, and company records that are stored in a database for retrieval on an as-needed basis. More recently, such systems support collaboration that builds and promotes sharing of knowledge across learners, roles, or organizations through the use of tools such as discussion forums and online white boards (Greenberg & Dickelman, 2000; Shadbolt & Wielenga, 1990).

Performance support systems are typically role or job related and guide performers as they perform specific tasks. An example of performance support could be an electronic job aid with procedures for calibrating a monitoring device in a chemical facility. These kinds of systems purport to offer users a greater level of simplicity and efficiency as they seek to manage courseware, knowledge, and performers. Blended solutions incorporating online knowledge building and learning activities, workplace performance support, and face-to-face classroom learning experiences are powerful examples of how knowledge, performance, and learning integration can be accomplished in a collaborative manner. Collis, Waring, and Nicholson (2004) describe a project at Shell in which workers collaborate online in preparation for classroom activities. Collaboration is supported by a LCMS where contributions are stored in a repository and may be accessed by other learners or by facilitators for classroom use. Participants learn at their own workplace and are able to improve individual and organizational performance as a result of online participation in discussions with other Shell employees across the world.

OBJECTS AND THE CONTENT REPOSITORY

Object thinking, dividing knowledge into discrete granular chunks, represents the next step in the progression toward increasing reuse potential within a KPL system. Object thinking should not be constrained to end products, for example, learning objects used in courses; it also applies to analysis and design knowledge (Due, 2002). By integrating object thinking into analysis, a higher level of reusability as well as adaptability, interoperability, and durability may be achieved (Schaffer & Douglas, 2004). An object approach with a results focus (i.e., each object relates to a specific result required on a job) applied throughout the development process can make it easier to obtain, develop, and implement the solutions to organizational problems or opportunities.

What is an Object?

Gibbons, Nelson, and Richards (2002) refer to a learning object, educational object, knowledge object, intelligent object, or data object as an instructional object. However, since the focus of this framework is problem solving, any learning, performance, knowledge, or instructional object is referred to as a sharable content object (SCO), taken directly from SCORM (n.d.) version 1.2.

The SCORM defines an SCO as "a set of representations of media, text, images, sounds, web pages, assessments objects, or other pieces of data that can be delivered to a Web client" (SCORM, n.d.). A single representation, according to SCORM 1.2, is called an asset. A single asset is unusable in an educational/performance setting, but by conjoining these assets, a shareable content object is created. A set of shareable content objects is referred to as content aggregation. Content aggregation consists of "a map (content structure) that can be used to aggregate learning resources into a cohesive unit of instruction, to apply structure, and to associate learning taxonomies" (SCORM, n.d.).

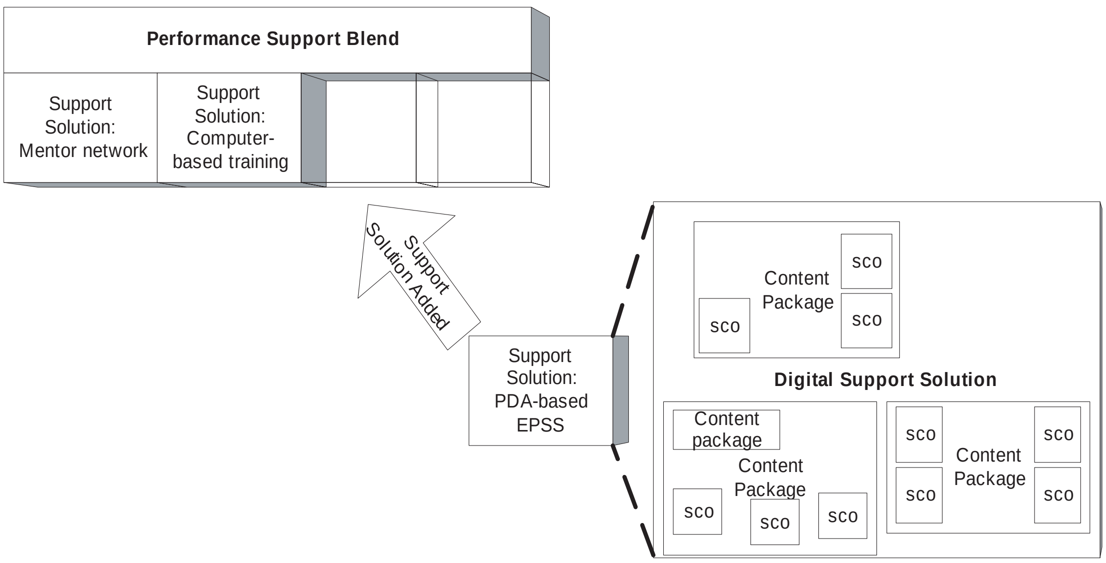
For an object to be SCORM compliant, it must meet specific criteria. Any object developed for performance/instructional purposes must be accessible, interoperable, durable, and reusable. "Without them [the criteria], anyone with a significant investment in either content or a learning system is locked in to that particular content or system" (Robson, 2001).

To ensure that the criteria exist within an object, metadata is tagged to each asset, SCO, and/or content aggregate. Metadata is tagged to an asset, SCO, and content aggregate to ensure that during the process of content creation, the information within each is reusable as well as discoverable. By integrating

The basic asset level is combined into SCOs, the SCOs into packages, and the packages into digital support solutions. Currently, the thinking around SCOs and packages is for them to be delivered in traditional training courses accessed through an LMS or documents accessed through a content or knowledge management system. In a KPL system, the idea is to have all digital support blended together and organized by the particular performance goals people have to achieve in their employment.

Figure 1 illustrates the manner in which SCO's may be packaged to create customized performance support solution packages. In the example shown, a personal digital assistant-based (PDA) support system is developed and slotted together with other solutions available to support a particular role. Examples of other support solutions shown in Figure 1 include a mentor network, which provides a collaborative community for support and knowledge development in a particular performance role, and computer-based training which is specific, structured instructional activities. These are just some of the many possible forms of support that could be developed to support a particular performance role.

Figure 1. Example of performance support solution blend



Why are Important Objects Within the Framework?

The reasons for using objects are simple: they enhance the resulting solution package by defining the separate components of problem-solving knowledge, provide methods for standardization, and offer potential economic advantages through reuse.

There has been a growing emphasis on objects within the fields of instructional design and performance technology. Peters (1995) states:

objects enabled by [an] emergent artifact of digital libraries will be much more like 'experiences' than they will be like 'things,' much more like 'programs' than 'documents,' and readers will have unique experiences with these objects in an even more profound way than is already the case with books, periodicals, etc.

This statement leads Gibbons, Nelson, and Richards (2002) to suggest the need for "model components that can be brought together in various combinations to create the environments and systems" to represent a variety of problems. A contribution-oriented approach to using artifacts and objects to represent problems supported by visual modeling tools goes a long way toward experiencing problems as opposed to simply categorizing and storing them. Furthermore, a comprehensive framework combining an analysis, design, and object orientation in a sequential process would allow such problem representation. Collaborative approaches to the development of objects enable the users/learners to continually reflect upon and evaluate the usefulness of objects. Repositories of analysis and design knowledge provide analysis and design teams with support throughout their respective processes. A content object repository has the potential to provide learner-designers with solution packages that match the recommended solutions identified during analysis. The representation of problems as a result of collaborative and systematic analysis ensures that resulting objects created through design and development processes may be evaluated following use.

Repositories

The purpose of repositories is to support problem solvers, designers, or learners by providing a centralized location for the storage and reuse of standard artifacts and objects. An artifact generally refers to any template, documentation, data, visual model, or component of a visual model that can be accessed and used during any phase of an analysis and design process, for example. We envision that interlinked artifacts will exist for various levels of performance (organizational, process, and individual). For example, an object could contain specifications for the support requirements of a specific task, which will enable early identification of content objects that may be useful in the construction of customized solutions related to performance of that task.

The purpose of a repository is to allow creation of an easier, adaptable, and reusable analysis, design, and development process. This process would also support the collaborative development of organizational problem-solving capacity and ultimately link to the identification of solutions. Creating a common standard for artifacts and objects will enable the sharing of information about common performance problems or opportunities across different organizations. Tools such as groupware and visual modelers support teams as they create shareable objects. As contributions to a repository are reused, they may also be evaluated, revised, or replaced depending on utility and perceived value by members of the community.

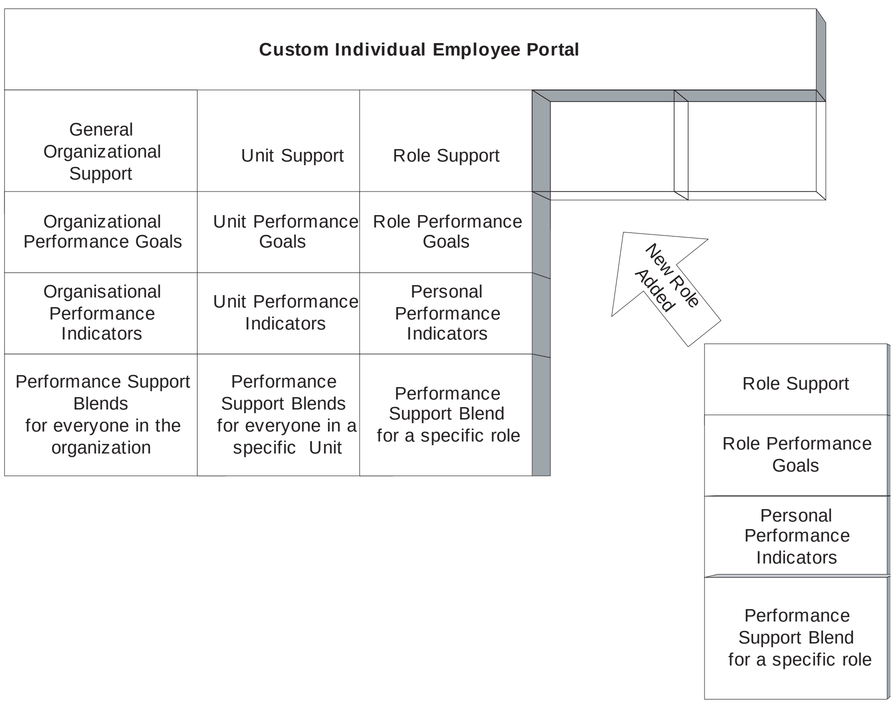
SYSTEM DEVELOPMENT

In system and object development, there are two parallel tasks. Initially, at the systems level for each solution selected, design teams must decompose the system into subsystems (e.g., a course unit in the case of a training system), distribute the objects to the subsystems, and create the packaging and sequencing structure to bind the objects together. Second, for those analysis objects not matched against pre-existing objects, teams must design and develop content, package it into a SCORM compliant object, and submit a copy to the repository. Figure 2 illustrates how these packages and sequencing structures might be bound to create support solutions.

Decomposing the system into subsystems is critical if aligning the results of KPL systems across individual, functional, and organizational levels is desired. For example, in Figure 2, a custom individual employee (student) portal is modeled that illustrates the emphasis on roles that a problem solver in an organization would play rather than using the traditional job title to identify required performance. Roles often cut across traditional job title designations and may be performed by many different employees. Consider the many roles related to a formal title such as manager. Roles often include budgeting, staffing, developing people, proposing projects, and so on. These roles may be performed by many other employees in various job titles across an organization in much the same way.

Organizations that are continuously developing their capacity to solve problems, that is, learning organizations, are able to store and share relevant knowledge, performance, and learning support related to each of these roles. Figure 2 illustrates how goals, indicators of success in achieving goals, and related support are aligned across the organization, unit (department, function), and individual levels. A new role is shown as it is added to a particular employee's portal. This employee has likely assumed this role as part

Figure 2. A model for the services provided by a performance support portal



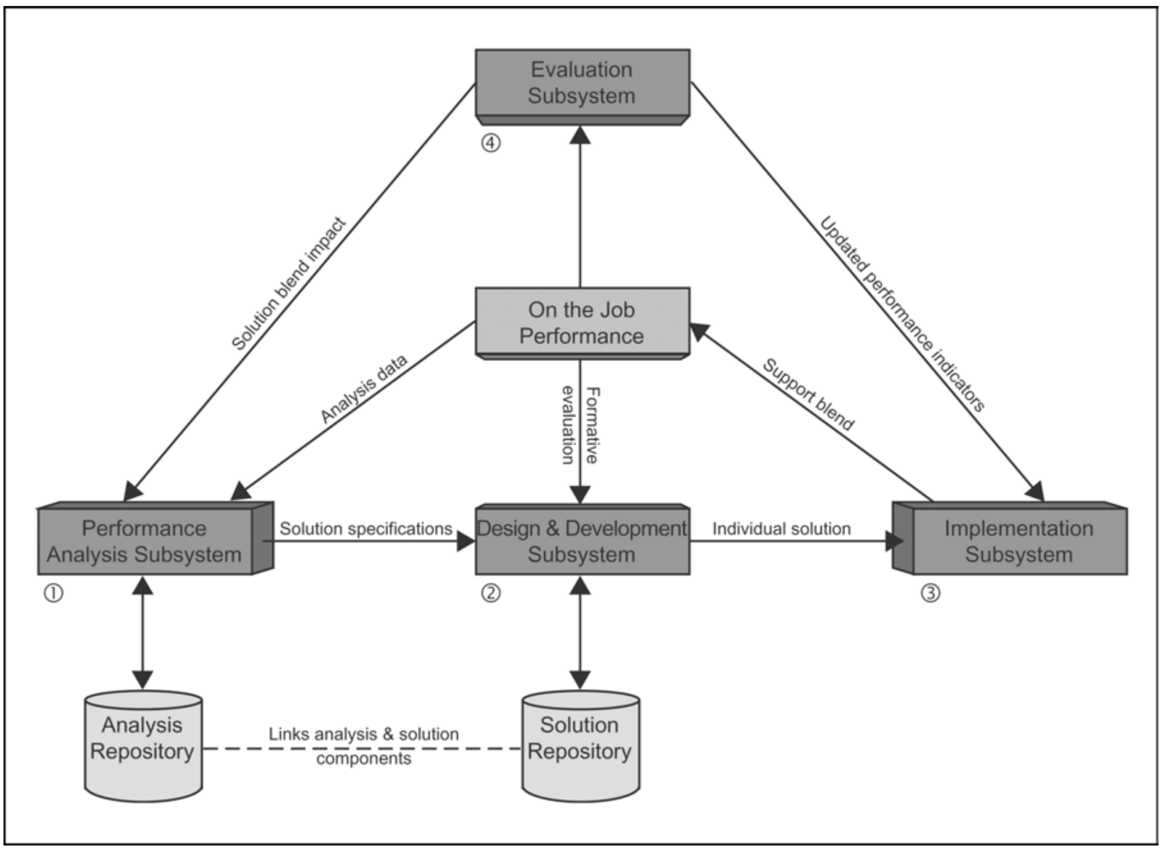
of changing job requirements or as a member of a problem-solving team.

INTEGRATING THE SILOS

There is still a training-oriented bias within the standard setting community in that objects are conceived as learning objects. The main solution considered is computer-based training delivered through a learning management system. As noted in the introduction, the trend is toward thinking in terms of integrated solutions rather than being fixated on the training solution that assumes a knowledge or skill gap for the performer. This not only requires research into how problems are analyzed and solutions are selected, it also requires a reconsideration of how solutions are delivered and managed.

If we look at the way support solutions are currently delivered, we see a lack of integration with systems often developed and delivered independently in silos. Such silos often require that learners and performers discover, integrate, and synthesize the resources that are available to support them. This can lead to usability problems, as users have to contend with a variety of different systems with different interface designs. There may also be reduced utility in some of the systems due to the redundant, irrelevant, inadequate

Figure 3. A model for a comprehensive organizational support system incorporating reuse



information. Learning management systems solve some of these problems for online learning, but they do not solve the problem for performance support in general.

A KPL is conceptualized as a dynamic performer/learner-defined system that links to a database of packaged KPL support systems. Performers using personal digital assistants, wearable computers, or desktop PCs can access available system and subsystem packages. Performance managers or instructors can create a customized performance support environment for a particular individual based on the roles they will perform or tasks to be completed. We would envisage the possibility for a certain amount of resequencing and packaging of systems within this environment. In addition to providing customized access to available performance support systems, the management system should act as a collection point for evaluation information concerning the systems use.

Figure 3 presents an initial model for how a KPL organizational support system might work. The model features two types of repositories. At the top is the reusable analysis knowledge repository which supports problem solvers by providing access to previous problem cases. These cases are linked to objects that may be useful in solving the current problem. Another repository, the reusable solution repository, supports solution developers by linking them to potentially useful objects that are related to the problem identified in the analysis.

The core of the model is on-the-job performance or, in the case of a learning environment, learning goals or problems. Analysis of performance roles or specific goals results in solution recommendations to close gaps between desired and actual role performance. The performance support development system locates reusable solutions if any exist or supports the design and development of SCOs to be packaged into a performance support system. This system is then made available to the performer via the performance support portal. This portal would automatically be made available to any performer with the responsibility of performing that role.

A key element of this model is the connection between on-the-job performance, performance evaluation, and the performance support portal. Indicators of successful performance as related to the performance support for a given role is constantly fed back to the performer. The evaluation subsystem is a key to continuously improving the quality and fidelity of the objects created within this model. Data from actual performance is relayed through the evaluation system to the performer and to the analysis team. Evaluation data is a key ingredient to successful integration of KPL systems since it allows for determination of the effect of a particular type of support system on individual and organizational effectiveness. Over time, patterns of particularly successful solutions may be quickly identified and made accessible to performers automatically. An automated system could monitor patterns of access and use, and automatically generate and administer questionnaires to gather qualitative data from performers when certain patterns are detected.

CONCLUSION AND FUTURE TRENDS

An outline of a new model for the IT systems support for the collaborative development and delivery of KPL management systems has been presented. The unifying strands of the framework are that it be performance, learning, and object oriented. The role of the KPL system is currently taken by learning management systems (LMS) or content management systems (CMS), and many of these systems are facilitating the technical aspect of learning objects; however, they are still rooted in the thinking that formal courses are the main solution to learning and performance problems and that objects are created by content experts. A reusable object and performance orientation should run through an entire support system from its initial conception to its delivery to the end users and the evaluation of its impact of the organization. Within this orientation is a contribution focus that supports the development of reusable objects by analyzers, designers, developers, and performers within the system. These contributors are supported in their efforts by tools such as discussion forums, other groupware, and visual modeling software that are integrated with object repositories.

Chapter 4.20
Working and Learning in Interdisciplinary Project Communities

Patrick S. W. Fong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION AND BACKGROUND: CREATING KNOWLEDGE IN INTERDISCIPLINARY PROJECT TEAM SITUATIONS

Designing a product or service does not form a complete and coherent body of knowledge that can be precisely documented or even articulated by a single individual. Rather, it is a form of knowing that exists only through the interaction among various collective actors (Gherardi & Nicolini, 2000). Existing literature (Kanter, 1988; Nonaka, 1994) has highlighted a need for the development of a diverse workforce if knowledge creation is to be promoted and sustained. This literature suggests that a diverse set of resources (experts with different backgrounds and abilities) provides a broad knowledge base at the individual level, offering greater potential for knowledge creation.

Sahlin-Andersson (1998) viewed projects as local arenas for knowledge creation, as individuals possessing different experience and skills work together to solve a common task within a limited timeframe. Through collaboration, new technical knowledge and knowledge for organizing the project are developed over time. March et al. (1991) argued that organizations learn from experience to improve future performance. By the same token, projects can be used as a medium for organizational learning, where knowledge and experience gained in one project can be transferred and utilized in the next. This strategy does not aim solely to save time and money, but also to avoid "reinventing the wheel", which is something that occurs frequently in every new project. Penrose (1959) argued that utilizing and employing experience and the knowledge thus created makes an organization grow.

Conceptually, a team can be viewed as a socially constructed phenomenon or linking mechanism that integrates individuals and organizations (Horvath et al., 1996). A multidisciplinary team is defined by Nonaka and Takeuchi (1995) as "a self-managed, self-organised team in which members from various functional departments, and/or areas of expertise, work together to accomplish a common goal" (p. 85). The primary goal of the multidisciplinary composition (see Figure 1) is to marry diverse bodies of knowledge in a way that forces out a synergistic knowledge outcome that is innovative, contextualized, difficult to imitate, and, as such, has strategic value. For the most part, project team tasks are nonrepetitive in nature and involve the application of considerable knowledge, judgment, and expertise.

The advantage of adopting multidisciplinary project teams is that they are quicker in integrating the expert knowledge of different functions, for example, design, construction, property management, marketing, and so forth. Cross-functional project teams with mutual accountability and collective work products have been found to decrease development time and increase product quality (Van de Ven, 1986; Wheelwright & Clark, 1992). Multidisciplinary project teams create a "task culture", facilitating close linkages and direct personal contacts between different functions (Cohen & Levinthal, 1990). These close connections are necessary, as new product development by its very nature includes uncertainty about the potential market response and about new technology (Henke, Krachenberg & Lyons, 1993). The multidisciplinary project team can be viewed as an unusual team arrangement primarily because it is composed of professionals from various disciplines who take pride in their fields of expertise. They are committed to the basic assumptions of their paradigms, and they perceive their roles in the team as representing their knowledge bases in the best possible way.

Figure 1. A multidisciplinary composition of team members with diverse knowledge, judgment, and expertise

KNOWLEDGE SHARING IN PROJECT TEAMS

To enhance competitiveness and meet organizational goals, organizations need to ensure that people share both tacit and explicit knowledge. The increased sharing of knowledge raises the likelihood of new knowledge being created, tending to support valuable innovation (Nonaka & Takeuchi, 1995). Though organizations can codify some of the knowledge people use, it is easy to find cases or examples that do not fit the codified knowledge of the organization. This unarticulated knowledge requires communication among people in the organization. Orr (1996) found that photocopier technicians often searched for solutions beyond their manuals. He explained that "the expertise vital to such contingent and extemporaneous practice cannot be easily codified" (p. 2). When documentation proves insufficient, people need to access each other's experience to solve more difficult problems. Orr showed how technicians sometimes use narrative to recount each other's experience. Technicians might use breakfast or lunch meetings to share knowledge. Other accounts of knowledge sharing demonstrate how workers use computer-mediated communication. For example, Constant, Sproull, and Kiesler (1996) showed how people use a computer-mediated network to seek help and advice. Similarly, Hargadon and Sutton (1997) explained how product designers search for knowledge by sending out pleas for help via electronic mail. In both cases, communication is the key to sharing knowledge.

Knowledge sharing relies on reaching a shared understanding of the underlying knowledge, in terms of not just the content but also the context of the knowledge, or "Ba", to use Nonaka and Konno's (1998) term. Exchanging information represents only a partial view of knowledge sharing activity. The essence lies in unveiling and synthesizing paradigmatic differences through social interaction.

Many definitions of the word *paradigm* exist. Neufeldt and Guralnik (1988) defined it first as "a pattern, example, or model" and second as "an overall concept accepted by most people in an intellectual community…because of its effectiveness in explaining a complex process, idea, or set of data" (p. 979). Kuhn (1970, p. 181), who popularized the term, provided two definitions for a paradigm. In the primary sense of the word, a paradigm is a "disciplinary matrix", the ordered elements of which are held by the practitioners of a discipline. According to this definition, a paradigm includes symbolic generalizations (laws and definitions), shared beliefs, and shared values. In an alternate use, Kuhn (1970, p. 187) defined paradigms in a more circumscribed manner as "exemplars" or "shared examples". More recent work by Boland and Tenkasi (1995) indicated the use of the concept of "perspective taking" and "perspective making" to resolve paradigmatic differences through appreciating individuals' different paradigms. By synthesizing the various definitions and insights, a paradigm as used in this chapter, is defined as a team perspective or belief which is collectively constructed and accepted by members of the team. This definition reflects the perspective of social construction as well as the opportunity for paradigmatic differences to be resolved through social interaction between members in collective settings, such as teams or organizations.

Knowledge sharing is not constrained to exchanges among and across the employees of a company. It can occur between employees and customers, or between organizations or firms in entirely different industries (von Hippel, 1988). Some of the very important knowledge identified in a survey among knowledgeintensive businesses includes customer, competitor, and product knowledge (Skyrme & Amidon, 1997). The more knowledge is shared about the needs of current and potential customers among project team members, the better they may understand realistic customer requirements. With such knowledge, greater value for customers may be created because the resultant products may better satisfy customer needs and expectations. Accordingly, they may have a better chance of success in the marketplace. In the same vein, shared competitor knowledge could be helpful in developing products ahead of market requirements (getting products to market ahead of competitors, developing products on schedule). It could yield high value to customers (extending a product's success in the marketplace), possibly improving product performance (better overall product performance than that of competitors). In addition, shared product knowledge (product advantages, disadvantages, strengths, history, and technologies) may be important in improving development productivity (reducing development costs) and production costs (reducing overall production costs).

It is clear that sharing diverse knowledge can enhance problem solving as well as create the culture required for knowledge creation. Communication is the key to knowledge sharing. Knowledge sharing is regarded as a combination of processes sharing and using knowledge directly without language (socialization) and with language (externalization).

KNOWLEDGE INTEGRATION IN TEAM SITUATIONS

More information and knowledge are not always the answer. What may be needed is to better integrate the information and knowledge already available within the team. According to Weick (1995):

more information will not help them. What will help them is a setting where they can argue, using rich data pulled from a variety of media, to construct fresh frameworks of action-outcome linkages that include their multiple interpretations. The variety of data needed to pull off this difficult task is most available in variants of the face to face meeting. (p. 86)

In a new product context, Hayes, Wheelwright, and Clark (1988) suggested that members of new product development teams should have a basic knowledge of other functions in addition to an in-depth knowledge of their own specialty. It is suggested that "specialists are inventors; generalists are innovators" (Galbraith, 1982, p. 22) and that people who are willing to cross functional or other boundaries are likely to be more innovative (Kirton, 1988), or to be able to resolve conflicts because of their ability to see both sides (Gregory, 1983). Nonaka and Takeuchi (1995) alluded to generalism when they talked about Japanese firms' support of "information redundancy" or knowledge overlap between people. Although the use of the term *redundancy* might seem to denote inefficiency, it might in fact turn out to be effective in an innovation situation. This positive effect of knowledge overlap may explain the positive association between the use of job rotation and new product success found in a number of product development studies (Souder, 1981; Wiebecke, Tschirky & Ulich, 1987). Wiebecke et al. (1987) proposed that job rotation promotes an understanding of the work of other functions and facilitated cross-functional "bilingualism". Souder (1981) found that in all the cases where "equal partners" harmony, associated with product success, was attained between marketing and research and development (R&D), the marketing personnel were all technically trained, most having worked in R&D previously. Cross-functional skills learned in job rotation may facilitate the combination of existing knowledge to produce new knowledge. Having considered the importance of integrating knowledge in team situations, the following section will focus on tensions in the process.

Following the above discussion, knowledge integration is defined as a collective process of synthesizing different knowledge and paradigms through the social interaction of team members/stakeholders in order to facilitate the construction of new knowledge or combine existing knowledge.

A project in which a multidisciplinary team is involved can be described as a transformation process, superimposed on the regular or cycled activities of an organization (Beale & Freeman, 1991). In this regard, a project becomes part of a wider venture (Beale & Freeman, 1991), the first part of which is the production of a product or service followed by an operating cycle. The project therefore takes place within a complex corporate, legal, financial, and regulatory environment (Fox, 1984). This environment leads to a number of parties having a stake in the project, from internal departments to external regulatory bodies and customers, since the project decisions have a potential impact on all stakeholders (Cleland, 1986).

As Grant (1996) indicated, competitive advantage does not evolve from knowledge, per se, but from the integration of such knowledge as facilitates the construction of new knowledge. The diversity of the specialized knowledge involved in the integration process determines its difficulty. Hence, the uniqueness of multidisciplinary teamwork is in its potential to integrate different bodies of knowledge into a new synergy. From an organizational standpoint, the prime purpose of the multidisciplinary team is to function as a knowledgeable entity engaged in creating new knowledge. In other words, the function of a project team is to convert knowledge inputs into new products and processes, bringing together participants with expertise in the right specialized knowledge domains and skills necessary to integrate and coordinate the knowledge of diverse participants. With these paradigms of divergent thinking, basic assumptions, and the "professional egos" (Dougherty, 1992) held by team members, this difference of opinion is likely to challenge invalid assumptions and bring more information and knowledge to bear on issues; it may also neutralize tendencies toward "groupthink" (Janis, 1982).

LEARNING AND PROJECT COMMUNITIES

The metaphor of projects as learning experiments for the company embraces an awareness of the importance of both exploration and exploitation of knowledge in organizations (Burgelman, 1991; March, 1991). To see an individual project as an experiment means that new knowledge is created and explored among project participants. The project knowledge and experience gained from earlier or current projects can be used to create new knowledge to suit current situations or problems. Projects, as a form of organizing work, can be one way to explore new knowledge, project-related as well as operational. During participation in a project, team members, through their engagement in the learning process, gain new experience and knowledge that could be used to solve problems. Furthermore, this knowledge and experience could be useful for other projects. In that sense, a project can be viewed as a learning experiment for the companies involved (Drew & Smith, 1995).

In project-oriented companies, learning from projects is the key to building strategic competitive advantage. During a project's existence, a number of decisions are made. Every decision involves a degree of uncertainty. Packendorff (1995), for example, argues that the problems or mistakes that cause this uncertainty are often of a similar character. Yet it is not clear whether this is a global generalization or whether it depends on the sector or stage of an industry's life cycle. Nevertheless, experience to date has shown that once experience is gained in a project, knowledge is created that may be reapplicable. The basic hypothesis of the project learning approach is that learning from projects can reduce the uncertainties that might lead to inefficiencies. The use of project experiences and their integration into the organization to expand the body of knowledge are important and valuable cornerstones in a project learning approach. Ensuring that people pass on their experience to others is one of the greatest challenges for an organization and its organizational memory (Morris, 1994). However, learning and projects are not a natural combination (Bartezzaghi, Corso & Verganti, 1997) since conflicts of a basic logical character are involved. These conflicts comprise the time aspect, the task orientation, the team structure, and the transitional culture of projects (Lundin & Söderholm, 1995).

To carry out their project work effectively, project team members need to develop the ability to manage across boundaries. If learning is assumed to be social, learning is engagement in practice and dealing with boundaries (Wenger, 1998). Project-based organizations offer an excellent opportunity to engage in learning and to acquire reflective habits that transcend the boundaries of projects. Learning is supported not only by the nature of single projects, but also by the web of relationships that is created in project management organizations.

Membership in projects is temporary and thus offers individuals the opportunity to belong to multiple communities. In project-based organizations, there are a large number of weak ties that help diffuse knowledge and practices (Granovetter, 1973). In the majority of organizations, project members maintain their links with their primary organizations (to which they will return upon the completion of the project). Membership in multiple existing teams contributes to the creation of informal webs of people who act as knowledge brokers (Wenger, 1998). Project-based organizations thus enable the continuous building and cultivation of relationships, nurturing the development of communities of practice (Brown & Duguid, 1999). Communities of practice are natural internal mechanisms where ideas and practices spread in work settings, although they tend to exist outside the boundaries of the formal hierarchy (Wenger & Snyder, 2000). Project-based organizations may grow into constellations of interrelated communities of practice, offering a web of mutual support for cultivating reflective practices. When projects share members, they are bound together and become embedded in the same social network (Granovetter, 1973). The recursive interaction among projects creates social networks of mutual assistance. Project-based learning looks to augment the natural workings of such social networks and communities of practice as already exist.

When a project is completed, the members either return to their functional units or organizations or move on to the next project, which makes project teams unique from any other organizational arrangement. In addition, it is not uncommon for individual team members to be members of several teams simultaneously (Henke et al., 1993).

CONCLUSION AND FUTURE TRENDS

Designing a service or product requires the collaborative interaction of individuals from different professional backgrounds. Their diverse expertise represents different interests and issues. These different experiences, mental models, and motivations can be expressed only partly in explicit language. Thus, socialization is a valuable mode of sharing knowledge in teams without language through imitation, observation, and sharing experience face-to-face. Nonaka (1994) emphasized that socialization was also an important way to further trust between partners. Saint-Onge (1996) referred to socialization as a way of creating a sufficient level of congruence to enable individuals to understand each other and work together toward their common goals from different perspectives. Social constructionists regard language as coordination of action (Burr, 1995) and therefore a fundamental tool in knowledge creation. The commonly employed tool in externalization is dialogue. Dialogue triggers the unconscious elements of knowing and not-knowing, as well as revealing gaps in knowledge compared to what the community knows (Ayas, 1996).

An important aspect of knowledge integration is the willingness to combine knowledge from within and outside the team. The more differentiated the knowledge inputs needed in a task, the higher the knowledge diversity and the greater the scope for knowledge integration. Design, involving art, engineering, finance, and business, is a process of knowledge integration, and a product's design emerges from the collaboration of project participants and stakeholders. Leonard-Barton (1995) viewed the creation of new knowledge as occurring by combining previously unconnected elements or by developing ways of combining elements previously associated.

In project-intensive companies, learning from projects is the key to building strategic competitive advantage. During a project's existence, a number of decisions are made. Every decision involves a degree of uncertainty. However, the problems or mistakes that cause this uncertainty are often of a similar character (Packendorff, 1995). Penrose (1959) argued that utilizing and employing the experiences and knowledge created makes an organization grow. Takeuchi and Nonaka (1989) found that learning could potentially occur within a project team along two dimensions: across different levels (individual, team, and organizational) and across multiple functions or disciplines.

Project team members have to incorporate new knowledge into their understanding in order to solve the technical challenges they face. Thus, learning is inherent in the work they do (Mohrman, Mohrman, & Cohen, 1995). In the role of reflecting expert (Schön, 1987), one is expected, like the technicalrational practitioner, to "know one's business", to possess the relevant know-how. However, one need not know everything, let alone have all the answers. One recognizes that others, too, possess relevant knowledge and that people can learn from each other, gaining insights that result in good solutions. New learning is created through the transformation of experiences, but that learning is not leveraged before an understanding of the experience and task is established (Kolb, 1984). Learning has to be linked to a change in an individual's interpretation of events and actions (von Krogh & Roos, 1996).

Membership in projects is temporary and thus offers individuals the opportunity to belong to multiple communities. In project-based organizations, there are a large number of weak ties that help diffuse knowledge and practices (Granovetter, 1973). Crossteam learning or interteam learning can occur when teams share their internal approaches with one another. Collective learning can be considered a vital mechanism (Huber, 1991) and a final product of knowledge creation (Senge, 1990).

Chapter 4.21
Knowledge Integration

INTRODUCTION

In most organizations, specialized knowledge is dispersed over organization members (Tsoukas, 1996). Organization members have different educational backgrounds and working experiences and develop different perspectives. Yet, the development and production of complex goods and services normally requires the application of multiple disciplines and perspectives. Therefore, the integration of knowledge is an important task for managers and other organization members (Carlile, 2002; De Boer, Van den Bosch, & Volberda, 1999; Galunic & Rodan, 1998; Grant, 1996a, 1996b; Kogut & Zander, 1992; Okhuysen & Eisenhardt, 2002; Ravasi & Verona, 2000).

Knowledge integration has to be realized through the actions of the specialists involved, but knowledge management professionals can facilitate this task. Several mechanisms can be deployed to realize knowledge integration. An important question is what instrument is suited for what circumstances, for example, which knowledge integration mechanisms fit an exploration strategy and which mechanisms fit an exploitation strategy (March, 1991). If organizations do not explore, they can get stuck in a suboptimal or deteriorating situation. In contrast, if organizations do not exploit, they will have high costs and low incomes. Yet, exploitation and exploration require contrasting approaches to knowledge integration.

The next section presents the theoretical background on the topic of knowledge integration. Subsequently, we describe the knowledge integration mechanisms that can be found in the literature and basic conditions for the successful utilization of these mechanisms. We introduce a framework that distinguishes knowledge integration mechanisms, which can be used to assess the value of particular mechanisms for different situations. This framework is applied in a discussion of the knowledge integration approaches that are required for exploration and exploitation. The concluding section suggests directions for future research.

BACKGROUND

Several disciplines have contributed to the study of knowledge integration. Economists and strategy theorists formulated the outlines of a knowledge-based view of the firm (Demsetz, 1991; Grant, 1996b; Galunic & Rodan, 1998; Kogut & Zander, 1992; Nelson & Winter, 1982; Teece, Pisano, & Shuen, 1997). They have built upon work in organization science, including the information processing perspective (Galbraith, 1973; Tushman & Nadler, 1978) and earlier work on the differentiation and integration of tasks (Lawrence & Lorsch, 1967; Thompson, 1967). Disconnected from those studies, social psychologists studied the effectiveness of knowledge integration under different conditions in experimental studies (e.g., Hollingshead, 1998; Stasser, Stewart, & Wittenbaum, 1995; Wegner, 1987). Combining insights from these disciplines, the problem of knowledge integration can be sketched as follows.

The development and production of complex goods and services requires a wide and expanding range of technological, marketing, and organizational knowledge (Demsetz, 1991; Grant, 1996a, 1996b; Tsoukas, 1996). For example, Ford not only needs a competency in road vehicles and engines, but in 15 other major technological fields as well, including chemical processing, metallurgy, semiconductors, and instruments and controls (Granstrand, Patel, & Pavitt, 1997). In addition to the breadth of knowledge involved, the depth of technologies—their analytical sophistication—also is increasing (Wang & Von Tunzelmann, 2000).

A single individual cannot have the breadth and depth of knowledge required for the development and production of most goods and services. Individuals have restricted learning capacities (Simon, 1991). Furthermore, due to the situatedness of learning processes (Lave & Wenger, 1991), individuals are only able to become experts in fields in which they are actively involved. Finally, learning processes are characterized by an increasing rate of return (Levinthal & March, 1993). That is, the more knowledge one has in a particular field, the easier it is to learn something new within that field. For these reasons, individuals have to specialize in a certain field in order to develop the level of expertise required. It is through the specialization of individuals in different fields, and hence the differentiation of knowledge, that an organization is able to acquire both the required breadth and depth of knowledge (Carlile, 2002; Marengo, 1993; Wegner, 1987).

When the knowledge required for innovation or production lies dispersed across individuals, departments, and organizations, a fundamental task for organization members and management is to integrate that knowledge. The differentiation of knowledge creates a need for knowledge integration. We define knowledge integration as "the process in which different pockets of knowledge, which are valuable for a particular organizational process and held by different organization members, are applied to that organizational process." As we will discuss next, this process can be realized through several mechanisms.

KNOWLEDGE INTEGRATION MECHANISMS

Six different knowledge integration mechanisms can be found in the current literature: (1) sequencing, (2) decision support systems, (3) direction, (4) thinking along, (5) group problem-solving, and (6) knowledge transfer. These mechanisms can be used separately and in combination with each other. This section describes each of them and discusses two basic conditions for the successful utilization of these mechanisms.

Sequencing

The first mechanism for knowledge integration is the sequencing of tasks (Demsetz, 1991; Grant, 1996b; Nelson & Winter, 1982). This mechanism exploits the specialization of organization members. As a knowledge integration mechanism, sequencing refers to the assignment of tasks to those organization members who have the relevant knowledge for it. When routines of sequenced tasks are created, individuals only need to know their part of the routine in order to realize that specialized knowledge is applied in a coordinated way (Nelson & Winter, 1982, p. 101).

Decision Support Systems

Decision support systems are a second way to integrate knowledge. When specialists codify their knowledge and embed it in a decision support system, their original specialist knowledge can be integrated in the practices of a wide range of other organization members (e.g., Davenport & Glaser, 2002). Advances in information technology and knowledge engineering have greatly enhanced the feasibility of this approach to knowledge integration, though there are also clear limits to its applicability (e.g., Dreyfus, 1992).

Direction

Specialists in one area of knowledge can issue rules, directives, and operating procedures to guide the behavior of non-specialists, less mature specialists, and specialists in other fields (Grant, 1997, p. 451). Demsetz (1991) called this mechanism "direction." Rules and directives can be interpreted as translations of a wider body of explicit and tacit knowledge into a limited instruction. The organization members applying these rules and directives do not need to fully understand the wider body of knowledge underlying them.

Thinking Along

Berends, Debackere, Garud, and Weggeman (2004) introduced thinking along as another knowledge integration mechanism. Thinking along takes place in interactions between organization members, but it differs from knowledge transfer. Thinking along consists in the temporary application of one's knowledge to somebody else's problem. The application of this knowledge—including tacit knowledge—may yield ideas, hypotheses, suggestions, comments, and questions that contribute to the process of knowledge creation. These contributions are much easier to communicate than the background knowledge used to produce them. Yet, through thinking along, that background knowledge gets applied to the organizational process involved. In the study of Berends et al. (2004) this mechanism was frequently found in the interactions between industrial researchers.

Group Problem-Solving

Okhuysen and Eisenhardt (2002) limit the concept of knowledge integration to group problem-solving. This mechanism consists of the direct combination of knowledge previously dispersed over individuals in order to solve a problem or make a decision. Okhuysen and Eisenhardt emphasize that this is not just a passive process of combining pieces of knowledge in a way comparable to building with LEGO blocks or making a jigsaw puzzle. The integration of knowledge involves the active use of knowledge and the generation of new ideas, aided by the combination of knowledge. In contrast with thinking along, group problem-solving concerns a shared problem and symmetrical contributions from those involved. Group problem-solving is widely researched in field studies, such as multi-disciplinary innovation projects (e.g., Carlile, 2002; Huang & Newell, 2003), and in experimental studies (e.g., Okhuysen & Eisenhardt, 2002; Stasser et al., 1995).

Knowledge Transfer

Knowledge transfer is presumably the most widely studied mechanism for knowledge integration (e.g., Hansen, 1999; Szulanski, 1996). Though knowledge integration can be realized through knowledge transfer, knowledge transfer alone does not constitute knowledge integration. Knowledge integration requires that the receivers of knowledge are able to absorb it, combine it with their existing knowledge, and apply it to an organizational process. Past research has discovered a wide range of factors that enable or constrain knowledge transfer (e.g., Cummings & Teng, 2003; Szulanski, 1996; Van der Bij, Song, & Weggeman, 2003). Among these factors are characteristics of knowledge such as its tacitness, characteristics of senders such as their motivation, characteristics of receivers such as their absorptive capacity, characteristics of relationships such as the level of trust, and characteristics of the organizational context such as the communication infrastructure. Furthermore, the literature distinguishes several types of knowledge transfer. For example, Dixon (2000) discerns five types of knowledge transfer: serial transfer, near transfer, far transfer, strategic transfer, and expert transfer. Dixon argues that these types of knowledge transfer are suited for different situations and conditions.

Past research has identified several conditions for successful knowledge integration. Two conditions are fundamental. First, organization members need to recognize opportunities for knowledge integration (Galunic & Rodan, 1998). Social psychologists have stressed the importance of a well-developed transactive memory system (Wegner, 1987). Transactive memory refers to the metaknowledge people have about the knowledge and skills of others (Wegner, 1987). Research has shown that such knowledge about others enhances sequencing (Moreland, 1999), thinking along (Berends et al., 2004), group problem-solving (Stasser et al., 1995; Okhuysen & Eisenhardt, 2002), and knowledge transfer (Hollingshead, 1998).

Second, many authors have mentioned the importance of shared understanding (e.g., Galunic & Rodan, 1998; Grant, 1996a; Tushman, 1978). The specialization of organization members not only enables an organization to acquire the range of required expertise, it also creates diverging thought worlds and frames of reference (Carlile, 2002; Dougherty, 1992). Boundaries between groups and practices may create serious barriers to knowledge integration. A basic level of common knowledge and a shared conceptual framework may help to overcome these barriers. Ethnographic field studies have emphasized the role of boundary objects for the success of knowledge integration. A boundary object is an object that is shared and shareable across different contexts and enables collaboration across boundaries (Carlile, 2002; Star & Griesemer, 1989). An example of such a boundary object is the drawing of a new machine, which can be used by different disciplines contributing to the machine.

CHARACTERIZING KNOWLEDGE INTEGRATION MECHANISMS

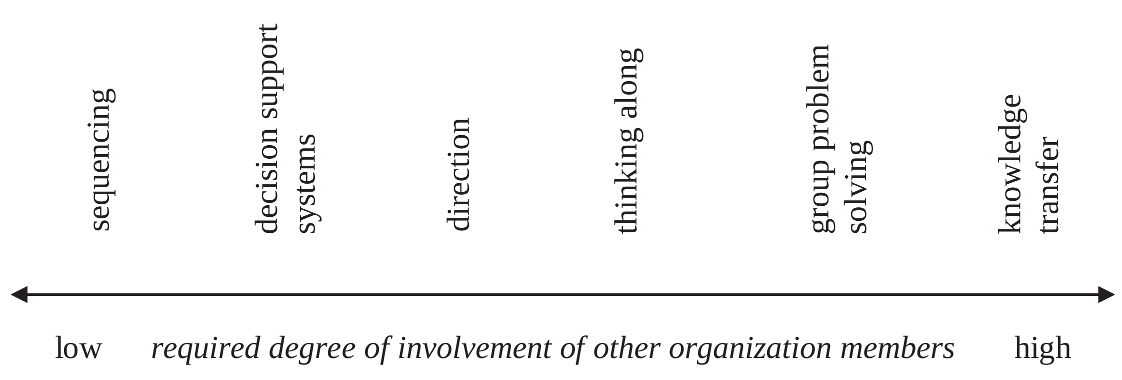
The existing literature describes a range of knowledge integration mechanisms. However, it does not offer a conceptual framework to distinguish and order these mechanisms. Grant (1996b), for example, does not offer an integrated perspective on the mechanisms he introduces. This deficiency in the literature limits our ability to assess the suitability of mechanisms for different organizational processes and conditions. As a first step toward filling this gap, we introduce a dimension that characterizes and distinguishes knowledge integration mechanisms.

Knowledge integration mechanisms differ in the degree to which the application of a piece of knowledge, which is valuable for realizing an organizational process, involves somebody else other than the person having that piece of knowledge. The knowledge of an organization member can be integrated into an organizational process by directly applying it, by incorporating it in a decision support system, by translating it into a rule, by using it when thinking along with someone, by using it in group problem-solving, and by transferring it to someone else. These options differ in the amount of effort required from other persons to realize that the knowledge is applied to a specific organizational process. Two extremes are knowledge transfer and sequencing. Knowledge transfer demands high involvement from the organization members receiving knowledge, since they should absorb the knowledge and apply it in their part of the organizational process. In contrast, sequencing only requires that everyone applies his or her knowledge to his or her own task:

"While each organization member must know his job, there is no need for anyone to know anyone else's job" (Nelson & Winter, 1982, p. 105).

Figure 1 locates each of the knowledge integration mechanisms discussed in the previous section on a continuum from a low to a high degree of involvement of other organization members. Integrating knowledge via rules and directives, for example, lies between the extreme cases of sequencing and knowledge transfer. To some degree it is like knowledge transfer. Organization members other than the ones issuing a rule are needed to apply rules in an organizational process. Yet, to the degree that rules and directives are translations of larger bodies of knowledge, direction does not require as much involvement of other organization members as the transfer of those complete bodies of knowledge would have taken. Similarly, decision support systems, thinking along, and group problem-solving occupy intermediate positions.

Figure 1. Characterization of knowledge integration mechanisms with regard to the required involvement of other organization members



EXPLOITATION AND EXPLORATION

Knowledge integration mechanisms characterized by a high or a low degree of involvement have different advantages and disadvantages. This has implications for their suitability for different organizational processes and conditions. In this section, we will focus on the distinction between exploitation and exploration (March, 1991). Whereas exploration is related to the creation of new knowledge and value, exploitation involves the extraction of value from existing intellectual capital (Sullivan, 1999). Several authors have argued that exploration and exploitation are facilitated by sharply different organizational characteristics (Benner & Tushman, 2003; Hill & Rothaermel, 2003; Levinthal & March, 1993; McNamara & Baden-Fuller, 1999). We will argue that exploration and exploitation also require different approaches to knowledge integration.

Exploitation is served by mechanisms that require a low degree of involvement of other organization members—except when those other organization members are able to reuse knowledge. Exploitation refers to "the use and development of things already known" (Levinthal & March, 1993, p. 105). Exploitation requires that available knowledge is applied where effectively possible, to low costs. In general, low degrees of involvement are less costly. Being deeper involved in the application of knowledge to a particular part of an organizational process takes more time and effort. Particularly, if knowledge has to be transferred to someone else to be applied, this requires time and effort of both sender and receiver. Efficient knowledge integration is realized when the division of tasks is in accordance with the division of knowledge. That is, it is most efficient when a task is assigned to the person who has the relevant knowledge for it. This minimizes the costs associated with knowledge transfer. Thus, Grant (1996b, p. 114) states: "If production requires the integration of many people's specialist knowledge, the key to efficiency is to achieve effective integration while minimizing knowledge transfer through cross-learning by organizational members."

Matching the division of tasks to the division of knowledge—and thus avoiding mutual involvement—can be done primarily by sequencing, but direction and decision support systems also exploit specialization. As Grant (1996b, p. 115) writes: "Thus it is highly inefficient for a quality engineer to teach every production worker all that he knows about quality control. A more efficient means of integrating his knowledge into the production process is for him to establish a set of procedures and rules for quality control." To a lesser degree, the matching of tasks to knowledge can be realized by thinking along. In thinking along, the person having relevant knowledge is not assigned a separate task, but applies his or her knowledge to a problem of somebody else and communicates resulting ideas for solving that problem.

Matching the division of tasks to the division of knowledge is more important when the knowledge involved is tacit and when boundaries exist between bodies of knowledge (Carlile, 2002). Those conditions make knowledge transfer more difficult, and therefore make it more important to avoid (Berends et al., 2004).

This reasoning points at limits to the usefulness of knowledge transfer. However, as stated, when other organization members are able to reuse knowledge in later activities, knowledge transfer may be valuable. When knowledge is in line with someone's specialization, economies of scale and scope make its transfer to that person more valuable (Grant & Baden-Fuller, 2004). For example, this is the case when best practices are transferred from one production facility to another one that uses the same kind of process (Szulanski, 1996).

Exploration requires a different approach to knowledge integration than exploitation. Exploration is "the pursuit of new knowledge, of things that might come to be known" (Levinthal &

March, 1993, p. 105). Schumpeter and many later authors have argued that innovation stems from the recombination of existing pieces of knowledge (e.g., Galunic & Rodan, 1998; Nelson & Winter, 1982). Accordingly, scholars working within the resource-based view argue that the innovative potential of a firm lies in its capability to recombine knowledge and other resources (Kogut & Zander, 1992; Teece et al., 1997). Furthermore, several authors have emphasized that exploration requires the generation of variety (Benner & Tushman, 2003; March, 1991). Given that "most new ideas are bad ones" (Levinthal & March, 1993), many ideas have to be suggested and tried before a successful innovation is created. Combining the ideas that innovation is realized through the recombination of knowledge and that exploration requires a variety of alternatives, we claim that exploration requires knowledge integration mechanisms that create variety in opportunities for knowledge recombination. We will argue that a higher degree of involvement facilitates such variation and that, therefore, group problem-solving, thinking along, and knowledge transfer are particularly suited for exploration.

That a higher degree of involvement enables variation in knowledge integration can be attributed to three factors. First, a higher degree of involvement gives more freedom to apply knowledge in diverse ways. For example, in an ethnographic study within a research organization, we observed the following interaction. In a biweekly cluster meeting, one researcher, Patrick, told about a lubricant he used to enhance the coating of optical discs. Jason, one of his colleagues, who worked on the coating of television screens, responded: "That's a nice solution. It might also work for the coating of screens. I will try that." When knowledge is transferred to others, those persons can decide in what ways to use that knowledge and, thus, how to integrate it with their existing knowledge.

Second, a higher degree of involvement enables one to detect more opportunities for the combination of knowledge. Galunic and Rodan (1998) introduced the notion of detection capability to refer to the capability to detect opportunities for fruitful recombinations of knowledge. In the previous example, Jason used his capability to detect a possible new application of the idea presented by Patrick. In group problem-solving or thinking along, each person involved can use his or her capability to detect ways to combine knowledge. Thus, especially when several people are jointly involved, the chances are higher that new combinations of knowledge are detected.

Third, the value of joint involvement for exploration also originates from the unexpected associations and reactions that interactions can trigger (Berends et al., 2004). For example, Okada and Simon (1997) found that specifically the questioning of each other's ideas is one of the strengths of group problem-solving. A question may trigger a new problem representation, which may trigger new ideas, which in turn may raise evaluative comments, and so on. Such a process prompts the knowledge bases of each of the persons involved in heterogeneous and unexpected ways.

CONCLUSION

Knowledge integration is of crucial importance when production or innovation requires knowledge from several organization members. The literature suggests several mechanisms for knowledge integration (though these mechanisms are not always interpreted in this particular way). In this article, we contributed to the study of knowledge integration by introducing a dimension that captures important differences between knowledge integration mechanisms. This dimension is the degree of involvement of other organization members that is required by a knowledge integration mechanism. Furthermore, we used this dimension in a discussion of the value of different mechanisms for exploitation and exploration.

Future research is required for the further development of theoretical and practical insight in knowledge integration. First, a number of conceptual issues require additional attention. What other dimensions can be used to differentiate knowledge integration processes and mechanisms? What is the relationship between task integration mechanisms and knowledge integration mechanisms? Second, theory building should extend beyond what has been presented in this article and include other characteristics of knowledge integration, contextual factors, and organizational outcomes. Furthermore, the arguments on the suitability of knowledge integration strategies for exploration and exploitation presented in this article should be rigorously tested. Third, we need more insight in the way in which each of the knowledge integration mechanisms can be realized and facilitated. Special attention is required for strategies to overcome boundaries between disciplines and strategies to deal with uncertainty and ambiguity within disciplines. We believe that the advancement of insight will be served by continuing the utilization of a multitude of methodological approaches, including qualitative field studies (e.g., Ravasi & Verona, 2000), quantitative survey research (e.g., Hansen, 1999), experimental studies (e.g., Stasser et al., 1995), and simulation studies (e.g., Marengo, 1993).

Chapter 4.22
Mobile Technology for Knowledge Management

Volker Derballa
University of Augsburg, Germany

Key Pousttchi
University of Augsburg, Germany

INTRODUCTION

IT support for knowledge management (KM) is a widely discussed issue. Whereas an overemphasis on technology is often criticized, the general consensus is that a well-balanced combination of technical and social approaches can be a rewarding departure (Alavi & Leidner, 1999). The usage of knowledge management systems (KMSs) (i.e., information systems including for example data warehouse techniques and artificial intelligence tools) is seen as a factor that can beneficially support different KM processes (Frank, 2001; Wiig, 1995). Due to the fact that an increasingly large proportion of work is not conducted in the context of stationary workplaces anymore, it becomes necessary to make KMSs available to those mobile workers (Rao, 2002; Sherman, 1999). Considering the different technological infrastructure in the stationary, as well as the mobile context, a KMS that so far is only available at a stationary workplace cannot simply become mobile without any changes. Further, the aspect of mobility implies specific design requirements for KMS. Taking together the rapid developments in the field of technology, allowing more and more mobile processes to be potentially supported through mobile KMS, as well as the current social and occupational developments, resulting in more mobile workplaces and business processes (Gruhn & Book, 2003), the relevance of mobile KM can be expected to increase in the future.

Once the focus is shifted away from the superordinate process perspective and addresses the design and development of applications to support mobile knowledge workers, technology and its use by human actors turns out as a major factor that has to be considered. The multiplicity of devices as well as the variety of KM applications, combined with technological and human limitations, all affect the development of mobile KMS. This article aims at addressing important design requirements pointing to different directions that need further research. By doing so, the goal is to put not too much emphasis on technological issues, but rather to introduce the relevant mobile technology and provide a basis for the further discussion of mobile technology usage in the context of KM.

BACKGROUND

Taking into account the wide range of literature available in the field of KM, the aspect of mobility as such is comparably under-researched so far. The same is true for the use of mobile information and communication devices in the context of KM. Studies on workplaces usually focus on stationary characteristics (Churchill & Munro, 2001). To approach the issue of mobile technology in the context of KM, input has to be taken from several different disciplines, including the area of computer-supported cooperative work (CSCW), which has been dealing for some time with the potential of mobile devices to support human decision-making and interaction processes is a comprehensive source. Further, literature dealing with mobile commerce can deliver some input as well. Finally, organization and work studies can contribute insights, especially when it comes to the wider context of mobile KM. In the following, relevant trends concerning the aspects of knowledge work and mobility are presented, and by doing so the basis for the further discussion is laid.

Knowledge Work

Knowledge work is, like many other types of work, influenced by development of an increasingly mobile workforce. Due to changes in work processes and structures as well as the adoption of information and communication technology (ICT), workplaces become increasingly mobile. In this context, not only dependent workers but also independent knowledge workers—freelancers—have to be considered, as their number is dramatically increasing (Kakihara & Soerensen, 2002b). This new form of worker is backed by ICT, allowing mobile workers to coordinate their interactions and communicate with other parties involved. This group of knowledge workers is also referred to as (digital) "nomads" (Soerensen, 2002; Hardless, Lundin, & Nuldén, 2001) or "post-modern professionals" (Kakihara & Soerensen, 2002b). The first term conveys the two characteristic properties of those workers. Firstly, they use ICT to connect and coordinate; secondly, they are on the move for a considerable amount of their working time.

Mobility

The concept of mobility can be seen from different points of view, which have to be addressed in order to develop a common understanding of mobile knowledge work. Literature is providing several different perspectives of mobility. Traditionally, mobility is considered as being geographically without constraints. Kakihara and Soerensen (2002a) however extend that view by focusing on the aspect of human interaction and provide a differentiation between three aspects of mobility. Spatial mobility refers not only to the geographical mobility of humans, but also to the mobility of objects and symbols. With the Internet they are no longer bound to a certain space, but are available regardless of their location. Temporal mobility pertains to the opportunities of ICT to enable asynchronous communication and thus frees the user from the restrictions of time. Contextual mobility serves next to spatial and temporal mobility as a major factor influencing human action. For the purpose of this article, we are focusing on that aspect of mobility that can be considered as spatial mobility, as this factor is most relevant for the perspective we are pursuing. Depending on the mode of spatial mobility, different requirements for the evaluation of mobile technology in the context of KM have to be considered.

Taking a closer look at the idea of spatial mobility can provide insights regarding the particular requirements during the period of being mobile. Kristoffersen and Ljungberg (2000) classify the following types of spatial mobility. Traveling refers to the process of changing from one location to another location usually using some kind of vehicle. Visiting describes the process of spending time in one particular location before traveling to another location. Visitors can either bring their ICT equipment with them or use the ICT that is already there. However, if visiting involves a certain degree of wandering (see below) between different offices and meeting rooms, the possibility to use existing ICT equipment is usually not a realistic option. Wandering refers to restricted spatial mobility in a building or a restricted area. This form of mobility is usually conducted by support workers or knowledge workers interacting with several other mobile workers. Due to the high degree of physical movement, the use of easily portable devices is feasible. Taking into account the fact that some forms of spatial mobility allow certain devices to be used and others not, stresses the importance of a detailed analysis for determining design requirements for mobile KM. While traveling in an airplane, it might for example be possible to use an laptop PC, although that is not always realistic, considering the fact that power supply is usually restricted to business class passengers. Thus, in that context it might for example be feasible to use a mobile device with less power demand, enabling longer running time.

MAIN FOCUS OF THE ARTICLE

After having addressed the issues of mobility and knowledge work, this section provides an overview of relevant mobile technologies and introduces certain mobility-specific requirements.

Mobile Devices

We use the term mobile devices for information and communication devices that have been developed for mobile use. Thus the category of mobile devices encompasses a wide spectrum of appliances. Although the laptop is often included in the definition of mobile devices, we have reservations to include it here without precincts due to its special characteristics: It can be moved easily, but it is usually not used during that process. For that reason we argue that the laptop can only be seen to some extent as a mobile device. In the following the devices are differentiated according to their relevant interfaces, functionality, as well as their possibilities for user interaction. In particular, the following four characteristics can be introduced enabling the realization of certain KMSs (Turowski & Pousttchi, 2003):

- Voice functionality, usage of IVR (Interactive Voice Response)
- Capability to send and receive short messages (Short Message Service, or SMS)
- Internet-enabled
- Capability of executing applications

Mobile phones are mobile devices that are primarily geared at the use of the telephone functionality. 2G mobile phones are usually Internet enabled and support Short Message Service. With Java support, even complex applications can be implemented. Smartphone is a device that can only be roughly defined as there is no clear delineation. Typical characteristics of a Smartphone include mobile phone functionality and an operating system that is similar to that of a personal digital assistant (PDA). A PDA is a handheld computer with core functionality similar to a personal information manager. Current models include the possibility to establish an Internet connection using modem-supported mobile phone, GSM cards, or integrated mobile phone technology. Operating systems are similar to that of conventional PCs. Tablet PC describes a modification of the laptop PC which can be used in stationary as well as mobile settings. Wearable computing is the term for miniature devices that can be integrated for example into clothing and thus have the characteristic to be immediately available. Additionally, proprietary devices that have been designed according to the specific needs of an organization have to be considered as well. However, as those devices are usually derived from the types introduced above, we are not going to specify them further.

Communication Standards

Where the communication standards are concerned, there are currently with 2G (e.g., GSM, IS-136, IS-95) and 3G (Universal Mobile Telecommunications System, or UMTS) two main standards available for the transmission of data. Whereas the 2G networks are generally capable for transmitting data, they are optimized for voice transmission. With 2.5 technologies like General Packet Radio Service (GPRS) and Enhanced Data Rate for Global Evolution (EDGE), however, packet transmission is possible, enabling always-on operation. Using up to 8 time slots, data speeds of a maximum of 171.2 kbps are theoretically possible.

Due to the restricted capacity of current mobiles devices and networks, a realistic downlink speed of approximately of 40.2 kbps to 62.4 kbps can be expected. The advent of UMTS will make bandwidth concerns increasingly negligible, enabling transfer rates up to 384 kbps (using UMTS FDD) respectively 2 mbps (using UMTS TDD), although the realistic speed—depending on network capacity—will be in the area of 128 kbps. For some KM applications, UMTS will act as an enabler; for example, videoconferencing will become possible.

Figure 1. Functionality of mobile devices

	Availabe Functionality			
Type of Mobile Device	IVR	SMS	Internet	Programm Code executable
Mobile Phone (speech functionality only)	x			
Mobile Phone (SMS-enabled)	x	x		
Mobile Phone (Internet-enabled)	x	x	x	
Mobile Phone (Java-enabled)	x	x	x	x
Smart Phone	x	x	x	x
PDA	(x)	(x)	(x)	x
Tablet PC	x	x	x	x
Wearable Computing	Depending on the combination with other mobile devices			x

For mobile devices used within the premises, the bandwidth problem can be neglected, considering the application of wireless LAN technologies. Handheld devices with WLAN connectivity are already in rapid advance in industrial production management, which provides a promising base for in-premises mobile KM. As the restricted range of wireless LAN cannot fulfill the requirement of ubiquitous access, this technology has to be treated with some reservations in this context.

Concept and Design Requirements

In contrast to mobile commerce, mobile KM aims almost exclusively at the intraorganizational or interorganizational use. That enables the particular organization to choose the most appropriate technology for the desired KM solution and regulate its use. The same is true at an intraorganizational level, where the employed technology can be determined by an agreement with the respective business partners. Compared with mobile commerce, that results in a considerable advantage, because that way an optimal fit between the type of mobile devices and the employed KM solution is ensured. Thus certain problems arising due to the heterogeneity of devices can be avoided. Further, the employment of devices can be intentionally managed in order to ensure the fit of individual users' KM needs and the particular features of the different mobile devices. But as stated above, the different modes of spatial mobility require the use of different mobile devices. That results in the fact that although in the organizational context the use of mobile devices can be regulated to some extent, there still exists a considerable amount of heterogeneity. Heterogeneity implies special requirements for the design process of mobile KMS solutions. As the different mobile devices possess diverse technological characteristics, there is no one-size-fits-it-all solution. For that reason it is recommended to choose a platform-independent approach for the implementation (Grimm, Tazari, & Balfanz, 2002).

Taking KM mobile has to account for further special requirements that are associated with mobile technology. Limitations for the use in the mobile KM context arise above all due to displays and input possibilities, as well as bandwidth and transfer modes. With the exception of tablet PCs, the display sizes range from a few lines only (mobile phone) to 240x320 or larger (PDA). Regarding the input methods, the possibilities vary from a restricted number of pushbuttons that enable operating simple menus to more sophisticated solutions like handwriting recognition or virtual keyboards. Further, design requirements for common user interfaces need to be adjusted, as they are developed for stationary use, assuming that all concentration is focused on the display. That is naturally not the case if the device is used on the move.

Where the employment of mobile devices is concerned, every type of device introduced earlier can be used in the KM process. Categorizing mobile KM into the following different groups enables delineation of the effectual technological requirements (Derballa & Pousttchi, 2004):

1. Mobile Information Exchange includes the transfer of data and information using e-mail, as well as the access to operational systems used in an organization to retrieve sales figures or market data.
2. Mobile Business Intelligence refers to the access of processed enterprise data using mobile devices. It involves the technologies introduced earlier (e.g., data mining and data warehouses).
3. Mobile KM describes that management process in the course of which mobile communication techniques in conjunction with mobile devices are employed for the creation, validation, presentation, distribution, or application of knowledge.

Mobile Information Access

For the retrieval of data and information, all mobiles devices can be used that feature the basic capability of displaying text. It has to be taken into account though that in reading longer textual information like e-mails, the use of small display devices is not very feasible. Mobile phones thus are suited best for the display of a small amount of data and information.

Mobile Business Intelligence

The display of processed enterprise data requires the mobile devices used to be able to display complex tables and maybe graphical visualization of the processed data. Thus more processing power is needed, which disqualifies simple mobile phones from being used in that context. Consequently, Smartphones as well as PDAs meet the minimum requirements for that mobile KM stage.

Mobile KM

In this context we are referring to the definition of KM in the narrower sense introduced above. The specific requirements for mobile devices used results from the type of KM technique that is taken mobile. For low-technology KM solutions like expert finder—as long as there is no graphical visualization—even mobile phones can be considered. However, with the richness of the KM solution, the requirements regarding display, processing power and entering methods, and required bandwidth increase dramatically. That is for example the case when a lessons learned database includes complex graphics for visualization purposes.

FUTURE TRENDS

Considering the fact that research for IT support for mobile business processes in general and mobile KM in particular is still in its early days, a considerable amount of work has to be done to catch up with the state of research in other areas of KM. The questions to be answered are manifold, but the following issues, without claiming to be exhaustive, are introduced as possible research topics.

We consider a KMS as a socio-technical system, according to Ropohl (1979), comprising the elements human actors, tasks, and technology. Based on that perspective, possible research questions are grouped into the following categories.

Human Actor-Related Questions

Apart from the potential to greatly improve mobile business and knowledge processes, the wide use of mobile devices might lead to some undesirable effects. A current example for this problem can be observed in the United States with the increasing popularity of the Blackberry. Its owner is always connected, always on, has the possibility to interact, and is never cut off from the information flow. According to recent reports, that results in an excessive overuse of the device, including derogatory effects on the mental condition of its user, which resulted in the fact that the Blackberry is ironically called "Crackberry" (e.g., Pilcher, 2004). Two main problems can be addressed in this area and need further empirical research: information overload and interaction overload. Certain types of (knowledge)work require outmost concentration. Considering the possibility to provide the user with information on a push basis, these moments of concentration might be interrupted, leading to unwanted performance loss of the individual user (Davis, 2002). It might however be possible to fight information overload with the possibility to deliver context-relevant information only, which is enabled through the aspect of context-specifity. Until today, it has however not been fully evaluated whether the delivery of context-specific information can be conducted with enough feasible practicability.

With an accretive amount of interaction shifting towards the space of mobility, there is further the problem of too much interaction, of interaction overload. Similar to information overload, the possibility to interact continuously might reach dimensions in which the amount of interaction is detrimental to the productivity of individual workers.

Task-Related Questions

Mobile knowledge work can be considered as work that includes a considerable amount of self-management. The introduction of mobile KM might reduce this amount of freedom in exchange for more structured processes and greater control. It needs to be tested how this development might influence worker's productivity. A basic precondition for the adoption of new technology, in this case mobile technology, assumes that the prospective users are willing to use new technology. That however might not always be the case. Further, organizational effects can be expected due to the extensive effect mobile technology can have on business processes. Adaptive Structuration Theory can provide a framework for the evaluation of the possible effects on work processes and organizational changes (DeSanctis & Poole, 1994).

Technology-Related Questions

With the focus on technology, it needs to be empirically tested which type of mobile device can be feasibly used during different types of spatial mobility. Krogstie (2003) cites a case study dealing with an electronic newspaper delivery guide, demonstrating that the usage of mobile devices to support workers with the task of route planning and scheduling of activities, is potentially remunerative compared to the earlier paper-based solution. As potential benefits he identified for example the optimized scheduling and planning process. Practice however showed that the mobile devices used were not robust enough to withstand snow, rain, and other environmental influences.

CONCLUSION

According to the general technological and social trends introduced above, mobile technology in the context of KM will become an increasingly relevant topic. Technology will act as an enabler in this field, with increasingly powerful mobile devices as well as higher data transmission speeds allowing significant KMSs to be taken mobile. Designing mobile KM solutions, however, has to cater for several different requirements that are still subject to further research. This article addresses important design issues in order to provide some leads for the further discussion of mobile KM, and presents an introduction to the relevant mobile technologies.

Chapter 4.23
Knowledge Sharing Between Individuals

Carolyn McKinnell Jacobson
Marymount University, USA

INTRODUCTION

As Peter Drucker (2000) has pointed out, the foundation of the 21st century organization is no longer money or capital or even technology; it is knowledge. In order for that knowledge to create value, it must be shared. Some discussions of knowledge sharing in organizations and, indeed, some knowledge management initiatives seem to assume that given the right technology and/or the proper culture, knowledge will flow readily throughout the firm. Technologies that facilitate knowledge sharing (e.g., databases, intranets, and groupware) currently exist and are constantly improving. But technologies are only part of the knowledge management equation.

In 1997, the Ernst and Young Center for Business Innovation conducted a study of 431 U.S. and European organizations (Ruggles, 1998). Of those responding, only 13% rated their organizations as good or excellent at sharing knowledge internally. Even when knowledge was accessible, only 30% reported that their organizations were good or excellent at using that knowledge in making decisions. When asked what was the biggest obstacle to knowledge sharing within their organizations, 54% cited culture. To understand knowledge sharing within an organization, we must look beyond culture and start with the individual.

BACKGROUND

There has been much written about defining, creating, assessing, and changing organizational culture. In most of these writings, the focus has been the organization as a whole (e.g., Deal & Kennedy, 1982; Kotter & Heskett, 1992; Schein, 1999) or its subdivisions (e.g., Sackmann, 1992). The focus has not been on the individual or on knowledge sharing.

What exactly do we mean by knowledge sharing? There are numerous definitions of knowledge ranging from the pragmatic to the philosophical.

We shall adopt a definition based on Turban (1992) that knowledge is information that has been organized and analyzed to convey understanding, experience, learning, and expertise so that it is understandable and applicable to problem solving or decision making. Although knowledge sharing and knowledge transfer are often used interchangeably, we shall make a distinction between them. Knowledge sharing as used here refers to an exchange of knowledge between two individuals: one who communicates knowledge and one who assimilates it. Knowledge sharing focuses on human capital and the interaction of individuals. Knowledge transfer focuses on structural capital and the transformation of individual knowledge to group or organizational knowledge, which becomes built into processes, products, and services. Strictly speaking, knowledge can never be shared. Because knowledge exists in a context, the receiver interprets it in light of his or her own background.

Several authors have looked at the organizational factors that inhibit the sharing of knowledge. Believing that most people "have a natural desire…to share what they know," O'Dell and Grayson (1998, p. 16) attribute the lack of internal knowledge sharing in organizations to "a set of organizational structures, management practices, and measurement systems that discourage-rather than encourage-sharing" (p. 17). Szulanski (1996, 2003) identifies four sets of factors that determine how readily knowledge will be shared within the firm: the characteristics of knowledge, the characteristics of the source, the characteristics of the recipient, and the organizational context. Hubert Saint-Onge, chief executive officer (CEO) of Konverge Digital Solutions Corp, offers a different explanation for the lack of knowledge sharing: "Sharing knowledge is an unnatural act. You can't just stand up and say 'Thou shalt share knowledge'-it won't work" (as cited in Paul, 2003).

E. von Hippel (1994) coined the phrase "sticky information" to describe "the incremental expenditure required to transfer that unit of information to a specified locus in a form usable by a given information seeker" (p. 430). The higher the incremental expenditure, the stickier the information is. Stickiness may be an attribute of the information itself, or it may refer to attributes and choices made by someone seeking information or by someone providing it.

If we are to understand knowledge sharing, we must examine what happens at the level of the individuals who are at the core of the knowledge sharing process. Maslow's (1987) hierarchy of needs provides one widely accepted explanation of the behavior and attitudes of individuals in organizations. Maslow identified five levels of human needs: physiological (e.g., food, water), safety (e.g., security, protection), social (e.g., love, affection, sense of belonging), esteem (e.g., respect and recognition from others, personal sense of competence), and self-actualization (e.g., fulfillment of one's potential). According to Maslow, an unsatisfied need motivates behavior. Because these five needs exist in a hierarchy, a lower level need must be satisfied before the next higher level need is activated until the highest level, self-actualization, is reached. The more the self-actualization need is satisfied, the stronger it grows. Although there may be a variety of ways to satisfy a need, individuals can be expected to engage in knowledge sharing behaviors to the extent that they perceive that knowledge sharing leads to the satisfaction of a need.

Shannon and Weaver (1949) provide us with a transmission model of communication. Their model consists of six basic elements: the source, encoder, message, channel, decoder, and receiver. Although this model is often referred to in explaining human communication, it was actually designed for information theory and cybernetics, and is therefore technologically oriented. As a result, it does not address factors that can affect human communication, such as the context of the communication or the content of the message itself. Nevertheless, it provides insight into the communication process by dividing that process into discrete units.

Berlo's (1960) model of communication also refers to the source, message, channel, and receiver, but his focus is on interpersonal dyadic communication. The source and receiver are defined in terms of communication skills, knowledge, social systems, culture, and attitudes. Communication skills include speaking, writing, listening, reading, and thinking or reasoning. Knowledge refers to the source's knowledge of his or her own attitudes, options for producing a message, choices of communication channels, and subject matter. Social systems are produced through communication and refer to the collective behaviors and structures associated with a group of individuals who have interdependent goals. Culture, which consists of our shared beliefs, values, and behaviors, will influence our communication patterns as well. Finally, attitudes toward self, the subject matter, and the receiver also affect communication.

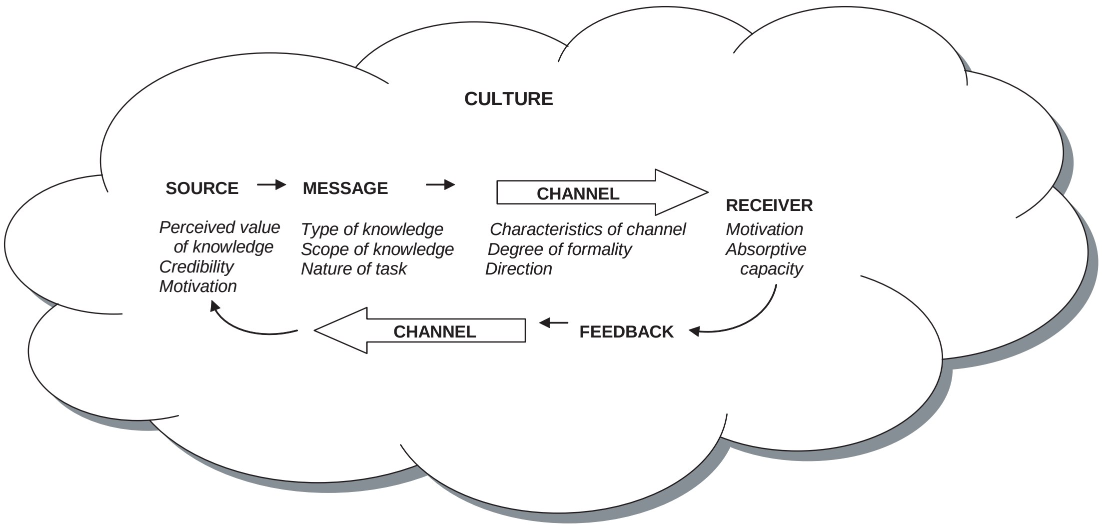
Models of the communication process, such as Berlo's (1960) model, apply to communication in general and not specifically to knowledge sharing, although knowledge sharing requires communication in some form (verbal or nonverbal, written or spoken, etc.). From an organizational semiotics perspective, knowledge sharing can therefore be analyzed in terms of communication functions.

Previous work on knowledge sharing has often focused on teams or groups and has overlooked important factors that affect the exchange of knowledge between two individuals. As Nonaka and Takeuchi (1995, p. 59) have pointed out, "An organization cannot create knowledge without individuals." The purpose of this article is to describe a model of knowledge sharing between individuals in organizations.

A MODEL OF KNOWLEDGE SHARING

Borrowing from the work of Shannon and Weaver (1949) and from Berlo (1960), we focus on six factors involved in knowledge sharing: the knowledge

Figure 1. A model of knowledge sharing between individuals in an organizational context (based on Shannon & Weaver, 1949)



source, the message, the knowledge receiver, the communication channel, feedback, and the environment or culture in which the knowledge sharing occurs (see Figure 1).

Knowledge Source

The knowledge source is an individual who possesses knowledge and transmits it. The transmission of knowledge may or may not be intentional (Hendriks, 1999). An example of unintentional transmission would be someone acquiring knowledge by watching you perform a task. Three characteristics relate to the knowledge source. The first characteristic suggests that, because the flow of knowledge between individuals has a cost associated with it, knowledge that is perceived by the source as being more valuable is more likely to be shared than knowledge that is perceived to be of lesser value or duplicative (Gupta & Govindarajan, 2000). Of course, it is always possible that the possessor of the knowledge does not realize the value of that knowledge. The second characteristic is the credibility of the source. Knowledge is more likely to be shared if the source is seen as credible. Factors associated with credibility include trustworthiness, status, education, and position (Szulanski, 2003).

The third characteristic relates to the motivation of the source to share knowledge. Individuals or groups who perceive that their unique, valuable knowledge provides them with power or status in the organization will be less likely to share that knowledge (Gupta & Govindarajan, 2000; Szulanski, 2003). Conversely, those individuals who are motivated to share their knowledge will have a positive effect on knowledge sharing (Gupta & Govindarajan). This motivation may arise from altruism (a desire to help others or to help the organization), from a passion for the subject, or from a desire to be recognized as an expert, what Maslow (1987) referred to as the esteem need). It may also arise from the expectation that, at some point in the future, the receiver will be willing to return the favor, either as knowledge shared or in some other form (Davenport & Prusak, 1998).

What kinds of rewards should an organization provide to motivate employees to share knowledge? In three large scale studies on knowledge management, the American Productivity and Quality Center concluded, "…if the process of sharing and transfer is not inherently rewarding, celebrated and supported by the culture, then artificial rewards won't have much effect" (O'Dell & Grayson, 1998, p. 82). If knowledge sharing helps people do their work better or more efficiently, or if it provides them with recognition as experts, they will be motivated to do it (Maslow, 1987). This is not to say that explicit rewards should never be used. In 1993, the most active participants in Buckman Laboratories' online knowledge sharing network received a surprise trip to a conference in Arizona, a $150 leather bag, and an IBM Thinkpad 720. The bag and computer quickly became status symbols around the company (O'Dell & Grayson).

The Message

The second factor in the knowledge sharing process involves the message itself. What is the type of knowledge that is being shared, and what is the scope of that knowledge (Dixon, 2000)? Although there are various typologies of knowledge (e.g., Blackler, 1995; Collins, 1993; Machlup, 1980; Quinn, Anderson, & Finkelstein, 1996; Wiig, 1994), we shall adopt Nonaka and Takeuchi's (1995) widely accepted framework because it focuses on the individual as central to the knowledge-creation process: "An organization cannot create knowledge without individuals" (p. 59). Based on the distinction first made by Michael Polanyi (1967), Nonaka and Takeuchi describe knowledge as existing on a continuum ranging from explicit to tacit. Explicit knowledge, sometimes referred to as codified knowledge, is objective knowledge that can be transmitted in formal, systematic language. It deals with past events or objects and can be transmitted electronically in documents and databases. Tacit knowledge is personal and context specific. It is more difficult to capture and express, existing primarily in people's heads (Nonaka & Takeuchi). Most knowledge found in organizations is a combination of the two, falling somewhere between the two ends of the continuum. Although explicit knowledge is generally considered easier to share than tacit knowledge, it may be that tacit knowledge simply requires different channels or different transmission processes. In a study of attitudes about information sharing in a technical context (Constant, Kiesler, & Sproull, 1994), it was found that participants were willing to share explicit knowledge in the form of documents that belonged to the organization. Although the participants were also willing to share personal expertise (tacit knowledge) such as providing assistance with a software package, when sharing tacit knowledge they expected something in return (e.g., acknowledgement of their expertise).

The scope of the knowledge, the second characteristic of the message, refers to the number of functional areas in the organization that will be affected by the knowledge being shared. Knowledge that is narrower in scope is generally less complex and more explicit, making it easier to share. Knowledge that involves multiple functional areas tends to be more complex and therefore more difficult to share (Dixon, 2000).

A third characteristic of the message concerns the nature of the task. Tasks may be routine or nonroutine, and may occur regularly or infrequently. Routine tasks that occur regularly involve knowledge that can be readily shared. Nonroutine tasks that occur less frequently or only under unusual circumstances make knowledge sharing more challenging. If the knowledge source and the intended receiver are doing similar tasks in similar contexts, knowledge can be shared more easily (Dixon, 2000).

Knowledge Receiver

The knowledge receiver, the target of the communication, is the third factor in the knowledge sharing process. The effectiveness of the knowledge sharing process will depend on the receiver's motivation and absorptive capacity. Motivation may be influenced by the "not-invented-here" syndrome, which suggests that we tend to regard knowledge from another source as less valuable than what we already know. This may derive from our reluctance to admit that someone else is more competent than we are. It might also derive from power struggles in the organization, which cause us to denigrate or disregard any knowledge contributions from an individual or a unit that we perceive to be a competitor. Or we may simply not see the value or relevance of that knowledge (Gupta & Govindarajan, 2000).

Several companies have created awards to encourage employees to use knowledge from other sources. Understanding the reluctance to use knowledge from another source and the motivation associated with recognition, Texas Instruments created the NIHBIDIA Award (Not Invented Here But I Did It Anyway) for ideas borrowed either from inside or outside of the company. British Petroleum bestows a Thief of the Year award to the person who has "stolen" the best idea (Davenport & Prusak, 1998).

The second characteristic related to the receiver is his or her capacity to absorb new knowledge, which is influenced by the ability to recognize the value of new knowledge that is encountered, to assimilate that knowledge, and to apply it (Cohen & Levinthal, 1990). Prior related knowledge will increase our ability to absorb new knowledge. Similarly, if the source of that knowledge is an individual like ourselves in terms of education, background, and so forth, we are more likely to absorb new knowledge or change our attitudes and behavior (Dixon, 2000; Gupta & Govindarajan, 2000; Szulanski, 2003).

Davenport and Prusak (1998) recount the story of a group of 23 surgeons who specialize in coronary artery bypass surgery. They wanted to find out if skill sharing and observing one another in surgery would improve their success rate. They started by sharing their success rates and comparing them with statistics of other surgeons in the medical center and in the region. They also received training in continuous improvement techniques. The overall result was that these surgeons achieved a 24% drop in the mortality rate associated with the surgery. A major factor in the success of this project was that these surgeons all worked in the same area of specialization and all shared almost identical training and experience. The similarity in background and experience allowed them to easily understand and absorb each other's words and actions.

Communication Channel

The fourth factor in the knowledge sharing process is the communication channel, or the means by which a message is communicated. A communication channel may involve seeing, hearing, touching, smelling, or tasting (Berlo, 1960). Telephone, the Internet, braille, airwaves, and roadside billboards are all examples of communication channels. Knowledge sharing will be enhanced by the richness, bandwidth, and reliability of the communication channel. For example, knowledge sharing may be facilitated by face-to-face meetings that involve seeing and hearing as opposed to electronic communication (e.g., e-mail, databases, or direct mail) that only involves seeing. Channels can be either formal or informal. Formal mechanisms for linking organizational units might include task forces, permanent committees, or formally appointed liaison personnel. Informal mechanisms would involve ad hoc, interpersonal interactions among employees. The better your relationships with your coworkers and the more opportunities you have to interact, the greater the possibility of knowledge sharing. These interactions are typically horizontal (peer to peer) or vertical (e.g., corporate mentoring programs or internships; Gupta & Govindarajan, 2000; Szulanski, 2003).

Some organizations have created open office spaces to encourage face-to-face interaction among employees. Newspaper offices have used this model for some time because editors understand that it facilitates rapid knowledge sharing so that deadlines can be met. Sun Microsystems' offices in Menlo Park, California, use architectural design to encourage interaction and knowledge sharing. Only about one third of their floor space is devoted to offices; the rest is designed to encourage informal project discussions with lots of light, comfortable couches, and white boards (Fisher & Fisher, 1999). Hewlett-Packard has also made open space offices compulsory for its subsidiaries (Sveiby, 1997).

Feedback

It can be argued that knowledge sharing has not occurred unless the knowledge receiver has assimilated what has been communicated. This can be determined by the response (either verbal or nonverbal) of the receiver. Feedback may consist of a verbal reply, a nod, or the successful completion of a task, indicating that the receiver understood the message. Conversely, a puzzled look may signal a lack of understanding. The receiver's response may thus influence future messages from the knowledge source. If the receiver has assimilated the knowledge, it should lead to increased value for the organization, either through a change in behavior or through the development of a new idea that leads to a change of behavior.

Culture

Finally, the knowledge sharing process takes place within an organizational culture, which Schein

(1985) has defined as a "shared view." Culture is reflected in an organization's values, norms, and practices such that values are manifested in norms, which determine specific practices (De Long & Fahey, 2000). Excellent companies have shared values that are clear to all employees throughout the organization (Peters & Waterman, 1982) and that determine how employees think and act. De Long and Fahey describe four aspects of organizational culture that influence knowledge-related behaviors: culture shapes assumptions about which knowledge is important; it mediates the relationships among individual, group, and organizational knowledge; it creates the organizational context for social interactions; and it impacts the creation and adoption of new knowledge.

One of the values that must be part of a knowledge sharing culture is trust, which is defined in terms of respecting the ownership of ideas (Andrews & Delahaye, 2000; Zand, 1972). Knowledge sharers must know that they will get credit and that others will reciprocate. Trust must be visible, it must be ubiquitous, and it must start at the top (Davenport & Prusak, 1998). Top management in particular must emulate trustworthiness because their actions define the values of the organization.

When asked to name the three critical factors in knowledge management, Robert Buckman, president, chairman, and CEO of Bulab Holding, Inc., replied, "Culture, culture, culture" (as cited in O'Dell & Grayson, 1998, p. 71). If top management believes that power comes from accumulating and hoarding knowledge, then knowledge sharing will not occur. In Buckman's view, "The most powerful individuals will be those who do the best job of transferring knowledge to others" (p. 77).

FUTURE TRENDS

Knowledge has arguably become the most important resource for organizations today. Because organizations cannot create knowledge without people, the knowledge worker has become an organization's single greatest asset. If knowledge is to create a competitive advantage for the organization, it must be shared. Any effort to effect knowledge sharing must begin with an understanding of the factors that influence knowledge sharing between individuals.

As the examples above clearly illustrate, organizations are beginning to address some of the issues involved in knowledge sharing. What is needed now is a model that brings all the relevant factors together in an organized fashion, and that model is provided here. Wiig and Jooste (2003) point out that the first generation of knowledge management in the 1990s focused on "visible aspects of work…The new second generation approaches seek greater impacts and better business results and therefore require more effective methods" (pp. 300-301). This model of knowledge sharing between individuals provides a shift from the isolated projects of the first generation to integrated practices, and from the more narrow applications of the 1990s to a broader approach and deeper understanding of knowledge sharing.

Understanding the factors involved in knowledge sharing is a first step in understanding how to manage the knowledge sharing process. Although a detailed framework for managing knowledge sharing is beyond the scope of this article, three general suggestions are offered.

First, an organization that values knowledge sharing must ensure that its culture (e.g., norms, values, and practices) consistently supports it. Individuals must receive appropriate rewards for knowledge sharing, and they must receive credit for their ideas. Knowledge sharing is facilitated when people share the same work culture (Davenport & Prusak, 1998), but it must be recognized that cultures are not always homogeneous throughout an organization (McDermott & O'Dell, 2001). An essential element of culture is trust, which must be ubiquitous, must be visible, and must be modeled from the top of the organization on down (Davenport & Prusak).

Second, motivation is a key factor for both the source and the receiver. With reference to Maslow's (1987) hierarchy of needs, knowledge workers are motivated by esteem and self-actualization needs. Individuals can be expected to engage in knowledge sharing behaviors to the extent that doing so satisfies these needs. Managers who want to promote knowledge sharing should therefore provide employees with opportunities for satisfying these needs through creative and challenging work, recognition, and promotion. Managers should also try to minimize or remove any obstacles that block need satisfaction and therefore inhibit knowledge sharing.

Herzberg's (1968) two factor theory provides us with another perspective on motivation. According to Herzberg, factors that produce job satisfaction (motivators) are separate and distinct from those that lead to job dissatisfaction (hygiene factors). Motivators relate to job content and include achievement, recognition for achievement, advancement, growth, and responsibility. These factors can increase job satisfaction, but they will not prevent job dissatisfaction. Hygiene factors relate to job context and include company policy, supervision, working conditions, salary, and security. These factors do not motivate behavior, but they may lead to dissatisfaction and therefore decreased motivation if they are absent. A manager's goal should be to keep job dissatisfaction low and job satisfaction high. High satisfaction can be expected to result in increased effort (i.e., increased motivation of the knowledge source and receiver) and receptivity to ideas and suggestions (i.e., the absorptive capacity of the receiver; Locke, 1970).

Third, managers need to provide and promote opportunities for knowledge sharing. While such opportunities are necessary for knowledge sharing, they are not sufficient and must be in conjunction with the proper culture and motivation. These opportunities may range from informal face-to-face meetings to formal electronic communication systems (e.g., e-mail, discussion boards). Mentoring programs may be used to encourage more seasoned employees to share knowledge with new hires. A physical environment that includes open office space and areas for informal interaction may also encourage knowledge sharing.

This model of knowledge sharing between individuals in an organizational context provides a framework for future research to explore these factors in greater depth. For example, how do the characteristics of the communication channel interact with the characteristics of the source or the receiver? Are some communication channels more appropriate for some kinds of messages? Is this model valid for all kinds of knowledge? How can trust be built in a colocated community? Are the same methods for building trust in a colocated community also effective in a virtual community? How can trust be built in a cross-cultural community? What is the relationship between this model and various organizational, or even national, cultures?

CONCLUSION

There have been several systematic research studies of knowledge sharing in organizations (e.g., Constant et al., 1994; O'Dell & Grayson, 1998; Ruggles, 1998), but much of what we think we know is based on anecdotal evidence. This model offers us a starting point for a more systematic and scientific approach. A better understanding of organizational knowledge sharing at the dyadic level will provide a foundation for understanding knowledge sharing within and among groups, and ultimately, within and among organizations.

Chapter 4.24
Client/Server and the Knowledge Directory

INTRODUCTION

Data, information, and knowledge are three related but not interchangeable concepts. Data are a set of discrete, objective facts about events. Information is organized data presented in context. Data become information when their creator adds meaning or value. Similarly, knowledge derives from information as information derives from data. Knowledge can be viewed as information in context, together with an understanding of how to use it. Knowledge can be either explicit (knowledge for which a person is able to make available for inspection) or tacit (knowledge for which a person is unable to make available for inspection) (Brooking, 1999; Davenpot & Prusak, 1998). In Table 1, a list of knowledge that is particularly critical for business organizations is given.

Knowledge is an intellectual property that although paid for in part by the employer is a difficult asset to control, as it is fragmented in documents, policies, procedures, and other data storage mediums. Another challenge for management is to retain this knowledge in a form that is easily retrievable. This is not an easy task, since the enterprise must first identify the location of all needed knowledge, and second, determine the easiest way to retrieve it.

There are many definitions of knowledge management, but the Gartner Group (1999) description seems most appropriate for the perspective expressed in our article: “Knowledge management

Table 1. Knowledge that is particularly critical (Brooking, 1999)

- Knowledge of a particular job
- Knowledge of who knows what in a company
- Knowledge of how to get things done in a company using the corporate culture
- Knowledge of who is best to perform a particular job or task
- Knowledge of corporate history (how and why)
- Knowledge of business customs
- Knowledge of a particular customer account
- Knowledge of how to put together a team that can achieve a particular task
- Knowledge of how to approach a particular problem that is difficult to solve

promotes an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets. These information assets may include databases, documents, policies and procedures, as well as the un-captured tacit expertise and experience stored in individual workers' heads."

This definition implies that information assets are plentiful and are stored in numerous locations throughout the organization. Storage options include documents, documents in document management systems, groupware such as Lotus Notes, and expert or knowledge-based systems (Brooking, 1999). Physically these information assets can be electronically stored on compact disk, laser disk, mechanical hard drives, microfilm, microfiche, and embedded in computer programs. Further, information assets are also stored in books, documents, and other paper-based medium.

BACKGROUND

In a world of multiple computer languages, database management systems, assorted collaborative and group support software, network technologies, and data storage methods, it can be a difficult and complex problem to locate and retrieve enterprise knowledge. If KM promotes an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets, then the challenge is to create a knowledge management system in order to get the right information to the right person at the right time.

"An integrated and integrative technology architecture is a key driver for Knowledge Management Systems (KMS) … KMS seem to require a variety of technologies: database and database management, communication and messaging, and browsing and retrieval. The need for seamless integration of the various technologies may lead to the dominance of the Internet and Internet-based KMS architectures" (Alavi & Leidner, 1999). Alavi and Leidner (1999) also note that "organizational intranets will also play a dominant role in support of internal knowledge management activities due to cost-effective technical capabilities including: access to the legacy systems, platform independence, access to multimedia data formats, a uniform and easy-to-use point-and-click interface, and capability for easy multi-media publication for knowledge sharing."

A CLIENT/SERVER ARCHITECTURE FOR KMS

Computing sources for the first 30 years of the information technology revolution were dominated by isolated hardware and network environments. Mainframes, mini-computers and local area networks were initially set up to support specific business functions. Each computing complex was installed with a separate physical data network. IBM mainframes used coaxial cable and 3270 terminal emulation and the IBM System 38 mini-computer used twin-axial cable and 5250 terminal emulation. Local area networks used their own respective cabling medium and data network architecture. As a result, these environments were isolated and data sharing was almost impossible (Kern et al., 1998).

Information systems written for these monolithic computer complexes contain three basic components: a presentation layer, a processing layer, and a data storage layer (Boar, 1996; Borthick & Roth, 1994). All three layers execute on one hardware platform. During the 1980s and 1990s, multiple protocol support between different platforms across inexpensive connections became more common. This connectivity enhancement helped the development of client/server technologies, which distributed these layers across hardware and operating systems platforms (Boar, 1996; Duchessi & Chengalur-Smith, 1998; Schulte, 1995). A client/server architecture consists of three layers: the presentation layer, the business logic layer, and the data layer. A two-tier client/server architecture places the presentation layer on the client and data layer on the server. The business layer may reside on either the client or server, or both. A three-tier client/server architecture places the presentation layer on the client, the business logic layer on a middle tier, and the data layer on a server. Although there are many variation of the client/server model, two-tier and three-tier are the two basic deployments (Edwards, 1999; Weston, 1998).

The three-tier client/server architecture has many advantages over the two-tier client/server architecture, including less complexity, higher security, higher encapsulation of data, better performance efficiency, excellent scalability, excellent application reuse, a good server-to-server infrastructure (via server-side middleware), legacy application integration (via gateways), excellent internal support, support for heterogeneous databases, rich communication choices, excellent hardware architecture flexibility, and excellent availability. The main disadvantage is the difficulties in development, but these difficulties are getting less and less over time (Orfali et al., 1999). One way around this development problem is to adopt a component-based architecture design.

Employing a three-tier client/server architecture would provide a good flexible architecture for KMS. The structure would be very similar to the three-tier client/server architecture detailed by Orfali et al. (1999), except it would also have a knowledge directory (covered in the next section). The client layer would have at least the following: a nice GUI, a Web browser, the client operating system, and any required client-side applications for KM (such as Lotus Notes). The middle layer would contain a network operating system, and transport stack (such as TCP/IP) and service specific middleware for: databases (such as ODBC, JDBC, and SQLJ), internet/intranets (such as HTTP and CGI), e-mail (such as SMTP and POP3), storing and accessing multimedia documents, coordinating group conferencing, linking individuals in group scheduling, and workflow processes. The server layer would contain the server operating system and specific server-based applications such as database management systems, document management systems, server side groupware, and so forth.

Knowledge Management Directory

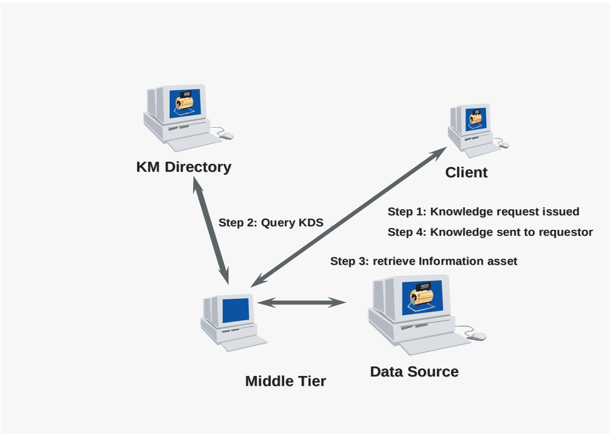
Achieving the connection to numerous data and information sources is a serious challenge for the development of KMS. Organizational knowledge management strives to cultivate, nurture and exploit knowledge at different levels and in different contexts throughout the organization (Handzic & Bewsell, 2001). The demands placed on the information technology infrastructure to support an integrated approach to identifying, capturing, retrieving, sharing, and evaluating an enterprise's information assets is a major undertaking; especially since these information assets may include databases, documents, policies and procedures stored in electronic forms.

One of the major requirements of KM is the ability to locate the knowledge and present it to the knowledge requester. The need for a directory of information assets is imperative. A facility, such as the Knowledge Management Directory (KMD), supports the central task of organizational knowledge management and knowledge mapping (Galup, Dattero, & Hicks, 2003). Knowledge mapping provides a continuously evolving organization memory by capturing and integrating knowledge sources and communicating knowledge in an understandable way (Wexler, 2001).

A knowledge directory (some sort of list or picture) points to knowledge (in people, documents, or databases) but does not contain it. The KMD resolves the client request to connect to an information asset by translating the keyword into a data source location, thereby permitting the

Figure 1.Knowledge management directory process (Galup & Dattero, 2000, 2002)

Step 1: The knowledge requester issues an inquiry for knowledge.
Step 2: An inquiry is sent to the Knowledge Management Directory and a summary listing similar to an Internet search is presented.
Step 3: A second request is sent to retrieve the information asset from the respective server.
Step 4: The knowledge is sent to the requester.



customer to navigate the numerous information asset resources and locate the best match.

The KMD categorizes the context of the knowledge and provides the computational tools to provide the user with access to the requested knowledge. To use the KMD, a user selects a topic from the user interface screen. When the topic is selected, a list of all resources of each type (expert/practice, decision support systems/warehouse, database, expert, and document) is displayed. The user then selects and evaluates sources until the knowledge is acquired. When multiple knowledge sources exist for a topic, the user will have to choose which knowledge source is most accurate and best suited to his or her needs. The knowledge seeker should be influenced to select the most complete and accurate knowledge available. In the KMD design, this is accomplished by ordering the knowledge sources by their inherent verification characteristics. The most accurate sources are placed at the top of the display, implying their desirability to the user. Expert systems and best practices represent complete, accurate solutions to specific problems, so they are the most desirable knowledge source and are ordered first. Data warehouses and decision support systems applications are the next highest in accuracy, followed by experts and documents (Hicks, Dattero & Galup, 2002, 2003).

CONCLUSION

Our three-tier client/server architecture for KMS has traits of the network model for KMS (Alavi & Leidner, 1999; Bowman, 2002). A network KMS "… focuses on building knowledge directories. This involves defining the knowledge categories that are relevant to the organization, identifying knowledge owners for each category, and creating a searchable directory to help others in the organization identify and locate knowledge owners" (Bowman, 2002). Our three-tier client/server architecture for KMS also has traits of the repository model for KMS (Alavi & Leidner, 1999; Bowman, 2002), because our KMS architecture retrieves explicit organizational knowledge. Therefore, our three-tier client/server architecture for KMS has the traits of the two major models for KMS. Further, it provides a seamless integration of the variety of technologies required for a KMS such as database management, document management, groupware, and e-mail.

Chapter 4.25
Assessing Knowledge Management System User Acceptance with the Technology Acceptance Model

William Money
The George Washington University, USA

Arch Turner
The George Washington University, USA

ABSTRACT

This article presents the results of a study investigating the applicability of Davis' Technology Acceptance Model (TAM) to user acceptance of a knowledge management system (KMS) in a modern organizational environment. The study endeavors to expand empirical research of two important and complex research questions: (1) What are the important factors, conditions, and mechanisms that affect people's acceptance and usage of collaborative and interdependent KMS in the modern organizational environment?, and (2) How applicable is the TAM, and the substantial body of information technology (IT) research around this model, to user acceptance and usage of a KMS in a modern organizational environment where collaboration, knowledge sharing, and role based system usage is necessary for the organization to function competitively? The study provides preliminary evidence suggesting previous TAM research may serve as a foundation for research of KMS user acceptance. Relationships among primary TAM constructs found in this study are in substantive agreement with those of previous research. These findings are significant because they suggest that the considerable body of previous TAM related IT research may be usefully applied to the knowledge management (KM) domain where interdependent social processes that

require knowledge creation, storage and retrieval, transfer, and application are required for effective organizational functioning.

INTRODUCTION

Although business investment in IT has declined somewhat in recent years, firms around the world still spend more than $2 trillion dollars a year on IT (Carr, 2003). It is also estimated that IT investment comprises approximately 50% of U.S. business capital investment, making it the top capital investment area for American businesses (Carr, 2003). With these continuing enormous business resource investments, understanding and creating conditions under which IT will be accepted and used in the organization remains a high priority within the IT research community (Venkatesh & Davis, 2000). Understanding why individuals accept or reject IT systems has proven to be one of the most challenging issues in information systems research (Doll et al., 1998). User acceptance of IT — a phenomenon that is not yet well understood — and usage are widely considered to be crucial factors in the ultimate determination of information system success, since information systems that are not used are of little value (Mathieson et al., 2001). Nevertheless, as will be discussed later, system usage alone may not be entirely representative of KMS organizational benefits.

A preponderance of research and accumulated knowledge of the factors affecting IT acceptance has as its foundation the technology acceptance model (TAM). TAM, originally conceived by Fred Davis in 1986, is an intentions based model derived from the theory of reasoned action (TRA) tailored to meet the needs of information technology research (Davis et al., 1989). Since its inception TAM has enjoyed growing acceptance and has proven to be a reasonably accurate predictor of both users' intentions to use an IT, and of IT usage. Evidence of the research community's growing acceptance of TAM is reflected in the fact that the Institute for Scientific Information Social Science Citation Index recently listed 335 journal citations since 1999 of the initial TAM research paper published by Davis et al. (1989). This represents a significant recent research citation increase when compared to February 2000 citation reference information cited by Venkatesh and Davis (2000).

A second related topic of considerable interest in the business world is the multi-faceted concept widely referred to as knowledge management (KM). KM can be defined broadly as the set of systematic and disciplined actions an organization can take to obtain the greatest value from the knowledge available to it (Marwick, 2001), and/or to efforts aimed at "identifying and leveraging the collective knowledge in an organization to help the organization compete" (Alavi & Leidner, 2001, p. 113). KM is rapidly becoming a critical integral business function as organizations increasingly realize their competitiveness in the intensely competitive global marketplace hinges on effective management of intellectual resources (Davenport & Grover, 2001). Increased interest and investment in KM can be attributed to the growing recognition that one of a firm's most unique and inimitable resources is the intellectual capabilities of its workers.

Reflecting this interest, recent literature is replete with research of a wide range of important issues related to the question of how organizations can best capitalize on their knowledge resources, develop processes to support KM, and broadly integrate KMS into organizational functioning. A cursory sampling of key KM issues reported recently include KM and new organizational structures (Malhotra, 2000), assessments of KM organizational capability prerequisites (Gold, Segar & Malhotra, 2001), KM strategies and taxonomies (Earl, 2001; Zack, 1999), the relative importance of various knowledge types (Lam, 2000), general discussions of KM benefits and challenges (Alavi & Leidner, 1999), the mapping of organizational knowledge (Vaill, 1999), the integration of information technology to enhance organizational KM (Bourdreau & Couillard, 1999), and the development of a KM research agenda (Grover & Davenport, 2001). Grant (1996) and Spender (1996) elevate the KM agenda further through their discussions of a knowledge-based theory of the firm.

An important topic in the evolving scholarly KM discourse is empirical research of factors, conditions, and mechanisms affecting individual acceptance and usage of IT implemented as a KMS. In their survey of KMS conceptual foundations and research issues, Alavi and Leidner (2001, p. 115) observed that while "the majority of knowledge management initiatives involve at least in part, if not to a significant degree, information technology….little research exists in the design, use, or success of systems to support knowledge management". Since then, measurable progress has been made. Ericsson and Avdic (2003) provided insightful ideas and directions relative to KM enablers and facilitating conditions. Jennex and Olfman (2002, 2003) have performed empirical KMS research based on the information system success model of Delone and McLean (1992). Their research incorporates the intention to use construct to help predict voluntary KMS usage and revealed that the perceived benefit model was useful for predicting continued use of a KMS in an engineering organization. Jennex and Olfman (2004) assessed KMS success factors and proposed a theory-based KMS success model that was shown to be a useful framework for assessing KMS success models.

Nevertheless, there remains a need for empirical field research into factors affecting KMS acceptance and usage. Evidence of this need can be found in Legris, Ingraham, and Collerette (2002), who synthesized findings of 22 scholarly IT acceptance studies. None of the studies considered in this meta-analysis addressed KMS acceptance. Furthermore, the majority was situated in educational settings that bear little resemblance to the modern organizational environment. Indeed, a survey of IT acceptance literature indicates most findings are drawn from analysis of individual usage IT, and are for the most part situated in settings not representative of the modern organizational environment. The importance of the distinction between the IT acceptance research that has been done to date, and that which is asserted to be needed around KMSs is reflected by Alavi and Leidner (2001, p. 123), who observe:

"… knowledge management consists of a dynamic and continuous set of processes and practices embedded in individuals, as well as in groups and physical structures. At any point in time and in any part of a given organization, individuals and groups may be engaged in several different aspects and processes of knowledge management. Thus, knowledge management is not a discrete, independent, and monolithic organizational phenomenon."

There is a consensus among organizational scholars and practitioners regarding the importance to organizations of leveraging their unique human intellectual resources. Additionally, in spite of a substantial research effort focused on IT acceptance and usage, numerous questions remain. As noted by Lesrig et al. (2002) and Kankanhalli et al. (2001), IT implementation in general, and KMS implementation in particular, continue to experience difficult challenges in the organizational environment. Due to the widely acknowledged social nature of successful organizational KM, KMS acceptance and usage represents a more complex phenomenon than individual acceptance and use of IT. It may involve a mix of voluntary and mandatory behaviors, integrated organization processes, and complex social forces and relationships. KMS acceptance research can be seen as the intersection of these two important areas and warrants increased attention.

KM SYSTEMS

KM is widely acknowledged to encompass a diverse mix of complex and dynamic factors. Furthermore, scholar and practitioner admonitions to resist the temptation to research exclusively technology matters at the expense of complex KM social and behavioral issues seem ubiquitous (Alavi & Leidner, 2001). Nevertheless, modern IT is unquestionably critical to current organizational KM. The ability of modern IT to synchronously or asynchronously span previously insurmountable organizational, time, and geographic barriers is a critical enabler that must be viewed as a catalyst for increased KM interest. Thus, it is not surprising that modern information technology has been the center of gravity for most enterprise knowledge management initiatives (Alavi & Leidner, 1999; Grover & Davenport, 2001). As Taylor (2003) and Kankanhalli et al. (2001) observe collectively, modern IT can be viewed as a virtually necessary, albeit not sufficient component of successful organizational KM.

Information-related technologies that support knowledge management include collaboration and community of interest/practice support technologies, structured and unstructured data indexing, categorization, and taxonomy producing tools, common databases, data warehousing technology, search and retrieval, and document management tools, to name just a few.

As with any IT implementation, the success of a KMS begins inevitably with individual acceptance. This research attempts to expand our understanding of the linkages between two important IT research topics: user IT acceptance and organizational KM. Davis' TAM is used as a framework to investigate the implementation of a KMS within an organizational unit of a large private consulting and technical services firm. TAM was selected for this research due to its broad — and seemingly growing — adoption among IT researchers, the well-established reliability and validity of its constructs, and the realization that the model had not been applied to KMS acceptance.

The firm studied has a global presence and is involved in a broad range of high technology product and service business areas. The specific organizational unit studied provides highly technical command and control, communications, computer, intelligence, surveillance, and reconnaissance project management and related consulting services to predominantly Department of Defense clients. The vast majority of the members of the organizational unit studied are well-educated professionals. They work in a highly competitive business environment and the work they perform can be accurately described as knowledge work. The KMS studied is a Web-based document repository and management tool intended primarily to support three organizational objectives: (1) improvement of internal software development processes to achieve Software Engineering Institute Level 2 accreditation, (2) enhanced diffusion of internal research and development (IR & D) products throughout the organization by providing employees better access to IR & D products, (3) enhance business process and employee professional development by providing convenient electronic access to current and past project information and documentation.

RESEARCH QUESTIONS

Given the broad reach of TAM IT acceptance research and the potential benefit of improved understanding of KMS acceptance, this research is focused on questions critical to KM acceptance using TAM. It is intended to develop preliminary answers to the following two basic questions:

1. What are the important factors, conditions, and mechanisms that affect people's acceptance and usage of a KMS in an organizational environment where collaboration, knowledge sharing, and role based system

usage are necessary for the organization to compete?

2. How well does TAM substantiate the predicted relationships and mechanisms relative to user acceptance and usage of a KMS in a modern organizational environment where collaboration, knowledge sharing, and role based system usage are necessary for the organization to compete?

THEORETICAL BACKGROUND AND DISCUSSION OF THE TECHNOLOGY ACCEPTANCE MODEL

Davis developed the TAM to provide an explanation of the determinants of computer acceptance that is general and capable of explaining user behavior across a broad range of end-user computing technologies and user populations, while also being both parsimonious and theoretically justified (Davis, 1989). TAM cuts a wide theoretical swath that includes the adoption of innovations, the cost-benefit paradigm, expectancy theory, and self-efficacy theory (Davis, 1989). Davis's original technology acceptance model is shown in Figure 1.

TAM is a derivative of the theory of reasoned action (TRA) model developed by Fishbein and Ajzen (1975). TRA focuses on situation-specific combinations of personal beliefs and attitudes, and the effects of the beliefs of others close to the individual (Szajna, 1996). The fundamental premise of TRA is that individuals will adopt a specific behavior if they perceive it will lead to positive outcomes (Compeau & Higgins, 1995). TAM is a TRA derivative tailored to the study of a broader range of user behavior in the context of IT acceptance (Davis, 1989). TAM includes two primary belief constructs hypothesized by Davis to affect a potential user's attitude and intention to

Figure 1. Technology acceptance model (Davis, 1989)

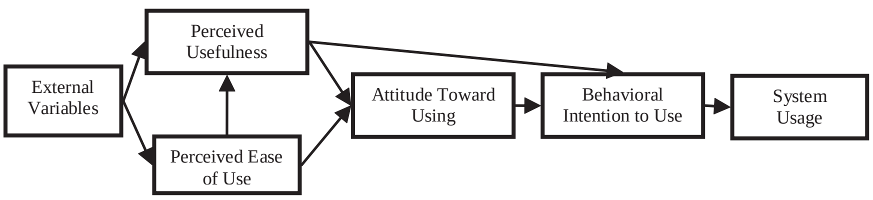

Figure 2. Theory of reasoned action (Fishbein & Ajzen, 1975)

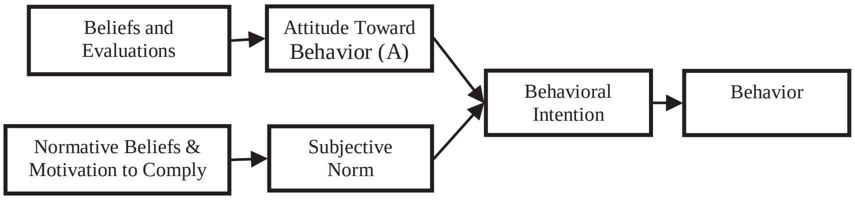


use an information technology: perceived usefulness ("the degree to which a person believes that using a particular system would enhance his or her job performance"), and perceived ease of use ("the degree to which a person believes that using a particular system would be free of effort") (Davis et al., 1989). Perceived usefulness and perceived ease of use and other TAM constructs relevant to this research will be discussed briefly next.

Perceived Usefulness

In developing TAM, Davis theorized that an individual's perception of usefulness would influence intention to use the technology primarily through the creation of a positive attitude. This was consistent with TAM's theoretical precursor, the TRA, which held that attitude (an individual's positive or negative feelings (evaluative affect) about performing a target behavior mediated the effects of beliefs (and subjective norm) on behavioral intention.

In a departure from the TRA, a direct effect of perceived usefulness on intention to use was also included in Davis' original TAM. Davis rationalized this effect by theorizing users may decide to accept and use a technology, regardless of their affective attitude towards it, if they have a sufficiently strong perception that it will contribute positively to their job performance (Davis et al., 1989).

Given the importance of perceived usefulness to the formation of a positive intention to use an IT, subsequent research has been directed to developing an understanding of the antecedents of usefulness. Venkatesh and Davis (February 2000) examined job relevance, output quality, and result demonstrability as antecedents to perceived usefulness. All three constructs were positively related to perceptions of information system usefulness.

Perceived Ease of Use

TAM's second principal belief construct, perceived ease of use, reflects an individual's assessment of the ease of use and ease of learning of a given system (Gefen & Straub, 2000). Davis (1989) and Davis et al. (1989) argued for the inclusion of ease of use as a separate belief construct based largely on the concept of self-efficacy (an individual's judgment of his/her ability to organize and execute tasks necessary to perform a behavior). They also cited factor analyses showing that usefulness and ease of use are statistically distinct constructs.

Venkatesh (2000, p. 344) noted that a "vast body of research in behavioral decision making and IS demonstrate that individuals attempt to minimize efforts in their behaviors, thus supporting a relationship between perceived ease of use and usage behavior, albeit through intention as suggested by TAM," and that "other theoretical perspectives studying user acceptance have also employed similar constructs".

The relationship between perceived ease of use and perceived usefulness has proven to be complex. There is a lack of consensus in the literature regarding how perceived ease of use affects attitudes and/or intentions to use IT. In the original TAM, Davis hypothesized perceived ease of use to affect both attitude and usefulness directly. As noted earlier, Davis et al. (1989) suggested elimination of the attitude construct, postulating a direct relationship between perceived ease of use and intention to use, rather than an indirect one through attitude. Finding that when the effects of usefulness are controlled for, the effect of ease of use "all but vanishes," Davis (1989) suggested that ease of use might be an antecedent to usefulness rather than a direct determinant of intention and usage. Subsequent research postulated dual TAM constructs; one for scenarios in which potential users were briefly introduced to a system, and another for scenarios in which users had acquired hands-on experience with the system (Szajna, 1996). According to this line of thinking, perceived ease of use would have a different effect in the two scenarios.

In brief introduction scenarios, ease of use was thought to have a direct effect on user intention to use that was anchored by the individual's computer self-efficacy. In scenarios in which users accumulated considerable experience with the system, it was hypothesized that perceived ease of use affected user intentions and usage only indirectly through perceived usefulness. This suggested that after hands-on experience, users create their own perception of a system's ease of use and consciously or subconsciously consider it a dimension of system usefulness. This stream of research also suggested that only after direct hands-on experience did a system's objective ease of use (as measured by comparing expert/novice task achievement times) become a factor in an individual's perception of system ease of use (Venkatesh & Davis, 1996).

Szajna (1996) found perceived ease of use influenced intentions only through usefulness and suggested that a single version of the TAM with this causal path was sufficient. Echoing others, including Davis, Szajna interpreted these findings to imply that unless individuals perceive a technology to be useful, its perceived ease of use characteristics are not critical. However, once an individual perceives a technology to be useful, then increased perceived ease of use contributes to its usefulness.

Gefen and Straub (2000) contributed another interesting perspective to the perceived ease of use discourse: that the effect of perceived ease of use on user acceptance would be task dependent. They noted most research had failed to address the nature of the task to be performed, focusing only on use, or intent to use. Their research, performed in the context of e-commerce technology, investigated the hypothesis that when a task was "extrinsic" to the IT (e.g., buying from an e-commerce site), ease of use was not a determinant of adoption. In contrast, when the task performed was "intrinsic" to the IT (e.g., gathering information) the individual's ease of use perception would affect his or her decision to adopt. Their findings supported this hypothesis, providing a potentially new interpretation of the effect of ease of use on IT acceptance that merits further investigation.

Most TAM research has substantiated Davis et al. (1989), who concluded that perceived usefulness is a "major determinant" of individuals' intention to use computers and that perceived ease of use is a "significant secondary determinant" of usage intentions. This logic is rationalized with the argument that users will tolerate ease of use shortcomings if they perceive the system is useful in their job. Conversely, users will not accept and use a system that is not useful - regardless of how easy it is to use.

Davis (1993) found evidence that perceived usefulness, perceived ease of use, and attitude fully mediated the effects of system design features on intention to use and usage. This research also found that perceived usefulness influenced attitude more than four times as much as perceived ease of use and that perceived usefulness was 50% more influential than perceived ease of use in explaining an individual's intention to use an information technology.

Attitude

Davis' original TAM theorized that an individual's perceptions of usefulness and ease of use would influence intention to use the technology primarily through the creation of a positive attitude.

Subsequent research suggests the role of attitude as a mediator of the effects of perceived usefulness on intention to use is less clear. Davis et al. (1989) found attitude was at best a partial mediator of the effect of perceived usefulness on intention to use and that it added little causal explanatory power. Davis (1993) found that the direct effect of perceived usefulness on intention to use was more than twice the influence of attitude on usage. Together, these findings led to the suggestion that attitude be eliminated from TAM to create an even more parsimonious model reflecting a direct influence of usefulness and ease of use perceptions on intention to use.

Behavioral Intention

Behavioral intention (a measure of the strength of one's intention to perform a specified behavior (Davis et al., 1989)) is a construct borrowed from the discipline of social psychology. Behavioral intention has been an important construct in most previous TAM research. The significance of behavioral intention derives from the theoretical perspective that intentions — as determined by a combination of attitudes and subjective norm — are the best predictor of an individual's behavior (Jackson et al., 1997). Davis et al. (1989) validated the notion that behavioral intention to use IT is a reasonably reliable predictor of use. Venkatesh et al. (2003, p. 427) note: "The role of intention as a predictor of behavior (e.g., usage) is critical and has been well established in IS and the reference disciplines". Evidence substantiating the hypothesized positive relationship between intentions and behavior is found in a meta-analysis of 86 TRA studies conducted by Shephard, Hartwick, and Warshaw (1989) that found a mean correlation of .54 between intentions and actions.

As Straub et al. (1995) observe, the purpose in measuring intention is to predict future behavior. Thus, in research scenarios associated with the brief introduction of an IT to predict future acceptance and usage, the TAM intention to use construct is particularly critical.

External Variables

Davis defined this construct to include system design characteristics, user characteristics (e.g., cognitive style and other personality variables), and task characteristics (nature of the development or implementation process, political influences, and organizational structure) that might affect attitude, intentions to use, and/or usage. It is a central tenet of TAM that the effects of these external factors on attitude, intentions, or usage are mediated by the individual's perceived usefulness and perceived ease of use beliefs.

System Usage

System usage is a construct of some controversy in IT acceptance research. With relatively few exceptions (e.g., Straub, 1995; Szajna, 1995; Taylor & Todd, 1995; Venkatesh, 2002), most TAM related research has measured the effect of the perceived usefulness and perceived ease of use constructs on intention to use (e.g., Jackson et al., 1997) and/or self-reported usage (Davis et al., 1989), as opposed to objective (actual) usage data. This widespread practice notwithstanding, there remain significant questions regarding its effect on research findings and a number of researchers who value actual usage over self-reported usage.

The research of Taylor and Todd (1995), using actual usage data, supported previous TAM research based on self-reported usage, concluding that an assessment of the usefulness of TAM in predicting usage behavior requires exploration of the model using objective actual usage data. However, Straub et al. (1995) found self-reported usage and actual usage constructs were not strongly related. Their findings also suggested the fundamental TAM constructs, perceived usefulness and perceived ease of use, were more strongly related to self-report usage data than to actual usage data.

Straub et al. (1995) also posed thought-provoking questions concerning the relevance of IT usage measurement in general. If one accepts the widespread assumption that system usage is the primary variable through which IT affects performance (Straub et al., 1995), it seems legitimate to question which of several alternative usage dimensions best captures the desired effect; frequency of use, duration of use per time period, type of use, and diversity of use are just a few candidates. One might even question the legitimacy of usage as the real variable of interest when attempting to ultimately understand and/or measure IT benefits. It could be argued usage is but a surrogate for what researchers really need to capture; that is, a measure of the benefit or utility derived from IT.

Szajna (1996) found statistically significant differences in the effects of user intentions on self-reported and actual usage data (stronger relationship for self-report than actual) and low correlation (.26 at < .05 significance) between the two. These results led her to conclude that substitution of self-report usage for actual usage should be discouraged.

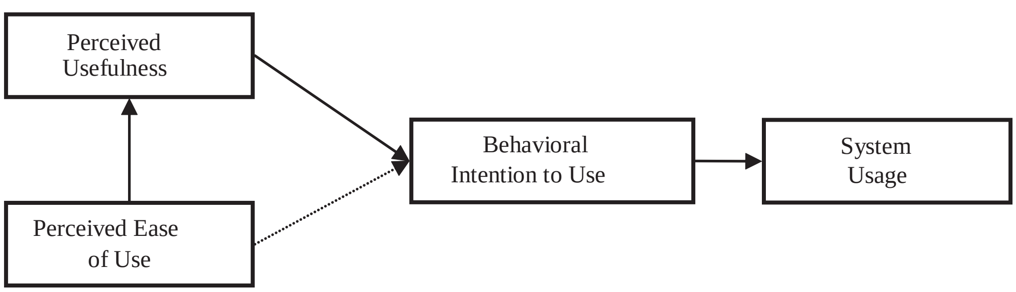
Igbaria et al. (1995) cited prior indications that users might over-report usage when self-reporting and called for additional research into the potential differences in the relationships between the TAM constructs and self-report usage data and actual usage data.

In summation, while there remain some inconsistent findings and beliefs surrounding the stream of TAM centered research, a significant and growing body of work has tended to confirm the model's usefulness as an IT acceptance research tool. As human knowledge has been recognized as an organization's most valuable resource and as a foundation of competitive advantage, there is widespread interest and investment in IT KMS systems (Kankanhalli, 2001). TAM research to date has focused on individual use IT and has been largely conducted in educational environments. Individual acceptance and usage of IT implemented to support KM objectives in an organizational scenario represents a more complex phenomenon. Empirical research is required to determine if past TAM research can help inform the understanding of factors affecting individual acceptance and use of IT implemented to support organizational KM objectives.

RESEARCH MODEL AND RESEARCH HYPOTHESES

The research model is presented in Figure 3. It supports the specific objective of this research to assess the relationships between TAM's two primary belief constructs: perceived usefulness and perceived ease of use, and users' intention to use, and their usage of the target knowledge management system. The research model is similar to Davis' original TAM (Figure 1). In accordance

Figure 3. Research model



with the findings of Davis et al. (1989), the attitude construct is not included. The "external variables" constructs are also not included in the research model since there is no intention here to investigate antecedents to perceived usefulness and ease of use.

The research hypotheses investigated in this study are:

H1: Perceived usefulness of the knowledge management system will exhibit a significant positive direct relationship with behavioral intention to use the system.

H2: Perceived ease of use will have both a direct and indirect effect on behavioral intention to use the system. The indirect effect (mediated by perceived usefulness) will be stronger than the direct effect.

H3: Behavioral intention to use the system will exhibit a significant positive relationship with system usage.

METHODOLOGY

A 14-item survey comprised of tailored measurement scales designed to measure each of the four constructs was used in this research. Measurement scales for each research model construct were drawn from previous IT acceptance research.

Perceived usefulness and perceived ease of use were measured using four-item measurement scales consistently demonstrating excellent psychometric qualities in previous research (Venkatesh & Davis, 1996).

A three-item scale measuring behavioral intention to use the target system was adapted from Venkatesh and Davis (2000). Subsequent research has shown it to have both high reliability and excellent psychometric qualities.

Three items were used to measure user self-reported system usage. The first self-report usage item was adapted from Davis et al. (1992). The third item was also drawn from the work of Davis et al. (1992) and has been used widely in information technology acceptance research.

Employees in two major Northeastern U.S. metropolitan areas with system access were identified by the organization as survey subjects. Each was provided password access to the survey that was hosted on a university server. Employee participation was optional but encouraged through correspondence from management that authorized employees to charge time spent completing the anonymous survey. Access to completed surveys was strictly limited to the researchers.

RESULTS

Fifty-one employees, approximately 20% of the identified survey subjects, responded. Sixteen responses had to be excluded: three due to significant incompleteness and 13 due to respondent comments indicating no system awareness and/or no experience using it. (This finding within the survey target group was an unhappy surprise to management, although, given the broad organizational scope of the KMS studied, this might have been a predictable finding.) Demographic information collected with the survey confirmed the 35 usable responses were submitted by a cross section of organization personnel that included division managers, project managers, technical specialists, configuration control technicians, and administrative personnel.

DATA ANALYSIS

Data analyses included reliability and validity analyses, correlation analysis, and simple and multiple regression. All statistical analyses were performed using Statistical Analysis System (SAS) Version 8.0.

Cronbach Alpha measurement scale reliability coefficients calculated for each construct are shown in Table 1.

The reliability of all measurement scales was comfortably above the recommended minimum level of .70 for social science research (Hatcher, 1994), and the accepted "desirable" level of .80 for social science research. The overall weighted reliability of the survey instrument was .938.

The perceived usefulness and perceived ease of use instruments used in this study have been validated extensively through prior research. Nevertheless, factor analysis was performed to assess their validity here. The eight questionnaire items comprising these two measures were subjected to exploratory factor analysis using squared multiple correlations as prior estimates of communality. Questionnaire items associated respectively with the two constructs loaded heavily (all but one well in excess of .80) on two different factors, thereby replicating the findings of Davis that the two beliefs comprise distinct constructs. Results of the factor analysis appear in Table 2.

The three behavioral intention to use construct items were also subjected to factor analysis. Results presented in Table 3 indicate they all loaded heavily on a single factor, providing evidence of construct validity.

Correlation analysis results appear in Table 4 and include the observed correlations and associated p-values (probability of observed correlation value under the null hypothesis of zero correlation) in the context of the research model in Figure 4. Data analysis results are discussed in the context of the research hypotheses.

H1 postulated a significant positive relationship between perceived usefulness and behavioral intention to use the KMS. Evidence supporting confirmation of this hypothesis can be found in

Table 1. Cronbach Alpha reliability coefficients

Construct (Items)	Cronbach Alpha
Perceived Usefulness (4)	.978
Perceive Ease of Use (4)	.938
Behavioral Intention To Use (3)	.925
Frequency of Use (3)	.896
Overall (14)	.938

Condition	β Ease of Use (p-value)	β Usefulness (p-value)	R^2
1. Bivariate: Usefulness = *f* (Ease of Use)	.783 (<.0001)	N/A	.632
2. Bivariate: Intention to Use = *f* (Ease of Use)	.615 (<.0001)	N/A	.403
3. Multivariate: Intention to Use = *f* (Ease of Use & Usefulness)	.1,7 (..327)	.534 (.012)	.511

the positive correlation (.704, p value <.0001) and regression analysis showing that perceived usefulness explained 49.6% of the variation in behavioral intention to use in the sample.

H2 hypothesized positive direct and indirect relationships between perceived ease of use and behavioral intention to use the system. It was further hypothesized that the indirect effect (mediated by perceived usefulness) would be greater. This hypothesis was examined using multiple regression techniques. The Ordinary Least Squares regression methodology was deemed most appropriate for this study due to the research model's simple factor structure and the fact that the TAM model structure has been extensively researched.

To establish perceived usefulness as a mediator of the relationship between perceived ease of use and behavioral intention to use, it is necessary to demonstrate the existence of four conditions: (1) a significant bivariate relationship between perceived ease of use and perceived usefulness, (2) a significant bivariate relationship between perceived ease of use and behavioral intention to use, (3) a significant relationship between perceived usefulness and intention to use when perceived ease of use is controlled for, and (4) a reduced or weakened relationship between perceived ease of use and perceived usage when usefulness is controlled for (Baron & Kenney, 1986).

Regression analysis results relevant to hypothesis two are presented in Table 5. The first two data rows of the table illustrate necessary statistically significant bivariate relationships between perceived ease of use and usefulness and ease of use and intention to use. Results of the multiple linear regression of behavioral intention to use on perceived usefulness and perceived ease of use appear in the third row. These results reveal the hypothesized multivariate relationship in the survey data. Consistent with required mediation conditions three and four, the relationship between perceived usefulness and behavioral intention to use is statistically significant when the effects of ease of use are controlled for (p value of .012). Additionally, as required, the relationship between perceived ease of use and behavioral intention is diminished (smaller β estimate) when the effects of usefulness are controlled for in the multiple regression.

These results are consistent with the mediation criteria of Baron and Kenny (1986) and support confirmation of hypothesis two that the effects of perceived ease of use on behavioral intention to use are mediated by perceived usefulness. They also show that when the effects of perceived usefulness are controlled for in multiple regression, perceived ease of use has very little unique explanatory value with regard to intention to use. Perceived usefulness uniquely accounted for more than seven times as much variation in intention to use (10.8%) as did perceived ease of use (1.49%). However, these two beliefs combined to uniquely account for only 12.3% of the variation in intention to use. Thus, almost 39% of the variation in intention to use was explained by the two constructs jointly (this is consistent with the high correlation (.795) between these two constructs shown in Table 4).

H3 hypothesized a positive and significant relationship between behavioral intention to use the system and system usage. Table 4 presents evidence of confirmation of this hypothesis in the positive correlation (.398, p-value .018) between these constructs. Regression analysis indicates behavioral intention explains only 15.9% of the variation in usage in the sample. This intention-behavior relationship is not as strong as expected. While some TAM research has yielded weaker intention-behavior correlations (e.g., Szajna, 1995), many have found evidence of a stronger tie between these constructs.

DISCUSSION

The only finding in this research not fully consistent with previous TAM research is that concerning the relationship between behavioral intention to use and system usage constructs.

Perceived usefulness and perceived ease of use combine to explain 51.1% of the variation in behavioral intention to use the KMS. This is consistent with previous TAM research. The individual relative effects of the two belief constructs are also consistent with previous findings. Both beliefs exhibit significant bivariate relationships with intention to use. However, when the effects of perceived usefulness and perceived ease of use are isolated in multiple regression, it can be seen that the effect of perceived ease of use on behavioral intention to use the KMS actually derives from potential users' perception of its usefulness (i.e., perceived usefulness mediates the relationship between perceived ease of use and intention to use the system). This is generally consistent with most previous TAM research addressing individual IT use, although a reduced direct effect was anticipated.

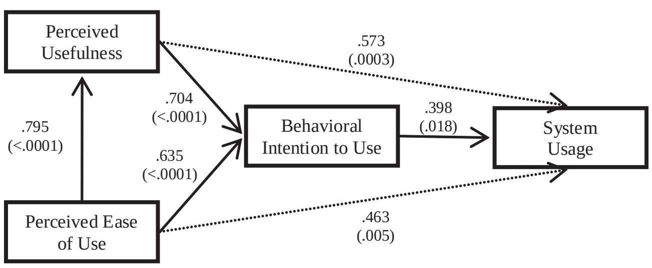
The correlation between intention to use the KMS and self-reported system usage found in this study is lower than what has been typically observed in previous TAM research.

This potentially inconsistent finding may be attributable to the nature of the study scenario. The research data were collected long after the introduction of the target KMS. As Straub et al. (1995) observed, the value of measuring inten-

Table 6. Summary of research hypothesis findings

Hypothesis	Comments
1. Perceived usefulness will exhibit a significant positive relationship behavioral intention	• Confirmed, consistent with previous research
2. Perceived ease of use will have both a direct and indirect (mediated by perceived usefulness) relationship with behavioral intention	• Strong mediation effect of perceived usefulness confirmed, consistent with most prior research • No unique perceived ease of use effect when perceived usefulness controlled for
3. Behavioral intention will have a significant positive relationship with system usage	• Confirmed • Intention-behavior relationship not as strong as many earlier studies

Figure 4. Research model and observed correlations (p-values)



tion is to predict future behavior. Therefore, in research scenarios characterized by a brief introduction of an IT intended to help predict future acceptance and usage, the behavioral intention construct is critical. In this research, the intent was not to predict usage, but to interpret experience with the target KMS through the lens of the TAM. Research by Davis et al. (1989) indicated that the strength of the link between intentions and behavior is positively correlated with user experience and negatively correlated with the elapsed time between the measurement of intentions and behavior (Venkatesh & Davis, 1996). In this case, respondents had an extended period in which to form their beliefs regarding the usefulness and ease of use of the target KMS. We believe measurement of intentions significantly post facto may have contributed to ambiguous results surrounding the relationship between the intention and usage constructs.

Other explanations of the intentions-usage relationship centering on whether or not frequency or accumulated time of system usage is really an important metric with regard to KMS usage and/or whether or not potential users' intention to use was adversely affected by the quality of the materials accessible in the KMS or its "output quality" are also plausible (e.g., see Kankanhalli et al., 2001).

CONCLUSION

The results of this research provide preliminary evidence that previous IT acceptance research based on TAM can serve as a basis for critically needed empirical research of KMS user acceptance. Relationships among primary TAM constructs found in this research are largely consistent with those typical of previous TAM research, with the exception of the correlation between intention to use the KMS and self-reported system usage. This correlation was found to be lower than what has been typically observed in previous TAM research. This potentially inconsistent finding may be attributable to the data collection long after the introduction of the target KMS; questions regarding the metrics with regard to KMS usage; and whether or not potential users' intention to use was adversely affected by the quality of the materials accessible in the KMS.

Perceived usefulness and perceived ease of use combined to explain 51% of behavioral intention to use the system. This result is consistent with a significant body of previous TAM research in which these two constructs have been typically found to explain 40% to 60% of the intention to use/usage variance. Significant positive relationships between perceived usefulness, perceived ease of use, intention to use, and the strong mediating effect of perceived usefulness on the effect of perceived ease of use on intention to use were consistent with previous TAM research.

LIMITATIONS

This research bears inevitable generalizability limitations of any study of one information system in one organizational environment. Additional investigation of knowledge KMS implemented in a representative range of modern organizational settings is essential to increased understanding of those factors, conditions, and mechanisms critical to their success. A second key shortcoming of this research is its limited sample size, both in absolute terms, and relative to the population of potential organizational users of the KMS. With approximately 12% of the population providing a usable response to the voluntary survey, one cannot summarily ignore the possibility of sample bias. However, the broad range of responses received across all measured constructs mitigates this concern somewhat. Another potential shortcoming of this research is its reliance upon self-reported usage. As noted earlier, previous researchers have raised credible and largely unanswered questions regarding the fidelity of self-report usage data and its relationship to key TAM constructs when compared with actual usage data. Finally, it must be recognized this study covers only a single point in time, whereas KMS adoption and usage issues are likely to evolve over longer time cycles. Given the complexity of KMS usage and adoption, longitudinal studies could provide valuable research insights not otherwise available.

FUTURE RESEARCH

Additional study of diverse KMS in a range of modern organizational settings is necessary to support the accumulation of knowledge and development of sound theory regarding the factors, conditions, and mechanisms critical to KM success. Given the complex and diverse nature of KMS and the approaches used to implement them (i.e., task/process oriented versus infrastructure/generic), a spectrum of situation- specific models/constructs may be required.

When possible, future researchers should attempt to collect and analyze both self-report and objective actual usage data. This will contribute to resolution of lingering questions regarding this important construct and its effect on previous TAM research. In addition and as suggested previously, further investigation of the relationship between intention to use and KMS usage is warranted.

Furthermore, although this research suggests previous TAM-based IT user acceptance research can serve as a basis for future investigation of KMS user acceptance, it seems inevitable that other factors associated with the complex socio-cultural organizational implications of KM must be explored.

To increase the explanatory power of the model relative to KMS, it will be necessary to incorporate additional theory-based constructs to the TAM. Given the social nature of KM, interesting candidates include items that measure important organizational culture and/or subjective norm influences.

Antecedents to the current TAM beliefs need to be researched to understand the components of perceived usefulness and perceived ease of use relative to KMS. This would be consistent with current trends in general IT user acceptance research such as those reported by Venkatesh et al. (2003).

Finally, more complete longitudinal and qualitative studies of organizational and user patterns that comprise the totality of a KMS over its development, implementation, and adoption should be pursued.

Given the critical importance of knowledge to the modern organization and the pivotal role of IT in organizational knowledge leveraging initiatives, further investigation of user KMS acceptance factors would seem a critical research priority.

Chapter 4.26
Open Collectivism and Knowledge Communities in Japan

Hideo Yamazaki
Nomura Research Institute Ltd. Knowledge MBA School Tokyo, Japan

INTRODUCTION

The aim of this article is to introduce an Eastern CoPs' specific approach that is quite different from that of Western communities. In a collectivist prevalent societal type, the "sharing of feelings should come first, naturally followed by knowledge sharing" type of approach works very well even in a business environment.

One of Japan's traditional manufacturers has launched several interesting knowledge communities that are different from the accepted Western KM approach that emphasizes cost and effect straightforwardly. Their approach emphasized the generation of social networking on intranet first, and at a later stage, they proceeded to knowledge sharing through communities of practice.

This "go slow to go fast" approach may look like one of the typical and traditional Japanese management styles. However, in this approach, the culture of this company group steadily changes from introverted and closed to extroverted and open.

Their approach to build open and extroverted collectivism that is generated by knowledge communities could be one of the new management style prototypes of Japanese companies in the future.

BACKGROUND

QP Corporation is a top-class Japanese company, manufacturing and marketing mayonnaise and salad dressings in Japan. One of the group companies manufactures jam. QP is one of the top brands in the food industry. They have been in the food manufacturing business more than 80 years with 2,200 employees. The total number of employees including group companies is 6,000.

This means that QP are typical of the traditional business group in Japan.

Their operation of knowledge communities has a 3.5-year history. In the past, their original KM approach failed when they built knowledge databases for knowledge sharing. This approach did not work well, let alone match the expectations of management. Therefore, this time, they decided against the mechanical approach such as building a knowledge database instead of building knowledge communities on their intranet was tried.

As far as the communities' approaches toward face-to-face activity, traditional socializing approaches such as company outings, pub drinking, and factory participation in local festivals where employees socialize with local people work very well in this company. And small-group employee activities for incremental improvement also work well. Therefore, the main activities of the revised QP KM plan focused on building knowledge communities on their intranet. The purposes was to change the company culture from a closed and introverted one to an open and extroverted one; promote employees to knowledge workers who are individually treasured; and promote workers into those who produce and share business ideas.

In the past, one of the features of Japanese companies was an introverted collectivism that supports the production of a quality product. However, in the 21st century of rapidly changing market environments, companies need fresh idea generation for new products and for new marketing, and it is clear that fresh ideas cannot emerge only between intimate colleagues. New ideas can come from anybody else inside and outside of organizations. Knowledge communities supply companies with "the strength of weak ties", backed by social networking that bridges silo type organizations.

SOCIAL NETWORKING BY KNOWLEDGE COMMUNITIES

KM Team Blogging

QP Corporation started building knowledge communities by using Lotus Notes software on their intranet. A centrally organized knowledge management team consisted of five employees. One of their roles is to behave as if they are company news reporters, and they compile different articles about the business and put them on the knowledge repository in Lotus Notes. They also provide company newsletters that brief all the employees of QP group by e-mail about these newly posted articles. After that, employees can voluntarily read some articles and post their comments. As far as posting comments are concerned, two different ways of posting were arranged by the KM team. One was posting for discussion on common forum, called the tea lounge, where a link from each article is prepared. Another way to comment is through the employee posting anonymously onto a bulletin board that is also linked to each article.

The category of these articles by the KM team varies from reports of shareholder meetings, introduction of new products, competitors' information to reports of management and employees' lives. As far as well visited articles are concerned, the articles relating to customers' voices are the most popular ones, and they convey customers' messages directly to all the employees. They sometimes include claims or request for product and services improvement.

The articles of customers' voices are compiled by the KM team, and the production process is the following: First, KM team contacts the call center to pick up customers' claims and needs. After that, the KM team contacts R&D or relevant manufacturing department for further information. Finally, compiled articles are posted on the bulletin board for employees' comments.

The same processes are repeated for the other categories of articles. They are regarded as KM team blogging, covering all the activities of companies. Interestingly, KM team blogging itself is declared as an informal message supply. It seems that currently, some articles are also voluntarily posted by local offices.

Employees' Regular Column Posting

In addition to the KM team article posting, individual employees' regular posting activities, called my opinion, are popular. My opinion is a weekly posted blogging by several employees. In my opinion, several volunteers such as young employees, experienced employees, men and women from varying divisions freely talk about their business and private life as either a diary or column, and the rest of the employees freely give their comments on them. In doing so, employees can get to know each other well, and they can share other employees' experiences and their way of thinking. For young employees, reading a senior's my opinion works as net-mentoring. Recently, female managers were employed in this company for the first time in its history. For these female employees, reading the female managers' my opinion is quite encouraging, and lots of them try to understand the way female managers think. It is a new form of tacit knowledge sharing in Japan. My opinion usually lasts for two to three months per employee. After that, they are replaced by different volunteers in rotation.

Business Volunteers' Recruiting

QP Corporation is a food manufacturer for consumers and businesses. Therefore, they sometimes recruit volunteers from employees to taste new products. For this purpose, knowledge communities are very useful and rewarding. When 10 to 20 employees are chosen for tasting volunteers, they sometimes voluntarily organize a community of practice on the intranet, and they regularly post their interesting reports for discussion about possible product improvements. They also sometimes recruit volunteer employees to distribute sample products in the employees' home neighborhood to pick up comments from their neighbors.

The recruiting and reporting by volunteers are all made known on knowledge communities. In particular, this reporting by volunteers is full of the voices of potential customers as well as their own feelings.

Usually, this type of business volunteers recruiting is requested from the KM team by official organizations such as marketing, and then the KM team coordinates between the knowledge communities and these divisions.

Business Q&A Exchange

The company recently started a business Q&A exchange. On the knowledge communities, knowledge seekers raise queries and knowledge givers post an answer. In this case, the KM team works as a facilitator.

COMMUNITIES OF PRACTICE AND FUTURE TRENDS

QP Corporation's Knowledge Community is a big community, called I-QP, covering all the group companies. As far as communities of practice are concerned, currently around 10 to 15 communities are operational. Among them, the working mother's community is the most fascinating. When it comes to the subject of raising knowledge workers, their current concern is how to raise the status of female workers. So far, the working mother's community is at an early stage, and the current central theme of discussion is baby food. However, this community has the potential to promote the improvement of female worker status in Japan.

As for business CoPs, the sales division has a community of practice, called find. In this CoP, all the sales staff are participants. All the noticed and found information in sales fields such as competitor's movement, distributor's movement, and popularity of new products is posted in this community of practice for knowledge sharing.

CONCLUSION

Throughout building knowledge communities, the QP organization has found that the employees have been gradually transforming themselves from "organization man" to self-supporting knowledge workers. Especially, the female workers have become more active and lively. However, from the building communities point of view, their approach to raise "open collectivism by knowledge workers" is still at an early stage and has a long journey ahead.

Chapter 4.27
Tacit–Explicit and Specific–General Knowledge Interactions in CoPs

Tunç Medeni
Japanese Advanced Institute of Science and Technology, Japan

INTRODUCTION

Over the last decade the fields of knowledge management and organizational learning have developed rapidly, showing increasing diversity and specialization in the academic literature. Ikujiro Nonaka has played a leading role in setting standards and earning academic legitimacy for the emergent field of "organizational knowledge management" (Easterby-Smith & Lyles, 2003). In the period 1995-2001, the book The Knowledge-Creating Company (Nonaka & Takeuchi 1995) was the most-cited knowledge management work from academic literature (Koenig & Srikantaiah, 2004). Interestingly, in this book and in following works, the authors themselves prefer to use the term "knowledge creation" rather than "knowledge management," later also dropping the term "organizational" from the initial proposition. Easterby-Smith and Lyles also state (2003, pp. 642-643) that in the field of organizational learning and knowledge management, among the topics of articles published in the last two years, "learning capabilities, experience, and absorptive capacity" is the largest category, including several articles that assess the impact of learning on performance. Seeming to be frequently interrelated, "organizational learning and knowledge management across boundaries," "knowledge creation and transfer," and "human resource management and human capital" are the next largest categories for articles. Communities of practice, socio-political processes, and the development of tacit knowledge or social identity are among the other topics frequently addressed in the literature, categorized in terms of "cognition, socio-political aspects, and tacitness."

Using the extant and emerging perspectives in knowledge management, organizational learning, and communities of practice literature, in the following sections of this short article, we will first discuss the importance of specific-general knowledge, and context for knowledge creation and management. Then we will introduce the conceptualization of "specific" and "general" knowledge interactions, and discuss a framework that proposes these interactions as contextual knowledge conversions for learning and practice. The following section will aim to contribute to the representation of our knowledge on these contextual knowledge interactions, using visualization tools like geometric figures. We will conclude our discussion by highlighting future research possibilities in the relevant research fields.

BACKGROUND

Specific-General Knowledge and Context for Knowledge Creation and Management

According to the organizational knowledge creation model of Nonaka and Takeuchi (1995), the continuous and dynamic interaction between tacit and explicit knowledge that happens at the individual, group, organizational, and inter-organizational levels can be significant for the sustainable development of any social setting. Nonaka and Takeuchi follow the distinction of Polanyi (1966) between tacit and explicit knowledge: Tacit knowledge is personal, context-specific, and therefore hard to formalize and communicate. Tacit-explicit knowledge interaction is identified as the epistemological aspect, while the interactions among the different levels (individual, group and organization, inter-organizational) correspond to the ontological aspect of the model. When the authors first introduced their model, at the epistemology level they identified four distinctive interactions between tacit and explicit knowledge: socialization, externalization, combination, and internalization. Socialization is the process of creating tacit knowledge from tacit knowledge, whereas externalization is that of articulating tacit knowledge into explicit concepts. Combination involves the process of systemizing concepts into an explicit knowledge system. Internalization is a process of embodying explicit knowledge into tacit knowledge.

Nonaka, Toyama, and Byosiere (2003) also suggest that at the foundation of their modeling lies ba: the context that knowledge needs in order to exist, in which it is shared, created, and utilized. Although the concept of ba shows similarities with that of communities of practice, especially highlighting the importance of context for learning and knowing, Nonaka et al. (2003) differentiate them according to the nature of the learning and participation that takes place within them. For instance, a community of practice is a place where members learn knowledge embedded in the community; ba is a place where new knowledge is created.

Real or virtual interactions among individuals or between individuals and their environments are key for the understanding of ba and knowledge creation. Especially, within the tacit knowledge conversions of socialization and externalization, a real ba where participants can interact face-to-face in the same time and space is essential (Umemoto, 2002). In general, with regard to the type of interaction (individual or collective) and the interaction medium (face-to-face contact or through "virtual" media) (von Krogh, Ichijo & Nonaka, 2000), four types of ba can be defined, corresponding roughly to socialization, externalization, combination, and internalization: originating ba, dialoguing ba, systemizing ba, and exercising ba (Umemoto, 2002).

Although initially knowledge creation and management was widely understood as simply the interaction between tacit and explicit knowledge, the type of interaction—individual (personal) or collective (group, social, societal)—is also increasingly being recognized as another dimension of knowledge interaction and conversion that parallels the tacit-explicit dimension of knowledge and knowledge interactions. For instance Wierzbicki (2004) sees socialization as the transition from personal tacit knowledge to group tacit knowledge; externalization, group tacit to group explicit knowledge; combination, group explicit to personal explicit knowledge; and internalization, personal explicit to personal tacit knowledge. In fact, tacitness relates to the transferability of knowledge, which also makes the location of knowledge an important issue (OECD, 2000).

According to von Krogh, Ichijo, and Nonaka (2001), knowledge can be observed and distinguished on two levels, individual and social. In addition, as recognized by various authors, there is "general knowledge," which is widely possessed by a large number of individuals and can be transferred easily among individuals, and "specific knowledge," which is idiosyncratic and narrowly possessed by a very limited number of individuals (Becerra-Fernandez, 2004). Whereas general knowledge is inexpensive to transfer, specific knowledge is expensive and costly (Jensen, 1998). Starting with global public knowledge, which is general and explicit, Stiglitz (2001) also analyzes the development of knowledge along two dimensions, general-local and implicit-codified. The description or classification of knowledge as a public or private good or asset retains an important place in the socio-economic modeling of knowledge (OECD, 2000). In order to redesign cross-cultural management, Holden (2002) discusses three domains of cultural knowledge as follows: general cultural knowledge, culture-specific knowledge, and cross-cultural know-how. While general cultural knowledge can be associated with explicit knowledge and cross-cultural know-how with tacit knowledge, culture-specific knowledge can be both tacit and explicit according to the convention. Gasson (2004) highlights the problems of managing and transferring local knowledge beyond its workgroup and specific context, and discusses the ways in which this distributed knowledge is managed, communicated, and translated across organizational boundaries. The shared explicit knowledge is transited into shared tacit knowledge, then to tacit distributed knowledge, and finally to explicit distributed knowledge.

Whether it is general, global, public, shared, common, collective, social, societal…or specific, idiosyncratic, local, private, distributed, individual, personal, and so forth, and although their units and levels of analysis differ, these various discussions all try to capture the same conceptual understanding about knowledge or knowing. However most of them remain as classifications of knowledge, rather than capturing the meaning of these knowledge types as knowledge interactions, and making use of these interactions for a better comprehension of knowledge creation.

"Specific" and "General" Knowledge Interactions

Nonaka and Takeuchi's (1995) generic knowledge conversion framework of socialization, externalization, combination, and internalization has become widely recognized in the academic and business worlds, and the organizational knowledge creation model has become known as the "SECI model." From this perspective, the main focus was on the tacit and explicit knowledge interactions as the epistemological aspect of the (organizational) knowledge creation model. There was no distinctive classification of knowledge interactions or conversions at what the authors called the ontology level, nor did the knowledge conversions of the SECI clearly identify the knowledge interactions at the individual, group, organizational, or social levels, and across these levels and entities. However, horizontal and vertical interactions among these levels and entities are just as important for organizational knowledge creation as the tacit-explicit knowledge interaction.

Nonaka and Takeuchi's classification of tacit and explicit knowledge interactions follows the logic that identifies from which knowledge to which knowledge the knowledge interaction occurs. The same distinction can be applied to

Table 1. Tacit-explicit and general-specific knowledge conversions in SECI interactions

Knowledge Interaction	**Tacit-Explicit Knowledge Conversion**	**Specific-General Knowledge Conversions such as**
Socialization	Tacit to Tacit	General to Specific
Externalization	Tacit to Explicit	Specific to Specific
Combination	Explicit to Explicit	Specific to General
Internalization	Explicit to Tacit	General to General

the various individual, group, organization, and society levels. One way of doing this can be the realization of the knowledge dimension of general versus specific (or global versus local) knowledge besides that of tacit versus explicit (or implicit versus codified) knowledge. Specific knowledge can mean the knowledge of one specific individual, group, society, time, or location. General knowledge, on the other hand, can be understood as the knowledge that goes across or is shared by particular individuals, groups, societies, times, and locations.

These definitions can then be incorporated into the conceptualization of the knowledge creation model. Knowledge is now seen not only as tacit or explicit, but also specific or general. Like tacit-explicit knowledge, specific-general (local-global) knowledge is not a discrete dichotomy, for actually all knowledge is both specific and general to some degree. At the ontological level, the recognition of knowledge as both specific and general comprehensively takes into account individual, group, organization, society, collective, and locative perspectives. This is also a relative understanding: knowledge that is general for one level or entity can be specific for another. For a generic knowledge creation model, this relative understanding is important in order not to become limited to specific levels of analysis. For the application of the model then, these levels and entities can be made clear such as individual or group, social versus personal, inter-organizational or universal.

According to this model then, we can find four distinct, different knowledge interactions like those within tacit and explicit knowledge: local to local, local to global, global to global, and global to local. Together, the tacit-explicit and local-global (specific-general) knowledge interactions can nurture efficacious knowledge management and creation in institutions and socio-economic systems. We can reinterpret the SECI interactions in light of the knowledge conversions between specific and general knowledge, in addition to those of tacit and explicit knowledge. For an example interpretation, please see Table 1.

Specific-General Knowledge Conversions as Contextual Interactions (for Learning and Practice)

All these specific-general interactions highlight the importance of the context within which knowledge creation takes place. Moreover, they are able to direct our attention to the interactions across boundaries, which are very crucial to understand if we want to improve our knowledge about knowledge, and its management and creation. This is the same as when we discuss learning through communities of practice. Wenger (1998) points out that knowing in practice involves an interaction between the local and global. Explaining organizational knowledge creation as simplified tacit-explicit knowledge conversions does not highlight the significance of this cross-boundary interaction, often placing too much emphasis on solutions to problems that cannot take advantage of the "landscape of practices" (p. 140). Since the processes of knowledge and learning are based and situated on the context, knowledge interactions on and across boundaries becomes essential.

In recognition of these cross-context transactions in knowledge transfer, in the academic and business literature, the "tacit-explicit"-ness and "specific-general"-ness of knowledge have noticeably been used together. For instance, Sudarshan (2000) concludes his discussion of the governance of economic and social development by claiming that a revival of concern for the role of local and tacit knowledge in development transformation should emerge as a global issue. He gives the example of India, which strongly rejected such local knowledge in favor of a world view derived from within the boundaries of codified and general knowledge, based on "colonial rule, with its accompanying territorial annexation and the need to create an elite with a shared world view and language…To revive the missing dimensions is a challenging, though not impossible, task" (p. 101).

Burton-Jones also contends (1999) that the commercial application of IT has had a 'leveling' effect, "reducing the specific to the general, the idiosyncratic to the standard, tacit knowledge to explicit knowledge, scarce goods and services to commodities." One reason for this is that businesses have historically "opted to use IT to control and standardize their operations." Another major reason is the tendency by firms to adopt standard software packages. For instance, SAP can provide "in detailed, explicit terms, a set of best practices for operating many routine functions of a business." Thus the companies can choose "to rely on externally provided knowledge of best practices, rather than have to develop and maintain that knowledge themselves…in doing so they may lose the benefits of firm-specific or tacit knowledge embedded in internal processes and procedures which are replaced by the standard system" (pp. 9-10). The same argument can also hold for other types of systemic interventions into institutions, including consultancy, management learning, and training and development activities.

To an important extent the literature has come to recognize the specific-general dimension of knowledge together with that of tacit-explicit. When it comes to the recognition of specific-general knowledge interactions alongside tacit-explicit ones, the existing knowledge base does not provide much beyond the works that we have discussed above or similar articles. However, the intermingling of these two types of interaction is very important for knowledge creation—identifying these interactive processes of knowing beside the classification of different knowledge types deserves special attention. This is especially true when we approach the concepts of knowledge, learning, action, and participation as contextual interactions within ba or communities of practice. For instance, originating ba through face-to-face interactions offers a context for socialization that yields "sympathized knowledge" (Nonaka & Takeuchi, 1995, p. 72), as important tacit knowledge can be shared among individuals. Empathizing with others, an individual transcends the boundary between self and others (Umemoto, 2002).

In Nonaka and Takeuchi's original model of organizational knowledge creation (1995), the starting point of knowledge creation, socialization, corresponds in practice to not only the sharing of tacit knowledge among the team members, but also to learning through apprenticeship. What is called "learning by doing" matches with internalization, although this interaction and the resulting tacit knowledge has also the meaning of feedback that can initiate a new knowledge spiral. These three concepts—sharing of tacit knowledge, learning by doing, and apprenticeship—have been incorporated into the conceptualizations of situated learning, legitimate peripheral participation, and communities of practice, while the term 'socialization' is understood with regard to its meaning in sociology literature (Lave & Wenger, 1991; Wenger, 1998).

On the other side, what is implicitly evident in the conceptualization of socialization as field-building tacit knowledge interaction in Nonaka and Takeuchi's original model (1995), is that a shared context exists among the participants of the knowledge interaction process. The participants share a background of common knowledge, which enables them to communicate without using explicit terms. As in the case of apprenticeship, newcomers can learn first by watching their seniors and then by practicing themselves. In the case of knowledge sharing among group members, ways of tacit interaction can be enough. Even conversation, which can be seen as a means of explicit knowledge interaction, actually incorporates important tacit and explicit elements together (Baker, Jensen & Kolb, 2002). For all these cases, in order to exchange and share tacit knowledge, participants should also share a common base of mutually understandable and usable knowledge, which enables them to transfer knowledge with tacit terms. Penrose (1989), for instance, exploits this tacit common base to explain the implicit understanding and communication between two mathematicians, even if they cannot express or do not understand each other explicitly. This common ground can start to develop with the start of the participant's acceptance in a community of practice. Then the members gradually learn and develop their knowledge with their practice and participation in the community.

In fact, the dynamic interaction between tacit-explicit and specific-general knowledge can be matched well with this mutual existence of learning and practice, or the duality of participation and reification in communities of practice (Wenger, 1998). Nonaka et al. (2003) try to differentiate ba from communities of practice according to the nature of the learning and participation that takes place. Nevertheless, both communities of practice (CoPs) and ba highlight the importance of context for learning and knowing, and the conceptualizations of SECI and ba can be integrated and contribute to our understanding of communities of practice. The conversions of knowledge can be enabled in the communities of practice, which can lead to the learning of existing knowledge or the generation of new knowledge, together with the development of community and its members. Nermian Al-Ali suggests (2003), for instance, that CoP strategies can be applied for creating new knowledge as innovations through the transfer of mainly tacit general knowledge.

Representation of our Knowledge on Contextual Knowledge Interactions

To represent our knowledge about communities of practices metaphorically, we can also use the geometric characteristics of an ellipse. Forming around the interplay and the duality of concepts like practice and learning, communities of practice can be visualized as an ellipse that is drawn over two center points of practice (or action) and learning (or knowing) (see Figure 1).

In this model we use the geometric characteristics of an ellipse to develop the existing models about learning, learning by doing (or doing by learning), and communities of practice. The ellipse has two fixed points, which are labeled practice (or action) and learning (or knowing) in our model. Thus we can suggest that our community of practice forms around the concepts of both practice and learning. In the ellipse, the sum of the distances between any point on the plane curve and the fixed points is constant. In our CoP ellipse, this also means that whatever is done in the community of practice always consists of some action and some learning, although their ratio could be different. Using other characteristics of ellipse, such as eccentricity, we can use this kind of approach to help us solve some problems related

Figure 1. Community of practice ellipse

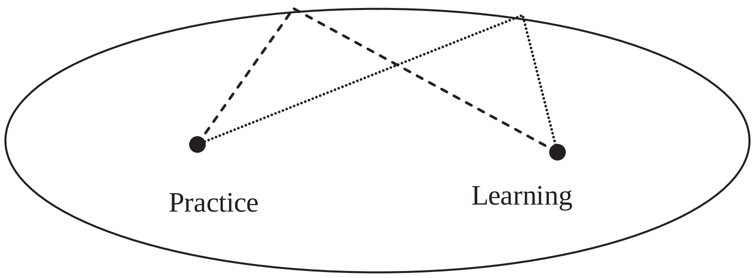

Figure 2. SECI interactions in the community of practice

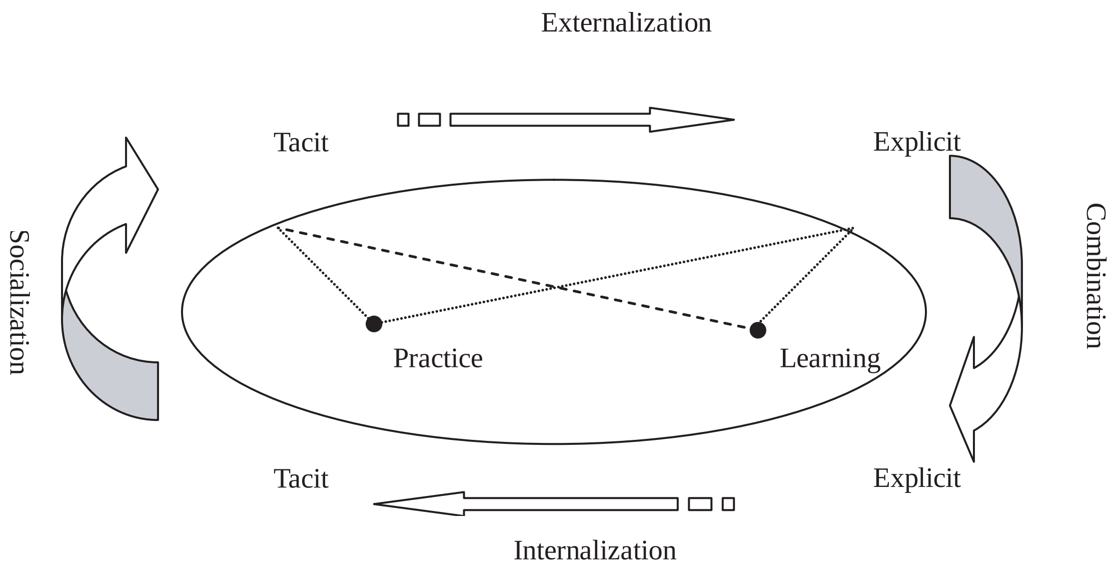

to the different taxonomies of learning and action, which can also be a topic of another article.

Secondly, we can fit the SECI interactions onto this ellipse of community of practice, benefiting from the attachment of tacit knowledge with bodily experienced practice and explicit knowledge with learnt theory in mind (Nonaka & Takeuchi, 1995). However, by no means do we aim to propose a taxonomy, which could end up with another dichotomy. On the contrary, this modeling suggests that both tacit and explicit knowledge are bound to be together. Then, in the ellipse of the communities of practice, the conversion of knowledge can be enabled, which can lead to the generation of knowledge and development of the CoP (see Figure 2).

Table 2. Local-global (specific-general) interactions

To \ From	Local	Global
Local	LOCAL	GLOCAL
Global	LOBAL	GLOBAL

Then the specific and general knowledge conversions identify the interactions that go beyond individual entities, passing across boundaries. We distinguish these interactions in Table 2.

As suggested earlier, these interactions have relative meaning depending on the positioning of the entity besides other entities and levels (see Figure 3).

It is also possible to reinterpret and visualize SECI conversions as contextual, transboundary interactions as in Figure 4.

The conceptualization of tacit-explicit and specific-general knowledge interactions in a

Figure 3. Specific-general knowledge interactions within and across contextual entities and levels

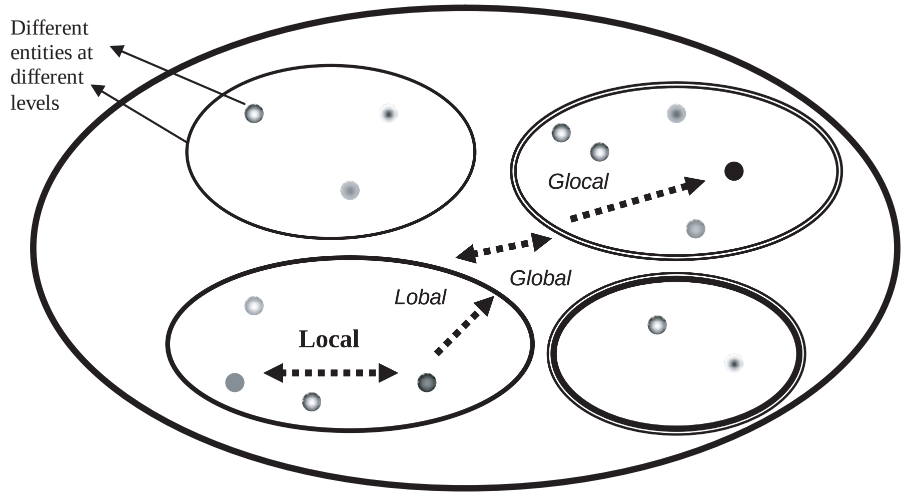

Figure 4. SECI conversions as contextual trans-boundary interactions

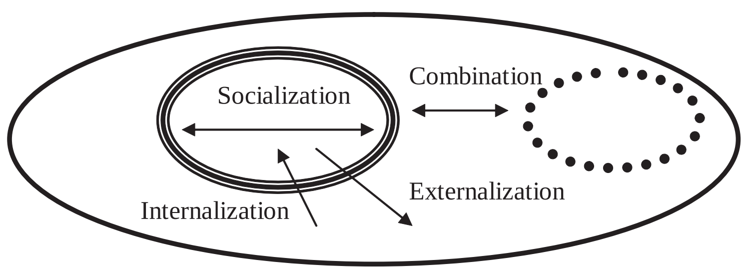

context for learning, participation, and knowledge creation highlights the existence of various processes as knowledge conversions or transactions. These processes of tacit-explicit and specific-general knowledge interactions, rather than the so-called "SECI" labels, can then be used to explain important mechanisms and dynamics in organizational knowledge creation and the communities of practice. For instance, a discourse can be seen as making any tacit knowledge explicit, which can only be truly understood with the specific knowledge of the context of that discourse. Relevant explanations can be made for other processes like reflection, justification, empathy, and different ways of learning. Even the tacit-explicit knowledge interaction within the knowledge conversion process itself can be better understood with the recognition of specific and general knowledge interactions. What makes these delicate knowledge interactions possible is the awareness of all participants of the similarities and differences among each other. Candid conversations in informal settings make community members aware of each other's background and personality characteristics, and then they can properly position themselves, adjusting their own attitudes and behaviors for the benefit of all individuals and the community.

FUTURE RESEARCH TRENDS

Distinguishing specific-general knowledge beside tacit and explicit underlines the necessity of a better articulated generic model of knowledge creation, which should aim to incorporate conceptualizations like context (ba or CoP), learning and action–knowledge and knowing (Cook & Brown, 1999); integrate different levels of analysis at individual, group, organization, and society level; and look more carefully to the interactions among various entities at these different levels. According to this, the knowledge interactions in a group can also be understood as knowledge interactions among individuals within the context of the group environment, and the knowledge interactions in an organization as knowledge interactions among individuals and groups within the context of the organizational environment. Moreover they are all under the influence of local, global, 'glocal', and 'lobal' dynamics coming from different levels and entities within and out of their own boundaries. The same applies to communities of practice and the community members, as well.

According to the findings of Easterby-Smith and Lyles (2003) about recent and future research trends, the following are likely to have the greatest impact on knowledge management and organizational learning in the next five years:

- research methods and measures of organizational learning/knowledge management;
- learning across boundaries;
- cognitive, socio-political aspects and tacitness, which also includes CoPs; and
- strategy, technology, and competitive advantage.

Among these, "learning across boundaries" has already become popular and is likely to continue its influence, in sharp contrast to the research on "learning capabilities, experience, and absorptive capacity." Less work has been done on the latter two areas; this is likely to change in the near future (pp. 645-646).

CONCLUSION

These findings point out that research on learning across boundaries and CoPs has a profound place in the literature of organizational development, and of knowledge creation and management. Studies on contextual specific-general knowledge interactions and CoPs, which can theoretically and practically identify and analyze the existing numerous interactions, knowledge transfer, and transitions, can contribute significantly to the knowledge-base of this emerging literature. The obverse is also true, that studies on organizational knowledge management can be used to further our understanding about CoPs and learning interactions across boundaries with regard to these communities and practices.

Chapter 4.28
Communities of Practice as Facilitators of Knowledge Exchange

Scott Paquette
University of Toronto, Canada

INTRODUCTION

For knowledge to create value in an organization, whether tacit or explicit, it must have the ability to be shared among employees. This intentional (or in some instances unintentional) flow of knowledge can become the driver for organizational learning. When examining knowledge sharing, it is important to consider the context in which the knowledge is developed, as the community in which the individual is learning can affect any knowledge that is created. Organizational learning is impacted by individuals, groups, and the organization as a whole, and how these three levels are linked by social processes (Crossan, Lane & White, 1999). However, it is very difficult to create the right social environment to produce optimum knowledge sharing and learning. Sharing knowledge is an 'unnatural act', and therefore firms must strive to create the right environment and means to assist employees in overcoming knowledge flow barriers (Ruppel & Harrington, 2001).

Previous research has identified communities of practice as a hub for sharing knowledge within an organization (Brown & Duguid, 1991; Ellis, 1998; Hildreth & Kimble, 1999). The ability of a community of practice to create a friendly environment for individuals with similar interests and problems to discuss a common subject matter encourages the transfer and creation of new knowledge. Practitioners with similar work experiences tend to be drawn to communities, and from this a common purpose to share knowledge and experience arises (Wenger, 1998). Blackler (1995) argues that the creation and deployment of knowledge is inseparable from activity, and different contexts manifest in the form of knowledge boundaries. A community of practice can help individuals remove this boundary through the creation of a common context that links different experiential knowledge in an environment suited for knowledge exchange.

BACKGROUND

Communities of practice bring value to individuals and organizations by allowing for the acquisition of knowledge that supports practice within a role or responsibility. Brown and Duguid (1998) distinguish between two types of knowledge: (1) "know-what" or topical knowledge, and (2) "know-how" or knowledge derived from experience and action. They define "know-how" as the ability for an individual to take his or her "know-what" knowledge and put it into practice.

Other perspectives focus on the knowledgeability of action (Orlikowski & Yates, 1994). Here the verb knowing is stressed, rather than the noun knowledge. The emphasis on the interactive requirement for individual learning rather than the passive receipt of knowledge is a perspective that fits well with communities of practice. The use of the verb participation, a requirement for membership within a community of practice, also suggests that knowledge is created and shared from participation in experience and active membership within a community. An individual's ability to know is inseparable from practice and context.

Communities of practice follow the logic that knowledge cannot be separated by practice, as what is learned is highly dependent on the context where the learning takes place (Hayes & Walsham, 2001). The concept of legitimate peripheral participation (LPP) is derived from this notion, as it postulates that members who are allowed the opportunity to fully participate in community activities begin to behave as community members, or as practitioners. It is through this membership that knowledge can be shared with the rest of the community. Learning within a community is situated, as it occurs through people interacting in context. The learner's situated perspective, including physical and social context, become an important aspect in their learning and interaction with the community (Lave & Wenger, 1991).

In some cases, a familiar context or environment becomes a crucial factor in a practitioner's ability to deal with unfamiliar, unstructured problems (Tyre & von Hippel, 1997). These members must have access to the periphery of the practice, which allows for either observation or participation in the practice that eventually contributes to their decision to join the community. The term periphery is not used in the geographical sense, but as the degree of involvement an individual may have with the community. Their participation must eventually become legitimized (though not in the formal sense), in order to empower the participants to participate in learning and personal development.

Knowledge is situated within these communities through the situated learning curriculum that is unique to each community of practice. Newcomers can access this curriculum to gain the common knowledge resident in the community as a first step towards full participation. However, learning is an improvised practice, and eventually the participant must go beyond this notion of structure and curriculum to acquire knowledge. Therefore, participation in any community where knowledge exists can be defined as the act of learning (Lave & Wenger, 1991).

Communities of practice are able to assist an individual with this knowledge conversion as long as the participants are situated within the same community. The transfer of knowledge across communities becomes more challenging due to the "sticky" nature of knowledge. As knowledge is situated within a particular context, the removal from this context may distort its value or meaning. Various means of overcoming this obstacle have been proposed. Boland and Tenaski (1995) propose the use of communication forums that span multiple communities, while both Star (1989) and Carlile (2002) support the use of boundary objects.

Facilitating Knowledge Sharing

Lesser and Storck (2001) examined communities of practice by identifying their influence on a firm's social capital. Social capital, or "the sum of actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit " (p. 833), emphasizes the value of a cohesive group in organizational learning. This value can clearly be seen through examining the three dimensions of social capital: the structural dimension, the relational dimension, and the cognitive dimension. The following considers each dimension and the related factors that encourage knowledge flow and learning.

The structural dimension refers to the ease of which individuals can make connections with other similar practitioners. It identifies the processes, resources, and tools the community creates in order to augment and encourage social interactions. These may be in the form of physical resources, such as systems, or intangible resources such as face-to-face meetings and communities of practice.

Communities of practice can bring many structural benefits to an organization's knowledge sharing initiatives. They promote the use of IT tools in knowledge sharing, which can stimulate the use of this infrastructure and create a well-networked organization by use of the provided resources. Distributed cognitive theory addresses how learning in such a collaborative environment takes place. It defines a person's horizon of observation as the portion of the workspace that a participant can observe or monitor. Technologies designed for communities and knowledge sharing expand a member's horizon of observation, allowing for the identification of different knowledge sources that can contribute to the learning within the community. These technologies typically incorporate tools such as recorder tools, forums, local memory storage, and other knowledge collection aids in order to increase the spread of knowledge (Eales, 2003).

The community can act as a boundary-spanning object for geographical barriers through its distributed social nature and its ability to successfully use global IT resources. By allowing communities to work or partner with other company functions, they can become the facilitator for knowledge transfer, and encourage these functions to develop new knowledge. This situates them in the role of the educator in organizational learning. When implementing a knowledge strategy, the leadership within an organization can employ communities of practice to communicate the vision of a knowledge organization, set knowledge-related priorities and funding levels, facilitate communication that crosses business unit boundaries, encourage employee participation, and ensure alignment of company-wide systems and policies (Wenger, McDermott & Snyder, 2002).

The second dimension of social capital is the relational dimension. Here, the interpersonal relationships and activities of interaction come together to create a community that is not only willing, but also trusting and caring to share information with others.

Useful or valuable knowledge in organizations is often developed not by specialists or the people known for their subject matter expertise who are detached from the problem, but those who can operationalize the problem based on their work and who stand to benefit directly from the solution. These people are usually members of the community of practice where the solution is discovered (Brown & Duguid, 2001). By possessing a common goal for community (such as problem solving), relational capital is formed.

One method of determining how communities of practice share knowledge is by examining why people participate in these communities. A participant's motivation and justification for involvement will shed light on how knowledge is transferred. Wasko and Faraj (2000) view knowledge with the perspective that it is embedded not only in individuals and organizations, but also communities. Therefore knowledge can be managed as a public good, which is defined as "a commodity that can be provided only if group members contribute something towards its provision: however, all persons may use it" (p. 156). Organizations can be conceptualized as a group of overlapping communities that treat knowledge as a public good. The role that these communities play in knowledge flow throughout the organization is crucial.

Employees' motivation to exchange knowledge is impacted by their view that the decision to participate in such communities is either primarily economic and motivated by self-interest, or non-economic and motivated by community interest and moral obligation. This perspective can determine what stimulates an employee to share knowledge in a community of practice. Some participants become involved to generate tangible returns, such as access to useful information and expertise, answers to specific operational questions, and personal gain. They find that information received is up to date, compared to other sources such as company manuals or other information sources. In some cases, an individual can receive personal gain, including enhanced standing in the profession, a better reputation, or even to generate personal business. On the other hand, a community of practice can be a source of intangible benefits to its members, in the form of intrinsic rewards. Certain people find participation challenging, refreshing, and a means to refine their thinking in order to develop new insights. These individuals enjoy learning and sharing with others, and become confident with their expertise. They can also enhance their own personal learning through exposure to a variety of viewpoints from around the world. These are people that believe helping people is "the right thing to do" (Wasko & Faraj, 2000).

The final dimension of social capital is the cognitive dimension. This dimension provides a common context that allows for the efficient transfer of knowledge between individuals. It provides not only a common language, but addresses acronyms, subtleties, and underlying assumptions that are common to the daily operations of members. It can provide taxonomies for the classification of knowledge, and means that allow for knowledge transfer.

Knowledge flows most efficiently when seekers and experts are considered members of the same community and thus share the same values, norms, processes, and narratives. Furthermore, this flow is supported through making knowledge available that is deemed useful, timely, and helpful to the community (Wasko & Faraj, 2000). However, Pan and Leidner (2003) argue that organizations need to provide multiple channels of communication to support diverse knowledge sharing needs and preferences. The boundary of a community of practice should be dynamic and include other functions, people, and external sources. This generates the requirement to consider issues such as the need for a shared context, language, and culture, which can be nourished through motivation to share knowledge with individuals from different communities or the expansion of existing groups.

Many people have argued that larger organizations do not have the structure or capability of producing continuous and valuable innovation. However, with an organization of communities as described in Brown and Duguid (2001), large organizations supported and recognized by the larger community can develop these smaller, specialized communities. This potentially develops the capability of producing new knowledge, whether individually or in conjunction with other overlapping communities. Thus, larger organizations that are 'reflectively structured' are well positioned to be both highly innovative and capable of dealing with high degrees of change.

Challenges for Communities Sharing Knowledge

In many cases, the simple establishment of a community of practice will not contribute towards knowledge sharing. Underlying factors in either its design or the individuals participating can block members from interacting and sharing their knowledge. Participants will not contribute to the knowledge sharing within a community of practice for many reasons. For example, if they are not comfortable with their level of expertise, they become the victim of attacks on their ideas and opinions, or become overwhelmed with too much information being circulated. As well, a community that provides knowledge that is not useful or not interesting to its members creates the concern that participation is too time consuming and not a valuable use of time or resources (Wasko & Faraj, 2000).

In some organizations, employees may not feel the organizational climate provides a safe or desirable forum to share their valuable knowledge. Communities of practice can provide safe enclaves from organizational social-political pressures and encourage further knowledge sharing. Safe enclaves are characterized by shared electronic and non-electronic social spaces that allow for underlying views to be expressed. When communities are used for political purposes, it has been found the participation from members is very limited. It is common for managers and those removed from the community to attempt to influence or govern these communities from a distance, which also negatively influences participation. Genuine participation only occurs when the use of technology does not mirror the career or financial reward structure, or the control activities of senior management (Hayes & Walsham, 2001).

FUTURE TRENDS

A recent trend in the knowledge management field is to look beyond a firm's external boundaries for new sources of knowledge. Knowledge management strategies are encompassing not only the focal organization, but its partners, suppliers, and customers. Organizations will receive further knowledge benefits from communities of practice as the communities encompass individuals and knowledge assets located outside the organization. This partnership in knowledge sharing, with the community as the base of the relationship, will infuse new knowledge into the community and expand its knowledge creation capabilities.

Communities of practice are increasing their functional contributions within organizations by closer aligning with corporate strategies. A community that has grown within an organization can be formalized to contribute to the operations of the business, while serving its members in the original intended fashion. For example, instead of forming a product development team, an organization can utilize an existing community of practice to identify and involve the most appropriate people who possess the relative knowledge and skills. These formalized communities of creation have advantages over non-formal communities as they receive management recognition and support, priority in resource allocation, and increased recognition for their members' contributions. Eventually, these formalized communities will be the product or system development team, rather than an ad hoc assembly of staff.

As communities of practice become more fully integrated into job functions and business processes, they will become visibly integrated within the organization. As an organization is a community consisting of smaller communities, the boundary between communities and the formal structure of the organization will become seamless, and each new department or working group will have traits similar to communities already found in organizations. The social benefits of these communities working for a common goal under a common community structure will impacts the organization's social capital, its employee productivity, and its success in the marketplace.

CONCLUSION

Communities of practice have the capability to grow an organization's social capital through the increase in knowledge sharing that naturally occurs within these communities. By connecting individuals with similar experiences and interests, creating relationships between individuals and groups who may have not had the opportunity to meet through the formal structure of the organization, and providing a common context that encourages people to share their knowledge, a formal or informal community of practice can create the foundation for successful knowledge sharing within an organization.

Communities of practice can result in the following benefits to an organization and its knowledge strategy (Wenger et al., 2002):

1. create new business opportunities by developing internal expertise and relationships with an organization's customer base, resulting in the conversion of insights into new products;
2. reconstitute expertise that can become lost in a dynamic organization, and create a method of locating such expertise;
3. enable companies to compete on talent, then for talent—by becoming known as a home for experts that encourages the development of skills and expertise by employees; and
4. capitalize on the participation in multi-organizational communities of practice—by extending the firm's knowledge resources beyond its traditional boundaries.

Also noted by Brown and Duguid (2001), communities can design, develop, and maintain significant repositories for the storage and dissemination of knowledge throughout the organization. Although these repositories may be technical in nature or located in the individuals who hold the knowledge, the community becomes an identified source for knowledge on a particular subject matter. As organizations recognize the importance of supporting and maintaining communities of practice, they will experience increased knowledge capabilities and business success.

Chapter 4.29
A Qualitative Study of the Characteristics of a Community of Practice for Knowledge Management and Its Success Factors

Eric W. Stein
Pennsylvania State University, USA

ABSTRACT

A Community of Practice (CoP) is an organizational form receiving increasing attention as a structure for sense making, knowledge management and learning. The central question addressed in this article is how and why these communities form and grow over time. These questions are explored through a qualitative analysis of a CoP formed to help knowledge management practitioners. In this case study, a description of how the organization formed, survived, grew and matured over a five-year period (1999-2004) is given. Several practices and structures related to CoP development are identified; for example, operations, roles and responsibilities, communications, sub-group structures, use of information technologies and other aspects of organizing. Using data from several sources (e.g., membership surveys, interviews with key informants, document analysis), four sets of factors that have helped this organization succeed are identified: Individual, Content, Meeting and Organizational. These factors are arranged into a preliminary descriptive model of the function and structure of CoPs over the life cycle. To practitioners, the work sheds light on how to set up and successfully grow a community of practice.

OVERVIEW AND OBJECTIVES

A CoP should have the ability to sustain and renew itself over time (Barab & Duffy, 2000).

This observation raises several questions. How are CoPs formed? Why do some survive? What is inherent in the structures and operations of successful CoPs that allow them to stay in existence? What other critical success factors are required, such as intrinsic or extrinsic rewards for members? The purpose of this study is to better understand CoPs, how and why they form, and what sustains them over time.

The answers are important to theory and practice. To theory, it can shed light on loosely structured extra- and intra-organizational forms and the factors that lead to their success over the life cycle. We define CoP success here as effectively forming, being in existence for a significant period of time and showing continued signs of growth and development. To practice, the answers provide insight for individuals who wish to set up a successful, long-term CoP within their organizations as part of a broad knowledge management (KM) strategy. For those specifically interested in developing KM-centered CoPs, this study provides insights into the formation, survival and growth of such structures.

LITERATURE REVIEW: CHARACTERISTICS OF COPS

This article is grounded in the literature on CoPs, organizational memory (OM) and KM. The concept of a CoP has emerged as a useful construct to describe a social form that has been in existence for centuries (e.g., guilds), but has been recently been "rediscovered" in the context of corporations and applications in KM. The concept owes its early modern formulation to the works of Lave (1988, 1991), Wenger (1998), Lave and Wenger (1991) and Brown and Duguid (1991, 2001). Initial works focused on the shared meaning and knowledge that developed in occupational groups such as midwives and butchers (Buysse, Sparkman & Wesley, 2003) or repair specialists (Iverson & McPhee, 2002). It now is applied to any knowledge-sharing group within and between organizations (Brown & Duguid, 2001; Swan, Scarbrough & Robertson, 2002) and is viewed as a non-technical component of many KM strategies.

Definition

The definition of a CoP has evolved over time. Wenger, McDermott and Snyder (2002) see a CoP as a set of people who "… share a concern, a set of problems or a passion about a topic, who deepen their knowledge and expertise in this area by interacting on an ongoing basis" (p. 4). Buysse, Sparkman and Wesley (2003) observe that "… a community of practice generally can be defined as a group of professionals and other stakeholders in pursuit of a shared learning enterprise, commonly focused on a particular topic…" (p. 4). Swan, Scarbrough and Robertson (2002) define a CoP as "an activity system about which participants share understandings concerning what they are doing and what that means in their lives and for their community. Thus, they are united in both action and in the meaning that that action has, both for themselves and for the larger collective" (p. 2). Brown and Duguid (1998) observe that "… collective practice leads to forms of collective knowledge, shared sense-making and distributed understanding that doesn't reduce to the content of individual heads. A group [in which] such know-how and sense-making are shared … has been called a 'community of practice'" (p. 5).

Characteristics

Wenger's (1998) work specifies three characteristics of CoPs: mutual engagement (i.e., interaction among the members), negotiation of joint enterprise (i.e., enacting meaning and significance; defining goals and priorities) and shared repertoire (i.e., the stories, methods, tools and theories used by members). The works of Buysse, Sparkman and Wesley (2003) and Barab and Duffy (2000) define three essential characteristics of CoPs: (a) shared cultural and historical heritage, as well as shared goals and meanings; (b) interdependent participants who are part of a larger social system; and (c) a reproductive cycle whereby older members leave and new members enter the community. Wenger's most recent work (2004) identifies three characteristics of a CoP that differ from his earlier works: (a) Domain (i.e., the area of knowledge that brings the community together); (b) Community (i.e., the group of people for whom the domain is relevant); and (c) Practice (i.e., "the body of knowledge, methods, tools, stories, cases, documents which members share and develop together" (p. 3)).

A careful reading of the prior works suggests that five distinct aspects of CoPs identify them as such:

1. A knowledge domain of interest;
2. A set of interested and interconnected participants;
3. Opportunities for ongoing processes of sense-making, knowledge sharing and discovery within the domain of interest;
4. A set of resources related to the domain of interest, including methods, tools, theories, practices and so forth, that are acquired, retained and accessible by the community; and
5. Processes by which the community maintains and refreshes its membership.

These five criteria are useful in distinguishing between CoPs and other similar but more narrow forms of organization such as communities of interest (CoI), communities of learners and learning communities (Barab & Duffy, 2000; Buysse, Sparkman & Wesley, 2003). For instance, communities of interest share only some, but not all of the characteristics of CoPs. According to Walters and Clark (1996, p. 1): "Communities of interest or electronic communities … offer people who live in the same locale and share common interests and concerns a virtual place to exchange information." The distinct focus of a CoI is on electronic information exchange, as opposed to the far-richer concept of sense making and enacted meaning found in CoPs; that is, sense making is seen as a key distinguishing feature of CoPs. The importance of sense making to organizing is found in management literature in several works. Sense making in organizations has been seen as a critical factor related to crisis management (e.g., Weick, 1979, 1995), strategic management (Gioia & Chittipeddi, 1991), organizational learning, knowledge management and performance (e.g., Thomas, Clark & Gioia, 1993; Thomas, Sussman & Henderson, 2001), creativity in organizations (e.g., Drazin, Glynn & Kazanjian, 1999), product innovation (e.g., Dougherty, Borrelli, Munir & O'Sullivan, 2000), managing organizational complexity (e.g., Moss, 2001) and information technology use (e.g., Griffith, 1999).

Another defining characteristic of CoPs is their ability to process knowledge through knowledge discovery, retention and use. This function finds support in the literature on organizational memory (e.g., Ackerman & Halverson, 2000; Anand, Manz & Glick, 1998; Cross & Baird, 2000; Croasdell, 2001; Moorman & Minor, 1997, 1998; Nissley & Casey, 2002; Rulke & Rau, 2000; Stein, 1995; Stein & Zwass, 1995; Walsh & Ungson, 1991; Wijnhoven, 1999; Wishart, Elam & Robey, 1996) and KM. According to OM research, organizations intentionally construct, acquire, retain and retrieve organizational memories to support organizational activities (e.g., positive memories) and adapt to cope with the effects of outdated knowledge and information (e.g., negative memories).

Knowledge management has been defined in the works of Nonaka (1994, 1995, 2001) and others as inclusive of the processes of knowledge creation, transfer and use. Earl (2001) segments KM interests and application into three areas. The first area (Technocratic) focuses on the use of information technologies to achieve such KM goals as knowledge retention and retrieval. The second area (Economic) pertains to how organizations use knowledge for competitive advantage and to formulate business strategies (e.g., Davenport, 1998). The third area (Behavioral) is most closely aligned with this work, which "… describes the use of organizational structures, or networks, to share or pool knowledge. Often described as 'knowledge communities,' the archetypal organizational arrangement is a group of people with a common interest, problem or experience" (Earl, 2001, p. 6). In a similar vein, Demarest (1997) divides the KM world into two parts: one that makes knowledge explicit and stores it using information technologies, or one that facilitates the growth and enrichment of knowledge through the formation of social networks bound by communication and learning processes. CoPs, it can be argued (Iverson & McPhee, 2002) offer "… a theoretical construct for understanding the interactive roles of information systems and people and also as a model for understanding how KM is negotiated communicatively between people" (p. 1). Brown and Duguid (1998) also recognize the importance of CoPs to KM, but caution that they "can easily be blinkered by limitations of their own world view" (p. 5). Less circumspect, Wenger (2004) argues that "communities of practice are the cornerstones of knowledge management" (p. 1). At the least, CoPs can be viewed as a means of implementing KM in organizations. For example, organizations reluctant to commit resources to KM information technologies often start with CoPs because they are perceived as a low-cost alternative. Others simply want to test the KM waters and view CoPs as a means of doing so. To those that embrace the human side of organization, CoPs are considered the primary way to implement KM.

In summary, CoPs are a useful social form that has been in existence for many years. Studies of these systems have illuminated much about their functional aspects; that is, ability to process knowledge and information, and usefulness to its members or to the organizations that support them. On the other hand, less is known about their actual structures, how they come into existence, how they grow and how they are self-sustaining over time. The goal of this article is to explore the evolution of CoPs and the organizing activities that contribute to longevity and success.

RESEARCH QUESTIONS AND PROPOSITIONS

The following research questions and propositions (see Table 1) were framed based on the author's field experience and the literature review. The central questions are: Why (and how) are some CoPs able to smoothly move from one life cycle phase to another? Why are some CoPs in existence for several years without a formal budget or commitment of resources? In short, this research hopes to identify the organizational factors that have led to success. These include motivational factors (e.g., what motivates organizational leaders and members to contribute) and factors related to context, knowledge content, organization and structure. The study also addresses several how-to questions related to CoP formation and development; for example, operations, roles and responsibilities, meeting management and so forth, which are of particular relevance to practitioners.

The propositions are grouped according to the life-cycle phases of organizations; that is, from formation to maturity. The concept of the organizational life cycle is not new, appearing first in the works of Haire (1959) and Chandler (1962), and later in several works in organization theory. Gupta and Chin's (1994) extensive review identifies five areas of impact on management literature: organizational effectiveness (e.g., Quinn & Cameron, 1983); entrepreneurship (e.g., Smith & Minor, 1983); strategy making (e.g., Gupta & Chin, 1992); organizational power (e.g., Mintzberg, 1984); and organizational politics (e.g., Gray & Ariss, 1985). The concept (which is applied typically to formal organizations, such

Table 1. Research questions and propositions

Research Questions	• Why are CoP's formed? How? • Why do some CoP's endure for years after they are formed? • Why do people join and contribute to a knowledge-based CoP? • How is a CoP structured? How is a CoP operated? • What benefits does a CoP deliver to its members?
Research Propositions	*Formation Propositions* • CoP's can form from a single meeting or presentation • The cost to form a CoP is low and only requires a small investment in a meeting place and refreshments • To ensure its survival, a core set of participants must commit to future meetings and establish means of communication and coordination
	Survival and Early Growth Propositions • Having a clearly defined and executed mission is important to survival and growth • Social networks of the members are important to survival and growth • Knowledge assets of the members are important to survival • Organizational champions are a key to survival • Pooled resources are a key to survival and growth
	Late Growth and Maturity Propositions • CoP's provide explicit benefits to members at meetings; e.g., topic, knowledge exchange, as well as implicit benefits such as recognition, affinity, expanding social networks, and emotional support • CoP's create organizational structures, establish roles and responsibilities, and create procedures to ensure operational efficiency and to move from survival to growth • CoP's can choose that its structures and processes remain informal and low-cost • Information technologies and communication processes play a key role in ensuring a CoP's continuation
	Decline or Renewal Propositions • CoP's that adapt to changing conditions will experience renewal • CoP's that fail to adapt to changing conditions, modify its mission, or recruit new members will experience decline and cease to exist.

as corporations) contends that organizations go through various stages throughout their development, pursuing different ends and exhibiting different characteristics over time. Most works specify a four-stage model: Formation, Survival and Early Growth, Late Growth and Maturity, Decline or Renewal.

The formation phase is characterized by the development and implementation of a plan or vision, acquisition of resources and fulfillment of customer needs (Jawahar & McLaughlin, 2001). In the survival and early growth phases, the organization stabilizes its position and pursues opportunities for expansion. Most organizations focus on product or service reliability and work to formalize organizational structures (Dodge & Robbins, 1992, Jawahar & McLaughlin, 2001). In the mature phase, the organization becomes more confident in its abilities but also more risk adverse. The rate of growth has slowed by this time and there is some uncertainty regarding new opportunities (Jawahar & McLaughlin, 2001). Finally, the organization faces a crisis: It reinvents itself and transitions to a new cycle or it goes into a decline phase that leads to its eventual termination.

These stage distinctions are useful in grouping the research propositions with the understanding that CoPs differ from formal organizations in important ways, yet they share some of the same evolutionary life-cycle characteristics.

RESEARCH DESIGN AND METHODS

A single case study design was chosen for this research. Case studies offer an opportunity to examine an organization in depth through the development of rich description.

Case Selection

A CoP devoted to knowledge management that has been viable for more than five years was selected for this study. This organization met the five criteria identified for CoPs as noted above: a domain of interest, set of interconnected participants1, opportunities for sense-making, tools and supporting resources and mechanisms for renewal (see Table 2).

Types of Data Collected

Data for the case came from multiple sources to provide cross checks of validity and to triangulate the results as suggested by Yin (1989) and Eisenstadt (1989). In general, the overall rigor of case studies can be increased by using multiple sources, establishing a chain of evidence and having key informants review drafts of the work (Yin, 1989). These methods were employed to the greatest extent possible in this study. The work is considered exploratory in nature and accompanied by the caveats that apply to such research.

Data sources included documents, interviews, surveys and participant observation by the author (the latter has been an executive member of the organization for more than five years). Documents were collected from the organization, including schedules, Web materials, lists, membership databases, minutes of meetings, postings of threaded discussions and e-mails. Interviews and surveys were conducted with present executive committee

Table 2. Characteristics of study case as CoP

Characteristic	Value
A knowledge domain of interest?	Yes. Knowledge management theory and practice
A set of interested and interconnected participants?	Yes. Drawn from area businesses and universities. Bound by strong to weak ties.
Opportunities for on-going processes of sense-making, knowledge sharing, and discovery within the domain of interest?	Yes. Monthly meetings and Executive Committee meetings. Threaded discussions on-line.
A set of resources related to the domain of interest including methods, tools, theories, etc.?	Yes. Knowledge is retained in people's heads and the documents produced by the community (e.g., presentations from the monthly meetings made available through the organization's web site).
Processes by which the community maintains and refreshes its membership?	Yes. The organization has grown from ten members to over two hundred over a five year period. New members attend and are added each month.

members to test assumptions and propositions regarding the organization. Surveys were also conducted with the entire membership. In addition to these sources of data, data regarding the organization were collected by the author as a participant-observer within the organizational setting. All data were collected using instruments and methods approved by the University's Office for Research Protections, which ensures the protection of human subjects according to federal guidelines.

Form of the Report

The data were compiled into three sets of findings and a case discussion section. The case discussion ties the findings back to the research questions and propositions noted in Table 1. Preliminary models are provided of the factors that contributed to the success of the organization. The insights of the discussion section are grouped according to the life cycle stages noted earlier.

FINDINGS 1: CHARACTERISTICS OF THE CASE ORGANIZATION

These findings are based on the collection, compilation and analysis of existing documents, informal discussions with members and participant observation.

Formation and History

The organization chosen for study was the Knowledge Management Group of Philadelphia, from its inception in April 1999 to April 2004. This is the third-longest continuously running KM group of this kind in the United States (U.S.) as of this writing. The organization has been through the formation, survival and growth phases and is in, or moving toward, a state of maturity2. The group evolved from a meeting held in March 1999. The original meeting described KM strategies and practices at Hewlett-Packard, with particular emphasis on its consulting division. Based on the interest generated by this meeting, a meeting sponsored by the local-area Chamber of Commerce was held in April 1999 to explore the possibility of starting a KM learning community. About 50 people attended this meeting, representing industry and academia. At the meeting, a handful of people willing to lead future meetings were identified. These eight people represented several industries, including education, engineering, energy, government and consulting. Of the eight, five became active members of an Executive (Steering) Committee (EC). The role of the EC was to coordinate and host meetings and set the organization's direction. The group met once a month in the morning throughout the calendar year (after the first year, meetings in July and August were not scheduled due to vacations and work slow-downs). As of April 2004, the group successfully concluded its fifth year of activity, having held more than 52 meetings. The group has more than 240 registered members.

Goals and Objectives

The stated aims of the KM Group are:

The Knowledge Management Group (KMG) was formed to address the needs of area organizations in managing knowledge assets. Knowledge assets include intellectual capital (e.g., what employees know, patents), procedural knowledge contained in documents and administrative structures and knowledge embedded in information systems.

Knowledge management includes activities related to the creation, capture, organization, maintenance, retrieval and use of organizational knowledge to promote improved decision-making and performance. KMG's goal is to promote the sharing of KM best practices, to provide a forum for group problem solving on KM problems, and to encourage networking and professional col-

laboration in the area of KM. (Reference: www.kmgphila.org)

Thus, the explicit goals of the group are to (a) to promote networking, and (b) to promote learning and shared understanding about KM. The group promotes networking between professionals in the area who work for knowledge-intensive organizations. These include pharmaceutical firms, consulting firms, software developers, manufacturers and academic institutions. The main learning objective is to share the latest theoretical and practical knowledge among the members. Each meeting is structured around a theme or idea, and presentations are made by member companies or by outside experts. The meetings provide a forum to challenge assumptions, foster sense making, absorb new ideas and developed a shared understanding of the domain.

Meetings

Meetings are scheduled on the second Wednesday of the month from 7:45 to 9:45 a.m. to allow members to attend and then return to work. The first half hour is devoted to networking. At 8:15 announcements are read, an introduction is provided to KMG and, time permitting, members introduce themselves. The main part of the meeting lasts about one hour, followed by questions/answers. People leave around 9:45 a.m. or stay to discuss issues informally. About two-thirds of the meetings are located in the suburbs, and one-third take place in the city to encourage a broad cross-section of attendees. Topics range from presentations of theory and frameworks (e.g., "Teams and the Social Construction of Knowledge") to case studies (e.g., "KM at the DuPont Company") to experiential exercises (e.g., "Knowledge Acquisition and Retention") to sessions about KM tools and strategies (e.g., "Communities of Practice," "IT support for KM")3. The meetings range in size from 30 to 50 people.

Membership

The organization began with a core group of about 20 members. After five years, the database of members included more than 240 members from several industries and organizations. Statistics summarizing the industries and positions held by the membership are presented in Table 3. About 40% of the members in the database consistently attend meetings. The largest percentage of organizations comes from the information technologies sector (18%), followed by pharmaceuticals (12%) and consulting (9%). Managers and senior mangers from these companies make up almost one-third (33%) of the attendees, followed by information technology (15%) and KM professionals (10%). The majority of the firms (>65%) are located outside the city in its suburbs or neighboring states.

Administrative Structures

The primary administrative structure of the organization is the EC. The purpose of the EC is to select topics for future meetings, find host sites, set policy and procedures, and guide the group. Members of the EC serve on a voluntary basis. The committee is composed of members of large and small organizations, consultants and academics. The board strives for a balanced representation of these three groups. Two of the current members, including the author, have been in the organization since its start in 1999. The EC members have both breadth and depth of knowledge about its activities.

The EC meets the Friday following the monthly meetings and conducts an after-action review of the event. These members are responsible for the running of the organization and have the highest levels of participation among the membership. In 2003-2004, the EC was composed of eight members. Membership on the EC requires taking responsibility for the welfare of the group. These

requirements are noted on the organization's Web site, which evolved over the five-year period and were not codified until the fifth year.

Several roles and responsibilities evolved over time within the EC group to meet the needs of running the organization. The most important logistical issue to deal with each month is to select a topic, get a speaker and find a venue to host the meeting. Ongoing activities include managing the membership list of names, the Web site and the

Table 4. Requirements for application and roles and responsibilities of EC members

Requirements for Application to the EC
• Attend and participate in KMG meetings for 6 months or more prior to application • Assist in the planning and management of one or more KMG meetings prior to application • Contribute to the intellectual capital of the KMG meetings for 6 months or more • Be nominated for participation on the board by two or more EC members • Commit to regularly attend and contribute intellectual assets and time to monthly main and EC meetings if elected to EC

Role*	Responsibility	Tasks
Meeting Coordinator	Take responsibility for coordinating the hosting of one or more meetings per year	• Find venue • Arrange for refreshments at meeting • Manage logistics at meeting
Speaker Coordinator	Take responsibility for obtaining a speaker for one or more meetings per year	• Find and manage speaker • Introduce speaker at meeting
Resources Coordinator	Solicit and identify resources on behalf of the organization	• Obtain in-kind services, host locations, etc.
Management Coordinator	Manage meeting and participate in the internal running of the organization	• Select topics for calendar year • Set agenda for EC meetings • Run meetings
Communications Coordinator	Manage communications of the organization	• Communicate announcements of meetings to members via email • Manage Web site • Manage Yahoo groups
Membership Coordinator	Maintain and grow membership	• Solicit new members • Manage member database

*Note: some roles are shared among one or more members

threaded discussion group on Yahoo. See Table 4 for a complete list of the requirement, roles and responsibilities of EC members.

IT and Communications

Information technology and related procedures have played a role in the development of the organization. The member database was one of the most important.4 A database (e.g., in MS Word or Excel) of members was set up early in the first year. The database was populated with information obtained at monthly meetings, through referrals and through the organization's Web site. At the monthly meetings, attendees sign in or verify contact information on a list. This information is used to augment or keep up to date the member database. The member database is central to the notification process of upcoming meetings. For instance, an e-mail is sent out about two weeks prior to a meeting announcing its whereabouts and the topic. The mailing list is not used for commercial purposes.

Notice of upcoming meetings is also posted on the organization's Web site. The Web site was started in the second year of the organization and includes a meeting calendar, links to other KM sites, a list of EC members and sponsors, contact information, document archives and member sign-up. The Web site was designed, maintained and hosted by one of the EC members5 for the first five years. More recently, it is hosted using an inexpensive ISP and is jointly maintained by two EC members.6 Calendars for each year are archived and presentations are made available through the site. Member communications are facilitated via e-mail and through Yahoo-Groups. At Yahoo-Groups, members can engage in threaded discussions and post documents of interest.7

FINDINGS 2: MEMBERSHIP SURVEY

Results of the Survey of the Membership

The following questions were posed to the general membership:

- How did you first learn of the existence of the Knowledge Management Group?
- Why did you join the Knowledge Management Group?
- What do you like most about the organization?
- Would you call this organization a success?
- Do think it is likely that the organization will continue to exist for another five years?

An anonymous online survey8 was conducted over a three-week period that concluded the first week of December 2003. E-mail invitations to participate in the study were sent to 241 members. Of these, 37 were returned due to incorrect e-mail addresses, leaving 204 invitations. Of these, 97 completed the five-question, Web-based survey, which yielded a response rate of 48%. The assumption was made that respondents were representative of the group, given the relatively high response rate.9

The results of the survey are provided in Table 5 and are as follows10. 74% of the respondents indicated that they learned of the group from a colleague, 9% through a Web search and 21% through other means. These data reinforce the networking and "word-of-mouth" aspects of communications regarding the group. The primary reasons that people joined the group were because they were interested in the topic (84%), to network (75%) and to learn practical methods regarding KM (62%). Of lesser importance were career advancement (13%) and to look for new business (19%). More than one out of every five joined the group to be in a supportive environment (21%).

The primary aspects of the organization that people liked the most included intellectual stimulation (66%), the quality of the topics (65%), the quality of the people at the meetings (59%), the quality of the speakers (57%) and networking opportunities (48%). The way the meetings were run and times of the meeting were also important (39% and 27%, respectively).

Overwhelmingly, the organization was considered a success by the respondents (99%), and 93% thought it would exist for another five years.

FINDINGS 3: EC INTERVIEW DATA

Data Collection and Methods

Data were collected from the current EC members via e-mail and informal interviews. The following questions were posed:

- Why was this organization started?
- Why do you think people join and participate in the organization?
- Why do you think someone volunteers to work on the EC?
- Why is the organization still functioning after five years?

Table 5. Results of the survey of the KMG membership, Dec. 2003

How did you first learn of the existence of the Knowledge Management Group? (check all that apply)	Number of Responses	Response Ratio
Colleague	72	74%
Web search	9	9%
other	20	21%
Why did you join the Knowledge Management Group? (check all that apply)	Number of Responses	Response Ratio
Required by job	0	0%
Career advancement	13	13%
Interested in topic	81	84%
To network with other professionals	73	75%
To learn practical methods and techniques of KM	60	62%
To be in a supportive environment	20	21%
To look for new business	18	19%
other	6	6%
What do you like most about the organization? (check all that apply)	Number of Responses	Response Ratio
Quality of speakers	55	57%
Choice of topics	63	65%
The way the meetings are run	38	39%
The people you interact with at meetings	57	59%
The times of the meetings	26	27%
Communications following the meeting	13	13%
Friendships	11	11%
Networking	47	48%
Intellectual stimulation	64	66%
Other	3	3%
Would you call this organization a success?	Number of Responses	Response Ratio
Yes	96	99%
No	1	1%
Do think it is likely that the organization will continue to exist for another five years?	Number of Responses	Response Ratio
Yes	90	93%
No	7	7%

- What are the factors that have led to the success of this organization?

All EC members (excluding the author) participated in the data collection (n=7), yielding a response rate of 100%. The written responses were compiled and analyzed using Atlas TI, a content analysis program. After all responses to each question were compiled for all respondents, codes were assigned to the material. The coding was done in an iterative fashion. First, the program provided frequency counts of words; these lists provided candidates for content codes. Next, the program searched for sentences that contained the codes identified in the previous step, and these were auto-coded. Several reviews of the material resulted in the addition of new codes and the refinement of existing codes. Finally, the remaining text was manually coded using the master list of codes that was created. The efficacy of the codes was tested with alternate raters (two university staff members11) who were asked to match the codes to a sample set of statements from the primary material. The first reviews found that inter-rater reliability was about 72%. Subsequent refinements improved rater reliability to better than 80% and the codes were considered to be reliable for the purposes of this article. Once the coding of the responses was complete, quotations from each member (e.g., P1, P2, P3,….Pn) were organized according to topic, and preliminary models (e.g., influence diagrams) were constructed.

Interview Results

Q1: Why was the organization started?

Three primary reasons were given: knowledge sharing, networking opportunities and a desire to learn more about the topic. As one member put it: "… [It was started] … as a way for people to build a network and share practices and learnings in an informal, low-barrier setting" (P3).

However, despite the clarity of its goals, it was not clear from the outset what the evolution of the organization would be and if it would exist for five years. One member put it this way:

"The initial focus was about learning and, likely, networking. But, I doubt there were expectations about what it would become and [it was] more about let's just get together and talk about a topic of interest and maybe we can learn some more." (P5)

The organization thus evolved in an organic way, with few initial expectations about its future.

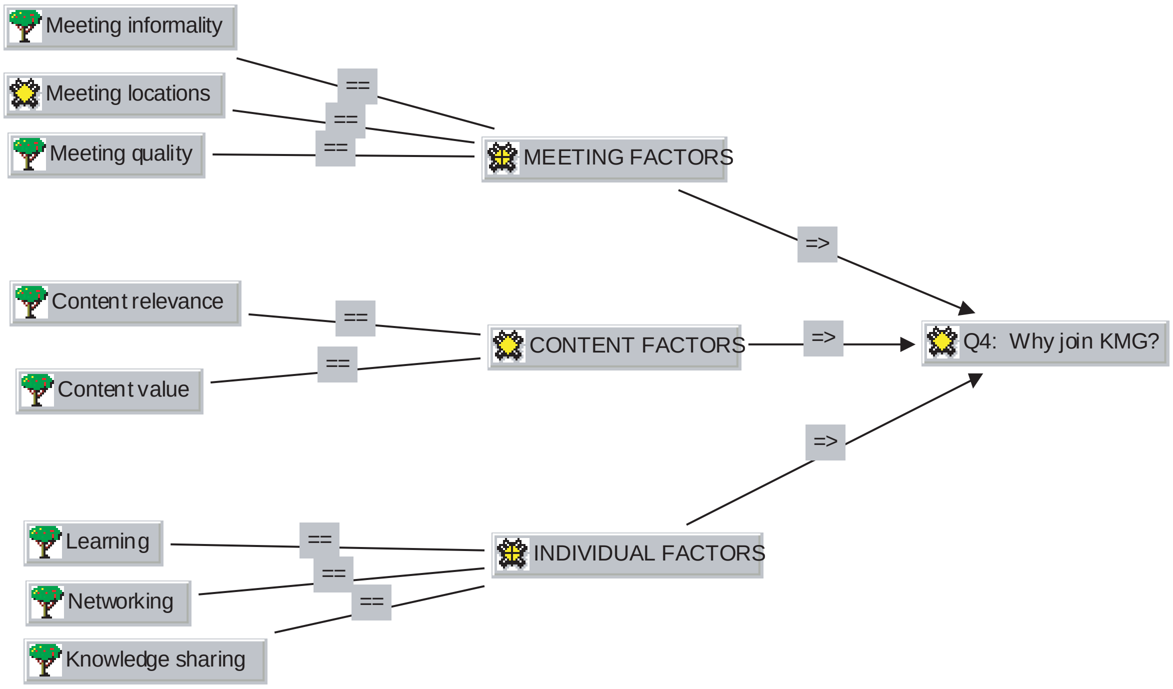
Q2: "Why do people join and participate in the organization?"

As noted in the previous question, knowledge sharing, networking and learning were important reasons to join the organization. One member said this:

"… [People join] … to learn …what KM is all about (everything from "what it is" to "how" and "why"), and how KM can drive their organizations to greater productivity, and help themselves in their efforts to manage their information and knowledge. To gain personal, realistic and first-hand experience and learnings from others in their same industry or area about KM. To network – personally with others sharing like interests and problems in the KM arena." (P6)

These primary variables (networking, learning and sharing) formed a cluster that was labeled Individual Factors. In addition, two other categories of variables were identified: Meeting Factors (i.e., characteristics of the meetings) and Content Factors (i.e., the characteristics of the knowledge exchanged at monthly meetings). For instance, positive meeting factors included the informality of the meetings, meeting locations, meeting quality and fostering a "fun" atmosphere.

Figure 1. Factors related to – Why join the organization?



Content factors included content relevance and content value. A model of these factors is shown in Figure 1.

One member summed up the reasons for joining this way:

"I came originally because a friend invited me. I have invited others. The loose structure makes it easy to participate; to come and go. The opportunities for networking are also valued. The communication about meetings and topics in advance of the sessions lets individuals decide when to participate. The atmosphere is inviting; questions and answers are valued." (P4)

Q3: Why do you think someone volunteers to work on the Executive Committee?

Reasons for participating on the EC ranged from very personal ones to more pragmatic considerations.

"I did it intuitively, because it felt right. Now I'm thinking about why it felt right, and here's what I believe. ...[I] tend to feel responsible for organizations in which I participate and ... believed it would be a good experience ... I thought it would get me more deeply networked with other KM practitioners. ... I figured I could help the group and add value. ... I continue to do it because, in addition to what's noted above, I really like everyone on the EC, we have a lot of fun, and it's a great group of people to work with." (P3)

Another member noted, "For me it is the desire to give back to the group and my profession; to support the continuation of the grassroots nature of the organization …" Another (P2) said that they had an "… interest in KM … [and a] … desire to contribute and lead …" (P4). Still another member said:

"Various motivators: (1) Deepen their social network. Get to know colleagues in broader ways — and they get to know you. (2) Professional recognition. The membership ascribes a certain status to those guiding a functioning organization. (3) Marketing purposes (e.g., "I am on the Executive Committee of the KMG"), [which] adds a level of credibility in talking about KM. (4) Deeper learning. ... Can tap a high level of knowledge and experience. (5) Pleasure of turning an idea into reality. It has certainly given me pleasure and a sense of accomplishment to having gone from nothing to a substantial something that has impacted people's careers and businesses." (P5)

Finally, one person saw the EC as a means to engage in sense making and deep learning as a sub-community within the larger community of practice:

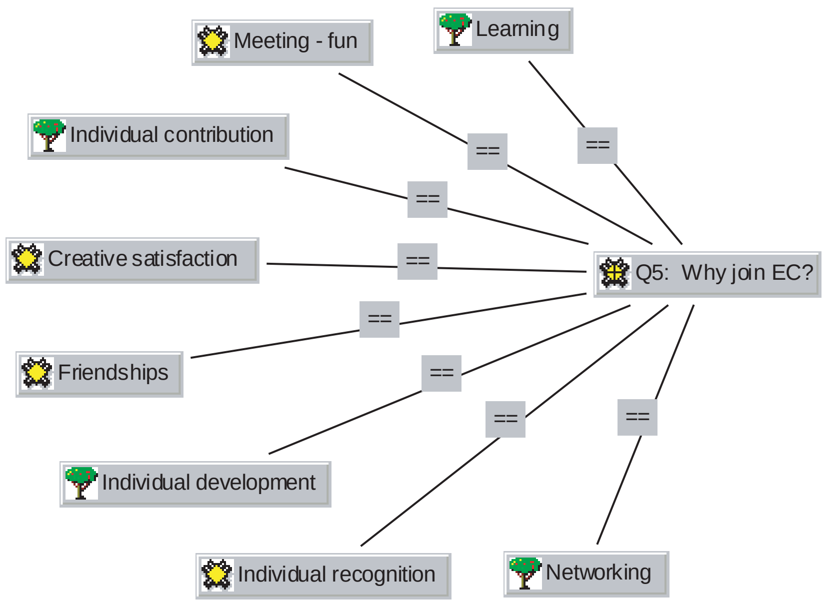
"Learning is social — [the] EC is a smaller social group than KMG that provides opportunities (occasionally) for debating, for sharing mental models and learning." (P7)

In summary, the factors that were most important included the quality of the experience, a desire to give back, intellectual stimulation and professional development. See Figure 2 for a model of the motivators to join the EC.

Q4: Why is the organization still functioning after five years;

and

Figure 2. Factors related to – Why join Executive Committee?



Q5: What are the factors that have led to the success of this organization?

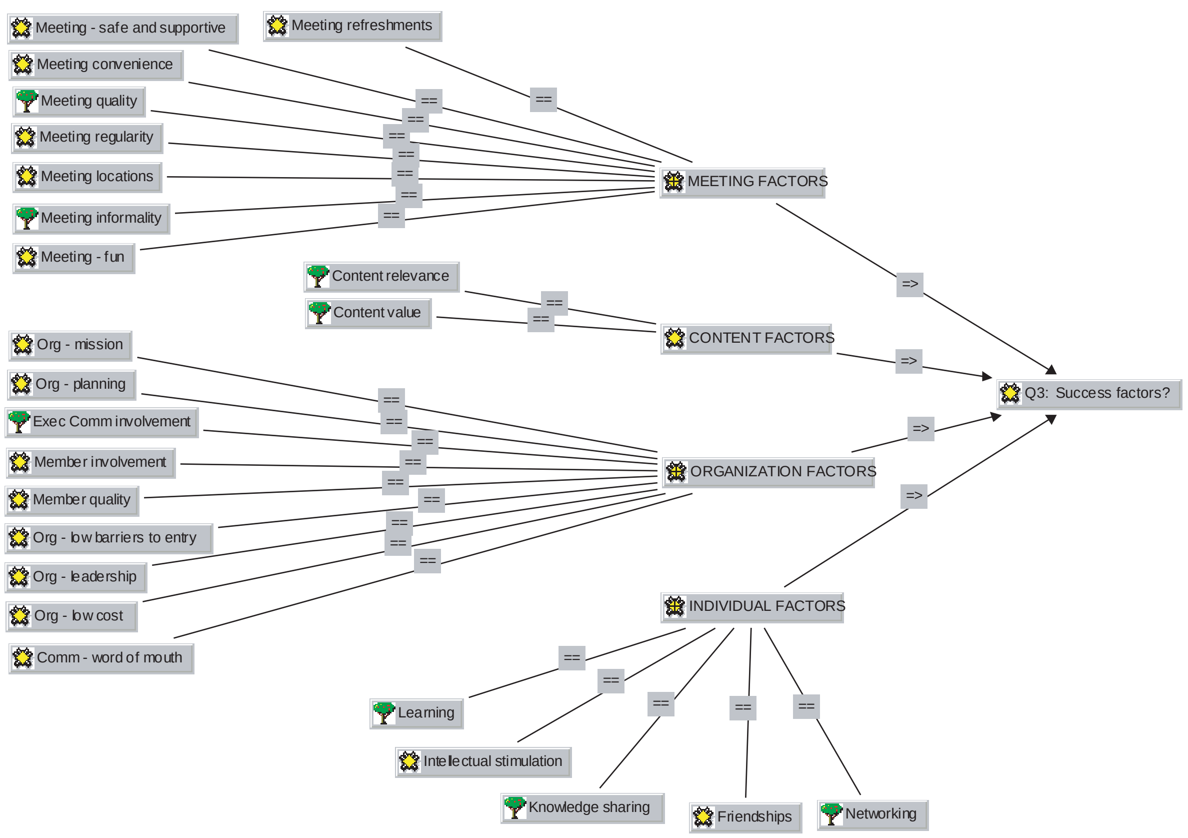
One of the key objectives of this study was to determine why the organization is still around after five years and in this sense is a "success." The critical success factors range from personal motivators to structural ones. For example, one member commented on the community aspects of the group:

"[It is successful] primarily because it ... meets the needs of participants as a "community." From a "community" perspective, it enables participants to be fully networked (CoP) with others in the same area, share experiences with others in like businesses or even just geographically co-located, or to participate as "interested parties" (CoI) or onlookers, feeling free to participate as interest and time permits. The personal touch, however, is [the] key to this organization's success." (P6)

Another member identified several positive aspects of the organization:

"Here are several factors I think are the main reasons KMG still exists after all this time ... Above all, KMG is focused on building on and extending learning around the broad topic of KM. ... the focus of the learning has first and foremost

Figure 3. Factors related to – Why is the organization successful?



been from a practitioner's viewpoint (e.g., practical things I can do tomorrow). This has kept the sessions very grounded. … A handful of people have continued to step forward to make sure the session topics reflected the interests and needs of those who were interested in attending KMG sessions. … With an emerging professional group, there is a need for affiliation. This plays out in many ways, such as just finding like minds; looking for jobs/projects so one can actually do KM and get paid … KMG has evolved because of an awareness and sensitivity to what is taking place in the field. Thus, topics have been timely and current … contributing to the value participants receive from attending meetings. No fees. No "official" membership. No administrative bureaucracy. Simply topics offered on certain dates and some minimal support infrastructure (Web site, YahooGroups). Essentially, nothing to interfere with the learning itself. …" (P5)

Still another person said:

"The group provides a safe environment for people to share ideas, no matter how controversial they are. People in the group have shared experiences and a history of sharing … and networks and friendships have formed between the members. … The topics are valuable and timely [and] focus on KM practices. The group consistently exceeds expectations of members. … I learn a lot of stuff that is immediately applied to my current situation. It makes me think. … It's fun … It's free. The EC has worked hard to make it a lasting program. Events are well planned and professional …" (P1)

The results of the content analysis show that several factors are responsible for the organization's success, according to the respondents. These findings have been grouped into four categories, based on an extension of the earlier categorization: Individual Factors, Content Factors, Meeting Factors and Organizational Factors. Organizational-level factors include leadership, EC involvement, barriers to entry, planning and member quality, among others. Figure 3 identifies the key variables in each category and illustrates the relationships among the variables.

DISCUSSION AND INTERPRETATION OF FINDINGS

The results of the interviews, the documents analysis, the content analysis and the surveys are synthesized into this case report and the findings are grouped according to the life cycle phases. Support is found for many of the research propositions appearing in Table 1.

Formation

This study has shown that a CoP can form around an idea or practice, in this case knowledge management. The initiating factor in this case was a presentation on the topic by a sponsoring organization. The costs to sponsor were low (e.g., less than a few hundred dollars). Based on the initial meeting, a subset of people from the group agreed to meet to explore the possibility of meeting again in the future on a periodic basis. The drivers for this new organization were to promote networking, learning and knowledge sharing. E-mail was the primary communication mechanism for the new group.

While the stated aims of the organization were to promote learning and networking, the community evolved in an organic way; that is, its features unfolded over time. In several ways, a CoP is a good example of a self-organizing system (Contractor, 1999; Houston 1999; Lorange, 1987). Self-organizing systems develop patterns out of a state of disorganization (Contractor, 1999), which aptly describes a CoP in its early stages. Its functions and structures develop over time in response to the environment, the available resources, and the goals and objectives of the members.

There are parallels here with new venture formation in the field of entrepreneurship and organizational life cycles (e.g., Cameron & Whetten, 1981; Quinn & Cameron, 1983). Like any start up, CoPs improvise procedures and policies until routines form (e.g., Nelson & Winter, 1982). In new venture organizations, structures are simple, there is little planning and control, and the primary focus is on turning ideas into reality (Dodge & Robbins, 1992; Flynn & Forman, 2001). CoPs share these same characteristics at this stage of development.

Survival and Early Growth

Following its inception, the KM group survived for a variety of reasons. The case study identifies several drivers, including organizational, individual, meeting, and content-related factors (see Figure 3). One of the key success factors in the organization category was having a clear sense of mission. In this case, the organization knew what it would focus on; for example, sharing KM practices and theory and promoting networking. Another key factor was the emergence of organizational champions who brought energy, drive and leadership to the group. They also brought assets in the form of social capital and access to resources. Without the extensive social networks of some key figures, the organization would not have had the connections necessary to grow and make it out of the formation stage. Furthermore, based on their positions within their respective organizations, these champions were able to get their organizations to commit modest resources in support of the meetings; that is, by providing food and space. Finally, the organizational champions brought sufficient knowledge of the domain of interest to foster a rich and creative intellectual environment. Several core members of the organization volunteered to make presentations until a network of "topic providers" was created. This collective knowledge base was certainly a critical success factor for the organization. Other factors in this category included event communication and planning, member participation and the low costs of membership (i.e., no costs and no dues).

In the second and third categories are grouped meeting and content-related factors. During the first year and beyond, significant time and effort was devoted to making the meetings relevant and convenient to attend. Topics were carefully selected by the core members prior to their announcement. The location of meetings was varied between the suburbs and the city to encourage diverse attendance. The general quality and consistency of the meetings was important to the group's early survival. The content was generally viewed as practical, relevant and value adding by the membership. Since this was the primary "product" offered by the CoP, we are not surprised by this result. Finally, there was a conscious desire to make the meetings informal and fun. This is consistent with research on the associations found between play and learning in work environments (e.g., Webster & Martocchio, 1992, 1993).

Finally, several individual factors were viewed as helping the organization survive and grow. One of the most important ones was intellectual stimulation. This finding is consistent with what may be viewed as a defining feature of a CoP; namely, the provision of an environment that allows for knowledge sharing and sense making. Making sense of the often conflicting theories and practices associated with KM is best done in a group where meaning can be tested, negotiated and refined. While such behavior is associated with and encouraged in universities, the reverse is true in most corporate environments. In the latter, there is a regression to the mean, strong pressure put on conformity, and usually little time to question corporate goals and objectives. While the learning organization (Argyris & Schon, 1978; Berends, 2003; Senge, 2003; Vera, 2004) is an ideal for many organizations, in practice, learning based on paradigmatic change is usually discouraged in favor of "getting the job done" or "fulfilling the client's needs." In contrast, a CoP offers an opportunity (albeit for a brief interlude) to question assumptions, refine ideas and sharpen vocabulary; that is, to learn. This finding is interpreted as another reason why CoPs have emerged as a functionally useful social form.

Late Growth and Maturity

Once the organization survived its first year of operation, several factors helped to ensure that it would continue to do so in the future. During the first year and beyond, the organization evolved key structures and processes to help it to grow. The most critical structure set up was the EC. This group was responsible for guiding the growth and development of the organization. Among the duties of the EC were planning, topic selection, finding host sites, review and evaluation, and setting policy and procedures. Several reasons cited for joining the EC include increased opportunities to learn, professional recognition, professional development, the opportunity for individual leadership, creative satisfaction and to make a contribution (see Figure 2). Also important was the "fun" atmosphere and friendships that developed. These factors served as potent motivators for the EC members as they took care of the numerous duties required to keep the organization functioning. Another closely related outcome among the EC members was the creation and adoption of roles in response to the evolving needs of the organization (see Table 4). This finding is consistent with what typically takes place in groups, usually in the context of formal organizations. Finally, the group established rules for admission to the EC, which were posted on the Web. For example, attendance and hosting requirements were set up for EC members. These criteria helped distinguish between those who were really committed to the organization and those who were not. For instance, some early EC members did not show up frequently to meetings nor did they significantly contribute to the welfare of the community. By publicizing the requirements, expectations for assigned tasks and roles were clear.

Another important factor that helped the organization grow and develop was the formation of routines. These included scheduling the meeting the same time each month (i.e., second Wednesday), holding it for the same duration (i.e., 7:45-9:45 a.m.), providing a similar structure to the meeting (e.g., first half hour devoted to networking, followed by announcements, the presentation and closing). EC meetings were also scheduled on the Friday immediately following the membership meeting to conduct after-action reviews and to plan future meetings. Meeting notices were sent out at approximately the same time each month. Taken together, these routines created a sense of security and permanence for the membership, despite the essentially virtual aspects of the community. In reality, the community had no physical assets, no financial resources, no space to convene, no offices and no paid human resources. It created its own reality through the use of e-mail, a Web site, virtual group workspaces, monthly meetings and its own routines and structures.

Although threaded discussions and other online activities were supported and encouraged by the community, for the most part, information technologies played a supportive but not dominant role in the organization's development. Information technologies served to coordinate the back-end activities in support of the human aspects of the experience; that is, the meetings where sense making and learning could occur. That being said, it is unlikely that the community could have continued to exist without e-mail and Web access to facilitate the planning, communication and coordination of meetings.

No organization continues to function unless it serves its members. The obvious benefits to members included learning about new topics and

KM practices, networking and opportunities for self-marketing. However, there were important implicit benefits. For example, the ideas of KM suffer from ambiguity. Members found the organization a "safe" place to test and share ideas, like one gets in a university classroom. In this sense, the organization provided an emotionally supportive environment for its members. Recognition was also built into the culture of this community. Iverson and McPhee (2002) observe that "Cultivation of knowledge can occur through three communicative actions: celebration, articulation and collaboration. The general point of celebration is to recognize knowledge accomplishments and problems solved …" (p. 3). It was not uncommon for members to receive public recognition at general and executive meetings. This produced the dual benefit of providing psychological reward for those doing the work and encouraging others to do the same.

Finally, there was a conscious effort on the part of the leadership of the community to choose the ways in which it would grow. Often times, organizations perceive growth as a "good thing" and simplistically make choices without regard to the consequences; not so with this CoP. For instance, while membership growth was an important consideration, the community did not want to grow without limits. Monthly meeting size was unofficially capped at 50 people. Holding larger meetings was problematic — it put a strain in the resources of the sponsoring organization and led to discussions of fees. Paying for space would have necessitated the creation of a dues structure for the community, which would have brought a whole set of administrative tasks, such as managing payments, invoicing, accounting, liability and so forth. The community chose not to incur these costs. Larger meetings also tend to become more formal and impersonal; the organization wanted to avoid this outcome. Another conscious decision of the community leadership was to limit commercialization. For instance, members were asked to refrain from making commercials at meetings (e.g., "buy my goods or services"). In addition, the EC decided not to sell its mailing list to any third parties, despite several requests from various organizations. In summary, this community chose how it wanted to grow in order to preserve an informal, yet rich, learning and sense-making context.

Decline or Renewal?

As of this writing, the CoP examined in this study is healthy and active. The members experience high satisfaction with the organization, and more than 93% of the respondents to the membership survey think the organization will continue for another five years. The question is: will it? Will it be able to adapt to changing conditions? The most dramatic change would occur if the theory and practice of KM simply diminishes in value and goes away. What would the community do then? Would it continue to meet as an affinity group based on member ties or would it organize around another practice issue and body of knowledge? Formal organizations often decline because they become rigid and inflexible. They are unable to adapt to changing conditions and are weighed down by extensive rules, policies, bureaucratic structures and cultures that are state maintaining. CoPs may suffer these same consequences, but further research is necessary to determine how and if this takes place. Perhaps what occurs with CoPs is not the result of over-structuring but increasing entropy and decreases in energy; that is, a CoP ceases to exist due to lack of member interest, loss of focus or insufficient resources.

Limitations and Next Steps

There are limitations to this study. First, this work represents a view of one organization over a five-year time period. Care must be taken in generalizing these findings to other organizational forms claiming to be CoPs. Second, since this work was exploratory in nature, the strengths of the associations found among elements were not measured. The next logical step is to replicate the results in other settings and to drill down into greater detail. Others are encouraged to test the propositions provided in this work and to use empirical methods that include hypothesis testing. One area for further research is to examine the strength of the interactions that bind the members. Weak ties suggest more of a network of practice (NoP), while strong ties suggest more of a CoP (Brown & Duguid, 2001). Further study using social network analysis would resolve the fuzziness around the issue.

To the practice minded, one of the findings of this study is that CoPs are relatively easy to set up and can be fostered with limited financial resources. The challenge is to find people willing to commit the time necessary to keep it going. On the other hand, CoPs can potentially reap big rewards, especially for corporations looking for ways to preserve and grow organizational knowledge. This study hopefully provides some practical insights about how to grow and sustain a community of practice over time.

SUMMARY AND CONCLUSION

This research has explored the formation, survival and growth of a CoP devoted to KM. Several factors that have contributed to the success of the organization over its lifetime have been identified. Future research needs to be done across several CoPs to verify these findings. Others are encouraged to frame and test hypotheses related to the strength of the associations identified in this work and to examine the life cycles of other CoPs. In closing, all organizational forms grow and contract and change over time. CoPs are no different in this regard. Rather than viewed as static and given, CoPs unfold in both expected and unexpected ways, just like formal organizations do. Just like people.

ACKNOWLEDGMENTS

Thanks go to the following individuals for giving their time freely in support of this research study: John Barrett, Jordan Corn, Marianne Gruber, Paul Hilt, Andrea Hornett, Dee Anne Kotzur-Cerruti and Mary Ellen Myers.

Thanks is also given to the general membership of the case organization for its contribution to the study.

Chapter 4.30
Knowledge Extraction and Sharing in External Communities of Practice

Reda Alhajj
University of Calgary, Canada

INTRODUCTION AND BACKGROUND

Communities of practice (CoPs) may be described as groups whose members regularly engage in sharing and learning, based on common interests (Lesser & Storck, 2001). Traditional communities of practice exist within organizations and are centered on work functions. These CoPs may be self-organizing or corporately sponsored. They exist to encourage learning and interaction, create new knowledge, and identify and share best practices for the organization's processes (Wenger, 1998). The members of a community of practice may be collocated (within an office) or spatially dispersed (e.g., a group may interact via electronic chat). There may also be communities of practice that are not centered on work functions. For example, several online groups exist for enthusiasts of new technology, politics, environment, and so forth. These groups qualify as bona fide CoPs. We classify the CoPs discussed so far as active communities of practice because the members actively seek to learn and share from each other. In this work, however, we examine passive communities of practice in which the members do not actively interact with each other. This class of CoPs shares the core characteristics of traditional communities of practice—the members can learn from each other, and the organization can gain useful knowledge capital and best practices. Our discussions will be based on user communities using cable-TV viewers as a case in point. In contrast to work-centered CoPs whose members share knowledge and learn how to perform their work tasks better, members of user-centered CoPs learn how to maximize the utility from the product/service of interest. In both cases, a learning organization can extract useful knowledge capital and best practices to improve its processes and products/services. In this work, we use the case of cable-TV viewers to show how useful knowledge can be learned and shared in passive user-centered communities of practice. Our techniques will be based on data mining and knowledge discovery, which are introduced in the subsection that follows.

DATA MINING AND NAVIGATIONAL PATTERN DISCOVERY

The widespread use of computers and the increased abilities to collect and store massive amounts of data have led to phenomenal growth in the popularity and use of data mining techniques. Data mining is the analysis of data with the goal of uncovering hidden patterns. Historically, technological advances that improve the collection of data have led to new domains for data mining. For example, advances in bar code technology and the ability to collect and store transaction data logs led to the growth of association rule mining (Agrawal, Inielinski & Swami, 1993) and its many variants (Fayyad, 1998). More recently, the widespread use of the World Wide Web and the ability to collect and store Web logs of user sessions have driven research interest in Web usage mining (Cooley, Mobasher & Srivatava, 1997; Srivastava et al., 2000). An interesting problem in Web usage mining that has attracted the attention of several researchers is the discovery of traversal patterns of Web users (Chen, Park & Yu, 1998; Nanopoulos & Manolopoulos, 2000). Mining path traversal patterns involves identifying how users access information of interest to them and travel from one object to another using the navigational facilities provided. Tracking user-browsing habits provides useful information for service providers and businesses, and ultimately should help to improve the effectiveness of the service provided. Previous works on identifying path-traversal patterns have been directed at traversals between relatively static objects (e.g., Web pages). By static, we mean information that can be regenerated by the user as required. Thus, dynamic Web pages fall under our definition of static objects because the user may regenerate the dynamic Web pages on each visit.

In this research, our focus is on navigational patterns in environments where the objects are continuously changing in time (i.e., streaming content). An example of such a system is cable-TV where the program sequence is continuously changing. The viewers of cable-TV are able to navigate from one object (channel/station) to another. However, if viewers navigate away from a station/channel and later return to that channel, the content displayed may have changed. Thus, there is a strong temporal component in the systems studied in this research. The temporal component in our framework motivates new techniques to capture navigational patterns, as existing techniques in the literature do not take temporal semantic information into consideration. Our framework can be applied to identifying navigational patterns in any environment with streaming content. However, the discussions in this article will be motivated by cable-TV viewing patterns. The choice of cable-TV viewing patterns is due to recent technological innovations that enable the collection of anonymous logs of viewing data through digital video recorders attached to cable-TV receivers. The logs are kept anonymous to protect the privacy of the viewers. This is similar to the ethical standards that have long been adopted in analyzing Web and transaction logs. In the past, there has been very limited ways to collect data on the viewing patterns of cable subscribers. The advent of digital video recorders and the ability to track and report logs on the channels viewed by subscribers (on a second-by-second basis) opens up several interesting areas for data mining. Digital video recorders are growing in popularity (with Tivo Inc. reporting over 700,000 subscribers in the US in 2003 and a projection of over a million subscribers by the year-end), and a massive deployment is expected in the near future (Tivo Inc., 2003). Digital video recorders keep track of the channels viewed through the cable receiver. The view logs are uploaded to the service provider daily. The challenge is to extract interesting patterns from all the view logs submitted to the service provider.

There are several interesting questions that can be addressed by analyzing the view logs. For example, an advertiser may be interested in knowing if more viewers stay tuned during the commercial breaks of prime-time programs than for regular programming. It may also be of interest to know the advertising slot that is most effective; that is, is it more likely for an advert to be viewed if it is the first ad during the commercial break or if it has the last slot, middle slot, and so on. It may also be interesting to discover the percentage of viewers that return to a program once they tune off during a commercial break. Several other interesting patterns may also be discovered. In our framework, we propose a novel technique that categorizes the dynamic content of sites into distinct event sequences and then explores the navigational patterns of users relative to the distinct event sequences. The behavioral/navigational patterns discovered may be used to improve the program sequencing for future broadcasts. The analysis may also be given a spatiotemporal dimension so that appropriate programming is directed at users based on their locations and times of broadcast. Viewers may be grouped or profiled based on common navigational behavior. In interactive TV environments, this would enable personalized programming and program recommendations tailored to particular viewer groups or individual viewers.

RELATED WORK

Several authors have studied communities of practice (CoPs) in organizations (Brown & Duguid, 1991; Hildreth, Kimble & Wright, 2000; Lesser & Prusak, 1999; Lesser & Storck, 2001; Wenger, 1998; Wenger & Snyder, 2000). These works are centered on work-related CoPs and differ from user-centered CoPs discussed in this article.

There are strong similarities between the behavioral pattern discovery techniques discussed in this work and Web usage mining. Web usage mining is the application of data mining techniques to discover usage patterns from Web data (Srivastava et al., 2000). The objects in our framework (e.g., channels) may be viewed as Web pages. Also, a viewer can jump to any object/channel just like a Web user may navigate to any URL. However, mining, viewing patterns in our framework, has a stricter temporal component. It is not sufficient to know the order in which the objects are viewed. There is a need to know the information content of the objects at the periods the viewer navigates to, or away from, the object. The work by Yang, Wang, and Zhang (2002) proposes an event prediction algorithm for Web usage mining. Their approach is aimed at predicting when Web accesses would occur. This is an extension of earlier works that only identify the order in which Web accesses would occur. The problem they address is different from the problem addressed in this article since we are interested in the information content of the objects at the times they are visited. Furthermore, the objects we study have streaming information content. Several other researchers have proposed techniques for identifying frequent path traversal patterns (Chen et al., 1998; Borges & Levene, 2000; Heer & Chi, 2002; Nanopoulos & Manolopoulos, 2000; Pei et al., 2000). However, these approaches do not incorporate the temporal semantics we introduce in our framework. Tivo Inc. (2003) has developed audience measurement tools that are able to report viewing statistics. However, their tools (just like tools for measuring Web hits) do not explore navigational patterns of users.

FRAMEWORK

The general framework of the class of information systems covered in our work consists of independent sites with links connecting all sites. Unlike Web pages that are grouped together into Web sites with internal navigational ordering, our framework is made up of stand-alone sites that are interlinked to each other. Using our example of a cable-TV system, each channel/station represents a site in our framework. A viewer is able to navigate from one channel to another either by following the ordering of the cable channels or by specifying the desired channel.

We define a user session as the complete set of activities by a user from the time the system is entered until departure. In our example, a user session starts when the user turns on the cable-TV and ends when the system is switched off. The system consists of sites with streaming content that can be divided up into categorical episodes. An episode is an event sequence that makes sense in its domain of application. In our example, we may identify three broad categories for the episodes: programming, commercials, and shutdown. The programming category can be further divided into specific types of programs (e.g., movies, sitcom, sports, news, etc.), and the commercials can be further divided into slots (i.e., first commercial slot, second, etc.). The categories may be abstracted further so that individual programs and commercials are identified. The choice of abstraction is determined by the data-mining analyst.

The information displayed by each site in the system can be broken into event sequences that fall into one of the episode categories defined. Thus, for each site, its streaming content (for 24 hours a day) can be categorized into definite episodes with the associated start and end times for each episode. Further, for each user of the system, the viewing patterns must be categorized for every user session during a given day.

IDENTIFYING NAVIGATIONAL PATTERNS

The first step in our framework is data preprocessing. The content/program information for each of the sites has to be preprocessed into a format suitable for mining. Similarly, the user logs have to be preprocessed. Each user session is counted independently; that is, one subscriber may have multiple user sessions in a day, and each of the sessions would be independently considered in the framework. For example, given that time is represented in the 24-hour format, hh:mm:ss, and that the numbers 4 to 62 represent channels/stations available to the user, a typical user log would specify the channels/stations the user viewed from the start of a session to its end. Table 1 gives an example of a typical user log for one subscriber for a given day.

The logs record the viewing activity for each second of the day. The broken lines in Table 1 represent periods when there is no change in the channel viewed. From Table 1, we can identify two user sessions: the first starting at 12:15:00 and ending at 13:30:00, while the second session starts at 18:05:05 and ends at 18:30:00. Preprocessing the user log involves identifying all the user sessions and breaking each session into time brackets for the channels/stations viewed. The result of preprocessing the user log in Table 1 is shown below:

User session 1:
    Channel 10: 12:15:00 - 13:05:15
    Channel 32: 13:05:16 - 13:30:00
User session 2:
    Channel 31: 18:05:05 - 18:30:00

Table 1. An example of a user log

Time of Day	Channel Viewed
00:00:00	-
00:00:01	-
12:15:00	10
13:05:15	10
13:05:16	32
13:30:00	32
13:30:01	-
18:05:05	31
18:30:00	31
18:30:01	-
23:59:59	-

Table 2. A partial listing of a sample program categorization for a channel/site

Program	Time Slot
N1	12:00:00 – 12:15:00
C1	12:15:01 – 12:17:00
C2	12:17:01 – 12:18:00
C3	12:18:01 – 12:20:00
N1	12:20:01 – 12:35:00
S1	12:35:01 – 12:55:00
C1	12:55:01 – 12:57:00
C2	12:57:01 – 12:58:00
C3	12:58:01 – 13:00:00
S1	13:00:01 – 13: 30:00
CO	13: 30:01 – 13: 33:00

The program content for each site (channel/station) in the system is also preprocessed. The analyst specifies categories for each program. For example, given that a station airs its programs between 08:00:00 and 18:30:00 and, also, given the complete program schedule of the station. If the categories specified are as follows: N—news; S—sitcom; C—commercials; and M—movies, a program episode can be represented by its category and an identifier. For example, the first news episode can be represented as N1, the second N2, and so on. Similarly, the first sitcom may be represented as S1 and the second S2, and so forth. The identifiers are necessary if it is of interest to keep track of complete program episodes since a program episode may be interleaved with another episode (e.g., several commercial episodes may interleave a program episode). It may also be of interest to separate the program content into slots. (For example, the first commercial in a commercial break takes slot one—C1, the next commercial takes slot two—C2, and so forth. Commercials that are not embedded within other programs may also be separated into a category, e.g., CO in Table 2.) Further, the analyst may choose to capture different segments of a program into separate categories. For example, it may be interesting to differentiate how users respond to the first segment of a program from how they respond to other segments, especially if they did not view the earlier segments. The salient point here is that categories may be defined for every program grouping of interest. Finally, the preprocessed program content for our example will be in a format similar to the one shown in Table 2. If the channel (or site) preprocessed in Table 2 is Channel 10 (from Table 1), then it is easy to extract the categories viewed during user session 1 (from Table 1).

Once the usage logs have been transformed into user sessions and the program schedules have been transformed into event categories, data mining procedures may then be performed on the processed data. The mining problem addressed in this work is formulated as follows:

- How do the users of the system navigate between sites in response to the contents displayed by the sites?

Details of the proposed techniques for discovering these behavioral and navigational patterns are discussed in the next section.

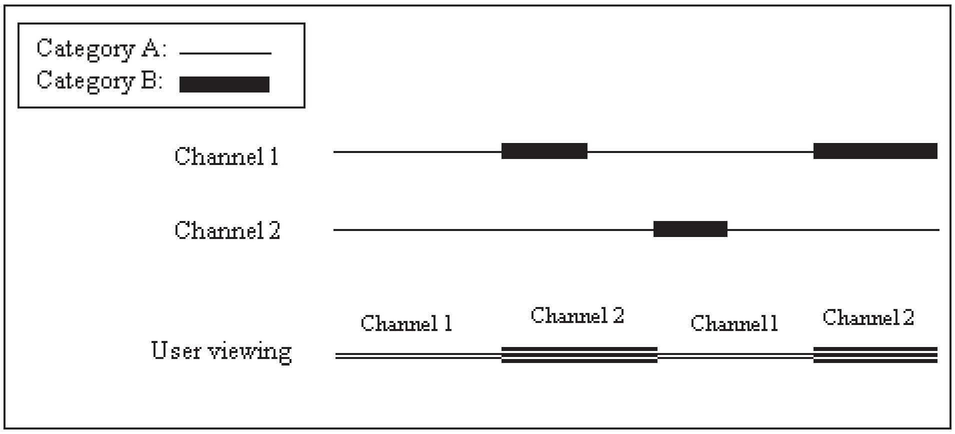
DISCOVERING EVENT-RELATED NAVIGATIONAL PATTERNS

This section examines the problem of identifying frequent navigational patterns of users relative to specific event categories (or collections of categories). For example, it may be of interest to know if viewers navigate away from a channel/station immediately after a news event begins, if they stay briefly before changing sites, or if they stay through the news event. It may also be of interest to discover if viewers navigate away at the commencement of a commercial break and whether they return to the same program once they navigate away. Figure 1 shows an example user navigation between two sites (channels). From Figure 1, it is easy to see that the user navigates away from program content that belongs to Category B, irrespective of the site/channel viewed. The data mining problem here is thus to determine all behavioral navigation patterns relative to program content that are frequently exhibited by various users of the system. Given that the user logs and program schedules (content) have been preprocessed into user sessions and categories, respectively, the next step in the framework is to define the behavioral predicates that would capture the users' navigational patterns in response to dynamic content categories.

The behavioral predicates chosen may include the following:

- Navigate away
- Stay through
- Stay briefly
- Return to the same program content (i.e., after navigating away)

Figure 1. An example of user navigation relative to event categories



The set of behavioral predicates considered in the framework depends on the interests of the analyst. Further, the quantitative time units attached to some of the predicates (e.g., the definition of briefly) are set by the analyst. Given a threshold confidence (e.g., 0.75), it is then possible to discover rules of the form: users of the system navigate away from program content in category B with x confidence (where x is a user defined threshold). It is also possible to capture navigational patterns of users in response to new program content in relation to the previous content they were viewing. An example of such a rule is: users of the system navigate away from content in category B given that they were previously viewing content in category C with x confidence (where x is a user defined threshold). The details of the data mining process are given in the paragraphs that follow.

Recall that all the user logs are preprocessed into independent user sessions. Each user session details the channels viewed and the viewing times. By examining each user session against the program categories airing at the sites/channels viewed, it is possible to extract the program categories viewed during each user session and the behavioral navigational patterns of the user during the session examined. Given that X is the set of categories over which a rule R is defined, then the set of active user sessions with respect to rule R, A, is made up of user sessions with events in each of the categories in X. For example, given the rule: users of the system navigate away from content in category B given that they were previously viewing content in category C with x confidence (where x is a user defined threshold), only user sessions with content in both categories B and C are active with respect to this rule (i.e., X = {B, C}). The confidence of a rule is calculated as the ratio of the support count of user sessions that satisfy the rule to the number of active user sessions with respect to that rule. The contribution of a user session to the support count of a rule is weighted and may range from 0 to 1. For example, if a user session encounters three instances of program content in category B and if in two of the three instances the user navigated away from the program content, then the contribution of this user session to the rule: users of the system navigate away from program content in category B with x confidence (where x is a user defined threshold) will be 0.67 (i.e., 2/3). The support count for the rule is then obtained by summing the support contributions of each user session for that rule. The outline of the algorithm is presented below.

INPUT:

- A set U of user sessions (obtained from preprocessing all the user logs)
- A set P of categorized program schedules for all the sites in the system
- A set B of behavioral predicates of interest
- An empty set R of all rules defined on the categories in P

OUTPUT:

Set of rules with associated confidence levels

PROCESSING:

FOR all $u \in U$ DO
Associate u with content categories by comparing its contents with relevant elements of P
Identify the rule set present in u with respect to B. If any rule found in u is not in R, add the rule to R.
Increment the count of active user sessions or all rules on program categories found in u.

FOR all rules $r \in R$ on categories found

in u DO
Calculate the support contribution of u to r
Add the support contribution to the total support for rule r
END FOR
END FOR

FOR all r∈R DO
Confidence of r = total support of r / number of active user sessions for r
END FOR

Given that U is the number of user sessions identified in he logs and is the average number of rules defined on program categories in the user sessions, then the algorithm has a time compexity of O(U). However, << U, thus the algorithm runs in O(U) time. (Note that rules are associated to user sessions if the behavioral predicates in the rule are present in the user session. This is analogous to constrained rule discovery using meta-rules.) The knowledge capital gained from the discovered patterns can be used by cable-TV companies and advertisers to improve their processes and produce better programming and scheduling. In interactive TV environments, the patterns can also be used to personalize programming and advertisements for individual viewers or viewer communities. The patterns may also be used to recommend programs of stations to viewers; thus individual viewers benefit from the collective knowledge of the viewing community.

CONCLUSION AND FUTURE TRENDS

This article abstracts external user communities as passive, user-centered communities of practice. Using a case of cable-TV viewers, we show that valuable knowledge capital can be learned from user-centered CoPs. The learned knowledge can be used to improve an organizations products and services and can also be filtered back to the user community to improve the overall user experience.

To achieve the learning of behavioral patterns from users, this article motivates a new domain for data mining that involves discovering user navigational patterns in information systems that disseminate dynamically changing (or streaming) content. The approach proposed in this work can be extended in several ways. For example, it may be of interest to separate ad-hoc and non-ad-hoc user sessions (i.e., some viewers may target certain programs while others may not). It may also be of interest to study the navigational behavior of users relative to the time of day the viewing occurred or navigational patterns relative to outlying content (e.g., a movie aired in a music channel). Several other extensions to the framework are also possible.

Chapter 4.31
Task-Based Knowledge Management

Frada Burstein
Monash University, Australia

Henry Linger
Monash University, Australia

INTRODUCTION

In modern organizations, the major role of knowledge management is supporting knowledge work. The concept of knowledge work assumes not only task performance, but also the review and evaluation of the work done in order to understand and learn from the experience. Knowledge work relies on a body of knowledge to support processes that address both the performance of work and the intellective aspects of the work activity (Zuboff, 1988). In this sense knowledge management becomes one of the most important mechanisms in implementing such support. In this article we present task-based knowledge management (TbKM) as an alternative approach to knowledge management (KM).

BACKGROUND

Most KM approaches focus on organizational knowledge and/or organizational processes and their management (e.g., Davenport & Prusak, 1998; Tiwana, 2000; Awad & Ghaziri, 2003). The TbKM approach addresses the management of knowledge work rather than knowledge. It is a bottom-up approach that focuses on the practicalities of work activities, as performed by individuals and groups. Thus TbKM is directed to supporting both:

- task performance to achieve organizationally defined outcomes; and
- work practices of actors including the generation and collection of experiential knowledge associated with task performance, as well as

single- and double-loop learning (Argyris & Schön, 1978).

The focus of TbKM is not directed towards automating any work practice. Task-oriented methods for knowledge-based systems were proposed in artificial intelligence projects to automate problem solving and reasoning by representing knowledge in a computable form (Chandrasekaran & Johnson, 1993). These approaches relied on capturing all organizational knowledge related to the task and creating a formally defined knowledge repository (Schreiber, Welinger & Breuker, 1993).

The TbKM approach provides an infrastructure for knowledge work where knowledge is a by-product of task performance. This infrastructure allows the knowledge worker to document the task instances in a way that is shareable with other actors performing that task. Thus TbKM is essentially an implementation of a knowledge work support system (KWSS) that systemically preserves knowledge of each instance of the task in a dynamic memory system. In order to support knowledge work, this memory includes the pragmatic outcomes as well as the knowledge created through task performance. Effective utilisation of this memory is facilitated by TbKM functionality such as reasoning, memory aids, explanation facilities, and learning capability. Moreover, the TbKM approach is consistent with reflective practice in that actors are encouraged to reuse and create knowledge through learning as an integral part of the task (Schön, 1991).

The task-based approach has been formalised as a theoretical framework that underpins our research. This approach has been used as an evolving framework analytically to diagnose research settings and determine the aspects of focus. Additionally, the framework has also been the core of the conceptual design for prototyping KM systems and KM development programs.

The task-based approach to knowledge management has evolved from a wide range of projects that have been undertaken and the practical requirements imposed by industry collaborators (Burstein & Linger, 2003, 2002; Linger & Burstein, 2001; Linger, Burstein, Zaslavsky & Crofts, 1999; Linger, Burstein, Ryan & Kelly, 2000; Fennessy & Burstein, 2000).

MAJOR ELEMENTS OF THE TASK-BASED APPROACH TO KNOWLEDGE MANAGEMENT

The TbKM approach focuses on knowledge work, not knowledge as the object of knowledge management. Thus the major elements of this approach are:

- a task focus
- a task-based model of knowledge work
- a community of practice
- an organizational memory
- task outcome
- knowledge work support

Task Focus

Underlying the TbKM approach is the focus on work practice. The approach aims to explore how the work is actually done, not how it is meant to be done or what individuals say they do. In this context, a task:

is a substantially invariant organizational activity with outcomes that include tangible outputs that are central to the organization's viability and the internal outcomes that are potential drivers of organizational change. (Burstein & Linger, 2003, p. 290)

In terms of this article, no distinction is made between an (organizational) activity and task, and the terms are used interchangeably unless indicated otherwise. Organizational activity, as used here, derives from Situated Activity Theory proposed by Iivari and Linger (1999, 2000) to characterize knowledge work. Such activity differs from the actions of individual actors, as the scope of the activity requires a number of actors for its completion.

For example, weather forecasting is organised around shifts that involve a number of forecasters. Each forecaster is given responsibility for particular forecast products, but each product needs to be consistent with the forecast policy that is set collectively by the shift. This example also highlights that such activity is socially situated in that all actors collectively engage in processes that enable them to gain a shared understanding of the activity. It is this understanding that enables each actor to intentionally complete their activity. Since the activity outcomes are organizationally determined, the actors' shared understanding of the activity also includes their understanding of the organizational imperatives that underlie the activity.

Task-Based Model of Knowledge Work

Task models produced for knowledge-based systems (KBS) development (see for example, Duursma, 1993) mapped the task into a generic task category (Chandrasekaran, Johnson & Smith, 1992). The intention was to generate a computational procedure based on Generic Task model represented as a hierarchical or tree model, including tasks, methods, and subtasks (Chandrasekaran & Johnson, 1993), that intended to mimic an expert's performance.

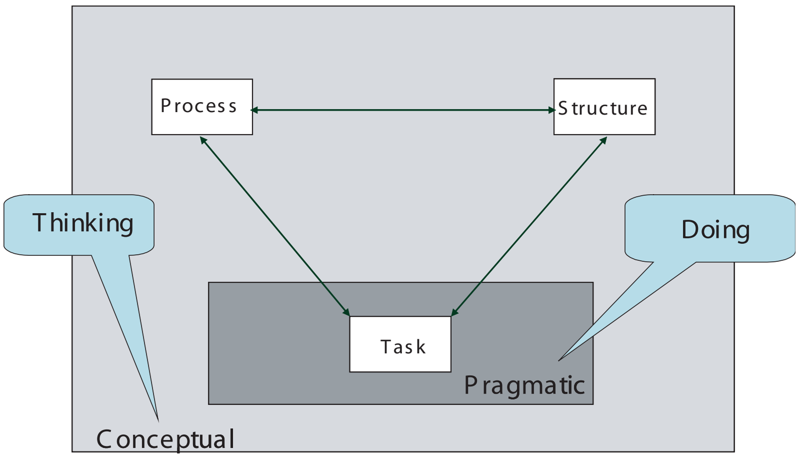
Such formal problem-solving methods are based on task structures that attempt to fully represent the problem-space and produce fully computable knowledge-level descriptions. For example, KADS and KADS-II European projects came up with a four-layered model of problem-domain knowledge (Schreiber et al., 1993). Although such knowledge-level descriptions made a major contribution in their analysis of task-oriented approaches to knowledge modelling, in many practical contexts the normative algorithms for solving real problems are "less useful than they seem" (Chandrasekaran & Johnson, 1993, p. 52).

The TbKM approach departs from the idea of generic representation of the task and its context. Organizational work, the task, is represented as two nested layers. The pragmatic represents actual work practice and the work that needs to be done. It is associated with the performance of the task, and is concerned with the efficient and effective execution of the task. The conceptual layer views the task from a more generalised, abstract perspective, expressed in terms of the overall goals and objectives of the task and related concepts and structures. The conceptual layer represents some aspects of the actors' understanding of the task in terms of models representing the structure of their knowledge and their knowledge of the process required to perform the task.

In a context of knowledge work, these layers correspond to doing (pragmatic) and thinking (conceptual) components of the activity as represented in Figure 1. From the point of view of knowledge management, we concentrate on the conceptual layer since the actors are knowledge workers who have the expertise to perform the task.

The model represents a generalisation of the task. We recognise two conceptual components associated with the task: a Structure and a Process. These two components come from the understanding of what concepts are involved in performing the task and how these concepts need to be applied. Task performance involves instantiating, and where necessary modifying, these generic components in a way that accommodates the current situation, and then executing the procedure. Reflection on and learning from task performance contributes to changes or improvements to the generic structure and process. In the context of knowledge work, specialising the structure and process, as well as reflecting on the instances of the task, is a fundamental feature of TbKM.

Figure 1. A task-based model of knowledge work (adapted from Linger & Burstein, 1997)



Each time a task is performed in a specific work context, the Structure and Process models are instantiated to reflect the specific work situation. Each instantiation then becomes a record of the task and cumulatively represents a task-based organizational memory (Ackerman & Mandel, 1995). The importance of this interpretation of the framework is that this memory is an essential part of the learning process. The historical evolution of these models is a representation of learning and a component of organizational memory (Spender, 1996).

A Community of Practice: CoP

Actors engaged in the task can be collectively termed a community, as they all have a professional interest in that work (Wenger, 1998; Brown & Duguid, 1991). In the TbKM approach, a community of practice is defined as a group of actors who are engaged directly in performing some aspects of the task. This conceptualisation of community is more restrictive than the commonly used definitions in the literature (e.g., Wenger, 1998). It is used deliberately to distinguish between members of the community and others who are potential stakeholders in the task or its outputs. However, actors are not restricted from participating in other communities within an organization through their engagement in other activities and tasks.

Restricting the community to actors engaged in task performance enables the community to establish and maintain the body of knowledge and shared meanings associated with the task. These are necessary elements to ensure the reliability and validity of each actor's contribution to the task. Moreover, each actor brings to the community contextual knowledge based on their other involvements within the organization. This enables computer-based knowledge management systems to be constructed as closed systems without the need for extensive contextual information to be included (Schatz, 1992).

Since the community is engaged in knowledge work, the actors have considerable autonomy in performing the task. However, as a community, working with other actors requires a degree of common understanding of the object of their work, the task, to ensure task outcomes meet organizational requirements. TbKM accommodates the idiosyncratic work practices of individual actors, but also provides the tools for the community to maintain its shared understanding of the task. Thus knowledge sharing is acknowledged as an integral part of work practices that still tolerates individual differences.

Organizational Memory

Each time the task is performed, it generates a collection of outcomes, related processes, and "stories" or narratives shared by the community (Czarniawska-Joerges, 1992). There is a potential of recording and preserving aspects of this experience in an organizational memory as instances and episodes of the task including the conceptual models that represent the individual and collective understanding of the task. As TbKM supports knowledge work, it needs to provide actors with the necessary tools to perform both the doing and thinking aspects of the task.

Instantiation of the whole range of tools to perform the task allows memory to be constructed as a by-product of task performance. Moreover, the more menial aspects of the task (doing) can be articulated and automated, the more time and space is left for the actor to be more involved with the tools for the intellective aspects of the task (thinking) without a punitive overhead. An example of this approach is in weather forecasting, where the forecast (and the rationale for the forecast) forms part of the memory that is used as input to future forecast preparation, as well as the basis for learning from past forecast performance.

Task Outcomes

Task performance must result in the organizationally defined outcomes that contribute to the organization's viability. In terms of TbKM, task performance also results in outcomes that relate the intellectual assets of the organization. These can be considered at two levels: individual and organizational. At the organizational level the outcomes contribute to the organizational productivity, through improved work practices, and knowledge assets in terms of contributions to organizational memory. Organizational outcomes also relate to effectiveness in terms of the organization's ability to deploy and exploit knowledge through knowledge sharing, reuse, and creation. At the individual level, task outcomes relate to the actor's ability to learn, use the knowledge assets productively, and contribute to and sustain the community of practice. TbKM is a heterogeneous approach in that it adopts a cognitive perspective when focussed on individual outcomes, but it has a social perspective when community or organizational aspects are in focus.

Knowledge Work Support System

We view technology as a very important enabler for knowledge management. This is consistent with the view expressed in mainstream KM research and practice (e.g., Alavi & Leidner, 2001; Davenport & Prusak, 2000). Task performance needs to be supported by a technological system that enables actors to produce tangible outputs. Much of IT development effort is directed to support the doing aspects of knowledge work. Less common is support for the thinking aspects. These support systems allow actors to engage in a joint cognitive process to evaluate, review, and reflect on task performance, as well as access and reuse past knowledge stored in memory. Memory can be deployed in processes that allow actors to understand and make sense of the task, as well as explore, innovate, and learn.

THE TBKM FRAMEWORK FOR ORGANIZATIONAL KNOWLEDGE MANAGEMENT

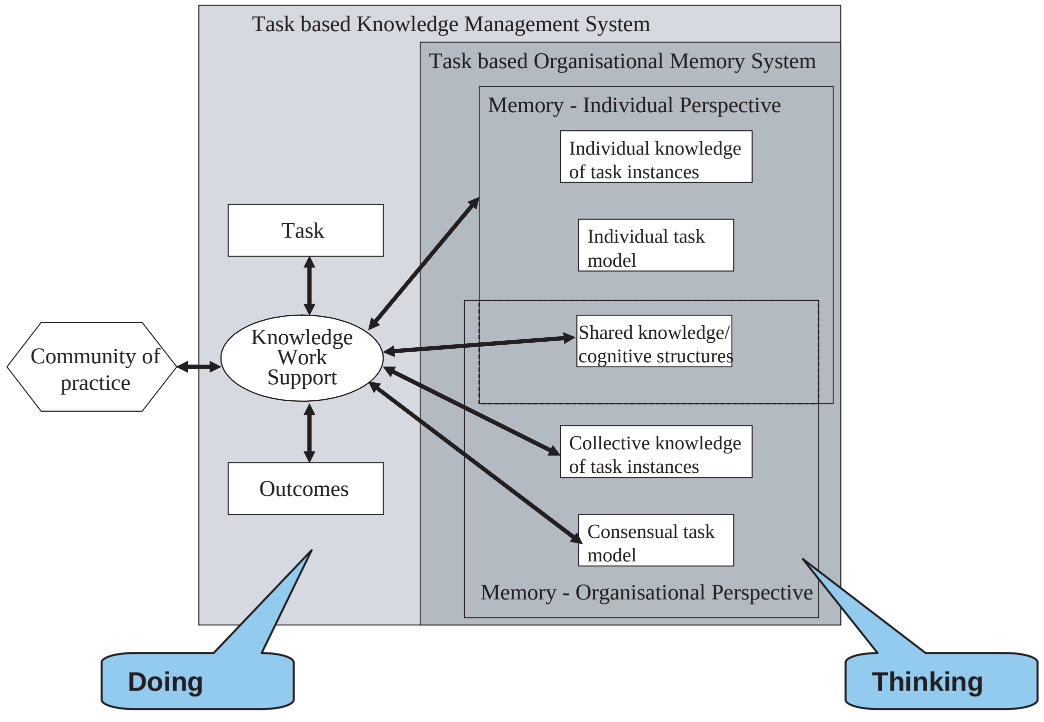
The TbKM approach to task performance is based on integrating production with knowledge processes. In this respect, technology, in the form of a knowledge work support system, mediates task performance by the community of practice. Figure 2 represents a TbKM system for organizational knowledge work.

In this framework the Knowledge Work Support (KWS) system is in the centre of two dimensions referred to as "doing" and "thinking" as in Figure 1. Thus in the vertical axis (Task, KWS, Outcomes) the KWS supports production, while in the horizontal axis (KWS, Memory) it supports knowledge processes.

The outcome of production is goods and/or delivery of services. By including the KWS system in the KMS, the task outcomes also potentially include improvement in the means of production of goods and delivery of services. Put differently, the functioning of the KWS system is concerned with organizational efficiency, its ability to supply market demands, as well as the organization's internal effectiveness including its ability to learn and create, share and reuse knowledge.

In the context of task-based KMS, the organizational memory system (OMS) needs to be a dynamic and multi-dimensional source of useful organizational knowledge. It needs to support

Figure 2. A model of a task-based knowledge management system (adopted from Burstein & Linger, 2003)



learning and other organizational knowledge processes, as well as accommodate individual perspectives. This contrasts with the more static view of OMS as a repository. We see it rather as an active component of an intelligent system supporting knowledge processes. The OMS contains the necessary information to perform the task, artefacts that express the actors' and CoP knowledge, and understanding of the task at the individual as well as collective and organizational levels. This material enables the OMS to support learning based on feedback, review, and evaluation. The diversity of the content of the OMS does not mandate any specific technology. In fact our approach is strengthened if different technologies are combined as it allows actors to express their understanding by constructing artefacts using inscriptions (Latour, 1990) that represent the task in a way that is consistent with the knowledge that underpins task performance.

FUTURE TRENDS

The TbKM framework explicitly supports knowledge work in the thinking and doing dimensions. Implicit in this formulation is the temporal dimension. The formulation of organizational memory in the thinking dimension allows the TbKM framework to represent temporal aspects of knowledge management in the form of past experiences. Moreover, this memory is a fundamental aspect of the thinking dimension and explicitly facilitates knowledge processes including double-loop learning (Argyris & Schön, 1978) to review work practices and for knowledge creation.

However, knowledge work is by definition a socially situated activity and implicitly assumes all actors, in the community defined by the task, interact and communicate. The challenge therefore is to explicitly extend the TbKM framework to incorporate another dimension—communicating. This would define knowledge management as existing within the three dimensions of thinking, doing, and communicating.

The TbKM framework currently assumes an organizational or enterprise context. This context is essential to situate the activities, the work practices, that are its focus. This bottom-up approach differentiates task-based knowledge management from the mainstream literature, but needs to be extended to explicitly incorporate the organizational perspective. To accommodate this perspective, we intend to extend the framework by adopting a three-level approach that deals with knowledge management at the micro, meso, and macro levels, as foreshadowed in Linger and Burstein (2001) and Linger and Warne (2001). The suggested approach accommodates the integration of organizational (macro), group (meso), and individual (micro) perspectives, as well as identifying capability (macro), collaboration (meso), and action (micro) as the discourse of these perspectives.

The TbKM framework as currently presented is grounded with the context of a specific organization. However, the imperative of the new (information or knowledge) economies requires consideration of inter-organizational as well as intra-organizational knowledge management strategies. This will require consideration of issues beyond work practices such as governance, collaborative arrangements, and the legal framework. In this context, the TbKM framework can be considered as a foundational structure for an inter-organizational knowledge management architecture.

CONCLUSION

The TbKM framework is general and applicable in any domain, as demonstrated by the diversity of the case studies we have undertaken (Linger et al., 1999; Linger et al., 2000; Fennessy & Burstein, 2000; Linger & Burstein, 2001; Linger

& Warne, 2001). Moreover, the generality of the framework is enhanced, as it does not prescribe any modelling formalism for any element of the framework. Rather, as the case studies illustrate, it is the task, and its underlying body of knowledge, that influences how elements are represented and modelled.

The framework provides a practical means for organizations to implement knowledge management regimes as it is applicable to any task that involves knowledge work. This flexibility derives from the fact that the framework is based on a theoretical understanding of knowledge work that allows TbKM to:

- add value to knowledge that the organization already has by explicitly recognising knowledge work;
- support actors performing the task, rather than automating it, in order to exploit knowledge processes;
- apply knowledge management on a scale that can be operationalised within a time scale that meets organizational imperatives;
- focus on knowledge creation and organizational learning rather than the self-limiting goal of organizational efficiency;
- produce outputs, in terms of products and services, while supporting the continuous improvements to these outputs and the means of their production;
- focus on work activities rather than modelling the organization; and
- integrate and support dynamic knowledge and production processes rather than view knowledge management in terms of a static knowledge repository.

In the literature there is a remarkable number of definitions of knowledge management, not least because of its currency and because of its perceived importance (Davenport & Prusak, 1998; Tiwana, 2000; Awad & Ghaziri, 2003). Our working definition is:

Knowledge management is a broad concept that addresses the full range of processes by which the organization deploys knowledge.

This definition is consistent with our premise that KM is about the management of knowledge work. This entails a conception of the actor as an professional (knowledge worker) working in a community of practice defined by the task. Each actor makes autonomous professional/ethical/moral judgements that are consistent with the task and its organizational context. Such judgements are an intrinsic part of the understanding of the task shared by the community.

The TbKM framework addresses all aspects of this definition. Moreover, TbKM reveals actual work practices in a way that allows organizations to integrate their production functions with learning. Thus the framework can be used diagnostically, to identify implicit knowledge management practices, and as an architecture to design the informational and technological infrastructure to support the organizational changes that underpin a knowledge management strategy.

Chapter 4.32
Virtual Communities as Role Models for Organizational Knowledge Management

Bonnie Rubenstein-Montano
Georgetown University, USA

ABSTRACT

Knowledge management serves to create value from an organization's intangible assets. Many organizations have adopted knowledge management practices in recent years. Some of those organizations have achieved success at knowledge management, but others have not. The focus of this chapter is on those organizations that have not been as successful at knowledge management as they originally planned. This chapter posits that organizations can look to virtual communities as role models for successful knowledge management because many of the features that have been identified in the literature as important for successful knowledge management are present in virtual communities. The very nature of virtual communities — their sense of community, the desire they create to share knowledge, the automatic archiving of knowledge for future use, etc. — are used in this chapter to support the claim that virtual communities can serve as role models for knowledge management in organizations.

INTRODUCTION

Organizations worldwide have embraced knowledge management as a way to create value from an organization's intangible assets, thus improving their bottom line (O'Dell & Grayson, 1998). Typically, organizations undertaking knowledge management initiatives treat knowledge as an important organizational resource, with the assumption that employees need incentives for sharing their knowledge with others in the organization (Gupta & Govindarajan, 2000). Under this model for knowledge management, there have been many success stories (e.g., Buckman Laboratories, The World Bank, Nucor Steel, KPMG Peat Marwick, Accenture, and Ford Motor Company). However, knowledge is often an individual, rather than organizational, resource residing within the minds of members of the organization, and the critical success factors of organizational culture, trust, and reward systems aligned with the principles of knowledge management remain difficult to attain in many cases. Organizations can expend significant resources to develop a culture, high levels of trust, and reward systems necessary for enabling effective knowledge management.

In contrast, virtual communities, which seem to emerge fairly effortlessly on the Internet, possess these critical success factors as inherent parts. Virtual communities are "social aggregations that emerge from the Net when enough people carry on public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace" (Rheingold, 2000). According to this definition, knowledge sharing is the very essence of virtual communities. Thus, it can be assumed that both a potent culture (along with at least some minimum level of trust) and incentives for sharing knowledge have developed within virtual communities. Otherwise, sharing would not occur and virtual communities would cease to exist.

A key question that emerges from this realization that virtual communities are essentially entities established for the sole purpose of knowledge sharing revolves around what virtual communities do that traditional organizations do not do to facilitate knowledge sharing. This serves as the general theme of this chapter, with specific research questions to address this theme detailed below.

It should be noted that knowledge sharing is selected as the focus of this study since it is a cornerstone of successful knowledge management (Davenport & Prusak, 1998; Hansen et al., 1999). A number of organizations have recognized the potential of knowledge sharing for enhancing organizational performance. Buckman Laboratories and Ford Motor Company have begun developing knowledge networks to facilitate knowledge sharing (Ruggles, 1998). American Management Systems has established knowledge centers where one of the center's four goals is to learn and share knowledge (Sensiper, 1997). KPMG Peat Marwick restructured its organization around its lines of business in order to facilitate knowledge sharing (Alavi, 1997). The World Bank reorganized to create horizontal relationships between staff in an effort to facilitate the sharing of knowledge (Valor, 1997).

Although some organizations have embraced virtual communities as a way to provide customer support (e.g., Microsoft), virtual communities and more traditional types of organizations are very different entities. As mentioned above, virtual communities are primarily concerned with social aggregations and personal relationships. Business organizations are primarily concerned with competing in the marketplace. Also, while organizations often have electronic components to supplement physical ones, virtual communities are strictly electronic. The typical model for knowledge management adopted by organizations, where knowledge is treated as a commodity, appears to be at odds with the critical success factors for knowledge management because this approach often results in those who possess knowledge seeking to keep it to themselves for personal leverage. In contrast, virtual communities seem to have already obtained the key characteristics for successful knowledge management. The specific research questions that this chapter seeks to answer, then, are:

1. What attributes of virtual communities show promise for knowledge management?
2. How can the attributes that make virtual communities successful at knowledge sharing be carried over to traditional organizations and used in knowledge management?

Because virtual communities exist only in cyberspace, technology is a fundamental part of them, and thus a fundamental part of the communication and knowledge sharing that occurs in virtual communities. The view of virtual communities as exemplars for knowledge management seems to counter recent work indicating that technology is more of an enabler of knowledge management than an essential component (Alavi & Leidner, 2001; Davenport & Prusak, 1998; Rubenstein-Montano et al., 2001). This chapter addresses the two primary research questions listed above while considering this "issue" of technology. Secondary research questions in this chapter include the following:

1. What is the role of technology in a virtual community versus a traditional organization?
2. What aspects of technology make it a better or worse enabler of knowledge management?
3. What barriers to knowledge management does technology add? What barriers does technology remove?

VIRTUAL COMMUNITIES

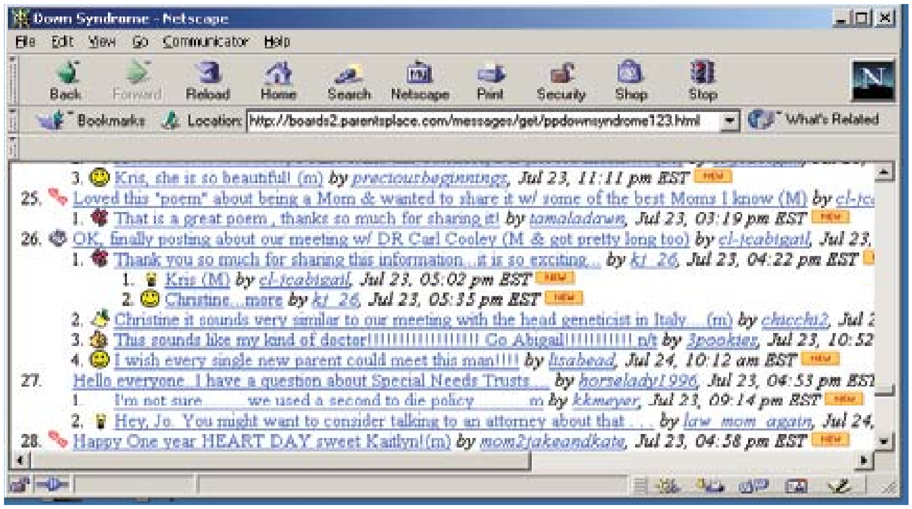
Internet sites have shifted from the static presentation of material to interactive communities, involving the members of the community in ongoing public dialog (Levitt et al., 1998). Sponsors of interactive sites hope such interaction will encourage individuals to spend more time at the site and return more frequently (Levitt et al., 1998). While information sharing over electronic networks, especially with relative strangers, has been examined in organizations (Constant et al., 1996), on the Internet sharing occurs outside of an organizational context in what are commonly termed "virtual communities" (VCs).

Virtual communities consist of people with shared interests or goals for whom electronic communication is a primary form of interaction (Dennis et al., 1998). Traditionally, the word "community" suggests a geographic area, such as a neighborhood (Wellman & Gulia, 1999), but the "virtual" part of the term "virtual community" indicates communities lacking a physical place as a home (Handy, 1995). Formally defined, VCs are groups of people that use a location on the Internet such as a listserv, chat room, newsgroup or bulletin board to communicate regularly. The groups have common practices and interests, and often have a notion of membership, formal or informal, and form personal relationships with others in the community. An example of a VC would be a Usenet newsgroup in which a group of people communicates regularly through the newsgroup and therefore forms personal relationships and bonds. VCs usually center on some common interest, hobby, or life event, such as surf fishing, collecting decorator plates, dealing with colon cancer, or raising a child with Down syndrome.

Not all virtual meeting forums can be considered VCs. For example, a bulletin board on the Web for selling used cars, where most of the postings simply advertise a car and do not have replies, and where people do not return after they sell or buy their car, would not constitute a VC. Authors have proposed certain minimum levels of interactivity in order for virtual spaces to qualify as VCs (Jones, 1997; Liu, 1999). These criteria are as follows: 80% of postings must have responses, a minimum of 15 different members must post over a three-day period, a minimum of ten postings a day per during any random three-day period must be posted, and at least 50% of the posters must post more than one time. It is important to note that individuals participate when they know many others are participating. Although the literature does not specify a particular frequency, a VC is generally understood to consist of persistently interacting members (Smith, 1999). VC sites can quickly fail when the membership, and therefore the usage, drops below some threshold (Ackerman & Starr, 1995).

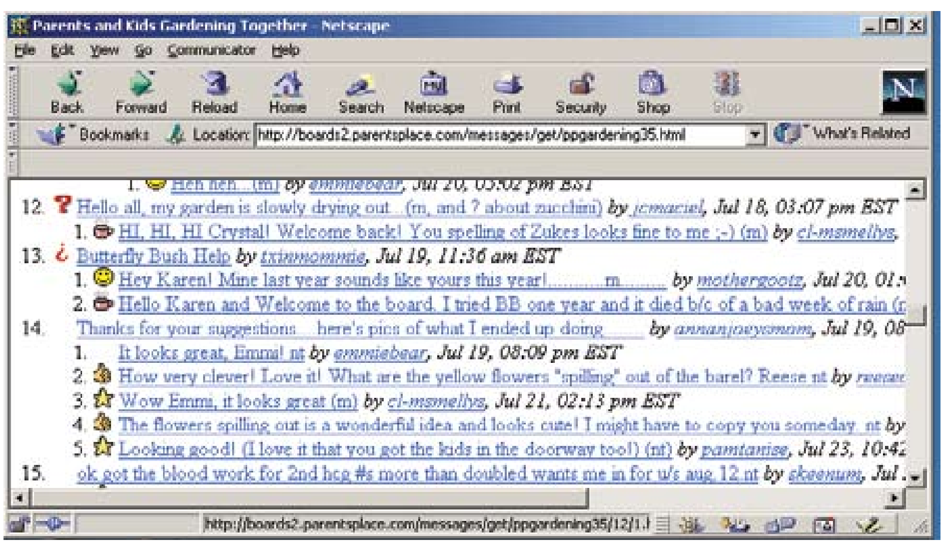
Figures 1 through 4 provide samples of VC exchanges, illustrating the types of knowledge shared in these communities, with specific examples identified below each figure.

Figure 1. Down Syndrome VC



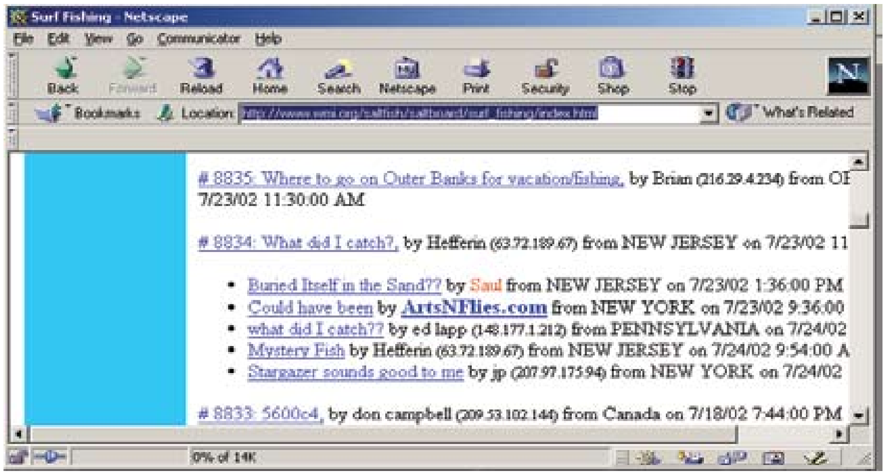
Explicit knowledge — "OK, finally a posting about out meeting w/ DR Carl Cooley"
Innovative knowledge — "we used a second to die policy"

Figure 2. Gardening VC



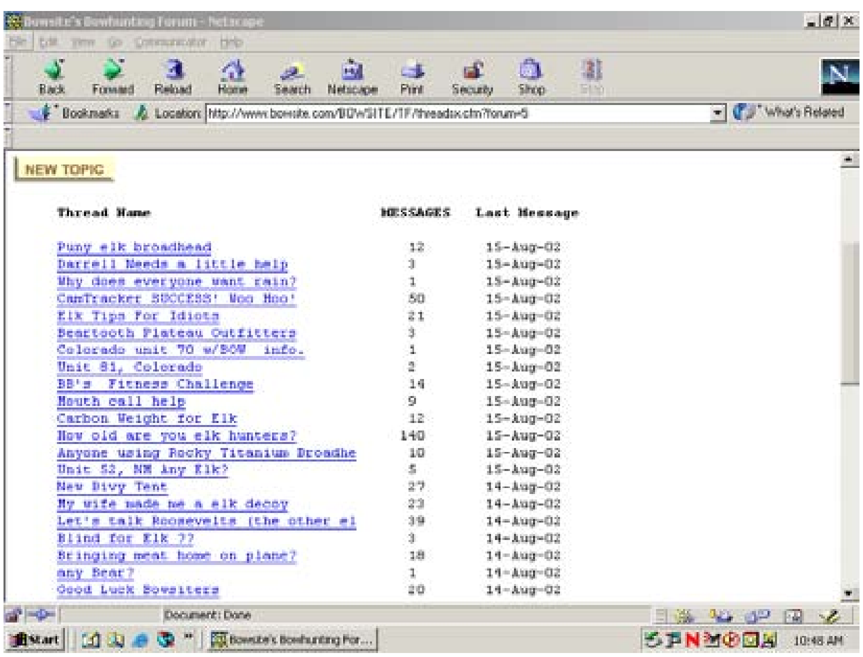
Explicit knowledge — "Mine last year sounds like yours this year!"
Feedback for previously shared knowledge — "Thanks for your suggestions ... here's pics of what I ended up doing... ."

Figure 3. Surf Fishing VC



Explicit and tacit (storytelling) knowledge — "Where to go on Outer Banks for vacation/fishing"
Explicit knowledge — "Could have been"

Figure 4. Bow Hunting VC



Tacit knowledge — "Why does everyone want rain?"
Explicit and tacit knowledge — "Mouth call help"

PROMISE OF VIRTUAL COMMUNITIES FOR ORGANIZATIONAL KNOWLEDGE MANAGEMENT

The description of VCs, and the included figures, given in the preceding section provides the basis from which the claim, "VCs can serve as role models for organizational knowledge management" is made. The overriding attribute of VCs that lends support to this claim is the fact that they are social aggregations established for the purpose of sharing knowledge. In organizations, the goal of KM is directly in line with the purpose of VCs — to get members of the organization to interact and share knowledge so the knowledge can be leveraged for organizational benefit. In addition to the fact that the primary purpose of VCs is to share knowledge, several specific features of VCs that lend themselves to knowledge management are discussed below. The features can be categorized as pertaining to members of the VC (people), interaction in the VC (communication), or means of communication in the VC (technology).

Communication

1. VCs are emergent communities that develop in a grassroots fashion (Rubenstein-Montano & Ridings, 2002). Conversations on a message board can grow naturally over time as knowledge of their existence and quality of conversation is disseminated. In this way, success of the VC is a result of direct need for the VC and the knowledge it generates. Site sponsors cannot "make" a site successful.
2. The definition of a VC indicates that social ties must exist between members of the VC for the online forum to be considered a VC. Thus, the social ties necessary to facilitate knowledge creation and sharing (Hansen, 1999) are in place when such creation and sharing occurs in a VC.
3. Members of the VC communicate when they want to, without pressure to communicate a certain number of times or at regular intervals. This feature of VCs allows members of the VC to generate and share knowledge when it is most appropriate and efficient for the member to do so. Thus, the knowledge sharing process is self-regulating and streamlined to some degree.
4. The focus of VCs is communication, with concern over how to profit from such communication as secondary, or at least transparent to VC members. That is, while VC sponsors depend upon the communities for revenue in some way, either in the form of selling advertising, selling products to members, providing market research, collecting subscriptions, or using them for customer support, seeking revenue does not change the underlying functioning of the VC as an online discussion forum. Focus of the VC remains on knowledge sharing.
5. The ongoing nature of discussion among users provides an incentive for members to repeatedly return to the VC to read others' comments and to respond, thus, continuing the process of knowledge generation and sharing. The very features that classify online entities as VCs — 80% of postings must have replies, a minimum of 15 different members must post over a three-day period, a minimum of ten postings per day per any random three-day period, and at least 50% of posters must post more than one time — dictate that ongoing discussion and repeat returns will be the norm.
6. The criteria for determining if virtual spaces qualify as VCs, membership levels, number of postings, and number of responses to postings (Jones, 1997; Liu, 1999), indicate that VCs are, by definition, successful in

knowledge dissemination (Rubenstein-Montano & Ridings, 2002). World Wide Web sites are public and therefore viewable by anyone with Internet access. Knowledge dissemination can occur regardless of whether individuals actively participate in the site (e.g., lurkers).

People

7. Members of VCs have direct control over the VC since their contributions and exchanges with other members serve as a part of the site's content (Levitt et al., 1998). Thus, VC members have a vested interest in the success of the VC.
8. VCs have low barriers to entry. Typically, individuals only have to click on a link, or enter a URL, possibly completing an online registration form. The infusion of people results in the infusion of new ideas and expertise, which are in turn shared with members of the VC.
9. Members of a VC are initially strangers to one another, allowing them to create any persona they choose. Members often choose to provide accurate information, but this is not required to participate in most VCs. The ability to remain unknown supports the need for anonymity, which has long been the focus of research on group decision-making (DeSanctis & Gallupe, 1985) and often leads to VC members feeling more comfortable participating and sharing knowledge with others in the VC.
10. Oversight and moderating of VCs tends to be somewhat transparent to users. Moderators, who vary from laizze-faire to heavy-handed, tend to adopt more of the laizze-faire attitude. This promotes an environment with some level of freedom from censorship and a sense of privacy (Levitt et al., 1998). Guidance that is visible to members of the VC tends to be in the form of knowledgeable responses to posted queries or gentle reminders to stay "on topic."
11. Oversight and moderation of VCs tends to be handled by individuals with some level of expertise in the domain area of the VC. This enables moderators to not only oversee interaction on the sight, but to provide knowledgeable responses (as mentioned above) on occasion. Moderators also allow other members of the VC to provide answers. This avoids the problem of the VC becoming dependent on the moderator to answer all questions, which is not consistent with the definition of "community." Allowing others to answer questions also increases the number of "experts" in the community, which is important for valuing the community overall.
12. Moderating responsibilities are typically assigned to more than one person so that moderating is coordinated and covered at all times.

Technology

13. The electronic nature of VCs makes storage of past discussions straightforward. VCs typically archive discussions and allow members to search archives when they are interested in retrieving knowledge that has already been generated by the VC.
14. VCs exist on the Internet and are therefore accessible from anywhere and anytime. This allows knowledge to get to the right people at the right time, which is an important part of knowledge management (O'Dell & Grayson, 1998).
15. The use of different technologies enables robust communication similar to that in face-to-face settings. Bulletin boards allow serial discussion, but chat rooms allow for real-time communication that includes

feedback and interruptions. Multimedia auditoriums allow for sharing of non-text knowledge such as video clips.

TRANSFERRING ATTRIBUTES OF VIRTUAL COMMUNITIES TO KNOWLEDGE MANAGEMENT IN TRADITIONAL ORGANIZATIONS

A number of attributes of VCs were identified in the preceding section as important reasons why VCs are successful at knowledge sharing. Some of these attributes are already a part of organizational knowledge management initiatives, and some may not be appropriate for an organizational setting. The VC attributes of particular interest, however, are those which are not typically adopted by organizations at present, but could be used to enhance knowledge management in traditional organizations. There are five attributes identified as critical for knowledge sharing success in VCs but not currently part of the typical organizational knowledge management initiative.

First, VCs were described as emergent communities. This counters the typical top-down establishment of work groups and teams in organizations. Formation of groups in a top-down fashion means members of the group are assigned to work together rather than allowing individuals to come together on their own, simply because they want to. While organizations cannot force the development of grassroots groups, they can work to nurture those that do develop without trying to control them in a heavy-handed manner. Organizations can also allocate space (physical or virtual) for gathering to talk about topics not related to work. Relationships that develop from these informal places may carry over to collaboration and knowledge sharing on work-related projects.

The second attribute of VCs, regarding social ties, can be handled in much the same way as nurturing grassroots groups. That is, employees should be encouraged, within reason, to develop personal relationships with other employees that do not necessarily revolve around work-related issues. Again, a location for social gathering can facilitate this and, in fact, many organizations already have this in place in the form of an employee lounge, cafeteria, or simple water-cooler/coffee pot. For social ties to develop, though, the organization must truly encourage such relationship building, with the focus on social and personal issues and not on work issues.

Third, there has been a trend in organizations to "encourage" knowledge sharing by mandating that individuals participate in communities of practice or write-up summaries of projects and contribute them to databases. This is very different from allowing individuals to contribute knowledge when they want to, without pressure to contribute a certain amount of knowledge. Rather than redesigning employee evaluations to account for how many times an individual contributes to an organizational knowledge base, businesses ought to illustrate how the knowledge base can help individual employees so they will want to participate on their own, perhaps include a reputation management system so participants will be benefiting by developing a better reputation without linking participation to specific employee evaluation processes. This would allow individuals to share knowledge only when they desire. Reputation has been shown to serve as a strong motivation to excel at a task (Nowak & Sigmund, 1998; Lotem et al., 1999) and there is no reason to assume such a motivating factor would be anything but successful for knowledge sharing.

This will require the implementation of new evaluation models in much the same way that the Internet has led to new business models. Although still evolving, the banner-ad model for Internet businesses is successful, not necessarily profit-wise, but in the sense that they enable countless people to view a site free of charge. The banner-ad model places the burden of revenue generation on advertisers rather than customers. Similarly, organizations can shift their focus from employees and the quantity of knowledge they share, to a support infrastructure that encourages knowledge sharing. Web sites that have adopted the banner-ad model gain through advertising, without requiring anything specific from users. Similarly, organizations can use a similar template and gain by filtering, organizing, updating, or "pushing" knowledge, without requiring employees to make predefined knowledge contributions.

Unfortunately, the idea of a reputation management system counters the concept of anonymity. Organizations can examine their culture and determine which approach is most appropriate for them — reputation-based or anonymous.

Fourth, in organizations, the focus is on money with communication and sharing as a way to achieve increased revenues. This makes sense for organizations since organizational self-interest depends on revenues. However, individual self-interest does not always revolve around wealth (Sloan, 2002) and VCs are capable of exploiting other drivers beyond self-interest. It is easy to say that organizations should focus on communication and knowledge sharing in their own right without considering economics, but this is an attribute of VCs that may not be realistic for organizations.

Fifth, because of the top-down approach and presence of managers typical in organizations, moderating any sites sponsored by the organization receives more oversight than typical VCs. This point spans several of the success factors of VCs that are lacking in organizations. Specifically, this can inhibit employee participation (especially when a sense of privacy is not engendered) and removes some of the control individuals have over which contributions are allowed to remain on the site for others to view. Several issues need to be addressed by organizations here. Since it is unlikely that management will be disbanded in order to create an organizational environment that better mimics the VC environment, resources ought to be allocated to building trust between management and staff. Also, oversight of organizational sites should shift toward the laizze-faire end of the scale rather than the heavy-handed end, and participants should have control over admissible content. If a reputation system is implemented as mentioned above, contributions should over time increase in quality and relevance so that oversight by a heavy-handed moderator will not be necessary.

The attributes of VCs already present in organizations, indicating what organizations are already "doing right," include: (1) the ongoing nature of discussion, (2) dissemination of knowledge, (3) individual control over their contributions (to some degree and depending on the organization), (4) low barriers to entry, (5) storage of knowledge in archives, (6) continual access to knowledge, and (7) multiple technologies for sharing knowledge. Most of these are straightforward, but I will comment on a couple of them. First, if knowledge is added to a company intranet site, it is disseminated the same way knowledge is disseminated in VCs. Second, individual control over contributions was discussed above, but can easily be adopted by organizations by allowing employees to upload information directly, with more transparent moderation similar to that of VCs. Significant scrubbing of submissions should not occur. Continual access to knowledge is easily achieved if employees can access intranet sites with knowledge from work, home, or while traveling.

The key feature of VCs, which may prove difficult to transfer to organizational KM, is that of anonymity. The World Wide Web is a much bigger place than a single organization, and fake information can be used to register for participation in a VC. However, in organizations a list of all employees is typically accessible via an intranet search, and anonymity may not be desirable if an individual is trying to obtain "credit" for participating in knowledge sharing. Even if anonymity is allowed by the organization, employees may not trust they are truly anonymous to superiors.

MODELING ORGANIZATIONAL KNOWLEDGE MANAGEMENT AFTER VCS

Table 1 summarizes the VC features discussed in the preceding two sections, and Figure 5 depicts how the three classes of VC features presented in this chapter relate to each other and influence organizational KM. As shown in Figure 5, technology serves as the basis upon which VCs can exist. People create the community, and communication among people sustains the community. The success of organizational KM rests upon these three classes of VC features.

ISSUES AND CONCERNS

While the attributes of VCs that enable them to serve as role models for organizational knowledge management have been outlined above, VCs are not without limitations. Because knowledge sharing in VCs occurs strictly through technology, the emphasis is on sharing explicit knowledge. Some tacit knowledge may be shared (Rubenstein-Montano & Ridings, 2002), but the majority of knowledge shared will be explicit since it can be written down. Some have argued that tacit

Table 1. Applying VC features to organizational KM

Feature	NOT Currently Present in Organizational KM	Currently Present in Organizational KM	Probably Cannot be Easily Transferred to Organizational KM
Communication			
Emergent communities	**3**		
Social ties	**3**

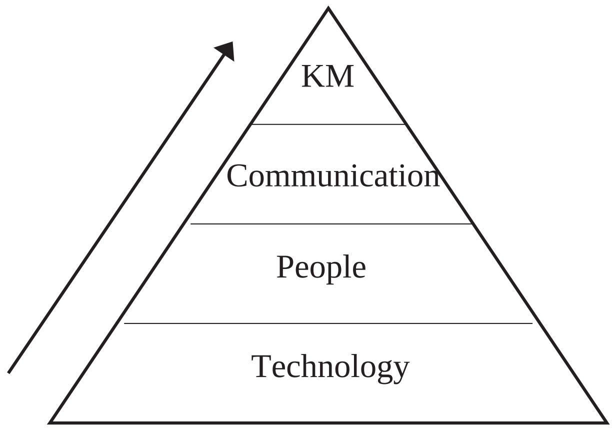
Technology			
Knowledge archiving		**3**	
Anywhere-anytime access		**3**	
Combinations of technologies		**3**	

Figure 5. VC features for organizational KM



knowledge is where much of the value added comes in (Sveiby, 2001), and this is lost if VCs emphasize explicit knowledge.

Also, quality control in VCs is questionable since anyone anywhere can contribute knowledge. The low barriers to entry and ability to create a fictional person mean there is no way to verify the expertise of contributors, and Internet fraud is becoming more commonplace (National White Collar Crime Center & FBI, 2000; National Consumers League, 2002). For example, web sites on which individuals have purposefully posted false stock information to drive up prices of stocks they own for personal gain have received a fair amount of media attention on. Also, comparison of two web sites — http://www.wto.org and http://www.gatt.org — illustrate how easy it is to publish false information online. Http://www.wto.org is the official web site for the World Trade Organization, but http://www.gatt.org appears the same as the official site with manufactured stories.

Because participation in VCs is technology dependent, only those with Internet access can contribute to a VC. Theoretically, this can limit the pool of available expertise. Enough people do have access that this probably is not a real concern, but it is mentioned for completeness. This is an issue that should not apply to organizations if we assume all relevant employees would have access to the company intranet. Of course, restrictive access rules for different classes of employees could lead to an artificial constraint on the amount of expertise available to others in the organization.

Lastly, some of the limitations of VCs for serving as knowledge management systems have been pointed out by Rubenstein-Montano and Ridings (2002). Fairly simple knowledge is shared, explicit rather than tacit knowledge is typically shared, and knowledge is archived by date rather than subtopic making location of stored knowledge difficult. Therefore, VCs cannot serve as a panacea for organizational knowledge management. Instead, they can serve as a starting point for future enhancements to organizational knowledge management.

FUTURE TRENDS

Both VCs and KM continue to evolve. In this section VC trends that can be applied to KM are presented. The first trend involves knowledge organization in VCs using semantic networks. Typically, knowledge is stored in VCs according to the date the content is added to the VC (Rubenstein-Montano & Ridings, 2002), but a newer approach for VCs is to use semantic networks. Semantic networks enable the organization of knowledge around topic areas. This is a change to knowledge organization that enhances search and retrieval of knowledge from storage locations. Consulting firms have already created knowledge management systems that employ semantic techniques for organizing knowledge about customers and their industries, projects, and competitors (Alavi, 1997).

Second, it is expected that emphasis will be on more anticipatory responses from the organization members who need to carry out the mandate of a faster cycle of knowledge-creation and action based on the new knowledge (Nadler & Shaw, 1995).

Third, community members must be able to find and bring to bear the relevant knowledge in the repository. In both today's VCs and knowledge management systems, the search engine is the main workhorse for finding stored knowledge. Search engines apply rudimentary natural language-understanding techniques. Over time, lessons learned about indexing and retrieval in case-based reasoning systems will be applied to KM. Furthermore, agents and distributed problem-solving technology will play an increasingly important role (Smith, 2000).

A couple of recent trends in KM involve enterprise portals and employee relationship management. Enterprise portals provide unified access across business units and enterprise boundaries to just about any resource an employee might need, including front-end and back-end resources, personal workspaces, and the World Wide Web. Individuals can customize their view of the enterprise portal (SAP & PriceWaterhouseCoopers, 2001). Employee relationship management (ERM) is aimed at getting employees, managers and senior executives on the same level and using the same vocabulary for increased productivity, efficiency and customer and market awareness (Ericson, 2002).

CONCLUSION

This chapter has outlined some of the key features of virtual communities that suggest they can serve as role models for knowledge management initiatives in traditional organizations. Because the primary purpose of virtual communities is sharing knowledge, there are prerequisites for the existence of a culture, along with at least some minimum level of trust, and effective incentives for facilitating knowledge sharing. The nature of virtual communities suggests that traditional organizations can look to virtual communities to learn what virtual communities do that traditional organizations do not do for facilitating knowledge sharing. However, there is no claim that virtual communities will serve as a panacea to solve all of the problems organizations face when implementing knowledge management. Instead, this chapter reviewed some of the features of virtual communities that show promise for improving upon current knowledge management practices in traditional organizations.

First, the chapter reviewed the attributes of virtual communities that support knowledge sharing and can thus help traditional organizations. These attributes include the presence of social ties, the emergent nature of virtual communities, the self-motivation present in members of virtual communities, the ongoing nature of discussion, low barriers to entry, community member control over content, some degree of anonymity, transparent oversight, anywhere-and-anytime access to the community, and technologies that enable robust communication.

The chapter then went on to note that traditional organizations already do many things "right" when it comes to knowledge management. However, since there is always room for improvement, organizations can adopt features of virtual communities that do not currently characterize them. Of the features of virtual communities that encourage knowledge sharing, those that traditional organizations do not typically possess, but that can be transferred to organizations to some degree include the following:

- Emergent, instead of top-down, development of communities for sharing knowledge.
- Development of social ties ought to be encouraged and nurtured.
- The emphasis on required contributions should be replaced by an emphasis on employee choice. Individuals should contribute knowledge when they feel self-motivated to do so. Perhaps a reputation system would serve as an effective motivator instead of employee evaluations that link knowledge contributions to pay raises and promotions.
- Exploit the drivers behind self-interest of employees to encourage knowledge sharing instead of placing the entire focus on wealth.

Although virtual communities cannot solve all of the problems of knowledge management that traditional organizations encounter, their very nature serves as a goal to which traditional organizations can strive.

Chapter 4.33
Virtual Teaming

Brenda Elshaw
IBM, UK

INTRODUCTION

Given the ongoing advances in technology and the consequent changes in the work environment with the introduction of a mobile workforce, it is inevitable that more activities will be undertaken by virtual teams.

As with any team, a virtual team is a group of people who share a common objective and combine to provide a variety of different and complementary skills in order to achieve that objective. Unlike traditional teams, they are not collocated and can be working from a variety of different geographical locations, which can be either office or home-based. Often, they work across different time zones, adding to the challenges involved in successfully bringing a team together.

BACKGROUND: THE STAGES OF TEAM DEVELOPMENT

Tuckman (1965) identified four stages of team development which detailed a process that all teams need to work through:

1. Forming: When teams first come together, knowing little about each other and the project.
2. Storming: When roles and responsibilities are being clarified, and team members are striving to establish their position within the team.
3. Norming: When trust is established between team members and communication becomes more open and honest.
4. Performing: When the team members undertake the tasks at hand.

Virtual teams go through the same stages, but this needs to be facilitated by a strong and competent team leader. Steps 1 and 2 are essential for trust to be established between the team members; therefore, team building sessions need to be scheduled to allow this to happen. Time has to be built into the schedule to enable the members to get to know each other and their respective roles within the team.

BUILDING A VIRTUAL TEAM

Bringing together a virtual team requires strong management, communication, and facilitation skills. Often, the team leader is the one common link in bringing the team together and ensuring that team objectives are successfully met.

Most traditional teams come together initially via a face-to-face kick-off meeting, where they get to know each other and agree on their "team charter". For the best results, this should still be done for all virtual teams as people tend to build trust faster once they have met their teammates. It is far more comfortable to meet virtually when you already know the person involved compared to dealing with just a faceless voice at the other end of a telephone call. This forming stage often continues beyond the initial formal meeting with the session extending to a team dinner or sociable drinks.

However, it is not always possible to bring the team together for an initial meeting, and this has to be carried out via other means. Where this is conducted remotely, for example, by means of a conference call, video conference, or e-meeting, the team leader should ensure that each team member is involved and gets an opportunity to introduce him/herself.

Team members should be encouraged to provide profile information in advance of the meeting, covering not only their contact details and skills, but also some personal facts and interests. Contact details should also include a photograph – putting a face to a voice often helps get over the problem of speaking to someone who you have never met.

It is recommended that, even if the team members only meet virtually, the team leader makes every effort to meet the team members face-to-face when first enrolling them into the team.

LEADING A VIRTUAL TEAM

When participating in a virtual team, it is essential that the team members get the opportunity to communicate and share ideas on a regular basis. Not only does the team leader need to be in regular contact with each team member to understand how they are performing, but the team members need to be proactively in regular contact with each other.

One advantage that team members have when they work in the same location is the opportunity of meeting informally over lunch or coffee, encouraging them to share information, report on progress and discuss problems, issues, and so forth. As this is not an option for a virtual team, communication has to be more formal and regularly scheduled. Processes need to be put in place to define the different communication methods and how and when to use them.

During formal team meetings, the team leader should ensure that each participant in the call reports on their progress. With large teams, this may mean splitting the team down into smaller, more manageable subgroups. A regular meeting schedule involving everyone at some level ensures that team members do not become isolated. This is a good forum at which to identify and share "quick wins" with team members to keep the momentum going. In addition to the formal meetings, the team leader should ensure that he/she has regular contact with individuals and subgroups outside the meeting schedule.

TOOLS AND TECHNOLOGY

A wide range of tools and technologies exist to support virtual teams. The level of functionality and sophistication of the tool set available to individual team members, irrespective of their location, is increasing rapidly, allowing them to easily and transparently communicate with each other. However, this puts an increasing reliance on the availability of a supporting infrastructure, from both an IT user support and training perspective.

Some of the tools available are:

- Broadband: The increasing coverage of broadband services allows mobile workers to have a permanent connection to office systems, irrespective of their location. This is particularly useful for home-based team members.
- Internet/Intranet: The increasing use of the Internet and provision of in-house intranets allows dispersed users to have access to common systems and information sources.
- Company Portals: The growth of role-based, personalized portals enables team members to log into their systems and obtain a common desktop from a variety of different locations. It also ensures that new team members can be set up with a common team work environment quickly and easily.
- E-mail: Team members can easily communicate via e-mail. Documents can also be passed between team members using this mechanism, but this could lead to problems with duplicate copies at different versions. It can also discourage sharing by allowing team members to store exclusive copies of documents in mail files. For that reason, the use of file servers or Web places for team documents should be encouraged.
- Videoconferencing: The use of videoconferencing allows team members to meet face-to-face from a distance. This works best when team members are based in office locations that have easy access to videoconferencing equipment, although it usually places restrictions on the number of participants and requires advance scheduling to ensure that the facility is simultaneously available from all locations.
- Instant Messaging: The use of instant messaging allows a dispersed team to remain in contact with each other. It is an excellent resource for quick, ad-hoc interchanges between individual team members and also for synchronous team discussions. It can reduce the feeling of isolation felt by some team members and can assist in making them feel part of a team. It can also help them identify when other team members are online, particularly when working across time zones.
- Web Place: A project Web place can provide the team with a shared workspace structured for their specific needs. It contains structured spaces for them to store content, discussion areas for them to communicate irrespective of location or time zone, and can also provide project-based facilities such as team diaries. It reduces the need for large documents to be passed around via e-mail and ensures that documents are easily accessible by team members. Access can be controlled by the team leader to ensure that content is accessible only by those team members requiring it.
- E-meetings: The availability of Web-based e-meeting tools allows teams to have scheduled and ad hoc meetings via nothing more sophisticated than a Web browser and a telephone. Most systems have the ability to white board ideas and share documents, allowing control to be passed between team members when required. This means that team presentations, demonstrations, and so forth can be seen by the team, and documents can be worked on collaborativel—regardless of location.

WORKING WITH THE RIGHT TOOL SET

The tools required to support the team in their activities should be selected once the requirements of the team have been identified. At no time should the team members feel that the technology is driving what they do. An effective technology is one that supports the team activities seamlessly and transparently. There should never be any doubt as to which tool should be used when.

As the team develops their team charter, they should define what the communication and storage requirements are to support them at each stage. Part of the charter should detail the rules of etiquette regarding usage of the systems. For example, items to be agreed could include:

- when to use e-mail as opposed to Web places;
- when to be available via instant messaging;
- how often to go into systems to check for new information;
- how long team members have to respond to questions; and so forth.

ADVANTAGES OF VIRTUAL TEAMS

- Virtual teams allow the team leader to bring together the best people for the job, regardless of their location and organization.
- Time spent by team members is used more effectively as less time is lost traveling.
- Travel and subsistence costs are reduced.
- Team members can work to their own schedules, allowing for people in different time zones to work together for a common cause. This can also allow for teams to be represented 24 hours a day.
- Team members get to know and work with colleagues outside of their immediate work groups. This can increase their personal networks and encourage the flow of knowledge and experience across boundaries.

EFFECTIVE TEAMING

As Opper and Fersko-Weiss (1992) stated of team behavior, "For the…team, the shift is from a mentality of working alone to one of being in a state of collaboration." Deborah Harrington-Mackin (1994) identified one of the attributes of a non-effective team—when the team has "focused on task activities to the exclusion of work on team member relationships."

One of the great strengths of a team is the ability of its members to work together and build on each other's ideas. In many respects, the techniques and tools required to achieve this for a virtual team are different to those of a more traditional, collocated team and can certainly prove more challenging. It is easy to promote an environment where each team member works in isolation rather than as part of a team. A skillful team leader is required to encourage an environment where team members build the relationships with each other to give them the impetus to collaborate on activities. This may mean that time has to be allowed for some team communications focused solely on building team trust rather than producing deliverables.

CONCLUSION AND FUTURE TRENDS

Virtual teams are becoming the norm in many organizations. While some members struggle with the concept of being part of a dispersed team, many find that the advantages outweigh the difficulties.

This is particularly true of the younger generation of employees who have grown up with and are more accepting of Web technologies.

For the organization, the ability to boost productivity by making best use of their expertise, wherever it resides, is of great benefit. For the employee, virtual teams open up opportunities to work within different teams, enabling them to increase skills and expertise by contact with a wider community. In turn, the organization gains a more skilled and satisfied workforce.

Virtual teams require a set of tools, selected and configured to meet their needs. The tool set used should be supportive rather than intrusive, responding to the varying needs of the team.

They also need to work within a framework of clearly defined processes and communication channels, facilitated by a competent and experienced team leader. When successfully achieved, a virtual team can bring all the benefits usually associated with team working, plus added benefits that only a virtual team can bring.

Chapter 4.34
Organisational Storytelling

N. A. D. Connell
University of Southampton, UK

INTRODUCTION

In this article we consider some of the ways in which narrative approaches might contribute towards a better understanding of organisational knowledge management. The telling of stories has a long, rich, and varied tradition, stretching back hundreds of years. In the study of organisations, storytelling can be seen as part of a wider field of enquiry, Organisational Discourse, which seeks to ascribe meaning to social exchanges within organisations (Grant, Hardy, Oswick, & Putnam, 2004; Grant & Hardy, 2003). Narratives have been explicitly identified (Wensley, 1998; Denning, 2000; Ward & Sbarcea, 2001) as one of the ways in which knowledge might be exchanged in organisational settings, but only limited consideration has been given to the ways in which storytelling approaches can increase our understanding of the creation and dissemination of knowledge in organisations. In this article we reflect on what we might learn from the application of narrative processes, particularly organisational storytelling, and from narrative content, particularly organisational narrative knowledge, to assess the place of such storytelling in KM.

WHAT IS AN ORGANISATIONAL STORY?

Many of us are actors, and sometimes narrators, in organisational stories that are potentially rich in knowledge. We all think we can recognise a story when we see one, perhaps by recognising the story's content, or by recognising the process by which certain knowledge is being exchanged. In this section we consider definitions surrounding the relationship between what we see as "organisational storytelling" and organisational knowledge.

The first broad issue to consider is the distinction between narrative and story. This article will treat both terms synonymously within the context of KM, but the reader should be aware that some authors' definitions offer subtle and interesting distinctions (for example, Polkinhorne, 1988; Czarniawska, 1998; Boje, 2001; Gabriel, 2004).

Stories can be seen as one of the ways in which we can encode data about our environment, both personal and organisational. A particular strength of storytelling for KM lies in its capacity not only to represent such sets of data, but also to offer some insights into the complex interrelationships between such data elements. In an organisational context, these interrelationships might help us to make sense of the organisation (e.g., Weick, 1995).

We may define these stories according to the form that they take (content definitions), or the way in which we recognise their use (process definitions).

Narrative Defined by Content

If we define stories (including organisational stories) according to their content, we can recognise that they have certain characteristics (Pentland, 1999):

- a plot (for example, the employee who has made a mistake, but is forgiven by the boss, who praises and rewards her honesty)
- actors in the story (the employee, her boss, an important client, etc.)
- a sequence of events (the mistake, her discovery of the mistake, how she attempts to rectify the situation, her boss's discovery of the mistake, etc.)
- an outcome or closure (the boss rewards her honesty rather than firing her)—which is often embedded within some sort of "moral context"(for example, honest behaviour is rewarded)
- a wider recognisable context within which the story operates (for example, a multinational company with a fierce reputation).

The balance of these properties is not always equal, but might shift as the circumstances (either of the narrative or its purpose) might demand.

Narrative Defined by Process

In process definitions, the situational characteristics of the performance of the story are considered by some authors (e.g., Boje, 1991) to be as insightful as its content. From a KM perspective, such performances might be rich in tacit knowledge, only some of which will be evident from a story's transcript. Boje's operational definition of a story performance—"an exchange between two or more persons during which past or anticipated experience was being referenced, recounted, interpreted, or challenged" (p. 111)—is typical of such definitions. A more general definition might view stories, within an organisational context, as the socially constructed accounts of past events that are considered important or significant to members of an organisation (Feldman, 1990). Within such a definition, stories need not be factual; some argue that they are seldom so (Hansen & Kahnweiler, 1993), reflecting instead what those involved in the storytelling process believe should be true. Although some stories purport to convey "facts," such facts are not always straightforward to identify or interpret (Gabriel, 2004).

Within both classes of definition, it is clear that organisational stories are often extraordinarily rich in tacit knowledge (see, for example, Orr, 1990; Hernandez-Serrano, Stefanou, Hood, & Zoumas, 2002; Hoopes & Postrel, 1999; Meyer, Connell, & Klein, 2003). Such knowledge has the potential to be stored (and perhaps through constant retelling, even archived) within the "package" of a story, and transferred in a succinct yet rich way. In this respect, a better understanding of organisational storytelling can contribute some useful insights into the ways in which knowledge exchange, in particular informal knowledge exchange, might be effected within organisations.

A number of authors have acknowledged this potential. In one of the earliest descriptions of the use of organisational storytelling and KM, Denning (2000) describes his experiences within the

World Bank, illustrating the use of storytelling as an enabler of organisational change. Snowden (2002) has demonstrated ways in which knowledge might be exchanged, using examples drawn from a number of large organisations. Yet it is clear that many questions are not fully answered within this literature. What sort of knowledge particularly lends itself to being encoded and transferred in stories? Why use stories in preference to other media? What are the organisational processes that might be implemented to encourage the use of stories? In the following section we address these questions in the context of three significant aspects of organisational KM—the creation, storage, and transfer of knowledge.

KNOWLEDGE CREATION AND STORYTELLING

Much of the existing literature has concentrated on viewing stories primarily, sometimes even solely, as a way of storing existing knowledge. Can stories also be seen as a way of creating new knowledge? If so, where do such stories originate? Boje (2001) offers the view that stories begin as what he describes as "ante-narratives," which contain the fragments or seeds of a story that might then be used to create the story. Whilst such fragments might be based on organisational events, this need not necessarily be the case. Although an organisational story, in the context of KM, is rarely an invented story, in the sense of a work of pure fiction, we are not always looking at a precise telling (or retelling) of some aspects of "organisational history." Instead, we are hearing a subjective interpretation.

This lack of objective accuracy in the creation of organisational "knowledge" makes the study and utility of stories interesting when considering knowledge creation in practice; most managers would probably consider accuracy to be a key desirable characteristic of organisational information, yet as we have seen above, some authors have questioned the importance of this aspect, whilst others have instead stressed the "performative" aspects of the storytelling. For such authors, the question of "an objective truth" appears secondary to the reader's or listener's appreciation of the narrative. In essence, the story is in some sense "well told," in a way which evokes understanding and interpretation in the listener or reader, and as a consequence "the 'truth' of these stories…is not the issue" (Rayment-Pickard, 2000, p. 280). The knowledge we are creating is not necessarily a telling or reretelling of "what actually happened," but is instead a structuralist interpretation. "Facts," such as they are, will be woven into each story (by the teller) and interpreted (by both the teller and the listener), sometimes in a selective way to serve the purpose of the story.

This selectivity in the creation (and subsequent transfer) of knowledge is referred to as glossing (Weick, 1981; Boje, 1991) or "colouring" (Hansen & Khanweiler, 1993), and is often intended to emphasise or sell a particular point of view: "A gloss is akin to marginal notes or digression that can exaggerate, simplify, or shift the meaning of the experience" (Boje, 1991, p 117). Although we have already noted that the "truth" of the story may be secondary to its intended use, we might reflect on whether this emphasis on, or deliberate exclusion of, particular aspects of the story is consistent with the typical organisational aspiration for the management of knowledge. Although the notion of "literary licence" appears to be a common feature of storytelling—such that we might reflect, for instance, that "we're not getting the whole story here"—some might argue that such licence is not restricted to storytelling, and that it is ubiquitous across other knowledge-bearing media.

Lastly, a feature of storytelling that might help to explain its potential as a knowledge-creating medium is its receptiveness to casual or informal use in the organisation. Most organisational knowledge is created continuously, yet only stored and reported upon (or transferred) periodically, typically in some formal or semi-formal way. The informal nature of some organisational storytelling allows these episodes not only to occur more frequently, but also in more flexible organisational contexts. This aspect will be returned to when we consider knowledge exchange.

KNOWLEDGE STORAGE AND STORYTELLING

In looking at the definitional characteristics of stories in an earlier section of this article, we noted the importance of context to both process and content definitions. Stories require a cultural context within which their knowledge content can be embedded and stored, and can sometimes provide the listener with a shortcut to knowledge about an organisation's cultural climate, particularly for new members of the organisation (Martin, 1982).

In their work on the different types of stories commonly found in organisations, Martin, Feldman, Hatch, and Sitkin (1983) identify seven types of story, each of which might be viewed as representing unique yet recurring organisational themes, such as rule-breaking, intolerance, or a "them and us" culture. Each theme can be told with a positive or negative story outcome. She suggests three reasons for the ubiquity of these themes.

First is the dualities of behaviour inherent in all organisations, for instance the tension between the firm's values and those of its employees, or whether the same rules apply equally to all, or how those in control behave towards those with less power. "Organisational stories," argues Martin, "express tension created by dualities, perhaps reducing that tension by expressing it" (p. 448). In considering the story as a knowledge storage medium, it might encode hope (or denial) for resolution of the duality, as well as some predictive knowledge about past organisational behaviour.

Martin's second reason suggests that these themes occur as illustrations of self-preserving rationalisations of past organisational events. Drawing on attribution theory, in which individuals attribute success to their own actions, and failures to external forces beyond their control, she argues that this helps to explain both positive and negative versions of each story theme, as each provides an appropriate vehicle for either version. The acquisition of such knowledge also helps the listener position him/herself about appropriate behaviour to adopt in certain situations, for example, when "to look the other way" or "to keep your head down."

Lastly, she maintains that the stories endow each organisation with a certain "uniqueness," either uniquely good—"a sanctuary in an otherwise difficult world" (p. 451), or uniquely bad—"uniquely unworthy of its employees" (p. 452). As stories change, or endure, so they store important knowledge for the teller and listener about the prevailing culture of the organisation.

Gabriel (1991) views content themed not in terms of organisational cultural characteristics, but of more generically recognisable story themes—for example, epic, tragic, and comic—each having familiar narrative themes, whilst operating within an organisational context. In the epic, the hero struggles against an unfair or weak boss; in the tragic story, the hero is a victim, powerless in the face of the organisation; and in the comic story, there is an ambiguity, where the characters are shown enjoying, or suffering, an uneasy mix of pleasure and anxiety. Gabriel (1998) identifies a further seven story types, each centred around emotions such as injustice, humour, or romance. The knowledge stored within such stories therefore focuses more on the emotional characteristics of the organisation, and although he cautions against the interpretive difficulties in gauging the precise emotional content of each story, it seems reasonable to conclude that the emotional climate of the organisation might be stored in such stories, and indicated by their use.

A further aspect of knowledge storage associated with stories lies in their plots. Much of the tacit knowledge is held in a story's plot, such that we "know" what aspects of the story are sad, what constitutes a "happy" ending, even what signals an "ending" to the story. Czarniawska (2004) refers to the strength of plots, and that this strength is derived from the repetition of a few "strong plots":

…some plots are strong—or stronger than others—because they have been institutionalised, repeated through the centuries, and are well rehearsed…One should therefore speak of conventional rather than traditional plots, and of dominant rather than strong plots; they are 'strong' in a given time and place. (p. 3)

This emphasis on the contextual aspect of the strong plot appears very resonant with the concept of tacit knowledge, embedded within a familiar story. If each story contains a recognisable "package" of knowledge, so each plot helps to anchor the relevance of that package within an organisational and cultural context.

There appears to be some agreement in the literature that stories provide a valuable way in which organisational knowledge, particularly tacit knowledge, might be encoded. The following section considers how this knowledge might be transferred.

KNOWLEDGE TRANSFER AND STORYTELLING

In this section, we consider how knowledge that has been created and stored in stories could be effectively transferred through storytelling.

Storytelling might be viewed as a process in which an individual shares his or her knowledge with others, typically in a face-to-face spoken encounter, during which the story is told and listened to rather than, say, written or read. Such storytelling might be formal, perhaps as part of a formal presentation that might be organisation-specific or to a wider audience (Clark & Salaman 1998), or informal, perhaps arising from a chance meeting or prompted by events. The nature of such encounters, particularly but not exclusively informal encounters, means that the listener role can be more active—s/he can interrupt, ask for clarification, and express emotions such as approval, disbelief, and so forth about the knowledge being transferred. Such interaction might change the behaviour of the teller, who might modify the story and its knowledge content, in light of such feedback. In this way, the story and its content are less rigidly defined, more dynamic, and perhaps more informal. In some circumstances, the story might be deliberately designed to elicit a response, which may have political or otherwise charged meanings. Informal stories may be counter-cultural or sub-cultural, and their political dimension should not be underestimated, both as a means of reacting to dominant organisational control, and of making sense of the storyteller's and/or listener's place within it. For both formal and informal telling, there will be a selectivity (and, by implication, exclusion) in the process, either deliberate (for example in informal telling) or perhaps as a by-product of organisational structure, culture, or politics (for example, "this story is not to leave the fifth floor").

So far we have considered informal or formal processes of organisational storytelling. What motivates the storyteller to choose stories to transfer knowledge, and will such motivation be influenced by or influence the choice of formal or informal organisational story use?

The literature on this question presents two opposing views; on the one hand a willingness of knowledge sharers to exchange knowledge to their mutual benefit (e.g., Orr, 1990), and on the other a reluctance of knowledge carriers to deposit their knowledge due either to its "stickiness" (von Hippel, 1994) or to absence of incentive (Huber, 2000). Much of the motivational literature seems to have less relevance in the context of informal storytelling; organisational storytelling is an optional activity, with willingness on the part of teller and listener to be involved, and therefore little need for incentives in the "management" sense. The "stickiness" of the knowledge, often seen as an inhibitor of effective knowledge transfer, is much less problematic in storytelling; in some respects it might be regarded as an enabler of more efficient transfer of tacit knowledge, as stories are a "sticky" medium (Connell, Klein, & Meyer, 2004).

Although stories have an inherent capability to capture rich tacit knowledge, it is by no means certain that it is this characteristic that makes them the "medium of choice" among their users. Such tacit knowledge is often exchanged unconsciously, in a taken-for-granted way, during storytelling. Because the teller and listener share the context, the story can often be abbreviated into a particular type of informal story that Boje (1991) refers to as a "terse story."

I call this filling-in-the-blanks form terse storytelling. Much of the story that is told is not actually uttered. A terse telling is an abbreviated and succinct simplification of the story in which parts of the plot, some of the characters, and segments of the sequence of events are left to the hearer's imagination. (p. 115)

The knowledge exchange taking place makes efficient use of this tacit dimension:

…the terser the telling, the more the shared understanding of the social context, since insiders know what to leave to the imagination…The terser the telling, the less sharing of understanding of the social context can be detected by outsiders. (p. 116)

Most of the preceding observations about knowledge transfer and storytelling relate to informal stories. Formal stories, for example those used in presentations or sales pitches, are also used to exchange knowledge, and in these cases the motivation is often easier to discern. Drawing on the work of Bowen (1978), Connell et al. (2004) describe four motives for story use, based on two criteria: control of story content and selection of audience (see Table 1).

Educational stories are those directed to meet the needs of particular people, with content di-

Table 1. Motives for organisational story use (Connell et al., 2004)

		Selection of story audience	
		Story directed at the needs of particular people	People selected who would benefit from story
Control of story content	Specific meaning or message	EDUCATION	EFFECT
	No specific meaning or message	ENRICHMENT	ENTERTAINMENT

rected towards a specific meaning or message. If there is no specific meaning or message, the story is intended to enrich the understanding of the audience. If a story has a specific meaning or message, but its audience is not identified until after the story has been created, such stories are designed to achieve a particular effect. Finally, a story carrying no specific meaning or message, whose audience is selected to hear it after it has been created, is probably being told for entertainment, as when one selects an audience who would enjoy or appreciate hearing about some experience one has recently had. The intention of this "four Es" categorisation is to help practitioners reflect on how and why a story might be an effective knowledge transfer medium in a particular situation, rather than an attempt to "pigeon-hole" stories, which might span two categories or might be used in different ways in different situations. Clearly, such reflections will be more relevant in addressing the deliberate use of stories, where the intention is to manage the story content and recipient reaction.

Both formal and informal stories appear to take advantage of a palatable contextual framework for knowledge transfer. This distinction is not dependant on the "truth" of a story, as we have noted above; formal and informal stories can be equally "untrue." The structure of stories appears to be supportive of their use as a knowledge exchange medium, in particular because stories appear to encourage, or perhaps even invite, retelling.

FUTURE TRENDS

There is a sparseness of empirical support for many of the assertions claimed for narrative approaches to KM. Both "descriptive" and "prescriptive" studies, within different organisational structures, would help to shed more light upon the knowledge processes within organisational storytelling, and if such encounters could, or should, be "managed." Evidence is available from communities of practice such as those identified by Orr (1990) and Shaw, Brown, and Bromiley (1998). Snowden (2002) describes a "private collaboration space" within IBM, containing stories recording "significant mistakes and associated learning that would only be shared by a small trusted community" (Snowden, 2002, p. 20). There is also some limited empirical evidence of story use from voluntary organisations such as Alcoholics Anonymous (Steffen, 1995; Swora, 2001), and caregiving environments (Kirkpatrick, Ford, & Castelloe, 1997; Meyer et al., 2003), where stories may perform a unique or special knowledge-sharing role. It has yet to be seen if the potential for the use of ICT-enabled knowledge exchanges (Meyer et al., 2003; van der Hoof & de Leeuw van Weenen, 2004) will act as an inhibitor or accelerator of organisational storytelling.

If we consider stories as knowledge-flow facilitation devices, and if we seek to explore the ways in which they might be used as effective knowledge transfer devices, then we may need to consider occasions when organisations might be particularly receptive, perhaps even vulnerable, to stories, and also to consider physical locations which might promote, formally or informally, their use.

CONCLUSION

In this article, we have examined both "process" issues—why, when, where, and how stories might be used to create, store, and exchange knowledge—and also "content" issues—the nature of the knowledge, its potency, and its perceived validity. Organisational knowledge is inextricably bound up within the context of the story, and for such knowledge exchanges to be "managed" we need to reflect on ways in which organisations can influence or encourage (or perhaps even inhibit) a storytelling culture through both formal and informal mechanisms; such conscious and deliberate organisational action might be termed "narrative engineering" (Connell et al., 2004).

Organisational stories have significant potential to shed light upon the characteristics of the organisations in which they exist, not least because of the tacit knowledge which is often inextricably bound up within them. We have noted how the stickiness of this knowledge is a valuable characteristic of stories when transferring knowledge, but that the dynamic and unpredictable nature of storytelling offers a challenge to the manager attempting to harness its power.

Chapter 4.35
Knowledge Transfer within Interorganizational Networks

Jennifer Lewis Priestley
Kennesaw State University, USA

INTRODUCTION

Increasingly, knowledge is recognized as a critical asset, where a firm or an individual's competitive advantage flows from a unique knowledge base. The subsequent degree to which knowledge is then recognized and valued as a resource has been the theme of many papers on competitive advantage (Barney, 1991; D'Aveni, 1994; Nonaka & Teece, 2001; Prahalad & Hamel, 1990; Spender, 1996; Teece & Pisano, 1994). As a result, the ability to value and leverage external knowledge has become recognized as the basis of competitive advantage.

Gulati and Gargiulo (1999) suggest that membership in a networked community satisfies the need for knowledge as a way to help cope with environmental uncertainty. Consequently, inter-organizational networks or communities of practice represent a significant conduit for knowledge transfer to help manage this environmental uncertainty (Madhavan, Koka & Prescott, 1998).1 Researchers in organizational learning have effectively concluded that organizations participating in a networked community will realize superior economic gains from their increased access to knowledge relative to independent or non-aligned firms (Argote, 1999; Baum & Ingram, 1998; Carlsson, 2002; Darr, Argote & Epple, 1995).

Although the implications of membership in a network having any structure versus no membership (and therefore no structure) are generally accepted, the implications of the different structural types that these networks can assume are less understood. Networks can accommodate, for example, different levels of competition, different degrees of centralization, and different operational objectives.

Knowledge may or may not transfer within different types of networked communities, raising an important question: Given that network membership is accepted as preferable for knowledge transfer relative to non-membership, does the specific network type in question have an effect on the degree to which knowledge will or will not transfer? This is the guiding research question of this article.

Prior to an exploration of this question, it should be noted that a multi-entity network (or community of practice) is very different from a dyad, and therefore represents unique challenges with respect to research. Unlike a dyadic relationship, networked communities can take on a life of their own that supersedes the presence of any individual member. Simmel (1950), who studied social relationships, found that social triads (and relationships involving more than three entities) had fundamentally different characteristics than did dyads. First there is no majority in a dyadic relationship—there is no peer pressure to conform. In any group of three or more people, an individual can be pressured by the others to suppress their individual interests for the interests of the larger group. Second, individuals have more bargaining power in a dyad. This is not only true because of percentages, but if one member withdraws from a dyad, the dyad disappears—this is not true in a networked community. Finally, third parties represent alternative and moderating perspectives when disagreements arise. As a result of these differences, multi-entity networks are more complex to study and less understood than dyads.

MAIN FOCUS: FACTORS OF KNOWLEDGE TRANSFER

A foundational concept from the Knowledge-Based View of the Firm is that within the context of knowledge management, knowledge is viewed as moving unencumbered by and transferring without cost within and among organizations (Grant, 1997; Kogut & Zander, 1992, 1996); although knowledge is recognized as an asset, unlike other assets its transferability has no associated costs. As von Hippel (1994) described, this may not be the case.

Knowledge has been described as a "sticky" asset that is costly to acquire and difficult to transfer between locations, even within the boundaries of a single firm. This stickiness is caused by, among other factors, the form of knowledge being transferred (Is the knowledge in question explicit? Or is it tacit?), as well as different attributes of the source(s) and the recipient(s), such as their situational absorptive capacity, their respective levels of causal ambiguity, and the degree of trust or motivation shared between the source and the recipient (Szulanski, 1996; von Hippel, 1994). I will refer to this last attribute as the source-recipient relationship. In this section, these three established factors of knowledge transfer—absorptive capacity, causal ambiguity, and the source-recipient relationship—are examined in terms of their effects on inter-organizational knowledge transfer.

Absorptive Capacity

Organizations must possess some degree of absorptive capacity to first recognize and then realize any value from the external knowledge to which it is exposed as a member of a network. The concept of absorptive capacity has received a significant amount of research attention since Cohen and Levinthal's seminal work on the topic (1990). Their definition of the concept is the most widely cited,

…the ability of a firm to recognize the value of new, external information, assimilate it and apply it to commercial ends is critical to its innovative capabilities. We label this capability as a firm's absorptive capacity. (p. 128)

In a networked context, the absorptive capacity of the recipient organization is integral to the success of the knowledge transfer process. In his work examining the effectiveness of inter-organizational alliances, Walker argues that firms that emphasize their relationships with other firms will be more successful, in large part because of their ability to recognize and apply new knowledge (1995). The ability to "sense" new external knowledge and have the processes in place to then bring it internal to the organization quickly becomes a competitive advantage when translated into economic rents. This "sensemaking" is a critical function, which enables an organization to more effectively connect with its operating environment and allocate resources efficiently (Teece, 1998). Cohen and Levinthal (1990) and others (e.g., Lane & Lubatkin, 1998) suggested four types of commonalities, which represent the contributors to a recipient's overall level of absorptive capacity. These commonalities include language, knowledge base, process, and problem solving. If these commonalities are not present, absorptive capacity is considered to be low and knowledge transfer is less likely to occur.

Causal Ambiguity

The concept of causal ambiguity centers around "knowability" (the extent to which something can be known) and "knowness" (the extent to which something is known) of two sets of elements—(i) the organizational inputs and (ii) the causal factors that are used in combination to generate outcomes. Organizational inputs can be understood, for instance, as the raw materials used to manufacture a product, and the causal factors can be viewed as the processes used. When an organization does not know what combination of inputs and process factors cause the final outcome, its knowledge is, at best, causally ambiguous. For example, in the 1890s, Procter and Gamble had been manufacturing Ivory Soap (outcome) utilizing the same ingredients (inputs) and the same processes (causal factors). When an employee had inadvertently left one of the soap-making machines on during his lunch break, he returned to a frothy mixture unlike any soap mixture ever seen. Because none of the inputs had changed, P&G elected to package and distribute the soap as normal. Several months later, they were inundated with orders for the "floating soap". At this point, they were operating under causal ambiguity: having forgotten about the frothy accident several months before, they were unclear as to what input or causal factor could have generated the outcome of floating soap. Eventually the connection to the extra air in the soap-making process was discovered, and "It Floats" became an advertising slogan for Ivory Soap.

Causal ambiguity has been recognized as a factor in knowledge transfer difficulty across much of the research in organizational learning and knowledge management. For example, Wilcox-King and Zeithaml (2001) examined, in part, the tacitness of the knowledge in question as an indicator of causal ambiguity. Mosakowski (1997) developed a useful typology through which to examine the effects of causal ambiguity on the transfer of knowledge and decision making. Extending the work of Lippman and Rumelt (1982), Mosakowski determined that although increased causal ambiguity has the potential to increase competitive advantage by increasing the difficulties associated with imitation by competitors, increased causal ambiguity has the impact of decreasing knowledge transferability, and by association its application.

In the intraorganizational context, Szulanski (1996) found causal ambiguity to be an important contributor to knowledge transfer difficulty. Specifically, Szulanski identified "fundamentally irreducible" (or high) causal ambiguity as a factor in knowledge transfer failure.

Extending the logic of these findings, it can be stated that as causal ambiguity increases, the difficulty associated with knowledge transfer is also expected to increase.

Source-Recipient Relationship

There is uncertainty that exists within the context of the relationship between a knowledge source and a knowledge recipient. The basic premise here is that the knowledge recipient can put the received knowledge to more than one use. That is, the recipient can choose from multiple possible actions to follow once the knowledge has been received. Where the knowledge source can effectively reduce the potential action set of the recipient, uncertainty can be reduced. This reduction in uncertainty may occur as a result of contractual or legal obligations or through a mutually beneficial outcome. The alternative is also true—if the actions of the knowledge recipient cannot be known either because of lack of experience or threat of opportunistic behavior, the recipient action set is considered to be unbounded. In addition, the issue of network size is paradoxical—as the size of the network increases, the potential base of accessible knowledge increases. However, the decision to share knowledge becomes more complex because the knowledge source must consider multiple recipient action sets, translating into greater uncertainty and greater knowledge transfer difficulty. However, inter-organizational networks can mitigate the uncertainties related to initially unbounded action sets through governance policies and controls. As will be seen below, some network forms can effectuate trust or eliminate the need of trust, and thus can help reduce uncertainties and reduce knowledge transfer difficulty. The greater the uncertainty associated within this relationship, the greater the negative impact to inter-organizational knowledge transfer (Szulanski, 1996).

To briefly summarize this section, three established factors of knowledge transfer have been explored: absorptive capacity is considered to have a negative relationship with knowledge transfer difficulty, while causal ambiguity and the uncertainty embedded within the source-recipient relationship are considered to have a positive relationship with knowledge transfer difficulty.

TYPES OF INTER-ORGANIZATIONAL NETWORKS

The basic concept of an inter-organizational network is generally understood and has received significant research attention. A simple network can be defined as "nothing more (or less) than a system…consisting of objects and connections" (Casti, 1995)—generally referred to as 'nodes' and 'linkages' in Social Network Theory. When addressing the concepts of inter-organizational communities of practice, a fundamental distinction should be made between durable, permanent "networks" and temporary "networks" (Westlund, 1999). My concern is with the former case, and conceptually I am more aligned with the characterism put forth by Johnson (1995) that networks are a static form of infrastructure, which support and constrain dynamic activity.

Researchers have studied inter-organizational networked communities from different vantage points. Thorelli (1986) and Almeida, Song, and Grant (2002) studied membership in a network from the perspective of Transaction Cost Economics as a strategy occupying the space between complete organizational self-sufficiency with no inter-organizational transactions and a complete outsourcing strategy with exclusively market-based transactions. Allee (2002) proposed the concept of a "value network" as the basis for understanding the activities related to the creation of intangibles such as knowledge. Carlsson developed a generalized framework of networks organized for the purposes of strategic knowledge management (2002).

Although these studies developed and defined networks, they did not examine the of knowledge transfer within different types of networked communities. Therefore, the question regarding how knowledge transfer difficulty, and its associated factors, varies with inter-organizational network type remains unanswered.

I approached the study of inter-organizational network communities from a slightly different perspective. Using the established foundational theories of Transaction Cost Economics, the Knowledge-Based View of the Firm, and Social Network Theory, I differentiate network types using three established characteristics—centrality of authority, scope of operations, and intensity of competition. I use these characteristics to create an abstract model of inter-organizational networks and then explain different inter-organizational networks that exist in practice.

Centrality of Authority

In an intra-organizational (and inter-personal) context, the two basic structures of centralization and decentralization have been studied extensively (e.g., Adler, 2001; Galbraith & Merrill, 1991; Van den Bosch, Volberda & de Boer, 1991; Volberda, 1998). Researchers have then looked to inter-organizational networks as an organizing principle residing between pure market transactions and complete organizational self-sufficiency. However, once within the community, the question of centralization remains, specifically to what extent governance and decision-making authority is centralized or decentralized.

Williamson (1973, 1975) describes a centralized structure as providing the authority to address issues related to opportunistic behavior, information impactedness, and bounded rationality. A (formal or informal) centralized authority would also have the ability to mandate standardization of operations, language, policies, and so forth. Alternatively, a decentralized structure is described as one of peer group associations, without subordination, involving collective and usually cooperative activities. This type of structure is deficient in its ability to address opportunism and "free-rider" abuses. However, recent researchers have found a decentralized structure to be particularly well adapted to facilitate innovation and new knowledge creation, without the encumbrance of the weight of a formal centralized hierarchy. Alternatively, the former structure has been found to better facilitate the diffusion and implementation of existing knowledge (Adler, 2001; Galbraith & Merrill, 1991; Van den Bosch et al., 1991; Volberda, 1998).

Scope of Operations

In this article, "scope" is defined as the degree of operational differentiation among the members of a community. Members of "narrow scope networks" engage in similar processes and exhibit some commonalities of knowledge base, process, language, problem solving, and so forth. On the other end of the continuum, the participating organizations within "broad scope networks" generally engage in very different types of business processes and often have different knowledge bases, use very different descriptive languages, and experience different types of problem-solving environments.

Intensity of Competition

Within the context of Social Network Theory, an important component of network structure that has been found to have significant impact on how well knowledge does or does not transfer is the ties or linkages among participants (Dacin, Ventresca & Beal, 1999; Granovetter, 1985; Uzzi & Lancaster, 2003). The linkages that exist among participants have been described as being either 'embedded' (integrated) or at 'arm's length' (Dacin et al., 1999). Integrated ties:

> *…are considered to create behavioral expectations that…shift the logic of opportunism to a logic of trustful cooperative behavior in a way that creates a…basis for knowledge transfer. (Uzzi & Lancaster, 2003, p. 384)*

By contrast, linkages at 'arm's length' are:

…cool, impersonal, atomistic…motivated by instrumental profit seeking. (Uzzi & Lancaster, 2003, p. 384)

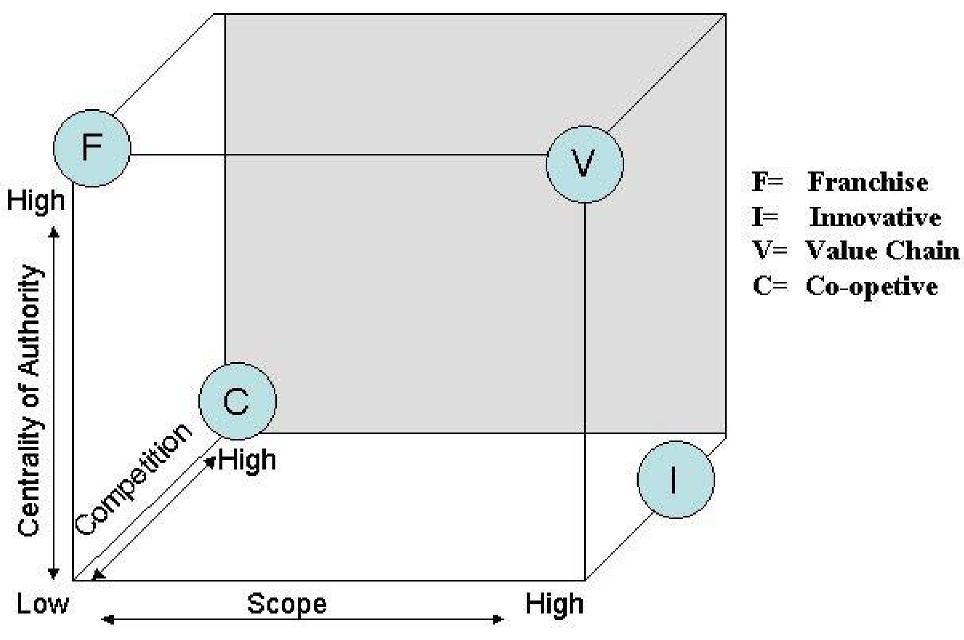
Although it may initially appear counterintuitive that organizations voluntarily join networks while maintaining 'arm's length' ties, consider VISA. Individual banks are fierce competitors, yet collectively benefit from the functionality of global payment card acceptance afforded by VISA—their relationships are "cool and impersonal," with linkages created for the purposes of decreased transaction costs. In addition, Powell, Koput, and Smith-Doerr (1996) found that as the technological sophistication of an industry increases, the intensity and number of competitive alliances also increases; although relationships are again "cool and impersonal," they come together to reduce the costs associated with R&D:

When there is a regime of rapid technological development, research breakthroughs are so broadly distributed that no single firm has all the internal capabilities necessary for success…Firms thus turn to collaboration to acquire resources and skills they cannot produce internally, when the hazards of cooperation can be held to a tolerable level. (1996, p. 117)

Using a more commonly accepted description of these integrated and arm's length linkages, I will refer to this characteristic as "intensity of competition" among the participants, with low intensity of competition equating to integrated linkages and high intensity of competition equating to arm's length linkages.

A graphical representation of these three network characteristics and the unique space occupied by four types of networks can be seen in Figure 1. These four types are explored.[2]

Figure 1. Types of inter-organizational networks



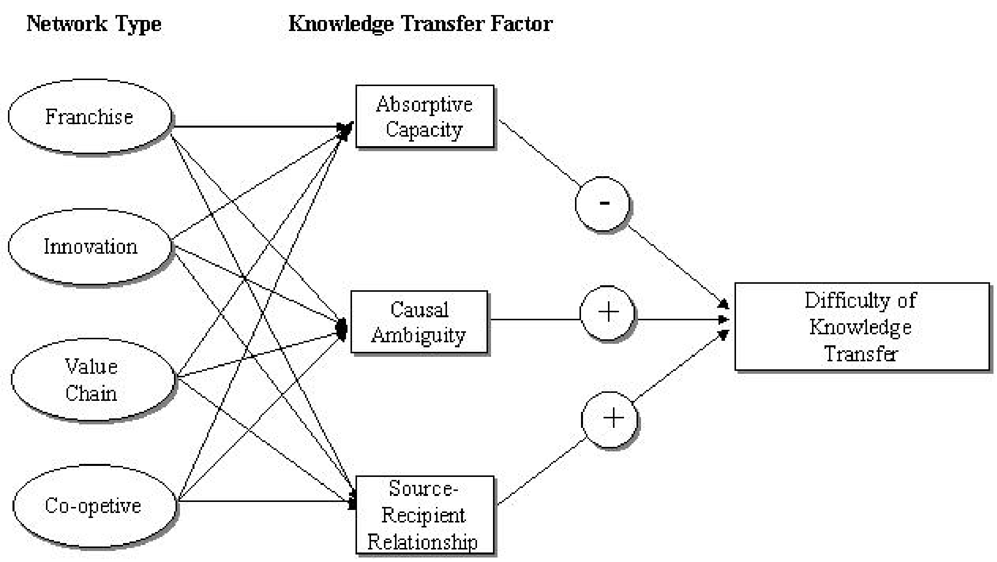
Three of the types identified in Figure 1 have already received some degree of research attention. These types include the franchise network (Argote, 1999; Darr et al., 1995; Thorelli, 1986), the value chain network (Dyer, 1997; Li, 2002; Thorelli, 1986), and the innovation network (Harris, Coles & Dickson, 2000; Harrison & Laberge, 2002). The value chain network type has been studied in three configurations, including dyadic (e.g., the manufacturer/supplier relationship), one-to-many relationships (e.g., the manufacturer with multiple suppliers), and N-to-N relationships (e.g., multiple manufacturers and multiple suppliers). A fourth type of interorganizational network, the co-opetive network, has had the least amount of formal treatment in the literature. The term "co-opetive" has been used to describe a situation where traditional competitors have agreed to cooperate to achieve a common objective (Brandenburger & Nalebuff, 1996; Loebecke, van Fenema & Powell, 1999; Shapiro & Varian, 1999). Using this accepted notion of "co-opetive," I extend this concept to define a co-opetive network as some formalized arrangement of N competitors collaborating to achieve some common objective.

A FRAMEWORK FOR CONSIDERATION

Based upon the discussion of knowledge transfer factors and the different types of networked communities above, I now put forth a framework to address the research question posed in the beginning of this article.

The model depicted in Figure 2 represents a framework to investigate how each of the four network types (franchise, innovation, value-chain, and co-opetive) affects the three factors of knowledge transfer difficulty (absorptive capacity, causal ambiguity, source-recipient relationship). As explored above, the respective relationships of each factor and knowledge transfer difficulty (the

Figure 2. Types of inter-organizational networks and factors of knowledge transfer



right side of the model) are relatively well established: an increase in absorptive capacity would be expected to lead to a decrease in knowledge transfer difficulty, an increase in causal ambiguity would be expected to lead to an increase in knowledge transfer difficulty, and more uncertainty in the source-recipient relationship would be expected to lead to an increase in knowledge transfer difficulty. It is the left side of the model or the relationships among the different network types and the factors of knowledge transfer that represent the greatest opportunity for further exploration.

Given the differences in the attributes of the networks—centralization, scope of operations, and intensity of competition—it would be reasonable to expect that each type would, in fact, experience each factor of knowledge transfer differently. For example, two of the characteristics of the franchise network are narrow operational scope and a hierarchical centralized structure. It could be argued that narrow scope provides a fertile environment for the four commonalities identified as necessary for absorptive capacity—language, knowledge base, process, and problem solving—while a strong hierarchical centralized structure has the ability to mandate standards governing, for example, service and quality. These standards would logically lead to the commonalities of process, knowledge, and language identified above—and therefore a high state of absorptive capacity. Similarly, the common processes that exist in a franchise community of practice would be expected to support a common knowledge of inputs and causal factors, both before and after outcomes associated with their use are known, thereby creating a low state of causal ambiguity. A related characteristic of causal ambiguity identified by Mosakowski (1997) is task complexity: the more complex tasks become, the more difficult it becomes to identify the specific cause and effect that each input or factor has on related outcomes. Where this complexity can be mitigated, causal ambiguity is reduced. Simon (1962) determined that a strong, centralized/hierarchical structure can mitigate task complexity through specialization of labor and standardization. Given the expected hierarchical centralized structure of the franchise community of practice, complexity of task is expected to be low, and again thereby contribute to low causal ambiguity. Finally, the franchise network is characterized by a low intensity of competition amongst the network members. Franchisees are generally stakeholders within a larger entity—they are economically interdependent. Adler (2001) and Kogut and Zander (1996) refer to this interdependence as "shared destiny." Shared destiny would help to mitigate actions related to opportunistic behavior and contribute to a bounded recipient action set. Another characteristic of a franchise community of practice is limited organizational scope, evidenced in part by a commonality of operational processes, again decreasing the uncertainty related to the knowledge in question. In addition, the franchise community of practice is generally considered to have strong central governance. A hierarchical centralized structure would include an authority for punishment associated with opportunistic behavior amongst the franchises. Assuming this threat of punishment is severe enough to prevent defection, trust (or at least trust-like behaviors) could be mandated. As a result, the recipient action set would again be considered to be bounded.

Using this logic, the franchise network type would be expected to demonstrate a high level of absorptive capacity, a low level of causal ambiguity, and limited uncertainty, leading to a bounded recipient action set. Given the expected relationships between each of these factors and knowledge transfer difficulty, the franchise network would be expected to exhibit limited knowledge transfer difficulty. Using similar logic, the relationships between each network type and each factor of knowledge transfer difficulty could be reasoned. These proposed relationships are shown in Table 1.[3]

Table 1. Proposed network type relationships

Factor/Network	**Absorptive Capacity**	**Causal Ambiguity**	**Source-Recipient Relationship Uncertainty**	**Knowledge Transfer Difficulty**
Franchise	High	Low	Low	Low
Innovation	Low	High	High	High
Value Chain	Low	Low	Low	Low-Med
Co-Opetive	High	High	High	Med-High

FUTURE IMPLICATIONS

Researchers have determined that the primary factors that affect knowledge transfer within and among firms include absorptive capacity, causal ambiguity, and the relationship between the source and the recipient (e.g., Cohen & Levinthal, 1990; Mosakowski, 1997; Szulanski, 1996). In addition, membership in some type of structured network has been generally accepted as superior to non-membership for the purposes of knowledge transfer (e.g., Argote, 1999; Darr et al., 1995; Powell et al., 1996). However, prior to this article, no researcher has attempted to frame or address the issues regarding how different network types affect these factors of knowledge transfer—and ultimately the transfer of knowledge itself—differently.

The theory developed in this article provides a framework through which to consider the differences that might exist among different network types regarding the transfer of knowledge. Understanding these differences, if they exist, would have implications for both practitioners as well as for researchers.

For practitioners currently operating within a networked community, this research study has several implications, including both descriptions of the phenomena as well as prescriptions for improvement. For example, if the states of the established factors of knowledge transfer provided in Table 1 are proven to be true, then the strengths and weaknesses of different network types could be considered and addressed in terms of their ability to facilitate the transfer of knowledge. Those individuals or organizations currently operating within a particular network type would be better prepared to anticipate potential challenges to the transfer of knowledge among network members, and proactively allocate resources appropriately.

CONCLUSION

For those engaged in knowledge management research, this article provides two potential contributions. First, although each of the three factors of knowledge transfer identified in Figure 2 are well established as unilateral contributors to the transfer of knowledge, this article provides a framework through which to investigate the relative effects of all three factors on knowledge transfer difficulty simultaneously. Through this framework, it may be determined that causal ambiguity strongly influences the transfer of knowledge within one network type, but is dominated by absorptive capacity within the context of a second network type.

Second, Grant (1997) explains the role of strategic alliances in the Knowledge-Based View of the Firm, from the perspective of resource (knowledge) acquisition and utilization efficiencies within the boundaries of the firm versus outside of the firm—analogous to the foundations of Transaction Cost Economics. However, the Knowledge-Based View of the Firm is currently void of any specificity regarding the general forms that these alliances assume and how these forms then affect knowledge transfer. This work may provide a basis to frame this specificity, thereby contributing to, and possibly extending, this foundational theory of knowledge management.

ENDNOTES

1 For the remainder of this article, the term "network" will be used to designate an inter-organizational community of practice consisting of more than two organizations. Most of the logic used to develop arguments in this article are common to both inter-organizational as well as inter-personal communities of practice. Where specific logic or research applies to one or the other, these differences will be highlighted.

2 The author acknowledges that while other configurations of inter-organizational networks may exist, these networks are com-

mon in practice and three configurations have already received significant research attention.

3 A complete development of these propositions is included in Priestley (2004).

This work was previously published in the *Encyclopedia of Communities of Practice in Information and Knowledge Management* edited by E. Coakes and S. Clarke, pp. 307-316, copyright 2006 by Idea Group Reference (an imprint of IGI Global).

Chapter 4.36
Intranet Use and the Emergence of Networks of Practice

Emmanuelle Vaast
Long Island University, USA

INTRODUCTION

Communities of practice (CoPs) are key to today's knowledge management (Schultze & Leidner, 2002; Von Krogh, 2002). Moreover, the capability of exchanging professional knowledge beyond distance has become a strategic asset for innovative firms. How can members of local CoPs exchange knowledge with remote colleagues and create networks of practice (NoPs)? This article contends that the use of information technology (IT), and more specifically, of intranet systems, is especially suited to link local CoPs to an overall network of practice.

BACKGROUND

Communities of practice are social groupings whose members work in the same material context, interact frequently, acquire common knowledge, and experience similar professional concerns (Brown & Duguid, 1991; Lave & Wenger, 1991; Wenger, 1998). Members of CoPs work together and achieve activities that are for some similar and for others complementary (Gherardi & Nicolini, 2000). As they share the same work environment, they have frequent occasions to discuss directly about their job and unusual issues (Orr, 1990). Communities of practice unfold from a shared situation that creates a context favorable to direct encounters, mutual assistance in practice, and collective goals (Iverson & McPhee, 2002). Even though members of a CoP may not spontaneously name their workgroup a community, they usually acknowledge their membership to their occupational group and value its rules and principles.

CoPs display three distinguishing features: mutual engagement, joint enterprise, and common repository (Wenger, 1998).

- Mutual engagement: People join a CoP by committing themselves in actions whose meaning is mutually negotiated. Members of a CoP are related to each other through their mutual engagement in social practices.

- Joint enterprise: The community exists and provides social support and identity to its members to favor the achievement of common goals. These objectives may be explicit or not, officially defined or not, but members of the community engage themselves to complete them.
- Common repository: Over time, shared practices, repeated interactions, and the emergence of a shared culture provide traces of the community. Its members may refer to a common repository to deal with daily or more unusual issues. This repository may be material and concrete (files, forms) or more intangible (routines, specific idioms).

The network of practice extends the notion of CoPs beyond geographical distance. NoPs relate local CoPs whose respective members share occupational competences, job duties, and tasks, but who do not directly interact because of geographical distance (Brown & Duguid, 2000, 2001). As the literature on this notion is extremely recent, the appellation has not been stabilized yet. Some refer to "constellations of practice" or to "virtual communities of practice" (Gherardi & Nicolini, 2000). This article relies on the notion of "network of practice" as the most direct extension of CoPs beyond geographical distance. This phrase also explicitly accounts for the practice foundation of both communities and networks of practice.

People who are not collocated and do not necessarily know each other, but still achieve the same kinds of activities and experiment with similar identification processes belong to an NoP (Vaast, 2004). The relationships among members of an NoP are looser than the ones that characterize CoPs. Members of the NoP can nevertheless exchange on occupational issues. Although each local community displays idiosyncratic features, the overall network is characterized by shared knowledge, culture, and patterns of action. To some extent, the NoP also experiments mutual engagement, joint enterprise, and common repository.

The ways in which local CoPs may get connected to each other and favor the emergence of an NoP are, however, anything but obvious. Given that CoPs rely heavily on the sharing of a material context and on situated recurrent direct interactions, how may these local CoPs get connected into a network of practice?

It has been proposed that specific IS may favor CoPs (Brown, 1998) and may help spread knowledge among communities (Pan & Leidner, 2003). More specifically, the use of intranet systems seems especially suited to relate communities and networks of practice (Vaast, 2004).

INTRANETS, IDEAL TOOLS FOR COPS AND NOPS

Intranets are internal networks based on Web standards that aggregate and integrate various computing applications, such as e-mail, databases, groupware systems, or forums (Bansler, Damsgaard, Scheepers, Havn & Thommesen, 2000; Curry & Stancich, 2000; Ryan, 1998). Since 1995, intranets have represented a major growth area in corporate computing thanks to the availability of standard network technologies like Ethernet, TCP/IP, Web browsers, and servers. They have become increasingly more sophisticated and have integrated dynamic databases and various occupational applications. Intra-nets are private networks that favor flows of information and applications among members of an organization or parts of it (Newell, Scarbrough & Swan, 2001). Specific groups may implement and appropriate their own intranet, and protect it with passwords and various levels of security. Moreover, intranets may easily be customized to various contexts and end-user needs.

Key features of intranets seem appropriate to fulfill the needs of CoPs and NoPs:

Interoperability: Based on universal Web standards, intranets connect local computing networks and unify multiple software systems. Interoperability is useful to connect various local groups, to create room for communication, and to share applications among members of diverse communities.

Cost- and time-efficiency: The wide availability of standard TCP/IP protocols and of other network standards have recently made the implementation of intranets easy, fast, and reasonably priced. Basic intranets only require the availability of one server and of local computers equipped with a browser and connected to the network. Thus, even informal communities may implement and appropriate their own intranet. This ensures that the specific needs of occupational groups are taken into account in the system.

Flexibility: Typical of the new generation of information systems, intranets are also highly flexible and may include multiple applications. IT professionals as well as end-users may thus customize them to take into account the specific needs of their occupational groups. Flexible intranets may also be transformed and enriched over time. As agents become more familiar with the network, they can upgrade or introduce changes. Moreover, the flexibility of intranets makes it possible to adapt them, along with the emergence of an NoP from local CoPs. In particular, as the NoP emerges, communication features (through e-mail, FAQ or forum systems, chat) may become increasingly critical to create and maintain links among local communities.

Privacy: Intranets are private networks. Their design and architecture restrict access to authorized users. For instance, firewalls screen requests to the servers to make sure that they come from acceptable domain names and IP addresses. Mobile users may access the private network thanks to secure logon procedures and authentication certificates. Various levels of confidentiality also ensure that members of CoPs feel that their computing network is to be used only by peers and that outsiders will not intrude into the most private parts of the system (such as the ones that deal with occupational applications). Moreover, access rights and authentication procedures allow for differentiated uses by localized employees. For instance, an intranet may simultaneously present information relevant to all local CoPs and include sub-parts or folders dedicated to specific CoPs. Discriminate access in and among local communities favors the exchange of information and encourages the building of trust throughout the NoP.

User-friendliness: Based on hypertext interfaces and on graphical commands, most intranet systems are intuitive to use. Thus, no matter whether end-users are computer literate or not, they can easily learn how to make good use of the resources the intranet systems provide. As human-computer interactions are made easier and more intuitive, even members of CoPs who are not familiar with computers and computing networks may nevertheless consequently spontaneously appropriate their intranet. User-friendliness also favors end-users' willingness to improve features of the system and to adapt it to fit the communication needs of the NoP.

Two Examples of Intranet Use Creating Links Between CoPs and NoPs

The following examples show how an NoP emerges from the use of an intranet system by members of local CoPs.

Insurance Company Vendors

Thirty-five hundred vendors of an insurance company were geographically dispersed and worked in local teams of about 15 people. Vendors in any one team had many activities in common with vendors in other teams, but traditionally most felt that they were in competition with other teams from the same geographical area. The central headquarters of the company introduced an intranet system dedicated to these professionals. The intranet was not widely used at first, because of limited IT competencies of salespersons and because of the perceived competition among teams. Gradually however, newcomers started to use the intranet and transmitted their expertise in browsing the intranet to old-timers. Members of local teams thus socialized around the intranet. Also, over time, the intranet was used to exchange professional experiences among local teams. It then favored the emergence of a feeling of membership to the same occupation beyond geographical distance.

Buyers of a Railroad Company

Buyers of a railroad company (about 2,500 employees working in local teams) implemented an intranet site dedicated to their work. They directly fully integrated use of an intranet into their daily business. Buyers used the intranet to order supplies and to get information about their shipments. By making it possible for distant local buyers to aggregate their orders, use of the intranet reinforced a pre-existing trend towards the greater centralization of procurement. It also deeply affected work processes and tasks: buyers' practices became more transparent to the other departments of the railroad company. The intranet also made buyers become more aware that, even though they worked in dispersed local services, they all belonged to the same occupational group. Finally, exchanges of experiences and electronic messages resulted in new communications among distant colleagues and favored the exchange of professional experiences and mutual learning.

THE USE OF INTRANETS RELATES COPS AND NOPS

The use of intranets favors the overlapping of local CoPs. When members of various situated CoPs appropriate an intranet system, they become aware that their occupational group is not restricted to their local community. Thanks to common repositories, shared databases, and the possibility to exchange electronically, members of different CoPs start interacting with remote colleagues. Intranet systems allow members of distant communities who share professional concerns to exchange knowledge and experiences with each other. Local communities remain geographically separate and their respective members do not interact directly, but the use of an intranet contributes to the overlapping of local CoPs and to the emergence of NoPs, as it increases the visibility of shared practice and favors more frequent electronic communications.

Furthermore, the availability of an intranet dedicated to a specific occupation favors identification to this occupation thanks to the external and internal recognition of the work accomplished by these professionals. As the intranet is visible (if not entirely open, because of security issues) to the overall organization, it publicizes the occupation throughout the organization. On the other hand, the availability of common information and applications increases the feeling of occupational membership by members of local CoPs and thus also increases the internal recognition of the occupation.

Specific features of intranets strengthen the links among CoPs and favor the emergence of NoPs thanks to the geographical extension of mutual engagement, joint enterprise, and shared repertoire from the community to the network level. Table 1 presents these features.

FUTURE TRENDS

Managers should be especially careful in their attempt to implement and manage intranets to relate CoPs and NoPs. In particular, managers have to deal with three delicate dilemmas: initiative vs. control, sharing vs. competitive emulation, and official vs. emergent processes.

Table 1. Three dimensions of CoPs and NoPs favored by intranet use

	Intranet Applications and Features	***Links Between CoPs and NoPs***
Mutual Engagement	**Repertory:** Index of all users of the intranet, of all members of the profession.	Access to all members of the profession beyond geographical distance. Repertory with name, phone number, e-mail, localization, competences.
	Forum: Discussion application where any end-users freely ask questions, answer, and react.	Discussions on occupational topics taking place at the level of the NoP, and not just of the CoP. Complementary to direct conversations.
	FAQ: List of answers to usual questions. Answers made by experts on covered topics.	Members of local groupings have access to competent and validated knowledge from experts from the whole network.
	E-mail system: Link from the intranet to the e-mail system.	Members of local CoPs may electronically get in touch with remote colleagues. Related to the repertory feature.
Joint Enterprise	**Homepage:** First page of the site that provides information on the site and links to applications.	Presentation of the overall purpose of the work of local CoPs and NoPs. General information on the CoPs and the NoP.
	Occupational applications: Migration of these applications to the intranet.	Members of local CoPs accomplish parts of their job by using the intranet. Nourishes sense of commonality of work throughout the NoP.
	Newsletters: Updated news of interest to end-users. Usually with comments on the news.	Members get quick information regarding their occupation and interpretation of the information by competent members of the NoP.
Shared Repertoire	**Documentation:** Written official, technical, or professional documentation of interest to members of the occupation.	Unique point of entry to exhaustive and up-to-date documentation for all members of the NoP. Sharing of documentation at the level of the NoP and not only of the CoP.
	Databases of experiences: Static or dynamic databases of accounts of experiences by members of the profession.	Access to experiences from all over the NoP. Members of local CoPs get to know what their remote colleagues did. Sharing and mutual enrichment of experiences.
	Shared agenda: As in a groupware system, link to shared agenda of the overall NoP.	Beyond geographical distance, all members of the network get informed of common events and may take part in them.
	Experts: Experts on various topics offer concrete advice on the intranet.	Identification of experts from the whole network and not only to local experts. Access to the best advice on specific topics at the network level.

Defining the intranet too tightly and preventing the expression of local initiatives presents obvious drawbacks, as members of CoPs will not appropriate systems that are imposed on them and that they are unable to customize. However, if too much room is left for local initiatives, multiple fragmented intranet sites may be created which do not favor the establishment of links among CoPs. Alternate phases in the management of the intranet may thus prove useful to deal with this dilemma between initiative and control. Initially, light management—as well as relative freedom of implementation and use—favors the appropriation of the intranet. Later, more control encourages expected positive outcomes at the level of the overall NoP.

The sense of community in CoPs and NoPs provides support to their members, but it does not always encourage the search of improved practices or new knowledge. Healthy emulation among members of CoPs thus fosters the continuous improvement of work process and the pursuit of innovation. On the other hand, leaving too much room for competition and for the expression of political struggles in the CoPs or the NoPs is detrimental to the sharing of valuable knowledge. It therefore seems important to ensure that a basic level of knowledge, practices, and rules are established at the network level to make the dialog among local communities possible and to provide incentives for competition and sharing throughout the NoP, notably through different sections of the intranet.

The official management may be unaware of emergent and improvisational dynamics of change that contribute to the richness of real-world practices. The lack of official support, however, weakens the legitimacy and visibility of local CoPs or of the overall NoP. Coaches at various levels therefore appear as useful intermediaries between informal workgroups and the management. They make it possible to connect CoPs, NoPs, and the official management of the firm. Coaches may also help deal with the two preceding dilemmas. In particular, they may decide when and how to introduce more control or more freedom in the management of the intranet. They may also know how to favor the sense of community and the emulation among members of the network thanks to initiatives on the intranet.

CONCLUSION

Intranet features and use constitute useful links between CoPs and NoPs. They make their users aware that, beyond geographical distance, they belong to an overall occupational network. Intranet use also makes it possible to store and exchange information throughout the network and to improve professional practices.

One would expect these occupational networks to expand even more as technologies such as extranets become more available. The extension of networks of practice from the intra- to the extra-organizational level will undoubtedly present new challenges and opportunities to knowledge management.

Chapter 4.37
Knowledge Exchange in Networks of Practice

Robin Teigland
Stockholm School of Economics, Sweden

Molly McLure Wasko
Florida State University, USA

INTRODUCTION

The concept of a community of practice is emerging as an essential building block of the knowledge economy. A community of practice consists of a relatively tightly knit group of members who know each other, work together face to face, and continually negotiate, communicate, and coordinate with each other directly. The demands of direct communication and coordination limit the size of the community, enhance the formation of strong interpersonal ties, and create strong norms of direct reciprocity between members (Brown & Duguid, 2000). These communities develop through the mutual engagement of individuals as they participate in shared work practices, supporting the exchange of ideas between people, which results in learning and innovation within the community (Brown & Duguid, 2000). However, typically not all of an organization's relevant knowledge resides within its formal boundaries or within its communities of practice. To remain competitive, organizations need to ensure that new knowledge found in the external environment is integrated with knowledge that is found within the firm (Cohen & Levinthal, 1990). Organizations must rely on linkages to outside organizations and individuals to acquire knowledge, especially in dynamic fields where innovation results from inter-organizational knowledge exchange and learning (Cohen & Levinthal, 1990).

BACKGROUND

Current research has focused on the role of communities of practice for encouraging knowledge exchange and innovation within organizations; however, we know much less about the role that members of communities of practice play in creating linkages to external knowledge sources. Previous research has found that organizational members may simultaneously be members of a community of practice as well as members of broader occupational communities (Van Maanen & Barley, 1984). These individuals perform the dual roles of generating local knowledge within an organizational community of practice while providing linkages to knowledge and innovations outside of the organization. These inter-organizational networks have been referred to as networks of practice. Networks of practice are social structures linking similar individuals across organizations who are engaged in a shared practice, but who do not necessarily know one another (Brown & Duguid, 2000). Although individuals connected through a network of practice may never meet one another face-to-face, they are capable of sharing a great deal of knowledge and may play a vital role in a firm's ability to acquire new knowledge.

While the participation of individuals in networks of practice is not a new phenomenon, the ability to access these networks has increased due to recent advances in information and communication technologies. Previous efforts to interact with others outside an organization's legal boundaries were often fruitless since they could be time-consuming or cumbersome, and individuals may not even have known whom to contact or how to find a relevant person. Furthermore, if management did not provide the resources to attend external conferences or other events, finding other like-minded individuals with whom to discuss work-related problems often proved difficult. However, communication technologies, such as cell phones, e-mail, IRC, chat rooms, bulletin boards, and so forth, have reduced the costs of informal inter-organizational communication. As a result, individuals may now easily access and discuss their work tasks with others outside their organization. These informal interactions are valued and sustained over time because the sharing of knowledge is an important aspect of being a member of a technological community or network of practice (Bouty, 2000).

Sharing knowledge across external organizational boundaries poses significant challenges to organizations attempting to manage their knowledge resources (Pickering & King, 1995). Through external sources, individuals gain access to knowledge not available locally and can interact informally, free from the constraints of hierarchy and local rules. However, accessing knowledge from external sources usually involves a high degree of knowledge trading and reciprocity. In order to receive help, individuals must be willing to give advice and know-how as well, some of which company management may consider proprietary (von Hippel, 1987). Of special interest to management is that individuals generally participate in networks of practice based on their own personal biases and preferences for others as opposed to what the formal organization dictates, and as a result, they may be exchanging knowledge with others who are working for direct competitors (Schrader, 1991). This makes the study of networks of practice of prime interest for researchers and practitioners.

PREVIOUS RESEARCH RELATED TO NETWORKS OF PRACTICE

Networks of practice are not a new phenomenon. They have existed for hundreds of years and have played an important role in the diffusion of knowledge through society. For example, the well-known term, invisible colleges, dates back to the 1640s when a group of 10 men who were well-educated within one field would meet informally in the taverns of London. These meetings later developed in 1660 into the Royal Society, the oldest scientific society in Great Britain (Price, 1963; Tuire & Erno, 2001). While there is considerable previous research on inter-organizational informal networks under a variety of names—such as scientific communities (Knorr-Cetina, 1981;

Polanyi, 1962), co-citation networks (Usdiken & Pasadeos, 1995), invisible colleges (Crane, 1972), epistemic communities (Haas, 1992; Holzner & Marx, 1979), thought-collectives (Fleck, 1935), paradigms (Kuhn, 1962), and occupational communities (Van Maanen & Barley, 1984)—a review of this literature reveals that research that explicitly focuses on knowledge sharing is quite limited. Below we present the relevant research and empirical studies that we found in our review. This research can be divided into two categories: (1) studies from the perspective of scientific communities and (2) studies from the perspective of high-technology firms.

Scientific Communities

Research on scientific communities suggests that knowledge sharing occurs between members as they engage in debate and discussion of each other's ideas and results, and through collaboration on joint research projects (Crane, 1972). Due to the universal nature of knowledge, shared language, and values within the scientific community, individuals can communicate relatively easily with one another (Tushman & Katz, 1980; Van Maanen & Barley, 1984). Thus, knowledge and innovations spread quickly across organizational, national, and cultural boundaries through these informal relationships. In many cases, these informal networks are more valuable for sharing knowledge than more formal channels, such as publications, since the results of failed experiments are rarely published, and learning about these can prevent their duplication.

In scientific communities, the central goals and values of the members are generally developed and spread throughout the network (Hagstrom, 1965). Strong norms that are well defined and socially imposed, such as reciprocity in knowledge sharing, respect for individuals' intellectual property rights, and honesty in research, facilitate knowledge exchange (Bouty, 2000; Liebeskind, Oliver, Zucker & Brewer, 1996). Trustworthy behavior and norms are enforced since the level of participation in the community is jointly determined by the community's members. Individuals who fail to follow the norms and implicit code of conduct can be excluded from participating in valuable exchanges with others (e.g., participation in research teams with leading researchers, access to the latest research findings, etc.). This exclusion can then negatively impact their career success (Tuire & Erno, 2001). As a result, the production and sharing of valuable knowledge is facilitated, allowing the frontier of knowledge to progress rapidly and at minimal cost

Structural studies of research-based communities of academic scientists have shown that these networks are generally characterized by a center and a periphery (Schott, 1988). The most important, visible, or active members are generally found in the center, and these individuals influence the direction of the development of the community's knowledge. The activities of the individuals in the core determine the community's dominating theoretical concepts, methods, and chosen research problems, which are then mediated through the community's links to individuals in the periphery (Schott, 1988). Through a process known as social contagion (Marsden, 1988), new members are socialized into the community and as such transform their personal identities, adapting their attitudes, behaviors, and values to those of the community (Holzner & Marx, 1979). Additionally, power is an integral part of scientific communities, with individuals often using knowledge strategies as components of power strategies (Holzner & Marx, 1979). Thus, the center of a scientific community is not only a realm of activity, but it also is a realm of identity and cultural values of the community (Schott, 1988; Tuire & Erno, 2001).

High-Technology Firms

Researchers have also taken the firm's perspective and focused on inter-organizational boundary spanning activity in high-technology firms. A major stream of this research began in the 1960s with an investigation into the communication patterns of scientists and engineers in R&D laboratories (see Flap, Bulder & Volker, 1998, for a review). One area within this research is why individuals communicate informally with others outside the organization. For example, von Hippel (1987) found that when specialist engineers could not find the required know-how in-house or in publications, they went outside their organization to their professional networks developed at conferences and other events. Further research has found that quite often professionals communicate with others in their professional networks in order to maintain contact with a reference group and to keep abreast of technological changes (Aiken & Hage, 1968). Allen (1970) has also found that low-performing individuals choose to go outside for help. He argues that this choice is a way to avoid paying a psychological price of loss of face that occurs when an individual asks a colleague who is not a friend for advice.

A second area of investigation has focused on the informal flow of knowledge across a firm's boundaries in a limited number of settings, such as semiconductor, specialty steel and mini-mill industry, and R&D operations (Carter, 1989; Schrader, 1991; von Hippel, 1987). This research provides evidence that participation by individuals in inter-organizational networks leads to knowledge sharing across a firm's legal boundaries that is generally not governed by firm contracts or other market mechanisms (Liebeskind et al., 1996). In many instances, this knowledge sharing may even include the exchange of confidential organizational knowledge, even with others who might even be working in rival firms (Schrader, 1991; von Hippel, 1987). Thus, it is argued that knowledge "leaks" across the firm's legal boundaries (Mansfield, 1985; von Hippel, 1988). Bouty's research (2000) raises a very interesting point though—confidentiality is socially constructed, and as one of her interviewees noted, there are "open secrets." Research by Jarvenpaa and Staples (2001) further touches on this aspect of socially constructed confidentiality since they find that the more individuals view their knowledge as personal expertise, the more individuals regard such knowledge as their own property and not that of the organization.

However, this research suggests that individuals do not just give the knowledge away to others outside their firm. Rather they consciously exchange knowledge with other carefully chosen individuals with whom they often have a long-term relation built on mutual trust and understanding (Bouty, 2000; Schrader, 1991). Research conducted by Schrader (1991) finds that individuals often expect that their chances of receiving valuable knowledge in return are likely to increase after they provide knowledge. Thus, participation in inter-organizational emergent networks results in reciprocity and dyadic exchange of knowledge (von Hippel, 1987), with knowledge sharing viewed as an 'admission ticket' to the ongoing 'back room' discussions within professional networks (Appleyard, 1996).

As a result, participation in inter-organizational networks leads to knowledge leaking in at the same time as it leaks out of the firm (Brown & Duguid, 2000). Research on the relationship between this knowledge exchange and performance at any level, however, is scant. One of the primary reasons is that it is very difficult for firms to manage and evaluate the benefits since it occurs "off the books" (Carter, 1989). Secondly, data regarding the sharing of potentially firm proprietary knowledge are difficult to collect due to their sensitive nature. However, there is some initial evidence of a positive relationship between knowledge trading and firm performance (Allen, Hyman & Pinckney, 1983; Schrader, 1991), between knowledge trading and project performance (Allen, 1977), and between knowledge trading and individual performance (Teigland, 2003; Teigland & Wasko, 2003).

AREAS FOR FUTURE RESEARCH

Networks of practice are proposed to be a valuable complement to intra-organizational face-to-face communities of practice. The implication is that in order to be competitive, organizations should focus on sponsoring participation in both traditional communities of practice and networks of practice, as well as stimulating the interaction between the two. This leads to several interesting areas in need of further research. One area that deserves attention addresses the question of why individuals participate and access knowledge in networks of practice. While the research within high-technology firms provides some initial suggestions—for example, the inability to find the required knowledge in-house, the desire to maintain contact with a professional reference group or long-term relations with close ties, to keep abreast of technological changes, and even to avoid loss of face—the ability to access knowledge through weak tie connections basically requires depending on the kindness of strangers (Constant, Sproull & Kiesler, 1996).

Prior research has emphasized the importance of shared language, values, and goals, as well as long-term relations built on mutual trust for knowledge exchange. Thus, another area of research should investigate the factors that lead to the creation of these facilitators within networks of practice, especially networks sustained through electronic communication. Future research should also investigate the relationship between network structure and knowledge sharing, how network structures change over time, and how network structure influences the cognitive aspects of shared language, values, and goals.

The studies reviewed above have also provided evidence that individuals in many instances participate in the exchange of confidential organizational knowledge, often making their own decisions to share knowledge without management's consensus or even awareness. As a result, knowledge "leaks" across an organization's boundaries, indicating additional areas for future research. For example, future research could investigate the factors leading to this leakage such as "open secrets," social construction of confidentiality, expectations of reciprocity, and so forth. Another factor to be investigated is that of commitment. Just as individuals have a certain degree of commitment to their organizations, they also have a degree of commitment to their profession or occupation (Van Maanen & Barley, 1984). In some professions, the degree of commitment to the profession can be so strong that the norms of the profession transcend the norms of the employing organizations. Finally, research on the relationship between knowledge leakage and performance at all levels is scant and is in need of significant research, especially due to management's concerns relating to the "leakage" of firm proprietary knowledge.

CONCLUSION

In conclusion, the purpose of this article was to direct our attention to networks of practice since current community of practice research has focused primarily on their role for encouraging knowledge exchange and innovation within organizations. While networks of practice are not a new phenomenon, a review of previous, related research reveals that the studies that explicitly focus on knowledge sharing are quite limited. As a result, we know much less about the role that members of communities of practice play in creating linkages to external knowledge sources and how participation in networks of practice influences performance at the firm, project, or individual level. Our review of the literature has also provided us with several areas for future research, and we hope that these suggestions, along with our review, will inspire researchers to further investigate networks of practice.

ABSTRACT

Emerging agent-based systems offer a new means of effectively managing knowledge to address complex decision processes, thereby enabling solutions to many real problems that have heretofore appeared intractable. This article presents an overview of expert system and agent technologies, and shows the latter as a powerful extension of artificial intelligence for systems development. To illustrate, a system developed first using an expert system approach and then an agent-based approach is used to identify the strengths and weaknesses of the agent-based approach. Last, the practical implications of a company adoption of agent-based technology for systems development are addressed.

INTRODUCTION

Expert systems have become the most important artificial intelligence technology since the early 1980s. Today, expert system (ES) applications are found widely in business and government, as ES development techniques and tool kits have multiplied. Many of the techniques applied to expert system development can be directly applied to the newly emerging field of Knowledge Management (KM). ES technology provides powerful tools to manage knowledge/expertise within specific domains. KM is the process of creating value from an organization's intangible assets. It deals with how best to leverage knowledge internally in the organization and externally to the customers and stakeholders. The focus is on how best to share knowledge to create value-added benefits to the organization. Simply put, KM is the process of capturing collective expertise and distributing it in a manner that produces a payoff (Liebowitz, 1999a, 1999b, 2000; Liebowitz & Beckman, 1998). The expert system, which provides a software representation of organizational expertise dealing with specific problems, is a useful mechanism to accomplish the knowledge-sharing task. However, traditional expert system development techniques have several shortcomings:

i. Expert systems are typically brittle, dealing poorly with situations that "bend" the rules. Further, the components of an expert system are not typically intelligent enough to learn from their many experiences while interacting directly with users. Thus, the rules encoded initially do not evolve on their own, but must be modified directly by developers to reflect changes in the environment.
ii. Expert systems are typically isolated, self-contained software entities. Very little emphasis is placed on tool kits that support interaction with other expert systems or external software components.
iii. As the system develops, functionality increases are accompanied by an ever-growing knowledge base in which inconsistencies and redundancies are difficult to avoid.
iv. Over time, portions of the process that initially required human intervention become well understood and could be totally automated, but there is no mechanism in place to support the transition from human-activated objects to autonomous objects.

These are exactly the types of shortcomings agent technology (AT) was developed to address. Today, as the system developer chooses between tools and techniques in addressing new system requirements, careful consideration must be given to the advantages of using an expert system versus enhancing it with an agent-based approach. The objective of this study is to analyze the added value of using AT, its significant features and characteristics that distinguish them from expert systems, and its strengths and weaknesses in systems development. The concepts are further illustrated through a case study in which the tradeoffs between these techniques are explored.

AGENTS AND WHAT THEY CAN DO FOR YOU

While no standard definition of an agent has yet emerged, most definitions agree that agents are software systems that carry out tasks on behalf of human users. Intelligent agents generally possess three properties: autonomy, sociability, and adaptability.

Autonomy means that an agent operates without the direct intervention of humans and has some control over its own actions and internal state. It is capable of independent action (Wooldridge & Jennings, 1995). An agent does not simply act in response to its environment; it is able to exhibit goal-directed behavior by taking the initiative.

Sociability refers to an agent's ability to cooperate and collaborate with other agents and possibly human users to solve problems. Agents share information, knowledge, and tasks among themselves and cooperate with each other to achieve common goals. The capability of an agent system is not only reflected by the intelligence of individual agents, but also by the emergent behavior of the entire agent community. The infrastructure for cooperation and collaboration includes a common agent communication language like the Knowledge Query Manipulation Language (KQML) (Finin, Labrou, & Mayfield, 1998) or the Foundation for Intelligent Physical Agent (FIPA) Agent Communication Language (FIPA, 2000).

Finally, adaptability refers to an agent's ability to modify its own behavior as environmental circumstances change. An agent learns from experience to improve its performance in a dynamic environment. That learning can be centralized, as performed by a single agent without interaction with other agents, or decentralized, as accomplished through the interaction of several agents that cooperate to achieve the learning goal (Cantu, 2000).

Agent technology represents a new and exciting means of decomposing, abstracting, and organizing large complex problems. Agents, as autonomous, cooperating entities, represent a more powerful and flexible alternative for conceptualizing complex problems. As attention is increasingly placed on distributed applications like mobile and Web-based systems, applications will not necessarily run from a central location. Communications can be costly in such environments. Direct routing of data to the recipient must be fast and efficient to make additional bandwidth available to others. Agent architectures provide a template for a distributed architecture that lends itself to many of these emerging applications. Agents can be used as mediators between heterogeneous data sources, providing the means to interoperate, using ontologies for describing the data contained in their information sources, and communicating with the others via an agent communication language (Broome, Gangopadhyay, & Yoon, 2002).

For problems characterized by dynamic knowledge, it is infeasible to predict and analyze all possible interactions among modules at design time. Flexible interaction among agents at run-time enables an agent-based system to effectively handle dynamic, unpredictable knowledge. Although knowledge of some problems is dynamic, the change is often local, affecting a subset of requirements. Therefore, some agents can be designated to deal with the dynamic knowledge of a problem, and the functionality of those agents can evolve, reflecting the changes encountered.

The inherent autonomy of agents enables the agent-based system to perform its tasks without direct external intervention. Agents cannot only react to specific events, but can also be proactive, polling the environment for events to determine the proper action in a given circumstance. Despite the increased level of autonomy in an agent-based system, however, the system itself may not be able to automate all levels of intelligent activity. Human users may be required to perform higher-level intelligent tasks. An intelligent distributed agent architecture that allows flexible interactions among participating agents maps well to applications, like expert systems, that require seamless integration with humans. Further, agent technology offers mechanisms for knowledge sharing and interoperability between autonomous software and hardware systems characterized by heterogeneous languages and platforms. Agents can be used as mediators between these various systems, facilitating interoperability.

ENHANCING EXPERT SYSTEMS WITH AGENT-BASED SYSTEMS

One way to better understand AT is to compare it with the more widely used expert systems. This does not imply that ES technology is obsolete or that ES development has nothing in common with agent-based system development. Nevertheless, in general there are some important distinctions between ES and agent-based systems, which make the latter ideal for integrating individual ESs with other ESs and other system types. Probably the most important distinction is that expert systems rely on the user to initiate the reasoning process and to accomplish any action associated with the recommendations provided by the system (Yannis, Finin, & Peng, 1999). The integration of human interaction, then, is assumed and has been greatly facilitated by development tool kits and environments. Agents, on the other hand, are inherently autonomous. That does not mean that the integration of human interaction is necessarily complex. The human is simply another agent in the society of agents. While the user roles vary dramatically between the two paradigms, both readily accommodate human interaction.

Another important distinction is that expert systems have a fixed set of rules that clearly define their reasoning process, while agents interact with their environment and adapt to new conditions. Thus, an application that characteristically incorporates dynamic changes in its data and rules is more naturally accommodated by agent-based techniques. Further, the expert system's knowledge base impacts the modularity and scalability of the system. As new functions are introduced into the system, the central knowledge base grows increasingly large. New rules risk conflicts with old, and changed rules potentially impact more functions than the developer may have planned. Agents, on the other hand, are extremely modular, like self-contained programs that can readily be reused across applications.

Finally, the social interaction inherent in agents facilitates mobile and distributed systems, with formal standards in place outlining interfaces between agents assumed to be heterogeneous in design. Expert systems, on the other hand, are fundamentally built as a cohesive product with a single overarching goal. Despite early emphasis on linking knowledge bases and integrating expertise, those goals are rarely achieved, perhaps because of the issues of combining knowledge bases without the benefit of a standard interface technique. Further, the system components are rarely reused outside the system for which they were built. In fact, it is quite common to throw away one prototype and completely rebuild the next version from scratch. Thus, tools are built with an emphasis on rapid prototyping rather than on facilitating component reuse.

AT WEAKNESSES

Most AT weaknesses can be traced back to lack of maturity. While agent concepts were under discussion as far back as 1985 (Minsky, 1985), applications have been slow to develop, due in part to a lack of mature system development tool kits that enable agents to represent and reason about their actions. A number of systems are now available or under development (Barbaceanu, 2001; Traverse, 2001), but they still suffer from a general immaturity.

A second weakness is the lack of software engineering techniques specifically tailored to agent-based systems. Although there are software development techniques such as object-oriented analysis and design, the existing approaches fail to adequately capture an agent's flexible, autonomous problem-solving behavior, the richness of an agent's interactions, and the complexity of an agent system's organizational structures; thus they are unsuitable for agent-based systems. If agents are to realize their potential, it is necessary to develop software engineering methods appropriate for developing such systems (Wooldridge, Jennings, & Kinny, 2003).

A third weakness is the general difficulty associated with decomposing goals and tasks in ways that balance the computation and communication requirements, avoid or reconcile conflicts, and still achieve the initial objective. Finally, the issue of privacy is particularly relevant for a system in which software components act independently across a distributed environment. While standards are under development for insuring that agents are locked out of systems where they are unwelcome, such standards generally require cooperative agents that do not intentionally attack an unreceptive host. As discussed by other authors (Lu & Guimaraes, 1989), whether or not to use ES technology in systems development is one major consideration. Once that decision has been made, various ES development approaches must also be considered (Yoon & Guimaraes, 1993).

Last, as the previous discussion indicates, the software developer must consider numerous issues in determining whether an agent-based approach is appropriate for a given application. In the final analysis, the system requirements must drive these choices. To illustrate the choice of using an agent-based approach over a strictly ES-based approach, a case study is presented next.

REVERSE MORTGAGE ADVISOR (REMA) CASE STUDY

REMA Background

A reverse mortgage is a special type of home loan that allows a homeowner to convert the equity in his or her home into retirement income. The equity, built up over years of home mortgage payments, can be paid to the homeowner in a lump sum, in a stream of payments, or a combination of the two. Unlike a traditional home equity loan or second mortgage, repayment is not required as long as the borrowers continue to use the home as their principal residence (HUD, 2001). While reverse mortgages have long been seen as a means of increasing the income of the poor or elderly, they have more recently been proposed as a mechanism for tapping home equity for a variety of options and at various stages in the life cycle (Rassmussen, Megbolugbe, & Morgan, 1997). In either case, "because each reverse mortgage plan has different strengths — and because fees and fraud can catch unsuspecting customers — experts say seniors should either shop smart with these tricky loans or not shop at all" (Larson, 1999). The Internet already plays an important role in supporting the dissemination of information about reverse mortgages. In an effort to increase public awareness of this unique loan opportunity, federal regulators, consumer advocates, and loan companies have all developed Web sites (AARP, 2001; FannieMae, 2001; HUD, 2001; Reverse, 2001) to supplement the publications and training currently available through more traditional media. Such Web sites provide information on mortgage options and sources, answers to frequently asked questions, and even "calculator" functions to help "shoppers" estimate the amount of loan for which they are eligible. The use of Web sites, however, can be quite daunting, particularly for the potential reverse mortgage client who is over 62 and of limited income. The REMA project was initiated to increase the accessibility of reverse mortgage information.

REMA I: A Traditional Expert System Approach

REMA I is an expert system designed to provide a structured approach to determining whether an individual qualifies for a reverse mortgage. Unlike the traditional Web site, users are not left to their own devices as they sort through information to better understand their loan options. Instead, REMA I provides advice on Web sites to visit and recommended loan types. It is meant to supplement the Web-based technologies that precede it.

System Architecture

REMA I was developed using Multilogic's Resolver® and Netrunner® tools. Resolver® is a knowledge-based system development tool that combines a powerful rule editor with a flexible visual decision tree interface and inference engine. While it supports backward and forward chaining, linear programming, fuzzy logic, and neural net reasoning, REMA used the default goal-driven backward chaining technique. Resolver® greatly facilitated the coding process, supporting not only the encoding of the initial logic representation, but the debug process as well. Once REMA was developed, the executable was ported to Netrunner®, the engine that supports Web-top publication of Resolver® applications. Figure 1 provides a conceptual illustration of the final application, though in fact, the knowledge base and inference engine are located in Resolver® and their output is located in Netrunner® at the time the application runs. The decision process was initially represented as a decision tree. One branch of that tree is depicted in Figure 2. The decision tree was then converted into a series of 34 "if-then" statements, similar to the sample rule in Figure 2. Each of the 34 rules resulted in the recommendation of one or more of 16 possible outcomes. The knowledge base represents the 34 rules the experts follow when providing advice to potential reverse mortgage consumers.

Queries provide links to local Hypertext Markup Language (HTML) files that provide reverse mortgage training. Those files may, in turn, reference additional information in HTML files at other sites provided by government agencies, consumer advocates, or loan companies. Those links are provided to the Web server through Netrunner®.

System Interface

Figure 3 illustrates a sample interface screen used to gather input for the system. Note that in addition to providing answers to fixed questions, the user may choose to view hypertext about home ownership issues (as illustrated in the bottom

Figure 1. REMA architecture

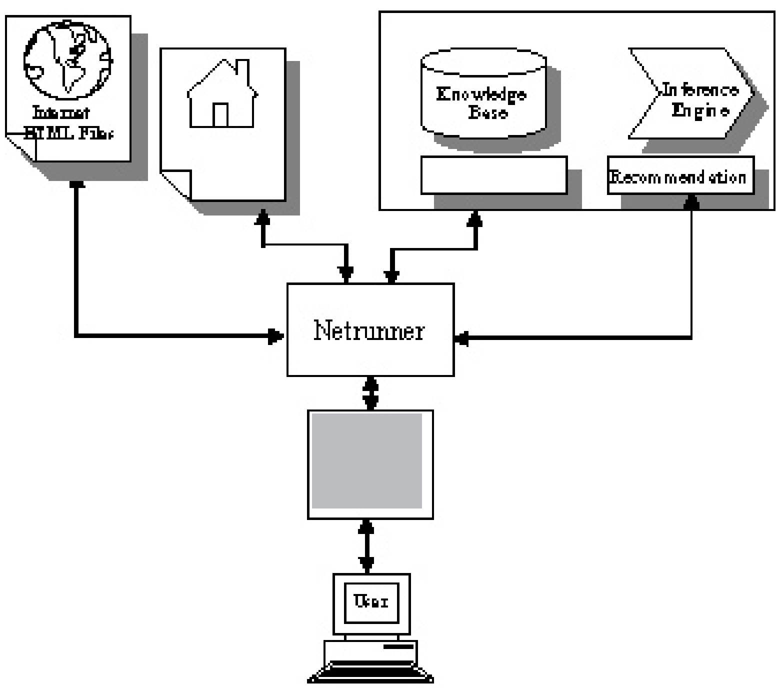

Figure 2. Decision tree illustrating generation of one of REMA's decision rules

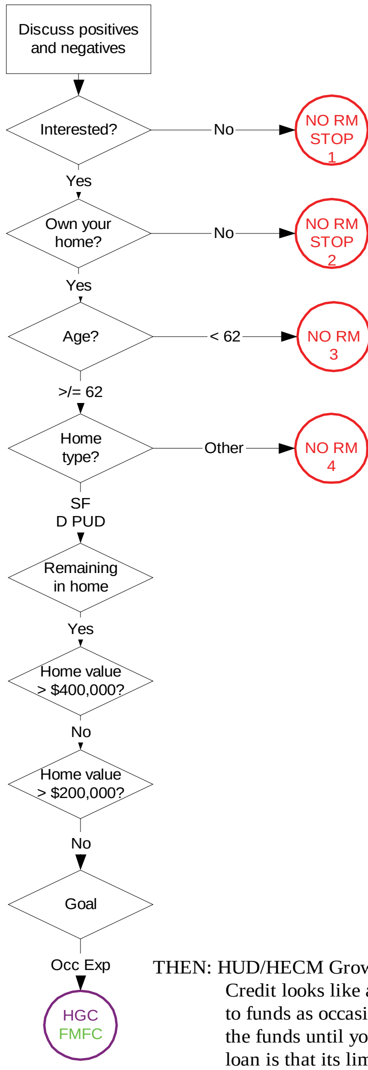


RULE NUMBER: 12

IF: What [type of home] do you own? Single Family Dwelling OR Detached Planned Unit Development

and Do you hope to [remain] in your home for the rest of your life? Yes

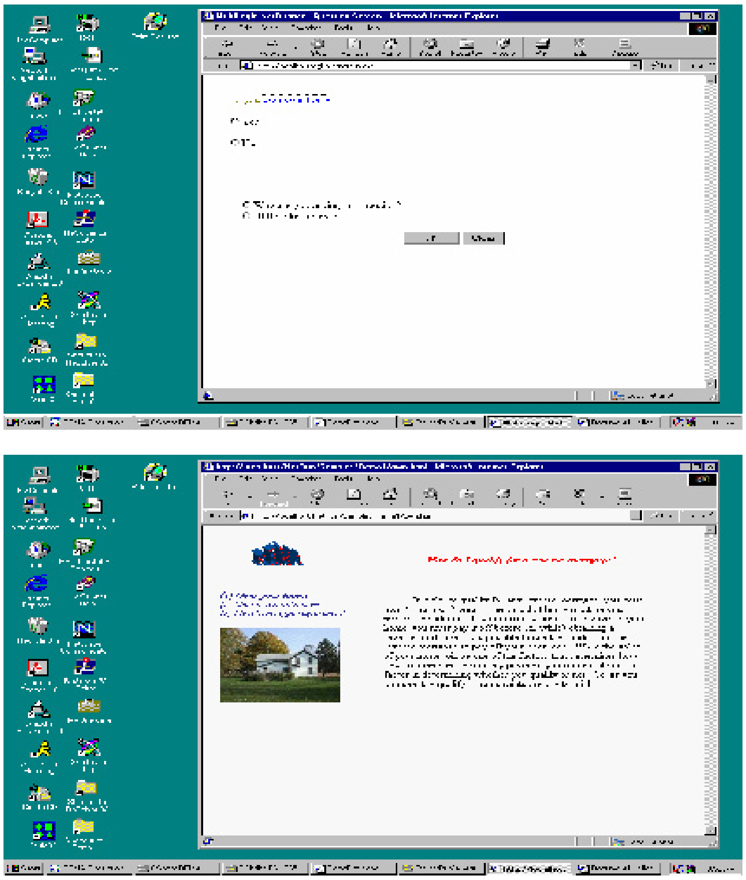
and What is the approximate [value of your home] UNDER $200,000

and Which [goal] most accurately describes your objective in seeking out a Reverse Mortgage loan? I need help when occasional expenses arise that I can't meet.

THEN: HUD/HECM Growing Credit Line: The HUD Growing Line of Credit looks like a good option for you. It will give you access to funds as occasional expenses arise. You don't pay interest on the funds until you actually use them. A nice feature of this loan is that its limit automatically increases as you grow older. That makes the HUD loan a particularly nice option.-Confidence = 8/10

and FANNIE MAE Fixed Credit Line: Fannie Mae's Fixed Line of Credit looks like a good option for you. With this loan, you will have access to funds as you need them, but you won't have to pay interest on the funds until you actually use them....-Confidence = 6/10

Figure 3. The top screen illustrates a query screen used to gather input. The bottom screen illustrates the results of selecting the hypertext link while viewing the query screen.



screen in Figure 3), view the rules associated with the question (by clicking on "Why are you asking this question?"), or return to a previous state by undoing the last answer. The UNDO option is useful if, for example, users find they are not old enough to qualify for a loan, but would still like to continue the analysis. The user must backtrack and modify the age answer to continue.

REMA I Shortcomings

As is common in the life cycle of an expert system, upon completing REMA I, the current system's shortcomings were identified for improvement in future iterations. The current version is clearly at an early stage of development, so it was expected that the developer would want to "grow the system" by incorporating more than the initial three loan companies selected for Phase 1. However, several of the problems identified indicate that the expert system design may not be best for meeting overall project objectives. The "build a little, test a little" approach associated with expert systems was quite useful in facilitating discussions with experts, but the outcome of those discussions indicates an alternative design option should at least be considered before moving to the next development phase.

First, beyond the original assessment of loan qualifications, a cost-benefit analysis is the primary basis for selecting the optimal loan type. While many of the rules for determining whether a user qualifies for a given loan are easily expressed in symbolic terms, the cost-benefit analysis is a computational rather than symbolic algorithm. In order to take full advantage of the Resolver□ tools, the cost-benefit analysis was replaced with a number of rules-of-thumb. For example, if the applicant's home is very expensive, the Freedom plan is usually best. Otherwise, the HUD and FannieMae options are best. One problem is that the concept of "expensive" varies from state to state. The REMA I rules were stated crisply (with "expensive" arbitrarily set to $400,000, for example), and at a minimum should be replaced with fuzzy rules. Ideally, however, the exact loan size, interest rates, application fees, and so forth should be used to provide accurate assessments. These inaccuracies must be avoided in future developments. In some cases, systems (like FannieMae's MorNet) are available to compute exact costs and benefits. While the original objective of the project was not to replace these previously developed computational systems, but to augment them with a training system, the longer term objective should most assuredly move toward a combination of the two types of systems. Otherwise, the advice portion of REMA will be inaccurate, which could have adverse legal implications. An agent-based design would more naturally accommodate the seamless integration of other software packages, while expert systems have very little support for interfacing with other expert systems.

Next, in generating REMA I, the developers discovered that both the rules for providing recommendations and the Web sites used for training users were extremely dynamic. A complete redesign of the decision tree and training files was required between building the baseline system, based on books and Web site information, and the current iteration, based on discussions with the experts. It was not just because tables of costs and benefits changed, though that did cause some system reconfiguration. Additionally, over a very brief period, Congress passed new regulations regarding applicant qualification requirements; companies opted out of the list of reverse mortgage providers; other companies restructured their programs to focus on different target audiences; and as always, Web pages appeared and disappeared across the Internet without notice to the sites that referenced them. Again, expert systems technology was not meant to accommodate such a dynamic environment.

Finally, the training aspect of the system was not as powerful as one might hope. This is due, in part, to the fact that the training simply took the form of instructional text. It certainly was an improvement over the baseline, in which users were on their own to wander the Web looking for relevant documentation. Instead, REMA I focused the Web searches addressing those specific issues of which a prospective applicant should be aware. An online system of this sort, however, has the potential of being a tutor, keeping up with a user's previous searches and expressed preferences to even further tailor the training process. It has a potential for notifying the user as better options arise in this dynamic loan environment. But reaching this potential requires greater autonomy than is typical of expert systems.

The easiest choice for Phase II of system development would be to continue building the next iteration of the current expert system. The next iteration would require: (1) an update of references to outside Web sites; (2) current system assessments from experts; (3) correction of any recently modified data for the HUD, FannieMae, and Freedom Plan options currently represented; (4) incorporation of at least one new loan source; (5) fuzzification of current crisp rules-of-thumb for loan source selection; and (6) incorporation of the MorNet expert system for calculating costs and benefits for those companies it covers. The general system architecture would continue as depicted in Figure 1. However, for the reasons outlined above, instead of enhancing the current ES-based REMA, a decision was made to first explore the use of an agent-based approach to the problem.

REMA II: AN AGENT-BASED APPROACH

System Architecture

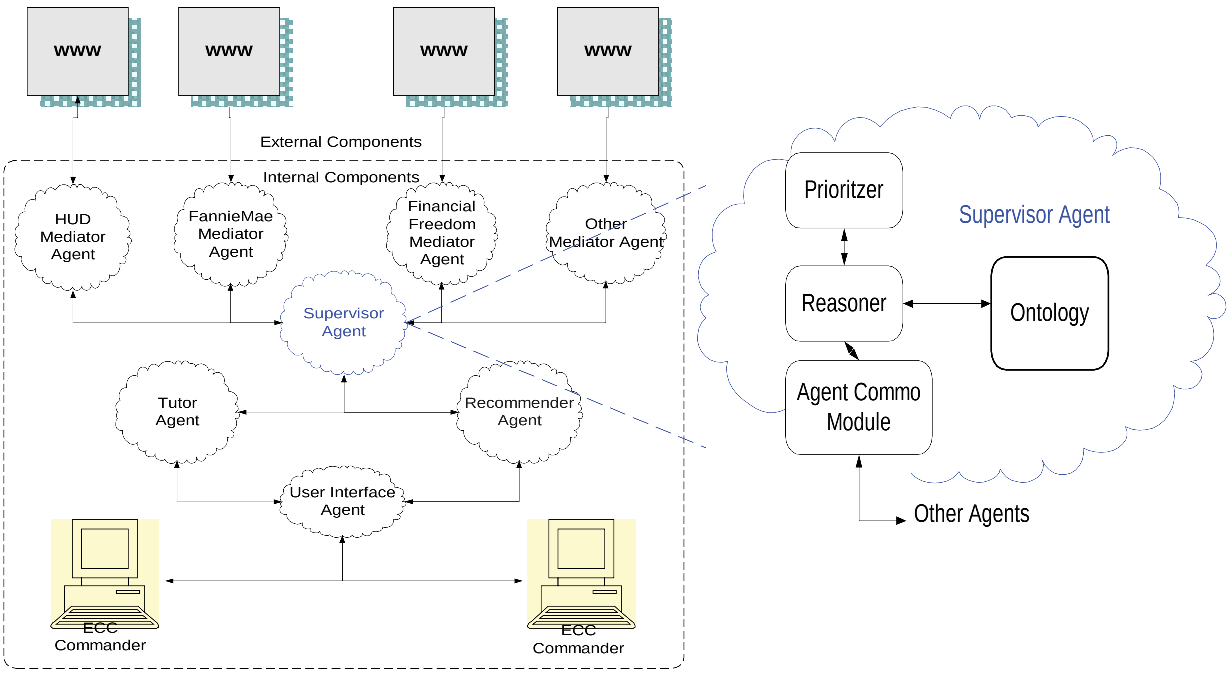
Agents are specific, goal-oriented abstractions of task requirements in systems. From the discussion of the current REMA I system presented in this article, we derive a set of system requirements that agents must implement. These are:

i. Mediating between multiple external agencies including HUD and Fannie Mae to ensure that external information contained in the system remains current.
ii. Translating between external information collected by the mediation with the external agencies (above) and the internal information on user characteristics and goals.
iii. Recommending the appropriate course of action to the user based on rules and expertise contained in the system.
iv. Interfacing with the user to guide him or her through collection of user characteristics and present the system recommendations to him or her.
v. Supervision of the entire process to ensure that the asynchronous collection of information from external agencies is assimilated and incorporated in the recommendations of the system and the information presented to the user.

The above system requirements, as derived from the design of the existing system, form the basis for an agent-based approach. The agent-based approach to REMA consists of multiple Mediator Agents, Tutor Agent, User Interface Agent, Recommender Agent, and Supervisor Agent, as shown in Figure 4.

Individual Mediator Agents are responsible for maintaining the most current information for calculating the costs and benefits of an individual company's reverse mortgage plan. These agents are responsible for interfacing with the external agencies that provide critical information about the programs available for REMA users and ensure that such information is available to the users of REMA. User Interface Agents collect and maintain information on the user's goals and personal characteristics, required for a reverse mortgage application. They are responsible for interaction with the user, and provide guided input of user goals and characteristics in addition to presenting users with the final results and recommendations of the REMA system. The User Agent receives information from the user, through the user interface, and presents user characteristics and goals to the Tutor Agent to determine which internal and external information is most required to teach the principles of reverse mortgages. A Recommender Agent incorporates user characteristics and the most recent loan company information in performing a cost-benefit analysis to determine the best loan source of those available. This information is passed back to the User Interface Agent with information on options that are available to the user given their characteristics and goals. Finally, a Supervisor Agent is responsible for the overall

Figure 4. Agent architecture for REMA



function of the agent system and performs critical meta-functions to prioritize data requests, supply the most recent loan company data, and interpret terminology from heterogeneous sources to consistent internal agents by providing and interpreting a shared ontology of concepts contained in the REMA system.

System Interface

REMA II is initialized with the user being assigned representation in the system through a User Interface Agent. This agent interacts with the user and collects information about the user through an interactive questionnaire. Information about the user is passed to the Tutor Agent who is responsible for matching the goals and characteristics of the user with information from the Mediator Agents to find the appropriate agency that may fulfill user needs. The Mediator Agents, under supervision of the Supervisor Agent, constantly and asynchronously, update their information of the most current programs that are available from the various agencies they interface with. Upon performing the matching, the Tutor Agent generates a match between the internal information provided by the user and the external information available from the financial agencies, through the Mediator Agents. These results are transferred to the Recommender Agent, which maintains the knowledge about courses of action based on specific information received by the Tutor Agent. The Recommender Agent maintains an active, in-memory representation of the decision tree illustrated in Figure 2. Upon receiving user-specific information, it can select the rules that are fired and present those rules and the associated explanations for the recommendations as the action-specific knowledge that is pertinent given the users' characteristics

Figure 5. Use-case diagram for agent-based REMA

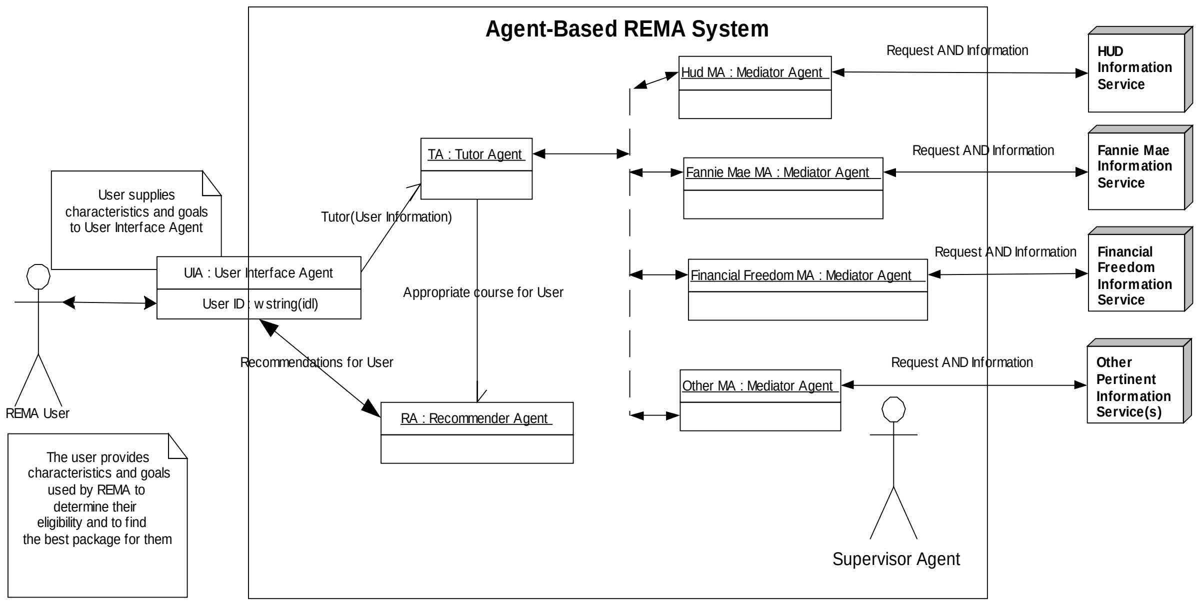


Figure 6. Sample interface screen of agent-based REMA

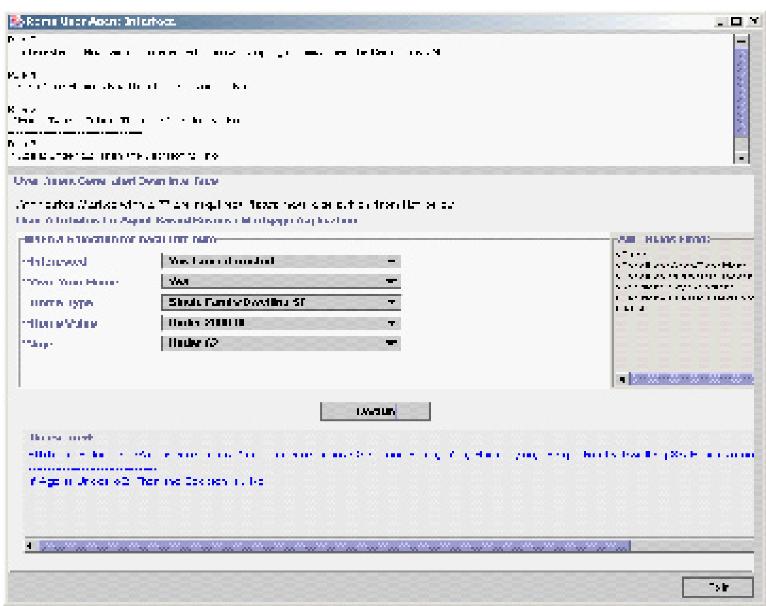

and goals. The Recommender Agent sends this knowledge, as specific recommendations for the user, to the User Interface Agent who is responsible for presenting the recommended course of action(s) to the user.

The overall flow of information and user-system interaction is presented in the Use-Case Diagram in Figure 5. The diagram shows the boundaries of the system and its interactions with external agencies, in addition to the oversight role of the supervisory agent.

Figure 7. REMA II rule in eXtended Markup Language (XML) format

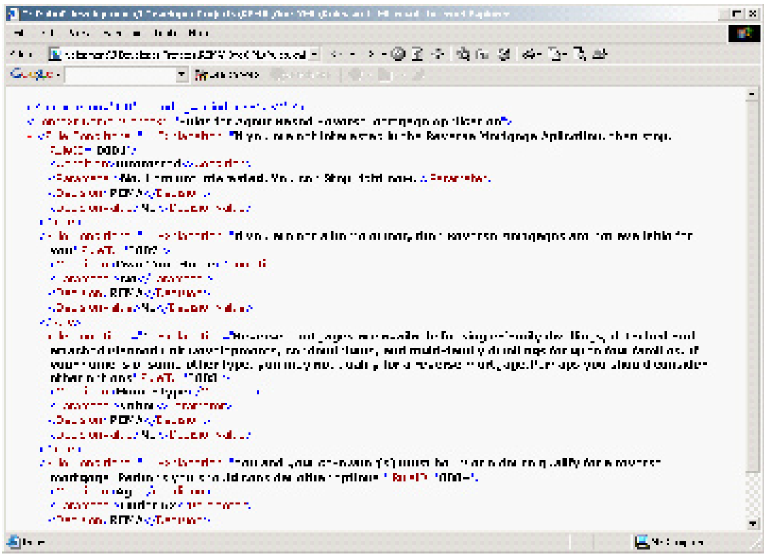

Figure 6 shows a sample screen generated for the REMA II user. The top panel shows the rules that are part of REMA II, allowing the user to gain more knowledge about the explanations offered. Each rule, as illustrated in Figure 7, contains a set of conditions and a matching result, or decision value, for the REMA application. Each rule also contains a user-friendly explanation to provide textual explanation of the rule to the user in a human interpretable manner. The User Agent Interface takes input from the user on various attributes, in terms of the parameters that are acceptable to REMA. For example, in answer to the question "Do you own your own home?," the user can only reply "Yes" or "No." After input of all required parameters, the user asks the system to advise him or her by clicking the decide button, and the rule space is searched and the result is displayed to the user.

ASSESSMENT OF ES VS. AGENT-BASED APPROACHES

ES Approach: Strengths and Opportunities

As outlined in Table 1, the enhanced expert system approach is best when meeting quick turnaround requirements. Multilogic's Resolver® and Netrunner® tools greatly facilitate the system development process, and the consistency of design further insures efficiency. The resulting system will most certainly continue to support faster decision making and improved consistency, less demand on experts, and improved public understanding of the reverse mortgage process. Further, it will continue to support direct-access local HTML files or inserting new ones. Because of its Web emphasis, the system continues to broaden the audience for reverse mortgage training over previ-

Table 1. Analysis of the strengths, weaknesses, opportunities, and threats associated with the agent-based approach and the expert system approach

	Agent Based Approach	Enhanced Expert System Approach
Strengths	Faster decision making. Improved consistency. Less demand on experts. Improved reverse mortgage understanding. Supports better focused web searches. Rules reflect changes in the environment. Other ES work more easily incorporated. Recommendations/training adapt to user.	Effective development tools. Faster decision making. Improved consistency. Less demand on experts. Improved reverse mortgage understanding. Supports better focused WEB searches.
Weaknesses	Limited sites with XML/ontology standard. Limited agent development tool kits.	Accurately addressing the cost-benefit analysis will render the expert system tools less effective. Dynamic data and rules, controlled outside. Training limited to informational text. Knowledge base isolated from WEB data. Does not incorporate other ES work.
Opportunities	Access information directly from source. Easily incorporate new training topics. Reach a broader audience. Formalize expert's process. Autonomous recommendations.	Access information directly from source. Easily incorporate new training topics. Reach a broader audience. Rapid prototype effective use of experts. Formalize expert's process.
Threats	Websites volatile, with distributed control. Changing interface standards. Insufficient training data.	Inaccurate recommendations costly. Potential legal impact from misinformation.

ous brochure and booklet techniques. Finally, its "build a little, test a little" techniques have been shown to make effective use of the limited time of experts in the field, while essentially serving to formally document a process that is not currently well documented.

ES Approach: Weaknesses and Threats

The major shortcoming of this approach, however, is that it fails to resolve the three problem issues identified in developing REMA I. While a link to MorNet will improve the computational component of system recommendations as new loan companies are added, those insertions will continue to be computational, rather than symbolic, in nature. The value of the more established tool sets associated with expert systems will be less noticeable than if the entire task were heavily symbolic in nature. Further, while this approach will incorporate changes to the current data and rules, bringing the system up to date, it does not address the fact that the rules and data will change again. The static nature of the expert system limits its ability to adapt to the dynamic reverse mortgage process it represents or the dynamic Web environment in which it resides. Its lack of advanced communication or interoperability tools limits its ability to incorporate the functionality of other expert systems or Web sites into its knowledge base. As a result, the system will require frequent manual updates or risk, providing inaccurate information that could cost its users money. Such losses may, in turn, carry negative legal implications. Finally, its lack of autonomy restricts the training function to the display of informational text rather than a full-blown tutor that learns about the user as it progresses or, on its own initiative, notifies the user of changes in loan options.

Agent-Based Approach: Strengths and Opportunities

Possessing the properties of autonomy, sociability, and adaptability, agent technology provides the potential for greatly enhancing the capabilities of the REMA system. As illustrated in Table 1, the strengths and opportunities of an agent-based system parallel in many ways those of the expert system approach. The system will most certainly continue to support faster decision making, improved consistency, less demand on experts, and improved public understanding of the reverse mortgage process. Further, it will continue to support direct access to a variety of loan sources by linking into their Web sites. Because of its Web emphasis, it continues to broaden the audience for reverse mortgage training over previous brochure and booklet techniques. The agent-based approach, however, has several additional strengths. First, it more specifically addresses the three problem areas identified at the end of Phase I:

1. Agent-based systems deal equally well with problems of a computational or symbolic nature.
2. It better addresses the dynamic nature of the reverse mortgage process. Rather than establishing fixed rules that must be intentionally modified by the developer at regular intervals, information agents are established to seek and substitute relevant parameters from regulated Web sites as appropriate.
3. The learning component of agent-based systems supports incorporating a well-designed tutoring system that is both diagnostic, discovering the nature and extent of the user's knowledge, and strategic, planning its responses based on its findings about the learner. Also, while the three alternative loan sources are, in fact, representative of the available alternatives, future work must incorporate more companies.

The agent-based approach provides a natural mechanism for incorporating new loan companies with minimal impact on previous software components. The ontology component of the supervisor agent requires updates as new loan sites are added, but it minimizes the effort in mediating between heterogeneous data sources. Finally, the autonomous nature of the agent facilitates an ongoing search for the best possible loan. Thus, the agent can provide information about a new or improved loan source without waiting for the user to think of querying for improvements.

Agent-Based Approach: Weaknesses and Threats

While agent development environments are available, they are generally not as mature as those for expert systems, so system development will generally be more time consuming. The interface to remote Web sites could be facilitated by the use of the XML standard and an ontology to resolve varied terminology across heterogeneous formats; however, these standards are relatively new, and most of the sites of interest are HTML-based instead. It will therefore be important to establish a working relationship with sites across which data is shared; otherwise, the volatility of the data and the distribution of control will render the project ineffectual. Since the standards are relatively new and not widely in force, the developer risks having a new standard move in and replace the one on which the system is based. Finally, while the agent-based approach supports the development of an adaptive tutor/advisor, most learning algorithms require large amounts of data, which may be initially difficult to obtain.

Recommendation for Next Phase of Development

Because of the dramatic increases in functionality associated with the agent-based approach, it is recommended that the fully functional system be built on the agent-based prototype, REMA II, rather than on the REMA I expert system. The only reason for selecting an expert system approach would be to support a fast-turnaround incremental improvement on the current system. Given current availability of a prototype system for immediate use, the plan that best incorporates the dynamic and heavily computational components of the advisor and the user-adaptive, self-initiating components of the tutor is preferred.

PRACTICAL IMPLICATIONS

A critical question for system development managers is, "Under what circumstances would it likely be better to use AT instead of the presently more widely used ES technology for the development of specific applications?" AT is extremely promising, and it behooves all system development managers to understand its potential and limitations and perhaps begin to experiment with AT for possible adoption in the future. However, there are limitations. There are situations where the use of AT will not be efficient in terms of system development cost and implementation time. Systems development managers must remember that presently AT is still at a relatively early stage of adoption in industry at large. The availability of systems developers competent with the technology is relatively limited. Also, there is a lack of systems development tool kits and shells, which today are commonly found for the development of ES. As discussed previously in this article, the fact that AT is useful for addressing relatively more complex application requirements makes the systems development analysis and design tasks correspondingly more complex, requiring software engineering methods that are still under development. In a similar fashion, the ability of AT to bridge the gap between distributed application components may raise questions about user privacy, data integrity, and human control over the agent-based system. Nevertheless, increasingly there are applications that will require the use of AT. The following conditions are likely to call for the use of AT in system development:

1. Applications requiring flexible decision making beyond fuzzy logic and/or the relatively strict rules required by ES.
2. Applications that require enough intelligence for direct system interaction with end users and for system learning from the experience

itself, whereby the rules will evolve on their own without the need for modification by systems developers.

3. Applications that require a flexible and complex integration of two or more ES and/or systems of other types.

As the business community puts greater importance on the role of knowledge management in capturing collective expertise and distributing it in a manner that produces a payoff, the use of agent-based technology will have increasingly significant business implications. With the dramatic increase in Internet activity over the past five years, agents can play an important role in monitoring, filtering, and recommending information, using user profiles to personalize their support. Agent Mediators can facilitate the exchange of data among heterogeneous sites, maintaining an ongoing record of variable site formats and mapping information seamlessly into a format more easily understood by their users. Network Management Agents can focus on increasing throughput and minimizing delay by adapting protocols to the current hardware and workload environment. In general, complex problems can be decomposed into smaller, segmented problems that can be more easily resolved. All of these advances open decision support and e-commerce opportunities to a wider community, and facilitate tapping more widely distributed knowledge bases to improve quality. Such advances are already within reach for many application areas. However, the ability to reach the full potential of these advances relies on continued development of software engineering methods specifically tailored to agent-based systems, software development tools, and security mechanisms that accommodate a widely distributed, mobile computing environment.

The effective use of agent technology enables developers to gain significant advantages over existing technologies in achieving their knowledge management goals. An increased level of software system autonomy limits the user burden for direct intervention and can relieve communication requirements in a bandwidth-limited environment. The distributed decision-making process can increase robustness, and because tasks are performed in parallel, overall system efficiency increases. The approach facilitates developing mediators that can integrate heterogeneous and legacy systems without requiring a single data representation structure. Further, the techniques support incremental development of complex systems via independent reusable components.

The REMA case illustrates some of the many powerful enhancements achieved by using agent techniques where expert systems were originally envisioned. To system designers/developers, one of the most compelling arguments for using only ES is the ready availability of software development tools to support this more mature development technique. Although there are many issues to be addressed for agent technology to realize its full potential, the technology has advanced at a fast rate due to the significant research effort in both academia and industry. Many of the components to build effective agents are moving beyond research communities and coming into common use in the immediate future. With their arrival we now have a powerful integrator for Web-based systems, with the more traditional types of systems (including ES) thus providing a strong infrastructure for managing corporate knowledge.

ACKNOWLEDGMENTS

The authors gratefully acknowledge: the Fannie Mae Foundation, for the grant that supported the development of the REMA I prototype; Dr. J. Liebowitz, who led that prototype development effort; and Mr. Ed Szymanoski, for his constructive review and comments on the REMA I effort.

Chapter 4.39
Knowledge Sharing in Legal Practice

Chad Saunders
University of Calgary, Canada

INTRODUCTION

Given the reliance on knowledge-based resources over traditional assets, the professional context serves as a heightened environment in which to investigate knowledge sharing. Within legal practice, the success of a law firm is connected to the firm's ability to leverage knowledge (Sherer, 1995), and this has led to a call for knowledge management to be a business imperative within legal practice (Parsons, 2004; Rusanow, 2003).

An underlying assumption within much of the knowledge management literature is that knowledge sharing is universally beneficial and to be encouraged both within and across organizations. However, in legal practice, sharing is often difficult to achieve or counter to current professional practice. This issue is most salient when considered in the context of the often-contradictory results observed by larger law firms implementing information technologies to increase knowledge sharing throughout their organization. In the remainder of this article, four perspectives that employ a logic of opposition (Robey & Boudreau, 1999) are used to explore the often contradictory outcomes observed when using information technology to increase knowledge sharing by considering factors both impeding and enhancing sharing within legal practice.

BACKGROUND

Despite the recognition of the importance of knowledge in the various professions, a deliberate effort to manage knowledge within the legal profession is a more recent development (Parsons, 2004; Rusanow, 2003).

Knowledge management initiatives are often implemented with the intent of improving aspects of the knowledge management problematic, and this is invariably associated with the implementation of information technology to assist or enable such initiatives (Grover & Davenport, 2001). Knowledge sharing has been identified as a key process in leveraging knowledge assets (Jarvenpaa & Staples, 2000; Nahapiet & Ghoshal, 1998), and within professional practice knowledge management, initiatives are often directed towards improving knowledge sharing throughout the organization (Weiss, 1999). Knowledge sharing in a legal context is typically motivated by a desire to share legal knowledge, but there is a growing interest in extending such efforts to knowledge of the client, industry, staff skills, key stakeholders, and the firm's market and financial position.

Within legal practice, inconsistent findings have been observed with respect to technology-based initiatives aimed at increasing knowledge sharing throughout the firm (Cabrera & Cabrera, 2002; Gottschalk, 1999; Hunter, Beaumont, & Lee, 2002; Terrett, 1998). For many firms the implementation of information technology represents the arrival of 'knowledge management' within the organization. This view positions information technology as a determinant or enabler of radical organizational change that once implemented transforms the organization to one where key processes such as knowledge sharing are not only possible but also inevitable. This deterministic logic of the organizational impacts of information technology has been critiqued and an alternate, more complex relationship purported between information technology and organizations that is emergent and reciprocal in nature (DeSanctis & Poole, 1994; Hirschheim, 1985; Kling, 1980; Markus & Robey, 1988; Orlikowski, 2000; Orlikowski & Robey, 1991; Schultze & Leidner, 2002; Walsham, 1993). These authors point to the possibility for different conceptualizations to the logic of determination for the relationship between organizations and technology. The logic of determination explains change as the result of variation in a set of predictor variables that account for the orderly relationships among the variables in a theoretical model; in contrast the logic of opposition is more suitable for accounting for contradictory outcomes by considering forces both promoting and impeding change (Robey & Boudreau, 1999).

Knowledge Sharing in Legal Practice

Institutional theory, organizational politics, organizational culture, and organizational learning draw upon a logic of opposition and are employed in the remainder of this article to account for the contradictory outcomes of information technology by considering the forces both enhancing and impeding knowledge sharing within legal practice. For the following discussion, these theoretical lenses are directed towards medium (300-750 lawyers) and large (greater than 750 lawyers) law firms in order to highlight the competing forces both enhancing and impeding knowledge sharing. These forces are anticipated to manifest in smaller firms, but to a lesser degree since many of these competing forces are influenced by the size of the practice, the level of geographic dispersion, the nature of the growth strategy (internal expansion or acquisition), and the nature of the competitive environment. Within the legal profession, larger firms are quickly becoming the norm as firms expand through rapid growth fueled by acquisition. Accompanying this growth is an increasing reliance on professional management beyond the traditional collegial shared management from which many of these firms originated. This tension has provided a heightened environment in which to consider the contradictory consequences of efforts to use information technology to improve knowledge sharing and a unique opportunity to highlight how alternate conceptualizations can be used to embrace these contradictions in practice.

Institutional Theory

Institutional theory points to the importance of historical and professional traditions and enduring values that are supported by the organization (Robey & Boudreau, 1999). Institutional theories have historically explained why organizational structures and values endure, despite strong reasons and efforts aimed at changing them (Robey & Boudreau, 1999).

Institutions consist of cognitive, normative, regulative structures and activities that provide stability and meaning to social behavior. Institutions are transposed by various carriers—cultures, structures, and routines—and they operate at multiple levels of jurisdiction. (Scott, 1995, p. 33)

Contemporary institutional theory exhibits a logic of opposition, recognizing that while the institutional environment presents normative forces that pressure conformity to maintain legitimacy, a wide variety of organizational responses may be manifest, and change in this context must be considered in terms of the structural factors both enhancing and impeding change (Robey & Boudreau, 1999).

Shifts in the discourses surrounding the wider institutional context of the legal profession have given rise to new conceptualizations of professionalism and partnerships. A new archetype has been proposed that characterizes professional practice through an amalgamation of components of professionalism and partnership□referred to as the P2 form to highlight the differences between the familiar M-form (Greenwood, Hinings, & Brown, 1990) and the recently proposed managerial professional business (Cooper, Hinings, Greenwood, & Brown, 1996). The P2 form emphasizes a fusion of ownership and control, where managerial tasks revolve among the owners with minimal hierarchy and strong links with clients and the local office. Managerial professional business (MPB) in contrast emphasizes effectiveness and efficiency, with client service and competition serving as the guiding force for a formalized central management team. Within the MPB form, there is increased specialization among lawyers, and integration is accomplished using hierarchy, cross-functional teams, and rules and procedures.

The increased focus on client needs while reducing forces within the firm for sharing increases the outside pressure to share. That is, clients are driving many of the knowledge management initiatives within law firms as they demand increased accountability, and are not willing to pay for 'reinventing the wheel' and are therefore demanding that firms ensure that their lawyers are sharing knowledge. From management's point of view, having the client receive mixed advice because internally the lawyers are not sharing is viewed very negatively. At the same time these clients are realizing that the firm has considerable additional knowledge that is relevant to their business so they are further demanding that the firm share that information with them. Management is eager to satisfy such requests since they wish the client to treat the firm as a 'trusted advisor' on a host of matters in a long-term relationship with the firm (Hunter et al., 2002). This produces competing demands on individual lawyers to hoard their knowledge on the one hand since they see this as guaranteeing their position within the firm by providing their specialized service to the client, while on the other hand knowing that their position also depends on how well they perform with others who also work for the same client.

The need for increased sharing usually begins with the development of a knowledge repository that is centrally administered. This is consistent with the MPB form since it assists in the goal increasing managerial influence throughout the firm. This is particularly important as firms typically consist of multiple offices of national and international affiliates. Centralized technologies based upon knowledge repositories might offer the ability to share knowledge, while at the same time affect institutional norms and cross-organizational boundaries that impede the very sharing that these technologies are intended to support. The very arrival of a specialized knowledge management group or a chief knowledge officer while demonstrating management support for such initiatives as increased knowledge sharing may also effectively separate the practicing lawyers from involvement with knowledge management initiatives within the organization.

The MPB form places significant emphasis on economic performance and efficiency, and this often conflicts with professional and personal expectations of work such as the connection to the public good or the desire for more personal time. The impinging on professional autonomy and representative democracy of the traditional P2 form conflicts with notions of hierarchical control and bureaucracy. Since the MPB form is essentially layered on top of the existing P2 form, there are inherent contradictions that arise, as these forms co-exist within the same organization.

Accounting for contradictory outcomes of information technology employing an institutional theory perspective highlights the dual consideration of the normative pressures on these organizations to not change in order to maintain legitimacy (e.g., highlighted by the factors constituting the P2 form) and forces enhancing change as in the case of the factors implicated in addressing increased pressure from clients (e.g., the MPB form).

Organizational Politics

Organizational politics draws our attention to opposing forces in the form of political resistance to change that must be balanced by negotiation and compromise; change emerges from groups with incompatible opposing interests politically jockeying for position, using information technology as a resource to such political ends along the way (Robey & Boudreau, 1999). Interestingly, it is not assumed that political conflicts can be resolved and that power struggles may be enduring aspects of the political climate. Organizations are regarded as arenas where the contributions and rewards of various parties are sometimes aligned, often misaligned, and occasionally realigned (Bacharach, Bamberger, & Sonnenstuhl, 1996). Professional management establishes an interesting power dynamic within the law firm. Traditionally, management was a shared responsibility and almost an afterthought, or at least something in addition to individual legal practices that had to be performed. The partners were essentially all at the same level, and all the other lawyers wished to be partners someday. However, formal management, while providing a central authority to facilitate sharing throughout the firm, also impedes that process by introducing a power dynamic that was not present when management responsibilities were shared. Before there was no 'us' and 'them', while now there is a clear distinction. Ironically, knowledge management in legal practice may drive a wedge between those demanding that sharing occur and those whom they wish to share (Hunter et al., 2002).

One of the underlying tenets of legal practice has been that 'knowledge is power', since progression within the firm is perceived to be based upon competitive advantage arising from withholding certain knowledge from others (Terrett, 1998). This power to essentially refuse to share was legitimated since there was a professional expectation of autonomy so one could not be forced to share. This autonomy was extends to the relationship with clients whereby individual lawyers essentially 'owned' particular clients, so there was no pressure to share with others since the individual lawyer could directly serve the needs of the client. The key metric for performance under this 'one-on-one' relationship with clients was the billable hour, and this was not negatively affected by knowledge hoarding as the client's needs were met and any inefficiencies resulting from 'reinventing the wheel' were rewarded since the lawyer was paid on a hourly basis. It is detrimental for lawyers to share under this regime since they potentially lose power and income. Incentives and metrics that focus exclusively on individual performance tend to impede knowledge sharing in this context, since they do not account for the positive externalities or recognize the additional value at the group or firm level that can result from such sharing. Consideration for metrics that encourage knowledge sharing focus on factors surrounding mentorship (e.g., student recruitment), industry-level measures that depend on the overall performance of the firm (e.g., market share), or group-level measures (e.g., customer satisfaction with legal team or peer recognition). Varied incentive structures attempt to encourage individual performance while aligning individual goals with those of the group or firm. That is, incentives make explicit the value associated with sharing among the group or firm.

The shifting power from individual lawyers to a central authority has eroded individual autonomy that has further contributed to changing power dynamics, so lawyers are now more mobile, with alternate career paths emerging apart from remaining with the firm for life by progressing to becoming a partner. In conjunction with this is the emerging practice of parachuting individual lawyers into the firm in a lateral move rather than the traditional vertical progression. These individuals are intended to bring a valuable knowledge base and a following of key clients. This climate may at first seem to not be conducive to knowledge sharing (e.g., reduced loyalty), but there may be other political forces at work. For example, attaching oneself to such 'stars' may prove extremely beneficial, and the infusion of new talent may enhance sharing as new practices are adopted.

The push from clients for increased cost accounting has shifted the legal practice of lawyers towards more attention being paid to financial cost considerations for the client and not exclusively on their legal requirements. Information technology in the form of extranets that permit secure access by clients to their ongoing legal files has tended to solidify this practice and shifted the power from the lawyers to the client, as they demand increased transparency and real-time updates on the progress of their file. A parallel power dynamic is evidenced in a reliance on information systems aimed at increasing sharing between law firms (Gottschalk, 2001; Khandelwal & Gottschalk, 2003).

The political considerations within a law firm highlight the competing forces for sharing that accompany an increased reliance on formal management. This view also points to the role of incentives in adequately addressing the positive externalities that can accompany group- and firm-level sharing while countering the individual pressures to hoard knowledge. Finally, the political perspective directs our attention to the increased pressure from clients for increased sharing to facilitate improved transparency and real-time updates, and the need for management to counter existing practices that discourage such sharing.

Organizational Culture

Organizational culture demonstrates the importance of recognizing that technology alone will not overcome resistance stemming from cultural persistence and that further steps will need to be taken to address these concerns in the long term (Robey & Boudreau, 1999). Information technologies are considered cultural artifacts that come to symbolize various beliefs, values, and assumptions (Robey & Boudreau, 1999). Three views of organizational culture have been identified: (1) integration—where culture is unified and consistent, and thus opposing organizational change; (2) differentiation—where conflicts occur at the boundaries between subcultures; and (3) fragmentation—where opposing and irreconcilable interpretations may be entertained simultaneously within and across subcultures, and thus culture is viewed as inherently ambiguous and contradictory (Martin, 1992).

The integration perspective points to areas of strong consensus where values, assumptions, and behaviors are shared, and highlights difficulties in implementing change due to cultural drag, thus producing friction between existing patterns and emerging ones (Robey & Boudreau, 1999). Lawyers are not generally viewed as great information sharers, owing to a career progression based upon acquiring a unique knowledge base and thus facilitating a culture of knowledge hoarding rather than sharing (Rusanow, 2003). Time-based billing further encouraged a reluctance to share since sharing required additional time for which the lawyers could not justify billing to clients, and lawyers were reluctant to dedicate 'non-billable' hours to sharing when they could be working for clients. Information technology in the integration perspective is therefore used to essentially force knowledge-sharing practice by 'culturing' lawyers in knowledge management (Rusanow, 2001). These efforts are then aligned with incentives that contribute to producing an essentially homogenous sharing culture for the firm over time.

The differentiation perspective suggests that even though a homogenous culture may exist within a group, there may be significant differences between groups, even within the same organization or area of specialization. Subcultures shape assumptions about what knowledge is worth managing, expectations of who must share and who can hoard or control specific knowledge, and contributes to the context for social interaction which influences how knowledge will be shared (De Long & Fahey, 2000). Subcultures have significant implications for knowledge sharing since common subcultures are essential for knowledge sharing, without which the tacit knowledge that provides the background understanding for explicit knowledge is not available (Heaton & Taylor, 2002). This implies that where practices are common, sharing can occur (Brown & Duguid, 1991). Using this perspective it is clear that even within the same firm, lawyers may not be able to share their knowledge because their areas of practice are so different. This would explain why it might be easier for lawyers to share with lawyers in another firm than with lawyers in their own firm. Sub-cultural differences are not always a threat, as such differences can also serve as the impetus for a more constructive dialogue, highlighting the complexities that arise in sharing across and even within subcultures.

The fragmentation perspective provides that any cultural symbol can be interpreted in different ways and irreconcilable interpretations can exist simultaneously (Robey & Boudreau, 1999). Even the technological artifact may embody certain cultural features that may affect the use of that technology in practice, and this can be expected to vary between individuals using the same technological artifact. Using technologies to increase sharing under the fragmentation perspective would imply that depending on how the cultural symbol of the technology is interpreted, it may increase or decrease levels of sharing. For example, if the information technology is seen as representing a centralized management culture that is divorced from the more collegial environment in which lawyers are accustomed, then this is likely to reduce sharing significantly. However, if the technology is seen to promote a customer-focused legal practice that is aligned with a preferred collegial culture, then sharing is likely to increase.

Since many of these firms have pursued an aggressive growth strategy fueled by acquisitions, the result is a firm that does not grow its own culture so much as it inherits numerous cultures from the acquired firms. Part of that acquisition is a legacy information technology situation that likely is inextricably linked with the culture of the acquired organization. Attempts to change the existing system or to introduce new systems are likely going to be viewed as a direct assault on the very culture of the firm. Such changes are also counter to the professional culture of lawyers. A collegial environment that provides the lawyer with considerable autonomy in their practice that is essentially self-regulated and underpinned with a connection to the public good and mentorship characterizes this professional culture. Any changes that adversely affect this professional culture are likely to be met with resistance. Within this professional culture are entwined legitimate legal reasons for not sharing such as protection of client confidentiality and intellectual property rights. The ability to segregate knowledge in this context can outweigh the benefits gained by sharing such knowledge with others within the firm.

Organizational culture offers considerable insight into the forces both impeding and enhancing knowledge sharing within legal practice. Multiple acquisitions and the considerable autonomy afforded to individual lawyers and offices on how they operate have left these larger firms severely fragmented. Efforts to increase knowledge sharing in this context must address the multiple cultural differences represented. By appealing to the professional cultures of these lawyers, considerable inroads can be made. The collegial context in which they were trained and the reliance on mentorship all provide unifying connections that can facilitate sharing both within one office and across the offices of these large organizations.

Organizational Learning

Organizational learning considers how organizations learn new responses and why they often fail to learn, while learning organizations achieve higher performance through their ability to learn from past experiences (Senge, 1990). Information technology through the organizational learning lens can have a role to play in both enabling and disabling organizational learning (Robey & Boudreau, 1999).

Learning relies upon an organizational memory, which can be defined as understandings shared by members of an organization about its identity, mental maps, and routines for thought and action (Fiol & Lyles, 1985). While such benefits can accrue for learning, organizational memory may be a poor guide for future action if things change, and therefore organizations must spend considerable time updating their memory (Fiol & Lyles, 1985). The prevailing technology-focused view of knowledge management in legal practice is aimed at capturing the organizational memory in a knowledge repository that can then be shared throughout the firm. However, looking at the constituent aspects of organizational memory, it is unlikely that such aspects could be captured so conveniently.

Legal practice has a strong tradition of mentorship that serves as the basis for learning and firm profits. This mentorship model is built upon the firm's ability to leverage the professional skills of the senior partners with the efforts of the juniors. The underlying motivation for many of the knowledge management initiatives within legal practice is that by improving knowledge management processes such as sharing, the firm will be able to better leverage junior lawyers while simultaneously increasing the effectiveness of the senior partners. While information technology can contribute significantly to knowledge sharing efforts by providing alternate communication channels or the availability of information that was not previously easily accessible, these changes do not necessarily provide the improved learning envisioned to originate from increased sharing. For example, even though e-mail may provide a new channel between senior partners and juniors, juniors may be reluctant to avail of that channel and thus maintain institutional norms, whereby juniors do not have direct access to senior partners.

The mentorship model is the preferred mode of learning with respect to the formalized relationship between junior lawyers and their more senior mentors. This relationship facilitates considerable sharing between the junior and the senior mentor, but the sharing is predominately unidirectional, with the junior lawyer being on the receiving end. This is likely an excellent learning model for the juniors, but may also impede sharing in other aspects. The mentorship model relies on the junior lawyer performing work for the mentor who then bills the client at their senior rate; in return the junior lawyer receives the case experience and guidance needed to progress in the firm. However, it is easy to envision with the forces already discussed in play that such a learning relationship can be shifted so that the junior is essentially performing the work without the benefits of the mentorship. Similarly, this model pairs mentor to junior, often to the exclusion of other lawyers, thus potentially reducing sharing opportunities that would be available if the junior worked with a range of lawyers. Mentorship at the more senior level is not generally as formalized; and when viewed through the increased pressures for individual performance and a reliance on a more centralized management, it is not hard to envision how such mentoring opportunities quickly are moved to the background in favor of short-term gains.

Firm-wide information systems that provide the lawyers with access to best practices, legal precedents, lists of experts, and a searchable knowledge base may in fact be contributing to the erosion of mentorship opportunities. By relying on the information systems as the source of such insights, the lawyers may be robbing themselves of the opportunity to both mentor and be mentored, and the associated benefits of such relationships.

Despite these challenges, the mentorship model appears to be one of the strengths of professional practice, albeit at risk of erosion within certain professional management- and technology-focused environments. The ability to formalize the mentorship model beyond the junior lawyers appears to offer considerable potential for addressing the competing forces both impeding and enhancing knowledge sharing within legal practice.

FUTURE TRENDS

The theoretical perspectives presented draw upon a logic of opposition that sheds new light on the contradictory findings of the effects of technology on knowledge sharing within law firms. Structuration theory (Giddens, 1984) may be a useful theoretical position to take in this regard since the concept of duality of structure points to a reciprocal connection between action and structure. A structuration view of information technology directs our attention to organizational consequences of these technologies as being produced and reproduced through human action (Orlikowski, 2000; Orlikowski & Robey, 1991; Schultze & Orlikowski, 2004).

Legal practice provides a heightened environment in which to investigate the forces both enabling and constraining knowledge sharing. Many of the implications are unique to the legal context of larger firms, but given the growing prominence of geographically dispersed service organizations that rely almost exclusively on their knowledge for their survival and the increased use of information technology to support these practices, the experience in these larger law firms may very well represent things to come for many organizations.

Future studies drawing upon a conceptualization of technology that simultaneously enables and constrains knowledge sharing over time would appear to be particularly beneficial to the field of knowledge management.

CONCLUSION

This article highlights the difficulty in offering prescriptive advice on how to use information technology to increase knowledge sharing within law firms, since any action aimed at increasing knowledge sharing can over time simultaneously produce the opposite effect. There are often good reasons why key aspects of legal practice are counter to knowledge sharing, so expecting lawyers to fundamentally change their practice in order to improve knowledge sharing is problematic if not considered in the context of the range of forces both enabling and constraining such sharing.

Institutional theory highlights the dual consideration of the normative pressures on these organizations to remain the same in order to maintain legitimacy and forces enhancing change in order to remain competitive. The professional institution of a law firm provides certain expectations for conduct, appearance, and practice which if not met severely affect the credibility of the firm. However, competitive pressures fueled by rapid expansion through acquisition have placed strong opposing forces that are shifting these firms to rely on centralized professional management approaches. The customer-centric view this shift entails has produced a push for increased sharing within the firm to produce a consistent and more transparent story for the client, while simultaneously reducing the sharing as individual lawyers see their value to the client as being guaranteed by hoarding their knowledge.

Organizational politics draws our attention to political resistance that impedes knowledge sharing that must be balanced with negotiation and compromise. Legal practice with its reliance on collegial shared management has traditionally relied on power originating from seniority in the firm, but this power is shifting towards professional managers for decisions on how the firm should operate. Firm-wide information systems are seen to both improve professional practice by increasing sharing, while at the same time serving to push a wedge between the lawyers and management that in turn impedes sharing.

Organizational culture points to the role that multiple acquisitions and professional autonomy have played in producing fragmented cultures for these larger firms. Professional cultures might serve as a link between these diverse organizational cultures by appealing to their collegial background and reliance on mentorship. Information technology in this context can be seen as a cultural artifact, and as such any attempt at changing or replacing the technology can be seen as a challenge to the organizational or professional culture that the technology espouses.

Organizational learning highlights the role played by the mentorship model in legal practice. The emerging professional management and a reliance on information systems for improved sharing may in fact be eroding this mode of learning within these large law firms. The mentorship model still appears to offer the most promise for improved knowledge sharing within legal practice, if combined with new approaches to mentorship that draw upon the available technologies and match professional expectations for practice.

The contradictory results observed by law firms when using information technology to improve knowledge sharing throughout their organizations provides an opportunity to employ alternate theoretical positions that instead of treating these findings as a problem embraces them and offers an explanation as to why they were observed. There are other theoretical positions that draw upon a logic of opposition (and other logics) that may prove useful in considering additional aspects of knowledge management in legal practice. This article provides insight into many of the opposing forces that arise within legal practice, and while not an exhaustive list, it is hoped that this will serve as the basis for further work.

Chapter 4.40
Knowledge Management in Law Firms

Petter Gottschalk
Norwegian School of Management BI, Norway

Law enforcement is of concern to law firms. A law firm can be understood as a social community specializing in the speed and efficiency in the creation and transfer of legal knowledge (Nahapiet & Ghoshal, 1998). Many law firms represent large corporate enterprises, organizations, or entrepreneurs with a need for continuous and specialized legal services that can only be supplied by a team of lawyers. The client is a customer of the firm, rather than a particular lawyer. According to Galanter and Palay (1991, p. 5), relationships with clients tend to be enduring:

Firms represent large corporate enterprises, organizations, or entrepreneurs with a need for continuous (or recurrent) and specialized legal services that could be supplied only by a team of lawyers. The client 'belongs to' the firm, not to a particular lawyer. Relations with clients tend to be enduring. Such repeat clients are able to reap benefits from the continuity and economies of scale and scope enjoyed by the firm.

Law firm knowledge management is the behaviors and processes by which a group of lawyers increases and maintains their personal and collective actionable knowledge to compete, to increase performance, and to decrease risk. By extension, a knowledge strategy is the intended action, the plan, or the road map, for those behaviors and processes (Parsons, 2004).

LAWYERS AS KNOWLEDGE WORKERS

Lawyers can be defined as knowledge workers. They are professionals who have gained knowledge through formal education (explicit) and through learning on the job (tacit). Often, there is some variation in the quality of their education and learning. The value of professionals' education tends to hold throughout their careers. For example, lawyers in Norway are asked whether they got the good grade of "laud" even 30 years after graduation. Professionals' prestige (which is based partly on the institutions from which they obtained their education) is a valuable organizational resource because of the elite social networks that provide access to valuable external resources for the firm (Hitt, Bierman, Shumizu, & Kochhar, 2001).

After completing their advanced educational requirements, most professionals enter their careers as associates in law. In this role, they continue to learn and thus, they gain significant tacit knowledge through "learning by doing." Therefore, they largely bring explicit knowledge derived from formal education into their firms, and build tacit knowledge through experience.

Most professional service firms use a partnership form of organization. In such a framework, those who are highly effective in using and applying knowledge are eventually rewarded with partner status and thus, own stakes in a firm. On their road to partnership, these professionals acquire considerable knowledge, much of which is tacit. Thus, by the time professionals achieve partnership, they have built human capital in the form of individual skills (Hitt et al., 2001).

Because law is precedent driven, its practitioners are heavily invested in knowing how things have been done before. Jones (2000) found that many attorneys, therefore, are already oriented toward the basic premises of knowledge management, though they have been practicing it on a more individualized basis, and without the help of technology and virtual collaboration. As such, a knowledge management initiative could find the areas where lawyers are already sharing information, and then introduce modern technology to support this information sharing to make it for effective.

Lawyers work in law firms, and law firms belong to the legal industry. According to Becker et al. (Becker, Herman, Samuelson, & Webb, 2001), the legal industry will change rapidly because of three important trends. First, global companies increasingly seek out law firms that can provide consistent support at all business locations, and integrated cross-border assistance for significant mergers and acquisitions as well as capital-market transactions. Second, client loyalty is decreasing as companies increasingly base purchases of legal services on a more objective assessment of their value, defined as benefits net of price. Finally, new competitors such as accounting firms and internet-based legal services firms have entered the market.

In this book, the notion "lawyer" is used most of the time. Other notions such as "attorney" and "solicitor" are sometimes used as synonyms in this book. In reality, these words can have different meanings, together with notions such as "barrister," "counselor," and "advocate." In Norwegian, a distinction is made between a lawyer ("jurist") and a solicitor ("advokat"). There is no need to make such distinctions in this book.

Lawyers are knowledge workers. To understand the organizational form of lawyers as knowledge workers employed in companies such as law firms, there is a need to recognize the dual dependent relationship between knowledge workers and the organization. On the one hand, for the purpose of channeling the motivation and effort of employees to serve the interests of the firm, management will seek to exploit knowledge workers' need to rely on the organization for resources (for example, advanced computer software and hardware that are available at a high cost) to accomplish their work tasks. On the other hand, management depends on knowledge workers for their esoteric and advanced knowledge, and their ability to synthesize theoretical and contextual knowledge. Management, therefore, need to meet these employees' aspirations and expectations. As for knowledge workers, they need to depend on the organization as the locale to develop contextual knowledge and to create new knowledge. However, their ability to apply theoretical knowledge in other contexts, that is, in other organizations, means that to a certain extent, they are also able to pursue a limited form of marketization. This enables them to reap market-level rewards for their expertise (May, Korczynski, & Frenkel, 2002).

KNOWLEDGE CATEGORIES

To get started on this job, legal industry knowledge has to be understood. Edwards and Mahling (1997) have suggested that law firms have four categories of knowledge: administrative, declarative, procedural, and analytical knowledge, as defined earlier in this book. These knowledge categories are all important to the law firm. While any law firm needs to maintain efficient administrative records, there does not appear to be any significant possibility for gaining strategic advantage in the firm's core competency of providing sound legal advice to its clients by using these records. The detailed administrative knowledge they contain is essential to the operation of the law firm, but does not contribute to the substantive content. Declarative, procedural, and analytical knowledge offer greater possibilities for creating strategic value to the firm.

Edwards and Mahling (1997) present a case drawn from the case collection of one of the authors to illustrate the differences in strategic value among procedural, declarative, and analytical knowledge. In the early 1990s, one of the authors, at the time engaged in the practice of law, represented a corporate client as seller in several sales of corporate businesses and real estate. At the time, buyers of businesses and real estate had become concerned about their possible liability for pollution existing on property when they purchased it. The U.S. federal laws governing the legal responsibility of landowners for environmental contamination on their property had been adopted a few years earlier, and their full impact on sale of businesses was just beginning to be understood.

The relevant declarative knowledge was an understanding of several related state and federal laws and agency regulations governing liability for environmental contamination. The relevant procedural knowledge, in part, was to know how to transfer the environmental licenses and permits used by a given business to a new owner, and how to transfer the real estate as an asset. The relevant analytical knowledge was to understand what risks the buyer of a contaminated property faced (legal and financial), and what contractual protections the seller could reasonably give to the buyer.

Law firms are interesting in themselves from both a knowledge and a management perspective. From a management perspective, law firm partners own a typical law firm. Among themselves, the partners appoint a board and a managing partner. In addition, they hire a chief executive officer (CEO) to run all support functions in the firm such as financial management (CFO), knowledge management (CKO), and information technology management (CIO).

Jones (2000) found that top-down directives are complicated in the legal industry. In large U.S. and UK law firms, the power can be spread among as many as 150 partners, most of who have different specialty areas, different work and management styles, and vastly different groups under their control. Earning a consensus is not an easy proposition, especially when the funding for new initiatives such as knowledge management initiatives is coming directly out of the partners' yearly income. At the same time, partners are the ones who have the most to gain if their firm is able to manage knowledge effectively to keep lucrative clients on board, and draw new ones through new services.

The human capital embodied in the partners is a professional service firm's most important resource. Their experience, particularly as partners, builds valuable industry-specific and firm-specific knowledge that is often tacit. Such knowledge is the least imitable form of knowledge. An important responsibility of partners is obtaining and maintaining clients. Partners build relationships with current and potential clients and, over time, develop social capital through their client networks. Therefore, the experience a professional gains as a partner contributes to competitive advantage (Hitt et al., 2001).

Partners with education from the best institutions, and with the most experience as partners in particular legal areas represent substantial human capital to the firm. As partners, they continue to acquire knowledge, largely tacit and firm specific, and build social capital. This human capital should produce the highest-quality services to clients and thereby, contribute significantly to firm performance. The job of partner differs from that of associate, and new skills must be developed. Partners must build the skills needed to develop and maintain effective relationships with clients. Importantly, partners in law firms serve as project and team leaders on specific cases and thus, must develop managerial skills.

Partners own the most human capital in a firm, and have the largest stakes using the firm's resources to the greatest advantage. One of the responsibilities of partners is to help develop the knowledge of other employees of the firm, particularly its associates. Associates at law firms need to learn internal routines, the situation of important clients, and nuances in the application of law (Hitt et al., 2001).

Information technology support for knowledge management in law firms has to consider the very special knowledge situation in each law firm. Edwards and Mahling (1997) argue that knowledge is dispersed among many different members of the firm, and others outside the firm may contribute to knowledge. Law firm knowledge has a wide variety of sources, both inside and outside the firm. Much administrative knowledge is generated by the members of the firm as billing records for their services. The firm's administrative staff creates other administrative information. Attorneys are the major source of analytical, declarative, and procedural knowledge. Legal assistants have some declarative knowledge based on their experience. Declarative knowledge can also be found in publicly available sources intended for research purposes, primarily books, online subscription research sources, and CD-ROM resources. The quantity of publicly available research material for any given topic depends significantly on the size of the market for the information. The more specialized the legal area, the smaller the potential market for material, and the less that is usually widely available. Experienced legal assistants are usually an invaluable source of procedural knowledge, since much procedural work is delegated to them. Legal assistants are common in countries such as the U.S. and UK, but they are seldom found in law firms in countries such as Norway and Sweden.

Experienced legal secretaries may have a significant amount of procedural knowledge for transactions they handle often. Law firms in Norway employ many secretaries. It is common to find more than one secretary for every three lawyers in a law firm.

The role of others, outside the law firm, in generating analytical and procedural knowledge needs to be noted. While much of the useful procedural and analytical knowledge resides in firm employees, it is likely that there are sources outside the firm as well. One belief frequently expressed in the knowledge management literature is the view that learning is social: people learn in groups. These groups are known in the literature as communities of practice.

Communities of practice have been defined as groups of people who are informally bound to one another by exposure to a common class of problem. It is quite likely that the communities of practice for the lawyers in the firm include other members of professional associations such as bar associations. These groups usually have a number of committees devoted to practice areas, such as environmental law. In Norway, Den Norske Advokatforening (Norwegian Lawyers Association) has such committees.

Generally, the idea of communities of practice developed in the organizational learning movement. The idea posits that knowledge flows best through networks of people who may not be in the same part of the organization, or in the same organization, but have the same work interests. Some firms have attempted to formalize these communities, even though theorists argue that they should emerge in self-organizing fashion without any relationship to formal organizational structures (Grover & Davenport, 2001).

A few more technologically advanced lawyers may use the Internet, or such subscription services as Counsel Connect in the U.S. on the World Wide Web, as a sounding board for analytical and procedural issues in a community of legal practice. These external sources can provide knowledge in the form of informal conversations, written newsletters and updates, briefs filed in relevant litigation, and other forms.

An obvious problem in law firms is that knowledge is not consistently documented. Much administrative information is captured in electronic form as part of the firm's billing records. Other administrative data resides in the firm's payroll and benefits records and file and records management systems. Much of the firm's declarative knowledge resides in the memories of the firm's attorneys, and in their work product. At the same time, the firm has access to publicly available declarative knowledge in the form of published reference works.

Much procedural knowledge is documented throughout the firm's files in the form of completed records of transactions that provide guidance about what legal documents were necessary to complete a certain type of transaction. The knowledge of procedure reflected in these documents is often implicit rather than explicit. Explicit procedural knowledge is contained in a collection of written practice guides for popular areas like real estate transactions. These guides include standard checklists of items necessary to complete a particular transaction for the kinds of transactions that occur frequently.

Analytical knowledge resides primarily in attorneys' heads. Analytical knowledge is occasionally documented in client files through the notes of an attorney's thought processes. More often, it is reflected in the completed contract documents or other transaction documents by the inclusion of specific clauses dealing with a particular topic. The analytical knowledge reflected in completed documents is very often not explicit, in the sense that it is often not clear from the face of the document what analytical issues are dealt with in the document.

Another law firm problem is that knowledge is often shared on an informal basis. Certain methods of sharing knowledge, at least within the firm, have traditionally been part of large law firm culture. One of the most important ways of sharing knowledge has been through the process of partners training associates to perform tasks. In larger firms, the practice of hiring young, bright law-school graduates who were trained, supervised, and rewarded by a partner has been followed throughout most of this century. The method focuses on transmitting knowledge from more experienced attorneys to less experienced attorneys, as distinguished from transmitting it to other partners in the firm, or to legal assistants and other support staff.

This attorney training customarily has relied on informal methods of transmitting knowledge, such as rotating young attorneys through a series of practice groups within the firm. Much of this informal training takes place via collaborative work on documents such as contracts and pleadings. Some of it occurs through informal consultation between a senior attorney and a junior attorney about the best way to handle a specific task. These consultations may be carried out by face-to-face discussions, e-mail, or telephone conversations. No attempt is usually made to capture the substance of the training through these informal methods, even where a form of communication such as e-mail may often be used that could produce documentation. It is important to note that this training often takes place under intense time pressure. Further, in an hourly billing system, there is often little or no financial incentive to produce documentation that cannot be billed directly to a client.

In addition to problems of knowledge dispersion, inconsistent documentation, and informal knowledge sharing, Edwards and Mahling (1997) argue that if knowledge has been documented, it is contained in a mixture of paper and electronic formats, and located in dispersed physical locations. Administrative information typically exists in a combination of print and electronic formats. A large firm would customarily maintain computerized databases for key matters such as tracking lawyers' hourly billings, for its client contact data, and for staff assignments to projects, but would usually generate paper invoices to clients. The data physically resides in the firm's computer network and in paper files.

Declarative, procedural, and analytical knowledge is often documented in attorney work product such as briefs, memoranda, and actual legal documents such as contracts, wills, and instruments of transfer. Work product documents typically are created in electronic form, but are customarily stored in print-format client files. The electronic-format materials are stored in standalone personal computers or on the network. Paper materials are located throughout the firm's offices.

Where knowledge has been documented in a law firm, often only a few simple tools exist to facilitate the retrieval of knowledge by topic. Attorney work files are usually indexed by client name and matter name, but their contents are seldom indexed for subject matter in more than the most general way. An attorney creating a particular item of work product may place it in a firm's standards database, maintained in electronic format. These standard documents can then be used by other lawyers as examples or models. In a typical installation, the standard forms library is stored on the network, and is physically available to those who have network access. The standard forms library allows access to individual documents by name, but subject matter classification is often limited to what can be included in a descriptive DOS-format file name. Retrieving material from the forms library, thus, usually requires tedious sequential search and review of the contents of the library.

Access to the procedural and analytical knowledge embodied in client files is difficult, at best, for those not familiar with the files. The client files are often not indexed by subject matter, making it difficult to locate procedural or analytical knowledge on a particular topic if the contents of the file are not already familiar. Document management systems do support network-wide searches for documents in electronic form by selected attributes such as document author name, or keywords appearing in the document. In the absence of a consistent system of classifying the document's contents by subject or topic, however, keyword searches by topic produce incomplete retrieval of all relevant documents.

Even if knowledge is documented by work product such as a memorandum to file, access to the implicit procedural and analytical knowledge embodied in the firm's files is often difficult, at best. Client files that are indexed according to a subject-based system may offer some help in searching for analytical knowledge. A large transaction, however, may include dozens of analytical issues, and it is unlikely that all of them would be indexed. Procedural knowledge is unlikely to be indexed at all. This means that the user must often rely on the ability to search by keywords for relevant fact patterns to retrieve relevant procedural or analytical knowledge.

Some knowledge in a law firm raises issues of security and confidentiality. There are few confidentiality concerns with declarative knowledge. This type of knowledge is meant to be public and readily accessible to all. Analytical and procedural knowledge within the firm can, however, raise issues of security and client confidentiality. Attorneys in the firm have professional ethical obligations to their clients to maintain the confidentiality of information furnished by the client. While these ethical obligations are customarily interpreted to permit sharing the information among the firm's members and staff, appropriate precautions still must be taken to avoid disclosures outside the firm.

KNOWLEDGE MANAGEMENT MATRIX

To identify knowledge management applications, we can combine knowledge levels with knowledge categories. Core knowledge, advanced knowledge, and innovative knowledge is combined with administrative knowledge, declarative knowledge, procedural knowledge, and analytical knowledge in Figure 1. We have created a knowledge management matrix with 12 cells for IS/IT applications.

The knowledge management matrix can first be used to identify the current IS/IT that support knowledge management in the firm, as illustrated in Figure 2.

Now the knowledge management matrix can be applied to identify future IS/IT as illustrated in Figure 3. The systems do only serve as examples, they illustrate that it is possible to find systems than can support all combinations of knowledge categories and knowledge levels.

Software and systems suitable for knowledge management in a law firm can now be identified using the knowledge management matrix. In Figure 4, examples of software to support systems in Figure 3 are listed.

Let us look at one example in Figure 4. Knowledger is listed as potential software in the innovative-analytical knowledge location. This is an ambitious location of a software product that has yet to demonstrate its real capabilities in knowledge firms. According to the vendor, Knowledge Associates (http://www.knowledgeassociates.com), Knowledger 3.0 is complete knowledge management software that can be integrated with other systems in the firm. Knowledger is Web based, and supports the firm in categorizing internal and external knowledge, as well as helps with linking incoming knowledge to existing knowledge.

Let us look at one more application in the most demanding location of innovative-analytical knowledge. There we find something called

Summation. Summation is a system for document handling for use in large court cases (http://www.summation.com). In the large court case of Balder in Norway, law firm Thommessen Krefting Greve Lund (TKGL) used Summation in 2001. The Balder case is a dispute between Exxon and Smedvig about the rebuilding of an offshore vessel costing 3 billion Norwegian crones. TKGL had more than 2,500 binders when the court case started in the city of Stavanger. All these documents were scanned into a database for use by Summation. When lawyers from TKGL present material in court, they submit it from their laptops. When new information emerges in court, then it is registered in Summation. When TKGL lawyers are to trace technical and financial developments for Balder, they make a search in the Summation database.

Another law firm is also using Summation. The law firm Bugge Arentz-Hansen Rasmussen (BA-HR) has the task of finding money after the late shipowner, Jahre. The money is expected to be found in banks in countries where there are no taxes. The hunt for Jahre funds has been going on for almost a decade, and BA-HR has developed a large Summation database enabling BA-HR lawyers to present important information in the court in the city of Drammen.

A third example of Summation use can be found in the U.S. The Justice Department used Summation in its legal struggle with Microsoft. It has been argued that Summation helped the Justice's lead prosecutor, David Boies, piece together the most damaging information for Microsoft. In presenting its defense, which ended on February 26 in 2001, Microsoft relied more than Justice did on a low-tech overhead projector.

According to Susskind (2000, p. 163), six kinds of expert systems can play an important role in law firms in the future:

- Diagnostic systems. Those systems offer specific solutions to problems presented to them. From the facts of any particular case,

as elicited by such a system, it will analyze the details and draw conclusions, usually after some kind of interactive consultation. These systems are analogous to the medical diagnostic systems that make diagnoses on the basis of symptoms presented to them. An example of a diagnostic system in law would be a taxation system that could pinpoint the extent to which, and why a person is liable to pay tax, doing so on the basis of a mass of details provided to it.

- Planning systems. In a sense, planning systems reason in reverse, for these systems are instructed as to a desired solution or

outcome, and their purpose is to identify scenarios involving both factual and legal premises that justify the preferred conclusion. In tax law, a planning system could recommend how best a taxpayer should arrange his affairs so as to minimize his exposure to liability. The knowledge held within planning systems can be very similar to that held within diagnostic systems; what is quite different is the way that knowledge is applied.

- Procedural guides. Many complex tasks facing legal professionals require extensive expertise and knowledge that is, in fact, procedural in nature. Expert systems as procedural guides take their users through such complex and extended procedures, ensuring that all matters are attended to and done within any prescribed time periods. An example of such a system would be one that managed the flow of a complex tax evasion case, providing detailed guidance and support from inception through to final disposal.
- The intelligent checklist. This category of system has most often been used to assist in auditing or reviewing compliance with legal regulations. Compliance reviews must be undertaken with relentless attention to detail, and extensive reference to large bodies of regulations. Intelligent checklists provide a technique for performing such reviews. They formalize the process. In taxation, an intelligent checklist approach could be used to assist in the review of a company's compliance with corporation tax.
- Document modeling systems. These systems, also referred to as document assembly systems, store templates set up by legal experts. These templates contain fixed portions of text, together with precise indications as to the conditions under which given extracts should be used. In operation, such a system will elicit from its user all the details relevant to a proposed document. This is done by the user answering questions, responding to prompts, and providing information. On the basis of the user's input, the system will automatically generate a customized and polished document on the basis of its knowledge of how its text should be used.
- Arguments generation systems. It is envisaged that these systems are able to generate sets of competing legal arguments in situations when legal resources do not provide definitive guidance. Rather than seeking to provide legal solutions (as diagnostic systems strive to do), argument generation systems will present sound lines of reasoning, backed both by legal authority and by propositions of principle and policy. These lines of reasoning will lead to a range of legal conclusions. Such systems would help users identify promising lines of reasoning in support of desired outcomes while, at the same time, advancing other arguments that may need to be refuted.

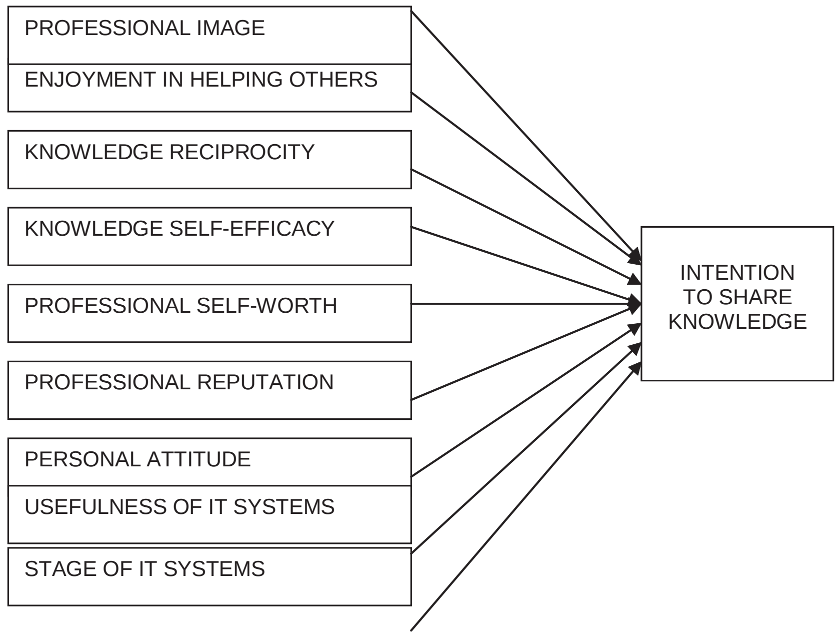
RESEARCH MODEL FOR KNOWLEDGE SHARING

The objective of this section is to deepen our understanding of the factors that increase or lessen employees' tendencies to engage in knowledge-sharing behaviors. Figure 5 depicts our research model. Intention to share knowledge is the dependent variable in the model.

Professional Image

In most organizations today, the importance of image is increasing as traditional contracts between organizations and employees based on length of service erode. In such working environments, knowledge contributors can benefit from showing others that they possess valuable expertise. This earns them respect and a better image. Therefore,

Figure 5. Research model for determinants of knowledge sharing intentions



knowledge sharers can benefit from improved self-concept when they share their knowledge. According to Kankanhalli et al. (Kankanhalli, Tan, & Wei, 2005), employees have been found to share their best practice due to a desire to be recognized by their peers as experts. People who provided high-quality knowledge have been found to enjoy better prestige in the workplace. Hence, this discussion suggests a positive relationship between image and intention to share knowledge.

Hypothesis 1: The more a lawyer's image is improved by knowledge sharing, the greater the intention to share knowledge will be.

Enjoyment in Helping Others

This benefit is derived from the concept of altruism. Altruism exists when people derive intrinsic enjoyment from helping others, without expecting anything in return. According to Davenport and Prusak (1998), altruism implies that a knowledge seller may be so passionate about his or her knowledge that he or she is happy to share it whenever he/she gets a chance. This seems to be the case with many university professors. Many knowledge sharers are motivated in part by a love of their subject and to some degree, by altruism, whether for the good of the organization or based on a natural impulse to help others.

Altruism exists when people derive intrinsic enjoyment from helping others, without expecting anything in return. Although there may be very few instances of absolute altruism (involving absolute lack of self-concern in the motivation for an act), relative altruism (where self-concern plays a minor role in motivating an act) is more prevalent. Knowledge sharers may be motivated by relative altruism based on their desire to help others. According to Kanhanhalli et al. (2005), prior research shows that knowledge contributors gain satisfaction by demonstrating their altruistic behavior. Such satisfaction stems from their intrinsic enjoyment in helping others. Knowledge sharers who derive enjoyment in helping others may be more inclined to share knowledge.

Hypothesis 2: The greater enjoyment a lawyer finds in helping others, the greater the intention to share knowledge will be.

Knowledge Reciprocity

Reciprocity has been highlighted as a benefit for individuals to engage in social exchange. According to Davenport and Prusak (1998), reciprocity implies payment in terms of knowledge. A knowledge seller will spend the time and effort needed to share knowledge effectively, if the person expects the buyer to be a willing seller when he or she is in the market for knowledge. Reciprocity may be achieved less directly than by getting knowledge back from the same person. In firms structured as partnerships, such as law firms, knowledge sharing that improves profitability will return a benefit to the sharer, now and in the future. Whether or not a knowledge seller expects to be paid with equally valuable knowledge from the buyer, the knowledge seller may believe that being known for sharing knowledge readily will make others in the company more willing to share with him or her. That is a rational assumption, since his or her reputation as a seller of valuable knowledge will make others confident of his/her willingness to reciprocate when he/she is the buyer and they have knowledge to sell: The knowledge seller's knowledge credit is good.

Reciprocity has been highlighted as a benefit for individuals to engage in social exchange. It can serve as a motivational mechanism for people to contribute to discretionary databases. Reciprocity can act as a benefit for knowledge contributors because they expect future help from others in lieu of their contributions. According to Kankanhalli et al. (2005), prior research suggests that people who share knowledge in online communities believe in reciprocity. Further, researchers have observed that people who regularly helped others in virtual communities seemed to receive help more quickly when they asked for it.

Furthermore, Kankanhalli et al. (2005) found a significant, positive relationship between reciprocity and usage of electronic knowledge repositories by knowledge contributors. These arguments suggest a positive relationship between reciprocity and intention to share knowledge.

Hypothesis 3: The more a lawyer expects knowledge reciprocity, the greater the intention to share knowledge will be.

Knowledge Self-Efficacy

Self-efficacy relates to the perception of people about what they can do with the skills they possess. When people share expertise useful in the organization, they gain confidence in terms of what they can do, and this brings the benefit of increased self-efficacy. This belief can serve as a self-motivational force for knowledge contributors to share knowledge. Knowledge self-efficacy is typically manifested in the form of people believing that their knowledge can help solve job-related problems, improve work efficiency, or make a difference to their organization.

Conversely, if people feel that they lack knowledge that is useful to the organization, they may decline from sharing knowledge because they believe that their contribution cannot make a positive impact for the organization.

These arguments suggest a positive relationship between knowledge self-efficacy and sharing by knowledge contributors that was found to be significant in the study by Kanhanhalli et al. (2005).

Hypothesis 4: The higher knowledge self-efficacy perceived by a lawyer, the greater the intention to share knowledge will be.

Professional Self-Worth

In an ongoing interaction setting such as knowledge sharing in an organization, appropriate feedback is very critical. When others respond in the way that we have anticipated, we conclude that our line of thinking and behavior are correct; at the same time, role taking improves as the exchange continues according to role theory, which is the cornerstone of the symbolic interactionist perspective on self-concept formation. According to Bock et al. (Bock, Zmud, & Kim, 2005), this process of reflected appraisal contributes to the formation of self-worth that is strongly affected by sense of competence, and closely tied to effective performance.

Therefore, Bock et al. (2005) found that employees who are able to get feedback on past instances of knowledge sharing are more likely to understand how such actions have contributed to the work of others, and/or to improvements in organizational performance. The understanding would allow them to increase their sense of self-worth accordingly. That, in turn, would render these employees more likely to develop favorable attitudes toward knowledge sharing than employees who are unable to see such linkages. Defining this cognition as an individual's sense of self-worth from their knowledge-sharing behavior leads to the fifth hypothesis.

Hypothesis 5: The greater the sense of self-worth through knowledge sharing behavior is, the greater the intention to share knowledge will be.

Professional Reputation

In order to share knowledge, individuals must think that their contribution to others will be worth the effort, and that some new value will be created, with expectations of receiving some of that value for themselves. These personal benefits or private rewards are more likely to accrue to individuals who actively participate and help others. Thus, the expectation of personal benefits can motivate individuals to contribute knowledge to others in the absence of personal acquaintance, similarity, or the likelihood of direct reciprocity (Wasko & Faraj, 2005).

According to Wasko and Faraj (2005), social exchange theory posits that individuals engage in social interaction based on an expectation that it will lead, in some way, to social rewards such as approval, status, and respect. This suggests that one potential way an individual can benefit from active participation is the perception that participation enhances his or her personal reputation in the firm. Reputation is an important asset that an individual can leverage to achieve and maintain status within a collective. Results from prior research on electronic networks of practice are consistent with social exchange theory, and provide evidence that building reputation is a strong motivator for active participation. Wasko and Faraj (2005) came to the same conclusion in their empirical study of knowledge contributions in electronic networks of practice.

Hypothesis 6: The more a lawyer can improve his or her reputation by sharing knowledge, the greater the intention to share knowledge will be.

Personal Attitude

Intention to engage in a behavior is determined by an individual's attitude toward that behavior. Here, attitude toward knowledge sharing is defined as the degree of one's positive feelings about sharing one's knowledge (Bock et al., 2005). This leads to the seventh hypothesis.

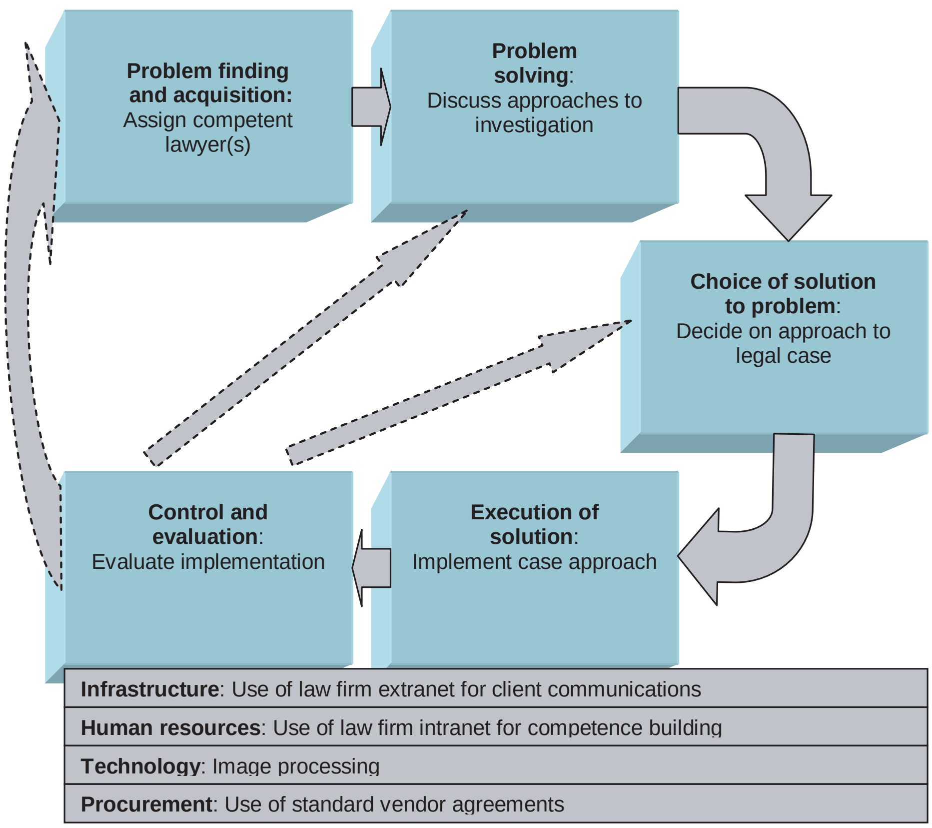
Hypothesis 7: The more favorable a lawyer's attitude toward knowledge sharing is, the greater the intention to share knowledge will be.

Usefulness of IT Systems

Information technology can play an important role in successful knowledge management initiatives (Kankanhalli et al., 2005; Wasko & Faraj, 2005). However, the concept of coding and transmitting knowledge is not new: training and employee development programs, organizational policies, routines, procedures, reports, and manuals have served this function for many years. What is new and exciting in the knowledge management area is the potential for using modern information technology (e.g., extranets, intelligent agents, expert systems) to support knowledge creation, sharing, and exchange in an organization and between organizations. Modern information technology can collect, systematize, structure, store, combine, distribute, and present information of value to knowledge workers.

The value of information presented to knowledge workers can be studied in terms of the organization's value configuration. A law firm has the value configuration of a value shop (Gottschalk, 2006). In the value shop, lawyers need information to access client problems, find alternative solutions to problems, select an optimal solution, implement the solution, and evaluate the

Figure 6. Law firm as value shop with activity examples



implementation. In this value creation, IT systems can help gain access to new cases, help find relevant court rulings, retrieve relevant documents, collect views from opposing sides, and support quality assurance of the work.

A law firm as a value shop is an organization that creates value by solving unique problems. Knowledge is the most important resource. A value shop is characterized by five primary activities: problem finding and acquisition, problem solving, choice, execution, and control and evaluation, as illustrated in Figure 6.

Hypothesis 8: The more a lawyer finds useful information in IT systems, the greater the intention to share knowledge will be.

Stage of IT Systems

The ambition level using knowledge management systems can be defined in terms of stages of knowledge management technology, as illustrated in Chapter I. When a firm reaches higher stages in the model, knowledge workers contribute information to the systems. At Stage 3, document systems and other information repositories are based on knowledge workers' contributions in electronic form. In our final hypothesis, we suggest that knowledge workers that are used to sharing information in IT systems will be more inclined to share their knowledge.

Hypothesis 9: The more higher-stage IT systems are available to a lawyer, the greater the intention to share knowledge will be.

The Case of Eurojuris

Eurojuris is a leading network of law firms in Europe, covering 610 different cities/locations in 17 countries: Austria, Belgium, Denmark, Finland, France, Germany, Ireland, Italy, Liechtenstein, Luxembourg, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and UK. Eurojuris groups some 5,000 lawyers.

Each country has a national Eurojuris association that selects as members medium-sized independent law firms well established in their country, and who satisfy Eurojuris selection criteria. The objective is to provide to companies, corporations, public authorities, and private clients direct legal advice and local representation all over Europe.

When clients consult their nearest Eurojuris law firm, they have access to legal and commercial advice not only all over Europe, but also worldwide. The local Eurojuris lawyer will contact the appropriate lawyer abroad, or provide the client with details of the legal practitioners that the client needs to contact.

All Eurojuris law firms are well-established and reputable firms in their community. They are carefully selected, and abide by defined quality standards relating to fees, mandatory professional indemnity insurance, knowledge of foreign languages, promptness, and confidentiality. All firms maintain their professional independence (Eurojuris, 2005).

In 1994, Eurojuris pioneered the quality policy for legal services with a system of quality standards to be applied to Eurojuris firms. It was the so-called 10 commandments that every firm has to respect. This was the first step towards quality that enabled the network to harmonize its cooperation in Europe, a great benefit to its clients. Largely inspired by the Eurojuris UK/LawNet quality standards, the rules evolved towards the ISO standards that have the advantage of being internationally recognized and controlled by an objective external body (Cyberfax, 2005).

Eurojuris firms became certified from 1996 onwards. Hereafter, some national organizations made the certification mandatory for their membership, which is the case for the UK, France, and Norway. Firms in Germany, Italy, and Belgium also received their ISO certificate.

In 2000, a member of the Board was appointed to be specifically in charge of the quality policy. In 2001, the General Assembly voted for a set of quality rules for the Eurojuris national associations. In 2003, Interjuris/Group Eurojuris was the first association to be rewarded with the ISO certification. In 2005, Eurojuris International was awarded the ISO 9001 certification. It is still not over, since it was hoped that in Berlin during the 2005 congress of the network, it could be announced that more than 50% of the network is involved with the ISO certification (Cyberfax, 2005).

Knowledge management has been at the top of the agenda of Eurojuris for a long time. Substantial investments in information technology and knowledge management systems are made to support lawyers as knowledge workers.

Europe does not have a single legal system. The method of conducting business varies from one country to another. Using local expertise from qualified lawyers, who are based on the spot where the client's problem arises, can be an effective way to serve the client or the correspondent lawyer. The local lawyer can draw on his knowledge of local authorities and procedures, speaks the language, and is able to act effectively and promptly in his own environment. Using a relevant and local law firm also avoids the extra costs of traveling expense. It may sometimes be inappropriate to use a large firm from the state capital when immediate advice may be more usefully and cost-efficiently obtained at a decentralized location anywhere in Europe.

Empirical studies of Eurojuris Norway were conducted some years ago (Gottschalk, 2005). Information was collected on software and systems used to support interorganizational knowledge management among law firms. Eurojuris law firms used Lotus Notes very extensively in their cooperation. Lotus Notes is an application covering both level II (person-to-person) and level III (person-to-information) in the stages-of-growth model for knowledge management technology. This result implies that Eurojuris law firms in Norway had already advanced to levels II and III. This result was confirmed by e-mail being ranked second after Lotus Notes, while end-user tools, such as word processing, had dropped to third place in a ranking of most important IT tools. The conclusion from these studies indicated that Eurojuris law firms are advanced both in terms of knowledge management and in terms of knowledge management systems.

Research Methodology

To test the proposed research model, we adopted the survey method for data collection, and examined our hypotheses by applying multiple regression analysis to the collected data. Our unit of analysis was the individual.

We developed the items in the questionnaire by adapting measures that have been validated by other researchers. Our dependent variable-intention to share knowledge was adapted from Bock et al. (2005). One part of the scale is measuring intention to share explicit knowledge, and the other part of the scale is measuring intention to share implicit knowledge.

Items are listed in Figure 7. Reliability in terms of Cronbach's alpha was .92 and .93 for the two scale parts, respectively, in the research conducted by Bock et al. (2005).

The first independent variable, professional image, was measured on a scale adapted from Kankanhalli et al. (2005). Similarly, enjoyment in helping others was adopted from the same authors. Both Kankanhalli et al. (2005), and Wasko and Faraj (2005) have measured knowledge reciprocity, but in different ways, so both scales are included in the instrument. Knowledge self-efficacy is from Kankanhalli et al. (2005), while professional self-worth is from Bock et al. (2005), and professional reputation is from Wasko and Faraj (2005).

Usefulness of IT systems was measured in terms of systems providing useful access, help,

Figure 7. Questionnaire items on intention and perceptions provided to survey respondents

Construct	Items in the survey instrument	Reliability
Intention to share knowledge Bock et al. (2005)	*Intention to share explicit knowledge*	.92
	I will share my documents in the firm more frequently in the future	
	I will provide my methods to firm members more frequently in the future (new)	
	I will contribute work reports to firm members more frequently in the future (new**)**	
	I always provide my models for members of my firm	
	Intention to share implicit knowledge	. 93
	I intend to share my experience in the firm more frequently	
	I will always provide know-where and know-whom at colleagues' request	
	I will try to share my expertise in the firm more frequently	
Professional image Kankanhalli et al. (2005)	**Sharing my knowledge improves my image within the firm**	.89
	Sharing my knowledge improves others recognition of me	
	When I share my knowledge, the people I work with respect me	
	People in the firm who share their knowledge have more prestige	
Enjoyment in helping others Kankanhalli et al. (2005)	**I enjoy sharing my knowledge with others in the firm**	.96
	I enjoy helping others by sharing my knowledge	
	It feels good to help someone else by sharing my knowledge	
	Sharing my knowledge with others gives me pleasure	
Knowledge Reciprocity Kankanhalli et al. (2005) Wasko and Faraj (2005)	Reciprocity by Khankanhalli et al.	.85
	When I share my knowledge, I expect somebody to respond when I'm in need	
	When I contribute knowledge, I expect to get back knowledge when I need it	
	I believe that my queries for knowledge will be answered in the future	
	Reciprocity by Wasko and Faraj	.95
	I know that others in the firm will help me, so it's only fair to help others	
	I trust someone would help me if I were in a similar situation	
Knowledge self-efficacy Kankanhalli et al. (2005)	**I have the expertise needed to provide valuable knowledge in the firm**	.96
	It makes a difference to the firm whether I add to the knowledge others have	
	Few other lawyers in the firm can provide more valuable knowledge than I can	
	I have confidence in my ability to provide valuable knowledge to others	
Professional Self-Worth Bock et al. (2005)	**My knowledge sharing helps other members in the firm solve problems**	.91
	My knowledge sharing creates new business opportunities for the firm	
	My knowledge sharing improves work processes in the firm	
	My knowledge sharing increases productivity in the firm	
	My knowledge sharing helps the firm achieve its performance objectives	
Professional reputation Wasko and Faraj (2005)	**I earn respect from others by sharing my knowledge**	.90
	I feel that participation improves my status in the profession	
	I participate to improve my reputation in the profession	
Personal attitude Bock et al. (2005)	**My knowledge sharing with others in the firm works fine**	.92
	My knowledge sharing with others in the firm is enjoyable	
	My knowledge sharing with others in the firm is valuable to me	
	My knowledge sharing with others in the firm is a wise move	
	My knowledge sharing with others in the firm is harmful to me (reversed)	

and information in the five primary activities of a law firm as a value shop. Questionnaire items are listed in Figure 8. All items were derived from previous empirical studies, by Gottschalk (2005), of Eurojuris Norway.

Stage of IT systems was measured both by the current stage and the stage 5-years ago. Questionnaire items are listed in Figure 9. These items were derived from research conducted by Gottschalk (2005). They found that most law firms in Australia

Figure 8. Questionnaire items on value shop activities provided to survey respondents

Use of IT systems for:	*My use of IT systems in lawyer collaboration in the firm provides me:*	*Reliability*
Problem access	**Access to new assignments** **Access to new clients** **Access to new cases** **Access to new projects** **Access to profitable cases** **Access to challenging cases**	.98
Problem solutions	**Help to solve difficult cases** **Help to find relevant laws** **Help to find relevant court rulings** **Help to analyze documents** **Help to draft documents** **Help to find experts in the field**	.92
Solution choice	**Information from relevant laws** **Information from relevant court rulings** **Information from relevant documents** **Information from relevant conclusions** **Information from relevant client advice** **Information about important views**	.94
Solution execution	**Solutions to client problems** **Clarification on opposing side** **Views from participating lawyers** **Views from clients** **Views from opposing side** **Information resolving issues with client**	.95
Execution evaluation	**Quality assurance of closed cases** **Evaluation of work quality** **Learning from own closed cases** **Learning from other's closed cases** **Ideas on how to better solve client cases** **Ideas on how to make a case more profitable**	.95

Please indicate with one check mark the description that most closely fits your firm's projects for information technology to support knowledge management in the firm in 2005:

- ( ) *End-user tools* will be made available to lawyers. This means a capable networked PC on every desk or in every briefcase, with standardized personal productivity tools (word processing, presentation software) so that documents can be exchanged easily throughout the firm. A widespread dissemination and use of end-user tools among lawyers in the firm is to take place.
- ( ) *Information about who knows what* will be made available to lawyers. It aims to record and disclose who in the organization knows what by building knowledge directories. Often called 'yellow pages', the principal idea is to make sure knowledgeable people in the firm are accessible to others for advice, consultation, or knowledge exchange. Knowledge-oriented directories are not so much repositories of knowledge-based information as gateways to knowledge.
- ( ) *Information from lawyers* are repositories of knowledge-based information that will be stored and made available to colleagues. Here data mining techniques can be applied to find relevant information and combine information in data warehouses. One approach is to store project reports, notes, recommendations, letters, and other documents from each lawyer in the firm. Over time, this material will grow fast, making it necessary for a librarian or knowledge manager to organize it.
- ( ) *Information systems solving knowledge problems* will be made available to lawyers. Artificial intelligence will be applied in these systems. For example, neural networks are statistically oriented tools that excel at using data to classify cases into categories. Another example is expert systems that can enable the knowledge of one or a few experts to be used by a much broader group of lawyers who need the knowledge. A third example is case-based reasoning where the system finds a similar case and comes up with a recommended solution for the current case.

and Norway develop according to the four-stage model for the evolution of information technology support for knowledge management.

NEW TECHNOLOGIES FOR LEGAL WORK

Mountain (2001) has posed the question: Could new technologies cause great law firms to fail? In her article, she addresses the question why law firms ought to invest in online legal services when studies to date show that there is no correlation between law firm technology capabilities and profitability. She divides online legal services into two types: digital delivery and legal Web advisors. The framework set out by Clayton Christensen in his book, The Innovator's Dilemma, is used to explain how legal Web advisors is a disruptive technology that law firm competitors (i.e., accounting firms, dot-coms, and corporate clients) are beginning to harness to erode law-firm margins. Unless law firms reinvent themselves as technology organizations, they could find themselves increasingly marginalized. Large law firms need to develop legal Web advisors, and should consider spinning off technology subsidiaries to do so. Small law firms need to link up with online advisory services on an application service provider basis.

Mountain (2001) finds that 15 years ago, artificial intelligence (AI) was set to radically change the face of the legal profession as we know it. As it turned out, neither expert systems nor any other kinds of AI lived up to their potential at that time. They required huge investments and provided marginal perceived payoffs. Eventually, both fell under the weight of their own start-up requirements. Today, AI has been reincarnated in the form of legal Web advisors. Legal Web advisors offer interactive legal advice delivered via extranets without human intervention, using questions to collect facts, and then using decision-tree analysis to produce answers. Some of the world's largest law firms in London, England are pushing ahead with developing legal Web advisors, despite the absence of a link between law firm profitability and use of technology. Why would the London firms, who bill out their services at the highest hourly rates in the world, involve themselves in such risky, low margin endeavors? The answers lie in the disruptive power of these new technologies.

According to Mountain (2001), legal Web advisors were pioneered in London in 1994 when the law firm, Linklaters, introduced a browser-based product called Blue Flag. Blue Flag is now a suite of products covering regulatory compliance, derivatives documentation, employee share plans, funds, share disclosure, and transaction management. Within months, another London law firm, Clifford Chance, followed with NextLaw, a Web-accessible online service that helps assess the legal and regulatory risks of e-commerce, and reportedly required an investment of more than 1 million pounds sterling. Today, there are approximately a dozen online legal services in the UK and Australia, and the pace of their introduction is accelerating. The revenue model, to date, has been to charge these services out by subscription, and then to have lawyers leverage from these online services to attract value added legal work.

Blue Flag is an interesting example. Blue Flag is a legal risk-management service designed to provide packaged legal advice on European financial and banking regulatory issues (hence the name Blue Flag). This service is designed to appeal to those concerned with legal compliance working in fund management, securities houses, investment, and commercial banks, and provides step-by-step legal advice on tap to subscribers for a fixed annual fee. Not surprisingly, having established the service, Linklaters have now extended it to cover other (non-European) jurisdictions where they have expertise. The benefits to clients of this Blue Flag type of system are clear. Consider the following fictional scenario (Terrett, 2000, p. 123):

An in-house lawyer works in a large corporate organization. The company is considering a purchase of a major overseas rival. The lawyer in question has been asked to present a paper to the board on the legal implications of this move. In-house lawyers, being generalists rather than specialists, might be tempted to instruct a firm of respected lawyers to be certain that they have all of the pertinent issues covered. However, they are also likely to be concerned about the resultant bill. Thus, they turn to Blue Flag. Here they can search for relevant information in the knowledge that it has been produced by a highly reputable firm of solicitors, they can print it out and present it to the Board and file it as though it were any other piece of legal advice. The task is completed more quickly and at no additional cost to the company. It is hardly surprising that the service is proving so successful. How have Linklaters achieved this in such a small space of time? They were very fortunate to have already produced much of the content that makes up the site and have it readily available in electronic form. All that was required *was a degree of innovative thinking about how the information could be delivered to clients (i.e., via the Web rather than CD-ROM or paper).*

Online legal services can be placed in two different categories: digital delivery services and legal Web advisors. Digital delivery services deliver human legal product by digital means: the simplest example is the use of e-mail to distribute legal documents. Both law firms and application service providers (ASPs) offer digital delivery. ASPs are companies that deliver software across the Internet by subscription instead of a packaged product. Many large London firms have opted for in-house capability instead, and host their own transactions through branded extranets (Web sites that provide a private body of information to a limited number of external organizations). Examples are Clifford Chance's Fruit Net, Allen & Overy's Newchange Dealroom, and Andersen Legal's Dealsight. Like e-mail, extranets will eventually become an invisible part of the technology infrastructure, and will not form a basis of competitive advantage.

Legal Web advisors, on the other hand, offer interactive legal advice delivered via extranets using artificial intelligence. Legal Web advisors use AI in a more cost-effective and pragmatic fashion than did the systems of 15 years ago. For example, they do not attempt to work independently of lawyer input. Lawyers and knowledge engineers work together to describe the order in which information is obtained and used to determine a solution. The software leads the client from one question to another using a decision tree system. This type of system uses a sequence of decisions based on user input to classify the problem before moving through nodes and subnodes to the problem solution. Once the client has completed the path and has answered all the relevant questions, the software produces output. This output is not in the form of a legal opinion; instead, it is in the form of "You need to do A, B, C, D, and E." It is more similar to the advice a lawyer gives to a friend at a party than it is to traditional legal advice. It provides 90% of the answer in situations where the client does not care about the other 10% and is not willing to pay for it. The distinction between digital delivery and legal Web advisors may blur in the future as online legal services become increasingly sophisticated.

In our perspective of knowledge management ambition, legal Web advisors represent knowledge management level IV. Expert systems are applied to give clients direct access to an information system that can develop and recommend a solution to the client's problem. The system is based on a thorough process, where lawyers and knowledge engineers worked together to describe the order in which information is obtained and used to determine a solution.

Chapter 4.41
Knowledge Management in Professional Service Firms

Dieter Fink
Edith Cowan University, Australia

Georg Disterer
Hannover University of Applied Sciences and Arts, Germany

INTRODUCTION

For professional service firms, such as consultants, accountants, lawyers, architects, and engineers, knowledge is a capacity to act. Knowledge can be used to take action and to serve the client. As market pressures increase, so does the demand for securing and exploiting knowledge for the firm. In addition, a shortage of high-potential professional service providers has increased the 'war for talent' in which firms compete in employing the most talented professionals. These situations are exacerbated by the decrease in lifelong loyalty, a traditional value within professional groups, and the departure and retirement of professionals, often the most experienced ones.

For professional service firms, the main assets are intellectual, not physical, and they have to seek new ways to leverage their professional intellect. It is therefore not surprising that the emergence of technology-enabled knowledge management (KM) has attracted much attention from those firms. The special relevancy of KM to professional service firms is clear: "…in professional services, we are selling the expertise of our people" (Townley, 2002, p. 4; see also Chait, 1999; Foy, 1999). If knowledge is the 'product' or the dominant ingredient, it is worth it to manage that asset, and to establish and manage systematically the acquisition, synthesis, and sharing of insights and experiences. Indeed consultants are seen as the earliest and most successful adopters of KM (Simmons, 2004; Terrett, 1998; Skyrme, 1999).

The core business of these firms is to provide highly developed knowledge-based services grounded on the existence of intellectual assets. "Thus, it makes sense that managing those assets effectively is now looked at as a vital aspect of maintaining competitiveness" (Davis, 1998, p. 11). Intellectual assets exist in various forms, and their exploitation is only restricted by the capacity and readiness of humans to do so. Quinn, Anderson, and Finkelstein (1996) observed:

The capacity to manage human intellect—and to convert it into useful products and services—is fast becoming the critical executive skill of the age. As a result, there has been a flurry of interest in intellectual capital, creativity, innovation, and the learning organization, but surprisingly little attention has been given to managing professional intellect. (p. 71)

BACKGROUND: PROFESSIONAL KNOWLEDGE

Much debate has taken place in recent years on what constitutes knowledge and knowledge management. In this respect comprehensive analyses is provided of this topic by researchers such as Drucker (1988), Swan, Scarborough et al. (1999), Tidd and Driver (2001), and Schultze and Leidner (2002). However, far less has been written about the nature of professional knowledge. Some understanding can be gained by examining the levels at which it operates. According to Quinn et al. (1996), professional knowledge operates at four levels as follows:

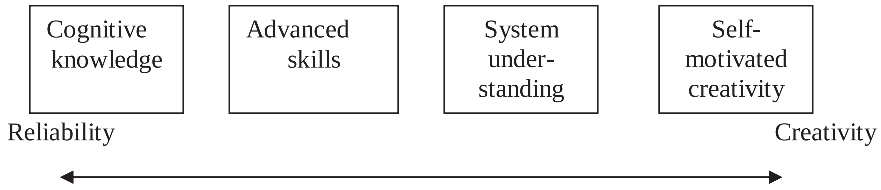
- Cognitive knowledge (know-what): This is the basic mastery of a discipline that professionals achieve through education and training.
- Advanced skills (know-how): This is the ability to apply cognitive knowledge into effective execution in a complex real world.
- Systems understanding (know-why): The deep knowledge of cause-and-effect relationships underlying a discipline, expressed as highly trained intuition.
- Self-motivated creativity (care-why): This is the will, motivation, and adaptability for success, enabling renewal of knowledge in the face of today's rapid changes.

To perform their knowledge work, professionals in the first instance acquire cognitive knowledge (know-what) by undergoing education. To advance their knowledge, to reach the know-why stage, they enter into a period of training in a professional firm, usually in the form of articles of clerkship, under the supervision of an experienced professional. As further knowledge is gained, they are able to demonstrate systems understanding (know-why) and self-motivated creativity (care-why). For professionals, the value of knowledge increases markedly as they move up the knowledge scale from cognitive knowledge to self-motivated creativity. Figure 1 shows the various forms of professional knowledge on a scale.

Evans and Volery (2000) defined the nature of services being able to be offered by professional service providers as intelligence, consulting, counseling, relationship networking, education, and training.

- Intelligence: The provision of quality information to sharpen, improve, or support the 'cleverness' of clients in situations such as decision making. Professional knowledge is required to structure and present the information so that is has optimum utility for clients.
- Consulting: The customization of information to satisfy the particular circumstances of a client. Consulting requires the ability to apply and transfer a high level of professional knowledge to the client.
- Counseling: Acting as mentor to the client, the service provider works with the client to structure, identify, and recommend appropriate approaches to the client's problems. High levels of professional experience, knowledge, and motivation are required and provide a good example of a 'care-why' knowledge type.

Figure 1. Professional knowledge and value



- Relationship networking: The ability of the service provider to bring clients into contact with other clients or parties that may have the potential to provide them with business benefits. At these meetings, exchanges take place in the form of information, ideas, experiences, and so forth.
- Education and training: Similar to counseling but in a more formal and structured setting, the service provider imparts knowledge, information, and skills to clients.

To understand the nature of professional services, they should be compared with the nature of products. This was done by Alexander and Hordes (2003) as reflected in Table 1.

It can be deduced that professional knowledge services are intangible in nature in that they do not have the physical dimensions and components of products. It is therefore not usually possible for a client to see, touch, or feel the professional service he or she is about to receive. Furthermore, the production and consumption of services occurs simultaneously. Usually this requires the service provider and client to be present during the conveying of the service. A further characteristic makes professional knowledge services heterogeneous—that is, neither homogenous nor of a standardized quality. The context in which services are demanded and delivered constantly change.

Table 1. Distinction between products and services

Dimension	**Product**	**Service**
Production	Built	Performed
Production Costs	Uniformity	Uniqueness
Involvement	Rarely	Usually
Quality Control	Compare output to specification	Compare expectation to experience
Poor Quality Procedure	Recall	Apologize and atone
Moral and Skill Level	Important	Vital

KNOWLEDGE MANAGEMENT

According to a well-recognized paper by Hansen, Nohria, and Tierney (1999), professional service firms employ two very different KM strategies. The authors used the consulting business as an example, but pointed out that the approach can be generalized across all professional service firms. According to them, some professional service firms concentrate on the codifiable knowledge of their employees and try to capture, store, and reuse it. In the codification approach, also called "people-to-documents" approach, knowledge is made independent of the individual who developed it and is reused for various purposes, for example within other consulting projects, for other industries, or in other countries.

The application of this strategy results in a repository of systematically encoded knowledge for subsequent distribution and usage. Because the approach exhibits a flow of knowledge into and out of a central repository, the approach could be named "integrative" (Zack, 1998, p. 92). This school of thought aims to codify and reuse knowledge to improve efficiency. As knowledge is transferred into documents and/or files and can be handled as knowledge products, the approach is akin to a "product-centered" KM approach (Mentzas, Apostolou, Young, & Abecker, 2001).

In other professional service firms, the most valuable knowledge is believed to be closely tied to the person who developed it. This knowledge is mainly transferred by direct person-to-person contact; the approach is therefore called a "personalization" approach (Hansen et al., 1999). As supporting communication processes among people is its main focus, it could be named an "interactive" approach (Zack, 1998) or "process-centered" approach (Mentzas et al., 2001). The approach is anchored in organizational learning theory and aims to build up organizational memory by facilitating learning processes. Strictly speaking the personalization strategy is not 'really' about the management of knowledge, but more about management of communication and conversation between people.

The main characteristics of codification and personalization strategies are summarized in Table 2.

The two approaches, codification and personalization, are not mutually exclusive (Hansen et al., 1999; Earl, 2001; Zack, 1998) but must be combined appropriately. However, the approaches give distinct hints about the use of information and communications technology (ICT) to support KM.

Codification focuses on identifying and explicating knowledge into knowledge objects in

Table 2. The two main KM approaches

Approach 1	**Approach 2**	**References**
codification	personalization	Hansen et al., 1999
people-to-documents	people-to-people	Hansen et al., 1999
integrative	interactive	Zack, 1998
product-centered	process-centered	Mentzas et al., 2001
knowledge as object	knowledge embedded in people	Wasko & Faraj, 2000
knowledge as object	knowledge as process	Garavelli, Gorgolione, & Scozii, 2002

order to give access to knowledge to all employees of the professional service firm. Extraction processes are implemented to identify specific knowledge and experiences, and make them more generic. Sometimes special roles like "knowledge harvesters" (DeVoss, 2000) or "catalysts" (Fitter, 2000) are defined to establish responsibilities for identifying, systemizing, editing, and documenting valuable knowledge in the form of checklists, precedents, or forms. The knowledge objects are then stored in databases that allow flexible and fast access and retrieval. Various ICT-enabled functions support the access, such as:

- classification systems to retrieve objects by keywords;
- full-text search features;
- topic maps to visualize content and relations between items; and
- push features, which alert a user when certain knowledge items are changed or when they are added to a specific topic.

Personalization fosters communication and conversation between employees of a professional service firm—across time, space, and hierarchy. Conservative habits within firms sometimes hinder free conversation across hierarchies or lines of business. Especially in large and globally distributed firms, employees can lose opportunities to exchange ideas and suggestions. ICT is therefore used to connect people and to mediate communication using features such as:

- expert finder systems containing profiles of employees so that their special expertise can be retrieved or they can be contacted for advice;
- communities of practice are built with the use of ICT, where employees with similar professional interests (e.g., consulting services for retail industry, auditing of banks) can meet and have discussions in an electronic environment;
- use of electronic blackboards, group calendars, or mailing lists to establish and support groups of employees working together;
- conference systems fostering personal contact and face-to-face communication.

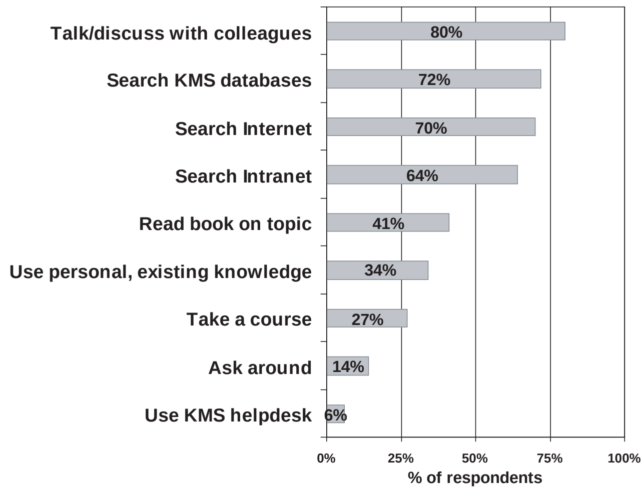
The literature reflects several comprehensive descriptions of how ICT can be used in innovative ways to support KM in professional consultancy service firms. They include Alavi (1997), Bartlett (1996), Christensen and Baird (1997), Ezingeard, Leigh, and Chandler-Wilde (2000), Heisig, Spellerberg, and Spallek (2003), Hirsh, Youman, and Hanley (2001), Manville (1999), Martiny (1998), Tallman, Horwitch, and Armacost (2002), Vorbeck and Habbel (2001), and Vorbeck, Heisig, Martin, and Schütt (2003). The large extent of publications may partly be driven by the desire of consultancies to promote their services to other firms doing KM projects by demonstrating their KM competencies through the media of publications.

In addition to describing KM systems, empirical data is available on how KM systems are used by professionals. An analysis of the KM system in one consultancy provides insight into the knowledge usage patterns of consulting professionals (Kautz & Mahnke, 2003). The case organization is a large global consulting firm with more than 100,000 employees located in more than 100 countries. The KM initiative of the firm started in 1995, with the case analysis being conducted in 2000. Figure 2 gives the knowledge sources professionals used when they need knowledge or information about a specific topic.

Kautz and Mahnke (2003) also identified serious problems and factors causing non-adoption of KM systems:

- The KM system is not used as the primary store of knowledge.
- Mostly general information is searched within the KM databases.

Figure 2. Information sources used by consultants



- Only half of the users are participating in knowledge networks.
- Usage is limited by professionals' lack of time.
- Participation in development of KM systems is low.
- Various functions of KM systems are not used heavily.

Other empirical findings from broader samples indicate more clearly that "lack of time," "lack of sharing culture," and "lack of general understanding of knowledge management" are the major barriers to KM initiatives (e.g., Ruggles, 1998; KPMG, 2003). It can therefore be concluded that technological issues may not be the dominant ones when supporting KM in professional service firms. Moreover, various cultural barriers need to be overcome to foster knowledge sharing (Disterer, 2003). For example it has been found that sharing knowledge is an "unnatural" behavior for many (Quinn et al., 1996; Barua & Ravindran, 1996; Holloway, 2000; Colier et al., 1996). People issues are seen to be critical for successful knowledge sharing: "In fact, if the people issues do not arise, the effort underway is probably not knowledge management. If technology solves the problem, yours was not a knowledge problem" (Ruggles, 1998, p. 88).

Linked to knowledge sharing is the question of what role incentives and rewards play in encouraging professionals to share their tacit knowledge. Laupase and Fink (2002) found from a series of case studies of management consulting firms that reward systems did motivate consultants to share knowledge with each other. The most effective scheme was found to be sharing knowledge in informal meetings and offering non-financial, intrinsic rewards. Consultants were found to be most comfortable in an informal environment, as they felt it was easier to engage and to ask further follow-up questions. They were also more in favor of intrinsic rewards, such as being recognized, encouraged to participate in decision making, and feeling a sense of belonging.

However, an opposing view to the preparedness of knowledge sharing exists. In professional service firms, employees compete directly with each other through their special knowledge, gifts, and talents. It might be part of the individual culture of the high-performing employees that they compete for the best positions in their career paths because they like to compete and to excel on principle (Quinn et al., 1996). Thus, with internal competition knowledge workers would be very cautious to openly share their knowledge with colleagues, because they would possibly give up individual advantages. Furthermore, they are often rewarded to build a unique expertise in a certain area and to provide that expertise to clients, rather than to share it with colleagues. Additionally, many professional service firms bill services to the clients based on chargeable hours. This approach tends to devalue an activity that is not 'billable', like helping colleagues with their professional problems.

As seen above, various individual and social barriers must be taken into account when initiating and establishing KM in professional service firms. Disterer (2003) categorized those barriers and gives a list of possible actions to foster knowledge sharing. These range from cultural actions like building trust and mutual understanding and support for give-and-take attitudes within the firm (to build up a knowledge-friendly culture), organizational actions to form groups of people working on similar issues, and human resource (HR) management to provide incentives and rewards to the professionals in order to enhance knowledge sharing.

A recent survey by the American Productivity and Quality Center (APQC) gives some insights about how top consulting firms organize their KM activities (Simmons, 2004). The survey shows that the most efficient firms do have a core KM team that centrally develops strategies, directs and coordinates activities, facilitates projects, and builds central systems like search engines and portals. Beside these central functions, the actual knowledge work is carried out in the decentralized business lines. The cost for all KM operations was found to be a median 0.5% of the revenue.

FUTURE TRENDS

It is expected that one major trend will be providing clients direct access to the knowledge base of professional service firms. Databases with 'lessons learned' and 'best practices' are shared with clients in order to raise customer loyalty. Ongoing information services to clients generated by software agents and pushed to clients will improve the client relationship. In the legal area, some examples are known where law firms are providing document assembly generators to enable clients to build up contracts on their own (Parnham, 2002).

Technology-enabled client services, mainly delivered through e-mail or on the Web, will consolidate existing client relationships, for example through more frequent interactions, and also invigorate them by the addition of new forms of client value. Fink (2001) investigated the evolution of professional accounting firms and found that "KM provides the opportunity to develop entrepreneurial versus the administrative capabilities of the firms" (p. 494). Opportunities identified included knowledge support and knowledge brokering. However, risks such as the reduction of context and a shift of power to the client were also acknowledged.

Integrating internal content of a knowledge base with external content will be a further challenge. Software agents will search through external databases and build references to internal knowledge objects. For better access to the knowledgebases, mobile access for those professionals working at the clients' premises will have to be implemented.

CONCLUSION

The management of knowledge in professional service firms deserves much attention since knowledge is the key resource of these firms. Effective KM systems therefore need to be developed and utilized. This article has shown that the value of professional knowledge increases over time, which in turn increases the urgency to have it captured and made available to those with lesser knowledge and/or experience. However, the nature of professional knowledge (intangible, perishable, heterogeneous) poses particular challenges to implementing KM systems.

It is clear that ICT has opened up many opportunities to supporting the KM activities of professional service firms. However, a number of strategic choices have to be made and importantly the use of ICT has to be supported by effective HR management. Essentially there are two approaches to KM, the codification or product approach and the personalization or process approach. Whatever approach is used, there are many obstacles that need to be overcome before KM systems are operational and become fully utilized. Success is largely dependent on the human element within the firms. Issues such as incentives and rewards for knowledge sharing need to be identified and resolved within the firms.

Many case studies have been published on leading professional firms and their experiences with KM. Valuable lessons can be learned from them. Furthermore, more developments are on the horizon which will ensure that the topic of KM in professional service firms will remain topical for years to come.

Chapter 4.42
Knowledge Management in Civil Infrastructure Systems

Hyung Seok Jeong
Oklahoma State University, USA

Dolphy M. Abraham
Loyola Marymount University, USA

Dulcy M. Abraham
Purdue University, USA

INTRODUCTION

This article reviews current research and practice of knowledge management (KM) in the management of Civil infrastructure systems. Civil infrastructure systems, such as energy systems (electric power, oil, gas), telecommunications, and water supply, are critical to our modern society. The economic prosperity and social well being of a country is jeopardized when these systems are damaged, disrupted, or unable to function at adequate capacity. The management of these infrastructure systems has to take into account critical management issues such as (Lemer, Chong & Tumay, 1995):

- the need to deal with multiple, often conflicting objectives;
- the need to accommodate the interests of diverse stakeholders;
- the reliance of decision making on uncertain economic and social issues;
- the constraints in data availability; and
- the limitations posed by institutional structure.

BACKGROUND

KM approaches can play a central role in facilitating the effective management of these infrastructures. While well-designed information systems can get the right information to the decision maker at the right time, the age of the components of the infrastructure and a lack of available and usable records leads to utility managers frequent inability to take proactive measures to prevent system failures. Further, these infrastructures are interdependent, and managers at the various utilities and agencies need to work together to mitigate the risk of such threats and vulnerabilities. Analyzing each individual infrastructure system and the knowledge derived from managing each individual infrastructure becomes insufficient when managers have to make decisions at the intersection of multiple disciplines in a multihazard context. Sharing of information and ideas become critical to help detect and mitigate hazards and plan the recovery and response strategy.

Traditionally, utilities (especially the water utility) have been rich in "raw data but poor in the aggregated information derived from these data" (Rosen et al., 2003). Transforming the data into knowledge necessitates an understanding of the quality of the data and the aggregation measures used. KM approaches provide the basis for the development of relationships between different data structures and decision makers and by developing a higher level understanding of how information and process knowledge relate to one another.

Perez (2003) identified four common trends in the utility industry: the diminishing workforce, growing competition within the public sector, deterioration of employee loyalty, and increasing public involvement in government. Due to the concern about the potential negative impact of these trends on the ability to retain and share the institutional knowledge they currently possess, utilities have sought to find a method to efficiently maintain and improve the knowledge level of utility management.

Rosen et al. (2003) also point out that utilities lack a mechanism to aggregate, analyze, and restructure information in order to create knowledge. In general, many potential data users within a utility are not aware of a significant amount of the available data. Besides, in most cases, data are stored at multiple areas for the needs of the users. An organized directory of the entire data rarely exists. This creates redundancy of data and inefficiency of data retrieval.

Utilities have been recognizing the benefits of adopting KM strategies in their organizations. Foremost among these include the reduction in lost knowledge from downsizing and restructuring. Improving efficiencies of operations and workflow and improving customer satisfaction are also cited as reasons for moving toward a KM environment. Privatization of public and municipal utilities and increased regulation requires utilities to maintain a better handle of these physical and intellectual assets and liabilities.

However, there are several barriers impacting the access and use of information within a utility. These include a lack of awareness of what information (both internal and external) is available; difficulty in obtaining data access; lack of appropriate software for accessing, analyzing, and interpreting data; and the lack of complete historical data about the utility infrastructure and GIS base maps. In addition, the traditional "paper centric" nature of many utilities and lack of a

central repository of information make it harder to access information that is available within a utility. Further, "a large array of critical information for the utility is maintained in the heads of a few critical people" (Rosen et al., 2003).

These problems may be compounded in the future with new security requirements that are likely to restrict the flow of information. While the absence of complete historical data is a problem that is not easily fixed, information stored on paper can have implications that are both positive and negative. It is likely to be more secure than data stored electronically while the cost of use and maintenance is likely to be higher. It is necessary to find a solution that makes information available to utility managers so that they can do their job more effectively while also controlling access to the information more effectively.

EXAMPLES OF KM APPLICATIONS IN UTILITIES

The American Water Works Association (AWWA) Research Foundation completed a study in 2003 that investigated the feasibility of application of KM in the utility industry, specifically in drinking water utilities (Rosen et al., 2003). In this study, a review of 20 case studies related to utility management literature indicated that the primary areas of interest in upgrading information and knowledge management are:

- Supervisory Control and Data Acquisition (SCADA);
- Laboratory Information Management Systems;
- Geographic Information Systems (GIS);
- Maintenance Management Systems;
- Customer Relationship Management (CRM) and Tracking Systems; and
- Enterprise-wide Information Systems to tie other systems together.

The first five areas are operational systems focused on automation of specific department's current workflow and needs. The last area emphasizes synergy in the use of data. Currently, applications of KM in utilities are very limited, but the following case studies briefly demonstrate how KM approaches can be successfully applied to utilities.

- Columbus Water Works serves drinking water and treats wastewater for almost 200,000 residents in the Columbus, Georgia region. A data warehouse was implemented to act as a central source of all information from all of their applications. The star schema database adopted in this case consists of six primary "stars", including customers, employees, inventory, measurements, work orders, and accounting. A star schema allows for each sector data to be independent but also allows for integration of data through the central data warehouse. The utility reported that the main benefit is cost control, and it allows them to collect and distribute information between applications, better manage expenses, monitor data trends over time, and explore any unexpected variations.
- The OTAY Water District provides water and/or sewer facilities to about 100,000 people in San Diego County. They are using a new information management system, Myriad viewing software, allowing employees direct access to maps on their laptop, eliminating the need for the GIS department to reply to requests for drawings from employees in different departments.
- The Canadian electricity company, Ontario Hydro, is responsible for providing access to the 16,000 Material Safety Data Sheets (MSDSs) on the hazardous materials used at the utility to all employees. These sheets originated at the 2,100 companies that produced the hazardous chemicals and were then sent to Ontario Hydro. Since there has been a concern about the employees getting the most accurate information about the data due to losing MSDSs or spilling oil on them, Spicer's Imagination imaging soft water was implemented and linked to their existing database allowing for images to be scanned or faxed, which facilitates viewing the MSDSs for the employees.
- Michigan Consolidated Gas Company distributes natural gas to approximately 1.2 million residential, commercial, and industrial customers. IBM developed and implemented a system, Interactive Voice Response (IVR), which integrated the utility's voice and data systems. The IVR provides information to customers, including balance and payment histories, budget, billing, enrollment, payment agreements, service requests, and repair status. This automated service increased productivity in customer

relations allowing the personnel more time to handle other issues.
- In 2003, the North Miami Beach Public Services Department was in the process of implementing a knowledge base for its water utility (Perez, 2003). In its early development stage, knowledge management focused on explicit knowledge sharing between internal subunits. The water utility operation was divided into three different segments including water production, water quality, and water distribution. All explicit knowledge in each segment, such as monthly operating reports, facility permits, record drawings, consultant studies and reports, and equipment data management sheet, was created in electronic format so that captured knowledge did not disappear. By placing the database for each segment within a secure network, critical information can be shared by the staff, improving efficiency of work by significantly reducing the amount of time spent on searching and retrieving a document.

The aforementioned cases illustrate that a variety of information technologies and systems are employed to support KM initiatives. What is important to note is that KM is not viewed as a technology solution; rather, it is planned as a set of management processes that utilize appropriate information technologies in an effective manner.

IMPACT OF THE INTERDEPENDENCIES BETWEEN UTILITIES

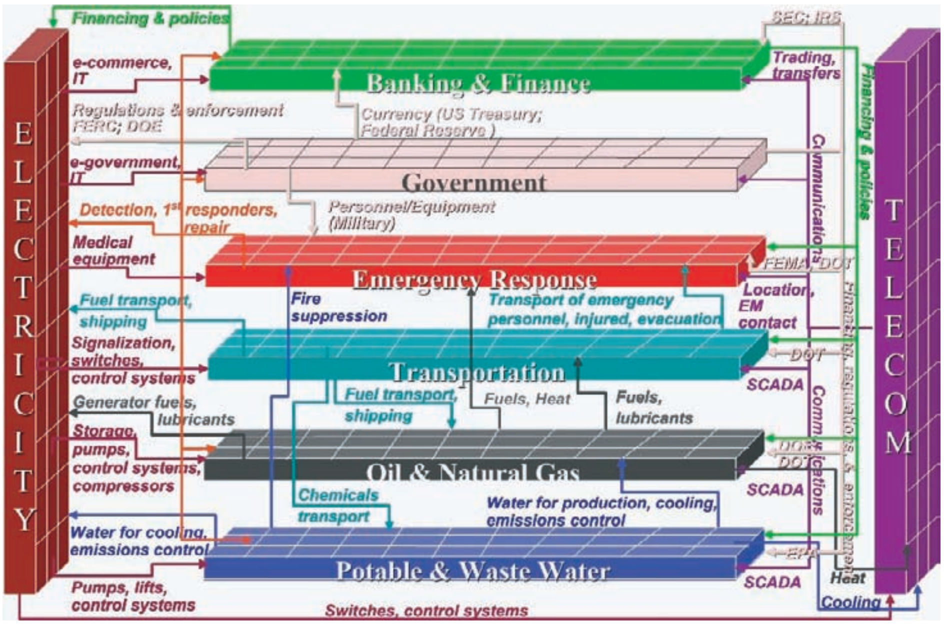
The August 2003 electrical blackout in the Northeast USA emphasized that the functioning of any utility is dependent on the effective functioning of other utilities. For instance, after the blackout, residents of New York's many high-rise buildings lost water, since electric pumps are required to get water to the upper floors. The blackout also compromised the water supply in Detroit, Michigan and Cleveland, Ohio in at least two ways: first, by decreasing the pressure in water pumps, allowing bacteria to build up in municipal water systems and, second, by effectively shutting down sewage treatment facilities (Johnson & Lefebvre, 2003). Some communication utilities, including telephone service and Internet communications could not operate properly as they had an inadequate level of electricity back-up systems.

KM ACROSS CIVIL INFRASTRUCTURES

Figure 1 illustrates how the utilities are interwoven with each other for their proper operation. Even with the growing interdependency between these utilities, there are few communication routes between utilities. More importantly, information sharing or knowledge management paradigm across utilities is rare. Developing KM initiatives to support utility managers without considering the interdependencies may lead to decisions that emphasize local efficiency instead of global efficiency of the utility. Knowledge management processes across utilities will help the managers to respond rapidly to reduce the adverse consequences due to malfunction of dependent utilities, or even to plan ahead before incidents in order to eliminate the cascading effects. Moreover, once knowledge is shared between utilities, a solution for the global optimum for profit maximization and/or service reliability can be sought by strategically managing their resources instead of developing locally optimal solutions solely for each utility's profit.

The issue of interdependence can be demonstrated using the case of Colorado Springs Utilities, an innovative water utility in the western US. This case study demonstrates how information sharing between utilities can simultaneously

Figure 1. Infrastructure interdependency (Heller, 2002)



improve efficiency of operation and reduce costs of operation (Heller, 2001; Jentgen, 2004). The energy and water quality management system (EWQMS) of Colorado Springs Utilities is conceptually an extension of electric utilities' energy management systems (EMSs), which include power generation control and real-time power systems analysis.

Some aspects of the EWQMS are substantially more complicated than EMS. For example, in an EWQMS where hydropower is an option, decisions about pumped storage are coupled with the selection of electricity sources to exploit time-of-day electricity pricing. Alternatively, if spot market prices are exorbitant, hydropower might best be used to generate electricity for sale. Whereas EMS's power generation control has a short-term load-forecasting component, the EWQMS has two sets of demands to predict and satisfy: one for electricity and one for water. In addition, scheduling decisions also consider the following aspects:

- what quantity of raw water from which source is subject to water rights, quantity, and quality constraints, given variable pumping costs;
- what quantity of water is to be treated at which plant, given variable treatment costs; and
- which pumps are to be used for distribution, collection, and wastewater treatment and which ones should be taken off-line for maintenance.

The Colorado Springs Utility estimated that the cost reduction using the aforementioned approach would be worth more than $500,000 per year, not including windfalls from higher electricity prices. Heller, Von Sacken, and Gerstberger

(1999) also discuss the concept of shared resources as a means of achieving regional eco-efficiency. In this context, "information system boundaries are extended to coordinate the shared production, consumption, treatment, or reuse of electricity, water, and wastewater resources among regional utilities and manufacturing facilities" (Heller, 2001).

BARRIERS TO THE PROPER APPLICATION OF KM IN UTILITIES

Many utility organizations are moving toward a KM approach to take advantage of the usefulness of information. However, implementing KM processes requires a significant change in a utilities organizational culture to be successful. For instance, the perception that data belong to one part of the organization to the exclusion of others must be changed. This cultural change is often more difficult than the investment and challenge of gathering and organizing all of the required information.

There is a general consensus that no single system will result in an effective KM initiative. Introducing KM processes will require careful thought and reorganization of workflow. Because management of a utility consists of various different business practices from laboratory operations to customer relations, careful studies regarding information structures and potential data transfer protocols and available information tools must be implemented before a KM initiative is launched.

A very low level of recognition regarding the need for information sharing and knowledge management framework across utilities is one of the significant barriers. Although the need to analyze the interdependencies between utilities were emphasized through the President's Commission Study (PDD 63, 1998), the mechanisms of these interdependencies is still not clearly known and is currently under investigation by researchers, including those at the Sandia National Laboratories, Argonne National Laboratory, and several universities.

The September 11, 2001 terrorist attacks and the blackout in the northeast US in August 2003 have propelled interest in further investigating these interdependencies. A report after the August 2003 blackout indicates that almost half of the companies that participated in a survey regarding the impact of the August 14th power failure were willing to invest their money to reduce the risk of their business to utility service outage in order to continue their business (Stoup, Slavik & Schnoke, 2004).

While it is possible to invest in information technology and systems to help reduce the risk of service outage, it is not possible to engineer a system that takes care of all possible eventualities. Because of interdependencies between utilities and causes for service outage are likely to be specific to a single utility, as well as pairs or groups of utilities, it is necessary for managers at these utilities to analyze interdependencies and to identify vulnerabilities. One approach to facilitate this analysis is the use of focus groups or brainstorming sessions with utility managers. Consecutive meetings of this group may help identify what data must be shared between utilities and what KM system can be structured in order to reduce risk to service outage due to outages in interdependent utilities.

Another concern is security of information. Utilities tend to hesitate sharing their internal information with others especially since September 11, 2001. Only minimal information is made available on the Web. The structure or topology of the utility network and information about operations is not disclosed to the public. While this trend may hinder the development of well-structured information systems to solve problems among utilities, it is necessary to find ways in which information and process knowledge can be shared without creating sources of vulnerability. This could be through predetermined and secure channels of communication.

KNOWLEDGE MANAGEMENT CONCEPTS RELEVANT TO MANAGEMENT OF CIVIL INFRASTRUCTURE

In managing critical infrastructures, the ability to capture and reuse tacit knowledge (Polanyi, 1967) is vital given the changing nature of threats, especially those that are intentional and human induced. Standard operating procedures and documented methods may not provide an appropriate guide under novel situations. In such a scenario, the decision maker needs support in the form of access to information about prior incidents and how they were handled. Further, given the interdependence between critical infrastructures, access to information about events in related utilities becomes important.

Each organization within an infrastructure works in a relatively unique manner based on its organizational culture and traditions. When comparing organizations in different infrastructures, the situation becomes more complex given disparate engineering set-ups and regulatory regimes. Information sharing about interdependencies is a starting point and is likely to be acceptable if the system links are designed with appropriate levels of security. In addition, given such a dynamic environment, the ability to "capture" discussions to glean ideas becomes extremely valuable.

The role that KM can play is one of accumulating knowledge from employees to make the organization work better. In the context of managing critical infrastructures, the purpose is to learn from each incident across infrastructures to enable a decision maker to handle a current or future unique incident for which there is not a standard operating procedure available.

Knowledge management is therefore about changing the way work is done. When threats are constantly changing, mere understanding of current threats and methods to mitigate them are not sufficient. It is necessary to have a process in place where the organization learns from each incident and develops strategies to improve the way in which vulnerabilities are assessed, disasters mitigated, and failures managed. KM processes create a structure that enables reflection of events, analysis of data, and procedures to facilitate learning and making more effective the decision-making process of utility managers. However, as Nidumolu, Subramani, and Aldrich (2001) point out "to be successful", KM initiatives "need to be sensitive to features of the context of generation, location and application of knowledge". The operating procedures, technology and information systems, and organizational culture will collectively impact the knowledge management efforts in infrastructure management.

CONCLUSION

The purpose of KM processes in civil infrastructure management is to assist owners to provide services economically and reliably. Utilities have to operate in an environment constrained by customer service requirements, regulations, shareholder expectations, and an aging infrastructure. Civil Infrastructure managers need the capabilities provided by KM approaches to help them manage more effectively.

However, implementing KM processes goes beyond deploying specific types of information technologies and systems. Systems that support the sharing of information and process knowledge within civil infrastructures must be coupled with changes to operating and managerial procedures. These changes have to take into account the interdependencies between related infrastructures as well as the security risks imposed by release of critical information. It is necessary for the owners and top-level managers at critical infrastructures to take a much closer look at this issue so that they can allocate the appropriate resources to implement effective knowledge management processes.

Chapter 4.43
Knowledge Management in Healthcare

Sushil K. Sharma

ABSTRACT

Healthcare organizations are facing many challenges in the 21st Century due to changes taking place in global healthcare systems. Spiraling costs, financial constraints, increased emphasis on accountability and transparency, changes in education, growing complexities of biomedical research, new partnerships in healthcare and great advances in IT suggest that a predominant paradigm shift is occurring. This shift is necessitating a focus on interaction, collaboration and increased sharing of information and knowledge which is in turn leading healthcare organizations to embrace the techniques of Knowledge Management (KM) in order to create and sustain optimal healthcare outcomes. This chapter describes the importance of knowledge management systems for healthcare organizations and provides an overview of knowledge management technologies and tools that may be used by healthcare organizations.

INTRODUCTION

Knowledge Management (KM) is an essential tool in today's emerging healthcare system. Hospitals that seek to deploy KM systems need to understand the human element in the process. Earlier, success factors were only restricted to a few healthcare variables such as patient care and cost, but over the years, technology (both clinical and administrative) has evolved as a differentiating variable, thus redefining the doctrines of competition and the administration of healthcare treatments. For example, in today's healthcare environment we are now treating patients with an emphasis on prevention and managing the patient through good health throughout their life. Such an approach requires significant investment in knowledge assets. One of the key objectives of a KM system is to insulate a hospital's intellectual knowledge from degeneration (Elliot, 2000).

Most hospitals are unaware of their acquired knowledge base. Further, knowledge capital is often lost from a hospital through employee attrition, high turnover rates, cost-saving measures and improper documentation (Chase, 1998). Specific KM tools and metrics help focus the hospital on acquisition, retrieval and storage of knowledge assets both tangible and/or other for activities such as learning, strategic planning and decision making (Oxbrow, 1998). This goes a long way in crafting a coherent and well-designed growth plan for the hospital (Allee, 1997, 1999). KM treats intellectual capital as a managed asset. Improved patient care is directly proportional to a hospital's intellectual assets. The tactical expertise and experience of individual workers should be fully captured and reflected in strategy, policy and practice at all levels of the hospital management and patient care activity (Conklin, 1998). The intangible asset of knowledge of the employee can nurture radical innovation in advance planning, change management, hospital culture and well balanced approaches. Fostering a knowledge-sharing attitude and competency of patient care processes are vital for any KM program in healthcare (Burca, 2000; Matheson, 1995). Hospitals managing and sharing their knowledge assets effectively will have benefits of cycle time reduction, cost reduction, improved return on investment, higher satisfaction index, and better medical and paramedical education levels (Antrobus, 1997; Atkins et al., 2001).

KNOWLEDGE MANAGEMENT

Knowledge Management (KM) is an emerging, interdisciplinary business model dealing with all aspects of knowledge within the context of the firm, including knowledge creation, codification, sharing and how these activities promote learning and innovation (Choo, 1998). Unfortunately there's no universal definition of KM, just as there's no agreement as to what constitutes knowledge in the first place (Beckman, 1999). For this reason, it's best to think of KM in the broadest context:

KM is a discipline that promotes an integrated approach to identifying, managing, and sharing all of an enterprise's information assets, including database, documents, policies and procedures, as well as unarticulated expertise and experience resident in individual workers (Wickramasinghe, 2003). There are many dimensions around which knowledge can be characterized such as storage media, accessibility, typology and hierarchy. Each of these dimensions is explained in this chapter (Brailer, 1999; Broadbent, 1998; Skyrme, 2001, 1999, 1998; Davenport & Prusak, 1997, 1998).

Knowledge Storage Media

There are several media in which knowledge can reside including: the human mind, an organization, a document and/or a computer. Knowledge in the mind is often difficult to access; organizational knowledge is often dispersed and distributed; document knowledge can range from free text to well-structured charts and tables; while computer knowledge can be formalized, sharable and often well structured and well organized. In order to effectively manage KM it is important to pay careful attention to the most useful storage media.

Knowledge Accessibility

Intellectual and knowledge-based assets fall into one of three major categories (Nonaka, 1994;

Nonaka & Nishguchi, 2001; Sharma & Wickramasinghe, 2004):

- Tacit (human mind, organization): accessible indirectly only with difficulty through knowledge elicitation and observation of behavior.
- Implicit (human mind, organization): accessible through querying and discussion, but informal knowledge must first be located and then communicated.
- Explicit (document, computer): readily available, as well as documented into formal knowledge sources that are often well organized, often with the help of IT.

In order for effective KM to ensue, it is necessary to understand these categories of knowledge as well as their subtle nuances.

Knowledge Typologies

Typologies are defined, characterized and described in terms of knowledge type-conversion, structural features, elementary properties, purpose and use, and conceptual levels. Knowledge typologies play an integral role in a robust KM system.

Knowledge Hierarchy

A further dimension considers the premise that knowledge can be organized into a hierarchy. Several authors draw distinctions between data, information and knowledge (Allee, 1997; Devenport & Prusack, 1998; Leonard, 1998).

- Data: Facts, images and sounds.
- Information: Formatted, filtered and summarized data.
- Knowledge: Instincts, ideas, rules and procedures that guide action and decisions and are context dependent.

Strictly speaking, KM is a process that identifies and creates knowledge assets. In healthcare, KM optimally utilizes these assets to fulfill the core healthcare objectives. Knowledge assets in hospitals are intangible but they can be defined as knowledge that a medical/paramedical/nonmedical person has with respect to patient care, medical needs, operating environment and technologies, something that he or she can utilize in routine medical and healthcare management. KM identifies and maps intellectual assets within the hospital, thereby generating precious knowledge capital for competitive advantage within the medical institution. Since knowledge is dynamically imbedded in organizational and healthcare networks and processes as well as in the staff that use them, hospitals need to have a built-in KM system that "crisscrosses" with its healthcare networks (Jackson, 2000). The result is that employees will then be better informed and continuously updated on the latest tools and best practices. It is important that the techniques adopted to enable KM must take into account some basic factors such as the type of hospital, its culture and its needs to ensure a successful KM system for a healthcare setting (Gokce, 2002; Johnson, 1998; Keeling & Lambert, 2000).

THE NEED FOR KM IN HEALTHCARE

The health sector is large, accounting for between 6% to 12% of GDP across OECD countries. Though the use of healthcare services varies between nations, public expectations of them globally have risen dramatically everywhere since 1950 and the trend is still upwards. Fresh demands arise from the appearance of new drugs and the invention of new technology, from advances in prevention and diagnosis as well as therapy, and from new categories of demand, such as care of the elderly (Eisenberg, 2002). The health sector is complex and includes a range of key actors: patients, providers, practitioners, payers, purchasers, pharmaceutical industry, and professors. The interaction among these actors shapes what counts as relevant knowledge as well as how it is produced, mediated, and used (Conner, 2001). Further, the domain of medical knowledge has expanded to such a degree that a human mind can no longer retain it all. There are now some 20,000 medical journals in the world. A professor of medicine spends on average one day a week to remain abreast of studies in his/her field of interest as well as for his/her research. What can a generalist physician do? How much time can he/she devote to "keeping up"? In France, there are some 7,000 prescription drugs based on some 3,500 active ingredients. A physician has the right to prescribe them all. Can he/she be familiar with all of them? He/she must also be aware of some 300 medical references, some 800 biological tests, more than 1,000 imagery tests, and more than 1,500 surgical interventions. If he/she prescribes six drugs, he/she must also be aware of some 720 potential sources of interaction. The figure reaches 3,328,800 if 10 drugs are prescribed. In addition to the therapeutic value of each molecule, the physician should also know their price and potential effect on specific population groups (diabetics, the obese, children, the elderly, etc. The growth in knowledge has necessarily led to specialization, which too has meant "balkanization" and lack of coordination, especially in hospitals but also in private practice (Halpern, Perry & Narayan, 2001; Dean, 2002). As knowledge is shared, responsibility and decisions about treatment should be shared as well (Eisenberg, 2002). Hospital Information Management (HIM) professionals, like other healthcare personnel, have always sought, used, and valued knowledge about their practice. Managers hire experience because they understand the value of knowledge that has been developed and proven over time. Unfortunately, they are bombarded each day with information in the form of e-mails, voice mails, faxes, reports, memos, and so on — much of which is repetitive or simply not useful. On the other hand, the same professionals spend a great deal of time looking for the information they need by accessing the Web, sending e-mails, making phone calls, and scouring computerized reports. It is in this process that KM can make a difference. Studies have shown that managers get two-thirds of their information from face-to-face meetings or phone conversations. Only one-third comes from documents or other knowledge bases. Unlike material assets, which decrease in value as they are used, the value of knowledge increases with use. For example, new ideas on records storage or retrieval breed other new ideas, and shared knowledge stays with the giver while it enriches the receiver (Jadad, Haynes, Hunt & Browman, 2000). The potential for new ideas arising from the store of knowledge in any healthcare organization is to provide a common entry point for corporate knowledge, such as formularies, clinical road maps, and key financial indicators (Einbinder, Klein & Safran, 1997). Thus what we can see is that the need for KM in healthcare is critical and becomes significant when it begins to focus on the needs of individual users, departmental indicators, and key processes in order to capture and display relevant, useful, and usable knowledge in a customized fashion (Sorrells & Weaver, 1999a, 1999b, 1999c).

APPROACHES TO CAPTURE, STORE AND SHARE KNOWLEDGE

For companies that need to leverage their corporate knowledge, the following four initiatives may help you establish a knowledge sharing system of your own. These initiatives draw upon a predominate, repository model but are also relevant to other models (Morrissey, 1998).

Build the Infrastructure Using Appropriate Technology

Technology enables connectedness to take place in ways that have never before been possible. Harnessing intellectual capital can be expedited through a network-computing infrastructure. Technology has emerged to support each different approach to knowledge management. Document management systems expedite document storage and retrieval. Web-casts allow synchronous communication between experts while discussion groups enable asynchronous interaction. Learning management systems track an employee's progress with continuous learning while data warehousing mines powerful SQL databases, which organize and analyze highly structured information. Paramount to the successful use of these technologies is naturally a flexible, robust IT infrastructure (Sharma & Wickramasinghe, 2004).

Build a Conceptual Infrastructure with Competencies as the Backbone

Technology is important in harnessing intellectual assets, but integrated solutions encompass more than that. You must rethink the conceptual infrastructure of your business. For example, you may need to: ensure intellectual assets reflect your vision and values; articulate the theoretical framework for your processes; establish a taxonomy or categorization scheme to organize your information; create cross references that reflect relationships between entries; or index your information using attributes or meta-tags. The notion of competence plays a critical role in knowledge indexing and sharing. Karl Erik Sveiby, noted Swedish expert on managing and measuring knowledge-based assets, observes, "The concept of competence, which embraces factual knowledge, skills, experience, value judgments and social networks is the best way to describe knowledge in the business context." Once competencies or target proficiencies are defined, they become the backbone, which connects users to useful, relevant knowledge.

Create a Repository of Reusable Components and Other Resources

Before the Industrial Revolution, products were handcrafted; each piece was unique and couldn't be reused. The genius of the Industrial Revolution centered on making reusable parts and components became standardized and interchangeable. The Information Revolution is similar. Instead of crafting a unique solution each time, knowledge sharing creates a warehouse of "stored parts" — e.g., standardized and interchangeable components which can be reused and adapted: skills, best practices, models and frameworks, approaches and techniques, tools, concepts, specific experiences, presentation aids, white papers, etc. Adding to this, resources such as directories of experts indexed by their field can help you gain access to knowledge outside of your core competencies.

Set High Standards for Quality and Usability

Ensure that your information complies with high quality standards because it is the foundation upon which to build a knowledge-centric healthcare organization. In addition, it is important to make sure that the system meets the users' needs, which may involve reworking or restructuring information. Leonard Caldwell observed: "Critical information must first be reorganized so that information is presented in a way that mirrors users' needs and parallels a thought process occurring within a job function or task." Establishing consistent patterns helps end-users find information quickly. Online coaching can provide users with tips and techniques on how to modify, customize, or tailor information. Leveraging organizational knowledge is not an option — it is an imperative if one is to flourish in the marketplace. It can lead into a new phase of quality and innovation. It will reduce cycle time and gives a competitive advantage as a company. The synergy will also contribute to growth as individuals. Companies who have the foresight to manage their knowledge capital now will have an advantage in the future (Herbig, Bussing & Ewert, 2001).

KM TOOLS AND TECHNOLOGIES

The paraphernalia of the information revolution — computers, communications networks, compact discs, imaging systems and so on — are now widely expected to make a vital contribution to helping doctors and other medical professionals do their work better (Gokce, 2002). New information technologies include:

- Electronic patient records, which are more up to date, easier to access, and more complete than paper ones;
- Standardized medical terminologies and languages, both within and across natural language communities;
- Methods and tools to support faster dissemination of information via the Internet that leads to new scientific understanding of diseases and their treatment;
- More timely and reliable methods and tools to support better communication and coordination among members of healthcare teams;
- A creative approach to KM can result in improved efficiency, higher productivity and increased revenues in practically any business function.

The technical goal of KM initiatives is to give the organization the ability to mine its own knowledge assets, which could include creating such tools as a centralized search capability, automatic indexing and categorization, content analysis and preparation, data analysis, and customizable features integrated in a digital dashboard. Process improvement is a precursor to providing a knowledge-centered environment. Before an organization can foster collaboration and knowledge sharing, the organization must possess an understanding of information flows and of the overall knowledge infrastructure. There is no such thing as the perfect KM product. Instead, different tool sets can be integrated with the organization's legacy systems (Heathfield & Louw, 1999). Technical issues that KM projects must address include:

- Setting up electronic delivery strategies for information
- Identifying information sources and services
- Building decision support tools and data-mining templates
- Establishing enterprise-wide business rules
- Implementing process improvement techniques

Knowledge Mapping

Knowledge management is rapidly becoming a critical success factor for competitive organizations. Carrying out knowledge management effectively in an industrial environment requires support from a repertoire of methods, techniques and tools, in particular knowledge engineering technology adapted for knowledge management. Knowledge mapping creates high-level knowledge models in a transparent graphical form. Using knowledge maps, management can get an overview of available and missing knowledge in core business areas and make appropriate knowledge management decisions. Knowledge mapping is a good example of a useful knowledge management activity with existing knowledge acquisition and modeling techniques at its foundations (Strawser, 2000). Knowledge mapping is a technique rather than a product. A knowledge map could be used as a visual example of how information is passed from one part of an organization or group to another and is usually a good place to start understanding what types of intellectual assets the organization has at its disposal. Most organizations that have implemented KM applications provide a context and framework for the way knowledge is gained. KM is usually an integral part of continuous quality improvement or total quality management projects. Several consultants offer knowledge-mapping methodologies (Heathfield & Louw, 1999).

Process-Based Knowledge Map

A process-based knowledge map is essentially a map or diagram that visually displays knowledge within the context of a business process. In other words, the map shows how knowledge should be used within the processes and sources of this knowledge. The overview of the business process is prepared before the knowledge and the sources are mapped to this process. Any type of knowledge that drives the process or results from execution of the process can be mapped. This could include tacit knowledge (knowledge that resides in people such as know-how, experience, and intuition) and explicit knowledge (codified knowledge that is found in documents); customer knowledge; knowledge in processes; etc.

Intelligent Agents

In the early days of online information retrieval systems, individuals met with search intermediaries who were trained to use the online systems. The intermediaries were often knowledgeable about the information seeker's area of interest. Today, technology in the form of personal computers and the Internet provides users with the means to access the online databases from their own offices. However, distributed sources of online information, e.g., the World Wide Web (WWW), compound the problem of information searching. Both novice and experienced users still need support with the search process and the integration of information. To address this problem, agents have been developed for information management applications. The goal of intelligent search agents is to allow end-users to search effectively, be it either a single database of bibliographic records or a network of distributed, heterogeneous, hypertext documents. The approaches range from desktop agents specialized for a single user to networks of agents used to collect data from distributed information sources. Intelligent agents use a combination of profiling techniques, search tools, and recognition algorithms to "push" information to the decision maker on a regular basis. Because intelligent agents use a standard Web analogy, users can quickly set up "net casts" of internal information to automatically receive knowledge bases when they become available. For example, a physician can request that lab results be forwarded to his or her individual dashboard as soon as the lab has completed the procedure. One cautionary note: using push technologies can result in an information flood if filters are not configured to reduce unwanted or unnecessary data (Strawser, 2000).

Web Browsers

Web browsers such as Microsoft's Internet Explorer are practical because of their cost and relative ease of use, and they have become the preferred presentation layer for accessing knowledge bases. The productivity potential inherent in browsers is similar to that of wireless phones. The freer the knowledge worker is of place, time, medium, and device, the less time is spent on the process of messaging, and the more time is available for results. The less time spent on process, the shorter the knowledge cycle, which can be a significant productivity advantage (Strawser, 2000).

KM Applications

Most new KM applications consist of two major elements (often integrated into one interface): a means for employees looking for specialized knowledge to hook up with other people in the organization with the same knowledge (usually via a web application), in other words, an easy way for employees to tap into tacit knowledge resources (people); and a means for employees looking for specialized knowledge to search relevant documents/data (also usually via a web application), in other words, an easy way for employees to tap into explicit knowledge. KM applications are usually designed to support a particular information set in an organization, such as length-of-stay margin management, physician profitability, or accounts receivable recovery. Some consulting firms offer a base set of templates as a core application, focusing on desktop applications, whereas others have developed information sets that provide encyclopedic knowledge of a particular healthcare segment, such as physician issues (Strawser, 2000).

Workflow Applications

In the software world, and in particular in the imaging subset of that world, the need arose to send a particular (bit-mapped) document to a particular workstation or users on a network. This simple routing and distribution was called "workflow." It was quickly learned that these work items could be "tracked," which allowed the accumulation of data about not only where an item had been but also on what happened to it along the way. Who worked on it, how long it was there, the status it had leaving a point, and where it went next was starting to look much more like the manufacturing model. If data was also accumulated about the workers in this operation (how many did they complete, to what status, how long did it take for each) the model was complete. Workflow applications, such as Lotus Notes or Outlook 2000, also play an important role in a KM implementation. For example, a KM solution based on Office 2000 could serve as a nurse triage application, integrating automatic call distribution and transaction-processing systems, in concert with a knowledge base of typical responses to patient questions and symptoms (Strawser, 2000). These described technologies and tools can be exploited to create data banks, knowledge banks and a KM software as shown in Table 1, which will be a great help for providing better solutions for healthcare.

These data banks can be readily accessed through a network (Internet or intranet) if the user has at his/her disposal a workstation, software, and passwords that give access to these networks

Table 1. Data banks, knowledge banks and KM software

Data banks	(Involving text and images as well as figures), which act as medicine's memory to be used for research (clinical, pharmacological, epidemiological, etc.).
Knowledge banks	(Bibliographies, sites for exchanges among professionals, etc.), which make it possible to have access at any moment to the state of the art and can help in making a medical decision (diagnosis or treatment).
Software	To help with diagnosis and prescribing which does not replace the physician but acts to extend their knowledge.

and their different sites. The system should be made flexible so that it can be adaptable in time and space, and can be customized: each physician can, when he/she wishes, consult one of the banks or receive specific information on the fields which he/she has chosen in advance. Access need not be limited to physicians alone, but can also be made available to health professionals and the public, and the latter could adapt behavior to help prevent the onset of illness. Of course, these data banks have to be organized, updated continuously and meet users' expectations by allowing them to ask questions and to engage in discussions among themselves, so that it is always possible to evaluate the quality of the information consulted (Fitchett, 1998). The knowledge bank can make it possible to consult experts located elsewhere and to transmit images and other elements of a patient's file to a colleague to obtain an opinion, a practice currently known as "tele-medicine" (Hansen & Nohria, 1999). Software can help to offer software diagnostic and prescription aids to extend this knowledge (Confessore, 1997; Wyatt, 2000; Timpson, 1998).

CONCLUSIONS

Until recently, most of the knowledge experience and learning about KM had been accessible to only a few practitioners. However, during the past three years an explosion of interest, research, and applications in KM has occurred. There is some concern among the practitioners that KM might suffer a fate similar to business reengineering, artificial intelligence, and total quality management. That is, interest in the discipline must last long enough to iron out the bugs while simultaneously delivering significant business value. The irony is that just when the discipline works well, potential users often have lost interest in the fad, point to the inevitable early failures, and thus miss out on the real benefits. Unless the very ambitious and interesting KM initiatives in healthcare evolve differently, even if they work in a technical sense, they will not work in the economic sense and the healthcare system will continue to be what it is today: an immense apparatus for reimbursing healthcare costs. However, there will still be a health/social services network and a medical profession that is familiar with the tools and power of the Internet. The experience will not be totally negative, even if it is likely to reach goals that are different from those set at the outset. Although considerable progress has been achieved in KM across a broad front, much work remains to fully deliver the business value that KM promises. Ultimately, in order to realize the enormous potential value from KM, organizations must motivate and enable creating, organizing and sharing knowledge.

This chapter has served to highlight the need for healthcare in general to embrace the strategies, protocols, tools, techniques and technologies of knowledge management in order to contend with key challenges pertaining to access, quality and value of healthcare delivery. The following chapters in the book will highlight specific areas within the healthcare industry and key issues regarding knowledge management that are pertinent. This will serve to develop a detailed understating of the essential requirements for creating knowledge-based healthcare organizations.

Chapter 4.44
Healthcare Knowledge Management

Kostas Metaxiotis
National Technical University of Athens, Greece

INTRODUCTION

The healthcare environment is changing rapidly, and effective management of the knowledge base in this area is an integral part of delivering high-quality patient care. People all over the world rely on a huge array of organizations for the provision of healthcare, from public-sector monoliths and governmental agencies to privately funded organizations, and consulting and advisory groups. It is a massive industry in which every organization faces a unique combination of operational hurdles. However, what every healthcare system has in common is the high price of failure. Faced with the prospect of failing to prevent suffering and death, the importance of continuously improving efficiency and effectiveness is high on the agenda for the majority of healthcare organizations (Brailer, 1999). Taking also into consideration that the amount of biological and medical information is growing at an exponential rate, it is not consequently surprising that knowledge management (KM) is attracting so much attention from the industry as a whole.

In a competitive environment like the healthcare industry, trying to balance customer expectations and cost requires an ongoing innovation and technological evolution. With the shift of the healthcare industry from a central network to a global network, the challenge is how to effectively manage the sources of information and knowledge in order to innovate and gain competitive advantage. Healthcare enterprises are knowledge-intensive organizations which process massive amounts of data, such as electronic medical records, clinical trial data, hospitals records, administrative reports, and generate knowledge. However, the detailed content of this knowledge repository is to some extent "hidden" to its users, because it is regularly localized or even personal and difficult to share, while the healthcare data are rarely transformed into a strategic decision-support resource (Heathfield & Louw, 1999). KM concepts and tools can provide great support to exploit the huge knowledge and information resources and assist today's healthcare organizations to strengthen healthcare service effectiveness and improve the society they serve.

The key question which remains is the following: How can we make knowledge management work in healthcare? The answer is given in the following sections.

THE HEALTHCARE INDUSTRY: A BRIEF OVERVIEW

The health care industry is one of the largest single industries all over the world and the largest one in the United States. It has increased by over 65% since 1990 and is expected to double by the year 2007.1 The IT industry is strategically positioned to become a powerful ally to the healthcare industry as it strives to adopt well-managed cost-efficient strategies. Advanced information technologies can give healthcare providers the opportunity to reduce overall healthcare expenses by lowering the costs of completing administrative and clinical transactions. Nevertheless, in comparison to other industry sectors, the healthcare industry has been slow to embrace e-business solutions and other advanced information technologies, as presented in Table 1.

The same study revealed that the healthcare industry spends substantially more on overhead and computer facility maintenance than other industry sectors. In 1997, for instance, the healthcare industry allotted 12% of its budget to maintain existing infrastructure—6% more than the industry norm. The high level of investment in this area by healthcare organizations indicates that many providers operate with the aid of old systems, which require constant repair and maintenance.

At this stage, it is worth emphasizing that the healthcare context differs from other information systems application domains in that it often concerns sensitive and confidential information and leads to critical decisions on people's lives (or quality of life). Thus, stakeholder conflicts have more of an impact than in other areas such as business, trade, and manufacturing. Healthcare is an area with quite intense differences of values, interests, professional backgrounds, and priorities among key stakeholders. Given the complex-

Table 1. Percentage of IT implementation in industry (Computer Economics, 1999)

Industry Sector	% in Place
Transportation	57.2
Banking and Finance	52.9
Insurance	48.1
State & Local Government	37.5
Trade Services	36.8
Retail Distribution	35.5
Process Manufacturing	34.9
Discrete Manufacturing	33.3
Wholesale Distribution	33.3
Utilities	26.9
Federal Government	25.0
Healthcare	21.8
Professional Services	21.7

ity of the context, health informatics in general cannot simply focus on technical or information systems aspects alone. It has to take account of their relationship with clinical and managerial processes and practices, as well as deal with multiple stakeholders and organizational cultures and accompanying politics.

Concluding, it should be stressed that healthcare is not only a significant industry in any economy (Folland, Goodman, & Stano, 1997), but also a field that needs effective means to manage data as well as information and knowledge. Managed care has emerged as an attempt to stem the escalating costs of healthcare (Wickramasinghe & Ginzberg, 2001) and improve the quality of services.

THE BACKGROUND OF KM IN HEALTHCARE

An increasing concern with improving the quality of care in various components of the healthcare system has led to the adoption of quality improvement approaches originally developed for industry. These include Total Quality Management (Deming, 1986), an approach that employs process control measures to ensure attainment of defined quality standards, and Continuous Quality Improvement (Juran, 1988), a strategy to engage all personnel in an organization in continuously improving quality of products and services. Nowadays, the importance of knowledge management is growing in the information society, and medical domains are not an exception. In Yu-N and Abidi (1999), managing knowledge in the healthcare environment is considered to be very important due to the characteristics of healthcare environments and the KM properties. We should always keep in mind that medical knowledge is complex and doubles in amount every 20 years (Wyatt, 2001).

The healthcare industry is nowadays trying to become a knowledge-based community that is connected to hospitals, clinics, pharmacies, physicians, and customers for sharing knowledge, reducing administrative costs, and improving the quality of care (Antrobus, 1997; Booth, 2001). The success of healthcare depends critically on the collection, analysis, and exchange of clinical, billing, and utilization information or knowledge within and across the organizational boundaries (Bose, 2003).

It is only recently that initiatives to apply KM to the healthcare industry have been undertaken by researchers. Firstly, in the second half of the 1980s, several authors tried to apply artificial intelligence (AI)—with doubtful success—to medicine (Clancey & Shortliffe, 1984; Frenster, 1989; Coiera, Baud, Console, & Cruz, 1994; Coiera, 1996). MYCIN is probably the most widely known of all medical (and not only) expert systems thus far developed (Shortliffe, 1976). And this is despite the fact that it has never been put into actual practice. It was developed at Stanford University solely as a research effort to provide assistance to physicians in the diagnosis and treatment of meningitis and bacteremia infections. PUFF, DXplain, QMR, and Apache III are also some of the most well-known medical expert systems that were developed and put into use (Metaxiotis, Samouilidis, & Psarras, 2000).

De Burca (2000) outlined the conditions necessary to transform a healthcare organization into a learning organization. Fennessy (2001) discussed how knowledge management problems arising in evidence-based practice can be explored using "soft systems methodology" and action research. Pedersen and Larsen (2001) presented a distributed health knowledge management (DKM) model that structures decision support systems (DSSs) based on product state models (PSMs) among a number of interdependent organizational units. The recurrent information for the DSS comes from a network-wide support for PSMs of the participating organizations.

Ryu, Hee Hp, and Han (2003) dealt with the knowledge sharing behavior of physicians in hospitals; their study investigated the factors affecting physicians' knowledge sharing behavior within a hospital department by employing existing theories, such as the Theory of Reasoned Action and the Theory of Planned Behavior. Torralba-Rodriguez and colleagues (2003) presented an ontological framework for representing and exploiting medical knowledge; they described

Table 2. Important Web sites dedicated to KM in healthcare

Web Site	Description
www.nelh.nhs.uk/knowledge_management.asp	The National Electronic Library for Health has a link dedicated to knowledge management. It describes how to manage explicit knowledge and outlines revolutions in KM in healthcare.
www.who.int	The World Health Organization has launched the Health Academy, which aims to demystify medical and public health practices, and to make the knowledge of health specialists available to all citizens through Web-based technology. The academy will provide the general public with the health information and knowledge required for preventing diseases and following healthier lifestyles.
www.cochrane.org	The Cochrane Collaboration is an international non-profit and independent organization, dedicated to making up-to-date, accurate information about the effects of healthcare readily available worldwide. The major product of the collaboration is the Cochrane Database of Systematic Reviews, which is published quarterly.
www.AfriAfya.org	AfriAfya, African Network for Health Knowledge Management and Communication, is a consortium formed by well-known agencies such as Aga Khan Health Service in Kenya, CARE International, SatelLife HealthNet, PLAN International, and the Ministry of Health in Kenya to harness the power of information and communication technology for community health.
http://www.hc-sc.gc.ca/iacb-dgiac/km-gs/english/kmhome.htm	The goal of knowledge management at Health Canada is to use the knowledge that resides in the department□in the minds of its staff, in the relationships they have with other organizations, and in their repositories of information□to fulfill their mission: to help the people of Canada maintain and improve their health.
http://www.ucl.ac.uk/kmc/index.html	The Knowledge Management Centre is part of the School of Public Policy of University College London (UCL). The Knowledge Management Centre's aim is to improve clinical practice, patient outcomes, and health service innovation and efficiency by promoting better health knowledge management by serving as a resource center and making efficient use of its resources internally and across a network of collaborators.

an approach aimed at building a system able to help medical doctors to follow the evolution of their patients, by integrating the knowledge offered by physicians and the knowledge collected from intelligent alarm systems. Also, Chae, Kim, Tark, Park, and Ho (2003) presented an analysis of healthcare quality indicators using data mining for developing quality improvement strategies.

Reviewing the literature, it is concluded that a KM-based healthcare management system should have the following objectives (Shortliffe, 2000; Booth & Walton, 2000):

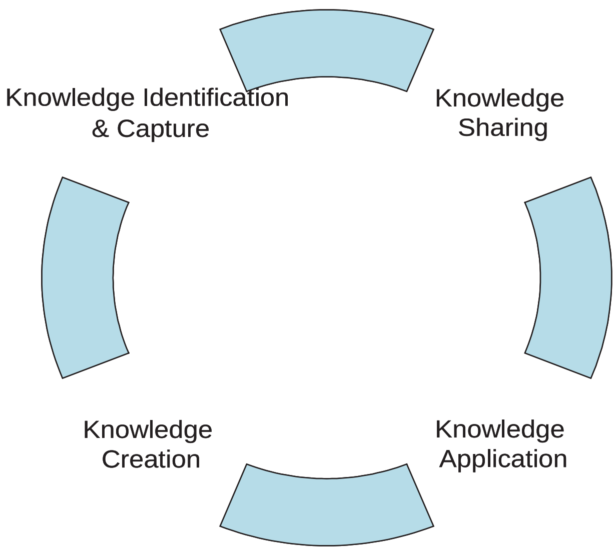
- To improve access to information and knowledge at all levels (physicians, hospital administrators and staff, consumers of health services, pharmacies, and health insurance companies) so that efficiencies and cost reductions are realized.
- To transform the diverse members (care recipients, physicians, nurses, therapists, pharmacists, suppliers, etc.) of the healthcare sector into a knowledge network/community of practice.
- To enable evidence-based decision making to improve quality of healthcare.

Table 2 presents important Web sites dedicated to the promotion and application of KM to healthcare.

THE KNOWLEDGE MANAGEMENT PROCESS IN HEALTHCARE

In order to examine whether knowledge management can really succeed in healthcare, we can analyze this proposition in terms of examining the knowledge management process and the likelihood of success for the healthcare organizations in achieving these steps in the process. The KM process consists of four key stages, as shown in Figure 1 (Schwartz, Divitini, & Brasethvik, 2000).

Figure 1. The knowledge management process cycle



Knowledge identification and capture refer to identifying the critical competencies, types of knowledge, and the right individuals who have the necessary expertise that should be captured. Then, this captured knowledge is shared between individuals, departments, and the like. The knowledge application stage involves applying knowledge—which includes retrieving and using knowledge—in support of decisions, actions, and problem solving, and which ultimately can create new knowledge. As new knowledge is created, it needs to be captured, shared, and applied, and the cycle continues.

Knowledge Identification and Capture in Healthcare

One way to identify the critical knowledge that should be captured and determine the experts in the healthcare organization who have the knowledge on a specific issue (e.g., disease, therapy) is to conduct a knowledge audit. The knowledge audit helps to identify the types of knowledge needed and the appropriate sources (e.g., patient records, medical research literature, medical procedures, drug references) in order to develop a knowledge management strategy for the organization.

On the other hand, the use of intranets is suggested as basic tools for the capture of implicit knowledge. St Helens & Knowsley Health Informatics Service—which covers 320,000 patients—designed and developed an intranet structure with the aim to generate the potential to capture organizational implicit knowledge (Mimnagh, 2002). The real challenge has been to create a health- community- wide intranet that implements directory services, communities of practice, and lessons learnedt in a way which builds on existing activity and looks for the synergistic effect of adding a KM focus to ongoing work.

Vast amounts of medical knowledge reside within text documents, so that the automatic extraction of such knowledge would certainly be beneficial for clinical activities. Valencia-Garcia and colleagues et al. (2004) presented a user-centered approach for the incremental extraction of knowledge from text, which is based on both knowledge technologies and natural language processing techniques. The system was successfully used to extract clinical knowledge from texts related to oncology and capture it.

Concluding, a key question is whether people would be willing to give up their competitive edge to have their knowledge captured via online repositories, lessons learned, best practices, and the like. This possible dilemma is especially valid in the healthcare sector.

Knowledge Sharing in Healthcare

Productive organizations have the ability to create an environment where specialized knowledge, skills, and abilities of all employees are leveraged to achieve advancements in service industry. However, healthcare organizations cannot be considered as a good example of such organizations. A healthcare organization is a collection of professional specialists who contribute to the delivery of patient care, but also often act competitively inside the organization, without being willing to transfer knowledge because of associated status and power within the organization and the society.

Taking also into account that people in general are not likely to share their knowledge unless they think it is valuable and important, it becomes clear why doctors and physicians are not willing to share and transfer their knowledge. In addition, due to minimal interdisciplinary training, the transfer of tacit knowledge which occurs through apprenticeship style work patterns—for example, internships where junior doctors work alongside a senior clinician in surgery or intensive care—remains problematic (Beveren, 2003).

Effective knowledge management requires a “knowledge sharing” culture to be successful. Especially in healthcare, it is crucial that doctors and physicians understand the benefits of knowledge sharing on a number of levels: benefits to the organization, benefits to patients, and benefits to them personally. The more you can clearly demonstrate these benefits, the more people are likely to be open to change. Doctors and physicians need to be recognized and rewarded in a formal way (e.g., promotions, cash awards) to make knowledge sharing a reality in healthcare.

The Wisecare (Workflow Information Systems for European Nursing Care) project—an EC-funded initiative (1997-1999)—has promoted knowledge sharing using the Internet and online communities. Wisecare provided nurses with a vast amount of information and knowledge about clinical practice through both the Wisecare Web site and data collection tool. This information has been specifically selected to meet their clinical needs and meant nurses had access to relevant knowledge extremely quickly.

Lesson learned systems can also be an effective knowledge sharing approach to be used in healthcare (Yassin & Antia, 2003).

Knowledge Application in Healthcare

Knowledge application refers to taking the shared knowledge and internalizing it within one's perspective and worldviews. For the healthcare organizations the reality is that technology can only fulfill some of their needs. And how well it fulfills them depends critically on managing the knowledge behind them—content management, assigning knowledge roles, and so forth. Tom Davenport (2002), a prominent author on knowledge management, is often quoted as offering the following rule of thumb: your investment in technology in terms of both cost and effort should stay under one-third of the total knowledge management effort—otherwise you are going wrong somewhere.

Knowledge-enabling technologies which can effectively be applied to healthcare organizations are:

- Groupware
- Intranet
- Collaborative tools (e.g., discussion boards, videoconferencing)
- Portals
- Taxonomies

Abidi (2001) presented the Healthcare Enterprise Memory (HEM) with the functionality to acquire, share, and operationalize the various modalities of healthcare knowledge. Davenport (2002) outlined how Partners Health Care System in Boston implemented an enormously successful expert-intervention KM solution. Case studies from the UK's National Health Service (NHS) and the Department of Health illustrated the drive towards modernization and more effective collaborative working among public-sector healthcare systems (Ark Group, 2002).

Knowledge Creation in Healthcare

In general, knowledge creation may take the form of new products or services, increased innovation, and improved customer relationships. In the healthcare setting, knowledge creation can take place in terms of improved organizational processes and systems in hospitals, advances in medical methods and therapies, better patient relationship management practices, and improved ways of working within the healthcare organization. Given the various constraints and barriers occur in the healthcare sector, it takes longer for a new idea to be implemented in the healthcare setting versus that in the business sector.

A few examples of knowledge creation technologies that can be used in healthcare are:

- Data Mining: Tools that analyze data in very large databases, and look for trends and patterns that can be used to improve organizational processes.
- Information Visualization: Computer-supported interactive visual representations of

abstract data to help improve understanding.

CONCLUSION

Knowledge is a critical tool for health, and knowledge management is the capacity to translate research results (knowledge) into policies and practices that can improve the quality of life and lengthen survival. Managing knowledge in a healthcare organization is like trying to knit with thousands of strands of knotted wool; data is held in a number of locations, managed by a variety of people, and stored in every imaginable format. Perhaps in no other sector does knowledge management have such a high promise.

Delivering healthcare to patients is a very complex endeavor that is highly dependent on information. Healthcare organizations rely on information about the science of care, individual patients, care provided, results of care, as well as its performance to provide, coordinate, and integrate services. The traditional single physician-patient relationship is increasingly being replaced by one in which the patient is managed by a team of health care professionals each specializing in one aspect of care. Hence, the ability to access and use the electronic healthcare record (EHCR) of the patient is fundamental. In addition, the transformation of healthcare data into a strategic decision-support resource is fundamental too.

KM can be approached in numerous ways to serve particular needs and conditions. Successful KM practices typically need to be supported by complementary efforts in different domains. IT-related support activities and infrastructures are very important. They serve vital functions, are complex, costly, and often take time to design and implement. In the case of healthcare, building the infrastructure for a KM practice requires extensive effort due to the peculiarities of the health sector (e.g., legal and ethical issues, complex procedures for provision of healthcare, doctors' behavior, etc.).

Coming back to the original question—How can we make knowledge management work in healthcare?—and by examining the knowledge management process, we can see that there are positive and negative points as to whether KM will truly work in the healthcare sector. Some people in healthcare think that KM is a passing fad like Total Quality Management, Business Process Reengineering, and other administration-backed initiatives. It is unfortunate to think in this light, as knowledge sharing should be encouraged so that lessons can be learned. KM solutions can facilitate the transfer of patient medical information, access to new treatment protocols as they emerge, knowledge exchange among experts, and so on.

Future research needs to be devoted to measuring the success of KM in healthcare organizations, showing quantitative benefits, and producing a "Return on Investment" index. Measurement is the least-developed aspect of KM because of the inherent difficulty to measure something that cannot be seen, such as knowledge (Bose, 2004). However, this is a very crucial issue since the future usage of KM is heavily dependent on both the quality of the metrics and whether output generated by this metric management would provide tangible value addition to the healthcare organizations. Integration of KM with e-health is also another direction for further research.

Chapter 4.45
How to Handle Knowledge Management in Healthcare:
A Description of a Model to Deal with the Current and Ideal Situation

A. E. Wahle
Cap Gemini Ernst & Young B. V., The Netherlands

W. A. Groothuis
Cap Gemini Ernst & Young B. V., The Netherlands

ABSTRACT

There are many arguments why healthcare organizations need knowledge management. In The Netherlands, there are some things going on, like a new defrayment and remuneration system for the hospitals, the increasing aging population, the focus on quality, efficiency and effectiveness and the existence of more, very specialized disciplines, that there is a need for knowledge management. This chapter describes a model that can be used to chart the current situation regarding knowledge management. The model is based upon the primary and supported processes, a division in types of knowledge and a knowledge cycle. The use of the model is demonstrated by a case description. Conclusions which are drawn from the recap of the case description showing that the model can be useful but some things must be taking into account, such as the size of a case and its boundaries.

INTRODUCTION

There are many arguments why healthcare organizations (HCO's) need knowledge management. The argument for HCO's to develop knowledge management lies in:

- the hospital, or any other HCO, is a knowledge intensive organization;

- there is a big demand for optimizing the support and primary processes;
- the demand for efficiency and effectiveness due to shortages on the job market;
- the requirement of the patient for better quality care and related provision of information;
- the introduction of Diagnosis Treatment Combinations (DTCs) in The Netherlands which makes the learning capacity and competitiveness of the hospital an important factor.

HCO's make use of multiple knowledge areas, such as those of medicine and policy making (Lucardie, Ribbens & Singeling, 1998). These multiple knowledge areas and the existence alongside one another of a large number of interdependent disciplines each with their own professional autonomy makes a healthcare organization a knowledge intensive organization. Furthermore, there is a tendency toward more superspecialism. Especially medical doctors specialize towards small but very specialized areas, and as a result they have very unique knowledge. And this very unique knowledge has to be secured, disseminated and utilized.

In The Netherlands, through an increasingly aging population, the demand for care grows. At the moment the care sector has to cope with a shortage of staff. Improving the present capacity is mainly an issue of the last couple of years. Particularly due to the existence alongside one another of interdependent disciplines, the shortage in one professional group can also be felt directly by other professional groups. The shortage of (good) personnel is a challenge to knowledge management. The available knowledge must be secured and disseminated.

In The Netherlands the focus has in particular been on improving the quality, efficiency and effectiveness of care. Certainly in the last decade the Dutch government has paid a lot of attention to quality in the care sector. In particular, it has attempted to ensure the quality of care through legislation (Van Dijen, 1999). Much of this legislation relates to quality control and improving the position of the client/patient. With respect to the latter position, the Dutch Consumer Association (Consumentenbond) carried out a large-scale survey in 2002 into the quality of hospital care based expressly on patient opinion (Consumer Association, 2002). The conclusions and recommendations of the Consumer Association report offer starting points for using knowledge management in (hospital) care. In particular the provision of information for the patient about the period after discharge, or after care, is often found to fall short. Improvements can also be made in the information transfer between the various professional groups.

The introduction of a new defrayment and remuneration system in the Dutch hospitals stresses the need to develop, disseminate and utilize knowledge. After all, due to the introduction of market forces into the Dutch healthcare system an institution is more dependent on its own knowledge and skills to stay a step ahead of (or at least level with) the competition. The current system is a system of job-based budgeting of hospitals and the lump sum funding of medical specialists. This system will be replaced by a new defrayment and remuneration system for hospitals and medical specialists. It is a system based on the Diagnosis and Treatment Combinations (DTCs).

Added Value of KM

When using knowledge management a number of objectives can be pursued (Konter, 2002). In our view the most important objectives that also show the added value of knowledge management are:

1. to make (better) informed decisions
2. uniform action through the entire organization
3. learning organization which continually improves one and two above

4. as a result achievement of:
   (a) common vision of policy and objectives
   (b) quality improvement
   (c) efficiency increase
   (d) cost saving
   (e) greater competitiveness
5. patient empowerment

Everyone makes decisions, from medical specialist to staff manager. By becoming aware of the available knowledge (knowledge management), one is in a better position to make informed decisions. This can involve using decision support systems as well as many other types of solution (see section "Knowledge Activities"). By making informed decisions, one can also increase the quality of patient care (Friedman, Gatti, Elstein, Franz, Murphy & Wolf, 2001).

It can bring an efficiency increase when everyone in the organization acts uniformly, i.e., everyone has access to protocols, guidelines and procedures and also follows them. Uniform action also implies a shared view of the organizations policy and objectives.

If protocols, guidelines and procedures have been drawn up in accordance with the latest (medical) state of the art, this leads to an improvement in patient care. In various publications (Everdingen, 1993; O. Y., 1999) it has been demonstrated that using protocols, guidelines and procedures reduces the inter- and intra-care provider variance and the number of errors in care provision.

When staff is given the opportunity to follow a continuous learning process, the organization as a whole has a greater learning capacity and competitiveness. The introduction of a new defrayment and remuneration system in the Dutch hospitals stresses the need to develop, disseminate and utilize knowledge. The success of a self-learning organization depends very much on the culture and behavior of the staff. Change management will therefore be an important aspect in the implementation and the continuous process of knowledge management (see also "Knowledge Activities").

Another important aspect of the learning capacity of an organization concerns the ability to learn from one another's mistakes. Good incident and accident records are important here, as well as a culture in which incidents and accidents are actually reported (van Everdingen, 1993). The number of reports says something about the quality of the prevention policy. However paradoxical that sounds, the more reports, the better the quality.

By sharing knowledge about diseases with (future) patients, for example through certified websites and databanks, a degree of self-care is encouraged. This means that with good patient information one can achieve a lower care consumption, but also when a patient reaches the consulting room, he is better informed and can ask more specific questions.

It can be argued that knowledge management, in addition to making informed decisions, will result in an improvement due to a uniform procedure, an increased learning capacity, a reduction in costs due to greater efficiency and improved communication with the patient, as well as an improvement in the overall quality of the care provided. The various objectives are interrelated and interdependent. Quality standards can, for example, be built into the decision support systems, enabling the system to take quality standards into account when giving advice to the user. The system can also take into account legislation and regulations, which contributes to an improved quality. By acting uniformly in accordance with prescribed procedures, the quality is also improved. Another point that improves quality is that everyone can have the information they want and so can make informed decisions.

KM and Quality Improvement Projects

Describing the added value of KM, we have described the ideal situation. Many HCOs do one of the mentioned activities and call it a quality improvement project. KM and quality management often have the same purpose, namely to improve the processes and outcome involved. However, the added value of active knowledge management is to see all these activities/processes in cohesion with each other while quality management tends to look at individual processes/activities.

An ideal situation can only be approached by getting insight in the current situation. To do this, we have described below a model with which the current situation can be mapped and the (knowledge management) activities are presented in cohesion with each other.

METHODS

Before we deal with the model, first we make clear our way of thinking about knowledge management. We feel obliged to do this for a better understanding of the structure and way of reasoning used in the model.

Definition of Knowledge Management

When talking about knowledge management, many aspects are covered. Still, well-functioning knowledge organizations can be characterized by:

- the coherent promotion of common knowledge;
- the screening/filtering of only the knowledge that is necessary (less is more);
- the stretching of knowledge, communication and capturing.

With knowledge management it is like looking through a magnifying glass at information management. For example, a structured look is taken of how the current and ideal provision of information, for example of the professional groups and patients, is organized.

We define knowledge management as the management of the knowledge cycle. The knowledge cycle consists of developing, disseminating and utilizing knowledge (Oldenkamp, 2001, 2002; Brailer, 1999). Development consists of both the gathering and creating of knowledge. Disseminate means structuring, making explicit, distributing and explaining. Utilize refers to finding and (re-)deploying knowledge.

Several other authors have introduced similar cycles or "knowledge value chains" (Van der Spek & Spijkervet, 1996; Weggeman, 1997). We have opted for the definition as described above because of its simplicity and because in our view the cycle and its management includes all aspects referred to by the other authors. On the basis of the "develop, disseminate and utilize" knowledge cycle, the section titled "Case" discusses this.

Knowledge

Knowledge management, as we have said, is the management of a cyclical process centered on knowledge. But what do we understand by knowledge? It can be defined as the capacity to act competently. In acting, we necessarily make use of information. Further information puts us in a position to act more competently (Oldenkamp, 2001)

We can distinguish different kinds of knowledge. A common, and much used, division is one into procedural, declarative, social and contextual knowledge (Oldenkamp, 2001; Boers & Kruithof, 1998; Boersma & Stegwee, 1996). We find the following terminology more suitable:

- know what (declarative) – factual knowledge. This knowledge often forms the basis for the "know how" type of knowledge;
- know how (procedural) – knowledge of procedures. To deal with routine matters,

established procedures are often available, which capture factual and background knowledge;
- know who (social) – who knows what or meta-knowledge. You do not have a monopoly on wisdom, so you need to call upon others with the specific knowledge you need;
- know why (contextual) – background knowledge. This knowledge is required when new procedural knowledge is drawn up and when lines of reasoning have to be explained.

The "know what" and "know how" types of knowledge are also seen as the two most important types of knowledge for management and control of the organization (Boersma & Stegwee, 1996).

We have chosen the above division because in our opinion it fits in with the terminology and the experience of the professional groups in the healthcare sector. For example, doctors and nurses use mainly factual knowledge, but also use background knowledge and experience. By calling in colleagues, they are calling upon who-knows-what knowledge or meta-knowledge and everyone in his or her work comes up against certain guidelines, procedures, etc. The medical specialist follows a particular procedure for an operation, the nurses follow procedure when dressing wounds and a receptionist follows procedure when identifying the patient.

The use of a division into types of knowledge has often been found useful in structuring the knowledge present (Oldenkamp, 2001).

A Model for the Care Sector

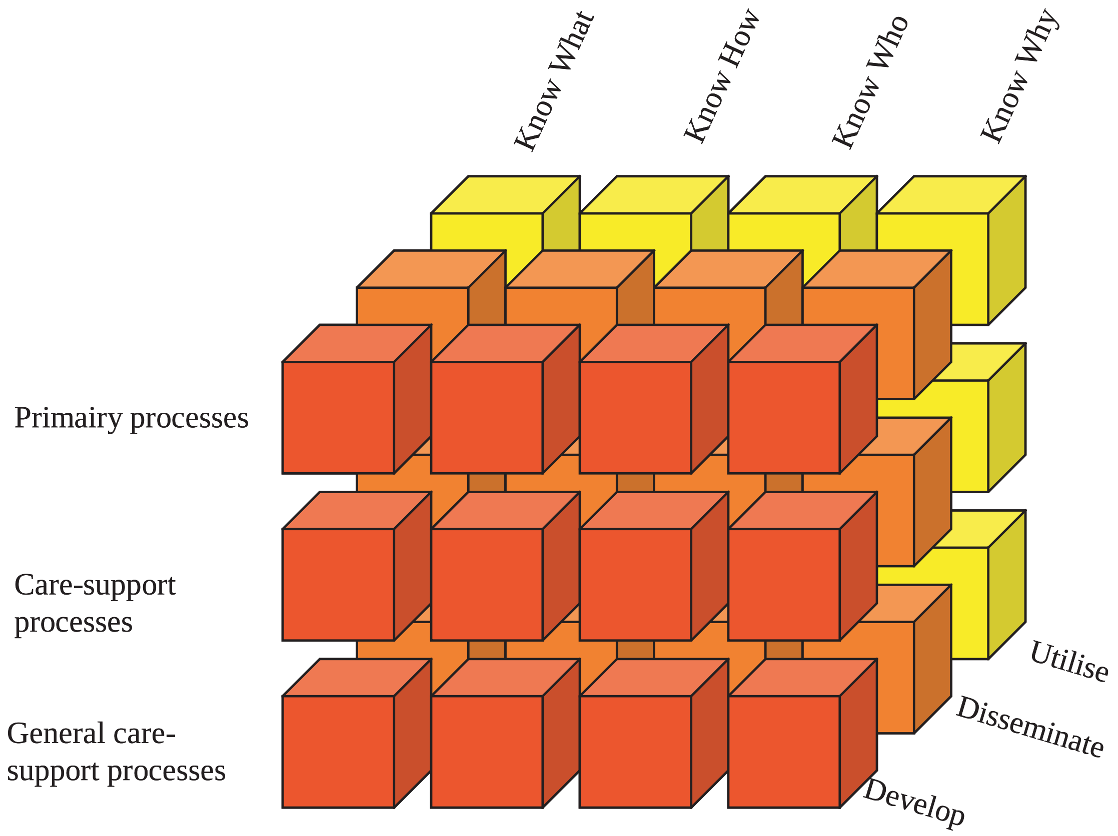
In the care sector a distinction is often made between primary and support processes. The primary processes are geared to (para)medical and nursing care. Support processes are geared to the direct support of the primary processes and the deployment of people and resources.

Table 1 sets out the processes in more detail. The support processes are broken down into care-support and general support processes. The aim is not for completeness here as different care institutions can have slightly different classifica-

Table 1. Breakdown of processes

Main groups	Sub-groups
Primary processes	1. Central registration 2. Outpatient consultation 3. Patient admission 4. Nursing and care 5. Outpatient treatment 6. Clinical treatment
Care-support processes	1. Medication 2. Diagnostic procedures[1] 3. Other care support
General support processes	1. Staff provision 2. Finance 3. Provision of information 4. Management 5. Facilities 6. Education

Figure 1. Model for the care sector



tions or names for the processes. The main lines do, however, correspond.

In combination with the knowledge cycle and the breakdown into types of knowledge, a framework is drawn up. For each process, for each type of knowledge and for each phase of the knowledge cycle, it is indicated which activities are being used in the current situation. Figure 1 shows the model. It shows the ideal situation because all parts are being filled.

The model can be filled in with even more detail, depending on the organization's requirement. The setup of the model is three-dimensional so that it can be looked at from three points of view of the knowledge processes. For example, what kind of process is used knowledge being used in, what sort of knowledge are we talking about and which phase of the knowledge cycle is the knowledge pointing at. In this manner a three-dimensional reproduction of the current situation can be acquired. In "Cases" we make clear how we can do this.

Knowledge Activities

In this section, brief examples of possible activities for applying knowledge management in an organization are given. These examples will be outlined to make clear what kind of activities are ranged under knowledge management. The framework of "A Model for the Care Sector" can be filled in with these activities, allowing one to see at a stroke where the activities are concentrated and to see them in cohesion with each other.

Per phase of the knowledge cycle, a few activities are listed, accompanied by a brief description. For each activity, the type of knowledge is indicated in brackets.

Develop

Developing knowledge involves gathering or creating knowledge. An example of gathering knowledge is recruiting new staff.2 New staff often have an unprejudiced view of existing — and often habitual — procedures and as a result they bring a measure of renewal, in addition to the knowledge and skill in a particular specialist area that they have made their own (know what, know why).

The buying of books3 can also be seen as gathering knowledge. For example, the (medical) library purchases specialist literature or the organization buys handbooks for interns/trainee specialist registrars and specialists to support them in their work (know what, know why).

By giving staff the opportunity to subscribe to specialist journals or other media — and to have these costs reimbursed — the development of knowledge is stimulated (know what, know why).

The development (or the creation) of knowledge is also carried out, for example, by continuing vocational training or via external training, courses, congresses or seminars. It is possible to work on knowledge development through continuing vocational training in the traditional lecturer-student form, as well as via online-training courses.4 Online-training courses have the advantage that they can be followed independently of time and place (know what, know why).

Registration systems are a separate example. Filling the registration systems with data so that the data can be subsequently analyzed, can be seen as the development of knowledge. Only when this is done, can we talk of disseminating and then utilizing the knowledge stored in the record systems.

Disseminate

Thanks to the facilities that ICT offers, copying and distributing knowledge takes hardly any time at all. However, the possible (ICT) solutions are very diverse. A well-known example is the knowledge bank, of which a protocol system5 is an example. This is the type of knowledge bank that is often found nowadays in hospitals. More and more hospitals also make their guidelines for treatment available for patients, though in understandable language6 (know how, know what, know why). This knowledge is made available through information pillars in the hospital or via websites containing a variety of information on treatment. Hospitals themselves also often refer to reliable sources on the Internet (know how, know what, know why).

In discussing the development phase, the registration system was already mentioned as a system for developing knowledge in the first instance. A specific example is a system for registering incidents and accidents. Making these records as complete and accurate as possible gives the organization an opportunity to learn from mistakes and so to increase the knowledge in certain areas as a result of which a quality jump and efficiency gain is achieved.7 Another example of a registration system for learning from mistakes is a system faults.

For disseminating knowledge, patient discussions or clinical lessons are an excellent form. By organizing regular meetings on certain clinical pictures or unique patients, knowledge can be disseminated (know what, know why).

Marketplaces, communities, discussion groups and forums are places, often on the Internet, where staff can exchange knowledge with one another (know what, know why). This is certainly not necessarily an internal or institutional matter, as they are more often aimed at groups such as heart patients or users of a particular software package. These places can moreover be regarded as a system for knowledge development.

Utilize

The investment of time, money and energy in the previous two phases is paid back in the last phase, i.e., knowledge utilization. By better utilizing the available knowledge, comparable work can be carried out (qualitatively) better, faster or perhaps cheaper. However, the success of this phase largely depends on the behavior of the staff and the culture of sharing knowledge. Does the staff think that they can learn something from others and do they also want to? This does of course happen in the first two phases of the knowledge cycle, for before the knowledge can be utilized, it is first necessary to develop and disseminate it.

A decision support system (DSS) is a well-known example of knowledge utilization. With the help of decision support systems, informed decisions can be made. Decision support systems are mainly important where many variables have to be weighed up against one another to arrive at a decision.8 This mainly occurs in the diagnostic process of the specialist (know what).

Other examples of a decision support system are an physician order entry system (POES) for achieving better decisions and savings on medication.9 In particular, general practitioners in The Netherlands make increasing use of POESs that are often already incorporated in their GP information systems.

Another example of utilizing knowledge is making use of literature. The modern physician is expected to base his decisions on the best and most recent evidence from the medical science literature (Rijssenbeek, 2001; Offringa, 2001). However, as Offringa (2001) notes, 40,000 medical science journals are published annually with more than one million articles. This means for an internist that he would have to read between 17 and 22 articles per day to keep up with the publication rate. For a general practitioner, this number is even higher. Medical information is easily available without restriction via MEDLINE. The Cochrane Collaboration is an organization that has taken upon itself “preparing, maintaining and promoting the accessibility of systematic reviews of the effects of healthcare interventions” (www.cochrane.nl). There are Cochrane Centers all over the world. By using the Cochrane Library, a doctor is able to obtain up-to-date information on the state of research regarding the efficacy of medical treatment (know what, know why).

In guidelines for medical practice, knowledge is stored or obtained through vocational training or external training or literature. By using a guideline this particular knowledge is utilized (know how).

Setting up a competence matrix can also facilitate the utilization of knowledge. With the help of such a competence matrix (who-knows-what), one can search for specific knowledge that is already present with a colleague (know who).

CASE

In this section the model will be put into practice by a case description and recap. This case will show our three-dimensional approach of the model.

Description

Mrs. W. is send by the midwife to the gynecologist because of an incomplete breech presentation of her baby. Mrs. W. is in her 34th week of pregnancy. With the help of echography, the gynecologist looks at precisely how the baby is presenting and also carries out an external examination. He discusses with Mrs. W. and her partner exactly what is happening — the baby is lying with its buttocks in the birth canal and with its head and legs upward — and what the policy will be for the coming weeks. This is in accordance with the guidelines drawn up for this specific condition by the scientific association (www.nvog.nl). Mrs. W. must come back the following week. The gynecologist expects that the baby can still turn itself.

The next week, Mrs. W. and her husband come back to see the gynecologist. An extensive echograph is scheduled and in addition to checking the presentation, a number of length measurements are taken of the baby and the pelvic passage. A co-assistant will accompany them. He tells them that if pelvic narrowing is suspected, there is an increased risk of fetal mortality/morbidity in case of vaginal birth. However, there is no question of this. The baby is also of normal length. Mrs. W's abdomen does not, however, offer the baby much room. The gynecologist decides to wait another week so that the baby can still turn itself, but considers that chance small. He also wants to wait as long as possible for any external turning. This is a guideline the gynecologists have implemented in their practice. There is a significant chance when external turning will be done, the delivery of the baby can start. When this is happening, the baby has to be mature/developed enough.

In the 36th week of her pregnancy, Mrs. W. comes back again. Again the gynecologist looks with the help of echography at how the baby is lying. The baby is still lying in an incomplete breech presentation. The doctor discusses the options with the couple. He does not want to turn the baby externally because of the limited room in the abdomen, the placenta that is under the navel and Mrs. W's very contractile abdomen. The two options for the delivery, which cannot be left for long, are a breech delivery and a planned caesarean section. He refers the couple to the website of the scientific association for some background information in order to make their choice. In the waiting room is a big notice on the wall drawing attention to the website as being reliable information.

Once home, Mrs. W. and her husband study the information on the website and discuss the risks, advantages and disadvantages of one option or the other. They decide on a c-section.

When they notify the gynecologist of this decision, he agrees with their choice. He tells them that he recently took part in a clinical lesson of a nurse from the gynecology/obstetrics ward where the results of a randomized "multi-centre trial" have been presented in which for more than 2,000 women with a fetus in breech presentations and with a pregnancy term of 37 weeks, a policy aimed at a vaginal delivery was compared with one aimed at a planned c-section. Perinatal mortality, neonatal mortality and serious neonatal morbidity were significantly lower in the group with a policy aimed at a planned c-section. Between the two groups, there was no significant difference in maternal mortality and serious maternal morbidity in the short term (www.nvog.nl). The gynecologist did not tell the couple this at the previous meeting so as not to influence their choice. As they leave, he gives them a brochure containing information on the how and what for a c-section.

The c-section is planned for two weeks later, in the 39th week of the pregnancy. However, a week after her last appointment with the gynecologist, Mrs. W. starts spontaneous contractions and a healthy baby boy is born after a c-section, without complications for either mother or son.

Recap

The recap is divided into three parts according to the model described earlier. The case will be analyzed by looking at the processes in which it takes place, what kind of knowledge is being used and to which phase of the knowledge cycle the case refers.

The knowledge activities are taking place in the primary and care-support processes. The patient has an outpatient consultation several times (primary process), whereby diagnostic procedures (care-support process), e.g., an echograph, are carried out. It is possible to break down the primary and care-support process to be more detailed in what specific part of the process the case is taking place. For instance, the knowledge is being transferred from the gynecologist to the patient while performing the consultation. Writing it down in the patient record is disseminating the information. Performing the consultation and writing down the information (i.e., knowledge to decide what kind of guideline to use) are subprocesses of outpatient consultation.

We can also point out the diagnostic procedure, e.g., an echograph, at a sub-level, namely radio-diagnostics. We can even go one level deeper, for example, by performing an echograph. During performance, the gynecologist gives the co-assistant, who has to learn this profession, information about what he is doing and why: he disseminates his knowledge.

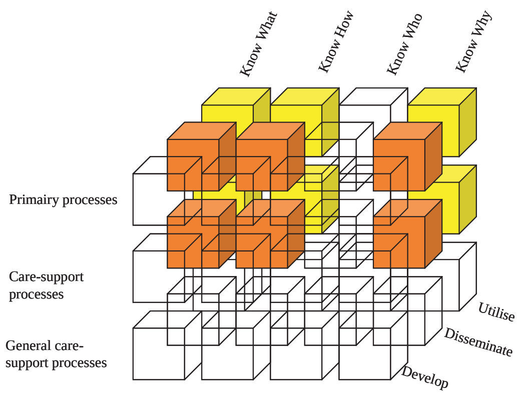
The case points itself especially at two phases (disseminate and utilize) of the knowledge cycle. The clinical lesson of the nurse, which the gynecologist took part in, and the website where the patient was referring to for reliable background information are knowledge activities which fall under the disseminating phase. The gynecologist, when explaining the "what" and "why" as he was doing an extensive echograph, disseminates his knowledge to the co-assistant. By using the guidelines for incomplete breech presentation and external turning, the gynecologist utilizes the knowledge, which is stored in these guidelines.

The case uses three kinds of knowledge: know what, know how and know why. The information on the web site contains factual and background knowledge. When the gynecologist quotes a remarkable survey, the patient and her husband are given more background knowledge. During his performance of the extensive echograph, he gives the co-assistant factual knowledge. The brochure contains know how, i.e., procedural knowledge.

Figure 2 shows the results of charting the case in the 3D model described where all the different activities are presented in cohesion with each other.

The case is an example of several objectives that can be pursued by using knowledge management, namely uniform treatment (all gynecologists follow the same guidelines), making informed decisions (clinical lesson and the choice the couple had to make) and patient empowerment (informing the patient by referring to a reliable web site and brochures).

Figure 2. Results of the case



CONCLUSIONS

In this chapter a model is presented that can be used to chart the current situation regarding knowledge management. A fully filled model represents the ideal situation, whereby all activities are in cohesion with each other. In the beginning of the chapter, we described the ideal situation. How the model can be used to chart the current situation is then described.

By applying the model to our case in section 3 the following conclusions can be drawn:

- The model appears to be suitable for positioning the case in terms of process types, cycle and types of knowledge involved. The question is, however, whether this picture is also obtained when a whole organization is examined. It is therefore recommended to use a more detailed breakdown of the primary and support processes so that more distinction is made within the processes;
- During the recap of the case, all the different activities were brought together in cohesion. This resulted in a useful overview, in addition to the separated descriptions of the activities one by one;
- Also, during the recap of the case, it was difficult to draw a boundary — what is the scope of a process and what is not. In practice this boundary will be difficult to indicate as a hospital is not independent and the processes extend outside the walls of the hospital. The process approach is a good starting point;
- The distinction between the types of processes gives a clear picture of where in the organization the knowledge processes are affected. The question is, however, whether the distinctions can be maintained in daily practice, as the processes tend to be so strongly intertwined. Take, for example, the diagnostic process which forms a considerable part of the out/in-patient treatment of the patient;
- To fill in the model, a person who knows much about knowledge management is needed.

When dealing with KM-projects, it is recommended to start with the processes where "quick wins" are to be expected. This will motivate the people involved to adapt to and work with the necessary change for a better KM process. It is expected that the outcome of active knowledge management, when the results become clearly noticeable, will have a positive effect on staff motivation and staff/patient satisfaction.

To conclude, knowledge management can certainly contribute to optimizing primary and support processes. The case in this chapter has shown that the objectives to be achieved with knowledge management are no utopian dream. By pursuing these objectives, one is not only working on the efficiency and learning capacity of the organization, but also on improving the quality of care which are, and should be, supplemental to each other.

ENDNOTES

1 Diagnostic procedures also include diagraphs and procedures in the clinical chemistry laboratory (clinical chemistry and hematology, parasitology and microbiology).

2 This can be done on an individual basis, but by mergers and take-overs new knowledge is also gathered in the form of new staff.

3 This does not necessarily immediately lead to the spreading and utilisation of knowledge. The acquired material must be brought to the attention of staff where there may be a potential need.

4 From the report "E-health in zicht" (E-health in sight) (Raad voor de Volksgezohdheid en Zorg, 2002) it appears that 84% of Dutch doctors would like to receive continuing vocational training via the Internet.

5 Guidelines are also often included in a protocol system.

6 A good example of this is the treatment of breast cancer in the Reinier de Graaf Groep (in Dutch) where various paths can be followed, depending on the treatment that is necessary for this diagnosis (www.rdgg.nl).

7 In The Netherlands the care institutions have MIP (Melding Incidenten Procedure - incident reporting procedure)-/FONA (Fouten, Ongevallen en Near Accidents — errors, accidents and near accidents) committees. Accidents and errors (for example, falls or medication errors) are reported via a form and dealt with by the committee or, in the most serious case, by the management. It does, however, appear that via the reporting committees an insufficient idea is obtained of the number and nature of the incidents. The number of reports does in fact say something about the quality of the prevention policy in institutions. It sounds paradoxical, but the more reports that are made, the better the quality (Everdingen, 1993). This does of course depend on the reporting culture in an institution.

8 Investigation shows that people can weigh up a maximum of seven related variables to come to the right conclusion. Often the assessment is influenced by things such as tiredness, mood, prejudice, etc. And knowledge and experience of other experts is not available.

9 According to a recent publication, the use of POESs is not what was expected (Lagendijk, Schuring & Spil, 2001). There is no appreciable saving among general practitioners because they already prescribe economically and sensibly and are not the greatest generators of medication costs. Being able to make better justified decisions for therapy is however considered an advantage.

Chapter 4.46
Issues in Clinical Knowledge Management:
Revisiting Healthcare Management

Raouf Naguib
Coventry University, UK

ABSTRACT

The objective of this chapter is to examine some of the key issues surrounding the incorporation of the Knowledge Management (KM) paradigm in healthcare. We discuss whether it would it be beneficial for healthcare organizations to adopt the KM paradigm so as to facilitate effective decision-making in the context of healthcare delivery. Alternative healthcare management concepts with respect to their ability in providing a solution to the above-mentioned issue are reviewed. This chapter concludes that the KM paradigm can transform the healthcare sector.

INTRODUCTION

In today's information age, data has become a major asset for healthcare institutions. Recent innovations in Information Technology (IT) have transformed the way that healthcare organizations function. Applications of concepts such as Data Warehousing and Data Mining have exponentially increased the amount of information to which a healthcare organization has access, thus creating the problem of "information explosion". This problem has been further accentuated by the advent of new disciplines such as Bioinformatics and Genetic Engineering, both of which hold very promising solutions which may significantly change the face of the entire healthcare process from diagnosis to delivery (Dwivedi, Bali, James, Naguib, & Johnston, 2002b).

Until the early 1980s, IT solutions for healthcare used to focus on such concepts as data warehousing. The emphasis was on storage of data in an electronic medium, the prime objective of which was to allow exploitation of this data at a later point in time. As such, most of the IT applications in healthcare were built to provide support for retrospective information retrieval needs and, in some cases, to analyze the decisions undertaken. This has changed healthcare institutions' perspectives towards the concept of utility of clinical data. Clinical data that was traditionally used in a supportive capacity for historical purposes has today become an opportunity that allows healthcare stakeholders to tackle problems before they arise.

Healthcare Management Concepts

Healthcare managers are being forced to examine costs associated with healthcare and are under increasing pressure to discover approaches that would help carry out activities better, faster and cheaper (Davis & Klein, 2000; Latamore, 1999). Workflow and associated Internet technologies are being seen as an instrument to cut administrative expenses. Specifically designed IT implementations such as workflow tools are being used to automate the electronic paper flow in a managed care operation, thereby cutting administrative expenses (Latamore, 1999).

One of the most challenging issues in healthcare relates to the transformation of raw clinical data into contextually relevant information. Advances in IT and telecommunications have made it possible for healthcare institutions to face the challenge of transforming large amounts of medical data into relevant clinical information (Dwivedi, Bali, James, & Naguib, 2001b). This can be achieved by integrating information using workflow, context management and collaboration tools, giving healthcare a mechanism for effectively transferring the acquired knowledge, as and when required (Dwivedi, Bali, James, & Naguib, 2002a).

Kennedy (1995, p. 85) quotes Keever (a healthcare management executive) who notes that "Healthcare is the most disjointed industry…in terms of information exchange... Every hospital, doctor, insurer and independent lab has its own set of information, and … no one does a very good job of sharing it." From a management perspective, these new challenges have forced healthcare stakeholders to look at different healthcare management concepts that could alleviate the problem of information explosion. The following are some of the new paradigms and concepts that have caught the attention of healthcare stakeholders.

EVIDENCE BASED MEDICINE (EBM)

EBM is defined as the "conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients" (Cowling, Newman, & Leigh, 1999, p. 149). A typical EBM process starts with an identification of knowledge-gaps in current healthcare treatment processes, followed by a search for the best evidence. This is then succeeded by a process to aid in the selection of appropriate electronic data/information sources and IT applications that focus on clinical competencies in the context of the best evidence generated.

The next step is to carry out a critical appraisal of the best evidence identified by carrying out checks for accuracy and diagnostic validity of the procedure/treatment identified by the best evidence generated. The costs and benefits of alternative procedures (i.e., the current best evidence procedure/treatment being recommended) are then considered. The last step is its application to patients' healthcare which calls for integration of the best evidence with the General Practitioners' (GP) clinical expertise so as to provide best treatment and care (Cowling et al., 1999).

MODEL OF INTEGRATED PATIENT PATHWAYS (MIPP/IPP)

Schmid and Conen (2000) have argued that the model of integrated patient pathways (MIPP/IPP) is a more comprehensive concept for healthcare institutions. As the acronym suggests, IPPs aim to enable better support for healthcare institutions by focusing on the creation of clinical guidelines for commonly accepted diagnostic and therapeutic procedures at a defined level of quality. This would lead to cost-efficient treatment. It could be argued that IPP calls for in-house development of standardized clinical treatment procedures for some pre-defined diagnoses and treatments.

Schmid & Conen (2000) elaborate that IPP aims to ensure that patients receive the right treatment which is based upon best practice guidelines that have sufficient evidence to warrant the label of "best practice" and which have been proven to be clinically adequate. They argue that when a hospital tries to implement IPP, it will automatically go through a circular chain process that calls for identifying sources of best practice, converting them to worldwide implementation practices and then, based upon their performance, converting them to benchmarks. Deliberation on current health reform is centered on two competing objectives: expanding access and containing costs. The challenge is to find an acceptable balance between providing increased access to healthcare services while at the same time conserving healthcare resources.

Pryga and Dyer (1992) have noted that, in the USA, hospitals receive a fixed amount per patient for each Medicare patient admission. As such, they have an objective of providing essential medical services whilst physicians are remunerated on the basis of the clinical service provided. The situation emerges where the physician and healthcare managers can have conflicting goals; such a dilemma is bound to affect formulation of best care practices particularly for preventive care.

CLINICAL GOVERNANCE (CG)

Clinical governance (CG) was first introduced in the UK by way of a National Health Service (NHS) white paper (Firth-Cozens, 1999) and calls for an integrated approach to quality, team development, clinical audit skills, risk management skills, and information systems. A typical CG process can be delineated into a sequential process that calls for (a) the means to disseminate knowledge about relevant evidence from research, (b) best treatments rather than focusing just on recognition of poor treatments, (c) better appreciation of what IT led solutions can do for clinical governance, and (d) knowing what data/information is available so as to provide baselines for best care and treatments.

Melvin, Wright, Harrison, Robinson, Connelly, and Williams (1999) have remarked that the NHS has witnessed the incorporation and development of many approaches that support and promote effective healthcare, but in practice, none of them have been successful. Research by Zairi and Whymark (1999) submits that the problem lies in the lack of proper systems to support the measurement of organizational effectiveness (i.e., clinical) in a healthcare delivery context.

According to Sewell (1997), one of the biggest challenges in having concise summaries of the most effective clinical practices is establishing what is meant by "quality in healthcare" (i.e., a measurement standard for clinical effectiveness). Sewell (1997) elaborates that measurement standards in clinical practice will change from each context and that this is attributed to the linkage between measurement standards and values and the expectations of the individual healthcare stakeholders (which, in turn, originate from the shared values and expectations to which all the healthcare stakeholders subscribe).

Melvin, et al. (1999) have noted that, in the UK, the NHS has started to support the concept of clinical governance by identifying individual best effective clinical practices. This process provides concise summaries of the most effective clinical practices in all key clinical areas. Summaries that are successfully substantiated are then disseminated throughout the NHS. Sewell (1997) has noted that the USA, Canada, Australia and New Zealand have adopted a formal accreditation system for the healthcare sector based upon the ISO 9000 approach.

COMMUNITY HEALTH INFORMATION NETWORKS (CHIN)

Modern day healthcare organizations have realized that in the future their survival would depend upon their ability to give the caregiver access to such information that would enable the caregiver to deliver personalized clinical diagnosis and treatment in real-time in very specific clinical contexts, a process termed Information Therapy (Dwivedi et al., 2002a). This vision has been translated into concepts such as Integrated Delivery System (IDS) and Community Health Information Networks (CHIN) (Lang, 1997; Mercer, 2001; Morrissey, 2000).

IDS refers to a Healthcare Information System (HIS), a business model based on computing technologies such as Object Orientation (OO) "to share key data, with partners and providers, that will allow faster and more accurate decision making … to deliver care to a broader population with fewer requirements for expensive and scarce resources" (Lang, 1997, p.18).

CHINs are integrated healthcare institutions based upon a combination of different technology platforms connected to enable support for data sharing amongst different healthcare providers (Mercer, 2001). Both IDS and CHIN are very similar in nature and both refer to an integrated network for allowing the delivery of personalized healthcare. CHINs were founded on the premise that patient information should be shared by competitors (Morrissey, 2000). The main aim of CHIN was to enable hospitals and other healthcare stakeholders to electronically exchange patient encounter summaries and medical records between emergency departments and related departments.

Another factor responsible for emphasis on CHIN was the perception in the healthcare industry that, for small-scale players to survive as individual entities, it was essential for them to form some sort of technological alliances (Huston & Huston, 2000). The original technological objective of CHIN was to enhance data-sharing capabilities amongst different healthcare stakeholders. The original technological infrastructure supported the creation of "point to point" connections. This did not succeed primarily due to limitations in technology coupled with the high amount of financial resources required to establish the "point to point" technological infrastructure (Morrissey, 2000).

The objective behind the incorporation of the CHIN concept is that it allows users to collect data which could be used to formulate "best practice protocols for effective treatment at a low-cost", that is, clinical best evidence practices for both healthcare diagnosis and delivery (Kennedy, 1995). It was anticipated that the advent of CHINs in conjunction with Internet technologies would empower healthcare stakeholders to provide healthcare to patients in real time whilst being in geographically distinct locations (Kennedy, 1995).

KM TAXONOMIES

KM has become an important focus area for organizations (Earl & Scott, 1999). It has been argued that KM evolved from the applications of expert systems and artificial intelligence (Liebowitz & Beckman, 1998; Sieloff, 1999). Almost all of the definitions of KM state that it is a multi-disciplinary paradigm (Gupta, Iyer & Aronson, 2000) that has further accentuated the controversy regarding the origins of KM. One of the main factors behind widespread interest in KM is its role as a possible source of competitive advantage (Havens & Knapp, 1999; Nonaka, 1991). A number of leading management researchers have affirmed that the Hungarian chemist, economist and philosopher Michael Polanyi was among the earliest theorists who popularized the concept of characterizing knowledge as "tacit or explicit" which is now recognized as the accepted knowledge categorization approach (Gupta et al., 2000; Hansen, Nohria & Tierney, 1999; Zack, 1999).

The cornerstone of any KM project is to transform tacit knowledge to explicit knowledge so as to allow its effective dissemination (Gupta et al., 2000). This can be best met by developing a KM framework. Authors such as Blackler (1995) have reiterated that the concept of knowledge is complex and, in an organizational context, its relevance to organization theory has not yet been sufficiently understood and documented. This is one of the fundamental reasons why KM does not have a widely accepted framework that can enable healthcare institutions in creating KM systems and a culture conducive to KM practices.

KM is underpinned by information technology paradigms such as Workflow, Intelligent Agents and Data Mining. According to Manchester (1999), a common point about software technologies such as (1) information retrieval, (2) document management and (3) workflow processing is that they blend well with the Internet and related technologies (i.e., technologies which focus on dissemination of information). Deveau (2000, p. 14) submits that: "KM is about mapping processes and exploiting the knowledge database. It's taking people's minds and applying technology." Deveau (2000) also noted that information technology puts the organization in a position to state the currently available information in the organizational knowledge base. At this point, the role of IT ends and the role of KM commences.

As KM deals with the tacit and contextual aspects of information, it allows an organization to know what is important for it in particular circumstances, in the process maximizing the value of that information and creating competitive advantages and wealth.

APPLICABILITY OF THE KM PARADIGM IN HEALTHCARE

A KM solution would allow healthcare institutions to give clinical data context, so as to allow knowledge derivation for more effective clinical diagnoses. In the future, healthcare systems would see increased interest in knowledge recycling of the collaborative learning process acquired from previous healthcare industry practices. This chapter puts forward the notion that this sector has been exclusively focused on IT to meet the challenges described above and reiterates that this challenge cannot be met by an IT led solution.

KM initiatives should be incorporated within the technological revolution that is speeding across healthcare industry. There has to be balance between organizational and technological aspects of the healthcare process, that is, one cannot exist without the other (Dwivedi et al., 2001a). This chapter emphasizes the importance of clinicians taking a holistic view of their organization. Clinicians therefore need to have an understanding of IT in a healthcare context and a shared vision of the organization. Clinicians and healthcare administrators thus need to acquire both organizational and technological insights if they are to have a holistic view of their organization.

The KM paradigm can enable the healthcare sector to successfully overcome the information and knowledge explosion, made possible by adopting a KM framework that is specially customized for healthcare institutions in light of their ICT implementation level. Adoption of KM is essential for healthcare institutions as it would enable them to identify, preserve and disseminate "best context" healthcare practices to different healthcare stakeholders.

PREFATORY ANALYSIS OF ALTERNATIVE HEALTHCARE CONCEPTS

The failure of some healthcare management concepts propelled a new stream of thought that advocated the incorporation of the KM paradigm in healthcare (Health Canada, 1999; Mercer, 2001). KM could allow healthcare organizations to truly take advantage of the driving forces behind the creation of the CHIN concept. However, very few organizations have adopted a comprehensive healthcare KM system. The main reason attributed is the failure of healthcare stakeholders in properly creating a conducive organizational culture. Based on a literature review above, a preliminary conceptual analysis of alternative healthcare management concepts is presented in Table 1. As can be seen from the table, healthcare stakeholders are searching for alternative paradigms that support collaboration in order to synergistically learn from others' experiences, training and knowledge within specific organizational cultures. Healthcare institutions have realized that existing concepts such as EBM and CG do not enable healthcare stakeholders to achieve this challenge as they do not holistically support effective integration of IT within specific organizational cultures and processes. Contemporary concepts such as EBM, CHIN, ICHDS and IPP focus on IT at the expense of having too little emphasis on people. This is further aggravated by the presence of dysfunctional organizational processes in the majority of healthcare institutions.

CONCLUSION

For any healthcare organization to succeed, it needs to excel in a number of key processes (i.e., patient diagnosis, care treatment, etc.) that are necessary for it to achieve its mission. If the

Table 1. Prefatory analysis of alternative healthcare concepts

Concept	Support for People	Support for Process	Support for Technology	Limitations
CG	Present	Insufficient	Present	Policy initiative
EBM	Insufficient	Insufficient	Present	Tacit Processes?
CHIN	Insufficient	Absent	Present	Limited Trials
IHCDS	Insufficient	Insufficient	Present	Technology focus
IPP	Insufficient	Present	Present	Tacit Knowledge?
KM	Present	Present	Present	Not validated

processes are repetitive, automation is possible via the use of IT. Modern IT applications in healthcare are not sufficient in meeting the information needs of current healthcare institutions as they lack the ability to deliver precise, accurate and contextual information to the desired caregiver at the desired time.

This chapter has presented an analysis of alternative healthcare management concepts with respect to their ability in providing a solution to the issue of information management. Furthermore, this chapter has examined the feasibility of the KM paradigm in solving the problem of information explosion in healthcare and has found validation for the proposition that the current focus on technological solutions will aggravate the problem of explosion in clinical information systems for healthcare institutions.

The chapter has also presented the key requirements for creating a KM framework, which can act as a template in enabling healthcare institutions in their attempts to initiate KM projects. This chapter concludes that any potential solution has to come from a domain that synergistically combines people, organizational processes and technology, thereby enabling healthcare stakeholders to have a holistic view of the entire healthcare continuum. This chapter further concludes that KM is the only paradigm that combines the above-mentioned perspectives (i.e., people, organizational processes, and technology) into healthcare and as such, KM is the next indispensable step for integrated healthcare management.

Chapter 4.47
Knowledge Management for Healthcare:
Using Information and Communication Technologies for Decision Making

Rajeev K. Bali

Raouf Naguib
Coventry University, UK

EXECUTIVE SUMMARY

This case study is based on data collected from a prominent UK-based healthcare software house (Company X Ltd). The organization specializes in information and communication technologies (ICT) solution development, implementations, support services (including system and application support and telephone hotline support), and training and consultancy services. The organization prides itself on the fact that, by providing unique customized ICT solutions based on the Internet and database technologies, it is able to ensure that its healthcare-based clients (hospitals and allied organizations) have strategic advantages. The case study describes the outcome of a three-year research project, the chief outcomes of which were the development of a knowledge management (KM) conceptual model for use in the healthcare solutions sector as well as detailed advice and recommendations for the organization.

BACKGROUND OF THE CASE STUDY

This case study presents an extensive discussion on the cultural, organizational, and technical implications of introducing the knowledge management (KM) paradigm in the healthcare sector. Company X Ltd ("Company X") is a UK-based healthcare information and communication technologies (ICT) solutions provider. The organization was concerned about the possibility of a sharp decline in its share of the UK healthcare-ICT solution provider market. Company X was interested in identifying the emerging trends in the highly competitive UK-healthcare ICT solution provider market. The market is composed of such organizations as the National Health Service (NHS) Trusts (government-funded hospitals and healthcare centers) which were becoming more skeptical and demanding, both in terms of service and price for new and innovative ICT products.

To accomplish the goal of identifying the emerging trends in this highly competitive market, Company X initiated a research collaboration with the Biomedical Computing Research group (BIOCORE) based at Coventry University, UK. One of the primary objectives of the research was to investigate the efficacy of the KM paradigm for Company X in order to redesign itself to meet the changing healthcare ICT needs.

ORGANIZATIONAL BACKGROUND

Company X is a software house based approximately 40 miles west of central London. Employing 45 persons as well as a number of external associates, the company specializes in ICT solution development, ICT implementations, support services (including system and application support, telephone hotline support), training, and ICT consultancy services, all primarily for the healthcare sector.

Most of the business solutions provided by Company X are based on the Microsoft Windows platform and on Web browser technologies. The company has extensive experience in integrating Web browser technologies with information databases. The company prides itself on the fact that by providing unique customized Web-based ICT solutions and database technologies, it is able to ensure that its clients have strategic and operational advantages.

Provision of such high-quality customized ICT solutions necessitates Company X to work in close collaboration with its clients. As a result, the company has considerable contacts with a wide cross section of the community (such as social services, NHS Trusts, GP practices, councils, care agencies, and charities).

Company X was started approximately 12 years ago by a managerial team that had close ties with the SQLBase development team at ORACLE. The Company X managerial team was responsible for introducing SQLBase into the UK. The company is almost entirely owned by its employees, and all research and development at Company X is remunerated from income generated from its consultancy services.

The original Company X business plan was to focus on the development of client-server solutions using Microsoft Windows, SQL, and information databases. Company X is also a synergy partner of Centura Software (formerly Gupta), an ORACLE reseller, an Informix business partner, and offers the services of Microsoft-certified trainers. Company X is also a Microsoft healthcare solutions partner. Company X also has an excellent relationship with a local telemarketing company that uses Company X to host its strategic telemarketing database for Europe, the Middle East, and Africa. Company X has proprietary rights over several solutions, the most prominent of which are a set of toolkits used for the rapid implementation and maintenance of customized solutions running on Internet-based technologies.

The organization provides professional services in the following areas:

1. ICT Consultancy and Application Development: The company has specialist skills in creating solutions relating to executive information solutions, management information systems, and office automation systems.
2. Business Expertise: Company X has considerable expertise in the use of ICT for creating solutions to assist its clients in achieving their business objectives. The company has created ICT solutions for a wide range of industry sectors including healthcare, banking, distribution, finance, insurance, manufacturing, oil, and gas.
3. Application Consultants: Company X has acted as application consultants on a wide range of business issues across diverse industry sectors and has extensive experience in building client-server ICT solutions using component and object-oriented techniques. The unique synergistic use of these two technologies has allowed the firm to develop a reputation for building fast and efficient ICT solutions that are also cost effective. Its solutions allow it to save both time and money for its clients as the software code can be effectively reused. This also allows its clients to reduce their maintenance costs.
4. MIS and EIS Consultants: The company also offers services in building management information systems and executive information solutions. The unique selling proposition (USP) of Company X's MIS and EIS solutions is that they include a graphical user interface which provides clients with significant information, allowing them to have more control over strategic business activities.
5. Technical and end-user training: The company offers bespoke end-user training for all of its solutions. It offers specialized training courses that cover the key aspects of various application development languages and client-server solutions.
6. Project Management: Company X also acts as a project management consultant; in this capacity, its main role involves the coordination of all procedures and operations within the software application development life cycle of each project so as to ensure that other software projects are completed on time and within budget.

The organization has a diverse client base (over 300 clients) that consists of a cross section of industry and public sectors. The company also acts as an adviser and trainer to some of the largest software houses in the UK.

SETTING THE STAGE

The Company X Toolkit

As mentioned previously, Company X offers a set of integrated toolkits which have been customized for healthcare institutions (HIs). Currently, the toolkit has been implemented at over 24 National Health Service (NHS) Trusts throughout the UK. The toolkit consists of four main modules:

1. Admin: offers users the ability to control access to databases. It allows authorized administrators to ensure the integrity of the databases. It supports simultaneous management and control of information over several different vendor databases such as Microsoft SQL Server and Oracle SQL Base.
2. Upload: supports the rapid development of applications that allow users to automate electronic feeds between different databases. It automatically generates integrity rules whilst establishing connections between different databases.

3. QuickBuild: allows users to maintain information (records) that is being held in databases.
4. Report Organizer: is a tool that supports information search and retrieval and supports presentation of the same on word processing applications.

As the toolkit has been built using component technology, it is possible to rapidly build customized applications from these modules. This leads to low maintenance costs and saves additional costs for making add-on applications. The use of eXtensible Markup Language and eXtensible Stylesheet Language as primary standards in the development of the toolkit ensures that other software applications have the ability to interact with existing data in the toolkit, thereby ensuring true heterogeneity. As the HTTP interface is an integral part of the toolkit, all applications built with it are accessible via Web browsers.

In recent years, the healthcare ICT solution providers' market in the UK has undergone a rapid transformation, allowing the company to exploit new opportunities in the market. The company has noted that, in recent years, the existing exclusive suppliers to NHS Trusts had become outdated with regard to the quality of services offered to them as compared with the quality of services offered to clients in the commercial sector by other solution providers. This gave the company an opportunity to demonstrate its RAD (rapid application development) techniques to Trusts, allowing it to efficiently develop solutions for the NHS based on components developed for the commercial sector.

Company X has noted that the existing exclusive suppliers to NHS Trusts had also become outdated with regard to after-sales service, which it was offering. The company overcame this by ensuring that it always worked in partnership with Trusts, allowing it to demonstrate its widespread after-sales experience, lessons learned from ICT projects in other industry sectors (i.e., banking, distribution, etc.).

Examples of Relevant Healthcare IT Experience in NHS Trusts

Examples of relevant ICT experience in healthcare organizations include the XYZ Oncology Information System Project, a consortium of 24 NHS Trusts and a regional cancer registry. At the end of a lengthy vendor evaluation process, Company X was selected to be the sole supplier for the entire oncology project. The evaluation board felt that Company X's key attributes were the fact that its solution eliminated programming code, was accessible via a Web browser, and ran on a Windows platform.

Another project involved the ABC Group of Hospitals. The Group was part of the XYZ Oncology Information System Project consortium. After reviewing the results of the oncology solution, the ABC Group decided that they wanted to use Company X's EPR toolkit to implement a Clinical Knowledge Solution (CKS). The CKS was a suite of operational solutions, which shared a common set of information such as patient demographics, but which maintained its own patient-related information. The first applications supplied by Company X were in general surgery, theater management, and endoscopy. Company X and the ABC Group are currently examining ways of implementing a Trust-wide CKS.

Typical of many solution providers, Company X had undergone several organizational changes. In the past year or so, the organization had acquired another healthcare ICT solution provider (which created clinical systems for NHS Trusts). This had led to a rebranding of its healthcare business. The company has entered the financial services sector by creating an alliance with another solution provider in order to cater to business opportunities in the banking sector, particularly in asset management systems and securities trading systems.

At the time of writing, Company X was in discussions with a US-based solution provider that was investigating organizations in the UK healthcare-ICT market in order to form a joint venture, the precise details of which were still at a preliminary stage. Company X was hoping to learn from the proposed American partner's expertise as it employed over 2,000 people, supplies clinical, practice management, and home health solutions to over 100 US-based hospitals and practices, and processes transactions for over 500 physicians.

PREVAILING ROLE OF ICT IN DECISION MAKING

Within Company X, an evaluation of how knowledge was being created, stored, and retrieved was carried out. It was felt that the intranet was being used only as a storage area for company documents and more importantly, it was not serving as an enabler in context of knowledge creation and transfer.

Case Description

The participants in the research program who were specialists in healthcare management were given a brief which required them to formulate a strategy, the adoption of which would enable Company X to be a leading player in the UK healthcare-ICT solution provider market. These participants formulated a strategy for Company X. This strategy was presented in the form of two reports. The first report was a preliminary report, which presented an analysis of the challenges facing UK healthcare-ICT solution providers. In the second report, high-level details for an alternate product (i.e., creation of a software which would allow HIs to create customized KM solutions) which would complement Company X's existing main product offering (i.e., a set of integrated toolkits for healthcare-ICT solution provider market) were presented. The main thrust of the second report was that it was important for Company X's future to start creating clinical knowledge management (CKM) solutions for the healthcare sector.

Report No. 1: An Analysis of the Challenges Facing UK Healthcare-ICT Solution Providers

The research project commenced with an analysis of the global healthcare industry, the findings of which were presented in the form of a preliminary report to Company X's senior management. The salient points of the findings were as follows:

(1) There is information overload for healthcare stakeholders — the average physician spends about 25% of his or her time managing information and has to learn two million clinical specifics (The Knowledge Management Centre, 2000). This is further compounded by the fact that biomedical literature is doubling every 19 years. In the UK, each physician receives about 15 kg of clinical guidelines per annum (Wyatt, 2000). The above indicators illustrate how difficult it is for HIs and healthcare stakeholders (HSs) to successfully meet the healthcare information needs that are growing at an exponential rate.

The impact of the above, particularly from a societal perspective, is enormous. Up to 98,000 patients die every year as a result of preventable medical errors (Duff, 2002). The financial cost of these preventable medical errors cost from US $37.6 billion to $50 billion and, in numerical terms, account for more deaths than from car accidents, breast cancer, or AIDS (Duff, 2002). A study has pointed out adverse drug reactions result in more than 770,000 injuries and deaths each year (Taylor, Manzo, & Sinnett, 2002).

Another study reported in the Harvard Business Review noted that, as early as 1995, there were indications that "more than 5% of patients had adverse reactions to drugs while under medical care; 43% of those inpatient reactions were serious, life threatening, or fatal" (Davenport & Glaser, 2002, p. 107). Advances in biomedical sciences have unalterably transformed the healthcare sector. Modern-day healthcare stakeholders (physicians, nurses, etc.) require information about "10,000 known diseases, 3,000 drugs, 1,100 lab tests, 300 radiology procedures … 2,000 individual risk factors … with 1,000 new drugs and biotechnology medicines in development" (Pavia, 2001, pp.12-13). An indicator of the enormity of the exponential increase in biomedical knowledge is witnessed by the growth in the National Library of Medicine's Medline database (4,500 journals in 30 languages, dating from 1996) of published literature in health-related sciences. In 2002, Medline contained 11.7 million citations and, on average, about 400,000 new entries were being added per year (Masys, 2002).

Observations evidence the impact of these exponential advances on individual stakeholders (Masys, 2002). Even if a typical modern-day healthcare stakeholder were to read two articles a day, it would take him or her 550 years to get updated with the new literature added every year (ignoring the existing literature level of 11.7 million). If we assume that about 1% of the new literature added every year is of relevance to a healthcare stakeholder, it would take a stakeholder five years (reading an average of two articles a day) to be updated with the healthcare advances of one year. It would appear that contemporary healthcare stakeholders are always behind the current state of knowledge (Masys, 2002).

(2) In today's information age, data have become a major asset for healthcare institutions. Recent innovations in information and communication technologies (ICTs) have transformed the way that healthcare organizations function. Applications of concepts such as data warehousing and data mining have exponentially increased the amount of information that a healthcare organization has access to, thus creating the problem of "information explosion." This problem has been further accentuated by the advent of new disciplines such as bioinformatics and genetic engineering, both of which hold very promising solutions which may significantly change the face of the entire healthcare process from diagnosis to delivery (Dwivedi, Bali, James, Naguib, & Johnston, 2002b).

(3) Healthcare managers are being forced to examine costs associated with healthcare and are under increasing pressure to discover approaches that would help carry out activities better, faster, and cheaper (Davis & Klein, 2000; Latamore, 1999). Work flow and associated Internet technologies are being seen as an instrument to cut administrative expenses. Specifically designed ICT implementations, such as work flow tools, are being used to automate the electronic paper flow in a managed care operation, thereby cutting administrative expenses (Latamore, 1999).

(4) One of the most challenging issues in healthcare relates to the transformation of raw clinical data into contextually relevant information. Kennedy (1995, p. 85) has quoted Keever (a healthcare management executive) who notes that "Healthcare is the most disjointed industry … in terms of information exchange.... Every hospital, doctor, insurer and independent lab has its own set of information, and … no one does a very good job of sharing it."

(5) Advances in IT and telecommunications have made it possible for healthcare institutions to face the challenge of transforming large amounts of medical data into relevant clinical information (Dwivedi, Bali, James, & Naguib, 2001b). This can be achieved by integrating information using work flow, context management, and collaboration tools, giving healthcare a mechanism for effectively transferring the acquired knowledge, as and when required (Dwivedi, Bali, James, & Naguib, 2002a).

(6) Until the early 1980s, ICT solutions for healthcare used to focus on such concepts as data warehousing. The emphasis was on storage of data in an electronic medium, the prime objective of which was to allow exploitation of this data at a later point in time. As such, most of the ICT applications in healthcare were built to provide support for retrospective information retrieval needs and, in some cases, to analyze the decisions undertaken. This has changed healthcare institutions' perspectives toward the concept of utility of clinical data. Clinical data that was traditionally used in a supportive capacity for historical purposes has today become an opportunity that allows healthcare stakeholders to tackle problems before they arise.

(7) The contemporary focus is only on how best to disseminate the information, which could be fatal for the future of the healthcare applications (i.e., current use is static). Rather than creating or disseminating contextual knowledge, healthcare applications are being used to disseminate data and information. Future healthcare industry applications would have to support the transfer of information with context (i.e., such schemes would have to become dynamic in nature).

Such a scenario is likely to lead to a situation where healthcare institutions would be flooded with large amounts of clinical data. The introduction of the KM paradigm would enable these institutions to face the challenge of transforming large amounts of medical data into relevant clinical information. Future healthcare systems would have to shift their emphasis to deal with the intangibles of knowledge, institutions, and culture.

Healthcare institutions require a framework that would help to assess how best to identify and create knowledge from internal and external organizational experiences and how best to disseminate it on an organization-wide basis in a manner that ensures that the acquired knowledge is available for preventive and operative medical diagnosis and treatment when required. This would call for the contextual recycling of knowledge which has been acquired from the adoption of healthcare industry trials. KM can assist the healthcare industry to become viable by giving healthcare information context, so that other healthcare providers can use the healthcare industry to extract knowledge and not information. The healthcare industry is focused on the technology aspect of healthcare and that the key to success of the healthcare sector in the 21st century is an effective integration of technology with the human-based clinical decision-making process. It is therefore important for Company X to develop a conceptual healthcare management framework that encompasses technological, organizational, and managerial perspectives for the healthcare industry.

(8) The first report ended by stating that, from a management perspective, these new challenges have created the need for a CKM (Clinical Knowledge Management) system that can assist healthcare stakeholders in alleviating the problem of information explosion in the healthcare industry. The

> primary obstacle to the report's recommended integration of the KM paradigm in healthcare was the lack of any established framework or model which had its roots in either clinical or healthcare environments.

KM does not have any commonly accepted or de facto definition. However, KM has become an important focus area for organizations (Earl & Scott, 1999). It has been argued that KM evolved from the applications of expert systems and artificial intelligence (Liebowitz & Beckman, 1998; Sieloff, 1999). Almost all the definitions of KM state that it is a multidisciplinary paradigm (Gupta, Iyer, & Aronson, 2000) which has further accentuated the controversy regarding the origins of KM. It has been argued that the main aim behind any strategy of KM is to ensure that knowledge workers have access to the right knowledge, to the right place, at the right time (Dove, 1999).

One of the main factors behind widespread interest in KM is its role as a possible source of competitive advantage (Nonaka, 1991; Havens & Knapp, 1999). A number of leading management researchers have affirmed that the Hungarian chemist, economist, and philosopher Michael Polanyi was among the earliest theorists who popularized the concept of characterizing knowledge as "tacit or explicit" which is now recognized as the de facto knowledge categorization approach (Gupta et al., 2000; Hansen, Nohria, & Tierney, 1999; Zack, 1999).

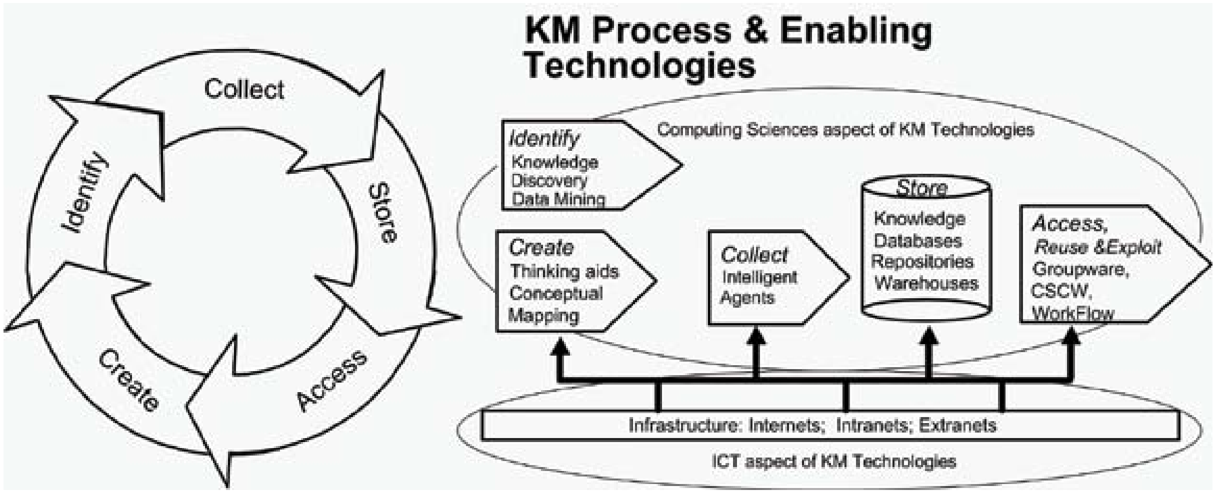
Explicit knowledge typically takes the form of company documents and is easily available, whilst tacit knowledge is subjective and cognitive. One of the characteristics of explicit knowledge is that it can be easily documented and is generally located in the form of written manuals, reports, and/or found in electronic databases (Dwivedi, Bali, James, & Naguib, 2001a). As such, it is easily accessible and in many cases available on an organization's intranet. The cornerstone of any KM project is to transform tacit knowledge to explicit knowledge so as to allow its effective dissemination (Gupta et al., 2000). This can be best met by developing a KM framework. Authors such as Blackler (1995) have reiterated that the concept of knowledge is complex and, in an organizational context, its relevance to organization theory has not yet been sufficiently understood and documented. This is one of the fundamental reasons why KM does not have a widely accepted framework that can enable HIs in creating KM systems and a culture conducive to KM practices.

Figure 1 illustrates how the KM process revolves around a cycle. As illustrated, KM is underpinned by information technology paradigms such as computer-supported cooperative work (CSCW), work flow, intelligent agents, and data mining. According to Manchester (1999), a common point about software technologies such as (1) information retrieval, (2) document management, and (3) work flow processing is that they blend well with the Internet and related technologies (i.e., technologies that focus on dissemination of information).

Deveau (2000, p. 14) submits that "KM is about mapping processes and exploiting the knowledge database. It's taking people's minds and applying technology." Deveau (2000) also noted that information technology puts the organization in a position to state the currently available information in the organizational knowledge base. At this point, the role of ICT ends and the role of KM commences. As KM deals with the tacit and contextual aspects of information, it allows an organization to know what is important for it in particular circumstances, in the process maximizing the value of that information and creating competitive advantages and wealth.

A KM solution would allow healthcare institutions to give clinical data context, so as to allow knowledge derivation for more effective clinical diagnoses. In the future, healthcare systems would see increased interest in knowledge recycling of the collaborative learning process acquired from previous healthcare industry practices. The report

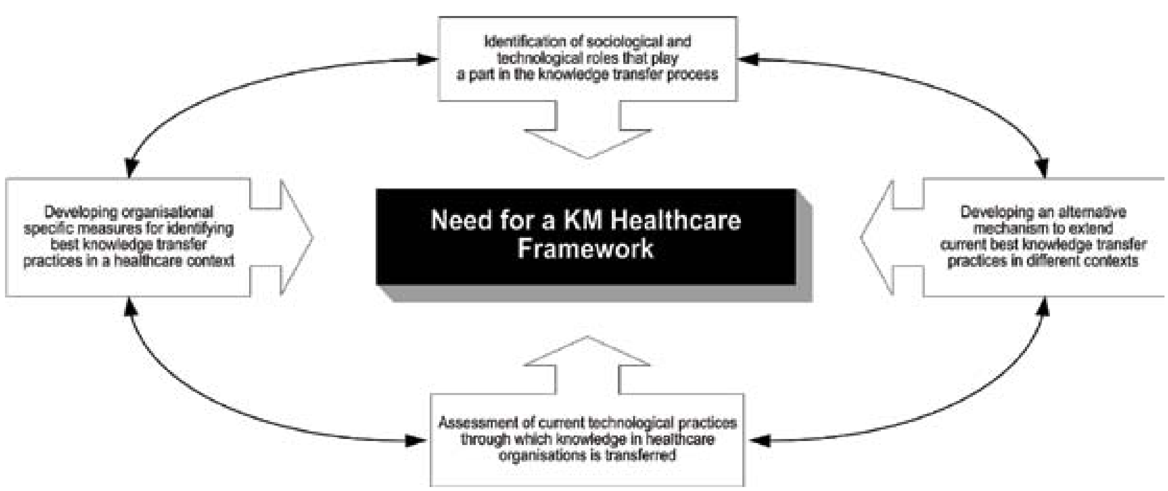
Figure 1. The KM cycle (Dwivedi et al., 2002b) (modified from Skyrme, 1999)



put forward the notion that the healthcare sector has been exclusively focused on ICT to meet the challenges described above and reiterates that this challenge cannot be met by an ICT-led solution.

KM initiatives should be incorporated within the technological revolution that is speeding across healthcare industry. There has to be balance between organizational and technological aspects of the healthcare process, that is, one cannot exist without the other (Dwivedi et al., 2001a). The report emphasized the importance of clinicians taking a holistic view of their organization. Clinicians therefore need to have an understanding of ICT in a healthcare context and a shared vision

Figure 2. Requirements for a KM framework



of the organization. Clinicians and healthcare administrators thus need to acquire both organizational and technological insights if they are to have a holistic view of their organization.

The KM paradigm can enable the healthcare sector to successfully overcome the information and knowledge explosion, made possible by adopting a KM framework that is specially customized for HIs in light of their ICT implementation level. Adoption of KM is essential for HIs as it would enable them to identify, preserve, and disseminate "best context" healthcare practices to different HSs.

The report additionally identified four elements (Figure 2) that would be integral to any such KM framework for the healthcare industry. It is emphasized that when an attempt is made to formalize knowledge in an institutional framework, the multidisciplinary nature of healthcare knowledge in an organizational context emerges.

Report No. 2: Creation of a Template for Clinical Knowledge Management (CKM) Solutions for the Healthcare Sector

Based on empirical data from the healthcare sector, Company X was presented with a four-layer KM framework, the Organization Current Knowledge Design (OCKD) model, which could serve as a generic toolkit for HIs who are interested in developing an understanding on how to develop a KM strategy (see Figures 3 and 4). As one goes on peeling one layer, another layer emerges, cumulating finally on the organizational core competencies.

The first step (layer 1 in Figure 3) in formulating a KM strategy involves the identification of the core competencies of an HI. This can be carried out in a number of ways (i.e., using the traditional five forces model by Porter [1985]).

Figure 3. Four-layer OCKD KM framework

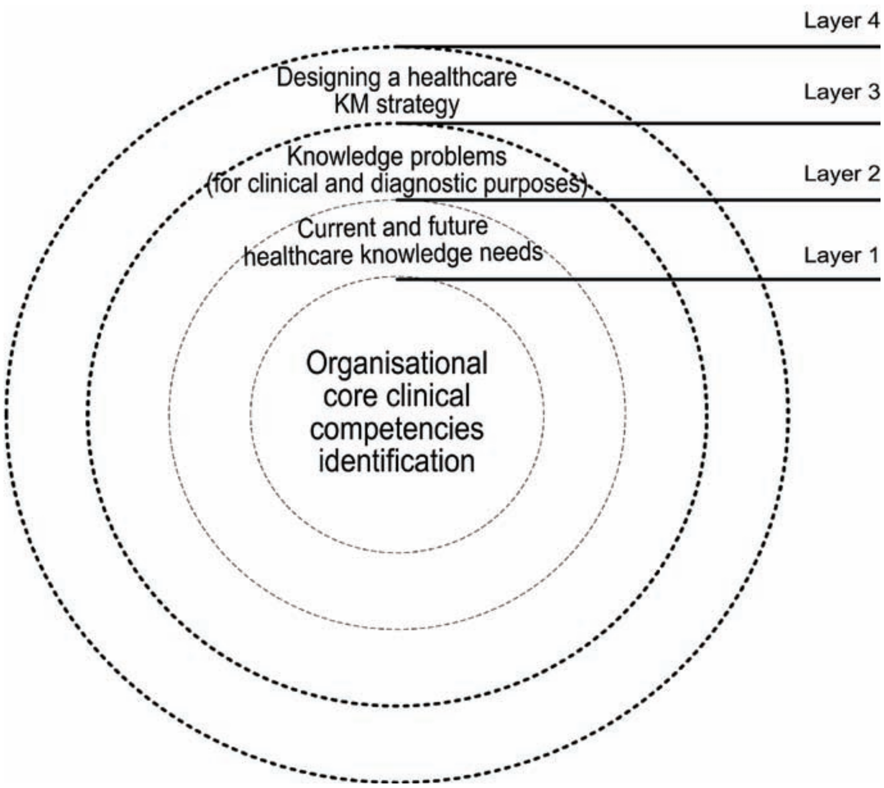


Figure 4. Elaborated OCKD framework for Company X

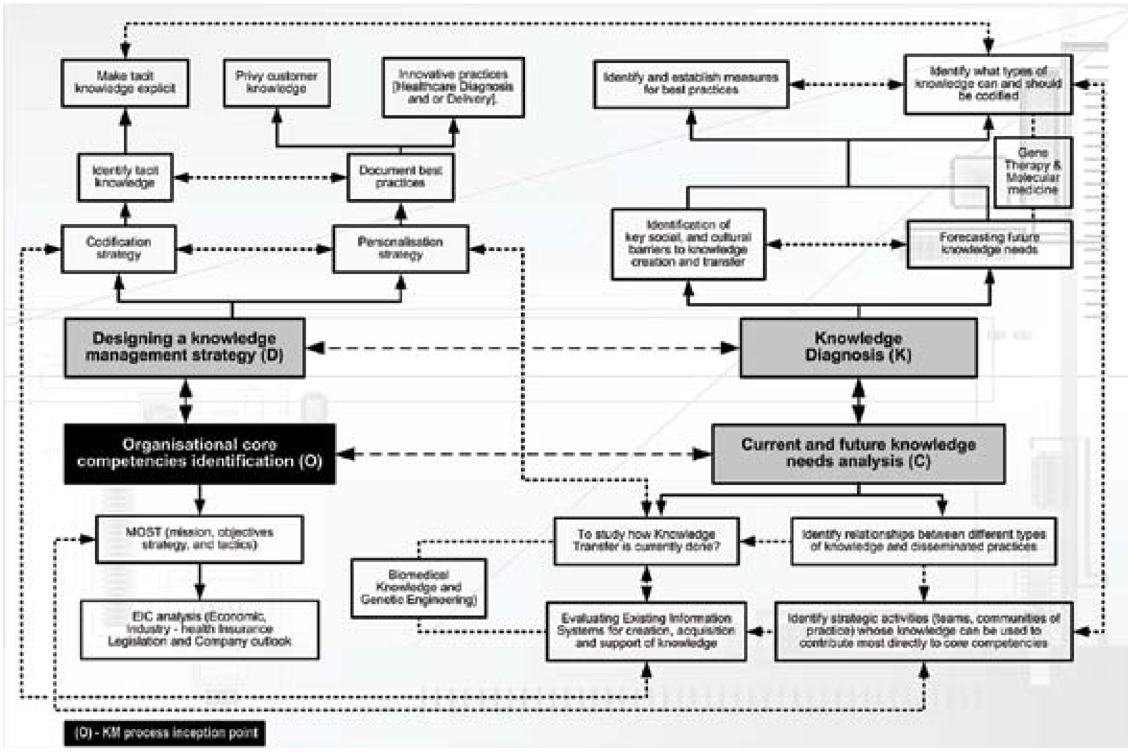

This process will enable an HI to be clear about its MOST (mission, objectives, strategy, and tactics). It would also allow it to notice how its MOST is aligned with its organizational core competencies, the EIC analysis (economic, industry, and company outlook). The next step would be a study to identify the HI's current and future knowledge needs (layer 2 in Figure 3). This would call for an analysis of the current technological infrastructure (i.e., support for m-health applications) that is in place for supporting knowledge transfer. After this process, an HI will need to assess how much knowledge should and can be codified (see layer 3 in Figures 3 and 4). This stage will result in the decision to adopt a KM strategy with emphasis on either personalization or codification. Irrespective of the strategy adopted, HIs would have to be clear on what constitutes best clinical innovative practices. This, to some extent, will help in capturing the tacit knowledge of clinical specialists. At the top layer (layer 4 in Figure 3), an HI has a KM strategy. Each HI can either adopt a KM strategy, which has emphases either on the tacit knowledge that resides in its resources or on a KM strategy that emphasizes the organizational processes: the codification strategy. This leads to the identification of relationships that exist between different types of knowledge (tacit or explicit) being transferred and to dissemination practices. It then results in a spiral transfer between the processes marked with the broken arrow signs (Figure 4).

CURRENT CHALLENGES FACING THE ORGANIZATION

Impact of New ICT in Decision Making

Senior management at Company X noted that the existing ICT (i.e., the intranet) was not enabling users to create new knowledge and/or exploit existing knowledge. It was decided to create a new IT infrastructure, one which would be seen as an enabler and which would comprise of various tools. At the same time, it was decided to restructure existing pay and reward schemes (i.e., remuneration), so as to reward information/knowledge sharers (both at an individual and group level). It was also decided to bring about a change in the leadership style and organizational culture, so as to enable members of staff to develop a strong feeling of cultural affinity toward each other.

As a first step, Company X carried out a network-wide installation of Lotus Notes. At the same time, it offered financial and nonfinancial incentives to those teams and individuals who adopted Lotus Notes to capture and share best practices. This scheme was complemented by senior management communication initiatives that emphasized integration of the new IT infrastructure in a new organizational culture—one that emphasized knowledge sharing.

As a result of the above initiatives, the following developments took place:

1. Middle- and lower-level managers have started to enable and promote learning. As a consequence, communities of practice whose focus is on creation and transfer of best practices have evolved.
2. Another interesting observation was in the use of ICT (after the installation of Lotus Notes and creation of a KM-conducive organizational culture) — ICT was perceived to be responsible for creation and transfer of information and knowledge in a bottom-up fashion. This was in sheer contrast to the top-down approach for creation and transfer of information and knowledge which has resulted from the use of the intranet as the key ICT (i.e., intranet, which was in existence before the installation of Lotus Notes and creation of a KM-conducive organizational culture).
3. The adoption of Lotus Notes resulted in the creation of a common process classification scheme (i.e., an organizational thesaurus) which uses a common language and terminology that allows users to find presentations, data and language models, schemas, best practices, and so forth.
4. Adoption of Lotus Notes was seen to create synergy between different departments of Company X. This success promoted senior managers at Company X to consider adopting the KM paradigm and in this context — they were interested in the OCKD model (Figure 4). This is discussed further in Section 5.2.
5. Senior managers at Company X believed that the next step would call for the creation of a customized expert system whose user interface would be as friendly and appealing as possible. They did add that such a system would allow Company X to eliciting the best available knowledge, but it would be quite a while before it would become a reality. They did add that they were working toward their long-term goal of creating a customized expert system, which would complement their initiatives (i.e., Lotus Notes and the communities of practice).

Adoption of the OCKD Framework at Company X

The participants in the research program for Company X presented the OCKD framework to Company X. The accompanying report argued that it was important that Company X starts to create CKM solutions for the healthcare sector. It continued that, as a first step for building an enterprise-wide (i.e., entire hospital) CKM system, Company X should make separate CKM suites for the following key healthcare ICT systems:

1. Radiology Information Systems (RIS)
2. Patient Administration System (PAS)

3. Laboratory Information Systems (LIS)
4. Clinical Patient Record (CPR)
5. Pharmacy Systems (PS)
6. Nursing Systems (NS)

The report stressed that the above-mentioned CKM suites, once implemented individually, should automatically be able to interface with each other, thus making the vision of an enterprise-wide CKM system a reality for the healthcare industry. No UK-based healthcare ICT solution provider has come up with such a product, and in light of its findings in its preliminary report, creation of a product like an enterprise-wide CKM system would ensure that Company X becomes the undisputed market leader in the UK market.

The OCKD framework was very well received within Company X. However, senior management noted that there remained several barriers to the possible acceptance of the OCKD model:

- A key constraint would be getting the top management of NHS Trusts to support any new projects and that Trusts and hospital administrators had first to recommend KM products. This would require NHS Trusts and hospital administrators to be convinced of the utility of the KM paradigm. This would call for substantiation of the results obtained from KM trials, preferably in health-related scenarios.
- NHS Trusts are now particularly more skeptical and demanding, both in terms of service and price, and more so for new innovative ICT products. They felt that the KM concept would take a few years to develop into a mature product.
- The UK solution provider market is driven by the centralized buying procedure of the NHS, that is, the NHS Purchasing and Supply Agency, which is currently very cost sensitive. The need for a new KM system has to be recommended by the Agency.
- There is no measurement tool that could quantify the impact of the OCKD model on the processes of an organization.
- They also noted that there could be legal liabilities for the sellers of the model in case the stated best practices are not properly validated in a healthcare context.
- An additional key constraint was finance. Building an enterprise-wide CKM would require additional funds.
- Detailed supporting technical documentation for each CKM application had to be developed. This would take both time and money.

CONCLUDING COMMENTS

Company X is currently working with several NHS Trusts in an attempt to develop jointly an enterprise-wide CKM product. It remains convinced on the feasibility of the KM paradigm solving the problem of information explosion in healthcare. The company is also in agreement with the fact that the current focus on technological solutions will aggravate the problem of explosion in clinical information systems for healthcare institutions. It remains convinced that any potential solution has to come from a domain that synergistically combines people, organizational processes, and technology, thereby enabling HSs to have a holistic view of the entire healthcare continuum and that an enterprise-wide CKM product, based on the OCKD framework, is the first step in this transformation.

Chapter 4.48
The Challenge of Privacy and Security and the Implementation of Health Knowledge Management Systems

Martin Orr
Waitemata District Health Board, New Zealand

ABSTRACT

Health information privacy is one of the most important and contentious areas in the development of Health Knowledge Systems. This chapter provides an overview of some of the daily privacy and security issues currently faced by health services, as health knowledge system developments risk outpacing medico-legal and professional structures. The focus is a mixture of philosophy and pragmatics with regard to the key "privacy" and "security" issues that challenge stakeholders as they try to implement and maintain an increasing array of electronic health knowledge management systems. The chapter utilises a number of evolving simple visual and mnemonic models or concepts based on observations, reflections and understanding of the literature.

INTRODUCTION

The focus of this chapter is largely shaped by the common themes and thoughts expressed, and dilemmas experienced, within the environment in which the Author works. However many of these local opinions are shaped by more universal forces, media, and experiences, and common themes, concepts and challenges can be found internationally, both within health, and other complex systems that handle personal information (Anderson, 1996; Coiera & Clarke, 2003; Tang, 2000). Health Knowledge Management systems are assisted by processes that provide complete, accurate, and timely information. Issues of security and privacy have the capacity to facilitate or inhibit this process. However, there are a myriad of perspectives with regard to the meaning, significance, and interrelation of the terms privacy, security, and health knowledge system, which shall be discussed throughout the chapter.

A Health Knowledge system should aim to integrate and optimise stakeholders' "capacity to act" (Sveiby, 2001) or "capacity to C.A.R.E." (that is, the capacity to deliver in a coordinated fashion the integral Clinical, Administrative, Research and Educational functions of healthcare). The Electronic Patient Record term typically aims to describe the technology or software that stores the record of care or provides a degree of decision support. However, the term "Health Knowledge Management System" aims to better capture or identify the overall system changes required to implement decision support systems, such as changes in underlying processes and the development of a culture that values, respects and protects the acquisition, distribution, production and utilisation of available knowledge in order to achieve better outcomes for patients (Standards Australia, 2001; Wyatt, 2001).

A Health Knowledge Management System should facilitate closing the communication gaps on an ongoing basis, between all the key stakeholders involved in optimising care, GPs, Allied health services (including hospitals), and the often forgotten Patients and their Supports, who all need and should benefit from an improved "capacity to C.A.R.E." The system should also aim to be fast, intuitive, robust, stable, and trustworthy (Orr, 2000).

PRIVACY AND SECURITY

Internationally there is a growing array of privacy and security codes, laws, and standards with many shared core themes (Office of the Privacy Commissioner, 2002; Standards Australia and Standards New Zealand, 2001). However, creating a shared understanding of the essential nature of "Privacy" continues to afford particular challenges, as many of its associated elements are contextual, percep-

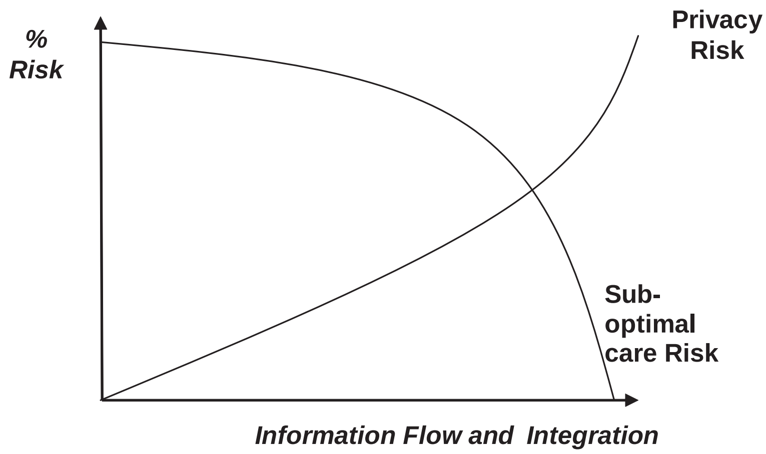
tual and personal. Clarke (2004) and Anderson (2004) provide comprehensive resources exploring the dimensions and complexities of privacy, security, and related concepts.

There is the potential for conflict, as well as the need for balance between the hierarchy of needs (Maslow, 1943) or wants of an individual or a particular group, versus the needs, and wants and capabilities of the wider community or system. The original Latin origin of the word "Privacy" aims to convey a sense of something "set apart", owned by oneself rather than the state or public (Online Etymology Dictionary, 2001). Therefore we could view private information as something we feel ownership of or particularly connected to, information that should be "set apart" and out of the public domain, or at least over which we should have particular control and an understanding of the competence and motivation of those who may use it.

However with regard to our health (and accordingly our health information) we are rarely truly "set apart" from the public or our communities. Our health, our health management, and our behaviour are continually impacted on by the complex biopsychosocial (Engel, 1977) system in which we live. The need or desire to be "set apart" or have control can lead to conflict or at least opportunity costs with the needs of other aspects of the finely balanced system within which we function. Each stakeholder group may attribute different weights to different factors and believe the balance should lie to one side or the other.

The Latin origin of the word "Security" conveys the sense of something safe or without care (Online Etymology Dictionary, 2001). Security with respect to Information Systems typically focuses on the preservation of confidentiality integrity, and availability. Confidentially refers to the need to limit access only to those authorised to have access, integrity refers to ensuring the completeness and accuracy of information and associated system processes while availability refers to the need to ensure that information and associated system processes are accessible to authorised users when required (Standards Australia/New Zealand, 2001).

Figure 1. Privacy versus sub-optimal care risk: Possible clinician view



Perceptions of privacy and sub-optimal care risk according to degree of information flow can be depicted by way of a schematic (Figure 1).

As a background to a discussion on the challenges of privacy impact assessment and informed consent or "e-consent" systems, it is worth trying to stimulate a shared conceptual understanding, of some of the perceptions of what the impacts or risks and benefits of a health knowledge management system might be. As a beginning, we might consider Figure 1, which illustrates how a clinician might perceive the relative decrease in sub-optimal care risk and increase in privacy risk as health information increasingly flows and is shared and integrated.

Privacy risk is defined as the perceived risk of an adverse outcome or sub-optimal care related to a privacy infringement. Sub-optimal care risk is defined as the perceived risk of non-optimal care related to information flow restriction or disintegration.

The focus of electronic health knowledge management system value analysis is often on preventing death or adverse events. However there is a whole range of care that, although it does not result in a reported adverse event or death, could be described as non- or sub-optimal. A health outcomes curve (Figure 2) may have optimal care at one end with everything else considered increasingly sub-optimal as it moves through various degrees of poorly co-ordinated and inefficient care, towards adverse events, permanent disability and death at the other end. This poorly co-ordinated or inefficient care may for example include duplication of assessment or investigation or the use of expensive or multiple interventions, without evidence of greater benefit over a cheaper or single intervention or simply failing to stop or review an intervention.

Therefore the hypothetical clinician's opinion (Figure 1) may be shaped by the perspective that, on balance, the greatest risk our communities face is a whole range of sub-optimal care, that at least in part is attributable to the poor flow and integration of health information. Based on this hypothesis, better integrated health information leads to better integrated healthcare, the desired outcome from an effective health knowledge management system would be to shift the norm of the health outcomes curve towards the optimal end of the curve minimising the degree of sub-optimal care.

However while not disputing the desire to minimise sub-optimal care, a patient may perceive the relative risks differently (Figure 3). It is currently, and likely to remain, difficult to

Figure 2. Health outcomes curve: Death to-optimal care

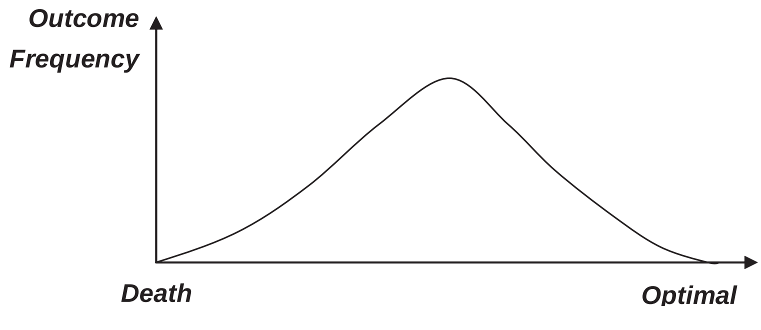


Figure 3. Privacy versus suboptimal care risk: Possible patient/consumer view

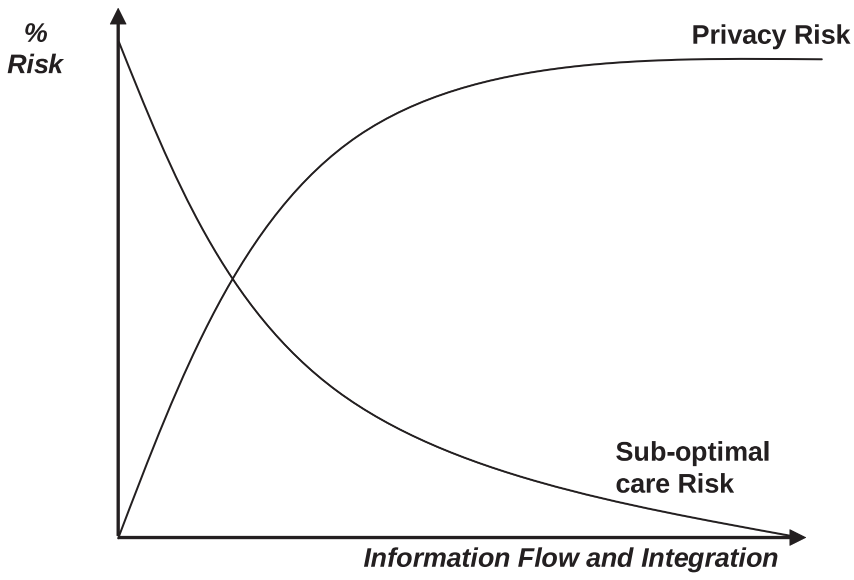


provide "evidence" based data on relative privacy versus sub-optimal care risks to an individual or indeed populations, as there will be strong perceptual differences as to what the scope of that evidence should be and how it should be weighed. However we could assume the relative risk graphs are unlikely to be reflected by straight lines. The relative risks are likely to be influenced by individual perception, respective roles, the nature of the data, and to change over time. The frequency, imminence, likelihood, and magnitude of risk would also need to be considered, as would the ability to identify, evaluate, manage, and review risk.

In the absence of definitive data, and with the recognition that the perceived risk arising from a privacy infringement has such a personal perceptual component, it is important to highlight some of the views and perceptions with regard to this matter.

It could be argued, that severe physical disability or death is unlikely except in the case of a privacy infringement leading to severe psychological distress resulting in attempted or completed suicide. However there are a number of counter arguments to this. These suggest that what we do now even with good intention could have future potentially unforeseen but not unforeseeable adverse impacts. These suggest that there is not only the potential for sub-optimal care, but also for active discrimination if not persecution and political or regime sanctioned killings.

Perceived risk of a privacy infringement may lead to a patient withholding information, or delaying presentation to health services. This may result in delayed investigation and treatment and potentially sub-optimal care including avoidable morbidity and death. This morbidity may extend to others particularly in the case of infectious diseases, not least partners and unborn children in the case of sexually transmitted diseases.

Current data integration, data mining, risk prediction, and genetic profiling developments have the potential for great benefit for our communities. However there is also the risk that without appropriate regulation, certain segments of the populations could be identified at high health risk and become unemployable, uninsurable and unable to obtain credit, a mortgage or appropriate affordable healthcare (Kennedy, 2004).

Insurers and employers are generally not innately bad. They are businesses charged with making a profit (or minimising loss) by their shareholders, and can be expected to use every legal means and loophole possible to identify and manage their risk particularly if it gives them an advantage over a competitor.

However it can be argued that the potential unfettered ability of insurance companies and health management organisations to be progressively able to segment or cut up the market, and discard those least profitable should be a concern for every community.

Unique Health Identification Numbers

Unique health identification numbers can facilitate the process of data integration across multiple electronic systems, and lead to better-integrated care. It can also be argued that within the context of a large integrated electronic system they may decrease privacy or security risk by minimising the amount of non secure activity around bringing a disintegrated paper record together, such as multiple phone calls to other services inquiring as to the availability of records, and the subsequent transfer of paper records.

However, it can be argued that if there is an infringement of an integrated unique identifier based electronic system, there is the opportunity for thousands of records to be accessed, with unique identifiers facilitating access to a wide range of comprehensive health information. An infringement could in theory be the result of a hacker gaining unauthorised access to the health network. However, of likely greater risk is a health service staff member, acting out of curiosity, malice or pecuniary gain, or having simply been misled or talked into it by someone posing as a patient or clinician on the telephone. This latter method of infringement has been highlighted by Anderson (1996). The risk of staff access, facilitating a range of crimes including murder has also entered the popular fictional literature (Gerritsen, 2001), also shaping community perceptions.

It could also be argued that significant parts of humanity's past and present has been dominated by war, invasion, totalitarian regimes, and state sanctioned terror, and even those of us currently living in relatively benign environments are naïve to believe that such horrors will not feature in our future. Such invading or totalitarian regimes have and would use every means possible to control and terrorise the population, including health data. The provision therefore of a national unique health identification number could facilitate this process, including the singling out of specific subgroups for discrimination, persecution or killing (Black, 2001).

There are also general privacy infringement concerns, including health information systems, being cross referenced, or matched with other government systems including social services, benefits and police, and the use of data for unauthorised research or commercial purposes.

Are patient privacy concerns sometimes just a smokescreen for clinician privacy concerns? Are clinicians sometimes just trying to minimize the transparency of a whole range of issues from limitations of their skill and efficiency to fraudulent practice? It is understandable why many clinicians would find these questions challenging if not insulting. However in terms of exploring the challenges that might impact on the effective implementation of health knowledge management systems, they are perspectives that cannot be ignored, and following is a brief limited discussion of some of the potential underlying issues.

Evidence Based Medicine (EBM) or the concept that treatment choices should be based on, or backed by, the best evidence available, has unfortunately in many situations, become perceived as an excuse for "evidence bound" medicine. That is the establishment of rigid regimes, or marked limitation of treatment choices that stifle innovation or new developments and do not recognise individual patient variation. This has particularly become associated with the term "managed care". Managed care is a concept that in its pure form has some worth, as it promotes the idea of effective clinical care pathways and efficient targeted integrated use of resources. However the form of "managed care" espoused by profit focused health organisations, and insurance companies is perceived as having little to do with effectively managing care in the patients interests, but everything to do with managing costs and subsequently maximising profits.

Accordingly clinicians may be rightly concerned with respect to whether, Health Information Management Systems that propose to support "evidence based medicine" and "quality management" are not just Trojan Horses, implemented with purely financial goals that will lead to a state of "evidence bound medicine" (Orr, 2000).

It can be argued that in a fee-for-service environment concerns for patient privacy may be a smokescreen to prevent monitoring of over-servicing and over-investigation and subsequent over-claiming. Unfortunately this argument might have some credence, but hopefully it applies to only a small minority of clinicians.

The clinician population, just like the patient population, will have a spectrum of views and needs and behaviours with regard to their own personal privacy. The view that those who are doing nothing wrong have nothing to worry about may have some validity, but it does not dismiss the fact that some of those who have done nothing wrong will worry, or certainly will not enjoy or embrace their employing, funding or regulatory body's ability to closely monitor or control their behaviour.

Clinicians may rightly question a health information management system's capacity for "evidence building medicine", the potential to support research and effectively improve clinical processes from their perspective and to augment their clinical skill and professionalism.

Coiera and Clark (2003) have comprehensively described some of the parameters, complexities, and potential solutions for the concept of "e-consent" with regard to the handling of electronic patient information. It may be useful to focus on some of the perceived potential limitations or challenges of the concept (or more specifically the concept of so called "informed consent") in practice, when it interacts with the complex system of health and clinical care information flows and utilisation. As a context to this discussion, a series of perspectives, and metaphors about how the current health system (and particularly clinical practice) functions is presented.

Informed consent implies some form of formal risk benefit analysis; or at least that a patient is freely consenting to a particular action having been appropriately informed of the potential risks and benefits of such an action. In relation to an electronic Health Information System, informed consent can be used to imply that a patient, based on perceived privacy risk, should have the right to suppress certain information, or to prevent certain caregivers from viewing specific information. Additionally, to protect privacy, it can be argued the caregiver should be given no indication that information has been suppressed or is deliberately being withheld from their view. One argument that can be used for this is that patients have always withheld information from caregivers, and caregivers have always been willing to make incomplete notes on patient's request.

A caregiver utilises a Health Knowledge System with a view to making more effective or optimal decisions about a patient's care. A clinician may recognise that, just like a paper record, the electronic record may not always be complete accurate and timely. However is it acceptable for an employer to provide systems that can deliberately deceive or mislead a clinician by suppressing information, while giving no indication that information is being withheld?

Biopsychosocial Healthcare (Engel, 1977) should be related to Biopsychosocial Pattern Recognition. Healthcare that seeks to address a patient's illness or disease, not just as biological pathology, but within a psychosocial context, needs to have an understanding of that context. From an information system perspective, assistance with pathology recognition and general treatment advice may be helpful, for example if a patient presents with certain symptoms and signs, the clinician is provided with list of potential diagnoses and general investigation and management advice.

However, for optimal biopsychosocial healthcare, it is important to know an individual's specific risk profile and psychosocial circumstances, their coping mechanisms and supports and how they may have progressed and responded in the past, with the aim of facilitating individualised chronic care and task management. Pattern recognition and appropriate interventions are often related to subtle changes for that specific patient. Longitudinal history and knowing not just how a patient is presenting now but how they have presented and responded over time is one of the major benefits of a longstanding relationship between a patient and a trusted clinician.

In an environment where patient and clinician relationships may be increasingly fragmentary, with multiple short term interventions by multiple caregivers, a health knowledge system should seek to act as an organisational glue and organisational memory, holding together and integrating both the shared collective and longitudinal knowledge of a patient and appropriately co-ordinated responses.

A Health Knowledge System should aim to bring together as soon as possible the required "pieces" that will increase the "capacity to act" (Sveiby, 2001), or capacity to C.A.R.E. (that is the capacity to deliver in a coordinated fashion the integral clinical, administrative, research and educational functions of healthcare). Like a jigsaw, the more pieces already in place, the quicker it is to start seeing the overall picture and what pieces (areas) best to solve next. Indeed, in terms of biopsychosocial pattern recognition, a clinician may sometimes think they are working on putting together the pieces to build one picture, but get more pieces and realise they are actually working on another.

Media reviews of adverse events or deaths using a "retrospectascope" often see simple clarity where none was evident to clinicians involved at the time. Using the "retrospectascope" often one can see all the pieces of the jigsaw at a single place and point in time when in reality the pieces will have emerged from multiple sources over time. In reality, a clinician often needs to solve the jigsaw, as if riding around it in a roller coaster through a dark tunnel with only glimpses from different perspectives of not only the index problem, but multiple problems for multiple patients they may be being asked to solve at the same time.

A machine or computerised jigsaw, with increasing levels of intelligence, could bring pieces together for you, sort and frame pieces into groups and provide decision support telling you a piece is missing or a piece cannot go here as it does not fit with another (e.g., preventing medication errors). If you switch on the privacy mode of this "intelligent" jigsaw should it place mittens on you, slowing the problem solving process or say "sorry you cannot see that piece" or even withhold pieces without even telling you? There will undoubtedly be situations where the withholding of specific information from specific caregivers can be justified. However the concept of informed consent should at least seek to convey an understanding of not just the perceived privacy risks and benefits of information flowing or not flowing, but also the clinical risks and benefits.

However there are different perceptions or perspectives of what those risks and benefits are, and these can differ for each disorder, patient, caregiver, and can vary over time. For example information typically considered sensitive includes that related to infectious and sexually transmitted diseases, alcohol, and drug and mental health history and obstetric and gynaecological history (particularly in relation to induced abortion).

However some patients may consider, for example a family or personal history of carcinoma as, or more, sensitive while one clinician suggested he would be more worried about an insurance company (via their GP) checking his lipids. We also need to consider the time and resource implications of information flow "informed consent" processes and how realistic it is at the time of information collection to make decisions on all information collected in terms of its current and future information flows; for example, that information item A can go to Doctor A but not Doctor B or Nurse C, but item C can only be viewed by Doctor D. In the common situation of resource limitation and prioritisation it can be argued there may be a pragmatic need for "implied consent", with the patient having to actively indicate they want a particularly piece of information limited in its flow.

Similarly it can be argued that it is misleading to even attempt to utilise the concept of informed consent to imply that a health service can truly offer a patient the option of control over their information flows. There may be clinical, statutory, regulatory or financial requirements that require a clinician or health service to pass certain information or partial information to other bodies. A clinician or health service can do their best to make a patient aware of the nature and purpose of the information they are collecting and how it may be utilised, but it is misleading to imply that the patient has total, un-coerced control over that information, for which they can freely offer or withdraw consent.

Accordingly a patient may be advised that if they do not agree to their information being stored or shared in a particular way, the clinician or health service may not be in a position to offer them a service. The Foundation for Information Policy Research (Anderson, 2004) has criticised the draft UK NHS patient information sharing charter (NHS 2002) for including a statement of this nature that makes specific reference to the potential refusal of treatment, if a patient's decision to restrict information sharing, is considered to make them untreatable or their treatment dangerous.

Challenges to Privacy and Security Processes

Healthcare, and indeed human physiology and disease progression are increasingly recognised for their complexity and non-linear dynamics, where there are limitations for reductionistic views and solutions that do not or can not recognise or adapt to that complexity (Plsek & Greenhalgh, 2001; Goldberger, 1996). This section will not attempt an exploration of the theory or to utilise the formal language of non-linear dynamics, but again, through the use of metaphor and perspectives, aims to convey some of that complexity, particularly as it relates to privacy and security and the implementation of electronic health knowledge management systems.

Knowledge Neurones and the Therapeutic Knowledge Alliance

From a distance and at a fixed point in time clinical information may appear to be exchanged in a simple linear chain like fashion. For example, organisation or person A communicates with organisation or person B who communicates with organisation or person C, and all may be expected to exchange the same information in a standardised format.

Therefore conceptually, one might hope to control the flow of information by mapping these connections and asking a patient who trusted connections they consent or agree to have in their own particular chain and under what conditions information should flow along it. However in reality there are often a series of intermingling web-like connections, both within and between multiple organisations and their constituent individuals that are continually being realigned, reshaped and restructured over time. Additionally, as opposed to information being passed in a single standardised format, there are often different variants or segments of the information passed between each connection.

Knowledge Neurones

In addition to electronic health information systems storing text-based records clinicians utilise a multitude of other channels to transfer and manage health information. These include paper records, phones, personal digital assistants, pagers, voicemail, fax, e-mail, and not least conversation or personal and group interaction. Therefore, rather than being considered a simple link in a linear knowledge chain, a clinician can be considered as being at the centre of a multi-pronged spherical neurone like structure, with each prong representing a different channel through which they may connect with others, to push, pull, and produce knowledge.

Electronic health knowledge management systems may assist the clinician in the continuous process of integrating these multiple channels and adding or discerning intelligence. The clinician may strengthen or utilise more channels perceived to add value and ignore or weaken channels perceived to add less value. "Value" may be a function of perceived ability to integrate and add intelligence, and can vary by individual, context, and time.

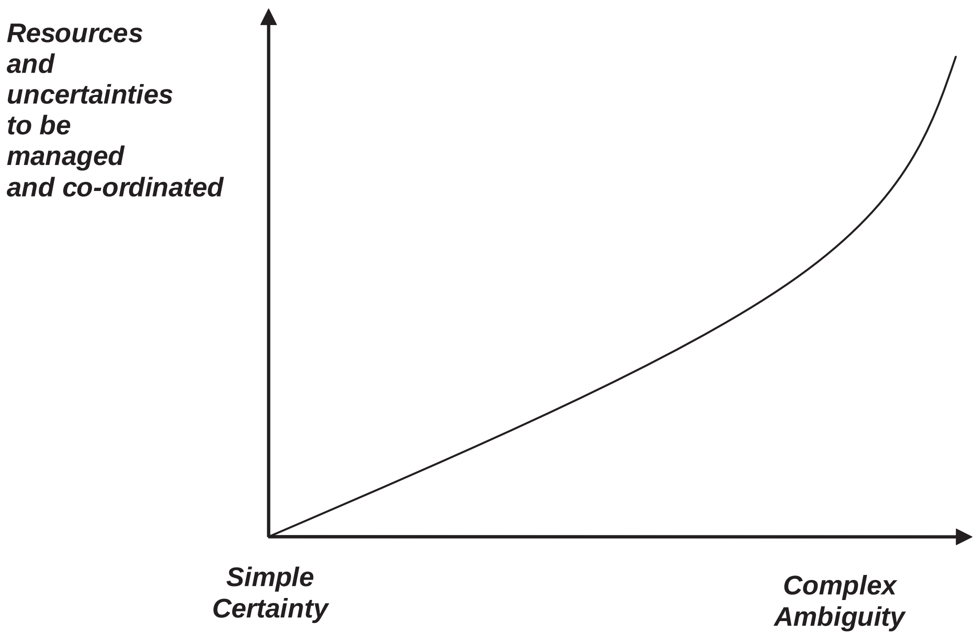
Historically the "therapeutic alliance" concept has had an evolving meaning, but carries the sense of clinician and patient working together (Goldstein, 1999). Similarly, the earlier definition of a health knowledge management system attempted to convey the sense of GPs, allied health services, and patients and their supports all working together. We could consider each of these groups as forming their own knowledge neurones and conceptualise a "therapeutic knowledge alliance" comprising of a web of these interweaving knowledge neurones, all supporting each other and working together to make a healthy difference.

Healthcare may involve a spectrum of clinical presentations or scenarios that have to be managed, which can be described as simple certainty to complex ambiguity (Figure 4). The range from simple to complex relates to the number of caregivers and interventions that may have to be coordinated in a patient's care in relation to their condition or multiple conditions. Certainty to ambiguity relates to the degree of perceived accuracy or certainty with regard to the diagnosis or diagnoses and the potential effectiveness of interventions or treatments.

Traditionally, as clinicians have moved from simple certainty to complex ambiguity, they have utilised an increasing array of resources within their therapeutic knowledge alliance. This typically includes their multidisciplinary team colleagues directly involved in the patient's care in the form of ward rounds or case conferences, but can also involve de-identified case presentations, to non-involved peers or senior colleagues for support and advice on how to best manage this complexity and ambiguity.

The quest for increasingly highly structured data runs the risk of adopting a cloak of scientific certainty that loses the art of dealing with this often-prevalent complex ambiguity in clinical practice. A specialist may have more factual knowledge or skill in a particular clinical area

Figure 4. Resources and uncertainty to be managed with increasing complexity and ambiguity



than a generalist or someone in training, but it is often their ability to recognise, adapt and cope with what they do not know, or what is not initially clear that provides their particular value. A patient's presentation may not fit neatly into a specific textbook or diagnostic category, but a specialist may say to a referrer: "I have a sense this patient may be suffering from condition A or maybe B; however, I do not know the exact answer either, but let's monitor and manage the situation this way." Similarly, the value in sharing a case with colleagues is often not so much that they provide an immediate diagnosis or recommend you dramatically change the management, but more that they provide support and contain anxiety that you have not missed anything obvious, and that you are taking a course that would best manage a range of possibilities that may become evident over time (Smith, 1996).

Intuition and learning from experience to cope with complex ambiguity is an aspect of the art of medicine that could arguably be just sophisticated learned pattern recognition and risk management that is and will be increasingly codifiable in electronic form. Indeed, a central aim of an electronic health knowledge management system should be to enhance and develop the capability of the health system and the individuals within it, to adapt and cope with varying degrees of complexity and ambiguity. However, at present there is a need to recognise the relative limitations of structured electronic data and guidelines, for dealing with complex ambiguous clinical scenarios, and to recognise the current reality of how clinicians cope with that complex ambiguity (Figure 5).

The above section and Figure 5 refer to the increasing relative utility of the wider therapeutic knowledge alliance versus structured data and

Figure 5. Therapeutic knowledge alliance versus structured data and guidelines

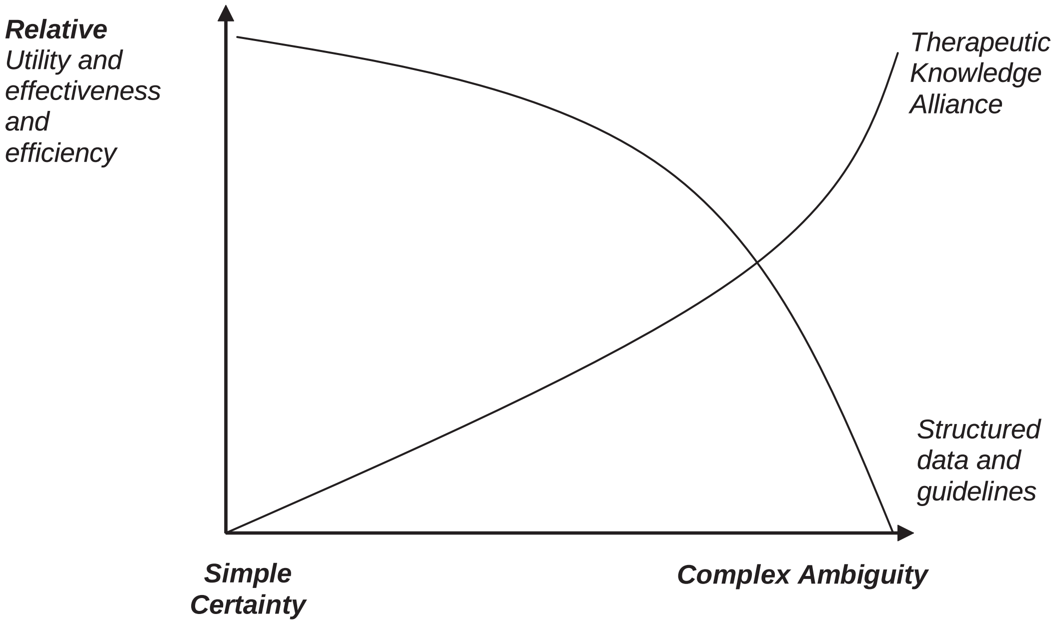


Figure 6. Utility of an electronic health knowledge management system in clinical scenarios of increasing complexity and ambiguity

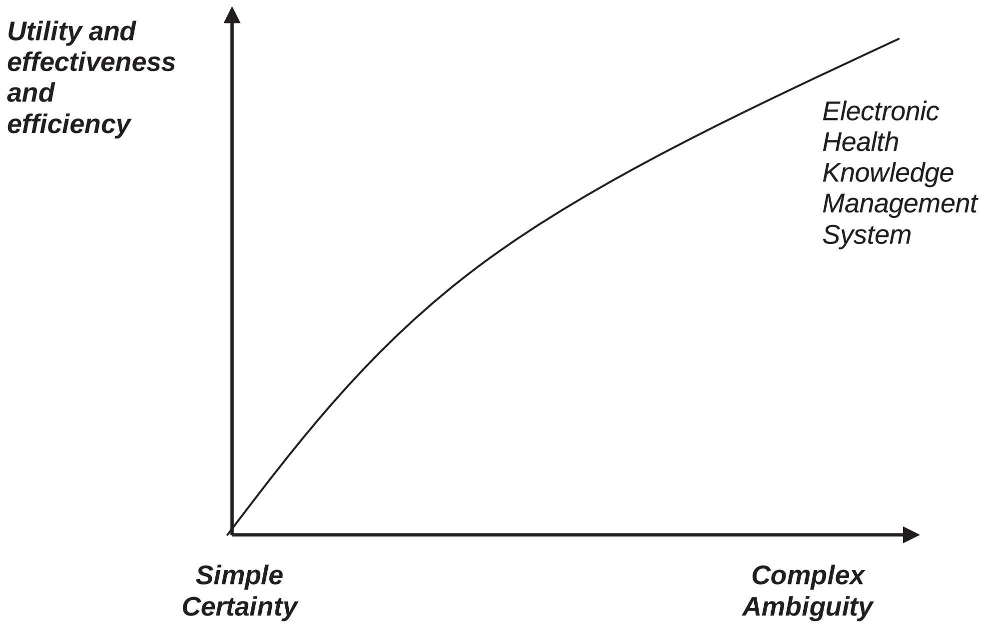


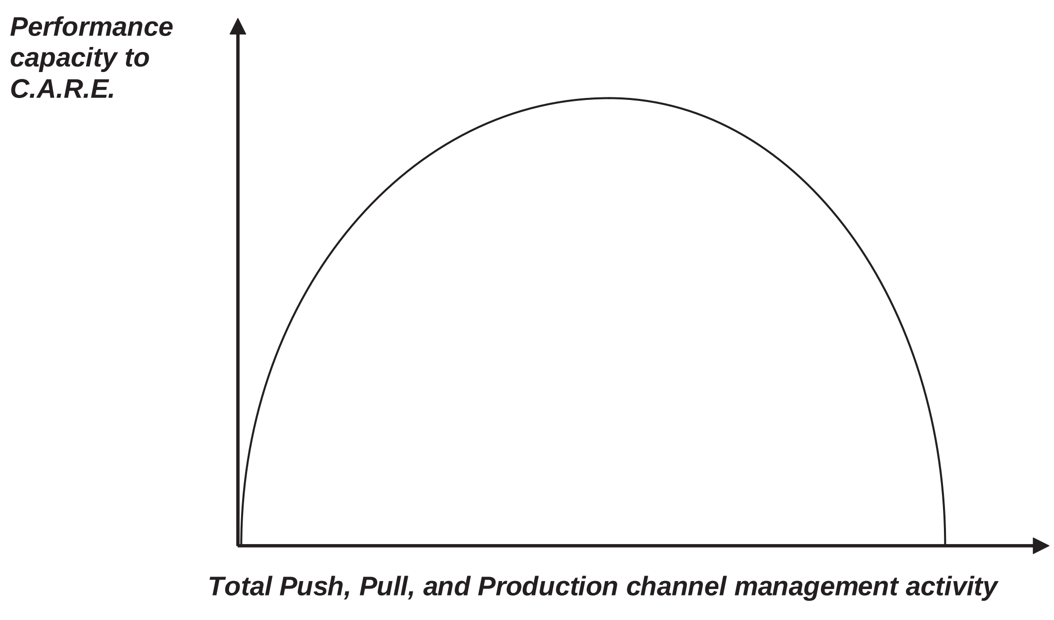
guidelines when dealing with increasing levels of complex ambiguity. However, this of course does not infer no utility. An electronic health knowledge management system, particularly one focused on care coordination management, could be of increasing utility, effectiveness, and efficiency in helping manage complex ambiguous health scenarios (Figure 6).

Channel Management and the Therapeutic Knowledge Alliance

Many Information System developments may just add additional channels to manage, diluting limited resource and consuming more time and may not be of immediate perceived benefit. The clinician may have to utilise multiple poorly integrated channels, with the concern that increasing levels of non-productive channel management activity may lead to decreased performance across the range of clinical, administrative, research, and educational activities. Privacy and security interventions should aim to optimise performance and minimise the level of associated channel management activities that may lead to decreased performance (Figure 7).

Senior clinicians' failure to use electronic information systems to the same degree as their junior colleagues is often attributed to their reluctance or fear of change or technology, when the reality may be they have established channel management methods that are more productive and efficient in terms of their limited time. The clinician, rather than seeking or entering data on a computer, may perceive the most efficient use of their time may be to seek information from a trusted colleague who can integrate, and quickly add intelligence or make sense of the data, or may communicate with a trusted individual verbally to carry out some recommended course of action. A telephone or face-to-face interaction may be perceived as a more effective way to clarify ambiguity and convey knowledge not easily structured

Figure 7. Performance versus channel management activity



or codified, and come to a shared understanding on the course forward.

Elevator, Corridor and Coffee Table Conversations

There have been longstanding concerns with regard to clinicians discussing patient information in public places, where they can be overheard (Vigod, Bell & Bohnen, 2003). A lack of respect or appreciation of patient confidentiality may be one facet of this behaviour. However within the concept of the therapeutic knowledge alliance we also need to consider some of the other drivers. These include the increasing mobility and fragmentation of the workforce and use of mobile communications and the decrease in segregated or dedicated space for clinicians. The clinician may be answering an urgent cell phone or pager call, or these locations may be one of the few contexts in which they perceive they can access a colleague or group of colleagues in a timely fashion to discuss or seek advice or support on a patient's care.

In terms of advising a patient on the risks and benefits of limiting their health information flow, there are limitations as to how much we can identify what will be the high value information, result, channel or knowledge neurone within the caregiver's therapeutic knowledge alliance that may facilitate the patient's healthcare at a future stage. Rather than denying or trying to close down the therapeutic knowledge alliance, we should increasingly recognise the centrality of patients and their supports within it, in terms of building trust and recognising and managing the complexity and ambiguity of their healthcare.

The Shift from Passive Decision Support to Active Autonomous Intervention

Many health systems worldwide are currently implementing electronic health knowledge management systems introducing various levels of electronic passive to active decision support. Oncken (1999) has described the concept of levels of initiative as applied to people. Similarly to the Oncken concept, we can expect to see the development of increasing levels of initiative and autonomous intervention by the computer or machine:

1. Online patient data and online textbooks which user has to actively seek out;
2. Computer generated prompts asking whether you would like to go and look at more information on a particular subject, for example, in the form of a hypertext link;
3. General suggestions automatically provided as information, or guidelines, for example, general drug or evidence based medicine disease management information;
4. Specific optional recommendations automatically provided. These may outline a specific course of action, but can be over ridden by various levels of clinician justification with clinician still effectively making decision;
5. Mandatory recommendations automatically provided. These, for example, may relate to preventing life threatening drug interactions, or allergic reactions. Here the system or machine can be viewed as moving from realm of decision support into realm of decision making, (if only under mandate of an overarching organisational protocol);
6. The machine, only if specifically told or requested, will utilise data to make a decision, which the machine rather than the clinician then acts on;
7. The machine, automatically utilises data to make a decision, which it then acts on, but advises clinician on all actions immediately;
8. The machine, automatically utilises data to make a decision, which it then acts on,

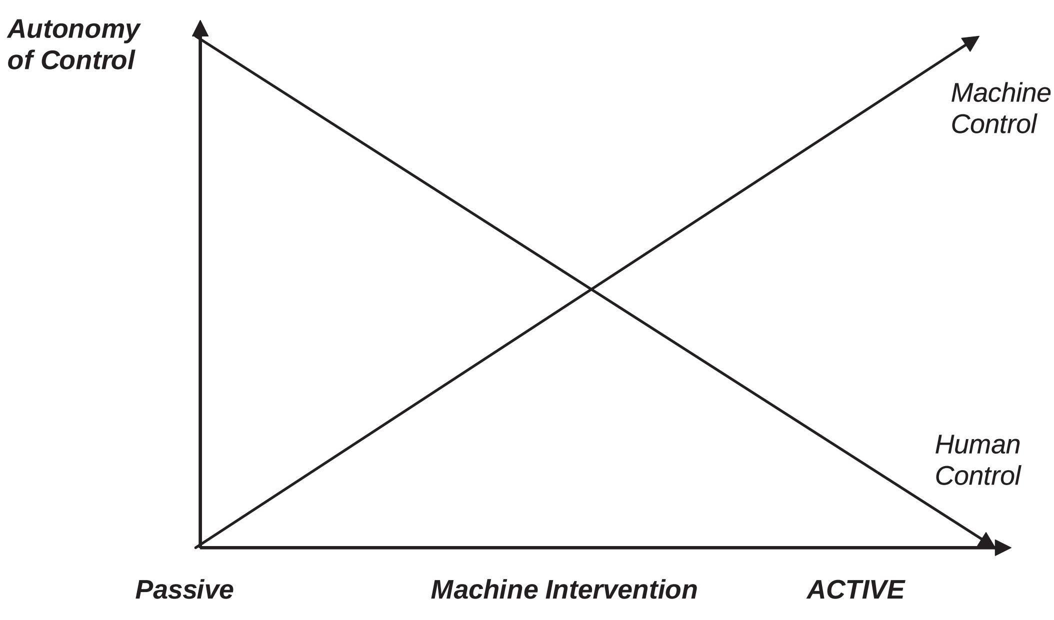
but clinician only advised immediately if exceeds certain parameters;

9. The machine automatically utilises data to make a decision which it then acts on, and reports to clinician at certain agreed periods; and
10. The machine automatically utilises data to make a decision, which it then acts on, with no active feedback to clinician.

Moving along this spectrum, there is a progressive increase in machine control and decrease in immediate human control (Figure 8). The clinical user is given increasing levels of active advice and overview by the machine, in terms of patient data and specificity of medical evidence and treatment recommendations, while the machine gets decreasing levels of active immediate advice and overview of its use of patient data by the individual clinician user. In general relatively few Health Knowledge Systems have reached level 3, but there is the capacity for this to change rapidly with significant privacy and security implications. For example, what are the privacy and security implications of a "booking system" that could draw data from several sources and act on its own to decide on suitability or eligibility, and then instigate certain forms of care?

Pragmatically this increase in the machine's capacity to act will be limited by the difficulties in coding for the complexities of the health environment. However, as the machine becomes less dependent on immediate human overview, there will be an increasing need to consider the risks and benefits in respect of privacy and security. The lack of overview, and integrity of the data and processes by which decisions are made, will be a significant issue. However possibly of greater moment, will be how we perceive, value, or balance the impartiality versus heartlessness of a

Figure 8. Machine versus human control



machine accessing our health information and making decisions based on protocols.

Internationally, there is a growing awareness of the need for information system developments to undergo a Privacy Impact Assessment, underpinned by a state sanctioned privacy code (Slane, 2002). For example the New Zealand Privacy Impact assessment recommendations and underlying code sets out a number of principles in relation to unique identifiers, the purpose, source, and manner of collection, storage, security, access, and correction, and limits on storage, use, and disclosure of personal information.

Internationally similar principles or rules are common to a myriad of legal, professional, and research codes and acts that relate to the collection, storage, and utilisation of health information.

Assessing the impact, or future consequences of current actions, presents a particular challenge for health knowledge systems. The risk-benefit equation, used to assess how certain information is handled may change over time and we have to question how far forward we can see, or how far forward we are expected to see.

PRIVACY AND SECURITY OBJECTIVES

Privacy and security developments may be focused on addressing a number of key objectives or concerns including medico-legal or patient trust or confidence concerns, within the context of a belief that better integrated information will lead to better integrated care for our communities. However what is perceived best by or for an individual may be in conflict with what is perceived as best for the community.

Each clinician and health service, depending on their location may be conceptually subject to a multitude of privacy and security codes and laws, for which in reality at the clinical coal face there is only limited compliance due to various combinations of lack of knowledge, attention, priority, will, ability, or perception of unacceptable costs and burden. There may be broad agreement that patient privacy should be protected, but a range of views as to what that pragmatically can or should mean in practice and how much any law or code may achieve this. For example, Marwick (2003) outlines similar views and responses as having greeted the introduction in the USA of the privacy rule of the Health Insurance Portability and Accountability Act.

However health organisations need to increasingly strive to create a culture that respects and protects health information, and seek to demonstrate and reinforce that culture through a number of basic or initial communication, human resource or technical steps. These include creating with, and communicating to, their communities clear open policies around the nature and purpose of health information flows and utilisation.

These include the risks and benefits of information flowing or not flowing and respective privacy versus sub-optimal care risks .In pragmatic terms this may take the form of conversations, leaflets, posters or web-sites.

Human resource processes may include training and development and professionalisation of all healthcare workers in terms of their attitude to health information and clear disciplinary procedures for malicious use. Anderson (1996) has highlighted the importance of training and procedures for the high-risk area of providing patient information on the telephone. Davis, Domm, Konikoff and Miller (1999) have suggested the need for specific medical education on the ethical and legal aspects of the use of computerised patient records.

Technical processes may include ensuring that an electronic information system has at least an audit trail that allows who has viewed or accessed a particular piece of health data to be monitored, providing some degree of psychological reassurance to patients and psychological deterrence against malicious use.

While having highlighted some of the concerns around restriction of information flows, particularly if the clinician is not advised of the suppression there is of course a place for restricted access for sensitive information. This may include allocating graded access levels to certain categories of information and graded access levels for providers or users, with the user only able to access information for which they have an appropriate level of clearance. The system may also include a "break glass" or override facility for emergencies, which allows access to restricted information, but triggers a formal audit or justification process. Denley & Smith (1999) discuss the use of access controls as proposed by Anderson (1996).

However for all these processes we can predict an inverse relationship between complexity and utility (and subsequent uptake or compliance). When planning privacy or security developments, we should strive to make it easier to do the right thing. This can include making login processes as fast and intuitive as possible, so as to decrease the behavioural drivers for clinicians to leave themselves logged in, or the sharing of personal or generic logins or passwords. With unlimited resource or the passage of time and decreasing costs, this may mean installing the latest proximity login or biometric authentication device that can log a clinician in or out as they move towards or away from a information access point, with instantaneous fingerprint or retinal scan verification. However initial steps may involve configuring systems so they minimise the login time, and developing fast, intuitive, and clearly understood administration systems for the issuing (and terminating) of logins or passwords so that new or locum clinicians can immediately access systems without having to utilise generic logins or "borrowing" other clinicians logins.

Our vision may be to make a healthy difference by facilitating the development of Health Knowledge Systems that help us provide safe and effective integrated care, within a culture that respects and protects both the value and privacy of health information. However recognising the difficulties of implementing an information system within the complex health environment (Heeks, Salazar & Mundy 1999), each step or building block towards attaining that vision , including privacy and security developments, needs to be SAFE: Scalable (while retaining usability and implementability), Affordable (in terms of resource time and risk); Flexible (enough

Table 2. SAFE-diffusibility factors

SAFE-Diffusibility factors	
Scalable	Retaining implementability / usability (Fast, Intuitive, Robust, Stable, Trustworthy)
Affordable	Resource/Time/Risk
Flexible	Individual/Local/National needs
Equitable	Perceived Equity/Relative Advantage

to meet individual, local and national needs) and Equitable (in that potential stakeholders perceive a relative advantage for them in terms of adopting the change or development) (Table 2).

FUTURE TRENDS

As we look to the future we can expect to see both increasing perceived benefits and privacy and security concerns with respect to data mining and risk profiling particularly genetic and geographic profiling, and increasing attention to the related actions of insurance, financial, and health organisations and government. We can expect to see greater use of technology in the provision of healthcare and broadening of the therapeutic knowledge alliance, both at the triage stage via call centres and so on to the chronic care management stage with the increasing use of texting, email and web broadcast reminders, as well as web based patient self evaluation and shared or self management.

With an increasingly elderly population, and corresponding ageing and diminishing healthcare provider population, we can also expect to see more healthcare workers working from home. While minimising the importance of travel distance to work and retaining the ability to for example support their own children or elderly parents at home, healthcare teleworkers will have an increasing technology based capacity to provide triage functions, telemonitoring of essential functions, parameters or progress, or telepresence while patients for example take medication or monitor their blood glucose level.

There will be ongoing debate around the issue of anonymity and the correlation and matching of data across databases. While there may be a current public focus on privacy or confidentiality issues, as health services become more dependent on electronic systems, we can expect a greater media, public, and clinician appreciation for the integrity and availability aspects of information system security. This would be true particularly if there were a major system availability failure causing at best major inconvenience or disruption; or if a data integrity error were to lead to a significant adverse event or sub-optimal care.

There is a need for ongoing iterative research into the identification and minimisation of privacy and security risk and the effective implementation of a local and national culture that respects, protects, and values health information. There is also an ongoing need for research into the public's views on health information privacy and security, and the priortisation of limited health resource. In the UK the NHS has published some work in this area (NHS Information Authority, 2002) but the methodology and results reporting have been criticised as unbalanced and misleading (Anderson, 2004).

There has been an underlying argument or assumption throughout this chapter that electronic health knowledge management systems providing better integrated information will lead to better integrated care and outcomes for our communities. However it has to be recognised that this is another area that requires ongoing research and development as there are still significant limitations and challenges to the evidence base of widespread successful implementations of electronic systems that make a cost effective positive impact on patient care and outcomes (Heeks et al, 1999; Littlejohns, Wyatt & Garvican, 2003; Ash, Berg & Coiera, 2004; Ash, Gorman, Seshdri & Hersh, 2004).

Unique identifiers will continue to be a cause for concern, and resistance in some countries, however whether through incremental stealth or necessity in combination with increased implementability, we can expect to see their wider use. Also we can expect the increasing use of unique clinician identifiers, which although facilitating the development of electronic ordering and task management systems may also be perceived negatively as a method to monitor, micromanage and restrain the clinical workforce. We can also envisage the increasing use of both patient and clinician unique identifiers linked to global positioning systems or tracking technologies, which although having potential benefits for both patient and clinician safety and resource management could also be perceived similarly negatively.

While we may initially see increasing integration between General Practitioners or primary care and allied healthcare or hospital services, over time we should expect increasing integration of patients and their supports into the health knowledge management system. These developments will increasingly highlight data availability and integrity, including who should have the right to access or view versus who should have the right to make entries or change data.

We may also see a movement from electronic decision support to decision making to autonomous active intervention, which will have significant implications for privacy and security.

We will also increasingly have to recognise that within our communities there will be a spectrum of different needs and ability to participate in and benefit from these technological developments together with an increasing knowledge gap between those that have and those that do not have the required technology to access the therapeutic knowledge alliance.

Should a health service spend limited resource on creating and maintaining complex email or web based assessment or self management channels that the most deprived or in need are least able to access? These complex systems may clearly be of benefit, but are potentially of greatest benefit to those already most able to advocate for themselves and access the resource. Subsequently we will need to continuously revisit the question of, what are the needs of our community and how can we best met those needs with limited resource? Should the more complex, resource intensive systems be provided on a user pays or targeted basis? Should a health service focus largely on the channels most accessible to most people, or the channels most appropriate for those sub groups with the greatest levels of deprivation and identified need? When considering the Therapeutic Knowledge Alliance, as a whole and not just electronic channels, the wider security issues of "integrity" and "availability" still need to be considered. Getting clinicians out into deprived communities, making "available" an "interpersonal" rather than "electronic" channel in the therapeutic knowledge alliance may be the most effective way to ensure data "integrity" and identify and address unmet needs.

CONCLUSIONS

Health information privacy and security is an area of at times, strongly held and diverse perspectives. The focus of this chapter has not been on supporting or refuting a single view, but introducing a range of perspectives (even if they challenge my innate clinician bias) and argue for balance and shared understanding. Privacy risk is not a single simple definable entity, but instead complex and multidimensional with quantitative and qualitative perceptual aspects, dynamically changing over time as various factors along the knowledge chain interact, change and possibly compete. Clinicians and patients and the wider community of healthcare stakeholders may vary markedly in their perceptions of privacy risk, particularly when compared to the sub-optimal care risk that may arise from the non flow of health information.

Knowledge management and data mining techniques, provide an opportunity to utilise large clinical data repositories to identify trends and patterns and "risk". This ability to identify risk can be perceived as a double edged sword. It can be used positively to promote or support further research and lead to changes in clinical processes and effective targeting of efficacious and cost efficient interventions; or could be used negatively to discriminate with potential perceived consequences ranging from increased insurance premiums, to refusal of insurance and health cover, mortgages or employment and the creation of an uninsurable, unemployable "under-class", to fears with regards to persecution from totalitarian regimes.

Sporadic incidents or reports of illegal "hacking", or privacy infringement of individual patient records by healthcare workers out of carelessness, malice or pecuniary gain will remain of concern. However as a community looking to the future, we should be possibly more concerned for potential frequent legal and systematic uses of health information that lead to discrimination by insurers, employers or indeed government agencies.

Before designing "privacy" solutions it is important to be clear on privacy risks and priorities (whether medico-legal concerns, deterring malicious access or use, or the increase in patient trust) and how any solution will contribute to or deter from providing better integrated information for better integrated care. Technical processes, such as firewalls, restricted access and audit trails, can provide important physical and psychological deterrents to malicious use and psychological reassurance to patients. However significant risk is likely to lie beyond the protection of our technological armour and within the behaviour of end users.

Pragmatic "privacy" solutions focused on end user behaviour can include making login processes as fast and intuitive as possible, (decreasing behavioural drivers to leave self- logged in or to share logins), privacy training and clear censure processes for malicious use.

There is a need for shared zones or models of acceptance within our communities, with regard to privacy risk, sub-optimal care risk and information flow. In building a shared zone of acceptance, we need to appreciate the complex ambiguity of many aspects of healthcare, and the non linear nature of the therapeutic knowledge alliance, and the need to integrate patients and their supports within that alliance. Recognising the difficulties of implementing change within the complex health system, we need to adopt an incremental iterative S.A.F.E. (Table 2) stepping stone ,or building block approach ,reflecting on and learning from each intervention, and progressively adapting to our changing context or understanding of that context.

Within an environment of limited resource, we need to recognise the diminishing returns or additional benefit we may receive for each unit of expenditure, and how individually worthy needs may have to be balanced against each other for an optimal outcome for our communities. Electronic developments may certainly assist with data confidentiality, integrity and availability, but education and the "professionalisation" of all health knowledge system users, (clinical, non-clinical staff, patients and supports), is possibly more important.

Clinicians and health services will increasingly need to "respect, value and protect" health information if they are to maintain patient confidence, and the comprehensiveness and integrity and validity of information volunteered by patients for entry into electronic systems. However potentially of greater risk is not clinicians or health services' use of patient data or an electronic health knowledge management system , to carry out their integral clinical, administrative, research and educational roles, but how much that data is respected, valued and protected within wider society. If the fears of discrimination and creation of an uninsurable, unemployable underclass come to pass it will be the result of individual and collective actions of all us. The simple individual action of for example accepting cheaper insurance or health premiums as we are in a highly identifiable low risk group, without at least recognising that our gain is someone's loss; the collective action of governments failing to legislate to protect against discrimination, and to provide a safety net for those most vulnerable.

Assessing or predicting the impact or future consequences of current actions will remain an ongoing challenge for health knowledge management system developments. We may certainly carry out Privacy Impact Assessments and risk benefit analysis, based on our current knowledge and context. However, as a global community, it is likely that the challenges of grasping the double-headed sword of electronic health knowledge management systems have only just begun.

Chapter 4.49
Knowledge Management Systems for Emergency Preparedness:
The Claremont University Consortium Experience

Murali Raman
Multimedia University, Malaysia

Terry Ryan
Claremont Graduate University, USA

Lorne Olfman
Claremont Graduate University, USA

ABSTRACT

This article is about the design and implementation of an information system, using Wiki technology to improve the emergency preparedness efforts of the Claremont University Consortium. For some organizations, as in this case, responding to a crisis situation is done within a consortium environment. Managing knowledge across the various entities involved in such efforts is critical. This includes having the right set of information that is timely and relevant and that is governed by an effective communication process. This study suggests that Wiki technology might be useful to support knowledge management in the context of emergency preparedness within organizations. However, issues such as training in the use of a system(s), a knowledge-sharing culture among entities involved in emergency preparedness, and a fit between task and technology/system must be there in order to support emergency preparedness activities that are given such structures.

INTRODUCTION

Research about emergency management information systems has accelerated since the September 11, 2001 events (Campbell, Van DeWalle, Turoff & Deek, 2004). However, researchers do not use a common terminology to describe emergency management information systems. Jennex (2004, 2005), for instance, calls these systems emergency information systems (EIS). Campbell et al. (2004) use the term emergency response systems. Turoff (2002) uses the term emergency response management information systems (ERMIS) and extends this idea to the notion of a dynamic emergency response management information system (DERMIS) (Turoff, Chumer, Van De Walle & Yao, 2004). Nevertheless, the majority of the researchers in this area seem to agree that, despite different naming conventions, emergency management information systems should be designed to support emergency preparedness and to guide effective response during an actual crisis situation. In addition, although researchers explicitly do not link the idea of emergency management information systems to knowledge management, the influence of the latter on emergency management systems is evident in the literature.

This article presents a case study about the implementation of a Web-based knowledge management system to support the Claremont University Consortium (CUC) and the Claremont Colleges, in general, in emergency preparedness. The academic nature of this study centers on how an information system (specifically, a knowledge management system) can improve emergency preparedness within a consortium environment. The practical nature of the research concerns how CUC was made more ready to respond to and recover from emergencies that it might experience.

This study suggests that Wiki technology might be useful to support knowledge management in the context of emergency preparedness within organizations. However, issues such as training in the use of a system(s), a knowledge-sharing culture between entities involved in emergency preparedness, and a fit between task and technology/system must be there in order to support emergency preparedness activities given such structures.

Turoff, et al. (2004) take a design stance in discussing emergency management systems. We suggest that design of any emergency management system can be tied to knowledge management principles. In addition, our findings suggest that, in addition to design, issues such as training with technology fit between tasks and technology and the existence of a knowledge-sharing culture are crucial when an organization intends to implement a knowledge management system to support emergency preparedness efforts.

The article proceeds as follows. Section two provides a snapshot of literature relevant to our study. Section three presents the methodology used, with emphasis on the case setting and the problem domain therein. Section four discusses how Wiki technology was used as an instantiation of a knowledge management system to overcome some of the emergency preparedness issues within the Claremont Colleges. Section five presents an evaluation of the system, which is presented in the form of qualitative data. The article ends with a discussion of how our findings might impact knowledge management theory and practice in the context of emergency preparedness.

RELEVANT LITERATURE

A knowledge management system in this study refers to any Information Technology (IT) based system that is “developed to support and enhance the organizational knowledge processes of knowledge creation, storage, retrieval, transfer and application” (Alavi & Leidner, 2001, p. 114). Gupta and Sharma (2004) divide knowledge management systems into several major categories, as follows: groupware, including e-mail, e-logs, and wikis; decision support systems; expert systems; document management systems; semantic networks; relational and object oriented databases; simulation tools; and artificial intelligence.

Jennex (2004) defines an EIS as any system that is used "by organizations to assist in responding to a crisis or disaster situation" (p. 2148). He further adds that an EIS should be designed to (1) support communication during emergency response, (2) enable data gathering and analysis, and (3) assist emergency responders in making decisions.

Lee and Bui (2000) document vital observations about the use of EIS during the massive earthquake that hit the city of Kobe, Japan, several years ago. Key lessons for emergency management systems designers that are based on Lee and Bui's (2000) work are as follows:

- Relevant information should be included in the emergency response system prior to the actual disaster situation. This is to ensure that emergency responders have sufficient information to guide decision-making processes when responding to an emergency. The authors imply that the task of gathering relevant information to support emergency response should be incorporated as part of the emergency preparedness strategic initiative.
- Information from prior experiences should become part of the emergency management system. The system somehow should be able to capture both tacit and explicit knowledge about how prior crisis situations were handled. Lessons learned can be used to guide future action. The authors in this regard imply that the design of any emergency preparedness system should support some form of organizational memory component.

In addition to designing relevant systems features to support emergency planning and response, researchers suggest that successful implementation of any emergency management system is contingent on how well people are trained to use such systems (Lee & Bui, 2000; Patton & Flin, 1999; Turoff, 1972). Turoff, et al. (2004) state that emergency management systems that normally are not used will not be used when an actual emergency situation occurs.

In summary, researchers indicate that emergency management information systems should support the following features inherent in any knowledge management system: (1) enable individuals and groups to create, share, disseminate, and store knowledge (Turoff, 1972; Turoff et al., 2004); (2) offer the ability to document experiences and lessons that have been learned to form the overall organizational memory for dealing with crisis situations (Lee & Bui, 2000); (3) support asynchronous and collaborative work (Campbell et al., 2004); (4) provide emergency response-related information that is relevant, accurate, and presented in a timely manner (Jennex, 2004; Turoff, 1972; Turoff et al., 2004); and (5) enhance the overall communication process among people involved in emergency preparedness and response by inserting more structure into the manner in which information is organized and documented (Turoff, 1972; Turoff et al., 2004).

METHODOLOGY

This article uses canonical action research to conduct this study (Davidson & Martinsons, 2002; Lindgren, Henfridsson & Shultze, 2004; Susman & Evered, 1978). Both qualitative and quantitative data were collected and analyzed throughout the research process.

One of the authors worked for CUC for three years as the Emergency Management Assistant. The research process in canonical action research starts with the involvement of the researcher with an identified organization. This is followed by the problem diagnosis by the researcher to determine issues and challenges faced by the organization.

The diagnosis leads to action planning; that is, a formal proposal is made to the client/organization in terms of a proposed solution/system. Upon approval by the client, the proposed solution is implemented. Action or intervention then occurs. Evaluation and reflection of the solution/system that is implemented then is conducted.

The Case Setting

The Claremont University Consortium (CUC) provides services to the seven members of the Claremont Colleges1 by operating programs and central facilities on their behalf. Each college maintains its own emergency preparedness plan. Every plan calls for the activation of a college-level emergency operations center (EOC) in the event of an emergency. The Multi Agency Coordination Center (MACC) exists to coordinate responses among the seven colleges and CUC. MACC's action plan is guided by the Claremont Colleges Emergency Preparedness Plan. This plan defines an emergency as preparing for and responding to any situation "associated with, but not limited to, disasters such as earthquakes, life threatening incidents, terrorist attacks, bio-terrorism threats and other incidents of a similar capacity" (p. 1).

MACC is a group that becomes active whenever emergencies occur at any of the colleges and at CUC that could impact any one or more of the consortium members. It is intended to (1) coordinate among the colleges and external agencies, (2) prioritize and fill requests for assistance from central resources, and (3) assist the colleges in returning to normalcy as soon as possible.

The Problem

Prior to embarking on the systems design and implementation initiatives, interviews were conducted with nine representatives from five colleges and CUC who were involved in emergency preparedness. Through these interviews, it was found that the top three issues pertaining to emergency preparedness at CUC (and within the Claremont Colleges at large) are (1) communication between college level EOCs and the MACC, both before and during an emergency can be improved; (2) coordination between CUC and college-level EOCs, in terms of activities and overall efforts in preparing for an emergency, can be enhanced; and (3) emergency related information/knowledge could be shared seamlessly. This includes access to information about drills; policy documentation; emergency notification protocols; access to college level emergency plans; and status and availability of emergency resources such as debris removal equipment, housing, and medical expertise. The following statements offer several examples:

Communication issues across the colleges in terms of who knows what, when they know it is vital, but I don't think that we are there yet. For example, in a recent incident, I was informed after five hours only. So communication is an issue. My struggle with that was, if we are indeed mobilized, we need to know and be contacted earlier. The communication of when there is an incident, when a contact is made, this is a concern for all of us.

Communication between colleges can be improved. We need a load of practice in this area to ensure better informational flow. Mutual aid agreement, sharing of resources to handle localized incidents needs to be shared and communicated. Training, and this would include training conducted in a jointly organized fashion. Use of technology during drills that are simulated can help the above.

We rely on written plans and rely on documentation when we need information. This can take time and cost. When we need to update some document *we need to make sure that everyone has updated their respective documents. Again, time and cost is involved. The documents that we have are easy to read, but knowing exactly what to do when something happens, remains a challenge.*

We at this college do have some of the information available online, on the Web [pdfs] which is used by the building managers. These are secured and restricted to those involved in emergency preparedness. Again, the information may not be easy to retrieve, even in Web format. We need more quick links, shortcuts, and need to know what is new when it comes to emergency preparedness.

Extended Problem Diagnosis

In stage two of the problem diagnosis, interviews were conducted with an additional 25 CUC personnel involved in emergency preparedness. The objective was to focus on the knowledge management issues in the context of emergency preparedness within the Claremont Colleges. A 15-question questionnaire was developed in order to ascertain the critical success factors for implementing a knowledge management system for CUC. These questions were based on the KMS Success Model (Jennex & Olfman, 2005). The KMS Success Model is based on three main constructs: System Quality, Knowledge/Information Quality, and Service Quality (Jennex & Olfman, 2005). The respondents were asked to rank the extent to which they either agreed or disagreed with the statements on a five-point Likert scale. Table 1 lists the statements and how these map to the KMS Success Model constructs. Table 1 also provides a summary of the data analyzed using SPSS.2

The average scores for the statements ranged from 3.12 to 4.56. The high average scores for most of the statements that relate to the key success factors of implementing a Web-based knowledge management system suggest the following:

- The system should provide key features of managing emergency related knowledge, such as being able to provide timely and relevant information.
- The system should provide links to both internal and external sources of knowledge about emergency preparedness.
- The top management within CUC must support the system implementation.
- The system must support committees involved in emergency preparedness to make strategic decisions.

The first three statements relate to post-implementation resource issues. The average scores for these statements (from 3.12 to 3.16) are relatively lower than the other statements. The majority of the respondents feel that CUC may not have the necessary resources to develop, update, and maintain a knowledge management system to support emergency preparedness. This is due to the fact that involvement in emergency preparedness activities, for the majority of the staff, is not part of their main job function. In addition, CUC has a limited budget for emergency preparedness activities.

PROPOSED SYSTEM

The potential use of Wiki technology as an instantiation of a knowledge management system to support emergency preparedness within the Claremont Colleges was discussed with the CEO and key IT personnel. Three criteria guided the selection of a suitable Web-based knowledge management system to support CUC's emergency preparedness efforts.

- Cost. During the initial discussion with the CEO, she made it clear that for the time being, any system developed to support CUC's emergency-related activities had to rely on

Table 1. Linking the KMS success model to emergency preparedness at the Claremont Colleges

	Concept (From the KMS Success Model)	**Constructs (From the KMS Success Model)**	**Min**	**Max**	**Mean**	**Std. Deviation**
CUC has the necessary resources to develop a KMS to support emergency planning/preparedness	System Quality	Technological resources	1.00	5.00	3.16	1.07
CUC has the necessary resources to update a KMS to support emergency planning/preparedness	System Quality	Technological resources	1.00	5.00	3.16	1.03
CUC has the necessary resources to maintain a KMS to support emergency planning/preparedness	System Quality	Technological resources	1.00	5.00	3.12	1.01
More information about emergency preparedness at CUC can be converted to Web format	System Quality	KMS form	2.00	5.00	4.04	0.79
Knowledge about emergency preparedness from individuals can be made available online	System Quality	Level of KMS	2.00	5.00	4.12	0.83
Knowledge about emergency preparedness from relevant groups can be made available online	System Quality	Level of KMS	2.00	5.00	4.24	0.72
Information about emergency preparedness could be automated, shared and retrieved from a single Web interface	Knowledge/ Information Quality	Richness	2.00	5.00	4.16	0 .90
A KMS for emergency preparedness should simplify searching and retrieving of information	Knowledge/ Information Quality	Richness	2.00	5.00	4.24	0.72
A KMS can enhance the strategic planning process for teams involved in emergency preparedness	Knowledge/ Information Quality	Knowledge Strategy/ Process	3.00	5.00	4.32	0.69

Table 1. continued

	Concept (From the KMS Success Model)	Constructs (From the KMS Success Model)	Min	Max	Mean	Std. Deviation
A KMS should provide timely information for staff involved in emergency preparedness to support emergency planning	Knowledge/ Information Quality	Richness	3.00	5.00	4.32	0.69
A KMS should provide accurate/ up-to-date information for staff involved in emergency preparedness to support emergency planning	Knowledge/ Information Quality	Richness	3.00	5.00	4.40	0.58
A KMS should provide relevant information for staff involved in emergency preparedness to support emergency planning	Knowledge/ Information Quality	Richness	3.00	5.00	4.36	0.57
A KMS to support emergency planning should provide linkages to external and internal information sources	Knowledge/ Information Quality	Linkages	3.00	5.00	4.56	0.58
Top management support is needed in implementation of a KMS to support emergency preparedness	Service Quality	Management Support	3.00	5.00	4.40	0.71
I welcome the idea of being trained in using a KMS to support emergency preparedness activities at CUC	Service Quality	Management Support	1.00	5.00	4.28	1.02

open source solutions. This is due to the fact that CUC does not have a sufficient budget to implement any commercially available knowledge management system.

- Our Experience. We were allowed to develop any system with which we were familiar, so long as it was in the best interest of the organization in the context of its emergency preparedness initiatives.
- Issues Faced. The system that is developed has to address the key emergency preparedness issues/concerns faced by the Claremont Colleges, as described earlier.

These criteria then were used to examine the list of options available to CUC. Gupta and Sharma's (2004) categorization of knowledge management systems was used to examine if a particular category met the three system selection criteria discussed previously. It was decided to implement an instantiation of a knowledge management system using Wiki technology, given budgetary and resource constraints, with regard to emergency preparedness faced by CUC. The technology also was selected because of our familiarity with using Wikis for teaching and learning (Raman & Ryan, 2004).

Why Wikis?

Wiki is a Hawaiian word that refers to being quick. Leuf and Cunningham (2001) define a Wiki as "a freely expandable collection of interlinked Web pages, a hypertext system for storing and modifying information—a database where each page is easily editable by any user with a forms-capable Web browser client" (p. 14).

Leuf and Cunningham (2001) suggest that Wiki technology can support knowledge management initiatives for organizations. The authors state that three collaborative models are available over the network today: e-mail exchanges, shared folders/file access, and interactive content update and access. They suggest that use of e-mail systems solely may not enable effective management of knowledge for an organization, based on the following reasons: (1) e-mail postings cannot be edited easily; (2) a central archiving system might be necessary to support effective documentation of information, which implies that using some form of database that hosts various postings directly might be a more effective manner of managing information flow for the organization; and (3) e-mail systems necessarily may not support shared access to a particular information base.

The second model to support collaborative work and knowledge sharing is the shared access system (Leuf & Cunningham, 2001). The main difference between a shared file system and an e-mail system is that the former enables users to access a common information base. In this regard, different users could be allowed to edit/update, "based on varying degrees of freedom" a particular information base (Leuf & Cunningham, 2001, p. 6). Nevertheless, this system is still similar to an e-mail system in that discussions and knowledge sharing is contingent upon threaded postings or, in a worst case, governed as a regular e-mail system (Leuf & Cunningham, 2001).

Wiki technology is an example of the interactive server model that offers users a newer avenue to share knowledge and to participate in online collaborative work (Leuf & Cunningham, 2001). The main components of an interactive server model are the database, the Web server, and user access to a common front end. The authors suggest that the main benefits of using collaborative server models include, among others: (1) allowing more effective organization of information by individuals and groups and (2) enabling ad hoc groups to collaborate on specific projects.

Wagner (2004) examines the use of different knowledge management systems that can be categorized based on two dimensions: (1) how knowledge is distributed in organizations and (2) the nature of the task involved. He asserts that in an organizational context, the source of knowledge is either centralized or distributed. The nature of the task is either ad hoc or repetitive. Based on these two dimensions, he proposes a particular form of knowledge management system to support a particular organizational need to manage knowledge. Table 2 summarizes the "knowledge management system fit based on knowledge distribution and task repetitiveness" in an organizational context (Wagner, 2004, p. 267).

Wagner's (2004) framework suggests that an organization's need for a knowledge management system is contingent upon the nature of the task involved and where knowledge resides in the organization. Use of FAQs, for instance, is suitable when knowledge is centralized and when

Table 2. Knowledge management system tasks and sources of knowledge[3]

Knowledge management system type	Knowledge source	Task
Conversational technologies	Distributed	Ad hoc
FAQ	Centralized	Repetitive
Search engine	Distributed	Repetitive
Portals	Distributed-Centralized	Ad hoc-Repetitive

tasks are repetitive in nature. Conversational knowledge management systems, in contrast, are more suitable when the source of knowledge is distributed. Wagner's classification of knowledge management systems implies that conversational technologies might be relevant to support emergency preparedness activities at CUC, because emergency preparedness at CUC involves tasks that are ad hoc and dependent upon knowledge that is distributed across the different EOCs and among the MACC members. Wiki technology can support numerous knowledge management requirements for organizations, including filtering knowledge from noise, ensuring knowledge quality, providing search functions, tracing the source of knowledge, building/enhancing knowledge continuously, and supporting the need for dynamically changing information content in a given system (Wagner, 2004). The system selection criteria, our prior experience with Wikis, and support from relevant literature led us to choose Wiki technology.

TikiWiki: Emergency Management System for the Claremont Colleges

The first step during the intervention stage of the project was to install and test a prototype Wiki clone. In December 2004, TikiWiki version 1.7.4 was installed on a test server. TikiWiki is only one instance of Wiki technology. TikiWiki bundles the requirements for a Web server (Apache), a database server (mySQL), and the front-end Web pages (written using Python).

Components of the TikiWiki that were viewed as relevant to the requirements specified by the users then were selected for activation. Only two features have been enabled in the current prototype of the system: the TikiWiki module and linking features. The module feature (administered by the system administrator) was used to create particular groupings of quick links to information about emergency preparedness. For the purpose of the prototype, the following modules were created:

- CUC Links: Provides links to key information sources about emergency preparedness for CUC. This module is based on CUC EOC's organizational structure. It has links to the information requirements for each of the EOC members, based on her or his respective job functions. The planning and intelligence coordinator, for instance, has access to weather information, notification protocols, phone trees, hazardous material information, lessons learned from tabletop sessions, and online maps of the Claremont Colleges.

- MACC Information: A quick link and reference to emergency resources and supplies available thorough CUC's Central Services/Physical Plant. The MACC module now is extended to include other key elements relevant to the MACC.
- Calendar of Events: Information about meetings, meeting summaries, drills, training events, and other related activities. The objective of this module is to assist all EOCs and the MACC in coordinating their respective activities.
- Knowledge Base: This module has links to local weather conditions, transcripts from tabletop (drill) sessions, and links to federal and local emergency response agencies.
- Maps: Online maps for the Claremont Colleges and CUC.
- Linking: Permits users to create multiple links within the system, which can be done through the use of the back link function. For example, through a back link, the CUC overview page is linked to the system's home page. TikiWiki also permits users to create links to external sources.

The focus of systems design and implementation in Stage 2 was to improve the communication issues related to emergency planning at CUC. When a crisis of a particular magnitude occurs within the Claremont Colleges, the MACC is activated. The MACC consists of members from CUC and a representative from all the Claremont Colleges. The MACC members provide input to the MACC Chair and Operations Co-coordinator, based on information received from the respective college EOCs. Based on the current protocol, the information flow between MACC and the colleges is facilitated through the use of telephones and information that is documented on a 6 x 8 foot white board located inside the MACC room.

The CUC was aware that during a crisis, the flow of information between the MACC and the college EOCs, was subject to noise and inaccuracy. The CUC also was aware, based on participation in drills, that the MACC does not have sufficient information about actual crisis situations within the respective colleges. This makes response efforts rather difficult during certain incidents. In order to overcome the communicational issues, an additional module in the system called the MACC Situation Board was developed. This module consists of the following four main elements:

- Situation: This section enables the MACC representatives to document real-time information about a particular situation at their respective colleges.
- Action: This section is used to document specific actions that a college/CUC has taken to address a particular emergency situation.
- Need: Links to another page that consolidates the emergency resources (i.e., debris removal equipment, temporary housing, search-and-rescue teams, food, and first-aid supplies) needed by all colleges and CUC in order to respond to an emergency. The MACC Chair and Operations Coordinator were given access to the consolidated resource needs page, which can be used to guide the decision on resource allocation between CUC and the colleges. The consolidated information about resources needed is expected to improve the communication between MACC and the respective college EOCs.
- Sharing: Links to another page that consolidates all information about resources that each college and CUC is willing to share to support a particular emergency response initiative. The type/category, quantity, and status of emergency related resources within the Claremont Colleges will be made known

to all MACC members through the system in the near future.

The purpose of this module is twofold. First, as mentioned, it is designed to facilitate documentation of resources required by respective colleges during an emergency. Through this module, member institutions can record a particular type of resource that they need and are willing to share with other colleges when a particular emergency situation occurs. This information, unlike before, is now available via the Web, easily accessible to every EOC and MACC member. Second, the information can be used by the MACC Operations Coordinator to facilitate resource allocation among the colleges when an emergency occurs.

EVALUATION

Effectiveness of the system was evaluated through a series of one-on-one interviews with the MACC members who had participated in two separate training sessions in February 2005, where the system was used. Thirteen individuals were interviewed. The instrument used to facilitate the process had 10 open-ended questions that were divided into two categories: (1) general feedback/overall impression of the system and (2) extent of goal achievement, or the ability of the system to facilitate the knowledge management requirements within the context of emergency preparedness.

FINDINGS

The following subsections list several of the respondents' answers to the open-ended questions. The responses are organized according to the two categories mentioned earlier. Given the action-oriented nature of this study, we acknowledge the potential bias of our involvement in the project and the findings, particularly with reference to the use of Wiki technology.

Category 1: General Feedback/Impression

Overall, the respondents were pleased with the system. The feedback was largely positive. The majority of the respondents felt that the system was simple to use. One of them said the following:

My immediate reaction was very good. I thought that the ease of use of the system was there and that the visual layout was very clear. That's not how I often feel when I am exposed to new systems. It was logical too. Visually it made sense to me. I don't always react very positively to new systems. My immediate reaction was very positive. In prior cases, I have had the experience of feeling "Oh My God," what do we have here? This was not the case this time.

However, not everyone was totally comfortable using the system. One respondent mentioned the following:

It is a key step but it is a little daunting in some ways. One must be a computer savvy person to really play with the system. I look at it from an end user standpoint, particularly how it can be used better. But it sure seems like we are moving in the right direction especially after the last drill at the MACC when there was chaos in there—that was really wild. This is a good start, but there are issues that we need to address.

Another respondent suggested that the system could improve the overall communication process. Specifically, she said:

It seemed like it would be a very useful tool and could eliminate many of the previous problems with communication. I was excited to hear there would *be a standard protocol for us to transfer information from our campus EOCs to the MACC.*

Assisting Emergency Preparedness Efforts

On balance, the majority of the respondents felt that the system could assist CUC and the colleges in emergency preparedness efforts. However, this is contingent upon continuous training, access control, and willingness of emergency planners to update the system with relevant information. The following statements offer evidence:

I do think that the system can assist emergency preparedness. Specifically, the system can provide better and quicker access to information. However, before this works, people need to populate the system and be diligent in updating the information base in the system. I am not sure about controlled access through with the Wiki technology. Anyone can update or delete the information. People can go in and mess around even though we can assume that they would not.

The system provides for an additional method of communication between all entities involved in emergency preparedness. The system facilitates a more effective written communication process. This can reduce any misunderstanding between the emergency responders. After all, visual aids are better to process and faster to comprehend, as well. By providing a place where various human and material resources can be listed prior to being needed, enables more common space and a means of documenting what happens during a response.

Aspect of Emergency Preparedness Supported

The general consensus from the respondents was that the system might support the following aspects within emergency preparedness: (1) coordinating planning efforts; (2) offering a better mechanism to document processes; (3) assisting in communication efforts; and (4) sharing emergency related information. The following statements offer evidence:

I am tempted to say that the system helps emergency planning, but I don't think the system supports planning solely. If used well, the system can save us all a lot of time in terms of communication. It provides us with an overview of what is happening across the colleges when an emergency occurs, through the MACC Situation Board Module. The campus status for every college is right there. This is why I say that it will help us in all future emergency planning efforts.

I think the system supports both information storing and the emergency response communication process. In terms of communication, the information that is available readily to the users can help them communicate more effectively. The right word might be information that is immediately viewable or accessible can support the communication process. Also, the system provides a quick way of getting information. The system surely helps to capture knowledge as well. As I mentioned, you have everyone from the respective colleges who report to MACC there, and they post their knowledge and information into the system. This seems like a very organized way of capturing information.

Category 2: Goal Achievement

Improving Communications

The majority of the users felt that the system can enhance emergency-related communication both before and during an actual emergency. One respondent even suggested that the system might benefit recovery communication with external agencies such as FEMA. However, before this happens, issues such as training, willingness to share information, and trust among one another must be resolved. The following statements offer examples:

The system can improve the overall communication process. This is due to the fact that all the schools have access to the system, and all the schools should be posting information relevant to emergency response. And one can access the system from anywhere. It does not matter which part of the world you are from, you can get to it, as it is Web-based.

The system helps us to communicate better even after an emergency has ended, as the information will be at everyone's fingertips, which could later be served as data for any report or justification in an inquiry, such as FEMA and other agencies that may need that information.

The system can facilitate communication during an emergency. However, before this works, we need to make sure that people are willing to trust each other. For example, under the resources-to-share and resources-needed pages, people need to be aware that just resources available as they have been posted pre-crisis may not necessarily be available when an actual crisis occurs.

Emergency Preparedness Knowledge Capture

The users also generally felt that the system can facilitate some aspects of knowledge management. Specifically, benefits such as being able to archive information, capture knowledge and information about emergency preparedness, and offer a more structured way to manage information were noted. The following statements offer evidence:

I think that it will help us create an archive of every drill, actual emergency, and also any other related activities that we conduct. This tells me that the system might serve as a useful knowledge book or "book of knowledge," so to speak. People must be willing to contribute to this book, though.

The system can help us capture information/knowledge about emergency planning and response. The scribe could copy and paste information into any Microsoft program such as Excel or Microsoft Word for later usage.

The system allows us to better manage emergency related information, because now we have a written record of everything that is done and by whom. This is useful for future references, too. The system also provides a common platform/space, structuring of information.

Knowledge-Sharing

The users were also optimistic about the ability of the system to facilitate knowledge and information sharing among individuals and entities involved in emergency preparedness. However, this is contingent upon the willingness of people to share information and trust the source of information/knowledge that resides in the system. Some of the responses to this issue are as follows:

Frankly, I don't think all the members from the various colleges have a knowledge-sharing culture. Based on my experience here, my guess is that people need to share more information about emergency planning with each other. It seems easier to share with some relative to others. I guess we are comfortable with speaking directly with people and may not be willing to share information in an open platform. This needs to change though. People must be willing to share information with each other.

As mentioned, easy access to the system and a fairly direct way to input ideas will allow people to share knowledge about emergency preparedness *with each other. It will allow them to populate the database or to fill in the blanks. But people must be willing to do this.*

The system has useful refreshing abilities and allows users to share information and knowledge with each other instantaneously. It provides timely information and, therefore, can help better communication between the EOCs and the MACC.

General Concerns

Several issues must be addressed before the value of the system to support emergency preparedness within CUC and the Claremont Colleges is maximized. The respondents mentioned the following general concerns:

I think for the system to work, training is key. People at MACC need to be trained to use the system. But, as you know, the people that report to MACC either don't show up for training sessions or keep changing. Then, there is this issue of the information sharing culture that I spoke to you about. This must change for the system to be used effectively. People should put personality differences aside and be willing to share and communicate with each other. The technology itself seems powerful and is a great idea. It can handle different and very dynamic sets of information when an actual crisis occurs. But at the heart of all of this is the willingness to be trained and share information. For this to happen, emergency preparedness must become part of peoples' job function. With the exception of a few people on MACC, for the majority of us, emergency preparedness is not of a primary concern. We prepare only when we think about drills; otherwise, it seems to be lost in our daily primary functions.

I would be concerned if we don't have Internet connectivity. I think we need a paper-based system as a backup. This is really my only concern. And I saw during our drill, some people are not too Web savvy. There might be issues with training; people who are not familiar with a Web-based system need to be trained. Also the colleges keep sending new people to the MACC. If we have new people who don't know how to use the system or have not been trained to do so, this could cause some problems as well. In the event of an emergency there might not be any IT staff to support the use of the system. This again could become an issue. Ongoing training for staff involved in emergency preparedness is necessary.

I think the challenge is keeping everyone constantly abreast of the system. I think the idea of playing with the system every month when the MACC meets is welcomed. Your relearning time or startup time will become longer if this is not done. We need to make sure that people know where to fill information and not do this inaccurately. Also, people should not edit other people's information.

I think people need to be trained continuously. In addition, it only makes sense if the EOCs for all colleges use this system, too; after all they need to provide MACC representatives with the information needed.

If it is used properly, updated, and maintained, then this will work. However, this is subject to some budget being approved for a system-resource or admin staff that helps in this task. Also, we need to make sure that people do not mess up due to poor access control.

DISCUSSION AND LESSONS LEARNED

Feedback from the evaluation phase suggests that the system that has been implemented can impact emergency preparedness activities for CUC and the Claremont Colleges in two ways: (1) improve communication and (2) assist in emergency preparedness knowledge/information sharing.

Communication

Key staff members involved in emergency preparedness now realize that, through the project, the Web-based system can assist the overall emergency preparedness communication process as follows:

- Provide a centralized information base about emergency situations, campus action, resource status, and MACC action, which are now accessible to all relevant groups and individuals involved in emergency planning.
- Minimize the overflow of information within MACC and thereby reduce the possibility of communication chaos.
- Empower staff members involved in emergency preparedness to update information as and when it is received, without the need for relying on the MACC scribe to do so.
- Provide a structured way to document emergency-related information, which can support external communication and recovery efforts (e.g., claiming reimbursement from FEMA and other federal agencies). Wiki technology has a function called history, which documents exactly what was entered into the Wiki, by whom, and when.

Knowledge Sharing

Anyone can contribute to a Wiki page in a given Wiki community (Leuf & Cunnigham, 2001). Wiki technology thrives on the principle of being open (Wagner, 2004). Emergency preparedness and response within the Claremont Colleges involves both knowledge and experience from a diverse set of individuals. Within CUC alone, there are staff members that have been trained in particular emergency preparedness areas. Examples are people who are trained in search and rescue, earthquake evacuation procedures, hazardous material handling, CPR, and first aid response.

Critical Success Factors

Our findings suggest that the positive outcomes of the system can materialize fully only if the following factors are taken into consideration by the CUC's top management involved in emergency preparedness:

- People involved in emergency preparedness are willing to share information with one another. The MACC Situation Board module, for instance, can support the Operations Coordinator to plan for and allocate resources during an actual crisis, only if the resource-available template is filled a priori by the respective college EOCs. As one respondent mentioned, "I am not sure if people will be willing to share information with one another, particularly about the status of their resources."
- The technology is designed to support a knowledge-sharing culture. However, we are uncertain if this culture exists among every EOC and individuals involved in emergency preparedness in this case.
- The system must play a vital role in every emergency response drill and training session. Unless the system is used during drills and such events, it will not be used during an actual emergency.
- The technology must support and not hinder the existing emergency response protocol. In this context the CEO indicated the following concern, "Everyone [with reference to the EOCs] can act prematurely and go talk directly to one another without going thorough the central body (MACC) to coordinate efforts. The system should support existing protocols that we have. People should be trained to use it to ensure that the technology supports MACC's role. This can be done."

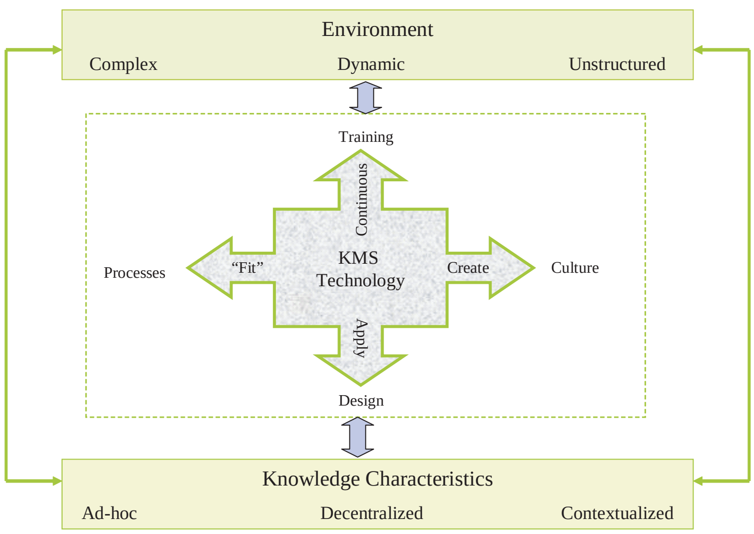
THEORETICAL IMPLICATIONS

Figure 1 illustrates how the project findings might further inform theory about emergency management information systems. This study suggests that the environment faced by emergency responders is complex, dynamic, and unstructured (Burnell, Priest & Durrett, 2004; Kostman, 2004; Van Kirk, 2004). The majority of literature about emergency management information systems does not state clearly that systems designed to support emergency preparedness are associated with knowledge management. This study suggests that the environment faced by emergency responders forces them to deal with the following characteristics of knowledge:

- Ad Hoc: Knowledge within emergency responders at the Claremont Colleges is largely tacit and utilized as and when an emergency occurs. Individuals and groups involved in emergency preparedness may not necessarily think about responding to a particular situation beforehand. This implies that the knowledge that they need to respond to an emergency is ad hoc in that it is required as and when a crisis occurs.
- Decentralized: The knowledge repository to respond to a particular crisis in a consortium environment is predominantly decentralized. In the case of the Claremont Colleges, this knowledge resides within eight EOCs and the MACC.
- Contextualized: Emergency preparedness requires responders to deal with knowledge that is highly contextualized. Every crisis is unique and requires a different set of ideas and response initiatives (Burnell et al., 2004).

Given these characteristics, the findings of this study suggest that any system designed to support emergency preparedness should be linked closely to ideas inherent within the domain of knowledge management. A particular technology selected to support emergency preparedness should cater to

Figure 1. Theoretical framework



knowledge that might be decentralized, ad hoc, and highly contextualized.

We suggest that Wiki technology might be a simple yet cost-effective option for organizations that intend to use or design any information system to manage information and knowledge related to emergency preparedness. Wiki technology is appropriate for knowledge that is dynamic and decentralized (Wagner, 2004). Nevertheless, technology alone is not sufficient to foster effective emergency preparedness initiatives. The system should be designed to cater to the requirements of emergency responders and must be used in every drill and emergency training activities (Turoff et al., 2004). Figure 1 suggests that, in addition to effective design and training considerations, the following two additional factors are required when thinking about emergency information management systems:

- A fit between the knowledge management system and the existing emergency preparedness policies must be sought. Stated differently, the technology should support and not hinder emergency response initiatives.
- There is a need to foster a knowledge-sharing culture among various entities involved in a given emergency preparedness organizational structure. In the case of CUC, this refers to the willingness of different EOCs to share information and knowledge with one another.

CONCLUSION

An organization's emergency preparedness activities might involve collaborative efforts among various entities. A vital activity is responding to an actual crisis situation that hits one or more of the member organizations or entities. For some organizations, as in this case, responding to a crisis situation is done within a consortium environment. Managing knowledge across the various entities involved in such efforts is critical. This includes having the right set of information that is timely, relevant, and governed by an effective communication process. Given such organizational structures and a need to manage knowledge in these environments, IT, which manifests itself in the form of knowledge management systems, might play a crucial role. However, before this occurs, the following issues must be considered: (1) sufficient training in the use of a system(s) must take place; (2) a knowledge-sharing culture among entities involved in emergency preparedness should exist; and (3) a fit between task and technology/system must be guaranteed.

Chapter 4.50
Knowledge Management and Hurricane Katrina Response

Tim Murphy
Autonomechs, LLC, USA

Murray E. Jennex
San Diego State University, USA

ABSTRACT

This article explores the use of knowledge management with emergency information systems. Two knowledge management systems that were utilized during the Hurricane Katrina response are described and analyzed. The systems specified were developed by federal agencies as well as grass root efforts without the support or mandate of government programs. These programs, although developed independently, were able to share data and interact in life-saving capacities, transcending traditional geopolitical boundaries. We conclude that emergency information systems are enhanced by incorporating knowledge management tools and concepts.

INTRODUCTION

Emergency response in the United States of America (US) is evolving from something that was handled locally to something that is standardized under federal control. The US implemented the National Incident Management System (NIMS) in 2004 to accomplish this. NIMS established standardized incident management protocols and procedures that all responders are to use to conduct and coordinate response actions (Townsend, 2006).

It was expected that on August 27, 2005, when President George W. Bush declared a state of emergency for three coastal states days before the August 29, 2005, landfall of Hurricane Katrina, this approach would be sufficient to handle necessary emergency response. However, Mississippi, Alabama, and Louisiana would be the site of the worst natural disaster in US history, stretching government resources far beyond their abilities to respond to the instantaneous and growing number of casualties. Running out of shelter and supplies for the growing number of victims, the government became logistically overwhelmed and underequipped. Private citizens and companies (all nongovernment offices) responded immediately. Multiple independent yet collaborative-by-design knowledge management systems (KMS) were developed and implemented for immediate use to help victims find housing and medical supplies and to post requests for immediate evacuation as well as help to find those separated in the storm. Via the Internet, people as far north as Michigan were able to help find housing in the state of Washington for people in southern New Orleans. This article proceeds to describe how theses systems were developed, implemented, and used. We will describe the situation that led to the need for these systems, how these systems were created, the resources required for each, within which category of knowledge management system each falls, the use of the systems by the end users, and finally the end result of these systems.

This article discusses two of these systems developed to respond to Hurricane Katrina. The purpose of this discussion is to illustrate the use of knowledge management (KM) and KMS in emergency response. The article will discuss how KM was implemented and how effective the resulting systems were.

BACKGROUND

Before discussing these systems, it is important that we establish what we mean by KM and KMS as well as provide a framework for how KM fits into disaster and/or emergency response.

Knowledge

Davenport and Prusak (1998) define knowledge as an evolving mix of framed experiences, values, contextual information, and expert insight, which provides a framework for evaluating and incorporating new experiences and information. Knowledge often becomes embedded in documents or repositories and in organizational routines, processes, practices, and norms. Knowledge is also about meaning in the sense that it is context-specific (Huber, Davenport, & King, 1998). Jennex (2006) extends the concepts of context to also include associated culture that provides frameworks for understanding and using knowledge. A simpler definition of knowledge is that it is the how and why of something. It is the insight into why something happens that creates knowledge. To be useful, though, this knowledge needs to be framed in context and culture, the information and data that explain how the knowledge was generated, what it means, and how it should be used.

Knowledge Management

Jennex (2005) defines KM as the practice of selectively applying knowledge from previous experiences of decision making to current and future decision-making activities with the express purpose of improving the organization's effectiveness. KM is an action discipline; knowledge needs to be used and applied in order for KM to have an impact. Inherent in KM is communication between knowledge creators and/or possessors and knowledge users. A KMS is the system developed to aid knowledge users in identifying, sharing, retrieving, and using knowledge that they need. The following section further defines a KMS.

Knowledge Management Systems

Alavi and Leidner (2001) defined a KMS as "IT (Information Technology)-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application" (p. 114). They observed that not all KM initiatives will implement an IT solution, but they support IT as an enabler of KM. Maier (2002) expanded on the IT concept for a KMS by calling it an ICT (Information and Communication Technology) system that supported the functions of knowledge creation, construction, identification, capturing, acquisition, selection, valuation, organization, linking, structuring, formalization, visualization, distribution, retention, maintenance, refinement, evolution, accessing, search, and application. Stein and Zwass (1995) defined an Organizational Memory Information System (OMS) as the processes and IT components necessary to capture, store, and apply knowledge created in the past on decisions currently being made. Jennex and Olfman (2002) expanded this definition by incorporating the OMS into the KMS and adding strategy and service components to the KMS. We expand the boundaries of a KMS by taking a Churchman (1979) view of a system. Churchman (1979) defines a system as "a set of parts coordinated to accomplish a set of goals" (p. 29) and that there are five basic considerations for determining the meaning of a system:

- System objectives, including performance measures
- System environment
- System resources
- System components, their activities, goals, and measures of performance
- System management

Churchman (1979) also noted that systems are always part of a larger system and that the environment surrounding the system is outside the system's control but influences how the system performs. The final view of a KMS is a system that includes IT/ICT components, repositories, users, processes that use and/or generate knowledge, knowledge, knowledge use culture, and the KM initiative with its associated goals and measures.

Key to the KMS is a strategy that determines what knowledge is captured; how well the KMS performs the mnemonic functions of search, retrieve, manipulate, extract, and visualize; and knowledge repositories. There are three types of knowledge repositories: paper documents, computer-based documents/databases, and self memories:

- Paper documents incorporate all hard copy documents and are organizationwide and groupwide references that reside in central repositories such as a corporate library. Examples include reports, procedures, pictures, videotapes, audiocassettes, and technical standards. An important part of this knowledge is in the chronological histories of changes and revisions to these paper documents as they reflect the evolution of the organization's culture and decision-making processes. However, most organizations do not keep a separate history of changes but do keep versions of these documents.
- Computer-based documents/databases include all computer-based information that is maintained at the work-group level or beyond. These may be made available through downloads to individual workstations or may reside in central databases or file systems. Additionally, computer documents include the processes and protocols built into the information systems. These are reflected in the interface between the system and the user, by who has access to the data, and by the formats of structured system inputs and outputs. New aspects of this type of repository are digital images and audio recordings. These forms of knowledge provide rich detail but require expanded storage and transmission capacities.

- Self-memory includes all paper and computer documents that are maintained by an individual as well as the individual's memories and experiences. Typical artifacts include files, notebooks, written and unwritten recollections, and other archives. These typically do not have an official basis or format. Self-memory is determined by what is important to each person and reflects his or her experience with the organization.

Repositories can overlap each other; for example, the computer repository stores the specific knowledge, but the context and culture needed to use the knowledge is captured in paper procedure documents used to guide the knowledge use and in the mind of the knowledge user as a result of training on how to use the knowledge. Other examples include paper documents being indexed or copied into computer databases or files, self-memory using paper and computer-based documents/databases, and computer databases or files being printed and filed. Typically, it is desired to capture as much knowledge as possible in computer- and paper-based memories so that the knowledge is less transient. It would be expected that organizations that are highly automated and/or computerized would be expected to have a greater dependence on computer-based repositories, while less automated organizations may rely more on paper-based or self-memory-based repositories.

A recent development in KMS technology is the use of the wiki. A wiki is a Web site or similar online resource that allows users to add and edit content collectively and/or collaboratively (Parlament of Victoria, 2005; Wikipedia, 2006). The wiki originated in 1994/1995 (Cunningham, 2005) but only recently has become popular as a content management system (Mattison, 2003). Very recent research has found that wikis are useful for KM, since they provide content management combined with knowledge exchange/communication and collaboration capabilities. Vazey and Richards (2006) found improved decision making and knowledge acquisition, while Raman, Ryan, and Olfman (2006) applied a wiki as a tool for improving emergency response.

Knowledge Management Systems and Emergency Response

Jennex (2004) identified an expanded model of an Emergency Information System (EIS). This model considers an EIS more than the basic components of database, data analysis, normative models, and interface outlined by Bellardo, Karwan, and Wallace (1984), adding trained users, methods to communicate between users and between users and data sources, protocols to facilitate communication, and processes and procedures used to guide the response to and improve decision making during the emergency. The goals of the EIS are to facilitate clear communications, improve the efficiency and effectiveness of decision making, and manage data to prevent or at least mitigate information overload. EIS designers use technology and work-flow analysis to improve EIS performance in achieving these goals. Turoff, Chumer, Van de Walle, and Yao (2004) expanded the expanded EIS model by introducing the concept of a dynamic EIS and identifying design requirements that expanded EIS capabilities in group communication and data/information/knowledge management. The result is that the focus of an EIS is on communication and facilitating decision making; both are also key attributes of a KMS.

Additionally, in recent years, disaster managers have realized the potential of KMS for faster and more organized response to natural disasters. The large number of groups that respond to a disaster needs access to a wide range of real-time information, which requires coordination. Groups have proposed and created KMSs that allow for more efficient use of data and faster response. One example that has been proposed is the Information Management System for Hurricane disasters (IMASH) (Iakovou & Douligeris, 2001). IMASH is an information management system based on an object-oriented database design and is able to provide data for response to hurricanes. IMASH was designed with the premise that the World Wide Web is the medium of choice for presenting textual and graphical information to a distributed community of users. This design is much more effective in the fast-changing environment of a natural disaster than the historical use of static tools that, out of necessity, have been the tools used in disaster response. Kitamato (2005) describes the design of an information management system, Digital Typhoon, designed to provide a hub of information on the Internet during a typhoon disaster. Digital Typhoon provides access to information from official sources (news, satellite imagery) as well as a forum for individuals to provide information (local, personal). It effectively became a hub of information but created questions about organization, filtering, and editing. Systems used for Hurricane Katrina response realized the benefits and difficulties of these systems. Like IMASH, the systems described next use the Internet to distribute data to a community of users, and like Digital Typhoon, the knowledge management systems described for Hurricane Katrina response became hubs of information that required data management to reduce repetition and allow for editing.

In summary, there is a fusion of EIS with KM and KMS. This is because decision makers, when under stress, need systems that do more than just provide data; they need systems that can quickly find and display knowledge relevant to the situation in a format that facilitates the decision maker in making decisions. It is expected that EIS evolution will continue to utilize KM concepts and approaches as experience in responding to disasters is showing that these systems are more effective than traditional EIS. Examples of how KM aids emergency response includes using knowledge of past disasters to design communication and data/information capture protocols and templates; capturing emergency response knowledge in procedures and protocols; incorporating lessons learned into response team training, interface and display design, and the generation of heuristics guiding decision making; and using knowledge to guide the creation of experience knowledge bases that responders can use to generate emergency response actions. The rest of this article illustrates how KM can help disaster response by looking at two systems used in response to Hurricane Katrina.

PEOPLEFINDER

Problem Emerges and Information Overload Occurs

During the first days after Hurricane Katrina hit the Gulf Coast, the Gulf Coast News Web site (http://www.gulfcoastnews.com) set up a Web page for people to talk about their hurricane stories. Obviously geared for stories about how New Orleans spent a few days without power, the site quickly became an online repository for people to look for victims and to post requests for help. Posts on the Web site ranged from asking for directions out of town to people from other states asking if someone could check on or save their family members at flooded addresses. This trend grew, and quickly 23 Web sites had people posting that they survived as well as people looking for information on victims that had not been found. Anyone looking for loved ones had to check each Web site, since at that time there was no central repository for information. There also was no way to leave contact information, should their search queries be matched. As Table 1 indicates, many Web sites hit upon the same idea at the same time to host servers on which survivors could post their status. Although this was a terrific response from mostly civilian Internet companies, it created

Table 1. Web sites and the number of survivor records each held (PeopleFinderTech, 2005)

Web Site	Number of Entries
http://www.msnbc.msn.com/id/9159961/	143,000

http://www.wecaretexas.com/	200,000
http://www.scribedesigns.com/tulane/	1,933

confusion on about which sites on which to post and search; this created the need for a site like PeopleFinder (PeopleFinderTech, 2005).

Proposed Knowledge Management Solution

David Geihufe of the Social Software Foundation had been working on an open source Customer Relationship Management (CRM) system called CiviCRM (Geilhufe, 2005). During the intelligence phase (Kersten, Mikolajuk, & Yeh, 1999), David envisioned using his CRM system to create a Web-based, data-driven Decision Support System (DSS) (Power & Kaparthi, 2002) form of KMS that would be a central repository for victims and the people looking for them. The Web site would accept data in an open standard from other Web sites as well as allow people to post information directly to the server. Not having the resources necessary to use this system, David received corporate support from the Salesforce Foundation. Within 24 hours, the Salesforce servers were accepting PFIF (PeopleFinder Interchange Format). Twenty-four hours after that, 60,000 records had been inputted by global volunteers to the PeopleFinder knowledge management system. Some inputs were parsed (scraped) from sites such as Craigslist and Gulf Coast News. Ultimately, more than 620,000 records were searchable, and more than 500,000 searches were processed. Tables 2 and 3 show the database schema.

The note table is necessary, as it is a lesson learned from the September 11, 2001, World Trade Center attacks (Lal et al., 2005). Entries may be updated multiple times, and syncing data between servers can become very difficult. The note table solves this problem by keeping a log of who has made what change and what changes were made. The timestamp on each file can be used as a quantitative metric on which entry is the most recent.

Integrity of data, a key component of a successful DBMS (Database Management System), while syncing between multiple servers, was nontrivial. Multiple approaches were considered, and the decision was made to keep all data sets as read-only throughout the entire transaction

Table 2. The note schema (Lal, Plax, & Yee, 2005); Note_record_id is the primary key

NOTE Table	
string	**note_record_id**
string	person_record_id
string	linked_person_id
date	entry_date
string	author_name
string	author_email
string	author_phone
bool	found
string	email_of_found_person
string	phone_of_found_person
string	last_known_location
text	text

Table 3. The person schema (Lal et al., 2005); Person_record_id is the primary key

PERSON table	
string	**person_record_id**
date	entry_date
string	author_name
string	author_email
string	author_phone
string	source_name
string	source_date
string	source_url
string	first_name
string	last_name
string	home_city
string	home_state
string	home_neighborhood
string	home_street
int	home_zip
string	photo_url
text	other

Figure 1. Data flow diagram (based on Lal et al., 2005)

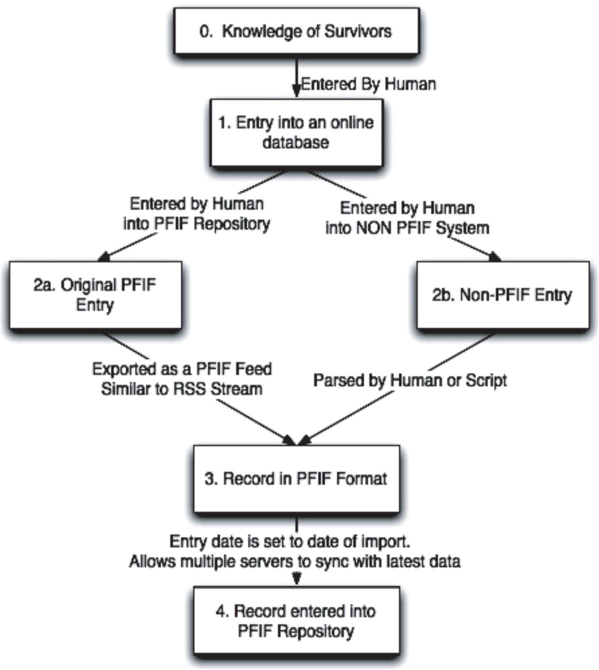

Table 4. Decision table for assessing how to proceed with new Web sites discovered

Potential Conditions	Actions to be Performed		
	Manual entry	Task a parser for later development	Task a parser for immediate development
If (postings) <25	X		
If (postings) <25 but anticipate growth	X	X	
If (postings) > 25		X	
If (postings) > 100			X

process, except for the field entry_date, which would indicate when that entry had been posted to the server (Lal et al., 2005).

Figure 1 shows the data flow diagram depicting how the data transverses the system. Table 4 details the decision table, providing a rule set for when to manually enter the data into the PFIF repository and when to request to have a parser written.

Leaderless Development

A wiki was used to coordinate tasks and development for the PeopleFinder system. Anyone wanting to make changes to the wiki had to register on it. Similar to public bulletin board Web sites, registration was automated and required no formal approval (Aronsson, 2002). When a developer found bugs or noticed new features that needed to be added to the system, he or she could post a task that needed to be completed. One of the other developers could assign themselves to the task to complete it, give status on its development, and clear the task upon completion. Sites to be scraped were handled like this as well. Sites that had information to share could be listed on the wiki, and people either could manually transfer the information record by record or coders could write parsers to grab the information and repost it into the Salesforce server in PFIF. The determination on whether to manually parse the site or to write a parser for it was determined by the number of entries on the site, the number of entries expected on the site, and whether or not the author of the original site had made safeguards to prevent scripts from parsing the site (PeopleFinderTech, 2005).

With any Web site that can be modified by the general public, vandalism is an immediate and valid concern. For example, there was nothing to keep political protestors from registering and defacing the Web site with a political message that had nothing to do with the purpose of the Web site. Fortunately, editors on the Web site kept vandalism suppressed by monitoring the Recent Changes page (Tanaka, 2005).

PeopleFinder Analysis

PeopleFinder went from an idea to operationally functioning within a 72-hour window. Due to the nature of the Web site, few users would be inclined to leave feedback in order to make the site more helpful. Therefore, features may have been incorrectly prioritized based on what the developers thought would be helpful rather than on what the user base needed. Future concerns about this type of project most likely will include privacy rights. When someone wants their online entry removed from the database, perhaps to avoid any risk of identity theft, there is currently no feature that allows them to be removed. In fact, the data network is set up to maintain the entries at all cost. It is also difficult to have an easy-to-use Web site that allows distraught people to find their family and friends while making sure that those with criminal intentions are filtered out. Regardless of the security downfalls, PeopleFinder was a success as soon as the first person was able to quickly ascertain the status of a loved one.

KM use in PeopleFinder is reflected in its construction. The system itself reflects the capture of lessons learned and is itself a repository of knowledge. Knowledge capture and use also are reflected in the capture of notes and the history of notes for each person. KMS features implemented in the system include knowledge repositories and the implementation of good mnemonic functions (search, retrieve, visualize). As stated, it was not expected that feedback would be left by users; this needs to be compensated by researchers who need to collect some system satisfaction data so that future systems can learn from mistakes in this system.

SHELTERFINDER

FEMA estimated that more than 500,000 people were left homeless and another 500,000 jobless (California Political Desk, 2005) by Hurricane Katrina. With that many people residing in such a close proximity to each other, finding a new place to live even for a limited amount of time can be nearly impossible. Employment in other cities could be located online through already existing job databases; however, there was no way to find somewhere to live for free during the victims' rebuilding from devastation. At the same time, hundreds of thousands of people across the nation offered their homes to let Katrina victims have somewhere to stay until they could find permanent housing. The problem was how to coordinate information so that people who were in the affected areas could find housing across the nation. Like PeopleFinder, multiple Web sites began to pop up to offer housing, but there was no organized metasearch that allowed users to check one centralized location.

Collecting Shelter Data for Hosting

ShelterFinder (2005) was set to solve the same problem as PeopleFinder. Continuing with open standards for the systems data formats, ShelterFinder maintained a means for a single server to stream new data feeds to multiple servers while simultaneously being ready to respond to requests for data from other servers. Rather than PFIF that was designed for victims, ShelterFinder used standard formats such as CSV (Comma Separated Values) and XML (Extensible Markup Language) (Walsh, 2003). These formats allowed an independent team of developers to write database search systems and another independent team to build the GIS front end for more efficient use of the database system. Like PeopleFinder, a wiki was used for distributed management of the project. ShelterFinder would become a Web-based, data-driven DSS (Power & Kaparthi, 2002) form of knowledge management system.

ShelterFinder Development

ShelterFinder, in addition to being a distributed development group, had three constant managing members for promoting collaboration, managing the direction, and developing the system. Despite the fantastic strides made in such a short period of time, in reflection, the team discussed that there are some key aspects of their implementation strategy that could have been executed differently in order to bring more attention to the system and users. While PeopleFinder was a more evolutionary approach to software development, ShelterFinder attempted to maintain a quality of service by not releasing code until it had been tested thoroughly by the users and implemented by the lead developer. Keeping the system off-line until specific milestones were met kept ShelterFinder unavailable during potentially critical periods of time. A different software development methodology could have helped to garner more resources and to get more users while attention was still focused on the amazing open-source efforts that were emerging.

ShelterFinder Analysis

ShelterFinder gained huge acceptance due to two major components. First, it was a combined search engine that hosted records for more homes or shelters than most housing search engines. Letting the victims choose a specific city, even if it was on the opposite side of the United States, allowed victims to try to find temporary housing near family or in areas where they might be able to get jobs. This helped families find shelter near helpful social resources while decreasing the stress that the increased number of people could inadvertently cause on the resources of an area. When large amounts of people have been displaced, any opportunity to place them in different geographic areas helps the relief effort.

Second, the GUI was uniquely easy to use and made finding homes or shelters near specific addresses incredibly easy and intuitive. The GUI was a result of the recent introduction of Google Maps (http://maps.google.com). Using the built-in Google Maps XML parsing engine provided a graphical front-end that allowed users to see where homes were available in America as well as an intuitive graphical representation on the map of how many spaces were free at each shelter, based on icon color. At a community level, Google Maps has developed a means for conventional GIS developers to become Web-based GIS developers and to create Web-based applications quickly and cheaply.

KM use in ShelterFinder also is reflected in its construction. The system itself reflects the capture of lessons learned and is itself a repository of knowledge. However, this system is actually a reflection of a failure to capture and use knowledge. The system should have been designed to capture and use knowledge of survivor preferences and housing and service characteristics in order to obtain better fits of survivors to available housing other than fits based on location. Allowing searchers to pick locations that they thought best is convenient but not ideal, as reflected in reported dissatisfaction with survivors in a number of communities that took in and housed survivors. A key issue was the widespread dispersion of current or former criminals to locations at which residents did not know what they were getting. Knowledge use could have mitigated these issues. KMS features implemented in the system included knowledge repositories, although they were weak repositories based on location knowledge, and the implementation of good mnemonic functions (search, retrieve, visualize).

LEADERLESS DEVELOPMENT APPROACHES

The alternative software development approach taken by ShelterFinder shows that leaderless development systems can explore the same variety of software development approaches as well as share the same need for system requirements as their traditionally managed counterparts. The nontraditional leaderless system does have the hindrance of not necessarily being able to replace the traditional roles that a managed software development project would identify at the start of the project. In a leaderless system, this role is replaced by a group of personnel that claims and executes the publicly obtainable tasks that typically would be reserved for a specific role. This type of open task claiming allows willing members of the development team to attempt and execute tasks that normally they would not be aware of if the task weren't normally assigned to the traditional role they would play. When a task is overburdened and risks are holding back the other parts of the project, team members that normally wouldn't characterize themselves within a specialty can claim tasks that they are capable of accomplishing.

CRITICAL MASS REQUIREMENT

Distributed, by definition, requires the capability to be stretched across large redundant numbers. Leaderless development worked especially well for the PeopleFinder project, given the varying expertise available to the project by the massive number of constantly changing contributors. PeopleFinder was fortunate to have some early members that specifically spent their time advertising PeopleFinder, which, in turn, helped attract more development personnel, feeding the leaderless system. ShelterFinder, relying on a lesser quantity of members to oversee these tasks, was overwhelmed partially with the amount of work and the pressing timeline and was unable to advertise the site in the same way as PeopleFinder. This identifies a weakness in the leaderless system that if sufficient numbers of personnel are lacking, necessary functions can go without execution. Without other team personnel that is able to identify underperforming tasks within the project, the lacking tasks will continue until noticeable system degradation occurs, if noticed at all. For example, without team members persistently advertising the system's capability, users won't know about the site, and the site won't be used to its maximum capacity. Nonmarketing groups, perhaps isolated from usage statistics, might not know that the site isn't being used or that factors might be keeping the site from being used. In a rapid application development with a critical timeline such as disaster response, this can be a fatal system flaw.

CONCLUSION

Even as recently as the Sumatra-Andaman earthquake of 2004, disaster management response required printed maps and specially trained disaster management personnel to coordinate the deployment of resources. Military groups, such as the US Army's Civil Affairs branch and NGOs such as the American Red Cross, have specially trained personnel to sort through the overwhelming amount of information that arrives and to interact directly with victims. The incoming information arrives in a variety of formats, inconsistent for the operations center but usually in a consistent format from each source. This type of work usually requires specialized operations centers and a specialty staff to manage the data, and requires significant time to sort through the paper records submitted from the disaster area. Everyday citizens that would like to contribute are unable to, not only because they are not inside the physical operations center but also because there was no way for responders to reach out to the community to look for resources. Knowledge management systems, such as IMASH and the Digital Typhoon, have been researched and developed to help coordinate response to disasters. However, only by assessing how these types of systems actually worked in a disaster can improvements be made and resources like these used most efficiently in the future.

The technologies discussed here are changing the traditional approach to disaster response. Conventional, expensive, and isolated operations centers are morphing into a series of scalable, cheap, distributed, and highly networked information portals that can be used wherever a computer and Internet access are available. The more wireless options that become available to people in disaster-struck areas, from WiMax to satellite, the more options this new breed of distributed systems will have for helping people in real time wherever tragedies strike.

The social approach of these two projects is fairly unconventional in comparison to both commercial America as well as traditional disaster response. Leaderless cells performing specific actions are historically more comparable to terrorist networks than they are to humanitarian operations. The concept of groups self-determining their order of operations is countertraditional management approaches. However, the unsuccessful initial Hurricane Katrina response by the government (CNN, 2005) has shown that a rigid management can become overwhelmed when emergencies are too geographically widespread or when too many people have been affected. Distributed teams that can utilize knowledge management systems and can dynamically call upon the continually growing user base of the Internet for expert resources and manpower have a better chance to respond to the myriad of future emergencies.

Finally, the use of KM and KMS functions is shown to improve the speed and quality of response actions. This is expected, and it is our conclusion that future EIS should incorporate KM considerations.

ABSTRACT

This chapter introduces practical issues of information navigation and organizational knowledge management involved in delivering customer service via the Internet. An adaptive, organic approach is presented that addresses these issues. This approach relies on both a system architecture that embodies effective knowledge processes, and a knowledge base that is supplemented with meta-information acquired automatically through various data mining and artificial intelligence techniques. An application implementing this approach, RightNow eService Center, and the algorithms supporting it are described. Case studies of the use of eService Center by commercial, governmental and other types of organizations are presented and discussed. It is suggested that the organic approach is effective in a variety of information-providing settings beyond conventional customer service.

INTRODUCTION

The phrase "organizational data mining" in the title of this book suggests the importance of tapping all sources of information within an organization. The bare term "data mining" is most often applied to the extraction of patterns and relationships from databases or other structured data stores, enabling the productive use of information otherwise buried in overwhelming quantities of raw data. More recently, methods have been developed to extract information from relatively unstructured text documents, or, at least, to render that information more available via techniques of information retrieval, categorization and extraction. But in spite of such progress, one major source of organizational knowledge often remains inadequately managed.

It is widely recognized that much of the knowledge of any organization resides in its people. A major difficulty in tapping this key resource is that much of this knowledge is not "explicit" but rather "tacit." For our present purposes, we call explicit the sort of knowledge that could be captured relatively easily in a document, such as a memorandum, a manual or a white paper. In contrast, tacit knowledge is generally not committed to any permanent, structured form, because it tends to be strongly dependent on context or other variables that cannot be described easily. Because of its difficult nature, as well as its importance, the concept of tacit knowledge has received much attention in the recent literature (e.g., Nonaka & Takeuchi, 1995; Stenmark, 2000; Richards & Busch, 2000), though its roots go back at least to Polanyi (1966). It has become clear that the obstacles to capturing such knowledge are not merely technical, but psychological, sociological and even philosophical. No simple solution can be anticipated to this inherently difficult problem. Nevertheless, one can hope to identify certain features of the problem that are likely to be important in designing systems to deal with it.

In the following, we shall present our view of some key aspects of human-centered knowledge acquisition and dissemination. We do this within the context of a specific software application, RightNow eService Center (RNeSC), which was originally developed and is primarily used for Web-based customer service. This is not the limited domain it might at first appear, for the basic paradigm of knowledge exchange between producers (e.g., customer service representatives, university staff or government agencies) and consumers (e.g., customers, students or citizens) can be applied very generally. To cover this broad spectrum using a common terminology, we shall refer to the producers as "experts" and the consumers as "novices" or "end-users," while the general term "users" will encompass both groups.

Focusing on the knowledge management aspects of our application, the fundamental goal is to facilitate information finding by end-users and information providing by experts. We recognize that the information transfer, though asymmetric, occurs in both directions. Indeed, one of our main points is that for end-users to learn effectively, the experts must also learn about the end-users and their information needs. Furthermore, we note that the same basic paradigm can also apply to the situation where experts and end-users are the same population. (Our software is actually used in that way within a number of organizations, including our own.)

Data mining is key to the function of RNeSC in more than the metaphorical sense of eliciting knowledge from experts or the conventional sense of extracting information to generate various reports on the system status, history and use. Beyond these, the continuous analysis of text exchanges and the mining of user interaction logs represent embedded data mining functions that are crucial to the performance of RNeSC. Their main purpose is to extract what could be considered tacit knowledge of both experts and end-users about the relationships among knowledge items in the knowledge base. This metaknowledge would be both tedious and overly demanding for users to provide directly, but greatly improves the operation of the system in terms of user experience, as we shall describe.

Our aim in this chapter is to present our approaches to knowledge acquisition and access, and show how they are implemented in the RNeSC application. We outline various statistical and artificial intelligence techniques that are used in the process. Based on extensive usage information provided by companies and educational and governmental institutions that have used RNeSC, we describe some practical aspects of deploying and using the application. Finally, we discuss future trends and draw several conclusions.

KNOWLEDGE MANAGEMENT FOR CUSTOMER SERVICE

Knowledge Management Issues

We begin with a few general observations relating to the tasks of collecting or acquiring knowledge from people and providing it to others. We make no attempt to survey the vast literature on knowledge management, but simply note that a great deal of effort has gone into analyzing the nature of knowledge in its various forms and, in particular, the feasibility of capturing it for re-use or training. As mentioned, much discussion has centered around the distinction between explicit and tacit knowledge (Nonaka & Takeuchi, 1995; Stenmark, 2000; Sternberg, 1999). Though not clearly separable, these two types of knowledge are equally significant. Because tacit knowledge is often unique to an organization, it is considered a major source of competitive advantage, distinguishing that organization from others. Furthermore, tacit knowledge presents special management problems as personnel changes. For some authors (Polanyi, 1966; Cook & Brown, 1999), tacit knowledge is by definition that which cannot be expressed, while others (Nonaka & Takeuchi, 1995; Stenmark, 2000; Richards & Busch, 2000) consider "externalization" of tacit knowledge to be possible in appropriate settings. We believe the latter view is more appropriate to the domain of generalized customer service.

The process of conveying knowledge — both explicit and tacit — from expert to novice can be divided into stages, each associated with certain artifacts. This division is not unique. One traditional approach, exemplified by the creation of product documentation, models the process in two stages: (1) the expert writes the documentation, and (2) the novice reads it. While straightforward and familiar, this approach places a heavy burden on the expert to anticipate all the knowledge that could be required and present it in a way that can serve all those who might need it. An equally heavy burden is placed on the novice who must extract from the resulting large body of knowledge just that part corresponding to his or her need. Naturally, it often happens that what the novice needs is not fully provided, or the context is different enough that the novice fails to find the separate "nuggets" that, combined, would meet the need.

For example, it is difficult, if not impossible, to write a service manual for some piece of equipment that covers all repair situations. Yet an experienced repairperson can usually figure out what is needed on a particular job. If that specific repair procedure is described, elements of tacit knowledge are implicitly captured. In most organizations, as described in Brown and Duguid (1991), such stories are circulated informally within a community of practice. If they can be recorded and made more widely available, as was done with the well-known Eureka system at Xerox, the resulting knowledge base can be of extraordinary value to the organization (Powers, 1999; Fischer & Ostwald, 2001).

A second traditional approach is simple dialogue between expert and novice, in which the expert can both assist in the expression of the novice's needs and convey the knowledge in the most effective way for the particular novice. Such a model is the ideal of the conventional help desk. It typically results in the greatest benefit to the novice, but, depending on the setting, it may be highly burdensome and expensive to have an expert always available for each novice.

The model of the knowledge transfer process embodied in the architecture of RNeSC comprises elements of both the traditional approaches described above. Our interactive approach starts with the novice's specific information need. This is not necessarily clearly formulated, so we provide various means for the novice to satisfy the need via a self-service knowledge base. If that effort is unsuccessful, the novice must express the need in the form of a text message, which is sent to an expert. The expert then responds, drawing on accumulated experience, including appropriate elements of tacit knowledge. The response is, thus, much more limited in scope and tailored to the immediate need. In this setting, tacit knowledge, which might not have found its way into a manual, is activated; the expert realizes intuitively what will work best in the case at hand. This leads to what we consider an important aspect of any approach that aims to capture such knowledge: it is easiest to do so at the point of application, that is, in the consideration of a particular situation that calls for such knowledge. In a final stage of the process, the expert can choose to add the newly articulated knowledge to the knowledge base, thus enhancing self-service capability on the part of other novices.

Knowledge management in our model contrasts with that in the traditional model in several key regards. First, knowledge creation by the expert occurs not in a relative vacuum but in a specific, situated context. This facilitates application and capture of tacit knowledge, which is stored in the knowledge base along with the context. The knowledge transfer is not limited to transmission via a static artifact, such as a manual, but either by direct, personal response of expert to novice or via the novice's ability to locate the knowledge on his own. Since the latter is preferred, it is important to provide tools that assist the novice in navigating the knowledge base. Finally, utilization of the knowledge tends to be more effective under our model because of increased relevance to the particular situation of the novice.

Note that we have so far taken the expert to be omniscient. In most real cases, the expert also might need to refer to the knowledge base in the course of responding to a novice, especially if the expert is really an expert-in-training.

The Customer Service Domain

Customer service represents a quintessential knowledge management problem. Answers, i.e., information or knowledge, must be identified, transcribed or acquired by or from experts (e.g., customer service representatives) and then provided to novices (end-users) in response to their questions. Because of the economic importance of customer satisfaction, significant resources may be devoted to this function. In recent years, many companies and other entities have found it necessary to maintain a presence on the World Wide Web, and customer service is naturally one of the functions that can be provided by this means. However, the journey has not always been easy or successful.

Historically, the first step toward Web-based service was that of simply listing contact phone numbers and e-mail addresses on a Web page; end-user inquiries were then handled through these more traditional channels. This approach has the advantage of using existing infrastructure, but is typically very expensive per transaction, especially as there is now a general expectation of rapid response, even 24 hours a day. The majority of organizations are still at this level.

A second generation of Web-based service provides a set of answers to frequently asked questions (FAQs) on a support Web page. The composition of such a FAQ list is based on the accumulated experience of customer service representatives (CSRs). If well written and organized, this can significantly reduce the number of repeated inquiries received by CSRs, reducing their overload and increasing their productivity. However, unless the common inquiries are quite stable over time, this method requires a significant maintenance effort to keep the FAQ list organized and up to date. In many cases, depending on the organization, change can be relatively great on a weekly or monthly time scale. This change can also be unpredictable. Although it may be easy to see that introduction of a new product will lead to inquiries related to that product, it is not so easy to foretell what external events, such as a new law or regulation, or new products offered by competing companies, will cause a shift in end-user information needs. A further problem with this type of service is that as the number of FAQs grows larger, it becomes increasingly difficult for users to find answers to their questions.

A third level of Web-based service involves the provision of search capability over a set of indexed documents that constitute the online knowledge base. With such a system, answer-containing documents can be added independently of each other, and the structure is essentially the invisible one provided by the search facility. Related documents are, by definition, those returned together in response to a specific search query. Depending on the design of the search engine, it may or may not provide additional features, such as natural language input or matching to related words such as word-form variants (drive, driver, driving, etc.) or synonyms (car, automobile, etc.). These well-known search engine problems have led some companies to deploy conversational question-answering systems, or "chatbots." Unfortunately, at their current stage of development, such systems require extensive knowledge engineering in the form of identifying input question patterns that should be recognized and the links to the corresponding answers. Beyond pre-scripted patterns, the performance degrades rapidly. Furthermore, this type of system either does not support overviews and browsing of the knowledge base, or again requires knowledge engineering to create and maintain a taxonomy and relate it to the collection of knowledge base documents.

At present, there is a wide range of levels of customer service available on the Internet. Some organizations have managed a good fit between what they need and what they provide. But many are still struggling with expensive, cumbersome systems that do not serve them well. In some cases, organizations simply don't have a good understanding of what state-of-the-art customer service can or should be. But probably most often it is a lack of resources — both human and financial — that limits the quality of service. For this reason, a constant aim in the development of RNeSC was to minimize the effort necessary to establish and maintain the system. This entailed an architectural design in accordance with the above and other considerations, as well as integration of data mining and artificial intelligence techniques to reduce the burden on users.

AN ORGANIC KNOWLEDGE BASE

The Organic Approach

To find a way to meet the sometimes conflicting needs of experts and end-users, we believe that attention must first be focused on the core of the system where knowledge is stored, namely the knowledge base. In the type of system we envision, this is a publicly available (via the World Wide Web), dynamic collection of documents that we shall refer to as Answers. We assume here that it is created and maintained by the experts (e.g., CSRs). In actuality, there may be distinct managers who perform various important functions, but whose role is outside the scope of this paper.

The knowledge base must first of all contain the knowledge sought by end-users. How does one know what this is? Within our organic approach, the reply is simple: Let the end-users identify what is needed by the questions they ask. This implies that the knowledge base does not exist in isolation; it must be closely coupled to channels through which end-users ask questions.

As a concrete example, take the case of a computer services help desk that receives several complaints about problems with a new software version. Though one might expect certain problems to arise with such upgrades, it would be extremely difficult to attempt to forestall complaints by preparing a comprehensive troubleshooting guide. In contrast, it is relatively easy for a technician to answer a specific question in a given context and easier for the end-user to understand that answer than the full troubleshooting procedure. If the Answer is published in the knowledge base, incoming questions on the topic may be reduced either because only that single case led to problems, or because other users could resolve their problems also by following the approximate answer. If not, new support requests will come in, and then either the first answer could be modified or expanded, or a new answer added. This adaptive "just-in-time" approach is very efficient in terms of experts' effort.

Thus, along with the knowledge base itself, end-users must have direct access to experts when they don't find the information they need in the knowledge base. It is their needs that drive knowledge creation, while the experts' effort is conserved. A similar concept of experts backing up a knowledge base in a system for organizational memory, an application close in spirit to customer service, has been described and studied by Ackerman (1998).

According to the organic growth scenario, the knowledge base is initially seeded with a fairly small set of Answers to known or anticipated FAQs. After that, Answers are added as needed to respond to new incoming questions frequent enough to merit creation of a public Answer. (Of course, Answers to predictable concerns can also be added even before questions arise.) Depending on the organization, the threshold could range from one to perhaps hundreds.

This approach has a number of advantages for experts:

- Tacit as well as explicit knowledge can be brought to bear on the specific questions.
- Answers can be based on existing private responses (made before reaching the threshold).
- No time and effort are spent creating unneeded Answers.

Furthermore, experts have a natural motivation to upgrade private responses to publicly available Answers: A single Answer can eliminate the need for many private responses. As in any knowledge management endeavor, it is also important for the organization to create a culture in which such contributions are recognized or rewarded in one way or another.

End-users also benefit. Unlike a traditional call center or contact center, this approach develops an authoritative, self-service knowledge base, accessible 24 hours a day, in which an end-user can generally locate information faster than she can compose, say, an e-mail describing her question or problem. This is especially true if the initial problem description is unclear and a series of back-and-forth communications would be necessary for clarification. End-users with novel or inherently personal questions can still receive service through the traditional channels, now improved because of the reduced load on the experts.

Critical to success of this approach is the ease with which end-users can actually navigate the knowledge base to find information. Frustration leads not only to negative attitudes towards the organization but, if anything, increases the burden on experts. In contrast, a positive experience for the end-user enhances trust and loyalty, key assets for noncommercial as well as business entities. Ensuring such a positive interaction requires attention to the psychology as well as the statistics of searching. To support each end-user's quest, the interface to the knowledge base must be as intelligent as possible and be adaptable to the range of search skills that different users may have. This entails use of natural language and artificial intelligence (AI) methods. Appropriately integrated, these techniques can also be applied to improving performance of the system from the experts' point of view.

Feedback from end-users to experts, in addition to that implicit in the asking of questions, should be such as to facilitate various forms of optimization, as well as provide understanding of end-user behavior that may be significant to the organization. This can be accomplished by mining records of user interactions with the knowledge base.

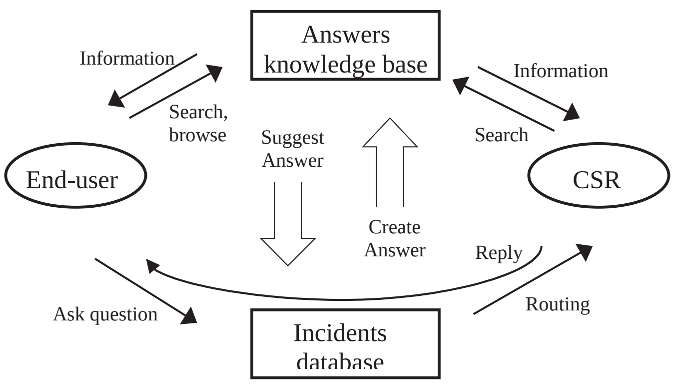
In the following, we detail how this organic approach is embodied in RNeSC. After briefly introducing the overall system, we focus on those aspects related to the knowledge base, since this is where most of the AI and data mining techniques come into play. We describe the use of the system in practice, as well as the algorithmic techniques employed and their multiple roles.

System Architecture

RNeSC is an integrated application that combines e-mail management, Web self-service, live collaborative chat, and knowledge management. The core of the application, from our present perspective, is the publicly accessible Answer knowledge base and the tools by which it is created, maintained and accessed. In addition, there is a database of customer-service Incidents, i.e., messages from end-users, which are fully tracked from initial creation—via e-mail, Web form or live chat—through resolution and archiving. Figure 1 illustrates these key components and how they are involved in end-user and CSR (or other expert) knowledge-related transactions.

As indicated in the previous section and in Figure 1, the architecture of RNeSC provides a strong interaction between question and answer

Figure 1. Principal Knowledge-Related Transactions in RNeSC (End-users search the Answer knowledge base for information; if they cannot find what they need, they submit a question, which is stored and tracked in an Incidents database, and replied to by a CSR. CSRs also use the knowledge base, and add to it by creating new Answers, typically suggested by frequently asked questions. Answers to questions can be suggested from the knowledge base either to assist CSRs in forming replies or as auto-replies to end-users. See text for a fuller description.)



channels. As CSRs respond to the questions submitted by end-users, they naturally become aware of trends and commonalities among them. At any time, a private CSR reply can be proposed as a potential public knowledge base item, or a new Answer can be composed on the basis of previous replies or predicted information needs. Depending on organizational practices, the item might be reviewed or edited by collaborators or managers before being made a publicly available Answer.

In typical operation, the main knowledge flow (in terms of volume) is from the knowledge base to end-users who are successful in their searching. But even if they are unsuccessful, or if they make no attempt at self-service, the contents of their question may suggest that one or more relevant Answers actually exist. In that case, Answers can be suggested automatically, based on search technology described later. These Suggested Answers can either be routed directly to the end-user as an auto-reply or to the CSR engaged in formulating a personal reply. Naturally, CSRs also make direct use of the knowledge base for their own information, especially novice CSRs.

In this paper we leave aside the multiple administrative functions of RNeSC, though these are vital to its overall ease of use (especially from a CSR's point of view). Some of these use AI techniques also employed in the central knowledge management functions. For example, one of the criteria that can be used in routing incoming questions to individual CSRs is an emotive index that estimates the degree to which the tone of a message is angry, neutral or happy. This determination uses the same natural language processing algorithms described later, in combination with wordlists and grammar rules. As RNeSC is available in about 15 languages and dialects, implementing this feature takes a significant effort. Also not indicated in Figure 1 is a module that generates a wide variety of reports to aid in evaluating transaction statistics, CSR performance and Web-site usage. These are developed through both batch and incremental analysis of system interaction records. Finally, except to mention a notification function that allows a user to be informed of any changes in a selected Answer, we won't detail here the many customization options that users can set.

Using the Knowledge Base

It is widely appreciated that knowledge comprises not only facts, but relationships among these, as well as perspective on their importance, relevance, etc. A knowledge base organized to incorporate or reflect such metaknowledge provides a much better match to user habits and expectations and is consequently easier to use. In RNeSC this metaknowledge is acquired through several techniques. In addition to intelligent searching, these include adaptive clustering and classification of text documents (the knowledge base Answers), and collaborative filtering techniques that mine usage patterns to extract implicit user feedback on importance, timeliness and relatedness of knowledge base items. We will describe these techniques as they might come into play while a user navigates a knowledge base.

An illustration of a simple end-user view of a knowledge base is shown in Figure 2. This page is reached after first selecting the "Answers" link on the support home page, before any search has been made. The Answers shown are listed in order of historical usefulness — called solved count — which measures how helpful an answer is likely to be based on the experience of previous users. If the knowledge base is not too large and the end-user is looking for information that is commonly sought, there is a fair probability that the appropriate Answer will be listed in the first set. If the solved count of answers happens to follow a Zipf distribution, then even with 500 items in the knowledge base, there is nearly a 50 percent chance that the appropriate Answer will be within the top 10.

The solved count is obtained from a combination of explicit and implicit user feedback. If enabled, each Answer page carries evaluation buttons (e.g., labeled 0 percent, 25 percent, 50 percent, 75 percent and 100 percent) that the user can select to indicate the degree to which his or her question was answered; these contribute proportionately to the solved count. Since relatively few users make the effort to provide explicit feedback, we also derive an implicit evaluation from the user's actions. Simply choosing to view a particular Answer is taken as a partial vote for its usefulness. If the Answer is the last one viewed, it is assumed that it provided the information sought, and the vote is given a higher weight (though still less than an explicitly approved Answer).

An Answer that appeared promising from its title might prove insufficient. If so, to the extent the title represented the content, an Answer with similar or related content might help the user. Each Answer page can be provided with links to a variable number of the most closely related Answers. The relatedness ranking, like the solved count, has explicit and implicit components. The explicit relatedness is derived from text similarity, currently based on the vector model common in information retrieval (see, e.g., Manning & Schutze, 1999, p. 296), with stopword removal and conflation of words having the same stem. To obtain an implicit relatedness score, the application maintains a link matrix, the corresponding element of which is incremented each time an end-user navigates from one Answer to another, presumably related one. The increment is larger if the second Answer is the final one viewed or is given a high explicit rating.

The methods just mentioned for capturing user perceptions of usefulness and relatedness are inspired by both collaborative filtering (Levy & Weld, 2000) and swarm intelligence (Dorigo, Di Caro & Gambardella, 1999) approaches. In our application, rather than software agents traversing a network as in the usual form of swarm intelligence, it is human users whose paths leave a trace as a pheromone-like record. The resulting link matrix certainly contains noise in the sense that not every item-to-item transition is made by users only on the basis of perceived relatedness. Nonetheless, averaged over many users who each tend to be searching for information related to a specific need, we have found that the strong links indicate useful relationships. By means of the accumulated links, the application learns which other items in the knowledge base are most closely related to a given one.

The algorithm as described so far would be appropriate for a static knowledge base but not for a changing one. Just as an insect pheromone trail evaporates with time, so we perform an aging process by which both solved count and link values are periodically reduced in strength when not reinforced. This aging keeps the knowledge base responsive by enforcing the primacy of recent usage patterns. By this means the most useful Answers float to the top of the list and appear on the very first page. For a more complete discussion of these collaborative and swarm intelligence methods, see Warner, Richter, Durbin and Banerjee (2001).

Both the solved count and the link matrix represent a form of knowledge acquired from users about items in the knowledge base. From a knowledge management point of view, the role of this metaknowledge is to aid in the principal knowledge transfer by making it easier for end-users to find the Answers they need.

To find Answers to less frequently asked questions, end-users may need to perform a search of the knowledge base. Intelligent search is a prerequisite for easy access to information. In RNeSC, queries entered into the search box (Figure 2) can be processed according to a variety of search modes, including natural language input and similar phrase searching (which carries out spelling correction and synonym expansion). Searches can also be restricted to predefined
