Although the response rate for survey two was quite high (71%), the sample size once again prohibits statistical data analysis. However, the main purpose of Survey 2, which was to inform the researchers prior to embarking on interview and case study processes, was achieved. Although the order of enablers in Figure 1 (importance of enabler by principle), Figure 2 (ranking of enablers), and Figure 3 (significance of enablers) differs, the data does indicate that all ten enablers are seen as having an important role to play in the overall performance of organisational IKM activities. Furthermore, practitioners were able to distinguish between what is theoretically ideal (Question 8 in Survey 1) and the actual "state of practice" regarding that principle in their organisation (Question 4 in Survey 2). We have shown the alignment data alongside the significance data to indicate the gap between the ideal and actual situations in our sample organisations. Further interpretation of this data could be used to show the fit against an aggregated benchmark for each organisation and enabler. This data could be then used by organisations to focus their IKM strategies. The data also suggest that a large quantitative data collection and analysis may produce some significant differences between theory and practice in this area.

FUTURE TRENDS AND CONCLUSION

This exploratory analysis of IKM frameworks in business contexts has provided answers to the two issues questions posed. The data from the two exploratory surveys confirmed that participants saw ten organisational factors as having a role in enabling information and knowledge management activities. The surveys also indicated that there are gaps between the significance of IKM enablers and the actual situation in our sample of Australian organisations. The true value in these findings lies in the opinions, understandings and experiences of the IKM practitioners underpinning the quantitative data. So, the quantitative data proved useful to inform the authors before engaging the respondents to the second survey in an interview and case study process.

As expected, this study raises a number of further challenges that we will be pursuing. Firstly, a clear distinction between the processes required to manage information and knowledge is needed. Secondly, we need to gather more data to confirm the integrated framework and its component enablers. Thirdly, we will elaborate on the characteristics of the candidate enablers. Fourthly, we will describe the impact of each key enabler on IKM initiatives after organisational assessment in further case studies. Finally, (for now) we plan to describe the role of each enabler within IKM.

The overall goal of this on-going research is to provide practical guidelines to assist organisations to optimize their environments so that the outcomes of IKM projects are beneficial to them. This exploratory study has provided the foundation to achieve this goal.

ENDNOTES

1. Although this interest does seem relatively recent, philosophical discussions about knowledge and knowing engaged Plato and Aristotle and many scholars since. The potential of untapped knowledge within peoples minds was succinctly stated by Polanyi (1966) who said "we know more than we can tell," thereby emphasizing the current challenge for business.
2. Another view is that the current popularity of KM is largely driven by the commercial imperatives of software vendors and consulting firms.
3. Further discussion about IM and KM framework development is the subject of another paper by Nelson and Middleton (2001) currently under development.

This work was previously published in *Knowledge Management: Current Issues and Challenges* edited by E. Coakes, pp. 104-115, copyright 2003 by IRM Press (an imprint of IGI Global).

Chapter 6.14
Managing Information Technology Component of Knowledge Management:
Outsourcing as a Strategic Option in Developing Countries

Adekunle Okunoye
University of Turku and TUCS, Finland

ABSTRACT

Information technology and social-cultural, organizational variables are considered major components to support knowledge processes in knowledge management. These components have to be carefully managed and be supported in balanced proportion for organization to create and retain greater value from their core competencies. The peculiar situation of developing countries, where there is lack of adequate information technology infrastructure, emphasizes the importance of strategic management of organizational information technology. Using a case study, we discuss the possibility of outsourcing the management of the information technology in order to have more focus on the other components in knowledge management.

INTRODUCTION

Knowledge management (KM) could be defined as the ability to create and retain greater value from core business competencies (Duffy, 2000; Bhatt, 2001; CIO, 2000). IT is one of the enablers of knowledge management. Its availability, management, and right application could increase the success rate of knowledge management efforts of organizations. Due to lack of human resources with required skills and lack of adequate IT infrastructure (ITI) in sub-Saharan Africa, IT outsourcing could be a better approach to IT management for an organization considering KM. In this chapter, we present part of the outcome of an empirical research and an in-depth analysis of a case organization where IT outsourcing seems to contribute to a high performance in knowledge management efforts. We suggest that organizations in sub-Saharan Africa that are considering knowledge management could look at the possibility of outsourcing the management of the information technology component in order to have more focus on the other enablers of KM

Information technology is one of the enablers of knowledge management and its management could have a great effect on the knowledge management efforts of organizations. IT management in sub-Saharan Africa is posing problems to some organizational activities in the face of low resources and expertise (Odedra et al. 1993; Moyo, 1996). Outsourcing IT has attracted a lot of attention in IT literature (e.g., Lacity and Hirschheim 1993; McFarlan and Nolan, 1995; Hirschheim and Lacity 2000). It could allow organization to focus more on development efforts such as reengineering process, just-in-time, total quality management, benchmarking, etc. For these reasons, IT outsourcing has become very popular. There is much evidence of its success after the understanding of the problems associated with earlier agreements (Shepherd, 1999). Firms focus on their core capabilities to have competitive advantage especially in today's dynamic, volatile business environment. When a firm focuses on core businesses that add unique value to its customers, it may outsource activities for which it lacks core capabilities (Quinn and Hilmer, 1994).

In our empirical study of six research organizations on ITI and KM in sub-Saharan Africa, two organizations presented exceptions to our assumption that organizations with high ITI capability are also likely to have effective knowledge management. In one organization, high level of IT infrastructure capability was not accompanied by high KM efforts while in another research institute, there were high KM efforts at instance of low IT infrastructure capability. Upon closer inspection of the later, the IT outsourcing strategy of the organizations with low ITI seems to be responsible for the high performance in knowledge management activities. Could the IT outsourcing strategy directly relate to the performance in KM efforts? We examine KM from core competence perspective and argue about the difference between the strategic and operational view of organizational IT. We illustrated this with a case organization upon which we will draw our conclusions and suggestions for further studies.

IT OUTSOURCING

Outsourcing is the transfer or delegation of the operation and day-to-day management of a business process to an external service provider. IT outsourcing can be regarded as the practice of transferring IT assets, leases, staff, and management responsibility for delivery of services from internal IT functions to third-party (Hirschheim and Lacity, 2000). According to Hitt et al. (1999), outsourcing is a strategic concept, a way to add value to the business that converts an in-house cost center into a result oriented service operation. The motivation for IT outsourcing is widely discussed in the literature. Shepherd (1999) provides a summary where he included financial restructuring, reduction or stabilization of costs, overcoming cultural and organizational problems, concentrating on core competencies, access to world class expertise, concern with economies of scale and scope, and possibly growth expectation. Generally, virtually all organizations are seeking the strategic value that can be captured through effective outsourcing.

IT outsourcing evolved from the early 1960s data processing service bureau to the contract programming approach of 1970s. The 1980s witnessed more focused efforts on vertical integration and internal control and a slowdown in outsourcing (Ketler and Willems, 1999). The 1990s are characterized by a renewed interest in outsourcing, following Eastman Kodak's much written-about outsourcing deal of 1989. At turn of the century, with various IT related problems (e.g., Y2K, skill demands, etc.) and developments (e.g., e-commerce) and the need for organizations to be more competitive and responsive, IT outsourcing has become a generally acceptable practice in various forms and scopes. Both small and large-sized organizations are taking advantage of outsourcing opportunities.

Since only few organizations if any, possess the resources and capabilities required to achieve competitive superiority in all primary and support activities, more especially with respect to information technology which required keeping with the dynamism of the industry and changing expertise (Hitt et al., 1999). IT outsourcing enables an organization to focus on their core competence and it provides possibility to make a right strategic decision that directly affects the work. It enables access to new technology and keeping up with the trends in the ever-changing world of IT (Ketler and Willems, 1999; Goo et al., 2000). In a situation where there is low availability of human resources, it relieves the organization of the burden of continuous recruiting due to the high turnover rate in the sector (Slaughter and Ang, 1996). Thus, we also agree that IT outsourcing could be a good decision for an organization that does not use IT for strategic purposes, but mostly for operational functions (Currie and Pouloudi, 2000), especially in a region where there is lack of adequate expertise to support in-house IT management.

According to Ang and Straub (1998), organizations apply selective outsourcing analysis in which outsourcing relationships are focused on specific IT activities where external providers supply expertise that is currently lacking. Also, organizations apply selective outsourcing analysis is applied where outsourcing relationships are focused on external providers that furnish assets or competencies for which they have a comparative advantage in terms of economies of scale. Analysis is also applied to external providers that take on responsibilities for IT activities not considered mission critical so that the organization can deploy released resources into strategic activities. Using the last option could enable an organization to nurture few core competencies and thus, increase the organizations probability of developing a competitive advantage or a tremendous improvement in a particular process (Chesebrough and Teece, 1996).

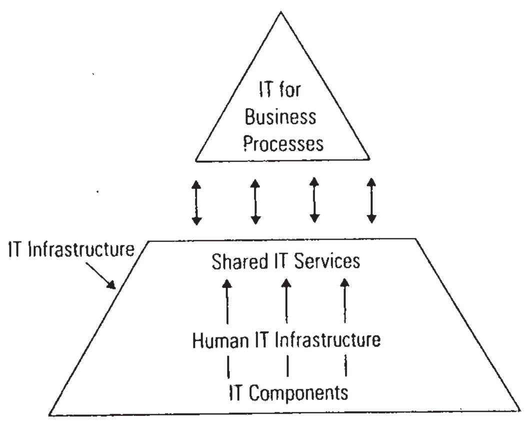
Although outsourcing IT to India and other developing countries has attracted attention, the outsourcing arrangements within developing countries are less written about. In the case of non-profit research organizations, IT could be viewed as a set of operational tools. The scientists are mainly interested in getting their work done and they may have little interest in state-of-the-art-IT. Their core competence is far from IT, though in the modern world where they operate, IT use appears essential. In as much as they are able to carry out their primary duties with IT, the kind of IT installed or the style of its management might not in any direct way provide competitive advantages to them. In fact, these non-profit organizations do not consider other organizations as competitors, but rather collaborators. They need IT to support the process of their work, communication, collaboration and coordination. For these reasons, it could be convenient for the research organizations to outsource their entire IT management functions.

INFORMATION TECHNOLOGY INFRASTRUCTURE (ITI)

IT infrastructure is a major business resource and a source for attaining sustainable competitive advantage (Broadbent et al., 1999; Keen, 1991;

McKenney, 1995). It is increasingly seen as a fundamental differentiator in the competitive performance of the organizations, its investment leads to new competitive strategies and progression through higher levels of organizational transformation. IT infrastructure capabilities enable the emergence of new organization forms, facilitate electronic commerce and knowledge management; it is critical to globally competing firms (Broadbent et al., 1999). Strategically, the importance of an organization's information technology infrastructure capability is increasingly recognized as critical to an organization's competitiveness. These infrastructures are important for organizations going through dynamic change, for organizations reengineering their business processes, managing individual and organizational knowledge and for those with multiple business units or extensive international or geographically dispersed operations (Broadbent et al. 1999). IT infrastructure, according to Broadbent and Weill (1997) is the base foundation of information technology capability, delivered as reliable services shared throughout the firm.

Figure 1. Elements of IT infrastructure (Broadbent and Weill, 1997)



ITI is coordinated centrally, usually by the information systems group or external people when outsourced. They use a pyramid to illustrate the different components of information technology infrastructure (see Figure 1).

At the base of the pyramid there are components such as computer and communications technologies (hardware and software), that are largely commodities and readily available for purchase and hire. The second layer comprises of a set of shared services such as management of large-scale data processing, provision of electronic data interchange (EDI) capability, groupware, Internet or management of firm-wide databases. The human resources turn the components into reliable, shared information technology infrastructure services. Each of these components could be outsourced completely or in part, the decision depends on the factors already described above.

They also identified four views of IT infrastructure with different benefits and investments: none, utility, dependent, and enabling. None view implies that an organization does not invest in IT infrastructure at a firmwide level. The utility view primarily considers investment in IT infrastructure as a way to reduce costs through economies of scale. The dependent view ties the investment in IT infrastructure to the current organizational strategies and the enabling view is a dependent view with extra investment to cater for long-term goals and developments (Broadbent and Weill, 1997). It has earlier been recognized that ITI can be a significant barrier or enabler in the practical options available to planning and changing organization processes like KM (Broadbent et al., 1999), thus adequate support of enabling technologies and platforms is an important factors in the success of organizational changes. Therefore, organizations that consider IT as part of their core strategies are likely to take the dependent and/or enabling views. On the other hand, while organizations that consider IT as operational tools are likely to take the none and /or utility view, thus, they are likely to outsource their IT without fear of losing knowledge and have more time to concentrate on core capabilities.

KNOWLEDGE MANAGEMENT (KM)

Several authors acknowledge that the ultimate goal of KM is to improve organizations efficiency and productivity, hence profitability (APQC, 1996; Davenport and Prusak, 1998). For the purpose of this chapter, we lean towards the definition that KM is the ability to create and retain greater value from core business competencies (CIO, 2000) and a practice that finds valuable information and transforms it into necessary knowledge critical to decision making and action (Beveren, 2002). This could be achieved by various strategies to provide the right knowledge for the right people at the right time (APQC, 1996). Organizations are using various approaches to achieve these goals. Some are focusing on management of people and others on the management of information (Sveiby, 1996).

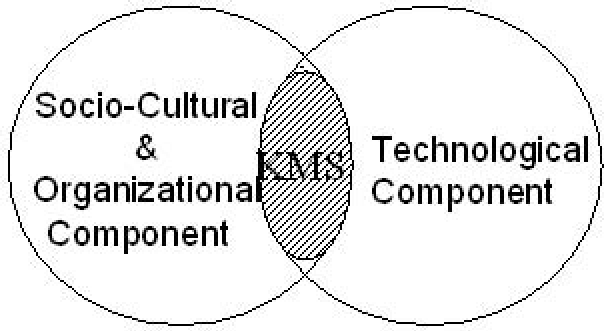
Tyndale (2000) further explained Sveiby's view, using the terms codification and personalization. He used codification to explain KM that is IT focused. This strategy includes attempts to codify knowledge and carefully store it in a database where it can be accessed and used easily by anyone in the company. This approach considers knowledge as objects that can be identified and handled in information systems. Personalization was used to explain KM that is people-focused. This approach regards knowledge as a process that is closely tied to the person who developed it. This kind of knowledge is shared mainly through direct person-to-person contacts. In this approach, technology is only used as the infrastructure that enables the capture, storage, and delivery of contents to those who need it when they need it. Bhatt (2001) also suggested that exclusive focus on codification or personalization does not enable the firm to sustain its competitive advantages but rather it is the interaction between technology, techniques and people that allow an organization to manage its knowledge effectively.

KM AND IT OUTSOURCING

The focus of previous studies on the relationship between IT outsourcing and KM has been on the knowledge issues between the contracting parties. For example Currie and Pouloudi (2000) relate the outsourcing decision to the value the organization attaches to their knowledge-based assets, they conclude that consideration of the value of knowledge-based assets, knowledge creation, growth, and retentions could affect the outsourcing decision. Their conclusion also supports the view that organizations that considered IT as core competence are likely to insource while organization that think otherwise may likely outsource. However, they did not elaborate further on whether the outsourcing decision allows the organizations to focus more on their core competency. Although it is the core competencies that really distinguish a company competitively and reflect its personality. According to Hitt et al. (1999), core competencies emerge over time through an organizational process of accumulating and learning how to deploy different resources and capabilities. Like in product development where organization can focus on their core competency, organization could also focus on the issues that they understand better in a dynamic organization change like knowledge management.

Although KM is currently being viewed as a combination of the technological component and the social-cultural, organizational component, relatively little attention has been paid to the issue of outsourcing the IT component. Balancing these components could yield effective KM and improve productivity, efficiency, innovation and competence of an organization. In the knowledge management components described by Alavi

Figure 2. Knowledge management components (Alavi, 1997)



(1997), effective KM occurs at the intersection of the technological component and social-cultural and organization component (Figure 2).

Therefore, for an organization to have an effective KM practice, there should be a balance between the technological component and the social-cultural, and organizational component. Technology is often considered to be the easier component. Dan Holthouse in his foreword to Information technology for Knowledge management (Borghoff and Pareschi, 1998) remarked on this: "Technology is the easier piece of the problem to solve, it's far more challenging to change people's behavior and to create a learning environment that fosters the expansion of individual's personal knowledge. Therefore, organization could do better if the internal resources [were] focused on the people aspect and allow an external organization that has the adequate [expertise], to handle the (easier piece of) technology."

THE EMPIRICAL STUDY

As part of a study to investigate how information technology infrastructure generally affects knowledge management efforts of research organizations in sub-Saharan Africa, we conducted a multiple case study (Yin, 1994) using six different organizations in two countries in sub-Saharan Africa (Okunoye and Karsten, 2001). Three of the organizations are international: International Institute of Tropical Agriculture (IITA), Nigeria, Medical Research Council (MRC) Laboratories, and International Trypanotolerance Center in The Gambia. Three are national: National Agricultural Research Institute (NARI) in The Gambia, Nigeria Institute of Social Economic Research (NISER) and Nigerian Institute of Medical Research (NIMR) in Nigeria.

The national organizations are primarily dependent on the national government for their basic funding. Usually the international organizations enjoy supports from various sources around the world. They have a substantial number of expatriates working in them and have better support for the IT. The multiple-case study was conducted between January and March 2001. We interviewed, observed and presented questionnaires to research scientists, management staff, librarian, and IT staffs on knowledge management and use of ICTs. We interviewed the head of IT where applicable and the people responsible for IT department. KM was evaluated using the knowledge management diagnostic (KMD) created by Bukowitz and Williams (1999) and ITI was assessed using the approach developed by Broadbent and Weill (1997) where IT infrastructure is linked to the business by maxims, which reflect the company's strategic context. The KM assessment and ITI capability has been fully described in Okunoye and Karsten (2002).

INFLUENCE OF IT ON KNOWLEDGE MANAGEMENT

Four of the organizations appear to correspond to our expectations on the influence of IT on KM: In NARI in the Gambia and in all Nigerian organizations, the ranking in IT is similar to ranking in KM. Two exceptions to this consistency were found. In MRC, a high level of ITI existed with low level of KM. In ITC, a high level of KM existed despite low level of ITI capability.

The ranking of IITA and NISER in both KM process assessment and their IT infrastructure capability tallied and reflects the way they have been able to apply the available IT infrastructure in supporting their knowledge management efforts. IITA had a well-developed IT infrastructure. NISER had a reasonable level of infrastructure, which is put into proper usage. In these two organizations, people have been able to put the IT infrastructure into proper use for the purpose of their work. NIMR and NARI had low IT infrastructure rank and they were also low in their KM assessment, thus showing the relationship between IT infrastructure and KM processes similar to IITA and NISER. MRC needs to be studied further to find out their specific deterrents to efficient KM despite high ITI capability. The performance of ITC in KM efforts could be explained by their strong focus on organizational efficiency and on research, leaving all the IT management of the small organization to be taken care of by an outside vendor (see Table 1).

ITC is the smallest among the case organizations, with about 122 staff members and attracts visitors and researchers from major agricultural research laboratories with interest in tropical agriculture. Due to their small size and their view towards IT, they do not see the need for running in-house IT department, as remarked by one interviewee. Hence they outsource the management of the IT unit to local companies.

"If your staff strength is not high, the cost benefit is not there…We have IT support from ITS and other ISP, that is better for us, because again of critical mass, there is no point hiring a permanent staff, if no computer breaks down in a month then

Table 1. Nature of IT management, IT infrastructure capability and KM rankings

Name	IT Unit	Status of the Head	Outsourced services	IT Staff No.	Est. expenditure on IT per year (in US dollars)	Total Staff Strength	ITI capabilities ranking	KM efforts ranking
MRC	Yes	Expatriate	Some	7	$ 142 243	600	2	5
NARI	Yes	Local	Some	2	Not known	211	5	4
ITC	No	N/A	All	N/A	Not known	122	4	2
IITA	Yes	Expatriate	Some	10	$ 200 000	1400	1	1
NISER	Yes	Local	Some	8	$ 8 900	500	3	3
NIMR	Yes	Local	Some	4	Not known	130	5	6

he sits down idle. If there is a problem, then we call our engineers."

The Gambia is one of the smallest countries in the sub-region. There is a shortage of IT personnel. It also shares other difficulties facing the countries in the sub-region in the areas of training and low expertise. Nevertheless, there are a few IT companies serving the needs of local businesses. We do not go into detail of the kind of agreements ITC have with the outsourcing partners. However, they tried to avoid opportunism and monopolistic bargaining by using multiple competing vendors strategy (Ngwenyama and Bryson, 1999). From our interview, we are aware that they use at least two different outsourcing partners, the Internet service provision is from one company while the regular IT management services are from another.

"Now it is difficult and we have asked for a network and we are hoping, a man was just here from QuantumNet or ITS to make a budget for Network."

IT OUTSOURCING – A STRATEGIC CHOICE FOR KM

Even though ITC had a low infrastructure services, they performed well in their knowledge management efforts. Their outsourcing decision is likely to be responsible for it. They were able to concentrate on the particular infrastructure required for their work. In ITC, the Internet is enabling collaboration among the staff and connecting them to external sources of knowledge that used to require travelling abroad in the past.

"That used to be quite a difficult thing, it was a problem, the only way you could get access to journals would be either to go to Europe in person and then do a literature search. I normally go to Wageningen every year, that's my almamater, but now I can liase with the Royal Tropical Institute in Amsterdam. I only send keywords of research topic and they will do the relevant search and send back to me abstracts. I will request the document I am interested in and they will send it to me… I get table of contents of recent journals and if something is of interest to me, I send to them by email and they send it back to me."

ITC have extended their computing infrastructure by using the Internet to exchange files even to next door.

"…we don't want to go into the cost of having a LAN, so even for me to send things next door, I go through the Internet."

Technology is seen to a vital role in knowledge management, but that technology on its own cannot make knowledge management happen (Hibbard, 1997). This was evident with ITC: their low ranking in IT infrastructure capability did not affect their KM efforts, because knowledge actually resides in people, technology can only assist in making things work more efficiently. Moreover, there was a presence of a minimum IT infrastructure supported by their outsourcing partner, which they were able to balance with other variables as suggested by Leavitt (1965). While the availability of IT infrastructure is important, support for its applications, usage, and technical components can significantly lower its usefulness.

CONCLUSION

We have discussed how IT outsourcing appeared to be having a positive effects on KM efforts of a research organization in sub-Saharan Africa. As an exception to a consistency that the availability of IT infrastructure has a direct relationship with KM efforts, we examined the concerned organization further. The outsourcing of the IT management seems to enable them to put the available IT infrastructure into proper usage and the main success factor in their KM efforts. It would be appropriate to study several organizations that have a similar arrangement to see if a similar pattern could be found before we could make any generalization. Nevertheless, there is an implication of this finding for the organizations in sub-Saharan Africa considering knowledge management as part of their strategy. This chapter implies that they might fare well by focusing on the social, cultural and organizational issues while outsource the technological component. For the researchers with interest in IT outsourcing and knowledge management, this chapter raises additional issues to be considered in the IT outsourcing and knowledge management relationship.

Chapter 6.15
Small Business Transformation Through Knowledge Management

Nory B. Jones
University of Maine Business School, USA

Jatinder N. D. Gupta
University of Alabama in Huntsville, USA

INTRODUCTION

In the last decade, the importance of knowledge as a source of sustainable competitive advantage has gained widespread acceptance. Business practitioners and academics alike recognize that what is "between the ears" (Tiwana, 2000) of their employees represents the source of creativity and innovation that nourishes and sustains the organization. Furthermore, the ability to harness the intellectual capital in an organization probably represents the most important aspect relating to the creation of an intelligent enterprise.

However, most research on the topic of knowledge management (KM) and intellectual capital has focused on larger organizations. Because small businesses account for a major portion of the total number of businesses, jobs, and growth in many world economies (Wong & Radcliff, 2000), it is important to understand the impact of knowledge management on small businesses as well. We need to understand the correlation between knowledge management practices, the ability of a small business to transform itself into an intelligent enterprise and any resulting performance or competitive improvements KM may provide.

Because a "build it and they will come" approach to knowledge management usually does not work, this article discusses and integrates the concepts of adoption and diffusion of innovations with knowledge management theories to help transform a small business into an intelligent enterprise. The ultimate goal of this chapter is to provide small businesses with some consistent theories and practices that may help improve their competitiveness in a turbulent world.

KNOWLEDGE MANAGEMENT IN SMALL BUSINESS

What is Knowledge Management?

Karl Wigg is credited with coining the term "knowledge management" (KM) at a 1986 Swiss Conference sponsored by the United Nations International Labor Organization. He defined KM as "the systematic, explicit, and deliberate building, renewal, and application of knowledge to maximize an enterprise's knowledge-related effectiveness and returns from its knowledge assets" (Wigg, 1999). Thus, KM represents an organization's ability to capture, organize, and disseminate knowledge to help create and maintain competitive advantage. It is becoming widely accepted as a key part of the strategy to use expertise to create a sustainable competitive advantage in today's business environment. It enables the organization to maintain or improve organizational performance based on experience and knowledge. It also makes this knowledge available to organizational decision-makers and for organizational activities (Beckman, 1999; Pan & Scarbrough, 1999). Therefore, we can assert that knowledge management represents a key strategy in creating and sustaining an intelligent enterprise, capable of outperforming its competitors.

Using KM in Small Business

Why is it important for small businesses to use knowledge management to become "learning organizations" or "intelligent enterprises"? According to Wong et al. (1997), "Many of the factors which have promoted the growth of SMEs also require their managers to acquire new skills. In fast-growing small firms, the management team will be constantly developing and the skills needed will change as both cause and effect of the development of the firm itself." The bottom line is that for a small business to succeed and thrive in a changing world, it must continually learn and adapt better and faster than its competitors. Knowledge management provides the tools and strategies to achieve this (Anderson & Boocock, 2002).

Guimaraes (2000) further suggests that small businesses face greater pressures from chains owned by large corporations, increased regulations and politics, and greater competition due to increasing business globalization. He asserts that innovation, facilitated by knowledge management, may be the key to their survival and success in difficult times. Chaston et al. (2001) support this view in their statement: "Organizational learning [knowledge management] is increasingly being mentioned in the literature as a mechanism for assisting small firm survival". It is "the most effective and practical way through which to increase Small and Medium-Size Enterprise (SME) sector survival rates during the early years of the new millennium". They contend that by assisting employees and facilitating their learning and knowledge sharing, they can creatively develop new products, better and more efficient processes, and identify new ways of building better relationships with customers. Thus, it appears that knowledge management techniques of acquiring, sharing and effectively using knowledge may represent a crucial means of transforming a small business into an intelligent enterprise, resulting in improved performance by facilitating innovation, idea creation, and operating efficiencies.

Influence of Adoption and Diffusion

How do adoption and diffusion factors influence KM in small businesses and their goal of becoming an intelligent enterprise? By understanding factors that facilitate the adoption and diffusion of innovations, small businesses may improve their chances of success in a knowledge management initiative. Based on many years of adoption and diffusion of innovations research, Rogers (1995) developed a model often considered the foundation for the adoption and diffusion of innovations. We include strategies and processes in the definition of "innovations" in the context of this chapter. This model proposes three main elements influencing the adoption and diffusion of innovations, including: the innovation, communication channels, and social systems.

Based on the research of Rogers and others, the factors that appear to significantly influence adoption and diffusion include the relative advantage of an innovation (the degree to which the innovation is perceived as better than what it supercedes), which is positively related to its rate of adoption and continued and effective use and the influence of culture and social systems. The social systems similarly influence people's attitudes and willingness to adopt new processes or technologies. Finally, communication channels such as mass communication and interpersonal channels have been found to be effective promotional avenues to facilitate the successful awareness and use of a new process or technologies. Other studies propose that technological change within organizations represents a cumulative learning process where firms will seek to improve and diversify their technology in areas that enable them to build upon their current strategies in technology (Alange et al., 1998). Thus, prior experience appears to influence the willingness to adopt and the rate of adoption and diffusion in addition to Rogers' variables. The concept of absorptive capacity (Cohen & Levinthal, 1990) further suggests that an organization's ability to absorb new knowledge or for an innovation to diffuse throughout is based on its prior experience with this knowledge or innovation. In terms of creating a learning organization or an intelligent enterprise, this theory says that the greater the absorptive capacity of the organization, the greater is the ability of its employees to absorb and use new knowledge effectively.

APPLICATIONS TO SMALL BUSINESS

How can these theories be applied to a small business for transformation into an intelligent enterprise? First, relying on Rogers' classic theories, a small business can easily communicate the advantages of these new technologies and practices using mass media channels, such as company newsletters, e-mail, or company meetings. After making people aware of the new KM system, the business can use interpersonal channels to effectively persuade people to try them and continue using them. By using homophilous colleagues (individuals with similar attributes such as common beliefs, education, social status and values), a small business can more effectively persuade people to adopt and then use the KM systems. These "knowledge champions" represent very important motivators and influencers because they are trusted and respected by their peers (Jones et al., 2003). This is very important because the literature is replete with cases of companies investing in new technologies and new management strategies, which are simply viewed with skepticism as the "latest fad". However, by carefully selecting peers who are trusted and respected, the adoption and diffusion process can be greatly facilitated.

Similarly, the literature describes the huge influence of culture on the effectiveness of KM systems and the development of a learning organization (intelligent enterprise). Rogers' theories can be effectively applied to the cultural aspect as well. The effect of norms, opinion leaders, and change agents can exert a profound influence on the adoption and diffusion of an innovation throughout a social system. This is because norms (culture) can exert a powerful influence on people's willingness to accept or reject an innovation depending on whether it is compatible with their existing values and norms. Therefore, by using change agents as cultural influencers, small businesses can greatly enhance the transition to becoming a learning organization/ intelligent enterprise while using knowledge management systems to provide competitive advantages. Finally, in an organizational social system, such as within a small business, a powerful individual within the organization, such as the business owner, can also exert a strong influence on the adoption and diffusion of a KM system as well as facilitating a cultural shift to becoming a learning organization. Table 1 summarizes these factors.

FUTURE TRENDS

As mentioned, small businesses often face major challenges of coping with resource deprivation. This includes not only fewer technological resources, but also less focused expertise to enable them to make critical decisions or improve

Table 1. Contributing factors to the adoption & diffusion of innovations

Success Factor	Characteristic
Innovation:	
o Relative advantage	o The perceived benefit from the innovation that makes it superior to existing tools or processes.
o Compatibility	o How well the innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters.
o Complexity	o How difficult it is to understand and use.
o Triability	o Ability to experiment with the innovation.
o Observability	o Ability to see tangible results from using it.
Communication Channels:	
o Type of communication channel	o **Communication Type:** Mass media: used for initial awareness of innovation versus interpersonal: used to persuade potential people about benefits.
o Type of individual	o **Individual Type:** Homophilous; opinion leader, knowledge champion.
Social Systems (Culture):	
o Organizational Leaders (Change Agents)	o People in a position of authority who can make the adoption decision.
o Opinion Leaders (Peers)	o Those individuals who can exert a positive influence on others to adopt and use an innovation; individuals who have similar attributes such as common beliefs, education, social status and values, who can persuade their peers to adopt the new system and change values and norms within the culture.
o Prior knowledge/ experience/ attitude towards innovation	o Attitudes and prior experience and knowledge may influence the adoption and diffusion of an innovation. The theory of absorptive capacity tells small businesses that the more knowledge they provide their employees, the greater their capacity to absorb more and become a more proactive learning organization/intelligent enterprise.

products or processes. They need to learn how to learn, change, and adapt better and faster than their competitors and better meet the needs of their customers. By understanding how they can facilitate a knowledge sharing initiative, a small business may be able to make better use of scarce resources and become more intelligent than their competitors; become better at learning, innovation and creativity. For a small business to increase the speed and effectiveness of the diffusion process for a knowledge management initiative or other processes/technologies, it may be important for them to understand the components of an innovation, communication channels, and/or social systems within the context of a small business environment.

Therefore, incorporating a knowledge management strategy holds some promise as a mechanism for small businesses to improve performance. However, the "build it and they will come" philosophy may be simplistic and an investment in knowledge sharing technologies may be wasteful if the systems are not used effectively. Therefore, small businesses should be aware of the issues associated with adoption and diffusion of knowledge management practices.

Similarly, small businesses should understand that creating a learning organization/ intelligent enterprise potentially involves huge cultural changes. Thus, a major challenge is whether a small business owner is interested in fundamentally changing the culture of the organization, including the reward and recognition structures. For example, Pan and Scarbrough (1999, 2000) found that the major challenge to implementing a knowledge management initiative was successfully overcome when the CEO initiated cultural changes that actively promoted and rewarded knowledge acquisition, knowledge sharing, and knowledge use. This led to significant performance improvements such as considerably reduced time in process for product development, reduced costs and improved customer satisfaction. However, this involved a complete commitment to cultural change by a new CEO, who made dramatic changes in the culture and the reward/recognition structures and company policies.

CONCLUSION

With respect to opportunities and challenges for SMEs, knowledge management appears to represent a mechanism for survival, growth and prosperity. As knowledge management continues to diffuse throughout the global business world, the competitive pressures may necessitate some form of KM as a pre-requisite for survival. Therefore, implementing these diffusion methods should prove beneficial to small business owners and operators.

Small businesses can benefit from understanding the factors associated with diffusion, including Roger's five major elements. Another important consideration for small businesses is the cultural issues surrounding their organizations and resources issues that will prove important to employees. By understanding these issues, small businesses may be able to tailor the adoption and diffusion of technologies or a knowledge sharing system to their unique situation, thus improving their chances for success.

While the small business studied represents only one situation, it is interesting that several consistencies with the literature emerged, lending some possible connections and conclusions between the effective diffusion of knowledge management systems and a causal relationship with improved performance. The implication is that knowledge management can facilitate the creation of a learning organization or an intelligent enterprise. This improves creativity and innovation that further enhances productivity, problem solving and customer satisfaction. By promoting a culture that continually learns and improves, organizations can develop a sustainable competitive advantage that is not easily imitated by competitors.

Chapter 6.16
Transforming Small Businesses into Intelligent Enterprises through Knowledge Management

Nory B. Jones
University of Maine Business School, USA

Jatinder N. D. Gupta
University of Alabama in Huntsville, USA

ABSTRACT

As small businesses struggle to survive in the face of intense competitive pressures, an emerging strategy to help them involves using knowledge management tactics to harness their intellectual capital and improve their sustainable competitive advantage. This chapter discusses the issues involved with the transformation of small businesses into intelligent enterprises via knowledge management tools and strategies. However, because a "build it and they will come" approach usually leads to failed initiatives, this chapter further addresses the issues of how small businesses can successfully incorporate adoption and diffusion theories to help them effectively transform themselves into successful learning organizations or intelligent enterprises. Finally, a case study from one small business is presented to validate some of the theories.

INTRODUCTION

In the last decade, the importance of knowledge as a source of sustainable competitive advantage has gained widespread acceptance. Business practitioners and academics alike recognize that what is "between the ears" (Tiwana, 2000) of their employees represents the source of creativity and innovation that nourishes and sustains the organization. Furthermore, the ability to harness the intellectual capital in an organization probably represents the most important aspect relating to the creation of an intelligent enterprise.

However, most research on the topic of knowledge management (KM) and intellectual capital has focused on larger organizations. Because small businesses account for a major portion of the total number of businesses, jobs, and growth in many world economies (Wong & Radcliff, 2000), we need to understand the impact of knowledge management on small businesses as well. We need to understand the correlation between knowledge management practices, the ability of a small business to transform itself into an intelligent enterprise and any resulting performance or competitive improvements KM may provide.

The fact that small businesses impact world economies is well documented. In the United States, The U.S. Small Business Administration's "Small Business Economic Indicators for 1999 (2001) states, "Small businesses continued to employ more workers than large companies; they employed 68.2 million people in 1999 or 58% of the private-sector workforce." In Australia, there are about 951,000 small businesses in the private nonagricultural sector, employing 3.1 million people (Shaper & Raar, 2001). Kolle (2001) similarly states, "SMEs are the backbone of what makes Hong Kong special in world trade." Small and medium sized enterprises (SMEs) similarly account for a large percent of businesses and are responsible for the net job creation in many economies (Wong & Radcliffe, 2000).

However, the failure rate for small businesses is staggering. According to Dun & Bradstreet reports, "Businesses with fewer than 20 employees have only a 37% chance of surviving four years (of business) and only a 9% chance of surviving 10 years" (Holland, 1998). Why are small businesses so susceptible to failure? According to Wong & Radcliffe (2000), "SMEs must contend with challenges that are not as pressing in large organizations. First, they are susceptible to 'resource poverty' in technology and recruitment. They are also susceptible to external forces such as competition and changes in government regulations. They often have limited access to capital and money markets and sometimes are forced to make critical decisions without the aid of internal specialists." In addition, if knowledge is concentrated in a few key employees, the company becomes vulnerable to resource deprivation if these people leave and take their valuable knowledge with them.

Because a "build it and they will come" approach to knowledge management usually does not work, this chapter also discusses and integrates the concepts of adoption and diffusion of innovations with knowledge management theories to help transform a small business into an intelligent enterprise. It does so by presenting the results from the study of one small business. The ultimate goal of this chapter is to provide small businesses with some consistent theories and practices that may help improve their competitiveness in a turbulent world.

The rest of the chapter is organized as follows. First, the role and importance of knowledge management in a small business to create an intelligent enterprise is discussed. This discussion includes the ways a small business can enhance the adoption and diffusion of knowledge management systems to facilitate competitive advantage. Second, existing research on relationships between knowledge management and a sustainable competitive advantage in small businesses is examined to identify some challenges inherent in the process of developing successful knowledge management systems. A case study is then presented to substantiate or refute the offered theories in the context of a small business. This case study is also used to understand the process required to obtain sustained performance improvements in a small business and to transform it into an intelligent enterprise. Finally, the chapter concludes with a summary and limitations of the study findings and some fruitful directions for future research.

ROLE OF KNOWLEDGE MANAGEMENT IN SMALL BUSINESS

Why is it important for small businesses to use knowledge management to become "learning organizations" or "intelligent enterprises?" According to Wong et al. (1997), "Many of the factors which have promoted the growth of SMEs also require their managers to acquire new skills. In fast-growing small firms, the management team will be constantly developing and the skills needed will change as both cause and effect of the development of the firm itself." The bottom line is that for a small business to succeed and thrive in a changing world, they must continually learn and adapt better and faster than their competitors. Knowledge management provides the tools and strategies to achieve this (Anderson & Boocock, 2002).

What is Knowledge Management?

Karl Wigg is credited with coining the term, "knowledge management" (KM), at a 1986 Swiss Conference sponsored by the United Nations International Labor Organization. He defined KM as "the systematic, explicit, and deliberate building, renewal, and application of knowledge to maximize an enterprise's knowledge-related effectiveness and returns from its knowledge assets." Thus, KM represents an organization's ability to capture, organize, and disseminate knowledge to help create and maintain competitive advantage. It is becoming widely accepted as a key part of the strategy to use expertise to create a sustainable competitive advantage in today's business environment. It enables the organization to maintain or improve organizational performance based on experience and knowledge. It also makes this knowledge available to organizational decision-makers and for organizational activities (Beckman, 1999; Pan & Scarbrough, 1999). Therefore, we can assert that knowledge management represents a key strategy in creating and sustaining an intelligent enterprise, capable of outperforming its competitors.

Karl Wigg (1999) also described the benefits of a knowledge management system as reducing costs due to benchmarking and sharing best practices between different groups inside and outside the organization, decreasing time-in-process, reducing re-work and increasing customer satisfaction and quality. Innovations in products, services and processes can increase due to sharing of knowledge among different functional areas. Increased knowledge of customers often results in the ability to better satisfy their needs, resulting in increased market penetration and increased profit margins (Reisenberger, 1999).

In other words, if an organization can collect and store the knowledge (both tacit and explicit) of its employees in an easily accessible and searchable organizational memory mechanism, when an employee leaves the organization, all their knowledge, skills, and expertise do not necessarily leave with them. With an effective knowledge management system, the firm can prevent knowledge gaps when they lose their employees, who represent valuable sources of knowledge. Rather, that expertise and knowledge can be retained in the organizational memory. In a small business, this represents a crucial asset. Finding a way to leverage a small business' intellectual capital represents a means of lessening the problem of resource poverty and employee resignations.

Using KM in Small Business

Guimaraes (2000) further suggests that small businesses face greater pressures from chains owned by large corporations, increased regulations and politics, and greater competition due to increasing business globalization. He asserts that innovation, facilitated by knowledge management, may be the key to their survival and success in difficult times. Chaston et al. (2001) support this view in their statement, "Organizational learning [knowledge management] is increasingly being mentioned in the literature as a mechanism for assisting small firm survival." It is "the most effective and practical way through which to increase SME sector survival rates during the early years of the new millennium." They contend that by assisting employees and facilitating their learning and knowledge sharing, they can creatively develop new products, better and more efficient processes, and identify new ways of building better relationships with customers. Thus, it appears that knowledge management techniques of acquiring, sharing and effectively using knowledge may represent a crucial means of transforming a small business into an intelligent enterprise, resulting in improved performance by facilitating innovation, idea creation, and operating efficiencies.

Influence of Adoption and Diffusion

How do adoption and diffusion factors influence KM in small businesses and their goal of becoming an intelligent enterprise? By understanding factors that facilitate the adoption and diffusion of innovations, small businesses may improve their chances of success in a knowledge management initiative. Because these theories emerged from research on both large and small organizations, they serve as initial models for research in most organizations. It has been shown repeatedly that a "build it and they will come" approach usually will not work. Therefore, if small businesses understand the factors that motivate executives and associates within a small business to adopt or reject these KM practices and philosophies, KM champions can plan and implement a KM initiative with greater success.

Based on many years of adoption and diffusion of innovations research, Rogers (1995) developed a model often considered the foundation for the adoption and diffusion of innovations. We include strategies and processes in the definition of "innovations" in the context of this chapter. This model proposes three main elements influencing the adoption and diffusion of innovations including: the innovation, communication channels, and social systems.

The primary success factors are related to the innovation. According to Rogers, five main attributes of innovations can predict an innovation's rate of adoption and diffusion including: (a) the relative advantage of an innovation (the degree to which the innovation is perceived as better than what it supersedes) is positively related to its rate of adoption and continued and effective use. (b) The perceived compatibility (the degree to which an innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters) of an innovation is positively related to its rate of adoption and continued and effective use. Furthermore, if the technology can be standardized in its use, the rate of adoption and diffusion will increase (Alange et al., 1998). (c) The perceived complexity (the degree to which an innovation is perceived as relatively difficult to understand and to use) of an innovation is negatively related to its rate of adoption. (d) The perceived triability (the degree to which an innovation may be experimented with on a limited basis) is positively related to its rate of adoption. (e) The perceived observability (the degree to which the results of an innovation are visible to others) is positively related to its rate of adoption.

Other studies propose that technological change within organizations represents a cumulative learning process where firms will seek to improve and diversify their technology in areas that enable them to build upon their current strategies in technology (Alange et al., 1998). Thus, prior experience appears to influence the willingness to adopt and the rate of adoption and diffusion in addition to Rogers' variables. The concept of absorptive capacity (Cohen & Levinthal, 1990) further suggests that an organization's ability to absorb new knowledge or for an innovation to diffuse throughout is based on its prior experience with this knowledge or innovation. In terms of creating a learning organization, or an intelligent enterprise, this theory says that the greater the absorptive capacity of the organization, the greater is the ability of its employees to absorb and use new knowledge effectively.

Applications to Small Business

How can these theories be applied to a small business for transformation into an intelligent enterprise? First, relying on Rogers' classic theories, a small business can easily communicate the advantages of these new technologies and practices using mass media channels, such as company newsletters, e-mail, or company meetings. After making people aware of the new KM system, the business can use interpersonal channels to effectively persuade people to try them and continue using them. By using homophilous colleagues (individuals with similar attributes such as common beliefs, education, social status and values), a small business can more effectively persuade people to adopt and then use the KM systems. These "knowledge champions" represent very important motivators and influencers because they are trusted and respected by their peers (Jones et al., 2003). This is very important because the literature is replete with cases of companies investing in new technologies and new management strategies, which are simply viewed with skepticism as the "latest fad". However, by carefully selecting peers who are trusted and respected, the adoption and diffusion process can be greatly facilitated.

Similarly, the literature describes the huge influence of culture on the effectiveness of KM systems and the development of a learning organization (intelligent enterprise). Rogers' theories can be effectively applied to the cultural aspect as well. The effect of norms, opinion leaders, and change agents can exert a profound influence on the adoption and diffusion of an innovation throughout a social system. This is because norms (culture) can exert a powerful influence on people's willingness to accept or reject an innovation depending whether it is compatible with their existing values and norms. Therefore, by using change agents as cultural influencers, small businesses can greatly enhance the transition to becoming a learning organization/ intelligent enterprise while using knowledge management systems to provide competitive advantages. Finally, in an organizational social system, such as within a small business, a powerful individual within the organization, such as the business owner, can also exert a strong influence on the adoption and diffusion of a KM system as well facilitating a cultural shift to becoming a learning organization.

Both leaders and opinion leaders often need to help workers unlearn or abandon earlier, often deeply entrenched practices in order to break the status quo inertia before a new technology or system will be fully adopted and used. Subordinates will often observe the behavior of their managers to find out what is really important, emphasizing the need for involvement by managers and top executives in this process. The CEO's innovativeness and IS knowledge were also found to contribute positively to the adoption decision (Alange et al., 1998; Thong, 1999; Daugherty et al., 1995).

In several studies on small business (Thong, 1999; Daugherty et al., 1995), results showed that businesses with a positive attitude toward technology were more likely to adopt, emphasizing the importance of relative advantage, compatibility, and complexity. The CEO's innovativeness and IS knowledge were also found to contribute positively to the adoption decision. In addition, the greater the employee knowledge and experience with technology, the more likely was the adoption decision as well as continued use of the technology. In a study of technology uptake in small businesses in New Zealand (McGregor &

Gomes, 1999), they found that small businesses required extensive external sources of information to facilitate first the awareness of need for the adoption of new technologies. Therefore, in terms of relevance to creating an intelligent enterprise via KM systems, the moral of the story for small businesses is to provide a compelling reason for employees to create an intelligent enterprise, have strong leadership support and a culture that facilitates this endeavor. Table 1 summarizes these factors.

Inherent Challenges

As mentioned, small businesses often face major challenges in coping with resource deprivation. This includes not only fewer technological resources, but also less focused expertise to enable them to make critical decisions or improve products or processes. They need to learn how to learn, change, and adapt better and faster than their competitors and better meet the needs of their customers. By understanding how they can

Table 1. Contributing factors to the adoption and diffusion of innovations

Success Factor	Characteristic
Innovation:	
o Relative advantage	o The perceived benefit from the innovation that makes it superior to existing tools or processes.
o Compatibility	o How well the innovation is perceived as consistent with the existing values, past experiences, and needs of potential adopters.
	o How difficult it is to understand and use
o Complexity	o Ability to experiment with the innovation
o Triability	o Ability to see tangible results from using it.
o Observability	
Communication Channels:	
o Type of communication channel	o **Communication Type**: Mass media: used for initial awareness of innovation vs. Interpersonal: used to persuade potential people about benefits.
o Type of individual	o **Individual Type**: Homophilous; opinion leader, knowledge champion.
Social Systems (Culture):	
o Organizational Leaders (Change Agents)	o People in a position of authority who can make the adoption decision
o Opinion Leaders (Peers)	o Those individuals who can exert a positive influence on others to adopt and use an innovation; individuals who have similar attributes such as common beliefs, education, social status and values, who can persuade their peers to adopt the new system and change values and norms within the culture.
o Prior knowledge/ experience/ attitude towards innovation	o Attitudes and prior experience and knowledge may influence the adoption & diffusion of an innovation. The theory of absorptive capacity tells small businesses that the more knowledge they provide their employees, the greater their capacity to absorb more and become a more proactive learning organization/intelligent enterprise.

facilitate a knowledge sharing initiative, a small business may be able to make better use of scarce resources and become more intelligent than their competitors; become better at learning, innovation and creativity. For a small business to increase the speed and effectiveness of the diffusion process for a knowledge management initiative or other processes/technologies, it may be important for them to understand the components of an innovation, communication channels, and/or social systems within the context of a small business environment.

Therefore, incorporating a knowledge management strategy holds some promise as a mechanism for small businesses to improve performance. However, the "build it and they will come" philosophy may be simplistic and an investment in knowledge sharing technologies may be wasteful if the systems are not used effectively. Therefore, small businesses should be aware of the issues associated with adoption and diffusion of knowledge management practices.

Similarly, small businesses should understand that creating a learning organization/intelligent enterprise potentially involves huge cultural changes. Thus, a major challenge is whether a small business owner is interested in fundamentally changing the culture of the organization including the reward and recognition structures. For example, Pan and Scarbrough (1999, 2000) found that the major challenge to implementing a knowledge management initiative was successfully overcome when the CEO initiated cultural changes that actively promoted and rewarded knowledge acquisition, knowledge sharing, and knowledge use. This led to significant performance improvements such as considerably reduced time in process for product development, reduced costs and improved customer satisfaction. However, this involved a complete commitment to cultural change by a new CEO, who made dramatic changes in the culture and the reward/recognition structures and company policies.

EMPIRICAL INVESTIGATION

In an effort to validate or refute the literature, a small study was undertaken to examine factors influencing the diffusion, as well as the continued, effective use of a knowledge management collaborative technology within one small business. Knowledge sharing is acknowledged as a critical component within a knowledge management system. Because this small business, a contract research organization, was considered knowledge intensive, the effective diffusion and implementation of a knowledge sharing technology was considered a significant goal.

In this study, an assumption was made that within an organizational setting, top managers make most adoption decisions. Therefore, the adoption by subordinate users throughout the organization represented a forced adoption. Therefore, the initial adoption decision was not considered. Rather, the primary focus was on the continued and effective use of the technology after the initial adoption; a specific focus on how and why people might be willing and motivated to use or to resist using a particular technology effectively.

The sample consisted of 37 users of a knowledge-sharing collaborative technology. This technology, called BSCW (Basic Support for Cooperative Work, http://bscw.gmd.de/) represented a Web-based system that enables collaboration over the Web, allowing users to share knowledge irrespective of time or location. The convenience sample was drawn from a total user population of approximately 50. There were approximately 250 employees in this small business. E-mail was sent to all 50 users requesting an in-depth interview. Thirty-seven people agreed to be interviewed on their perceptions of use, benefits, and obstacles in knowledge sharing. This sample included five of the six top executives, who represented the heaviest users of the system. These individuals included the president/CEO, three of the four vice presidents, and the chief financial officer. In addition, five of the six business development (marketing) managers, who represented moderate users, were interviewed as well as the director of information systems. Finally, from the remaining pool of approximately 37 occasional-moderate users, 20 were selected by using a quota system to represent the remaining functional areas. Eight managers, four quality-assurance/compliance, and eight data entry people agreed to be interviewed. In addition, actual usage of this collaborative technology was monitored on a daily basis during an eight-month study period.

While this was an exploratory study in one small business, the results both supported and refuted the literature. One general finding was that, in this business, not all of the factors were found to be equally important in the diffusion and effective use of a knowledge sharing system.

The major finding was that perceived relative advantage was the major influence on usage to facilitate knowledge sharing. The second major finding was that leadership influence was also very important in the effective use of a knowledge sharing system. While this was a forced adoption situation, this finding is based on the issue of accountability in using the system. When employees knew that they were being monitored and evaluated in terms of their use, it motivated their effective and continued use of this knowledge sharing system. Therefore, the second finding combines the aspect of leadership influence with a reward/compensation structure that is integrally tied in with a knowledge sharing initiative.

Performance Improvements

Did this create performance improvements and make this small business a better intelligent enterprise? Respondents clearly articulated their enthusiasm for using BSCW to share information and knowledge with statements emphasizing the large efficiency, timesavings, and quality gains derived from having access to needed information regardless of time or physical location. Another benefit cited from relative advantage was the ability to share information with multiple users as well as the issue of accountability introduced by the collaborative system. Accountability provided by a version control system was perceived as increasing quality and timeliness of input. Therefore, it does appear that the successful adoption and diffusion of this knowledge management system did contribute to some extent to some performance gains in the organization. It could also be asserted that this small business did increase its learning capability and became a better and more effective intelligent enterprise because people who used the KM systems were able to better share knowledge, solve problems, and increase efficiency and customer satisfaction.

Adoption of Knowledge Management

Why did people in this small business adopt this KM system? Again, relative advantage emerged as the factor that contributed to the adoption and continued, effective use of this knowledge sharing system. The employees could clearly see that using this system saved them time and improved their performance. They were also able to see that sharing ideas led to better ideas and better solutions to problems.

Many researchers including Pan and Scarbrough (1999), Reisenberger (1999), and Puccinelli (1998) among others stressed the critical need for strong and active executive commitment to and support of a collaborative technology to facilitate knowledge sharing. They suggested that leaders not only champion the collaborative system and knowledge sharing, but also possess the power and authority to invest in the needed technology, create the collaborative culture to enable it, and to create reward/incentive structures to reinforce it. In this particular organization, the forced adoption of a new technology appeared to have a powerful influence on adoption and continued, effective use of the collaborative technology to facilitate knowledge sharing.

Scheraga (1998) suggests that the best way to overcome employee resistance to sharing their knowledge was to reward them for it. Reisenberger (1999) similarly contends that top management needs to develop new reward systems to recognize and reward knowledge sharing activities. Pan and Scarbrough (1999) documented the success of rewarding employees for sharing their valuable knowledge at Buckman Laboratories. Rogers (1995) found that the main function for incentives was to increase the degree of relative advantage for the innovation. In this study, many respondents in the interviews acknowledged the benefit of some sort of incentive or reward system with the belief that people do what they are rewarded for. Interestingly, a large number of respondents indicated that incentives would be useful to initially help people overcome their fear of or resistance to using a new technology or sharing knowledge.

Lessons Learned

By understanding the factors that motivate employees in a small business to adopt and embrace the new systems and culture necessary for knowledge management, it may be possible for small business owners and managers to recreate this. The first factor involved the importance of relative advantage. Perhaps we can speculate that human nature provides the answer here. The "what's in it for me" effect may provide the common sense answer. When people see a clear reason for using the new technology such as reduction in time leading to greater efficiency in their work, they see a compelling reason to actively use this new technology regardless of the size of the company. Therefore, in any organization, it is wise to demonstrate the benefits (relative advantage) it will provide the users.

In addition, consistent with the literature, was the need to gain top leadership commitment and support before introducing new technologies for effective diffusion. Inherent in this recommendation is a reward/compensation structure directly related to the initiative. Users should be held directly accountable for their relevant and valuable contributions to knowledge sharing as well as use of the system. A direct cause and effect relationship with the annual performance evaluation appears to work well.

Another consistency with the literature was that users expect innovations to be compatible with their normal work routines and easy to use. This is especially important in a small business where resources for training and time are especially scarce. Users also expect a knowledge sharing system to be recent and relevant. The element of trust is also crucial. Davenport and Prusak (2000) explain that if employees do not trust the information or knowledge contained in the system, they will not use it. Similarly, if people do not trust that they will be rewarded for sharing their valuable knowledge, they will not be motivated to do so.

Limitations of the Research

One small study cannot provide the generalizations needed to promote acceptance of theories by small business practitioners. However, it was rewarding to see that the results of this one small study did reinforce the findings of many researchers from larger studies including the importance of relative advantage, leadership support, and cultural change. In addition, the context of this study was industry specific, focusing on a contract research business in the scientific arena. Therefore, we cannot assert that these findings would be generalizable to other, dissimilar industries. However, in the context of understanding human nature, it seems reasonable to speculate that these variables may be consistent across different industries.

Some Fruitful Directions for Future Research

Based on the limitations mentioned in the previous section, we recommend continued research on the strongest variables including relative advantage, leadership support, and cultural change in different industries and across different cross sections of SMEs with varying sizes, cultures, and product/service lines. In addition, research is greatly needed on causal relationships between the use of knowledge management practices and their impact on real transformation into learning organizations/intelligent enterprises, and whether significant performance improvements can be measured and correlated. The field of metrics associated with knowledge management, intelligent enterprises and specific performance improvements is still in its infancy and represents a fruitful line of research in itself.

CONCLUSION

With respect to opportunities and challenges for SMEs, knowledge sharing appears to represent a mechanism for survival, growth and prosperity. As knowledge management continues to diffuse throughout the global business world, the competitive pressures may necessitate some form of KM as a prerequisite for survival. Therefore, implementing these diffusion methods should prove beneficial to small business owners and operators.

Small businesses can benefit from understanding the factors associated with diffusion including Rogers' five major elements. Another important consideration for small businesses is the cultural issues surrounding their organizations and resource issues that will prove important to employees. By understanding these issues, small businesses may be able to tailor the adoption and diffusion of technologies or a knowledge sharing system to their unique situation, thus improving their chances for success.

While the small business studied represented only one situation, it is interesting that several consistencies with the literature emerged, lending some possible connections and conclusions between the effective diffusion of knowledge management systems and a causal relationship with improved performance. The implication is that knowledge management can facilitate the creation of a learning organization or an intelligent enterprise. This improves creativity and innovation that further enhances productivity, problem solving and customer satisfaction. By promoting a culture that continually learns and improves, organizations can develop a sustainable competitive advantage that is not easily imitated by competitors.

Chapter 6.17
Market of Resources as a Knowledge Management Enabler in VE

Maria Manuela Cunha
Polytechnic Institute of Cavado and Ave, Portugal

Goran D. Putnik
University of Minho, Portugal

INTRODUCTION

Knowledge is, undoubtedly, an indispensable asset for organizations to compete effectively (Alavi & Leidner, 2001; Murray, 2002).

New organizational models, such as the virtual enterprise (VE) model, characterized as dynamically reconfigurable information-based global networked structures, are emerging. New technological environments and solutions are being developed to support them, and the importance of knowledge and the capability of managing it by creating the organizational conditions that facilitate the generation, sharing, and application of knowledge are more and more critical.

In a global organization, as defended by Kluge, Stein, and Licht (2001), face-to-face relationships are not possible, giving rise to difficulties in accepting knowledge from outside. This applies more deeply in virtual enterprises (or in virtual organizations) in the interactions among the independent partners who tend more and more to fear the leakage of private knowledge. This situation promotes competition and rivalry and, as suggested by Prahalad and Hamel (1990), impedes collaboration and knowledge sharing, precisely two of the main underlying issues of this organizational model. A supporting environment, such as the market of resources proposed by the authors, is the way to assure effective knowledge management between the members of a virtual enterprise and business strategic alignment enabling the performance improvement of the VE.

In an environment to support VE integration, knowledge management is simultaneously a tool and an object. As a tool, knowledge management can be used by the market of resources to reduce transaction costs in VE integration and VE reconfiguration; as an object, knowledge must be protected and knowledge leakage prevented to assure trust and protection of VE participants.

The broker (an integrating element of the market of resources) is, besides other attributions, responsible for advising the VE owner in identifying and communicating the role of knowledge management within the VE business plan and for ensuring the permanent alignment between business strategy and knowledge strategy within the network of independent enterprises that constitute the VE. The broker must ensure that the global knowledge sharing is not threatened by deficient knowledge management procedures and, simultaneously, that any instance of the VE (as a reconfigurable network) at a given time, is able to respond to the market requirements with its maximum performance, that is, is business aligned.

In this article, we introduce the VE disabling factors and the functionalities for VE integration, briefly present the market of resources as an environment to support VE integration, assuring business alignment and knowledge management, identify the main strengths and problems associated with the implementation of knowledge management functions, and, finally, discuss the main opportunities associated to the implementation and exploitation of the market of resources.

BACKGROUND: VIRTUAL ENTERPRISE INTEGRATION

The virtual enterprise model can be viewed as a global networked and information-based organizational structure in dynamic adaptation (reconfiguration) to the market or business requirements. Virtual enterprises (in a broad sense) are defined as enterprises with integration and reconfiguration capability in useful time, integrated from independent enterprises, primitive or complex, with the aim of taking profit from a specific market opportunity (Byrne, 1993; Camarinha-Matos & Afsarmanesh, 1999; Cunha, Putnik & Ávila, 2000; Preiss, Goldman & Nagel, 1996; Putnik, 2000). After the conclusion of that opportunity, the virtual enterprise dissolves itself. During its lifetime, the VE changes its physical structure (reconfigures) to be permanently aligned with that market opportunity.

We designate, by resource, any function, service, or product provided by independent enterprises (resources providers), candidates to integrate a VE. The resource is a recursive construct; resources can be primitive or complex where a complex resource consists on a meaningful combination of primitive resources.

There are several factors determining the performance of the VE model. In the BM_Virtual Enterprise Architecture Reference Model (BM_VEARM) (Putnik, 2000), the author presents "fast adaptability" or "fast reconfigurability" as the most important characteristic for the competitive enterprise, enabling the agile alignment with the market.

In this section, we introduce the VE disabling factors, the tools proposed to overcome the disabling factors, and the functionalities required to efficiently implement this organizational model.

The Virtual Enterprise Disabling Factors

The main critical aspects associated with the recent concept of dynamically reconfigurable global networked structures; that is, the main factors against networking and reconfigurability dynamics are the transaction costs and the leakage of private knowledge.

In an ideal business environment, a firm makes an informed assessment of the relevant costs, benefits, and risks of outsourcing vs. internal procurement. If there exists a profitable opportunity to outsource a service or operation, the client and the suppliers enter into a contract with full knowledge of the nature of the work, signing a complete and explicit written agreement covering all aspects of the outsourced service and payments, eventually including contingency plans. But in most contractual relationships, things do not happen this way; processes are much more complex than idealized.

In concrete, when integrating a VE rather than outsourcing a service or a set of simple products or operations, difficulties arise. Selection, negotiation, contractualization, and enforcement can be too complex and too delicate. There is a vast spectrum of available resources providers, each with different characteristics, leading to difficult selection and integration decisions.

The costs of outsourcing are composed of both the explicit cost of carrying out the transaction as well as hidden costs due to coordination difficulties and contractual risks. The major costs associated with outsourcing include (1) the transaction costs and (2) the leakage of private knowledge.

Transaction Costs

Transaction costs include the time and expense of negotiating, writing, and enforcing contracts. They include the adverse consequences of opportunistic behavior, as well as the costs of trying to prevent it. In the VE model, transaction costs are the firm (re)configuration costs, associated with partners search, selection, negotiation, and integration as well as permanent monitoring and the evaluation of the partnership performance (Cunha & Putnik, 2003a). If externalizing functions can involve high transaction costs, networking relies intensively on extending the enterprise boundaries, partnering functions, and the VE model is extremely dependent not only on networking but on dynamically reconfiguring. This way, the implementation of the VE concept requires tools to overcome the transaction costs barrier, and knowledge management is a tool, assured by the market of resources, supported by an intelligent knowledge base and by the human brokerage function.

Leakage of Private Knowledge

The preservation of firm's knowledge on organizational and management processes is the firm's competitive factor.

A firm's private knowledge is based on information that no one else knows and gives a firm an advantage in the market. Most of the time, this private knowledge is a core competitive advantage that distinguishes a firm from its competitors (Prahalad & Hamel, 1990). It may concern production know-how, product design, or consumer information.

Networking or partitioning tasks between resource providers increases the risk of losing control of such type of information, which only through complete contractual agreements, could be safeguarded and, furthermore, through an environment assuring trust and accomplishment of the duty of seal. The implementation of the VE model enables the preservation of the firm's knowledge.

Overcoming the Disabling Factors

The implementation of networked and dynamically reconfigurable organizations requires the existence of tools and environments that overcome these two disabling factors, improving knowledge management and allowing dynamics as high as required to assure business alignment. The main tools suggested in the BM_VEARM (Putnik, 2000) for managing, controlling, and enabling networking and dynamics are:

- The market of resources is the environment for enabling and management of efficient configuration and assuring virtuality at low transaction costs and reduced risk of knowledge leakage, this last requiring particular attention by the definition of knowledge management procedures.
- The broker or organization configuration manager is the main agent of agility and virtuality, acting either between two operations of the VE (off-line reconfigurability, providing agility only) or online with the operation (online reconfigurability, providing virtuality and a higher level of agility).
- Virtuality that makes possible the transition from one physical structure (instance) to another in a way that the enterprise or process owner is not affected by the system reconfiguration and is not aware of the reconfiguration (the underlying service structure and reconfiguration process are hidden).

Functionalities for Virtual Enterprise Integration

The organizational challenges of (1) partitioning tasks among partners in the distributed networked environment so that they fit and take advantage of the different competencies in an VE, (2) integration of the same, (3) coordination and reconfigurability management in order to keep alignment with the market requirements are of main concern and can determine the success or failure of a VE project.

As discussed in (Cunha & Putnik, 2004, 2005), in order to achieve its maximum competitiveness, that is, to be competitive in delivery time, quality, and cost and to yield satisfactory profit margins, the implementation of the VE model requires a supporting environment assuring two main interrelated aspects (designated virtual enterprise requirements): (1) Reconfigurability dynamics (assuring fast transition between VE instantiations) and (2) Business alignment (maintaining the VE aligned with the market).

An environment designed to assure the two above-mentioned VE requirements should present as main characteristics the ability of (1) flexible and almost instantaneous access to the optimal resources to integrate in the enterprise, negotiation process between them, selection of the optimal combination and its integration; (2) design, negotiation, business management, and manufacturing management functions independently from the physical barrier of space; (3) minimization of the reconfiguration and integration time; and (4) managing knowledge within each instance of the integrated network.

The first characteristic implies the existence of a market of independent candidate resources for integrating a virtual enterprise. This market role is (a) to provide the environment and technology and the corresponding procedure protocols, that is, an open system architecture for the efficient access to resources, efficient negotiation between them, and its efficient integration and (b) to provide a domain for selection of participant resources providers in a VE, large enough to assure good options.

The second characteristic implies the utilization of advanced information and communication technologies to the operation of the market of independent resources, that is, technologies providing technical conditions to efficiently access to the globally distributed resources providers, efficient negotiation between them, and its efficient integration.

The third characteristic is necessary in order to provide flexibility, as high as possible, that is, reconfigurability as fast as possible.

The fourth characteristic is assured by the broker, supported by the market of resources knowledge base and information infrastructure by specific contractual agreements settled by the market of resources between the involved parties in a given VE instance and by a VE management regulation.

Any environment attempting to support the VE model, that is, to assure VE dynamic integration and business strategic alignment should implement a set of functionalities traducing the VE requirements, which, as proposed in Cunha, Putnik and Carvalho (2002), include:

- Responsiveness or almost real-time answer, as one instantaneous physical structure (or one instance) of a virtual enterprise may last (on the limit) only for a few days or even hours. It should be possible to reduce negotiation time and time-to-contract.
- The permanent alignment of the VE with the market (business) requirements, which can justify a dynamic process of VE performance evaluation and the analysis of reconfiguration opportunities.
- The ability to find the right potential partners and further efficient negotiation are essential; this should require a normalized description of products, operations, and services (resources) participating in the environment.
- Monitoring the performance of every integrated resource, increasing trust and the highest possible performance of the VE.
- Risk minimization through contractual agreements.
- Provision of knowledge in VE creation/reconfiguration through appropriate algorithms, artificial intelligence support, intelligent knowledge base, and brokerage systems.

MARKET OF RESOURCES: AN ENVIRONMENT FOR VIRTUAL ENTERPRISE INTEGRATION

Offer and demand are usually matched under several different circumstances from unregulated search to oriented search, from simple intermediation mechanisms to the market mechanism, all of them with the possibility of being either manually performed or automated (Cunha, Putnik & Gunasekaran, 2002). A marketplace of resources providers will enable the matching between firms looking for potential partners for integration and firms offering their resources, facilitating VE integration, and offering to participants a larger number of business opportunities.

Several supporting infrastructures and applications must exist before we can take advantage of the VE organizational model such as electronic markets of resources providers, legal platforms, brokerage services, efficient and reliable global information systems, electronic contractualization and electronic negotiation systems, and software tools (Carvalho, Putnik & Cunha, 2002; Cunha, Putnik & Carvalho, 2002).

The authors have proposed the market of resources concept as an alternative to existing applications, which were developed to support isolated activities within supply chains such as partners search and selection, negotiation, and enterprise collaboration but without the purpose of responding to the VE requirements.

The market of resources is an institutionalized organizational framework and service assuring the accomplishment of the competitiveness requirements for VE reconfigurability dynamics, business alignment, quality assurance, trust and optimization in resources utilization, and quick response to market. It is an alternative to the dispersedly developed Internet-based solutions that can be used to support search and selection of partners to integrate in a given supply chain.

The operational aspect of the market of resources consists on an Internet-based intermediation service, mediating offer and demand of resources to dynamically integrate in a VE, assuring low transaction costs (demonstrated in (Cunha & Putnik, 2003a, b)) and the partners' knowledge preservation. Brokers act within the market of resources as intermediation agents for agility and virtuality (Ávila, Putnik & Cunha, 2002) and, simultaneously, as knowledge management promoters and consultants.

In this virtual environment, offer corresponds to participants (enterprises, resources providers) that make their resources available, as potential partners for VE integration, and demand corresponds to the client (or VE owner), the entity looking for a product, components, or operations (resources) to create/integrate/reconfigure a VE to satisfy the customer.

The service provided by the market of resources is supported by (1) a knowledge base of resources and results of the integration of resources in previous VE, (2) a normalized representation of information, (3) intelligent agent and algorithms, (4) a brokerage service, and (5) a regulation covering management of negotiation and integration processes. It is able to offer (1) knowledge for VE selection of resources, negotiation, and its integration; (2) specific functions of VE operation management; and (3) contracts and formalizing procedures to assure the accomplishment of commitments, responsibility, trust, and deontological aspects, envisaging the integrated VE accomplishes its objectives of answering to a market opportunity (Cunha, Putnik & Gunasekaran, 2002).

A comprehensive explanation of the market of resources structure and operation can be found in Cunha et al. (2005).

MARKET OF RESOURCES: AN ENVIRONMENT FOR KNOWLEDGE MANAGEMENT AND BUSINESS ALIGNMENT

In the context of VE integration, by aligning, we mean the actions to be undertaken to gain synergy between business, that is, the market opportunity (or business opportunity) and the provision of the required product with the required specifications at the required time with the lowest cost and the best possible return (financial or other) (Cunha & Putnik, 2005). In particular, we propose alignment strategies between business and the integration of resources in a VE to answer to a market opportunity, supported by the environment of a market of resources.

The Market of Resources Entities and Relationships

As introduced in Cunha and Putnik (2005), the entities present at the market of resources are:

1. Clients (or VE owner): Those looking for a product, components, or operations to integrate a VE, according to a VE project. Information considered relevant concerns the product to be produced and its process plan, the negotiation parameters, project constraints, and so forth.
2. Virtual Enterprise: The set of integrated resources providers respecting the VE project, able to answer to a market opportunity. The VE created/reconfigured is itself a complex entity, constituted by the client and the resources integrated to provide the operations to manufacture the product or its parts. The resulting VE is expected to produce the specified product, according to the process plan defined by the client, respecting all the project constraints. Information considered relevant concerns the network structure, dependencies between the resources providers, the contract and commitments between them and the client, and all the details in order to manage the process.
3. Resources Providers (enterprises registered in the market of resources to specifically provide resources or add value to products or processes): Resources providers are mapped into resources (products and operations). Information considered relevant concerns the enterprise, its structure, products/operations provided, conditions, and negotiation

details. The same enterprise can be present in the market offering several resources.

4. Products (we are including services in this entity): Resources providers are mapped into components or parts of products. Information considered relevant concerns conditions in which resources providers provide each product or part, negotiation details, and availability.
5. Operations: Associated to each component of a product; elementary operations performed by resources providers while executing an operation on a specific product or part. Resources providers are mapped into operations, and operations are mapped into products. Information considered relevant concerns conditions under which resources providers provide each operation, negotiation details, information to allow further production control, and evaluation.

Knowledge Management and Business Alignment in Virtual Enterprise Integration

Business alignment in VE integration is complex and challenging, as alignment has to incorporate immaterial components in the relationships within the integration of resources. It is not just an internal strategy but a set of integrated and interrelated integration strategies that must be verified so that the integrated VE is able to meet the objective giving rise to the VE itself, that is, to meet the market requirements (Cunha et al., 2005). Business strategic alignment is a matter for knowledge management.

The introduction of the VE concept and of the corresponding supporting environments requires the definition of business alignment strategies. If organizations respond to market requirements (end-users requirements), traducing these requirements into a project of VE and pushing them along the process of selection and integration of resources providers under the format of a VE, the role of the market of resources is to assure the permanent (dynamic) alignment of the resulting VE with the market. The market of resources is the environment enabler for efficiency and effectiveness in the integration process, thus, generating, sharing, and using knowledge to strategically align the virtual enterprise with business.

Strategic alignment between business and VE integration involves a mix of dependencies between market requirements, product requirements, and resource providers requirements.

The market of resources must assure the client the alignment between the market and the resources providers selected and integrated in the VE. Also, the market of resources must try to assure that the client has correctly captured the market requirements, which is a task performed by a broker. This way, the process must align the client with the market (business) and then align the resources (by the selection and integration processes) with the client and business (Cunha & Putnik, 2005).

Integrating a VE corresponds to aligning the five entities of the previous section with business. The market of resources is expected to guide the client in aligning the VE with the market opportunity. The process consists on pushing downstream the market requirements.

The referential for alignment proposed in Cunha and Putnik (2005) considers:

1. Market Alignment (alignment with customer or market requirements): Before the creation of the VE, the client traduces the customer requirements into product specifications and projects the system of resources for the VE. The VE project consists on the generic identification of the characteristics of the resources that will accomplish the execution of the process plan to the required product, that is, the process plan that will allow the production of the product verifying the market requirements.

2. Product/Service and Operations Alignment: Aligning the product with the specifications, that is, with the market requirements. Operations provided by the selected resource providers must conduct to the desired product.
3. Resources Providers Alignment: Aligning resources providers with the market requirements involves the verification of which characteristics resources providers must assure so that the client can trust that the selected set of enterprises is able to be integrated in a VE able to produce the product that meets the requirements previously captured by the client (market requirements).

Resources providers requirements include economical, managerial, and organizational aspects.

These three sets of requirements for alignment are grouped in Table 1. In Cunha and Putnik (2005), the interested reader can find a development of these alignment strategies between business opportunities and the creation/reconfiguration of the VE that is expected to meet that opportunity.

KNOWLEDGE MANAGEMENT FUNCTIONS: STRENGTHS AND PROBLEMS

In this section, we highlight some strengths and problems associated with the implementation of knowledge management procedures and supporting technologies in the market of resources.

Knowledge Management Strengths

Knowledge management in the market of resources enables some functions such as (1) the ability to assure trust (given by the partnership performance monitoring and utilization of historical information in processes of search and selection) and responsiveness; (2) knowledge based guidance in VE design and integration (assured by the introduction of brokers); (3) electronic automated negotiation and contractualization;

Table 1. Checklist of requirements to be considered in alignment (Cunha & Putnik, 2005)

Market Alignment	Product/Service/Operations Alignment	Resources Providers Alignment
– Price, cost, and profit – Quality – Quick response: the desired product, on time, in the required conditions – Transparency and legality – Trust and confidence – Correct capture of market / customer requirements	– Cost – Quality – Integrability – Interoperability between different providers – Standards	– Availability – Ability to meet product/service/ operation requirements – Certification – Dependability – Flexibility – Responsiveness – Competitiveness and proactiveness – Past information of previous VE integrations

(4) performance evaluation of the VE participants; and (5) contract management and enforcement (based on performance evaluation of the VE participants).

Trust and Responsiveness

Trust is a major concern that any environment to support VE integration must assure. In the market of resources, trust is assured by a detailed regulation, enforcement procedures through contracts and safety mechanisms, duty of seal, and so forth. Responsiveness or almost real-time answer is essential. The market enables the reduction of the integration time and increases integration efficiency as demonstrated in Cunha and Putnik (2003a, b).

Knowledge-Based Guidance in VE Design and Integration

Brokerage implementation (human brokerage), search, and selection support algorithms and an efficient organization of the market of resources intelligent knowledge base and business intelligence are on the origin of this knowledge-based guidance. The broker, supported by computer-aided tools, validates all the steps in the process of designing the VE project that is most suitable to achieve the VE underlying objectives, manages VE integration, and monitors VE operation.

Electronic Automated Negotiation

The market of resources service is designed to offer different processes of electronic negotiation (passive and active) and is supported by automated tools of search, selection, and negotiation, which can increase the performance of the process when the solution space size is high.

Performance Evaluation of the VE Participants

The requirement for permanent alignment of the VE with the market (business) asks for a dynamic process of VE performance evaluation and analysis of reconfiguration opportunities. To answer to this requirement, the market of resources offers procedures for performance monitoring and, through the broker allocated to a given VE project and using computer aided coordination mechanisms, is permanently monitoring the partnership and recording historical information to be used in the future. The market makes use of historical information of the behavior of the resources providers in previous integrations, in the search processes, to increase trust and achieve better results. This activity of monitoring the performance of every integrated resource increases trust and contributes to the highest possible performance of the VE.

Contracts Management and Enforcement

The market of resources offers mechanisms for contract generation, management, and enforcement. To reduce the contractualization time, the market of resources (empowered to represent the parties in the contract formalization), is able to perform almost real-time contractualization between the parties to integrate in the VE.

Knowledge Management Problems

Two of the main difficulties identified are related with (1) the difficulty of expressing the resources requirements by the VE owner who must be able to use a resources representation language to traduce the VE project and resources requirements in the knowledge base of the market of resources and (2) the necessity of implementing partnerships with other similar services in order to extend the coverage domain.

Difficulty in Expressing the Resources Characteristics

The efficiency of the service is dependent on the ability of representation and organization of the resources information in the market of resources intelligent knowledge base and the capture and translation of the requirements for resources selection and negotiation parameters. If the first is dependent solely of a unified representation language, the second requires also the ability of the VE client to translate the requirements for the VE project into this language, which is far more complex than describing the individual resources provided by resources providers. These functions are essential to knowledge organization, maintenance, and extraction.

The developments toward unified representation languages, such as the XML-based developments, represent a tremendous contribution that should help to overcome this problem.

Limitations in Coverage: Dependability on Similar Services

A project can touch many different areas, and our market is both vertical and horizontal (matricial) to allow a better coverage of domains of activity. To overcome the lack of coverage, it is necessary to establish partnerships with other similar markets so that the broker does not see its search space limited to the market of resources database, but this situation of partnering with similar services is constrained by the existence of unified representation languages. If this does not happen, translating software will be required to support interoperability between services, or the broker will have to know different representation languages in order to transport requests into other services.

OPPORTUNITIES FOR A MARKET OF RESOURCES AS AN ENVIRONMENT FOR KNOWLEDGE MANAGEMENT AND BUSINESS ALIGNMENT

Cost savings do not seem to be a major key driver for enterprises to use the market of resources. Rather, they should be interested in time and quality benefits, trust, dynamic reconfigurability, and so forth. Opportunities should come from technological developments, which will enable more efficiency in the implementation and from the current state of ICT investment and usage by the enterprises, which traduces the willingness to drive business online. But the main opportunity seems to come from the actual strong competition environment, which is expected to force companies to the adoption of VE models, and this shift may represent an opportunity for services as the one provided by the market of resources.

Emerging VE Organizational Model

As demonstrated in Cunha and Putnik (2003a, b), the market of resources environment is more efficient in coping with the VE model than the Internet-based traditional ways (e.g., WWW search using search engines, e-mail, etc.). With the predictable evolution of the organizational models, services as the one provided by the market of resources will appear as the previewed evolution toward a new generation of business-to-business electronic marketplaces and support services.

Technological Development

The rise of Internet-based business-to-business marketplaces is progressing rapidly. At the same time, we are assisting the fast appearing of networked enterprises, extended enterprises, and VE. However, the developments or solutions still do not respond to the VE model requirements. Several enabling technologies are suffering significant developments from electronic payment to security. Finally, the emerging standards for information representation will be a major requirement for efficiency and integrability in electronic business.

Investment in Information and Communication Technology

Several surveys (for example, Boston Consulting Group, 2002) suggest that there is a very favorable environment for the adoption and increased usage of new value-added services, as enterprises have invested in the enabling technology and are looking for reducing costs and increasing productivity, which means that it could be understood as potentiating the acceptability for the market of resources.

Competitive Pressures

We feel that enterprises of all sectors perceive the threat of competition and see, both in the emergent virtual enterprise organizational models and in the Internet-based applications, a possibility to improve productivity and reduce some type of costs. This is pushing traditional business to adopt business-to-business electronic commerce practices and represents an opportunity for the deployment of new applications, one of these, the market of resources.

At the same time, companies providing e-business services represent a competitive pressure toward the success of the market of resources (while competition is simultaneously a threat).

Technology Accessibility to Small and Medium Sized Enterprises

A key driver of growth of business-to-business electronic commerce will be the increased adoption of e-commerce initiatives by small- and mid-sized companies. Solutions, up until recently, associated with huge investments and dedicated to large companies are now accessible to small and medium enterprises.

CONCLUSION AND FUTURE TRENDS

This article intended to provide a better understanding of the environment supporting virtual enterprise integration from a knowledge management perspective. We have introduced the support to VE integration by the creation of a market of resources and introduced a referential for knowledge management to assure the alignment between business requirements and the integration of resources providers in a VE.

The development of environments to support the VE model in general are of increasing importance, and the market of resources intends to be a contribution toward that direction. However, it is an innovative approach when compared with the other developments that literature provides, which are not as integrated as the market of resources is and covering only aspects of the VE life cycle in a less dynamic approach to the virtual enterprise concept.

All the technologies and techniques necessary to support the several phases of the life cycle of a VE, as well as many valuable applications, already exist and some are in operation, but most of them fail to answer to the VE integration requirements, as they were not developed specifically to support this model. What we have designated as an adequate environment to support the requirements of the emerging VE paradigm is missing.

Simultaneously, besides the strengths identified for the implementation of knowledge management functions in the market of resources, some problems are also identified. The article also identifies some opportunities associated to the implementation and exploitation of the market of resources as an environment to support knowledge management in VE integration.

EXECUTIVE SUMMARY

The die- and mold-making industry can be characterized by small and medium enterprises (SMEs), sophisticated technologies, and highly skilled employees who have to cooperate in order to fulfill orders of customers with which they are engaged in an intensive process of knowledge exchange. The knowledge-intensive production process of die and mold makers consequently requires an integrated organizational and technical solution to support the sharing of documented knowledge as well as collaboration. Standard knowledge management systems (KMS) primarily target the organization-internal processes and documented knowledge of large organizations.

Know-CoM intends to overcome the limitations of these solutions and explicitly targets SMEs as well as knowledge processes that cross organizational boundaries. Know-CoM is a European Commission-funded CRAFT project that provides an advanced concept of decentralized management of access privileges to personal, protected, and public knowledge spaces. An easy-to-use solution supports the capturing of experiences. A joint knowledge structure brokers context across organizational boundaries and eases discovery of knowledge and experts. Finally, a knowledge management certification technique allows for a coordinated reuse of knowledge that is integrated with the daily work practices of die and mold makers.

BACKGROUND

Dies and molds are characterized by hard, low-wear materials, complex geometry, and structures. Their production requires sophisticated technologies, for example, five-axis machining, high-speed cutting, and so forth, and highly experienced and qualified staff (Antoñana, 2000). Dies and molds are used in many industries, for example, by suppliers of components in the automotive industry. Their prices vary by an average of 45,000 from 20,000 to 800,000, whereas the margins are about 6%. The lead time for the production of a die or mold ranges from one to 10 months. For toolmakers, the most important competitive factors are time to market, personnel costs, and quality of the resulting tools. The last ISTMA Annual Report (Antoñana, 2000) highlighted some of the handicaps of the European tool and die industry competitiveness:

- Continuous pressure to reduce time to market
- Strong pressure on prices and high personnel costs
- Growing difficulty to attract and acquire skilled workers

In many SMEs, these handicaps lead to bad working conditions, accidents, and even social problems (Antoñana, 2000).

The market size is 25,000 million euros worldwide (Antoñana, 2000). The European die- and mold-making industry is composed mainly of small and medium-sized enterprises (SMEs) with an average of 23 employees. There is a wide variety of dies and molds (e.g., die casting, plastic, or glass molds) for different purposes and industries. Typically, die- and mold-making companies (DMCs) specialize in certain areas of the industry. Many products require the combination of several dies and molds from different fields and thus customers regularly need to obtain them from more than one producer. Thus, cooperation between DMCs holding complementary competencies is necessary in many cases, particularly to acquire large orders. Producers have to coordinate their activities closely and communicate intensively in order to jointly execute orders. However, the specialization of the DMCs is not only complementary, but also overlapping. Therefore, the relationship between the DMCs can be described as coopetition, because they cooperate and collaborate on the one hand during the joint execution of orders and on the other hand, they compete in markets. Regarding the introduction of knowledge management (KM), the state of coopetition on the one hand requires advanced instruments that create an environment for unobstructed knowledge exchange between the cooperating DMCs and on the other hand, competition poses a significant barrier for the exchange of knowledge across organizational boundaries. In addition to the cooperation and exchange of experiences with other die and mold makers, the DMCs often need to exchange and jointly develop knowledge with their suppliers and customers. Suppliers hold expertise concerning characteristics of materials, tools, and about standard parts needed to manufacture dies or molds. Customers possess knowledge about how the parts that are produced using these dies or molds meet the requirements of the customer's customers. For example, when a plastic part for the automotive industry, such as a car dashboard, is produced, the part has to fulfill requirements regarding surface structure or stability. These requirements must be considered by the die and mold maker during the design phase of the tool with which later the car dashboard will be produced. Additionally, customers of DMCs use different injection-molding and die-casting machines to manufacture parts, which vary in the dimensions power, feed, stroke, clamping surface, force, and so forth. Die- and mold-making companies depend much on experiences with customer machines and materials because the produced tool has to fit in the injection-molding or die-casting machine.

In the next section, we discuss the representative knowledge-intensive core business process of DMCs and study the main issues concerning knowledge exchange, application, retention, and securing.

SETTING THE STAGE

For the detailed analysis of the core process and the technical environment of DMCs, we used questionnaires as well as expert interviews with CEOs, designers, and production planners of seven European die- and mold-making companies. Based on the actual state and requirements identified, we derived a number of knowledge-related challenges. The questionnaires were composed of questions concerning the following areas:

- IT infrastructure and use of IT in the companies
- Production process and its information and knowledge flows
- Handling of knowledge in the company
- Cooperation with partners, customers, and suppliers
- Software requirements and expectations from a KMS

The IT part investigated the technical environment of DMCs as well as the employees' technical expertise. Alongside the hardware available and the software used, we studied the media preferred for internal and external communication.

The questionnaire was used to obtain information about typical development processes of DMCs and to distill the core process. For each process step, it was analyzed which data, information, or knowledge is needed; which sources it comes from; which data, information, or knowledge is created; and where knowledge gaps or potential for improvement exist. Furthermore, experts and persons responsible for process steps were determined.

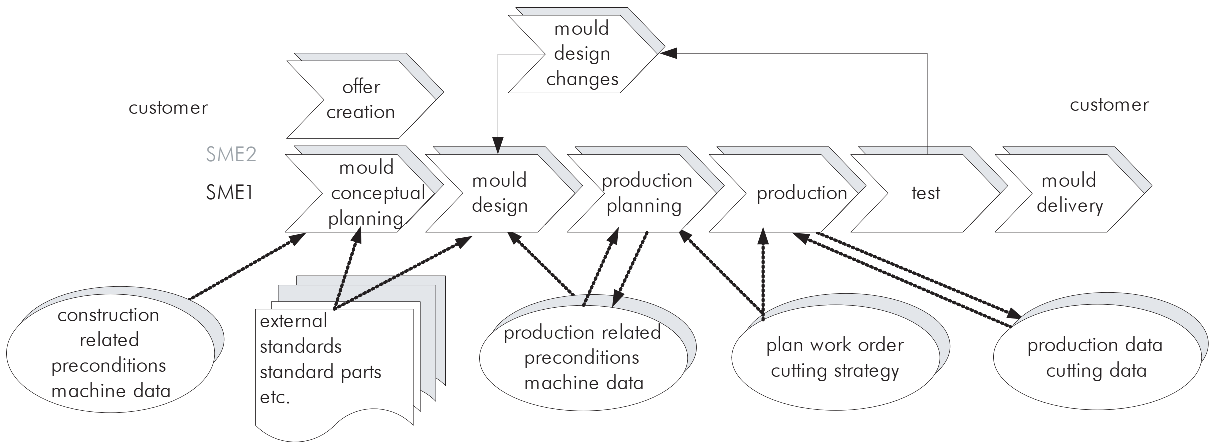
We asked which kinds of knowledge (e.g., knowledge about products, partners, skills) are stored in which way (e.g., electronically, on paper, or in the heads of people), which criteria were used to structure documents, and what were the main topics. Next to the handling of knowledge, the use of KM-related tools was analyzed. Concerning cooperation, it was examined which roles perform cooperative activities as well as which activities the DMCs intend to carry out with Know-CoM in the future. Additionally, we examined confidentiality of the knowledge shared with partners and customers as well as barriers that prevent knowledge sharing across organizational boundaries.

Finally, it was analyzed which KM-specific functions should be integrated in the software (e.g., knowledge maps, automatic classification, personalization).

The Core Process

The typical development process of die- and mold-making companies derived from expert in-

Figure 1. Core process of die- and mold-manufacturing SMEs



terviews and questionnaires (see section "Setting the Stage") is depicted in Figure 1. The symbols below the process illustrate some examples of data needed or created during the particular process phases.

Offer creation is carried out in parallel to mold conceptual planning and is triggered by customer requests. Customers send a drawing of the part and a list with required mold or die materials. The documents have different formats such as sheets of paper (handmade sketch, printings, etc.) or electronic documents (CAD files, etc.). Having received the request, the company calculates an offer and sends it back to the customer. Calculation depends on different information gathered or delivered by the customer, for example, type and characteristics of the materials and the part's complexity. The more detailed the request is, the better the company is able to plan and provide a solution for the request. Independent of the information delivered by the customer, calculating offers is difficult due to the high variety of dies or molds formerly produced. Particularly, estimating the number of cost-intensive redesign cycles is very hard (see process step, mold design changes). The systematic comparison of the die or mold to be produced to already-produced ones with respect to geometry, material, and so forth, can ease the offer creation process, particularly the estimation of the redesign loops significantly and improve the margin. Based on our interviews and questionnaires, we observed that previous offers, CAD drawings, and so forth, are stored unsystematically.

Mold conceptual planning is based on the customer's requirements regarding functionality, behavior, number of parts per mold or die, number of injections per mold or die, and structure of the planned form. Conceptual planning requires information about preconditions related to the construction such as data of the injection mold or die machines, and usability of standard parts. Internal information about availability of production lines and production skills are also needed for suggestions and decisions. As identified by the questionnaires, the required information is rarely delivered completely by the customer and therefore further time-consuming inquiries are the consequence.

When an order is placed, the design starts from an in-depth study of the use of the final product and consists of optional mold-filling simulations, construction and creation of technical documents (e.g., in AutoCAD, CATIA, Solid Edge), specification of CNC (computerized numerical control) programs, as well as the design of inserts, sliders, and cooling system. Examples for the variety of information required during this phase are production-related preconditions, customer machine data, as well as internal machine tool data, and information about standard parts and their specifics.

Based on the product's specifications, the production planner uses information about production-related preconditions such as the company's capacities and capabilities to plan further steps. To implement CNC programs, select cutting strategies or plan work orders, detailed information, and experiences are necessary.

In production, dies and molds are produced using CNC machines or other production facilities. Examples of information required in this process step are standard part information, cutting data and cutting strategies, machine data, as well as production plans. Particularly, the choice of an adequate cutting strategy including selection and sequence of cutting tools is strongly based on experience. To define cutting strategies, the mold material, the tool used (diameter, length, notation, supplier, number of cutting edges, coating), and the cutting parameters (revolutions per minute, cutting speed, feed rate, radial cutting depth, axial cutting depth) have to be taken into account. Knowledge about cutting data and cutting strategies is mostly tacit and therefore not documented. Quality criteria for a cutting strategy are, for example, the wasted material or the lifetime of a cutting tool that is additionally influenced by characteristics of the machine tool used.

The following step test is dominated by extensive testing of dies and molds in compliance with the customer's requirements. Tested parameters are especially surface structure, dimensions of the mold/die, or stability of critical parts. Possibly, improvements concerning design are necessary, if the injection mold or die cast part does not meet the expectations of the customer or the requirements catalog. Insufficient test results can lead to changes of mold design. These changes are expensive, because the process has to restart from the mold design. Every point mentioned as failure in the test phase has to be corrected in the production phase. The number of redesign cycles ranges from 4 to 20 cycles per mold or die and has in Europe an average of seven cycles. Regarding costs, the reduction of the number of redesign cycles promises large improvements in time and costs.

Redesign can be handled by reducing some areas of the die or mold (e.g., milling, grinding, etc.) or adding some material (through welding), if necessary. Adding material to forms reduces the quality extremely and most companies do not give a high lifetime guarantee for such dies or molds. Thus, new design, production, and test cycles can be necessary. When all requirements are fulfilled, then the form is delivered to the customer.

Technical Environment

The degree of process automation and of the use of IT varies much from company to company depending on its size, the region, the type of product, and the customers. However, an average die- and mold-making company has a number of PCs that are distributed in all departments (production, design, management, commercial, after-sales) and are connected by a LAN.

Computer-aided systems such as CAD (computer-aided design), CAE (computer-aided engineering), and CAM (computer-aided manufacturing) are widely used in the business.

Although many companies have licenses for three-dimensional CAD tools, two-dimensional basic tools are still used for designs and drawings of the parts and their assembly. However, a full migration to three-dimensional tools seems inevitable, because of its advantages in terms of design flexibility and visualization. Software for the simulation of injection molding is useful, but requires a high investment in terms of personnel. Therefore, many companies avoid these costs by subcontracting this task to consultants or relying on their experience and test protocols. Additionally, many European DMCs use ERP (enterprise resource planning) systems to store data concerning products, their structure, production routes, orders, suppliers, customers, and so forth.

A substantial part of the data is stored in an unstructured way on individual PCs of the employees. This can range from worksheets or data created and maintained with tailor-made programs that support, for example, the offer creation process, tools for solving technical problems, or project management applications.

Concerning the communication infrastructure, telephone, fax, and face-to-face meetings still dominate information exchange within the company, with partners, as well as with suppliers and customers. E-mail is increasingly gaining acceptance, especially when complex surface parts are the object of orders. However, for simpler 2-D parts, a handmade drawing transmitted via fax is still popular.

In general, die- and mold-making companies are quite familiar with a number of IT tools and systems, but there is a lack of integration of the different systems.

Challenges

The key challenges in the die- and mold-making industry gained from expert interviews and questionnaires during our research (see section, “Setting the Stage”) are as follows:

- Lack of experience management: Experiences are crucial in many process steps of die or mold manufacturing. Missing documentation of experiences, lessons learned, or good practices can lead to mistakes and design failures. Also, relevant experiences from production and production planning are not available for the conceptual design of molds. Information about testing and redesign is also not provided in the conceptual design step.
- Insufficient knowledge about customer production facilities: Missing or insufficient customer machine and environmental data can also cause design changes after delivery of a die or mold which worked fine in the test scenarios at the toolmaker’s site, but does not work on the customer’s machine. Testing thus requires exchanging experiences about these working conditions as well as (planned) changes between representatives of the customer and designers.
- Need for collaboration environment: Subcontracting and splitting of orders require extensive coordination between the DMCs due to minimal tolerances of dies and molds. In some cases, problems arise concerning assembly of the mold or die parts manufactured by various DMCs. Therefore, it is important that an appropriate basis for context-based sharing of knowledge and context-based collaboration between DMCs is established.
- Management of intellectual property: DMCs cooperate on the one hand in certain areas and on the other hand, they compete in markets (coopetition). This fact creates a significant barrier for knowledge sharing across organizational boundaries and requires measures to ensure confidentiality and protect the individual company’s intellectual property.

- Distributed incompatible sources of data: Publicly available information about standard parts or cutting data has to be collected from several sources for each single process step. These retrieval activities are extremely resource consuming and it is not guaranteed that they deliver up-to-date information.

CASE DESCRIPTION

The Know-CoM solution aims to bridge the gap between a technology-oriented and a human-oriented KM approach (Maier, 2004, p. 355). On the one hand, there is a substantial amount of documented knowledge that is spread across the knowledge bases of cooperating SMEs, customers, and suppliers that have to be semantically integrated. On the other hand, important knowledge resides in the heads of highly skilled die and mold makers that act in a number of roles with respect to the production process. Thus, the Know-CoM solution consists of an organizational design of the knowledge processes that have to be supported by a technical solution and a procedure model that guides the implementation of KM in the toolmaking companies.

Standard KMS have a centralized architecture and normally aim at large organizations, but do not focus on the cooperation between multiple small companies in different locations. However, decentralized KMS seem to fit better for SMEs because they help (see Maier, 2004, p. 284)

- to reduce the substantial costs of the design, implementation, and maintenance of centralized knowledge management suites, in terms of hardware, standard software, as well as the often underestimated costs of designing, structuring, and organizing a centralized knowledge server;
- to reduce the barriers of individual knowledge workers to actively participate in and share the benefits of a KMS, because knowledge-sharing procedures are integrated in their daily work processes;
- to include individual messaging objects (e-mails, instant messaging objects) into the knowledge workspace that are rarely supported by centralized KMS; and
- to overcome the limitations of a KMS that (almost) exclusively focuses on organization-internal knowledge whereas many knowledge processes in die- and mold-making companies cross organizational boundaries.

Concerning DMCs and cooperation between them, particularly the low-cost criterion and the consideration of knowledge processes across organizational boundaries are specifics that have to be considered and seem to be better supported by decentralized KMS.

Regarding the company-specific part, we focus on capturing as well as providing experiences in the relevant process steps whereas concerning the cooperation across organizational boundaries the solution focuses on enabling knowledge exchange in a controlled environment on the basis of a shared context. Therefore, a multidimensional knowledge structure should foster a joint understanding between cooperation partners and to provide documented knowledge in the process steps of the core process.

The following section comprises the definition of a joint knowledge structure as basis for cooperation and the definition of knowledge spaces. Additionally, we describe in this section a method to capture experiences and the technique KM certified which aims at the systematic application of previously documented experiences. Afterward, we discuss to what extent the challenges of the die- and mold-making industry could be solved or reduced by the Know-CoM solution. Finally, we outline the reasons of the platform decision and present a procedure model for the rollout.

Definition of Knowledge Structure

A knowledge structure contains knowledge elements and the relations between them as well as metadata, which give further information about their content, and associations. To facilitate knowledge sharing, a joint knowledge structure has to be established in order to create a joint understanding between cooperating partners. Simple hierarchical knowledge structures are not suitable for cooperation, because different enterprises classify their knowledge elements or documents on the basis of different criteria (e.g., processes, topics, etc.) and end up using individual, incompatible taxonomies. Thus, it is difficult to find a structure that meets the needs of all participating companies. Additionally, nontext files (e.g., CAD drawings), which are important in the die- and mold-making industry, are hard to find by navigating the structure. Therefore, we developed a multidimensional knowledge structure on the basis of expert interviews and questionnaires (see section, "Setting the Stage") that classifies knowledge elements and documents using metadata according to the following dimensions (Maier & Sametinger, 2003, p. 4):

- Time: classifies a knowledge element according to time-related characteristics such as time of creation, time of last modification, or time of last access.
- Process: represents the step of the core process and comprises, for example, the subdimensions offer creation, design, production planning, production, or test.
- Topic: provides keywords intended to be relevant for the user. In the case of Know-CoM, the topics represent the most relevant knowledge areas of the die- and mold-making industry (e.g., molds, machines, parts, etc.).
- Person: includes suppliers, manufacturers, customers, and enterprise-internal persons, as well as their different roles within the organization. Regarding messages, the subdimensions, sender or receiver are relevant.
- Format: comprises formats specific to production industry (e.g., CAD file, CNC programs, etc.) next to widely used formats (e.g., .xls, .doc, .html, etc.).
- Type of knowledge: can be classified in contextualized data, experiences (approved, unapproved, private), lessons learned, good or best practices.
- Location: refers to the location described in a knowledge element which a knowledge element or in which a knowledge element was developed, for example, production facilities of customers as well as DMCs.
- Language: is required because Know-CoM is used by companies in several countries.

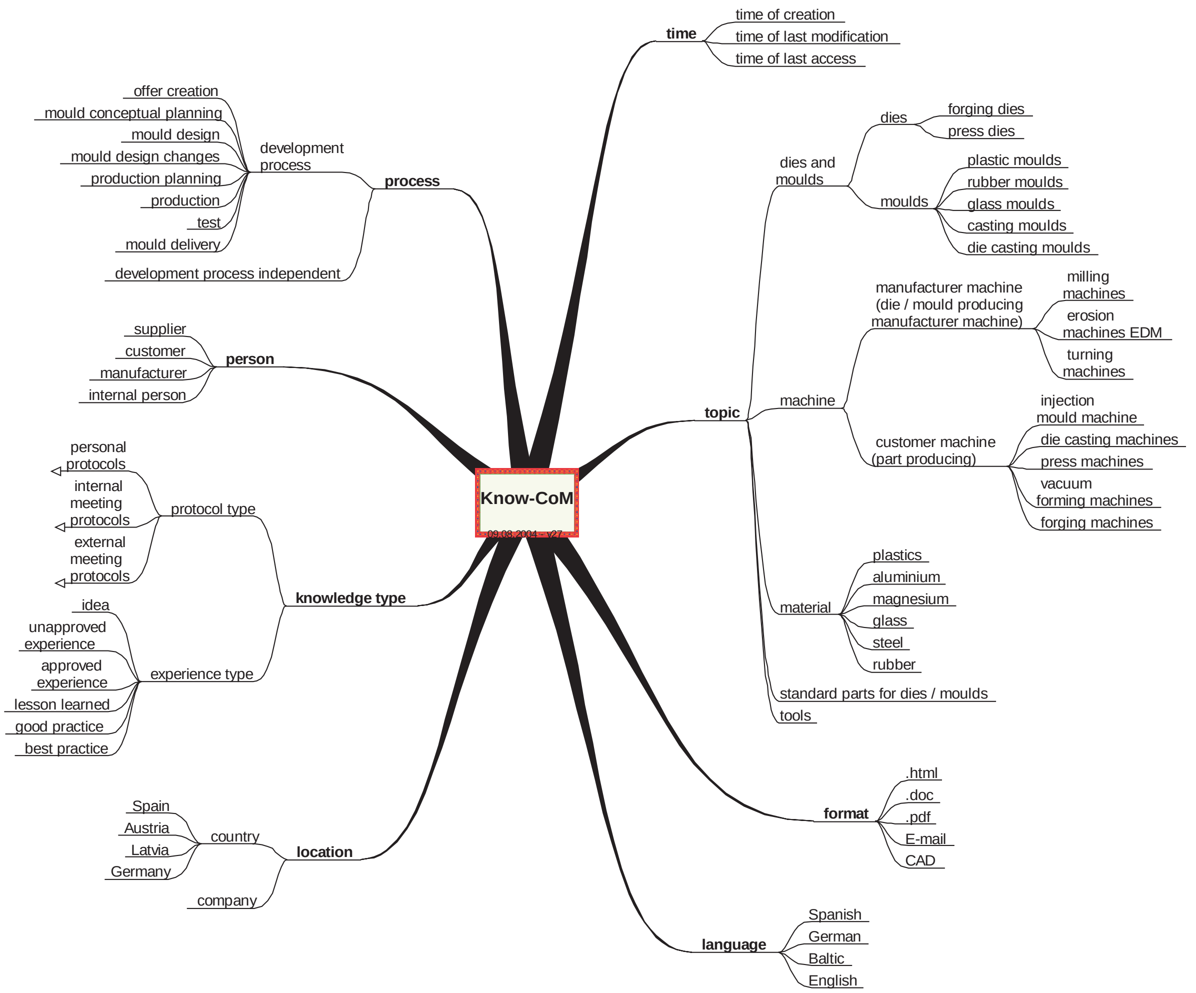
Figure 2 depicts the dimensions described above as a MindMap, which represents a minimal joint knowledge structure for the enterprises participating in Know-CoM.

According to these dimensions, nearly every document can be classified (semi)automatically. With the following example, the classification of a document corresponding to the eight dimensions will be illustrated:

If a tester xy (1) from the Spanish (2) company z (3) gains experiences (4) during the mold-testing phase (5) related to the plastic press mold (6) functionality on August 10 (7) and documents these experiences in the format .doc (8), then the following characteristics of the dimensions result from this documentation:

(1) person: → internal person → tester → tester xy
(2) language: → Spanish
(3) location: → company z in Spain
(4) knowledge type: → experience type → unapproved experience

Figure 2. Joint knowledge structure



(5) process: → development process → test

(6) topic: → dies and molds → mold → plastic mold → plastic press mold

(7) time: → time of creation → August 10, 2004

(8) format: → .doc

The metadata are collected automatically according to the actual working context of the employee or semiautomatically applying, for example, wizards, to guide users through a subset of metadata that cannot be derived automatically. Based on the knowledge structure, specifications of the dimensions are suggested and the user only has to approve or reject these suggestions. This multidimensional structure builds the basis for joint understanding, which is necessary for cooperation with knowledge spaces that are outlined in the following section.

Definition of Knowledge Spaces

Knowledge elements are stored in so-called knowledge spaces. Referring to the fact that SMEs in the die- and mold-making industry on the one hand cooperate in certain areas and on the other hand, compete in markets, we chose to trisect the knowledge spaces on the particular company server in private, protected, and public ones (Maier & Sametinger, 2003, p. 5) in order to reduce barriers for knowledge sharing and to protect the company's intellectual property:

- Private knowledge spaces: Every employee has a private knowledge space, which contains knowledge elements that are only accessible to the employee.
- Protected knowledge spaces: We distinguish two kinds of protected knowledge spaces: (1) team or role-oriented protected and (2) private protected. The first kind of knowledge space is used for sharing knowledge with a limited group of people based on predefined roles. The group can be, for example, an organization-internal or external defined role, group, or project team (e.g., designers, sales persons).
  Additionally, the individual knowledge worker can apply for a protected knowledge space, share knowledge independent of roles or teams, and grant as well as revoke access rights as he/she pleases.
- Public knowledge spaces: Every company server has one public knowledge space, which includes contents that are accessible for every employee in the company as well as for all members associated with Know-CoM.

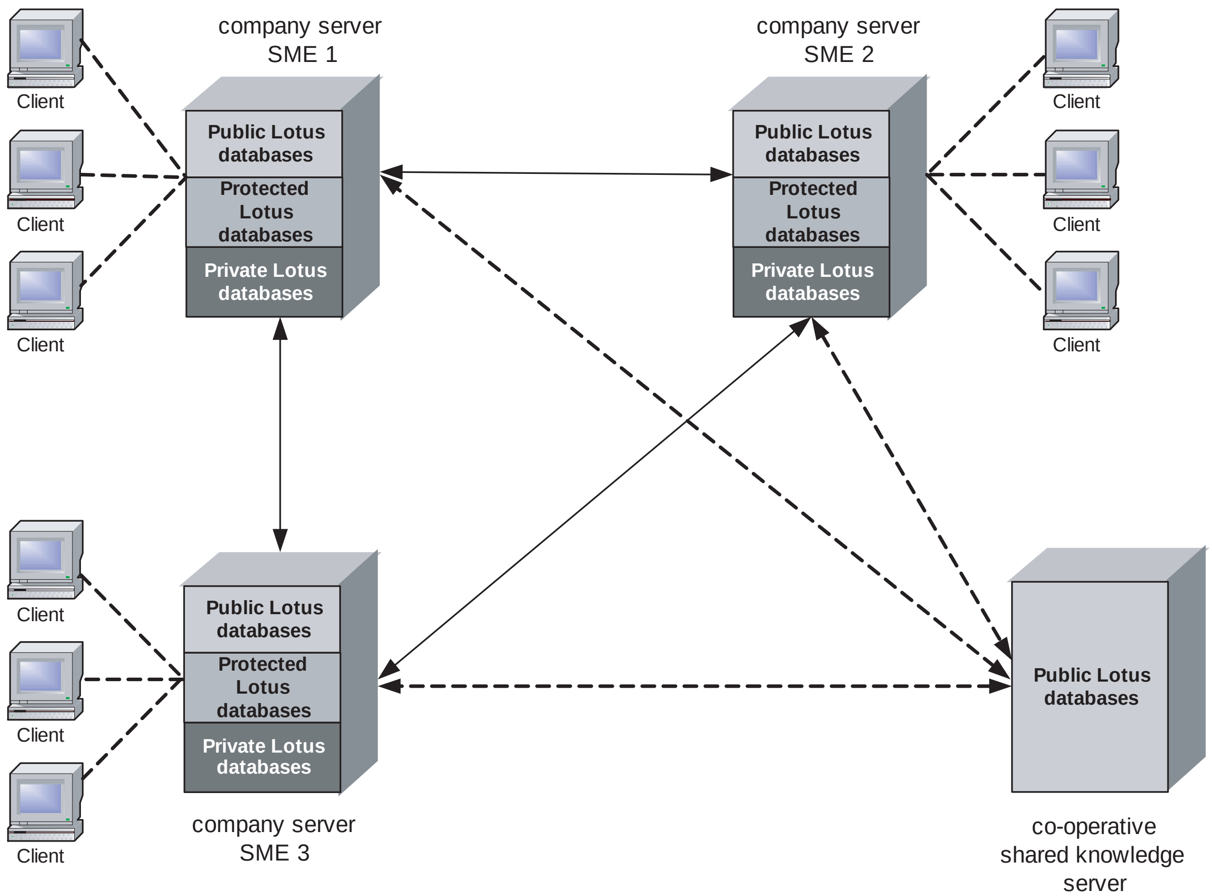
In this environment, significant barriers of knowledge sharing can be reduced, because participants or organizations can decide on their own who is allowed to use their knowledge spaces and have in this way control over their intellectual property. Because of limited user groups, it can be assumed that trust between cooperating employees is higher than without such a limitation and thus sharing of explicit as well as implicit knowledge (e.g., informal exchange of ideas or experiences) is fostered. Access rights which work on the basis of user profiles and the knowledge structure can be adjusted, if a cooperation (e.g., a project spanning enterprises) is dissolved or an employee leaves the cooperation.

Every enterprise participating in Know-CoM has its own company server (Figure 3), which is trisected in different kinds of knowledge spaces. Dashed arrows show connections between the company servers and the cooperative shared-knowledge server, whereas solid arrows illustrate connections between several company servers.

The role of the cooperative shared server is twofold. On the one hand, the server is used to provide publicly available industry-specific information, such as standard part catalogs, cutting data, and so forth, as well as community home spaces for topic-related knowledge exchange of the DMCs. On the other hand, the server should help to localize other companies, find expertise, and bring them together for cooperation. The identification of other companies is supported by company portraits stored on the cooperative server and comprise information about the companies´ areas of competency, machines, capacities, number of employees, location, contact data, and so forth, whereas the cooperation itself occurs in a peer-to-peer mode via protected knowledge spaces of company servers. Concerning roll-out of the Know-CoM solution, this server supports the creation of awareness (see section, "Rollout").

Search inquiries collect relevant documents from the adequate private database of the employee, accessible protected databases and public

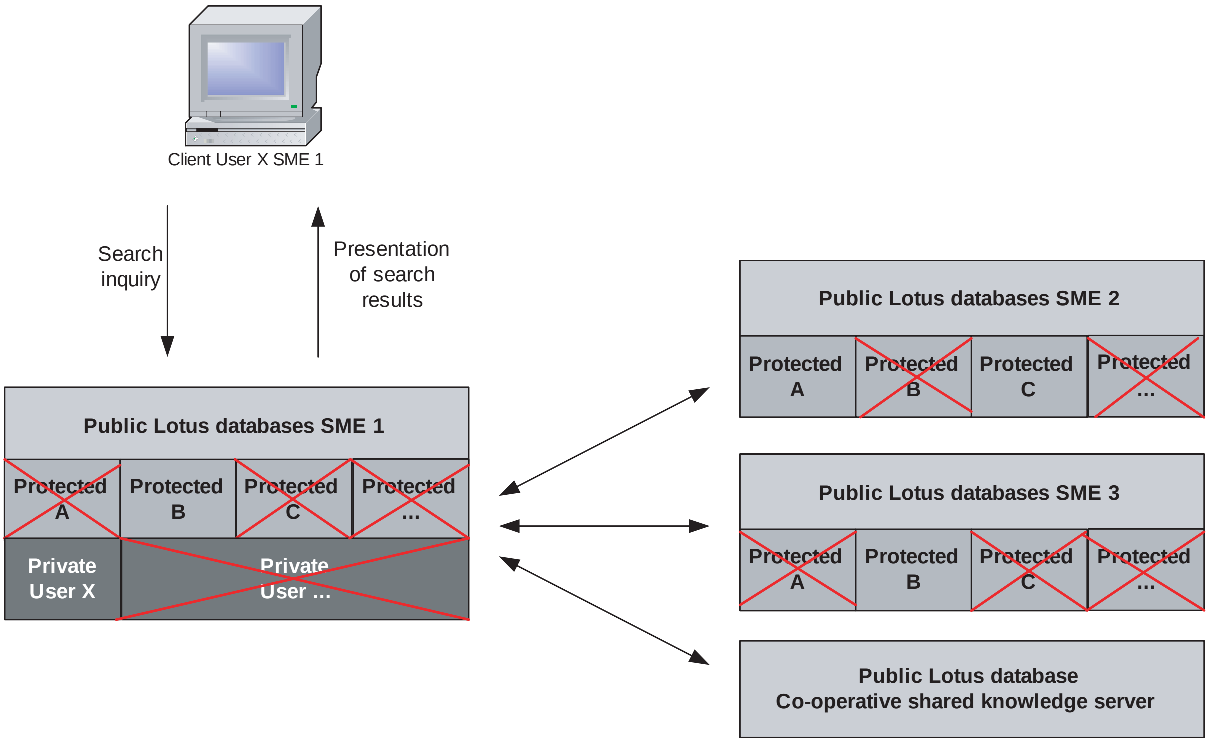
Figure 3. Network of the company servers



databases of the company servers, as well as documents from the cooperative shared-knowledge server according to user profiles and access rights. Figure 4 illustrates processing of search inquiries.

If an employee (here: user X) of a company (here: SME 1) formulates a search inquiry concerning any topic, the company server of the SME the employee works for executes the request and scans his/her private knowledge space and protected knowledge spaces, for which the employee has permission to access. As depicted in Figure 4, the employee can access only the protected knowledge space B in SME 1. Additionally, the company server forwards the request to other connected servers. Also, only protected knowledge spaces accessible for the employee are scanned as well as public knowledge spaces that are not limited to a certain user group. In the example, user X has access to the public knowledge spaces of SME 2, SME 3, and to the cooperative shared-knowledge server as well as to the protected

Figure 4. Processing of search inquiries



knowledge spaces A and C of SME 2 and the protected knowledge space B of SME 3. Private knowledge spaces of other SMEs are generally not accessible. After scanning the knowledge spaces, the company server of SME 1 presents the results of the search inquiry to user X. Depending on the privileges, the user can also insert, update, comment, or delete knowledge elements in the workspaces of participating companies.

After describing the knowledge structure and the network of the Know-CoM solution, including the different kinds of workspaces, the next section focuses on capturing experiences from business processes.

Capturing Experiences

The analysis of DMCs (see section, "Setting the Stage") showed that most experiences are collected in an unstructured way via paper-based or individual electronic notes (e.g., commented test results, etc.) or remain in people's heads. Therefore, the systematic and collective reuse of previously gained experiences is at the actual stage of nearly impossible and the same problems or failures occur over and over again. Thus, the KM solution aims at a technically supported and structured gathering of experiences as well as at providing these experiences in an appropriate format in relevant process steps.

The systematic documentation of experiences enables a company to solve recurring problems more effectively and can lead to sustainable competitive advantages. However, there are some barriers, that prevent documentation of experiences or reuse of already-documented experiences. The required time is a critical factor, because employees have to document in addition to other organizational duties. Therefore, the organization has to provide time tolerances to their employees. However, it must be considered that the effort concerning documentation has to be as low as possible, but simultaneously, sufficient context of the experience has to be provided. The detection of context is important, because reusability of documented experiences depends much on the context. Next to these organizational barriers, personal barriers hinder distribution or application of codified experiences. Typical personal barriers are for example insufficient willingness to share knowledge or to apply knowledge that was created by other employees (not-invented-here syndrome). Regarding the cooperation in a competitive environment, particularly the latter seems to be a serious barrier, which has to be considered by accompanying measures, such as change management, trust management, and incentive systems.

Several approaches exist for capturing experiences such as micro-articles, learning histories, RECALL, after action review, and postproject appraisal (for details, see Schindler & Eppler, 2003; Disterer, 2002; Willke, 2001; Sary & Mackey, 1996). In Know-CoM, experiences should be captured as small articles supported by templates that are structured according to topic, story, insight, and conclusion of the micro-article (according to Willke, 2001). Topic considers the context provided by the knowledge structure. Story describes the experience or learning context. Insight stands for the learning reason (e.g., the cause of the problem). Conclusion comprises the solution (e.g., a procedure) of the problem or a specific situation based on the insight. Experiences that are structured in this way might have a high reusability and traceability due to the provided context. In order to ease codifying experiences, the employees have to answer questions supported by wizards according to the context (story) and document their insights and solutions.

During the whole development process of dies and mold, characteristics of the multidimensional structure are collected. For every order, the collected information is forwarded and extended along the steps of the development process. Metadata are added step-by-step either automatically or semi-automatically by the application of predefined checkboxes that comprise the elements of the joint multidimensional knowledge structure. Intelligent metadata management means that based on the knowledge structure, specifications of the dimensions are suggested to the user for approval. Particularly, the automated suggestion and filling of predefined checkboxes with check marks minimizes the employees' documentation effort. This means that, for example, during work on an incoming order, metadata are added according to part, part's material, customer, customer's machine, and so forth. Metadata already collected are extended in the following steps of the core process (e.g., design, production, and test).

Additionally, employees can document experiences in every process step. After completion of the process step or of one task, wizards ask the employee whether there were specifics or problems he/she solved. The following example should explain the procedure of the capturing of experiences in detail:

A toolmaker uses in the process step production not the cutting tool suggested by the production planner and changes the tool supplier, because he knows that tool wastage is above average due to the material's hardness and machine characteristics. This experience has to be documented during or after the execution of the production step in order to avoid this problem, especially when another less experienced toolmaker uses this cutting tool on a similar mold. Table 1 illustrates a possible

Table 1. Example for capturing experiences

topic:	High tool wastage
insight:	The material was too hard and therefore the tool not suitable.
conclusion:	Use cutting tool xx when you mill material z on machine y

documentation, which contains the elements topic, insight, and conclusion.

Cause and solution of the problem or the specific situation are free-text fields. This kind of documentation helps on the one hand to increase traceability for other employees and on the other hand, implicit knowledge could be externalized when employees write down their interpretations. The context variables (story) can be detected according to the order document forwarded and extended because metadata regarding material, material's hardness, machine, cutting tools, and so forth, are in this example already collected in former process steps such as design and production planning.

Search inquiries are formulated automatically according to the context variables of the actual process step. The results are presented and ranked in dependency on the matching of the documented experiences' context variables with the variables of the actual working context.

Next to capturing experiences, their systematic application is crucial for the success of the KM initiative. This is supported by the technique KM certified.

KM Certified (KMC)

It cannot be taken for granted that employees apply previously documented knowledge. Additionally, success of the application of knowledge in business processes is hard to identify. Know-CoM contains a dynamic checklist (a kind of work flow) according to the core process which shows what KM-related activities they have to do or should perform. The following example illustrates this technique:

When the price for an offer is estimated, the sales person has to search for documented knowledge (e.g., approved documented experiences, documented lessons learned, or good practices) concerning previous similar offers. After viewing the knowledge elements, the sales person encloses or references them. The designer has the task to evaluate CAD drawings by using previous drawings and has to attach the viewed drawing and his/her annotations and eventually the e-mail traffic with cooperating designers. Additionally, he/she should comment on his/her experience-based assumptions related to possible design changes or other problems he/she identified. The die and mold maker has several tasks concerning the offer pricing. He/she also has to attach the knowledge elements viewed and his/her experience-based annotations. In analogy to the work flow activities described above, the tester as well as other employees involved can review all annotations and enclose the documented knowledge viewed according to their tasks. After completing the tasks in the checklist and after reviewing the attached knowledge elements, the audited object, for example, an offer, becomes KM certified.

If a participant identifies a good practice that seems useful or necessary for integration in the work flow, he/she proposes an item to be supplemented to the checklist. An approval process is important in this context to coordinate and check the addition of KM tasks. The possibility of suggesting new tasks renders the KM certification checklist dynamic. Moreover, the checklists are predefined for each process step and designed so that the systematic reuse of experiences and particularly good or best practices are considered. Good practices are proven as valuable for an organization, whereas best practices are worthwhile for the whole community of Know-CoM users. Subsequently, some core tasks of the development process are outlined:

During offer creation, especially experiences and information concerning the number of redesign cycles of similar molds are needed. Therefore, the checklist for offer creation comprises tasks regarding the estimation of the number of redesign cycles of similar molds as well as the application of good or best practices in this area, next to the use of templates for the collection of customer information. During conceptual planning, valuable experiences about standard parts in particular have to be reused. Additionally, employees from the areas of production, design, and test might have to be contacted when this contact turned out as worthwhile in the past. The design is a process step, which has a high potential for improvement for the lowering of costs when proven test experiences are reused systematically. Therefore, typical tasks included in this checklist are, for example, the application of test protocols and documented test experiences to similar molds as well as discussion with the die and mold maker and/or the tester. Such discussions can be supported by the use of application sharing and aim at exchanging knowledge as well as at avoiding mistakes. Particularly, when designers of cooperating enterprises communicate, tools for application sharing (e.g., for CAD) are useful and provide additional context.

The main focuses of the checklists for the production planning and production steps lie in the reuse of good or best practices regarding cutting tools, their sequence, and the sequence of the machines as well as the cutting strategies. Additional tasks aim at fostering communication and knowledge exchange with the toolmaker. The checklist of the tester comprises tasks such as the consequent application of former test protocols or the discussion of test results with the die and mold maker and the designer.

KM certified should help to ensure or foster the application of existing knowledge in the process phases described, to reduce previously made mistakes, and to increase the quality of the dies and molds produced.

Discussion

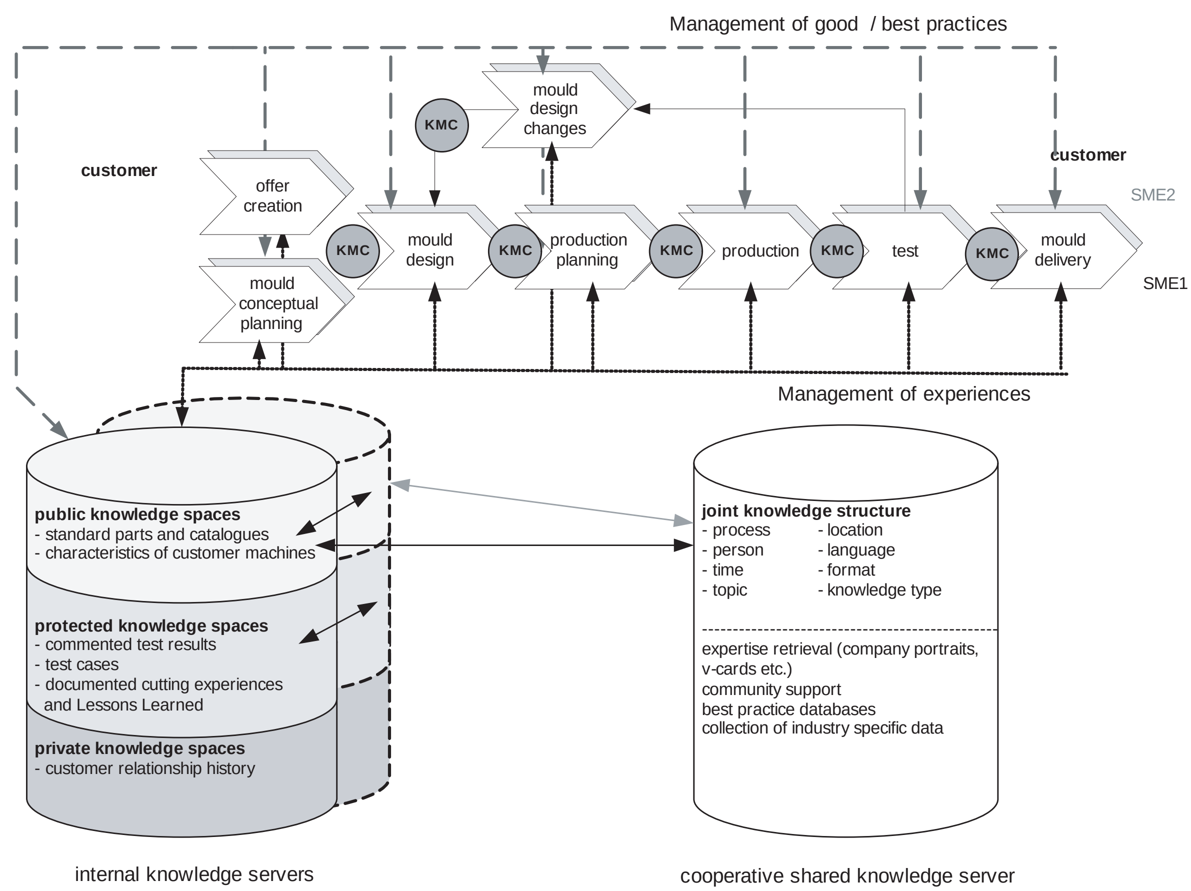
In the following section, we discuss how the elements of the Know-CoM solution could meet the challenges described.

- Lack of experience management: Know-CoM aims at capturing experiences during the execution of process steps supported by templates. In particular, templates and wizards ease the codification and lower documentation effort. The main target is ensuring high reusability by other employees, which is supported by semiautomatically detected context. By the technique KM certified, feedback loops between the steps of the core process are established and previously documented experiences and good/best practices are provided systematically after verifying their value. Thus, quality and efficiency can be enhanced, because especially the missing feedback loops from later to early stages in the development process as well as between cooperating SMEs impact these two factors.
- Insufficient knowledge about customer production facilities: Gathering of customer information is supported by prestructured protocols for customer correspondences with mandatory fields. The information collected in customer communication is documented and forwarded by work flows along the core process. Thus, the information is available in all steps. In order to avoid misunderstand-

ings and to identify problems concerning the mold or die, application sharing and instant collaboration (e.g., Lotus Sametime. See section, "Know-CoM Software Prototype") between the customer and manufacturer can take place.

- Need of collaboration environment: The joint multidimensional knowledge structure provides a shared context and builds the basis for a collaborative environment. Concerning the technical infrastructure, tools for application sharing and instant collaboration provide additional context and support cooperation between DMCs. Moreover, the use of protected workspaces improves flexibility, because access rights can be assigned and revoked depending on the requirements of the companies.
- Management of intellectual property: The management of intellectual property and particularly its security is the basic requirement for the cooperation in a competitive environment. The trisection of the individual company servers in public, protected, and private knowledge spaces provides such a secure environment and flexibly adaptable

Figure 5. Overview of the KM solution for die- and mold-manufacturing SMEs



access rights foster the controlled knowledge exchange.
- Distributed incompatible sources of data: The distributed sources of data such as standard parts, cutting data, machine characteristics, and so forth, are stored on the cooperative shared-knowledge server or on the public knowledge spaces of the DMCs. Thus, search time can be shortened. The shared knowledge structure also provides context for linking previously incompatible sources of data.

Figure 5 visualizes the elements of the Know-CoM solution. Every company participating in Know-CoM has its own company server, which is trisected into public, protected, and private knowledge spaces. Next to the trisected company servers, a cooperative shared-knowledge server supports cooperation between DMCs by providing community home spaces and tools for expertise retrieval. Both the company and the cooperative server work on the basis of the joint multidimensional knowledge structure, which provides a shared context to the participating enterprises and eases knowledge exchange between the companies. The internal core processes of the SMEs are supported in two ways. On the one hand, experiences are captured during the execution of the process steps and on the other hand, the management of good or best practices is supported by the technique KM certified that is symbolized in Figure 5 with the KMC icons. The management of experiences aims at a low documentation effort as well as at high reusability and is therefore supported by an intelligent metadata management. The latter helps employees to classify knowledge elements according to the dimensions of the knowledge structure. Next to capturing of experiences, particularly their approval and the systematic anchoring in the core process are important in order to ensure that valuable experiences, good or best practices are applied in processes and thus improvements concerning costs, time, and quality are realized. The management of good or best practices is realized by the technique KM certified.

After summarizing the elements of the Know-CoM solution, the following section describes the software prototype.

Know-CoM Software Prototype

The Know-CoM software is currently implemented as a Web-based application on a Lotus Notes system (www.lotus.com). Lotus Notes was chosen as the platform for the software prototype, because it provides a set of advanced functions to support database and document management, communication, coordination, collaboration, administration of users, and security mechanisms in a Web-based environment. The CSCW (computer-supported cooperative work) approach provides easy access to communication solutions such as Lotus Sametime (instant messaging and Web conferencing) and Lotus Quickplace (team workplace). Additionally, Lotus Notes comprises integrated discussion boards and supports work flows. Particularly, an integrated and easy-to-use CSCW approach is important in order to foster cooperation between DMCs. Additionally, a VPN (virtual private network) connection is not needed to access a Lotus Notes server, because an encrypted data transfer between clients and servers is supported. This allows secure data or information sharing. Further, advanced applications are full-text retrieval on the local server, mail and calendar integration, the possibility to replicate data of local databases on portable computers, the provided security features, and a policy-based management for different roles. Next to the CSCW integration, particularly the fact that Lotus Notes stores documents on the basis of metadata, influenced the platform decision because this approach fits well with the multidimensional knowledge structure.

As described in the section, "Technical Environment," die- and mold-making companies are quite familiar with a number of IT tools, but their collaboration and communication infrastructure is weak. Actually, much time is lost in communicating details off-line, by sending printed drawings between customer and manufacturer. So the possibility of sharing a CAD application in combination with discussion functionalities and session protocols will bring an enormous time benefit for the participating companies.

Furthermore, a Web-based application needs no local client or sophisticated configuration and can be accessed via Web browsers. As mentioned in the section, “Technical Environment,” die- and mold- making companies normally do not have powerful hardware and software systems in production areas, and also lack advanced knowledge for the administration of sophisticated software. Thus, a Web-based application has been chosen because it is easy to use.

As basis for this software system, the decision was taken to create an application out of the box. This means the delivery of the Know-CoM system with a preconfigured server. A company has to configure the network address and local (company-specific) parameters, such as roles and shared-knowledge spaces, and so forth, to start working with the software. The server does not influence other servers and there is no need for advanced integration efforts.

Lotus Notes provides full support for existing layers of the architecture of a KMS (see Maier, 2004, pp. 257–259). The Notes Web client allows full access to all existing databases and solutions, included in the Know-CoM software. Concerning knowledge services, Lotus Notes provides full-text retrieval for information and knowledge discovery, push-and-pull functionalities in work flows, and a wide range of applications for collaboration like Sametime, Quickplace, team calendars, online communication, and so forth. As complete solution provider, Lotus comes with these last two areas: integration services and infrastructure services. These services are part of the Lotus Notes database philosophy, which is the basis for all applications on upper architectural levels.

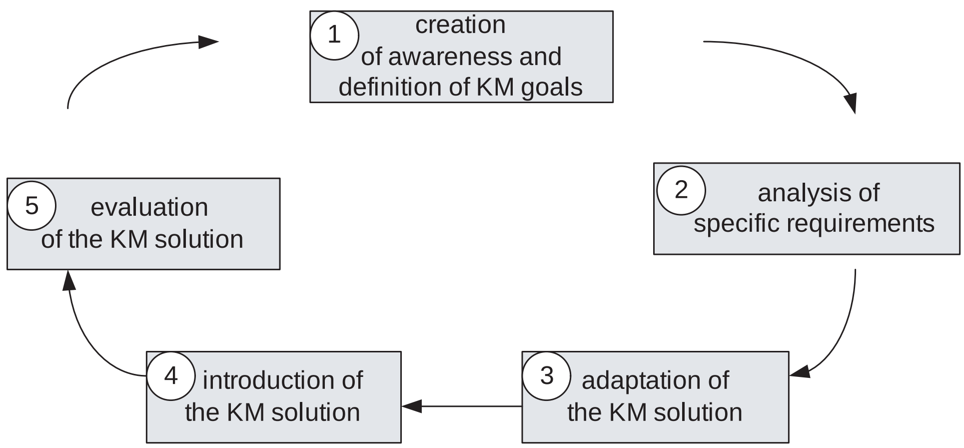
The Know-CoM software prototype builds upon this Lotus Notes solution and implements the services required in order to support the organizational KM instruments laid out in the previous sections.

Rollout

Concerning the process-oriented introduction of knowledge management, the literature provides several approaches. The phases of the process-oriented approaches GPO-WM1 (Heisig, 2002) and PROMOTE (Hinkelmann et al., 2002) build a basis for this KM solution. Additionally, a “road map” for the introduction and customizing of standard software (e.g., SAP) is considered for the amalgamation of the procedure model. Based on these literature studies, we developed the procedure model depicted in Figure 6.

- Creation of awareness and definition of KM goals: The DMCs analyzed are normally not aware of the potential benefits of knowledge management. Therefore, one of the focuses of the introduction of KM is creation of awareness for the KM initiative. The technical initiatives are rather concentrated in basic ICT infrastructures than in sophisticated KM functions. A preconfigured company server is installed that ensures some basic functionality. Thus, in this stage the employees can explore the cooperative shared-knowledge server and the public knowledge spaces of other DMCs participating in the Know-CoM community. Additional support is delivered by FAQ databases that contain questions and answers concerning KM in general and the Know-CoM solution in particular and by an employee who is responsible for the introduction of the solution.

Figure 6. The Know-CoM procedure model



Finally, the communication of the predefined Know-CoM-specific KM goals, such as the improvement of knowledge exchange or the systematic application of documented knowledge and their extension by enterprise-specific KM goals, is important in order to create transparency in the goals and benefits.

- Analysis of the specific requirements: Before the adaptation of the KM solution can occur, an analysis of the company-specific requirements has to take place. The analysis concerns the organizational structure, the development process, the work flows, and the existing knowledge structure. Within the organizational scope, especially the roles and the intra- as well as inter-organizational collaboration structure have to be analyzed in order to consider additional roles or deduce the need for the definition of knowledge spaces. The analysis of the dimension "process" comprises the matching of the core process with the development process of the enterprise concerned in order to consider variations and variants. The analysis of the work flows is necessary for the implementation of KM certified. Additionally, specifics concerning the technical infrastructure of the SME on which Know-CoM should be installed have to be taken into account.
- Adaptation of the KM solution: Based on the analysis of the specific requirements, the Know-CoM solution has to be adapted. During this phase, two different areas of customizing are relevant, on the one hand the technical customizing of the solution and on the other hand, the conceptual customizing of the knowledge structure, the core process, the roles, and the knowledge spaces.
- Introduction of the KM solution: The introduction step comprises the connection of the clients with the company server, the registration of the users, and the setup of private and protected knowledge spaces according to the user profiles on the server.

Information about an employee has to be registered and user profiles created when the

Know-CoM solution is introduced. Person-related information that has to be collected is, for example, skills, topics of interest, and work experience. Additionally, roles, organizational tasks and process steps have to be assigned to the employee for which he/she is responsible or works on. In analogy to the partition of the knowledge spaces in private, protected, and public, this trisection should also be used for the employees´ profiles. Recommendations of interest- or task-related knowledge groups can occur automatically according to the user profile of the employee. Based on the analysis of the organizational design, protected knowledge spaces are introduced for teams, projects, and so forth.

- Evaluation of the KM solution: After the introduction of the solution, there may be needs for improvement that lead to the adaptation of the solution. There are a number of indicators that allow for a systematic evaluation of the use of the solution. In particular, the experiences captured and the dynamics observed in the KM-certified processes as well as the establishment and regular use of knowledge workspaces give hints for subsequent improvements of the KM-supported core processes of the die and mold makers.

Next to the evaluation of the solution aiming at the identification of the needs for improvement, the measurement of the solution's success is also a central issue. Based on the interviews and questionnaires (see section, "Setting the Stage") the most important factors for success measurement in the die- and mold-making industry are lead time from (mold) order to delivery as well as the production time required. A shortened delivery in general or production time in particular also affects production costs of a mold or die. Quality is another key factor in this industry. Referring to the development process, there are a number of indicators that can be used to assess the effects of the Know-CoM solution on time, cost, and quality. These indicators have been documented at the beginning of the project and will be measured again one year after the introduction of the solution. Subsequently, some of these indicators are outlined in Table 2.

Table 2. Indicators for success measurement

criteria	Indicator
time	• average number of design-test-redesign cycles and time required • average lead-time • average time required for the execution of the process steps • average time needed to get complete customer information • search time
cost	• average production costs / mould • average personnel costs / mould • average material wastage • average cutting tool wastage
quality	• average number of internal rejects • average number of external rejects • average lifetime of mould

The average number of design-test-redesign cycles is one of the most important indicators because it affects time, cost, and quality. This means that the more cycles needed, the longer the lead time, the higher the costs, and eventually, the lower the quality. The quality is not necessarily affected negatively by a high number of redesign cycles, but in some cases, a high number of redesign cycles can reduce the stability of the mold and so its lifetime. Also the number of external rejects from the customer is an indicator that affects the quality of the mold and, in particular, the reputation of the toolmaker.

The integration of distributed sources of data can reduce the time required for searching data. Particularly, the systematic reuse of previously documented experiences can shorten lead and production time and can also reduce personnel, production cost, and wastage as well as the number of rejects.

CURRENT CHALLENGES

This case presents an organizational and a technical KM solution that specifically targets die- and mold-making SMEs. Know-CoM particularly considers capturing, sharing, and reuse of experiences both within the knowledge-intensive business process of a die and mold maker and across the organizational boundaries with customers and cooperating DMCs.

In the following section, some preliminary results concerning the application of Know-CoM by the industrial partners are reflected. We concentrate on the management of protocols and experiences, which have been the first focus of the application of Know-CoM. First, those process steps were analyzed where an immediate benefit could be identified as highly feasible. These are the processes not governed by an ERP system, which in this case were the offer creation and the die setting up and testing. The procedure was to detail subprocesses, assign documents to them if necessary (protocols and experiences), and extract the references required to define and manage the mentioned documents. For example, the following subprocesses were identified in offer creation: (1) offer request reception, (2) information request to the customer, (3) obtain main die parameters (pitch and bandwidth), (4) obtain costs, (5) decide on the probable delivery time, and (6) decide on final price.

Protocols used currently include the die characteristics sheet, the offer calculation sheet, and the formal offer document. These protocols are linked mainly to the first four tasks. The need for establishing protocols in the remaining two stages is being discussed at the moment.

Experiences are gathered for any of the mentioned processes. Guidelines or good practices were elaborated for the process of obtaining main die parameters, a key task that was not documented and greatly relied on the experience of certain key personnel in the company. The formalization of this task has allowed a far shorter training period for newcomers and has lowered the dependency that the company as a whole had on certain personnel for running this process with a guarantee for the final result. A number of references were extracted to be used as metadata for the process of searching and filtering the documents mentioned. Examples in the case of the die characteristics sheet are the number of stations, die dimensions, bandwidth, band pitch, number of columns, type of sliding, number of pieces per year, and number of pieces per stroke.

However, there are a number of challenges for the implementation of the solution since there are possibly significant barriers in DMCs that prevent the effective use of the KM solution. In the following, some of these barriers are outlined.

SMEs are characterized by the scarcity of resources. Particularly, limited human resources make it hard for SMEs to assign employees who are dedicated to the KM implementation or perform tasks that are related to the KM initiative (Wong & Aspinwall, 2004, p. 56).

The protection of intellectual capital is an important issue for SMEs since the unintended loss of knowledge to partners can erode competitive advantages of the company. In particular, compared to larger organizations, SMEs that are less diversified and more dependent on the knowledge of key employees fear losing competencies or employees to cooperation partners. These fears create significant barriers concerning interorganizational collaboration and knowledge exchange and it remains unclear if a secure environment for knowledge sharing is sufficient.

Compared to larger organizations the processes and procedures of SMEs are less formalized and standardized, which increase the probability that employees resist the introduction of the KM solution (Wong & Aspinwall, 2004, p. 52) or resist to perform tasks associated with it.

Capturing and applying experiences can also be prevented by individual barriers such as lack of skills to explicate knowledge or low reliability of the knowledge providers as well as by limited absorptive, processing, or learning capacities of the knowledge seekers. Furthermore, on the organizational level, factors like lack of management support or lack of time can prevent the success of the solution as well as interorganizational factors such as groupthink or an exaggerated unified organization culture that particularly affect the external relationships. Individual, organizational, as well as interorganizational barriers can affect the implementation and the use of the solution as well as knowledge sharing across organizational boundaries negatively (Maier, 2004, p. 130).

Finally, building and management of trust will be a crucial factor that influences the use of the protected knowledge spaces significantly. Due to the shared context supported by the knowledge structure, the cooperative shared-knowledge server and the joint KM principles underlying the solution, a community of Know-CoM users might be fostered that ensures trust.

Epilogue

It seems that centralized KMS offered on the market increasingly live up to the expectations of large organizations ready to apply ICT to support a KM initiative. These solutions are too complex, time-, and resource-consuming for SMEs. Peer-to-peer KMS promise to resolve some of the shortcomings of centralized KMS, especially concerning the time-consuming effort to build and maintain a central knowledge repository. However, major challenges still lie ahead until decentralized systems can truly be called KMS and used to support the still-growing share of users involved in knowledge work. Examples for technical challenges that have to be overcome in decentralized KM concern connectivity, security, privacy, fault tolerance, availability, scalability, and interoperability. Moreover, applying the peer-to-peer metaphor to KMS requires a substantial shift in the perspective on organizational knowledge. Executives might fear losing control over the organization's knowledge assets if all documented knowledge is handled by autonomous knowledge workspaces. Consequently, future KMS solutions might attempt to include the "best of both worlds."

Lessons Learned

- In SMEs, particularly the creation of awareness is an important issue concerning the implementation of a KM solution since SMEs are normally not aware of KM and its benefits. Thus, the availability of some basic functionalities and a person responsible for the implementation is favorable.
- Referring to the fact that processes and procedures in SMEs are compared to larger organizations less formalized and standardized a KM solution that is more rigid or directive seems to be appropriate for SMEs.

- SMEs in general and die and mold makers in particular are less diversified and strongly specialized as well as depend often on key employees. These facts combined with the state of coopetition require the providing of a secure environment for cooperation.
- Die- and mold-making SMEs are familiar with certain IT, but concerning the design of KMS, it has to be considered that the solution is easy to use.

Chapter 6.19
The Contribution of Communities of Practice to Project Management

Gillian Ragsdell
Loughborough University, UK

INTRODUCTION

More and more organisations are using projects as a means of managing their business; increasingly, 'new initiatives' are the focus of organisational life. Such initiatives could include cultural change programmes, organisation redesigns, or process improvements. Tackling the sociological and psychological aspects of the project is a great enough challenge, but there is often a requirement to develop a technological dimension too. Accelerating technical advancements brings an extra level of complexity to the projects so that, in general, projects have become more complex—not only do they tend to have a wider variety of customers to satisfy, but they also tend to utilise more sophisticated technology and have more far-reaching implications than ever before. It is not too surprising that some projects 'fail'; the increased complexity of projects brings an obvious rise in the associated risks. However, the increased complexity of projects also brings a rise in the opportunities for learning through the management of knowledge therein. These are opportunities that are not being fully exploited at present, as illustrated by the continuation of the 'failure-to-learn' and 'learning-to-fail' themes in the literature (e.g., Lyytinen & Robey, 1999; Cannon & Edmondson, 2004); a more active stance would consciously draw lessons from projects, from 'successes' and 'failures' alike.

Parallel to the growing emphasis on projects in organisational life and their changing nature, there is growing recognition of the interplay between the fields of project management (PM) and knowledge management (KM). Reference has already been made to the opportunities for more effectively managing knowledge within a project setting. This article operates at a finer level of detail and draws attention to the potential synergy between project teams and a much popularised social network derived from the KM arena—that of communities of practice (CoP). In doing so, the disciplines of PM and KM are explicitly bridged and, it is put forward, the prospect of breaking the 'learning-to fail' and 'failing-to learn' loops is raised.

BACKGROUND

New Knowledge and a Commitment to Action

The following brief literature review is a platform from which to launch the main thrust of the article when CoPs are compared and contrasted with project teams. Inevitably the reference material is taken from the second-generation KM arena where human and social aspects are central. Most authors agree on the general characteristics of CoP; this agreement can be tracked chronologically. Of more interest and significance to this article is the changing emphasis on CoPs' intention to act and the distinction that is, at times implicitly, made about the possibility of CoPs generating new knowledge.

Seminal works on CoPs are those of Lave and Wenger (1991) and, later in that decade, Wenger (1998). The concept is now well known throughout the second-generation KM movement and used by various authors. Pór (1998) describes communities as "connecting islands of knowledge into self-organising, knowledge sharing networks." Skyrme (1999, p. 170) goes on to say:

While some communities focus on a particular profession or discipline, the most powerful communities are customer or problem focused. They transcend disciplines and bring in different perspectives. They exchange, develop and apply knowledge.

The indication from Skyrme is that CoPs share knowledge and in turn increase their knowledge base and their sphere of application. However, this is through the development of knowledge rather than through its creation.

When distinguishing between their concept 'enabling context' and CoPs, Von Krogh, Ichijo, and Nonaka (2000, pp. 179-180) assert:

While a community of practice is a place in which members learn knowledge that is embedded there, an enabling context helps create new knowledge. The boundary of a community of practice is firmly set by the task, culture, and history of that community, but an enabling context is determined by the participants and can be changed easily. Membership in a community of practice is fairly stable, and it takes new members time to become full participants. But the many organisational members who interact in an enabling context come and go. Instead of being constrained by history, an enabling context has a here-and-now quality—and it is this quality that can spark real innovations.

There are various angles from which Von Krogh et al.'s (2000) work could be challenged—aspects such as the stability of a group and notions of 'participation' and 'task' will be clarified in the next section. However, Wenger (2000, p. 206) confronts the aspect of whether CoPs generate new knowledge when he states:

What these groups have in common is that engaging with each other around issues of common interest, sharing insights and information, helping each other, or discussing new ideas together are all part of belonging to the group.

He goes on to be more specific when he states that CoP provide "the resources that members use to make sense of new situations and to create new knowledge" (Wenger, 2000, p. 209), and refers to good practice in World Bank and Daimler

Chrysler. So the notions of new knowledge and of action are reinstated, and Von Krogh et al.'s (2000) interpretation of CoP is refuted.

In current times authors, such as Lehaney, Clarke, Coakes, and Jack (2004) retain Wenger's (2000) line, even though, initially, the foci on new knowledge and on action are not obvious. Lehaney et al. (2004, p. 46) say that CoPs are "willing to develop and share tacit and explicit knowledge" and that CoPs have become important means for "sharing information within professions and between like-minded people" (p. 50). However, the balance is redressed when they also say that CoPs may encourage creativity and problem solving through the diversity of their population (p. 49).

This article goes forward with the understanding that KM is concerned with the generation, capture, storage, and sharing of knowledge with an intent to take action in order to increase an organisation's competitive advantage. Therefore, if CoPs are an effective tool for KM, their capacities to create new knowledge (as well as to develop 'old' knowledge) and to apply knowledge, are crucial. The same is true for the argument to embrace CoPs in PM. Otherwise, there could be a tendency to continue to work with the same knowledge with little intention to move into the practical arena, and the 'learning-to-fail' and 'failing-to-learn' cycles of current projects are supported.

COMPARISON OF COMMUNITIES OF PRACTICE WITH PROJECT TEAMS

Sapsed, Besant, Partington, Tranfield, and Young (2002) and Crawford and Cooke-Davies (2000) started to draw together the notions of KM and teams, and KM and PM respectively. I move specifically to project teams and communities of practice, at a different level of focus from these authors. CoPs and project teams probably implicitly co-exist in practice. This section makes their co-existence explicit by identifying their differences and their areas of overlap. In doing so, it is anticipated that the areas of overlap and their associated untapped synergy will be better managed.

A holistic approach is taken and attention is given to features such as purpose, culture, composition, structure, and accountability. Melcrum (2000) was a useful starting point for a comparison, and the table below builds on some of his key themes.

Project teams and communities of practice are not one and the same. One is accepting that project teams are formed for the purpose of completing a project within agreed time, budgetary, and quality constraints, and that CoP develop as a result of a common interest in a field or problem area. However, the table shows that there is some common ground—for instance, their common intent to share and apply knowledge, and their potential interdisciplinary nature and possible cultural overlap.

FUTURE TRENDS

At first sight, CoPs and project teams may appear to be at opposite ends of the spectrum. Nevertheless, CoPs are increasingly being recognised by companies as an effective vehicle for increasing the sharing of learning about projects and, in turn, for improving the success rate of their projects. It is noted, however, that the 'CoP' may be referred to as a 'network' or a 'special interest group', and that this lack of clarity over use of language can cause confusion. With the growing emphasis on projects as a means of managing organisations, it is anticipated that this trend will continue.

There is much work to be done in this area, and I would suggest that future research aim for a deeper discussion about the underpinning ideology of project teams and CoPs. This in turn will enable the features in Table 1 to be expanded

Table 1. Comparison of communities of practice and project teams

	Communities of Practice	**Project Teams**
Purpose		
Overall	To increase capacity for improved action	To successfully complete project
In relation to knowledge	To generate, capture, store, and share knowledge	To share and apply knowledge within project boundaries
Composition		
Membership	Voluntary	Contractual
Profile of membership	Can be multi-disciplinary	Tend to be multi-disciplinary
Life span	'Natural' lifetime	Project lifecycle
Accountability		
Reporting structure	Informal	Formal
Rigidity of structure	Fluid	Relatively fixed
Measures of effectiveness	Intangible	Tangible
Culture		
Based on	Trust	'Esprit de corps'
Leadership style	Empowering	Variable

upon. Of a more practical nature, empirical work needs to be undertaken to discover how to manage the aforementioned similarities more effectively and how to minimise the potential conflict that the differences between project teams and CoPs may bring. Indeed, in "Project Teams and CoPs in the Construction Industry" Remington and Ragsdell explore some specific challenges for CoPs in traditional project environments such as construction.

CONCLUSION

This article has continued a theme that is evident in recent literature—that of building bridges between the disciplines of project management and knowledge management. This has been achieved by advancing discussion of the two groupings known as project teams and CoPs. In doing so, it has drawn attention to their complementary and contradictory aspects, and raised the possibility of tapping the synergy between the complementary aspects.

Chapter 6.20
Knowledge Management in Supply Chain Networks

Dolphy M. Abraham
Loyola Marymount University, USA

Linda Leon
Loyola Marymount University, USA

INTRODUCTION

This article reviews current research and practice of knowledge management (KM) and inter-organizational learning in supply chain networks. Knowledge management is the organizational process for acquiring, organizing, and communicating the knowledge of individual employees so that the work of the organization becomes more effective (Alavi & Leidner, 1999). Knowledge management is an increasingly important process in business organizations because “managing human intellect—and converting it into useful products and services—is fast becoming the critical executive skill of the age” (Quinn, Anderson & Finkelstein, 1998). Grover and Davenport (2001) state that KM becomes “an integral business function” when organizations “realize that competitiveness hinges on effective management of intellectual resources.” Grover and Davenport also argue that knowledge management works best when it is carried out by all the employees of the organization and not just KM specialists.

Business organizations frequently partner with other firms to complement their core competencies. To collaborate effectively, partner firms have to communicate with each other information about business processes as well as share ideas of how to design or improve business processes. This phenomenon of knowledge sharing across organizational boundaries is called inter-organizational learning (Argote, 1999). Knowledge management, we posit, is necessary to facilitate inter-organizational learning and direct it in a way that supports the organization’s overall objectives.

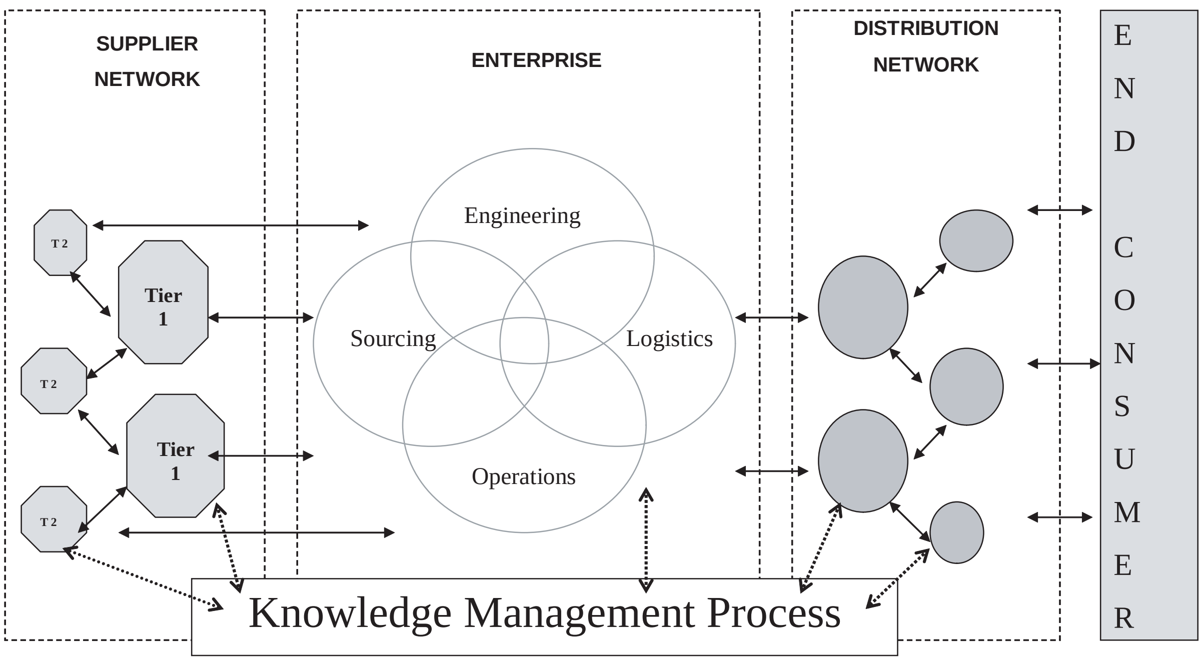
Supply chain systems are an example of business networks. Supply chains involve not only multiple corporate entities but also organizational units within a single organization. We present practices used in business organizations and networks of businesses to manage the information and knowledge sharing processes using the context of supply chain systems.

BACKGROUND

A supply chain consists of all parties involved, directly or indirectly, in fulfilling the end consumer's request. Its primary purpose is to satisfy customer needs while maximizing the overall profitability of the chain. A typical supply chain involves a variety of stages that may include customers; a distribution network of retailers, wholesalers, and distributors; manufacturing enterprises; and tiers of suppliers (Figure 1). Information, knowledge, funds, products. and services flow along both directions of the chain, where more than one player is often involved at each stage. The structure of supply chain systems can be described as a business network where inter-organizational learning and information sharing are critical factors in determining the chain's competitiveness.

The performance of a supply chain depends upon how well its processes are managed for the type of product that is associated with the chain. Fisher (1997) classifies products on the basis of their demand patterns, claiming that a product falls into one of two categories, either primarily functional or primarily innovative. Functional products satisfy basic needs and include the staples that people buy in a wide range of retail outlets such as grocery stores and gas stations. These products have stable, predictable demand, and long life cycles. Due to well-developed competition,

Figure 1. The integrated supply chain



low profit margins occur, requiring the chain to focus almost exclusively on minimizing physical costs. Companies need to coordinate the ordering, production, and delivery of supplies in order to minimize inventory and maximize production efficiency in order to meet predictable demand at the lowest cost.

Innovative products, such as fashion apparel and technology products including plasma TVs, cellphones, and iPods, are differentiated from competition by their designer options and new features and capabilities. The novelty of these products allow higher profit margins, but also result in more demand uncertainty as it is difficult to predict how the market will respond to the newest design features and options. The life cycle for innovative products is short as ensuing competition forces companies to introduce newer innovations in order to maintain the higher profit margins. The short life cycles and the great variety typical of these products further increase demand unpredictability. The demand uncertainty from the market environment increases the risk and costs of shortages and excess supplies throughout the chain. To mitigate this risk, it is crucial that information flows not only within the chain but also from the marketplace to the chain. Fisher (1997) describes managers' primary focus in supply chains for innovative products as market mediation, the need to read early sales numbers or other market signals and have the chain respond quickly. The critical decisions to be made are not about minimizing costs but about where in the chain to position inventory and available production capacity in order to hedge against the uncertain demand and be responsive. Supply chain systems reduce the external environmental uncertainty by introducing formal information and knowledge transfer mechanisms between supply chain partners. In supply chains with innovative products, suppliers are evaluated based on their reliability, speed, flexibility, and product development skills as well as for their cost.

Due to the emphasis on market mediation, supply chains for innovative products require more collaboration about product design and improvement of business processes than supply chains for functional products. While information sharing can improve the performance of functional product supply chains, inter-organizational learning is essential to support the overall objectives of the innovative product supply chain.

KNOWLEDGE MANAGEMENT IN SUPPLY CHAINS

As the goal for functional products is to minimize the physical costs associated with the production and delivery of the product, many supply chains have improved their coordination efforts by sharing information. Efficient Consumer Response (ECR) and Quick Response (QR) initiatives are efforts that certain industries have implemented to reengineer the supply channel to make it more responsive to customer demand. Controlling the flow of information and product between different stages within the chain is a major focus of these initiatives as it helps decrease the costs of inventory and shortages. Chains have used technologies such as electronic data interchange (EDI), the Internet, and satellite systems for transmitting point-of-sale data to provide real-time information. Improved coordination is achieved with this information even when the decision-making responsibilities remain decentralized. A $14 billion savings in the food service industry (Troyer, 1996) and $30 billion savings in the groceries industry (Kurt Salmon Associates, 1993) have been documented as a result of implementing these initiatives. Current MS/OR research (e.g., Lee, So & Tang, 2000) studies the value of different types of information that can be shared given the decentralized decision-making framework. For example, Wal-Mart's Retail Link program provides an online summary of point-of-sale data for Johnson & Johnson and

Lever Brothers as well as direct satellite transmitted point-of-sale data. Cachon and Fisher (1997) describe the cost savings that Campbell Soup's continuous replenishment program generated for the grocery supply chain. In this instance, retailers transmitted daily inventory information via EDI to Campbell Soup, and the manufacturer assumed responsibility for managing retailer inventories, a process commonly referred to as vendor managed inventory. This particular continuous replenishment program reduced inventories in retailer distribution centers by 50%, while increasing service levels from 98.7% to 99.5%.

Some chains have extended their collaborative efforts to include information about processes as well as more centralized decision making. Aviv (2001) and Raghunathan (1999) describe Collaborative Forecasting and Replenishment (CFAR) as a new inter-organizational system that enables retailers and manufacturers to forecast demand and schedule production jointly. CFAR allows the exchange of complex decision support models and manufacturer/retailer strategies so that the two supply chain parties can reduce demand uncertainty and coordinate their decisions. Wal-Mart and Warner-Lambert embarked on the first successful CFAR pilot, involving Listerine products in 1996. Since then several major manufacturers of functional products, such as Procter and Gamble, have undertaken CFAR projects.

Due to the demand uncertainty and short life cycle, supply chains for innovative products need to develop strategies that will create flexibility and responsiveness within the chain. The exchange of knowledge about processes, innovations, and market interest are vital to the members of the chain as it works to design and distribute the newest product to the market quickly. The Knowledge and Learning in Advance Supply Systems (KLASS) pilot project (Rhodes & Carter, 2003) seeks to develop collaborative learning in networks of suppliers in the automotive and aerospace sectors. Focusing on the tiered supplier network, as illustrated on the left side of Figure 1, KLASS utilized an inter-company, computer-mediated learning network that focused on both immediate performance improvements and longer term objectives. It developed learning and knowledge to advance collaborative functioning and improved performance between the tiered companies linked in the supplier network. Similarly, to manage knowledge across the supplier network and enterprise boundaries, as shown in Figure 1, Chrysler developed a successful supplier-suggestion process to reduce costs and build collaborative relationships with its suppliers (Hartley, Greer & Park, 2002). Both of these are examples of inter-organizational systems.

In another example of an inter-organizational network, Mak and Ramaprasad (2003) introduce the idea of knowledge supply networks, which they define as "integrated sets of manufacturing and distribution competence, engineering and technology deployment competence, and marketing and customer service competence that work together to market, design and deliver end products and services to markets." They outline the nature of the business processes associated with designing and delivering innovative products and describe the need to effectively coordinate the knowledge in the market, design, and supply distribution chains. As costs for product development increase and faster time-to-market is expected, more and more original equipment manufacturers (OEM), such as Motorola and Nokia, are refocusing their competence on marketing, research and design, and critical high level design, and outsourcing everything else to contract manufacturers. This changes the chain structure as outlined in Figure 1 and requires the OEM to create a knowledge management network that will allow them to leverage the supplier and contract manufacturer knowledge, yet still preserve their own knowledge and control.

In order to be competitive, supply chains for innovative products must have processes in place to exchange product and market knowledge. Unlike the chains associated with functional products, innovative chains will not incur much competitive advantage as the result of demand and inventory information sharing. Due to high future demand uncertainty and potentially high profit margins, there is often distrust between the stages of the chain. This distrust can result in parties making uncoordinated decisions that are in their best individual interest (local optimization) and not in the best interest of the supply chain.

For instance, in the PC market, manufacturers suspect their distributors of inflating orders to ensure availability of the product. Dell Corporation removed the distributor stage in its supply chain so that it could improve its market mediation and receive end-consumer information directly. In the automotive and aerospace industry, manufacturers provide suppliers with forecasts that are often wrong, resulting in extreme shortages or excess capacity with no return on investment for the suppliers. Suppliers often make locally optimal decisions as a result. When a supplier could not provide an adequate supply of ashtrays and glove compartment doors, GM lost nearly two months of production of the Buick Roadmaster (Suris & Templin, 1993). In 1999, GM canceled two new models, leaving their suppliers with newly developed capacity and no return for their investment (Pryweller, 1999). In 1997, Boeing could not fill their plane orders largely due to a shortage of 500 different parts from 3,000 part suppliers who did not have enough capacity, resulting in a $1.6 billion charge against Boeing's third-quarter earnings (Cole, 1997).

A survey done by Lee and Whang (2000) identifies that firms are also concerned about the confidentiality of shared information when competition exists, and that it is one of the major hurdles that information sharing in a supply chain must overcome. Besides intentional information leaks, Li (2002) defines the leakage effect as the indirect effect of vertical information sharing that occurs when the shared information becomes known to competition as the result of observing the behavior of the party that receives the information. Li illustrates how competing firms can react to the observed behavior and how this reaction can change the strategic interaction, causing additional gains or losses to the parties between which the information was directly exchanged. Powell, Koput, and Smith-Doerr (1996) point out that firms will continue to work with their partners, once the risks are managed at a "tolerable level."

In addition to trust, several other factors impact the ability of a firm to share information and knowledge productively with other parties in a supply chain. These include the technology infrastructure, application software used to manage the supply chain operations, and the culture of knowledge sharing within a firm as well as within the supply chain.

Scott (2000) studied the process of and reasons for information technology (IT) support for inter-organizational learning. Studying the disk drive industry, Scott identified the need for inter-organizational learning to help "cope with the complexity of new products and the capital intensity" in the industry. She noted that the industry had consolidated with several firms working very closely in a "vertically integrated virtual organization." IT helps the organizations streamline the information flow between them, making it easier to provide feedback between partners and facilitate learning across organizational boundaries. The model developed by Scott helps to explain the role of IT in lower and higher levels of inter-organizational learning. In lower level learning, an organization makes changes to its operations based on feedback from a partner. In higher order learning, partners change operating assumptions and procedures based on a new understanding typically resulting from collaborative work. An important finding from her study was that inter-organizational learning strategies "with customers and suppliers in the disk drive industry were facilitated by IT and constrained by lack of trust."

Kent and Mentzer (2003) conducted a study of the impact of inter-organizational information technology (IOIT) in a retail supply chain. They found that when suppliers invest in IOIT, retailers perceive a commitment to the relationship from the suppliers and are willing to reciprocate. The commitment to the relationship leads to the partners working together to improve logistics efficiency. Therefore, the payoff from the investment in IOIT comes from the reduction of costs in the supply chain as a result of improvements in logistics efficiency. Their findings also support Scott's (2000) observation about the role of trust between partners in a supply chain. In addition to the investment in IOIT, they show that firms must also "demonstrate characteristics of trust such as integrity and faithfulness." Only then will partners perceive the commitment to the relationship. As Kent and Metzer state, "relationship trust and investment in IOIT can lead to relationship commitment that can lead to logistics efficiency."

The above examples pertain to inter-organizational systems; however, KM plays an important role even within a single organization. Intra-organizational systems and initiatives are needed to facilitate knowledge sharing across organizational units. Edwards and Kidd (2003) treat knowledge management "as a process rather than as an organizational system" or a piece of technology. In order for this process to work across organizational boundaries, they identify trust, organizational culture, and the "relationship between top down strategy and bottom up organizational learning" as enabling factors. Trust needs to exist between individuals as well as between organizations. There needs to be compatibility between the cultures of organizations for knowledge management processes to work. Aligning the top down strategy with bottom up learning requires the organization to make its strategy for KM clear and create and maintain an atmosphere that supports organization learning. Trust between individuals and organizations can be enhanced by setting up exchange programs and by facilitating voluntary exchange of knowledge.

Another set of factors that Bessant and Kaplinsky (2003) recognize as necessary for learning in supply chain is the "accumulation and development of a core knowledge base," as well as the "long-term development of a capability for learning and continuous improvement across the whole organization." In order for each organization in a supply chain to manage how learning takes place, they need to have formal mechanisms and a clear understanding of the value of learning. Only then can long-term efforts be sustained.

This set of factors is based on the concept of absorptive capacity (Cohen & Levinthal, 1990). Cohen and Levinthal describe this as the capacity of an organization to "recognize the value of new, external information, assimilate it, and apply it to commercial ends." Lane and Lubatkin (1998) suggest that the absorptive capacity of a firm is relative to its partner firms and is dependent on "the similarity of both firms' knowledge bases, organizational structures and compensation policies," and one firm's familiarity with the other firm's "set of organizational problems." Szulanski (1996) shows that a unit's lack of absorptive capacity, a distant relationship with other units and lack of a clear understanding of cause and effect relationships can all become impediments to intra-organizational learning.

In addition to efficiency in logistics is the issue of effectiveness of sourcing in enterprises that have multiple personnel handling the purchasing task. Rozemeijer, Van Weele, and Weggeman (2003) identify three constructs to help corporate purchasing officers create coordinating mechanisms that facilitate purchasing synergies within the corporation. The constructs include purchasing maturity, corporate coherence, and business context. The mechanisms they identified include:

- formal organizational mechanisms such as corporate steering boards or commodity teams;
- informal networking mechanisms such as annual purchasing conferences and job rotation;
- enterprise-wide information and communication systems; and
- advanced management and control systems.

These four mechanisms or systems represent different options for intra-organizational KM. These mechanisms were illustrated for a supply chain with functional products. Rozemeijer et al. (2003) also point out however that purchasing performance depends on increased coordination between multiple purchasing officers and requires constant monitoring to ensure that the purchasing function is aligned with the business context and corporate strategy, which is associated with the type of product and supply chain objectives involved.

CONCLUSION

As the studies cited above show, information technology that supports information sharing is a necessary element for knowledge management processes to work in supply chains. In supply chains for functional products, decentralized decision making can result in good decisions when IT support is effective. However, in innovative supply chains, IT by itself is not sufficient. The other factors are needed as well. Without the other factors, such as trust within and across organizations or an organizational culture that supports learning, the supply chain does not benefit. Even with good IT and information sharing, each company is likely to make decisions that are locally focused, resulting in suboptimal supply chain performance.

Practitioners interested in creating and managing knowledge management efforts in supply chains should consider the following issues carefully:

- The information flow between the tiers in the supply chain and how the systems and organization support information sharing.
- The utilization of information within an organization, especially to support decision making. Decentralized decision making can be beneficial for the supply chain as long as the firms trust each other and want to optimize the performance of the chain. Incentives need to be in place to ensure that each party is motivated to maximize the performance of the chain.
- The organizational culture with respect to learning within each firm and across the tiers in the supply chain. The culture must support learning and facilitate the process of learning.
- Trust between organizations in the supply chain is critical. Unless the firms develop this trust, they will make decisions solely based on their self interest, and that may be detrimental to supply chain performance.
- How the network assimilates the information and how the network changes its actions based on what it has learned is the effect of the knowledge management effort. In the case of functional products, this can be in the form of firms modifying processes to increase efficiency. In the case of innovative products, suppliers may be elevated to status of true partners, taking on more responsibility and risk and sharing in decision making as decisions are made in a more centralized manner.

Chapter 6.21
Corporate Semantic Webs

Rose Dieng-Kuntz
INRIA, ACACIA Project, France

INTRODUCTION

An organization is made up of people interacting for common objectives, in a given structure (may be rather formal in the case of a company, an administration, or an institution, or rather informal in the case of an interest community or a practice community), in an internal environment, and with an external environment.

Based on definitions of Grundstein (2004) and O'Leary (1998), we define knowledge management (KM) as the "management of knowledge resources of an organization in order to ease:

- access, sharing, reuse of this knowledge (that can be explicit or tacit, individual or collective), with an objective of capitalization;
- creation of new knowledge, with an objective of innovation."

Among the various approaches for KM, this article focuses on those aimed at knowledge capitalization and sharing. They can rely on the notion of corporate memory (or organizational memory (OM)) that, extending van Heijst's definition (1996), we define as the "explicit and persistent materialization of crucial knowledge and information of an organization in order to ease their access, sharing out and reuse by the members of the organization in their individual and collective tasks" (Dieng-Kuntz et al., 2001).

As such an OM relies on individuals interacting in an organization, with support of software tools, construction and management of a corporate memory require a multidisciplinary approach, taking into account at least three dimensions: (1) individual (memory must be compatible with users' cognitive models and their work environment), (2) organization (memory must be compatible with culture and strategy of the organization), and (3) technology (the chosen software tools must be adapted to the memory objectives and to the environment of future users).

This article will detail a particular approach of OM called the "corporate semantic Webs" approach, proposed by the Acacia team which the author deeply thanks.

BACKGROUND

From Knowledge-Based Systems to Knowledge Management

If the need of KM in enterprises has long been emphasized in management sciences (Grundstein, 2004), this notion started to be studied thoroughly at the beginning of the '90s by artificial intelligence researchers who had previously worked on expert systems and knowledge-based systems (KBSs), and had evolved towards knowledge engineering (KE): Steels (1993) was one of the first researchers in this community to stress the notion of corporate memory in order to promote knowledge growth, knowledge communication, and knowledge preservation in an organization; since 1993, the ISMICK conferences have been dedicated to these topics (Barthès, 1996). In 1996, the KE community emphasized the interest of OMs and its differences with regards to KBS: definitions were proposed (van Heijst, Van der Spek, & Kruizinga, 1996), as well as concrete examples (Dieng et al., 1996). Then several workshops at KAW, ECAI, IJCAI, and AAAI thoroughly studied methods and tools for building and using OMs (Dieng & Matta, 2002).

Ontologies and Knowledge Management

Meanwhile, the KE community was working on ontologies (Gruber, 1993). The Banff Knowledge Acquisition workshops (KAW)1 enabled a better comprehension of foundations of ontologies (Guarino & Giaretta, 1995; Guarino, 1996). Researchers proposed tools for collaborative building of ontologies (Farquhar, Fikes, & Rice, 1996; Domingue, 1998; Tennison & Shadbolt, 1996), as well as concrete, huge ontologies in KM large applications (Swartout et al., 1996; Golebiowska, Dieng, Corby, & Mousseau, 2001). Moreover, some researchers on ontologies emphasized the interest of ontologies for KM (Benjamins, Fensel, & Gómez-Pérez, 1998a; Dieng et al, 2001).

The (KA)2 initiative (Benjamins et al., 1998b) was a significant example of collaborative building of an ontology and of semantic annotations by the knowledge acquisition community.

Knowledge Management Based on Ontologies and Documents

The evolution from KBS to KM was based on the idea that a corporate memory could be naturally materialized in a knowledge repository without any reasoning aims; therefore ontologies seemed to be a quite natural way to make the conceptual vocabulary shared by an organization explicit. But this evolution led to recognition that the most frequent knowledge sources that could be integrated in an OM were documents. The need for a link between documents (considered as informal knowledge sources) and knowledge bases/ontologies (expressing formal knowledge) was emphasized by research that associated to a document a knowledge base aimed at making the underlying semantics of the document explicit and at improving information retrieval by reasoning on this knowledge base (Martin, 1997; Euzenat, 1996). The advent of XML led several KM researchers to rely on XML-based formalisms and on the future semantic Web (Rabarijaona, Dieng, Corby, & Ouaddari, 2000; Martin & Eklund, 2000). Shoe (Luke, Spector, Rager, & Hendler, 1997) and Ontobroker (Fensel, Decker, Erdmann, & Studer, 1998) offered an ontology-guided information retrieval approach; community semantic portals were developed using such tools (Staab et al., 2000).

Knowledge Management and the Semantic Web

The interest of the Web for KM and knowledge distribution over the Internet, either through an intranet or through the open Web, was stressed by O'Leary (1997), by the KAW'98 track on "Knowledge Management and Distribution over the Internet,"2 as well as some special issues of journals (Dieng, 2000) and books (Schwartz, Divitini, & Brasethvik, 2000).

In 1998, Berners-Lee proposed his vision of the semantic Web:

The Web was designed as an information space, with the goal that it should be useful not only for human-human communication, but also that machines would be able to participate and help. One of the major obstacles to this has been the fact that most information on the Web is designed for human consumption, and…that the structure of the data is not evident to a robot browsing the Web. Leaving aside the artificial intelligence problem of training machines to behave like people, the Semantic Web approach instead develops languages for expressing information in a machine processable form.

He gave a roadmap for evolving "from the Web of today to a Web in which machine reasoning will be ubiquitous and devastatingly powerful" (Berners-Lee, 1998).

Several research communities (database, intelligent systems (Schwartz, 2003), knowledge engineering and knowledge representation, information retrieval, language technologies, distributed artificial intelligence and multi-agent systems, machine learning, Computer-Supported Collaborative Work, etc.) recognized in this ambitious objective a fabulous potential application of their research.

Last, the importance of social networks in which interactions and cooperation could be enhanced through the Web explains the privileged role of the semantic Web as a basis for supporting such networks, in particular with participants distributed geographically.

European Projects on Knowledge Management and the Semantic Web

Several collaborative European or national projects studied semantic Web approaches for KM:

- The C-WEB3 (Community Webs) project (Christophidès, 2000) proposed an infrastructure for Web portals in user communities requiring efficient query answering using various information sources. This infrastructure, aimed at semantic portals, can be seen as an architecture for a community semantic Web.
- The On-to-Knowledge4 project (Davies, Fensel, & van Harmelen, 2002) offered languages—such as OIL (Fensel et al., 2000), one precursor of OWL—methods, and tools aimed at applying ontologies to electronically available information for improving KM quality in large, distributed organizations.
- The CoMMA5 (Corporate Memory Management through Agents) project (Gandon, Dieng-Kuntz, Corby, & Giboin, 2002) developed an ontology (O'CoMMA), as well as a multi-agent system for managing a distributed corporate memory materialized in a corporate semantic Web, some agents having machine learning capabilities.
- The British AKT (Advanced Knowledge Technologies) project (Shadboldt & O'Hara, 2004) relies on an integrated approach, combining artificial intelligence, psychology, linguistics, multimedia, and Internet technology, for developing the next generation of knowledge technologies in order to support organizational KM, from acquiring and maintaining knowledge, to publishing and sharing it.
- OntoWeb6 (Ontology-Based Information Exchange for Knowledge Management and Electronic Commerce) network studies

thouroughly techniques and methodologies for building and using ontologies in the framework of the semantic Web.

The convergence of all these research topics led to the idea of the corporate semantic Web, which the next section will explain more precisely.

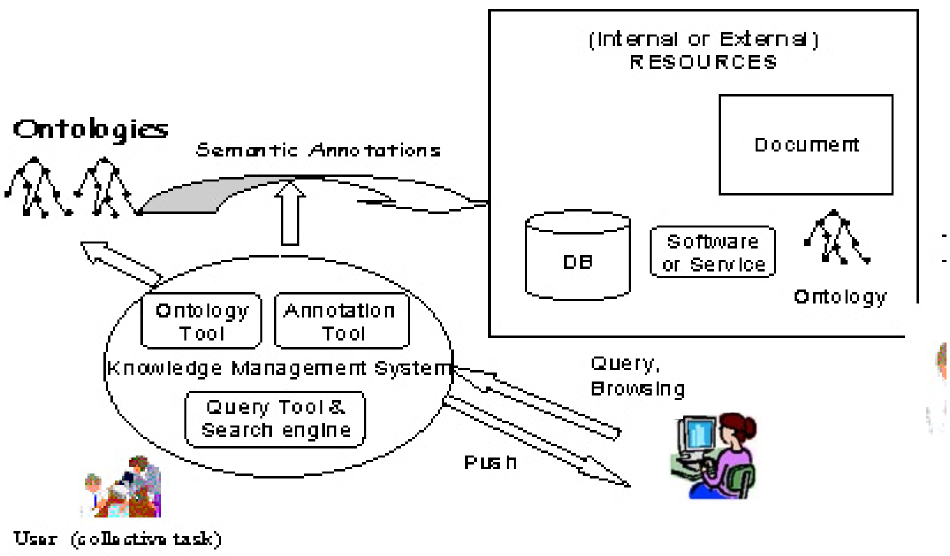
MAIN FOCUS OF THE ARTICLE

The corporate semantic Web approach proposed by the Acacia team relies on the analogy between Web resources and corporate memory resources. Intranets or IntraWebs, based on Web technologies, are a widely used means of information diffusion aimed at improving information and knowledge sharing out in enterprises. As the Web users, members of an organization need to access competent persons, to retrieve relevant information in documents, to discover useful services, and to communicate or publish in order to share specific knowledge.

The semantic Web aims at making semantic contents of Web resources understandable, not only by humans, but also by programs, for a better cooperation among humans and machines, according to Berners-Lee's vision (Berners-Lee, Hendler, & Lassila, 2001). The most popular approach consists of making semantic annotations on Web resources explicit, such annotations being represented in the RDF language recommended by W3C.

Our hypothesis is that the social Web constituted by all actors interacting in an organization could be supported by a KM system materialized in an organization-wide web inspired by the World Wide Web. The importance of semantics of the concepts to be handled leads naturally to a corporate semantic Web, inspired by the semantic Web, but at the scale of the organization.

Figure 1. Architecture of a corporate semantic Web

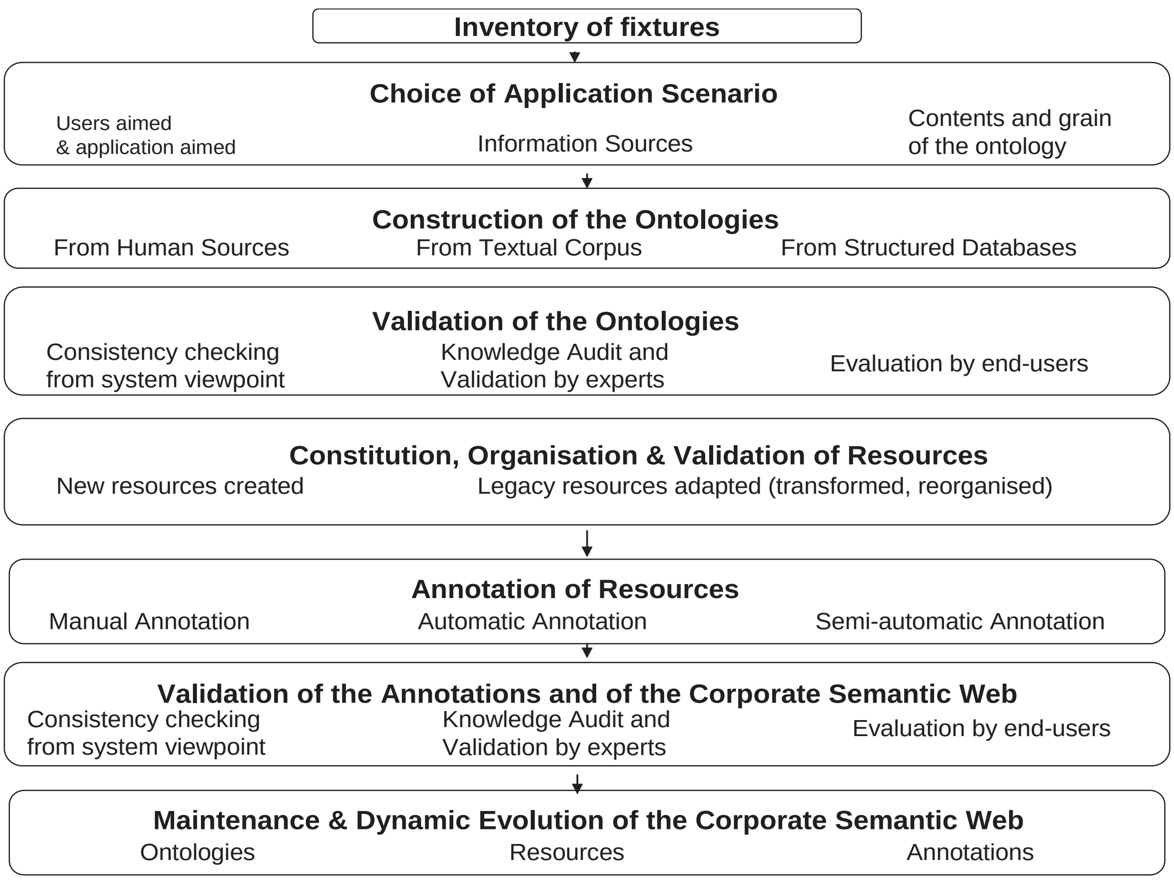


Therefore, we propose to materialize a corporate memory through a corporate semantic Web (or organizational semantic Web) consisting of:

- Resources: These can be documents (in various formats such as XML, HTML, or even classic formats), but these resources can also correspond to people, services, software, or programs.
- Ontologies: Describing the conceptual vocabulary shared by one or several communities in the company.
- Semantic Annotations on Resources: Contents of documents, skills of persons, or characteristics of services/software/programs, based on these ontologies, with diffusion on the intranet or the corporate Web.

However, a corporate semantic Web has some specificities with regards to the Semantic Web. The fact that an organization is bounded allows an easier agreement on a corporate policy, an easier creation of ontologies and annotations, an easier verification of validity and reliability of

Figure 2. Method of construction of a corporate semantic Web



information sources, a description of more precise user profiles, and a smaller scale for corporate documents and for ontologies. But an organization has security and confidentiality constraints, as well as a need to rely on stable tools or standard languages, compatible with the internal work environment.

Figure 1 shows the architecture of a corporate semantic Web, and Figure 2 summarizes our method for building it. Researchers study how to build, represent, use, and evolve each component of the system and the links among such components. After stressing the actors involved, we will analyze the components of a corporate semantic Web (resources, ontologies, annotations).

COMPONENTS OF A CORPORATE SEMANTIC WEB

The Actors

We distinguish several roles among the involved actors:

- The knowledge holders or authors of resources (for example, authors of documents, software, or services constituting the memory resources).
- The end-users: The objective of annotations is to allow end-users to retrieve resources ("pull") or to disseminate these resources towards end-users in a proactive way ("push"), in a more precise and relevant way in both cases.
- The annotators, who can be either knowledge holders or mediators (such as documentation centers). They must annotate resources in order to ease their retrieval by the future memory users. These annotations must thus take into account, on the one hand, the semantics aimed by the authors, and on the other hand, the users' needs for search for information. Objective annotations correspond to an interpretation common to any user, whereas subjective annotations are related to interpretation by a particular reader. As the annotator cannot guess all possible uses of the resources and all the future users' needs, s/he can collect information about profiles of the intended users and about their work contexts.

Resources in a Corporate Semantic Web

One can regard as resource any human, documentary, or software entity that can possibly be considered as a knowledge source thanks to its interpretation by a human accessing this resource. Resources can be documents with various formats (classic formats or formats dedicated to the Web like XML, HTML), but they can also correspond to people (in the case of a memory aimed at easing access to knowledge holders), services, software, programs, databases (DBs), ontologies, knowledge bases (KB), case bases, and so forth. According to the granularity chosen, the elementary resource enabling access to a knowledge element can consist of an entire document or of an element of document, of a whole database or of a DB record, of a whole KB or of a rule, and so forth, provided that this element is identifiable and can be referred.

Resources can be internal or external to the organization: for example, in a technological watch scenario, the semantic annotations of external resources useful for some employees can be considered as part of the corporate semantic Web.

Ontologies in a Corporate Semantic Web

An ontology is the explicit specification of a conceptualization according to Gruber (1993), or more precisely, according to Borst (1997), the formal specification of a shared conceptualization. We can characterize an ontology by:

- its root concepts, indicating the principal semantic axes or points of view considered;
- its concepts: each concept can be characterized by the terms enabling to designate it, its informal definition in natural language, its formal definition in intension in the case of a defined concept, its attributes, and its possible relationships with other concepts (parents, brothers, or concepts to which it is connected by a relation);
- the structure of the ontology: subsumption link enables the structuring of a concept hierarchy (resp. a relation hierarchy), part-of link enables structuring of a partonomy of concepts;
- possible relations between concepts, with the signatures of these relations;
- the instances of concepts when they play an ontological part (such as, for example, some constants in a mathematical or physical field: e.g., π, c, g);
- the axioms on concepts and relations.

The roles of an ontology in an OM are varied (Gandon, Dieng-Kuntz, Corby & Giboin, 2002):

- The ontology can be a component of the memory, a component aimed at being browsed by the end-user: in this case, natural language definitions or explanatory texts understandable for a human user must be associated to concepts and relations of the ontology. Moreover, the ontology contents must be adapted to users' tasks—at grain level, detail level, visibility level, and so forth.
- The ontology can be a reference for indexing/annotating semantically the memory in order to improve resource retrieval or information retrieval in the memory. In this case, the ontology must include concepts significant for annotation (e.g., User, Competence, Organization, Document, Task, Project, Domain), so as to enable annotation of the resources of the memory (e.g., This resource is a document of this type, created by someone having this competence in this department of the organization, related to these domain concepts and useful for this type of user in the framework of this task in the context of this project), and then reuse these annotations and the ontology in order to make inferences for information retrieval.
- Finally, the ontology can be a basis for communication and exchange of information among programs or among software agents. In this case, a formal ontology (with an accurate, non-ambiguous meaning), represented in the formal language of the messages exchanged by these agents, is needed. The content of the ontology must correspond to the needs in messages of the software agents that must be able to handle it formally.

When the OM is materialized in a corporate semantic Web, the situation corresponds to the second case since the ontology must at least be used for semantic annotation of memory resources. However, as we stressed in the previous section, ontologies can also form part of the memory resources, and they can also be annotated semantically.

In the three cases, it is necessary to choose ontology contents (i.e., its domain and its level of granularity), as well as its method of construction and evolution. The following sections will study more thoroughly these two points.

Contents of the Ontology

The applicative objective can help to choose the degree of granularity of the ontology: the contents of an Automobile ontology intended to be used by a design engineer working in the drawing office of a car manufacturer will be different from the Automobile ontology for an accidentologist analyzing road accidents.

Knowledge on the future users or on applications in which the ontology will be integrated can thus be useful to determine whether it is relevant to integrate a given concept, and can help to choose the adequate width and depth of the ontology.

If the ontology plays the role of a reference for annotating the memory elements semantically, it can be compared with an index on the memory. But, instead of the terms of an index or of a thesaurus, a semantic annotation by the ontology allows to associate to an element of the memory concepts, relations, instances, or particular relations between instances. Moreover these annotations can relate to an elementary resource which can, according to the case, consist of an entire document or of an element of document.

In this case, the criterion to build the ontology will be the answer to the question: By which concepts/relations/instances will the annotator need to annotate the resource in order to ease the retrieval of this resource in the most relevant way?

In the OM scenario, the intended user type or even the use context can be helpful for this purpose:

- In a scenario of project memory, concepts allowing description of a project and its organization, its participants, its tasks, problems encountered and possible solutions, lessons learned in the project, and concepts of the project domain will be useful to integrate in the ontology. The SAMOVAR application (Golebiowska, Dieng, Corby & Mousseau, 2001) illustrates such a scenario of project memory. In this scenario—in the context of design of new car—an engineer of a car manufacturer tries to solve a problem encountered on a given part of the vehicle designed, and s/he tries to retrieve in past projects whether the same problem (or a similar one) occurred, which solutions were considered, and which one was adopted for solving it. S/he will then be able either to reuse this solution (perhaps after adapting it) or, if the change of context makes reuse of this solution impossible, to study whether one of the other solutions previously evoked and eliminated would be convenient to be used or adapted.
- In a scenario of skills management (Benjamins et al., 2002), the ontology can include the concepts allowing description of various types of competences (technical, organizational, social, or relational skills) and their links with various functions or tasks within the organization.
- In a scenario of support to a newcomer integration, the ontology can be based on the needs of a newcomer and on all the actors likely to interact with this newcomer; the ontology can, for example, describe the types of documents having to be consulted by a newcomer or to be used by a mentor/tutor, those describing the organization, and those useful for the Human Resources department. The ontology will be able to also include some concepts of the domain (for example, technical concepts useful for the activity of the newcomer or concepts s/he must learn to master). The CoMMA application (Gandon, Dieng-Kuntz, Corby & Giboin, 2002) illustrates such a scenario.
- In a scenario of e-learning, the ontology can rest on the needs of training for acquiring the competences required in the various functions of the company, on the teaching approaches to use, on the profiles of the students, or of the people/companies likely to carry out teaching, on the available e-learning tools, on the possible uses of the Web as exchange medium, on the educational

resources. The MEMORAE application (Abel et al., 2004) illustrates this scenario of e-learning.
- In a scenario of watch (i.e., scientific, strategic, or technological monitoring, business intelligence), concepts allowing description of the actors involved in the watch process of the company, as well as concepts on the relevant domain and all those likely to be watch targets, could be included in the ontology (Cao, Dieng-Kuntz, & Fiès, 2004). For example, in a scenario in the pharmacological sector, the watch department analyzes all documents on published patents of their competitors in order to detect new significant trends of research (confirming their own research strategy or to take into account in this strategy).

The ontology creation depends on the modeling choices and rests on several actors: ontologist, experts serving as knowledge sources, experts taking part in the validation. Some modeling choices will also be influenced by the future application and by the future users of the ontology (either those who will consult it directly, or those who will seek resources annotated through it). Thus the ontology must be viewed as the result of a construction process, via a negotiation between several actors: ontologist, experts, and users.

Construction of the Ontology

The ontology construction methodology can be inspired by manual methods of ontology development from experts (Gómez-Pérez, Fernández-López, & Corcho, 2004; Uschold & Gruninger, 1996) or by methods based on corpus analysis (Aussenac, Biébow, & Szulman, 2000; Bachimont, Isaac, & Troncy, 2002).

The construction of the ontology can be manual, semi-automatic from textual corpora, or semi-automatic from a structured database.

Manual Construction

The method of construction of ontologies proposed in Gandon (2002) and Gandon et al. (2002) for building an ontology in the framework of a corporate semantic Web relies on the following phases:

- collection of data and scenarios, starting from discussions with some knowledge holders and through manual analysis of documents provided by the company, without use of natural language processing tools;
- terminological phase, allowing to determine terms associated with concepts and to solve terminological conflicts (cf., a case where different concepts are designated by the same terms or a case where several terms refer to the same concept);
- structuring of the ontology, through specialization links between concepts or relations;
- validation by experts;
- formalization in an ontology representation language (such as the languages recommended by W3C). According to the expressivity degree needed, one can use RDF(S) (Lassila & Swick, 1999) for basic ontologies, or OWL (Dean & Schreiber, 2004; McGuinness & van Harmelen, 2004) and one of its layers, OWL-Lite, OWL-DL, or Full OWL, for more expressive ontologies.

This method allows development of an ontology by possibly structuring it in several levels:

- a high level including abstract concepts, very reusable but not very usable by end-users in their daily work, and thus needing to be hidden when the end-user browses the ontology;
- an intermediate level comprising concepts useful for the OM scenario and for the do-

main considered, and thus reusable for these scenarios and similar domains;
- a specific level including concepts specific to the company and thus very useful for end-users, but not very reusable apart from this company.

The O'CoMMA ontology (Gandon, 2002), dedicated to two scenarios of corporate memory (support to integration of a new employee at T-Systems Nova, and support to technological monitoring at CSELT and at CSTB) is thus structured in three such levels.

Semi-Automatic Construction from Textual Sources

The methodology of ontology construction from texts proposed by the TIA group7 and described in Aussenac-Gilles et al. (2000) consists of the following stages:

- Set up of the textual corpus, taking into account the aims of the application.
- Linguistic analysis, consisting of choosing and applying to this textual corpus the adequate linguistic tools such as: (a) term extractors allowing to propose candidate terms, (b) relation extractors allowing to propose relations between these terms, (c) synonym managers allowing to detect synonym terms, and so forth.
- Normalization includes two phases:
    - Linguistic normalization: Allows the knowledge engineer to choose among the terms and lexical relations extracted previously, those which will be modeled in the ontology. The knowledge engineer will associate to each term and relation kept, a definition in natural language, if possible close to the text in the corpus. If a term or a relation has several meanings in the domain (i.e., polysemy), the knowledge engineer decides which meanings attested by the corpus will be kept because of their relevance.
    - Conceptual modeling: Semantic concepts and relations are then defined in a normalized form using labels of concepts and relations already defined.
- Formalization consists of ontology construction and validation. Existing ontologies can help to build the ontology top level and to structure it through main sub-domains. Semantic concepts and relations are then formalized and represented in chosen knowledge representation formalism (for example, description logics or conceptual graphs). If needed, additional concepts (i.e., structuring concepts, not necessarily attested by the textual corpus) can be added to structure the ontology. In a corpus-based approach, the terminological concepts (attested in texts) are distinguished from the other concepts (created by the ontologist in order to gather, factorize information, or structure the ontology). A complete validation can be carried out as soon as the ontology reaches a stable state.

This method was, for example, adapted for a vehicle project memory, within the framework of the SAMOVAR project (Golebiowska, Dieng, Corby & Mousseau, 2001), whose objective was to capitalize knowledge on problems encountered during a vehicle design project.

Semi-Automatic Construction from a Structured Database

One can also start from a structured database to translate it into an ontology represented in a standard representation formalism. The translation algorithm will depend on the database internal format, but the generic idea of building an ontology by decoding a database—the principle of coding of which is known—and to represent this ontology in a standard knowledge representation formalism, is interesting for companies having DBs from which they wish to reconstitute an ontology. This semi-automatic construction of ontologies from DBs is illustrated with the example of the Life Line project (Dieng-Kuntz et al., 2004), aimed at developing an organizational semantic Web dedicated to a medical community cooperating in the context of a healthcare network. By using an approach of "reverse engineering" relying on the analysis of its coding principle, Nautilus medical database was decoded to reconstitute a Nautilus ontology represented in RDF(S): the ontology could then be browsed and validated via a semantic search engine, and used for annotating and retrieving documents, and so forth.

Annotations in a Corporate Semantic Web

The construction of annotations relies on the ontology. The choice of grain of resource elements depends on the level to which the user needs to access the OM.

If one compares ontology-based semantic annotation with traditional indexing in information retrieval, their roles are similar, but the hierarchy of concepts, the relations, as well as the presence of axioms, allows several possibilities of reasoning: ontology-guided information retrieval enables retrieval of resources in a more relevant way (Fensel et al., 1998; Dieng et al., 2001; Corby & Faron, 2002; Corby, Dieng-Kuntz, & Faron-Zucker, 2004). An annotation is interpreted as: "This resource speaks about such concept, speaks about such instance of concept, expresses such relation between such concepts or such instances of concepts." One could be more precise and indicate the nature of annotation relation: some annotations can be viewed as argumentations, examples, assertions, and so forth.

For the construction of these annotations, one can use manual annotation editors or semi-automatic annotation tools such as those described in Handschuh and Staab (2003).

The user can then retrieve resources of the corporate semantic Web, which offers semantic browsing or semantic querying capabilities, based on resource annotations related to the ontology. There may also be specific annotations on user profiles and centers of interest if the ontology comprises concepts describing types of profiles or of interest centers. Semantic search engines such as Ontobroker (Fensel, Decker, Erdmann & Studer, 1998), WebKB (Martin & Eklund, 2000), or Corese (Corby, Dieng, & Hébert, 2000; Corby & Faron, 2002; Corby, dieng-Kuntz & Faron-Zucker, 2004) are useful to carry out such a search guided by ontologies. The interest of the ontology is to guide reasoning: this reasoning is based either on concept hierarchy or improvement in answers to users' queries. For example, for a request to retrieve patients suffering from a stomach disease, these reasoning capabilities enable a semantic search engine to retrieve a patient who had a surgery for a stomach cancer.

LANGUAGES AND TOOLS USEFUL FOR CREATING CORPORATE SEMANTIC WEBS

For representing semantic annotations of a corporate semantic Web, one can use RDF (Resource Description Format), a language recommended by the W3C for creating metadata for describing Web resources (Lassila & Swick, 1999). For representing ontologies, according to the expressivity level needed, one can use RDF Schema (RDFS) for simple ontologies or, for more complex ontologies, OWL (Ontology Web Language) (Dean & Schreiber, 2004; McGuinness & van Harmelen, 2004)—the ontology representation language recommended by W3C and intended for publishing and sharing ontologies on the Web.

Several tools can support building, use, and maintenance of a corporate semantic Web:

- Ontology development tools, enabling creation of a new ontology from scratch or modification of an existing ontology: e.g., Protégé (Noy, Fegerson, & Musen, 2000), KAON (Volz, Oberle, Staab, & Motik, 2003), WebODE (Arpirez et al., 2003).
- Annotation tools, enabling manual or semi-automatic semantic annotations on resources (e.g., instances of concepts and of relations)—for example, MnM (Vargas-Vera et al., 2002) or OntoMat-Annotizer (Handschuh, Staab, & Mäedche, 2001).
- Ontology-guided information retrieval tools, allowing retrieval of resources using their ontology-based annotations. Examples include semantic search engines such as Ontobroker (Fensel, Decker, Erdmann & Studer, 1998) or Corese (Corby et al., 2000; Corby & Faron, 2002; Corby et al., 2004), or semantic browsers such as Magpie (Dzbor, Domingue, & Motta, 2003).
- Multi-agent platforms, enabling the handling of distributed corporate semantic Webs—for example, tools described in Gandon (2002), and van Elst, Dignum, and Abecker (2003).

The interested reader can find a detailed description of several of such tools in Gomez-Pérez, Fernández-Lopez & Corcho (2004).

FUTURE TRENDS

Research needs to be performed on the construction, management, and evolution of the different elements of a corporate semantic Web. The most important topics seem to be:

- Maintenance and dynamic evolution of a corporate semantic Web: More specifically, how do we tackle the problems linked to evolution of ontologies, of resources, and of annotations (Klein, 2004; Stojanovic, 2004)?
- Validation of knowledge included in a CSW: Integrity and coherence of the corporate semantic Web (i.e., of the ontology and of the annotations, both after their creation and when they evolve), human validation by experts and evaluation by end-users.
- Automation in the construction of ontologies and of annotations: Progress is needed in ontology and annotation learning, using machine learning techniques, statistical or linguistic techniques.
- Heterogeneity: Integration of heterogeneous sources in a corporate semantic Web, management of multiple ontologies in a single organization/community or in several organizations/communities, management of multiple, contextual annotations according to multiple viewpoints, building and management of interoperable inter-organizations or inter-communities semantic Webs.
- Multimedia resources: Capability to handle multimedia resources and to create semi-automatically semantic annotations on multimedia resources (images, sound, video, etc.).
- Distribution: Large, distributed organizations/communities; intelligent agents, peer-to-peer architectures.
- Semantic Web services: Since Web services can play the role of resources annotated in a corporate semantic Web, current research on ontology-guided description, discovery, and composition of semantic Web services is useful.
- Human factors: Participative design of corporate semantic Webs, taking into account all stakeholders, analysis of social interactions/collaboration through a corporate semantic Web, personalization of interfaces to user, support to such interactions.

- Human-machine interaction: Research on ergonomic, intelligent, adaptive interfaces will be crucial for acceptance and usability of organizational semantic Webs.
- Scalability: Even if it is less crucial than for the open semantic Web, scalability is required for very large organizations or for watch scenarios in order to be able to handle a huge number of resources, huge ontologies, or huge annotation bases.
- Reasoning and inference capabilities: They may help offer a better personalization of interaction with users, according to their profiles.
- Evaluation of a corporate semantic Web: Knowledge valuation criteria need to be studied thoroughly (Giboin, Gandon, Corby, & Dieng, 2002; O'Hara & Shadbolt, 2001).

This research will naturally benefit from general research performed by several research communities on the (open) semantic Web, but it needs to be guided by an actual understanding of the KM needs of an organization or a community.

CONCLUSION

This article has illustrated the "corporate semantic Web" approach that enables us to guide information retrieval from corporate memory by ontologies and annotations. This approach can be applied in various scenarios: memory of a team, of a department, or of a project; strategic, scientific, and technological watch; skills management; collaborative work in a community of practice or in a virtual enterprise.

With joint collaboration of all research communities focusing on the semantic Web, of human factor specialists, of researchers in management sciences, instead of being "yet another technology for KM," corporate semantic Webs can be a natural and popular approach for supporting human social Webs dynamically created in (or between) organizations or communities.

ABSTRACT

This chapter constructs the concept of e-commerce as knowledge management. The socially constructed approach to knowledge management is adopted. Through qualitative research, rooted in the Social Constructionist-Critical Theory paradigm, the chapter examines how consumers use the Internet in commercially related activity. Through semi-structured interviews with consumers three main themes are identified and explored (interaction with commercial organizations, consumer-to-consumer interaction, power and control in business-to-consumer interaction). The chapter concludes that the Internet facilitates the construction and sharing of knowledge amongst consumers, but appears to strengthen barriers and boundaries between consumers and companies. An illustration of how companies could effectively utilize the Internet to communicate with customers is offered in an analysis of a discussion forum.

INTRODUCTION

Customer and company expectations of e-commerce are far from aligned. While companies value the Internet as a marketing channel, customers value the Internet for its connectivity and potential for increased communication.

This dichotomy reflects two extremes of technology adoption. In the first wave of e-commerce, companies rushed to establish a virtual presence and generally adopted a transactional approach.

The technology was available to facilitate online "virtual" retail exchanges, so that's what companies did. It was generally believed that these new Internet start-up companies or dot-coms would supplant traditional business models and change the face of business forever. Newspaper headlines declared, "Britain prepares for boom.com. Exciting times are ahead for the stock market as Internet start-up companies get set for flotation" (Keegan, 1999) in a fervor of optimism.

However, within a matter of months, headlines such as "Net bubble@burst.com: Analyst warns that only a few big online firms will survive" (Martinson, 1999) replaced the optimism of the initial wave. The stakeholders weren't ready for e-commerce, they hadn't seen it evolve, or more importantly they hadn't been involved in its construction. The success of this phase of e-commerce demanded too much immediate change. It was a technologically determinist, reactionary phenomena. The customers rejected the technology.

This dichotomy is visible in today's e-commerce world as well. The Internet is changing the way that companies do business, and technology is impacting business practices. For companies, "consumer knowledge" is knowledge about the consumer's lifestyle, preferences and significant life events. They are operating in a knowledge gathering culture. In contrast, for customers, "consumer knowledge" is knowledge that consumers have about different products, companies and services. People's lives are made up of conversations and the Internet facilitates conversation amongst and between a wide circle of individuals. On neutral ground away from the commercial Web, a knowledge sharing culture is evolving. Here, the impact of the Internet is vast. Nobody planned it this way. Discussion forums, review sites, chat rooms and communities have all evolved as people have shaped the way that the Internet is used.

In the technological integrationist or constructivist tradition (Elster, 1983; Kimble & McLoughlin, 1995), and echoing the work of Bijker (1999), ordinary people are constructing the World Wide Web, shaping the way it is used in a recursive, proactive and evolutionary process. Outlining

Full Review

They make the most durable & colorful toys I have ever seen. Customer Service is Outstanding! My children are now 18, 16 and almost 7 and we have purchased everything --sand boxes & pools to swings to ride on toys to club houses. If a part falls off, which rarely happens, I just call their customer service number on their website www.littletykes.com and before I know it the piece is in my mailbox!

They also almost always do not charge for a replacement piece. I know other people who have been charged for replacement parts, but this has not been my experience.

Today I wrote this opinion after calling their customer service. I asked them if there was a replacement plug for my Little Tykes pool. Seems we misplaced it last year while putting it away.

The gentlemen was very helpful locating the part, even though I do not have a name or model number for the pool. He asked for my name, address and telephone number. That was it - The plug is in the mail!

Little Tykes is the Best!

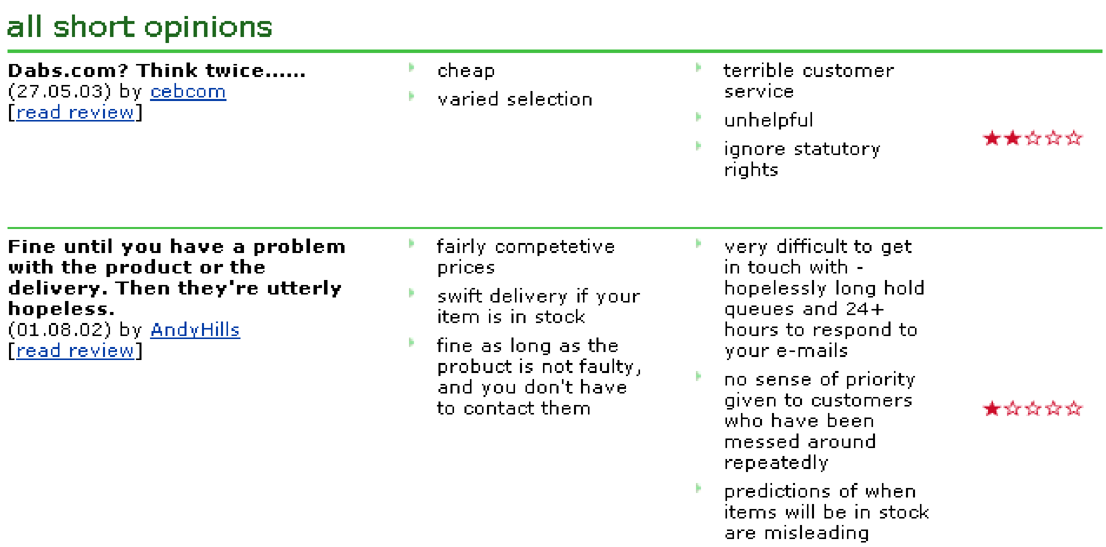
Polanyi's theory of knowledge (Polanyi, 1962), Nonaka and Takeuchi suggest that "scientific objectivity is not the sole source of knowledge. Much of our knowledge is the fruit of our own purposeful endeavors in dealing with the world" (Nonaka & Takeuchi, 1995). "New knowledge" is created by people as they interact with others in society. The potential for this interaction has increased significantly through the Internet. In terms of commercial activity, consumers are using the Internet to gather and share knowledge about products and companies. They are using the Internet as a consumer knowledge exchange forum, claiming neutral territory away from the commercial Web as their own. There has been an increase in the amount of sites such as epinions.com (see Figure 1 for a screenshot), notacceptable.com and bitchaboutit.com and DooYoo reviews (see the screenshot featured in Figure 2) where, significantly consumers have conversations with each other, and share their experiences or stories of interacting with companies and using products.

KNOWLEDGE MANAGEMENT

Drawing on the theory of the "personalization strategy" and on the "socially constructed models" of Knowledge Management identified by McAdam and Mcreedy (1999), this research project constructs the concept of e-commerce as knowledge management. In order to justify the knowledge management approach and model adopted here it is necessary to review and critique the "classic models" more traditionally adopted by academics in the field of knowledge management, and to illustrate why they are not considered appropriate for application to a study of consumers' knowledge creation and exchange via the Internet.

Knowledge creation and conceptualization are context-dependent. They depend upon our ways of viewing the world (Johnson & Duberley, 2000). From a positivist perspective knowledge is "true fact" which can be objectively observed. Whilst from an interpretivist or constructivist perspective knowledge is constructed and negotiated by

Figure 2. DooYoo reviews



people in day to day interactions, and can only be understood and communicated subjectively (Chua, 1986; Burrell & Morgan, 1979). The different approaches to the creation of knowledge are echoed in approaches to knowledge management (Hansen, Nohria, & Tierney, 1999). McAdam and McCreedy's paper, A Critical Review of Knowledge Management Models, (McAdam et al., 1999) identifies and critiques three models of knowledge used in a management context:

- Intellectual capital models
- Knowledge category models
- Socially constructed models

Table 1 illustrates the characteristics and key thinkers of each approach.

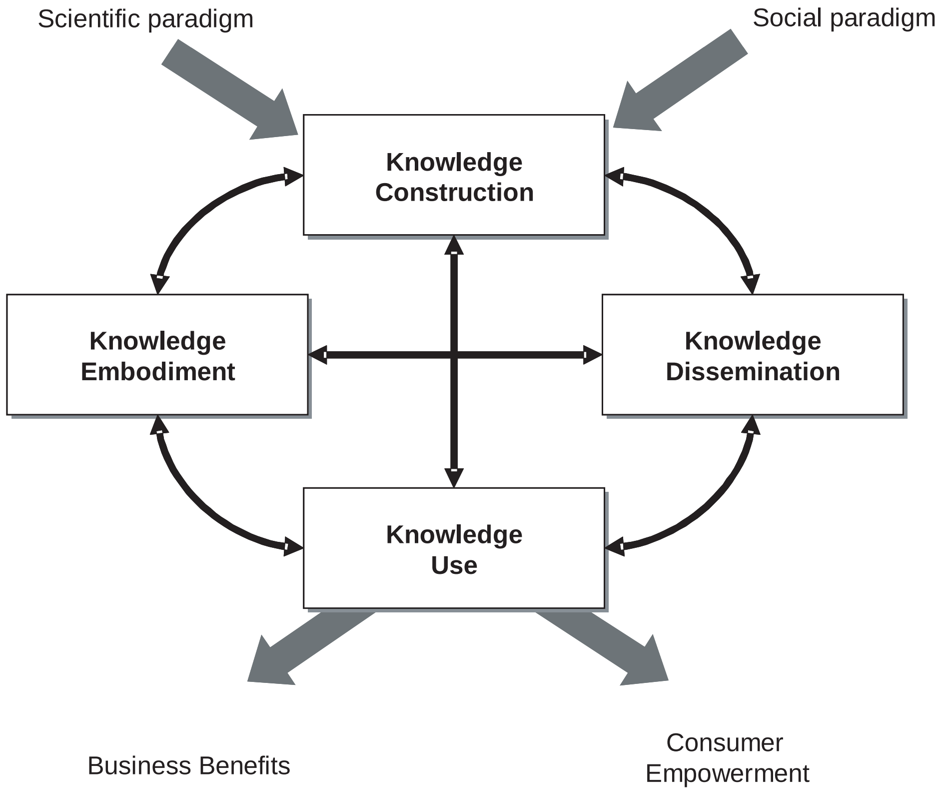
The theory of socially constructed knowledge management does not assume one given definition of knowledge, but adopts a more holistic approach linking knowledge to social and learning processes. This holistic view allows the models to "be used to represent the key dimensions of Knowledge Management in the widest possible sense" (McAdam & Reid, 2000) and, therefore, renders them suitable for a consumer focused exploration of e-commerce as knowledge management.

This study takes the socially constructed approach, arguing that knowledge is socially constructed and subjectively understood. The model that is adopted for this research is a version of Demarest's (1997) adaptation of Clark and Staunton's (1989) model, modified by McAdam and McCreedy (McAdam et al., 1999). This model emphasizes four stages in the knowledge management process, "knowledge construction," knowledge embodiment," "dissemination" and finally "use," but it adds "emancipatory enhancements" through employee use of knowledge and subsequent empowerment. The model is adapted to adopt a consumer focus in order to explore consumer empowerment through knowledge use (Figure 3).

Table 1. Key thinkers and characteristics of knowledge management models

Model	***Characteristics***	***Key Thinkers***
Intellectual Capital	• Objectivist stance. • Knowledge is objectified, measured, valued and controlled. • Focus is on explicit or tangible knowledge. • Neglects social processes.	(Stewart, 1997) (Edvinsson, 1997) (Van Buren, 1999) (Roos & Roos, 1997)
Knowledge Category	• All knowledge can be identified and categorized. • Focus is on dichotomies (e.g. tacit / explicit, personalized / codified). • Cursory consideration of social processes.	(Nonaka et al., 1995) (Hedlund,) (E.G. Carayannis, 1999) (Earl, 2001)
Socially Constructed	• Constructivist stance • Holistic approach to knowledge • Knowledge cannot be controlled • Focus is on communication and knowledge created through social processes	(Clarke & Staunton, 1989) (Demarest, 1997) (McAdam et al., 1999)

Figure 3. Socially constructed model of knowledge management



Adapted from McAdam and McCreedy (1999)

Knowledge Management and E-Commerce

It has been argued that to add maximum value for a company, the e-commerce function should attempt to replicate the way people shop in the "real world" and "create a sense of community and opportunities to communicate" (IPA, 1995). The success of companies such as eBay, which doesn't actually sell anything but simply facilitates consumer-to-consumer exchanges, or Amazon.com, a pioneer of electronic consumer reviews, illustrates the demand for consumer connectivity.

At the same time, consumer research has moved away from the view of a passive, cognitive, information-processing consumer to recognize a more pro-active, discriminatory and social individual. Foxhall et al. state that:

"It is almost certain that …he or she will seek information from friends, neighbours or relatives about the relative merits of different brands. Indeed several studies indicate that informal word-of-mouth communication may be more effective than formal advertising in moulding consumers' decisions." (Foxhall, Goldsmith, & Brown, 1998)

There is substantial literature on word-of-mouth (WOM) marketing (Sheth, 1971; Haywood, 1989; Buttle, 1998; Engel, Kegerris, & Blackwell, 1969). WOM is generally defined as interpersonal communication concerning products, companies or services where the listener regards the communicator as impartial. Established definitions have recently been refined to include not only oral communications, but also electronic communications such as the Internet which is "a growing source of recommending and complaining communications" (Buttle, 1998; Stokes & Lomax, 2002).

Traditionally, a consumer's "information-seeking process" may include an internal search evoking the consumer's memories and previous experiences, and an external search gathering information and knowledge from explicit sources such as consumer guides and reviews. It may also include knowledge of products, services and companies constructed through interactions with family, friends, colleagues, manufacturers, and suppliers. It is into this stage of the consumer experience that electronic channels are most likely to be accommodated. Qualitative research with consumers supports this, suggesting commercial benefits of online communities:

"There appear to be commercial benefits for organizations providing virtual communities on their Web sites. Many … people would like to use a virtual community to communicate with the company itself." (Evans, Wedande, Ralston, & Hul, 2001)

And even a reliance upon a virtual community:

"I go to Amazon instead of a regular bookstore because if I'm interested in a book, I can find out what 100 other people think about it. If I go to a bookstore now, I'm lonely. Where are those 100 people?" (Brewer, 2000)

The reach and impact of word-of-mouth marketing is vastly amplified by the Internet.

Social Constructionists argue that it is through communication and social interaction that knowledge is created. This may be knowledge about products on the market, or the quality of customer services departments of various companies. Through the Internet, the potential for consumer connectivity or interaction is vast. A person can exchange opinions and experiences of a product or company with thousands of other consumers. She can read a customer review of a book, and then read how useful that review was to others before making her decision to purchase. Finally, she can add her own ratings. She can compare the experiences of consumers who purchased different brands of cameras a year ago, reflect on their experiences of using the product and interacting with the company before deciding which brand she should purchase.

Through the Internet, a whole new world of such conversations has opened up. It has even been suggested that online communities of consumers operate a "gift economy," investing great time and effort in contributing their "knowledge." These practices have resounding echoes of the Knowledge Management practices promoted within many organizations, and in particular of the models of socially constructed knowledge management models proposed by Demarest (1997) and McAdam and Mcreedy (McAdam et al., 1999). To explore consumer's use of the Internet as a Knowledge Management system, and to propose ways in which organizations could create maximum value from knowledge created and shared by consumers through the Internet the following research study was carried out.

THE RESEARCH PROJECT

Introduction

This research explores consumers' use of the Internet through the lens of knowledge management with the following research objectives:

- To investigate how consumers use the Internet in commercial activity.
- To explore the idea that consumers currently use the e-commerce facility as a knowledge management function, to seek and share knowledge about products and services.
- To explore the idea that consumers are "empowered" by the Internet.
- To explore what business benefits are achieved through the social construction of knowledge and the empowerment of consumers via the Internet.
- To propose a framework for e-commerce to facilitate interaction, and integrate knowledge exchange with consumers into normal working practices.

Methodology

The approach selected for this research is informed by the debate into philosophical approaches to consumer research. As a generative exploration into the experiential perspective of consumers' uses of the Internet, with the aim of developing a framework for organizations to learn and benefit from the consumer experience, this research is rooted in the interpretive paradigm. The epistemological stance that is adopted is one of Social Constructionist-Critical Theory.

From the approach that this study took, it was important to survey relevant groups with "high experience levels of the phenomena under study" (Pettigrew, 1990), in this case online shopping. Questionnaires were adopted as a preliminary data collection method, and as a means of identifying suitable interview participants with relevant experience. To ensure consideration of stable usage patterns the sample was made up of consumers who are experienced Internet users and have engaged in commercial activity (transaction, product/company research) on the Internet for at least one year.

Twenty-two semi-structured interviews with consumers were carried out, each one lasting between 30 and 60 minutes (for question guide, see Appendix 1). Interviews were recorded with the permission of the participant, and verbatim transcripts were produced from the recordings. In analysis, the researcher made use of transcripts, recordings and field notes. The method of data analysis selected is pattern coding and theme analysis. Such analysis is an iterative process involving data collection and analysis simultaneously. From emergent themes theories are generated and confirmed or refuted by further exploration.

Emergent Themes

The major themes that emerged from the pattern coding and theme analysis of the interview transcripts are:

- Interaction with commercial organizations
- Consumer-to-consumer interaction
- Power and control in business-to-consumer interaction

Before considering each one of these in more detail, and to "set the scene," we describe how the participants thought of the Internet. Participants see the Internet as a source of information (or knowledge), and a means of communication:

"It's a huge body of information…. Like huge libraries ... So it represents a huge body of knowledge really, more so than anything." (Interview 6, male, age 38)

"A source of information really on anything." (Interview 10, female, age 52)

"It's actually made communication a lot easier for me." (Interview 9, male, age 42)

"It's very easy to get in touch with people all over the world, and I find that very empowering, a very positive sort of thing. In terms of a source of information, if you want to know anything, it's all there." (Interview 5, male, age 41)

When asked directly about their use of the Internet in commercially related activities, participants frequently referred to the information available about different products rather than the ability to purchase:

"We used it just to gather information really relating to the product." (Interview 2, male, age 37)

"It tells you instantly all the information about it ... you can go on and compare the different prices that they have for the same thing." (Interview 8, male, age 24)

More significantly, they referred to the range of perspectives available through the Internet:

"Because it's available, it's accessible, I'll get information about the product itself. Whereas before you'd rely on a salesperson to give you that information, I've got there from other sources. So it's different ways of getting information on products that I'm going to purchase." (Interview 12, Female, age 32)

Interaction with Commercial Organizations

Given that participants related that the Internet has opened up communication and information channels, the strong sense of barriers separating customers and companies that emerged was surprising. Narratives using language which constructed dichotomies of oppressor/oppressed, and metaphors of power and control, invasion, and revolution were pervasive. The barriers participants experienced separating them from companies ranged from poorly designed or inefficient Web sites:

"Some Web sites you get a list of topics and it could be in there, it could be in there, so you click on here and that gets you to somewhere else where it might be there or it might be there. It's a labyrinth and you get fed up with it. They're thrown together by people who write PC software." (Interview 5, male, age 41)

"When something hasn't worked and I've found a blockage that I couldn't get around, you know it gives you very negative feelings. Because you've got nobody directly to speak to it can be very frustrating. It's almost like dealing with a faceless bureaucracy kind of thing — you know, there's simply no way around the system and it leaves me feeling useless." (Interview 4, male, age 49)

and lack of channel integration:

"I e-mailed them and I had to ask them by e-mail could they give me a phone number to contact them…. They e-mailed me back with a telephone number and I phoned up, but I couldn't have dome that from their Web site alone so that was a problem." (Interview 12, female, age 32)

To a more negative construct of companies as dishonest, deceitful and controlling: For example in interview 2 (male, age 37), the respondent says:

"…they lie. Companies are selling products that they haven't got in stock."

Interviewer probes:

"What do you mean? Have you had a problem with a company?"

Respondent elaborates with:

"I ordered a little digital camera that's taken seven weeks. The big incentive with the Internet is the immediacy of it and all sorts of convenience and that all goes out of the window if you order something and it takes seven weeks to get there."

Similarly in Interview 1 (male, age 48) the respondent says:

"Of course you hear loads of stuff like ... if you order online you get not so fresh produce. 'Let's get rid of it on our Internet buyers'."

Interviewer probes:

"Do you buy groceries online?"

Respondent elaborates with:

"No I don't. I wouldn't buy fresh produce anyway, I wouldn't trust them."

Another respondent commented negatively on companies' use of his personal details:

"I've filled in enquiry forms and that sort of thing, where they are basically gathering data on me … I just don't like the idea anyway because all they need to do is put in your postcode and your name and there you go! They've got you! And how do they link that up with other databases? You don't know do you?" (Interview 4, male, age 49)

Another barrier to consumer/company interaction was simply failure to reply to e-mails. Significantly, one participant responded that:

"If you talk to someone it's just that you feel like they're doing something about it. It might not actually be any different, it's just a perception. If I get something personal saying so and so has received you order, you know, you can tell when it's not just an automatic reply." (Interview 6, male, age 38)

This suggests that standard automatic replies are not perceived as opening up communication channels, but reinforce the perception of barriers between customer and company. Similarly, electronic marketing communications prompted strong reactions expressed in terms of power and control and, in many cases, ending rather interestingly with imagery of closing down communication channels.

One respondent (interview 6, male, age 38) commented:

"I hate it. It irritates the hell out of me. I hate being bombarded with junk e-mail. I can't stand it. It's the scourge of the Internet. I really think that it needs controlling. There's no control, you know with the Internet it's unstoppable isn't it? It's going to put people off."

Interviewer probes:

"So you wouldn't be likely to respond to a promotional e-mail?"

Respondent replies:

"If someone starts bombarding me with e-mails I'd just refuse to buy anything from them just out of principle."

Another participant responded even more strongly to questions about electronic marketing communications:

"I don't like having to look at advertising. If you log onto the Internet, you're becoming increasingly bombarded with stuff coming into your computer.

You come off the Internet and you realize that there's three or four windows up of advertising stuff and you weren't even aware that they had come into your machine and I don't like that. They do it so that the window is slightly shifted so that you can't get to the cross. Somebody's thought all this through and it's just irritating and they should be shot." (Interview 5, male, age 41)

In the narratives of the participants in this research, the Internet does not facilitate communication with companies, nor does it enable the erosion of organizational boundaries, but appears to strengthen them. For them, the social processes that encourage knowledge construction are not taking place on commercial Web sites. While "scientific" or factual information about products and services may be included on commercial Web sites, knowledge construction through socialization is not facilitated, blocking both outcomes of "Business Benefits" and "Consumer Empowerment" on the model of knowledge management adopted in this study (Figure 3). Consumer discussions, narratives and reviews could provide a company with a rich source of knowledge about their market sector, and their own services and products. In disregarding the contributions made by consumers interacting via the Internet, companies are not hearing a valuable source of knowledge about their products and services.

Consumer-to-Consumer Interaction

Participants were not asked directly about their participation in, or membership of online communities, but the theme strongly emerged. One participant noted that the Internet is "a very good way of making contact with like minded people" (Interview 9). Field notes made by the researcher immediately after each interview frequently highlighted one point at which the participant became animated and enthusiastic. The change in tone was in stark contrast to that used in narratives of researching and buying products or in communicating with companies. One participant became animated when talking about the Web site of a farm where she regularly takes holidays:

"There's a place we go in Scotland who now have a Web site where you can keep up to date with the site. Because I'm into pigs and I collect pigs and this particular place we went was on a farm and they had pigs, so she puts photographs of the pigs on the Web site and you can e-mail and ask how the pigs are. She obviously sends out marketing information too about, you know, we've just bought another cow or whatever and they've built up a real base of people who go. She's even got a forum, I mean she's got the right idea." (Interview 3, female, age 27)

For another, it was a self-help group for a specific medical condition that sparked enthusiasm (Interview 4, male, age 49):

Respondent: "My wife was looking at medication, certain medicines that the doctor had recommended and before taking them, she'd sort of heard that they might be harmful and she's gone on there to collect all kinds of research. She got a lot of information on it, which altered what she actually settled for, got a lot of information about medical conditions and was much more informed about what options she should take and that sort of thing."

Interviewer: "Did what she found change her decision about what to take?"

Respondent: "Yes, inevitably it did, yes, what to take and what action to take as well. It's a sort of non-standard product, but information is out there and it's there in such a way that people can understand it and it's an area of deep personal interest. Looking for this extra information, which five years ago wasn't available really helped."

Interviewer: "What sort of sites were they?"

Respondent: "Yes, they were self help for users — people with medical conditions had set up these self help groups and so on and they have discussion boards and they put on their own experiences of taking certain medicines and that sort of thing."

Interviewer: "So she got some information from other people who had used these products?"

Respondent: "Yes, so there was so-called 'factual information' and then actual users' experiences were on as well."

Interviewer: "Assuming that you were involved in this as well, that she talked to you about it, what value did you place on the other consumers that you'd never met or never had anything to do with?"

Respondent: "Well, they had no reason to put any falsities on there so it was … sometimes they weren't saying anything you didn't already know it was all supporting information and it's very valuable because it's things that you don't normally get."

A third participant spoke very animatedly about eBay:

"Then because I had some questions I actually e-mailed the fella and he was just brilliant because he kept e-mailing me back saying, 'Hello, Susan. Now let me just tell you about this game that I'm sending you,' and it was brilliant, it was like making a new friend. It was really, really good. I was very impressed with eBay. It's like a community. It's like you see names coming up time and time again and you can read what they've done in the past with other people and how good they've been and things like that. They say things about you and you say things about them, it's a two-way thing so it's worth it." (Interview 12, female, age 32)

This contrasts greatly with another participant's comment that corporate marketing messages are "a one-way thing" (Interview 11), preventing social interacting and exchange. These accounts also illustrate how meaningful and valued interchanges are most frequently constructed around an area of interest rather than within a purely commercial interaction. More significantly, even though participants spoke of how they valued reviews by other consumers "because they had no reason to put any falsities on there" (Interview 4), a totally different belief about consumer reviews within a commercial Web site emerged:

"It's whether you would actually trust that as a source. Would they actually put very disparaging comments from consumers on their particular site or would they just be full of glowing reviews for their products?" (Interview 3, female, age 27)

As another participant responded, "you're looking for a negative to prove the positive" (Interview 1, male, age 48), and ultimately:

"If you wanted something a bit less biased perhaps you could go to a forum, there's lots of forums where they discuss anything and everything so if you wanted to know what someone really thought about a subject you'd go on one of those." (Interview 6, male, age 38)

Power Relations in Business-to-Consumer Interaction

Throughout the interviews a discourse of power and control strongly emerged. So, too, did a sense of resigned acceptance on the part of the consumers. Critical to this is the sense of communication breakdown between companies and consumers. One participant narrated his experience of house hunting on the Internet:

"I saw one yesterday, phoned up and it was gone because they haven't updated their Web site. Well, why not? This is really annoying, especially over something like that… I mean, I, being the kind of person I am, I was [makes action to imply speaking on the telephone] WELL, WHY NOT?" (Interview 1, male, age 48)

When asked what the response from the company was, the participant responded, "Oh, they just gave me some line, you know," suggesting a resigned acceptance of a corporate message. Habermas proposed that "where power is present, communication is systematically distorted," and further that "power would act as a barrier to the free and unconstrained realization of the human interest in achieving rational truth or enlightenment" (Clegg, 1989). The model of knowledge management proposed for this explorative research is a model of socially constructed knowledge, which brings about consumer emancipation and business benefits. The process of socially constructing knowledge depends upon effective communication networks.

The participants of this research do not construct a view of the Internet as opening up communication channels with companies where social interaction may facilitate the construction and exchange of knowledge. When asked how commercially oriented use of the Internet could be improved, one participant responded that they would like to see more transparency or transaction tracking devices. It was significant that the language he used to express this constructed an image of the company as a fortress to be invaded. Three times he used the phrase, "You could go right into the company":

"If you could search right into the company without having to phone them up, you could track the progress of where my house purchase is just now, where my will is just now where my injury claim is just now…I think some companies are starting to put these gateways in to go right into the company so you don't have to talk to anybody, but the security implications must be a minefield because you go right into the company." (Interview 1, male, age 48)

This image of invasion also reinforces the idea of organizational boundaries, and barriers between companies and consumers.

Significantly, the participants generally did not feel that the Internet empowered them as consumers. Some participants did say they felt empowered, quoting convenience, choice, or competitive prices available through the Internet. However, the same respondents commented that they tend to return to the same sites, or only use "well known and well trusted" companies' Web sites (Interview 8), implying limitation. Generally however, participants responded that the Internet was "potentially very empowering" for consumers (Interview 6) or simply that they did not feel empowered by it. Several participants commented that they were aware of Web sites where consumers can post their complaints or reviews of companies, but commented that they hadn't done that as, "They just hadn't got round to it" (Interview 3) or because, "There's not much point" (Interview 8), implying a resigned powerlessness.

CONCLUSIONS

Knowledge possessed by consumers can only become a source of organizational knowledge offering business benefits to companies if consumers are given a voice. In order to create value for themselves, companies should explore ways of participating in the consumer-to-consumer conversations that are already taking place around virtually any topic of interest. It is essential that companies that do participate do so without appearing to dominate consumer territory with an obviously commercial motivation. Companies must facilitate interaction, and integrate communication and knowledge exchange with consumers into normal working practices, offering some benefits to the consumers. While consumers are aware that through the Internet they have the potential to share their views of products and services with other consumers, unless their views are responded to by companies, they can have little effect and fail to bring about "Consumer Empowerment."

Consider the following example of a company director engaging in conversation with consumers. This example was brought to the attention of the researcher by one of the interview participants. Following negative comments about

#1508, "Airflo Fly Lines - The background - The Future"

May I first introduce myself as the Group Managing Director of BVG Airflo. I have read the many comments on this forum relating to Airflo fly lines with interest.

If I may I seek to provide a little background and to address some of the comments posted on this forum.

The Airflo technology was truly ground breaking when its was launched, and to this day offers benefits unmatched by any competitor.

Like any new technology there were the inevitable teething problems. In Airflo's case these problems went on for far too long. Airflo's reputation , particularly for floating lines suffered tremendous damage.

I accept that large numbers of fly fishers purchased fly lines which were sub standard and did not offer the performance promised.

In 1995 I became the MD and the company was completely restructured with the focus placed firmly on long term R&D, thorough product testing and relentless quality control procedures.

The result was that by late 96 Airflo was producing some of the best fly lines in the World, export sales rocketed in markets unaffected by Airflo's prior reputation. In particular Airflo sinking lines have set the standards by which all others follow

You may be surprised to know that there are just four fly line manufacturers of any consequence in the World. Very positive comments on this board (placed by Anti Airflo people) on private label fly lines actually relate to product produced by Airflo. Airflo's historic problems clearly affect peoples opinions.

To prove the point I would be happy to provide a FREE fly line to the first 30 people who respond on this forum with their details and fly line model required. Those connected to the fly fishing trade need not respond.

In exchange for the free fly line all I ask is that the line is tested and a fair review placed back on this forum. If you hate the product then come back on the board and slate it, if as I suspect you agree that the lines are some of the best available then please let everyone else know about it.

Kind Regards

the company's products on a message board, the Managing Director writes:

Airflo's historic problems clearly affect people's opinions. To prove a point, I would be happy to provide a FREE fly line to the first 30 people who respond on this forum with their details and model required. In return, all I ask is that the line is tested and a fair review placed back on this forum. If you hate the product, then come back on the board and state it, if as I suspect you agree that the lines are some of the best available then please let everyone else know about it. (See Figure 4 for screen shot.)

The following responses were posted (Figure 5 for screen shot):

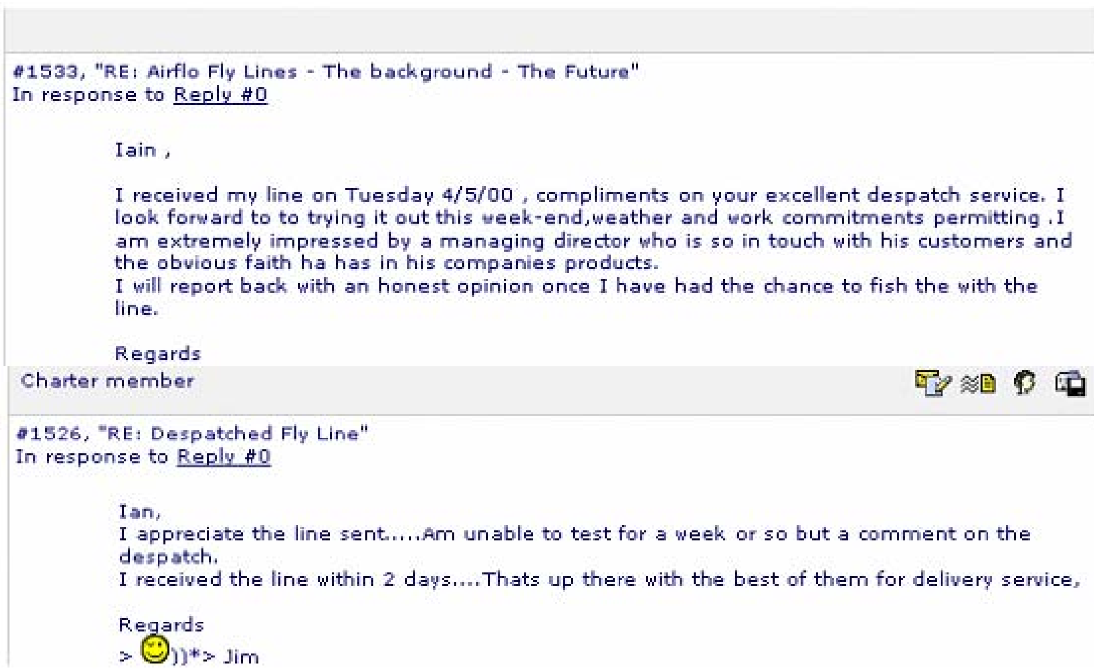
"I appreciate the line sent…. Am unable to test for a week or so but a comment on the dispatch. I received the line within two days…That's up there with the best of them for delivery service." (Posting No. 86)

"I am extremely impressed with a Managing Director who is so in touch with his customers and the obvious faith he has in his products." (Posting No. 95)

"I would have no hesitation in recommending this line to any other angler." (Posting No.100) (Fish and Fly Messageboard, 2000)

By engaging in conversation and exchanging knowledge with his customers, the Director

Figure 5. Fish and Fly message board responses



appears to have improved the reputation of the company and its products. In an earlier posting, he even gains input for a possible new product to develop: "Any chance of an intermediate, with non-stretch core, in double taper format?" (Posting No. 75). This interaction takes place on an independent message board. The customers are offered the power to improve or further damage the company's reputation, and for their views to be archived for future members of the group. In this case, the Managing Director has achieved the business benefits of an improved reputation. This exchange will be archived and available to future customers for some time to come, and provide input from customers for product development.

Consumers are already utilizing the technology to communicate and share knowledge. "The same technology that has opened up a new kind of conversation in the marketplace has done the same within the corporation, or has the potential to do so" (Levine, Locke, Searls, & Weinberger, 2000). Companies must now focus on the communication capabilities of the Internet and use the technology to facilitate conversations across the corporate boundary. They must meet consumers on neutral ground and encourage consumer-to-consumer and consumer-to-business interaction in order to leverage a most valuable resource: the knowledge constructed by and embodied in the customers. In return, they must share corporate knowledge with the consumer. Sinkula proposes that for organizations to learn from their customers:

"Particular attention should be paid to serendipitous, unsolicited, customer information, particularly that which revolves around complaints. Marketing managers must do two things to better listen to customers…" (Sinkula, 2002).

Firstly, he argues they, "must process the information better," and secondly they should "become more open to criticism" (Sinkula, 2002). This research suggests that before they can do this, companies must first learn to have conversations with their customers.

RECOMMENDATIONS

How can Company Representatives Engage with an Online Community?

To be effectively adopted, this new marketing channel demands that you analyze how you communicate with customers, and challenges how you traditionally measure the success of this communication. In general, classically hard outcomes such as complaints resolved or sales achieved are used to measure communication success. Participating in an online community initially offers less tangible benefits. For example, it may enhance the value of the knowledge socialized within the community to the benefit of both customers and companies, or improve the reputation of a brand.

The starting point is to recognize that you will have to adopt a new approach to communicating with customers — an approach that challenges many of your traditional assumptions about customer relationship management. You will need to accept that the power and position that you naturally project into conversations and interactions with customers are counter-productive when interacting in this new channel. You are advised to remodel your ingrained communication patterns. Customers welcome natural speech through an individual human voice rather than a scripted corporate monologue. Discussion forums and online communities facilitate this kind of interaction.

For those most unsure of how to start, the best place is to take the position of the customer. Participate as a customer in forums discussing things you have an affinity to or feel passionate about (a sport, cars, music). Join in, contribute to the discussions and make time to do it regularly. You will quickly get a feel for the tempo and social "Netiquette" within the groups. These will be variable so don't expect to replicate them in discussions about your company, but you will see a range of examples of how to do it and how not to. Critically evaluate the exchanges that take place and reflect upon how effective they could be in relation to the forums your company could participate in.

Consider the contribution made by the Managing Director in Figure 4:

"May I first introduce myself as the group managing director of Company X? I have read the many comments on this forum relating to Company X fly lines with interest."

The Director succinctly establishes his position and invites himself into the discussion. It is extremely pertinent that he doesn't just "barge in" and start to sell his product. Note the heavy use of first person "I" and complete lack of references to the corporate line or "what the company says" throughout the entire posting. This man has power within the organization, but he projects it very subtly, almost with a suggestion of, "You may want to hear my opinion, but you don't have to."

He then moves quickly to establish the background and balance of opinion in the postings. He accepts the problem. He demonstratives a willingness to validate the customers' experience and offers empathy with their issues. He then moves swiftly to the defensive:

"I accept that large numbers of fly fishers purchased fly lines which were sub standard and did not offer the performance promised. In 1995, I became the MD and the company was completely restructured with the focus placed firmly on long term R&D, thorough product testing and relentless quality control procedures."

However, he just manages to avoid a "yes, but" followed by a corporate line which may alienate customers as it demonstrates a lack of empathy and a negation of their experience.

He then switches to a pitch that borders close to a direct attempt to market the company voice in the community. He is walking on the edge of acceptance and rejection based on the customer's evaluation of his credibility to make such statements. It is a signature of this posting how swiftly it moves through these phases. It is fast, but not slick in an obvious manipulative way. He retains a genuine voice of concern and natural tempo throughout. It reads like a stream of consciousness, rather than stock phrases from a brochure.

The second to last paragraph in the post is perhaps one of the most significant. The Director invites others in. From an early pitch that engages the individual, he suddenly switches to the onlookers in the crowd and seeks to pull them closer to the action:

"To prove the point I would be happy to provide a FREE fly line to the first 30 people who respond on this forum with their details and fly line model required."

He is challenging the community on conventional measures of product performance, but also challenging the community to increase their collective knowledge of these products through their interaction. This is real skill with unmistakable echoes of marketplaces of the past. The director moves beyond the attempt to develop a personal conversation with customers to developing an inherent right of focus within the community. He is seeking to host the dialogue, as distinguished from controlling it, and is increasing his importance as a credible central voice within the community.

To judge whether he succeeded, consider the responses and again witness the importance of the first person "I" in the customer evaluations quoted:

"I appreciate the line sent…. Am unable to test for a week or so but a comment on the dispatch. I received the line within two days…That's up there with the best of them for delivery service." (Posting No. 86)

"I am extremely impressed with a Managing Director who is so in touch with his customers and the obvious faith he has in his products." (Posting No. 95)

"I would have no hesitation in recommending this line to any other angler." (Posting No.100) (Fish and Fly Messageboard, 2000)

If this does not convince you, consider the closing words of the Director himself:

"I would like to thank the visitors to this forum for their feedback. I have learnt a great deal from the discussions and thank you all for your input. Most of all, I have confirmed my position that our reputation lies purely with floating lines produced prior to 96."

"I have learned from this forum that trial products are the best way to convince people of the performance of our fly lines. Thanks for your comments, as you can see, they make a difference."

What is most significant is that nothing will make a customer happier in a discussion forum than the words, "Sorry I got that wrong... let me try to put it right."

APPENDIX 1

Consumer Interview Schedule

I am researching into how people use the Internet in consumer related activities. I want to hear about your experiences, opinions, thoughts, lessons learned. So far I have looked at reports and research papers and commercial Web sites. Now I need some input from people who actually use the Web sites to gain a richer understanding of how people use the Internet in consumer related activity.

The Interview will address the following issues:

- Your general views on the Internet
- Significant changes (that the Internet has brought about for you)
- Internet in consumer activity
- Communication (business-to-consumer and consumer-to-consumer)
- General conclusions

1. What does the Internet represent to you?
   - Understanding & experiences of the Internet.
   - Opinions about what the Internet is good/bad at.
   - Whether their general expectations are met.
   - How they think it could be improved

2. What has changed for you as a result of the Internet?
   - New things achieved/learned?
   - Cultural shifts
   - Any area of life that has changed significantly?

3. Tell me about your experiences of researching products online.
   - How would you research a product through the Internet?
   - Where would you look?
   - Why?
   - Have you learned anything new?/Had a change of opinion about a product or company?

4. Tell me about your experiences of buying products online (good/bad)

Communication

5. Can you tell me about any experiences of using the Internet to communicate with or consult other consumers?
   - Have you ever shared your opinions of products/services online? Why? Why not?
   - Have you ever shared your experiences of a company online?
   - How much value would you place on the opinions of other online consumers?

6. Can you tell me about any experiences of using the Internet to communicate with companies?
   - Are you more or less inclined to communicate with a company online?
   - How do you feel about companies contacting you through the Internet?

Empowerment

7. How far would you say the Internet "empowers" you as a consumer?

- Do you feel that you have more choices available to you through the Internet? (products/companies/time/space)

General Conclusions

8. How effective do you feel commercial Web sites are?

9. How would you like to see businesses using the Internet for commercial purposes in the future?

This concludes the interview.
Thank you for your time.

Chapter 6.23
Knowledge Producers and Consumers

Atreyi Kankanhalli
National University of Singapore, Singapore

Bernard C. Y. Tan
National University of Singapore, Singapore

Kwok-Kee Wei
City University of Hong Kong, Hong Kong

INTRODUCTION

In a knowledge-based economy, organizations find it difficult to compete based upon the individual knowledge of a few organizational members. This provides the rationale for knowledge management wherein organizational knowledge must be shared, combined, and reused in order to enable organizations to compete more effectively. Hence, knowledge sharing is considered an essential process in knowledge management. Unfortunately, sharing is often unnatural for the parties involved in it, that is, knowledge contributors or producers and knowledge seekers or consumers. Hoarding knowledge and not accepting knowledge from others are natural tendencies that are difficult to change (Davenport & Prusak, 1998). Knowledge contributors may be inhibited from sharing their knowledge due to perceptions of loss of power, lack of time or incentives, and other barriers. Knowledge seekers may find it laborious to seek advice from others and desire to discover solutions for themselves. Therefore, it is vital to understand and foster the motivations of knowledge contributors and seekers toward participating in knowledge sharing.

With the attention to knowledge management and the knowledge-based view of the firm, research in knowledge sharing and its motivations has gained interest over the last decade and a half. The initial focus of research was on investigating what motivates knowledge contribution (e.g., Orlikowski 1993; Constant, Kiesler, & Sproull, 1994) as this appeared to be a more intractable problem than motivating knowledge seeking. Subsequently, knowledge seeking behavior also has been researched (e.g., Goodman & Darr, 1998; Jarvenpaa & Staples, 2000; Kankanhalli, Tan, & Wei, 2001), although there is still considerably more attention devoted to studying knowledge contribution behavior.

Concurrently, the role of technology (known as knowledge management system or KMS) in enabling knowledge sharing has received research interest. However, in spite of the advent of new technology enabled forms of knowledge sharing such as knowledge logging (the enterprise flavor of blogging), the challenges of promoting knowledge sharing persist. This is because culture and management issues appear to dominate over technological issues in ensuring knowledge sharing success. For example, Ruppel and Harrington (2001) found that employee acceptance of or resistance to Intranets as a knowledge-sharing environment was more of a management and culture problem rather than a technology hurdle. Calls have been made to address both social and technical issues together (Zack, 1999) in order to be able to reap the benefits of knowledge management that have been experienced by some organizations (Davenport & Prusak, 1998).

BACKGROUND

Knowledge sharing is typically defined in two ways depending on the perspective toward knowledge. Researchers who view knowledge as an object tend to use the term “knowledge transfer” while others who see knowledge as a process use the term “knowledge sharing” (Allee, 1997). The notions of knowledge sharing and knowledge transfer can be combined by defining knowledge sharing as voluntary activities (process) of transferring or disseminating knowledge from one person to another person or group in an organization (Hansen, Nohria, & Tierney, 1999). A number of theoretical perspectives have been used to investigate the motivation of knowledge contributors and seekers.

Public Goods Theory

One of the initial lenses employed in studying motivations in knowledge sharing has been public goods theory (e.g., Thorn & Connolly, 1987; Fulk, Flanagin, Kalman, Monge, & Ryan, 1996). Knowledge shared in an organization through means such as a knowledge repository (referred to as a discretionary database in some previous literature) can be considered as a public good, that is, non-excludable, non-rival, and exhibiting jointness of supply. Knowledge shared is considered non-excludable because other repository users who did not contribute to its production are not prevented from access to the knowledge. The knowledge is non-rival because even if one consumer uses the knowledge, it still remains available to others, who also may apply the knowledge in their own situations. The knowledge contributed exhibits jointness of supply because it costs as much to produce for use by one person as for use by many.

Research along this perspective tends to focus on the motivational dilemma faced by knowledge contributors to such repositories. The dilemma for knowledge contributors is that collective interests bid them to share knowledge whereas self-interest may discourage them from contributing. Collective interest suggests that knowledge contributed will allow it to be combined or reused for greater benefit to the organization (Fulk et al., 1996). However, self-interest seems to dictate that contributing knowledge would reduce the unique knowledge possessed by the individual and thereby make him or her more replaceable in the organization (Kollock, 1999). In a broader sense, the dilemma for the community is that all members of the community stand to gain if everyone contributes. However, individually members are better off free-riding on the contributions of others. Therefore, research along this stream tries to understand how to promote collective action of knowledge contribution when it does not appear individually rational (Wasko & Faraj, 2000).

Expectancy Theory

Another perspective on studying motivation for knowledge contribution and seeking has attempted to apply more rational theories of motivation such as expectancy theory (Vroom, 1964) to understand the phenomenon. These studies (e.g., Kalman, 1999) suggest that individuals contribute knowledge based on their expectancy of certain benefits. Kalman's research found that organizational commitment, organizational instrumentality (the belief that sharing knowledge will produce organizational gain), and connective efficacy (the belief that the repository can be used to reach other people) positively influence individual's motivation to contribute to a repository.

Studies on knowledge seeking also have made use of expectancy theory (e.g., Nebus, 2004). Nebus' study proposed that the relationship between perceived value from knowledge seeking and knowledge seeking behavior is moderated by the perceived expectation of obtaining value. The perceived value from knowledge seeking depends on contributor's expertise and credibility while the perceived expectation of value depends on trust, obligation, and contributor's willingness to help. The perceived cost of seeking depends on monetary and time costs as well as the seeking risk in terms of the distance between the contributor and seeker.

Technology Adoption Theories

Theories of technology adoption have been applied to study motivation to use technologies for knowledge sharing. Particularly, the theory of planned behavior (Ajzen, 1991), which has been applied to technology adoption, has been used for this purpose. The theory proposes that the intention to use a technology depends on the attitude toward the technology, subjective norms, and perceived behavioral controls. Studies of knowledge contribution (e.g., Bock & Kim, 2002) have sought to find the antecedents of attitude, subjective norms, and perceived behavioral controls for knowledge contributors. Bock and Kim (2002) found that anticipated reciprocal relationships affected the attitude toward knowledge contribution while autonomy, innovativeness, and fairness of the organization impacted the subjective norm to contribute knowledge. As expected, attitude and subjective norm were positively related to knowledge contribution intention and to actual knowledge contribution behavior. Anticipated extrinsic rewards were found to play a facilitating role in individual's knowledge contribution.

The theory of planned behavior in conjunction with the task-technology fit model (Goodhue & Thompson, 1995) has been used to explain knowledge seeking behavior (Kankanhalli et al., 2001). Kankanhalli and colleagues' study found that technology-related factors (perceived output quality) and organization-related factors (availability of resources) directly impact seeking behavior, while task factors (task interdependence and task tacitness) play a moderating role on the effect of incentives on knowledge seeking from repositories.

Gaps in Literature

Prior empirical studies tend to focus on the benefits (acting as motivators) rather than the costs (acting as inhibitors) of knowledge contribution. This is in spite of the fact that practitioner literature (e.g., O'Dell & Grayson, 1998) and conceptual academic literature (e.g., Ba, Stallaert, & Whinston, 2001) suggest that costs are important in determining knowledge contribution behavior. Another feature of the prior research is that most studies consider knowledge sharing for all electronic media without focusing on a particular form of KMS. Even when studies are situated in the context of a particular technology, they may not refer specifically to the technology features and the consequences thereof. However, it is likely that differences in antecedent factors of contributing and seeking and the relative importance of antecedent factors can be expected for different forms of KMS. Further, since most empirical studies have been single case studies or surveys within one organization, there is a lack of theoretically grounded, empirically generalizable results regarding the phenomenon of interest.

Considering these gaps, newer research in knowledge sharing attempts to develop socio-technical frameworks for knowledge contribution and knowledge seeking via KMS considering both cost and benefit factors as antecedents. Organizational community factors that provide the context in which sharing takes place also are included in the frameworks. Particular forms of KMS for knowledge sharing are being studied (e.g., Goodman & Darr, 1998; Wasko & Faraj, 2000) and more generalizable research is being undertaken (e.g., Kankanhalli et al., 2001; Bock & Kim, 2002) as knowledge about the phenomena evolves.

FOCUS

This section describes a sample of the newer approaches toward explaining knowledge contribution and knowledge seeking behaviors that can obtain better explanatory power as compared to previous studies. They make use of social exchange theory, which accounts for both costs and benefits of knowledge sharing using collective technologies such as knowledge repositories.

Social Exchange Theory

Social exchange theory explains human behavior in social exchanges (Blau, 1964), which differ from economic exchanges in that obligations are not clearly specified. In such exchanges, people do others a favor with a general expectation of some future return but no clear expectation of exact future return. Therefore, social exchange assumes the existence of relatively longer-term relationships of interest as opposed to one-off exchanges (Molm, 1997). Knowledge sharing through knowledge repositories can be seen as a form of generalized social exchange (Fulk et al., 1996) where more than two people participate and reciprocal dependence is indirect, with the repository serving as intermediary between knowledge contributors and seekers. Knowledge contributors share their knowledge with no exact expectation of future return. Knowledge seekers consume knowledge without certainty of when they will reciprocate in the future. The quantity and value of knowledge contributed or consumed is difficult to specify.

Resources (tangible and intangible) are the currency of social exchange. Resources given away during social exchange or negative outcomes of exchange can be seen as costs. Resources received as a result of social exchange or positive outcomes of exchange can be seen as benefits. Social exchange theory posits that people behave in ways that maximize their benefits and minimize their costs (Molm, 1997). This is in agreement with knowledge management research, which suggests that increasing the benefits and reducing the costs for contributing or seeking knowledge can encourage knowledge sharing using KMS (Goodman & Darr, 1998; Wasko & Faraj, 2000; Markus, 2001).

During social exchange, costs can be incurred in the form of opportunity costs and actual loss of resources (Molm, 1997). Opportunity costs are the rewards foregone from an alternative behavior not chosen. During social exchange, benefits can be extrinsic or intrinsic in nature (Vallerand, 1997). Extrinsic benefits are sought as means to ends. Intrinsic benefits are sought after as ends by themselves. Research has established extrinsic and intrinsic benefits as drivers of human behavior in several domains including knowledge sharing (Osterloh & Frey, 2000). Although cost and benefit factors can impact knowledge contribution and seeking, this impact is likely to be contingent upon contextual factors (Orlikowski, 1993; Goodman & Darr, 1998). Social capital theory accounts for several important contextual factors.

Social Capital Theory

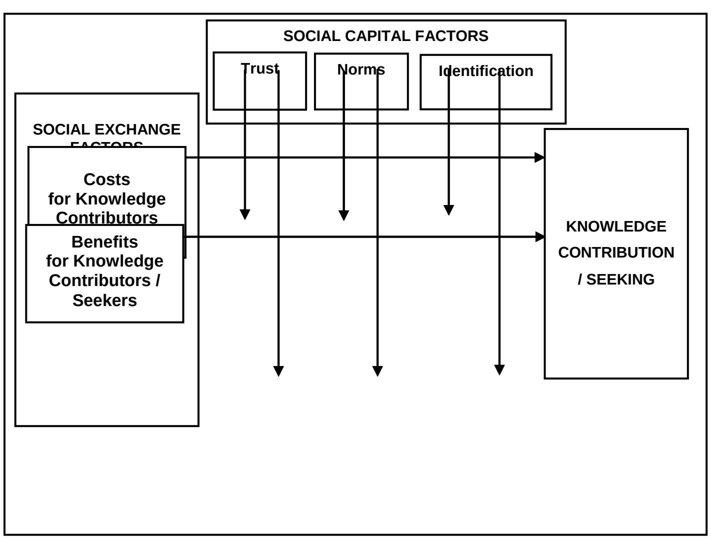
Social capital theory emphasizes the resources (social capital) embedded within networks of human relationships (Nahapiet & Ghoshal, 1998). The theory posits that social capital provides the conditions necessary for knowledge transfer to occur. Three key aspects of social capital that can define the context for knowledge transfer are trust, norms, and identification (Nahapiet & Ghoshal, 1998). Prior research has hinted on the moderating role of aspects of social capital in knowledge sharing (Constant et al., 1994; Jarvenpaa & Staples, 2000).

Trust is the belief that the intended action of others would be appropriate from our point of view. It indicates a willingness of people to be vulnerable to others due to beliefs in their good intent and concern, competence and capability, and reliability (Mishra, 1996). Generalized trust (trust within a community) has been viewed as a key contextual factor affecting cooperation and the effectiveness of knowledge transfer (Adler, 2001).

A norm represents a degree of consensus in the social system (Coleman, 1990). Pro-sharing norms that have been reported to enhance knowledge transfer are norms of teamwork (Starbuck, 1992), collaboration and sharing (Orlikowski, 1993; Goodman & Darr, 1998; Jarvenpaa & Staples, 2000), willingness to value and respond to diversity, openness to conflicting views, and tolerance for failure (Leonard-Barton, 1995). The first two norms can create an atmosphere where people are motivated to share knowledge as an accepted common practice. The last three norms can be crucial to promote knowledge sharing by reducing the risks of sharing.

Identification is a condition where the interests of the individual merge with the interests of the organization, resulting in the creation of an identity based on those interests (Johnson, Johnson,

Figure 1. Framework for knowledge contribution/seeking



& Heimberg, 1999). Three key components of identification have been identified: similarity of values, membership, and loyalty toward the organization (Patchen, 1970). Similarity is the extent to which members of an organization possess joint goals and interests. Membership is the degree to which self-concept of members is linked to the organization. Loyalty refers to the extent to which members support and defend their organization. Identification can enhance communication and knowledge transfer among organizational members (Nahapiet & Ghoshal, 1998).

A framework for explaining knowledge contribution and knowledge seeking incorporating constructs from social exchange theory and social capital theory is shown in Figure 1.

Knowledge Contributor Motivation

In the contributor framework, opportunity costs (e.g., contribution effort) and other costs (e.g., loss of knowledge power) are proposed to negatively impact knowledge contribution. Both extrinsic (e.g., economic rewards) and intrinsic (e.g., enjoyment in helping others, and image) benefits are proposed to positively affect knowledge contribution. Contextual factors (i.e., trust, norms, and identification) may moderate the relationships between cost and benefit factors and knowledge contribution. For example, trust can moderate the relationship between contribution effort and knowledge contribution, and identification may moderate the relationship between economic rewards and knowledge contribution.

Knowledge Seeker Motivation

In the seeker framework, both opportunity costs (e.g., seeker effort) and other cost factors (e.g., future obligation) are proposed to negatively impact knowledge seeking. Extrinsic (e.g., economic reward) and intrinsic (e.g., knowledge growth) benefits are proposed to positively affect knowledge seeking. Contextual factors (i.e., trust, norms, and identification) can moderate the relationships between cost and benefit factors and knowledge seeking. For example, identification may moderate the relationship between future obligation and knowledge seeking while pro-sharing norms can moderate the relationship between knowledge growth and knowledge seeking.

FUTURE TRENDS

Based on practice and previous research, several avenues for future research are suggested. The directions are discussed in terms of studying additional motivational influences and relationships, application of theories across other settings (e.g., different KMS, users, organizations, and other nations or cultures), and extension to allied socio-technical problems.

Additional Influences and Relationships

Additional motivational influences in terms of individual costs (e.g., system learning cost, review cost, and follow-up cost), benefits (e.g., network benefit), organizational context (e.g., size of KMS user community), and task factors (e.g., task interdependence and tacitness) can be included in the frameworks to possibly enhance explanatory power. Interactions and links among cost, benefit, and social capital factors and between factors from different theoretical perspectives can be explored. This will allow us to understand why certain costs or benefits dominate others and why certain factors moderate the effect of others on knowledge contribution or seeking.

Investigation of Different Knowledge Sharing Contexts

Studies examining usage of different types of KMS for knowledge sharing could be conducted based on previous frameworks. The effect of different user demographics on perceived costs and benefits and consequent usage of KMS could be assessed. This will allow specific usage enhancement measures to be catered for different demographic groups. Similar studies could be conducted across different industry sectors. For example, knowledge sharing models could be compared across sectors where different cost, benefit, and contextual influences are expected. Further, the models could be extended to other national and cultural settings. Since knowledge sharing behavior may be culture-dependent and knowledge sharing in global organizations is likely to extend across cultural boundaries, studies of cross-country or cross-cultural nature can better inform the applicability of knowledge sharing theories under different national and cultural conditions.

Allied Socio-Technical Problems

Knowledge contributor and seeker perspectives can be combined to formulate an overall model for knowledge sharing. Other aspects of social capital such as structural and cognitive aspects could be investigated to observe their effect on the motivation, access, and shared understanding for knowledge transfer. Frequency of knowledge transfer transactions as well as contribution and seeking cost per transaction could be studied. These parameters may vary for different forms of KMS and direct knowledge transfer. This may allow for explanation of user decision to choose a particular KMS or form of knowledge transfer. Organizational controls for monitoring knowledge contribution and seeking behavior could be investigated. Finding better ways of monitoring such behavior could help to design appropriate incentive systems for promoting knowledge sharing. Mandates for KMS usage could be explored to understand whether they produce full compliance, and whether the quality of knowledge contributions and reuse would be different for mandated vs. voluntary use. Mechanisms for seekers to evaluate contribution quality could be studied with the purpose of facilitating knowledge seeking.

CONCLUSION

Conceptual frameworks based on social exchange theory and social capital theory can be applied to explain and predict knowledge contribution and knowledge seeking behavior in different contexts. The research has practical implications for organizational management and technology architects. Implications are suggested to promote knowledge sharing by enhancing significant benefits and alleviating significant costs for knowledge contributors and seekers.

Encouraging Knowledge Contribution

Contributor benefits such as enjoyment in helping others and knowledge self-efficacy need to be increased in order to encourage knowledge contribution. Enjoyment in helping others could be increased by connecting knowledge seekers with contributors and allowing them to express their appreciation of how useful the knowledge contributed has been in their work. Perceptions of knowledge self-efficacy could be enhanced by highlighting knowledge contribution success stories and their positive impact on organizational performance. Economic rewards for knowledge contribution could be targeted toward individuals who have greater identification with the organization. High identification individuals may be more readily motivated by incentives to contribute knowledge. Negative effects of contribution effort on knowledge contribution could be alleviated through increasing trust. Higher trust could be promoted by ensuring that credit is given for knowledge contributions, that is, all knowledge contributions are duly acknowledged. Alternatively when trust is low, contribution effort could be reduced by allocating time for their employees to share knowledge and integrating knowledge sharing into work processes.

Encouraging Knowledge Seeking

Seeker benefits such as perceived utility of results and knowledge growth need to be increased to encourage knowledge seeking. Perceived utility of results could be increased by ensuring that knowledge repositories are populated with relevant, accurate, and timely knowledge pertaining to the needs of seekers. This requires that contributors be encouraged to share their knowledge using various recommendations suggested in the preceding section and the quality of knowledge be vetted by implementing appropriate content review processes. Perceptions of knowledge growth can be increased by highlighting the learning benefits of seeking knowledge. If seekers are convinced of personal knowledge growth, they may be motivated to seek knowledge even when knowledge found is not directly relevant to their immediate work. Promoting employees' personal growth and development would also lead to higher employee satisfaction and morale in the long-term. Such measures would be necessary particularly under conditions of low pro-sharing norms. High pro-sharing norms could override the need for such benefits.

Technology Considerations

KMS technology designers could promote usage of their products for knowledge sharing by reducing knowledge contribution effort and increasing utility of results for knowledge seekers. KMS should be designed so that entry of knowledge is as minimally onerous to contributors as possible. Mechanisms to facilitate knowledge entry include intelligent acquisition and improved content taxonomy. An interactive system that prompts for knowledge and organizes the knowledge can reduce contribution effort. A comprehensive domain categorization that captures inter-category relationships can ease contribution effort. Knowledge contribution effort also can be reduced by allowing more natural forms of knowledge acquisition (e.g., audio or video contribution) as opposed to purely text contribution. This may be particularly appropriate for more tacit forms of knowledge.

Utility of results for knowledge seekers can be increased by designing filtering, indexing, and retrieval technologies that ensure appropriate content goes into KMS and can be readily found. Indexing and retrieval technologies need to be designed that can efficiently customize and refine searches and provide relevance feedback. Knowledge seekers need to be provided information about the quality of knowledge retrieved to enable them to make reasonable judgments about reuse. Examples of such information include quality ratings and reviews.

Although large amounts of investments are being made in knowledge management initiatives, a significant number of organizations have difficulties with implementing these initiatives due to the challenges of motivating employees to contribute and reuse knowledge. The above discussion attempts to explain the motivations of knowledge contributors and knowledge seekers and thereby throw light on this problem. Organizational knowledge leveraging would be possible only if both contributors and seekers are motivated.

Chapter 6.24
Work and Knowledge

Tom Butler
University College Cork, Ireland

Ciaran Murphy
University College Cork, Ireland

INTRODUCTION

It is widely believed that knowledge work is a relatively new phenomenon and that it constitutes the main form of activity in post-industrial organizations. While the term remains undefined, knowledge work is taken to refer to the knowledge that individuals apply in performing role-related business activities in "knowledge-intensive" organizations. In this scheme of things, the conventional wisdom holds that the subjective knowledge of individual social actors is applied to "objectified" organizational knowledge (i.e., data held in various paper and electronic repositories) as the raw material of the production process. Thus, knowledge is considered to be both an input to, and an output of, business processes: It also is argued to underpin the process by which knowledge inputs are transformed to outputs.

Cooley (1975) was one of the first to employ the term "knowledge worker," however, his conception encompasses both white and blue-collar workers, professionals, and craftspeople alike. This is to be contrasted with Drucker's (1999) perspective on knowledge work, which focuses primarily on the upper echelons of management. This article echoes Cooley's perspective in many respects, however, it seeks to strengthen, extend, and apply it in a contemporary context. The following section provides the rationale and context for this article's thesis by illustrating the socially distributed and collective nature of knowledge. It also helps illustrate certain deficiencies in the conventional understanding of this important topic; these are then addressed in the third section's exploration of the social construction of knowledge. The third section also deconstructs commonly held beliefs on knowledge by examining its relationship to data and information. The fourth section then presents this article's main contribution by presenting a conceptual model and taxonomy of knowledge in organizational contexts. It is hoped that this will help researchers and practitioners better understand the relationship between knowledge and work going forward.

In sum, the article's motivation is to eliminate the misunderstandings that surround the concept of knowledge work and to propose an understanding of the phenomenon that is more in tune with the "reality" of organizational life. The article's marriage of philosophy (Aristotle, 1945; Gadamer, 1975; Heidegger, 1976) and institutional theory (e.g., Berger & Luckmann,1967, from sociology, and Nordhaug, 1994, from economics) acts to "inform" researchers who seek to understand the know-how, -why, and -what of social action in organizational settings. For practitioners, it highlights areas where experiential and skill-based knowledge are of value in organizations and illustrates for them the relative importance of task- and firm-specific knowledge.

BACKGROUND: EVERYBODY KNOWS…BUT ONLY COLLECTIVELY

Aristotle argues that no one individual can know or possess all of the available knowledge, rather, knowledge is dispersed among individuals in society (Aristotle, 1945; Hayek, 1945; Berger & Luckmann, 1967). However, Grant (1996) maintains that knowledge creation is an individual activity, and that the extant emphasis on "organizational knowledge" is misplaced—he argues that organizational knowledge does not exist as a distinct phenomenon (see Stata, 1989; Taylor, 1993; Pfeffer, 1994). Therefore, what Hayek says about society also may be applied to organizations, viz knowledge of and about an organization and its activities will be dispersed among organizational actors and the "communities-of-practice" which they constitute (cf. Tsoukas, 1996). The problem facing social groupings such as organizations, societies, and cultures is therefore "a problem of the utilization of knowledge not given to anyone in its totality" (Hayek, 1945, p. 450). A portion of this dispersed knowledge may, and particularly in more formal institutions will, be codified as information in documents, manuals, books of operating procedures, and so forth, which may be paper-based, electronic, or both (Bruner, 1990; Davenport & Prusak, 1998). Berger and Luckmann (1967) consider this as pretheoretical recipe knowledge and, as such, it forms an operational backdrop for organizations by supplying institutionally appropriate rules of conduct, by placing boundaries on acceptable actions and by defining and enumerating activities to be performed by social actors (see Taylor, 1993; Tsoukas, 1996). Therefore, it acts as both a controlling and predictive mechanism for such conduct.

Thus, institutions are akin to "collective minds" (Weick & Roberts, 1993) whose cultures become a learned product of group experiences, particularly those of the organization's founders (Schein, 1985). Over time, the cognitive dispositions and dispersed knowledge of individual social actors, who actively participate in the dialogic process of institutional reality construction within the aforementioned unarticulated background of wider social and institutional contexts, come to populate this metaphorical "collective mind," which emerges as the unarticulated background of organizational experience. Hence, it is an individual's Heideggerian "fore-knowledge" of the type of actions required of him or her by other actors in the relevant "community-of-practice" and in the wider organization that shapes his or her ongoing actions and utterances (Heidegger, 1976); in turn, these actions once taken and linguistic expressions uttered influence the actions and cognitive dispositions of others (Lincoln & Guba, 1985). Thus, it is the existence of previously acquired knowledge of social convention, in the form of what may be described as a Gadamerian "effective-historical consciousness" (Gadamer, 1975), that guides the self-reinforcing, reciprocal "typification of habitualized" action and dialogue among social actors and which enables individuals to share knowledge relevant to their social grouping or organization (Berger & Luckmann, 1967; cf. Latour, 1993).

This shared corpus of social, communal, or organizational knowledge manifests itself in the form of relatively fixed repertoires of highly reproducible routines, recipes, reciprocal social action, and intersubjective cognitive arrangements (e.g., Nelson & Winter, 1982; Hannan & Freeman, 1984; Spender, 1989; Weick & Roberts, 1993). Alternatively put, an organization's "collective mind" is manifested in the actions and linguistic expressions/narratives of social actors as they commit to and engage in a network of communal and organizational activities (see Bruner, 1990; Law & Callon, 1992). This "collective mind" is, in as much as it represents a collective knowledge of the social groupings concerned, also sedimented in the products of these activities, in the "fused horizons of understanding" of participating actors (Gadamer, 1975), and also in a community's or organization's texts, electronic documents, and databases (Bruner, 1990; Hall, 1994; Boland & Tenkasi, 1995; Kusunoki, Nonaka, & Nagata, 1998). Therefore, it must be emphasized that an organization's "collective mind" is not the property of a single actor, neither is it contained in its entirety in the Gadamerian "horizons" (fused or otherwise) of all actors; rather, it is distributed among all participating actors as a knowledge of and about communal and/or organizational activities (Weick & Roberts, 1993).

The logical conclusion of this argument is that all work in organizations is "knowledge work," as knowledge about organizational activities is dispersed either within "communities-of-practice" or across them. The next section further elaborates on this and explores how knowledge is socially constructed; it also differentiates between practical wisdom or experiential knowledge and technical or skills-based knowledge. This helps put knowledge in context and points toward a more inclusive appreciation of knowledge work.

AN ONTOLOGICAL PERSPECTIVE ON THE SOCIAL CONSTRUCTION OF KNOWLEDGE

Boland (1987) gives an account of five misguided fantasies that surround the concept of information, viz that it is structured data, that an organization is information, and that information is power, is intelligence, or is perfectible. This observation could be extended to the concept of knowledge. For example, conventional wisdom dictates that knowledge is processed information and as such is capable of objective representation. In order to dispel such notions, the ontological basis of knowledge is explored. This fosters an understanding of how people come to know what they know and provides insights into the constitution of knowledge.

It is clear from Gadamer's (1975) hermeneutics that data, information, and knowledge are loosely coupled: Depending on the "worldview," "lived experience," and "tradition" of the recipient, the same data can yield different knowledge and understanding. Consider, for example, Heidegger's (1976) argument that Dasein's "'Being-in-the-world" is characterised by a "pre-understanding" or "fore-knowledge" of the nature of being and its constituent phenomenon. Consider also Heidegger's argument that Dasein, as the mode of being characteristic of all humans, always understands itself in terms of its existence and the possibilities it presents. Any "breakdown" in Dasein's understanding of phenomena results in the search for data that will enable phenomena to be interpreted in a new light and thereby repair the "breakdown" by developing an enhanced understanding. Thus, as Brown and Lightfoot (1998) argue, "knowledge occurs in the wake of the breakdown. It proceeds slowly, perhaps without clear direction" (p. 293).

In Gadamerian terms, the process of acquiring new knowledge-informing data on a phenomenon is governed by the hermeneutic "circle of understanding," which involves the cycling back and forth between the actor's existing "horizon of understanding" and that suggested by the phenomenon of interest. A dialectic of question and answer, of thesis, antithesis, and synthesis, operates to help the actor interpret new data in light of the old. Hence, a new understanding is arrived at when a "fusion of horizons" occurs between the interpreter's horizon of understanding and that of the phenomenon under consideration (Butler, 1998). Thus, knowledge is, first and foremost, an enigmatic and personal phenomenon in that it arises from the practical experience of social actors. In order to delineate the dimensions of such experience, the work of Aristotle is presently explored.

Phronesis and Techne as the Core Constituents of Practical Knowledge

Gadamer (1975) and Dunne (1993) drew on Aristotle's Nicomachean Ethics to extend further our understanding of individual knowledge. Aristotle presents what he considered to be the core components of practical knowledge in social contexts—phronesis as experiential self-knowledge (practical wisdom) and techne as skills-based technical knowledge. The conduct of social affairs involves the application of phronesis in a thoughtful and competent manner, this Aristotle refers to as praxis. The social activity that has as its concern the "making" or "production" of social artefacts is called poiesis and involves the application of techne. A techne is knowledge of how to perform task-based activities in pursuit of some practical end: This end may be tangible or intangible. Thus, techne provides managers, professionals, craftsmen, labourers, and scientists with an understanding of the why and the wherefore, the how and with-what of their concerns. The skills of qualified craftsmen, artists, musicians, surgeons, computer programmers, physicists, accountants, and so on, all fall into this category—as indeed does the oft-ignored skills of ordinary "unskilled" workers. On the other hand, a social actor's "self-knowledge" (phronesis) is a synthesis of his temporal experience of social phenomena and his ability to take or perform practical action in relation to such phenomena—and this clearly applies to every class of worker. All this has important implications for the way in which knowledge is viewed in research and practice, as will be seen in the concluding sections. However, it is clear from Aristotle that phronesis and techne possess a social nature, accordingly, the social context of knowledge construction is now explored.

The Social Construction of Knowledge Work

Researchers point out that social action is the dominant means of knowledge diffusion in organizations (Berger & Luckmann, 1967). However, it must be noted that individual knowledge is inseparable from the social context and practices that help construct it and which shape and influence its acquisition (Berger & Luckmann, 1967; Bruner, 1990; Brown & Duguid, 1991). Following this line of argument, Tsoukas (1996) argues that a social actor's knowledge lies, first and foremost, in the social and occupational practices in which he or she engages and, in effect, knowledge is socially constructed (Berger & Luckmann, 1967). It is clear, however, that while knowledge is embodied in the social actors that comprise the various "communities-of-practice" that constitute organizations, no one actor or group of actors possesses all the knowledge required to effect social action. This gives rise to the notion that knowledge in organizations is dispersed (Hayek, 1945), as actors may not be in a position to observe, at first hand, the knowledge embedded in the actions of others or communicate linguistically with them (Kogut & Zander, 1992). Therefore, social actors resort to texts and other media, such as IT, to augment their limited cognitive capacities (Bruner, 1990); these mechanisms provide conduits or repositories for the spatial and temporal transfer of knowledge-informing data between actors (Boland & Tenkasi, 1995). They are not, as this article argues, knowledge repositories and therefore cannot be managed as such. It is clear, however, that social narrative is the dominant mechanism for understanding acts of meaning in social contexts, hence, this issue is next explored.

The cultural psychologist Jerome Bruner (1990) illustrated the role of narrative in all human understanding (see Brown & Duguid, 1991). Accordingly, Gadamer argues that language is an essential component of communication and understanding. Nevertheless, Heidegger (1976) maintains that:

Communication is never anything like a conveying of Experiences, such as opinions or wishes, from the interior of one subject into the interior of another... In discourse Being-with becomes "explicitly" shared, that is to say, it is already, but it is unshared as something that has not been taken hold off and appropriated. (p. 205)

Thus, strictly speaking, language is not normally used for the exchange of information, as is commonly assumed; instead, it merely calls attention to some aspect of the shared existence of social actors. As Taylor (1993) argues, human knowledge and understanding are based upon the unarticulated background of the "ready-to-hand," that is, the taken-for-granted understandings that constitute the web of human relationships (Heidegger, 1976). This has profound implications for the commonly held conception of knowledge. Accordingly, Winograd and Flores (1986) point out that "knowledge lies in the being that situated us in the world, but not in a reflective representation" (p. 74). Thus, individual knowledge is possible because of the social practices actors engage in. However, it is clear that social practices are not an aggregation of individual experiences; rather, they constitute the set of background distinctions that underpin individual action. In addition, actors are socialized into institutional practices which involves internalizing the set of background distinctions that constitute such practices (see Brown & Duguid, 1991; Taylor, 1993). Knowledge is therefore open-ended and its creation goes far beyond the mere processing of knowledge-informing data.

Working on Data, Not Knowledge

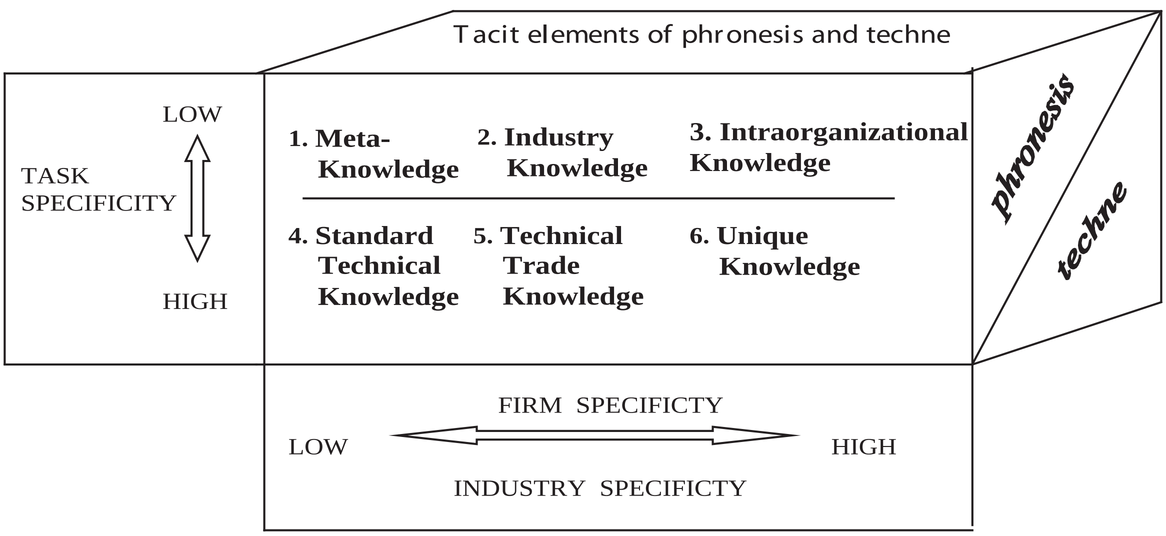
Von Foerester (1984) states "information is the process by which knowledge is acquired" (p. 193). However, texts, documents, computer files, databases, and so forth merely provide data. Why? Individuals become informed through the process of interpretation and the application of individual "fore-knowledge" (Introna, 1997). Therefore, as a text (social action is included here) is read and interpreted, it informs. So, from a hermeneutic perspective, texts and narratives contain data that when interpreted inform the reader. Hence, information is abstract and ambiguous in its depiction, and data is all that can be represented, stored, transferred, and manipulated by information and communication technologies (ICT) (Galliers & Newell, 2001). Ultimately, all that can be said of knowledge then is that it is always in a process of becoming, extending beyond itself (Fransman, 1998). This "becoming" refers to different interpretations or meanings attributed to data derived from the multi-voiced dialectic that takes place within and between social actors who are embedded in cultural contexts that are historical, on the one hand, and that are oriented toward the future, on the other (Bruner, 1990).

FUTURE TRENDS: TOWARD A CONCEPTUAL MODEL AND TAXONOMY OF KNOWLEDGE IN ORGANIZATIONS

It has already been established that the two basic components of social actors' knowledge are phronesis and techne. When coupled with the tacit knowledge that arises from the unarticulated web of social activities and relationships, these types of knowledge combine to provide social actors with a unique stock of knowledge and a "worldview." There is, however, a need for an extended conceptualization that incorporates a pragmatic, taxonomic perspective on knowledge in organizational and institutional contexts. Nordhaug's (1994) taxonomy of organizational competencies is of particular interest here, as it indicates the focus and application of individual phronesis and techne in organizational and institutional "communities-of-practice." Therefore, it is of particular relevance to this article's thesis as it contributes to the formulation of a conceptual model and taxonomy of knowledge within organizational settings (see Figure 1). It is hoped that this will inform the future deliberations of practitioners and researchers in the area.

By way of representing the various dimensions of phronesis and techne in finer granularity, the taxonomy of knowledge presented captures what is regarded as organizational knowledge from an individual perspective. In Figure 1, the term specificity refers to the degree to which an individual's knowledge is general or specific1 to (a) the execution of organizational tasks, (b) the organization itself, and (c) the industry the organization competes in. For example, meta-knowledge, which is general background knowledge and which possesses a significant tacit component,

Figure 1. A conceptual model and taxonomy of knowledge in organizational contexts (adapted from Nordhaug, 1994)



can be used in the performance of a range of organizational activities—social and technical. Examples of meta-knowledge are individual literacy, knowledge of a foreign language, and so on. This type of knowledge also is generally available within the firm and the industry as a whole; nevertheless, the widespread possession of such knowledge by individual actors is important for an organization's general "stock of knowledge."

Industry-based knowledge also is a general type of knowledge, widely available to individuals in their role-related organizational activities, across both firms and industry. It is not specific to either organizations or any individual organizational tasks as such, but it is, however, highly industry specific. Examples of this type of knowledge are knowledge of the industry structure, its current state of development, and of the key individuals, networks, and alliances in an industry.

Intraorganizational knowledge is highly firm and industry specific but is not specific to organizational activities or tasks. In effect, this component of social actors' knowledge is firm-specific meta-knowledge. Examples are knowledge about colleagues, knowledge about elements of the organizational culture, communication channels, informal networks, knowledge of a firm's strategy and goals, and so on.

Standard technical knowledge is task specific, industry and firm non-specific, and involves a wide range of technical, operationally oriented knowledge that is generally available to all actors. Examples are knowledge of financial and management accounting practices, knowledge of computer programming and standard software packages, and knowledge of craft and engineering principles and methods.

Technical trade knowledge is task specific, industry specific, and is generally available among firms in an industry. Examples of such knowledge are knowledge of automobile construction methods, knowledge of the techniques of computer hardware construction, and so on.

Finally, unique knowledge is specific across all dimensions and applies to the possession by social actors of knowledge—self-knowledge and skills-based knowledge—of unique organizational routines, production processes, and IT infrastructures, to mention a few.

This section of the article explored the socially constructed nature of individual/collective knowledge in organizations. In order to provide insights into the type of knowledge relevant to social actors in organizational contexts, a taxonomy of individual knowledge in organizational contexts was then offered. The strands of the arguments made are now woven together in the concluding section.

CONCLUSION

An understanding of phronesis and techne is, we believe, essential to an understanding of knowledge work. If the observation that phronesis and techne constitute the practical components of individual knowledge in social contexts is accepted, then those who apply experiential self-knowledge and/or skills-based technical knowledge in institutional settings can be considered knowledge workers. It is clear that this definition applies to workers in pre-industrial and industrial settings, as well as IT-enabled post-industrial organizations. Certainly, the appearance of ICT in the post-industrial age has led to the development of IT-related knowledge and skills by many workers. One example is professional workers who employ personal productivity tools, such as spreadsheets and DSS, while another is scientists and practitioners who develop skills in the use of sophisticated technologies to develop new understandings of natural or social phenomena. But this in itself does not make these individuals any more or less knowledge workers than their industrial or pre-industrial predecessors. What does, then?

Many clearly feel that the quantity and quality of data that can be stored, accessed, communicated, analyzed, and processed by contemporary workers using ICT renders the work they perform a special status (i.e., knowledge work). Maybe it does. And maybe this is why academics and practitioners now accord to data the status of knowledge. In contrast, the argument presented in the second section of this article illustrates that knowledge, unlike data, cannot exist outside the heads of knowers, and that such knowledge has an explicit social context. In the context of ICT, this article posits that "so-called" knowledge workers work on data, not knowledge. In addition, the all-pervasive Taylorist prejudice against workers has led to a focus by decision-makers on the management of what has been described as "objective knowledge" in and by ICT, rather than attempting to leverage the "subjective knowledge" of workers, which is the real and only source of organizational knowledge. Thus, like the emperor in the fairytale, practitioners have been duped by consultants and some well-meaning academics into believing that there is something special in the "knowledge management paradigm." What can and should be managed are workers and the data they create, collate, and disseminate, but stating the obvious would not make many consultancy dollars or help have papers accepted for publication. How then can researchers begin to understand what is happening in organizations where workers employ ICT in innovative ways? Taken in the context of the theoretical argument articulated in the foregoing sections, the model and knowledge taxonomy presented in the fourth section should act to "inform" researchers who seek to understand the know-how, -why, and -what of knowledge and social action in organizational settings. Accordingly, it highlights areas where experiential and skill-based knowledge are of value in organizations and recognizes the relative importance of task and firm specific knowledge.

Chapter 6.25
Key Performance Indicators and Information Flow:
The Cornerstones of Effective Knowledge Management for Managed Care

Alexander Berler

ABSTRACT

It is paradoxical that, although several major technological discoveries such as Magnetic Resonance Imaging and Nuclear Medicine and Digital Radiology, which facilitate improvement in patient care, have been satisfactorily embraced by the medical community, this has not been the case with Healthcare Informatics. Thus, it can be argued that issues such as Data Management, Data Modeling, and Knowledge Management have a long way to go before reaching the maturity level that other technologies have achieved in the medical sector. This chapter proposes to explore trends and best practices regarding knowledge management from the viewpoint of performance management, based upon the use of Key Performance Indicators in healthcare systems. By assessing both balanced scorecards and quality assurance techniques in healthcare, it is possible to foresee an electronic healthcare record centered approach which drives information flow at all levels of the day-to-day

process of delivering effective and managed care, and which finally moves towards information assessment and knowledge discovery.

INTRODUCTION

The advantages of the introduction of Information and Communication Technologies (ICT) in the complex Healthcare sector have already been depicted and analyzed in the Healthcare Informatics bibliography (Eder, 2000; Englebardt & Nelson, 2002; Harmoni, 2002; Norris, Fuller, Goldberg, & Tarczy-Hornoch, 2002; Shortliffe, Perreault, Wiederhold, & Fagan, 2001; Stegwee & Spil, 2001). It is nevertheless paradoxical that, although several major technological discoveries such as Magnetic Resonance Imaging, Nuclear Medicine and Digital Radiology, which facilitate improvement in patient care, have been satisfactorily embraced by the medical community, this has not been the case with Healthcare Informatics. Thus, it can be argued that issues such as Data Management, Data Modeling, and Knowledge Management have a long way to go before reaching the maturity level that other technologies have achieved in the medical sector.

A variety of reasons could be proposed for this issue, though with a short analysis it becomes rather clear that modern ICT present integration problems within the healthcare sector because of the way the latter is organized. Healthcare is a strongly people-centered sector in which ICT has been considered more as an intruder, as a "spy" to the healthcare professionals' way of doing things and as a competitor to this people-centered model. Thus, if ICT intend to prove its advantages towards establishing an information society, or even more a knowledge society, it has to focus on providing service-oriented solutions. In other words, it has to focus on people and this has not been the case in most of the circumstances. It is common knowledge that in order to install any type of information system in healthcare, especially if it involves knowledge management, six main groups of issues have to be dealt with (Iakovidis, 1998, 2000):

1. The organizational and cultural matters related to healthcare. This issue is rather important, regardless of any information system, since organizational models and culture do not endorse the continuity of care or any type of structured data collection. Issues such as mistrust between different specialists, between the different healthcare structures or between doctors and nurses prevent in many cases the effective sharing of information. Health reforms are currently under way in many countries stressing the will to deal with this problem.
2. The technological gap between healthcare professionals and information science experts. Doctors are often reluctant to use information systems that they believe are not designed for them. From another point of view, Healthcare Informatics have been introduced in healthcare institutions mostly on pilot-based projects aiming at addressing specific issues and have proposed solutions addressing a small number of healthcare practitioners, resulting in establishing a complex map of information niches. This approach is the consequence of applying information technology to procedures that where not designed for it, thus creating a panspermia of information models which are neither compatible nor interoperable, even within a single institution's environment. Efforts in creating interoperability standards and protocols such as HL7 are proposing solutions to address this issue, thus enabling data manipulation and knowledge management.
3. The legal requirements on the confidentiality of personal and patient related data and on data privacy. It is clear that if this issue is not addressed at a managerial and procedural

level by imposing suitable policies to meet these requirements, there is little chance that medical data will be kept digitally in a structured manner (thus allowing the transition from digital islands of clinical data towards a structured electronic healthcare record). The implementation of an information system, where the electronic healthcare record is considered to be the core of the system (patient-centered model), is the only way to drive data management towards creating new knowledge. The complexity of the problem can be explained if one just observes the course of implementation of both the Health Information Privacy and Accountability Act (HIPAA) in the US and Directive 95/46/EC in the EU. The issues seem to have been dealt with at the strategic level, but still a lot has to be done in the implementation and setup of those strategies.

4. The industrial and market position of Healthcare Informatics. In general, the healthcare market is seen by the industry as large in size but not highly profitable, mainly due to the lack of standards in implementing and interoperating healthcare informatics products. As a consequence, the industry has focused on creating mostly small-scale products (i.e., Laboratory Information Systems, Radiology Information Systems, Clinical Information Systems) and not on evangelizing the production of information system that are dealing with healthcare as a whole. The lack of end-to-end solutions is dealt with by interconnecting heterogeneous information systems (a rather complex task with constant change management issues) and by introducing solutions from other business sectors (i.e., ERP, SCM, CRM) that have often been rejected by "key users" as non-compliant with their job description. Nevertheless, the new Web technology approaches (Web services, XML, etc.) and the new information technology strategies (i.e., service oriented architecture) could be the drivers towards merging information technology and healthcare services and thus enabling the establishment of knowledge management products.

5. The lack of vision and leadership of healthcare managers and health authorities, and the lack of willingness to re-engineer healthcare processes for the benefits of efficiency and quality of care delivery. Some countries are in the process of introducing or implementing such Business Process Reengineering projects in order to address healthcare delivery in a more information flow conformant way. This is a key point in reaching knowledge management, knowledge re-use and sharing, and finally proposing a solution for the knowledge-based society of tomorrow. This issue should be dealt with by proposing strategies that focus on processes and by establishing key performance indicators, balanced scorecards, or other metrics that are the upper level of a structured information flow-based model.

6. User acceptability and usability of the proposed information systems. This issue is the one most strongly related to the problem of dealing with the people-centered approach of the healthcare sector. This issue deals with information systems' user friendliness, with usability issues such as the time to reach a data entry point, the speed of information retrieval, the quality of information retrieval, the complex security procedures, and so on. In order to implement information systems and knowledge management systems, education and training must be addressed with high priority since user acceptability is strongly related to them. Service oriented models and patient-centered information systems have a higher chance of passing the user acceptability test. A system that is not accepted

by the user is often a system with poor data quality (or no data at all) and knowledge management, business intelligence or data warehousing solutions are consequently inoperable and unsuccessful.

Taking all of the above issues into consideration, this chapter proposes to explore trends and best practices regarding knowledge management from the viewpoint of performance management, based upon the use of Key Performance Indicators (KPI) in healthcare systems. By assessing both balanced scorecards (Kaplan/Norton) and quality assurance techniques in healthcare (Donabedian), it is possible to foresee an electronic healthcare record centered approach which drives information flow at all levels of the day-to-day process of delivering effective and managed care, and which finally moves towards information assessment and knowledge discovery (both with administrative and medical data). KPIs should be regarded as the strategic assessment tool, for both the executives and the clinical decision-makers, that will lead healthcare delivery to excellence and to knowledge discovery and assessment.

BACKGROUND

Knowledge Management as a Transformation Driver in Healthcare

Today, Knowledge Management (KM) is on everyone's mind. Healthcare organizations are no exception and are accepting the challenge to more effectively share knowledge both internally and externally (Strawser, 2000). The growth of KM projects (i.e., decision support systems, data mining tools, business intelligence solutions) signals a growing conviction that managing institutional knowledge is crucial to business success and possibly business survival. When the hype and confusion are stripped away, it is apparent that KM initiatives can profoundly change a healthcare enterprise for the better, and bring numerous advantages to Healthcare Information Management (HIM) professionals. For HIM professionals, KM is worthy of special attention because it informs them not only on how to do things, but also on how they might do them better. In order for this to happen, data should be provided in specific patterns and should be based upon a strategy that will empower a healthcare system by gaining knowledge of its processes, its outcomes, and its structures.

Despite the obvious advantages, many healthcare decision makers view the idea of a KM initiative with scepticism, possibly because of an incomplete or incorrect understanding of the tools needed to achieve it. Many of the tools and strategies associated with implementing KM are not new; what is new is a cohesive approach to KM design and implementation. Certainly there are pitfalls and limitations in using information technology for KM—trying to force fluid knowledge into rigid data structures, for example, or focusing too much on the tools and not enough on the content. But networks and computers, with their ability to connect people and store and retrieve virtually unlimited amounts of information, can dramatically improve departmental efficiencies. Some examples of knowledge management applications are listed below:

- Data Mining tools enable decision makers to search and analyze large sets of data by using specific querying methods and tools (Standard Query Language, Rough Data set, On Line Analytical Processing).
- Document and Content Management systems are widely used to store and archive files of any type (text, images, video, etc.) and correlated them with keywords that have a business meaning to the end user.
- Knowledge Maps are graphical or other representations of how and by whom a specific

set of information is created, distributed and assessed. Knowledge Maps are very important tools in Total Quality Management projects.

- Intelligent Agents use a combination of profiling techniques, search tools, and recognition algorithms to provide up to date specific information to the end user. For example, intelligent agents could be used to forward completed test results to the corresponding physicians of a patient.
- Web Browsers are the most commonly used tools for searching information in an intranet or the Internet. As such, Web browsers are increasingly becoming the most common graphical user interface, even for specific software products such as financial accounting and patient order entry systems.
- Business Intelligence tools and Data Warehouses enable the decision maker to have predefined access to specific information of interest regardless of the physical location of the data. Such systems are ideal for performance management and executive reporting and serve as the technological base for supporting the idea of a digital dashboard of indicators.
- Workflow applications play a very important role in KM since knowledge is created during the process-based operations that take place in a healthcare institution. A computerised patient order entry system is a classic example of a process-based operation in healthcare that requires the constant monitoring of the workflow status.
- E-learning and collaboration tools are part of the knowledge distribution process, which is extremely important in healthcare, since continuous education is a key factor in effective practice of care.

The essence of effective knowledge management does not rely on the use of one or more existing or forthcoming information technology tools. It is mostly about people, about processes and about capturing the results of people following processes, about transforming information into knowledge (explicit or tacit) and reusing it within a healthcare framework.

Performance Management: Monitor and Manage Healthcare

In order to persuade healthcare decision makers to assess the added value of KM tools, the latter should initially be used to propose new performance measurement and performance management techniques at all levels of a healthcare system (Hurst & Jee-Hughes, 2001). In that sense, performance management has long been considered as a tool for controlling spending and for increasing the efficiency of healthcare systems (Oxley & MacFarlan, 1994). There are three broad goals that governments generally pursue in the healthcare area:

- Equity: where citizens should have access to some incompressible minimum level of healthcare and treatment based on the need for care rather that solely on income.
- Micro-economic efficiency: where quality of care and consumer satisfaction should be maximized at minimum cost.
- Macroeconomic cost control: where the healthcare sector should consume an “appropriate” share of GDP.

In addition, healthcare systems are often facing factors that put pressure on the system. As a consequence, an effective performance management framework is the only solution towards controlling factors such as:

- Population aging
- Increased income and higher demand for healthcare services;

- Increased access to healthcare services; and
- Increase of high technology usage which in turn increases the healthcare services usage creating sometime unnecessary demand (from a medical point of view).

Most existing policies for controlling the performance of healthcare systems were based upon financial assessment of past results (macroeconomic control of spending and micro-efficiency improvements) by giving incentives to payers and providers of a healthcare system. By its very nature the financial measurements are not forward looking and are exclusionary to non-financial measures. In addition, the emergence of the Information Society in the late 90s rendered many of the fundamental performance management assumptions obsolete. Information Society has brought a new set of assumptions that institutions have to include into their strategy. Amongst others we could refer to:

- The cross functional aspects of processes based upon specialisation, increased skills and high technology
- The integration of processes in the healthcare sector from the suppliers to the patient and the ability to manage and monitor materials upon requests and needs
- The ability to offer specific services to patients in accordance to their needs while being able to constraint costs of this customised care. In fact this is the essence of managed care: providing satisfactory and high quality of care at a reasonable cost.
- The global scale of healthcare: This sector is no exception to any other global marketplace, thus making healthcare delivery more comparable at a national or regional level and within accepted standards (e.g., clinical procedure guidelines)
- Innovation, which has been a key driver towards quality of care and quality of life for many years in the healthcare sector
- Knowledge workers: the increasing complexity of medicine and technology has created a need for highly skilled personnel at every level of a healthcare institution. Employee empowerment is driven by knowledge as it is created in the daily process of delivering healthcare services.

Nowadays, performance measurement is moving towards the adoption of a set of objectives for a healthcare system. To our knowledge, there is no complete agreement on what is meant by “performance” of health systems and many sets of objectives are generally proposed. The use of Key Performance Indicators (KPI) helps to establish this set of objectives more thoroughly by focusing on the real needs.

Using Balanced Scorecards

In order to address the issue of creating a set of KPIs , the Balanced Scorecard (BSC) framework (Kaplan, 2001; Norton & Kaplan, 1996) initially proposed by Kaplan and Norton for the strategic management of financial organizations in the mid 1990s, is one of the most suited approaches in that direction. This model has now proven its value and since it is a generic framework it is applicable to the healthcare sector. The BSC concept involves creating a set of measurements and objectives for four strategic perspectives:

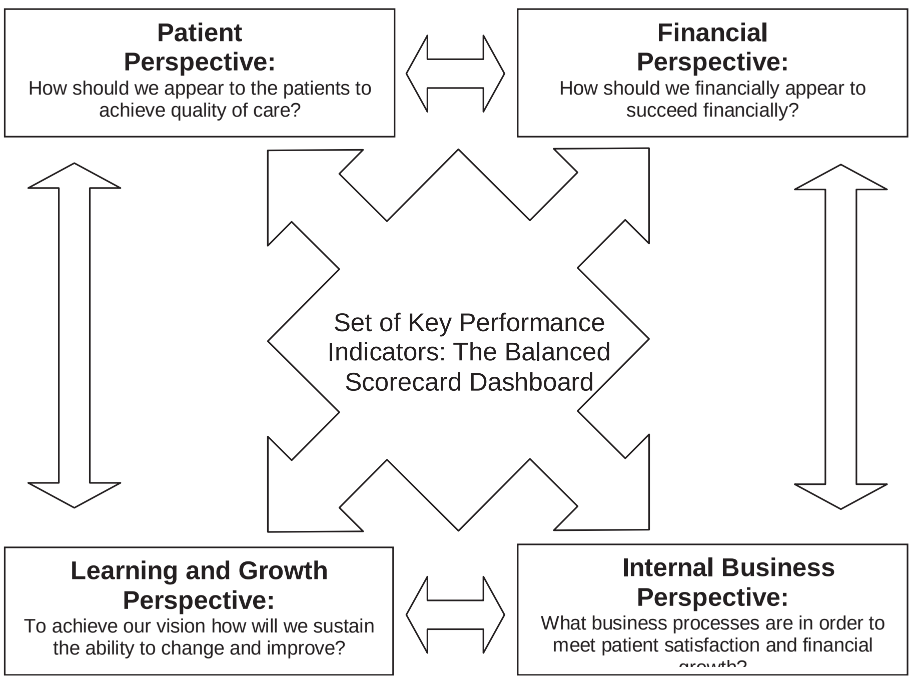
- Financial: financial performance measures typically indicate whether a proposed strategy implementation and execution is contributing to bottom line improvements, based upon an accurate summary of economic consequences of actions already taken.
- Customer (i.e., the Patient): this perspective is a set of objectives that focuses on identifying

the patient's needs, the targeted market (this could be the case of a specialised institution) and on measuring the performance of each specific business unit (i.e., a department) that has some influence on how the patient sees the healthcare organization.

- Internal Business Process. This perspective should gather all objectives related to processes and the way these are monitored and fine-tuned in order to achieve both excellence in financial accomplishments and patient satisfaction. In that sense, the BSC approach is a constant business process reengineering process based upon specific goals to meet and not on improving de facto established processes.
- Learning and Growth (innovation and vision). This is an important perspective of a BSC implementation because it focuses on the objectives and goals to achieve the incorporation of business innovation (e.g., installing a Positron Emission Tomography Device) and the continuous education of medical and administrative staff. In that sense, this perspective identifies measurable tasks in order to build long-term growth and improvement. In the healthcare sector, improvement is also measured by assessing the outcome of treatment and care.

These four perspectives comprise a framework, meaning that they must be assessed and populated in accordance to each business case. In order to achieve this, one has to set for each category a list of objectives that can be feasibly measured. To each objective, a specific target should be set and the initiative to reach that target well described.

Figure 1. A healthcare oriented BSC framework



The BSC approach retains the "traditional" financial perspective, which mostly focuses on reporting about past events. Financial figures, even if prospected in the future by statistical means, are inadequate for guiding and evaluating the journey that healthcare institutions must make to create future value through innovation, knowledge, patient satisfaction, employee empowerment, process refinement, technology assessment and material management. In that sense, the three other cited perspectives are completing the puzzle in order to create a more valid and future-oriented performance management strategy. In recent years, there have been some implementations of BSC frameworks in the healthcare sector mostly on a single institution base (i.e., a hospital, a clinic, an information technology component). Readers are encouraged to read and assess the best practices, cited as references to this chapter (Aidermark, 2001; Castaneda-Mendez, Mangan, & Lavery, 1998; Forgione, 1997; Freeman, 2002; Gordon & Geiger, 1999; Inamdar, Kaplan, & Bower, 2002; Oliveira J, 2001; Pink, Mc Killop, Schraa, Preyra, Montgomery, & Baker, 2001; Tarantino, 2003; Weber, 1999)

The model in Figure 1 enables decision makers to also value how the latter three perspectives have worked and thus it enables the measurement of intangible aspects of a system. The measurements focus on a single strategy that can be easily broken down to the various levels of depth, depending of the organization type. Thus, by using BSC one can create a top-to-bottom design of a system, starting up from the needed strategy (what is the market, who are the customers, what are the critical processes, what is required by the stakeholders) going down to design metrics, processes, structures and finally the needed technical and functional specification to create an information system and a knowledge management framework capable of producing the right data and serve the strategy.

QUALITY ASSURANCE IN HEALTHCARE AND THE ROLE OF INFORMATION TECHNOLOGY

Known Problems and Issues of the Healthcare Sector

It is rather of common knowledge that the healthcare sector is not a sector without problems. Especially in Europe, the great majority of healthcare organizations are state funded. This means that institutions have in some cases very restricted budgets to satisfy their needs thus making performance management a critical issue in their daily routine. Other common problems are increased bed coverage (some institutions are almost at 100 percent), long length of stay, increased waiting lists, poor facilities, and so on. Taking all this into account and adding the life-related processes, one can clearly see that healthcare organizations are difficult to manage even for experienced managers of other sectors. One could list some of the major issues that healthcare stakeholders are confronted with:

- Diversity of cases
- Need of high technology medical devices
- Public Policy Restrictions (e.g., payment by per day quotas that do not cover the inpatient treatment costs)
- High lengths of stay
- Increased waiting times
- Obsolete facilities
- Restricted funds for training
- Restricted funds for maintenance
- Increased number of medical errors (sometimes fatal)
- Erroneous drug prescription and intake (sometime fatal)
- Geographical issues (too many patients, too few nurses and medical staff)
- Large lists of materials to be managed (more than 3000 on average)

- Excessive waste management (10 m3 per day on average)

Quality Assurance and Performance Management

The application of a BSC framework will not by itself solve any of the aforementioned problems and issues. One could even say that BSC projects often fail as a consequence of misunderstanding or of not using a BSC strategy. BSC projects also fail because the variables of the scorecard are incorrectly identified as the primary drivers and because the improvement goals (the targeted objectives) are negotiated across an institution instead of being based upon stakeholders' requirements, fundamental processes and improvement process capabilities. They also fail because there is no deployment system installed to disseminate, maintain and promote the BSC framework, or because some very important KPIs are not used, or metrics are poorly defined.

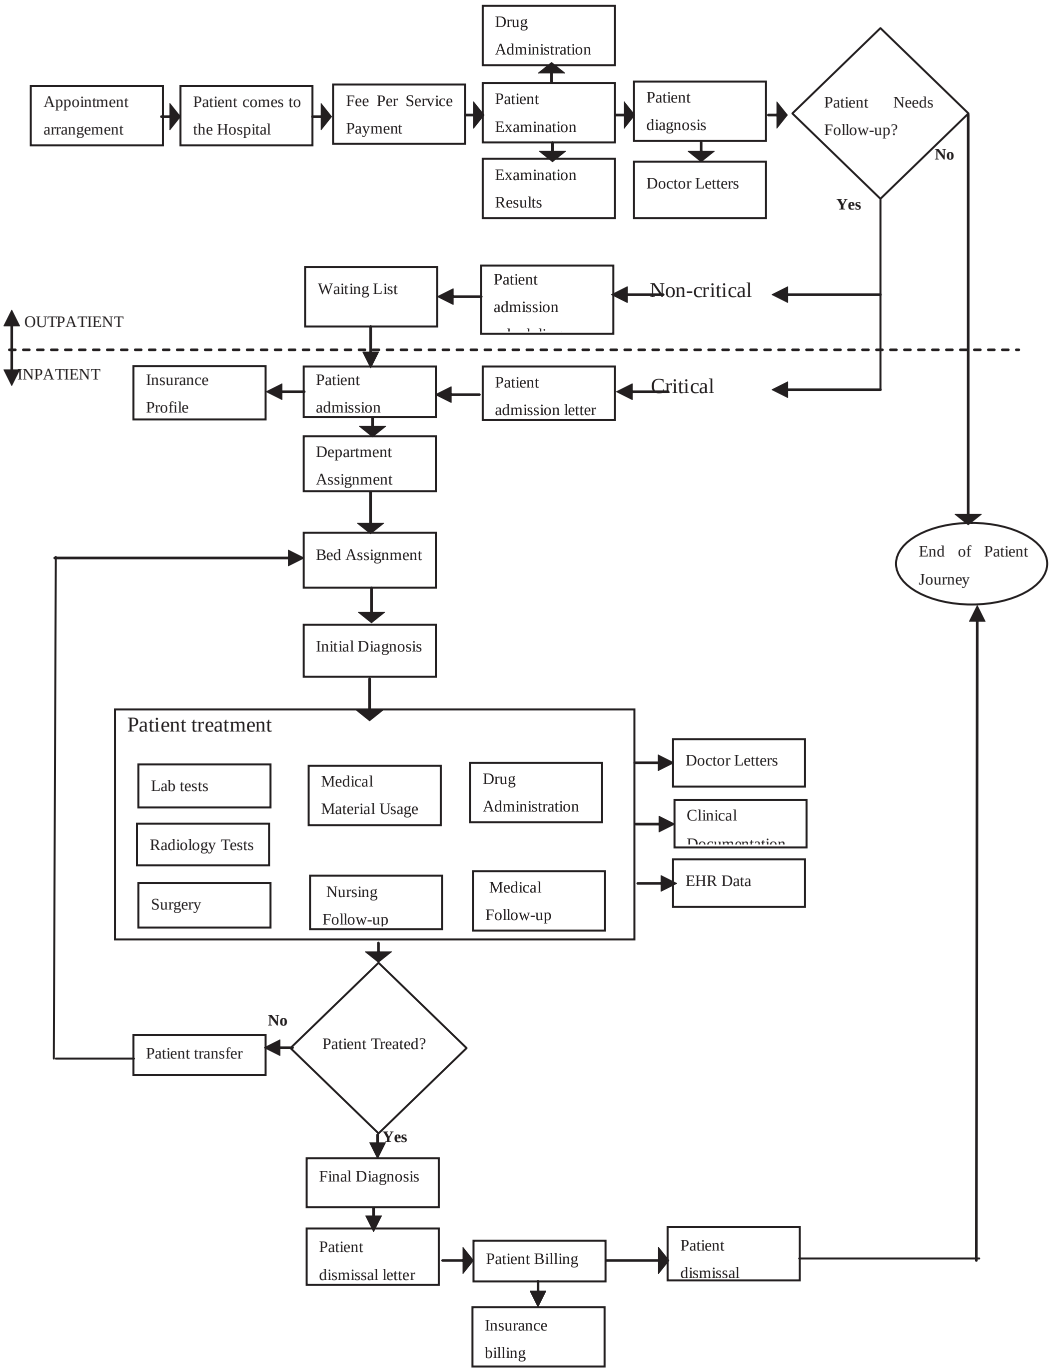
Furthermore in order to create a structure that can be monitored the KPIs should not be more that 10 for each perspective, while non financial metrics should overcome the financial metrics by approximately six to one (Schneiderman, 1999). In order to support any BSC framework, a deployment and maintenance system based upon quality assurance specially designed for Healthcare should be established. Traditionally in healthcare, Quality Assurance (QA) has been meant to apply predominantly to healthcare itself as provided directly to patients by legitimate healthcare practitioners. We also include other services that directly affect the ability of practitioners to perform well, meaning services such as radiology, pharmaceutical, laboratory, and patient admission. The basic quality assurance terms (Donabedian, 2003) are:

- Efficacy: the ability of the science and technology of healthcare to bring about improvements in health when used under the most favorable circumstances.
- Effectiveness: the degree to which attainable improvements in health are in fact attained.
- Efficiency: the ability to lower the cost of care without diminishing attainable improvements in health.
- Optimality: the balancing of improvements in health against the costs of such improvements.
- Acceptability: conformity to wishes, desires, and expectations of patients and their families.
- Legitimacy: Conformity to social preferences as expressed in ethical principles, values, norms, mores, laws, and regulations.
- Equity: Conformity to a principle that determines what is just and fair in the distribution of healthcare and its benefits among the members of the population.

One can clearly see the benefit of applying quality assurance components in the development of a BSC strategy. A BSC framework that meets quality assurance in healthcare is most probable that will meet patient needs, practitioners' feelings, patient-practitioner relationship, amenities of care (e.g., confidentiality, privacy, comfort, cleanliness, convenience), as well as financial and organizational aspects required.

The most popular quality assurance model in healthcare is based, to the best of our knowledge, upon the Donadebian approach (Donabedian, 1980, 1982, 1985, 1993, 2003) where a healthcare organization (i.e., a hospital) is a system formed by the interaction of structures, processes, and outcomes. Structures are used to establish processes in order to create healthcare outcomes that have an effect on structures that need to change or adjust processes to meet the required outcomes. Strongly believing that healthcare outcomes

Figure 2. The patient journey centered model for a hospital institution



are more important than financial outcomes in a healthcare system, we are confronted with a model where intangible assets are more important than tangible assets. This last statement makes a healthcare system very difficult to manage and a straightforward strategy hard to define.

The Need for a Specific Implementation Plan

In order to implement a viable performance management strategy (i.e., a BSC framework) the steps one needs to take include:

- Determining what to monitor
- Determining priorities in monitoring
- Selecting an approach to assessing performance
- Formulating criteria and standards (i.e., Key Performance Indicators)
- Obtaining the necessary information
- Determining how and when to monitor
- Constructing a monitoring system
- Managing changes and improvements

Building a Patient-Centered Healthcare Model

Finally, the proposed KPIs are directly or indirectly driven from healthcare processes. As an example, we propose to analyze a standard patient journey of a citizen in a healthcare institution. Figure 2 shows how the patient journey for a hospital is conceived (the patient journey in a primary care setting may be simpler). This workflow is the heart of the healthcare system and a prerequisite for any patient-centered information system to properly manage the information flow. This workflow is nowadays extended to include new processes such as emergency pre-hospital care and home care monitoring in order to create the hospital without walls of the 21st century.

Based on Figure 2 one can create a table where quality assurance and balanced scorecard features are confronted, analyzed, assessed and finally set. Table 1 is an example (non exhaustive) of the initial process.

From the above, it becomes apparent that the design and proposal of KPIs is not an easy task. KPI selection can vary upon specific measurement needs, upon goal set, and so on. In order to manage and validate the proposed KPIs by each BSC strategy, a set of KPI dashboards for each management entity, department or any other region of interest should be created.

USE CASE: REGIONAL HEALTHCARE AUTHORITIES IN GREECE

In 2001, a reform of the Greek National Healthcare System was introduced in order to enhance the performance and control of healthcare provision in Greece (Greek National Healthcare System Reform Act, 2001; Vagelatos & Sarivougioukas, 2003). One of the main changes was the division of the country in 17 autonomous healthcare regions where the Regional Healthcare Authority (RHA) is responsible for the regional healthcare strategy. This reform introduced the need to establish a three-level decision-making and performance management mechanism as described in Figure 3.

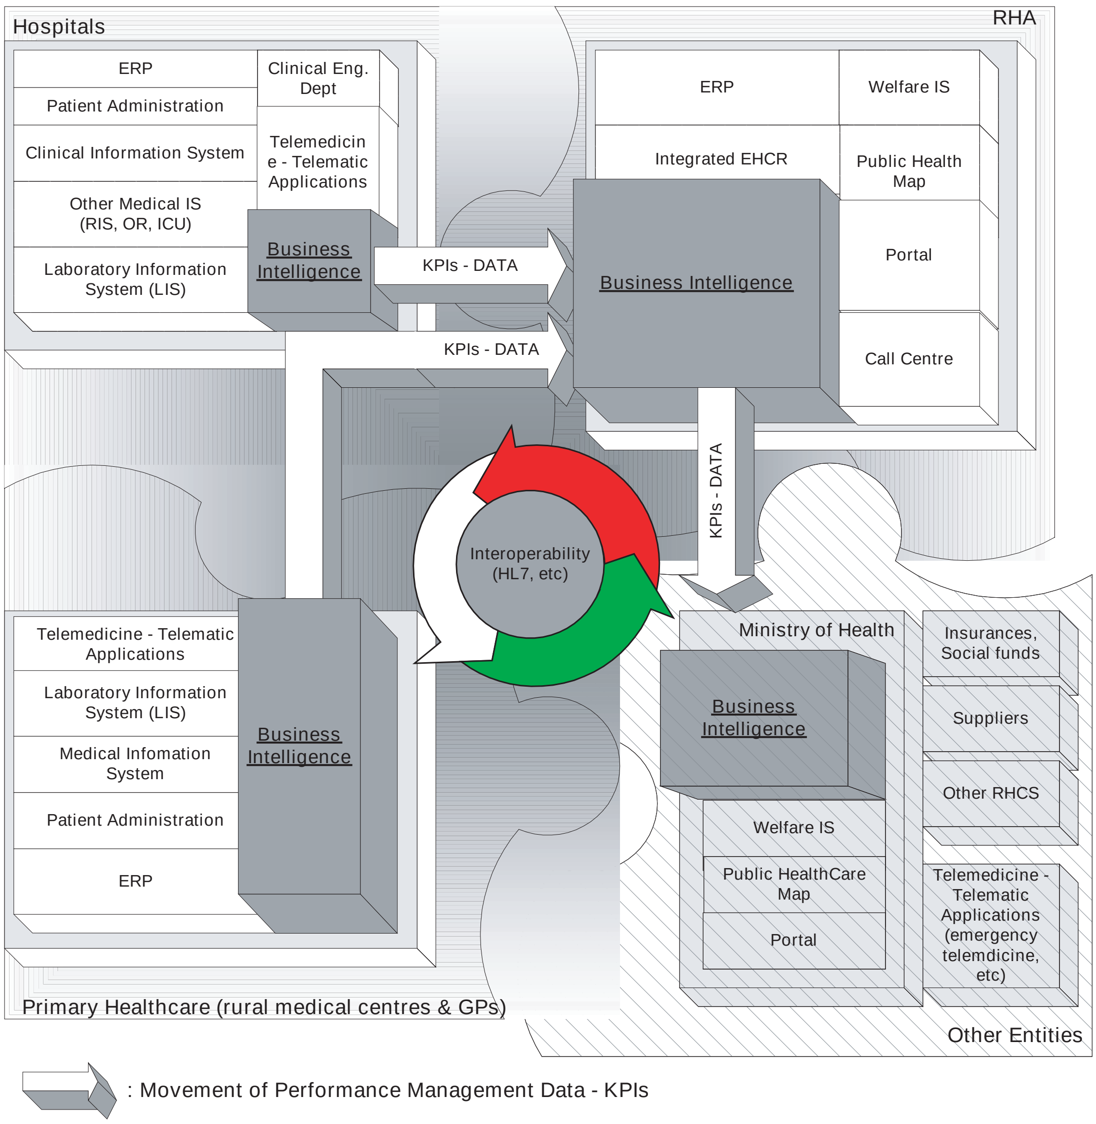
The proposed methodology was used to reach an initial set of KPIs by assessing existing knowledge and future needs (Decision No 1400/97/EC, 1997; McKee & Healy, 2002; Polyzos, 1999). Those KPIs were processed especially to serve the new strategy introduced in Greece.

As described in Figure 3, the regional healthcare system is comprised of a series of information systems covering the whole structures existing at any level, the processes required to meet the administrative and medical needs and finally, the outcomes that must come out from the implementation of such a complex interpolation of informatics infrastructure. The above information

Table 1. Defining KPIs from processes, an example

Workflow process	BSC Perspective	KPI	QA approach	Source of information
Appointment arrangement	Patient	Appointments/day	Process	Hospital Information System (HIS), Scheduling S/W
Patient comes to the Hospital	Process	Number of outpatients	Process	Hospital Information System
Fee Per Service Payment	Financial	Mean cost per examination	Process	Billing, ERP S/W
Drug Administration	Process	Number of prescription/ drug	Outcome	Patient Order Entry S/W, HIS
Patient Examination	Patient	Patient satisfaction	Process	HIS, surveys
Examination Results	Growth	Number of patient with re-examination	Outcome	HIS, Electronic Healthcare Record (EHR)
Doctor Letters	Process	Number examinations/practitioner	Outcome	HIS, Electronic Healthcare Record (EHR)
Patient diagnosis	Growth	Visits/ICD codes	Outcome	HIS, Electronic Healthcare Record (EHR)
Patient Needs Follow-up?	Process	Number of inpatient from outpatient clinic	Process	HIS
Waiting List	Patient	Waiting time in days	Structure	Hospital Information System (HIS), Scheduling S/W
Patient admission scheduling	Patient	Equity of delivered care	Process	Hospital Information System (HIS), Scheduling S/W
Patient admission letter	Process	Number of emergency cases/day	Process	HIS
Patient admission	Process	Number of inpatients	Process	HIS
Insurance Profile	Financial	Net cash flow per insurance company	Process	HIS, ERP
Department Assignment	Financial	Mean operational cost per department	Structure	HIS
Bed Assignment	Process	Bed coverage rate	Structure	HIS
Initial Diagnosis	Process	Admission per case type (ICD 10)	Outcome	HIS, Electronic Healthcare Record (EHR)
Lab tests	Process	Mean value of lab test per doctor, per patient	Outcome	Laboratory Information System (LIS)
Radiology Tests	Process	Mean value of radiology test per doctor, per patient	Outcome	Radiology Information System (RIS)
Surgery	Financial	Mean cost of surgical procedure	Structure	HIS, Electronic Healthcare Record (EHR)
Medical Material Usage	Financial	Mean cost of medical material consumption	Outcome	HIS, ERP
Nursing Follow-up	Growth	Number of Nurses per bed	Process	HIS, Electronic Healthcare Record (EHR)
Medical Follow-up	Growth	Number of practitioners per bed	Process	HIS, Electronic Healthcare Record (EHR)
Clinical Documentation	Process	Number of medical procedures per day	Outcome	HIS, Electronic Healthcare Record (EHR)
EHR Data	Patient	Number of cases with EHR	Outcome	HIS, Electronic Healthcare Record (EHR)
Patient transfer	Process	Number of patient transfers/ patient or /day	Process	HIS
Patient Treated?	Growth	Number of patients treated under a specific critical pathway	Process	HIS, Electronic Healthcare Record (EHR)
Final Diagnosis	Growth	Cases per final diagnosis	Outcome	HIS, Electronic Healthcare Record (EHR)
Patient dismissal letter	Patient	Inpatient Satisfaction	Process	HIS, surveys
Patient Billing	Financial	Mean treatment cost per day	Process	Billing, ERP S/W
Patient dismissal	Process	Mean length of stay /per dept. per ICD code	Process	HIS
Insurance billing	Financial	Return of Capital Employed (ROCE)	Process	Billing, ERP S/W

Figure 3. Regional healthcare information systems framework and interoperability



model was introduced to establish a community of networked healthcare organizations (hospitals, primary care) that are interoperating in order to support and implement the new healthcare strategy: to provide integrated and high quality healthcare services to the citizens based upon equal access to the resources (Information Society SA, 2003). In order to achieve this goal, two main issues were raised:

- How and when will information systems interoperate?

Table 2. KPIs in a regional healthcare setting

No	Financial KPI description	No	Process KPI description
F1	Mean treatment cost per day	P1	Length of stay
F2	Mean cost of medical treatment per patient	P2	Patient admission rate per medical unit
F3	Mean cost of drugs consumption	P3	Percentage of bed coverage
F4	Mean cost of radiology testing	P4	Vaccination rate
F5	Mean cost of laboratory testing	P5	Mean value of performed test per patient, per doctor
F6	Mean cost of material consumption	P6	Number of inpatients
F7	Mean cost of surgical procedure	P7	Number of outpatients
F8	Mean operational cost per dept./clinic	P8	Number of drug prescription
F9	Mean cost of vaccination procedures	P9	Number of laboratory tests
F10	Mean cost per medical examination	P10	Number of surgery procedures
F11	Return of capital employed (ROCE)	P11	Number of radiology tests
F12	Net Cash flow	P12	Number of visit in outpatient clinics
F13	Income per employee	P13	Number of visits in primary care institutions
F14	Payroll rate versus operational costs.	P14	Number of dental care processes
		P15	Number of processed emergency cases
		P16	Number of unprocessed order entries on the same day
		P17	Number of preventive care visits
		P18	Number of home care monitored patients
		P19	Assessment of patient satisfaction

No	Customer (patient) KPI description	No	Learning and Growth KPI description
C1	Mortality rate	L1	Medical device usage growth
C2	Morbidity rate	L2	Healthcare professionals training rate
C3	Number of medical staff per 1000 inhabitants	L3	Employee Satisfaction rate
C4	Number of beds per 1000 inhabitants	L4	Number of doctors per bed
C5	Accessibility of patients to the medical units	L5	Number of nurses per bed
C6	Time in a waiting list	L6	Number of existing healthcare professionals versus expected job positions
C7	Equity of delivered care	L7	Personnel productivity rate
C8	Number of readmission per patient	L8	Number of medical interventions per doctor
C9	Mean length of stay	L9	Number of patient with re-examinations
C10	Patient Satisfaction rate	L10	Visits/ICD codes
		L11	Admissions per case type (ICD 10)
		L12	Dismissals per case type (ICD 10)

- What is the minimum required dataset to achieve the proposed strategy?

The first issue can be answered by using standards and protocols such as HL7 to meet with interoperability issues in healthcare (Spyrou, Berler & Bamidis, 2003). The second issue is partially addressed by the proposed initial set of KPIs presented below. The proposed KPIs are forming a complete set of metrics that enable the performance management of a regional healthcare system. In addition, the performance framework established is technically applied by the use of state-of-the art knowledge management tools such as data warehouses and business intelligence information systems.

The proposed KPIs are categorised into the four perspective stated by Norton & Kaplan, having also taken into account the raised quality assurance issues stated earlier. The performance indicators in a regional healthcare setting are depicted in Table 2 as below.

Each of the above KPIs is the result of analysis based upon the needs of a standard regional healthcare authority. The proposition of a set of KPIs is nevertheless not the complete solution of the problem. Implementing KPIs is a constant process based upon specific metrics that each regional healthcare authority and each department or institution under its control must periodically assess and reengineer. Assessment should be based upon specific goals met and reengineering is often required due to administrative, demographic or other important changes that must occur. Focusing for example in the KPI marked as "mean treatment cost per day" one should notice that the KPI does not mean much without a metric. In Greece, most of inpatient treatments are based upon fixed prices per day and do not follow the pay per service model which is financially more viable.

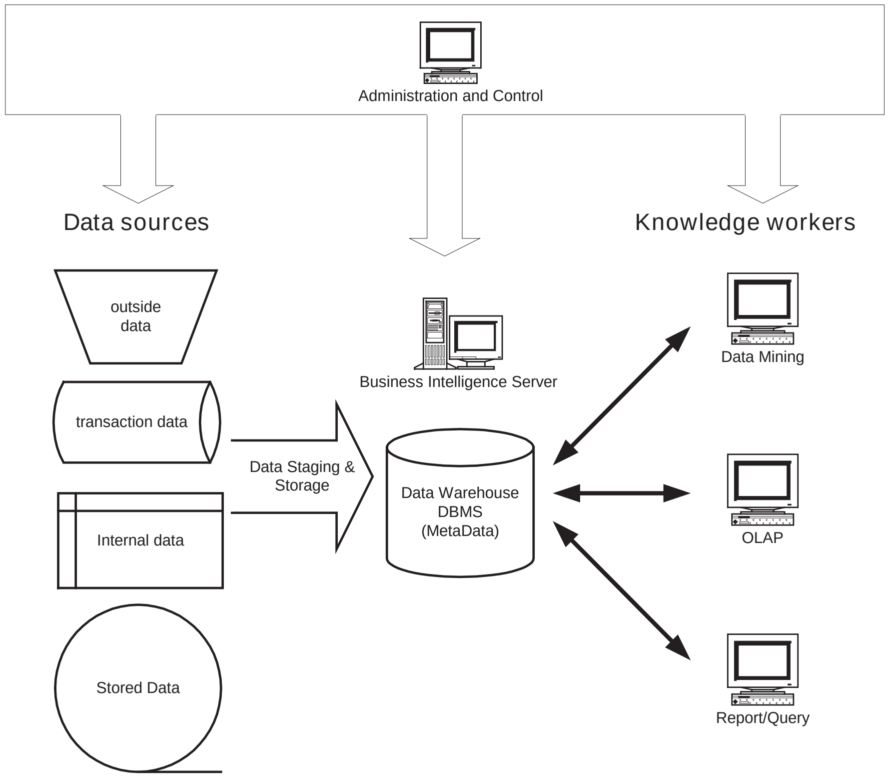
Healthcare financials are part of a national policy aiming at providing high quality healthcare services to all citizens regardless of their income, social status or other characteristic. As a consequence, the use of the fixed price model (per day quotas) in Greece serves that purpose albeit with its advantages and disadvantages. Current treatment cost per day (for an inpatient) has been fixed to about 135 Euros and this value could be used as an initial metric. If this value is exceeded this would mean that the RHA budget will cover the difference or transfer the cost to insurance companies and social welfare. In addition, a regional healthcare authority will then have credible proof that national standards are outdated and require revision in order to support the system. As a result, this KPI has now a specific meaning linked to regional strategy and budgetary needs. Following that example, all financial KPIs are therefore an important perspective of BSC since they are the measurement of the financial viability of the regional healthcare authority. In fact, all KPIs should be associated with adequate metrics in order to be assessed, thus driving the RHA towards the right strategic decisions.

In order to meet and populate the above-mentioned KPIs a regional healthcare authority has to implement a complex information technology system in order to gather up all needed information. Then the information collected through the use of enterprise resource planning software, hospital information systems, clinical information systems, radiology information system, and laboratory information systems has to be processed and interpolated to produce the final metadata set from which the KPIs are driven. In other words, the model is complemented by a business intelligence solution similar to the one depicted in Figure 4.

Figure 4 shows how data are collected from the various data sources, cleansed and homogenised, and finally redistributed to the knowledge workers and decision makers of the regional healthcare authority (Extraction, Transformation and Load—ETL).

The data collection process is extremely important since it is a basic feature of successfully populating the KPIs. In that sense both organizational

Figure 4. Regional healthcare authority business intelligence framework



and technological issues to achieve data quality should be considered. In the proposed setting, the regional healthcare authority has imposed on its healthcare units the use of specific classifications, codifications and taxonomies such as the 10th edition of the International Classification of diseases (ICD10). In addition, the proposed KPIs can be seen as attributes of structure, process or outcome (based upon the Donabedian approach) so that they can be used to draw an inference about quality. As such the KPIs are proposed, designed, tested and assessed by a panel of experts (executive officers of the RHA, practitioners). By implementing this organizational structure the quality level of the proposed KPIs is such that technological issues are greatly reduced.

FUTURE TRENDS

Up to this point, this chapter has mostly dealt with organizational and strategic features of knowledge management in healthcare. In the proposed use case we have shown an ongoing implementation of a Balanced Scorecard Framework in a regional healthcare authority environment. This has been done intentionally wishing to state that the technological part on such an implementation is probably the less important issue. If one regards the future trends in knowledge management, one can see that a multitude of new tools are already proposed for use. This chapter will briefly set the focus on the trends that to our knowledge are the most promising and present more opportunities to healthcare organizations in creating effective performance management facilities.

Service Oriented Architecture and Patient-Centered Architecture (Based on the Electronic Health Record)

The term of patient-centered architecture has been already in the literature for some years. Many techniques have been used in the past such as Corbamed (Object Management Group, 2001) and Distributed Healthcare environment (DHE). The introduction of web technologies such as the Extensible Markup Language (XML), the Simple Object Access Protocol (SOAP), the Web Services Description Language (WDSL), and more precisely the concept of Web Services (Deitel, Deitel, DuWaldt, & Trees, 2003; W3C, 2003) are driving information technologies towards a Service Oriented Architecture (SOA).

A service is a software component that is suitable for cross-application access. A service is never a complete application or transaction. It is always a building block. SOA is the architecture of an application that uses services. Services define reusable business functions; SOA binds services into applications. Logically, services are defined by their interfaces. Technically, services are defined by their implementations (sometimes complex integrated flows, other times a single simple program). SOA is a logical concept, and its design is focused on the definition of service interfaces and interactions between service interfaces. Fundamental to SOA is the loose coupling between its components. At the logical level, this translates to the ability to add a new service for the end-user unobtrusively to the service provider. At the technical level, this translates to the ability of software developers to deploy a new application that calls a service without the need to redeploy or change the service. The use of SOA will allow the creation of process-based components of applications that will manipulate knowledge and information based upon the processes and the required or designed outcomes.

The Semantic Web

The Semantic Web goes beyond the World Wide Web by encoding knowledge using a structured, logically connected representation, and by providing sets of inference rules that can be used to conduct automated reasoning. Whilst the idea of knowledge representation languages is not new, existing languages generally use their own set of ontologies and inference rules to identify and eliminate logical contradictions and inconsistencies. The Resource Description Framework—RDF (W3C, 2003) and XML Topic Maps (TopicMaps.Org, 2001) are the most promising tools towards the implementation of the Semantic Web in practice. Nevertheless, a long way towards maturity has still to be covered since issues such as specific metadata frameworks and data quality are not yet solved. In any case, the Semantic Web should enhance the promotion of clinical practice guidelines and evidence based medicine. They can be seen as taxonomies of medical cases that could be both used for performance monitoring (in respect to commonly agreed levels of delivered care) and decision support for the healthcare practitioners.

Critical Pathways

Critical Pathways (Wall & Proyect, 1998) are mechanisms for transforming a reactive bureaucratic ritual to a dynamic, indispensable, clinical improvement process. A critical pathway when established is a mechanism for:

- Integrating continuous quality improvements with traditional patients' care review
- Managing and impacting of clinical and financial outcomes for a specific treatment procedure
- Proactively addressing economic and regulatory changes
- Improving clinical outcomes through reduction in variation
- Controlling unnecessary cost and resource usage without jeopardising quality of care
- Fostering multi-disciplinary approach to patient care
- Linking quality management to staff education
- Managing limited financial resources
- Making efficient use of scarce organizational resources
- Increasing readiness for anticipated changed in healthcare
- Applying and using clinical practice guidelines and other taxonomies set up by different professional societies

Critical Pathways can be seen as "specialized" performance management tools that would provide a BSC framework with very specific performance indicators for each treatment or clinical process.

CONCLUSIONS

Performance management is a key issue in the continuous process of delivering high quality healthcare services. The use of KPIs has proved that the design of a Balance Scorecard acts as the "cockpit" of a regional (or national) healthcare authority where all metrics are the flight instruments enabling the provision of healthcare based upon equity, financial control, continuous process and structure refinement, and outcome measurements. In that sense, the proposed infrastructure is, technologically speaking, an important knowledge management tool that enables knowledge sharing amongst various healthcare stakeholders and between different healthcare groups. The use of BSC is an enabling framework towards a knowledge management strategy in healthcare since KM is about discovering knowledge from existing information, about creating new knowledge and about implementing processes and taxonomies that enable the reuse and assessment of information as part and bits of knowledge.

Knowledge can be seen as a performance management tool both for administrative purposes and clinical improvements.

During the implementation process of deploying a technological platform for performance management or any other type of knowledge management infrastructure, one must have in mind that:

- The six issues described in the introduction section must being taken into strong consideration from day one.
- It is important to focus on people, processes and outcomes, and to set-up a straightforward strategy to plan, manage, assess, educate, disseminate, and maintain the developed BSC framework.
- Any type of knowledge management project bases its success on continuous improvement and assessment. Metrics and processes are meant to change in order to reflect improvements towards quality of healthcare.
- The knowledge and technology is there, but still very limited best practices have been successfully implemented.
- The implementation of BSC framework is a time consuming process that has to involve all stakeholders' representatives.

Chapter 6.26
Operational Knowledge Management

Fons Wijnhoven
University of Twente, The Netherlands

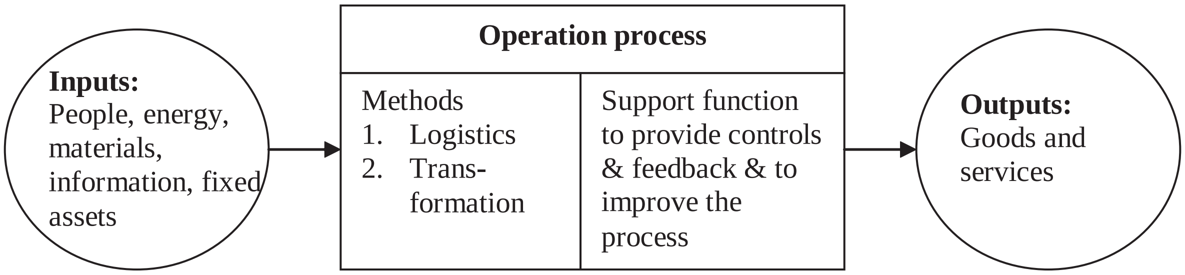
INTRODUCTION

The differences between the paradigms of knowledge management (KM) and operations management are huge. Whereas KM is rooted in the disciplines of human relations, sociology, organization analysis, and strategic management, the operations management paradigm finds its roots in industrial engineering, business economics, and information systems. These differences result in poor acceptance of KM ideas in operations management and vice versa. Several approaches to this problem are possible. For instance, one may state that the operations management paradigm is irrelevant for knowledge management. This is incorrect, because besides of the traditional person-oriented knowledge management processes, modern knowledge intensive firms use reengineered knowledge processes intensively (e.g., Hansen, Nohria, & Tierney, 1999). An alternative approach may be to forget about the KM paradigm and only use the operations management paradigm. This is wrong again, because most industrial enterprises compete on the development and exploitation of their expertise and human capabilities (Hamel & Prahalad, 1994; Quinn, 1992). Consequently, if knowledge management is relevant and if operations management is not irrelevant, then the main question is how to translate knowledge management issues into an operations management framework. I provide a conceptual framework for such a knowledge operations management (KOM) perspective.

BACKGROUND

Operations management studies the handling or transformation of inputs to outputs (the operations function), and the consequent realization of organizational goals via certain means (management of operations) (Hill, 1983). Operations management thus distinguishes objects, which are the inputs and outputs of operations, related support tasks,

Figure 1. The operations function (based on Hill, 1983, p. 25)



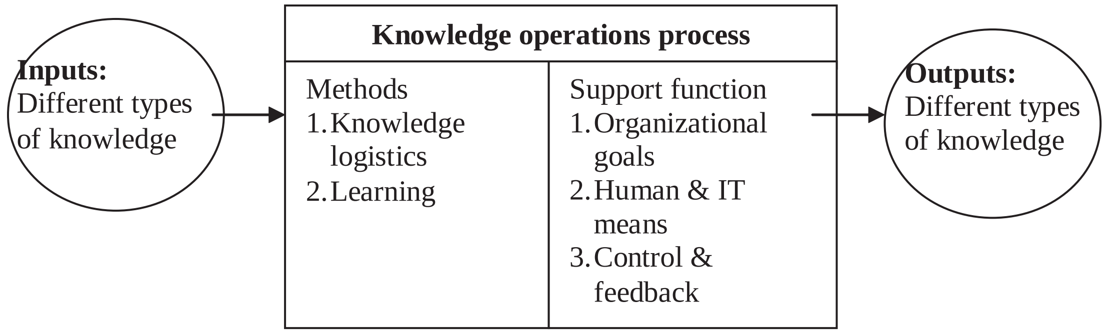
and the setting of goals and application of means. In the operations, I distinguish logistics as the delivery of the input to a client without changing this input (Ballou, 1992) from transformation as the change of the input object to something different (see Figure 1).

Given the wide paradigmatic differences between operations management and KM, not many attempts have been made to apply operations management on KM. One of the scarce attempts is from Armistead (1999), who distinguishes knowledge inputs and outputs and four related operations processes, that is,. two transformation processes (knowledge creation and knowledge embedding) and two knowledge logistics or transfer processes (exchange of knowledgeable people and the exchange of knowledge representations). The KM literature sees knowledge creation and embedding as related organizational learning processes (Nonaka, 1994), therefore, the term learning better covers what we mean by knowledge transformation. Finally, Armistead also defines metrics to control and feedback to improve these processes. This article continues the attempt made by Armistead with a further specification of a knowledge operations management model. Such a model does not only structure the KM field, but at the end of the article I also will explain some of its heuristic value.

MAIN FOCUS: THE KOM MODEL

In the context of KOM, the input-output objects are different types of knowledge. The input objects may be handled in operations without fundamentally changing them. This is what I call knowledge logistics and includes the storing and distributing of knowledge and its related representations. Alternatively, in learning processes, the knowledge inputs are transformed to new or different knowledge objects. The logistic process is an important support for learning, especially when done in organizations where learning is essentially a group process. Authors in the artificial intelligence discipline (e.g., Turban, Aronson, & Bolloju, 2001) have stated that besides people, machines also can learn. Although this is basically correct, the artificial intelligence field mainly regards learning at the behavioral and statistical level and not at the level of understanding and human skills formation, which is the focus of the KM literature. Thus, I exclude machine learning from KOM. In the knowledge operations management framework, the operation methods are supported by human and information technological means for specific goals, and metrics are used to control and deliver feedback on process performance as presented in Figure 2.

Figure 2. The KOM framework



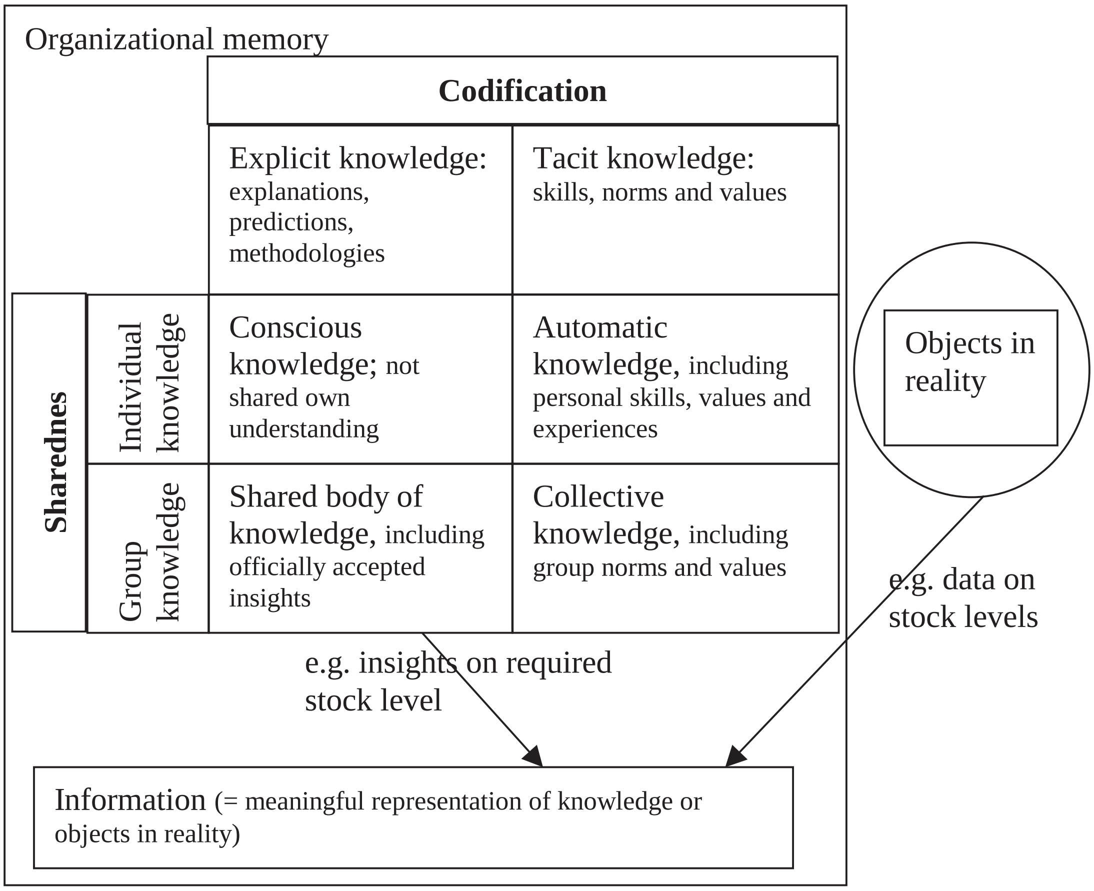
I first treat the input-output knowledge objects, then I discuss the knowledge operation methods. After that, a description of the support function, by a typology of possible organizational goals, means, and metrics for knowledge logistics and learning is given.

Knowledge Objects

Scientists often restrict the term knowledge for explicit understanding, which consists of explanations, predictions, and methodologies (Hempel, 1965). In information management, the term information is mostly reserved for representations of thoughts (e.g., explicit understandings), or the representation of objects and events, which may be stored or communicated (Stamper, 1973). Much of what popularly is called knowledge is neither an explicit understanding, nor a representation, but refers to effective behavior or skills (Spender, 1998). Especially in the arts and professions, people do not express (represent) how they do the job, and they also may not be successful in explaining their success. Thus, effective behavior is "what walks out the organization each day and hopefully returns the next morning" (Senge, 1990), and it is personally owned human capital. Some personal or individual knowledge consists of explicit knowledge that is not shared, while other individual knowledge consists of personal values. Much of a person's effectiveness, though, is based on individual knowledge and the social setting in which the work is done. More precisely, groups have norms and values, based on an underlying (sub)culture, that explain much of a group's effectiveness. For instance, decision-making norms and values that are well shared may speed up decision-making. These norms and values are often tacit knowledge (Leonard-Barton, 1992; Nonaka & Takeuchi, 1995). Their abilities of being shared require longer term and complex organizational change processes (Leonard-Barton, 1992).

The dimensions of sharedness (individual vs. group) and codification (explicitness vs. tacitness) make up four ideal types of knowledge (Spender, 1998; see Figure 3). Besides these types of knowledge, organizations use representations of knowledge to store, reuse, and distribute knowledge (Markus, 2001). Organizations also use representations of objects in reality as part of potential knowledge (Earl, 1994). Knowledge and information, which both form the content

Figure 3. Organizational memory, classes of knowledge, information, and objects in reality



aspects of an organizational memory, are both needed in effective decision-making (Stein & Zwass, 1995).

Knowledge Management Operation Methods

The KM literature often defines the following knowledge operation methods: knowledge generation, distribution and sharing, usage, maintenance, and storage (Alavi & Leidner, 2001; Stein & Zwass, 1995). Generation and maintenance are knowledge transformation processes (i.e., learning). The other knowledge operations are knowledge logistics. The next two subsections describe the activities of these operations in relation to the input-output objects.

Learning

Following Nonaka (1994), learning consists of interactions between tacit and explicit knowledge. The interaction of knowledge as input and output relations is given in Table 1.

Table 1. Learning modes and knowledge objects

Learning mode	**Knowledge object inputs**	**Knowledge object outputs**
Socialization	Individual norms and values	Collective knowledge
Externalization	Automatic and collective knowledge	Shared body of knowledge and related representations
Internalization	Shared body of knowledge	Automatic knowledge and accepted collective and shared body of knowledge
Combination	Conscious knowledge and individual owned information	Shared body of knowledge and information

Socialization transfers individual tacit knowledge to other people, such that these others adopt these tacit insights and collective knowledge is created. Externalization changes tacit knowledge to explicit knowledge, so that the knowledge becomes person-independent. Internalization is the reverse process of externalization and implies that the shared body of knowledge is personally accepted as automatic knowledge and integrated with existing individual norms and values. Finally, combination merges different kinds of individual conscious knowledge to a larger body of shared knowledge. When defining the support function later on, I will explain how goals, means, and metrics can be selected to improve these learning processes.

Knowledge Logistics

As I stated, knowledge logistics is about the sharing, distribution, storage, and retrieval of knowledge and its representations. The sharing and distribution of knowledge can be more or less formal and planned, and the sharing and distribution of information occurs in different reuse contexts. The storage and retrieval of knowledge and information is done by human and person-independent media (see Table 2).

Formality of Knowledge Logistics

Distribution of knowledge objects might vary from very formal and organized to ad hoc. Standard

Table 2. Characteristics of knowledge and information logistics

	Knowledge	**Information (representations)**
Logistic procedures	More or less formal	Different reuse contexts
Storage	Individual, group and cultural media	Ecology and information systems

reporting is most organized, by automatic dissemination of knowledge and information. This may be extremely efficient, though often insufficiently flexible. Less organized is a knowledge communication with a predefined procedure of starts and finish. Even less formalized is the case when a potential user can retrieve specific knowledge objects from a larger resource. For instance, this is the case of libraries, which use an information pull logistic model. Even more informal are research and development activities. However these might be planned, it is mostly unclear what answers they should deliver and the moment of delivery is often unpredictable. These research activities share an organization and the people involved are recognizable, which is not the case in ad hoc search. Ad hoc searching can be done actively (by action of individual's with specific knowledge needs) or passively (by knowledge provision). The message might contain information about knowledge or knowledge itself.

Knowledge Reuse Contexts

According to Markus (2001), knowledge reuse processes can be described in the stages of capturing or documenting knowledge, packaging knowledge for reuse, distributing or disseminating knowledge, and reusing knowledge. A fundamental point here is that after the documenting and packaging of knowledge, only the knowledge representations (and not the knowledge itself) is distributed and reused. Consequently, the receivers and reusers have to interpret the messages. Interpretation errors can easily happen if the distance between the knowledge producer and the knowledge representation user is large (Ackerman & Halverson, 2000). The context of reuse can vary in terms of the cognitive distance of knowledge producers and knowledge (representation) reusers, which supports Markus's (2001) classification of reuse contexts as (1) reuse by shared knowledge producers, (2) reuse by shared work practitioners, (3) reuse by expertise-seeking novices, and (4) reuse by secondary knowledge miners.

Storage and Media

Walsh and Ungson (1991) and Wijnhoven (1998) have listed a number of storage media and related knowledge types. Each medium has different potentials for the handling of different knowledge objects. Table 3 gives a list of the potentially best combinations.

The knowledge logistics can be subject to evaluation with the same criteria as any other

Table 3. Knowledge media and related knowledge objects

Knowledge media	Possible effective media for the following knowledge objects
Individual	Professional skills; personal ethics and beliefs; individual routines
Culture	Schemes; stories; external communications; cultural routines
Transformation	Tasks; experiences; rules, procedures and technology; patents
Structure	Task divisions; hierarchy; social structure; formal structure
Ecology	Layout of work place; building architecture
External	Client and market characteristics; list of knowledgeable people and organizations
Systems	Process control systems; GroupWare, computer aided design systems, knowledge based-systems; administrative systems

logistic process (Wijnhoven, 1998). I will describe these criteria in the next section.

The Support Function for Knowledge Logistics and Learning

This section first presents a typology of goals that the support function may have. Next, I describe some of the human and information technological means for the knowledge logistics and learning processes. Finally, I mention a few metrics for control and feedback of these processes.

Support Function and Organizational Goals

Operations knowledge management may contribute to several organizational goals. These organizational goals may be categorized as follows: (1) organizational integration, (2) adaptation, (3) goal attainment, and (4) pattern maintenance (Quinn & Rohrbaugh, 1984; Stein & Zwass, 1995). The integrative goal aims at multi-local and instantaneous access to shared knowledge and the sharing of knowledge over time and space. The adaptive goal aims at boundary-spanning activities to recognize, capture, organize, and distribute knowledge about the environment to the appropriate organizational actors. Goal attainment aims at assisting organizational actors in planning and control. The emphasis of the pattern maintenance goal is on human resources. "Pattern" pertains to attitudes, values, norms, personal routines, and personal knowledge. Effective organizations "maintain" values, attitudes, and norms that contribute to corporate cohesion and morale. Some of the requirements for the learning and logistic processes are listed in Table 4.

Support for Knowledge Logistic Processes

Knowledge logistics may be parsed into acquisition, retention, maintenance, search, and retrieval of knowledge objects. Knowledge acquisition is the gathering and placing of knowledge into

Table 4. KM objectives and KM process requirements

Organizational goal	**Requirements for KM process**
Integration	Knowledge logistics investments to realize temporal and spatial integration of knowledge resources, for instance by temporally indexed databases.
Adaptation	Investments in knowledge logistics and learning to realize the retention of cross-linked historical information on stakeholders, memory bases of user preferences, links to external sources of information (Stein & Zwass, 1995), and availability of software and people for interpretation of acquired data (Daft & Weick, 1986).
Goal attainment	Investments in learning through the development of templates of the context-plan-result nature, expert planning knowledge, evaluation models, company performance data, past and current performance forecasts (Stein & Zwass, 1995).
Pattern maintenance	At the individual level: knowledge logistic like the creation and dissemination of work history of individuals. At the organizational level: knowledge logistics and learning through the preservation and communication of organizational protocols (Stein & Zwass, 1995).

knowledge stores. This necessitates a knowledge directory giving a storage location for knowledge objects and an index with retrieval keys. The seven storage media mentioned before (individuals, culture, transformation, structure, ecology, external environment, and information systems) all differ on their opportunities and limitations for storing knowledge, as well as in speed, reliability, physical degeneration, and availability. Knowledge maintenance is the management of the integrity of retained knowledge. An inherent problem is the integration of new knowledge with existing knowledge, and applying an effective method of removing obsolete knowledge. Search is the process by which retained information is selected as relevant to particular problems or goals on the part of the user. Retrieval is the reconstruction of the selected information in order to satisfy the user's request. Sometimes the retrievable knowledge permits satisfactory formal definition and the knowledge management system is able to deliver standard reports with interpretations. Often, however, the retrieval demands are unpredictable and the required knowledge is difficult to describe. Consequently, much knowledge may best be kept tacit, which means that only the location of knowledge will be retrieved. Table 5 summarizes several human and IT means to realize the objectives of logistics.

Metric for Knowledge Logistics Control and Feedback

I propose distinguishing at least two classes of knowledge logistic metrics: (1) measures related to the logistic processes and (2) measures related to the customer satisfaction of the outcome of the logistic process. Armistead (1999) and Wijnhoven (1998) mention the following logistic process measures:

- Timeliness: This involves speed and compliance with agreed schedules.
- Reliability: This is the number of deliveries that are according the agreement.
- Completeness: This is the amount of information and knowledge delivered in relation to what is needed; thus, a delivery may be incomplete or over-complete.

Table 5. Knowledge logistic process and means

Knowledge logistics	**IT means**	**Human means**
Acquisition	Business intelligence system, Internet resources	Researchers, library collection service, data collection activities
Storage	Databases, library systems, data warehouses, document management systems	Archiving professionals, database administrators, indexing experts
Maintenance	Content management systems, databases	Content maintenance procedures and quality circles
Search & retrieval	Search engines, retrieval technology	Search and retrieval experts, social networks to find people, information service suppliers
Dissemination	Content publishing software, Internet facilities	Publication procedures, public relations policies, publishing expertise

- Accessibility: This is the ease of getting a knowledgeable person or entering a system that has the knowledge or information.
- Costs and efficiency: Cost is what people have to pay for the service. Efficiency is what costs and other efforts are involved as objects that should be measured to control and feedback the logistics processes.

Measures related to customer satisfaction have been studied intensively in the information systems literature under the heading of information systems end-user satisfaction. Doll and Torkzadeh (1988) have found five main constructs, which have been empirically replicated several times and are relevant for knowledge satisfaction as well:

- Content is the perceived level in which the information (and knowledge) precisely meets the receivers' needs and in which the information and knowledge is regarded as relevant and sufficient.
- Accuracy is the level in which people regard the information and knowledge as reliable and the level in which people feel they can depend on the information and knowledge.
- Format is the level in which people regard that the information and knowledge is well presented, clear, understandable, and, with respect to the information, has a good layout.
- Ease of use is about the user friendliness of the system and the ease of interactions with the knowledge owner.
- Up-to-dateness of the information and knowledge received. Doll and Torkazadeh (1988) use timeliness as the fifth factor, which includes delivery on time, but this is more a logistic feature and not an end-user satisfaction measure. Therefore, I propose up-to-dateness instead of timeliness here.

Support for Learning

The learning processes transform knowledge objects from rather explicit to rather tacit and reverse. These transformations are further analyzed here to define means for the learning support function.

- Socialization: The creation of new tacit knowledge from old tacit knowledge is highly inter-personal. Socialization requires a strong personal commitment of each of the participants and is obstructed from the negative attitude, which is often placed on the communication of uncertain and incomplete knowledge. Possible solutions for these knowledge-sharing obstructions are the creation of reward structures (Lawler & Rhodes, 1976), creation of synergy among knowledge owners (Quinn, 1992; Senge, 1990), and the development of an IT knowledge infrastructure.
- Externalization: The transformation of tacit knowledge to explicit knowledge—requires the coding of experiences, personal and group skills, norms, and values, and thus needs highly motivated experts to give away an important source of personal success. It also requires high communication skills of the system engineer in understanding experts from another discipline. Some methods for knowledge representation are (1) proposition and predicate logic, (2) production rules, (3) scripts, and (4) semantic nets. Besides the quality of the externalization, the importance of maintenance of the knowledge base is high. Particularly in complex knowledge bases, this is hard to realize.
- Combination: The putting together of pieces of explicit knowledge requires configuration or synthesis (Galunic & Rodan, 1998). Configuration puts together the owners

of different objects of explicit knowledge in workgroups, teams, or departments, or just letting each other know each other or refer to each other's knowledge objects (Liebeskind, Oliver, Zucker, & Brewer, 1996). Configuration also can be enabled by information technology, through the creation of Web links between different knowledge objects, the creation of Semantic Webs (Berners-Lee, Hendler, & Lassila, 2001) or ontologies (Borst, Akkermans, & Top, 1997), and the detection of patterns among data in data mining (Singh, 1998). Synthesis is the integration of different knowledge objects to one or more new knowledge objects.

Table 6. Learning processes and possible means

	Means	
	IT	*Human*
Learning processes		
Socialization		
Quickly find people with specific skills.	Skills database	Motivated individuals who submit content, but knowledge delivery pay is likely ineffective.
Development of mutual interests and collaboration among experts.	Communication infrastructure	Requires additional reward structure and reinforcements by management.
Externalization		
Machine processing of knowledge. Reduction of errors in routine processes.	Knowledge-based systems	Knowledge representation. This is difficult in unstable domains and experts sometimes are not willing to participate.
Standardization of work and decision-making.	Electronic manuals	Maintenance of knowledge is especially complex in larger domains.
Combination		
Combination of distributed and formalized knowledge.	Ontologies, Semantic Webs, Internet links	Complex, only applicable on static knowledge. Requires engineers who manage the complexity.
Brings together experts.	Communication infrastructure	May lead to insufficient commitments and poor goal achievement.
Analyzing databases to find explicit understanding.	Data mining and knowledge discovery	Human interpretation needed by adding tacit and explicit knowledge to the data patterns.
Explicit knowledge distribution in an organization.	Word-of-mouth emulator	May lead to poor utilization of insights gained. Need a knowledge coordinator.
Internalization		
Feedback on repertory of action and improves efficiency in routines	Computer aided instruction and decision support	The model needs validation and usability improvements, thus the role of the trainer is not obsolete.

- Internalization: The process by which externalized knowledge is merged with personal existing frames of reference assumes that knowledge is only truly adopted when it leads to changes of existing tacit knowledge (Senge, 1990). This will be manifested in changes of people's repertory of action.

Table 6 summarizes some human and IT means to realize the objectives of the learning processes. Though information technology (IT) is not a necessary component of KM means, in KOM information technology is often indispensable.

Metrics for Learning

Armistead (1999) gives a list of possible measures for learning (what he calls knowledge creation and knowledge embedding). These are presented here with a short explanation:

- Reliability of learning: This implies that we should know if the learning has been done well
- Completeness of learning
- Acceptability of learning: True knowledge needs (organizational) justification before it can be used (Nonaka, 1994)
- Readiness for learning: This is especially a problem when people lack sufficient knowledge to understand the new knowledge, or when people do not recognize the importance of the lessons gained
- Economics of learning: This is about the costs and expected economic benefits.
- Number of new ideas and patents
- Contribution on individual knowledge: It is not always clear how this benefits the organization, because it may raise the power and prestige of individuals and lower the access and control of the organization over this knowledge
- Organizational learning: This is a contribution to collective knowledge and the shared body of knowledge
- Knowledge productivity: This is the speed in which people are able to create new knowledge and the level to which they are able to embed this new knowledge in new products and business processes
- Evidence of best practices

FUTURE TRENDS

The KOM framework distinguishes knowledge objects, operations methods, and the aspect of the support function. Of course, all the distinctions and insights mentioned are more aiming at explaining the KOM framework than pretending that this would be the final word about KOM. I will discuss some of the challenges related to each topic.

In the KM literature, the differences in knowledge objects and their related representations is mentioned many times, but the consequences of these differences is seldom explicitly studied. This omission of the KM literature can be understood from KM research's emphasis on holistic insights instead of a study of a specific type of knowledge. The KOM model indicates the need to more seriously study the consequences of these differences for the development and management of related operations. Such an approach also helps to avoid misfits of knowledge and operation types. For instance, such research could help avoid an overreliance or underutilization of IT means for the management of specific types of knowledge.

I proposed four types of learning, based on Nonaka's work and knowledge input transformations. There is substantial evidence that these four explain most learning processes in and between organizations, though lack of space also prevented me from mentioning Argyris and Schön's (1978) classification of single loop and double loop learning (which emphasize the organizational adoption of innovations), and the different levels of abstraction (Bohn, 1994) that an organization can realize (e.g., changes from elementary observations to complex explanatory models). These different theoretical approaches require the definition of different inputs and outputs, and different operation methods.

I described knowledge logistics in terms of formality, reuse contexts, and storage and media. These are suggestions from the literature, but neither much descriptive nor explanatory research in these fields has been done at the moment.

With respect to the selection of means, goals, and metrics, I have been able to collect several examples, some better and some less based on empirical evidence, but also this can be studied further. The current KM movement seems more rooted in human relations, organization studies, economics, or computer science, which results in less priority for rigorous studies in the mentioned support function. The KOM framework more or less logically indicates the need for such studies. A research topic here could be the study of effective goal specification in KM. Also the tradeoff and balance of human vs. IT means may be a fruitful research topic. The development of KM metrics and their effective use for feedback in the KM context is another topic to study.

Finally, I want to note that the KOM framework is independent of the question if we study KM in an intraorganizational or interorganizational perspective. Though for KOM this probably is true, for the practical implementation of KOM, the context matters a lot. I believe much fruitful research can be done on comparing KOM in intraorganizational contexts (e.g., knowledge management in a department) and an interorganizational context (e.g., KM in interfirm codesign projects and KM by optimally using the Internet; cf. Schwartz, Divitini, & Brasethwik, 2000).

CONCLUSION

This article started from the idea to apply concepts from the operations management field to knowledge management. I gave an elaboration of a knowledge operations management framework (KOM). The framework states that KOM wants to operate on four types of knowledge objects and related representations (of knowledge and of objects in reality). These objects may be transformed by learning and handled without transformation to clients via knowledge logistics. The support function has to manage these knowledge operation methods by selecting specific organizational goals, selecting the best set of human and IT means, and applying metrics for control and feedback. These concepts may be used for the innovation and design of KM, and they (as the Future Trends sections demonstrated) are a fruitful heuristic model for further KM research.

Chapter 6.27
Knowledge Management in a Project Climate

Elayne Coakes
University of Westminster, UK

Anton Bradburn
University of Westminster, UK

Cathy Blake
Taylor Woodrow, UK

EXECUTIVE SUMMARY

This case study concerns the company Taylor Woodrow, which is a housing, property, and construction business operating internationally in situations where frontline operations are characterised by project management. Construction projects can sometimes carry substantial risk, and this case examines the role of knowledge management at Taylor Woodrow in minimising the probability of mischance by promoting best practice and lessons learned. The case shows how best practice can be developed through knowledge-sharing facilitated by networks of relationships. Some relationships are external — between the company, its partners, suppliers, and customers. Other relationships are internal — between frontline managers on construction sites and headquarters' staff. The case study indicates how knowledge is collated and distributed for the mutual benefit of all stakeholders.

BACKGROUND

The UK construction industry contributes about 10% of the UK's gross domestic product (GDP) and employed some 1.4 million people in 2001-2002 (DTI, 2002). Construction in the UK is a fragmented trade where there is constant pressure from clients for improvement and innovation in performance. Such is this pressure that the DTI

(Department of Trade and Industry, the Government body responsible in the UK) invested £16.5 million in 2002 on a programme of construction-related innovation and research to develop and disseminate information and knowledge.

Taylor Woodrow: General Company Background

Taylor Woodrow is an international housing and development company employing over 7,000 people worldwide. Its primary business is house building, which accounts for more than 95% of its operating profit. The company is the second largest UK-based house builder, delivering 10,000 new homes in the UK, along with around 3,800 new homes in North America, Spain, and Gibraltar each year. The company's UK house-building operation trades mainly under the Bryant Homes brand. In Canada, homes are marketed as Monarch, and in the United States and Spain, directly under the Taylor Woodrow brand.

In the UK, the company currently trades from a network of 11 regional offices, incorporating a central office based in the West Midlands and the construction headquarters in Watford. In addition to housing and commercial property developments, Taylor Woodrow also undertakes Private Finance Initiative (PFI) projects under the UK Government's Private Finance Initiative, mainly in healthcare. The company also undertakes facilities management and specialist engineering consultancy through Taylor Woodrow Construction. This unique skill base of integrated housing, property, and construction expertise ensures that Taylor Woodrow is particularly well equipped to tackle more complex developments, often on brownfield sites in high-profile city centre locations, and up to 30% of the company's construction activity is now in-house support to deliver large and mixed-use housing and commercial projects for the company.

Taylor Woodrow's core market is the UK with 71% of revenue in 2002 (http://uk.biz.yahoo.com/, 2003). The remainder of revenue comes from North America (25%), and the rest of the world (mainly Spain and Gibraltar) supplies the remaining 4%. In 2003, turnover was up 7% and profit before tax was up 20% on the previous year (Interim Results Statement, June 30, 2003, available on Web site).

According to the company's Web site (http://www.taylorwoodrow.com/), Taylor Woodrow's vision is to be "the leading developer of living and working environments in the UK and other chosen markets."

The company Web site also details full information about the company's

1. stated culture;
2. principles;
3. objectives;
4. responsibility (to shareholders, customers, people, those with whom they do business, and society);
5. business integrity;
6. health, safety, and environment;
7. community (they seek to be responsible corporate citizens);
8. political activities (they do not support political parties or policies in any form);
9. competition (they support free enterprise);
10. communication (open); and
11. corporate governance (detailing the directors, the board, and other committees, how internal control is carried out, investor relations, and corporate social responsibility policy).

SETTING THE STAGE

Knowledge management began in Taylor Woodrow in 2000 and centred on technical knowledge managed by a team based at the Technology Centre in Leighton Buzzard, UK. The remit of the knowledge manager at Taylor Woodrow was to manage knowledge on a groupwide basis. The main reason that knowledge management was introduced related to the board recognising that Taylor Woodrow needed a systematic process to better manage its substantial technical knowledge base. Hence improving the dissemination of best practice and lessons learned, thus reducing technical risks on its projects. So the knowledge management initiative was an approach to sharing technical excellence and best practice, and to demonstrate added value and business differential to their clients. It was able to demonstrate reduced costs and successful learning on projects to both new and existing clients, which helped maintain client relationships and encouraged repeat business. In 2001-2002 its main emphasis was on defect reduction and producing better buildings for clients, thus KM has been integrated into its construction project processes to add value from which both customers and shareholders benefit.

CASE DESCRIPTION

KM, according to Taylor Woodrow's KM manager "is primarily about people and how they behave and how they solve problems." In order to ensure the initiative is well supported, she felt that one needs to persuade the senior management initially as they are the real influencers of construction project outcomes. The KM process incorporates managers to reduce risks early in the construction process and consider the outcomes of actions, which were taken in previous projects. Enthusiasm for the initiative has come from board level and this is essential to gain support from operational (frontline) managers.

A number of forums have been set up in Taylor Woodrow for design managers, project managers, graduates, and commercial managers, which look at improving processes and sharing knowledge. It would seem that the most important motivator in Taylor Woodrow for participation in these forums and to undertake KM was not only kudos but being able to make improvements to the business. The forums were headed up by senior managers, and to be seen to be actively participating and encouraging improvements at the forums was good for professional development for some participants.

So far, the forums have primarily concentrated on sharing best practice and the Taylor Woodrow KM manager hopes that in the future more project managers will feel able to talk about projects where processes went wrong, how they have learned from the experience, and how they can do better next time. To start the process, Taylor Woodrow has begun to publish a Top Tips bulletin, which anonymises the projects and issues. This particular initiative is similar to a Government scheme, which is called Movement for Innovation, where best practice on construction projects will be captured and disseminated across the industry.

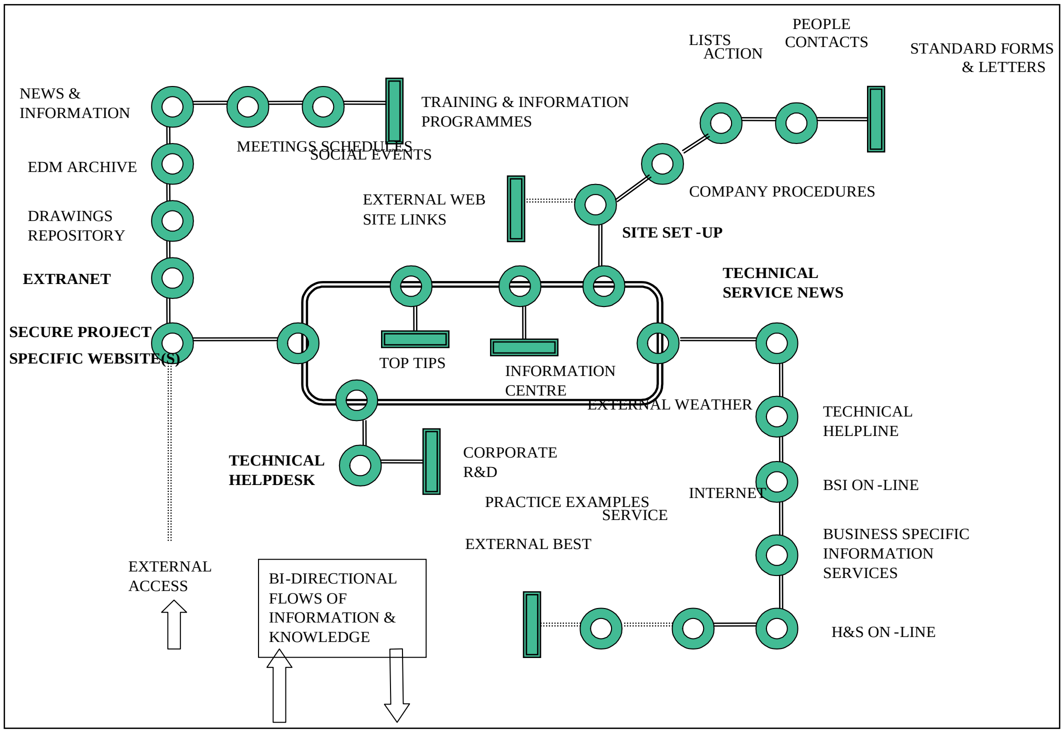
Whilst the KM manager sees herself as a facilitator within the company, Taylor Woodrow has developed and implemented an IT-enabled infostructure called Tayweb for the distribution of organizational knowledge. There are seven main areas that Tayweb supports. These are as follows:

1. One Company – company information;
2. News;
3. People – HR and training;
4. The Way We Work – processes;
5. Knowledge Share;
6. Central Services;
7. Office Zone – information on regional offices.

The Knowledge Share portal of Tayweb can usefully be modelled in terms of a subway metaphor as shown in Figure 1.

This subway operates continuously beneath Taylor Woodrow's business operations supporting the enterprise and its business strategies. In this activity, it is analogous to a computer program constantly running in the background behind other applications. The model, however,

Figure 1. Taylor Woodrow's IT-enabled KM system – Tayweb



only represents the KM system in a single plane, which belies its complexity as it functions in a multidimensional space having a form more like a bowl of spaghetti (Kolind, 1996). The company utilised an eight-step knowledge transfer model (O'Dell, Greyson, & Essaides, 1998) in order to inform the design of its KM system. This involved "focusing on creating, identifying, collecting and organizing best practices and internal knowledge, in order to understand what [organizations] know and where [the knowledge] is. The process must explicitly address sharing and understanding of those practices by motivated recipients. Finally, the process involves helping the recipients adapt and apply those practices to new situations, to create new 'knowledge' and put it into action" (O'Dell et al., 1998).

Tayweb is Taylor Woodrow's intranet, which carries users to any one of seven portals as detailed previously. Technical Service News is an electronic, interactive publication summarising the latest technical innovations, legislation, and best practice and is available in the Knowledge Share portal on Tayweb. This provides access to Taylor Woodrow's in-house technical helpline, to online British standards, construction information, online health and safety standards, and provides links to external Web sites for weather information and industry best-practice examples via the Internet. It is also e-mailed on a monthly basis to technical staff.

The Technical Help Desk (THD) is a facility through which the company's Technology Centre offers its specialist technical expertise. Frequent analyses of inquiries to the THD are used to generate Top Tips (technical guidelines), which demonstrate what lessons have been learnt and what innovations have been introduced, both of which constitute new organizational knowledge. In addition, the queries to the THD will also generate seminars and workshops for training purposes (note here that engineers and surveyors who are members of professional bodies such as the Institute of Building and Civil Engineering, or the Institute of Chartered Surveyors, are required by their professional bodies to do a certain number of continual professional development hours per year in order to maintain their qualification).

An important part of the tendering process for projects includes risk assessment and the KM system is a vital source of both technical and historical data that project managers need to access to discover what has been done in the past, and what are the current best practices. In addition, as the managers on construction project sites have laptops issued and the project managers for homes building operate from a regional office with computer access, they will also have access to these technical guidelines. Site general foreman tend not to have computers and so phone for information, their knowledge requirement is part of their social network — they need to know who to phone for help.

Site Setup is primarily an information portal and is an interactive guidance tool the purpose of which is to assist a project manager in setting up a new construction site. At this one-stop shop, project managers have links to external Web sites for other organizations such as the police service, the fire brigade, and the local authority. In addition to the company's own procedures, the site provides a checklist of actions required for sites being newly established as well as a yellow pages of people contacts. There is also a repository of standard forms and business stationery. The intranet also contains organizational structures, what the company's departments do, project profiles, and so forth.

Although Figure 1 shows only one portal through which a secure Web site can be accessed, there could be several. Taylor Woodrow establishes these extranets on a project-specific basis for blue-chip clients such as airports and supermarkets. These are vortals, collaborative project Web sites bounding virtual communities of practice, which are live for the duration of each contract. These vortals confer all the advantages of electronic document management repositories but with additional benefits deriving from Internet access. Each community member has available a directory of teams, a repository of drawings in two and three dimensions continually updated, a document archive including photographs of work in progress, news and information, schedules of meetings, programmes of induction and training, and even listings of social events.

Finally, Tayweb's Knowledge Share portal features a centralised interactive facility, which is available to Taylor Woodrow's entire workforce providing an extensive range of library information services. Here, there are online services such as British standards, health and safety information, and construction information. It also enables users to access a technical library and to order documents.

The perceived returns by Taylor Woodrow from its investment in KM are primarily in terms of the use of best practice and lessons learnt to improve the quality and reduce the defects of their product. In the construction industry, defects can be very costly both in monetary terms and client relationships. Thus KM in this company supports quality management. Measures are now in place for quantifying the return on investment for Taylor Woodrow's KM system and they are being developed to demonstrate added value in monetary terms. The benefits of qualitative outcomes and some assessments of cost savings are collated in Table 1.

CONCLUSIONS

Over the period we have been studying Taylor Woodrow, the organization has become more aware of the value KM has been able to add to

Table 1. Returns from knowledge management at Taylor Woodrow

	Technical News Service	**Technical Helpdesk**	**Top Tips**	**Site Set-Up News**	**Secure Project Web Sites**	**Infor-mation Centre**
Increased Efficiency Of Information Management	Reduction in time spent by senior managers searching for information			Project managers spend less time implementing site set-up procedures	Faster access to information and quicker response times	Offers Taylor Woodrow fast access to knowledge
Permanent Global Availability	24/7 access	24/7 access	24/7 access	24/7 access	Instant global access anytime	24/7 access
Administrative Cost Reduction	Reductions in paperwork	Reductions in paperwork	Reductions in paperwork	Reductions in paperwork	Reduces routine administration	Reductions in paperwork
Access & Response Time Reductions					Faster access to information and quicker response times	
Dissemination Leadtime Reduction	Proactively keeping managers informed of the latest innovations			More time available to concentrate on value added activities		
On-Site Productivity Improvement	Enabling managers to make better informed decisions			Project managers spend less time implementing site set-up procedures		
Savings - examples		1. Investigation of tar macadam defects saves £60,000; 2. Cavity wall ties save £14,000 in stone façade fixture; 3. Design life technology applied to a flat inverted roof saves client £10,800; 4. Re-designed stainless steel wind posts save £20,000.		More time available to concentrate on value added activities	Relatively inexpensive to establish	Enables Taylor Woodrow to work more efficiently

the organization. Increasingly, project staff and management have seen the benefits of communicating their innovations to others in the organization and lessons learnt are being captured in an increasingly systematic way. Taylor Woodrow is able to demonstrate conclusively to its clients that it is a learning organization. KM has a very high significance for the board, which provides specific funding for its development and dissemination.

DISCUSSION

Construction projects embody risk. The larger the project the higher the potential cost penalties. How can risk of this nature be mitigated? Obviously, insuring against risk is one course, but this generates additional costs, as a third party — an insurance company — requires compensation for assuming the construction company's risk. Another way of insuring against risk by reducing the probability of mischance is to leverage knowledge assets within the business.

How then to capture what individuals know and then to distribute this knowledge so that it can be shared throughout an organization? The willingness of individuals to articulate knowledge gained through involvement in work processes may depend on the organization's prevailing cultural paradigm. Some organizational cultures may be resistant to knowledge sharing — others may facilitate it. Sometimes knowledge transfer can be encouraged by incentivising staff in some way. Taylor Woodrow's approach seems to be driven primarily by the self-esteem generated from peer recognition. The company's culture seems to be receptive to KM and has enabled it to become embedded in the organizational fabric.

The importance of ICTs needs to be recognised, but these technologies are only enablers. They are not the key drivers. The critical driver in this instance may be seen as social capital, which comprises sets of relationships and networks underpinning knowledge sharing. Out of knowledge sharing comes learning, and learning at an organizational level delivers a range of business benefits in addition to ensuring that potentially costly errors are not repeated. Some of the Tayweb links signify the importance of these relationships in partnering and collaborations of various kinds not only through the intranet, but also through the various project-specific extranets.

Chapter 6.28
Assessing Knowledge Management Success

Murray E. Jennex
San Diego State University, USA

Lorne Olfman
Claremont Graduate University, USA

ABSTRACT

This article proposes a framework for assessing knowledge management system (KMS) success models. The framework uses three criteria: how well the model fits actual KMS success factors, the degree to which the model has a theoretical foundation, and if the model can be used for both types of KMSs. The framework is then applied to four KMS success models found in the literature and is determined to be a useful framework for assessing KMS success models.

INTRODUCTION

Knowledge management systems (KMSs) are systems designed to manage organizational knowledge. Alavi and Leidner (2001) clarify KMSs as IT-based systems developed to support/enhance the processes of knowledge creation, storage/retrieval, transfer, and application. Additionally a KMS supports knowledge management through the creation of network-based organizational memory (OM), and support for virtual project teams and organizations and communities of practice. A final goal of a KMS is to support knowledge/OM creation.

There are several taxonomies of KMSs from Zack's (1999) integrative and interactive KMS to KMS classified according to knowledge lifecycle (Alavi & Leidner, 2001), KM spectrum (Hahn & Subramani, 2000), KM architecture (Borghoff & Pareschi, 1998), and so forth. However, this article classifies KMS by the context captured and the users targeted, resulting in two approaches to building a KMS—the process/task approach and the infrastructure/generic approach. The process/task approach focuses on the use of knowledge/OM by participants in a process, task, or project in order to improve the effectiveness of that process, task, or project. This approach identifies the information and knowledge needs of the process, where they are located, and who needs them. This approach requires the KMS to capture minimal context because users are assumed to understand the milieu of the knowledge that is captured and used.

The infrastructure/generic approach focuses on building a system to capture and distribute knowledge/OM for use throughout the organization. Concern is with capturing context to explain the captured knowledge and the technical details needed to provide good mnemonic functions associated with the identification, retrieval, and use of knowledge/OM. The approach focuses on network capacity, database structure and organization, and knowledge/information classification.

Both approaches may be used to create a complete KMS. The process/task approach supports specific work activities, while the infrastructure/generic approach integrates organizational knowledge into a single system that can be leveraged over the total organization instead of just a process or project. Morrison and Weiser (1996) support the dual approach concept by suggesting that an organization-wide KMS be designed to combine an organization's various task/process-based KMSs into a single environment and integrated system.

Once a KMS is implemented, whichever type it is, its success or effectiveness needs to be determined. Turban and Aronson (2001) list three reasons for measuring the success of a knowledge management system:

- To provide a basis for company valuation
- To stimulate management to focus on what is important
- To justify investments in KM activities

All are good reasons from an organizational perspective. Additionally, from the perspective of KM academics and practitioners, the measurement of KMS effectiveness or success is crucial to understanding how these systems should be built and implemented.

To meet this need, several KMS success/effectiveness models have been proposed. It is the purpose of this article to propose a framework for assessing the usefulness of these models. To do this the article describes an evaluation model based on comparing the KMS success model to KMS success factors, determining the degree to which the model has a theoretical foundation, and determining if the model can be applied to both approaches to building a KMS.

The article will first define the assessment framework. Then four KM/KMS success/effectiveness models will be described, followed by an analysis with respect to how well the models match the assessment framework and a conclusion on the usefulness of the framework. KM/KMS success/effectiveness will not be defined, because we found that each model defines success/effectiveness as part of the model.

METHODOLOGY

The proposed assessment framework consists of three main questions: how well the KMS success model meets KM/KMS success criteria, the degree of the model's theoretical foundation, and if it can be applied to both approaches to building a KMS. Stinchcombe (1968) suggests testing theories by determining how well they reflect observed data and that the more observations that can be compared, the better. The proposed framework does this by comparing the KMS success models to a set of KMS success criteria. The set of KMS success criteria was determined through a literature survey. Several studies were found that reported issues affecting the success of a KMS. The studies used in this article utilize a variety of methods, including surveys, case studies, Delphi studies, and experimentation. A total of 78 projects or organizations were investigated using case studies. Three surveys were administered, and one Delphi study and experiment were performed.

The second criterion is the theoretical foundation of the KMS success model. This criteria is based on being able to generalize the model. It is proposed that a model that is based on accepted theory or other widely supported models will be more generalizable. The theoretical foundation is determined by reviewing the publication the model is presented in. A judgment is made as to the appropriateness of the theoretical foundation.

The third criterion is for the KMS success model to be applicable to both KMS approaches. This criterion is determined by judging the focus of the model to determine if it is specific to either the task/process approach or the generic/infrastructure approach.

KM/KMS SUCCESS FACTORS

A successful KMS should perform the functions of knowledge creation, storage/retrieval, transfer, and application well. However, other factors can influence KMS success. This section creates a KMS success factor framework by reviewing research related to identifying KMS success factors. Additionally, findings from studies looking at knowledge management and organizational memory success are also included. KM is included using a Churchman (1979) view of a KMS which can be defined to include the KM initiative driving the implementation of a KMS (also the counter view is valid, as looking at KM can also include looking at the KMS). OM is included, as Jennex and Olfman (2002) found that KM and OM are essentially the same with the difference being the players. End-users tend to do KM where KM is concerned with the identification and capture of key knowledge. Information systems (IS) personnel tend to be concerned with OM where OM is the storage, search, retrieval, manipulation, and presentation of knowledge. KMS and OMS are the systems built to support KM and OM, and are essentially systems designed to manage organizational knowledge. As stated previously, Alavi and Leidner (2001) clarify KMS as IT-based systems developed to support/enhance the processes of knowledge creation, storage/retrieval, transfer, and application. Additionally a KMS supports knowledge management through the creation of network-based organizational memory, and support for virtual project teams and organizations and communities of practice. A final goal of a KMS is to support knowledge/OM creation. Stein and Zwass (1995) define OMS as the processes and IT components necessary to capture, store, and bring to bear knowledge created in the past on decisions currently being made. Jennex and Olfman (2002), using these definitions of KMS and OMS, along with a Churchman (1979) view of systems, combined the KMS and OMS into a single system.

A success factor framework is constructed by reviewing the literature by author. This is done so that the context resulting in the generation of the success factor can be presented. The identified success factors are then analyzed for similar concepts and combined into composite success factors. The composite success factors are ranked based on the number of authors mentioning the factor. This is problematic, but is done as it implies greater consensus on the existence of the success factor; that is, the more often a success factor is mentioned, the greater the consensus that it is a success factor and the greater the likelihood it is important. Table 1, presented at the end of this discussion, provides the ranked list of composite success factors.

Mandviwalla, Eulgem, Mould, and Rao (1998) summarized the state of the research and described several strategy issues affecting the design of a KMS. These include the focus of the KMS (who are the users), the quantity of knowledge to be captured and in what formats, who filters what is captured, and what reliance and/or limitations are placed on the use of individual memories. Additional technical issues affecting KMS design include knowledge storage/repository considerations, how information and knowledge is organized so that it can be searched and linked to appropriate events and use, and processes for integrating the various repositories, and for reintegrating information and knowledge extracted from specific events. Some management issues include how long the knowledge is useful, access locations as users rarely access the KMS from a single location (leads to network needs and security concerns), and the work activities and processes that utilize the KMS.

Ackerman (1994) studied six organizations that had implemented his Answer Garden system. Answer Garden is a system designed to grow organizational memory in the context of help-desk situations. Only one organization had a successful implementation because expectations of the capabilities of the system exceeded the actual capabilities. Ackerman and Mandel (1996) found that a smaller task-based system was more effective on the sub-organization level because of its narrower expectations. They refer to this narrower system as "memory in the small."

Jennex and Olfman (2000) studied three KM projects to identify design recommendations for building a successful KMS. These recommendations include:

- Develop a good technical infrastructure by using a common network structure, adding KM skills to the technology support skill set, using high-end PCs; integrated databases; and standardizing hardware and software across the organization.
- Incorporate the KMS into everyday processes and IS by automating knowledge capture.
- Have an enterprise-wide knowledge structure.
- Have Senior Management support.
- Allocate maintenance resources for OMS.
- Train users on use and content of the OMS.
- Create and implement a KM strategy/process for identifying/maintaining the knowledge base.
- Expand system models/life cycles to include the KMS, and assess system/process changes for impact on the KMS.
- Design security into the KMS.
- Build motivation and commitment by incorporating KMS usage into personnel evaluation processes, implementing KMS use/satisfaction metrics, and identifying organizational culture concerns that could inhibit KMS usage.

Additionally, Jennex and Olfman (2002) performed a longitudinal study of KM on one of these organizations and found that new members of an organization do not use the computerized KMS due to a lack of context for understanding the knowledge and the KMS. They found that these users needed pointers to knowledge more than codified knowledge.

Jennex, Olfman, and Addo (2003) investigated the need for having an organizational KM strategy to ensure that knowledge benefits gained from projects are captured for use in the organization by surveying Year 2000 (Y2K) project leaders. They found that benefits from Y2K projects were not being captured because the parent organizations did not have a KM strategy/process. Their conclusion was that KM in projects can exist and can assist projects in utilizing knowledge during the project.

Davenport, DeLong, and Beers (1998) studied 31 projects in 24 companies. Eighteen projects were determined to be successful, five were considered failures, and eight were too new to be rated. Eight factors were identified that were common in successful KM projects. These factors are:

- Senior management support
- Clearly communicated KMS purpose/goals
- Linkages to economic performance
- Multiple channels for knowledge transfer
- Motivational incentives for KM users
- A knowledge-friendly culture
- A solid technical and organizational infrastructure
- A standard, flexible knowledge structure

Malhotra and Galletta (2003) identified the critical importance of user commitment and motivation through a survey study of users of a KMS being implemented in a health care organization. They found that using incentives did not guarantee a successful KMS. They created an instrument for measuring user commitment and motivation that is similar to Thompson, Higgins, and Howell's (1991) Perceived Benefit model, but based on self-determination theory that uses the Perceived Locus of Causality.

Ginsberg and Kambil (1999) explored issues in the design and implementation of an effective KMS by building a KMS based on issues identified in the literature and then experimentally implementing the KMS in a field setting. They found knowledge representation, storage, search, retrieval, visualization, and quality control to be key technical issues, and incentives to share and use knowledge to be the key organizational issues.

Alavi and Leidner (1999) surveyed executive participants in an executive development program with respect to what was needed for a successful KMS. They found organizational and cultural issues, associated with user motivation to share and use knowledge, to be the most significant. They also found it important to measure the benefits of the KMS, and to have an integrated and integrative technology architecture that supports database, communication, and search and retrieval functions.

Holsapple and Joshi (2000) investigated factors that influenced the management of knowledge in organizations through the use of a Delphi panel consisting of 31 recognized KM researchers and practitioners. They found leadership and top management commitment/support to be crucial. Resource influences such as having sufficient financial support, skill level of employees, and identified knowledge sources are also important.

Koskinen (2001) investigated tacit knowledge as a promoter of success in technology firms by studying 10 small technology firms. Key to the success of a KMS was the ability to identify, capture, and transfer critical tacit knowledge. A significant finding was that new members take a long time to learn critical tacit knowledge and a good KMS facilitates the transference of this tacit knowledge to new members.

Barna (2003) studied six KM projects with various levels of success (three were successful, two failed, and one was an initial failure turned into a success) and identified two groups of factors important to a successful KMS. The main managerial success factor is creating and promoting a culture of knowledge sharing within the organization by articulating a corporate KM vision, rewarding employees for knowledge sharing, creating communities of practice, and creating a "best practices" repository. Other managerial success factors include obtaining senior management support, creating a learning organization, providing KMS training, and precisely defining KMS project objectives

Design/construction success factors include approaching the problem as an organizational problem and not a technical one; creating a standard knowledge submission process; developing methodologies and processes for the codification, documentation, and storage of knowledge; developing processes for capturing and converting individual tacit knowledge into organizational knowledge, and creating relevant and easily accessible knowledge-sharing databases and knowledge maps.

Cross and Baird (2000) proposed that KM would not improve business performance simply by using technology to capture and share the lessons of experience. It was postulated that for KM to improve business performance, it had to increase organizational learning through the creation of organizational memory. To investigate this, 22 projects were examined. The conclusion was that improving organizational learning improved the likelihood of KM success. Factors that improved organizational learning include:

Table 1. KMS success factor summary

ID	Success Factor	Source
SF1	Integrated Technical Infrastructure including networks, databases/repositories, computers, software, KMS experts	Alavi and Leidner (1999), Barna (2002), Cross and Baird (2000), Davenport, et al. (1998), Ginsberg and Kambil (1999), Jennex and Olfman (2000), Mandviwalla, et al. (1998), Sage and Rouse (1999), Yu, et al. (2004)
SF2	A Knowledge Strategy that identifies users, sources, processes, storage strategy, knowledge and links to knowledge for the KMS.	Barna (2002), Ginsberg and Kambil (1999), Holsapple and Joshi (2000), Jennex, Olfman, and Addo (2003), Koskinen (2001), Mandviwalla, et al. (1998), Sage and Rouse (1999), Yu, et al. (2004)
SF3	A common enterprise wide knowledge structure that is clearly articulated and easily understood	Barna (2002), Cross and Baird (2000), Davenport, et al. (1998), Ginsberg and Kambil (1999), Jennex and Olfman (2000), Mandviwalla, et al. (1998), Sage and Rouse (1999)
SF4	Motivation and Commitment of users including incentives and training	Alavi and Leidner (1999), Barna (2002), Cross and Baird (2000), Davenport, et al. (1998), Ginsberg and Kambil (1999), Jennex and Olfman (2000), Malhotra and Galletta (2003), Yu, et al. (2004)
SF5	An organizational culture that supports learning and the sharing and use of knowledge	Alavi and Leidner (1999), Barna (2002), Davenport, et al. (1998), Jennex and Olfman (2000), Sage and Rouse (1999), Yu, et al. (2004)
SF6	Senior Management support including allocation of resources, leadership, and providing training	Barna (2002), Davenport, et al. (1998), Holsapple and Joshi (2000), Jennex and Olfman (2000), Yu, et al. (2004)
SF7	Measures are established to assess the impacts of the KMS and the use of knowledge as well as verifying that the right knowledge is being captured	Alavi and Leidner (1999), Davenport, et al. (1998), Jennex and Olfman (2000), Sage and Rouse (1999)
SF8	There is a clear goal and purpose for the KMS	Ackerman (1994), Barna (2002), Davenport, et al. (1998), Cross and Baird (2000)
SF9	Learning Organization	Barna (2002), Cross and Baird (2000), Sage and Rouse (1999), Yu, et al. (2004)
SF10	The search, retrieval, and visualization functions of the KMS support easy knowledge use	Alavi and Leidner (1999), Ginsberg and Kambil (1999), Mandviwalla, et al. (1998)
SF11	Work processes are designed that incorporate knowledge capture and use	Barna (2002), Cross and Baird (2000), Jennex and Olfman (2000)
SF12	Security/protection of knowledge	Jennex and Olfman (2000), Sage and Rouse (1999)

- Supporting personal relationships between experts and knowledge users
- Providing incentives to motivate users to learn from experience and to use the KMS
- Providing distributed databases to store knowledge and pointers to knowledge
- Providing work processes for users to convert personal experience into organizational learning
- Providing direction to what knowledge the organization needs to capture and learn from

Sage and Rouse (1999) reflected on the history of innovation and technology, and identified the following issues:

- Modeling processes to identify knowledge needs and sources
- Using a KMS strategy for the identification of knowledge to capture and use, as well as who will use it
- Providing incentives and motivation to use the KMS
- Developing an infrastructure for capturing, searching, retrieving, and displaying knowledge
- Displaying an understood enterprise knowledge structure
- Defining clear goals for the KMS
- Measuring and evaluating the effectiveness of the KMS

Yu, Kim, and Kim (2004) explored the linkage of organizational culture to knowledge management success. They found that KM drivers such as a learning culture, knowledge sharing intention, KMS quality, rewards, and KM team activity significantly affected KM performance. These conclusions were reached through a survey of 66 Korean firms.

These studies provide several success factors. As previously discussed, to analyze the factors they have been reviewed and paraphrased into a set of ranked composite success factors where the ranking is based on the number of sources citing them. Table 1 lists the final set of success factors in their rank order. Additionally, success factors SF1 through SF4 are considered the key success factors, as they were mentioned by at least half of the success factor studies.

KNOWLEDGE MANAGEMENT SUCCESS MODELS

Bots and de Bruijn: Knowledge Value Chain

Bots and de Bruijn (2002) assessed KM and determined that the best way to judge good KM was through a knowledge value chain. In this evaluation process KM is assessed for effectiveness at each step of the knowledge process and is good if each of the indicated activities is performed well, with the ultimate factor being if the KMS enhances competitiveness. Figure 1 illustrates the KM value chain. The model was developed by viewing and contrasting KM through an analytical (technical) perspective and an actor (user) perspective. These perspectives are conflicting, and KM assessment occurs by determining how well the KMS meets each perspective at each step.

Massey, Montoya-Weiss, and Driscoll KM Success Model

Massey, Montoya-Weiss, and O'Driscoll (2002) present a process-based KM success model derived from their Nortel case study. The case study suggested that KM cannot be applied generically and that a process approach to KM will help an organization to understand how it can apply KM to

Figure 1. Bots and de Bruijn (2002) KM value chain

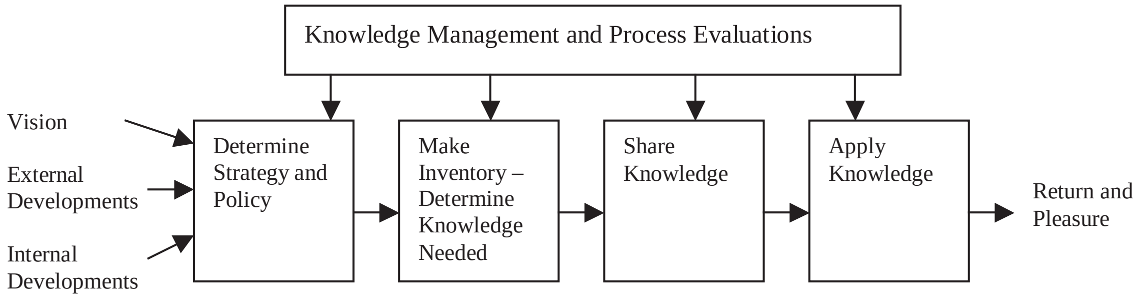

Figure 2. Massey, Montoya-Weiss, and Driscoll (2002) KM success model

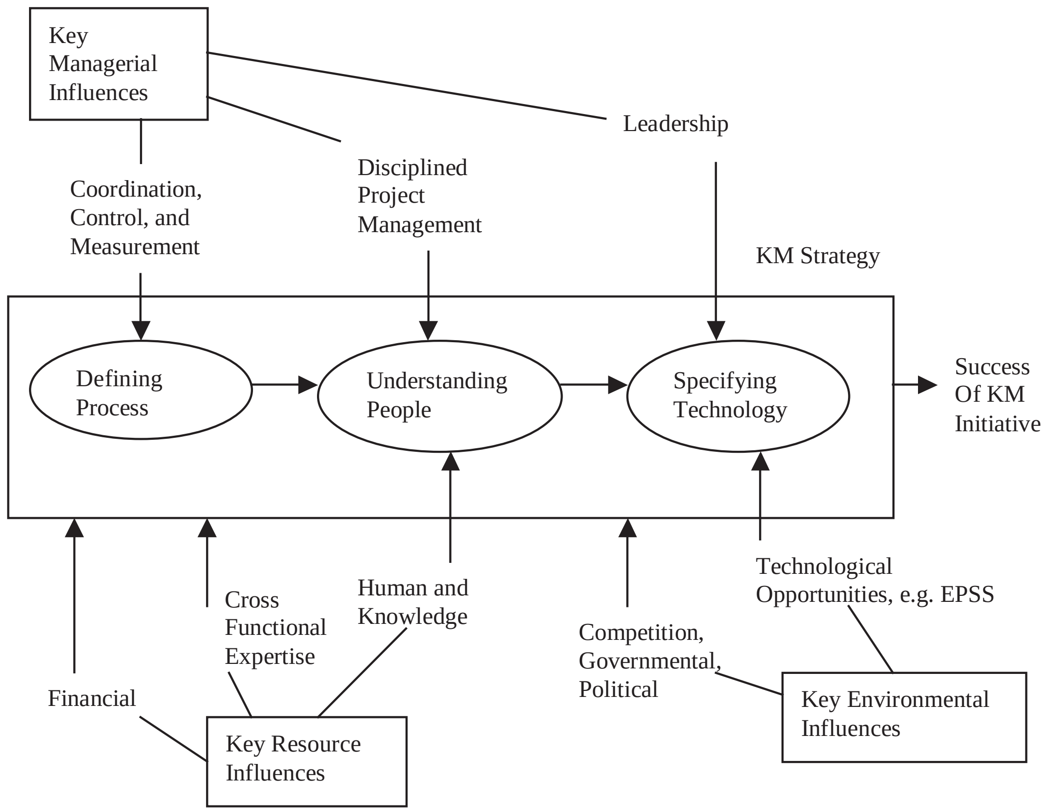
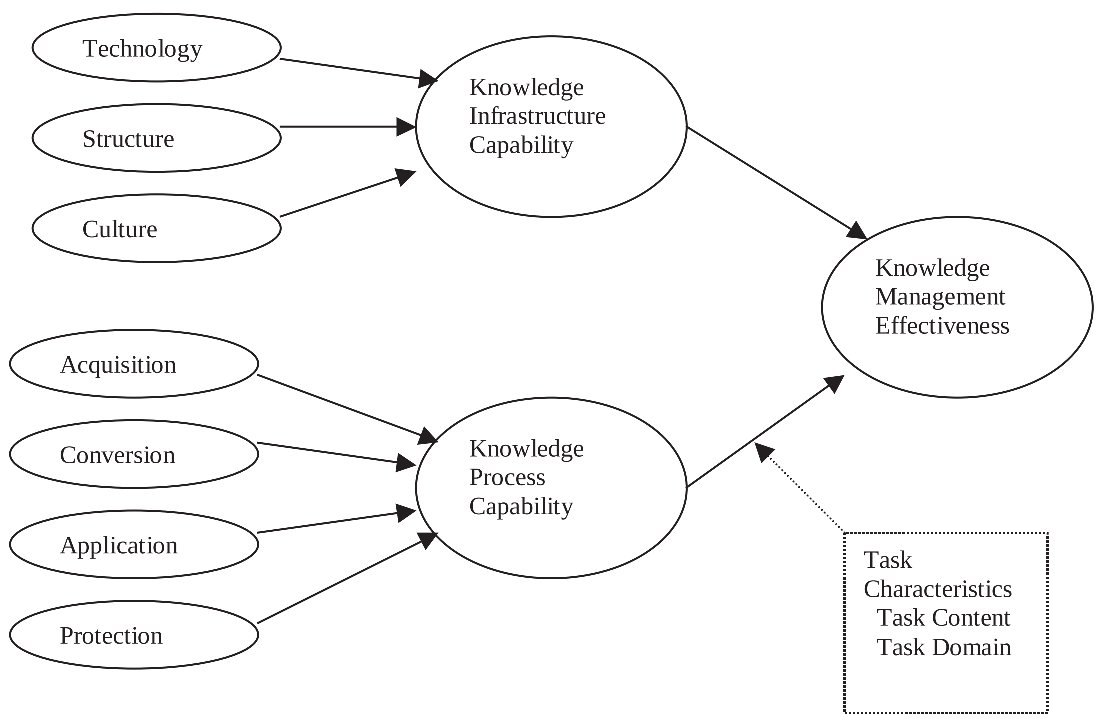


improve organizational performance. The model is based on the framework proposed by Holsapple and Joshi (2001), and reflects that KM success is based on understanding a process-oriented KM strategy and its effects on the organization, its knowledge users, and how they use knowledge. It recognizes that KM is an organizational change process and KM success cannot separate itself from the organizational change success with the result the KM success is essentially defined as improving organizational or process performance. The model is presented in Figure 2. Key components of the model are:

- KM Strategy—defines the processes using knowledge and what that knowledge is; the sources, users, and form of the knowledge; and the technology infrastructure for storing the knowledge.
- Key Managerial Influences—defines management support through leadership, allocation, and management of project resources, and oversight of the KMS through coordination and control of resources and the application of metrics for assessing KMS success.
- Key Resource Influences—the financial resources and knowledge sources needed to build the KMS.
- Key Environmental Influences—describe the external forces that drive the organization to exploit its knowledge to maintain its competitive position.

Figure 3. Lindsey (2002) KM effectiveness model



Lindsey KM Effectiveness Model

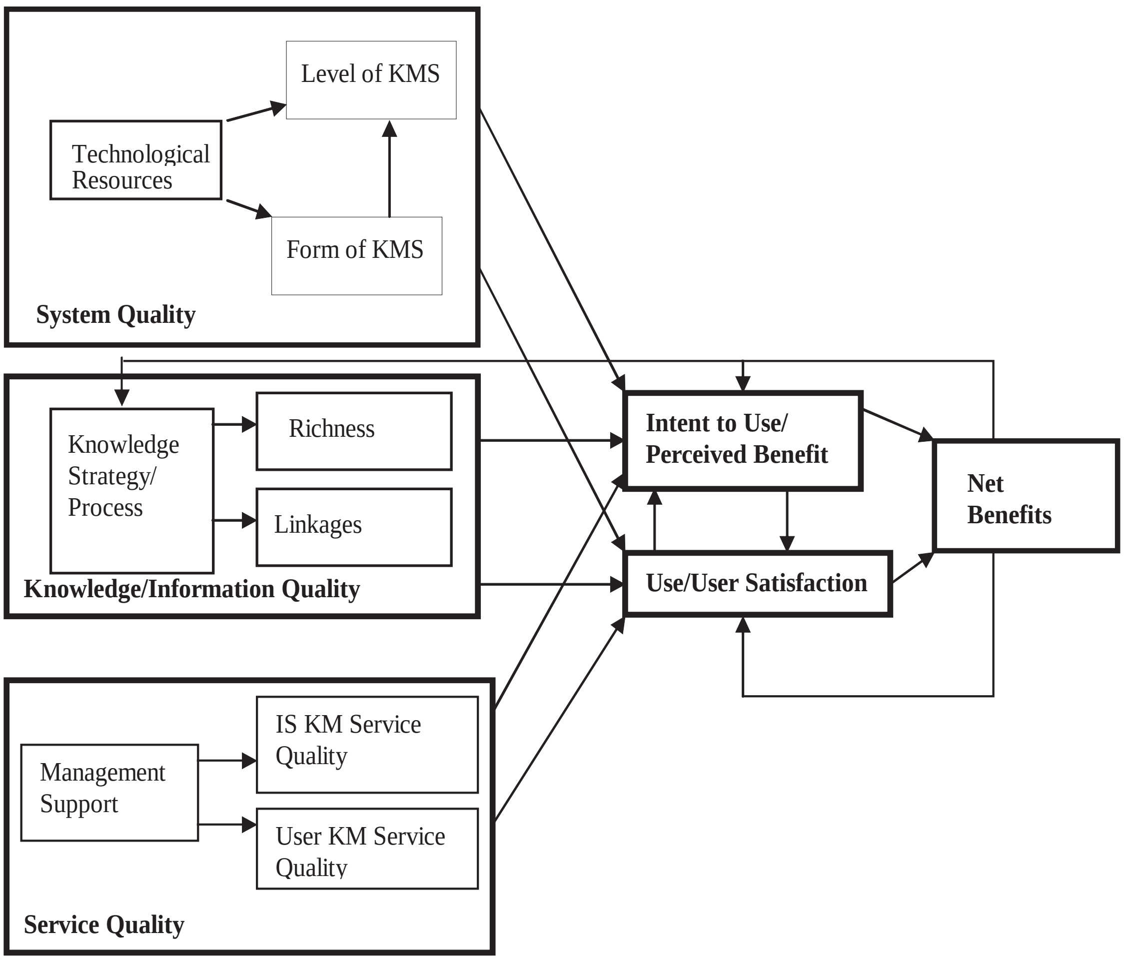
Lindsey (2002) proposes a conceptual KM effectiveness model based on combining Organizational Capability Perspective theory (Gold, 2001) and Contingency Perspective Theory (Becerra-Fernandez & Sabherwal, 2001). The model defines KM effectiveness in terms of two main constructs: knowledge infrastructure capability and knowledge process capability, with the knowledge process capability construct being influenced by a knowledge task. Knowledge infrastructure capability represents social capital, the relationships between knowledge sources and users, and is operationalized by technology (the network itself), structure (the relationship), and culture (the context in which the knowledge is created and used). Knowledge process capability represents the integration of KM processes into the organization, and is operationalized by acquisition (the capturing of knowledge), conversion (making captured knowledge available), application (degree to which knowledge is useful), and protection (security of the knowledge). Tasks are activities performed by organizational units and indicate the type and domain of the knowledge being used. Tasks ensure the right knowledge is being captured and used. KM success is measured as satisfaction with the KMS and is considered a weak definition of success. It is proposed that research be conducted into KMS effectiveness to find ties into organizational effectiveness. Kaplan and Norton's (1992) Balanced Scorecard may be useful in establishing measures for KMS effectiveness. Figure 3 illustrates the Lindsey model.

KMS Success Models Based on the DeLone and McLean IS Success Model

Jennex and Olfman (2004) present a KMS success model that is based on the respecified DeLone and McLean (2003) IS success model. The model in Figure 4 was derived from a longitudinal case study, a quantitative study across an industry, and action research applying the model in the field. The model evaluates success as an improvement in organizational effectiveness based on use and impact of the KMS. Descriptions of the dimensions of the model follow.

- System Quality—defines how well the KMS performs the functions of knowledge creation, storage/retrieval, transfer, and application; how much of the OM is codified and included in the computerized portion of the OM; and how the KMS is supported by the IS staff and infrastructure.
- Knowledge/Information Quality—ensures that the right knowledge/OM with sufficient context is captured and available for the right users at the right time.
- Service Quality—ensures that the organization has adequate service support from management, user organizations, and the IS organization.
- Use/User Satisfaction—indicates actual levels of KMS use, as well as the satisfaction of the KMS users. Actual use is most applicable as a success measure when the use of a system is required. User satisfaction is a construct that measures satisfaction with the KMS by users. It is considered a good complementary measure of KMS use when use of the KMS is required, and effectiveness of use depends on users being satisfied with the KMS.
- Perceived Benefit—measures perceptions of the benefits and impact of the KMS by users, and is based on Thompson, Higgins, and Howell's (1991) Perceived Benefit Model. It is good for predicting continued KMS use when use of the KMS is voluntary, and amount and/or effectiveness of KMS use depends on meeting current and future user needs.

Figure 4. Jennex and Olfman (2004) KMS success model



- Net Impact—An individual's use of a KMS will produce an impact on that person's performance in the workplace. Each individual impact will in turn have an effect on the performance of the whole organization. Organizational impact is typically not the summation of individual impact, so the association between individual and organizational impact is often difficult to draw, which is why this construct combines all impact into a single construct. This model recognizes that the use of knowledge/OM may have good or bad benefits and allows for feedback from these benefits to drive the organization to either use more knowledge/OM or to forget specific knowledge/OM.

Maier (2002) also proposes a KMS success model based on the DeLone and McLean IS success model (1992). This model is similar to the

Jennex Olfman model. Breakdown of the dimensions into constructs is not provided, but specific measures for each dimension are identified. This model is illustrated in Figure 5 and uses the following dimensions:

- System Quality—taken directly from DeLone and McLean (1992) and refers to overall quality of the hardware and software.
- Information, Communication, and Knowledge Quality—refers to the quality of the stored data, information, and knowledge, and to the quality of knowledge flow methods.
- Knowledge-Specific Service—refers to how well subject matter experts and KMS managers support the KMS.
- System Use/User Satisfaction—taken directly from DeLone and McLean (1992) and refers to actual KMS use and the satisfaction users have with that use.
- Individual Impact—taken directly from DeLone and McLean (1992) and refers to the impact KMS use has on the individual's effectiveness.
- Impact on Collectives of People—refers directly to the improved effectiveness within teams, work groups, and/or communities that comes from using the KMS.
- Organizational Impact—taken directly from DeLone and McLean (1992) and refers to improved overall organizational effectiveness as a result of KMS use.

APPLICATION OF THE FRAMEWORK

To illustrate the use of the framework, the KMS success models are first analyzed by comparing them to the identified set of success factors and determining how well the models reflect the set of success factors. Table 2 summarizes this comparison. Assessing responsiveness to the top four success criteria finds that the Value Chain, Maier, and Lindsey models are not as good at reflecting the observed data as the Massey et al. and Jennex/Olfman models. Also, the only difference between the Massey et al. and Jennex/Olfman models is SF5, Culture. Given that this would be the next

Figure 5. Maier (2002) KMS success model application of the framework

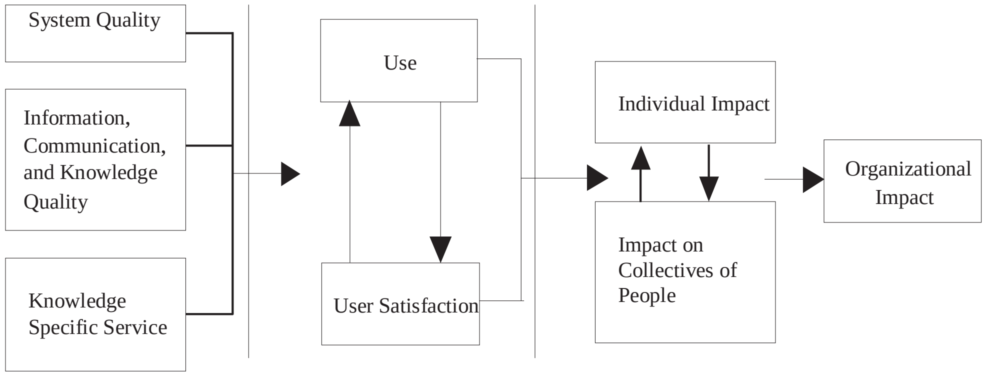


Table 2. KM success models versus KM success factors

Success Factor ID	Value Chain	Massey et al.	Lindsey	Jennex Olfman	Maier
SF1	No clear tie – Share knowledge stage	KM Strategy	Technology construct – networks	Technical Resources and Service Quality Constructs	System Quality and Knowledge Specific Service Quality
SF2	Strategy stage	KM Strategy	Task and Acquisition constructs	KM Strategy / Process Construct	Information, Communication and Knowledge quality
SF3	No clear tie	KM Strategy	Structure and Conversion constructs	Form Construct	Information, Communication and Knowledge quality
SF4	Weak – Apply knowledge stage	Key Management Influences	No clear tie	Perceived Benefit Construct	No clear tie
SF5	No clear tie	No clear tie	Culture construct	Perceived Benefit Construct	No clear tie
SF6	Implied – no clear tie	Key Management Influences	No clear tie	Perceived Benefit Construct	No clear tie
SF7	Return stage	Key Management and Environmental Influences	Task construct	Net Impacts Construct	Impact dimensions, Information, Communication and Knowledge quality
SF8	Strategy stage	KM Strategy	Task construct	KM Strategy/ Process Construct	Information, Communication and Knowledge quality
SF9	No clear tie	No clear tie	No clear tie	No clear tie	No Clear Tie
SF10	Share knowledge and Apply knowledge stages	KM Strategy	Conversion and Task constructs	Level Construct	System Quality
SF11	Apply knowledge stage	KM Strategy	Application construct	Perceived Benefit Construct	No Clear Tie
SF12	No clear tie	No clear tie	Protection Construct	No clear tie	No Clear Tie

most important success factor, it is determined that the Jennex/Olfman model most closely fits the observed data as reflected by the success factors model. It should be noted that further derivation of the Maier model dimensions may improve its fit to the KMS success factors.

Looking at the theoretical foundation for the KMS success models finds that all four have some theoretical foundation. The Value Chain model uses the commonly used Value Chain approach. The Massey et al. model relies on the Holsapple and Joshi (2001) framework. The Lindsey model utilizes organizational capability perspective theory and contingency perspective theory. The Jennex/Olfman and Maier models utilize the widely accepted DeLone and McLean IS success model. Assessing the ability to generalize from the theory, it can be determined that the Value Chain, Jennex/Olfman, and Maier models are utilizing theory that is more widely utilized for assessing effectiveness. However, the Massey et al. and Lindsey models' theoretical foundation may be proven to be more widely applicable after being applied and studied in a variety of organizations and applications.

Assessing the KM success models for applicability to both approaches for building a KMS, it can be determined that the Jennex/Olfman model has no characteristics that would limit its applicability to either KMS approach, while the Massey et al., Value Chain, Maier, and Lindsey models could be interpreted as being specific to an approach. The Value Chain model is typically applied to organizational systems to determine strategic processes, focusing this model on generic/infrastructure uses of a KMS. The Massey et al., Maier, and Lindsey models specifically incorporate task-specific components that may make it difficult to focus the models on assessing organizational effectiveness. However, it can be concluded that all four models could be applied to both KMS approaches if the user is aware of the differences between the approaches and the limitations of the models.

In summary, the proposed framework provides a user a measuring stick for selecting a KMS success model. Users wanting a model based on widely accepted success models and one that fits the observed data (as expressed in the KMS success factors) would rank the models in order of preference as Jennex/Olfman, Massey et al., Value Chain, Lindsey, and Maier. Users wanting a model specifically for assessing a project/task KMS may opt for the Massey et al., Maier, or Lindsey models. Users focusing on generic/infrastructure KMS may opt for the Value Chain model. Users implementing both types of KMS and wanting a single KMS effectiveness model may opt for the Jennex/Olfman model.

CONCLUSION

The proposed framework for assessing KMS success models appears to be useful. It allows users to validate that the KMS success model they are using reflects observed factors that have been found to affect KMS success. The use of the KMS success factors to assess this fit is very powerful and is the major contribution of this article. The KMS success factors were identified from a large number of studies, projects, and KMSs providing a broad view of KMS success.

The use of the other two criteria of the framework is less powerful but still important. It is important to determine that a KMS success model has a theoretical foundation, as otherwise it could simply be a reflection of a single data point's success criteria and may not be applicable to the KMS to be assessed. Additionally, it is also important to ensure that the KMS success model being used applies to the approach of the KMS under consideration. It is inappropriate to apply an organizational effectiveness model to a task/process KMS and vice versa.

Chapter 6.29
Linking Small Business Networks with Innovation

Patrice Braun
University of Ballarat, Australia

INTRODUCTION AND BACKGROUND

Today, with an economy enabled and driven by connectivity, a fundamental shift in business models is occurring whereby information, knowledge, and relationships underpin competitive advantage. In order to compete in what some refer to as the networked economy, companies across the globe must use technology-mediated channels, create internal and external value, formulate technology convergent strategies, and organize resources around knowledge and relationships (Scott & Storper, 2003).

The rise of information and communication technologies (ICT) and electronic information networks has led firms of all sizes to implement more technology driven solutions for improved productivity and information flow. Malhotra (2000) identified three general information management (IM) developments that have revolutionized company information processes over the last 40 years. The first phase, the automation phase, increased company efficiency of operations. The second phase, the rationalization phase, streamlined those procedures by eliminating bottlenecks made apparent by the automation. The third phase, the business reengineering phase, radically redesigned information and knowledge management processes through technology-intensive implementation of procedures in workflows and work processes (Malhotra, 2000). Now we have reached a fourth phase, the knowledge creation and knowledge transfer phase, that, if possible, is even more closely associated with technology than business process reengineering.

With embedded knowledge flows and innovation linked to communities of practice as well as through linkages using technology, companies of all sizes have the potential to both collaborate and compete by taking advantage of connectivity and new relationships founded on the exchange and sharing of embedded knowledge. This article discusses how knowledge sharing environments such as communities of practice and virtual business communities can be important determinants of commercial viability and business success for small and medium sized enterprises (SMEs), provided that both the (virtual) environment and inter-firm relationships are conducive to information sharing and knowledge flows.

COMMUNITIES OF PRACTICE

Once the domain of special business units and cross-functional teams to perpetuate ideas and embed core competencies, a new form of collective community building has emerged through a spontaneous new knowledge exchange trend known as communities of practice, or CoPs. Burk (2000) simply calls CoPs expansions of one-on-one knowledge sharing. Theorists, Wenger, Snyder, and William (2000) describe them as informal groups of people who regularly share their expertise and experiences; are not formulated or controlled by management; set their own leadership; and follow their own agenda. Lave and Wenger (1991) were among the first to introduce CoPs as context-bound groups of workers who share knowledge around a particular practice.

In many ways, communities of practice are the Western adoption of the holistic Japanese approach outlined by Nonaka and Takeuchi (1995) in acknowledging the importance of tacit company knowledge and transforming it into explicit company assets. However, one of the central benefits of these self-constituting communities is that they sidestep the "ossifying tendencies of large companies and develop rich, fluid non-canonical worldviews to bridge the gap between their organisation's static canonical view and the challenge of changing practice" (Brown & Duguid, 1991, p. 50). This spontaneous think-tank mode of team building through face to face meetings, e-mail, knowledge sharing networks, intranets, and technology-mediated conferencing is an inherently innovative process and is proving to be a crucial aspect of organizational learning and innovation.

Initially, most communities of practice were internal company networking groups to foster shared learning and practices to encourage team-based incentives that directly influenced company profits (McDermott, 2004). Showing great promise in driving organizational learning and innovation, this form of knowledge creation is being adopted in both the public and private sectors, as it is considered the key to survival in the knowledge economy. Communities of practice have also flourished with members from different companies, as exemplified by the chief executive officers (CEOs) of different US companies who make up the Business Roundtable (Wenger et al., 2000).

The application of CoPs to an inter-firm context is in line with the new business models that are favored in the networked economy, in which connectivity, relationships, and knowledge sharing are key assets for competitive advantage (Soekijad, Huis in 't Veld & Enserink, 2004). Within the networked environment, the relationship between connectivity and companies should be seen as reciprocal, whereby ICT and related capabilities – such as virtual community environments like chat rooms and e-mail forums used for product development, product review, and other business information exchange—have a significant impact on how inter-organizational relationships are developed. Examples of new economy inter-firm knowledge sharing may be found in Internet-based companies such as Amazon and e-Toys, which have successfully redefined the value of knowledge assets by fostering information flows between organizations and industries in virtual community environments (Malhotra, 2000). It should be noted that, contrary to the latter example, there are many different forms of sociocultural communities of practice proliferating in the virtual environment with objectives other than competitive advantage, discussion of which falls outside the scope of this article.

While CoPs and other complementary inter-firm relationships have been the subject of considerable empirical research in large enterprises (e.g., McDermott, 2004, p. 624; Pfeffer, 2000, p. 358; Soekijad et al., 2004, p. 623), studies on the role of CoPs with regard to small and medium sized enterprises (SME) are less abundant. Building on the concept that global positioning and competitive advantage for SME may be achieved through clustering or network building and collaborative knowledge creation, the rest of this article explores the potential of a timely synergy between connectivity and collaborative business models for SME in embracing knowledge community practices.

SMALL BUSINESS NETWORKS

As seen above, ICT and related capabilities such as virtual community environments can have a significant impact on how inter-organizational relationships are developed. However, the structure and culture of an existing network of organizations itself also seems to have considerable predictive power for the way in which the telecommunications network is developed, implemented, and used (Nouwens & Bouwman, 1995). Adoption of network structures and networked technologies by SME is generally related to the size and nature of SME and largely depends on their perception of affordability and business growth opportunities for their business (OECD, 2000).

New ways of doing business to achieve success in the techno-economic innovation paradigm bring to the fore ICT adoption and strategic planning issues. Research into the adoption of networked technologies by SME indicates that SME generally approach clustering and networked infrastructures such as the Internet with caution and still hesitate to invest their time and money in a rapidly changing economy (NOIE, 2000), nor do SME necessarily view the Internet as a vehicle to transform their individual business capability from a parochial to a networked or global level, which may be achieved through the set-up of electronic commerce (e-commerce) portals or other Web-enabled cluster structures (Murray & Trefts, 2000). The latter study cites lack of technology skills, lack of a strategic sense of how to move forward, and fear of competitor use of the Internet as significant barriers for uptake of networked technologies by SME. Therefore, creating network infrastructures and knowledge flows between small firms is contingent, not on adoption of ICT technology alone, but on economic and social contexts as well.

European studies on SME positioning in the networked economy point to SME networking and knowledge sharing as contingent on favorable economic conditions, for example, by providing government-sponsored external networks (Cooke & Wills, 1999; Fariselli et al., 1999). An Asian study similarly provides empirical evidence that successful SME collaboration needs to be underpinned by resources that provide SME with the tools to become global players (Konstadakopulos, 2000). The European studies on SME positioning in the new economy also associate social capital with enhanced business, knowledge, and innovation performance (Cooke & Wills, 1999; Fariselli et al., 1999). Social capital can be roughly understood to mean “the goodwill that is engendered by the fabric of social relations” (Adler & Kwon, 2002, p. 17). While social capital and embracing connectivity through public or private initiatives may facilitate the electronic linking of SME to one another for potential business-to-business (B2B) resource and information sharing, and help to reduce isolation of individual SME, there is another critical factor to consider in terms of knowledge exchange between SME, and that factor is trust.

There is a considerable body of literature on inter-firm trust. Trust and social capital are attributes not only of organizations but also of communities, industry networks, or even entire geographic regions, which can help expedite economic development and facilitate large-scale economic activities (Fukuyama, 1995). Trust between network partners is said to reduce fear of opportunistic behavior and improve collective learning and knowledge sharing. The trust may be historical and already exist between different firms, as illustrated above, or it can be built during the relational exchange (Gulati, 1995; Ring & Van de Ven, 1992). Some scholars argue that relationships do not necessarily have to be based on trust as long as systemic mechanisms are in place which allow stakeholders to have confidence that network partners will exhibit cooperative rather than opportunistic behavior and not take competitive advantage of knowledge-based exchanges (Das & Teng, 1997). In the aforementioned Asian example of SME collaboration, information sharing and learning was in fact taking place based on prior existence of trust and in an atmosphere of continued trust building between stakeholders (Konstadakopulos, 2000).

Corporate company members tend to join a community of practice or a community of interest for networking or learning purposes in their field, trusting other company members in the exchange of explicit and implicit company knowledge for the public good aspect and building of company assets. This type of collaborative learning and innovation in large companies is facilitated via the company infrastructure such as e-mail, company intranets, and other technology-mediated tools such as video-conferencing. Given the lack of networked infrastructure between SME and the frequent individualistic nature of small firms, SME are more likely to compete than collaborate in a knowledge exchange milieu. Thus, to approximate community of practice results, if indeed such results are desirable, SME networks are likely to require infrastructure and knowledge exchange conditions that engender trust (Braun, 2002).

FUTURE TRENDS FOR SME

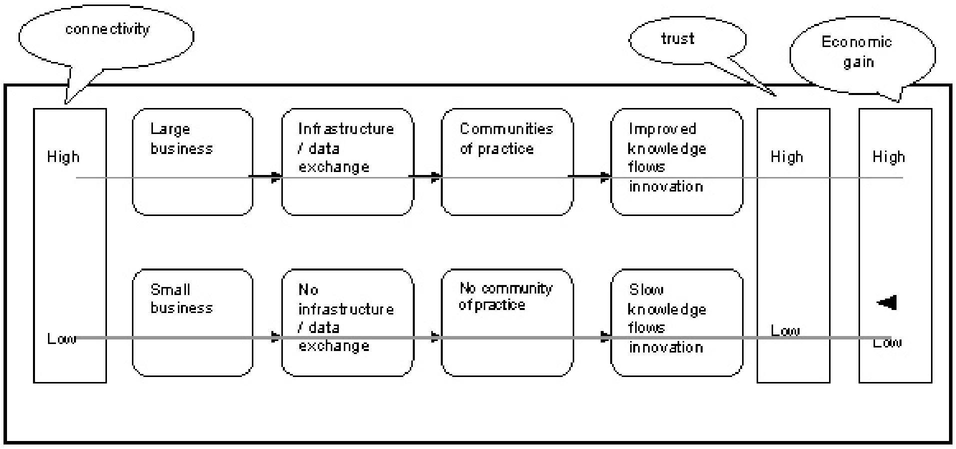
With networking, collaborative information flows, and communal knowledge creation providing potentially beneficial economic outcomes for SME in today's economy, SME may be willing to engage in collaborative knowledge sharing relationships, provided that connectivity (infrastructure), network relationships, and trust conditions are present.

Figure 1 maps knowledge flows against limitations such as size, connectivity, and lack of interaction and suggests that fostering a culture of connectivity, cooperation, and trust building between SME to initiate and encourage community of practice type knowledge diffusion may offer a potential solution to possible loss of competitive advantage for SME in the networked economy.

The top of the knowledge flow model shows how a large company with high connectivity and an integrated infrastructure for information and knowledge exchange via communities of practice can lead to a high level of trust and subsequent innovation and competitive advantage. The bottom part of the knowledge flow model shows how an SME with low access to a networked infrastructure and a low level of knowledge exchange leads to a low level of trust in industry or alliance partnering, which in turn can lead to isolation and loss of competitive advantage for individual SME in the networked economy.

The model displays two extreme positions, for example, a large company with highly integrated connectivity vs. a small company with little or no connectivity. Alternative scenarios in terms of company size, connectivity, and level of interaction would impact on competitive advantage and the level of innovation; for example, a large

Figure 1. Knowledge flow model



company without an integrated infrastructure and a climate of data exchange would likely exhibit lower levels of knowledge flow and innovation. A small company with full connectivity (to the Internet) but without active participation in an online knowledge network would have competitive advantage over a small company with little (e-mail only) or no connectivity, while a high connectivity SME subscribing to a networked knowledge exchange culture would have competitive advantage over a connected yet network-isolated SME. Considering connectivity, local network conditions, the character of local practice, and the uniqueness of social capital within each region is pivotal in developing SME networks for competitive advantage.

In terms of connectivity, large firms with deep pockets have the ability to build their own integrated architecture, while SME access to a networked infrastructure may involve relying on the public purse. Where SME do not have a history of networking and knowledge sharing for the local or regional common good, a knowledge exchange culture will need to be cultivated and coupled to an economic framework that provides clear collaboration benefits and that is linked to tangible results for participating SME (Braun, 2003b).

In addition to offering a networked environment where SME can both collaborate and compete, a culture of trust needs to be fostered through personal interaction and strong relational or social cooperation between firms to learn critical information and know-how from alliance partners (Nonaka & Takeuchi, 1995). Established business networks and regional industry associations can play a key role in stimulating loose collaboration and knowledge exchange between SME.

Stronger ties could potentially be fostered through regional supplier and customer network linkages, as demonstrated by online companies such as Amazon.com. Such linkages can function as conduits for SME communities of practice. With networked technologies now able to provide centralized supplier and customer relations management functionalities, regional SME portals, SME intranets, and other interactive networked environments such as video and desktop conferencing may well provide the required interactive collaborative context to evolve into SME information and learning platforms (Lechner, Stanoevska-Slebeva & Tan, 2000; Stahl, 2000).

Joining the global market as a sole trader, let alone becoming an inter-firm network stakeholder may entail an enormous conceptual leap into the future for many SME owners and managers. Network novices will hence need substantial encouragement and support to make them willing to take the network plunge (Braun, 2003a). Creating awareness of networked opportunities, developing skills in using networked technologies, and providing educational processes around inter-firm relationship building may be beneficial to increase SME understanding of the potential of collaboration. Once individual SME and collective goal orientation is realized, participation in an SME community of practice or industry cooperative is likely to perpetuate trust between SME, which in turn would produce economically beneficial outcomes.

CONCLUSION

This article has discussed how collaborative relationships are becoming one of the most important determinants of commercial viability and business success in the networked economy. With embedded knowledge flows and innovation linked to communities of practice as well as through linkages using technology, SME have the potential to both collaborate and compete by taking advantage of connectivity and new relationships founded on the exchange and sharing of embedded knowledge.

There are obvious differences between large and small firms both in terms of availability of resources for connectivity and in terms of community of practice membership. Given the often independent nature of SME, exact emulation of a large company community of practice may not be feasible or even desirable, but a variety of models can be examined to identify appropriate connectivity-driven inter-firm network structures for SME and approximate desired community of practice results.

Having drawn on the inter-disciplinary fields of economic development, new business models, collaboration, and trust, it is suggested that overcoming potential loss of competitive advantage for SME in the networked economy will require strategic SME community building with connectivity, trust, and relational capital as pivotal building components. Taking communities of practice as the vehicle for knowledge sharing between SME, attention must be paid to local conditions, the concept of practice (Brown & Duguid, 2001), and how practice relates to trust. While this article demonstrates the importance of knowledge sharing in the networked economy, it also shows that the key to economic staying power is vested in people and their culture rather than in technology.

Chapter 6.30
Managing the External Provision of "Knowledge Management" Services for Projects

Hedley Smyth
University College London, UK

ABSTRACT

Knowledge management has largely been considered from the perspective of internal generation. It is posed that external provision will increase due to the diversity of problems and scarce resources, the arising issues being explored through a case study. The aim is to explore this process for construction projects. It will be shown that the successful delivery of knowledge services for the construction industry depends upon the way in which the provider conducts its marketing and the operation of gatekeepers in the project organisation. These issues are explored in relation to the main concepts and theories, applying and evaluating these through the case study approach.

INTRODUCTION

This chapter explores the issues for knowledge management where the knowledge and the application are derived in one organisation and used in another—the external provision of information and knowledge management services. The aim of the chapter is to explore this process for construction projects. It will be shown that there are particular issues to be addressed in the successful delivery of knowledge services for the construction industry, specifically the role of marketing and the operation of gatekeepers where the project is the main means of delivery. These issues will therefore be explored within the project working environment, bringing to bear the main concepts and theories, and applying and evaluating these through a case study approach.

LEARNING OBJECTIVES

This chapter provides the opportunity for:

1. Analysing the issues involved in the external provision of KM.
2. Gaining an understanding of the gatekeeping role of the knowledge manager in the user firm.
3. Securing a knowledge of the marketing requirements of the supplier in external knowledge provision.

BACKGROUND

Nonaka and Takeuchi (1995), following Polanyi (1966), have classified knowledge as being explicit or tacit. It has been argued that specific strategies and processes are needed to make tacit knowledge explicit and to manage that knowledge to the benefit of the organisation (Teece, Pisano, & Sheun, 1997). The process of developing competencies and capacities to achieve these requirements has been divided into four areas of organisational activity (Leonard-Barton, 1995):

- Shared creative problem solving
- Integrating and implementing new methods and adopting new tools
- Formal and informal experimentation
- Learning outside of the organisation

This chapter focuses upon the last of the four areas—the external provision of learning. For external provision from one organisation to another, the knowledge has to be made explicit and managed in such a way that it can be marketed and sold either as a knowledge management service package or a bespoke service to meet specific needs. This is an important and under-researched area in industry and in the whole sphere of knowledge management. The external provision of knowledge management services for problem solving is likely to increase. The strategy for an organisation demands choices, which precludes options, hence the allocation of resources in support (see, for example, Mintzberg et al., 2002; Johnson & Scholes, 2002). KM may not be a strategic area for investment, but even where it is, there are two primary reasons why external KM provision will increase:

1. The specific processes selected by any one organisation to realise knowledge management and organisational learning objectives inherently limit the range of knowledge that can be captured, managed, and successfully applied.
2. There is a high cost to the generation of knowledge and learning, so efficiency of generation is likely to be maximised by those specialising in certain areas of expertise and bodies of knowledge.

Strategies and specific processes provide direction for a firm, which provides the context for knowledge management and organisational learning pursuit both in overall emphasis and the specific areas in which it can be maximised. Other aspects of learning and knowledge management will therefore take second place or be excluded. Hughes and Kao (2001) also demonstrate that there can be advantages to acquiring external information rather than developing it in-house in an integrated way (cf., Shavell, 1994). These include speed and cost of provision, as well as potentially effective solutions mobilised from a different resource base.

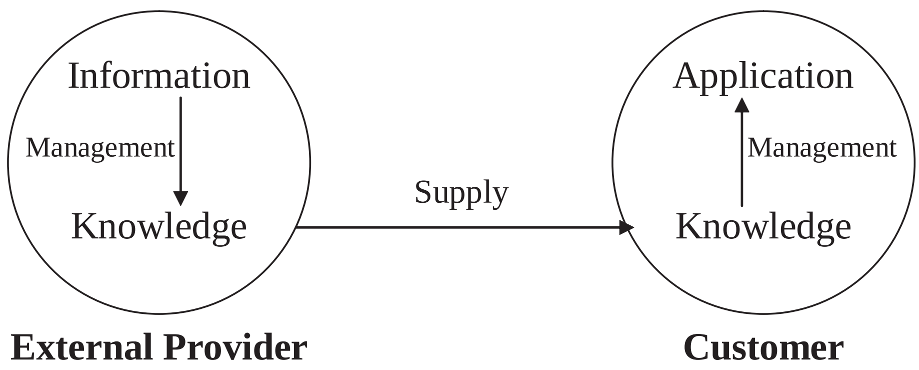
Cost, the second issue, will relate to the above in that budgets and spending will be focused upon the areas of strategic preference. The areas where less effort has been focused will have higher costs as the starting point and will be weaker or at a comparative disadvantage. The internal costs will be high. Thus, when the cost of internal generation becomes high, the cost of purchasing a solution in the market is more favourable. The external production and transaction costs are lower than the internal production costs (Williamson, 1985).

There is the market for information and knowledge. The provision process in the sense of the knowledge generation and application is demonstrated in Figure 1. The market exists where there is asymmetry of information between internal sources (including those that can be obtained 'free') and the external provision of information (Milgrom & Roberts, 1992). Although the quality of information is uncertain in advance (Akerlof, 1970), and therefore the transaction costs may prove to increase in order to search out the quality and assess risk (Williamson, 1985), the external provision may prove the best option. Shavell (1994), however, argues that partial disclosure of valuable information provides an incentive for buyers to acquire remaining information. In these ways the market for knowledge is similar to the market for information. Drucker (1995) was amongst the first to view knowledge as a capital asset or resource to be utilised, and therefore intellectual capital becomes recognised as a scarce commodity. Drucker (1989, 1993) identified the knowledge worker with ways of thinking that transcends industries. Groák (1994) coined the concept demand chain to indicate how technology and innovation for construction projects can be drawn from a range of industries. In this context, the external knowledge can then be injected from outside the construction enterprise, whether in design or contracting, into the other three activities, mostly the first concerning problem solving in a project working environment.

In construction and many other project working environments, teams are multi-organisational (Cherns & Bryant, 1983), giving rise to two additional costs:

1. The creation and realisation of knowledge at the level of the project and capturing; management and diffusion of that knowledge across the organisation and other projects (Smyth, 2004).
2. The transfer of knowledge and learning across organisational boundaries at the project level.

Figure 1. Information and knowledge generation and application from an external provider



External sources of knowledge are therefore a valuable supplement, if complementary and additional to internal sources. Project-specific knowledge is therefore a notion or concept for which external provision is likely to be a practical solution to meeting the practical need—a socio-technical solution for construction. In summary, such sources will be accessed where the value added is greater than the marginal cost to the service or product, or where the organisation secures a competitive advantage relative to the costs.

THE KNOWLEDGE MANAGEMENT MARKET

What is the knowledge service, product, or commodity? Egbu and colleagues (2003a) have drawn attention to the paucity in definition and articulation of the tools for knowledge management (KM). The tools can be divided into:

- KM techniques
- KM technologies

The tools of techniques and technologies both imply a service, which can be dynamic and tailor-made, created and applied internally, or sourced from an external provider. External provision can be sourced as a pre-packaged service or bought off the shelf, hence reconstituted to appear as a product. Such products can be used by a number of clients; the higher the rate of usage, the more the product becomes a commodity, and the value, hence price, diminishes over time. Bespoke services will be relatively, if not totally unique, hence are of potentially high value and price. KM techniques require strategies for development and realisation (Egbu et al., 2003a), yet the external provision of KM services requires a particular form of strategy—marketing principles (Smyth, 2000). The particular problems the KM-marketing interface must address are:

- Identifying the KM needs of consultants and contractors managing projects in order to generate KM service packages and bespoke solutions.
- Marketing the bespoke services and packages to consultant and contractor organisations to create awareness in advance of their perceived need for the KM services.
- Getting past those responsible for information, areas of expertise, and knowledge—gatekeepers—in the organisations to the real end user requiring the project-specific knowledge.

This chapter explores these issues for KM provision in construction through a case study. The case study, Concrete Information Limited (CIL), has its origins in the forerunner to and within the British Cement Association as its former library and information service. The British Cement Association has operated an extensive library and information service for many years. This has been restructured into a knowledge-based service. There are two foci. The first is pre-specification, which is the historic focus for information, which is now being developed around market data. This switch in 'product' area is in its infancy; therefore, this chapter mainly develops the case around the post-specification segment of CIL's business. The pre-specification market segment is composed of a number of areas, The Concrete Centre being a key client. TCC was launched in September 2003 as a new initiative to help specifiers in the choice of structural materials in design. The second and recent focus is on KM service provision post-specification for the cement and concrete sectors. CIL is thus an external organisation responsible for supplying knowledge within a complex field of business-to-business social networks, a large proportion of which are and will increasingly be aimed at problem solving within projects. This case arises from a two-year research project on CIL, during which CIL has been restructured from an information provider based upon a public-sector approach to a commercial KM provider. It is providing information and knowledge to a range of end users, and especially to serve project-specific needs as a key market segment. It is jointly owned by the British Cement Association and the Concrete Society, both trade bodies representing concrete and cement interests.

CONCEPTUAL ISSUES IN THE EXTERNAL PROVISION OF KM

The main objective is to address the three problems cited: identifying the KM needs of consultants and contractors managing projects, marketing the bespoke services and packages, and reaching the real end user. This is achieved by engaging with the literature and by exploring the practical outworking through the case study.

Identifying KM Needs

Using the classification identified in recent research by Egbu et al. (2003b), a profile of services can be generated. Their classification is:

1. Main triggers of knowledge production (and in this case it includes need):
    - Problem solving
    - Innovation
    - Managing change
2. Main sources of knowledge production:
    - Expert individuals
    - Team and supply chain
    - Routines
    - Repositories
    - Communities of practice
    - Knowledge gatekeepers

In the case of CIL, the primary trigger is problem solving in developing the design details and production information or site-based problems on a project. The main source in this context is the repository, CIL, which is external, and therefore knowledge has to be accessed as a free advice service or purchased as a service. CIL therefore operates as part of a community of practice (Egbu et al., 2003a), that is, part of a network of different skill bases, histories, and experience that combine at points to realise shared goals (see Ruggles, 1997; cf., Egbu et al., 2003a). These can be located within a diversified organisation, but in a project context typically include a range of organisations working to realise mutual or compatible goals in completing a project.

The knowledge needs of experts and managers of knowledge, often assigned to the role of technical director and/or knowledge manager in large contracting organisations or consulting groups, will be rather different from a contract's director or a site manager, whose requirements are project-specific knowledge. The technical director or knowledge manager will serve design and production functions, and thus will apply knowledge to reduce uncertainty further down the project process and ensure quality for the finished structure. The KM need is primarily problem-solving innovation according to the classification above. Project-specific knowledge will be entirely focused upon problem solving. These will be issues that have not been recognised upstream or were totally unexpected and require an immediate solution, not only in their own right, but also in the context of completing the project on time and within budget without compromising quality. These needs at the project level are difficult to predict for an external provider, just as they are unforeseen internally. Therefore these needs have to be met from the repository of information available, the external provider creating generic packages of services. The provider derives the packages from experience of past patterns of demand, feedback, and market research. Other services will be bespoke of necessity.

The next issue is to make the market aware of the service and to sell them. This is the marketing function.

Marketing Bespoke Services and KM Packages

Organisational learning and knowledge management are perceived as competencies for the creation of effectively serving clients and improving internal efficiencies. This perspective of KM concerns strategy. At a tactical level, few people in practice talk about knowledge management as a starting point. They talk of performance. Knowledge management follows as a means to enhance performance. Harnessing KM is a means to an end, and is not the driver (Construction Productivity Network 2003). The consequence is that the awareness of the need for KM is secondary within an organisation, performance being primary. Where knowledge is provided from an external source, the perceived need for KM becomes one step removed and thus is tertiary in priority. Within a project environment, especially where the project is spatially removed from the organisational hub, the need for KM becomes a further step removed or quaternary in priority. This is of crucial significance. The final step is where the role of the gatekeeper within the organisation becomes critical and will be returned to below. At this stage, the main aim is to look at the overall picture created by this 'distance' and the role of marketing in bridging this gap.

Marketing is concerned with how to sell services, and the implementation is the sales process. Marketing is about managing the market; that is, creating and retaining a customer (see Kotler, Armstrong, Saunders, & Wong, 1996; Levitt, 1983; and in the construction context, Smyth, 2000). An initial issue for marketing is how to create awareness of the service and then how to promote the content of the service, both in package and bespoke forms. It has been stated that the quality of information is uncertain in advance (Akerlof, 1970); therefore, the transaction costs may increase in order to search out the quality and assess risk (Williamson, 1985). The marketing strategy and the promotion effort are designed to overcome these obstacles that arise from the external provision of information and KM services. The obstacles to overcome are greater in this case:

- Lack of advance need for KM services without increased awareness—project-specific knowledge is mobilised to solve problems as they arise.
- Distance created by external provision—a barrier to being aware of availability.
- Uncertainty of information quality in advance—location in a separate organisation, coupled with private ownership, prevent the uncertainty being automatically overcome.
- Internal distance created by dislocated projects and (in)action of gatekeepers.

These latter two factors arise out of the way in which organisations are constituted and operate (Child & Heavens, 2001).

There are two primary marketing paradigms: the marketing mix or transaction approach and the relationship marketing approach (see, for example, Gummesson, 2001; Smyth, 2000). The marketing mix approach grew up in the post-war era of mass markets of the United States and thus has its origin in the consumer or over-the-counter (OTC) retailing market. The mix is made up of four ingredients, measured out according to the recipe required for the circumstances. The ingredients are called the 4Ps:

1. Product
2. Price
3. Place
4. Promotion

Setting the right price to a product design and specification are clearly key. The delivery channel, which embraces distribution and the retail outlets, are the elements of place. Promotion embraces the full range of branding, advertising, PR, endorsements, and so on. Put simply, if you get the mix right, the marketing campaign will prove successful. This approach works where a number of factors exist:

- The product or service can be specified in advance.
- The market is of sufficient size to justify the packaging and promotion of the services.

This approach is certainly not suited to meeting very specific problems at any stage of the project life, but especially on site. A bespoke service is required. Over the last 20 years, it has been argued that business-to-business marketing is more appropriately conducted on a relationship basis. The Nordic School developed the paradigm of relationship marketing (see, for example, Gummesson, 2001; Smyth, 2000) in recognition that this is how people originally sold their wares, that it had become more problematic as organisations grew, but that systems could be put in place to replicate what had been lost on a business-to-business basis, often articulated through some key personnel.

This paradigm has received much wider recognition, even in consumer markets through reward cards. In this way retailers can profile the spending patterns of groups of customers representing particular market segments. There is a level of certainty of demand patterns that can be derived from aggregated data. In a business-to-business service environment, that feedback comes from listening to and interacting with the customer. The issue with a project problem-solving context once the project is underway on site is that there may be a relationship with the technical director, but not those solving problems on the project itself. The technical director or equivalent essentially becomes the prime relationship, acting as a gatekeeper to others.

The Project End User and Gatekeepers

Gatekeeper is a sociological concept applied to managers of a system in relation to the allocation of scarce resources, and was investigated widely in the public domain (see, for example, Pahl, 1975, for an early influential example). There has been less attention within private enterprises to the allocation. As in the public domain, allocation of resources in private organisations provides a source of power for the gatekeeper. The gatekeeper is an important information source for KM within the customer organisation. In the KM context the gatekeeper is a facilitator of knowledge production, or for its flow from the external environment to the project. However, the gatekeeper can also be an obstacle to effective dissemination of knowledge within an organisation. Child and Heavens (2001) give two reasons:

- Historical embeddedness of processes that goes against the grain of KM creation and dissemination in terms of;
  - Social systems (see also Stinchcombe, 1965; Johnson, 1990)
  - Social behaviour (see also Granovetter, 1985; Leonard-Barton, 1995)
- Leadership and authority systems that do not legitimise or facilitate dissemination—Senge (1993) places leadership in a key position for initiating learning and hence KM.

Child and Heavens recognise that learning and knowledge management are not only a process of generation and processing, but are also outcomes, that is, they impact upon performance, which does not automatically flow from the inputs. The issue about external provision is that it flows at that point of potential disjuncture between the processing and application. In that sense demand is not driven by strategy from above, but is driven by needs at the operational level. Therefore three levels for generating learning and knowledge occur: senior management, operational, and external suppliers (see Figure 2).

From this a model of learning and KM can be constructed that encompasses internal and external sources, which demonstrates the interface both in terms of how firms are organised in hierarchy and the horizontal management functions (see Figure 3).

The boundary of the firm must simultaneously be retained whilst being penetrable. Using a military analogy, the management issue is to know when the drawbridge of the castle should be up or down. In an economic and management environment, where the ability to generate a range of learning and knowledge to be effective and efficient in performance is constrained by management strategy and costs, external sources are becoming and will continue to become of greater significance. Boundaries therefore need to be penetrable—the drawbridge must be down so that key players in the firm are open to external ideas from the stage of receiving information that creates awareness to the stage when a problem surfaces that needs resolving using external information and KM services, hence the possibility of the key player connecting the awareness of the external source with the source to create the solution (cf., Tushman & Katz, 1980).

The key player becomes the gatekeeper of the knowledge source and some of the content, especially service packages. The role of the gatekeeper is:

- Being aware of the external sources and services
- Accessing information and knowledge

Figure 2. Three relationship channels for effective organisational learning (adapted from Child & Heavens, 2001, p. 314)

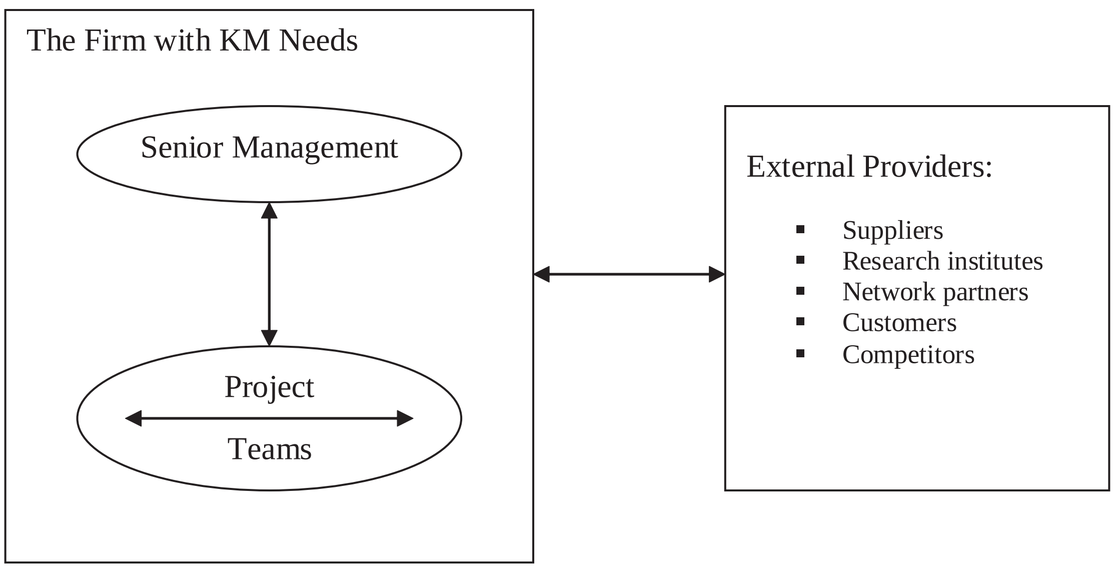


Figure 3. The interface between internal and external learning and KM

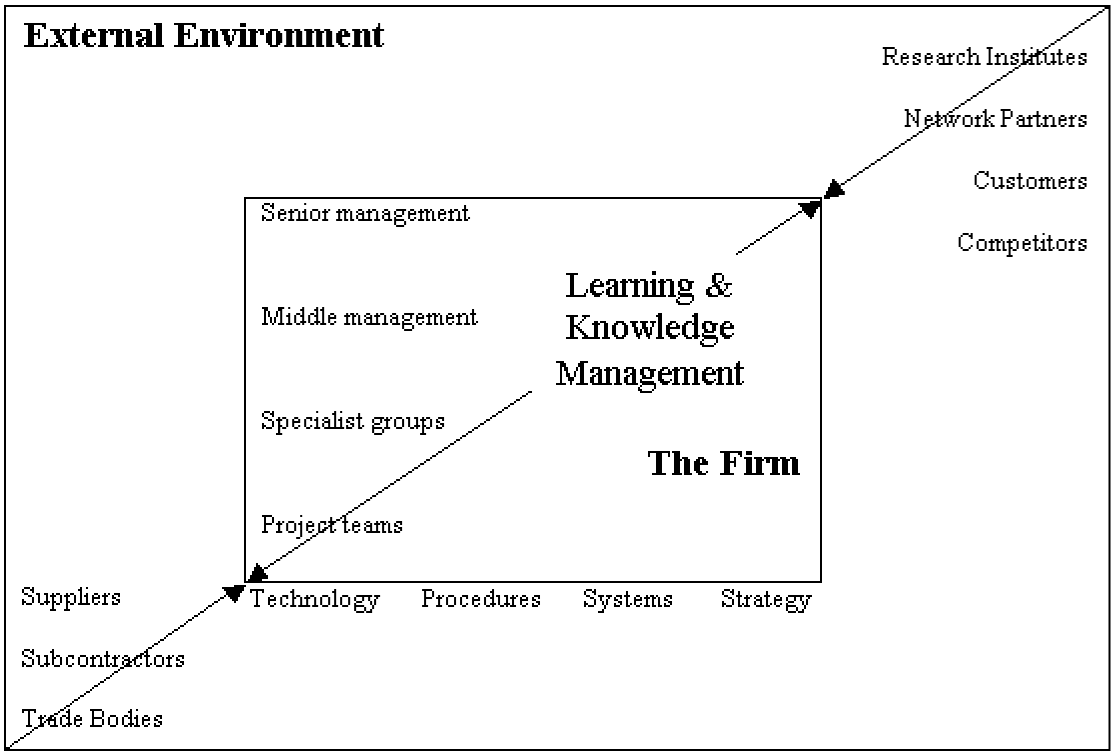


- Processing information into knowledge and integrating knowledge to match the culture, systems, and technical needs of the firm
- Disseminating the right knowledge to the right problems at the right time

In practice, there are problems with the effective functioning of those who are responsible for technical information and knowledge management—the gatekeepers:

- Those who primarily have an inward focus will have a tendency to have low levels of awareness of services and therefore will be ineffective at identifying the relevance of external knowledge to fit current and future internal needs.
- Those who primarily have an external focus will have a tendency to be less aware of internal needs and will have more difficulty processing knowledge to fit the internal language, systems, and strategy.
- Knowledge is power and some gatekeepers may use their role to reinforce their position, profile, or political stance in the firm, hence trading off effectiveness in the best interests of the firm in favour of personal power.

THE CASE OF THE CEMENT AND CONCRETE SECTOR IN THE UK

Case Study Method

The methodology is ethnographic, whereby participation and observation occurred within the primary actors (see Dunnette, 1976). The primary actors are CIL, a joint venture between the British Concrete Association (BCA) and the Concrete Society (CS). There has also been an element of action research, as participation has led to influencing the shape of service provision. This started initially with a consultancy contract and then developed through the UK government Teaching Company Scheme, now called Knowledge Transfer Partnerships.

The data is therefore mixed in sources, using observation, formal documentation, and notes derived from participatory activities. The evidence is primarily qualitative and provides greater capacity to address "how" questions in a dynamic and complex context. The method has permitted close contact with the subject over a long timeframe. It assures data validity through both: (1) an iterative process of evaluation over an extended time in conducting the research, and (2) reflection among the actors in examining the findings, thus offering the opportunity to address misunderstandings or misinterpretation in the data analysis. It is inappropriate due to confidentiality to reference all internal documentation. This is provided where possible.

Context

The British Cement Association (BCA) is a key trade organisation for the sector. It provided specialist technical information to the concrete and cement industries through its former library and information services. This service was characterised as being the provider of information, the aim being to provide a service that would help to promote the use of concrete and cement in construction and the design of projects. The approach was a quasi-public sector one. Recipients were typically technical directors and heads of specialist fields, who were responsible for dissemination within their organisations. Some were occasional users, some regular users and subscribed as members, receiving documents, standards, books, and other publications on a preferential basis. Other income was received through some sales and direct support from the BCA.

Restructuring

This service has been restructured, exhibiting some classic features of 'marketisation', to independently serve the knowledge management market. Serving this market requires not only the provision of information for others to process, but also the processing of information into knowledge. The service is now delivered through Concrete Information Limited (CIL).

This change has gone hand in hand with some restructuring of the information services. In essence, the sector launched The Concrete Centre (TCC) in September 2003 to parallel the successful initiatives of the steel sector. TCC is supported by the industry trade organisations and by leading producers. Its remit is to focus upon the specifier market. This was the traditional operating area of CIL. BCA continues direct support to CIL and has also brought in the Concrete Society, having transferred 50% of its shareholding in CIL to this other leading trade association.

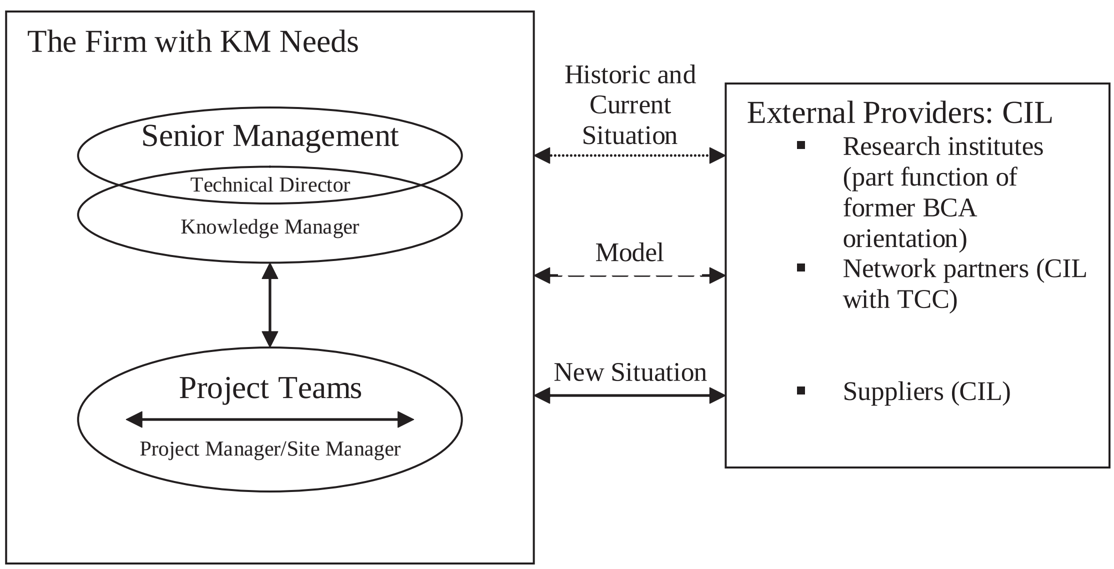
Market Reconfiguration: Awareness, Marketing, and Gatekeepers

Under the new configuration CIL is working towards being a commercial entity in its own right, income derived from open market sales and through membership. One of the key member clients is TCC; therefore a relationship marketing approach is most appropriate, and it is anticipated that the links will strengthen over time. TCC has a pre-specification focus and therefore is one important CIL client in this area. CIL will serve the regional representatives of TCC, and through them build relationships with their customers where concrete is specified and innovation or problem-solving services are required. TCC regional representatives are acting as facilitators rather than gatekeepers. They are more akin to sluice gates, that is, encouraging the rate of information flow, than gatekeepers, who tend to keep back knowledge that is not perceived to be in the best interests to release. The particularities for these circumstances are shown in Figure 4.

Whilst the model may infer that the relationship is three-way due to the automatic dispersal or dissemination up and down the client organisation, it was always dependent upon the internal functioning of the client organisation. That has changed into a new situation. An additional primary market target is the project level, and the technical director, knowledge manager, or people with the responsibility cannot be assumed to be motivated nor committed to making those who may need the service aware of the possibilities, nor be in an informed position to give advice to call upon the services of CIL. In terms of Figure 3, the target has moved from the top right-hand segment—the Research Institutes and Network role of supplying the senior management within the firm—to the bottom-right segment—the Suppliers and Trade Body relating to the project of the firm—where it was always partially located, but is now more concentrated, except for its role in relation to TCC.

While clients, some introduced through TCC, may be tracked and the contact maintained, many other projects may not require the involvement at CIL at the initial stages. So generally, the prime point of contact is no longer solely nor mainly the technical director or the knowledge manager for the entire consultant, contracting, or supplier organisation to those implementing the project.

Figure 4. Relationship channels for CIL



This raises a crucial issue about reaching the end user at the project level. The two main and related marketing issues are:

1. Paradigm choice
2. Creating awareness

Theoretically, a relationship marketing approach would be the ideal choice in this context, as the needs are likely to be very different for each project. However, the project staff confronts a number of issues that have been identified earlier in the chapter which act as filters:

- Uncertainty about the need for information and knowledge in the future (Milgrom & Roberts, 1992)
- Uncertainty of the quality of information and knowledge available (Akerlof, 1970)
- Uncertainty of the availability of information and knowledge
    - Role of gatekeepers
    - Effectiveness of awareness creation from external provider

CIL is facing all these issues and thus the relationship approach is difficult to establish, particularly at the front end of the market changes. Reputation in the new market will help and the project network will create referrals in due course. Until such time, CIL is dependent upon relationship opportunities introduced through TCC and a marketing mix approach. The mix is generated from several sources:

- Market feedback and intuitive feel for service packages based upon experience
- Short-term market research and longer term monitoring of demand patterns

Price is a sensitive issue. The construction industry is reticent to invest by economic predisposition. The previous regime led to a 'free' or minimum charge service. The service is being developed to reflect the high value with a corresponding price tag (Oxon Consulting, 2001). The true cost of production, transactions, and renewing the resource has to be recovered to perpetuate availability. The remix of the services, tailored to needs, will help the transition. Hence the 'product', in this case the service package, is changing. The delivery channel is essentially the same, but both more proactive and more targeted towards the end user segment concerned with projects. Promotion is reliant upon mailouts targeted both across the market and towards niches.

It is recognised that there are limits to this type of marketing mix promotion. The market is not so large that it can withstand too many and sustained direct marketing campaigns of this nature. However, it creates awareness, generates cash flow from a low cost base, and hence is an important baseline for growing more sophisticated and targeted marketing in the longer run. Repositioning in the market and creating awareness amongst a new customer base is a dynamic process, which requires a changing mix (Concrete Information Limited, 2003). The industry network is strong. The former network was based around the roles of technical directors, experts, and whoever performed these information gathering and disseminating roles. This new market is a slightly different network, a network of end users looking for project-specific knowledge to solve problems. Gaining access is the key, as market research indicates that the traditional gatekeepers are proving to be a barrier—rather than facilitators—to reaching the new market. The motives for this are unclear—pure stress and volume of work, wishing to use information as a tool of power within the organisation, or some combination. It is probably that gatekeepers are working in different ways in different organisations—some using their role as political kudos, some as a power position, some simply overloaded to search out and disseminate the information.

Successful access to the market will help to build relationships at the individual level. Multiple needs will help convert some relationships into members. There used to be one key membership package. Conversion is being facilitated by a series of different membership packages designed for different needs and closeness of relationship. It is anticipated that firms will identify the appropriate entry level and subsequently purchase bespoke services. The rationale is that through membership, issues of uncertainty are overcome concerning quality and availability of information.

Some direct enquiries are being made. These unsolicited enquiries have a long history. Most of these have been one-off requests for information or have been treated as such. Those that were not one-off tended to be from existing members or individuals well known in the industry network. What has changed in the market is that there are a number of enquiries that are being made which are more complex. In essence the demand is for knowledge, not information alone. This is positive market data for the changing patterns of demand and the need for external KM services. In addition, direct enquiries are being treated as potentially longer term, with the opportunity to establish or develop relationships. In all these cases where one-off information services are not required, the relationship approach is being used to define and develop bespoke KM services.

PRIMARY RESULTS

The restructured library and information services, formerly of the British Cement Association, have been re-branded Concrete Information Ltd. (CIL) and placed under joint venture ownership between the Concrete Society and the BCA. The restructuring has been aimed at providing the context for new service provision, summarised as:

- From information services to information and knowledge, especially for the project-specific KM market, that is, at the post-specification project end of the construction business
- From a low-cost service to a commercially sound service, priced to reflect the historic high value and value-added bespoke and service packages
- From a predominantly (and frequently re-active) marketing mix approach, towards securing new business to a combined highly proactive marketing mix and relationship marketing approach to new business
- From targeting technical directors or equivalent to also gaining access to end users on a project's post-specification

While there was some initial internal inertia and adjustment within CIL in the face and wake of restructuring, the new approach has been embraced and actively developed, momentum building up over the duration of change. CIL has faced constraints to the implementation of a commercial approach due to:

- The need for additional market data of client needs
- The reactive nature of demand within client organisations
- The inability of client organisations to be able to adequately identify their future needs

The run up to the launch of TCC provided a surrogate framework for CIL in identifying packages that mirror the services offered pre-specification in the post-specification market. CIL now offers levels of membership associated with different service packages (in addition to pay-as-you-go services). Membership levels are important, as services frequently have to be paid out of project budgets, at least initially.

However, the main constraint is external. Gatekeepers within the client organisation are creating a major obstacle to awareness creation of the services. Developing Internet and e-based solutions will provide wider access, hence awareness to the marketplace; however, targeted contact has to be established. The combination of a marketing mix and relationship marketing approach has been developed through a series of short campaigns to gain access and build new networks in the market.

CONCLUSION

The case study has been used to explore some of the issues raised in the literature. The results are of significance. The external provision of KM services to customers requires that KM theory on developing services needs to be engaged with marketing paradigms. This determines the approach to selling in the market. Theoretically, and even intuitively, the relationship approach would appear most suited. Both KM and relationship marketing are competency based and both therefore typically are located at the interface of human capacity and systems. However, this case has shown that this is not always necessary or appropriate. The larger the market, the more potential for a marketing mix approach, but also gaining market access to create awareness is a major issue and the marketing mix approach is efficient. This is likely to be the case in more start-up cases or cases of restructuring provision, as established networks and relations will not exist or will have been 'broken'.

It has also been demonstrated that the role of people within organisations is key. This is the case in terms of relationship building generally, and critical where gatekeepers are evident. They can be a very positive force—the internal marketers of the external service. Gatekeepers can also be a negative force, constraining the ability to create awareness and reach the end user. While CIL presents a case with some unique features, and thus it is not expected that gatekeepers will present an issue for some external providers, it is anticipated from this case evidence that there will be similar circumstances in place in many customer organisations for external providers.

Therefore the management of knowledge in the context of external provision becomes a potential nexus of knowledge-relationship-gatekeeper management. The areas are interlinked conceptually and empirically. The theoretical issues, such as those giving rise to uncertainty and a lack of awareness, asymmetry of the quality of information in advance can be overcome by addressing marketing and gatekeeper management in this context.

The impact also serves to highlight the need for further research to explore the external provision of KM services. The potential for market growth of external services needs further exploration. Further research at the KM-marketing interface is needed in terms of the application of KM tools, that is, techniques and technologies. In addition, these need to be explored within the paradigms of the marketing mix and relationship marketing. Specific research is needed into whether the experiences of the cement and concrete industry and CIL in particular are replicated elsewhere.

In terms of project managers and industry, this chapter is itself part of the awareness-creation process and thus makes an impact in its own right. In terms of the content, project managers are provided with lessons and guidance on accessing KM from external sources on proactive and reactive bases. External providers are provided with lessons and guidance on the creation of KM services through to the delivery of these services to the end user within the client organisation.

PRACTICAL TIPS AND LESSONS LEARNED

This chapter has provided pointers and insight into the following areas:

- Traditional information providers and consultants with strengths in particular areas of learning and knowledge can explore opportunities for externally providing KM services to others.
- Careful consideration should be given to the role of marketing, especially weighing the marketing mix and relationship marketing approaches against costs and opportunities.
- KM user firms must carefully manage the knowledge managers in order that the best interests of the firm are served and that project needs are clearly identified in time.
- Project managers and teams must be equipped in advance with sources of knowledge for problem solving both internally and externally from their firms, being aware that external provision of KM is expected to increase in the coming years.

Chapter 6.31
From Strategic Management to Strategic Experimentation:
The Convergence of IT, Knowledge Management, and Strategy

V. K. Narayanan

ABSTRACT

The new competitive landscape of the 21st century is forcing organizations to move away from traditional conceptualizations of strategy formulation towards an approach of strategic experimentation. The central objective of this chapter is to articulate the requirements that will be placed on IT as organizations move toward strategic experimentation. We base our central argument in contingency theory, which has postulated that to maximize organizational effectiveness, the IT infrastructure must be congruent with organizational structure and processes. Strategic experimentation requires different IT and knowledge management tools to support it than the ones currently prevalent. Information technology, knowledge management, and strategy formulation will have to coevolve for strategic experimentation to fulfill its promise. Each will have to change while maintaining its fit with the other two elements. This gives a renewed mandate for a strategic role of IT in organizations, a role that is central to organizational success.

Over the last decade, developments in information technology (IT) and strategic management have become increasingly intertwined in two major ways. First, advances in information technology and associated business processes (CAD, CAM, CIM, MIS, to name a few) have enabled an ever-increasing pace of product and process innovation, leading to a "hypercompetitive environment" (D'Aveni, 1994). Second, this new competitive landscape is forcing organizations to move away from traditional conceptualizations of strategy formulation towards an approach labeled "strategic experimentation." Still in its infancy and hence only partially practiced in many organizations, the emergent approach relies on knowledge management and enabling information technologies. It has, in turn, renewed the mandate for a strategic role of IT in organizations. Thus, as we enter the 21st century, the merging of the roles of strategy formulation and IT is fast becoming a major requirement for the competitiveness and success of the modern corporation.

The central objective of this chapter is to articulate the requirements that will be placed on IT as organizations move toward strategic experimentation. We base our central argument in contingency theory, which has postulated that for organizational effectiveness, the IT infrastructure should be congruent with organizational structure and processes. During the 1980s, the IT infrastructure changed to keep pace with the evolution of strategy formulation; indeed, the present "state of the art" IT infrastructure has emerged to support the dominant mode of strategy formulation—"strategic management"—practiced in large corporations. However, the hypercompetitive environments of the late 1990s have made it necessary for organizations to move towards a strategic experimentation mode, which requires different knowledge management tools to support it than the ones currently prevalent. We will argue that some fundamental changes in IT infrastructure are needed to support these knowledge management tools.

The plan of this chapter is as follows. First, we define key terms and introduce contingency theory as the root theory of our argument. Second, we articulate the concept of strategy and discuss its use of knowledge and information. Third, we focus on the role of IT and knowledge management in traditional strategic management approaches. In the fourth section we go on to argue that technological and environmental shifts increasingly require a new approach to strategic planning. This "strategic experimentation" approach is highlighted in the fifth section, setting the stage for our discussion of strategic experimentation's knowledge management and information technology requirements. We conclude with some thoughts on the developments in IT that are needed to enable this evolution towards strategic experimentation.

THEORETICAL BACKGROUND

Clarification of Terms

Information technology. When discussing technology, people often use the terms information systems and information technology interchangeably. While in some contexts the differences are relatively insignificant, we choose to differentiate between the two. For the purposes of this chapter, information technology is defined as the physical equipment (hardware), software, and telecommunications technology, including data, image and voice networks, employed to support business processes (Whitten & Bentley, 1998). The overarching plan for IT deployment within an organization is called the IT architecture. Technology infrastructure refers to the architecture, including the physical facilities, the services, and the management that support all computing resources in an organization (Turban, McLean, & Wetherbe, 1996).

Knowledge management. The meaning of the term "knowledge" has been the subject of much debate in the literature, especially in relation to data and information. We adopt the view that data are objective, explicit pieces or units, information is data with meaning attached, and knowledge is information with an implied element of action. Davenport and Prusak (1998) offer the following definition:

Knowledge is the fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms. (p. 5)

Knowledge management is "a set of business practices and technologies used to assist an organization to obtain maximum advantage from one of its most important assets—knowledge," (Duffy, 2000, p. 62). In other words, it is the process of actively capturing, sharing, and making use of what is known within the organization. IT often facilitates knowledge management initiatives by integrating repositories (e.g., databases) and indexing applications (e.g., search engines), and user interfaces. Davenport and Prusak (1998) note that knowledge management involves, in addition, traditional management functions: building trust among individuals, allocating resources to knowledge management initiatives, and monitoring progress of the initiatives.

Knowledge management leverages the prevailing IT infrastructure; in turn, the IT infrastructure is typically designed to meet organizational requirements. The dominant prescriptions have flowed from contingency theory, which is the foundation for our argument.

Contingency Theory

Dating back to the mid-1980s, the information systems community has relied upon prescriptions from contingency theory for the design of IT infrastructures. Originally developed in organization theory (see Narayanan & Nath, 1993, for a historical review), contingency theory, when applied to information systems, asserts that organizations are interpretation systems: They continuously scan their environment for information (Daft & Weick, 1984), interpret the information, and take action based on their interpretation, learning over time from their experiences. The right type and amount of information will reduce uncertainty and ambiguity as decision makers analyze their environments. Thus the thrust of IS design should be to match the type of information to the level of uncertainty present in a given situation (Daft & Lengel, 1984).

Organizations generally have an abundance of data and information; their challenge is to make intelligent use of the data to solve business problems by reducing uncertainty and dealing with equivocality (lack of clarity or problem definition; Daft & Lengel, 1986). In other words, in situations of high uncertainty, the very richest information is necessary. For example, if a problem is complex, a face-to-face meeting is suggested as most effective. Therefore, according to the theory, better fit between the IT infrastructure and organizational structure and processes leads to superior organizational performance. Research studies have recently tested this hypothesis, with findings partially supporting the premise (e.g., Keller, 1994). The general rule of thumb is for the organization to use the simplest technology available that will satisfactorily meet the decision makers' needs (Warner, 2001).

We will argue that IT, following contingency theory, has successfully evolved to support the strategy creation process as presently practiced. But, since strategy creation processes are themselves undergoing fundamental transformation, IT will also have to evolve further.

THE CONCEPT OF STRATEGY AND THE ROLE OF KNOWLEDGE

The concept of "strategy" explicated in strategic management is one of marketplace strategy, i.e., winning in the marketplace against competitors, entrenched or incipient. To quote Fahey and Randall (2001), for example, "to enjoy continued strategy success, a firm must commit itself to outwitting its rivals" (p. 30). A large body of literature on strategic management has persuasively argued that effective strategy creation and execution are central to a firm's performance (e.g., Covin, Slevin, & Schultz, 1994; Wisner & Fawcett, 1991). Strategy creation involves both formulating goals—defined in terms of external stakeholders rather than operational milestones—and crafting the strategic means by which to accomplish these goals (Hofer & Schendel, 1978). The means typically include business scope, competitive posture, strategic intent, and the organizational mechanisms for implementation.

Strategy creation processes are distinct from operational decision processes in several ways. First, strategic decisions involve irreversible commitment of substantial resources (Grant, 1996). Second, they have consequences that are removed in time and not clearly discernible. Third, and perhaps most important to our purpose, they represent "messy" problems (Mason & Mitroff, 1973). That is, the decision context is characterized by incomplete and ambiguous stimuli, contradictory and sometimes vaguely felt data, and partially controllable contexts. The decision makers in strategic situations have to interpret and make sense of this messy data and chart the firm's course into the future.

Without a doubt, strategy makers use several sources of explicit or codifiable knowledge while they craft and implement a strategy. To facilitate strategy creation, firms typically employ several complementary approaches: competitive intelligence systems (e.g., Codogno, 1999; Hilmetz & Bridge, 1999; Martinsons, 1994), market research that focuses on customer surveys and behavior (e.g., Denny, 1998; Sterling & Lambert, 1989), and financial modeling and related knowledge bases of the impact of decisions on financial and human resources (e.g., McAleer & Wightman, 1993; Farin, 1991; Asch, 1991; Mockler & Dologite, 1988).

In addition to explicit data or information in the "objective" sense, the decision makers involved in strategy creation rely heavily on the subconscious tacit knowledge (Nonaka, 1991) they have accumulated over the years. This includes judgment, intuition, well-reasoned conjecture, and individual cognitive maps (Dutton, Fahey & Narayanan, 1983). Tacit knowledge is highly subjective, uncodified, and shaped by the individuals' past experiences. It may include predictions of competitive behavior based on the intimate knowledge of the actors in competitor organizations, of how consumers and distribution channels may respond based on vaguely articulated past experience, or even an intuitive assessment of how the internal organization may execute a strategy.

In practice, the process of strategy creation has often taken the form of strategic planning. Comprehensive strategic planning (Gluck, Kaufman, & Walleck, 1978) has historically been practiced in large corporations: A celebrated example is the use of scenarios by Royal-Dutch Shell ("The Worldwide Search for Oil," 1975). It typically consisted of several sequential stages of decision making involving diagnosis, alternative development, evaluation and choice, and implementation. In each step, the strategic planners emphasized deliberate juxtaposition of "objective data" and careful analysis, with top management judgment, thus highlighting the role of tacit knowledge.

The conjunction of explicit and tacit knowledge, indeed the emphasis on tacit knowledge, has fueled an evolution of our conception and practice of strategic planning over the years. Writing in the '70s, Gluck et al. (1978) identified four phases of evolution: budgeting, long-range planning, strategic planning, and strategic management. Each phase of evolution incorporated the lessons from the earlier phases but also took into account the emerging realities faced by corporations. Gluck (1985) noted that during the 1980s the "strategic management" phase represented the cutting edge of practice in the world. We will first examine the role of IT and knowledge management in the (now) traditional "strategic management" phase for comparison purposes.

THE ROLE OF KNOWLEDGE MANAGEMENT AND IT IN TRADITIONAL STRATEGIC PLANNING

Traditionally, the focus of IT infrastructure was to capture the knowledge of experts in a centralized repository (Davenport & Prusak, 1998; Grover & Davenport, 2001). The users of technology approached the repository with a specific purpose, i.e., to obtain knowledge—or more often, simple data—in a narrowly defined domain (Broadbent, Weill, & St. Clair, 1999). Most of the knowledge contained in databases was characteristically explicit and historical (e.g., competitor pricing, market share), and the infrastructure served to facilitate functional decision making or to automate routine tasks (as in reengineering).

Consequently, IT originally played a significant, yet ultimately limited role in the strategy creation process because of its initial emphasis on codified knowledge and explicit databases. Management information systems (MIS) arguably generated information that was only moderately applicable to strategy creation, as noted in early writings on the linkage between MIS and strategic planning (e.g., Lientz & Chen, 1981; Shank, Boynton, & Zmud, 1985; Holmes, 1985). As indicated in our earlier discussions of the information demands of strategic decision making, the complex and ambiguous problem-solving contexts confronted by strategic planning require rich media interaction and tacit information exchange beyond the scope of traditional MIS (Daft & Lengel, 1986).

The active management of knowledge was similarly underdeveloped. Despite the fact that strategic decision makers emphasized the role of tacit knowledge (albeit using other terms such as "judgment"), the actual importance of knowledge was not explicitly recognized. Formalized knowledge management (Davenport & Prusak, 1998) with its associated terminology and tools is a recent development and, as such, did not traditionally inform the strategic planning process.

Recent Advances

However, IT and knowledge management have not remained stagnant. The shifts that have taken place in IT infrastructures over the last decade have brought them closer to the creators of strategy; indeed, IT and knowledge management are enablers in the contemporary strategic management practice. Table 1 compares traditional with "state-of-the-art" IT infrastructures to illustrate this point. The basic focus of IT infrastructure is moving from the functional work unit to a process orientation. Whereas computer systems were once the focal point, the new infrastructure is network-centric, with an emphasis on business knowledge (Nidumolu, Subramani, & Aldrich, 2001; Broadbent, Weill, & St. Clair, 1999). For example, traditional search engines utilized rule-based reasoning to identify elements matching specific search criteria; the "state-of-the-art" knowledge management systems employ case-based search techniques to identify all relevant knowledge components meeting the user's request (Grover & Davenport, 2001). It now takes into account contexts that include cross functional experts and knowledgeable on a wide variety of potentially relevant issues. Additionally, there is greater emphasis on the integration of infrastructure with structure, culture (Gold, Malhotra, & Segars, 2001), and organizational roles (Davenport

Table 1. A comparison of traditional and state-of-the-art infrastructures

	Traditional Infrastructure	State of the Art Infrastructure
A. Components of IT Infrastructure		
Focus	Functional unit.	Processes.
Approach	Computer-centric and technology oriented.	Network-centric and process-oriented.
Purpose	Facilitate batch processing; process simplification; codification and uncertainty reduction.	Facilitate transactions across unit boundaries; promote process innovation; personalization and communication; encourage exploration.
Structural Characteristics	Static and Formal Structure, with separate, functionally independent legacy systems.	Dynamic and flexible structure; distributed systems, including firm-wide integration.
Physical Equipment	Desktop computers; local area networks (LAN) and wide area networks (WAN).	Mobile and wireless computer capabilities: E.g., laptops and cellular phones.
B. Types of Knowledge Management Supported		
Type of Knowledge	Emphasizes systems knowledge; explicit; narrow domain.	Emphasizes business knowledge; broad domain.
Implementation of Knowledge Management	Projects.	Integration of knowledge with business.
Knowledge Infrastructure	Fragmented knowledge repositories. Deliberate structure development.	Fluid exchange of knowledge and communities of practice (collaboration). Emergent structure.
Search Mechanism	Rule-based search engines.	Case-based search criteria.

& Prusak, 1998). In many ways, the newer IT infrastructures have enabled marshalling of explicit knowledge throughout the organization to speed up strategy creation and implementation.

Strategic management was a response to the environment of the 1980s. Since then, Gluck's work has not been updated and few have highlighted the emerging landscape of strategic planning. In the following, we will discuss the environmental developments that have altered the context for strategy creation processes.

THE CHANGING ORGANIZATIONAL ENVIRONMENT

The 1990s witnessed a revolution in information and telecommunications technologies, bringing in their wake radical changes in organizational environments. For example, Fahey and Randall (2001) identify several concrete marketplace changes: product proliferation, technology convergence, breakdown of industry boundaries, and global competition, among others. Michael Hammer (in Pink, 2001) notes the transition of technologies that lie at the core of information systems: from mainframe computing to personal computers, the Internet, various intranets, and eventually, to extended networks across linked businesses. As we noted in our introduction, the competitive landscape created by rapid technological change has recently been described as "hypercompetition" (D'Aveni, 1994).

The changes in organizational environments—both intensified competition and the possibilities opened up by technological developments—have created three major imperatives for organizations: time compression, globalization, and technology integration (Narayanan, 2001). In addition, the increased environmental dynamism also contributes to an increase in the degree of uncertainty confronted by strategic managers, calling into question traditional planning practices.

Thus, the environmental changes and the potential for business process transformation triggered by technology are altering the traditional strategic planning processes outlined by Gluck (1985). During the 21st century, a new type of strategy creation process is evolving which we term "strategic experimentation." With this evolution, the relationship between strategy creation, knowledge management, and IT is undergoing a profound shift. In the remainder of the chapter we elaborate on this transition to strategic experimentation, describe the emerging roles of knowledge management and IT, and outline a set of theoretical and practical implications.

FROM STRATEGIC MANAGEMENT TO STRATEGIC EXPERIMENTATION

Throughout all four phases of strategic planning documented by Gluck et al. (1978, 1980), including their final phase of "strategic management," three implicit assumptions have remained largely unchanged:

1. There is one guiding strategic vision, derived from the analysis of the current and future internal and external environment.
2. This vision is translated into one strategic initiative (or very few initiatives) that involve large parts of the organization.
3. The strategic initiative is implemented with the aim of maximum impact, i.e., using significant resources to ensure its success.

In its most extreme form, this relatively sequential approach to strategy creation and execution leads to the identification of the one winning strategy that has the highest probability of success; thus, it is logical to commit the maximum available resources to its implementation in order to further increase this probability. The goal is to obtain a sustainable competitive advantage vis-à-vis the firm's rivals. Uncertainty is reduced ex ante using analytical forecasting techniques as well as market research. This approach to planning seems to have been effective during the 1980s when the environment was moderately dynamic, and as a consequence firms faced limited uncertainty.

In contrast, firms today often face high velocity environments (Bourgeois & Eisenhardt, 1988; Eisenhardt, 1989). In high tech industries, for example, market participants frequently confront great uncertainty over technological possibilities, consumer preferences, and viable business models. This high level of ambiguity often results in a situation where (a) traditional methods of ex ante uncertainty reduction (e.g., market research) fail, and (b) the costs and risk of the traditional "big bet" strategic management approach begin to outweigh its advantages in terms of focus, decisiveness, and concentrated resource commitment. It is in this situation that the emerging strategic experimentation approach holds significant promise.

Strategic experimentation (Brown & Eisenhardt, 1998; McGrath, 1998; McGrath & MacMillan, 2000) draws on real-options reasoning (e.g., McGrath, 1997), discussions of exploration vs. exploitation (March, 1991), as well as trial-and-error learning (e.g., Van de Ven & Polley, 1992). Companies engaging in strategic experimentation continually start, select, pursue, and drop strategic initiatives before launching aggressively those initiatives whose value is finally revealed (McGrath & MacMillan, 2000, p. 340). Strategic initiatives thus serve as low-cost probes (Brown & Eisenhardt, 1998) that enable discovery learning about product technology and market preferences. They also serve as a stepping stone option for future competitive activity in that particular product-market domain. The role of the strategic manager is to administer a portfolio of strategic initiatives which represent an appropriate mix of high and low uncertainty projects and to maximize the learning from these real options (McGrath & MacMillan, 2000).

Table 2 highlights a number of key differences between the traditional strategic management and the strategic experimentation approach. While strategic experimentation is to some extent the logical extension of the strategic management philosophy, it represents a fundamentally different view of the practice of strategic planning and the path to competitive advantage. Movement is emphasized over position in this approaches. Thus, competitive advantage is viewed as temporary at best, and hence, innovation and learning are considered crucial to success. The spirit of strategic experimentation is perhaps hinted at by Jack Welch, the (now retired) legendary chairman and CEO of General Electric, who in a 1999 interview told the The Wall Street Journal that every acquisition GE makes has

[…] a perfect plan, but we know that 20 or 30% will blow up in our face. A small company can

Table 2. Comparison of approaches: Strategic management and strategic experimentation

	Strategic Management	Strategic Experimentation
Premise/Goal	Seek sustainable competitive advantage	Seek disruption and temporary competitive advantage
Focus	Single core strategic initiative	Portfolio of initiatives
Resource commitment for each initiative	High	Mostly low, higher for more mature initiatives
Role of Uncertainty	Uncertainty is reduced ex-ante, e.g. through market research or futurism	Uncertainty is reduced ex-post by direct experience through small-scale experiments with real options character. These then reduce uncertainty for new or revised strategic initiatives.
Role of Knowledge	Fact based, explicit knowledge is used to identify opportunities and to reduce uncertainty over the outcome of strategic initiatives. Decision makers' tacit assumptions also play a role.	Experiential knowledge is discovered stepwise through series of experiments.
Role of IT	Supply and analyze explicit knowledge	Support acquisition of experiential, tacit knowledge, sensemaking support.
Environmental Context	Slow-paced, low uncertainty	Fast-paced, high uncertainty
Planning Timeframe	Usually long	Usually short

only afford to make one or two bets or they go out of business. But we can afford to make lots more mistakes, and in fact, we have to throw more things at the walls. The big companies that get into trouble are those that try to manage their size instead of experiment with it [italics added]. (Foster, 2001, p. A18)

Strategic experimentation is especially appropriate for high velocity environments such as emerging product markets with high uncertainty surrounding both technology and customer preferences (e.g., the early personal digital assistant (PDA), Internet appliance, and satellite-based telephony markets). Here, low-cost probes can be very effective in gaining knowledge and reducing uncertainty while minimizing exposure to the results of faulty assumptions. To illustrate, when Apple introduced its Newton handheld computer (see Case Vignette 1), it followed a traditional paradigm of immediately launching a highly complex product, with heavy marketing support, in order to gain a sustainable first-mover advantage. Although the market did not yet exist, sales expectations were built on market research. In contrast, the strategic experimentation approach would have implied a small-scale launch of one (or potentially even multiple) simple version(s) with limited resource commitments in order to learn from the market reaction. Subsequently, that learning experience would be used as input for future products.

THE ROLE OF IT AND KNOWLEDGE MANAGEMENT IN THE ERA OF STRATEGIC EXPERIMENTATION

Since “strategic experimentation” represents the cutting edge of ideas in strategic management, we should expect significant advances in tool development and utilization in the next few years. These advancements will enable firms to move the idea towards normal organizational practice. Knowledge management is critical in strategic experimentation, at the core of which lie innovation, experimentation, and learning. Therefore, it is not surprising that many of the tools currently being developed have emerged from the knowledge management field. IT can accelerate the development of strategic experimentation by designing infrastructures that accommodate the new knowledge management demands imposed by this new mode of planning.

We develop the above argument in three steps: (a) identifying the requirements for implementing strategic experimentation, (b) summarizing the knowledge management tasks to fulfill these requirements, and (c) discussing the imperatives the knowledge management tasks generate for the IT infrastructure. Our arguments are summarized in Table 3.

Functional Requirements of Strategic Experimentation

Strategic experimentation necessitates four major functions to be performed by an organization: (a) rapid decision making, (b) integration of learning from experiments, (c) diffusion of learning across organizations, and (d) managing a portfolio of strategic experiments.

1. Rapid decision making. Recall that the need for strategic experimentation was triggered by the emergence of hypercompetitive environments, where rapid decision making is a major requirement for success (Eisenhardt, 1989; Nadkarni & Narayanan, 2001). At the strategic level, decision making relies on tacit knowledge that incorporates the judgment and experience of top-level executives. Thus, the ability to quickly marshal tacit knowledge in all phases of decision making is a central requirement in strategic experimentation. At a minimum, this involves embedding urgency and speed in

Table 3. Knowledge management and IT requirements in the era of strategic experimentation

Strategic Experimentation Challenge	Knowledge Management Tool	Benefits and Outcomes	Examples of IT Tools / Applications in Current Use	Future Development Needed
Rapid decision making	Visualization tools	Reduces decision time by allowing rapid visualization and prototyping as a basis for feasibility and go / no-go decisions.	Rapid prototyping, Computer-Aided Design, CASE tools	Real time display
	Group decision facilitation tools	Reduces decision time by allowing users to share knowledge asynchronously or in real time using rich media independent of geographic location.	Group Support Systems (GSS), MS NetMeeting, Lotus Notes	Advanced multimedia and communication capabilities
	Knowledge representation	Intervention to identify individual mental models and to promote development of shared assumptions and goals.	Decision Explorer	Repository of mental models to promote knowledge sharing
Rapid integration of learning from experiments	Decision histories	Learning requires the understanding of the original situation as well as the assumptions, goals, and reasoning behind the decision to initiate the strategic experiment.	Relational Databases, Decision Support Systems (DSS)	Qualitative databases
	Group brainstorming and decision support	Capture and integration of knowledge from a wide variety of members involved with the experiment	GSS using rich media, Decision Explorer	Multimedia enhanced communication facilitation
	Shared communication platforms	Enable efficient exchange of information and collaboration on individual documents and applications.	Electronic Mail, NetMeeting, Workflow Management Systems, GSS, Lotus Notes	Open platforms – integrating multiple communications systems
Diffusion of learning from experiments throughout the firm	Knowledge Maps or Networks	Represent who knows what; allow rapid access to experts and expertise.	Databases	Dynamic expertise coordination
	Repositories of case histories (learning histories) to identify relevant precedent that sheds light on a particular problem	Compiles chronology of events and decisions; enables access to case histories; facilitates distribution of knowledge	Case based expert systems, Intranets, DSS	Case-based and focused search engines
Management of a portfolio of experiments	Tools for monitoring experiment status	Provides continuous feedback about both qualitative and quantitative performance of strategic experiments	DSS, Content Analysis Applications	Neural networks

three activities: development of pathways or scenarios to the future, identification of failures, and investment of resources in potential blockbuster strategies if, and when, they become apparent.

2. Integration of learning from experiments. Organizational learning, another core concept in strategic experimentation, requires that appropriate learning be distilled from each experiment. This orientation combines decision making and learning: Initiatives judged to be failures are not merely weeded out, nor are successes viewed simply as alternatives to be financially backed. Rather, failures become occasions for discovering root causes, and successes are opportunities to identify best practices.
3. Diffusion of learning. In addition, organizational learning has to be diffused throughout the organization. Since formal organizational channels may stifle transmission of tacit knowledge, diffusion may require interactions among "communities of practice" (Grover & Davenport, 2001; Davenport & Prusak, 1998). An organizational architecture, incorporating relevant tools and IT infrastructure, has to be designed to support these interactions.
4. Managing a portfolio of strategic experiments. Unlike in previous eras, strategic experimentation requires maintenance and management of a portfolio of initiatives. This has three major implications. First, the knowledge base for decisions must be broader and richer, simply due to the increase in the number of initiatives. Second, the knowledge base becomes much more complex, since the initiatives themselves differ in terms of the mix of tacit and explicit knowledge. In essence, newer initiatives are likely to be more dependent on tacit knowledge, whereas mature ones can be augmented by explicit knowledge. Finally, and flowing from the above, the sheer number of people involved in the process will be larger, given that specialized pockets of tacit knowledge would have developed around specific strategic initiatives.

Taken together, these four functions have brought about the need for tools that can accelerate acquisition, assembly, and processing of tacit knowledge, which is likely dispersed throughout the organization.

Knowledge Management Tools

As detailed above, during the strategic experimentation phase, the key purpose of knowledge management is not one of uncertainty reduction and process simplification, but one of rapid decision making, integration of learning from strategic experiments, diffusion of learning, and managing a portfolio of experiments (cf., Broadbent, Weill, & St. Clair, 1999). Table 3 also displays the key knowledge management tools that have evolved to support strategic experimentation. As shown in the table, the tools facilitate:

1. Rapid decision making with the help of tools designed to promote collaborative work in groups. Current tools support visualization and prototyping, group decision facilitation, and knowledge representation. Each method attempts to reduce the time needed for a group to progress from problem identification to solution implementation. These tools help to coordinate the use of data, systems, tools, and techniques to interpret relevant information in order to take action (Little, Mohan, & Hatoun, 1982).
2. Rapid integration of learning from experiments using learning histories (Roth & Kleiner, 1998), group brainstorming, and shared communication platforms.
3. Transmission of learning through knowledge maps identifying the experts in specific areas and repositories of case histories. These

systems are evolving to include dynamic updating of repositories and focused search tools to reduce information overload.
4. Managing portfolios of experiments, currently through DSS and other rich data applications including cognitive mapping, which can be used to capture both knowledge and feedback.

In Case Vignette 2, we have summarized a Cap Gemini Ernst & Young methodology, that (while much more general and not explicitly designed for this purpose) illustrates how some of the knowledge management tools are able to support a specific strategic experiment. During the era of strategic experimentation, organizations will have to learn to do similar strategic experiments on an ongoing basis. Thus, knowledge management tools will be called on to perform four interrelated functions: to customize knowledge for specific decisions on a recurring basis, to connect communities of practice, to assist the simultaneous processing of explicit and tacit knowledge, and to embed speed in decision making.

Since some tools designed to accomplish customization — that have already found their way into practice — originated with IT professionals, they are built upon existing IT infrastructures. For example, the state-of-the-art knowledge management systems that employ case-based search techniques to identify all relevant knowledge components meeting the user's request (Grover & Davenport, 2001) were developed by IT professionals. However, many of the tools detailed in Table 3 have emanated outside the IT field. For example, knowledge representation tools that capture tacit and explicit knowledge have emerged from decision sciences (Eden & Ackermann, 2000) and managerial cognition (e.g., causal mapping, see Narayanan & Fahey, 1990; Nelson, Nadkarni, Narayanan & Ghods, 2000; Kemmerer, Buche & Narayanan, 2001). Similarly, the tacit knowledge transfer among communities of practice is enhanced by telecommunications technologies (e.g., videoconferencing). The potential advancement of tools that have not originated with IT can be enhanced by further evolution of IT infrastructures in organizations, a point to which we now turn.

Needed Developments in the IT Infrastructure

As Davenport and Prusak (1998) state, "knowledge projects are more likely to succeed when they can take advantage of a broader infrastructure of both technology and organization" (p. 155). This is as true in strategic experimentation as it is in typical knowledge management projects. Cap Gemini Ernst & Young's ASE is a case in point: It uses a combination of IT and process tools to facilitate the rapid integration of explicit and tacit knowledge and supports knowledge exchanges through rich media visualization tools as well as knowledge repositories that supply the needed explicit knowledge. In the end, such integrated organizational, IT, and knowledge management tools are needed to implement fast sense making in organizations (Boland, Tenkasi, & Te'eni, 1994).

Knowledge characteristics of strategic experimentation and the application of knowledge tools detailed above impose additional requirements on the IT infrastructure over and beyond those in the strategic management phase. Consider how each of the following functions can be enhanced by IT infrastructure development:

1. Future advances can significantly reduce the time expended in solution development through real time displays and expand opportunities for geographically dispersed collaboration. Also, advanced multimedia and communication capabilities would increase the benefits of GSS and DSS tools.
2. Learning from experiments can be enriched by qualitative database construction, multimedia enhancements to communication applications, and open platforms to permit

the sharing of knowledge over various communication channels, including wireless media.

3. Today, diffusion is hampered by information overload that has intensified competition for the user's attention (Hansen & Haas, 2001). To solve the problem, search tools should include separate parameters for content, rationale, and purpose of the query in order to isolate salient responses. Additionally, knowledge repositories must be maintained to ensure the contents are accurate and of high quality. Also, maintenance that is currently provided by intermediaries (Markus, 2001) might be performed faster by automated systems.
4. Expert systems or neural networks may be developed to manage and track portfolios, promoting reuse of the knowledge captured.

From our discussion, the significant implication for IT infrastructure is the need for technology integration (Narayanan, 2001), i.e., integration with other technologies and disciplines. We can identify two fundamental thrusts of technology integration:

1. IT infrastructure should exploit the potential for integration with other hard technologies such as telecommunications to enhance the organizational capacity for speed and carrying capacity for tacit knowledge.
2. IT should seek to interface with decision sciences to embed AI-based processing tools and with cognitive theorists to capture the tacit knowledge pervasive in organizations.

CONCLUSIONS AND IMPLICATIONS

We have argued that the technological changes of the 1990s have ushered in the need for strategic experimentation as the metaphor for planning practice. Strategic experimentation involves (a) maintaining a portfolio of strategic thrusts, (b) rapid decision making so that successful experiments are backed and failures are weeded out quickly, (c) learning from both successes and failures, and (d) diffusion of both explicit and tacit knowledge throughout the relevant segments of an organization. This phase requires fundamental shifts in our view of knowledge management, including its significance, use, and tools. Finally, we have argued that the shift to strategic experimentation requires fundamental shifts in the development of IT infrastructure. Instead of developing in relative isolation to other disciplines, IT should focus on technology integration by working in close collaboration with telecommunication technologies, artificial intelligence community, and managerial cognition scholars.

Information technology, knowledge management, and strategy formulation will have to coevolve for strategic experimentation to fulfill its promise. Each will have to change while maintaining its fit with the other two elements. In our opinion this gives a renewed mandate for a strategic role of IT in organizations, a role that is central to organizational success.

Case Vignette 1

Traditional Strategic Management in an Uncertain Environment: The Apple Newton

Apple launched its Newton PDA in August 1993, a first major entry into an emerging market full of technological and marketing uncertainties. Apple had made large-scale investments into the development and marketing of the Newton, launching it with great fanfare. However, the product was a flop and was ultimately discontinued in 1998. Several reasons can help explain this failure: At the time of launch, the demand for handheld computers was still very small and would not take off until years later. Similarly, technological challenges (e.g., handwriting recognition) were as yet largely unresolved, despite claims to the contrary. Finally, what consumers wanted from a PDA was far from clear, and a dominant design exemplifying typical product category attributes had not yet evolved. In the end it was the much less advanced, smaller, simpler Palm that would define the PDA mass market. Given the uncertain environment in 1993, a strategic experimentation approach would have probably been more appropriate than a traditional strategic management approach. Early sales numbers—encouraging by other standards—were seen as a failure due to Apple's high resource commitments, encouraging a threat rigidity response of persistence and incremental improvements. In contrast, a less costly and high profile launch would have allowed Apple to declare initial sales a conditional success. It could then have exploited its first-mover advantage by leveraging the insights it had gained about consumer needs and technological challenges to launch another, completely redesigned product into an environment with less uncertainty and risk. As it turned out, it was another company—Palm Inc.—that learned from Apple's mistakes and, in essence, appropriated the rents of Apple's failed experiment. Case Vignette 2

Using IT to Support Strategic Experimentation: CGEY's Accelerated Solutions Environment

Cap Gemini Ernst & Young's Accelerated Solution Environment (ASE) is an integrated combination of group process, physical environment, and technology that supports rapid problem solving and strategy making for complex issues. The ASE combines behavioral process components with IT-based support tools and infrastructures. In 2-3 day ASE events, IT is used in the form of intranet support, online research options, document libraries, documentation of key sessions and session outcomes, graphic support, rapid prototyping, and simulation and modeling tools. The ASE is an example of a new tool that uses IT in a way capable of supporting strategic experimentation. First, it uses IT to improve the speed of decision making, which is key to strategic experimentation that confronts rapidly changing environments and multiple decision points due to its incremental real-options logic. Second, the ASE focuses on creativity, facilitating the exchange of tacit knowledge while also providing necessary explicit knowledge. Thus, IT moves from simply providing the inputs for decision processes to facilitating the individual and collective sense making processes of decision makers. Real-time documentation functions, in addition to supporting the current decision process, also provide a documentary basis to later understand the history and rationale behind decision outcomes achieved. This knowledge is necessary for individuals and firms to be able to extract the maximum possible learning from the strategic experiments conducted. As an integrated process and information tool that can accommodate multiple stakeholders, ASE supports the rapid creative formulation of strategic experiments as well as the integration of the tacit experiential learning from these experiments. It also aids in the translation of such knowledge into new experiments and initiatives.

ACKNOWLEDGMENT

The authors thank the Fulbright Alumni Initiatives Program for an award supporting the PhD seminar in Knowledge Management that led to the formulation of this chapter. The proposal for the chapter was written when the first author was the director of the Center for Management of Technology at the University of Kansas.

Chapter 6.32
What Difference Does it Make: Measuring Returns of Knowledge Management

Abdus Sattar Chaudhry
Nanyang Technological University, Singapore

ABSTRACT

This chapter provides an overview of performance measurement in the area of knowledge management. Salient features of main measures have been described and their role in determining the return on knowledge management work highlighted. While Balanced Scorecard and Intangible Assets Monitor provide comprehensive coverage, several other measures are also in use. A recent study and review of applications of main KM performance measures in selected organizations showed several areas of commonality in the objectives of performance measurement and revealed differences in approaches to the application and presentation of various performance measures. Developing a measurement system for knowledge management is considered the key to the competitive success of the organization.

INTRODUCTION

It is becoming increasingly important that organizations are able to show the value of knowledge management applications by measuring the return on investment of knowledge management activities. A variety of approaches have been used for performance measurement. Most of these measures, however, seem to provide only a partial coverage towards the measurement of the impact of knowledge management work. The processes of knowledge management that underlie and contribute to the creation of knowledge assets and the success of the knowledge management projects have not been covered in depth and effectively by these measures.

This chapter highlights the importance of using appropriate measures to determine the value of knowledge management in an organization.

Based on an extensive literature review, the chapter provides an overview of the main measures currently in use for measuring knowledge assets. The chapter also reports the results of a study carried out to review the use of KM performance measures in selected organizations. Commonalities of applications of performance measures are pointed out and the need for development of more relevant measures is stressed.

An extensive review of web sites and portals in the knowledge management area was carried out. Information was sought from selected organizations through interviews and e-mail communications for verification and validation purposes. The discussion is expected to be helpful in understanding and promoting the use of performance measurement in the context of knowledge management. With the growing importance of performance measurement, the examples of performance measurement systems used by organizations that are active in knowledge management will be useful in offering some practical insights into the use of performance measures to measure the impact of knowledge management, as well as serve to highlight the way these measures can be used to enhance the organization's overall performance.

Context

Measuring the impact of knowledge management (KM) processes is important in determining the benefits that can be reaped by appropriate KM efforts. O'Dell and Grayson (1998) identified measurement as one of the key enablers in their model for transfer of best practices. They defined the measurement as the process of creating and using indicators/measures to determine how each enabler impacts the best practice transfer process within the organization. Traditionally, organizations have used financial indicators for measurement. These indicators, however, are not adept at capturing the measurement of the intangible impact of knowledge management practices and processes on the organization. Some organizations have tried to measure learning and knowledge through the application of a combination of indicators such as customer satisfaction, financial performance, and job satisfaction, among various other measures. But most of these measures are not precise enough to assess the use of knowledge management and may only give a superficial view of the impact of KM. These measures also tend to commodify knowledge and capture it as a static and tangible asset.

Recently, there have been attempts to use the Balance Scorecard (Kaplan, Norton, 2001) and the Intangible Assets Monitor (Sveiby, 1996) to measure the intellectual capital. Barchan (1997) has cautioned that, even though measurement is essential in knowledge management, it is better not to just simply jump on the bandwagon without giving proper thought to what appropriate measures will be used. He stresses that it is pertinent to create an internal understanding of what the intangible assets are and what they mean to the overall performance of an organization (Barchan, 1998, 1999, 2000).

The identification of the performance measurement models in knowledge management and the characteristics of performance measures and their criteria will allow for the use of these indicators for comparative purposes. This will allow organizations to compare and benchmark their knowledge management work with other organizations. As an emerging area of importance in knowledge management, there is a dearth of information available on this aspect.

Wenger, McDermott, and Snyder (2000) discuss the benefits of KM measurement for communities of practice. They stress that measurement efforts are well worth the investment. Measures of value are instrumental for communities of practice to gain visibility and influence, and to evaluate and guide their own development. Measures legitimize the function of communities of practice in the organization, reinforce member participation, and provide a basis for prioritizing activities. Measures help communities translate the value of what they do for teams and business units into the lingua franca of the organization. These authors feel that measures support management processes that help to further integrate and institutionalize the role of communities in the organization. Communities need measures to know how they are doing and to guide ongoing efforts to become more vibrant and effective. It is, therefore, very important for knowledge professionals to be aware of the measures in use and to be comfortable in applying these measures to determine the value and impact of knowledge management in their organizations.

Major KM Measures in Use

Dhansukhlal and Chaudhry (2002) have summarized the features of major measures used in the area of knowledge management. Main measures in use include the Balanced Scorecard (BSC) and the Intangible Assets Monitor (IAM), and Skandia's Intellectual Capital Taxonomy (ICT) & AFS Business Navigator (ABN). These measures provide a comprehensive, developed and tested approach to performance measurement in knowledge management. A summary of salient features of these measures is given in the following section.

Balanced Scorecard (BS)

The Balanced Scorecard (BS), first developed by Kaplan and Norton in the early 1990s in the United States, represented a "method of measuring the performance of a firm beyond the typical financial measures." The Balanced Scorecard was designed primarily to take a more "balanced view" of internal performance measurement (Giaever, 1999). The Balanced Scorecard emphasized that financial and non-financial aspects are part of the information system for employees at all levels of the organization (MeansBusiness, 2000).

The Balanced Scorecard was a strategic management approach where a vision could be translated into a clear set of objectives or critical success factors and this allowed for the linking of corporate goals with direct performance measures within a framework specific to a firm. Each of the critical success factors formed the basis for key performance indicators, which then helped to measure each objective's performance, representing a broad range of outcome measures and performance drivers. This multi-faceted measurement and management tool has been used for communications, alignment, improvement and control. This tool has also been identified as one of the methods of measuring the impact of knowledge management.

It was best summarized by the BMA Group (2000) as a "management system that focuses on the efforts of people, throughout the organization, toward achieving strategic objectives" and could be used to motivate staff "to make the organization's vision happen." Essentially, the Balanced Scorecard is a concept helping to translate strategy into action (QPR Online, 2000). Olve, Roy and Wetter (1999) have pointed out the main measures, objectives, targets and initiatives need to be defined, as shown in Table 1.

For all these perspectives to operate in a meaningful way, a chain of cause and effect between the various objectives and measures through all of the four perspectives was worked out. For instance, an operational zed example given by the BMA Group (2000) was as follows: "Training and improving skills of operating staff (a learning and growth objective) could lead to a reduction in cycle times (an internal process perspective objective) that may lead to improved customer satisfaction and loyalty through shorter delivery times, and hence greater sales revenue (an objective of the customer perspective) leading to an increase in return on capital employed (an outcome measure in the financial perspective)."

Table 1. Measures in the balanced scorecard

Perspectives	Focus Areas	Measures Used
Financial Perspective	How do our owners see us?	Operating incomes, return on capital employed, economic value-added
Customer Perspective	How do our customers see us?	Customer satisfaction, customer retention, new customer acquisition, customer profitability, loyalty of customers, market share
Internal Processes	How effective and efficient are our business processes?	Quality, response time, cost, new product introductions, innovation processes
Learning and Growth Perspective	How well do we generate and adopt new knowledge?	Employee-based measures like employee satisfaction, retention, training and skills

The Balanced Scorecard approach can be used as one of the ways to measure performance of internal business processes. It would serve to assess the impact of knowledge management within the organization through the use of financial and non-financial indicators. The Gartner Group has estimated that 40 percent of Fortune 1000 companies would use some form of the Balanced Scorecard by the year 2000 (Shand, 1999).

Intangible Assets Monitor (IAM)

Sveiby was one of the first to develop a method for measuring intangible assets, in the 1980s, in an attempt to demonstrate how the intangible assets accounted for the difference between a company's market value and book value (Giaever, 1999).

This was sometimes referred to as "The Invisible Balance Sheet," which was a practical exercise for facilitating an understanding of the value of intangible assets. Sveiby's ideas formed the basis of a discussion centred on the "dollar value" of the organization's intangible assets and helped to shape and develop the Intangible Assets Monitor, a tool used by organizations to track and value their intangible assets. Swedish companies like Celemi and Angpanneforeningen AF were the first few companies to consider the value of intangible assets and measure the impact of their knowledge management initiatives through the use of the Intangible Assets Monitor. This method also contributed to the development of Skandia's Business Navigator. The Intangible Assets Monitor is comprised of three main focus areas, as shown in Table 2.

The various indicators for each of these parts of the Intangible Assets Monitor demonstrated change and have been categorized by the following areas of growth/renewal, efficiency and stability. Sveiby (1996) have highlighted various indicators of Intangible Assets Monitor.

Since 1995, the Intangible Assets Monitor has been used by Celemi to report their intangible assets as part of their annual report. Celemi realised early that their financial statements did not represent the true value of their firm (Barchan, 1998). Celemi worked with Sveiby to create a learning process that would simulate the real-life challenges

Table 2. Focus areas of the intangible assets monitor

Focus Areas	**Definitions**	**Examples**
External Structures (Customer capital)	Relationships between customers and suppliers.	Brand names, trademarks and reputation or image.
Internal Structures (Organizational capital)	Created by the employees and were therefore owned by the organization and adhered to.	Patents, concepts, models, computer and administrative systems, the informal organization, the internal networks and culture.
Individual Competence (Human capital)	One's ability to act in various situations.	Skills (including social skills), education, experience and values.

of managing a knowledge-driven company and help people understand the nature of this unique business environment, as well as the value of their own intangible assets (Barchan, 1998). The main philosophy behind Celemi's business strategy was that they "generated profits not by selling a product, but by selling their capabilities, experience and expertise" (Barchan, 2000). Celemi used the three aspects of the Intangible Assets Monitor in their measurement: the customers represented the external structure, their people represented their competence and the organization represented the internal corporate structure. Using the Intangible Assets Monitor, Celemi monitored and used the valuation of both their financial aspects and intangible assets to help their organization to grow as explained by Margaret Barchan, Celemi's President and CEO (Barchan, 1997).

There are several similarities in the Balanced Scorecard and Intangible Assets Monitor, though the models have been developed independent of each other. Giaever (1999) pointed out that the main proposal for both approaches was that non-financial measures must complement the financial indicators.

Skandia's Intellectual Capital Taxonomy & AFS Business Navigator

This worldwide-known approach was one of the first attempts to measure and present the intellectual capital in an organization attributable to the use of knowledge management processes. Developed in 1993 by Leif Edvinsson of Stockholm-based Skandia Insurance, the first corporate Director of Intellectual Capital, this represented the world's approach to reporting the company's intangible assets through an integrated intellectual capital model. As a spin-off of the Konrad Group of the Swedish Knowledge Companies, this method relied primarily on non-financial indicators to monitor and publicly present their intangible assets.

Originating from the Swedish Konrad School, this approach combined Sveiby's conceptual framework with the presentation format of the Balanced Scorecard to produce the accounting term of "Intellectual Capital," instead of the use of the term "intangible assets" used by the former approach. A fifth focus for human resources had also been added to the original four found in

Kaplan and Norton's Balanced Scorecard model (Olve, Roy, Wetter, 1999). This integrated intellectual capital model permitted the definition and classification of intangibles not shown in the balance sheet and tried to detect hidden costs, incomes and values to increase the transparency of intangibles. This model was built on the difference between market capitalization and assets, which gave rise to the business's intellectual capital (Huang et al., 1999).

Since 1994, Skandia has used non-financial ratios and published them in their annual reports. This was published as a supplement to their annual report in 1994, known as "Visualizing Intellectual Capital in Skandia" (Olve, Roy, Wetter, 1999). With much support from management and the effort to give a high profile, such supplements to subsequent annual and biannual reports have also followed every six months (Olve, Roy, Wetter, 1999). Table 3 defines key indicators of the Intellectual Capital Index.

Other Measures

The Business Excellence Model was not specifically designed for the measurement of knowledge management. However, it has many elements that are useful and relevant to today's knowledge-based organizations and has been used by some organizations to gauge their business excellence and efforts in knowledge management. The overall view of the framework followed by the specific enablers and results produces innovation and learning (The Business Excellence Model, 1994).

Intellectual Capital Index (ICI), introduced by Goran and Johan Roos of the London-based Intellectual Capital Services Limited (Skyrme, 1999) is similar to Balance Scorecard. Shand (1999) states that ICI forces managers to define what activities are important. It covers all the intangible resources that contribute to the creation of value for the organization including knowledge, competence and skills, working methods,

Table 3. Key indicators of the capital index

Type of Capital	**Definitions**	**Key Indicators**
Organizational (Structural) Capital	Physical assets that impacted the organization's capability to effectively create and produce knowledge.	Number of accounts per employee and administrative costs per employee.
Customer (Relational) Capital	Increased customer retention and satisfaction and the ability of employees to be ready to anticipate and meet customer demands	Number of accounts, number of brokers and number of lost customers.
Human Capital	Knowledge, skill and capability of individual employees to provide solutions to customer problems	Personnel turnover, proportion of managers, proportion of female managers and training / education costs per employee.
Development/Renewal Focus	Ensuring human performance was reaching its full potential through investment in individual as well as organizational learning	Satisfied employee index, marketing expense / customer and share of training hours.

processes and systems. ICI also emphasizes a culture that support the people, the image in the marketplace and relationships with customers, alliance partners and suppliers.

The Montague Institute provided a synopsis of the various methods of measuring intellectual capital in terms of 12 techniques that could be used to value intangible assets. These include: relative value, balance scorecard, competency models, subsystem performance, benchmarking, business worth, business process auditing, knowledge bank, brand equity valuation, calculated intangible value, micro lending, and colorized reporting (Measuring Intellectual Assets, 1998). These techniques represent various ways in which intangible assets could be measured to show the impact of knowledge management. It is interesting to note that most of the measures are non-financial. This appears to be recognizing that knowledge management is an intangible object and requires special measures to measures its impact on business processes.

The American Productivity and Quality Center (APQC) collaborated with several companies to find real-world examples of measures and suggested a five-stage process for measurement highlighting the importance of best practices (Hartz et al., 2001). These steps include stages of: Enter and Advocate, Explore and Experiment, Discover and Conduct Pilots, Expand and Support, and Institutionalize Knowledge Management. These guidelines highlight different steps that could be used to measure the impact of knowledge management during different stages of the life cycle.

Dhansuklal and Chaudhry (2002) highlighted that though there were many models for measuring the impact of knowledge management, as well as the intellectual capital and intangible assets within the organization, application of these measures for measuring the value of knowledge management work was a real challenge. They conducted a study of the application of major KM measures in selected organizations (Chaudhry, Dhansukhlal, 2002). A summary of their findings is produced in the next section of this chapter.

Application of Measures by Selected Organizations

Chaudhry and Jasna (2002) studied the use of major measures in FUJI XEROX, MICROSOFT CORPORATION, INFOSYS TECHNOLOGIES, and ARTHUR ANDERSEN. A checklist containing major areas related to performance measurement was used to guide the data collection.

FUJI XEROX developed "Eureka" to respond to the problem faced by technicians not being able to solve problems. Microsoft developed a blueprint for the "Digital Nervous System." ARTHUR ANDERSEN focused knowledge management in the area of business consulting. INFOSYS TECHNOLOGIES' knowledge management was introduced as a "Learn once, Use anywhere" paradigm. The knowledge management initiatives of these organizations seem to have been guided by a clear-cut vision and appropriate value propositions. It appears from the statements on their web sites, that knowledge management in these organizations was not viewed as an additional function, but rather as an enabler to facilitate their internal business operations. Their knowledge management work seems to be at a level suitable for review of performance measurement in this area.

In FUJI XEROX, the purpose of measurement was to track the progress of the Eureka system. More than 150,000 problems were solved using Eureka. In MICROSOFT, real knowledge management solutions began by objectively looking at the firm's strategic strengths, weaknesses and goals for clues where knowledge management would have high impact and should provide specific, measurable benefits in the critical areas of the organization. In INFOSYS, the main purpose was to provide a value to the off-balance-sheet assets of the company and to show the financial and non-financial parameters that determined long-term success. In ARTHUR ANDERSEN, the purpose was to justify the outcome of investments in knowledge management and the resources in terms of the involvement of teams in knowledge management.

The selected organizations used a different set of performance measures, but there was an element of commonality in the indicators used to measure the impact of knowledge management. FUJI XEROX focused on the areas of deployment, knowledge content, and productivity; MICROSOFT emphasized Products & Services Design & Development, Business Planning, and Employment Management; INFOSYS selected external and internal environment as their main focus; and ARTHUR ANDERSEN focused on Strategy, Process and Culture. Measures used by the organizations included in this study are given in Table 4.

As shown in Table 4, each of the organizations had adopted and developed a different performance measurement mechanism to suit the needs and focus areas of their knowledge management initiatives. In the case of FUJI XEROX, MICROSOFT and ARTHUR ANDERSEN, customized performance measurement systems were developed pertaining to the different focus areas. In FUJI XEROX, detailed measures were observed for each topic area. For MICROSOFT, the measures were divided among the key areas of the organization. Measures were defined in quantifiable form for the key areas of the knowledge management framework in ARTHUR AN-

Table 4. Performance measures used by selected organizations

FUJI XEROX	**MICROSOFT**	**INFOSYS**	**ARTHUR ADNDERSEN**
Deployment # Of users connected % Of users updating weekly	Product & Services Design & Development Product success rate Cycle time Low design rework	Customers (External Structure) Growth/renewal (revenue and new customers)	Strategy Time saved in proposals and engagements
Knowledge content and quality # Of solutions submitted Number days taken to validate solutions	Customer & Issue Management Customer satisfaction Needs captured in products Breadth of service coverage	Organization (Internal Structure) Growth/renewal (IT and R&D investments) Efficiency (proportion of staff and sale) Stability.(average age of support staff)	Process Number of contributions Contributors Organizing office People accessing documents Useful of documents
Productivity # Of customer problems solved % Reduction in service hours % Reduction in parts dollars Total $ saved in cost of service and support	Business Planning Discovering trends Crisis response times Competitive awareness Acting on complete information	People (Competence) Growth/renewal (education index) Efficiency (value added per employee) Stability (average age of all employees	Culture People reaction about knowledge management

Table 5. Presentation of performance measurement results

FUJI XEROX	MICROSOFT	INFOSYS	ARTHUR ANDERSEN
Names of author and validator available in databases	Results presented and used through the Knowledge Management Platform	Intangible Assets Score sheet is used to evaluate the market worthiness of a company	Measurement of knowledge sharing behavior of staff is included as a section in the staff appraisal

Table 6. Follow-up actions for knowledge management initiatives

FUJI XEROX	MICROSOFT	INFOSYS	ARTHUR ANDERSEN
Worldwide Customer Service Global Program Hall of Fame for Authors (cash and trophy) and Hall of Fame for Validators (cash rewards for outing and trophy)	Use of technology as a foundation for managing knowledge assets and bringing people together in a dispersed organization	Embarked on a number of initiatives aimed at taking the prevailing knowledge sharing culture to even greater heights	Use of formula to translate knowledge management initiatives into dollars and cents to reinforce KM culture by making people see the benefits

DERSON. INFOSYS adopted already available performance measurement models.

In order to demonstrate the results of the performance measurement systems in place, various formats and techniques were used. A summary of presentation formats is given in Table 5.

Each of the selected organizations defined follow-up actions that defined the use of performance measurement results and ensured that measurement played a crucial role in the knowledge management processes. The follow-up actions are given in Table 6.

The follow-up mechanisms seem to ensure that the measurement systems continue on regular basis. These also help in further enhancing and promoting the knowledge sharing culture. Regular knowledge management surveys helped these organizations to assess the levels at different times and also translated the results into monetary value to justify knowledge management investments.

Commonalities in Applications

Despite having different performance measurement systems, there were several common elements between the systems. The main emphasis in all the systems was on the customer and this emphasized the customer orientation of the models. In FUJI XEROX, the topic area of productivity related to the number of customer problems that were solved. In MICROSOFT, one of the perspectives was on customer and issue management, where customer satisfaction, needs and breadth of service coverage were measured. In INFOSYS, the external structure related to their customers and aspects relating to customers were also reflected in growth/renewal, efficiency and stability. In ARTHUR ANDERSEN, the measures were also tied to the customer in that retrieving the right knowledge at the right time would enable them to meet their client needs.

Another common emphasis in all the performance measurement systems was that the contribution of people was recognized as an important factor that needed to be measured. This was evident in all models used by these organizations. In FUJI XEROX, the three topic areas of deployment, knowledge content and quality and productivity related to the technicians involved. In INFOSYS, people were one of the key areas of the monitoring system in terms of their competence. Under this measure, the education index of employees, value added per software engineer and employee and the average age of employees were measured to derive a valuation of the intangible assets of the organization. In Arthur Andersen, individual knowledge-sharing behavior and the usage of the corporate intranet were measured.

KM performance measurement systems in the organization under review did take into consideration intangible factors in their measurements and attempted to quantify, where practical. For instance, FUJI XEROX tried to quantify the intangible factor of knowledge content and quality by measures like number of solutions submitted by country and number of days to validate the solutions. Similarly, INFOSYS used percentage of revenue from image-enhancing, customer sales from the five largest customers over the total revenue, and value-added per software engineer in measuring the intangible aspects of growth/renewal, efficiency ad stability in the internal and external structure and competence of people. ARTHUR ANDERSEN tried to translate all the key areas of the knowledge management framework into measurable indicators, e.g., time saved in new product development/regulatory processes, time to implement a best practice and number of mistakes made twice.

The performance measure used by the organizations selected for this study varied. Some used established systems like the Balance Scorecard and Intangible Asses Monitor, while others developed their own systems of measurement. The emphasis was no longer solely on financial measures, but on the inclusion of intervening, non-financial measures. The focus, however, still seems to be on measuring the intellectual capital and assets, rather than the actual processes of knowledge management. It is understandable that measuring the KM processes is a complex task and is not easily quantifiable, but nonetheless important and essential to make the measurement more useful.

SUMMARY AND CONCLUSIONS

There are various ways in which the impact of knowledge management can be measures using different criteria and dimensions. Major measures used for assessing the KM performance by the organizations (e.g., Balance Score Card, Intangible Assets Monitor, and Intellectual Capital Index) focused on the general aspects related to knowledge management work, e.g., infrastructure, technology, culture, and people. While useful in highlighting the value of KM in general, these measures only provided a partial assessment of the impact of knowledge management in organizations. To provide a comprehensive coverage of the measurement of knowledge management processes, emphasis needs to be placed on examining the processes and developing measures that are more specific to measure the steps involved in these processes.

The measurement system adopted by FUJI XEROX for their Eureka system could be considered a step in the right direction. It does emphasize capturing and measuring tips and sharing and using knowledge in terms of quantified statistics. Similarly, ARTHUR ANDERSEN demonstrated commendable efforts in converting intangible knowledge management concepts into measurable criteria. However, these performance measures should go beyond valuation of intellectual assets and the concept of intellectual capital and focus on the value of the knowledge management processes. These should help measure how different steps in these processes make a difference in the success of knowledge management efforts. Some lessons may be drawn from existing performance measurement systems like the Balance Scorecard and the Intangible Asset Monitor in terms of the perspectives and measures they highlighted. For instance, the four perspectives adopted by the BSC provide a holistic way of measuring different systems within the organization and identifying the major stakeholders. Likewise, IAM may be useful to use the valuations of intangible assets at different periods of time to see if there has been an improvement, and if this could be attributed to the use and implementation of knowledge management within that organization.

In drawing up a blueprint for a measurement system, it is vital to define the purpose of measurement relating to the needs and structure of the knowledge management initiative of the organization. More mature knowledge management initiatives will use a knowledge management framework or paradigm to provide guidelines for the initiative. In contrast, organizations new to knowledge management may have neither yet developed nor be using a well-defined knowledge management framework for their initiatives. Either quantifiable or more intangible measures can be used, depending on the needs of the organization and the purpose of the measurement system. Martin (1999) rightly pointed out that there is no one set of measures applicable to all firms, or even within a company. What is being measured currently may change, owing to changes in the external environment or in the company's direction. Companies should not give up on measurement. Developing a measurement system for knowledge management may well be the key to the competitive success of the organization, allowing it to manage more effectively and efficiently what it can measure.

Chapter 6.33
Where Knowledge Management Resides within Project Management

Jill Owen
Monash University, Australia

Frada Burstein
Monash University, Australia

EXECUTIVE SUMMARY

This chapter explores how an engineering consulting company creates, manages, and reuses knowledge within its projects. It argues that the informal transfer and reuse of knowledge plays a more crucial role than formal knowledge in providing the greatest benefit to the organization. The culture of the organization encourages a reliance on networks (both formal and informal) for the exchange of tacit knowledge, rather than utilizing explicit knowledge. This case study highlights the importance of understanding the drivers of knowledge transfer and reuse in projects. This will provide researchers with an insight into how knowledge management integrates with project management.

INTRODUCTION

To sustain their competitive edge, businesses are continually searching for ways to differentiate themselves from their competitors. One method of achieving this is for an organization to develop a knowledge management strategy. A knowledge management strategy articulates how the organization creates, values, preserves, and transfers knowledge critical to its operations. The development of an effective knowledge management strategy is important for project management organizations. Crucial factors in achieving these objectives are to manage and more effectively apply and reuse knowledge gained throughout the project life cycle. If useful information is identified, assimilated, and retained within the organization, it represents intellectual capital that can be reused on other projects, reducing the time staff spend recreating what has already been learned. The reuse of knowledge can assist an organization in not reinventing the wheel and ensuring that past mistakes are not repeated. Effective project management is a key enabler for business success. However, where corporate knowledge is ineffectively managed during the project life cycle, valuable intellectual capital is lost, causing rework and lost opportunities.

As a global engineering project management consulting firm Engineering Consulting XYZ consults on projects to organizations worldwide, these projects can potentially reuse knowledge from earlier projects.

The purpose of this case study is to explore how project team members at Engineering Consulting XYZ acquire and reuse knowledge. The chapter analyzes and describes how project staff capture, transfer, and reuse knowledge. The findings are positioned within the Project Management Body of Knowledge's (PMBOK) methodology, the de facto global standard for project management methodology (Project Management Institute, 2000). The case study determines the relative importance and use of tacit, implicit, and explicit knowledge in managing projects.

At the beginning of the research, there was an expectation that the majority of knowledge was obtained via formal means and would provide the most benefit to the organization. However the empirical data suggests that the informal transfer and reuse of knowledge played a more crucial role and provided greater benefit to Engineering Consulting XYZ. The culture of Engineering Consulting XYZ encourages collective learning and sharing.

The chapter initially provides a background to how knowledge management integrates with project management, grounded in relevant literature. The next section looks at how Engineering Consulting XYZ acquires and reuses knowledge on projects, followed by current challenges facing the organization.

BACKGROUND

Project management companies continually compete for business against competitors. The challenge for these companies is to ensure that they deliver their projects faster and more effectively than their competitors. To achieve this, organizations can utilize knowledge gained from earlier projects, or project phases — that is, not reinvent the wheel. Knowledge gained from earlier projects or project phases can be obtained via explicit or tacit means.

Importance of Learning

To succeed competitively and to achieve their business strategies and goals, organizations need to gain knowledge of both the internal and external worlds. An effective knowledge management strategy will help an organization achieve these ends. Stata (1989) suggested that to maintain a competitive advantage, organizations need to learn and obtain knowledge faster than their competitors. Learning allows an organization to respond to changes in the business environment (Baldwin, Danielson, & Wiggenhorn, 1997). A knowledge management strategy is developed by the organization for improving the way it develops, stores, and uses its corporate knowledge. Both tacit and explicit knowledge are important in the creation and reuse of knowledge. Organizational memory forms the basis of intellectual capital that is held in an organization. Intellectual capital is the knowledge and capability to develop that knowledge in an organization (Nahapiet & Ghoshal, 1998).

If an organization is to continually change, it needs to evolve and learn continuously. Kim (1993) defines learning as the acquiring of skills (know how) and "the ability to articulate a conceptual understanding of an experience" (p. 38). Learning is a process of continual improvement and innovation (Baldwin, Danielson, & Wiggenhorn, 1997). Senge (2002) describes a "learning organization" as one "where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning to see the whole together" (p. 3).

For a learning organization to continually learn and develop, organizational learning needs to occur. Organizational learning is the capacity or process within an organization to maintain or improve performance based on experience (Nevis, DiBella, & Gould, 1995).

For an organization to learn, knowledge must be created, shared, and reused (Arygris & Schon, 1978). The learning process has identifiable stages: knowledge acquisition, knowledge sharing, and knowledge utilization (Nevis, DiBella, & Gould, 1995).

Arygris and Schon (1978) define organizational knowledge as knowledge about the organization that can be held in individual's heads, files, physical objects, and embedded in cultures and procedures. McElroy (2003) extends this with his concept of organizational knowledge production—at an organizational level, knowledge is created by individuals and groups building on existing knowledge and creating new knowledge.

Schneider (2002) argues that the new or emerging model of an organization is where organizations are characterized by fuzzy organizational boundaries, flattened hierarchies, and work relationships sometimes brought about by contracts (alliances and contingent workers). Knowledge is predominantly created and used across social networks. It could be argued that knowledge creation and sharing at the organizational level relies on a combination of explicit knowledge and social networks.

Project management organizations are a natural arena for knowledge management as project management staff continually interact with and build on both explicit and tacit knowledge as they move between different projects and phases of a project.

In a project management organization, learning is important as it helps project managers deliver not just one but a succession of successful projects, and to develop the right sorts of capabilities, that is, the project management process, the product development process, and the knowledge management process (Kotnour, 1999). Learning within and between projects is required for this. Organizational learning in the project management environment involves both intra- and interproject learning. Intraproject learning occurs within a project at all phases of the project. Interproject learning is applying knowledge gained from previous projects so that it is reused and new knowledge is created (Kotnour & Hjelm, 2002). Knowledge needs to be developed within a project, where it is used and tested, before it can be transferred to other projects. Projects can have a variety of intra- and interorganizational relationships, especially long-term projects. The challenge within these types of projects is to look at the process for the capture and reuse of knowledge in future projects (or phases of the same project) and to ascertain how intra- and interproject learning occur (McLoughlin, Alderman, Ivory, Thwaites, & Vaughan, 2000).

Learning within a project provides an ongoing store of data, information, and knowledge (Kotnour, 2000). Knowledge can also be transferred between projects (Kotnour, 2000). At a project level, knowledge is created by individuals and groups building on existing knowledge and creating new knowledge (adapting McElroy's [2003] definition of knowledge production at an organizational level).

Definition of a Project

Project Management Institute (2000) in PMBOK defines a project as "a temporary endeavour undertaken to create a unique product or service. Temporary means that every project has a definite beginning and a definite end. Unique means that the product or services is different in some distinguishing way from all other products or services" (p. 4).

For a project management organization to be competitive, project managers need to retain and build knowledge and improve project performance (Cooper, Lyneis, & Bryant, 2000).

Explicit, Implicit, and Tacit Knowledge

Explicit, implicit, and tacit knowledge help to ensure project success. Tacit knowledge is stored in a person's head and cannot be readily expressed in words, while explicit knowledge is knowledge that is expressed tangibly and can potentially be stored in databases or documents (Bollinger & Smith, 2001). Implicit knowledge is knowledge in a person's head that could be coded and stored in databases or documents (Nickols 2000). Tacit and implicit knowledge held within the corporate structure and contexts (e.g., as described by Nelson & Winter, 1982) and from individuals and explicit knowledge together provide a complete picture of the project. Tacit knowledge exists in the corporate structure (in the form of contexts and routines [Nelson & Winter, 1982; Von Krogh & Roos, 1995]) and implicitly and tacitly in members of the organization. Individuals also produce and consume explicit knowledge existing within the organization or from its environment. Sharing of knowledge among multiple individuals with different backgrounds is a critical step in project knowledge creation and reuse. Tacit knowledge based on previous experiences in a similar context is important to project success, as is the transfer of explicit knowledge (Koskinen, 2000). Knowledge can be captured and transferred tacitly within the organization via social networks, while implicit knowledge can potentially be captured and coded.

Knowledge Transfer and Reuse

Knowledge that is gained in a project needs to be transferred to an organization's memory for reuse on other projects; the challenge is to capture and index this knowledge for retrieval while it is available, as project teams are temporary (Damm & Schindler, 2002).

Dixon (2000) identifies five different types of knowledge transfer or reuse: serial transfer, near transfer, far transfer, strategic transfer, and expert transfer.

Project completion is an important phase of the project life cycle in capturing knowledge and preparing it for transfer to other projects. Postimplementation reviews/lessons learned can either occur via the project team members or an independent reviewer. Lessons learned provide a full description of the project with examples that can be used on other projects. In some instances, lessons learned only focus on the success of the project (Disterer, 2002). There is a need to focus on both the positive and negative lessons to ensure that successes are identified and publicized and mistakes not repeated. At NASA, to ensure that lessons learned get to the right people, they are "pushed" out to people who have similar profiles and can benefit from the lessons (Liebowitz, 2002). The challenge is to ensure that knowledge is captured without taking project team members away from their day-to-day tasks. For lessons learned to be effective (both positive and negative), they need to be indexed or searchable for easy retrieval of knowledge for future projects or project phases.

The reason for knowledge reuse failures can be that knowledge capturing processes are too informal, are not incorporated into the organization's processes, or are not supported by the structure of the organization (Komi-Sirvio, Mantyniemi, & Sepannen, 2002).

The Organization Used in the Case Study

Engineering Consulting is a multidisciplinary global engineering consulting company operating across five different business units: buildings and property, heavy industry, resources environmental, and infrastructure. They are a global, internationally recognized leader in the marketplace. Engineering Consulting XYZ is employee owned and has grown organically and via strategic mergers with organizations with similar cultures and values. Its mission is "to focus on valued client relationships to achieve remarkable success for them. The firm has a commitment to service, quality, and high standards of safety and business ethics."

Management of Engineering Consulting XYZ follows a global management structure. The management structure reflects the regional, business, and functional unit structure. Engineering Consulting XYZ employs a wide range of professionals, including architects, engineers, project managers, scientists, economists, and planners servicing a wide range of clients and market sectors.

A key strategy for Engineering Consulting XYZ for the next three to four years is to invest time in the future of the business. This strategy looks at a number of measures where time invested today will secure the long-term future for the company. Knowledge management is highlighted as a key area in which time should be invested on an ongoing basis. To assist in achieving these strategies, there is most likely a reliance on knowledge — explicit, tacit, and implicit.

Engineering Consulting XYZ has recognized the importance of knowledge management within its organization by appointing a knowledge manager and creating an environment that fosters knowledge sharing. The knowledge management strategy is people-centric or personalized rather than systems driven.

In support of its strategy, Engineering Consulting XYZ is pursuing the following:

- Communities of Practice: to try and recreate the informal networks in a slightly more formal way across regions.
- A Human Yellow Pages: to help identify and contact the right person when faced with a problem.
- Lessons Learned: to capture lessons learned through the Communities of Practice (focused by discipline) and through interviews for larger more generic project management-type projects.
- A Knowledge Management System: with access to all documents/drawings at a global level.

SETTING THE STAGE

As a global company, Engineering Consulting XYZ utilizes resources globally for certain projects. There are approximately 15,000 projects on Engineering Consulting XYZ's books at any one time ranging in size from $2,000 to $50 million per annum. Engineering Consulting XYZ has achieved yearly revenue in excess of $380 million.

The culture at Engineering Consulting XYZ is open and encourages everyone to achieve their full potential. The culture was developed by the founders of the company and has evolved with extensive staff consultation. Staff members are encouraged to network and share information within this culture.

- "Our culture is based around personal values of competitiveness and challenge, drive and motivation, high professional standards, controlled risk taking, steady wealth creation, and being good citizens through a demonstration of social and environmental responsibility in what we do.

- Our management style is one of openness, support for colleagues, focussing on success through sharing of strategic business information and no game playing.
- Our management approach is adaptive to change and built on exceptional service delivery and adding value.
- Our people philosophy is based on participative employee development to achieve each individual's potential.
- Our ownership structure is one of broad based sharing of equity, targeting continuity of the practice and equitable ownership transfer.
- Our commitment is to innovation in product quality that adds value to our Clients' businesses." (Engineering Consulting XYZ's Web site)

Engineering Consulting XYZ's key goal is to "achieve remarkable success" for its clients. It works with the client to understand the business and then utilizes the best people for the job in terms of skills and knowledge (both technical and local).

While Engineering Consulting XYZ is a global company, a high proportion of the client base is regional and requires project team members with local skills and a knowledge of regional issues; however, there has been a recognition that some of the most appropriate skills (people and technology) need to be obtained globally. The Human Yellow Pages reflects the need to be able to easily identify the appropriate people.

Engineering Consulting XYZ has recognized that people are the key resource of the consulting company and are critical for it to achieve a sustainable future. A part of this focus is to attract and retain talented staff. There are programs in place to ensure that managers are provided with the right people-management skills and staff are able to develop to reach their full potential.

The project management methodology followed by Engineering Consulting XYZ is based on the Project Management Institute's (2000) Project Management Body of Knowledge (PMBOK) covering the following:

- Initiation
- Planning
- Execution
- Controlling
- Closing

The project management methodology at Engineering Consulting XYZ is an evolutionary process broken into three stages: proposal stage (initiation), project stage (planning and execution), and finalization stage (closing). The controlling phase underpins the process with regular key review points. In addition, progress is monitored on a monthly basis. As part of the development and retention, staff project managers and team members are put through a project management course as well as other appropriate development courses.

As a consulting and project management company, Engineering Consulting XYZ has realized the importance of knowledge management; it tries not to reinvent the wheel on new projects. As part of its knowledge management strategy, a knowledge management system was purchased and implemented, and communities of practice were set up. Both of these were in the very early stages during the reviewed projects.

CASE DESCRIPTION

Engineering Consulting XYZ participated in an alliance project, with a major public client, where all alliance partners were encouraged to focus on agreed-upon project objectives. The role of Engineering Consulting XYZ was to provide the detailed design component of the project, with the deliverables being the design, documentation, and specifications. This case study looks only at Engineering Consulting XYZ's component, and does not take into account other alliance activities. The two phases of the project were treated as two separate projects by Engineering Consulting XYZ with separate deliverables, and as such, have been analyzed as separate projects. At its peak, the project consisted of 30 project team members, with a core of between 15 and 20 members (including the project director and project manager). Of the core project team, eight (including the project manager) worked on both projects.

For the first project, Engineering Consulting XYZ, along with other alliance partners, won an excellence award in their category of industry as

- new knowledge that furthered the knowledge base of the profession was developed;
- new process knowledge was developed; and
- existing knowledge was enhanced and transferred via documented reports.

This case study analyzes and describes how knowledge was captured, managed, and reused in these two projects. In addition, the role that social networks play in the project(s) will be analyzed.

Execution of Company Strategy

Projects are used to execute Engineering Consulting XYZ's strategies. Engineering Consulting XYZ's present vision is to continue to be a sustained consulting group and to be the premier consultant for valued clients. The strategies to achieve the vision focus on identifying and looking after key clients.

Processes

Engineering Consulting XYZ has a robust project management methodology with strong links to the methodology employed by the Project Management Institute's (2000) PMBOK. Each project in Engineering Consulting XYZ undergoes initiation, planning, execution, and closing phases. Business processes and project management systems also support the project.

One of Engineering Consulting XYZ's five business units assigns a project manager to the project. The project is structured according to the work breakdown structure. The project has a project director who provides a mentoring role and is responsible for client relationships, progress monitoring, and performance (quality time costs resources), and overall quality assurance, including risk. In addition, there are review points linked to the project management methodology and quality assurance procedures; these reviews assist in managing the project risks.

Knowledge Management Processes in Engineering Consulting XYZ

Engineering Consulting XYZ supports knowledge management processes throughout the organization. In recognition of this, it has appointed a knowledge manager to develop its knowledge management activities, including the introduction of communities of practice, capturing of lessons learned, and implementation of a knowledge management system.

Knowledge Reuse

Knowledge reuse occurred between projects. New technical knowledge that was created in the first project was reused in the second project. Specific knowledge from the first project facilitated improved designs in the second project.

In Engineering Consulting XYZ, knowledge is reused at all stages of the project life cycle. Project team members continually reuse knowledge and expect to reuse it; one project team member stated that:

In most instances, I expect a level of success. I expect to be able to reuse the information. In fact, if we can't, it will more than likely result in an unpleasant commercial outcome. It's really usually necessary to reuse that information. Every now and then, though, you'll stumble across a piece of information which is so beautifully presented, so valuable that it will deliver a result very quickly, indeed.

At the plan stage, both explicit and tacit knowledge are used. Explicit knowledge is in the form of tenders, proposals, project plans, general project documentation, project methodology, and technical documentation from earlier projects. Documents are stored by project number in hard copy and on the network server. At the tacit level, project team members reused knowledge from earlier projects, either their own knowledge base or via informal networks. Explicit knowledge is usually originated from earlier projects that the project team member has worked on, implying that they do not search electronically or physically for a document but rather use their tacit knowledge to obtain the documentation. Documentation is used as a starting point or for convenience while there is a reliance on networks to obtain more detailed and complex knowledge. As one project team member said:

We use the proposal for convenience because all the words and text are there, so it's readily used and saves you having to reinvent the wheel. But the hard questions like financials and methodology you will usually talk through with the person from the project.

Lessons learned from earlier projects are used at the plan stage to try and ensure that mistakes are not repeated or successes are applied. Most of the lessons learned that are applied are informal lessons. As one person interviewed stated:

Particularly when you are setting it up, you try and incorporate the lessons learned. So if something didn't work last time, you might set the team up a little differently and have different steps in your methodology to try and capture lessons learned previously. There's a lot more in your head than you are able to document.

During project implementation, there is a reliance on both explicit and tacit knowledge; however, there is a greater reliance on personal knowledge. If explicit knowledge is reused, it is obtained by asking an expert for the documentation rather than an electronic search being carried out. A key reason that knowledge is reused is to deliver a solution where any potential pitfalls are known in advance allowing them to be overcome. As one project team member interviewed stated:

You start by discussing how to go about solving a technical problem and how they go about it to ensure that mistakes are not repeated.

Knowledge Creation and Transfer

Knowledge is continually created and transferred within and between projects. In one area of Engineering Consulting XYZ, to overcome the issue of knowledge transfer a mentoring scheme has been implemented to allow the knowledge to be transferred to a number of people within and to become part of organizational memory.

A project director is appointed to each project to mentor the project manager, and review the project. The project director mentors the project manager by meeting with the project manager and discussing the project. Roadblocks, issues, potential risks, and risk mitigation strategies are discussed in these meetings. Knowledge is transferred from the project director to the project manager as he generally has more experience, but knowledge is also transferred to the project director in terms of understanding the status of the project and what impact it may have on the other projects and programs of work. As the project director meets with the alliance partners and the client at a strategic level, the impact that this project may have on the entire body of work is also understood.

Lessons learned, both formal and informal, are an important method of knowledge creation. Formal lessons learned occur at the end of a project or a phase of a project where formal workshops are used to identify issues/lessons and identify how they can be resolved (tacit to explicit knowledge creation and transfer). The lessons are documented and made available on the network server for future use. In addition there is a review process (between the project director and project manager or a reviewer and project manager/project team member), linked to the project methodology, where knowledge gained from one phase is incorporated into the next phase of the process. At the informal level, lessons learned occur throughout the project where project team members meet to resolve issues (tacit to tacit knowledge creation and transfer). At this level, in some circumstances the lessons may be documented in the form of meeting minutes (tacit to explicit knowledge creation and transfer).

Knowledge transfer occurs from the project to the strategic and business unit level allowing it to become part of organizational memory.

Knowledge is transferred from the project director to the project manager. The project director is a member of a formal network — a global group of regional business leaders. This group meets face-to-face three times a year and participate in telephone conferences every two weeks. Knowledge is rolled up from project level and is discussed at a strategic level. As part of this transfer, knowledge is becoming part of organizational memory.

External knowledge is transferred at a strategic level via external meeting that the project director has with alliance partners and customer reviews (monthly).

The project manager participates in a formal section meeting on a regular basis. Participants discuss proposals, projects, and potential business opportunities. This is a forum for knowledge creation, reuse, and transfer where issues can be discussed and resolved. Within this type of culture, knowledge becomes part of organizational memory as it is transferred to other employees.

Networks

The culture at Engineering Consulting XYZ encourages the use of networks. There is a reliance on obtaining tacit knowledge via personal knowledge or networks (both formal and informal). Informal networks are tapped into within and outside working hours. One project team member stated the following:

[You] build up relationships with people over a period of time. You work with them and find out who the specialists are in areas of the company. You talk to a specialist, call that person, and ask questions on how they have approached something and a relationship is established. As you build personal relationships you know who to call.

The project manager and senior project team members initially relied on personal knowledge and then their informal networks. Formal networks (e.g., as established in the corporate e-mail system) were only tapped into if the relevant knowledge could not be obtained from the other sources. In most cases, as well as utilizing tacit knowledge, people sought out explicit knowledge, that is, people interviewed said it was quicker to ask the person who knew where the relevant documentation was rather than searching for it on the server or in folders.

It's a lot more efficient if you know who produced the file last time and you can just go and ask them where it is. It saves having to search.

Informal Use of Knowledge

Knowledge is informally reused or re-created from one project to another (particularly at the plan, implementation, and closure phases) as the culture and system are not in place to formalize it (while a knowledge management system has been implemented, it was not implemented when these project phases were being conducted). Several project team members have worked with Engineering Consulting XYZ for a number of years, and given the length of time that they have been with Engineering Consulting XYZ, they have created informal networks (often with people whom they have worked with on previous projects). Interviewees commented that they just know who to go to. At the more senior levels of the organization formal networks (across the distributed enterprise) also played a crucial role. In addition there was one exception where one team member relied predominantly on informal knowledge transfer but also documented everything so that if he was not in the organization any longer, another person could access the information. The only issue is that as everything (including all e-mails) is stored in hard copy, it may be difficult to find the most appropriate knowledge.

Knowledge Management System

Engineering Consulting XYZ implemented a knowledge management system during the first project; however, it was at an immature stage and the project team relied on a network server to store project documentation in an electronic format. The documents (both project-related and technical documentation) are sorted by project number. In addition to being stored on a network server, they are also stored within files throughout the office making it difficult for people to find explicit knowledge unless they knew what they were looking for. Two areas had their own systems in which to store relevant project documentation; however these systems did not interact with other systems making it difficult for people in other areas to know how to access the knowledge without first asking someone.

The challenge for the sponsors and champions of the knowledge management system was to encourage people to see the benefits of using the systems.

I think the underlying theory and philosophy is pretty sound. The challenge is in the implementation and the culture to get the thing working so the people can see the full benefits of it.

In addition, the culture of the organization needed to change to encourage people to use the system.

It needs to be promoted in the right way from a cultural change perspective. I think it's about getting people to get used to the idea of collective learning and sharing it. It's going to take more time but we need to show people that the benefits outweigh the cost.

Table 1 summarizes the major knowledge processes within Engineering Consulting XYZ, and the methods and artifacts associated with it. The knowledge processes are also related to major stages from the PMBOK project management methodology (Project Management Institute, 2000).

As highlighted in Table 1, within these projects tacit knowledge and social networks play the most

Table 1. Knowledge creation and reuse in projects

Area of Analysis	Method/s	Artefacts	Phase of PMBOK
Knowledge Creation	Tacit knowledge/ Explicit knowledge	Personal knowledge/Networks Tender/technical/project documentation	Plan Implementation
Knowledge Capture	Formal Workshops Informal Meetings Web Portal/email	Lessons learned -(Tacit/Explicit) Meeting minutes Files	Closing
Knowledge Transfer	Tacit knowledge via Mentoring/ Networks Explicit Knowledge	Networks (Formal/Informal) Documentation	Plan Implementation Closing
Knowledge Reuse	Project Review	Review process minutes/notes	Plan Implementation
How do people share/ reuse knowledge	Informal and Formal networks Mentoring	Informal and Formal networks Mentoring	Plan Implementation Closing
Knowledge Management Systems	Web Portal/email Server	Server Database	Plan Implementation Closing

crucial role both in terms of knowledge creation and reuse. However, explicit knowledge may have been used more widely if a system allowing contextual searches was used (a knowledge management system is in the process of being implemented within the company). The culture of Engineering Consulting XYZ encourages the use of knowledge transfer and reuse tacitly at an informal level. For a knowledge management system to be used extensively, a culture (and processes) that fosters the use of formal knowledge would need to be implemented. One of the people interviewed stated that

There is a need to change culture to rely on systems and get people used to the idea of collective learning and sharing it.

CURRENT CHALLENGES FACING THE ORGANIZATION

Knowledge management is a key enabler for Engineering Consulting XYZ to maintain and improve its competitive advantage, reduce project costs, and remove the cost of duplicated learning. However, at the end of this project, the organization faced a number of challenges to ensure that knowledge management enabled it to achieve rather than impede its objectives.

The consulting market has become more competitive, and over the last five years, Engineering Consulting XYZ has adopted a strategy of growth to meet the challenge. This industry sector has also faced the emergence of the generation X with associated higher staff turnover indicative of less long-term organizational loyalty. This means that the informal networks have potentially become diluted and not as efficient.

One of the key challenges that Engineering Consulting XYZ faces is the reliance on informal networks and informal knowledge. As part of its knowledge management strategy, Engineering Company XYZ had purchased and tried to implement a knowledge management system and introduce the concept of communities of practice. Given that there is a reliance on informal networks and informal knowledge and the culture of the organization supports this environment, a key challenge is to encourage employees to belong to communities of practice that are formal and not necessarily linked to their networks or personal relationships. Processes and technology need to be put in place to support these communities of practice. In addition, given that documentation was either kept in hard copy or on a network server, project team members need to be encouraged to use the knowledge management system. In order to be accessible to others, the documents need to be stored in the knowledge management system as well as on a local area network. In addition, the information stored in the system needs to be maintained so that it is relevant and up to date. A culture that encourages the use of the knowledge management system to complement the reliance on tacit knowledge needs to be developed.

Project knowledge needs to be captured, stored, and indexed to allow for easy retrieval and contextual searches. Capturing the context of project knowledge is crucial for Engineering Consulting XYZ; without it, past knowledge may not be relevant and hard to reuse on future projects. Training in utilizing the system needs to occur.

The knowledge management system has been implemented across geographic regions, business units, and functional units. Training has occurred to ensure that staff know how to use the system. The key is to ensure that the culture of the organization accepts the use of a knowledge management system (both utilization and maintenance) and that the explicit knowledge complements the use of tacit knowledge and networks.

EPILOGUE AND LESSONS LEARNED

Epilogue

This chapter looks at how knowledge is created, transferred, and reused in project management. The culture of the organization plays a crucial role within knowledge management. Where there is a reliance on informal networks and informal knowledge and the culture of the organization supports this environment, a key challenge may be to encourage employees to belong to communities of practice that are formal and not necessarily linked to their networks or personal relationships. Processes and technology would need to be put in place to support these communities of practice. Given that culture plays such a key role in knowledge management, if a mature knowledge management system was implemented and the culture changed to reflect this change, tracking will need to occur to ascertain the long-term effects on the organization.

Lessons Learned

1. In this case study, there was an expectation that the majority of knowledge was obtained via formal means and would provide fruitful ground for a knowledge management system implementation. However, the informal transfer and reuse of knowledge played a more crucial role and provided proven benefit to Engineering Consulting XYZ. Thus the implementation of a knowledge management system resulted in a need for major cultural change.
2. The culture of an organization plays a major part in knowledge reuse. If the attributes

of a learning organization are part of the culture, then knowledge reuse can occur. An organization can have all the processes, formality, and structure it wants, but without the right attitude or culture knowledge, reuse may not occur.

3. A total reliance on knowledge management systems does not necessarily suit the needs of Engineering Consulting XYZ; the better use of the system would be desirable. However, as this organization has a culture that encourages collective learning and sharing, a knowledge management system needs to complement the reliance on tacit knowledge and networks.

ACKNOWLEDGMENTS

This research is partially funded by the School of Information Management and Systems, Faculty of Information Technology, at Monash University. We are grateful for the support and input from the case study site.

Chapter 6.34
Outcomes of Knowledge Management Initiatives

Vittal S. Anantatmula
George Washington University, USA

ABSTRACT

Establishing criteria for knowledge management (KM) is important because criteria help to establish a basis for assessing the value and evaluating its results. Literature review has revealed that widely accepted criteria and performance measures have not been developed for KM. Delphi Technique and survey-based research, using a questionnaire targeting KM professionals as respondents, were aimed at establishing criteria for assessing KM success for different types of organizations. The results show what organizations consider important outcomes of a KM initiative. Contributions from this research effort should support government, non-profit, and for-profit organizations in making decisions about KM initiatives and measuring KM efforts. Future research efforts can focus on developing these KM outcomes into detailed measures.

INTRODUCTION

The continuous progression of civilization is a testimony to its ability to develop, learn, and share knowledge. Recent advances in information and communication technologies have made it easy to develop, store, and transfer knowledge. Globalization, increasing international competition, and a free market philosophy are driving forces for these advances in technology, and many organizations have realized that the creation, transfer, and management of knowledge are critical for success today.

The increasing gap between the book value and the market value of some business entities indicates the increasing importance of knowledge-based intangible assets (Marr, 2003) and knowledge management (KM). However, the dimension of KM has not received adequate attention (Holsapple & Joshi, 1999). Also, the

KM concept is still understood as information management and is associated with technological solutions, such as intranets and databases (Marr, 2003). It should be understood that the primary focus of KM is to utilize information technology and tools, business processes, best practices, and culture to develop and share knowledge within an organization, and to connect those who possess knowledge to those who need the knowledge.

Several organizations are attempting to use KM to improve organizational performance, but commonly accepted KM principles are yet to be developed. KM's lack of focus (Fairchild, 2002) and absence of commonly accepted KM principles (Stankosky & Baldanza, 2001) are some of the gaps in this discipline. Among the commonly accepted KM principles or references that are missing are the criteria for measuring success associated with KM. In this article, a research effort is presented to address this knowledge gap from the practitioners' point of view and leading to identifying expected outcomes of a KM initiative in organizations.

BACKGROUND

Improving organizational performance by using a KM initiative is an investment decision; we must therefore have an understanding of its outcomes. While discussing approaches to building KM systems (KMS), Jennex and Olfman (2004) contend that the measurement of a KMS is crucial to understanding how these systems should be developed and implemented. They cite several reasons for measuring success of a KMS, including three from Turban and Aronson (2001): to provide a basis for valuation, to stimulate management's focus on what is important, and to justify investments.

However, inherent intangible characteristics of knowledge assets make them difficult to measure (Ahn & Chang, 2002). Unlike materials or equipment, the core competencies and distinctive abilities of employees are not listed on balance sheets (Austin & Larkey, 2002). As a result, factors that contribute substantially to a firm's success elude traditional means of quantification, thereby presenting significant challenges to KM performance measurement.

Bassi and Van Buren (1999) suggest that the lack of understanding of how to measure and evaluate impacts of intellectual capital is a major obstacle to turning investments towards promoting intellectual capital into a source of competitive advantage. Similarly, Ernst & Young's Center for Business Innovation survey identified measuring the value and performance of knowledge assets as the second most important challenge faced by companies, behind the challenge of changing people's behavior (Van Buren, 1999).

Instead of trying to measure knowledge directly, which may not be possible, a different approach is to measure its contribution to business performance, which is still considered a major research agenda (Ahn & Chang, 2002). Major consulting organizations agree that measuring KM effectiveness and contributions is a key concern for consulting organizations (Wikramasinghe, 2002).

Some studies have suggested non-traditional KM measurements. A survey of 100 FTSE (the index used by the London Stock Exchange and Financial Times) companies attempted to establish levels of engagement with KM, the organizational implications, and evidence of impact on performance (Longbottom & Chourides, 2001). The survey results suggest that performance measures are not well developed and these measures should be linked to balance scorecard frameworks. According to Fairchild (2002), KM activities are considered integral to other management activities and processes; measuring KM is about how and when KM is integrated into organizational activities, which can be measured. Thus, it is important to identify these activities and determine KM contributions to these activities. The study suggests that organizations should require less precision and exact figures, and more interest in trends using a balance scorecard approach, such as customer and employee satisfaction, and intellectual capital.

The above research findings lead to the conclusion that KM results are difficult to measure, and commonly accepted outcomes of a KM initiative are not yet established. This research effort is aimed at addressing this knowledge gap. This article uses a literature review to identify a number of KM outcomes at the organizational level that are then translated into KM criteria. Based on this literature review, a list of KM criteria and important research questions were established for the Delphi study. To support the Delphi findings, a survey consisting of the same list of criteria and questions was distributed. Based on these research findings, expected KM initiative outcomes from the practitioners' point of view were established. Finally, limitations of the study and future research opportunities are discussed.

LITERATURE REVIEW

Research related to KM success can be classified into two focus areas: KM success factors and KM outcomes. KM success factors can be viewed as facilitating factors for a KM initiative. Though the main focus of this article is on outcomes of KM initiatives, a brief discussion on success factors is relevant for this study to understand the distinction between the two.

There have been efforts to identify organizational factors for successful KM initiatives. While discussing KMS frameworks, Jennex and Olfman (2004) recommend that developing a successful KMS would involve designing a technical infrastructure, incorporating KM into processes, developing a secured KMS and knowledge structure for the enterprise, gaining senior management support, and building motivational factors into the system. Other research indicates that establishing leadership, investing in people, and developing supporting organizational conditions are critical to achieving success in a KM program (Chourides, Longbottom, & Murphy, 2003). Similar success factors were suggested based on a study of several projects (Davenport, DeLong, & Beers, 1998). While these are facilitating factors for a KM initiative, outcomes or results of a KM initiative are different.

A recent conference in London, "Measuring Knowledge Value 2002," addressed the knowledge measurement issue from both macro and micro perspectives (Perkmann, 2002). The macro perspective focused on quantifying intangible assets to capture the value of human capital, competencies, customer relationships, employee collaborations, and so forth, which are not purely financial measures and emphasize the importance of intangible assets. The micro perspective addressed the issue of quantifying the impact of individual knowledge projects. While analyzing the 2002 London conference proceedings, Perkmann (2002) supported the idea of case studies and anecdotal evidence by illustrating that ROI can capture only a part of the project's impact (efficiency and productivity concerns), and projects always have unintended consequences or effects (competency development and learning), negative or positive, that cannot be easily captured in quantitative or financial terms. However, anecdotal evidence and case studies are context-specific artifacts that may not reflect overall reality and may not be commonly accepted. In addition, they do not meet some of the desired characteristics of measures, such as reliability, applicability, and transferability.

In their case study of professional service firms creating competitive advantage through KM, Ofek and Sarvary (2001) identified reducing costs, enhancing product or service quality, or creating value to customers as business strategies for designing and implementing KM to create competitive advantage.

KPMG International, UK (1999) produced a report based on a survey of 423 organizations from Europe and the U.S. In the survey, KPMG identified several expected KM benefits, as shown in Table 1.

A 1997 survey of 431 business organizations in the U.S. and Europe identified four KM application areas (Ruggles, 1998): creation of intranets, data warehousing and knowledge repositories, implementing decision-support tools, and implementing groupware to support collaboration. These application areas focus on knowledge transfer, knowledge retention, better decision making, and support collaboration.

Successful KM programs achieve competitive advantage, customer focus, employee relations and development, innovation, and lower costs (Skyrme, 1997). Though KM promotes development and application of knowledge to attain an enterprise's ultimate goal of profitability, the implicit purpose of KM is to empower knowledgeable individuals with intellectual tasks to promote learning (Wiig, 1999).

Based on the discussions above and several other references, 26 factors were identified for inclusion in the list of outcomes (Anantatmula, 2004). All of them have direct references, not necessarily as outcomes, but under different terms such as "benefits," "impact," "focus," "performance factors," "metrics," "results," "strategies," and "value." Table 2 presents a summary of literature review consisting of KM outcomes and important sources.

The Table 2 list of outcomes is used in the Delphi as a reference list for its participants and in the survey questionnaire to establish priority.

RESEARCH QUESTIONS

The main research objective is to establish the criteria for measuring KM success. Since a criterion can be considered as a standard on which a judgment may be based, establishing criteria and using them to evaluate KM initiatives will lead to knowing expected outcomes of KM initiatives. Thus, the main research question is: What should be the criteria for measuring KM success?

Though KM principles are similar irrespective of the type of organization, criteria and consequent KM outcomes could be different for different types of organizations for two reasons. First, an organization's reason to invest in a KM initiative could be business specific and thus could be dif-

Table 1. KM benefits (KPMG, 1999)

• Better decision making	• Reduced costs
• Better customer handling	• New or better ways of working
• Improved employee skills	• Increased market share
• Faster response to key business issues	• Create additional business opportunities.
• Improved productivity	• Improved new product development
• Increased profits	• Staff attraction/retention
• Sharing best practices	• Increase share price

Table 2. Summary of KM outcomes

KM Outcome	Source
Better decision making	KPMG (1999), Ruggles (1998)
Better customer handling	KPMG (1999), Skyrme (1997), Kelly (2003), Van Buren (1999), Longbottom et. al (2001)
Faster response to key business issues	KPMG (1999), Van Buren (1999), BP Amoco (2001), Longbottom et. al (2001)
Improved employee skills	KPMG (1999), Skyrme (1997), Perkman (2002), Van Buren (1999)
Improved productivity	KPMG (1999), Perkman (2002), Kelly (2003), Van Buren (1999), BP Amoco (2001)

Improved business processes	Jennex et al (2002)

ferent. Second, this initiative is driven by what the organization's goals and objectives are, and each type of an organization may have different objectives and goals.

Many studies support that KM initiatives should be aligned with organizational goals and objectives. A poll of executives from 80 large companies in the U.S., such as BP Amoco, Chemical Bank, Hewlett-Packard, and Kodak, indicated that 80% believed managing knowledge of their organization should be an essential or important part of business strategy (Takeuchi, 1998). Strategic goals and business requirements drive process requirements, which in turn determine knowledge requirements (Massey & Montaya-Weiss, 2002). Massey and Montaya-Weiss (2002) contend that KM initiatives will be effective when they are aligned with the performance goals and requirements of a business, its processes, and its people. Citing that KM is about creating synergy in organizations, Davenport and Probst (2001, as reported by Chourides et al., 2003) contend that such action translates into aligning individual goals with organizational goals. In other words, aligning KM practices with organization goals is a desired way of implementing a KM initiative. Thus, an extension of the main research question is: Are the criteria for measuring KM success different for different types of organizations? The second research question focuses on establishing the criteria or outcomes for different types of organizations.

RESEARCH METHODOLOGY

Literature review findings and research questions discussed in previous sections suggest that those who are well versed with KM theory and practice can better address these issues. For this reason, this research effort uses the Delphi Technique, with occasional use of in-depth interviewing and personal discussions. The Delphi Technique uses a group of experts to deliberate a research issue or a problem anonymously, that is, without having a direct interaction among the group members and without knowing whom the other members of the group are. The Delphi Technique does not involve face-to-face group discussion (Anderson, 1990), and it does not have the disadvantages of conventional groups because it provides anonymity and controlled feedback. However, the Delphi Technique has certain disadvantages. It is time consuming (Anderson, 1990), and swiftness of the decision-making process is controlled by participating individuals to some extent. As results are limited by the number of experts and the number of organizations they represent (Anantatmula, 2004), the Delphi Technique research effort is supplemented by a survey questionnaire, which also helped to set up priority among the established criteria. The survey was aimed only at KM professionals for the same reasons the Delphi was chosen for this research effort.

THE DELPHI TECHNIQUE

The Delphi Technique was developed by RAND Corporation in the 1960s for forecasting purposes, and was later enhanced by the U.S. government for group decision making (Cline, 2000). It is a technique that has also been used to develop lists of objectives or indicators of successful programs (Abramson, Title, & Cohen, 1979). In the KM discipline, the Delphi Technique was used for identifying attribute dimensions to characterize knowledge (Holsapple & Joshi, 2001).

The Delphi Technique was used to gather responses to important research questions by choosing KM professionals and researchers. The Delphi Technique involved the following steps:

- Test research questions
- Select members of the expert group
- Have each member respond to questions
- Summarize responses and distribute the summary
- Seek second responses
- Summarize and distribute responses again
- Continue the process until an agreement emerges

The Delphi Technique addressed the following questions to the select group of KM experts:

1. If an organization wishes to measure success of its KM program, what should be the criteria for measuring KM success?
2. Are the criteria for measuring KM success different for government, non-profit, and for-profit organizations? If different, what should be the criteria for different types of organizations?

The chosen participants of the Delphi Technique were academicians and senior-level KM professionals in organizations such as the George Washington University, Gartner Research Group, Xerox Corporation, U.S. Federal Government, and independent consultants.

THE SURVEY

The initial survey instrument was generated from Table 2, then modified based on pilot test feedback (the pilot test checked the survey's reliability and validity). The final survey was designed with the following features:

- There are 19 questions divided in three parts, making the questionnaire short and less time consuming.
- A brief note about the purpose of the questionnaire is provided in the cover letter.
- Definitions are provided for important terms used in the questionnaire.
- An information sheet is included to obtain consent and ensure confidentiality of the responses.
- Instructions and questions are simple and easy to understand.
- Respondents are given an option to receive research findings.

The survey consisted of 17 closed-ended and two open-ended questions. The primary research question has three parts:

- Establish the criteria that are used to measure KM success
- Establish the importance of each criterion
- Establish the effectiveness of each criterion

The importance of the criterion gives the evidence of significance or consequence, whereas effectiveness denotes the capability of being used to a purpose. A criterion that is important may or may not be effective. If a criterion is chosen as both important and effective, it is considered useful.

The questionnaire was aimed at a target population of KM professionals and practitioners. Those surveyed were from government, non-profit, and for-profit organizations. The survey instrument was used to solicit responses from a number of KM professionals around the world. A total of 152 valid responses were received. Statistical analysis of the results presents the most useful criteria for measuring efforts associated with KM efforts.

FINDINGS

Final Delphi Technique responses are summarized below.

1. If an organization wishes to measure success of its KM program, what should be the criteria for measuring KM success?

All the participants agreed on knowledge sharing and learning, and organization performance as the criteria for KM. Table 3 lists the criteria identified in response to the question.

All Table 3 criteria can be found in Table 2, either with identical phrases or with similar meaning. However, this list could not be shortened, as no further agreement could be reached among the Delphi participants.

Table 3. KM criteria identified by the Delphi respondents

• improve efficiency and effectiveness • improve innovation • make faster, better decisions • improve processes • better business practices • improve capacity (learning and adaptation) • improve collaboration • bottom line (return on investment, increase profits)	• increase intellectual capital • improve knowledge sharing and learning • improve schedule • reduce cost • improve performance • improve customer satisfaction • improve employee satisfaction

2. Are the criteria for measuring KM success different for government, non-profit, and for-profit organizations? If different, what should be the criteria for different types of organizations?

Table 4 lists KM criteria for all three types of organizations. KM criteria for non-profit organizations could include criteria from those of both government and for-profit organizations and are influenced by government. One participant noted that the mission and objectives of each department or agency are different, and hence measures are different for each agency or department. Another participant felt that except for the bottom line argument, the criteria would be the same for all.

Similar to the literature review findings, the Delphi Technique results revealed a list of 15

Table 4. KM criteria for different types of organizations identified by the Delphi

Government	**Non-profit**	**For-Profit**
• cost (budget limitations and fair value) • schedule (milestone requirements) • performance (constituent satisfaction) • customer service • fulfilling government mandate • public service • mission accomplishment • mission results	• public service • mission results • mission accomplishment	• business cost (profit and loss) • schedule (cost reduction and meet customer needs) • performance (quality and customer satisfaction) • business results • customer satisfaction • financial results • innovation • customer loyalty • quality

criteria (Table 3), making it necessary to use a survey to determine the most useful criteria.

SURVEY RESULTS

All survey respondents have some KM experience, with 79% of respondents having more than three years of experience and 42% with six or more years of experience. When asked to rate themselves on KM expertise, only 3.3% of respondents rated themselves as novice, and more than two-thirds considered themselves to be either experts or close to being experts. The majority of those surveyed hold positions such as chairman/CEO, president/CEO, founder/CEO, chief knowledge of-

Table 5. Descriptive statistics of KM criteria (N = 152)

Criteria	Importance		Effectiveness	
	Mean	SD	Mean	SD
Better decision making	4.303	0.828	3.746	0.962
Better customer handling	4.135	0.936	3.727	0.971
Faster response to key business issues	4.023	0.919	3.563	1.005
Improved employee skills	4.094	0.926	3.829	0.985
Improved productivity	4.109	0.981	3.739	0.974
Increased profits	3.458	1.297	3.103	1.267
Sharing best practices	4.068	0.906	3.802	0.988
Reduced costs	3.708	1.069	3.388	1.100
New or better ways of working	3.992	0.897	3.692	1.083
Increased market share	3.067	1.241	2.790	1.081
Creation of new business opportunities.	3.815	1.137	3.416	1.194
Improved new product development	3.769	1.151	3.542	1.142
Better staff attraction/retention	3.604	1.048	3.316	1.118
Increased share price	2.593	1.412	2.493	1.298
Enhanced product or service quality	4.110	0.959	3.743	1.022
Creation of more value to customers	4.065	1.058	3.582	1.102
Enhanced intellectual capital	3.992	1.073	3.761	1.008
Improved communication	4.244	0.842	3.992	0.929
Increased innovation	3.875	1.050	3.627	1.148
Improved business process	3.974	1.021	3.819	0.998
Improved learning/adaptation capability	3.975	0.987	3.761	1.017
Return on investment of KM efforts	3.644	1.299	3.268	1.229
Increased market size	2.933	1.321	2.843	1.254
Entry to different market type	3.128	1.387	3.088	1.389
Increased empowerment of employees	3.844	1.132	3.653	1.108
Enhanced collaboration within organization	4.346	0.794	3.976	0.911

ficer, managing director, director (KM), director, KM architect, KM consultant, senior knowledge strategist, principal, and principal strategy officer. Through descriptive statistical analysis, it was evident that respondents have KM experience, consider themselves fairly knowledgeable about KM, and are involved in KM initiative decision making. Finally, their roles and responsibilities appear to be consistent with their organizational profiles.

Of the organizations represented, 31.5% have equal to or fewer than 100 employees, 36.2% have 2,500 to 10,000 employees, and 24.8% have 10,000 or more employees. In terms of revenue, 47% of organizations have more than $1 million revenue, with 21% having more than $1 billion. Revenue is not applicable for 37% of organizations. Since all the respondents indicated that they have KM experience and that they have answered KM-related questions, we can assume that most of these organizations are involved in implementing KM.

The mean value and standard deviation of importance and effectiveness of each criterion is computed and compiled in Table 5. Both importance and effectiveness have been used.

Both the importance and effectiveness measures have identical scales, with 5 representing very high and 1 representing very low, thus values closer to 5 indicate higher importance or effectiveness. Table 6 lists the most and least useful criteria based on quartile values, with the first quartile representing high importance/high effectiveness of criteria and the last quartile representing low importance/low effectiveness of criteria.

It is interesting to note that the least useful criteria can be quantified and easily measured, whereas the most useful criteria are difficult to measure and cannot be easily tied to bottom-line results. It can be concluded that KM efforts have internal focus and may have indirect impact on business results, specifically market performance.

Other criteria that are associated with business results—increased profits, reduced costs, improved new product development, return on investment of KM efforts, and enhanced product or service quality—are not among the most or least useful criteria. It is important to understand that KM efforts can also lead to results associated with the least useful criteria.

It was possible for respondents to employ one or more criteria not listed among the 26 criteria

Table 6. Survey results of KM criteria

Most Useful Criteria	**Least Useful Criteria**
• Enhanced collaboration	• Increased share price
• Improved communication	• Increased market size
• Improved employee skills	• Increased market share
• Improved productivity	• Entry into different market type
• Better decision making	• Increased profits
	• Better staff attraction/retention
	• Return on investment of KM efforts

presented in the survey. To address this issue, respondents were asked to provide any other criteria that they consider important for measuring KM success. Only 28% of respondents answered this question, which implies that the majority of the respondents (72%) found their useful criteria in the Table 2 list of criteria. Since there were no omissions in the criteria list, and not a single criterion was mentioned more than twice as a response to this open-ended question, they were not included in the results of the study.

KM CRITERIA AND TYPES OF ORGANIZATIONS

While a majority of the respondents agreed that the criteria for measuring KM success are based on an organization's mission, objectives, and goals, the pair-wise correlation analysis indicated that the aligned criteria are not necessarily the most useful criteria. Some of the criteria related to business performance and growth are easily measurable and aligned with the mission, objectives, and goals of an organization.

Pair-wise correlation analysis suggested that top management support is aligned with factors relating to business performance and the delegation of power. Participation of functional managers in KM efforts is aligned with many criteria effectiveness, which signifies its value to KM efforts. Respondents were asked to identify their organization from the options below; the percentage of responses for each is summarized as well.

- Federal or state government—21%
- Non-profit organization—26%
- For-profit organization—48%
- Other, please specify—5%

Responses to option 4 (Other) were eliminated for the analysis, as they are not relevant to the study, and a one-way ANOVA was attempted to determine whether the sample mean values of criteria (both importance and effectiveness) are different for each type of organization. Results showed significant difference in the sample mean value for only 6 and 4 variables of criteria importance and criteria effectiveness respectively

Table 7a. ANOVA – criteria importance

Criteria	Government		Non-profit		For-profit		Probability
	size	mean	Size	mean	size	mean	
Increased profits	16	2.250	20	3.000	54	3.963	<0.0001
Increased market share	15	1.667	21	2.953	49	3.429	<0.0001
creation of new business	18	3.055	28	3.536	58	4.156	0.0004
Increased share price	15	1.800	19	2.211	43	2.954	0.0116
Increased market size	16	2.062	25	2.800	44	3.205	0.0106
Entry to different market	16	2.250	22	3.046	44	3.364	0.0224

Table 7b. ANOVA – criteria effectiveness

Criteria	Government		Non-profit		for-profit		probability
	size	Mean	Size	mean	size	mean	
Increased profits	15	3.667	19	3.210	49	3.368	0.009
Increased market share	13	1.693	20	2.850	45	3.089	0.000
creation of new business	17	2.923	27	3.186	54	3.704	0.013
increased empowerment	22	3.318	27	3.334	48	3.917	0.035

(Tables 7a and 7b). The differences of mean value are not significant for 20 and 22 (out of 26) criteria importance and effectiveness, respectively, for different types of organizations.

While the differences of mean value are significant, their mean values are not. Except for the criterion, creation of new business opportunities, which has a mean value of 4.156 for for-profit organizations, all others have lower mean values. Table 8 uses a similar methodology to that used for Table 6 to identify the most useful criteria for each type of organization.

These results indicate that criteria for measuring KM efforts are different for different types of

Table 8. KM criteria for different types of organizations

Government	Non-profit	For-Profit
• Improved communication • Improved productivity	• improved communication • Enhanced collaboration within organization • Improved learning, adaptation capability	• Enhanced collaboration within organization • Improved employee skills • Improved communication • Enhanced product or service quality • Sharing best practices • Better customer handling • Better decision making • Creation of more value to customers

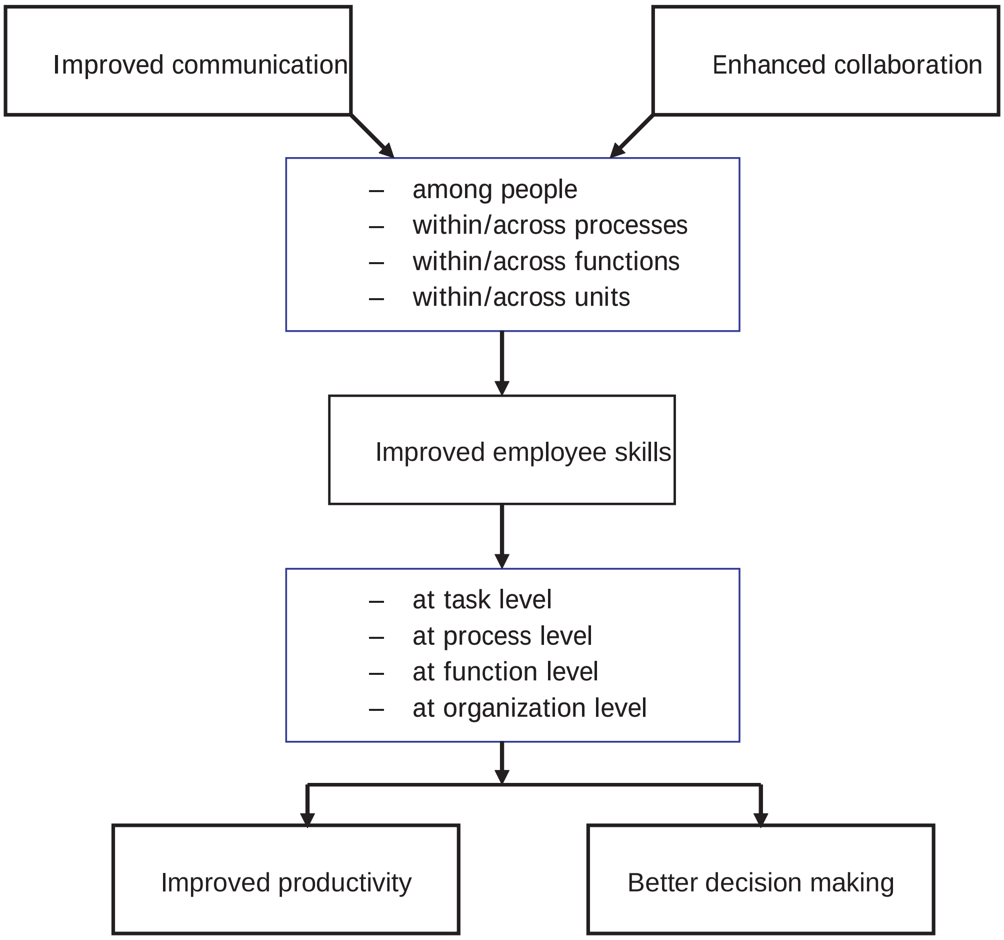
organizations. While government and non-profit organizations focus on internal performance only, for-profit organizations focus on both internal and external performance.

MEASURES OF THE MOST USEFUL OUTCOMES

Through this research, both the most useful and the least useful criteria are established for outcomes of KM initiatives. While the most useful outcomes are difficult to measure, the least useful outcomes can be quantified and are easily measurable. The research identified enhanced collaboration within organization, improved communication, and improved employee skills as the top three outcomes overall, followed by improved productivity and better decision making. As these criteria are difficult to measure, it is important that they need to be further broken down to different levels to develop detailed measures as shown in Figure 1.

Developing measures for improved communication and enhanced collaboration requires

Figure 1. Significant KM outcomes



critical thinking. Some of the suggested methods to develop measures for these criteria are discussed below.

Improved Communication

- A gap survey to determine communication effectiveness is a first step. Once these gaps are identified, organizations should address these issues through KM initiatives and tools, which could be organization specific. Impact of these actions can be measured by using controlled groups or by conducting a similar gap survey later. Some of the tools to address communication gap are newsletters, kiosks, and news desks. However, these tools should be designed to communicate key business knowledge, with a focus on improving organizational performance.
- Constant and continuous transformation of individual learning to organizational learning and vice versa is a source of effective communication. To facilitate this transformation, organizations must encourage both formal and informal communication channels and monitor their performance. Communities of practice, electronic yellow pages, intranets, and best-practice database systems should help this transformation, and their effectiveness measures in terms of business performance can be developed.
- Organizations must develop skill development workshops and employee training development seminars to improve communication and ensure transformation of explicit knowledge to tacit knowledge and vice versa. Effectiveness measures of these workshops and seminars can be easily developed.
- Quantification of organizational or explicit knowledge and developing measures for their usefulness is another way of measuring communication. For example, a number of documented and well-defined processes, project management practices, and decision-making procedures can be developed; frequency of reference and number of revisions could be guiding factors for measuring the effectiveness of these communication tools.

Enhanced Collaboration

- Opportunities for individuals to participate in management activities such as decision making should be designed to improve collaboration, and it should be aimed at improving organizational performance. The effectiveness of these actions can be measured by controlled group studies.
- Formation of committees at several levels of management to develop new problem-solving methods and resolve management problems will ensure enhanced collaboration. It is relatively easy to measure the effectiveness and contribution of these committees.
- Constant and continuous transformation of individual learning to organizational learning and vice versa is a source of effective communication and enhanced collaboration as well. Some of the measures discussed above are applicable for enhanced collaboration also.
- Delegation of authority and accountability to encourage individuals would result in greater collaboration at lower levels of management. It would lead to increased employee morale, motivation, and individual performance, which can be measured.

Improving employee skills can be achieved by improved communication and enhanced collaboration. In addition, recognition programs—such as employee of the month, years of service, and attendance awards—would create incentives for employees to improve their individual performance. There are many ways to measure improved productivity and better decision making, which can be judged by results associated with decisions.

CONCLUSION

Knowledge, as a source of competitive advantage, will continue to gain strategic importance, and organizations will be compelled to implement KM initiatives to improve organizational performance. KM will continue to evolve to develop industry and organization-specific systems and processes. Through future research efforts, the most useful outcomes identified through this research can be further developed into detailed measures of KM success. The author is presently engaged in expanding these research findings and in developing detailed metrics for KM initiatives.

Limitations of the Study

As mentioned earlier, the number of experts and the number of organizations they represent limit Delphi Technique results. The survey questionnaire is similar to a one-time case study in which all the respondents were asked to respond to the questionnaire only once.

Of the internal and external validity factors (Campbell & Stanley, 1963), only statistical regression and biases are relevant to the survey and the Delphi Technique. Others are relevant for controlled experimental studies. External validity factors are no threat to the research study. Statistical regression, which is concerned about selection of groups on the basis of their extreme scores, is part of the research design, as responses from KM professionals and experts are sought for this research and its findings are limited to KM initiatives only.

Bias, which results in differential selection of respondents for the comparison groups, is not directly related to the current research, as there are no comparison groups. However, selection bias is a possibility for the Delphi Technique. To avoid this, the Delphi Technique group was selected by a leading KM expert and professor, who is not directly involved with the study.

The study grouped organizations into government, non-profit, and for-profit organizations, and research data was separated using these groups to examine hypotheses using statistical analysis. The underlying assumption is that within each group, organizations have similar KM purpose and focus, which may or may not be true.

Incomplete responses were ignored for the statistical analysis. Of the valid responses received, 48% of responses represent for-profit organizations, whereas responses from government and non-profit organizations constitute 21% and 26% respectively. Due to this imbalance in organizational representations, the results may be biased towards for-profit organizations.

Some respondents chose to not answer questions associated with importance and effectiveness of the criteria that they did not use. As a result, responses to criteria importance and effectiveness varied from 75 (criteria effectiveness—increase in share price) to 135 (criteria importance—sharing best practices). However, more than 80% of responses were in the range of 105-135. Since not all respondents provided their contact information, it was not possible to do a follow-up mailing or phone call to get full responses.

Research findings and conclusions of this research must be seen in the context of the profiles of the respondents and organizations they represent. Specifically, these findings are not tied to any specific geographical region.

Suggestions for Future Research

Statistical analysis and research findings helped to identify the criteria for measuring KM efforts, which in turn can be described as desired outcomes. The research study also helped in identifying new areas of interest for further research. Some of these gray areas and new areas of interest are:

- The most useful criteria identified through this research can be further developed into detailed measures of KM success, as discussed briefly in the previous section. The research questions—What are the detailed measures for enhanced collaboration within an organization? What are they for improved communication and improved employee skills?—are required to be answered in this effort. The research effort would entail establishing detailed measures for each useful criterion, validating their relation to the criteria, and validating their effectiveness through research.
- Based on geographical location as well as industry type, the differences in KM criteria can be analyzed using multiple factors. The research questions—What are the differences in KM criteria based on geographical location? Are they industry specific?—will have to be addressed in a follow-up research effort. However, using data similar to those obtained from this research, the differences in KM criteria can be examined for Europe and the U.S.

Relationships among all the 26 criteria can be explored to establish associations and classifications among these criteria by factorial analysis. KM criteria and outcomes may be classified based on business results, market results, customer service, and internal performance.

Section 7
Critical Issues in Knowledge Management

This section contains 25 chapters addressing issues such as intellectual capital and knowledge management, communities of practice and critical social theory and ontology-supported web service composition. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study while developing an excellent model for researchers and practitioners as attempts are made to simultaneously ease and expedite the transfer of knowledge from the private to the public sector. Forming frameworks in which to position the issues faced in this growing field are provided by research found in chapters that take the core psychological paradigms of sociology and translate them into applicable ideas within the exploding realm of information sharing. Crucial examinations serve to reinforce the ideas presented in this section while simultaneously enticing and inspiring the reader to research further and participate in this increasingly pertinent debate.

Chapter 7.1
Knowledge Creation

Nilmini Wickramasinghe
Cleveland State University, USA

INTRODUCTION

Knowledge management (KM) is a newly emerging approach aimed at addressing today's business challenges to increase efficiency and efficacy of core business processes, while simultaneously incorporating continuous innovation. The need for knowledge management is based on a paradigm shift in the business environment where knowledge is now considered to be central to organizational performance and integral to the attainment of a sustainable competitive advantage (Davenport & Grover, 2001; Drucker, 1993). Knowledge creation is not only a key first step in most knowledge management initiatives, but also has far reaching implications on consequent steps in the KM process, thus making knowledge creation an important focus area within knowledge management. Currently, different theories exist for explaining knowledge creation. These tend to approach the area of knowledge creation from either a people perspective—including Nonaka's Knowledge Spiral, as well as Spender's and Blackler's respective frameworks—or from a technology perspective—namely, the KDD process and data mining.

The following discusses each of these major theories on knowledge creation and suggests the benefits of taking a holistic approach to knowledge creation—namely, incorporating both the people and technology perspectives in all knowledge creation endeavors, and thereby facilitating the realization of a broader knowledge base, better knowledge inputs to impact on the consequent KM steps, and hence an increased likelihood in more successful knowledge management initiatives.

BACKGROUND

Knowledge Management

Knowledge management offers organizations many strategies, techniques, and tools to apply to their existing business processes so that they are able to grow and effectively utilize their knowledge assets. In essence then, knowledge management not only involves the production of

Figure 1. The KM Triad

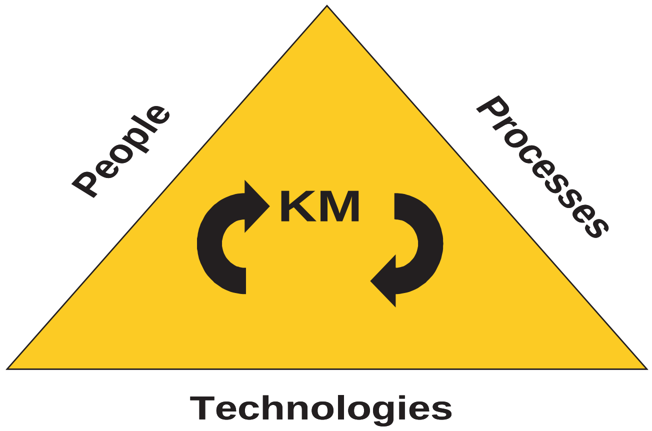

Figure 2. The KM Diamond

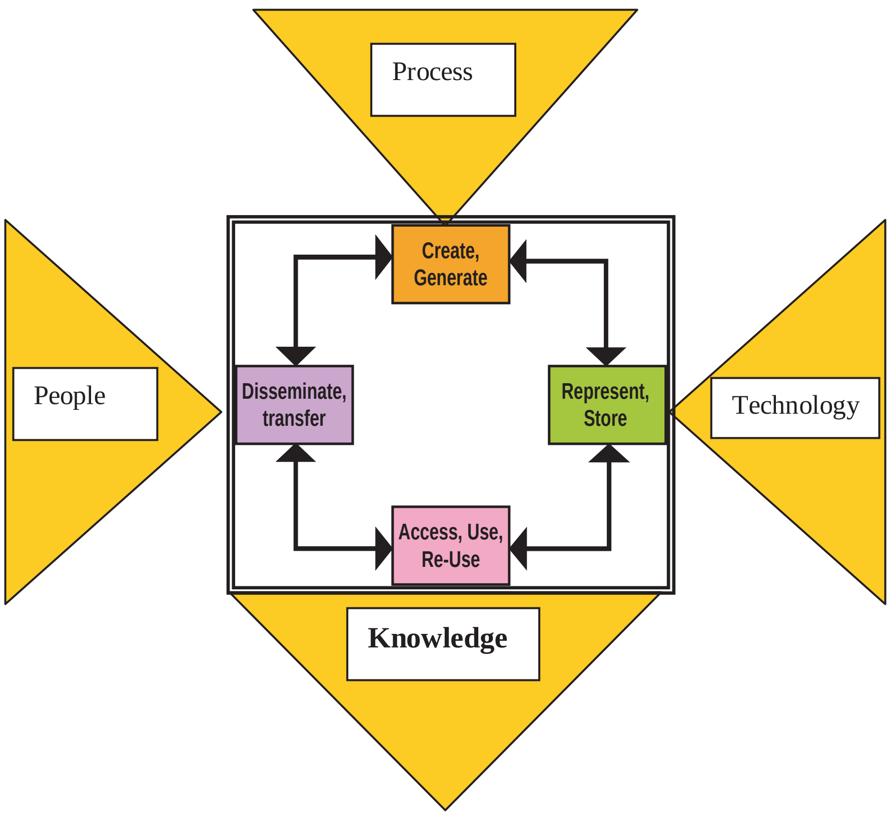


information, but also the capture of data at the source, the transmission and analysis of this data, as well as the communication of information based on or derived from the data to those who can act on it (Swan et al., 1999). Integral to knowledge management is incorporating the socio-technical perspective of people, processes, and technologies (Wickramasinghe & Mills, 2001). We can visualize this in terms of the KM Triad as shown in Figure 1. The significance of the KM Triad is to emphasize that knowledge can be created by people and/or technologies, and can also be embedded in processes.

Broadly speaking, knowledge management involves four key steps of creating/generating knowledge, representing/storing knowledge, accessing/using/re-using knowledge, and disseminating/transferring knowledge (Davenport & Prusak, 1998; Alavi & Leidner, 2001; Markus, 2001). By combining the KM Triad with these four key steps, it is possible to form the KM Diamond as shown in Figure 2. The KM Diamond highlights the importance of the impact of the three elements of KM—namely, people, process, and technology—on the four steps of knowledge management. In other words, successful KM initiatives require consideration and interactions among all of these components.

Knowledge creation, generally accepted as the first step for any knowledge management endeavor (as depicted in Figure 2), requires an understanding of the knowledge construct as well as its people and technology dimensions. Given that knowledge creation is the first step in any knowledge management initiative, it naturally has a significant impact on the other consequent KM steps (depicted in Figure 2), thus making knowledge creation a key focal point of many theories currently in the literature. In order to fully appreciate the need for taking a holistic approach to knowledge creation, it is important to first discuss the subtleties of the knowledge construct itself.

Table 1. Multiple perspective on knowledge (Wickramasinghe & Sharma, 2005)

School of Thought	*Basic Ideas on Knowledge*	*Some Proponents*
Positivism	Knowledge is gained from the observation of objective reality.	Comte
Constructivism	Knowledge is constructed in our minds, thus is not objective.	Erlangen School
Critical Theory	Uses knowledge to integrate the tension between reality of society and the real societal function of science.	Habermas, Horkheimer
Critical Rationalism	All knowledge must be open to empirical falsification before it can be accepted.	Popper
Empiricism	Knowledge can be created from experiments, and thus only mathematics and natural sciences can provide secure knowledge.	Locke, Russel
Sociology of Knowledge	Knowledge is a socially constructed reality.	Mannheim, Scheler
Pragmatism	Knowledge represents a local reality based on our experiences.	Dewey

Historical Understanding of Knowledge

We owe much of our current understanding of knowledge today to the discussions and debates of ancient Greek philosophers such as Socrates, Plato, and Aristotle. The knowledge construct and trying to pin it down, as well as define the process of knowing itself, dominated their thinking. For these ancient Greek philosophers, knowledge was a homogenous construct that ultimately was representative of the truth. Thus knowledge was truth. Other important challenges to what knowledge is then came in the 17th and 18th centuries when philosophers such as Decartes, Leibnitz, and Locke challenged the ideas of knowledge as faith and developed ideas of knowledge as accurate, provable facts, while other philosophers such as Hegel and Kant defined knowledge as divergent meaning or justified true beliefs. Since the 19th century, many different philosophical schools of thought have emerged, and they have all tried to once again pin down this elusive, yet important knowledge construct. Table 1 summarizes the major perspectives.

The Multifaceted Knowledge Construct

As with many concepts in organizational theory, the existence of duality as discussed by Orlikowski (1992) applies when we examine the knowledge construct. Traditionally researchers have turned to Burrell and Morgan's (Malhotra, 2000) well-established framework of objective and subjective characterizations, or a more recent approach elaborated on by Schultze and Leidner (2002) is Deetz's four discourses of organizational inquiry to highlight these dualities. In trying to manage knowledge, it is necessary first to understand the binary nature of knowledge—namely, its objective and subjective components (Malhotra, 2000) or consensus/dissensus dimensions (Schultze & Leidner, 2002). Knowledge can exist as an object, in essentially two forms: explicit or documented and formal knowledge—that is, "know-what"—and tacit or experiential—that is, "know-how" (Polyani, 1958, 1966; Nonaka & Takeuchi, 1995; Beckman, 1999). It is well established that while both types of knowledge are important, tacit knowledge is more difficult to identify and thus manage (Malhotra, 2000; Newell, Robertson, Scarbrough, & Swan, 2002). Of equal importance, though perhaps less well defined, knowledge also has a subjective component and can be viewed as an ongoing phenomenon, being shaped by social practices of communities (Boland & Tenkasi, 1995). The objective elements of knowledge can be thought of as primarily having an impact on process, while the subjective elements typically impact innovation. Both effective and efficient processes as well as the functions of supporting and fostering creativity and innovation are key concerns of knowledge management. Thus, we have an interesting duality in knowledge management (Wickramasinghe, 2001) that some have called a contradiction (Schultze, 1998) and others describe as the loose-tight nature of knowledge management (Malhotra, 2000).

The loose-tight nature of knowledge management comes to being because of the need to recognize and draw upon several distinct philosophical perspectives, including the Lockean/Leibnitzian stream and the Hegelian/Kantian stream. Models of convergence and compliance representing the tight side are grounded in a Lockean/Leibnitzian tradition. Such a perspective views the pursuit of knowledge and its management as necessary to provide the correct solution to a problem or decision, and thus enables organizational effectiveness and efficiencies to ensue (Wickramasinghe, 2005). This in turn leads to the development of models that are essential to support the information processing aspects of knowledge management, most notably by enabling efficiencies of scale and scope and thus supporting the objective view of knowledge management (Malhotra, 2000; Wickramasinghe, 2005). In contrast, the loose side provides agility and flexibility in the tradition of a Hegelian/Kantian perspective. Such models recognize the importance of divergence of meaning and the need to support discourse within communities of practice (Boland & Tenkasi, 1995), which is essential to support the "sense-making," subjective view of knowledge management. In terms of knowledge creation then, in order to ensure the creation of a rich, germane, and useful knowledge base, it is prudent to be mindful of these philosophical perspectives that highlight the key dynamics relating to different types of knowledge creation.

MAIN FOCUS: THEORIES ON KNOWLEDGE CREATION

The processes of creating and capturing knowledge, irrespective of the specific philosophical orientation (i.e., Lockean/Leibnitzian versus Hegelian/Kantian), is the central focus then of both the psycho-social and algorithmic theories of knowledge creation. However, to date knowledge creation has tended to be approached from one or the other perspective, rather than a holistic, combined perspective (Wickramasinghe, 2005).

The Psycho-Social Driven Perspective to Knowledge Creation

In this section three well-known psycho-social knowledge creation theories—Nonaka's Knowledge Spiral, and Spender's and Blackler's respective frameworks—are presented. Organizational knowledge is not static; rather it changes and evolves during the lifetime of an organization (Davenport & Prusak, 1998; Malhotra, 2000). Furthermore, it is possible to change the form of knowledge, that is, to transform existing tacit knowledge into new explicit knowledge and existing explicit knowledge into new tacit knowledge, or to transform the subjective form of knowledge into the objective form of knowledge (Nonaka & Nishiguchi, 2001; Nonaka, 1994).

This process of transforming the form of knowledge, and thus increasing the extant knowledge base as well as the amount and utilization of the knowledge within the organization, is known as the knowledge spiral (Nonaka, 1994). In each of these instances, the overall extant knowledge base of the organization grows to a new, superior knowledge base. According to Nonaka (1994):

1. Tacit-to-tacit knowledge transformation usually occurs through apprenticeship type relations where the teacher or master passes on the skill to the apprentice.
2. Explicit-to-explicit knowledge transformation usually occurs via formal learning of facts.
3. Tacit-to-explicit knowledge transformation usually occurs when there is an articulation of nuances; for example, as in healthcare if a renowned surgeon is questioned as to why he does a particular procedure in a certain manner, by his articulation of the steps the tacit knowledge becomes explicit.
4. Explicit-to-tacit knowledge transformation usually occurs as new explicit knowledge is internalized; it can then be used to broaden, reframe, and extend one's tacit knowledge.

These transformations are often referred to as the modes of socialization, combination, externalization, and internalization, respectively (Nonaka & Nishiguchi, 2001).

The following scenario serves to depict these knowledge transformations in the context of healthcare (Wickramasinghe et al., 2004). Specifically, the scenario outlines the application of the knowledge spiral in the domain of reconstructive orthopedic surgery. Advancing age often leads to the degeneration of a patient's knee and hip joints such that reconstruction of the joint with metal and plastic components is often required. Given the explosion of the population over the age of 65 over the next 40 years, these devices are being implanted in increasingly larger numbers during major surgical procedures in which the degenerative joint surfaces are removed and replaced with the artificial components. There are a multitude of variables in these reconstructions, ranging from the patient characteristics and healthcare status to the implant design and implantation methodologies. The surgeon's tacit knowledge determines the 'best' implant design and combinations and implantation methodologies that are used for each particular patient. The examination of the clinical results leads to the explicit knowledge that determines if those choices are appropriate for each patient population.

However, the examination of the results of these interventions has been limited at the very least to just a few of the thousands of clinical data points and rarely to more than one surgeon or one clinical site. Moreover, at each clinical site, the data of interest is often housed in divergent databases from administrative, clinical, financial, imaging, and laboratory sources. The complete and accurate examination of the clinical results of joint replacement requires an examination of each of these data sets for the relationships that may exist within and across databases. Post-operative and regular radiographs of these implanted devices are used by clinicians to determine if the implant methodologies, such as device alignment and bone-implant interface, are appropriate. Migration of the implant within the host bone or wearing of the plastic component can be visualized on the radiographs and is indicative of impending failure of the component. Combinations of the various data sources—that is, combinations of explicit knowledge—will assist with the handling of failures and complications, and offer the clinicians the opportunity to develop solutions to problems as or even before the problems develop into patient symptoms—that is, increase the existing knowledge base. The knowledge transformations of the knowledge spiral from extant explicit and tacit knowledge to the creation of new explicit and tacit will assist in the search of clinical perfection and ultimately lead to improved clinical outcomes and increased healthcare value. Thus, in this one simple scenario from healthcare, all four of Nonaka's knowledge transformations are being effected.

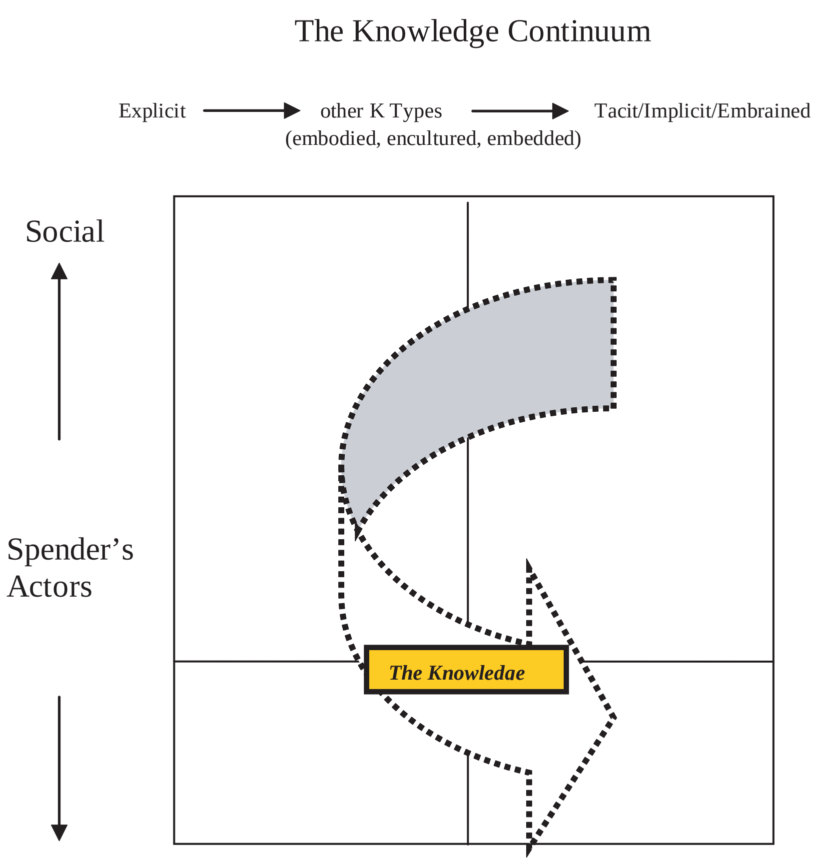
Integral to this changing of knowledge through the knowledge spiral is that new knowledge is created (Nonaka, 1994); this can bring many benefits to organizations, as seen in the above scenario of the orthopedic reconstruction of knee and hip joints. Specifically, in today's knowledge-centric economy, processes that effect a positive change to the existing knowledge base of the organization and facilitate better use of the organization's intellectual capital, as the knowledge spiral does, are of paramount importance. It is noteworthy that while the knowledge spiral is well discussed in the literature as a cornerstone in knowledge creation, few frameworks, if any, exist on how to actualize the transformations of the knowledge spiral as evidenced by extensive literature review studies (Schultze & Leidner, 2002; Alavi & Leidner, 2001).

Two other primarily people-driven theories that focus on knowledge creation as a central theme are Spender's and Blackler's respective frameworks (Newell et al., 2002). Spender draws a distinction between individual knowledge and social knowledge, each of which he claims can be implicit or explicit (Newell et al., 2002; Spender, 1998). From this framework we can see that Spender's definition of implicit knowledge corresponds to Nonaka's tacit knowledge. However, unlike Spender, Nonaka does not differentiate between individual and social dimensions of knowledge; rather he just focuses on the nature and types of the knowledge itself. In contrast, Blackler (Newell et al., 2002; Blackler, 1995) views knowledge creation from an organizational perspective, noting that knowledge can exist as encoded, embedded, embodied, encultured, and/

or embrained. In addition, Blackler emphasized that for different organizational types, different types of knowledge predominate and highlighted the connection between knowledge and organizational processes (Newell et al., 2002; Blackler, 1995).

Blackler's types of knowledge can be thought of in terms of spanning a continuum of tacit (implicit) through to explicit, with embrained being predominantly tacit (implicit) and encoded being predominantly explicit, while embedded, embodied, and encultured types of knowledge exhibit varying degrees of a tacit (implicit)/explicit combination. In other words, Blackler takes a more integral calculus perspective to the types of knowledge. An integrated view of all the three frameworks is depicted in Figure 3. What is important to note here is that this integrated view is not in conflict with any of the philosophical perspectives discussed earlier. This means that the existence of tacit and explicit knowledge, and more importantly the knowledge spiral itself, the most general of the three psycho-social frameworks, is relevant to both the Lokean/Leibnitzian and Hegelian/Kantian perspectives, as well as the other philosophical perspectives identified in Table 1. One key benefit of such an integrated view (as in Figure 3) is that it shows the inter-

Figure 3. People-driven knowledge creation grid/map



relationships among these three frameworks and how their respective views of knowledge map to each other.

Specifically, from Figure 3 we can see that Spender's and Blackler's perspectives complement Nonaka's conceptualization of knowledge creation and more importantly do not contradict his thesis of the knowledge spiral wherein the extant knowledge base is continually being expanded to a new knowledge base, be it tacit /explicit (in Nonaka's terminology), implicit/explicit (in Spender's terminology), or embrained/encultured/embodied/embedded/encoded (in Blackler's terminology). What is important to underscore here is that these three frameworks take a primarily people-oriented perspective of knowledge creation.

The Algorithmic Perspective to Knowledge Creation

In contrast to the above, primarily people-oriented frameworks pertaining to knowledge creation, knowledge discovery in databases (KDD), and more specifically data mining, approaches knowledge creation from a primarily technology-driven perspective. In particular, the KDD process focuses on how data is transformed into knowledge by identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad, Piatetsky-Shapiro, & Smyth, 1996; Adriaans & Zantinge, 1996; Becerra-Fernandez, 2001; Chung & Gray, 1999). KDD is primarily used on data sets for creating knowledge through model building, or by finding patterns and relationships in data using various techniques drawn from computer science, statistics, and mathematics as illustrated in Figure 4 (Cabena, Hadjinian, Stadler, Verhees, & Zanasi, 1998).

From an application perspective, data mining and KDD are often used interchangeably. Figure 5 presents a generic representation of a typical knowledge discovery process. Knowledge creation in a KDD project usually starts with data collection or data selection, covering almost all steps (described above and illustrated in Figure 5) in the KDD process. As depicted in Figure 5, the first three steps of the KDD process (i.e., selection, preprocessing, and transformation) are considered exploratory data mining, whereas the last two steps (i.e., data mining and interpretation/evaluation) in the KDD process are considered predictive data mining.

The primary tasks of data mining in practice tend to be description and prediction. Description focuses on finding human-interpretable patterns describing the data, while prediction involves using some observations or attributes to predict unknown or future values of other attributes of interest. The relative importance of description and prediction for particular data mining applications can vary considerably. The descriptive and predictive tasks are carried out by applying different machine learning, artificial intelligence,

Figure 4. Key techniques involved in data mining (adapted from Wickramasinghe et al., 2004)

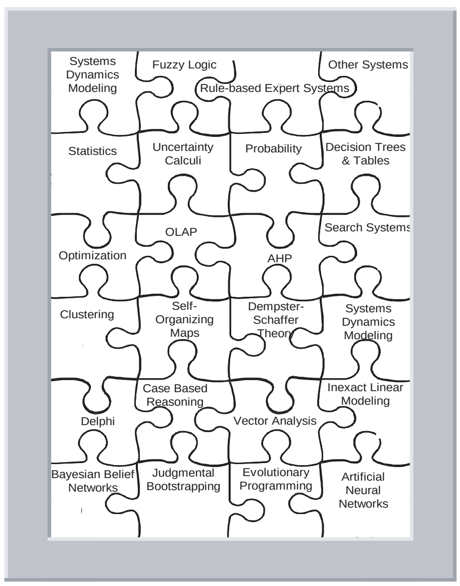


Figure5. Integrated view of the knowledge discovery process (adapted from Wickramasinghe et al., 2004)

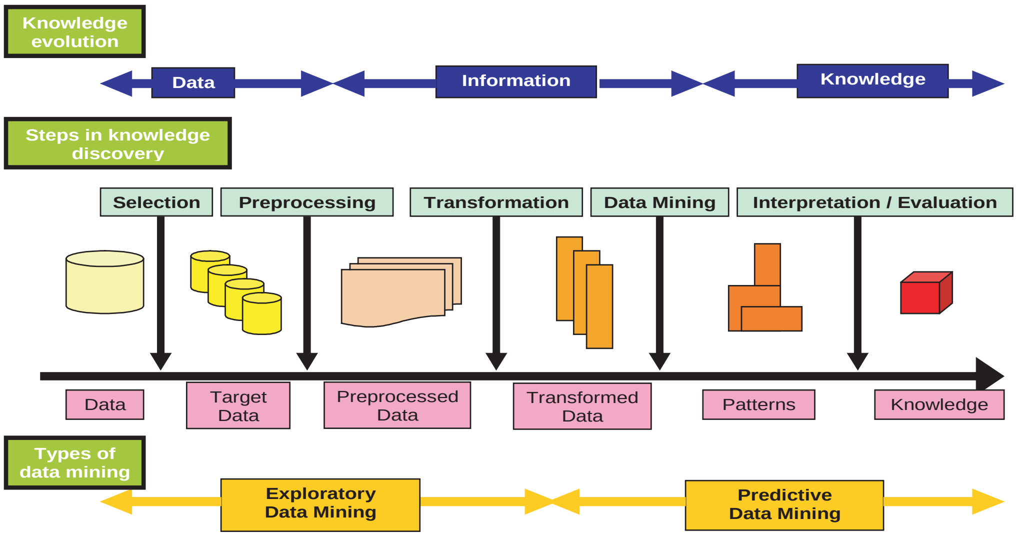


and statistical algorithms. Irrespective of the type of data mining, knowledge creation is the ultimate goal.

Figure 5 captures all the major aspects connected with data mining and the KDD process, and emphasizes the integral role of the KDD process to knowledge creation showing how data is transformed into knowledge via information. However, unlike the frameworks discussed earlier, where knowledge is subdivided into various constituent parts, it is important to note that typically in the KDD process, the knowledge component itself is treated as a homogeneous block.

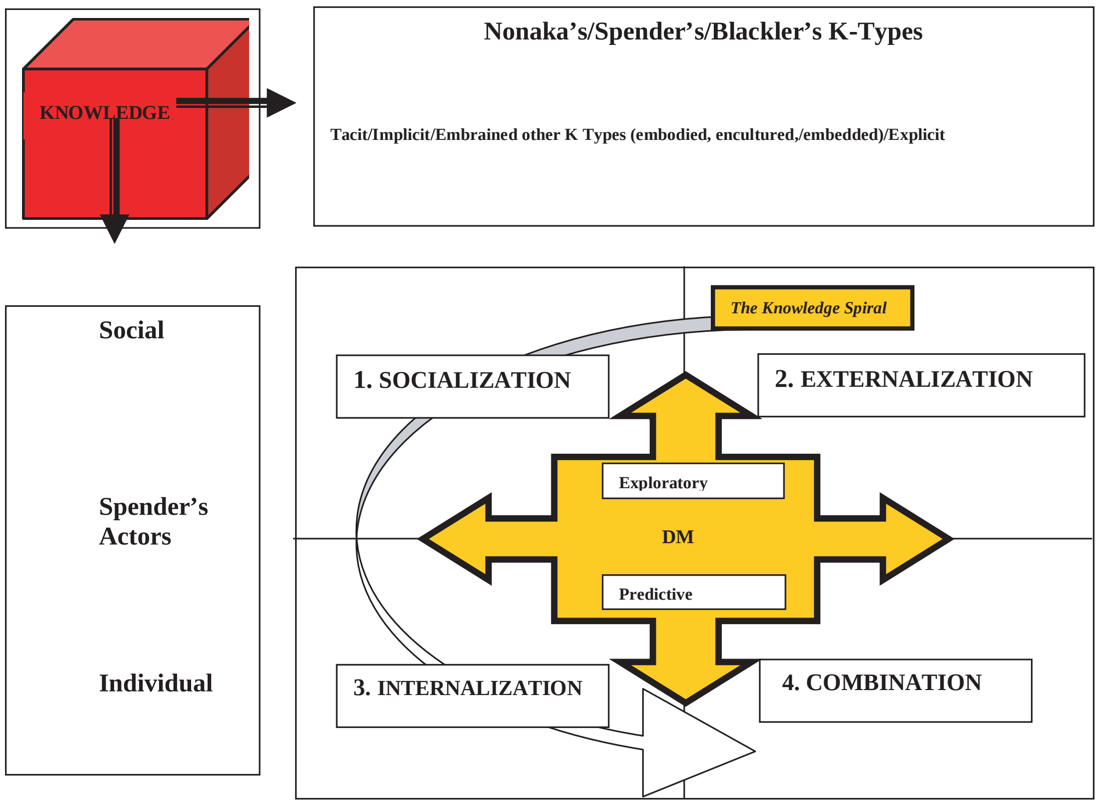
FUTURE TRENDS

"Land, labor, and capital now pale in comparison to knowledge as the critical asset to be managed in today's knowledge economy." Peter F. Drucker

The nations that lead the world into the next century will be those who can shift from being industrial economies, based upon the production of manufactured goods, to those that possess the capacity to produce and utilize knowledge successfully. The focus of the many nations' economy has shifted first to information-intensive industries such as financial services and logistics, and now toward innovation-driven industries, such as computer software and biotechnology, where competitive advantage lies mostly in the innovative use of human resources. This represents a move from an era of standardization to customization, to an era of innovation where knowledge, its creation and management hold the key to success (Bukowitz, & Williams, 1997; Drucker, 1993, 1999).

In today's knowledge economy, it is indeed vital to begin to take a holistic approach to knowledge creation, and thus combine the people-driven and technology-driven theories of knowledge

Figure 6. Holistic view of knowledge creation



creation into an integrative, all-encompassing meta framework in order to truly capture the subtle nuances and complexities of knowledge creation (refer to Figure 6). The two significant ways to create knowledge are: (1) synthesis of new knowledge through socialization with experts—a primarily people-dominated perspective, and (2) discovery by finding interesting patterns through observation and a combination of explicit data—a primarily technology-driven perspective (Becerra-Fernandez et al., 2004). By incorporating a people perspective into data mining, it becomes truly possible to support both these knowledge creation scenarios and thereby realize the synergistic effect of the respective strengths of these approaches in enabling superior knowledge creation to ensue.

DISCUSSION AND CONCLUSION

The preceding discussions have highlighted the key knowledge creation theories that focus on either a people-driven perspective or a technology-driven perspective. Irrespective of which knowledge creation perspective is adopted, it is important for effective knowledge creation to firstly realize that knowledge is a multifaceted construct and knowledge management is a multidimensional approach (consequently the individual steps of knowledge management also should exhibit this multidimensionality).

Given the importance of knowledge management in today's knowledge economy, it is indeed useful to combine the people-driven and technology-driven perspectives into an integrative, all-encompassing meta framework in order to truly capture the subtle nuances and complexities of knowledge creation, and hence realize the synergistic effect of the respective strengths of these frameworks. For example, from the KDD process perspective, we can see how knowledge is created from data, while from the people-driven perspective, we can see the various types of knowledge. Furthermore, such an integrative meta framework or holistic perspective to knowledge creation provides a broader scope and thus better accommodates the different possible knowledge creation scenarios. This is particularly important in today's competitive business environment, as KM is becoming more prevalent in organizations irrespective of the organizational structures or industry. For example, more structured organizations would be more likely to use explicit knowledge more than tacit knowledge, while dynamic and informal organizations are likely to use more tacit/implicit knowledge (Spiegler, 2003; Wickramasinghe & Mills, 2001). Similarly, technologically savvy organizations would be more likely to create knowledge (and consequently achieve a strategic advantage) by using the KDD process.

Thus, knowledge creation involves a people dimension, technology dimension, and the processes that link the people and technology. In addition, knowledge creation plays a catalytic role in effecting knowledge management. Hence, the need for an integrative meta framework and holistic perspective that serves to bring these two key dimensions together—that is, an amalgamation of data mining with the knowledge spiral.

ACKNOWLEDGMENT

The author wishes to acknowledge Adam Fadlalla for his suggestions and contribution in earlier versions and the development of these ideas.

Chapter 7.2
Intellectual Capital and Knowledge Management

Gil Ariely
University of Westminster, UK and Interdisciplinary Center Herzliya, Israel

INTRODUCTION

Knowledge management (KM) and intellectual capital (IC) are not one and the same, and although some overlap is apparent, the relationship is far from trivial and requires exploration. Some intellectual capital such as brand is not knowledge, and some knowledge that cannot be transformed into value is not intellectual capital.

This article illustrates the paradigm of IC and its measurement, focusing then on tensions in the relationship of KM and IC and their origins.

Sullivan (2000) moves us toward the understanding of KM as value creation in all its aspects, vs. IC, or ICM (IC management), as value extraction (thus, measurement, accountability, explicability, etc.). He defines intellectual capital very briefly as "knowledge that can be converted into profit" (p. 192), implying that some quantification of the value of knowledge is required.

BACKGROUND

The history and development of intellectual capital and intellectual-capital management somewhat correlate to that of knowledge management, and it seems superfluous to elaborate on the practicality of intellectual capital, where practice was preliminary to theory. The IC movement is a paradigm derived from a practical need: to bridge the apparent gap between the firm's books and the classic accounting vehicle, and the actual market value. According to Petty and Guthrie (2000):

[t]he intellectual capital movement is undeniably grounded in practice (Roos et al., 1997; Larsen et al., 1999; Mouritsen, 1998). The development of intellectual capital reports, for instance, can be traced back to the desire for individuals working with or within businesses to improve their understanding of what comprised the value of the business so as to manage better those things

that generate value. (Sveiby, 1997; Edvinsson & Malone, 1997; Johanson et al., 1999)

They also say (p. 158; see also the definition of IC in "Key Terms"), "Often, the term 'intellectual capital' is treated as being synonymous with 'intangible assets.'"

The paradigm of IC is established rather commonly in the literature as divided into three subdomains: human capital, organizational capital, and customer capital (or human capital, structural capital, and relational capital; Bontis, 2002; Edvinsson & Malone, 1997; Stewart, 1997; Sullivan, 1998). This division is meaningful toward measurement, a focal point of the IC movement.

IC Measurement and Models

Valery Kanevsky and Tom Housel write, "Understanding how to accelerate the conversion of knowledge into money is the real challenge in the information age" (as cited in Von Krogh, Roos, & Kleine, 1998, p. 269). Tracking that process of conversion into value leads to measurement. Roos, Roos, Edvinsson, and Dragonetti (1998) emphasize that the definition of intellectual capital must be clear and measurable: In order to manage intellectual capital, it must be measured.

However, the measurement of knowledge assets triggers both great interest and great skepticism. Indeed, the measurement of IC is still being experimented with various models.

One of the ultimate goals of measuring intellectual capital is its proper acknowledgement and reporting, similar to the more familiar accounting and reporting system of tangible assets in firms. The perspective of the stocks and flows forms of knowledge (following the resource-based view of the firm) inspired a comparison to familiar forms of accounting reporting. According to Bontis, Dragonetti, Jacobsen, and Roos (1999):

In a way, the identification of stocks creates a series of still photos of the company's intangible resources, whereas the flows provide the animation. Adding a flow perspective to the stock perspective is akin to adding a profit and loss statement to a balance sheet in accounting. The two perspectives combined (or the two reporting tools, in the case of accounting) provide much more information than any single one alone.

Indeed, Lev (2000a, 2000b) says, "Accounting's 500 year exceptional durability is being severely tested…a major contributor to such asymmetries are the archaic accounting rules which treat most investments in knowledge as regular expenses."

As to the principle behind actually calculating intellectual capital, Mouritsen, Bukh, Larsen, and Johansen (2002, p. 11) say, "Authors such as Edvinsson and Malone, and Stewart suggest that intellectual capital is a combination of human, structural and customer capital, whose worth can be identified by subtracting the firm's book value from its market value."

Although measuring IC is recognized to be crucial, frameworks have not yet reached statutory recognition as paradigms, thus allowing us but a sample and flavour of some available models and tools implemented toward the metrics of "intangibles" within the scope of this article. This is not due to the lack of models, but to the lack of standards. Further literature reviews of the tools elaborate beyond the scope this theatre allows (Bontis et al., 1999).

According to Petty and Guthrie (2000), "it is the limitations of the existing financial reporting system for capital markets and other stakeholders [that] have motivated an evolving dialogue on finding new ways to measure and report on a company's intellectual capital." The product of this dialogue is a plethora of new measurement approaches that all have the aim, to a greater or lesser extent, of synthesising the financial and non-financial value-generating aspects of the company into one external report. Principal among the new reporting models are the intangible asset monitor (Sveiby, 1988; 1997; Celemi, 1998); the balanced scorecard (Kaplan and Norton, 1992; 1996); the Skandia value scheme (Edvinsson and Malone, 1997; Edvinsson, 1997); and the intellectual capital accounts (DATI, 1998).

It is interesting to compare the frameworks of several of the main classification schemas for reporting intellectual capital. These three principal ones, which emerge prominent in IC literature, show progress toward alignment within the IC paradigm (Table 1).

A conclusion from this comparison is that by now there are the first signs of an aligning idea in the perception of intellectual capital, hence, its measurement. There is clear identification in classification between capital relating to human assets, and capital relating to structure—be it internal or inclusive of the external values.

Moreover, entwined in all frameworks is the profound realization of the value and qualitative characteristics of the attempts to quantify the qualitative via various proxy indicators, as the nature of knowledge, and in particular the nature of its value, is qualitative.

But we must remember that there is no widely accepted standard, and firms may measure their intangible assets rather than be obliged to do so. What measure, metric, tool, or approach is preferable is purely dependent on the circumstances of the organization as there is no binding authoritative view or legislation in the matter (although the need for it is reoccurring in the literature; Bassi & Van Buren, 1999; Van Buren, 1999).

Tools that resemble the familiar accounting tools for reporting are being developed, such as intellectual-capital statements (Mouritsen et al., 2002; Mouritsen, Larsen, Bukh, & Johansen, 2001), and attempts through practice raise a lantern for future recognition and regularity (Wyatt, 2002).

THE RELATIONSHIP BETWEEN KM AND IC

To sum up intellectual capital, and in particular its possible measurement and reporting, it is possible to consider intellectual capital as the knowledge phase in accounting using the principle analysis of knowledge; that is, the accounting reports and balance sheets familiar to us consist merely of the information of the firm, whilst the intellectual-capital reports are in fact the actual accounting knowledge of the firm and its values.

Table 1. IC paradigm

Developed by	Framework	Classification
Sveiby (1997, 1998)	The intangible-asset monitor	Internal structure External structure Competence of personnel
Kaplan and Norton (1992)	The balanced scorecard	Internal-processes perspective Customer perspective Learning and growth perspective Financial perspective
Edvinsson and Malone (1997)	Skandia value scheme	Human capital Structural capital

We have so far taken "raw financial data" (Edvinsson & Malone, 1997, p. 77), the signals, and put them in formation in order to inform (hence it becomes information) in the accounting reports. The knowledge of the firm, mostly tacit, was created in the mind of the reader, be it an accountant, investor, or so on, using other various tacit and explicit sources to inform. The intellectual-capital movement is trying to make explicit as much of this knowledge as possible; much of it arrives as qualitative data and qualitative information.

Continuing the "IC equals firm's tree roots" metaphor (Edvinsson & Malone, 1997, p. 10), although such an effort is not futile, the full (tacit) underground nature of the roots as well as the effect of the soil (context) can never be exposed in full. Evermore, trying to examine the roots in depth by taking out the tree in full cannot be done without harming the roots, as is taking them out of their soil. Thus, we are left with data collected through secondary methods attempting to x-ray the roots from above ground, or inductively taking a sample of the roots. These inseparable connections are discussed further when we recall the dualities incorporated in the concept of value.

The empiric foundation of this article was research implementing grounded theory in a multiple-case study in three organizations (the National Health Service, National Transportation Authority, and the military), from which the illustrated theory emerged. The organizational creation of the paradigms of KM and IC and their relationship was examined by researching KM as a methodology toward IC (Ariely, 2003): an array of methods transformed into perceived value and intellectual capital.

Knowledge is first and foremost inherent in people and in interactions. Viewing knowledge as part of human capital leads to the idea that managing knowledge is part of the structural capital (although not limited to structure). So, successful KM is in itself part of the organization's intellectual capital in addition to the knowledge incorporated in it as a process and in its people. But in order to fully understand the relationship between KM and IC, which surrounds the transformation of knowledge and managing it into value, we must stop to consider the meaning of value within the dual contexts of KM and IC.

What Does Value Mean?

The duality in the definition of value (see "Key Terms") is crucial since the meanings of the word reflect on the quantitative—vs.—qualitative tensions incorporated in the concept of value. Patrick Sullivan (2000) writes,

Economists view value as the sum of a stream of benefits (or income) stretching into the future, summed and discounted to a net present value in dollars. Yet value has meaning for many others besides economists [p. 247]…The economics of information applies to any idea, expression of an idea, or fact that is known by one person and is potentially of value to another. (p. 271)

Any capital or currency is dependent upon its market: so is intellectual capital. Its value, as any currency, is in the eyes of the beholder. Diamonds may be worthless on a deserted, isolated island, or they may bring their worth as a tool to start a fire, multiplying perhaps their true value to our Robinson Crusoe beyond any market value.

The value of knowledge implemented toward action in one context (or having the potential to be) may be absolutely worthless in another. Sullivan (2000) further explores the concept of value, differentiating between defensive and offensive value types for the organization, and creating the organization's value chain.

The relative value placed on innovative ideas is largely dependent upon the firm's view of itself, and upon the reality of the marketplace. Put another way, each firm exists within a context that shapes the firm's view of what is or is not of value. (p. 247; see also Sullivan, 1998; Sveiby, 2001; Von Krogh, Nonaka, & Nishiguchi, 2000).

The perception of the value of the organization's intellectual capital is what becomes its intellectual property and intellectual assets. Assessing it is essential as is assessing the investment in intellectual capital (Bassi & Van Buren, 1999) similarly to any other capital. Furthermore, there is a different value to knowledge, and different behaviours of intellectual capital and intellectual property in different organizational contexts (Sullivan, 2000), for example, intellectual-capital development at a spin-off company (Manfroy & Gwinnell, 1998) in mergers and acquisitions (Sullivan, 2000). According to Joyce and Stivers (1999), "[r]esults indicate that firms…tend to differ in organizational structure and technology orientation, as well as in the perception of the value of various non-financial performance factors and intangible assets."

The operative meaning is that things that are valuable do not necessarily have intrinsic value. They are value-able, with the potential for value, perception making their value ability come true within the organization and in its environment.

Tension Between Production Factors

The tensions that lie beneath the surface between knowledge management and intellectual capital are derived from their basically different nature in relation to the conservative production factors (land, capital, labour). Intellectual capital relates to capital, whilst knowledge management relates to labour. Yet the behaviour of IC is not the same as capital. Mouritsen et al. (2002, p. 10) note that "[i]ntellectual capital is, even if it refers to 'capital,' not a conventional accounting or economic term." The rules for its depreciation, creation, and so forth are complex and irrelevant to "hard capital" (e.g., depreciation of knowledge occurs when it is not used, contrary to tangible assets).

The management of people as human resources has been dealt with within the division of labour. However, when arguing that knowledge is not just people, but their "cognitive contact with reality" (Zagzebski, 1999), their knowledge might be acknowledged, but not managed directly in the classic definition of management in the same way we manage resources within the division of labour. Streatfield and Wilson (1999, p. 70) say, "We cannot manage knowledge directly—we can only manage information about the knowledge possessed by people in organizations." Indeed, we can always manage the yellow pages, which are pointers to knowledge. These pointers accrue in themselves information about the formations of the knowledge.

As to the tensions between the division of knowledge and the division of labour, Klein and Scarbrough (2002) emphasize that:

[t]he very identification of knowledge as a factor of production as distinct from labour, and the irreducibility of the one to the other invites conflict between the two. While much of the literature on knowledge management seeks to legitimise and exploit knowledge as a quasi-autonomous resource of the organization, we see knowledge as simultaneously different from, but not wholly independent from labour.

Indeed, the management of resources such as knowledge in the postindustrial age suggests a much more permissive and updated approach to management.

Boisot and Griffiths (1999) note that "[i]n a 'post Marxist' world, knowledge workers are once more becoming the owners of the means of production," owning the most important production factors: knowledge and intellectual capital.

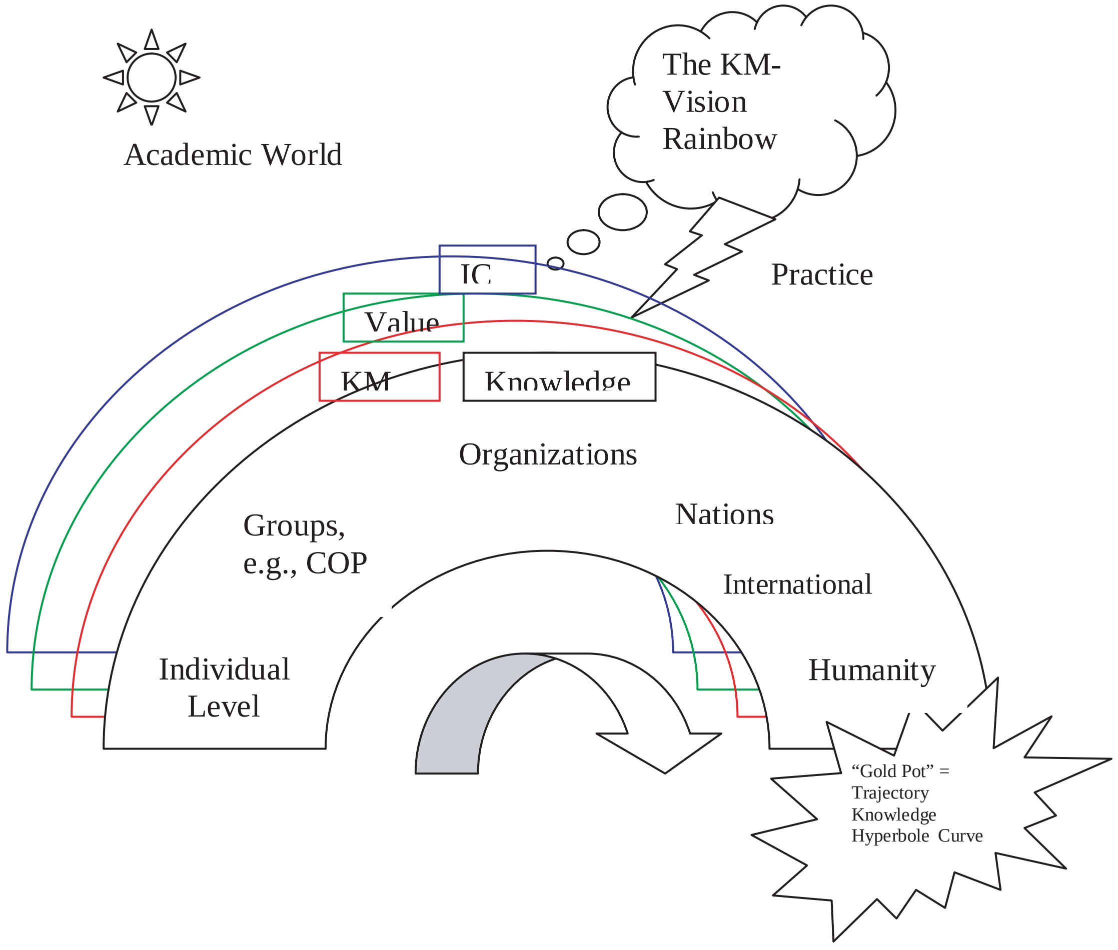
Epistemological Tensions

As our ground is knowledge, it is worth going into geological depth about the theoretical layers beneath it. There lies one more real foundation for the tension between these two domains of knowledge—knowledge management vs. intellectual capital—perhaps to a degree, between their correlating communities of practice (with the overlap that exists between the fields existing between the communities, too). Some tensions date, as geological issues tend to, as far in the past as the origins of that ground.

There is an epistemological diversity, as in many fields, amongst thinkers in the most intrinsic approaches to the world, knowledge, truth, and validity. However, it reflects on not only the derived methodological researching ideology, but rather on the core itself.

For instance, many approach the field of intellectual capital from the need to measure and quantify the organization's value (Petty & Guthrie, 2000), the very need that arouses interest in IC at first being the apparent gap between the firm's actual value and its "book value," by using conservative accounting measures. Accountants, as

Figure 1.



well as many managers, tend to derive from the epistemological foundations of positivism since positivism seems to have been management's mainstream (Johnson & Duberley, 2000) and the most appropriate for Taylor's scientific approach of the industrial age.

It is the same behaviour of knowledge as a differentiated production factor from the conservative ones in the industrial age (land, labour, capital) that justifies a different epistemological, philosophical approach.

Many approach the field of knowledge management from very different epistemological foundations and approaches, such as social constructivism. Wenger (1998, p. 141) says:

Knowing is defined only in the context of specific practices, where it arises out of the combination of a regime of competence and an experience of meaning. Our knowing—even of the most unexceptional kind—is always too big, too rich, too ancient and too connected for us to be the source of it individually.

Hence, "[k]nowledge is socially constructed" (Despres, 2002), which tends to form a real challenge for positivists' measurement.

It is that tension, derived from epistemological differences, that highlights the need for an attempt to approach the field of intellectual capital from a social constructivist's orientation. Also, the derived approach and methodology, in order not to neglect the real essence of value, which is interwoven with perceptions, is constructed socially.

Einstein reminded us that not all that can be counted counts, and not all that counts can be counted. Value and perception become components (or methods in the array) of the modeled methodology. It is perception that brings realization to the potential for value of value-ables.

The emotive theory of values, as one of the principles of logical positivism, acknowledges that "[s]tatements of value are neither true or false, but are simply expressions of attitude" (Cruise, 1997; Gross, 1970; Wedberg, 1984). We can extend that principle within the definitions of value. Thus, one type of value is dependent on the other—on values, perception, and attitude.

Indeed it follows that some tension is also derived from the very essence of the term measurement, which implicitly tries to quantify the very qualitative.

FUTURE

Viewing knowledge management as a catalyst for the creation of human knowledge moves us up the trajectory curve in the hyperbola of human-knowledge creation by allowing us to build better on past generations and current knowledge.

The importance of the connection to intellectual capital is a catalyst for the industry to invest in research and the implementation of KM and IC. This brings the short- and medium-term benefits that organizations and management so often seek, but brings us all the long-term benefits from the blossoming of KM, knowledge, and knowledge on knowledge. According to McElroy (2002, p. 30):

Not surprisingly, managers interested in getting their arms around intellectual capital are searching for ways to describe, measure, and manage their intangible assets with a particular emphasis on capturing their favorable effects on the bottom line and on shareholder values.

Indeed, through a different visualization from the hyperbola of knowledge creation, we can imagine a rainbow model on which the different dimensions are aligned (e.g., value) from an individual level to humanity.

While the academic world should shed light on the whole spectrum, practitioners tend to focus on organizational levels due to economic reasons. The benefits for humanity go beyond organizations, supporting a trajectory knowledge-creation hyperbola. Carrillo (1999) says:

In Post Capitalist Society, Peter Drucker wonders whether anyone will dare to undertake the intellectual manifesto of the Knowledge Economy, something like The K-Capital. One of the most distinctive challenges to the KM movement is the extent to which it is capable of gaining self-awareness and self-management capabilities. To the extent that this happens, it will be able to facilitate the process for achieving the best human account on the principles of knowledge economics.

It seems clear that the intellectual-capital movement picked up the glove dropped in 1993 by Peter Drucker.

CONCLUSION

Exploring the relationships between knowledge management and intellectual capital by incorporating epistemological tensions reveals one such relationship that can be modeled into an empirically grounded methodology.

Knowledge, and managing all of its elements (knowledge creation, sharing, and transfer, etc.), becomes part of the organization's intellectual capital. The intellectual capital is then transformed through its value to the organization (a matter of perception, as discussed, dependant on the eye of the beholder) into the organization's owned intellectual property so that it can be protected.

Explicitly exploring knowledge management as a mechanism that moves us toward intellectual capital and property allows the KM process to become part of the intellectual capital in itself.

According to Fahy (2000):

The management literature highlights that executives play a role in the process of converting resources into something of value to customers (Williams, 1992). This involves resource identification, development, protection and deployment (Amit & Schoemaker, 1993) and managerial skill in these activities is in itself a source of sustainable competitive advantage (Castanias & Helfat, 1991). It is important that future research finds suitable ways of operationalising this management role.

Knowledge management is indeed a suitable way, and managerial skill in KM and IC activities, and the activities themselves, are indeed yet another resource that is value-able, hence potentially another source of sustainable competitive advantage.

The proxy indicators used in different organizations to express the value of qualitative knowledge and of managing it are unique to each and even amorphous. The problem with their acceptance by the society in which they exist is the epistemological tension that results from past industrial-age managerial education and accounting systems that were dominated by positivism. Organizationally, these indicators are derived from the organization's perception of value in light of core competencies and the organizational mission and vision. Such an evolution of thought and of paradigms within the organizations occurred in a spiral manner, collecting and recollecting on previous evolution, and leading to an aligning idea that allows the perception of unification amongst paradigms.

Thus, an epistemological, evolutionary adaptation is required in managerial education complementing that of the postindustrial age rather than suffice for the positivistic approach.

Furthermore, the empiric results and the emerging theory support and accord the evolution of the KM and IC paradigms by and large and their relationship, aiming at an aligning idea, or perception of unification, between them as experienced in many domains in the history of science (Kuhn, 1962).

Chapter 7.3
Mathematical Knowledge Management

William M. Farmer
McMaster University, Canada

INTRODUCTION

Mathematical knowledge is significantly different from other kinds of knowledge. It is abstract, universal, highly structured, extraordinarily interconnected, and of immense size. Managing it is difficult and requires special techniques and tools.

Mathematicians have developed (over the last two or three millennia) many techniques for managing mathematical knowledge. For example, there is a large collection of techniques based on the use of special symbols and notations. Although these techniques are quite effective and have greatly advanced mathematical practice, they are primitive in the sense that the only tools they require are pencil and paper, typesetting machines, and printing presses.

Today mathematics is in a state of transition. Mathematicians are using the Internet in new ways to find information and to share results. Engineers and scientists are producing new kinds of mathematical knowledge that is oriented much more to practical concerns than to theoretical interests. This is particularly true in the field of software development where software specifications and code are forms of mathematical knowledge. Computers are being pushed to perform more sophisticated computations and to mechanize mathematical reasoning. Mathematical knowledge, as a result, is being produced and applied at an unprecedented rate.

It is becoming increasingly difficult to effectively disseminate mathematical knowledge, and to ascertain what mathematical results are known and how they are related to each other. Traditional ways of managing mathematical knowledge are no longer adequate, and current computer and communication technology do not offer an immediate solution. Since mathematical knowledge is vital to science and technology, and science and technology is vital to our society, new ways of managing mathematical knowledge based on new technology and new theory are needed.

This article introduces the main issues of managing mathematical knowledge. It is organized as follows. The Background section describes mathematics as a process of creating, exploring, and connecting mathematical models. The special characteristics of mathematical knowledge and the four main activities that constitute the management of mathematical knowledge are discussed in the Main Focus of the Article. The Future Trends section introduces Mathematical Knowledge Management (MKM), a new field of research, and discusses some of the challenges it faces. The article ends with a conclusion, references, and a list of key terms.

The management of mathematical knowledge is an emerging field of research. Researchers are just starting to build a foundation for it. This article focuses on the core concerns of the field. Except for a few remarks, it does not discuss the parallels between mathematical knowledge management and mainstream knowledge management. Nor does it discuss how techniques for managing mathematical knowledge can be applied to the management of other kinds of knowledge. These are important topics for future research.

BACKGROUND

People often associate mathematics with a body of knowledge about such things as numbers, spatial relationships, and abstract structures. However, this view of mathematics is misleading. It suggests that mathematics is something static and dead, but mathematics is actually the opposite—dynamic and alive. It is more productive and accurate to view mathematics as a process for comprehending the world that consists of three intertwined activities (Farmer & von Mohrenschildt, 2003).

The first activity is the creation of mathematical models that represent mathematical aspects of the world. Mathematical models come in many forms. A well-known and important example is the model of real number arithmetic composed of the set of real numbers, and operations and relations involving the real numbers such as +, ×, and <. Real number arithmetic includes various submodels such as arithmetic of the natural numbers 0,1,2,... and arithmetic of the rational numbers like 2/3, 31/17, and so forth. Real number arithmetic and its submodels capture the essential elements of counting, measurement, motion, and much more. Real number arithmetic itself is a submodel of complex number arithmetic and many other mathematical models.

The second activity is the exploration of mathematical models to learn what they say about the mathematical aspects of the world they model. There are several means of exploration. The explorer can state a conjecture about a model and then attempt to prove that the conjecture is true by virtue of being a logical consequence of the defining properties of the model. The explorer can also formulate a problem concerning the model and then compute a solution to it by mechanically manipulating a representation of the problem using rules determined by the model. A third approach, which is sometimes very effective, is to visualize some facet of the model with a diagram, picture, or animation.

The last activity is the connection of mathematical models by identifying and recording relationships between models. Models can be related to one another in various ways. Examples includes two models being equivalent in a certain sense, one model containing another as a submodel, and one model generalizing another model. A collection of interconnected models facilitates the creation and exploration of new models. New models can be built from old models, and then the results about the old models can be applied to these new models according to how they are connected. Thus, models rarely need to be developed from scratch.

MAIN FOCUS OF THE ARTICLE

Mathematical knowledge is knowledge about mathematical models. Each piece of mathematical knowledge is understood relative to a context of a mathematical model or group of mathematical models. For example, the statement "there is no square root of -1" is true in the model of real number arithmetic, but actually false in complex number arithmetic (the square root of -1 is the complex number i). Although a piece of mathematical knowledge is not meaningful without its context, the context of mathematical knowledge is often not explicitly stated. For example, one might say that as a mathematical fact, "every nonzero number has a multiplicative inverse" without mentioning the context of the statement. Of course, this statement is true for rational number arithmetic and real number arithmetic, but false for natural number arithmetic.

The context for understanding mathematical knowledge is analogous to the context for understanding other kinds of knowledge. Knowledge, mathematical or otherwise, that is applied out of its proper context is not reliable. The context of a piece of knowledge, mathematical or otherwise, is often imprecise or not fully articulated. However, a context for mathematical knowledge, unlike a context for many other kinds of knowledge, can be made as precise as is desired.

Mathematical knowledge is direct knowledge about mathematical models, but it is also indirect knowledge about the mathematical aspects of the world which are being modeled. As indirect knowledge, mathematical knowledge is useful, often even vital, to engineers and scientists. It is routinely used to help solve real-world problems.

Mathematical knowledge has several characteristics that sharply distinguish it from other kinds of knowledge. These characteristics make managing mathematical knowledge significantly different from managing other kinds of knowledge.

Abstractness

A mathematical model is an abstraction of the world; it ignores everything about the world except some part of the world's underlying mathematical structure. Other kinds of knowledge can be abstract, but mathematical knowledge is inherently abstract. Moreover, mathematics is, to a large degree, the study of abstractions.

Universality

Direct knowledge about a mathematical model is indirect knowledge about any situation in the world that exhibits the mathematical structure captured by the model. For example, it is true in the model of rational number arithmetic that, for any two integers m,n, if m/n is an integer, then m = m/n + ... + m/n (n times) is sum of equal integers. As a result, any set of m objects can be divided into n subsets of equal size if m is divisible by n. Mathematical knowledge is thus universal in the sense that it can be applied to every domain of interest that exhibits the right kind of mathematical structure.

Language

Mathematical knowledge is usually expressed in a language with a carefully controlled syntax and a precise, unambiguous semantics. The language allows one to express statements about a certain collection of objects. The language may be an informal language based on a natural language such as English in which ordinary words such as "implies" and "function" have special meanings. The language may also be a formal language that can be read, analyzed, and presented by software.

Semantics

Unlike other kinds of knowledge, mathematical knowledge can be given a precise semantics. This is usually done by representing the context of the mathematical knowledge as a “mathematical theory.” For example, an axiomatic theory is a pair T = (L,A) where L is a language and A is a set of statements of L called axioms. The axioms express properties that the objects of L are assumed to possess. A mathematical model is a model of T if it has the same objects as L and it satisfies each axiom in A. T thus represents “axiomatically” the context composed of the models of T. A piece of mathematical knowledge about the context represented by T can then be expressed as a statement of L that is true in each model of T.

Representation

A body of mathematical knowledge can be represented in different ways. It can be represented declaratively as an explicit set of statements or as the set of logical consequences of a mathematical theory. It can be represented procedurally as the knowledge that is embodied in a computation system such as a calculator. It can be represented visually by diagrams and animations. A body of mathematical knowledge can also be represented by a combination of declarative, procedural, and visual means.

Proof

Most knowledge is obtained by empirical observation and experimentation. Mathematical knowledge is usually not obtained empirically. One way that it is obtained is by proving a conjecture within a context. A proof is an argument that shows that a statement S of a language L is a logical consequence of the axioms of an axiomatic theory T = (L,A), and therefore, that S is true in each model of T. In other words, a proof verifies a conjecture by logical reasoning alone.

Computation

Another way that mathematical knowledge is obtained is by computing a solution to a problem. A computation from an expression A of a language L to an expression B of L is a sequence of meaning-preserving, mechanical manipulations that transform A into B. A expresses a problem to be solved and B expresses a solution to the problem. For example, A could be the equation

x2 - 3x + 2 = 0,

B could be the statement

x = 1 or x = 2,

and a computation of A from B could be the sequence of manipulations that are used to algebraically solve a quadratic equation like A.

Interconnectedness

The body of mathematical knowledge is extraordinarily interconnected. The same piece of knowledge may appear in many different places and in many different forms. For example, the models of real number arithmetic and rational number arithmetic—which are quite different in certain ways—both satisfy a common set of properties about +, ×, and <.

Size

The body of mathematical knowledge is unimaginably immense. It can even be argued that it is inherently infinite and thus possibly even bigger than the physical world. For instance, the model of natural number arithmetic, which is relatively simple, includes facts about each of the infinitely many natural numbers.

Mathematical Knowledge

Mathematical knowledge is produced by exploring mathematical models by means of proof, computation, and visualization. Mathematicians and other mathematics practitioners have traditionally been more concerned about its production than its management. As a result, the management of mathematical knowledge has historically been a collection of loosely related activities and for the most part not a highly disciplined process. In our opinion, there are four major activities—articulation, organization, dissemination, and access—that would be crucial components of any disciplined approach to the management of mathematical knowledge.

Articulation

Mathematical knowledge cannot be communicated unless it is articulated. An articulated body of mathematical knowledge has three components. The first is the language in which it is expressed. The second is the context of mathematical models within which it is understand. And the third is the representation by which it is conveyed.

Most mathematical knowledge is not articulated at all or only partially articulated. Many mathematical details have never been articulated; they reside only in the minds of mathematicians.

Mathematicians rediscover the details using hints provided by the original discoverer. Since fully articulating mathematical knowledge is burdensome, in most cases the language, context, and representation are only partially presented. The user of the knowledge is expected to be able to fill in what is missing as needed. This works well with human users who have strong mathematical skills. It does not work as well with students and average human users, and it does not work at all when the user is a computer program.

Organization

The prodigious size and interconnectedness of mathematical knowledge is a huge obstacle to effective management. Articulated mathematical knowledge needs to be carefully organized to avoid redundancy, to capture connections, and to express results in a compact form. This requires identifying and abstracting common structure and then formalizing it as a mathematical theory.

Mathematicians have always been very interested in organizing mathematical knowledge. However, their interest in the organization of mathematical knowledge is usually motivated by research or education and not by the practical management of mathematical knowledge. To be effectively managed, mathematical knowledge must be organized in a more practical way.

Dissemination

After mathematical knowledge is articulated and organized, it needs to be disseminated. The traditional modes of dissemination are as natural language text in journals and textbooks, and as computation procedures in calculators and mathematical software. Emerging modes of dissemination are as digital information that is accessible on the World Wide Web, and as formally represented declarative and procedural knowledge that is incorporated in mechanized mathematics systems such as computer algebra systems and computer theorem proving systems.

Historically, only the most general and widely applicable mathematical knowledge has been disseminated to the public. Mathematical knowledge generated by engineering and scientific endeavors, such as software development, is usually not widely disseminated even though it would be of value to many mathematics practitioners. New approaches and technology are needed to disseminate this latter, more practical kind of mathematical knowledge.

Access

People need software tools for finding the mathematical knowledge they require in a body of knowledge that has been disseminated. Tools are needed for doing searches and making queries, for performing deductions and computations with mathematical software systems, and for understanding how the knowledge has been articulated and organized. These software tools need to be much more sophisticated and easier to use than current tools. For example, search engines must understand the semantics of mathematical languages and, for example, when syntactically distinct expressions such as x2+1 and 1+x.x are semantically equivalent.

How effectively mathematical knowledge can be accessed strongly depends on how the mathematical knowledge is previously formed. Mathematical knowledge needs to be articulated, organized, and disseminated so that access is facilitated.

FUTURE TRENDS

Mathematical Knowledge Management (MKM) is a new interdisciplinary field of research in the intersection of mathematics, computer science, library science, and scientific publishing. The objective of MKM is to develop new and better ways of managing mathematical knowledge using sophisticated software tools. MKM is expected to serve mathematicians, scientists, and engineers who produce and use mathematical knowledge; educators and students who teach and learn mathematics; publishers who offer mathematical textbooks and disseminate new mathematical results; and librarians and mathematicians who catalog and organize mathematical knowledge.

The challenges facing MKM researchers are daunting. The following are some of the major issues (expressed as questions) that are challenging researchers in MKM:

1. What kind of tools are need to put mathematical knowledge on the World Wide Web? (see, e.g., the MathML (www.w3.org/Math), MoWGLI (www.mowgli.cs.unibo.it), and Open-Math (Dalmas, Gaëtano, & Watt, 1997) programs)
2. What kind of software support is needed to convert an informal articulation of mathematical knowledge into a formal articulation? (see, e.g., Davenport, 2003)
3. How should the context of mathematical knowledge be expressed?
4. How should mathematical knowledge be organized? (see, e.g., Brownie & Stanway, 2003)
5. How can libraries of mathematical knowledge be searched? (see, e.g., Bancerek & Redneck, 2003)
6. How can mathematical knowledge be shared between mathematical systems? (see, e.g., Carette, Farmer, & Wajs, 2003)
7. How can declarative representations of mathematical knowledge be integrated with procedural representations? (see, e.g., Farmer & von Mohrenschildt, 2003)
8. What role should universities, governments, professional societies, and publishers play in disseminating mathematical knowledge?
9. Who should own and administer mathematical knowledge?
10. How should the role of mathematicians differ from the role of librarians in the task of organizing mathematical knowledge?
11. How should disseminated mathematical knowledge be certified?
12. What mechanism should be used to standardize and integrate MKM software tools?

The grand challenge of MKM is to develop a universal digital mathematics library (UDML). Composed of many heterogeneous, intercommunicating systems, it would be easily accessible via the World Wide Web. It would be constructed in an open, cooperative fashion in the same way that the Internet was constructed. Never finished, it would continuously grow and in time would contain essentially all mathematical knowledge (intended for the public). It would also be continuously reorganized and consolidated as new connections and discoveries were made.

A UDML would contain a highly structured and interconnected mixture of axiomatic, algorithmic, diagrammatic, and other kinds of mathematical knowledge. Each piece of mathematical knowledge in it would carry a certification of its correctness (relative to a specified set of assumptions). It would also include an integrated collection of tools for exploring its contents. It is important to note that a UDML would be a library and not an archive. That is, its primarily purpose would be to make mathematical knowledge widely accessible, not just to store and catalog mathematical knowledge.

Creating a UDML will be a Herculean project requiring the development of many new kinds of technology. Some of this technology is being developed now on current formal mathematics library projects including the NIST Digital Library of Mathematical Functions (dlmf.nist.gov), the Formal Digital Library (www.nuprl.org/FDLproject), Hypatheon (DiVito, 2004), Logosphere (www. logosphere.org), Mizar (mizar.org), and the Wolfram Functions site (functions.wolfram.com).

As a new field of research, MKM was launched by the First International Workshop on MKM (www.risc.uni-linz.ac.at/institute/conferences/MKM2001) in September 2001 in Hagenberg, Austria. Organized by Bruno Buchberger and Olga Caprotti, MKM 2001 led to the founding of the MKM Consortium in December 2001 under the leadership of Michiel Hazewinkel and to a special issue (Buchberger, Gonnet, & Hazewinkel, 2003) of the Annals of Mathematics and Artificial Intelligence dedicated to MKM.

The MKM Consortium is an international group of researchers dedicated to the promotion of research and interest in MKM. It has organized two subsequent international MKM conferences: the Second International Conference on MKM (www.cs.unibo.it/MKM03) was held in February 2003 in Bertinoro, Italy, and the Third International Conference on MKM (mizar.org/MKM2004) was held September 19-21, 2004, in Bialowieza, Poland. The MKM Consortium currently consists of a European Chapter (monet.nag.co.uk/mkm/index.html) and a North American Chapter (imps.mcmaster.ca/na-mkm).

CONCLUSION

Mathematical knowledge has special characteristics that require management techniques and technology different than the techniques and technology needed for other kinds of knowledge.

Researchers in the new field of MKM are beginning to develop new and better software for managing mathematical knowledge. Since mathematical knowledge is universal knowledge about mathematical aspects of the world, this software, and certainly the ideas on which it is based, may be applicable to the abstract and mathematical parts of other kinds of knowledge.

Chapter 7.4
Communities of Practice and Critical Social Theory

Steve Clarke
University of Hull, UK

INTRODUCTION AND BACKGROUND

In philosophical terms, a key issue of communities of practice (CoPs) can be located within one of the key philosophical debates. The need for CoPs is traceable to the inadequacy in certain contexts of the so-called scientific or problem-solving method, which treats problems as independent of the people engaged on them. Examples of this can be drawn from the management domains of information systems development, project management, planning, and many others. In information systems development, for example, the whole basis of traditional systems analysis and design requires such an approach. In essence, in undertaking problem solving, the world is viewed as though it is made up of hard, tangible objects, which exist independently of human perception and about which knowledge may be accumulated by making the objects themselves the focus of our study. A more human-centered approach would, by contrast, see the world as interpreted through human perceptions: the reason why the problem cannot be solved is precisely because it lacks the objective reality required for problem solving. In taking this perspective, it may or may not be accepted that there exists a real world "out there", but in any event, the position adopted is that our world can be known only through the perceptions of human participants.

This question of objective reality is one with which philosophers have struggled for at least 2,500 years, and an understanding of it is essential to determining the need for, and purpose of, CoPs. The next section therefore discusses some of the philosophical issues relevant to the subjective-objective debate: a search for what, in these terms, it is possible for us to know and how we might know it.

A FOUNDATION IN KANTIAN CRITICAL PHILOSOPHY

Kant's critical problem, as first formulated in the letter to Herz (February 21, 1772) (Gardner, 1999, pp. 28-29), concerns the nature of objective reality. Prior to Kant, all philosophical schema took objective reality as a given and sought to explain how it was that we could have knowledge of this reality. If this were taken as definitive, it is easy to see how we might build (empirical) knowledge in the way suggested by Locke (1632-1704): that we are born with a "tabula rasa", or blank slate, on which impressions are formed through experience. This explains the pre-Kantian debate of reason vs. experience as the source of our knowledge: the rationalist view was that, by reason alone, we are able to formulate universally valid truths (for example, around such issues as God and immortality); empiricists, by contrast, see experience as the only valid source of knowledge.

Kant's insight and unique contribution was to bring together rationalism and empiricism in his new critical transcendental philosophy, the basis of which is his Copernican Revolution in philosophy. Loosely stated, this says that objective reality may be taken as existing, but that, as human beings, we have access to this only through our senses: we therefore see this objectivity not as it is but as we subjectively construct it. Unlike Berkeley (1685-1753), Kant does not claim that objects exist only in our subjective constructions, merely that this is the only way in which we can know them: objects necessarily conform to our mode of cognition.

For this to be so, Kant's philosophy has to contain a priori elements: there has to be an object-enabling structure in our cognition to which objective reality can conform and thereby make objects possible for us. This is what lies at the heart of Kant's Transcendental Idealism.

- While objects may exist (be "empirically real"), for us, they can be accessed only through their appearances (they are "transcendentally ideal").
- Our cognition does not conform in some way to empirical reality, rather this objectivity should be seen as conforming to our modes of cognition. In this way, we construct our objective world.
- Objects of cognition must conform to our sense experience. So, in this sense, knowledge is sensible, or the result of experience.
- These objects must conform to the object-enabling structures of human cognition. The resultant transcendental knowledge is (at least) one stage removed from objective reality, and is, according to Kant, governed by a priori concepts within human understanding.

This brief review of some key philosophical ideas has led neatly back to the subjective-objective debate. Seen from a Kantian perspective, we simply have no access to objective reality. (Interestingly, and again quite uniquely, Kant did not maintain there to be no objective reality; on the contrary, he argued that there must be real objects, or we would be in the ludicrous position of having perceptions of a world, but there being nothing to give rise to those perceptions.)

What objects may be in themselves, and apart from all this receptivity of our sensibility, remains completely unknown to us. We know nothing but our mode of perceiving them—a mode which is peculiar to us….Even if we could bring our intuition to the highest degree of clearness, we should not thereby come any nearer to the constitution of objects in themselves. (Kant, 1787, p. 82)

In summary:

1. Objectivity is conceivable only from the perspective of a thinking subject.

2. Central to Kantian philosophy is the question of how it is possible for subject and object to be so joined—what conditions must apply in order that this might be so?
3. In the Transcendental Deduction, Kant argues that subject and object make each other possible: neither one could be represented without the other.
4. All of this rests on their being: (a) a world of objects which is unknowable to us and (b) a priori concepts in understanding which enable representation of this world of objects.

A WAY FORWARD THROUGH CRITICAL THEORY

Theoretically, this philosophical position leads to a grounding in those theories relevant to human understanding and interaction, which are to be found in the social and cognitive domains. Given that in CoPs we are seeking a pluralistic, human perspective, those theories which best explain social interaction might be seen as especially relevant. Drawing again on the stream of social inquiry emanating from Kantian philosophy, this leads through the critical social theory of the early 20th century Frankfurt School to contemporary social theorists such as Foucault and Habermas (see, for example, Habermas, 1971, 1987).

Key concerns within Habermasian critical social theory are issues such as social inclusion, participation, and a view of how we ought to undertake intervention in social domains, all of which are fundamental to the functioning of CoPs. Habermas (1971, 1976, 1987) follows Kant in arguing that reliable knowledge is possible only when science assumes its rightful place as one of the accomplishments of reason. While the achievements of scientific study are not disputed, the problem perceived through the route followed by Kant and Habermas is that the methods of science which have grown out of modernity are effectively self referential: that scientific study sets up rules and then tests itself against its own rules is a procedure which has given considerable advances to modern society, but to regard this as representing all knowledge is mistaken. Habermas refers to the worst excesses of this as scientism: that we must identify knowledge with science.

Habermas further argues that the scientistic (positivist) community is unable to perceive self-reflection as part of its process, and that such reflection must be built into an understanding of knowledge. As with Kant, Habermas' challenge is whether knowledge is reducible to the properties of an objective world, leading him to a definition of knowledge which is based on perception but only in accordance with a priori concepts that the knowing subject brings to the act of perception. Since the knowing subject is a social subject, all knowledge is mediated by social action and experience, leading to Habermas' grounding certain theories in communicative interaction.

In the study of CoPs, this leads us to the following problems:

1. Accepting all human actions as mediated through subjective understanding leads to the possibility of a pluralist basis for CoPs.
2. There is no longer a dichotomy between subject and object.
3. The difficulty now left to resolve is essentially a practical one, of how to incorporate these ideas into a pluralistic foundation for CoPs.

From the position of viewing all human interactions with the so-called objective world as perceptual and subject to the a priori understanding that we, as human actors, bring to the act of perception, we begin to see CoPs as part of our normal social interaction. Research into problem analysis within the domain of management science, where communicative action theory has been used to further develop the concepts, is helpful in making sense of this. The ability to communicate by use of language is something that human beings bring to the world by nature of their existence: that is to say, it is not developed empirically but is a priori. To the extent that any theoretical position can be grounded on such an a priori ability, such a position may be seen as fundamental to us as communicative human actors.

To the extent that communication, at least partially, may be oriented toward mutual understanding, it might be argued as the foundation of CoPs, insofar as all such analysis is seen (after Kant) as perceptual. In these terms, CoPs never relate directly to the properties of an objective world but can be defined both objectively and according to the a priori concepts that the knowing subject brings to the act of perception. This knowing subject, being social, mediates all knowledge through social action and experience: subject and object are linked in the acts of cognition and social interaction.

In essence, then, it is argued that our difficulties disappear once a scientific basis for our thinking is denied. This echoes Habermas' view that science should be seen as just one form of knowledge, which in any case is simply a convenient human perception of how the world works. Now, all human endeavor becomes mediated through subjective understanding, leading to the possibility of a basis for CoPs in the universal characteristics of language. The difficulty is now essentially a practical one, of how to incorporate these ideas into CoP practice.

Within Habermas' (1976, 1987) theory of communicative action is presented a universal theory of language. Oliga (1996) summarizes this from its basis in locutionary, illocutionary, and perlocutionary speech acts, based on Austin (1975). Locutionary speech acts are concerned with saying something in a meaningful form which can be understood and are effectively a necessary precondition for communication. Perlocution is concerned with communication "strategically oriented toward individual success over [an] opponent" (Oliga, 1996, p. 246). According to Habermas (1984), only illocutionary speech acts "count as communicative action." The logic of this should not be lost in relation to the objectives of this research in relation to CoPs. The remaining tasks may be summarized as:

1. CoPs are an enactment of the perspective that objective reality is questionable and that we see our world according to our own views and perceptions (Oliga, 1996).
2. To the extent that these views are communicated by language, communicative action theory can help with the process.
3. The communication undertaken, both as spoken and as documented, can be tested for its locutionary (i.e., it should be meaningful and understandable) and its perlocutionary content, that is, it should not be concerned with "influencing the decisions of a rational opponent" (Oliga, 1996).
4. The primary test is then to deconstruct illocutionary speech, which is oriented toward understanding.

Illocutionary speech acts are oriented toward three fundamental validity claims: truth, rightness, and sincerity. What is most compelling about this theory, however, is that all three validity claims are communicatively mediated. This viewpoint is most radically seen in respect of the truth claim, where it is proposed that such a claim results not from the content of descriptive statements, but from the Wittgensteinian approach casting them as arising in language games which are linked to culture: truth claims are socially contextual and are therefore to be assessed not by reference to fact, but by reference to communication. Rightness is about norms of behavior, which are culturally relevant and are therefore to be determined by reference to that which is acceptable to those involved and affected in the system of concern as a cultural group. Finally, sincerity is about the speaker's internal world: his/her internal subjectivity.

These ideas can now be taken forward to provide an approach to CoPs which is theoretically grounded and closer to that which is experienced in (communicative) action.

AN APPLICATION FRAMEWORK FOR COPS

It is now possible to design an application framework containing these concepts; revisiting CoPs from a philosophical and theoretical perspective dictates that an interventionist must always pay heed to the following:

- All problem analysis is perceptual; any approach to it must therefore be conducted through the views and opinions of participants, since only through these can objectivity be seen.
- An explicitly critical perspective must be maintained with a particular focus on normative ("ought") positions to counter factual ("is") claims.
- Critique must be applied to both content and the material conditions (norms and values) within which the content is set.
- Communicative action should be used as the social medium through which values are judged.

In order to make judgments about communicative action, it is necessary to first record and then deconstruct the communications that have taken place. Recording is less problematic than might be imagined: while it is not uncommon for group sessions to be recorded and transcribed, this is only one of the ways in which conversations can be documented. Recent work by Alford (see Future Trends), investigating virtual tourism, used the Internet as the medium through which conversations were conducted and enabled not only transcription but also sound and vision recording. From this and other data, the process of deconstructing the conversations has been started with, at its core, the need to determine communication as:

- Meaningful and understandable to all concerned.
- Not oriented toward coercively influencing the decisions of others.
- Truthful: the "ought" test.
- "Right": acceptable to those involved and affected as a cultural group.
- Sincere: related to the speaker's internal subjectivity.

FUTURE TRENDS

An essential precursor to applying the framework is the recognition that (after Kant and Habermas) problem analysis is not possible without participant involvement and that CoPs are a medium for achieving this.

Making judgments about communicative action is more complex, but there are some existing guidelines to help with this. There are, of course, numerous ways in which conversations can be both set up and recorded, some of which have already been mentioned earlier in this entry. Technology is proving particularly helpful in this respect, and, perhaps unsurprisingly, the domain of information systems is one in which significant progress has been made. Lyytinen (1992), for example, cites conferencing technology, which could encourage discursive activity, and information technology, which would allow the anonymous submission of "radical change proposals", while Kemmis (2001, p. 100) argues there to be considerable potential for IT to create "communicative spaces" in which communicative action can take place.

Research carried out in the field of critical qualitative research (Carspecken, 1996; Carspecken & Apple, 1992; Forester, 1992) provides guidance toward a framework for analyzing the validity claims raised during communicative action. A detailed analysis of this is beyond the scope of this article, but these and other ideas (some examples of which are given below) are now being applied to develop techniques which adhere to the guidelines provided by communicative action theory.

Validity claims relating to truth are concerned with defining perceptions of reality. Participants all have access to the "world of truth" but will have different interpretations of it. While this may to some seem esoteric, nowhere is this more important than in the often highly pragmatic domain of information systems. Frequently, in a systems development exercise, truth will be colonized by a powerful group, and issues important to the success of the development will be ignored (see, for example, Bentley, Clarke & Lehaney, 2004; Clarke, Lehaney & Evans, 2004).

Rightness is about the cultural acceptability of the claimant's position. One of the most powerful ways to challenge these claims is by a critically normative approach. Ulrich's (1983) Critical Systems Heuristics is helpful here: asking "ought" questions about an "is" position is something worth perfecting.

Sincerity relates to the subjective position of the claimant. Carspecken (1996) suggests ways in which the researcher can check this sincerity: checking recorded interviews for discrepancies and asking the interviewee to explain them; comparing what a person says with what they do and seeking clarification; or showing the person a summary of your reconstruction and ask them to comment on its accuracy.

In the Centre for Systems Studies at Hull, these ideas are used to inform research into information systems. One such development is headed by Paul Drake (see, for example, Clarke & Drake, 2002; Drake & Clarke, 2001), a research student attached to the center. Paul is applying Habermas' systems/lifeworld concept and theory of communicative action to develop a deeper understanding of information security. Similarly, Philip Alford is looking at communicative action as a means of deconstructing conversations in the development of virtual tourism. Phil's conversations are collected mostly through Internet-based discussion forums, and the tests for communicative competence are proving to be of considerable value in understanding a way forward for this highly dynamic domain.

CONCLUSION

Seeing CoPs from a perspective based in critical theory gives us a new perspective. From this theoretical and philosophical basis can be derived a view of CoPs as based fundamentally on the perceptions of those involved in and affected by the system of concern. Any truly pluralist method must embrace this and must therefore pursue an approach which takes subject and object each to be a condition of possibility for the other.

Following this stream of thought, CoPs enable us to define our world both objectively and according to the a priori concepts that the knowing subject brings to the act of perception. This knowing subject, being social, mediates all knowledge through social action and experience: subject and object are linked in the acts of cognition and social interaction.

From this research project, a framework has been developed for implementing these ideas, based on theories of communicative action drawn from Austin and Habermas, and an approach to how this might be implemented in practice has been outlined. To the extent that CoPs involve communication through language, evidence of this communication can be gathered, and, from the documentation, communicative validity can be tested. All of this provides a wider framework within which methodological application can be undertaken.

Chapter 7.5
Facilitating and Improving Organisational Community Life

Angela Lacerda Nobre
ESCE-IPS, Portugal

INTRODUCTION: A CHANGE OF PARADIGM

The growth in importance of communities within organisational settings is a sign of a change in paradigm. When management and organisational theory introduce the critical notion of communities, in parallel to the concepts of collaborative work and of knowledge sharing, there is an internal revolution going on. Therefore, communities of practice theory (Lave & Wenger, 1991; Wenger, 1999; Wenger, McDermott & Snyder, 2002; Brown & Duguid, 1991) has a critical role to play in today's development of management and organisation theory.

At a broader level, there is an ongoing metamorphosis that is highly visible through the vertiginous development of technology, the globalisation of markets, and the acceleration of the increase in complexity. Equally important are the less visible, and thus harder to acknowledge, changes in the way we think, reason, communicate, and construct our image of ourselves and of the world.

The changes brought by the knowledge society of the information age (Kearmally, 1999) triggered the development of theoretical approaches to management. Among these, knowledge management and organisational learning have developed. These theories have acknowledged the importance of information and communication technology within organisations, and have explored alternative insights into mainstream management approaches. The knowledge management and organisational learning sub-disciplines represent an innovation effort that affect areas of organisational life which had been marginalised or ignored under traditional management theory. Communities of practice is the single most important example. Therefore, communities of practice represent a critical aspect of the present understanding of the complexity of organisational life.

Within the broad and varied development of organisational theories, semiotic learning emerges as a particular approach to organisational learning. Semiotic learning may be described as a dynamic practice. It incorporates theoretical contributions from social philosophy and adapts them to a specific approach to facilitate learning at the organisational level. It is a learning and development tool for action at the organisational level. The central aspect of the semiotic learning approach is the focus on the quality of community life at the organisational level.

Through a semiotic learning approach to organisational learning and development, it is possible to intensify and to unleash the true potential of current challenges at personal, organisational, and societal levels. By focusing on the social practices, structures, and processes which underlay human interaction, and by calling attention to the way we construct ourselves and our image of the world through those interactions, it enables the development of a rationale that supports collaborative as well as transformative forms of work and learning.

BACKGROUND: SUBTLE AND HIDDEN NEEDS

The contribution of the semiotic learning approach to the fields of organisational learning, knowledge management, and communities of practice is that it offers an integrative theoretical approach. The organisational learning, knowledge management, and communities of practice theories deal with issues which they cannot themselves explain, or rather with issues which they cannot yet explain. The call for a greater depth and breadth in terms of theoretical grounding may be achieved by the semiotic learning perspective. This approach consists of an organisational design and organisational development instrument to be implemented in parallel with other existing initiatives. The rationale is simple and direct: it aims at recovering the balance between the necessary functionalistic efforts, and the subtle and hidden needs of the organisation's community life. It is the projection of powerful insights arising from philosophy mediated, translated, and adapted to organisational reality. It is based on both theory and practice, as it is through its application that it becomes reified. The theory, the description, the narrative is just a means to an end, an end which is an action-based and action-led organisation.

The semiotic learning approach rests on three broad groups of theories: social semiotics, critical realism, and action theory. The semiotic learning approach works as a cascade, so that within social semiotics, it includes Bakhtin Circle's social theory of discourse; within critical realism, it takes a pragmatic perspective; and within action theory, it questions current epistemological positions and recovers an ontological and hermeneutic perspective. The breadth of theory is directed at informing and illustrating how rich and diverse the universe of options is in terms of approaches that directly answer to the 'subtle and hidden' needs of organisational life. This diversity could even be extended, never reduced. It is this diversity which expands our thought horizons so that it becomes a kind of didactic or pedagogic process, thus the word "learning" in semiotic learning. This corresponds to the "thought-possibilities" and "action-possibilities" that Jaspers explored.

Heidegger's disciple, Karl Jaspers, explored thought-possibilities and action-possibilities following the guide of Max Weber's approach as an historian:

…in order to grasp reality, we must see the possibilities…Weber employs the category of 'objective possibility' in his historical appraisal of past situations. The historian considers a situation. His knowledge enables him to construct the possibilities of the day. By these constructions he first measures the possibilities of which protagonists were aware. And then, by the possibilities, he measures what really happened, in order to ask: for what

specific reason did a particular possibility among several materialise? (Young-Bruehl, 1981)

Theoretical approaches such as critical realism (Archer, Bhaskar, Collier, Lawson & Norrie, 1998), complex systems theory (Chekland, 1999), social semiotics (Halliday, 1978; Lemke, 1984, 1995), or hermeneutics (Ricoeur, 1998) did not develop as an answer to today's virtual, fast-paced, and often chaotic communication forms. However, their insights represent a powerful tool in order to understand, cope with, and enable one to profit from the opportunities that are being opened by the knowledge society. Similar to the implicit unity between the individual and the social, there is a close connection between theory and practice. All these theoretical approaches have an intrinsic pragmatic nature and therefore do not separate the individual from the social or the theory from the practice.

It is within communities that organisations continually create and redefine meaning, and it is this meaning-making capacity that conditions the organisational identity, degree of cohesion, and potential to innovate. Meaning-making is part of the action- and thought-possibilities, part of the horizon of possibilities that is open through the practices and processes of organisational community life. Semiotic theory is unavoidably related to meaning—and therefore the importance of the term "semiotic" in semiotic learning.

MAIN FOCUS: MEANING-MAKING AND SOCIAL SEMIOTICS

Social semiotics developed out of the work of sociologists interested in language issues and of linguistics interested in the social influences within language use. Under this perspective, human development is as much the development of individuals as that of the social communities to which they belong, and language is the working tool and enabler of this process. Semiotics is commonly related to language, though it covers all forms of communication or rather 'characterisation' of a practice so that dressing, teenage gear, wrestling, or cooking have a semiotic content. Barthes (1996) developed this approach, including studies of advertising, media, and cinema. From another perspective and according to Umberto Eco, the implicit domain of semiotics is the whole history. Sebeok (1994) and other authors study semiotics in all life forms, because the ability to manufacture and recognise signs is a basic survival strategy. So they study biosemiotics, zoosemiotics, semiochemistry, and phytosemiosis. Semiotics was already present in ancient Greece through the works of Plato and Aristotle. In the Middle Ages, it continued to develop through the works of Augustine in the fourth and fifth centuries, and Ockham in the fourteenth century. Locke, in the seventeenth century, also focused on signifying processes.

Semiotics as a discipline is simply the analysis of signs or the study of sign systems. The idea that sign systems are of great consequence is easy enough to grasp. Yet the recognition of the need to study sign systems belongs to the modern age. A full-blown semiotic awareness arose at the turn of the century, and in the early 20th century, through the works of Saussure in Europe and Peirce in North America. Different schools of thought emerged from these roots, giving rise to diverse currents that deeply influenced both the linguistic turn and the context turn throughout the twentieth century. From Saussure's work, structuralism developed, as well as different branches, including one that would give rise to social semiotics. From Peirce's work, pragmatism developed, which was one of Peirce's creation, later followed by James, Dewey, Popper, Morris, Sellars, Putman, and others (Delanty & Strydom, 2003).

Jay Lemke is a contemporary social semiotitian who started as a physicist. According to Lemke (1995), Bourdieu's and Bernstein's work as sociologists, between 1970 and 1990, and Halliday's and Gunther Kress' work as a linguists, during more or less the same period, gave rise to that which is known today as social semiotics.

Halliday's social theory of discourse suggests that our uses of language are inseparable from the social functions, the social contexts of actions and relationships in which language plays its part…This is what is meant by seeing language as a social semiotic, a resource to be deployed for social purposes. (Lemke, 1995, p. 27; emphasis used in original text)

Lemke also relates the origins of social semiotics with the work on discursive formations by Foucault and, most importantly, to the early works of the Russian Bakhtin's Circle starting in 1918 (Lemke, 1984, 1995).

The works of Bakhtin and his colleagues introduced highly rich and complex terms and concepts which capture meaning, or cultural and semiotic related issues within texts, which can be literary texts, or else any social reality that may be read and interpreted as a text (Brandist, 2002). Bakhtin's work became known internationally in the 1970s; in the 1980s it spread within the areas of literary and cultural theory, and since then it has continued to disseminate, now influencing social theory, philosophy, and psychology. Bakhtin's four essays (1984), edited by Holquist, with 12 prints until 2000, were published in Moscow in 1975, after his death, and were written in the late 1920s and in the 1930s. Concepts such as heteroglossia, intertextuality, chronotope, dialogue, and dialogic relationships are some of the key concepts of Bakhtin's group of thinkers. Lemke (1995) refers to five major theories of discourse which have emphasised its social dimension: M. Bakhtin was the first one, then M. Foucault, M. Halliday, B. Bernstein, and finally P. Bourdieu, though he was not a discourse theorist.

Although semiotics is a wide area, enabling the coexistence of radically different approaches, including reminiscences of past positivist trends, social semiotics represents the cultural, historical, political, and social readings, interpretations, and meaning-making processes present in all symbolic systems. It is this richness as well as this complexity which makes social semiotics an attractive and powerful theoretical framework for organisational learning initiatives.

FUTURE: THE MEDIATION ROLE OF SEMIOTIC LEARNING

Social semiotics, together with hermeneutics and critical realism, acknowledge the importance of social structures in determining social practices and vice-versa. The notions of self and agency are intrinsically connected with how individuals are determined, and how they themselves determine the social contexts to which they belong. Pragmatism stresses the importance of integrating the individual and social dimensions into a single whole. The semiotic learning approach takes into account these contributions and mediates their insights by adapting them to an organisational context.

Critical realism is a multidisciplinary movement in philosophy and the human sciences which started with Roy Bhaskar's publication in 1975 of A Realist Theory of Science (Archer et al., 1998). The term 'critical' suggests affinities with Kant's idealism and rationalism, though the term 'realism' indicates that there are fundamental differences. Bhaskar's philosophy is reflexive as transformatively practical, or presents a transformational model of social activity. According to this theory, social life has a recursive character, as agents reproduce and transform the social structures they use and are constrained by in their substantive activities.

…actors' accounts are both corrigible and limited by the existence of unacknowledged conditions, unintended consequences, tacit skills and unconscious motivations…but, in opposition to the positivist view, actors' accounts form the indis-

pensable starting point of social enquiry. (Archer et al., 1998, p. xvi)

Critical realism, as a theory of science, presents three distinctive features:

(i) it recognises science as a social practice, and scientific knowledge as a social product; (ii) it recognises the independent existence of the objects of scientific knowledge; (iii) it has an account of scientific experiment and discovery as simultaneously material and social practices, in virtue of which both (i) and (ii) are sustained. (Benton & Craib, 2001, p. 130)

The fundamental links between individual and social arenas is a central issue to an organisational learning initiative. On one hand, individual action and thought—and the social structures and practices that contributed in the shaping and moulding of that action and that thought—and, on the other hand, the human agency capacity to strike back—to reconfigure or sustain those social structures and practices—may be acknowledged and recognised through the use and application of social philosophy theory.

The semiotic learning approach focuses on four philosophical categories: action, language, knowledge, and meaning. It claims that knowledge and meaning are already prefigured by action and language. Communities of practice theory implicitly acknowledges the social embeddeness of individual cognitive processes. In order to further develop the importance of the relations between social and individual processes, the semiotic learning approach uses six working concepts that are derived from the works of six social philosophers. These are Bakhtin's concept of dialogism (1981), Halliday's notion of grammar, Wittgenstein's idea of language-games (1958), Foucault's discursive formations (1972), Heidegger's instance of being-in-the-world (1996), and White's master tropes (1978). These philosophical contributions are introduced into four learning steps that represent the practical and applied nature of the semiotic learning approach. These are: ice-break—raising key issues; experiencing—confronting reality; action horizons—transformative learning; and innovative practice—open dynamism. There is a mediation between central notions of philosophical inquiry and key organisational issues. These key issues are: appreciative inquiry, open complex systems, socio-technical systems, collaborative work and learning, knowledge creation and sharing, reflexive practice and double-loop learning, and trust and social capital.

CONCLUSION

To finalise, two comments: Probably the best image to describe the subtle and hidden issues that the semiotic learning approach claims to tackle in order to facilitate organisational learning is that of the gap between what an organisation is supposed to be, its formal and public discourses, and the way it is felt and lived by the people actually involved, both directly and indirectly, from within and from without, from above and from below. The second issue is that the semiotic learning perspective reflects and projects a continual questioning and a work in progress—not in the sense of an unfinished work but in terms of its internal dynamic; its furthest aim is the broadening of horizons and the revolution of mentalities.

The subtle and hidden thought revolution starts within communities in general, and within communities of practice in particular. It is through communities that it reaches people at an individual level. If knowledge is in people's heads, communities of practice tell us how it got there.

Chapter 7.6
Knowledge Management Systems Acceptance

Fredrik Ericsson
Örebro University, Sweden

Anders Avdic
Örebro University, Sweden

INTRODUCTION

Knowledge management is a set of systematic actions that organizations can take to obtain the greatest value from the knowledge available to it (Davenport & Prusak, 1998). Systematic means that knowledge management is made up of intentional actions in an organizational context. Value means that knowledge management is measured according to how knowledge management projects contribute to increased organizational ability (see for example Prieto & Gutiérrez, 2001; see Goldkuhl & Braf, 2002, on the subject of organizational ability). The motivation for knowledge management is that the key to competitive advantage for organizations in today's business world is organizations' ability to manage knowledge (Nonaka & Takeuchi, 1995; Davenport & Prusak, 1998). Knowledge management as an intentional and value-adding action is not easy to accomplish in practice (Scarbrough & Swan, 1999). Scarbrough and Swan (1999) present several case studies in knowledge management, successful and unsuccessful in their respective knowledge management projects. A major point and lessons learned from the case studies is that prevalent approaches in knowledge management overstate technology and understate how technology is implemented and applied.

To succeed with knowledge management, encompassing development of information technology-based information system, some requirements have to be fulfilled. An important aspect in the development process is system acceptance. Implementation is at large a process of acceptance. Implementation is the process where the system becomes an integrated part of the users' or workers' work practice. Therefore implementation is essential to make a knowledge management project successful in order attain an increased organizational ability and to succeed with knowledge management.

ISSUES OF KNOWLEDGE MANAGEMENT—SYSTEMS AND ACCEPTANCE

In this section we provide broad definitions and discussion of the topics to support our positions on the topics of knowledge management and systems acceptance.

MANAGING KNOWLEDGE

Work in knowledge management has a tendency to omit social or technological aspects by taking on one of two perspectives on knowledge management, the anthropocentric or the technocratic view (Sveiby, 2001; Swan, 1999). The anthropocentric and the technocratic views represent two contradictory views on knowledge management and can be summarized as technology can or technology cannot. The gap between the anthropocentric and technocratic view depends on a difference of opinions concerning the notion of knowledge. The technocratic view conceives knowledge to be some organized collection of data and information, and the anthropocentric view conceives knowledge to reside in humans, not in the collection (Churchman, 1971; Meredith & Burstein, 2000). Our conception of knowledge is that of the anthropocentric view. Taking on an anthropocentric view on knowledge management does not mean that we discard knowledge management technologies; we rather take on a balanced view on the subject. Information technology can support knowledge management in an organization through a number of different technological components, for example intranets, extranets, data warehouses, and database management systems (Borghoff & Pareschi, 1998; Tiwana, 2000; Ericsson & Avdic, 2002). The point in taking on an anthropocentric view of knowledge management is not to lose sight of the knower who gives meaning to the information and data found in IT-based knowledge management systems.

KNOWLEDGE MANAGEMENT SYSTEMS

Information systems can include either operative or directive and decision support information (Langefors, 1966; Yourdon, 1989). Operative systems provide system users with information necessary in workers' daily work, while directive and decision support systems provide system users with information that improves the quality of decisions workers make in daily work. Knowledge managements systems are systems developed to manage knowledge directly or indirectly to give support for an improved quality of a decision made in workers daily work, and as an extension, an increased organizational ability. A knowledge management system typically includes directive information, for example in guiding a user's choice in a specific work situation. Such systems are often optional in the sense that users can deliberately refrain from using the system and/or refrain from taking the directed action. Accordingly, user acceptance is crucial for the degree of usage of knowledge management systems.

ACCEPTANCE OF TECHNOLOGICAL SYSTEMS

Technology acceptance has been subject of research by, for example, Davis, Bagozzi, and Warshav (1989), who developed the well-known

Technology Acceptance Model (TAM) and later a revised version of the original model, TAM2 (Venkatesh & Davis, 2000). TAM is an explanative model explaining user behavior of computer technologies by focusing on perceived ease of use, perceived usefulness, attitude towards use, and behavioral intentions as determinants of user behavior. TAM2 is an extension of the original model including external factors related to perceived usefulness.

The framework for system acceptance, Requirements of Acceptance Model (RAM) have some resemblances with TAM and the later TAM2. RAM is in comparison with TAM descriptive in nature. Workers' work practice is treated as an integrated element of RAM, compared with not being treated as a determinant of system use in the original TAM and as an external factor in TAM2. Further, RAM covers acceptance of knowledge management systems, and TAM/TAM2 cover a broad range of computer technologies. RAM systematically acknowledges factors important in implementation of knowledge management systems to gain acceptance of such systems.

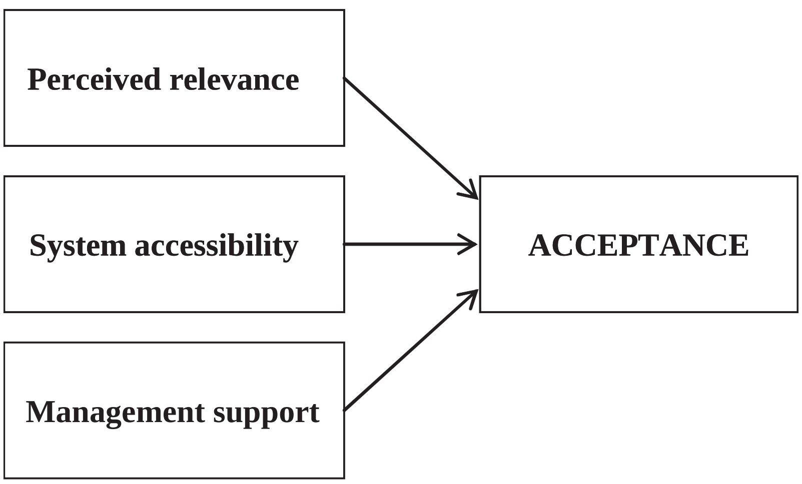
REQUIREMENTS OF THE ACCEPTANCE MODEL

We perceive acceptance to be a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. In this section we present the requirements of acceptance in RAM. The Requirements of Acceptance Model is illustrated in Figure 1.

PERCEIVED RELEVANCE

The workers, who are to use the system, must perceive the knowledge management system as relevant. Since it is possible for workers to work without using the system, it has to be obvious that usage of the system implies adding value to the work result. An additional aspect of relevance related to perceived relevance is how the system should be integrated in running work, that is, to make the system an integrated part of the workers' work practice.

Figure 1. Requirements of acceptance model (Ericsson & Avdic, 2003)



In summary, perceived relevance is about workers, who are to use the system, perceiving the system as (Ericsson & Avdic, 2003)

- adding value to the work results; and
- being integrated in running work.

ACCESSIBILITY

To obtain acceptance of knowledge management systems, accessibility has to be satisfactory. It must be accessible to the workers who are to use the system. Accessibility is a question of who is to be the user (type of workers concerning organizational position), what action and work the system is to support (daily work, product development, innovation, etc.), where users get access to the system (the physical access), when the system is ready to use, and how the system's interface fulfills the goal of the system.

In summary, systems accessibility is about (Ericsson & Avdic, 2003):

- knowing who the user is;
- systematizing the actions workers perform in the work practice the system is to support;
- deciding the system's physical access;
- securing a certain degree of usage before the system is put into operation; and
- ensuring the system's design meets the goals of the system.

MANAGEMENT SUPPORT

Management support is vital according to many models on information systems development, especially when the system is a directive/decision support system (Yourdon, 1989). Knowledge management systems are typically directive systems, and workers have a choice in deciding whether to use the system or not. Management support is important to stress the value for workers to use the system and to make conditions for workers to do so.

DEVELOPMENT IS A PROCESS OF ACCEPTANCE

There must be a fit between workers' work practice and technology to get acceptance of knowledge management systems. The technology used to create a knowledge management system must fit the actions workers perform in their work practice. On an overall level there must be a fit between technology and actions performed by individual workers, and between individual workers and the organization as a whole, thus forming a coherent whole. It is in the development of knowledge management systems that the requirements of acceptance are fulfilled. A common conception concerning information systems development is that it constitutes analysis, design, construction, and implementation of information systems (Hirschheim, Klein & Lyytinen, 1996).

The groundwork for acceptance is made during the design, but foremost when implementing the system. Workers who are to use the system should be engaged at an early stage of the development process. The point of including workers at an early stage is to acquaint users with the system and the purpose of the system. Further, this is an opportunity for workers to influence the system's design and content. The most prominent aspect addressed when involving workers at an early stage is that of choosing and determining the meaning of crucial concepts managed by the system. Crucial concepts managed by the system are the knowledge represented in the system, and by determining concepts, knowledge represented in the system takes on a systematized character. Further, by involving the workers in the process of choosing and determining the meaning of crucial concepts managed by the system, the knowledge represented in the system does not lose its origin or meaning. The point is to keep the knowledge represented in the system within a frame of understanding or meaning, as perceived by workers. A knowledge management systems should be seen as a tool developed to support workers in learning and acquiring knowledge about actions taking place at work. This requires closeness between how concepts are perceived by workers and how such concepts are represented in a system.

FUTURE TRENDS

Research on technology acceptance (i.e., Davis et al., 1989; Venkatesh & Davis, 2000) has focused on user behavior of computer technologies. RAM is developed for and is used to assess acceptance of knowledge management systems. Acceptance has not been a crucial issue within the knowledge management area. A problem with knowledge management systems is that they work in theory, but seldom in practice (Wickramasinghe, 2003). A contributing factor to that picture may very well be that of having overlooked usage-related problems connected to knowledge management systems. In that sense, knowledge management systems acceptance can be expected to be an area for further research in the future.

CONCLUSION

Acceptance of knowledge management systems is a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. RAM is summarized in Table 1.

The Requirements of Acceptance Model point towards several important aspects concerning relevance, accessibility, and support. The groundwork for system acceptance is the development

Table 1. Summary of RAM (Ericsson & Avdic, 2003)

Perceived relevance—Workers, who are to use the system, have to perceive the system as:

- Adding value to work results
- Being integrated in running work

Systems accessibility—System accessibility is about:

- Knowing who the user is
- Systematizing actions workers perform in the work practice the system is to support
- Deciding the physical location where users get physical access to the system
- Securing usage of the system before it is put into operation
- The systems' design must meet up to the goals of the system

Management support—Fundamental because management authorizes development of systems process. Development is very much a process of acceptance as a process of developing the system itself. Through requirements of acceptance, knowledge management systems can remain and continue to be a contributing factor for the organization's ability to do business.

Chapter 7.7
Organizational Communication

Dov Te'eni
Tel-Aviv University, Israel

INTRODUCTION

All organizations depend on communication. Communication is the exchange of information between two or more people with the intent that the sender's message be understood and considered by the receivers in their cognition, affect, and behavior. As organizations are designed for action, most organizational communication eventually leads to action and to working relationships between actors. Indeed, communication plays a pivotal role in organizations and may even be seen as the foundation for most organizational action (Galbraith, 1977; Weick, 1979).

KM and communication go hand in hand. On the one hand, communication is the basis for knowledge sharing, which is a necessary component of successful knowledge management. On the other hand, knowledge is crucial for effective communication, and KM is therefore potentially central in facilitating communication. This article concentrates only on the latter direction, namely, the role of KM in promoting effective communication, although as we shall see, the two directions are interrelated. (For literature on the former, i.e., the role of communication in knowledge sharing, see numerous resources in Alavi & Liedner, 2001). Furthermore, our discussion is restricted to computer-based knowledge management, as well as computer mediated communication. Therefore, the terms KM and communication, whenever used here, imply that these functions involve computer support.

Despite the central role of communication in organizations, organizational communication is unfortunately susceptible to numerous obstacles and barriers to effective communication. Barriers to communication occur at the individual and organizational level. At the individual level, interpersonal dynamics interfere with communication, individuals choose inappropriate channels and media, the sender and receiver use different semantics, making it difficult to communicate, and people send conflicting cues in different messages and channels. At the organizational level, different functions and departments see things differently, power and politics interfere with open and sincere exchanges, and organizational norms or policies dictate ineffective channels and inappropriate forms of messages. KM can help overcome these barriers and improve organizational communication, and, in particular, KM can enhance computerized communication support systems such as structured e-mail, video conferencing, listservs, and so forth. However, to do so, designs of KM systems must be based on an understanding of communication.

BACKGROUND

Our understanding of communication, and particularly computer-mediated communication in the organizational context, has developed dramatically in the last few decades. The classical information-transmission model introduced by Shannon and Weaver (1949) has transformed into more active, psychological, and social models of communication (Axley, 1984). See, for example, Riva and Galimberti (1998) for an overview of these transformations in theories and metaphors of communication. In the interest of brevity and in order to identify the role of KM in enhancing communication, we select one model of organizational communication (Te'eni, 2001) that helps to define the link between KM and communication. The model has three main factors, each of which includes several attributes:

1. Inputs to the communication process include (a) distance between sender and receiver, (b) values and norms of communication, and (c) attributes of the task that is the object of the communication;
2. A cognitive-affective communication process of exchanging a message that describes the choice and implementation of (a) one or more communication strategies used to transmit the message, (b) the form of the message and (c) the medium through which it is transmitted; and
3. The communication impact: (a) the mutual understanding and (b) the relationship between the sender and receiver.

Consider the following example. A product designer in an industrial plant may send a message to the marketing director about a new product under development, explaining the bill of materials expected for the product. This information is useful to the marketing director when pricing the product. The communication (semantic) distance between the communicators may be large due to their different background disciplines (engineering and marketing). However, working for the same company, they accept the same communication norms by which information in the organization is always openly shared as early as possible. The sender may choose to communicate the message by a typed letter (choice of medium) and using the formal template for internal budgeting (choice of message form). Additionally, the sender sends an informal memo in the form of a story describing how this product has been developed at home by one of the engineers. This story provides contextual information about the product and explains the rather expensive list of required materials (this is an example of a communication strategy). Finally, the impact of the communication is essentially that the marketing director understands the message and prices the product accordingly. This example demonstrates how organizational communication can take on different forms and media and how the communication situation and people involved adapt these communication parameters to ensure effective communication. This article explores how KM can help communicators achieve this goal.

KM FOR SUPPORTING COMMUNICATION: A FRAMEWORK

Four concepts in this model are especially relevant to the link with KM: context, levels of abstraction, adaptation, and organizational memory. The idea of context is central to the model. We assume that in any communication there is a core message that the sender wishes to convey to the receiver. Senders add contextual information to the core message to increase the likelihood that the receiver will understand their intentions. Whatever information receivers choose to use (from the information available to them) in reasoning about the core message can be regarded as context. Part of this context is in the receivers' heads or in other available sources and part needs to be provided to the receivers by the senders as contextual information to ensure mutual understanding. Some first steps toward a formal treatment of context can be found in Ghidini and Giunchiglia, 2001.

Contextual information refers to several possible aspects of the core message: the situation in which the message was produced, the situation in which it is anticipated to be received, an explanation about a statement, an explanation how to go about executing a request for action, or the underlying assumptions about an argument. Providing the contextual information to explain the core message is a common communication strategy called contextualization. Contextual information can be seen as layers of information around the core message and contextualization can be seen as the act of adding more coats of information. KM techniques capable of determining and identifying context, retrieving or generating the information, providing the information in effective message forms and through effective media, and testing its impact may play a crucial role in enriching communication with appropriate contextual information.

The second idea involves levels of abstraction in the core and contextual information communicated. In thinking and communicating, people represent action at multiple levels of abstraction, and at any one moment, one of these levels is their focal level (Vallacher & Wegner, 1987; Berger, 1998). Moreover, people tend to remain on higher rather than lower levels of abstraction, but shift their attention to a lower level of abstraction when communication complexity increases and breakdowns occur. The lowest levels of abstraction in communication concern the lexicon and syntax (i.e., the terminology and grammar of the language). A higher level is the semantics (i.e., meaning of the message). Finally, the highest levels concern the task or pragmatic aspects of the message (i.e., the impact of the message on thought and action). A failure of communication at any level will hinder mutual understanding. KM techniques capable of identifying communication breakdowns and correcting them must rely on knowledge of communication at all levels of abstraction (such knowledge may be modeled as a multi-level model of communication analogous to the Open Systems Interconnect seven-layered protocol model). These KM techniques would be essential for ensuring effective communication and correcting lower levels of communication in order to enable communicators to concentrate on higher levels.

Another concept is that of adaptation in communication. Effective communicators match the medium, the message form, and the communication strategies to the communication situation, and the dynamics of the dialog. For example, communication between heterogeneous communicators should include more contextual information and may be more effective when richer, rather than leaner, media is selected. Knowledge of the communication situation (e.g., the relationships between communicators) as well as knowledge of how to communicate can be used to generate more effective communication. Communication complexity can be seen as a systemic measure of the communication situation and its susceptibility to communication breakdowns (Te'eni, 2001). It can therefore act as a sensor to trigger adaptation. KM techniques capable of detecting the need to adapt and also capable of adapting the system parameters can play an important role in facilitating communication support systems that provide tailored communication.

The last concept is the role of organizational memory (OM) in communication (Anand, Manz, & Glick, 1998). OM is a general term for the collection of information and knowledge "known" to the organization, as well as the KM necessary to acquire, store, and utilize this knowledge. Therefore, OM is essential for communication not only because it is a source of contextual information but also because it embodies the knowledge of how to communicate effectively in the organization (e.g., who knows, or should know, what). Furthermore, the information known to the organization is, in a substantial part, represented in organization communication on digital media such as e-mail and bulletin boards. It follows that computer-mediated communication can be a major source of the information stored in the OM. In other words, communication is a major provider of knowledge as well as being an essential enabler of KM. Referring to Figure 1, while the focus of this article is the arrow flowing from the OM to communication; we also see how communication injects knowledge into the OM. The relationship between communication and KM is bidirectional. Indeed, KM techniques are needed to store, organize, and make the information embodied in the communication available, via the OM, for distribution in future communication. Very often the core message of today becomes the context of tomorrow.

These four concepts (context, levels of abstraction, adaptation, and OM) are interrelated. In particular, OM should be modeled to enable effective contextualization, comprehensive support for all levels of abstraction and a basis for adaptation. OM will need to encompass a wide range of message forms (e.g., formal as well as informal materials and structured as well as unstructured information) and utilize a mix of media such as text, voice and video. Without such a mix, computer-supported communication will fall short of the flexible and adaptive nature of effective organizational communication. Moreover, OM will need to include information organized along levels of abstraction in order to support communication that fluctuates between levels, for instance, design OM to store and retrieve episodic memories (e.g., in the form of stories) as well as abstract rules generalizing the episodes. We return to the design of OM later on.

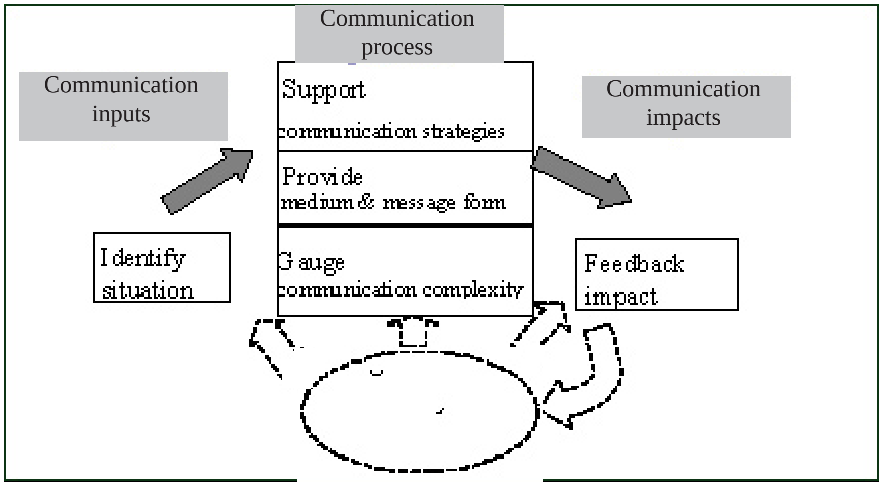
The three factors of the communication model, along with the four concepts discussed, create a framework for analyzing the role of KM in communication (see Figure 1). One can conceive of KM technologies that: (1) identify the inputs (e.g., the initial distances between communicators); (2) support the formulation of goals and the choice of communication strategies, choose and provide medium and message form, and gauge the complexity of communication in order to adapt it; and (3) provide the user with feedback on impact. Organizational memory is a key resource in supporting each of these types of functionality, but it also builds on the information and feedback from the communication.

APPLICATIONS AND FUTURE TRENDS

Following Figure 1, we examine several demonstrations of the potential roles of KM in the support of computer-mediated communication. First is the identification of the communication situation as well as the partners to communication. Groupware that helps the user identify "who knows what" and "who knows whom" in the workplace are examples of systems that employ KM techniques to identify whom to communicate with (e.g., Moreland, 1999). For example, IKNOW (Contractor, Zink, & Chan, 1998) is a program that organizes information about a network of colleagues and what knowledge each one has. In other words, the software attempts to answer the question: "Who knows who knows what?"

Given that two communicators are about to communicate, the relation between them can be characterized using organizational and personal

Figure 1. Communication enhanced by organizational memory (adapted from Te'eni, 2001)



knowledge. For example, knowledge of the organizational structure or of personal ontologies is the basis for computing the linguistic distance between the communicators (Maedche & Staab, 2001). Similarly, systems that employ collaborative filtering based on user profiles can compute a measure of similarity between profiles to decide what information to provide. For example, electronic media is personalized on the basis of user profiles (e.g., www.crayon.net), and similarly Intranet-based communication can be personalized according to internal employee profiles.

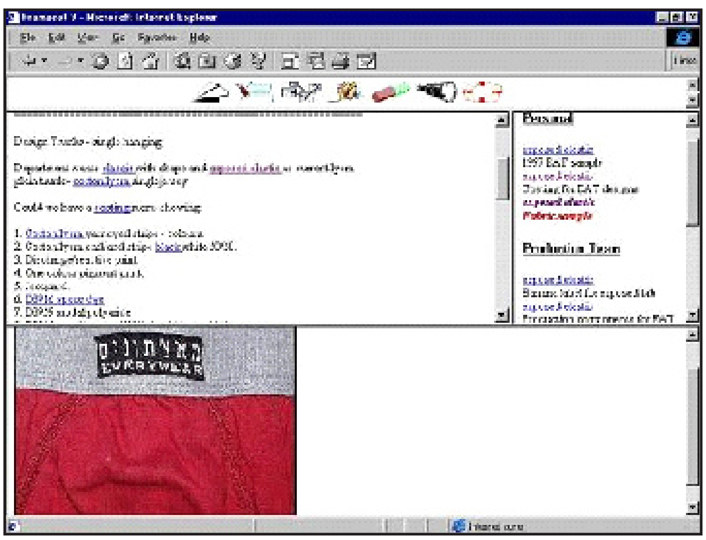
Finally, the information included in senders' signature files also can be used to define work relations between communicators (e.g., levels of expertise). As users may use different signatures, depending on the role they wish to assume in a particular communication, knowledge of the organizational structure combined with the user's choice of signature is particularly informative. When a sender from one department communicates with a colleague from the same department, a communication support system based on an OM that includes the organizational structure will be able to recognize the communicators as presumably sharing the same terminology. When the receiver is from a different organization, the signature could provide some clues on the semantic distance between the communicators. On the basis of such information, the communication support system can adapt the communication process to provide more or less contextual information.

KM can enhance the communication process in several ways. First, the initiation and control of the communication process relies on knowledge. For example, organizational maps can determine who should be contacted on what occasion. LiveMaps (Cohen, Jacovi, Maarek, & Soroka, 2002) tracks and analyzes colleagues using the same information. Another example is the early work on Coordinator (Winograd & Flores, 1986), which shows it is possible to assign to each message its purpose. A related communication support system is CHAOS (De Cindio, Simone, Vassallo, & Zanaboni, 1986), which organizes communications as a bank of conversations that serves as the basis for supporting communication and action. It includes a knowledge builder that observes messages and updates the bank of conversations accordingly.

Contextualization is perhaps the prime meeting point between communication and KM. First, the smart organization of messages (e.g., intelligent categorization of messages into folders and keywords) and then the advanced retrieval of information (e.g., text mining techniques) are crucial for effective contextualization. A knowledge-based mailer called kMail is an example of contextualization in communication support systems (Schwartz & Te'eni, 2000). The system builds links to relevant information automatically by parsing outgoing messages to detect possible information that elaborates the message. Indeed, contextualization highlights the role of knowledge management techniques in computer mediated communication. Such techniques are essential for detecting relevant knowledge, linking it to the core message and delivering it in context and in time.

Moreover, different people hold different views of context for the same core message. For instance, a production manager will think of a particular product, such as men's trunks, in terms of a production specification and the resulting product. In contrast, the marketing manager's mental model of the same product may be a packaged set of 10 pairs of colored trunks, with its associated sales and customer information. In kMail, the different views, owned by different communicators, are indexed so that people can see a message in light of alternative perspectives (see Figure 2). While the current picture of the trunks is part of the marketing view (mental model), an alternative view may depict a sketch with dimensions and other production specifications such as color options. Being able to depict the different views of the same product so that the communicators can appreciate the different

Figure 2. Contextualization based on organizational memory, showing on the right hand side different perspectives of different communicators



context held by their partners requires advanced KM. Another communication support system is Spider (Boland, Tenkasi, & Te'eni, 1994), which is designed to present context in a variety of forms so that it can lead more efficiently to better and richer communication. The system displays the different rationales behind an issue in the form of cognitive maps that highlight the similarities and differences in the communicators' perspectives. This requires KM that is not only capable of maintaining individuals' ownership over their own perspectives but also KM techniques that can compare and contrast perspectives (e.g., by comparing cognitive maps).

Contextualization can very quickly overload and needs to be prioritized according to the communicators, task, norms, and situation (see Figure 1). Prioritizing contextual information found in the OM so as to show only the most relevant information or enable the user to select, say, the 10 most relevant items requires advanced KM techniques such as those employed in search engines. For example, if knowledge in the OM is organized according to levels of abstraction, context can be presented at higher levels and expanded to lower levels only when needed. In kMail, knowledge items in the OM were classified as either a definition or a related item. A definition of a term (such as "BOM-bill of materials") can be shown at the highest priority, while lower abstraction levels of context can provide guidelines and templates for preparing a BOM and also may include examples of previous cases. KM is needed to organize the knowledge and provide it according to a hierarchy of levels. kMail also relies on the organization's communication maps to determine the likelihood of the communicators using the same or different terminologies, and accordingly recommending high or low levels of contextualization. A more recent system based on a Formal Language for Conversations, which also relies on previous messages in organizational memory, builds threads of associated messages and provides them as the context of the message sent (Takkinen, 2002).

Organizational knowledge can be managed so as to preserve the progression of information items from low to high formality (e.g., stories, facts, and abstract principles). Cleverly designed KM could be used to enable communication systems to supply the right level at the right time. Clearly, some knowledge sharing involves close human-to-human interaction and cannot rely on automatic processes for storing and retrieving data via structured databases. KM must therefore not only maintain knowledge in different forms but also enable their exchange through different media to support rather than replace human-to-human communication. Some messages such as stories are best sent as texts but accompanied by voice messages highlighting or interpreting some complex or sensitive point. In other words, human knowledgeability combines with predefined rules embodied in the KM systems to provide more effective communication. Furthermore, complex, tentative, and fuzzy ideas are often communicated informally and safely between colleagues (friends) in the form of conversations or ongoing dialog. Communities of practice (Wegner, 1998) are an essential enabler of meaningful conversations, and knowledge-based software (sometimes called "communityware") helps organize such conversations (Wellman, 2001).

Ultimately, feedback on the impact of communication must come from the user's own reaction, but future systems may effectively channel this feedback back to the sender. The OM can be designed to include results of successes and failures of communication that are provided to the sender at the appropriate time. For example, in a multinational organization, a history of poor communication between certain departments in two different nations should be fed back to these communicators in order to take the necessary precautions such as a higher level of information redundancy and more detailed feedback. Little research has been carried out in this area but as communication support systems become more common, the importance of informing senders of the communication impact will grow. Some form of feed-forward may be possible, for example, a simulation of probable errors due to a high semantic distance between communicators (e.g., communicators speaking different languages.) Furthermore, advanced computer support may be able to dynamically sense fluctuations in communication complexity and adapt the communication accordingly to ensure effective communication. Clearly, there is still much to do in terms of developing ways of identifying and reporting on communication failures.

CONCLUSION

In conclusion, KM is becoming a crucial element in the design and enhancement of organizational communication. The model shown in Figure 1 provides a framework for understanding the different types of enhancement to computer-mediated communication contribution that can build on knowledge (stored in OM) and KM. The knowledge is of two types: knowledge about the issue communicated and knowledge about how and with whom to communicate. KM must be designed to utilize both types of knowledge to enhance communication. It does so through techniques such as content and document management, contextualization, profiling people in the organization, finding contextual information through text and data mining, categorizing information, and more. Several of the systems described use these techniques to capitalize on organizational knowledge for enhancing communication.

Not all knowledge, however, can be communicated explicitly. Some forms of knowledge sharing are inherently tacit. KM techniques that rely on explicit information are therefore necessarily limited to part of organizational communication. Nevertheless, as computer-mediated communication accounts for a growing part of organizational communication, KM is rapidly becoming a necessary component of computer-supported communication systems. Moreover, our discussion has focused on cognitive aspects of communication and KM. Future research will need to expand to include cultural and political aspects as well as affective aspects of organizational communication. Future communication systems will learn to adapt to the communicators' emotions as well as their genres of communication. KM will undoubtedly be called on again.

As computer support for organizational communication expands within organizations, including dispersed organizations, and extends to different forms of knowledge (data, stories, policies, best practices, etc.) and different media (synchronous and asynchronous text, voice, multimedia, etc.), KM will have to invent new ways to organize and integrate the multiple sources of knowledge available in the organization. Communication relies on knowledge regardless of its form and medium and KM will have to rise to the occasion.

Chapter 7.8
Organizational Attention

Eyal Yaniv
Bar-Ilan University, Israel

David G. Schwartz
Bar-Ilan University, Israel

INTRODUCTION

Attention is a term commonly used in education, psychiatry, and psychology. Attention can be defined as an internal cognitive process by which one actively selects environmental information (i.e., sensation) or actively processes information from internal sources (i.e., stored memories and thoughts; Sternberg, 1996). In more general terms, attention can be defined as an ability to focus and maintain interest in a given task or idea, including managing distractions. Attention is selective by its nature. According to Pashler (1998, p. 37), "The process of selecting from among the many potentially available stimuli is the clearest manifestation of selective attention."

Why do firms respond to certain events or stimuli in their environment while neglecting others? It seems that organizations, just like individuals, have limited attention capacity. Hence, they must select from among the many potentially available stimuli and respond to these selected stimuli only. Organizational attention is defined as the socially structured pattern of attention by decision makers within the organization (Ocasio, 1997). Organizational attention, like human attention, is a limited resource: "Attentional limits filter or screen incoming information such that a great deal of data pertinent to strategic decision may never get processed" (Corner, Kinicki, & Keats, 1994, p. 296). Garg, Walters, and Priem (2003) show that the extent to which CEOs (chief executive officers) are selective in their attention to sectors of the environment is a significant predictor of performance.

Knowledge management (KM) models and process theories, almost without exception, incorporate a stage or phase in which a given knowledge item is brought to bear on a current decision or action. This stage, referred to alternatively as externalization (Nonaka, 1994) or awareness (Schwartz, Divitini, & Brasethvik, 2000), is of crucial importance in any knowledge-management cycle. The flow of knowledge in and out of an awareness stage is not merely a function of the universe of available organizational memory or the technological tools available to filter and identify such knowledge. It is influenced to a large degree by organizational attention. The second area in which organizational attention is key is knowledge acquisition and creation as discussed by Ocasio (1997), and Yaniv and Elizur (2003).

Successful knowledge management requires attention. Davenport and Volpel (2001) argues that attention is the currency of the information age. Knowledge consumers must pay attention to knowledge and become actively involved in the knowledge-transfer processes. This is particularly important when the knowledge to be received is tacit (Nonaka, 1994). Knowledge can be part of the organization's repository, however, if it does not get the attention of decision makers or other knowledge workers, it is not effective. This knowledge can be very important and relevant to the organization, but since it does not get attention, it does not become useful. Organizational attention is crucial in the context of knowledge management as it lays the infrastructure for knowledge acquisition and transfer.

Like human attention, organizational attention is limited in its capacity. Davenport and Volpel (2001) terms this as the attention-deficit principle: "Before you can manage attention, you need to understand just how depleted this resource is for organizations and individuals." Organizational attention limits the ability of organizations to process knowledge and thus it should be of major concern when knowledge management is discussed.

The limited organizational attention span reduces the number of sources that the organization can use as knowledge sources. The organization has to pay attention to some sources while ignoring or paying less attention to others. An increased likelihood of missing key information when making decisions is the direct result of this selective attention. In this article, organizational attention is discussed in the context of organizational knowledge flow and processing.

BACKGROUND: ORGANIZATIONAL ATTENTION AND KNOWLEDGE PROCESSING

The fact that a situation demands information to fill cognitive gaps, to support values and beliefs, or to influence affective states, and that sources of information are available and accessible to the decision maker is no guarantee that the information will be processed (that is, incorporated into the users' framework of knowledge, beliefs, or values) or used (that is, lead to changes in behavior, values, or beliefs).

Mintzberg's (1973) model of the managerial use of information includes information acquired from the external environment. In his conceptualization of top managers as information-processing systems, the managers' interpersonal roles provide access and exposure to information from a large number of external and internal information sources. The manager in the informational role of monitor "continually seeks and receives information from a variety of sources in order to develop a thorough understanding of the organization and its environment" (p. 97).

Ocasio (1997) developed a framework for an attention-based view of the firm. He defines corporate strategy as "a pattern of organizational attention, the distinct focus of time and efforts by the firm on a particular set of issues, problems, opportunities, and threats, and on a particular set of skills, routines, programs, projects and procedures" (p. 188). Simon (1947) describes organizational behavior as a complex network of attentional processes. Ocasio argues that since the environment of a firm's decision is of infinite complexity and firms are bounded in their capacity to attend to all environmental stimuli, decision makers are selective in those aspects of the environments of the decisions that they attend to. Different environmental stimuli are noticed, interpreted, and brought into conscious consideration. According to this view, attention is the noticing, encoding, interpreting, and focusing of time and effort by organizational decision makers on both issues and answers. Issues are problems, opportunities, and threats, and answers are action alternatives, such as proposals, routines, projects, programs, and procedures.

A basic example of organizational attention in action is as follows. Consider a cellular service provider in a very dynamic, competitive environment. Decision makers are faced with an overwhelming number of problems to deal with: competitive rivalry, customers' demands, technological innovation, and so forth. Their sources of information about these issues are diverse. Competitors' behavior and expected moves can be determined to a certain degree from public sources, such as newspapers and conferences, or by business intelligence activities. Different evaluations of the future behavior of competitors are available. Customers' demands are also based on different sources of information. Technological news come both from internal and external sources. Decision makers are bombarded with more information than they can effectively attend to and assimilate as their attention capacity is bounded. They have to select which problems, issues, and inputs they can deal with among the infinite available sources. Organizational attention is the pattern that is derived from decision makers' selections. The organization as a whole responds, according to this pattern, to certain issues while paying less attention to others. In our cellular example, the firm might ignore signals about the intention of a competitor to launch a new technology if the source that provides this information is not in the attention focus of the firm.

Durand (in press) investigates organizational attention in terms of the firms' investment in internal and external information, and finds that higher relative investments in market information appear to reduce errors and bias in forecasting.

Organizational attention affects both the forward and backward search for information in order to solve organizational problems and acquire new knowledge (Cyert & March, 1963), and to perceive opportunities or threats in the environment (Gavetti & Levinthal, 2000).

Decision makers differ in their knowledge of alternatives and consequences (March & Simon, 1958), their values, and their cognitive styles (Hambrick & Mason, 1984). These factors may contribute significantly to managers' focus of attention.

Ocasio (1997, p. 204) stresses that "the focusing of attention by organizational decision makers allows for enhanced accuracy, speed, and maintenance of information-processing activities, facilitating perception and action for those activities attended to." As stated by Cockburn, Henderson, and Stern (2000, p. 1142):

Ex post, it is clear that some firms actively identify, interpret, and act upon early signals from their external and internal environment, and so position themselves to effectively exploit these opportunities well in advance of others' demonstration of the pay-off from the strategies which emerge later on as best practices.

Two major aspects of human attention are capacity and selection. These aspects are adaptable and applicable to the discussion of organizational attention. Contemporary research discusses attention within the framework of the information-processing approach (Pashler, 1998). At the individual level, capacity is the amount of stimuli that can be noticed and processed in a given time. Kahneman (1973) suggests that the allocation of finite resources might account for a broad range of limitations people have in doing different activities at the same time. Due to these limitations, the individual has to select from the available stimuli those she or he will focus on and process. According to Kahneman focused attention facilitates perception and actions toward issues and activities being attended to, while inhibiting perception and action toward those that are not.

MAIN FOCUS: THE IMPORTANCE AND IMPACT OF ORGANIZATIONAL ATTENTION IN A KNOWLEDGE-MANAGEMENT SETTING

In the organizational context, capacity can be defined as the amount of issues that can be processed by decision makers, and selection refers to the specific issues that were selected and are being processed by the firm and its decision makers. These two dimensions complement each other. According to Ocasio (1997), "The environment of decisions is of infinite complexity and firms are bounded in their capacity to attend to all (or even most) environmental stimuli that impinge, directly or indirectly, upon any particular situation." Within the constraint of limited capacity, organizations have to select the issues that they can attend to while filtering the rest. Organizations differ in both factors. They differ in attention capacity and they select different issues or stimuli to deal with (Yaniv, 2004; Yaniv & Elizur, 2003). As organizational attention is the socially structured pattern of attention by decision makers, the attention capacity of the organization is a function of the decision makers' attention capacity and the organizational knowledge-flow structure.

The organizational knowledge-flow structure is an intangible resource that is part of the organizational tacit knowledge that embodies strategic advantage (Baumard, 1999; Eisenhardt & Santos, 2002). The knowledge-flow structure is a major factor in creating new knowledge (Corner et al., 1994). This structure creates differences between firms when they absorb and create new knowledge. Even more interesting is how this structure hinders the exploitation of available knowledge that might be very valuable.

In the context of knowledge processing, organizational attention is a filter mechanism that enables focusing on some of the available inputs while suppressing the rest. While organizational attention is rarely discussed in the literature, some related terms depict organizational limits. Absorptive capacity and bounded rationality can be mapped to the above attention-related constructs selection and attention capacity, respectively.

Absorptive Capacity

Cohen and Levinthal (1990) describe the ability of the firm to evaluate and utilize new knowledge to the evolving knowledge base already accumulated by the firm. They define absorptive capacity as the idea that prior related knowledge confers an ability to recognize the value of new information, assimilate it, and apply it to commercial ends. Cohen and Levinthal argue that when a firm wishes to acquire knowledge that is unrelated to its ongoing activity, the firm must dedicate efforts to creating or increasing absorptive capacity.

Since absorptive capacity affects the ability of the firm to recognize the value of new knowledge, it acts as a knowledge filter. The firm's existing knowledge influences the absorption of new knowledge and filters unrelated knowledge. In other words, the existing knowledge directs the firm's attention to new related knowledge. Absorptive capacity is an organizational situational feature that determines which knowledge sources the firm will choose to focus on. In terms of organizational attention, absorptive capacity is akin to selection. Absorptive capacity explains some aspects of accumulating new knowledge by the organization and considerably influences selection, yet it does not fully explain selection behavior. There are more factors to be considered.

Bounded Rationality

The limited attentional capability of humans results in their bounded capacity to be rational (Simon, 1947). The bounded-rationality problem (Simon, 1955) is the inability of firms to maximize over the set of all conceived alternatives when dealing with real-life decision problems. These problems are often too complex to comprehend. Based on the bounded-rationality problem, Nelson and Winter (1982) focus on the evolution of simple, stable routines that are used to guide action. Because of the bounded-rationality problem, these routines cannot be too complicated and cannot be characterized as optimal since they are taking into account only partial information. However, Nelson and Winter claim that “they may be quite satisfactory for the purposes of the firm given the problems the firm faces” (p. 35).

The bounded rationality of the individual is parallel in many ways to organizational attention. It is based on the limited ability of decision makers to pay attention to all aspects of the problems they deal with. Their attention capacity is limited, and they therefore make shortcuts. Bounded rationality is akin to attention capacity. What causes decision makers to choose certain knowledge to focus on and ignore other knowledge? They do have a limited capacity, but they still could choose to use this capacity in different ways and focus on different sets of knowledge.

The two filters discussed here—bounded rationality and absorptive capacity—are closely related to organizational attention. Bounded rationality is the result of attention’s limited capacity, while absorptive capacity is a major factor that affects attention selection. The following section discusses the affect of attention selection on the creation of new knowledge.

Organizational Attention and Knowledge Creation

Gavetti and Levinthal (2000) present an iterative process of knowledge creation, illustrated in Figure 1. The influence of the outcome on knowledge is mediated by the reinforcement of routinized patterns of action.

Building on this model, organizational attention can be incorporated into the process of new knowledge creation. The new knowledge is not

Figure 1. Knowledge creation (Gavetti & Levithal, 2000)

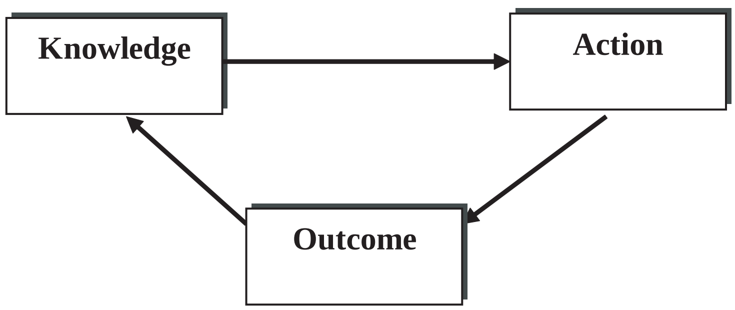

Figure 2. Knowledge creation mediated by organizational attention

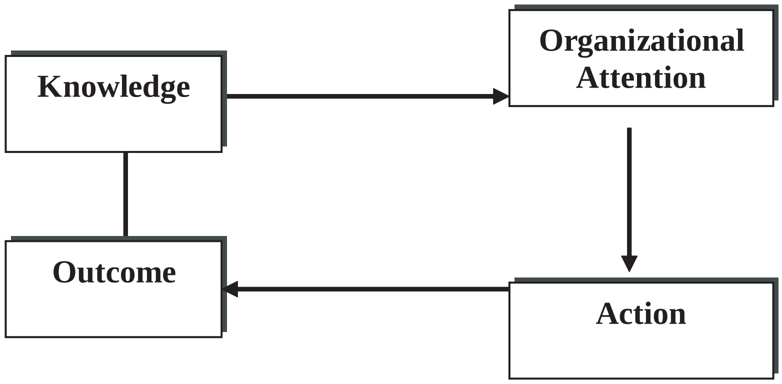
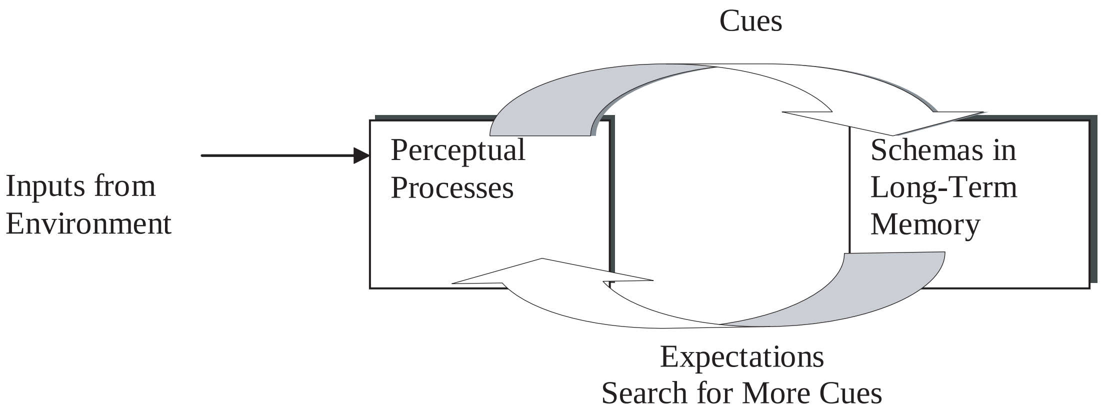


derived automatically from the outcomes, but filtered and directed by organizational attention. The process is illustrated in Figure 2.

Organizational attention mediates knowledge and actions. Since not all the available knowledge can be noticed and used by the firm for its actions, organizational attention affects the creation of new knowledge. In other words, the creation of new knowledge depends on the knowledge that penetrates the organizational attention filter.

Figure 3. The perceptual cycle (Neisser, 1976)



Neisser (1976) describes the human perceptual cycle. He suggests that perceptual processes produce a preliminary and temporary representation of input features that act as cues to activate knowledge-schema representations, which in turn can direct attention to a more detailed analysis of cue features. The perceptual process is depicted in Figure 3.

The organizational processes of acquiring and accumulating knowledge can be characterized by a similar cycle. These knowledge-transfer processes are cyclic, thereby the existing knowledge directs the organizational attention to certain knowledge and ignores others. The organization receives inputs from its environment, both internal and external, and processes them according to its existing knowledge. The organizational existing knowledge is stored in organizational memory (Ackerman, 1996; Tuomi, 1999; Walsh & Ungson, 1991). Knowledge is stored in several physical locations (Simon, 1947), individuals (Argyris & Schon, 1978), procedures (Cyert & March, 1963), and culture (Ackerman; Barney, 1986). Walsh and Ungson posit the existence of five storage bins that compose the structure of organizational memory and one external source. The storage bins include individuals, culture, transformations (procedures), structures (roles), and the ecology (physical plant). By external source, they refer to external archives.

FUTURE DIRECTIONS

The knowledge-seeking behavior of an organization is not simply the sum of the parts of its individual members. In order to better understand how organizational attention influences the knowledge-management cycle, there are two main areas that require additional research and development.

First is the development of analysis techniques that can effectively identify and quantify organizational attention. By understanding the detailed elements within an organization that impact and influence attention, we can begin to harness it.

Second is the use of models of organizational attention as an intervention tool to help modify and steer the direction of KM in an organization. Viewing organizational attention as a systemic part of a firm's KM processes opens the door to focusing that attention in more effective ways.

SUMMARY

Organizational attention is an important concept that can explain organizations' knowledge-seeking and -awareness behavior. Organizational attention affects a firm's behavior by controlling organizational knowledge flow and knowledge processing. Explaining firms' behavior is a basic issue of strategic management (Rumelt, Schendel, & Teece, 1994), and strategy formulation is a process of guided evolution (Lovas & Ghoshal, 2000). The firm can be viewed as a collection of discrete organizational activities (Porter, 1985; Sigglekow, 2002), and the mechanism that guides the evolution of the strategy within the firm is organizational attention. Organizational attention is guided by the selective attention to organizational issues and initiatives (March & Olsen, 1976; Ocasio, 1997).

Like individual attention, the capacity of organizational attention is bounded. Nevertheless, organizational attention capacity is varied as a function of the organizational decision structure. Efficiency of decision processes and knowledge flow in the organization can result in the extended attention capacity of the organization. This limited capacity determines the amount of information inputs that can be effectively handled by the firm's decision makers.

The selection of inputs to be considered in knowledge-intensive tasks depends, of course, on the available attention capacity. Since the capacity is limited, this process must be economical, and being economical in the context of knowledge processing means optimizing the use of processing resources. One way of doing so is to select inputs that are easier to deal with: often inputs that are related to existing knowledge as they are easier to perceive and process. This notion is compatible with Cohen and Levinthal's (1990) definition of absorptive capacity, where existing knowledge plays a critical role in the ability of the organization to absorb new knowledge. Both attention capacity and existing knowledge predispose the organization's selection of knowledge inputs from available sources, and an improved understanding of the factors that affect organizational attention will lead to better use of these scarce resources.

Chapter 7.9
Tacit Knowledge Sharing

Syed Z. Shariq
Stanford University, USA

Morten Thanning Vendelø
Copenhagen Business School, Denmark

INTRODUCTION

When people solve complex problems, they bring knowledge and experience to the situation, and as they engage in problem solving they create, use, and share tacit knowledge. Knowing how context emerges and transforms is central if we want to understand how people create, use, and share tacit knowledge. Consequently, this article focuses on the three questions: What is context? How does context emerge and transform? What is the relationship between context and tacit knowledge sharing?

Initially the article describes how context is conceptualized in the theory of the firm as a knowledge-creating entity, and it argues that this theory lacks a detailed account for how context emerges and transforms. Thereafter, we define context, and based on the writings by the Austrian sociologist Alfred Schütz, a theory of how context emerges and transforms is put forward. This theory is illustrated with an empirical case describing the Carbon Dioxide filtering problem, which occurred during the ill-fated Apollo 13 mission. The article concludes by explaining how a theory of context helps us to understand the role of context in tacit knowledge sharing.

BACKGROUND: CONTEXT IN THE THEORY OF THE FIRM AS A KNOWLEDGE-CREATING ENTITY

Knowledge management scholars have put forward ideas for a theory of the firm as a knowledge-creating entity, and suggest that the firm can be conceptualized as a dynamic configuration of 'ba' (roughly means place) (Nonaka, Toyama, & Nagata, 2000a). More precisely, 'ba' is defined as the context shared by those who interact with each other, and 'ba' is the place where they create, share, and use knowledge.

Putting knowledge in context is important as "knowledge creating processes are necessarily context-specific, in terms of who participates and how they participate in the process. The context here does not mean "a fixed set of surrounding conditions but a wider dynamical process of which the cognition of an individual is only a part" (Hutchins, 1995, p. xiii). Hence, knowledge needs a physical context to be created, as "there is no creation without place" (Casey, 1997, p. 160; Nonaka et al., 2000a, p. 8).

The initial step towards a theory of the firm as a knowledge-creating entity (Nonaka et al., 2000a) has given many insights to knowledge creation in organizations, and with the introduction of the 'ba'-concept, a step towards a conception of context has been taken. However, it remains unclear what exactly 'ba' is, how 'ba' emerges, and what exactly happens inside 'ba'. The definition of 'ba' offered by Nonaka et al. (2000a) is unclear or ambiguous at best. On the one hand they note: "Knowledge needs a physical context to be created, as 'there is no creation without place'" (p. 8). On the other hand they note that "'Ba' does not necessarily mean a physical space. Rather, it is a specific time and space" (p. 9). Furthermore, 'ba' seems to be a very inclusive concept. According to Nonaka and Konno (1998, p. 40), "'Ba' can be thought of as a shared space for emerging relationships. This space can be physical, virtual, mental, or a combination of them." We therefore think it is fair to ask: What is not included in 'ba'?

Concerning the emergence of 'ba' then it seems that on the one hand 'ba' is created spontaneously. "'Ba' is constantly in motion. 'Ba' is fluid, and can be born and disappear quickly" (p. 9). On the other hand 'ba' can be built intentionally (Nonaka, Toyama, & Konno, 2000b). According to Nonaka et al. (2000a, p. 12): "…building 'ba' such as project teams or functional departments, and determining how such 'ba' should be connected to each other, is an important factor in determining the firm's knowledge creation rate." In addition, it is worth noting that "the boundary for 'ba' is fluid and can be changed quickly as it is set by the participants. Instead of being constrained by history, 'ba' has a 'here and now' quality. It is constantly moving; it is created, functions and disappears according to need" (Nonaka et al., 2000b, pp. 15-16).

Finally, regarding the question: What exactly happens inside 'ba'? The closest we get to an answer to this question is provided by Nonaka and Toyama (2000, p. 3) who write "…'ba' is…an open space where participants with their own contexts can come and go and the shared context (that is, 'ba') can continuously develop." Therefore, although the concept of 'ba' (Nonaka & Konno, 1998; Nonaka et al., 2000a) represents an attempt to define context, we are still far from an explanation of how context emerges and transforms, and thus, we have yet to understand what happens inside 'ba'.

MAJOR FOCUS I: DEFINING CONTEXT

We maintain that contexts are not 'just there' as static entities, but that they are emerging phenomena. A similar perception is put forward by Erickson and Schultz (1997), who describe context as a mutually constituted, constantly shifting, situation definition emerging through the interaction of the involved individuals. "Contexts are not simply given in the physical setting…nor in combinations of personnel…Rather, contexts are constituted by what people [do and where and when they do it]. As McDermott puts it succinctly (1976), "People in interaction become environments for each other" (p. 22), and Dilley agrees (1999): "Context is both constitutive of social action and itself the outcome of social action, it is both a generative principle and a resulting outcome" (p. 19). Yet, neither of these authors make clear if they perceive context as an collective or individual construct. Based on Polanyi's (1962) statement that all knowledge is personal knowledge, we suggest that context is an individual construct. Furthermore, we propose that context emerges as an individual encounters a situation, including others and artifacts, as it is the individual's interpretation of a situation that results in a context. After its emergence the context transforms as the situation evolves, for example, as a result of the acting of the individual and the others involved.

By claiming that the individual interpretation of a situation results in a context, we imply that the context emerging for an individual in a specific situation is based on that individual's previous experiences. As two individuals never have fully similar experiences, the contexts emerging for two individuals can never be similar, yet similarities among individual experiences might result in contexts with many similarities. Another important implication of our context definition is that if individual X encounters situation Y in both t=1 and t=2, then the contexts emerging for individual X at these two points in time will differ as individual X brings a different set of experiences to the two instances of the situation Y.

By defining context as an emergent and individualistic construct, we are in agreement with Rapport (1999, p. 190) who writes:

Context is determined by the questions which people ask of events…Just as many questions can be asked of events, so there will be many contexts; just as different people can ask different questions of events, so different people will determine different contexts; just as people can ask a number of different questions of events at the same time, questions of which other people may or may not be aware, so different people can simultaneously create and inhabit multiple contexts, contexts whose commonality is questionable.

Further, Ackerman and Halverson (1998) emphasize that "To reuse a memory, the user must then recontextualize that information. The information, if not supplied by the same individual, must be reunderstood for the user's current purpose" (p. 47). Hence, assuming that the questions individuals ask of events are determined by their experience, then there can be little doubt that contexts emerge and transform during acts of interpretations. In the following section we therefore take a closer look at acts of interpretations.

MAJOR FOCUS II: INTER-SUBJECTIVITY, TYPICALITY, IDEAL TYPES, AND CONTEXT

We recognize Schütz (1962, 1964, 1967), as a major focus in his research was on how cooperation evolves among actors who are more or less anonymous to each other (Ebeling, 1987). Thereby, his research can be used to provide insight into the emergence of contexts for sets of individuals with different degrees of similarities among their experiences. Schütz explains (Augier, 1999, pp. 158-159):

…that our 'life world' consists of a multitude of others, with whom we live and interact, although our knowledge about them is scarce. That is, we are more or less 'anonyme' to each other, despite the fact that the life world in which we are both is full of structures containing inter-subjective knowledge (see Schütz & Luckmann, 1973, 1989). This knowledge is used by imputing 'typical' 'course of action-types' and 'personal ideal types' to the individuals to analyze what happen if he/she follow[s] particular 'roles' (personal ideal types) or pursue[s] certain ends ('course of action-type').

Ideal types are used when we act and interpret events in the social world, and ideal types are abstractions from the particulars and the idiosyncrasies of the world; thus, they produce statements of general validity. Ideal types can be:

…arranged according to the degree of increasing anonymity of the relationship among contemporaries involved and therewith of the context needed to grasp the other and his behavior. It becomes apparent that an increase in anonymity involves a decrease in fullness of content. The more anonymous the [ideal type] is the more detached is it from the uniqueness of [other individuals involved] ... If we distinguish between (subjective) personal ideal types and (objective) course-of-action types we may say that increasing [anonymity] of the construct leads to the superseding of the former by the latter. (Schütz, 1962, pp. 17-18)

In addition to our ideal typical knowledge, we possess more specialized information about particular kinds and groups of others. If we formerly had direct experience of the particular other facing us now, we can use the specialized information extracted in these experiences (Schütz, 1964, p. 30).

The individual brings ideal typical knowledge and more specialized information about others, artifacts, and situations, to a situation. Here they constitute the basis for the individual's interpretation of the situation, including others and artifacts, and thereby for the individual's conception of context. Consequently, specialized information and ideal types are the basic elements from which context emerges.

We, Thou, and They Relations

When we encounter others in the social world, they do not appear to us in identical perspectives, and our relations with them have different degrees of intimacy and anonymity (Schütz, 1964, p. 22). It is possible to distinguish among three types of relations: they, thou, and we relations (Schütz, 1967). In we relations individuals are aware of each other and of the awareness, and they are able to obtain understanding of each other's motives. In thou relations no such reciprocal awareness exists, and understanding involves more anonymous types of meaning. Finally, in they relations individuals use ideal types in order to impute 'typical' motives into each other and thereby understand each other's actions.

In we relations we experience others directly, we and they share a common sector of time and space, and thus we and they age together. The sharing of a common sector of space implies that we and others appear to one another in person as ourselves and nobody else (Schütz, 1964). "In the ongoing experiences of the we relation I check and revise my previous knowledge about my partner and accumulate new [specialized] knowledge about him. Thereby my general stock of knowledge also undergoes a continuous modification" (p. 30).

In they relations our partners are not concrete and unique individuals, but types, and "the experiences of contemporaries appear to [us] more or less anonymous processes" (p. 43). As a result we obtain relatively little specialized information about their motives and actions. Also, in they relations my experience of my contemporaries is not continuously modified and enriched. "Each new experience of contemporaries adds, of course, to my stock of knowledge; and the ideal types by which I am oriented to others in a they relation do, indeed, undergo modifications…But these modifications remain minimal as long as a given situation and my interests in it—which have determined the original application of a given typifying scheme—remain constant" (p. 55).

Even if the ideal typical knowledge and the more specialized information that we obtain in our relations with others enable us to interpret and give meaning to the behavior by others, then these meanings may not correspond to the meanings of the others, as "…the subjective meaning of another person's behavior need not to be identical with the meaning which his perceived external behavior has for…an observer" (Schütz, 1967, p. 20).

In we relations we can assign our meaning to others with greater confidence, as the world within their reach coincides with ours. In they relations this reciprocity of experiences is replaced by acts of reflection on the typifying scheme which presumably orients the conduct of both they and us. The validity of our assumption that they share a given typifying scheme with us cannot be verified, since they are not present (Schütz, 1964, p. 54). "I cannot presuppose, for example, that my partner in a they relation will grasp a nuance of a word or that he will place a statement of mine in the proper context unless I explicitly and 'objectively' refer to that context. The direct evidence that I have been understood, which I have if my partner is present in the community of space and time, is lacking in a they relation" (Schütz, 1964, pp. 55-56).

From above it follows that individuals who have prior experience from a range of we relations with each other are likely to establish contexts with many similarities. In contrast, individuals who have little prior experience from we relations with each other are likely to establish contexts with few similarities. Therefore, as a group begins problem solving, the members of the group are not necessarily in the position to understand one another. Yet, as individuals we assume that everybody takes the world around us for granted in essentially the same way as we do ourselves, and thus we orient our actions towards other people, assuming that they will behave in a 'typical' manner. Consequently, it might take time before we register that this is not the case, and thereby register that little common understanding has emerged.

MAJOR FOCUS II: PEOPLE SOLVING COMPLEX PROBLEMS

We illustrate the emergence and transformation of context with a case where a complex problem is solved within a constrained timeframe, as we believe it is in such problem-solving processes that emergence and transformation of context are most visible. We build this belief on Ciborra, who some years ago suggested that "people improvise when they are overwhelmed by the world, and thus, is forced to read the world in a different way."1 Improvisation "is purposeful human behavior which seems to be ruled at the same time by intuition, competence, design, and chance" (Ciborra, 1999, p. 78). Thus, it is the lack of time to solve complex problems that leads people to improvise. Furthermore, improvisation is grounded in memory of the past (Weick, 1998, p. 547), and thereby, in the ideal typical knowledge and more specialized information that individuals bring to the process.

Complex Problem Solving During the Ill-Fated Apollo 13 Mission

The Apollo 13 mission was on schedule when the message "Okay, Houston, we've got a problem here..." came from the Apollo 13 Command Module. An oxygen tank had exploded, damaged the Service Module, and left the Command Module without power and air. After a health assessment of the spacecraft, it was decided to abandon the mission, move the three astronauts to the Lunar Module, and attempt a loop around the moon in order to get the spacecraft back to the planet earth.

Soon after the explosion, the assessment of life-support systems determined that although oxygen supplies were adequate, the system for removing Carbon Dioxide in the Lunar Module was not. The Lunar Module was designed to support two men for two days and was being asked to care for three men nearly four days. Thus, removal of Carbon Dioxide in the Lunar Module became a concern. The system in the Lunar Module used canisters filled with Lithium Hydroxide to absorb Carbon Dioxide as did the system in the Command Module. Unfortunately the canisters were not interchangeable between the two systems, so the astronauts were faced with plenty of capacity for removing Carbon Dioxide but no way of using it.

Facing this potentially fatal problem, a ground crew team at NASA Mission Control in Houston brought into a room all the items available on board the spacecraft, including the space suits originally planned for use during the visit to the moon. Using these items the team worked on a solution and constructed a device it believed could be implemented by the astronauts. After a test in the spacecraft simulator, the solution was verified and the instructions were transmitted to the astronauts on board the spacecraft. The astronauts succeeded in assembling the two carbon dioxide removal devices:

There was, of course, a fix; and it came in the form of an ingenious combination of suit hoses, cardboard, plastic stowage bags, and Command Module canisters—all held together with a liberal application of gray duct tape. As was usual whenever the Apollo team had to improvise, engineers and astronauts on the ground got busy devising ways around the problem and then checked out the new procedures. A day and a half after the Apollo 13 accident, the ground team had designed and built a filtering device that worked to their satisfaction. They promptly radioed instructions to the crew, carefully leading them through about an hour's worth of steps. As Lovell wrote later: 'the contraption wasn't very handsome, but it worked.'

Emergence and Transformation of Context in the Apollo 13 Case

We draw three inferences about the emergence and transformation of context in the Apollo 13 case. We show how the need for problem solving by improvisation emerged, we interpret how the ground crew responded to the problem, and finally, we discuss the conditions for their success with problem solving.

The explosion on board the spacecraft created a novel problem and forced the NASA Mission Control Team into action. The team was overwhelmed by the urgency of the crisis, as the challenge was to create a solution that could be implemented by using the items available on board the spacecraft. Hence, the ground crew had to move beyond their ex ante knowledge, and include and create knowledge useful in the present situation.

In our interpretation of the ground crews' response, we claim that as soon as the Carbon Dioxide filtering problem was known, each of them produced a personal interpretation of what it meant and how it could be solved. As a result a context emerged for each of them, with their individual contexts including their knowledge about how each of the other ground crews could contribute. This knowledge was based both on ideal types of these others and on more intimate experiences from past we relations with them.

Realizing that the solution could not be found within the potential solutions available on ground, but should be created from the items available on board the spacecraft, the ground crew experienced a transformation of their contexts, as now they had to perceive their knowledge about Carbon Dioxide filtering within the permutations of possibilities that existed within the scope of items available on board the spacecraft. By acknowledging this as a constraint, they adapted their contexts to the complexity of the problem situation. We assert that when adapting their contexts, they took into account what they knew about the fellow team members' knowledge about Carbon Dioxide filtering and the possibility of applying it within the constraints imposed by the situation. Consequently, they experienced that knowledge previously irrelevant to the Carbon Dioxide filtering problem might be relevant in this particular situation.

Reviewing the Carbon Dioxide filtering problem-solving process, we suggest that the ground crew experienced that none of them held sufficient knowledge to solve the problem on their own. Hence, they realized that knowledge sharing was necessary for creating a solution. It is our assertion that knowledge sharing required that the problem solvers took on we orientations towards each other, and thereby established we relations in the problem-solving process, as otherwise they could not obtain verifications of similarities in typifying schemes among themselves and their partners, and had not been able to solve the problem.

Establishment of we relations in problem solving is however not sufficient to give way for effective knowledge sharing. Also, the intimacy of we relations is important—that is, how easy problem solvers experience it to follow each other's lines of thoughts. We suggest that the intimacy of we relations is a result of the extent to which the context emerging and transforming for each of the problem solvers exhibits similarities with the contexts emerging and transforming for the other problem solvers. In turn the emergence of contexts with many similarities requires that problem solvers have shared many common sectors of time and space prior to the problem solving in situ. Consequently, the less anonymous problem solvers are to each other, the fewer obstacles to tacit knowledge sharing they will experience. These preconditions existed in the Apollo 13 case where the ground crew and the astronauts held similar experiences from prior training and collaboration. Had this not been the case, then we assert that the ground crew had experienced difficulties in following each other's line of thought and in gaining a common ground for problem solving.

In sum, we find that problem solving in the Apollo 13 case was conditioned on: (a) the ability of the ground crew to register the world and form novel views of the available resources (the suit hoses, cardboard, plastic bags, tape, etc.) as possible components of a new Carbon Dioxide filtering devices; and (b) the establishment of we relations, which allowed for the emergence of contexts with many similarities and thereby for tacit knowledge sharing. Accordingly, it is the ability to create contexts with many similarities as well as the possession of in-depth knowledge about the items available for the creation of a solution that enables people to solve complex problems.

CONCLUSION AND FUTURE TRENDS

In the introduction we asked: What is context? How does context emerge and transform? What is the relationship between context and tacit knowledge sharing?

First, using Polanyi (1962) as our point of departure, we defined context as an individual construct, which emerges as an individual encounters and interprets a situation, and therefore contexts are not "just there" as static entities.

Second, building on the theories of Schütz (1962, 1964, 1967), we argued that an individual's interpretation of a situation happens as that individual brings his experience in the form of ideal typical knowledge and more specialized information to the situation. Subsequently, his context transforms over time, as he is confronted with other problem solvers and constraints imposed on the problem-solving process.

Third, we argued that sharing of tacit knowledge in complex problem solving requires the emergence of contexts with many similarities, as otherwise the problem solvers cannot obtain verifications of similarities in understandings. We also argued that contexts with many similarities solely emerge if problem solvers have shared many common sectors of time and space prior to the problem solving in situ.

Having established the relationship between context and tacit knowledge sharing, we argue that the salience of context will become increasingly important to problem solvers as they face compressed timeframes for problem solving, while at the same time the complexity of problems to be solved requires bringing together knowledge from experts in several specialized domains. For success with such problem solving, the possibility of establishing intimate we relations is of paramount significance, and therefore, organizations must consider if there are areas for which it makes sense for them to invest in preparation for emergence of contexts with many similarities, as only such contexts allow for tacit knowledge sharing. For these areas, we relations among experts should be fertilized as only these, and for example not they relations, will breed the ground tacit knowledge sharing.

In this article we have showed that contexts are not just there, and even more important we have moved beyond the highly general conceptions of context and provided insight into the processes that result in the emergence of contexts, which allow for tacit knowledge sharing. Now returning to the initial discussion of the context concept 'ba' provided by Nonaka and peers, we remember that they acknowledged the importance of context, because knowledge-creating processes are necessarily context specific. Yet, from their writings, for example Nonaka and Konno (1998) and Nonaka and Toyama (2000), it was unclear what context is and how it emerges. In this article these two questions were addressed and answered, and thus the article provided new insights of significance to future knowledge management research. Our definition of context, its emergence and transformation do not go against Nonaka et al. (2000b), as for example they note that "…'ba' has a here and now quality, and that it is constantly moving, it is created, functions and disappear according to need" (pp. 15-16). However, a verification of our theory of context calls for more empirical studies of complex problem solving, and thus, such studies must be the next step in the research focusing on context and its implication for tacit knowledge sharing.

Chapter 7.10
Epistemology and Knowledge Management

Jeremy Aarons
Monash University, Australia

INTRODUCTION

This article surveys and explores the relationship between epistemology and knowledge management (KM). Epistemology is the branch of philosophy concerned with the nature and extent of human knowledge (Klein, 1998b). Knowledge management is clearly deeply indebted to many ideas derived from epistemology. Much of the seminal work in KM discusses epistemology in a fair amount of detail, and explicitly appeals to insights from epistemology in developing a theoretical account of KM. In particular, the groundbreaking works by Sveiby (1994, 1997, 2001), Nonaka (1994), and Nonaka and Takeuchi (1995) make explicit appeal to the philosophical insights in epistemology, which has provided the groundwork for much of their pioneering work in knowledge management. One would thus expect there to be a fairly intimate connection between epistemology and knowledge management. The relationship between these two fields, however, is far from straightforward.

This article argues that traditional philosophical discussions about epistemology are generally quite limited in their application to KM. This is because they focus mainly on the production of individual or personal knowledge, rather than sharing and use of knowledge in a collaborative context. Thus many of the insights from traditional epistemology are largely irrelevant for the enterprise of KM.

There are, however, recent developments in epistemology which seem more promising for KM. This article ends with a brief overview of some of these developments, looking at recent work in both the philosophy of science and social epistemology. These approaches seem extremely promising for developing a sounder philosophical and methodological basis for KM.

BACKGROUND: KNOWLEDGE IN EPISTEMOLOGY

Epistemology—the theory of knowledge—is one of the core branches of philosophy. It is concerned with exploring the nature, sources, and limits of human knowledge (Klein, 1998a). With a history tracing back to Plato and Aristotle, the field of epistemology has attempted to provide an analysis of what the concept of knowledge is—a definition of knowledge. Epistemology also attempts to specify what legitimates knowledge, so that we can distinguish genuine knowledge from false or spurious knowledge. To a lesser degree epistemologists have also inquired into how we acquire knowledge, and whether there are limitations on the scope of our knowledge (Pappas, 1998). Some have even adopted a position of extreme scepticism, claiming that genuine human knowledge is impossible (Cohen, 1998).

The focus of contemporary debates in epistemology essentially traces back to the work of Descartes and his method of doubt. In his Meditations on First Philosophy, Descartes (1640) undertakes an inquiry into the nature of knowledge. Here Descartes attempts to find the foundational principles upon which our knowledge rests, by trying to identify some sort of fact that we can be entirely certain of. Thus he advocates that we need "to demolish everything completely and start again right from the foundations" (Descartes, 1996, p. 12). For Descartes the real challenge here is scepticism—if there is any possibility of doubt about so-called knowledge being true, then it cannot be genuine knowledge. Descartes' inquiry tries to ascertain just what facts about the external world are beyond scepticism, in order to discover the basis of all our knowledge. Following this methodology Descartes famously arrives at the proposition "cogito ergo sum"—I think, therefore I exist—which he claims puts the proposition "I exist" beyond doubt. Contemporary epistemology has followed strongly in this Cartesian tradition, focusing of the question of the justification of knowledge in the face of scepticism. Because of this, questions about the actual generation of knowledge, and of the uses and contexts of knowledge, have been of peripheral concern for the majority of theorists in epistemology.

In this respect, epistemology has typically defined knowledge as an essentially personal item that concerns true facts about the world: knowledge is an individual's true, justified belief.1 Additionally, the majority of research in epistemology has generally been concerned solely with propositional knowledge: factual knowledge that can be expressed in a sentence, and can be evaluated for truth or falsehood. Thus traditional approaches to epistemology are concerned primarily with what knowledge is and how it can be identified, rather than how knowledge is created or used.

KM AND EPISTEMOLOGY

The traditional approach to defining knowledge in epistemology contrasts markedly with the definitions typically proposed in the KM literature. For example, Rumizen defines knowledge as "Information in context to produce actionable understanding" (Rumizen, 2002, pp. 6, 288). Similarly, Davenport and Prusak define knowledge thus:

Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organisations, it often becomes embedded not only in the documents or repositories but also in organisational routines, processes, practices, and norms. (1998, p. 5)

These definitions do not view knowledge as essentially personal, true, justified belief, but instead have a notion of knowledge as a practical tool for framing experiences, sharing insights, and assisting with practical tasks. For KM, knowledge is something other than just an individual's understanding of the true facts of the world—it is a pragmatic tool for manipulating and controlling the world. It is in this sense that Iivari proposes that knowledge is communal, activity-specific, distributed, and cultural-historical (Iivari, 2000).

Compared to traditional epistemology, KM focuses not so much on the justification knowledge, but instead on understanding the uses of knowledge in order to effectively deal with the practical tasks that involve knowledge-based activity. Thus KM is primarily concerned with knowledge as it is generated, shared, stored, and used within a collaborative environment. KM is also concerned with all aspects of knowledge within an organisational framework: the factual knowledge of the individuals within the organisation, as well as their practical knowledge, tacit knowledge, and technological knowledge. Thus for KM, knowledge must be far more than just personal certainty about the world—it must involve practical ability as well as conceptual understanding. More importantly, KM is concerned with far more than just the justification of knowledge—it is concerned with the production, storage, and processing of knowledge in a group or shared sense. Thus the relevance of the concept of knowledge for KM is quite different to its relevance for philosophers.

The important point here is that, as far as KM is concerned, there are significant limitations in traditional approaches to epistemology. Traditional epistemology is not concerned with the production and processing of knowledge in a group or shared sense—it is not really concerned with the pragmatics of knowledge production and use. The main issue in epistemology is the status of the final product rather than the process of getting there and what happens after knowledge is acquired. Yet these are precisely the factors that are of interest for KM.

The upshot of this is that, beyond an initial analysis of what knowledge is, the traditional approach to epistemology offers very little in the way of useful insights for KM. Epistemology may offer some assistance when dealing with some forms of explicit knowledge, but beyond that it is of little use. Thus we must look beyond standard epistemology to find useful contributions from philosophy.

On the other hand we also should not stray too far from standard epistemology: KM should not dismiss the importance of the insights of traditional epistemology into the nature of knowledge. Although the different disciplines have fundamentally different interests in the concept of knowledge, the concepts in each discipline are still very closely related. The standard approach in epistemology may be too limited and too narrow for KM, but it also is not totally irrelevant. At its foundation the KM conception of knowledge should at least be compatible with the epistemological definition, since even thought the disciplines have different interests in the concept, at its base it is still essentially the same idea. Factual, tacit, practical, technical, and other forms of knowledge must still all meet certain criteria in order to be genuine knowledge: they must correspond to some aspect of the world, accurately reflect a reliable way of manipulating the world, and stand up to the harshest of pragmatic tests. Although precisely what it takes to meet these criteria is the topic of vigorous debate, it is clear that genuine knowledge must have some standards.

FUTURE TRENDS: RELEVANT PHILOSOPHICAL INSIGHTS FOR KM

This article has argued that traditional epistemology can only be of limited use to KM since it focuses on the origins and justification of personal knowledge, rather than the pragmatics of knowledge use, sharing, and dissemination. Since

KM is primarily concerned with knowledge as it is generated, shared, stored, and used within a collaborative environment, if we are to look to epistemology to provide a foundation for the tasks of KM, we must look for those areas that can deal with these practical issues, as well as provide insights into these differing forms of knowledge and the relationships between them. The philosophical theory must also help our understanding of the underlying processes that are relevant for KM.

The suggestion here is that the most fruitful places to look for relevant philosophical insights for KM is in recent work in both the philosophy of science and the emerging field of social epistemology. Although there are still limitations associated with these philosophical theories, these areas are engaged with fairly similar questions to those that interest knowledge management, and can thus provide insights into these issues. Thus they should be able to provide some useful theoretical tools that can be applied to building a theoretical account of knowledge work.

Philosophy of Science

There is already a strong tradition within KM of applying insights from the philosophy of science. In particular the works of Kuhn (1970, 1977) and Popper (1959, 1972) have been of great interest to a number of KM theorists. Kuhn's notion of a paradigm, a particular world view, has played a pivotal role in understanding how a community of thinkers—or knowledge workers—need to share certain base beliefs in order to work together effectively. Kuhn's ideas on incommensurability have also been extremely important for many KM theorists. Popper's insights into the basis of scientific knowledge, and his distinction between Worlds 1, 2, & 3, have also helped enrich the understanding of KM. However KM has paid relatively little attention to more recent developments in the philosophy of science which take a quite different approach in their investigations.

The trend in the philosophy of science over recent years has been to shift from trying to develop a general account of what science is (as evident in the work of Popper and Kuhn), to looking more closely at the fine detail of science. These fine details concern the complex methods by which scientific theories are developed, in terms of how scientists work, reason, experiment, collaborate, and so forth. In this way, the emphasis of recent work has been less about the justification of knowledge claims, and more about the creation and use of knowledge.

There have been two general approaches taken to this type of work. The first falls loosely under the banner of Social Studies of Science (SSS), and includes the work of Latour and Woolgar (1979), Latour (1986, 1987, 1998), Charlesworth, Farrall, Stokes, and Turnbull (1989), Knorr Cetina (1981, 1999), and Law and Mol (2001, 2002). This work focuses on sociological investigation into the world of the scientist, looking closely how scientists construct knowledge through their shared understanding of language and observational phenomena, which drives their interpretation of observation and experiment and facilitates their creation of ontological categories. This body of work explores the social details of these processes, uncovering how knowledge plays a pragmatic role in our understanding and manipulation of the world. As such it has provided rich material for application in KM contexts. For example, Latour's (1986) notion of inscription plays an important role in Burstein and Linger's (2003) task-based approach to KM.

The second body of work that looks at the details of scientific knowledge construction is more in the tradition of standard philosophy of science. Unlike SSS, this work is not so well known outside the philosophy of science community, and many of its ideas have yet to filter in to other disciplines. This work is closely related to SSS in that it similarly looks at the details of how scientists work, and how knowledge claims are constructed and used. However, unlike SSS, where ideals such as realism and truth are largely eschewed in favour of more social constructivist modes of thought, this work maintains a connection with realist metaphysical intuitions. Thus Cartwright (1989, 1999) emphasises the importance of causal capacities in science, and Dupré (1993) explores the metaphysical implications of the disunity of perspectives that coexist across the ranges of sciences. The detailed work of Galison (1996, 1997) looks at the role of social dynamics and politics in the theoretical life of nuclear physicists. Hacking (1999) also explores these issues in some detail, showing how the social construction of the world does not entail losing contact with traditional epistemological ideals such as accuracy and truth. Finally, Kitcher (1993) develops a complex model of scientific reasoning in a collaborative environment, which factors in the interactions between different researchers in building up a detailed picture of knowledge production in group context.

In science these forms of inquiry can deliver powerful predictions and detailed explanations, by rejecting the central importance of fundamental laws, by being open to the possibility of disunity, and by focussing on solving particular problems in particular contexts rather than developing generally applicable theories. This methodology is particularly applicable in the realms that involve complex physical systems in complex environments, where this approach has significant heuristic power, derived from uncovering and modelling the properties and processes that underlie the complex systems. This approach thus provides powerful insights for guiding our understanding, manipulation, and management of these systems. For these reasons these second set of approaches seem particularly suitable for analysing other types of complex systems, such as those involved in complex organisational environments. They should be directly applicable to these knowledge-based settings, thus providing a methodology for managing and supporting knowledge work. These approaches thus provide a good framework for KM, since they aim to provide a clear account of the underlying processes at work in knowledge production and knowledge-using environments. In doing so they strive to maintain the link between knowledge and truth, and thus provide a good metaphysical foundation for KM research. They also take into account all the relevant cognitive factors, including social dynamics and collaborative factors, providing a complete analysis of knowledge production in these contexts. They thus go some way to providing just the sort of pragmatic approaches to knowledge required by KM, over and above the conception of explicit knowledge provided in traditional epistemology.

Social Epistemology

Another promising area of philosophical inquiry is the emerging field of social epistemology (Schmitt, 1998). Work in this area is closely related to the above approaches in philosophy of science, with many of the same people working in this field. Some of the most significant works in this field include Goldman (1999), Longino (2001), Solomon (2001), and Turner (1994, 2002).

Social epistemology is an extension of traditional epistemology, which adds in the relationship between the social and rational factors in its analysis of the knowledge production process. Social epistemology looks at the social context of knowledge, and posits that knowledge may be a collective rather than an individual entity, and may be distributed amongst individuals. Social epistemology focuses on the shared aspect of knowledge, as well as the social situatedness of the knowers. Thus it moves away from the Cartesian paradigm of individual knowledge and the associated challenge of scepticism, and instead views knowledge as being a shared product of groups of individuals.

This reconceptualisation of knowledge as a collaborative entity has obvious advantages for KM. In particular, it is directly appropriate to many of the contexts that concern KM, since these are generally complex collaborative settings, such as in large organisations. Additionally, the closer look at the dynamics of collaborative knowledge in social contexts, as provided by social epistemology, can provide invaluable insights of great relevance to KM. For example, understanding the dynamics involved in the distribution of cognitive labour on a complex task, as discussed by Kitcher (1993), can provide clear guidance for how to provide added support in the form of a KM support system.

The closely related field of social metaphysics (Schmitt, 2003) has delved into very similar issues, including conceptions of joint actions, the autonomy of different social levels, and the relationship between individual and group knowledge. This area of research aims to build an account of the nature of social relations, social entities and institutions, and sociality more generally. As such it can, for example, provide an account of the metaphysical difference between individuals, groups, and the whole of a society. It can also be used to unpack the core theoretical notions of KM and specify the details of its framework. For example, the philosophical tools provided by social metaphysics can give a detailed account of what constitutes practice in a collaborative environment (Schatzki, Knorr Cetina, & von Savigny, 2001). Thus it can provide an account of what constitutes a task within an organisation, and describe the collaborative nature of the task, and how the task is conceptualised and constituted at different structural levels of an organisation: the individual, group, and enterprise level. In this way the insights from social metaphysics and epistemology can be applied to the particular domain of KM, and can lead to more effective approaches to KM methodology.

CONCLUSION

The conception of knowledge as developed in recent philosophy of science and social epistemology is of great relevance to the pursuits of KM. In particular, it seems that these areas could be very useful for developing a theory of collaborative knowledge work. It also seems clear that these approaches can support this theory within a realist and pluralist metaphysical framework (as outlined in Cartwright, 1999), and are consistent with the principles of naturalism (Quine, 1969). These approaches acknowledge the significant social dimension in knowledge production, while retaining the idea of knowledge being deeply connected to real properties and processes. Thus, applying insights from the social epistemology will make it possible to build a theory of knowledge work that is grounded in reality, but also incorporating the relevant social, practical, and pragmatic concerns that are central to the tasks of knowledge management. The starting point of such an analysis would be to determine precisely what aspects of knowledge are relevant to the enterprise of knowledge management, and to give an account of the factors that underlie these knowledge components. This will involve assessing the relevant cognitive, social, and pragmatic factors involved in KM projects. This will develop into a theoretical foundation for the practical work done in KM that maintains a connection with real-world processes and properties. Such a foundation will avoid the problematic conclusion that knowledge is purely socially constructed, and thus will present a powerful analysis of knowledge work.

However, in terms of the aims of knowledge management, current approaches in the philosophy of science and social epistemology are still somewhat lacking. As they stand they provide a detailed account of knowledge production, but little or no account of knowledge use. Thus, at present, they have little to say about the pragmatics of knowledge storage, knowledge sharing, and knowledge dispersal, all essential aspects of knowledge management projects.

Part of the problem here is that philosophers typically do not seem to be interested in the sorts of questions that are essential for KM. Epistemology in particular is still largely stuck in the Cartesian paradigm, obsessed with understanding the origins and justification of knowledge rather than the dynamics of knowledge as a process. Here we can actually turn things around and look to KM to provide some inspiration for philosophy. The challenges posed by KM projects can be used to show how these issues are indeed significant ones that need to be investigated in detail. The insights gained from current KM projects can also be fed back into the philosophical theory. This will involve extending the accounts of collaborative knowledge production, as provided by philosophy, to broader accounts of collaborative knowledge use. This is where the practical dimension of KM can actually help to enrich our philosophical understanding of the nature of knowledge, and thereby lead to stronger approaches to KM that are grounded in coherent and sound philosophical theory.

ENDNOTE

1 This formal definition of knowledge is quite controversial and is the subject of ongoing vigorous debate (Gettier, 1963). However, most analytic philosophers tend to agree that this definition is roughly correct, and the controversy is mainly over the fine details of this approach—especially on the question of what constitutes an adequate justification.

Chapter 7.11
Ontology-Supported Web Service Composition:
An Approach to Service-Oriented Knowledge Management in Corporate Financial Services

Ye Chen

Dongsong Zhang
University of Maryland, Baltimore County, USA

ABSTRACT

Web service composition can enhance the efficiency and agility of knowledge management by composing individual Web services together for complex business requirements. There are two main research streams in knowledge representation for Web service composition: syntactic-based and semantic-based approaches. Despite the promises brought by each approach, the two streams are largely separated from each other. In this paper, we propose an integrated ontology-supported Web service composition framework, which provides a novel solution to organizational knowledge management. By synergistically leveraging both syntactic-based and semantic-based approaches, this framework provides dual modes to perform service composition. Ontologies are employed to enrich semantics at both service description and composition levels. The proposed conceptual framework has been implemented in the corporate financial services domain. It is demonstrated that the shared ontology helps fulfill automated and on-the-fly service composition in particular and knowledge management in general.

INTRODUCTION

The competition in today's business world requires significant involvement of organizations' intangible assets. Innovative approaches to knowledge management can provide competitive advantages to organizations. Although a variety of information technologies for knowledge management, such as information retrieval, databases, data mining, and knowledge representation, have considerably advanced, organizations are still facing challenges in automated and dynamic knowledge discovery, sharing, reuse, and consumption.

A Web Service is a software system designed to support interoperable machine-to-machine interaction over a network (W3C, 2003), which emphasizes such essences as: (1) componentization guarantees platform- and programming language-independency; (2) interoperability benefits communication and collaboration; (3) the architecture involves three basic roles: service provider, service broker, and service consumer; and (4) fundamental technologies include WSDL, SOAP, UDDI, and so on (Zhang, 2005). The latest Web services standards and technologies make it a reality to compose individual Web services into more complex services for e-businesses. Unfortunately, current approaches to service composition are rigid, time- and resource-consuming, ad hoc, and error-prone (Cardoso, Bussler, Sheth, & Fensel, 2002; Medjahed, Bouguettaya, & Elmagarmid, 2003; Papazoglou & Georgakopoulos, 2003).

This research contributes to the body of knowledge management research by proposing an ontology-supported and service-oriented approach to organizational knowledge management. We introduce an integrated framework for Web service composition by synergistically leveraging both syntactic-based and semantic-based approaches. It takes advantage of the Semantic Web technology to enrich semantic representation of domain knowledge and complements traditional syntactic service composition methods. We have applied the proposed conceptual framework to a corporate financial service application. The prototype shows that the framework can support semantic, dynamic, and automated Web service composition effectively.

The rest of the paper is organized as follows. First, we briefly introduce the concept of Web service composition and syntactic-based and semantic-based approaches. Then, an ontology-based integrated conceptual framework for Web service composition is presented. Next, we illustrate the proposed framework with a prototype system, followed by the discussion of implications of our research. Finally, we conclude the paper with future work.

WEB SERVICE COMPOSITION AND RELATED WORK

Web service composition (WSC), namely choreography of Web services, is to construct higher level services based on existing multiple individual services in order to fulfill more sophisticated business requirements (W3C, 2002). It is viewed as a step-stone through which to reach the Mecca of Web services, and even the vision of the Semantic Web (Berners-Lee, Hendler, & Lassila, 2001; Medjahed et al., 2003). A typical example of Web service composition is to generate a comprehensive conference travel plan, including conference registration, flight ticket booking, hotel reservation, car rental, map request, and so on, from existing services. Depending on whether a composition decision is made at design time or run time, it falls into either static or dynamic composition, respectively (Cardoso et al., 2002). From a process standpoint, service composition can be done horizontally, vertically, or both. The aforementioned example involving flight and lodging reservations belongs to vertical composition, because hotel booking cannot be carried out until the flight ticket is issued. However, car rental and map request can be performed simultaneously in a horizontal way.

WSC poses challenges from multiple aspects along the composition course (Cardoso et al., 2002): (1) description or representation of Web services; (2) discovery of Web services; (3) integration of interoperable or composable individual services; (4) quality of services (QoS) or efficiency of composed services; (5) execution and supervision of composite services, as well as other issues. The syntactic-based and semantic-based approaches to WSC that address these issues with distinct technologies are discussed as follows.

The syntactic-based service composition approach has already been widely used by the industry (Srivastava & Koehler, 2003). Business Process Execution Language for Web Services (BPEL4WS) supplements XML with more vocabularies (e.g., Process, Partner, Container, Sequence, Flow, and Receive) to support composition of processes (Andrews et al., 2003). Web Service Choreography Interface (WSCI) describes the flows of messages involved in service choreography (W3C, 2002). Although more vocabularies are added for service description, messaging, and registry, those constructs are still mainly concerned with document structure or syntax. The service discovery, matching and integration primarily utilize keyword searching, which has been proved ineffective in many cases by information retrieval researchers.

The semantic-based service composition addresses the semantics-absent problem of the syntactic-based approach. This method exploits the vision of the Semantic Web (Berners-Lee et al., 2001). In the WSC context, the Semantic Web, especially RDF+OWL technology, can help service description, advertisement, discovery, integration, interoperation, invocation, execution, and monitoring, which all converge at service composition (Cardoso et al., 2002). RDF (Resource Description Framework) uses a triple <*resource, property, value*> to describe and exchange resources or metadata. OWL (Web Ontology Language) is built to represent ontology on the Web with richer vocabularies and more expressive syntax. An ontology is generally defined as "shared formal conceptualizations of particular domains, providing a common understanding of topics that can be communicated between people and application systems" (Decker et al., 2000, p. 63). In the context of service composition, ontologies can be employed to distill all concerned concepts in a certain domain as a centralized repository, which shows superiority for on-the-fly service choreography by specifying semantic relationships between service terms.

Ankolekar et al. (2002) proposed a semantic service description model, where a service contains three objects: profile, model, and grounding. The service profile describes what a service does (functionalities, parameters, etc.); the service model indicates how the service works (process flow); and the service grounding tells how to access the service (binding, protocol, RPC, etc.). Based on this semantic service specification, along with semantics-enriched vocabularies, RDF and OWL can benefit service composition. For example, a profitability report service combines sales, cost, administrative expense, and even currency exchange rate information. It can be defined as a subclass of both *CompositeProcess* and *Sequence* using RDF constructs, and then uses an OWL construct, *unionOf*, to specify all individual services.

In comparison with the syntactic approach, semantic specifications are still evolving. Another challenge is that there are no systematic rules to follow in ontology engineering (Green & Rosemann, 2004; Weber, 2003). Therefore, the answer to which approach is applicable depends on the application, domain, resource availability, and so on. As a matter of fact, the current status of both syntactic-based and semantic-based service composition requires a certain level of manual coding of composition process (Srivastava & Koehler, 2003). It is promising to combine syntactic-based and semantic-based methods for service composition.

There are four lines of research that are related to this study. The first one centers on frameworks or architectures for Web service description and composition. Recently, some researchers have started incorporating ontologies into conceptual modeling and service frameworks (Kim & Karp, 2004; Milton & Kazmierczak, 2004; Pahl & Casey, 2003; Solanki, Cau, & Zedan, 2004; Tsai et al., 2003). The second line of research aims to map syntactical service description to semantic specifications (Patil, Oundhakar, Sheth, & Verma, 2004; Shen, Yang, & Lalwani, 2004). The third line of related work is concerned with ontology development for Web services (Lozano-Tello & Gomez-Perez, 2004; Mika, Oberle, Gangemi, & Sabou, 2004; Williams, Padmanabhan, & Blake, 2003). The fourth stream is called compositional modeling (Ba, Lang, & Whinston, 1997; Falkenhainer & Forbus, 1991). Their knowledge description framework includes both models' conditions and domain theories, which are analogous to the semantic description scheme and business rules in our proposed framework, respectively.

ONTOLOGY-SUPPORTED WEB SERVICE COMPOSITION

An Ontology-Supported Framework for Web Service Composition

We propose an integrated conceptual framework for dual-mode Web service composition. This framework exploits the advantages of both syntactic and semantic composition approaches, powered by ontologies at both service description and composition levels. We keep fundamental syntactic-based Web service building blocks in that those industry standards can fulfill most straightforward requirements for service development, discovery, and composition. Building on top of that, we introduce an ontology-based semantic approach. First, the semantic Web service specification model (Ankolekar et al., 2002) provides a mechanism to enrich atomic services with more semantics than does syntactical method. Second, the intrinsic correlation between the syntactic-based and semantic-based approaches helps materialize the above semantic service specification model. Third, mapping atomic services and other relevant concepts into a centralized shared ontology offers a knowledge repository for service choreography. The objective of semantic enhancement is not to perform the base level service related operations, but to support ontological heuristics so as to enable automated and dynamic service composition. The proposed framework is shown in Figure 1.

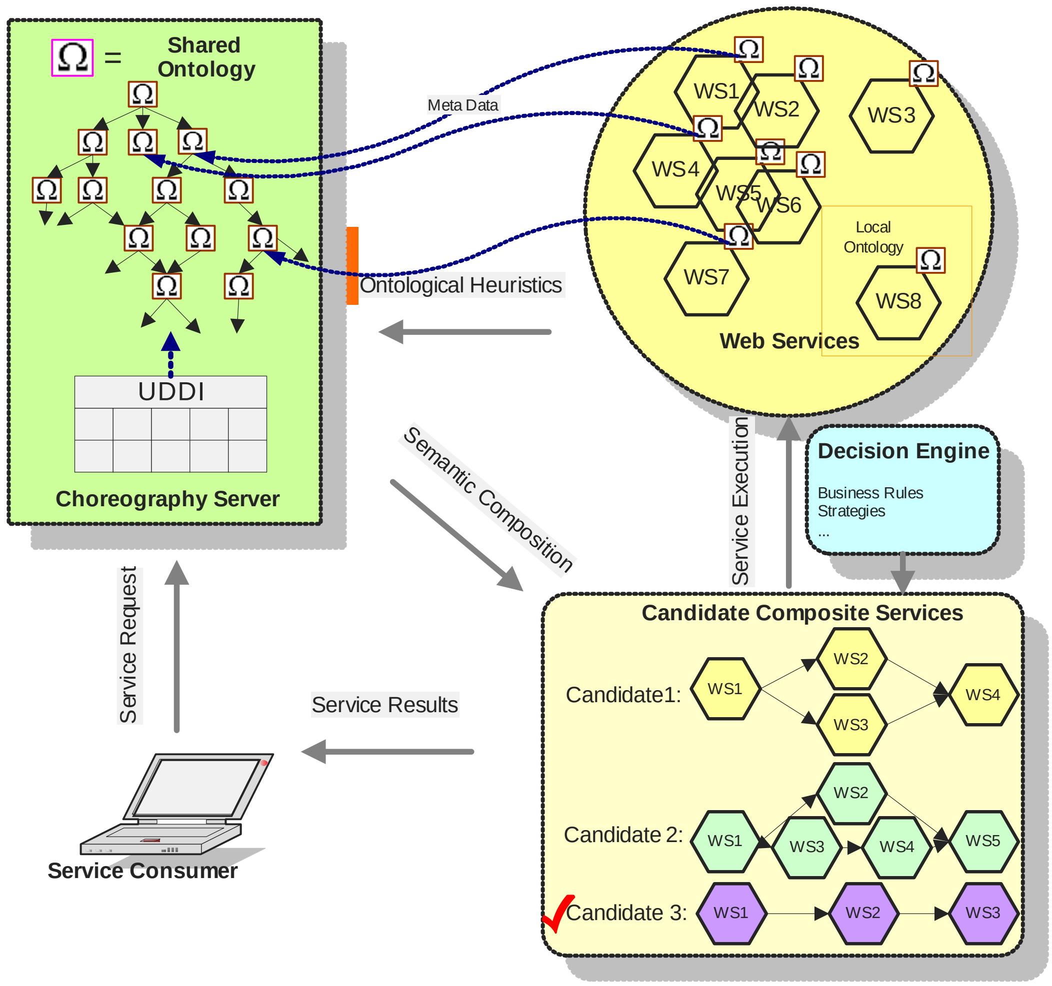
When a service-oriented business application receives a service request from a consumer, it first searches an ontology-based choreography server. This server enhances the traditional UDDI with a shared ontology (the upper part in the choreography server in Figure 1). This centralized ontology represents relevant services and concepts in a specific domain, constructed by mapping and integrating (denoted by the dotted arrows in Figure 1) individual local ontologies for Web services. In this paper, we refer to ontological heuristics as applying heuristics to ontology applications, serving as guidelines to respond to a service request.

After using ontological heuristics on the shared ontology, the choreography server generates a number of alternative solutions to service composition. These alternatives are then evaluated against a set of criteria specified by the service consumer and a decision engine. Such criteria may include QoS requirements, business rules and strategies, resource availability, and so on. A selected optimal composition scheme is then executed.

Semantic Service Description

At the service description level, we integrate syntactic service description in WSDL with se-

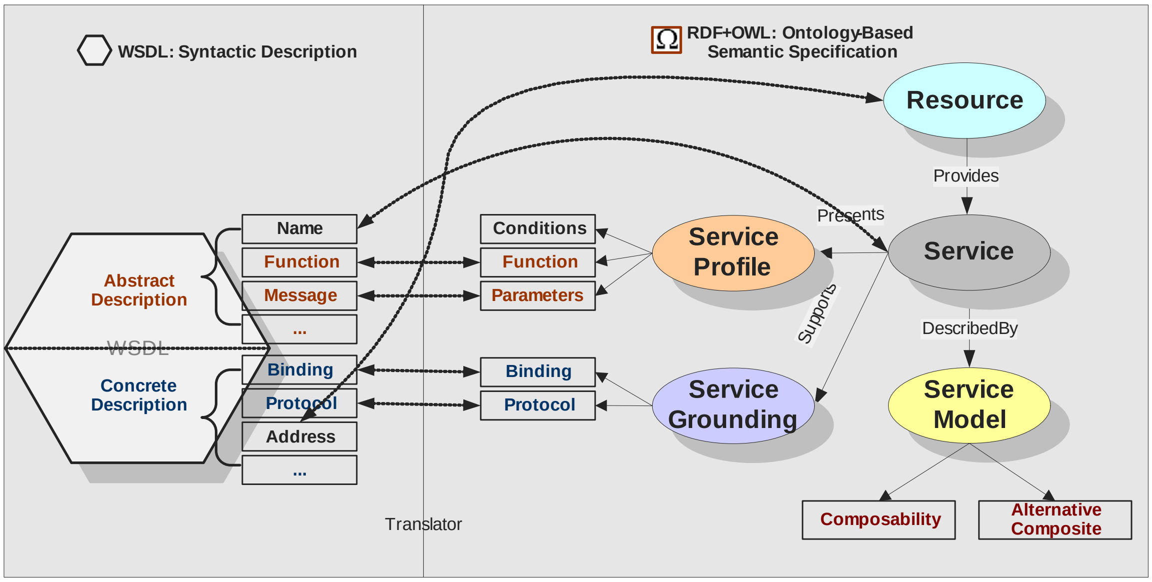
Figure 1. An ontology-supported framework for Web service composition



mantic specification (Ankolekar et al., 2002) in RDF+OWL, as shown in Figure 2, which zooms in the local ontology square in Figure 1.

When combining both service description methods, the correlations between them can be sketched. The proposed framework emphasizes those relationships because certain types of translators can be employed to convert service description back and forth. As illustrated in Figure 2, the main information contained in the abstract and concrete description in a WSDL document matches the service profile and service grounding subjects on the ontology side, respectively. One step further, the elements in the WSDL file link to the corresponding properties in the ontology. For example, the *message* element in the WSDL file

Figure 2. Ontology-enabled semantic service description



corresponds with the *parameters* property in the RDF+OWL, both of which contain information about input and output of this service. Although the matching is not strictly parallel (e.g., *address* in the WSDL corresponds to the *resource* class in the ontology), the linking paths are still structured and can be predefined, given the widely accepted WSDL standard.

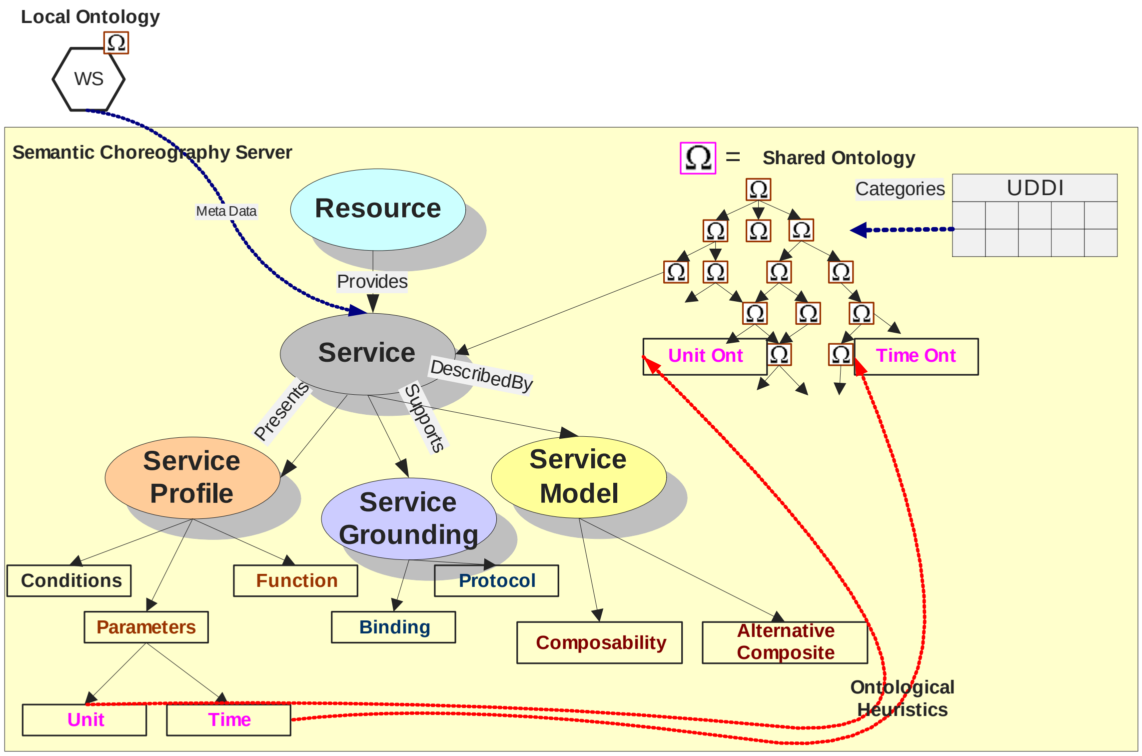
As for the semantic side (the right part in Figure 2), we employ RDF+OWL to develop a local ontology for each service, which allows enriched semantics. For example, the service profile subclass for each service has a property called *conditions*, which specifies pre- and post-conditions for execution. Similarly, the service model subclass is especially beneficial for composition. The proposed framework utilizes the service model class in two ways. For base services, a service model keeps information about *composability*, which specifies when the service can be used in a composite service. For composite services, a service model maintains *alternative composite* solutions incrementally for reuse. This semantic enrichment provides a self-learning capability of service composition.

Semantic Service Choreography

Local ontologies are consolidated in the choreography server by ontology mapping and integration. As a result, all relevant concepts and services in a domain are registered in the shared ontology, as shown in Figure 3.

In Figure 3, a local ontology for a service is mapped into the shared ontology (denoted by the dotted arrow in the upper left part of Figure 3), appearing as a node in the ontology tree. How to organize all services into the centralized reposi-

Figure 3. Semantic service choreography

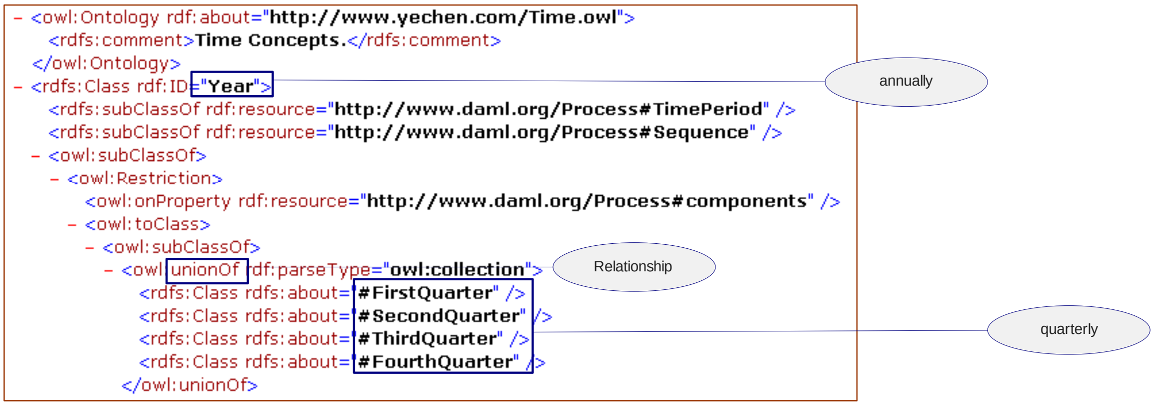


tory depends on specific domains or application requirements, and the category information in UDDI as well. For example, for corporate finance, the *financial planning* service can have such subclasses (services) as *budgeting* and *forecasting.* In this way, we can maintain semantic relationships (e.g., hierarchical and sibling relationships) between financial operations.

The shared ontology also represents other application-specific concepts for mapping and integrating services. The mapping and integration (denoted by the dotted arrows in the lower right side of Figure 3) not only unite service descriptions and concepts, but also add more semantics. For example, the difference between *budgeting* and *forecasting* services can be found by mapping both to the *time* ontology: *budgeting* is performed *annually*, while *forecasting* is a *quarterly* task. *Annual* and *quarterly* are subclasses of the *time period* node (the other sibling class might be *time point*), which in turn belongs to the *time* ontology.

Moreover, the shared ontology enables ontological heuristics, thus facilitating dynamic service composition. For example, we can analyze composability of services based on some generic concepts. As discussed above, *budgeting* and *forecasting* are conducted at different periodical levels: *annual* and *quarterly.* At the first glance, these two services cannot be composed if *time*

Figure 4. Annually and quarterly semantics in RDF+OWL



period is a parameter. However, the relationship between *annual* and *quarterly* is revealed in the *time* ontology: one *year* equals to four *quarters*. The RDF+OWL document excerpt in Figure 4 shows how OWL uses *unionOf* vocabulary to represent this relationship.

In an enterprise context, a dedicated team would be responsible for the specification of local and shared ontologies. This team mainly consists of IT professionals and domain experts. From a system development life cycle (SDLC) perspective, the functional side should focus more on the analysis part (e.g., determine the domain and scope of ontologies; consider reusing the existing ontologies; and enumerate important terms in ontologies), while the technical side takes charge of the implementation (e.g., define classes and the class hierarchy; define properties of classes; define facets of the slots; and create instances). The ontologies developed should be reviewed periodically.

Our proposed ontology-supported framework represents an innovative approach to organizational knowledge management. The shared ontology systematically incorporates relevant knowledge into a centralized repository, which is a combination (explicit to explicit) from a knowledge conversion perspective. Knowing that management changes may have substantial impact on production yield and marketing strategy is tacit. By including a *controller* subclass of *manufactory*, we capture a clue to this know-how, thus externalize, to some extent, this tacit knowledge to explicit knowledge. The agreed ontologies can also facilitate knowledge socialization (tacit to tacit) and internalization (explicit to tacit) (Bonanno, 2003). For example, the knowledge represented in the shared ontology can be accepted by other parties besides the knowledge owner (financial experts) and be further used as a basis to create other higher-level knowledge, such as how to make use of market changes to optimize inventory management and logistics.

WEB SERVICE COMPOSITION IN FINANCE

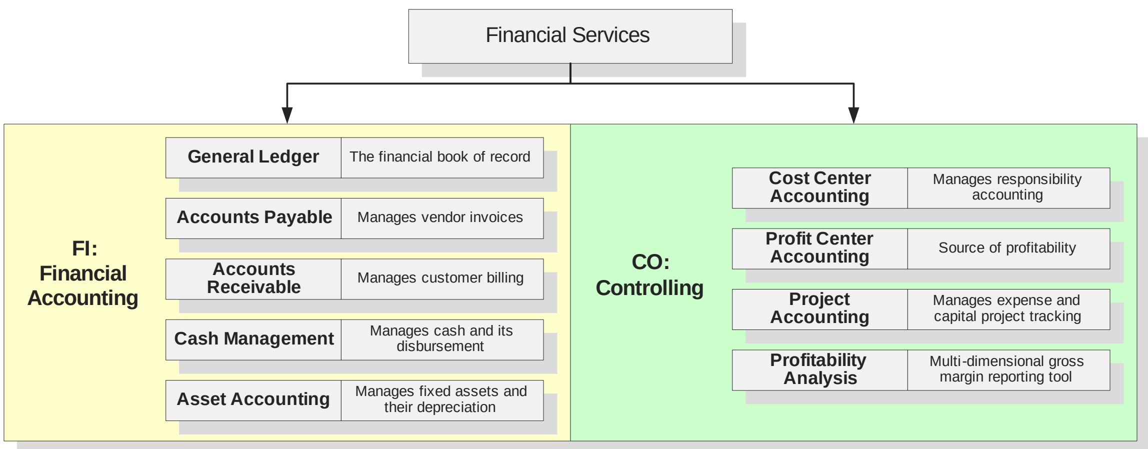
In this section, we present a prototype system for corporate financial service composition, which is developed based on the proposed ontology-supported Web service composition framework. We use several scenarios to illustrate how this framework can facilitate automated and dynamic service composition. We simplify some business problems for presentation purpose.

Domain Service Description

The selected application is financial operations at Motorola Asia, where the first author worked as a system analyst for three years. The major financial services in this organization are summarized in Figure 5, following the SAP R/3 ERP Financial service scope (SAP, 2004). The domain and scenario examples are extracted from real business cases. The Web services and ontology development examples used in our illustration are fictitious but address real business problems. In addition, the business data is constructed in a way that suffices to demonstrate the proposed framework but conceals the real business scale.

In general, the financial accounting modules (the left part of Figure 5) are responsible for accounting for public reporting, while the CO (Controlling) modules (the right part of Figure 5) are designed for internal accounting for enterprise management. For example, General Ledger (GL) is a financial service that records a book for financial data, which is organized by account; Accounts Payable (AP) provides information about payments for material purchasing; Accounts Receivable (AR) tracks sales and cost information through customer billing; Cost Center Accounting (CCA) is the accounting for factories; and Profit Center Accounting (PCA) is to control a sales center or representative. All these financial services will be represented as local ontologies, and then mapped into a shared ontology. The scenarios for illustration will focus on AR, CCA, and Currency Exchange (CurEx) services.

Figure 5. Organization of financial services



Web Service Development

Before we deploy the entire prototype system architecture for service choreography, we first need to develop some individual Web services for later composition. We have developed three individual Web services for AR, CCA, and CurEx using Microsoft Visual Studio.NET 2003, particularly ASP.NET, ADO.NET and Visual Basic.NET. As for database, the prototype uses Microsoft SQL Server 2000. The Web server is Microsoft IIS 5.1.

The AR service allows clients to query sales related information. The inputs to this service include period (beginning date and ending date), product, factory, and customer. The outputs are sales, material cost (direct cost), and booking currency. The input and output screens are shown in Figure 6.

In Figure 6, the input arguments are <*4/21/2004, 4/30/2004, Mobile Telephone, Motorola ESG China, PCSCN*>. The outputs are sales *8600* and cost *5000*, in *USD* (US Dollar). We define outputs in an XML-based format, which can be easily parsed and retrieved later.

Similarly, the CCA service can answer questions like how much administrative cost (indirect cost) is committed for producing a certain product at a certain factory during a specified period. For example, between *4/21/2004* and *4/30/2004*, to produce mobile telephones at the *Motorola ESG China* factory, the administrative cost was 326 *RMB* (Chinese currency Renminbi). The CurEx service is for clients to retrieve the exchange rate

Figure 6. The AR service

Figure 6.1. Input arguments

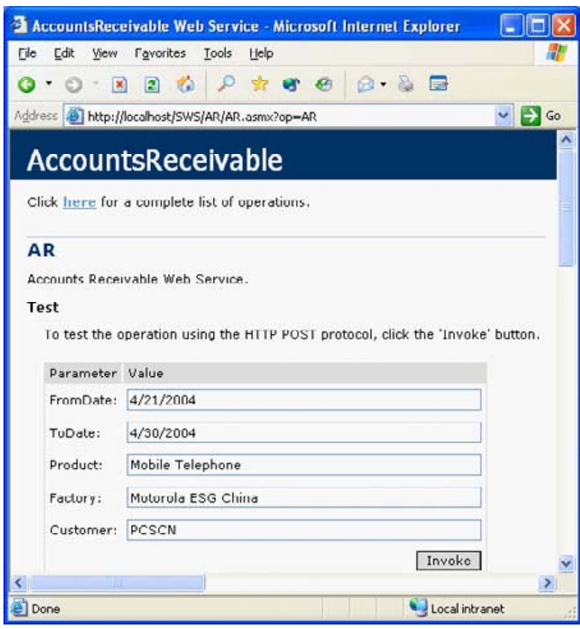


Figure 6.2. Outputs

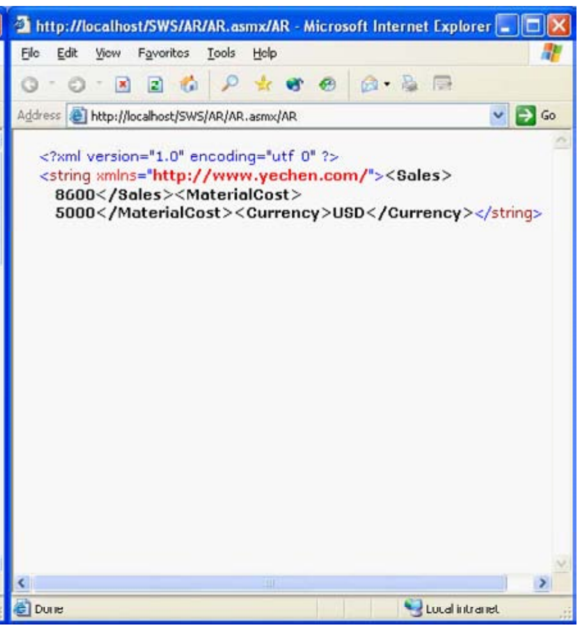


of a specific foreign currency to *USD*. If the input currency is *RMB*, the retrieved exchange rate is *0.1194* to *USD*. Once all individual services are available, the next step is to enrich semantics about them.

Semantic Enrichment by Ontological Engineering

Based on the developed services, ontologies for both individual services and centralized choreography server are built. Our prototype system employs W3C recommended standards (namely RDF+OWL) for semantic description and ontological engineering. The software utilized for this task is Protégé 2.1 beta (Protégé, 2004).

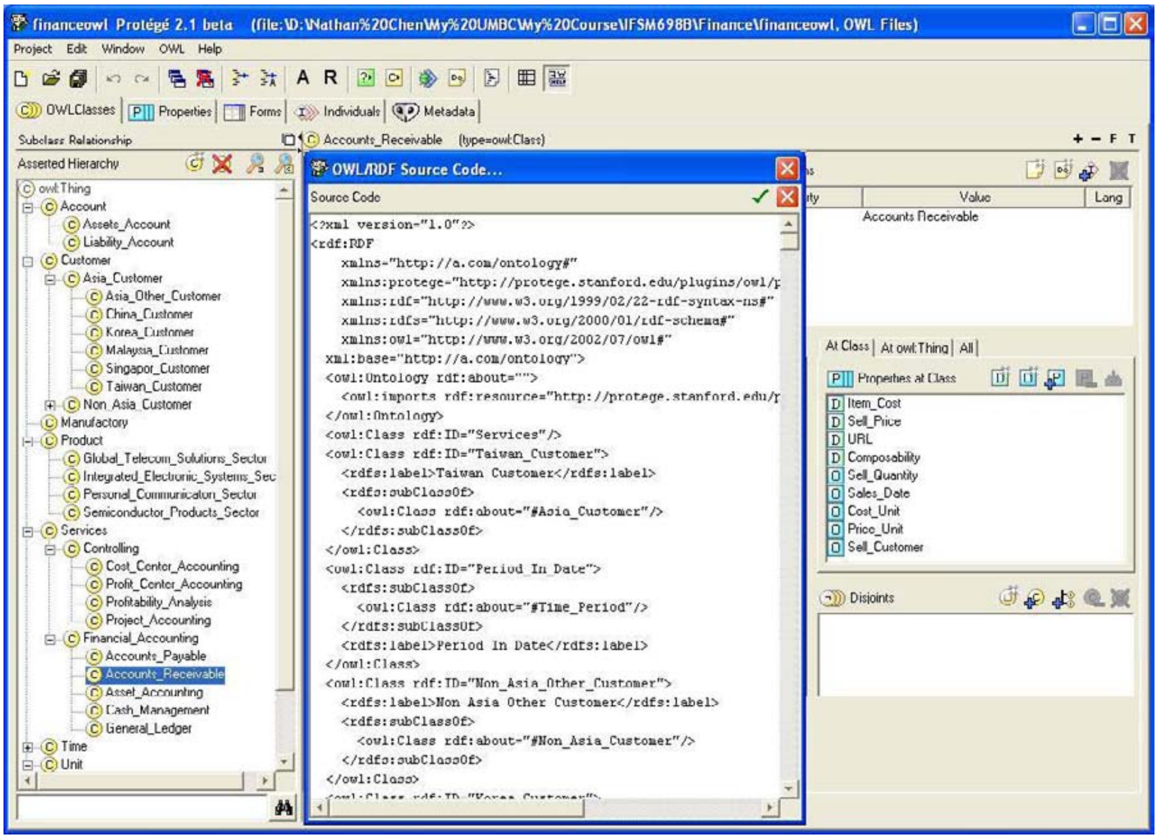
At the service description level, the prototype system translates service descriptions from WSDL to RDF+OWL, and then adds more semantics in the service model class. The *composability* property of the service model class can have values denoting possible ways for service composition. Taking the AR service as an example, its *composability* contains a list of possible parameter flows (from inputs to outputs): *period*→*sales*, *period*→*cost*, *period & product*→*sales*, *period & customer*→*sales & cost*, and so on, each of which can be a part of an alternative path in a composite service. Another way to exploit *composability* is to first attach *composability* to other properties with concrete meanings, then associate *composability* with composition rules. For example, assuming *composability* is a property of *time*. If a financial service is *time period* based, while another one is *time point* based, these two services should not be composed together. As a result, the value of the *composability* property for the *time* of the former financial service can be ¬*time point*.

At the service choreography level, all designed local ontologies are mapped together following the aforementioned SAP R/3 ERP financial services organization, appearing as nodes or subclasses in the shared ontology, as each service or group of services has a registry in UDDI. For example, the *AR service* is a subclass of the *services* class. The prototype can extract some metadata from local ontologies and map into the shared one. Also, the shared ontology can be developed based on UDDI category information. After organizing those base financial services into a shared knowledge repository, the prototype adds other concepts relevant to financial operations, either domain-specific or generic, such as *account*, *customer*, *manufactory, product*, *time*, and *unit*. One thing worthy to mention is that the *currency* class is a subclass of the *unit* class.

The semantics obtained so far are limited to hierarchical and sibling relationships. Ontological mapping and linkage supplement a richer set of semantics, which can be performed through the *value type* constraint and *inverse* property, among others. For example, the AR service has a property called *price unit*, whose *value type* is *currency* class. As for the *inverse* property, the *product* class has properties '*produced by*' and '*sold to*', which are inverse properties of *produces* under *manufactory* and *buys* under *customer*, respectively. These mappings reveal the interrelationships among customer, product, and manufactory. Although such relationships can also be maintained in a relational database, ontology emphasizes shared knowledge more than specific details of individual transactions. Collectively, the shared ontology for financial services is shown in Figure 7.

The left part of Figure 7 shows the tree view of the shared ontology. The highlighted *Accounts Receivable* service is under the *services*→*financial accounting* hierarchy. It has sibling classes (services) including *Accounts Payable*, *Asset Accounting*, and so on. Besides services, this ontology maintains concepts of *account*, *customer, manufactory, product, time*, and *unit*. The middle section is the RDF+OWL source code of the ontology. The right part of Figure 7 illustrates property definitions of the AR service. Among those properties, *composability* is used to describe the service model; *URL* is a part of the service

Figure 7. Shared ontology for financial services



grounding and indicates the resource of the service; other properties such as *sales date* and *sell customer* belong to the service profile.

Usage Scenarios

To demonstrate the potential of the proposed ontology-supported service composition framework, we will go through two usage scenarios in this section. The first scenario is to answer a financial management question, and the second one is to address an ad hoc business query.

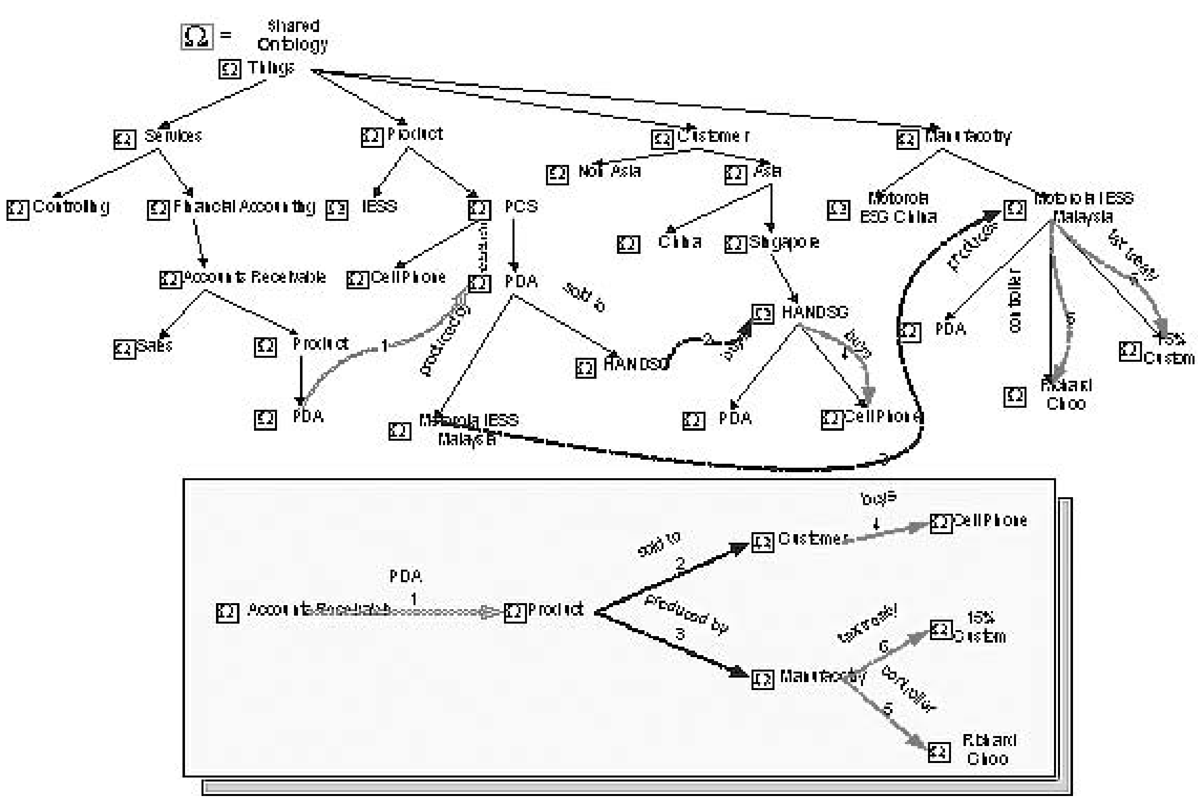
Scenario 1: Why were the sales in the last month extraordinarily high?

This question is exploratory in nature and cannot be answered by a single query. There are many possible reasons for sales growth, such as supply push, demand pull, or even tax treaty change. The question can be addressed by ontological heuristics capability of the framework. The starting point is the key word *sales*. From the shared ontology, the prototype system learns that *sales* is an output of the AR service. There might be some other services providing sales information, such as PCA. The prototype can select candidate services based on different criteria, including query constraints, business rules, and service consumption cost, etc. For example, the AR service guarantees that the sales data are first-hand. Thus it is selected first and supplemented with values of input parameters such as the *last month*. The analysis of results from the AR service reveals that the product *PDA* had an irregularly high sales amount last month. Such an explanation is useful, but is still not able to answer the original question conclusively.

Given the above information, the question is transformed into: *Why did PDA have high sales in the last month?* The prototype shifts to the *product* ontology (class) in the shared ontology (denoted by Arrow 1 in Figure 8). The *product* class has two properties: *sold to* and *produced by*, inversely mapping to the *customer* and the *manufactory* classes, respectively. Therefore, the prototype has at least two directions to investigate the intermediate puzzle: *Was the PDA sales growth caused by customer demand pull or factory supply push?*

Along the *customer* direction, the *customer* class is linked through the property *sold to* (denoted by Arrow 2 in Figure 8). It is found that the customer *HANDSG* (Handheld Singapore) purchased a large amount of PDAs last month.

Figure 8. Ontological heuristics to answer an exploratory question



Then the question is further changed to: *Why did HANDSG buy so many PDAs last month?* The examination of other products purchased by this customer may show that *HANDSG* had large purchases for almost all products it used to buy, such as *cell phone* (denoted by Arrow 4 in Figure 8). At this point, we can provide one possible answer to the original question: *The sales growth benefits from Handheld Singapore's business expansion.*

Along the *factory* direction, the *manufactory* ontology is triggered via the property *produced by* (denoted by Arrow 3 in Figure 8). A search on manufactories of PDA may reveal that *Motorola IESS Malaysia* assembled much more *PDAs* last month. The follow-up question is: *Why did Motorola IESS Malaysia produce so many PDAs last month?* Thus, two properties of the manufactory class, *tax treaty* and *controller,* are activated (denoted by Arrows 5 and 6, respectively). If it is found that the Malaysia factory just changed its financial controller, by comparing with the historical report or tracking the time stamp of the updates, the final answer might be: *The strategic adjustment in the Malaysia factory might account for the sales growth.* If the truth is that Malaysia government just favorably altered the tax treaty for foreign companies, the final explanation will be: *The Malaysia factory increases its production to take advantage of the tax benefits, thus promoting the sales.*

As illustrated in the scenario, an exploratory business question can be investigated through all possible dimensions by performing heuristics along the shared ontology. According to the results of ontological heuristics, an applicable service composition solution can be executed to answer the question. The final answer can come from service execution results along one or more dimensions. Such an ontological heuristics procedure is illustrated in Figure 8. The ontological heuristics paths are displayed at the bottom of the diagram. We will use the second scenario to highlight the composability analysis before and during the service composition using heuristics of the shared ontology.

Scenario 2: How much was the gross profit for the mobile telephone, produced at Motorola ESG China, sold to PCSCN (PCS China), during 4/21/2004 through 4/30/2004?

This is an ad hoc financial managerial question, which cannot be answered using a predefined query either. It needs dynamic service composition based on ontological heuristics to answer this question.

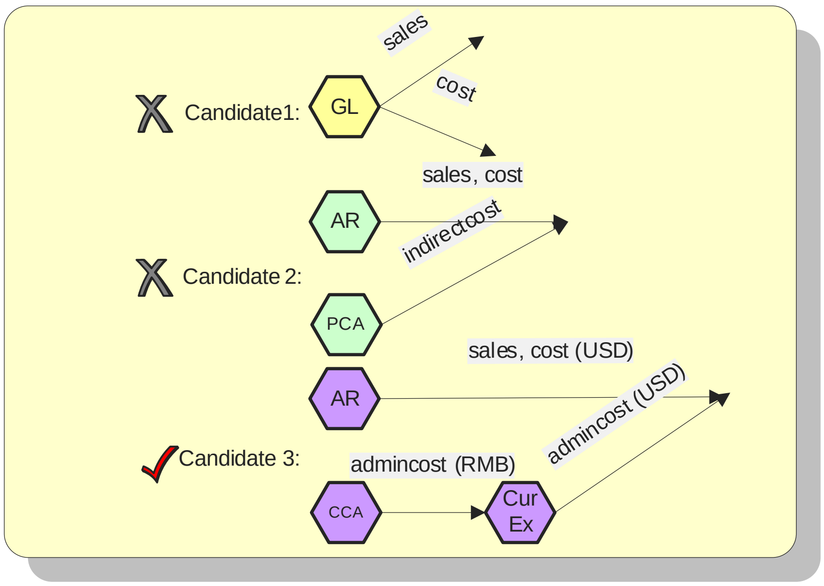
The investigation still starts with a keyword phrase in the question: *gross profit*. According to accounting knowledge, *gross profit = sales – direct cost – administrative cost*. After examining the *function* property of individual services, it is found that no single service can provide all required information, but composing some of them can fulfill the request.

As for *sales* and *direct cost,* both GL and AR services can produce those outputs. However, the scenario question needs financial data to be reported at a *date* level, not by *month* or by *quarter*. The prototype checks the *time* and related *composability* properties of GL and AR services, along with their mappings to the *time* ontology. The GL service is at a *month* level, and its *composability* has a value like ¬*time period.date*. Therefore, the system chooses AR to provide sales and direct cost information, given that all other properties (e.g., *booking currency*) are composable.

To obtain *administrative cost,* the candidate services include CCA, PCA, and AP, because all of them provide information about indirect cost. But the composability analysis reveals that some cost information is redundant between CCA and AP, and PCA's cost is not production related. Thus, the CCA service is selected for *administrative cost* information.

The system preliminarily invokes AR and CCA services separately and gets *sales 8,600, direct*

Figure 9. Service composition to answer an ad hoc question



cost 5,000, both in *USD*, as shown in Figure 6, and *administrative cost 326*, but in *RMB*. Due to the difference in currency units, these two services cannot be composed directly to calculate the gross profit.

To find out if these two services are composable in this scenario, the prototype system tracks their *unit* properties to the *unit* ontology (denoted by one dotted arrow in the lower part of Figure 3). The latter reveals a relationship between *USD* and *RMB*, and provides a currency exchange rate service called CurEx to bridge the gap. Therefore, the system relies on CurEx to help compose AR and CCA services. This on-the-fly service composition decision is made based on the shared ontology and business rules.

Figure 9 shows that candidate 3 is the final service composition solution. The system composes these atomic services to develop a Profitability composite Web service, called *ProfitComp*. Then, the management can answer the original question using this composite Web service. The result indicates that gross profit is *$3,561.08* (to verify: $8600 - 5000 - 326 \times 0.1194 = 3{,}561.08$).

DISCUSSION AND CONCLUSIONS

In this paper, we have proposed an integrated ontology-supported Web service composition framework by leveraging both syntactic-based Web services building blocks and semantics-oriented technologies. The semantic enrichment to the syntactical approach shows superiority for automated and on-the-fly service composition. As demonstrated in the usage scenarios, new lists of candidate services are generated along the course of problem solving. In most cases, the direction of the next step is dynamically determined based on the results of current service execution. The proposed framework has theoretical and practical implications for organizational knowledge management. Ontologies are beneficial to knowledge representation, discovery, and sharing, while Web services facilitate knowledge integration, delivery, and consumption. To demonstrate the benefits of the proposed framework, we have applied it to the financial services and provided a solution to knowledge management in that domain.

However, cautions should be taken when extending the framework to other areas. First, we assume that the shared ontology is accepted by all parties within an organization or a community, which is not always the case in a public domain. Similarly, in a situation where service description and domain knowledge cannot be easily translated into concepts represented in ontologies or ambiguities may arise from the conceptualization, task-specific solutions can be undertaken. But the ideal measure of conceptualization should rely on industry-wide standardization, such as more formalized financial and manufacturing ontologies. Second, the use of ontological heuristics through the shared ontology tree may consume substantial computational resources, especially when the ontology tree grows very large. More efficient ontology structures and searching algorithms need to be developed. Third, some other approaches to service composition, such as AI planning techniques and workflow technology (Ganesarajah & Lupu, 2002; Petrie et al., 2003; W3C, 2002), might provide further solutions and insights, although they are beyond the scope of the current study.

We believe that this integrated framework is an effective approach towards automated and dynamic service composition. Furthermore, implementing such an enterprise-wide knowledge management system that is based on the proposed framework offers an innovative approach to knowledge extraction, representation, organization, conversion, and creation. It also has advantages in addressing unstructured and unpredictable business management issues. In this sense, what are embodied in ontologies are of strategic importance.

Some future work needs to be done to fully realize the potential of the proposed framework. First, from a theoretical perspective, we need to address what relationships between the syntactical layer and the semantic layer are, and how to couple these two layers. Second, as a technical extension, software tools have to be developed to translate WSDL specification to RDF+OWL representation and to integrate local ontologies into a shared ontology. Third, service composition deals with data at a conceptual level, while service consumption also needs data from an instance level. How to organize and link these two levels of the ontology? What level of knowledge should local and shared ontologies encompass? Those questions have not been fully investigated yet. Finally, formal evaluation of the proposed framework will be conducted using a set of business problems with different levels of complexity.

Chapter 7.12
Ontology

William Buchholz
Bentley College, USA

INTRODUCTION

An ontology comprises the explicitly articulated and shared concepts of a knowledge community or domain. These concepts are arranged formally in a taxonomy and are governed by specifically defined rules and axioms. Ontologies often play an important role in knowledge management information technology (KMIT). An enterprise knowledge management IT system, for example, may use an ontology "to facilitate communication, search, storage, and [knowledge] representation" (O'Leary, 1998, p. 58). A general survey of the literature suggests that ontologies are capable of improving performance in a large variety of knowledge management IT functions, especially relative to knowledgebases for best practices, lessons learned, human resource skills, Help Desks, FAQs, document collections, standards and regulations, products, services, proposals, and the like. In addition, as we look to the future, ontologies will function centrally in agent-mediated knowledge management (AMKM), distributed knowledge management (DKM), and the Semantic Web (Daconta, Obrst, & Smith, 2003; Fensel, 2001; Heflin, Volz, & Dale, 2002; McGuiness, 2002), as these technologies become pervasive in a global economy that distributes KM knowledgebases across companies and cultures.

The term ontology is rarely used in knowledge management circles. In fact, after researching "the KM literature both in print and online" and visiting KM Europe for "two consecutive years," Mika and Akkermans (2004) only "found prototypes of ontology-based KM applications in the ontology literature, [and] very few of the KM sources even mentioned the use of ontologies." When ontologies were mentioned, they were termed "future KM technologies." In the opinion of Mika and Akkermans, "The relation between KM and technology is only superficially developed in the business-oriented side of KM" (p. 6). Holsapple and Joshi (2004) are in the process of remedying this situation by developing a high-level, general knowledge management ontology that "provides a unifying view of KM phenomena" that will help researchers, educators, and practitioners (p. 593) "to characterize KM technologies,…structure

KM case studies, and…develop a KM model for competitive analysis" (p. 594). To provide a deeper understanding of just such an ontology, and to offer a general sense of the ontological aspect of IT in KM, this article defines the history, purpose, scope, and function of the term ontology.

Ontology has its origins in philosophy, and to this day informs a vital approach to philosophical inquiry. Philosophical ontology deals with metaphysical aspects of the nature of existence, touching upon the various meanings, relationships, and instances of the abstract, the concrete, the general, and the specific. It could be said that historically much of philosophy has been devoted to constructing a high-level ontology, an abstract model of reality, its primary constituents, their essential/accidental characteristics, and the various relationships that pertain among them.

Ontological philosophers often examine existence by delineating its parts categorically in accordance with an explicit theory. Aristotle's categories, syllogisms, definitions, and axioms, for example, form the basis of identifying, classifying, and theorizing about existence in just this way. So too have modern philosophers such as Kant, Peirce, Husserl, Whitehead, and Heidegger (Sowa, 2000, pp. 56-77) attempted to understand reality through categorization and logic. Much of their philosophical groundwork, in fact, forms the basis of ontology as it is presently understood in practical applications for computerized systems of information. Additionally, the mathematician and logician Stanislaw Lesniewski supplied a key component of the computerized sense of ontology when he used "an artificial formal language to represent his formal theory of parts (mereology)." He thereby "inaugurated philosophy's use of artificial languages and formal logic in expressing ontologies" (Mayhew & Siebert, 2004, pp. 1-2). Thus, the philosophical sense of the word ontology, with its long and rich history, forms much of the theoretical and logical base of the computer sense of the word. The relatively modern use of ontology, as applied to computerized information systems, appears first in 1967 in G.H. Mealy's "Another Look at Data," a paper dealing with "the foundations of data modeling" (Smith, 2004, p. 22).

Today's computerized ontologies attempt to capture some aspect of the explicit knowledge of a specific domain, such as medicine, accounting, finance, or engineering. With this knowledge, the ontology helps a computer agent or program function in some practical way to operationalize the key concepts made explicit and constrained by highly specified rules. An agent operating on the Semantic Web, for example, could theoretically consult various ontologies distributed on the Web to gather the meaning of key terms, assertions, processes, and actions that would allow the agent to shop for your dinner, buy your favorite wine, get the best price available for both, make sure that everything is delivered at a specified time, charge your credit card, and have your garage door open when you arrive home for dinner. Only an agent with a brain could perform all these activities. But computerized agents do not have brains. They have ontologies—ontologies to consult in carrying out your instructions for dinner. Computers cannot understand as humans do; but ontologies help to create the illusion that they can.

Within the last 40 years, ontology has become a central component in computerized information processing, especially in constructing large databases (sometimes termed knowledgebases). Ontologies have also figured predominantly in software application development, Artificial Intelligence initiatives, Web services, e-business, information and document retrieval, e-commerce, decision-support, medical informatics, the Semantic Web technologies, and, of course, in various IT applications of knowledge management. Within all these areas, the highly theoretical (philosophical) view of the term ontology undergirds the very pragmatic outcomes sought in computerized knowledge systems. Ontologies, formal and informal, will continue to be major functional elements in the design, maintenance, handling, and implementation of the large-scale information stores at the heart of knowledge management initiatives.

BACKGROUND: ONTOLOGY DEFINED

While never pretending to duplicate exactly the workings of the human imagination or experience, ontologies attempt to capture conceptually the rational building blocks of the mind by modeling our knowledge of reality. The whole purpose of this is to give the computer humanlike, albeit modest, thinking ability, by providing an explicit vocabulary for things, ideas, actions, relations, and approved behaviors. Ontologies with the expressive power that provides these capabilities are generally termed formal ontologies.

FORMAL ONTOLOGY

A formal ontology seeks to capture the essence of selected aspects of existence by stating explicitly and formulaically the concepts of the various constituents of the domain being modeled and the relationships that pertain among them. Ontologies are said to be "formal" or "formalized" when they are capable of being rendered into a computer programming language. Probably the single most famous definition of ontology is offered by Gruber (1993), who defines ontology simply as "an explicit specification of a conceptualization." Concepts, Gruber notes, are abstract, "simplified view[s] of the world" (p. 1) that become the models for the objects and ideas of some part of the world as we know it. Guarino and Giaretta (1995), emphasizing that purpose determines how these concepts are specified, note that an ontology can give only a "partial account of a conceptualization" (p. 7). Knowledge, after all, is in the mind of the beholder, and an ontology will necessarily represent only the point of view of the ontology builder. An ontology, in short, will never be omniscient nor all-encompassing.

What follows examines two inherent aspects of Gruber's classic ontology definition: explicitly specified concepts and the relationships among them.

Explicitly Specified Concepts

The concepts, which represent selected aspects of reality in a formal ontology, are variously termed entities, objects, or elements. Concepts can represent concrete entities (books, cameras, toads, clouds), abstract notions (fictional places, ideas, theories), beliefs, processes, tasks, goals, events, states, or methods—in short, anything that needs to be modeled in the knowledge domain (the universe of discourse). Entities can further be specified to make explicit some chosen characteristics or attributes, such as color, size, price, manufacturer, location, name, and the like. Ontologists thus work with declarative representations, also termed declarative knowledge or declarative formalisms, because they are using descriptive logic to represent symbolically a selected set of real-world objects and events in their abstract models or knowledge representations.

Ontologies formally express concepts, not just words. For example, the word "cell" in an ontology must clearly represent its concept; ambiguity is not allowed. To disambiguate "cell," a polyseme or word with multiple meanings, the ontologist needs to create an unequivocal nomenclature that reflects accurately the usage context and the purpose of the ontology. The nomenclature must also be formalized, that is, rendered to allow the ontology to be set into formal notations used in first-order predicate logic that can be translated into any suitable programming language. Thus, the various possible meanings of cell, from biological (AnimalCell, PlantCell), to jail (JailCell), to phone (CellPhone), to electronic engineering (BatteryCell), must be indicated overtly and succinctly in the nomenclature of the concept itself.

In addition, the ontology should supply concept definitions in Natural Language sentences, and if appropriate declare the physical attributes of the elements being modeled. Thus, a communication ontology could focus on CellPhone attributes such as Manufacturer, UnitPrice, BatteryLife, Color, HasVideoCamera, ServiceProvider, CountryOfOrigin, and the like.

Relationships Among Concepts

The semantic relationships of the concepts must be clearly determined, and the antecedents or parents, as well as the children, of each concept must be established. Ontologies establish concept relationships primarily as is-a or part-of. Some further possible relationships could include isMemberOf, subscribesTo, overseesJointly, isAuthorOf, isCausedBy, and the like. This article focuses on the two primary relationships, is-a and part-of, as they form the core hierarchy of the ontology.

Is-a

In a truly formal ontology, the categories (classes) of aggregated concepts are related hierarchically in a specialization taxonomy: lower categories fall under higher categories in subsumption relationships. The backbone of an ontology is its taxonomy (Guarino & Welty, 2002; Daconta et al., 2003, p. 150), as that ineluctably establishes the concept relationships which must be rigorously enforced.

Historically, the epitome of practical categorization is the 18th century taxonomy of Linnaeus. The Linnaean principles of organization, relationship, and inheritance today inform our use of ontologies. Linnaeus classified plants and animals in taxa (groups or classes) with various delineated properties inherited by the organisms residing (instantiated) in the lowest taxa. The eight major categories proceed from the most general down to the instance of a species (instantiation): Kingdom, Phylum, Class, Subclass, Order, Family, Genus, and Species. Each category in the taxonomy inherits the qualities or attributes of its parent category (inheritance through nesting). For example, a human being (Genus: Homo, Species: Sapiens) inherits all the characteristics of its superordinate category "mammal," which inherits all the characteristics of its ultimate superordinate category "animal" (Daconta et al., 2003, p. 148). This process of going from the particular to the general is known as traversing a specialization hierarchy, going from the species to the genera, from the special case to the general case. A specialization hierarchy, then, is nothing more than a collection of carefully arranged is-a relationships. Thus, homo sapiens is a (belongs to the category) primate; a primate is a (belongs to the category) mammal; and a mammal is a(n) (belongs to the category) animal.

The same kind of taxonomy can be constructed using the concept vehicle, where instances of vehicle can be grouped a number of ways relevant to the domain of discussion. For example, vehicles could be classified as operating on land, sea, in the air, or in outer space. Land vehicles could be classified as trains, trucks, trolleys, automobiles, bicycles, scooters, and the like. Automobiles could be classified by make, model, year, and country of origin. What is happening in this classification process is that a concept or model is being explicitly "realized" as the classification becomes less abstract and more concrete. Ambiguity is eliminated by deriving explicit attributes that allow us to articulate clearly exclusive differences. Once these mutually exclusive differences are made explicit, various objects can be appropriately categorized. When categorized, the objects can be further defined to the point where a human being, computer program, or agent could perform simple or complex logical operations on the categorized instances. For example, if it is known that a Toyota Celica is a type of automobile, it is also known by inference that a Toyota Celica is a land vehicle and that land vehicles do not float or fly. Thus, it is categorically illogical—indeed silly—to express the hope to land a man on the moon using a Renaissance Red 1997 Toyota Celica GT Convertible.

Formal ontologies seeking rigor must be composed of concepts whose instances exist exclusively in their class location in the hierarchy. In defining a class, the ontologist seeks the necessary and sufficient characteristics or exclusive differentia that define the set of members in that class. An instance of one class should never reside simultaneously in other classes at the same level in the hierarchy (sibling classes). Often in fact, out of desperation, taxonomists will opt for this kind of polyhierarchy (placing a single instance in numerous sibling classes), but the purist tries always to avoid polyhierarchy, as the power of the specification is weakened. For example, in a taxonomy of fruits and vegetables, a truly rigorous ontology would classify the entity "tomato" as either a fruit or a vegetable, but not both. In defining the classes fruit and vegetable, the ontologist would be careful to articulate a definition, supply attributes, and provide constraints that would unequivocally differentiate fruits from vegetables. Then all members of each class would inherit these characteristics. If too many individual members of the class sets can live in either class (tomato is a fruit, tomato is a vegetable), then the ontology is ambiguous—less rigorous and less useful in describing the domain. A computer agent, forced to make a single choice, would not know how to proceed, simply because the agent cannot tolerate ambiguity. You might get a scoop of ice cream plopped on your tomato if the computer agent infers that tomatoes are fruits.

Part-of

Besides the is-a relationship, hierarchies can also express part-of relationships. This type of hierarchy is sometimes called an aggregation taxonomy (Daconta et al., 2003, p. 149), but more strictly speaking it should be termed a partonomy or composition hierarchy. Here is how an ontology of geography could represent hierarchically the part-of relationships of concepts.

The relationships in this partonomy are known as part-of relationships because lower elements in the hierarchy are part of higher elements; that is, a lot is part of a street, which is part of a neighborhood, which is part of a city, and so forth. In formal notation, this could be expressed as (is Part Of Street Lake Neighborhood 10) which in Natural Language is saying that Lake Street is located in neighborhood 10. This monocline subsumption of named concepts moves from the largest and most general term (World) in a progression that becomes increasingly and logically narrower until the smallest conceptual unit is reached (Lot). Note that every larger concept preceding a given concept must have characteristics or attributes that allow it to contain properly every concept lower and to the right. Thus, streets have as their direct parents neighborhoods and as their direct children lots. A city is subsumed under a county which is subsumed under a state.

What makes all of these relationships work ineluctably is the agreement among the ontology engineers about nomenclature (class names), lexicon (explicit definitions for what to include and exclude in each class—the differentia, based upon various qualities or attributes), and mereology (establishing a whole-part relationship from parent to child that pertains in the formalized partonomy). Partonomical hierarchies or mereologies (Simons, 1987) are used extensively in ontologies for medical informatics, bioinformatics, genetics, chemistry, and physics—any domain that must aggregate concepts according to their parts and constituents.

Other Key Elements of a Formal Ontology

As we have seen thus far, formal ontologies are characterized by their rigorous use of explicit definition and logical structure, which makes it possible for them to be shared and reused in various computer applications that need accurate and succinct information models for processing. To make computer processing possible, terms and their relationships in a formal ontology are often expressed in a first-order logic predicate calculus language such as Knowledge Interchange Format (KIF) or related languages such as LOOM, CycL, Classic, Flogic, KRIS, Ontolingua, or OWL. The ontology is encoded in such a way that computerized agents can access its knowledge representations to carry out some specified practical action. Figure 1 shows how an axiom stated in natural language might be encoded in KIF.

Sowa (2000) has further delineated formal ontologies into two subgroups: axiomatized and prototype based. The axiomatized ontology is characterized by its logical definitions and axioms (assumed truths) that ultimately have great power because they "can support more complex inferences and computations" (p. 493). As examples, Sowa cites "formal theories in science and mathematics, the collections of rules and frames in an expert system, and specifications of conceptual schemas in languages like SQL." In modeling a concept of reality, the axiomatized ontology carefully presents well-named concepts (the nomenclature) and well-defined concepts (the lexicon) arranged hierarchically to expose the ineluctable relationships of the concepts. Rules in the ontology allow for inferences to be drawn from the explicitly defined terms and relationships (Perez & Benjamins, 1999, p. 2).

Figure 1. Example of an axiom in KIF

This natural language statement:

If any two animals are siblings, then there exists someone who is the mother of both of them.

When axiomatized in KIF looks like this:

```
(=> (sibling ?sib1 ?sib2)
    (exists (?mom) (and (has-mother ?sib1 ?mom)
                        (has-mother ?sib2 ?mom)))
```

Source of KIF: Knowledge Systems Laboratory (KSL), Stanford University. *A Glossary of Ontology Terminology*. http://www-ksl-svc.stanford.edu:5915/doc/frame-editor/glossary-of-terms.html

The axiomatized ontology, as a "statement of a logical theory" (Gruber, 1993, p. 2), also contains some number of assertions, axioms (Figure 1), rules, constraints, theorems, functions, explanations in Natural Language, instances, or anything else that expresses descriptively what is allowed and disallowed to obtain in the ontology of the domain being specified.

Sowa's prototype-based ontology tends, unfortunately, to complicate the definition of formality. The prototype-based ontology does not contain axioms nor does it rely necessarily on logical definitions or theories. It is by and large simply a hierarchical arrangement of categories with sets of "typical instances or prototypes" (Sowa, 2000, p. 495). Prototype-based ontologies are commonly devoted to categorizing (cataloging) products, books, computer files, music, and the like. They fulfill an important function in e-business, e-commerce, the Internet, and the Semantic Web. Helping to clarify a specific distinction between formal and informal ontology, Gruber (1993) maintains more strictly than Sowa that all formal ontologies claiming "to specify a conceptualization" must have "axioms that do constrain the possible interpretations for the defined terms" (p. 2, note 1).

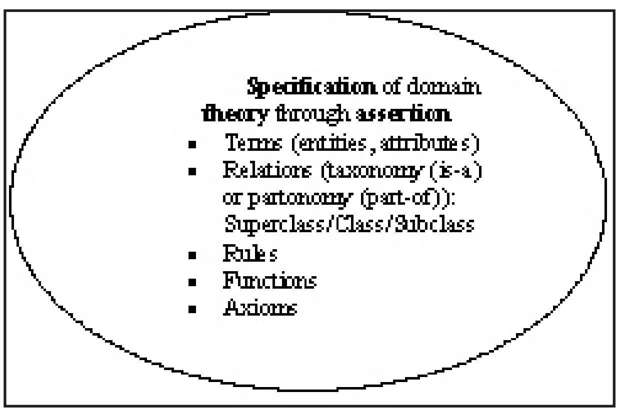
Much confusion about ontologies can be avoided if Gruber's distinctions are maintained. This strict definition of a formal ontology is depicted in Figure 2, a simplified schematic of a formal (axiomatized) ontology that specifies a universe of discourse (anything one chooses to model). The conceptualization of this domain is being specified through explicit assertion of the truths of the universe. Specification of a conceptualization in a formal ontology usually consists of all the bulleted items (and even more, if desired).

Sample Formal Ontologies

Formal ontologies are often divided into two basic types: foundational (also known as upper-level or top-level) and applied.

Foundational (upper- or top-level) ontologies specify conceptualizations that are more general and have universal applicability. They may focus on defining logical concepts, relationships, human understanding, and the like. Good examples of foundational ontologies include:

Figure 2. The conceptualization of a knowledge domain (Universe of Discourse)



- CYC top-level ontology: http://www.cyc.com/
- DOLCE (Descriptive Ontology for Linguistic and Cognitive Engineering): http://www.loa-cnr.it/DOLCE.html
- Generalized Upper Model (GUM): http://www.darmstadt.gmd.de/publish/komet/gen-um/newUM.html
- GOLD (General Ontology for Linguistic Description): http://emeld.douglass.arizona.edu:8080/index.html
- PhysSys (The Physical Systems Ontology):
  http://ksi.cpsc.ucalgary.ca/KAW/KAW96/borst/node2.html
- IEEE SUMO (Suggested Upper Merged Ontology): http://ontology.teknowledge.com/

Applied ontologies, which are domain specific, more strictly focus on a functional application related to a particular domain, such as enterprise modeling, knowledge management, chemistry, law, e-commerce, medicine, botany, and zoology. A few representative application fields and their actual ontologies include:

- Biology: Ontologies for Ethology—http://www.mesquiteproject.org/ontology/
- Business: The Open Source Business Process Management Ontology, BPMO—http://www. bpiresearch. com/Resources/RE_OSSOnt/re_ ossont. htm
- Knowledge Management: KM Ontology (under development), which "provides researchers with a relatively comprehensive, organized foundation and common language for studying KM. It gives practitioners a frame of reference for assessing KM practices and recognizing KM opportunities. It points toward a structure and content for developing a formal KM curriculum." (Holsapple & Joshi, 2004, p. 2)
- Manufacturing: The Process Specification Language Ontology, PSL—http://www.mel.nist.gov/psl/ontology.html
- Math: An Ontology for Engineering Mathematics—http://www.ksl.stanford.edu/knowledge-sharing/papers/engmath.html
- Medicine: Systematized Nomenclature of Medicine, SNOMED—http://www.snomed.org/

The vast majority of applied ontologies are proprietary and unavailable to the general public.

INFORMAL ONTOLOGY

"Informal ontologies" (Sowa 2000, p. 493), to a greater or lesser degree, have some of the characteristics of formal ontologies, particularly selected groups of terms or labels relevant to some topic or area of interest (a document collection, Web site, product catalog, or business area). When the components of the informal ontology are arranged hierarchically, they are often termed taxonomies (Verity's Classifier, http: // www.ultraseek.com /products /vcc/;InmagicClassifer,http://www. esprit soutronpartnership . com /Products /Classifier. asp), directories (Yahoo, http://www.yahoo.com; DMOZ, http://www.dmoz.com), subject-heading lists (Library of Congress Subject Headings, http://www.loc.gov/), or thesauri (Medical Subject Headings, MeSH®, http://www.nlm.nih.gov/mesh/). When including definitions, they may be called lexicons (WordNet, http://www.cogsci.princeton.edu/~wn/) or glossaries (Information Architecture Glossary, http://argus-acia.com/white_papers/iaglossary.html). If they are simply computer files containing sets of controlled terms, they may be called controlled vocabularies or synonym rings.

Informal ontologies, because of their weak semantics (term meanings), are incapable of rich expression (McGuiness, 2002; Daconta et al., 2003, pp. 157-167); they simply do not provide enough significant meaning about a knowledge domain. Compare the semantic richness, for example, of a well-explained scientific theory to the semantic poverty of a mere listing of chemistry terms.

While offering some control over the knowledge domain, informal ontologies cannot by themselves be used for automated purposes. Computer programs, agents, and applications may refer to them for various reasons, but the informal ontology itself does not have the power of a formal ontology. Informal ontologies are not driven overtly by logical constraints, are not formalized in a knowledge representation language, are not axiomatized—in short, they do not have the expressive power that may need to be harnessed for sophisticated purposes in academia, business, medicine, law, or government.

ISSUES, CONTROVERSIES, AND PROBLEMS

The literature has tried for years to define exactly what constitutes an ontology (Chandrasekaran, Josephson, & Benjamins, 1999; Daconta et al., 2003; Gruber, 1993; Gruber, 2003; Guarino & Welty, 1995; Heflin et al., 2002; McGuiness, 2002; Noy & McGuinness, 2001; Sheth & Ramakrishnan, 2003; Smith, 2004; Sowa, 2000). While this article has presented the consensus view as depicted in the literature, the concept of ontology is still very slippery. For example, vendors, IT professionals, knowledge management experts, and technicians often erroneously equate simple taxonomies with formal ontologies. While a formal ontology contains a taxonomy or partonomy in expressing the relationships of the concepts, a taxonomy or partonomy is only a part of the formal ontology. A formal ontology also includes community-shared definitions, rules, and axioms.

Ontology has also been equated with Web directories such as DMOZ and Yahoo, neither of which is, strictly speaking, a formal ontology. Both employ rough classification schemes (loose aggregations) to order groups and subgroups of Internet resources, but again they do not provide concept definitions, rules, or axioms. Thus, to see those very rough schemes as formal ontologies is to abuse the term. They are simply directories. Lists of controlled words, glossaries, and thesauri are also often erroneously termed formal ontologies, but should be seen more properly only as potential parts of formal ontologies.

People often confuse terminological ontologies (Sowa, 2000) with formal ontologies. Thus, WordNet and Sensus are lexicons, not strictly formal ontologies. They contain words, their definitions, their relationship to other words in the hierarchy (in WordNet these are synonym sets), and part-whole (mereological) distinctions, but the definitions are not always complete, the taxonomic structure is faulty at many points (Guarino & Welty, 2002), and the collections are usually not axiomatized. Terminological ontologies have their uses, certainly, but primarily as starting points for more rigorous and limited formal ontological applications.

Formal ontological rigor is not easy to establish. One of the main stumbling blocks in establishing rigor is modeling the formal ontology to reflect strict and mutually exclusive is-a relationships in a specification hierarchy and not confusing is-a relationships with part-of relationships. The work of Guarino and Welty (2002) is dedicated to exposing these kinds of identity and subsumption weaknesses in formal ontologies. The less rigor a formal ontology has, the less value it has in accurately and unambiguously depicting a knowledge domain. This is not to say, however, that informal or semi-formal ontologies have no value; indeed, they may well meet many general and large-scale information needs, especially as we look forward to increasing numbers of ontology applications on the Semantic Web (Sheth & Ramakrishnan, 2003; Gruber, 2003).

Because so much of formal ontology building is still an art rather than a science (Abou-Zeid 2003; Gruber 1993; Gruninger & Fox, 1995; Guarino & Giaretta, 1995; Perez & Benjamins, 1999), even formal ontologies are selectively based on subjective choices. Ontologies, therefore, are capable only of representing the knowledge (specifying the concepts) that humans provide. If the ontology builders are not domain experts; if they make knowledge representation choices for political, organizational, or personal reasons rather than sound ontological reasons; if they omit important elements, attributes, or axioms because they rush to publication; if they construct the ontology based on the limitations of the programming language with which they are familiar (encoding bias); if they do not adequately understand the purpose and the audience for the ontology; if they fail to standardize their nomenclature; if they choose to model too much or model too little, their ontology is very likely doomed to fail.

How might these issues be avoided and these problems be solved? Only by establishing and following clear guidelines and standards in constructing ontologies will we ever hope to realize the full potential of the major initiatives in which ontologies play such a fundamental role. Much work remains to be done in standardization and implementation technologies, but much is at stake. If the Semantic Web, distributed global knowledge management initiatives, and the various application projects underway in areas such as e-business, government, publishing, Artificial Intelligence, and medical informatics are to be successful on a large scale, they will have to be buttressed by well-designed ontologies.

CONCLUSION

This article discusses the philosophical origins and modern practical implementations of ontology. For easier understanding, approaches to ontology building were divided into formal and informal. Formal ontologies were explained, focusing in particular on specifying concepts by establishing relationships through is-a and part-of approaches. The other components of a formal ontology were briefly mentioned. Informal ontologies were defined and contrasted with formal ontologies. Finally, issues, controversies, and problems in the implementation of ontologies were briefly explored.

Ontologies will continue to play an important role in the development of large-scale, computer mediated, and global knowledge management projects. Communicating knowledge within an organization, and among organizations worldwide, will be facilitated by ontologies, as they create a knowledge layer critical to the automated sharing and reuse of essential explicit knowledge.

The research agenda in ontologies includes solving many of the technical problems that bedevil organizations at the application level, developing stable and standard methodologies and tools to move ontology construction out of the area of art and into that of science (ontological engineering), and continuing to hone the theoretical insights that will allow construction and implementation of rigorous high-level and application-level ontologies.

Chapter 7.13
A View on Knowledge Management:
Utilizing a Balanced Scorecard Methodology for Analyzing Knowledge Metrics

Alea Fairchild
Vesalius College/Vrije Universiteit Brussel (VUB), Belgium

ABSTRACT

IT professionals who want to deploy foundation technologies such as groupware, CRM or decision support tools, but fail to justify them on the basis of their contribution to Knowledge Management, may find it difficult to get funding unless they can frame the benefits within a Knowledge Management context. Determining Knowledge Management's pervasiveness and impact is analogous to measuring the contribution of marketing, employee development, or any other management or organizational competency. This chapter addresses the problem of developing measurement models for Knowledge Management metrics and discusses what current Knowledge Management metrics are in use, and examines their sustainability and soundness in assessing knowledge utilization and retention of generating revenue. The chapter discusses the use of a Balanced Scorecard approach to determine a business-oriented relationship between strategic Knowledge Management usage and IT strategy and implementation.

INTRODUCTION

"Knowledge has become the key economic resource and the dominate — and perhaps even the

only- source of competitive advantage." Peter Drucker, Managing in a Time of Great Change (1995)

Knowledge Management may be defined as a set of processes for transferring intellectual capital to value – processes such as innovation and knowledge creation and knowledge acquisition, organization, application, sharing, and replenishment (Knapp, 1998). Enterprises work in generating value from knowledge assets by sharing them among employees, departments and even with other companies in an effort to devise best practices.

From the point of view of information technology (IT) investment, it is important to note that the definition itself says nothing about technology; while Knowledge Management is often facilitated by IT technology, by itself it is not Knowledge Management.

"Now that knowledge is taking the place of capital as the driving force in organizations worldwide, it is all too easy to confuse data with knowledge and information with information technology." Peter Drucker, Managing in a Time of Great Change (1995)

The definition of knowledge is a complex and controversial one, and 'knowledge' can be interpreted in many different ways. Much of the Knowledge Management literature defines knowledge in broad terms, covering basically all the "software" of an organization. This involves the structured data, patents, programs and procedures, as well as the more intangible knowledge and capabilities of the people. It may also include the way that organizations function, communicate, analyze situations, come up with novel solutions to problems and develop new ways of doing business. Knowledge Management in an organization can also involve issues of culture, custom, values and skills as well as the enterprise's relationships with its suppliers and customers. Knowledge Management is a strategic, systematic program to capitalize on what an organization "knows" (Knapp, 1998).

Managerial interest in Knowledge Management stems from a number of economic facts about knowledge utilization in today's environment. These facts are shown in Figure 1.

- Long-run shifts in advanced industrial economies which have led to the increasingly widespread perception of knowledge as an important organizational asset.

Figure 1. Economic reasons for the interest in knowledge management (KPMG Consulting, 2000)

- Long-run shifts in advanced industrial economies that have led to the increasingly widespread perception of knowledge as an important organizational asset.
- The rise of occupations based on the creation and use of knowledge.
- Theoretical developments -- for example, the resource-based view of the firm -- which emphasize the importance of unique and inimitable assets such as tacit knowledge.
- The convergence of information and communication technologies, and the advent of new tools such as Intranets and groupware systems.
- A new wave approach to packaging and promoting consultancy services in the wake of the rise and fall of Business Process Reengineering (BPR).

- The rise of occupations based on the creation and use of knowledge.
- Theoretical developments - for example, the resource-based view of the firm — which emphasize the importance of unique and inimitable assets such as tacit knowledge.
- The convergence of information and communication technologies, and the advent of new tools such as Intranets and groupware systems.
- A new wave approach to packaging and promoting consultancy services in the wake of the rise and fall of Business Process Reengineering (BPR).

Organizational requirements for Knowledge Management involve leveraging intellectual capital, not just retaining it, which requires attention to what have been recognized as "knowledge enablers", i.e., structures and attributes that must be in place for a successful Knowledge Management program. Besides technology, these enablers include content, learning, culture and leadership (KPMG Consulting, 2000). In order to measure Knowledge Management, some attention needs to be paid to measurement of the enabling factors as well.

The chapter discusses two possible sets of metrics, containing both qualitative and quantitative components, to aid management in understanding Knowledge Management initiatives and the necessary IT investments in relation to the company's strategic direction. This chapter addresses the question: What set of industry standard metrics, containing both hard and soft elements, can be adapted for use in Knowledge Management initiatives?

The chapter first explores literature on current Knowledge Management metrics. It then examines, from published research, how Knowledge Management is viewed in organizations to examine the sustainability and soundness in metrics that assess knowledge utilization and retention of generating revenue. It then creates an extension of the Balanced Scorecard framework in terms of two possible perspectives, so as to address Knowledge Management metrics. The conclusion of the chapter ties the Knowledge Management perspectives suggested in this research to the original intent of a Balanced Scorecard so as to show the relationship to strategy.

BACKGROUND ON KNOWLEDGE MANAGEMENT

How is Knowledge Management Measured?

A number of Knowledge Management thought leaders, such as Larry Prusak and Thomas Davenport, have stated a belief that it is impossible to develop direct, meaningful measures of knowledge assets. They believe it is possible to measure only the outputs of knowledge, given that knowledge is, by definition, intangible and therefore unobservable. But by developing an understanding of what makes a "unit" of knowledge, one might be able to create the necessary relationship between knowledge and the value it creates for the organization.

Although the focus on corporate culture and organizational change may extend the timeframe for a Knowledge Management program, only measurable benefits justify increased duration and cost in the eyes of senior management. Those benefits include better preparation for implementation and the ability to take advantage of existing technology.

Knowledge Management investments are thus likely to include the extension of existing enterprise software to eliminate barriers between transactional applications and repositories of corporate knowledge. Increasingly, companies will exploit corporate knowledge and provide it to users within the context of business problems, a more effective alternative to simply storing this content in and accessing it from a centralized knowledge repository (Dyer & McDonough, 2001). Given that there is no clear single activity that is Knowledge Management, it is more how and when Knowledge Management is integrated into organizational activities that can be measured.

In general, however, intellectual and knowledge-based assets fall into one of two categories: explicit or tacit. Included among the former are assets such as patents, trademarks, business plans, marketing research and customer lists. Generally, explicit knowledge consists of anything that can be documented, archived and codified, often with the help of IT. Much harder to grasp is the concept of tacit knowledge, or the know-how contained in people's heads. The challenge inherent with tacit knowledge is figuring out how to recognize, generate, share and manage it. While IT in the form of e-mail, groupware, instant messaging and related technologies can help facilitate the dissemination of tacit knowledge, identifying tacit knowledge in the first place is a major hurdle for most organizations (Surmacz & Santosus, 2001).

A recent Platinum Technologies study found that only 20% of Knowledge Management programs have used some form of metrics on how business performance is influenced. This may be that traditionalist management who use ROI for calculations have to find an appropriate equation for Knowledge Management (Shand, 1999). Platinum Technologies developed a method that was two parts hard, or quantifiable, measurement and one part soft, or more qualitative, measurement. By consolidating and better managing the different delivery channels for sales and marketing, Platinum significantly reduced the costs of maintaining and distributing collateral. This represents a hard and indisputable measure. The other third (the "soft" measure) resulted from increases in sales productivity, a measure with less clear impact on revenue. Senior management appreciated the difference between these hard and soft measures, especially the lesser emphasis on a metric that could be easily contested. This appreciation needs to be considered when assessing harder metric methods like return on investment (ROI) (Shand, 1999).

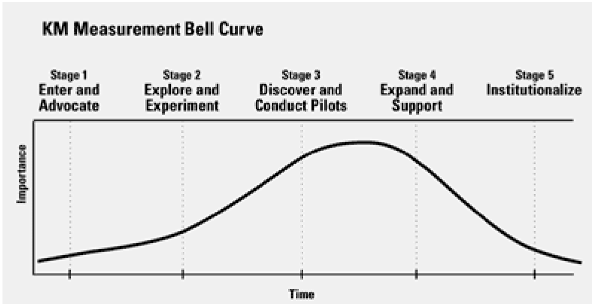
When is Knowledge Management Measured?

Figure 2 emerged from observing the numerous organizations that participated in an American Productivity and Quality Center (APQC) project (2001) and how they measure the value of Knowledge Management. During its 2000 consortium learning forum entitled 'Successfully Implementing Knowledge Management', APQC focused on how some of the most advanced early Knowledge Management adopters implement a Knowledge Management initiative, mobilize resources, create a business case, and measure and evolve their Knowledge Management programs. This multi-client benchmarking project helped APQC and project participants identify measurement approaches, specific measures in use, and how measures impact and are impacted by the evolution of Knowledge Management.

In the earliest stages of Knowledge Management implementation, formal measurement rarely takes place, nor is it required (APQC, 2001). As Knowledge Management becomes more structured and widespread and companies move into Stages Two, Three, and Four, the need for measurement steadily increases. As Knowledge Management becomes institutionalized — a way of doing business — the importance of Knowledge Management-specific measures diminishes, and the need to measure the effectiveness of knowledge-intensive business processes replaces them.

According to the APQC, the key is to begin to ensure that direct business value is perceived by the organization as a result of the knowledge-enabling projects. During its 2000 consortium learning forum entitled 'Successfully Implementing Knowledge Management', APQC focused on how some of the most advanced early Knowledge Management adopters implement a Knowledge

Figure 2. APQC project



Management initiative, mobilize resources, create a business case, and measure and evolve their Knowledge Management programs. This multi-client benchmarking project helped APQC and project participants identify measurement approaches, specific measures in use, and how measures impact and are impacted by the evolution of Knowledge Management.

The APQC Knowledge Management Measurement Bell Curve can be seen to parallel the five stages of the IT Balanced Scorecard (BSC) Maturity Model developed by Van Grembergen and Saull (2000), in that as the use of Knowledge Management matures in the organization, defined and managed measurement processes develop and become linked to business process cycles. The Van Grembergen and Saull (2000) IT BSC Maturity Model highlights five maturity levels (Initial, Repeatable, Defined, Managed and Optimized) to classify to what extent the IT BSC Maturity Model is integrated into the strategic and operational planning and review systems of the business and IT.

As seen from the APQC data, it is important to establish a mechanism to capture the hard and soft lessons learned in the Knowledge Management pilots with their initial IT investments, as these will be the building blocks for the later Knowledge Management implementations (APQC, 2001).

CHALLENGES IN DEVELOPING KNOWLEDGE MANAGEMENT METRICS

Knowledge Management Diversity of Practice

The economic facts listed in the Introduction section may help to explain the breadth of interest in Knowledge Management ranging across many different industrial sectors. They also can help to explain the diversity in the actual practices which have been labeled as Knowledge Management (KPMG Consulting, 2000). Although such practices share a common interest in targeting knowledge rather than information or data, they tend to perform distinctively different functions depending on the business context. Therefore, measuring the impact of these different functions on the business potentially requires different approaches.

One may distinguish between at least four different types of Knowledge Management (Business Process Resource Centre, 2001; Sveiby, 2001a):

Valuing Knowledge. This approach is of interest in consulting firms and financial institutions — for example, the Skandia organization — and in management accounting areas. Knowledge is viewed as 'intellectual capital', and the focus is on quantifying and recognizing the value of the organization's knowledge-base.

An example of this approach would be PLS-Consult in Denmark, who categorizes customers according to value of knowledge contribution to the firm and follows up in its management information system.

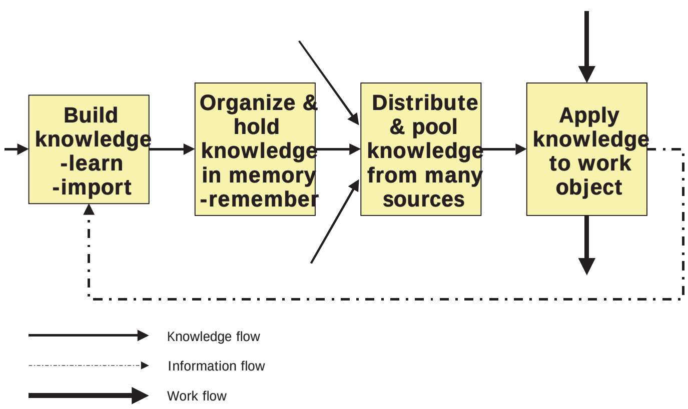
Exploiting Intellectual Property. This approach appeals to firms with a strong science and R&D base — typified by a number of pharmaceutical firms, the Buckman Labs organization, and so on — which are looking beyond the conventional approach based on patents, etc. to more effective ways of tapping into the commercial value of their existing knowledge-base.

An example of this approach would be the development of the Boeing 777, which was the first "paperless" development of aircraft. It included customers in design teams, with more than 200 teams with a wide range of skills who both designed and constructed sub parts, rather than the usual separated organization of design team and construction team. Suppliers world-wide used the same digital databases as Boeing.

Capturing Project-Based Learning. As firms increasingly move towards innovation and project-based organization, many are recognizing the need to capture the learning from individual projects and make it available throughout the organization. Consultancies, professional service firms, aerospace companies, etc., are in the vanguard of developing systems to codify and communicate such knowledge. The client who initiated this research effort also looks at Knowledge Management in this respect.

An example of this approach can be seen in the use of Knowledge Management by firms such as McKinsey and Bain & Co. These two management consulting firms

Figure 3. Four stages of knowledge transition (Wiig, 1997)



have developed 'knowledge databases' that contain experiences from every assignment, including names of team members and client reactions. Each team must appoint a 'historian' to document the work.

Managing Knowledge Workers. The shift towards knowledge work in many sectors creates problems for traditional ways of managing and motivating employees. In many firms, Knowledge Management reflects managers' desire to increase the productivity of knowledge workers, breaking down some of the barriers to knowledge-sharing which are associated with 'professionalism' (BPRC, 2001).

An example of this approach can be seen at Analog Devices in the US. CEO Ray Stata initiated a breakdown of functional barriers and competitive atmosphere and created a collaborative knowledge sharing culture from the top down. The company encourages a 'community of inquirers' rather than a 'community of advocates'.

Why the different methods of viewing Knowledge Management is important is related to the knowledge, information and work flows associated with each type of Knowledge Management, as shown in Figure 3.

Knowledge Management and IT Investment

The impact of Knowledge Management on IT investment can be related to the effect that each Knowledge Management initiative will have on increased costs of deployed services and technology tools. Based on a 2001 survey of 566 respondents done together by KM magazine and market research firm IDC, these survey results estimate that an average Knowledge Management budget will increase from $632,000 in 2000 to more than $1 million in 2002. These figures fall lower than expected, according to IDC, because two-fifths of the respondents represented companies with 500 or fewer employees, which shows the pervasiveness of the Knowledge Management concept into the reaches of the small and medium size businesses. Past data that emphasized larger companies showed an average budget of $2.7 million in 2000.

IDC believes from this survey that the budgets specifically designated for "Knowledge Management" initiatives decrease as these efforts become part of other technology or business process investments (Dyer & McDonough, 2001). For example, a company may perceive itself as investing in a customer service solution, though one with significant Knowledge Management capability, rather than categorize this investment as a Knowledge Management initiative. This again shows a need for measuring Knowledge Management and associated IT investment in a way to show its role in the organizational structure, benefiting business processes.

Measuring these roles via the Balanced Scorecard approach has already been established for evaluating IT and its investments, as Gold (1992) and Willcocks (1995) have already indicated in a conceptual manner and that has been further developed by Van Grembergen and Van Bruggen (1997), Van Grembergen and Timmerman (1998) and Van Grembergen (2000). Extending this Balanced Scorecard approach to the Knowledge Management environment would assist companies in understanding the use of Knowledge Management in relation to their knowledge capital resources, including IT implementation.

CONNECTION BETWEEN KNOWLEDGE MANAGEMENT METRICS DEVELOPMENT AND A BUSINESS PROCESS VIEW OF KNOWLEDGE MANAGEMENT

Irrespective of the terms used, the practical management objectives of measuring Knowledge

Management are similar: to find out how well the organization has converted human capital (individual learning/team capabilities) to structural capital (organizational knowledge or 'what is left when people go home', such as documented processes and knowledge bases) and thereby moved from tacit to explicit knowledge, and reduced the risk of losing valuable knowledge if people leave the organization. Loss of 'corporate memory' as a result of downsizing is one of the prime reasons given for adopting formal Knowledge Management practices. Other factors often mentioned include global competition and the pace of change; organizations see Knowledge Management as a means of avoiding repetition of mistakes, reducing duplication of effort, saving time on problem-solving, stimulating innovation and creativity, and getting closer to their customers (Corrall, 1999).

For all the interest and money spent on Knowledge Management there seems to be relatively few attempts to actually quantify the impact and results in business terms. The rationale is that knowledge exists in the context of its use (Svoika, 2001). Superior Knowledge Management frees companies to operate on fewer assets, collect their cash faster and have less volatility. The challenge is to make sure that the scope and the goal of the process is clear and focused, by providing a method to display indicators that measure objectives and are focused on the mission as set by the management. Given that Knowledge Management requires a mix of technical, organizational and interpersonal skills, the mix and emphasis varies according to responsibilities, but everyone involved needs to be able to understand the business and communicate business needs effectively, one approach to do this for Knowledge Management could be the Balanced Scorecard.

Van Grembergen and Timmerman (1998) and Martinsons, Davison and Tse (1999) were some of the first to have suggested that the Balanced Scorecard can be the foundation for the strategic management of information systems in organizations. Martinsons et al. (1999) use the Balanced Scorecard metrics to guide attainment of efficiency and effectiveness not only of information systems development but also of the use of the resulting information systems products in the operation of the business. They propose adaptations of the Balanced Scorecard framework based on the premise that IT is essentially an internal support function within an organization in contrast to the original framework, which focused on the impact of the business on the external market. The same analogy might be used for Knowledge Management, given that knowledge supports the activities of the organization.

POSSIBLE SOLUTION OF UTILIZING BALANCED SCORECARD TO KNOWLEDGE MANAGEMENT METRICS

Rationale for Balanced Scorecard in Knowledge Management

In their book, The Balanced Scorecard, Kaplan and Norton (1996) set forth a hypothesis about the chain of cause and effect that leads to strategic success. Kaplan and Norton (1996) have introduced the Balanced Scorecard at an enterprise level. Their fundamental premise is that the evaluation of a firm should not be restricted to a traditional financial evaluation but should be supplemented with measures concerning customer satisfaction, internal processes and the ability to innovate. Kaplan and Norton (1996) distinguish Financial, Internal, Customer, and Learning and Growth perspectives on organizational processes essential to an overall strategy. In looking at the original Kaplan and Norton (1996) implementation, Knowledge Management clearly fits within, if it does not define, the Learning and Growth aspect of their framework. If this is true, Knowledge Management outputs will impact on other processes. This is one reason why the significance in measuring Knowledge Management benefits or costs to other processes in organizations is an important area for extending the present Kaplan and Norton work (Firestone, 1998). Managers can track measures as they work toward their objectives, and measurement metrics aid in showing how to build internal capacity, such as human capital, tacit knowledge, and a knowledge culture. And a metrics framework keeps measures from being ad hoc, providing a reference point for Knowledge Management measurement after an implementation.

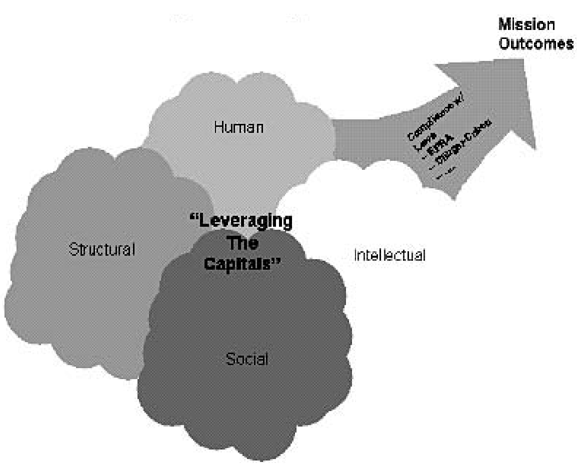
Use of Perspectives in Knowledge Management

Perhaps the key to proper initiatives and drivers is selecting the right perspectives, to use the Kaplan and Norton phrase, to view the interaction between Knowledge Management and the organizational strategy. This paper suggests that there might be two unique approaches to perspectives that would enhance the measurement of Knowledge Management in the organization.

First Approach. The first approach would be to use the different types of capital available in an organization, as shown in Figure 4, to be the four different scorecard perspectives of how Knowledge Management is leveraged in the organization. This approach is already in use in areas such as the US government, who is empowered to these Knowledge Management initiatives by the Clinger-Cohen Act of 1996 (Public Law 104-106), formerly known as the IT Management Reform Act. This Act requires CIOs in government to focus on the core competencies which represent skills and knowledge needed for effective mission support using information technologies. The four capitals which make up a knowledge-centric organization (KCO) are (Neilson, 2000):

- Human capital is all individual capabilities, the knowledge, skill and experience of the employees and managers.
- Intellectual capital includes the intangibles such as information, knowledge and skills that can be leveraged by an organization to produce an asset of equal or greater importance than land, labor and capital.
- Structural capital includes the processes, structures and systems that a firm owns less its people.
- Social capital is the goodwill resulting from physical and virtual interchanges between people with like interests and who are willing to share ideas within groups who share their interests.

Figure 4. Leveraging knowledge management with balanced scorecard



The dynamic mixing of human, intellectual, social and structural capital provides the fuel for creating and using knowledge. As retention and recruitment are major concerns in both public and private industry, an organization's success in leveraging its knowledge capital will ensure an organization remains competitive. The four capitals shown in the diagram can be directly related to the traditional Balanced Scorecard method in the following manner, shown in Table 1.

As seen in financial and other 'hard' measurements, when it comes to numbers, all sorts of

Table 1. KCO method

Balanced Scorecard Perspective	Generic measures	Intellectual Capital Perspective	Generic measures
Financial	ROI, EVA	Intellectual	A wide variety of measures exist. See Table 2.
Customer	Satisfaction, retention, market and account share	Social	Social capital was originally defined and measured by the World Bank in terms that related entirely to density of horizontally organized social networks, subsequent investigations have resulted in complicating any such straightforward measurement. A variety of measures exist, one interesting one from Cap Gemini Ernst & Young and Henley College is called the KOPE survey. This covers the following categories: Knowledge Management strategy and link to business (K), organizational and cultural enablers (O), process enablers (P) and enabling technologies (E). For each of these categories there are between 10 and 13 dimensions. The survey has been designed to allow organizations to identify strengths and weaknesses in their Knowledge Management practices (Truch, 2001).
Internal	Quality, response time, cost and new product introductions	Structural	Andriessen & Tiessen's (2000) Value Explorer™ is an accounting methodology proposed by KPMG for calculating and allocating value to 5 types of intangibles: (1) Assets and endowments, (2) Skills & tacit knowledge, (3) Collective values and norms, (4) Technology and explicit knowledge, (5) Primary and management processes.
Learning and Growth	Employee satisfaction, IS availability	Human	From the work of Jac Fitz-Enz (1994), Human Capital Intelligence sets of human capital indicators are collected and benchmarked against a database. Similar to HRCA (Johansson, 1996), which calculates the hidden impact of HR related costs that reduce a firm's profits.

measurements come out of the woodwork. Table 2 is a listing of various IC measurements compiled by Karl Erik Sveiby, one of the predominant academics in this field.

Edvinsson and Malone (1997) measure intellectual capital with an 'all-encompassing' reporting model. They assume that if enough aspects of intellectual capital can be captured, one can have a 'complete' understanding on the utilization. What is missing from their approach is an integrated framework to show how the indicators are related. This is where an approach such as Balanced Scorecard can be useful. However, Sveiby (1997) claims his Intangible Asset Monitor is a more suitable approach for Knowledge Management than Balanced Scorecard, based on its notion of a 'knowledge perspective' of a firm. Thus he believes his Intangible Asset Monitor becomes

Table 2. Types of intellectual capital measurement (Sveiby, 1997)

Authors	Name of Measurement	Description
Edvinsson and Malone (1997)	Skandia Navigator™	Intellectual capital is measured through the analysis of up to 164 metric measures (91 intellectually based and 73 traditional metrics) that cover five components: (1) financial; (2) customer; (3) process; (4) renewal and development; and (5) human.
Lev (2001)	Value Chain Scoreboard™	Matrix of non-financial indicators arranged into three categories according to the cycle of development: Discovery/Learning, Implementation, and Commercialization.
Roos, Roos, Dragonetti and Edvinsson (1997)	IC-Index™	Consolidates all individual indicators representing intellectual properties and components into a single index. Changes in the index are then related to changes in the firm's market valuation.
Pulic (2000)	Value Added Intellectual Coefficient (VAIC™)	Measures how much and how efficiently intellectual capital and capital employed create value based on the relationship to three major components: (1) capital employed; (2) human capital; and (3) structural capital.
Sveiby (1997)	Intangible Asset Monitor	Management selects indicators, based on the strategic objectives of the firm, to measure four major components of intangible assets: (1) growth; (2) renewal; (3) efficiency; and (4) stability.

a more demanding option for a management team; to get the best value, one should start by redesigning the strategy to be more 'knowledge focused'. Both approaches are fine for firms such as consulting houses and other service-oriented industries that focus on utilizing human capital. It is difficult to assume that other firms will have been converted enough to Knowledge Management to be knowledge-centric in their strategy. Therefore, we turn to our other suggestion, using a resource-based management approach.

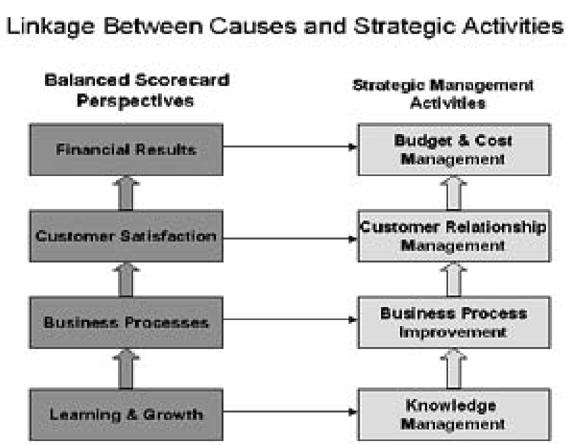
Second Approach. The other approach possible in viewing the role of Knowledge Management in organizational strategy via a Balanced Scorecard would be to use a resource management-based approach, focusing on intellectual capital resources combined with business processes of the organization. This is based on the work of Mouristen et al. (2001) at the Copenhagen Business School, using the work on intellectual capital balance statements of Sveiby (1997). Table 3 correlates this approach to the Balanced Scorecard perspectives of Kaplan and Norton (1992).

To tie the use of Knowledge Management into an organization, using either method, the relationship between Knowledge Management and organizational strategy must be understood and goals clearly defined. Figure 5 demonstrates the relationship between business processes in Balanced Scorecard terminology, and the use of Knowledge Management in an organization.

Table 3. Intellectual capital resources in a balanced scorecard approach

Balanced Scorecard Perspective	Generic measures	Intellectual Capital Statements (Mouristen et al., 2001)	Generic measures
Financial	ROI, EVA	Employees	Measurement of intellectual capital, as discussed above in Table 3.
Customer	Satisfaction, retention, market and account share	Customers	Customer satisfaction with 'quality of service' and product, related to Knowledge Management efforts
Internal	Quality, response time, cost and new product introductions	Processes	Internal hours on Knowledge Management process improvement, average response times for information gathered using Knowledge Management
Learning and Growth	Employee satisfaction, IS availability	Technology	Investment in Knowledge Management technology, number of hits on Knowledge Management project web sites, employee satisfaction with Knowledge Management project sites

Figure 5. Knowledge management linkage: Cause and activity



Correlating Knowledge Management Metrics to Strategy

Both of the suggested approaches above make use of such concepts as intellectual capital and the value of core processes in the organization. The rationale for this is that intellectual capital as a concept says more about the future earning capabilities of a company than any of the conventional performance measures we currently use (Roos, 1996). Kaplan and Norton (1996) discuss using Balanced Scorecard measures for assessing potential investment. In creating a mechanism that ties long-term objectives into measurable metrics, they claim that executives can see the relationship between investment and strategic plans. But should knowledge be considered a cost element, or a revenue generator? This is one challenge in using the Balanced Scorecard versus other mechanisms in industry. Until we view business processes in other ways than the traditional production function (input, output), approaches such as the Balanced Scorecard are still valid in the knowledge economy.

But there is also an element of debate of whether Balanced Scorecard mechanisms help promote the use of knowledge in organizations. Kaplan and Norton (1996) in their approach did not question the foundation of 'what constitutes a firm', but regard the notion of the firm as given by its strategy. They just want managers to take a more 'balanced view'. As they argue in their book (1996, p. 8): "The Balanced Scorecard complements financial measures of past performance with measures of the drivers of future performance. The objectives and the measures of the Scorecard are derived from an organization's vision and strategy." If Knowledge Management is not part of the firm's strategic view, then investment and management of intellectual assets will not take priority. Use of Knowledge Management requires firms to think about knowledge as a production element, but trends in Knowledge Management lead us to believe that knowledge will be viewed as a service economy, therefore with more intangible measurement. This is also true in the education field, where universities such as Manchester Metropolitan University's business school are examining how to measure their own use of Knowledge Management, and are exploring these two approaches discussed in the chapter as possible metric views.

Many corporations have not clearly articulated a need to manage knowledge. Of the 158 companies surveyed by the Conference Board (Beyond Knowledge Management: New Ways to Work and Learn, 2000), 80% had launched some kind of Knowledge Management activity, but only 15% had specific, stated Knowledge Management objectives and goals. Competitive necessity dictates that executives understand how Knowledge Management and knowledge sharing impact the bottom line, but many do not. KPMG Consulting reports that while most of those it surveyed understand that Knowledge Management can boost profits and reduce costs, less than 30% expected it to help increase their company's share price. The most important and useful metrics are those that directly inform the improvement of business performance and that can best be considered within the context of a learning process that embeds the metrics within the work process.

One Learning process, as an example, is that used by BP - Amoco (BP) as a central part of their Knowledge Management strategy — 'Learn Before, Learn During, Learn After'. Essentially BP - Amoco embeds Knowledge Management within the everyday work process by making it a normal part of doing business. At the beginning of any project they conduct a 'Peer Assist' (alternatively known as 'Prior Art'), where they get knowledgeable colleagues together to consider all that BP - Amoco knows about this particular subject. 'Learn During' involves a version of the US Army's well-known 'After Action Review' (AAR). BP - Amoco use the AAR after each 'identifiable event' rather than at the end of a project; thus it becomes a 'live' learning process that constantly informs the direction of the project. The third part is what BP - Amoco call a 'Retrospect', which is a team meeting designed to identify 'what went well', 'what could have gone better' and 'lessons for the future'.

By ensuring that time is made available within the actual project and that this learning process does not become extra work, BP - Amoco has managed to make it a normal part of doing business. The results have been real tangible business benefits visible in dollar terms that have turned around critics: "the Schiehallen oil field, a North Sea field considered too expensive to develop until a team spent six months pestering colleagues to share cost-saving tips. They were called wimps for not rushing out to 'make hole', but the learn-before-doing approach saved so much time on the platform (at $100,000 to $200,000 a day, not counting drilling costs) that they brought the field into production for $80 million less than anyone thought possible." Indeed, Tom Stewart recently stated about the CKO of BP: "Greenes is, as best I can figure, Knowledge Management's top moneymaker" (World Bank, 1999). This Learning Cycle then becomes the facilitating infrastructure for developing a process of Knowledge Management Metrics which allow the identification of real business value in each aspect of the necessary IT and other investments.

SUMMARY

Measurement has always been perceived as a science of precision; however, the measurement practice in most organizations today is anything but precise. Indeed, the issues looked for in scorecards, such as customer and employee satisfaction, and in intellectual capital, tend to require less precision and entertain more interest in trends than in exact figures. Kaplan and Norton's (1996) cause-and-effect hypothesis could be essential to understanding Knowledge Management metrics in a way that the Balanced Scorecard prescribes. Although the Balanced Scorecard can form the foundation for organizational strategic success, it is, however, not sufficient in itself. Along with strategies, there must be initiatives, such as business process improvement efforts, to steer the organization in the right direction and improve Knowledge Management implementation.

At the heart of an ideal definition of knowledge capital is the creation and provision of 'value'. Without linkage to strategic initiatives reflected through forms of measurement or recording of value, whether simply anecdotal or more quantifiable, Knowledge Management might degenerate into superficial business management hype. A conscious effort in conceptualizing, designing and putting to practice metrics like the ones described above may, however, assist in realizing the true worth of Knowledge Management.

As regards IT investment in particular, information technology may help growth and the retention of organizational knowledge if care is taken to continuously recall that IT is only a part; corporate culture and work practices being equally relevant to the whole. Information technologies best suited for this purpose should be expressly designed with Knowledge Management and organizational capital in view. Thus, while technology can support Knowledge Management, it is not the starting point of a Knowledge Management program.

Chapter 7.14
Knowledge Transfer Between Academia and Industry

Franz Hofer
Graz University of Technology, Austria

INTRODUCTION

Many policy makers and researchers consider knowledge transfer between academia and industry as one of the most promising measures to strengthen economic development. The idea of linking academia and industry is not new. Back in 1910 research universities were established, which strongly emphasized industry-related research as part of their activities and were funded by enterprises in order to tap this knowledge (see Matkin, 1990, for the history of technology transfer at four U.S. research universities—MIT, U.C. Berkeley, Penn State, and Stanford). Knowledge transfer has increased considerably during the last few decades. Many universities have established offices aimed at improving relations with industry. The performance of these offices varies considerably. One example for a quantitative performance indicator is license revenues of U.S. universities (Artley, Dobrauz, Plasonig, & Strasser, 2003). Only a handful of examined universities actually draw profit from it. The majority pay more for legal advice and fees than they earn from license income. It is obvious that the performance variances depend on many factors like staff resources at the transfer offices, type of university research (basic vs. applied, technical vs. non-technical domains), the brand of the university as well as prior industrial relationships, to name just a few. Not all of these factors can be changed in the short run, but knowing them and streamlining actions towards their improvement can lead to sustainable changes, in the end positively influencing economic performance. Despite the long history and recent efforts to improve university-industry collaborations, the full potential does not yet seem to be exploited (Starbuck, 2001). Jankowski (1999) and Clough (2003) confirm the decrease of federal funding for universities and point to increasing collaborations between academia and industry, which in their view comprises the danger of leaving fundamental frontier research, vital for breakthrough innovations, behind. At the same time, industry increasingly relies on external knowledge sources to keep up with the pace of their competitors (Business-Higher Education Forum, 2001; Tornatzky, 2000). In many cases, these external sources are customers and suppliers (Adametz & Ploder, 2003; Dachs, Ebersberger, & Pyka, 2004). This may be due to similar rationales, profit, and already-existing customer-client relationships. However, industry more and more turns to universities when looking for support. According to Godin and Gingras (2000), universities are still one of the major producers of knowledge, despite an increase of other R&D institutions. Collaborations between academia and industry bring partners with different competencies together and cover the whole range of the R&D chain, from basic research to application. By fulfilling the needs of both partners, universities as well as enterprises, and building up trust, knowledge transfer leads to knowledge flows and production of new knowledge, and thus creates a fertile environment for innovation. The article at hand examines motives as well as barriers related to knowledge transfer out of a systemic as well as a process-related view and provides some general suggestions for further improvements.

BACKGROUND

The earlier focus of knowledge transfer between academia and industry was on technology, in the sense of technological processes and artifacts inhibiting technological knowledge without paying much attention to the soft facts important for the success or failure of the transfer. Nowadays, technology transfer often comprises more than technological knowledge, including data as well as technology-related organizational knowledge (Abramson, Encarnacao, Reid, & Schmolch, 1997). As Schumpeter (1912) explained, technology is not exclusively the base of innovations. Using the term knowledge transfer instead of technology transfer reinforces Schumpeter's view of innovation, which additionally includes, for example, social innovations like new organizational structures or incentive systems (see Hofer, Adametz, & Holzer, 2004, for an example of a knowledge transfer program implemented by a university of technology in collaboration with a classical university). Knowledge transfer schemes range from regional programs and initiatives to national and international ones. Besides the different geographical focus, also the target group, at which knowledge transfer measures are aimed, can differ (broad approach vs. focus on specific industrial sectors). All these characteristics influence knowledge transfer at the operative level and require diverse additional partners and processes. Knowledge transfer between academia and industry as understood herein refers to activities, aimed at enabling and facilitating industry to tap knowledge produced at universities. The article examines knowledge transfer in general without limiting it to certain geographic borders. Knowledge transfer does not only comprise large collaborative R&D projects, but also measures like informal consulting as well as diploma theses commissioned by enterprises. The primary objective of knowledge transfer is to strengthen the competitiveness of both partners, leading in succession to improved economic development.

MAIN FOCUS OF THE ARTICLE

The article addresses regional as well as national governments trying to provide the right framework for parties involved in knowledge transfer—universities' managers, who would like to establish closer links with industry, as well as representatives of industry, who plan to or already use external knowledge sources like universities. The first part of this article deals with motives at different organizational levels of the parties directly involved; the second part discusses barriers negatively influencing knowledge transfer. The article concludes with some suggestions for future actions in order to amplify motives and overcome barriers, thus increasing the performance of knowledge transfer initiatives and programs.

What are the Driving Forces in Knowledge Transfer?

In order to improve knowledge transfer between academia and industry, it is not sufficient to examine solely existing barriers; one must also examine possible motives, as the driving power must be identified and intensified. This is not only important at the agency but also the individual level, where knowledge transfer ultimately takes place (Lipscomb & McEwan, 2001). The following comments are based on the results of a literature study performed for a paper presented at the 2004 Exploiting Change in the 21st Century international conference (Hofer, 2004). Motives for universities to get involved in knowledge transfer are mainly financial as well as legal ones. At many universities, the share of industrial funding already makes up a substantial part of the total budget. Without the financial commitment of industry, these universities would have to cut their expenses dramatically. The trend of increasing industrial funding of universities is likely to grow even more in the future, with governments stabilizing or even cutting resources and increasingly interdisciplinary R&D projects demanding researchers from various professional areas. But universities are involved not only for financial reasons, but also because they are legally bound to perform knowledge transfer with industry. For example, the Austrian Universitaetsgesetz 2002 [University Law 2002] lists "support to practically use and apply universities' R&D results" as one of the primary tasks of Austrian universities. Etzkowitz (2003) calls this additional task the third mission of universities besides doing research and educating students. Despite all perils like stronger emphasis on applied research, universities at the agency level are committed to perform knowledge transfer with industry and thus offering their knowledge. The commitment at the individual level does not always reflect this opinion. This is comprehensible if one considers that legal claims at this level do not exist as part of contracts between universities and their employees. Usually, there are no financial benefits, which recompense researchers for efforts to perform knowledge transfer with industry, except for researchers, whose jobs directly depend on external funds. Knowledge transfer does not seem to be perceived as important as other tasks (Kremic, 2003). If the researcher's employment does not depend directly on industrial funding, that person is free to decide whether or not and to which degree to get involved in knowledge transfer. Therefore the issue of what motivates researchers at universities to invest some of their time budget in projects with industrial partners is of particular interest. The majority of literature referred to in the following regards individuals in public laboratories. It is assumed that governmental scientists and their universities' counterparts are motivated by similar factors because of the similar framework such as public funding and similar kinds of R&D. Differently from their colleagues, university researchers must also teach their students, thus having even more time constraints. Studies performed by Large, Belinko, and Kalligatsi (2000), Schartinger, Schibany, and Gassler (2001), and Spivey, Munson, and Flannery (1994) identified personal interest and satisfaction as the primary motives of researchers to deal with industry. They do not seem to be motivated by extrinsic factors like additional income. Frey and Osterloh (2000) describe researchers as people typically motivated by intrinsic motives, which additionally confirms the results of the various studies. The main objective of private industries is to make profits, to be profitable for their owners, and to be a better investment than other corporations (Kremic, 2003). Industry collaborates with universities because it promises to be profitable. However, large-scale enterprises (e.g., in the life science industry) in some cases are funding blue-sky research at universities; they do not do it for the sake of basic research, but because this gives them the right to be first to exploit possible inventions and to recruit high potentials before others get a hold of them. Challenges like fast and highly specialized knowledge production, shorter product lifecycle due to increasing share of data as part of products, and increased marketing of universities, which present themselves as R&D partners of industry, push enterprises to get involved in knowledge transfer activities.

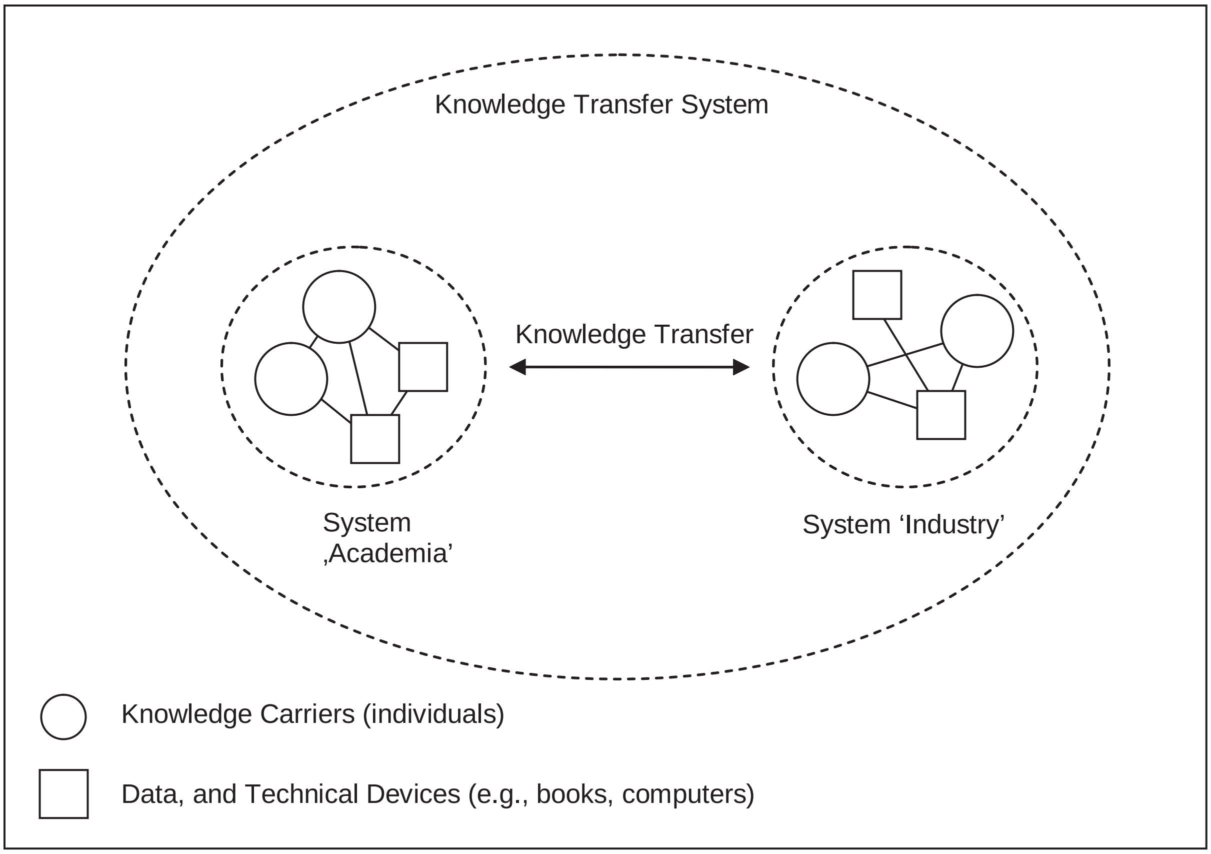
Large et al. (2000) identified various motives of individuals at enterprises for collaborating with public laboratories. The first three motives for enterprises' individuals are: (1) expected technical benefits for the end user, (2) expected proprietary knowledge for the manufacturer, and (3) expected financial benefits for the manufacturer. The comparison with the motives identified for scientists reveals a stronger profit-orientation on the part of the manufacturers. Kremic (2003), who points to the strong link between enterprises' performance and employment, also supports this view.

What are the Forces Hindering Involvement in Knowledge Transfer?

Motives are one side of the coin, but knowing what hinders industry and academia to transfer knowledge mutually is equally important in order to design holistic approaches. The following section will systematically examine barriers and suggest efforts to overcome them by providing suitable measures. The first part focuses on barriers deduced with the aid of system theory. The second part examines process-based barriers. The two directly involved parties here are universities and industry. As socio-technological systems, they consist of various elements: individuals as carriers of knowledge; data in the form of, for example, publications or entries in databases; and technical devices supporting information and documentation processes as well as data exchange. Links connect the elements of both systems, whereby these relations are not necessarily physical ones.

The knowledge transfer system displayed in Figure 1 shows the two primary parties: academia and industry. This form of knowledge transfer takes place directly between universities and industry. Reinhard (2001) lists four types of barriers, which apply to the systemic view and can equally apply to both parties: (1) not knowing each other, (2) not being allowed to work with each other, (3) not wanting to work with each other, and (4) not being able to work with each other. High search costs limit the possibilities on both sides to look for suitable partners (Beise & Spielkamp, 1996). The use of the Internet can actually help to limit such costs (Czarnitzki & Rammer, 2003), but especially for risky projects with insecure outcomes, it cannot replace prior hands-on experience. Additional barriers, which are part of the prior classification, are different organizational structures and objectives, prior or current projects of the university with enterprises' competitors, lack of motivation, or low qualification, which negatively influences the absorption capability (Reinhard, 2001). The fifth barrier identified from the systemic view stems from the characteristics of knowledge. Unlike products, which can be rather easily priced and tested, knowledge is characterized as an experience good (Watanabe, Yoneyama, Senoo, Fukushima, & Senoh, 2004). This makes it difficult for industry in an early stage to identify suitable knowledge sources. To some extent the identified barriers differ, taking

Figure 1. Knowledge transfer system—the system consists of two sub-systems, academia and industry, with various elements, which are linked with each other. Knowledge transfer takes place on an inter-organizational level between the two sub-systems.



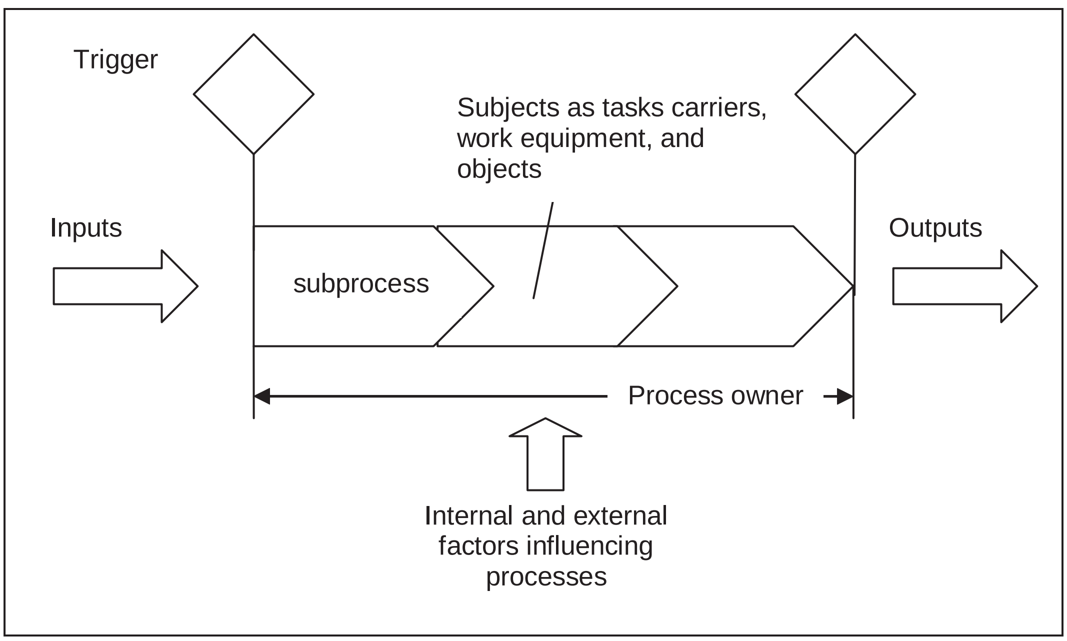
into account various geographic extensions. For example, the characteristics of knowledge will always remain the same, but enabling extensive face-to-face communication facilitates the decision on both sides whether collaboration could be fruitful or not. The following process-related view complements the systemic view and reveals additional barriers hindering the full exploitation of knowledge transfer. Although the whole range of knowledge transfer measures requires different processes (Pries & Guild, 2004), the following examination focuses on a general process definition, which should make it possible to apply the results to specific knowledge transfer processes. Processes are defined as a sum of various activities with a defined beginning and end which transform and/or transport objects (physical ones or data) following defined rules. They are logical, spatial, and chronological chains of activities (Remus & Schub, 2003; Schwickert & Fischer, 1996). The main reason to introduce process management is to overcome intra- and/or inter-organizational functional barriers, thus reducing 'frictional losses' and improving the quality of outcome.

Knowledge transfer processes can be divided into two major types: (1) looking for external knowledge, and (2) offering internal knowledge. If in need of external knowledge, sub-processes look like this: (a1) identifying missing knowledge, which at the same time demands the identification of the internal knowledge stock; (b1) identifying possible knowledge providers; and (c1) balancing knowledge needs and offers. Sub-processes for knowledge providers are: (a2) identifying the internal knowledge stock; (b2) identifying possible knowledge customers, which look for this kind of knowledge; and (c2) balancing knowledge needs and offers. The sub-processes at this level are the same, only the order is different. Hence, knowledge transfer processes have an intra- as well as inter-organizational dimension. Therefore, it is not sufficient to optimize processes solely at the interface of universities and industry. Additionally, internal processes like brokering of external enquiries and responsibilities for processes have to be taken into account. Some of the properties—like subjects, inputs, outputs, and internal and external factors influencing the process—are closely connected with the barriers identified above. Additional barriers identified with the help of the process-related view are associated to the trigger and process owner. Knowledge transfer processes between academia and industry can be triggered either by enquiries from industry or by universities (e.g., promoting proactive support services). Besides these physical triggers, other processes can also act as starting point; for example, successful R&D projects can automatically lead to defined knowledge transfer processes. In the past, industry often acted as a trigger and knocked at the ivory tower for support, but due to environmental changes like decreasing public funding, universities are more actively looking for contacts with industry. It is necessary for a holistic knowledge transfer approach to consider different forms of triggers and design the processes accordingly. Another important action to remove barriers is the unmistakable assignment of process owners. They are responsible for their processes, ranging from initial enquiries to the delivery of the outcome to the customer. This is especially important in the beginning of potential collaborations, in the idea or pre-project phase, where industry usually evaluates different collaboration partners. Due to the involvement of intermediaries, who are usually not the professionals (the ones actually performing the collaborative research project), handing over responsibility to the professionals at the right moment is critically important for further collaborations. If this happens too early, it could lead to unnecessary delays and misunderstandings. If it happens too late, both partners, academia and industry, perceive intermediaries as unnecessary bureaucratic entities slowing down the project advancement.

DIRECTIONS FOR FURTHER IMPROVEMENTS OF KNOWLEDGE TRANSFER ACTIVITIES

Simultaneously increasing motives and lowering barriers should help to further improve the accessibility of research institutions like universities to industry and thus promote economic development. The benefits for universities at the agency level are quite clear, but knowledge transfer ultimately depends on individuals. Especially, intrinsic motives like satisfaction and personal interest seem to play a major role for researchers (Frey & Osterloh, 2000; Large et al., 2000; Schartinger et al., 2001; Spivey et al., 1994). The motives for industry to use academic knowledge at the agency level are mainly profit driven, because of the close link between fulfilling the requirements of the employers and employment; this motive is likely to be valid also for individual employees in industry. Specifically, relations between universities' researchers and small and medium-sized enterprises seem to have potential for further improvements. Small and medium-sized enterprises typically lack strategic tools. Therefore, they usually concentrate on short-term projects and as a result on short-term profit. This limits the possibility to exploit knowledge transfer with academia, and in succession leads to a perceived low value of universities' research. The main barriers identified relate to: (1) not knowing each other, (2) not being allowed to work with each other, (3) not wanting to work with each other, (4) not being able to work with each other, (5) characteristics of knowledge, (6) not considering different forms of triggers, and (7) unclear assignment of process owners. Some of the barriers can be lowered or even eliminated by universities and industry on their own; others require additional support by, for example, intermediaries, governments, or funding agencies. The barriers given in the systemic view make it clear that a mix of different partners can greatly enhance knowledge transfer. The support by funding agencies as well as governments can play a vital role. The task of intermediaries is to bridge the gap between universities and industry. They can offer support services that are out of reach for research departments at universities because of time restraints. Funding agencies as well as funding programs introduced by governments can support the upgrading of industry's absorption capabilities, an important requirement for successful collaborations with external partners like universities. Setting up suitable processes, which consider barriers related to the different possible forms of triggers and clear assignments of process owners, are tasks of the involved institutions. The

Figure 2. Processes' properties—the process-related view enables the identification of further barriers using the properties that characterize processes.



more partners, the more complex are such tasks. However, as already mentioned earlier, only collaboration between complementary partners can provide the necessary critical mass to lower some of the barriers. Thus it is important to consider which institutions should be involved in knowledge transfer programs in order to facilitate such activities. Above all, changing external factors is a task that ultimately requires the support of local, regional, and national governments. The main results show the necessity of: (1) deciding at whom the knowledge transfer activities should be aimed, (2) the integration of additional partners besides universities and industry, and (3) arranging effective processes to eliminate barriers and increase motivation.

FUTURE TRENDS

Trends like growing global competition and rapidly changing environment put pressure on industry as well as academia. They have to establish and deepen their contacts with each other in order to keep up front. Therefore, knowledge transfer between academia and industry will increase in importance, and the winners will be the ones who fully understand how to utilize such activities. Traditional boundaries between institutions like universities, industry, and governments will be blurred further, thus following the idea of Etzkowitz and Leydesdorff (1995) which promotes close collaborations between universities, industry, and governments—the so-called triple-helix model.

CONCLUSION

Building on the framework provided here, the key for successful knowledge transfer activities lies in the following three key measures: (1) knowing the target group, (2) integrating all necessary parties, and (3) setting up the right processes. This requires the commitment and efforts of all involved parties. Despite global markets, regions still play important roles with respect to knowledge transfer, which includes amongst others tacit knowledge, learning, and innovation (Morgan, 2001). Therefore, establishing and enhancing regional initiatives and programs aimed at bringing academia and industry together could form the central part of regional economic development efforts and act as a springboard for national and international knowledge transfer measures. Through increasing intra-regional knowledge transfer, the collaboration capabilities of all involved parties will increase and thus make regions ready for other advanced measures.

INTRODUCTION

As the world is getting more and more technology savvy, the collection and distribution of information and knowledge need special attention. Progress has been made on the languages and tools needed for effective knowledge management and on the legal issues concerning the consumption and dissemination of critical knowledge. From a business perspective, a knowledge-management system (KMS) within a firm generally strives to maximize the human-capital utilization and profitability of the firm. However, security is becoming a major issue revolving around KMS; for instance, the KMS must incorporate adequate security features to prevent any unauthorized access or unauthorized dissemination of information. Acquiring the information that one needs to remain competitive while safeguarding the information one already has is a complicated task. Firms must balance the advantages of openness against its inevitable risks, and maximize the efficiency of electronic communication without making it a magnet for intruders. One must integrate offense and defense into a comprehensive strategy, and scholars have suggested that it is time to integrate intelligence and security imperatives with other knowledge-management strategies and processes (Barth, 2001).

Since the widely reported attacks on knowledge repositories in 2001 (e.g., Amazon was hit by denial-of-service attacks and the NIMDA virus hit financial markets), many organizations, especially the U.S. government, have increased their concern about KMSs. With the advent of intranets and Web access, it is even more crucial to protect critical corporate knowledge as numerous individuals now have access to the assets of a corporation. Therefore, we need effective mechanisms for securing data, information, and knowledge as well as the applications (Thuraisingham, 2003, 2004).

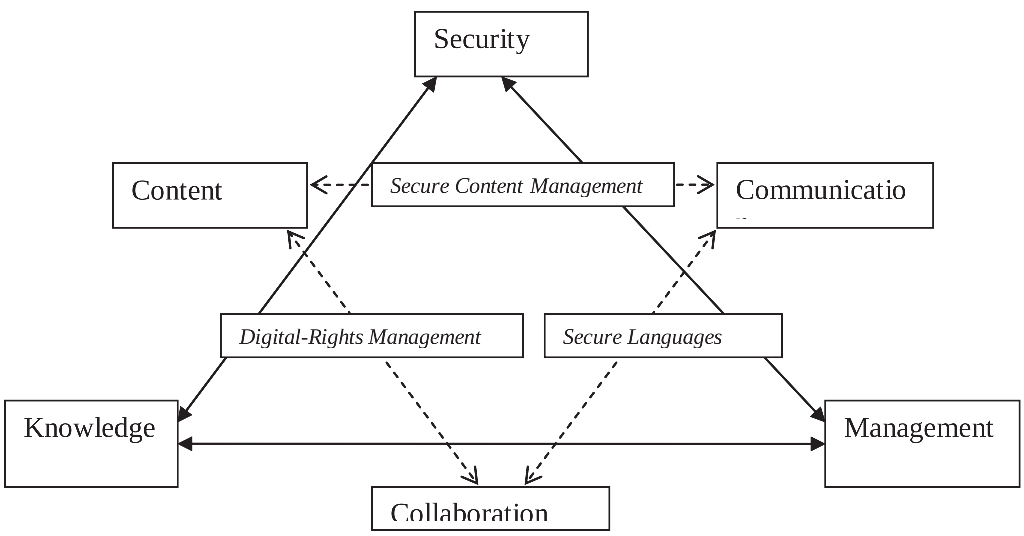
Security methods for knowledge-management systems may include authentication or passwords, cryptography programs, intrusion-detection systems, or access-control systems. Issues include insider threat (protecting from malicious insiders), infrastructure protection (securing against subversion attacks), and establishing correct policies, refinement, and enforcement. KMS content is much more sensitive than raw data stored in databases, and issues of privacy also become important (Thuraisingham, Chadwick, Olivier, Samarati, & Sharpston, 2002).

Asllani and Luthans (2003) surveyed over 300 knowledge managers about their job roles and found little or no evidence of security issues being considered in their jobs; their primary role was focused on communication within the organization. This article about secure knowledge management raises a number of issues in this critical area of research that need to be tackled by knowledge-management practitioners. The following sections focus on three important aspects of secure knowledge management: secure languages, digital-rights management (DRM), and secure content management (SCM).

BACKGROUND

A firm exists as a repository of knowledge over time (Zander & Kogut, 1995). Knowledge management is the methodology for systematically

Figure 1. A framework for secure knowledge-management systems



gathering, organizing, and disseminating information (Morey, Maybury, & Thuraisingham, 2003) in a firm. It essentially consists of processes and tools to effectively capture and share data, as well as use the knowledge of individuals within a firm. Knowledge management is about sharing information more freely such that firms derive benefit from such openness.

Secure knowledge-management (SKM) systems can be described in terms of the three Cs: communication, collaboration, and content. SKM systems act as a gateway to the repository of intellectual content that resides within an organization. SKM systems need to source and/or provide access to knowledge that resides in multiple machines across an organization or multiple organizations for collaborative efforts. Secure languages are utilized to transfer information safely. At the same time, digital-rights management becomes critical in cross-organizational transfers of knowledge, while access control and identity management play an important role in securing the knowledge-management system. A framework for secure knowledge management is shown in Figure 1 as two interlinked, triangular chains: The larger chain focuses on security, knowledge, and management, while the smaller triangular chain (with dotted links) focuses on content, communication, and collaboration. Different aspects within the smaller chain include secure content management, digital-rights management, and secure languages. This article focuses on the interarticulation of the different concepts in the triangles.

SECURE LANGUAGES

In order to communicate securely and collaborate with one another, organizations need to use secure languages. These languages can be implemented to enhance the security of knowledge-management systems. Some of these are detailed in the following sections.

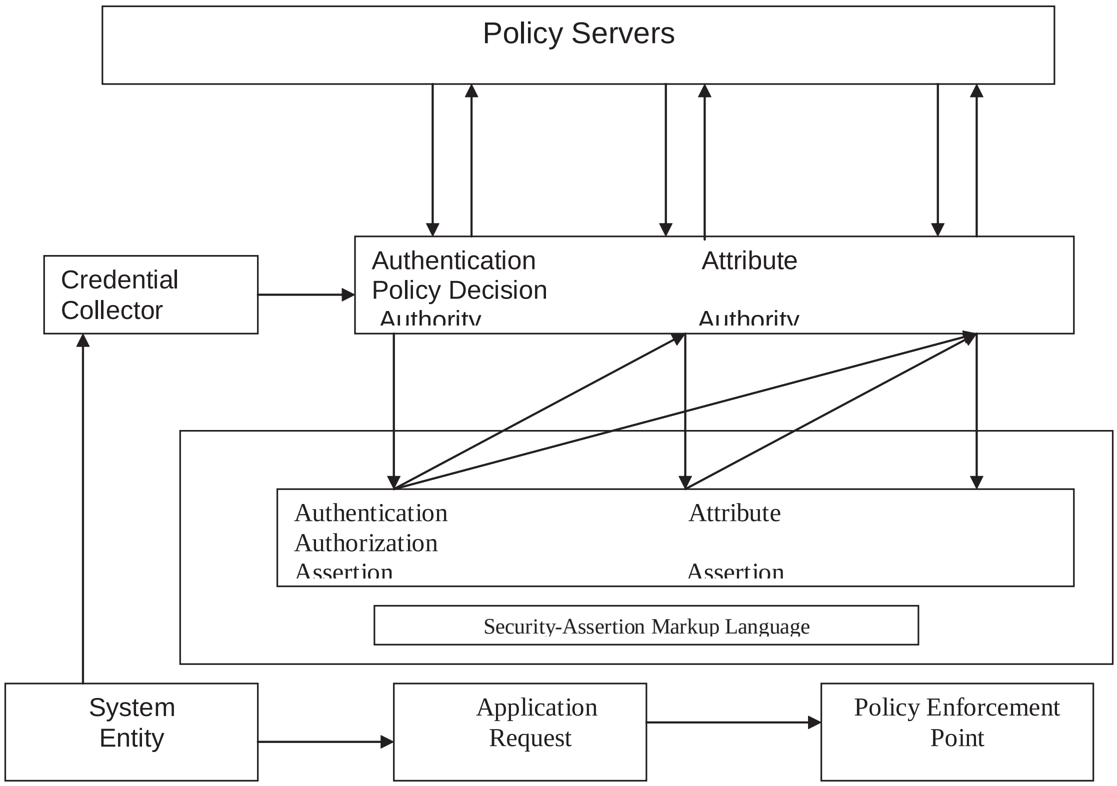
Security-Assertion Markup Language

The security-assertion markup language (SAML) can secure the KMS from insider or outsider threat by managing access control and identity. SAML is an extensible-markup-language- (XML) based framework (Cohen, 2003) for exchanging security information. In SAML, the expression of security is in the form of assertions about subjects. Most other security approaches use a central authority to authenticate the identity or the data. However, SAML does not use a central authority that authenticates the identity; it is up to the receiving application to accept if it trusts the assertion. The security-assertion markup domain model is depicted in Figure 2.

SAML shows how to represent users, identifies what data need to be transferred, and defines the process for sending and receiving authorization data (Cohen, 2003). SAML also has extensive applications in automated business-to-business (B2B) transactions that require secure transactions between the two parties. The increased collaboration among the various businesses has necessitated the need for such a technology (Patrizio, 2003). A case in point is that of Southwest Airlines (Wagner & Witty, 2003)—one of the first to use SAML-enabled identity management on a large scale to perform cross-domain trust. This implementation also marks an early step in the movement toward federated identity management.

SAML does not provide a complete security solution, but it does provide the identity-management functionality. In addition, it provides password management and access control, and a framework for implementing the "single sign-on" mechanism where authentication needs to be shared across multiple systems. Single sign-on becomes an absolute necessity when implementing complex KMSs that need to source or access data from multiple machines.

Figure 2. Security-assertion markup model



(Adapted from http://www.fawcette.com/xmlmag/2002_03/magazine/departments/marketscan/SAML/)

A number of commercial and open-source products provide SAML, including the following:

- Entegrity Solutions AssureAccess (http://www.entegrity.com/products/aa/aa.shtml)
- Internet2 OpenSAML (http://www.opensaml.org/)
- Netegrity SiteMinder (http://h71028.www7.hp.com/enterprise/cache/8258-0-0-225-121.aspx)
- RSA Security ClearTrust (http://www.rsasecurity.com/node.asp?id=1186)
- VeriSign Trust Integration Toolkit (http://www.xmltrustcenter.org/developer/verisign/tsik/download.htm)

Secure Knowledge-Query and Manipulation Language

KQML or the knowledge-query and -manipulation language is a language for exchanging information and knowledge. KQML focuses on an extensible set of performatives that defines the permissible operations that agents may attempt on each other's knowledge and goal stores. The performatives comprise a layer on which to develop higher level models of interagent interaction such as contract nets and negotiation. In addition, KQML provides a basic architecture for knowledge sharing through a special class of agents called communication facilitators, which coordinate the interactions of other agents. The ideas that underlie the evolving design of KQML are currently being explored through experimental prototype systems that are being used to support several test beds in such areas as concurrent engineering, intelligent design, and intelligent planning and scheduling (Lebrou, Finin, Sherman, & Rabi, 1997).

An extension of KQML is secure KQML, which is being developed to take into account security and privacy concerns that agents could encounter whenever they cross multiple administrative domains. Since traditional agent communication-language standards lack the necessary constructs that enable secure cooperation among software agents, SKQML enables KQML-speaking agents to authenticate one another, implement specific security policies based on authorization schemes, and, whenever needed, ensure the privacy of the messages exchanged. SKQML employs public-key cryptographic standards and it provides security mechanisms as an integral part of the communication language. In summary, SKQML incorporates a synthesis of public-key certificate standards and agent communication languages to achieve an infrastructure that meets the security needs of cooperating agents.

B2B Circles of Trust

As can be seen from the discussion above, while the secure languages do allow secure communication to an extent, they are not complete solutions. An alternate mechanism for enhancing secure communication and collaboration across organizations in the knowledge-management environment has been termed "circles of trust."

Circles of trust involve two or more organizations sharing supplier or customer authentication information among themselves via a common interface or single sign-on capability. XML provides the basis for operating circles of trust (Varney, 2003).

One of the premier organizations espousing the concept of circles of trust is the Liberty Alliance—a consortium of more than 150 organizations working worldwide to create open, technical specifications for federated network identity. The alliance outlines the specifications for simplified sign-on capabilities using federated network-identity architecture. Permission-based attribute sharing is utilized to enable organizations to provide users with choice and control over the use and disclosure of personal information. A commonly accepted platform and mechanism for building and managing identity-based Web services is based on open industry standards. The Liberty Alliance specification addresses privacy and security concerns, and enables the participating organization to build more secure, privacy–friendly identity-based services that can comply with local regulations and create a trusted relationship with customers and partners (Varney, 2003).

DIGITAL-RIGHTS MANAGEMENT

The confluence of content and collaboration across organizations has brought up the concept of digital-rights management. DRM has traditionally focused on security and encryption to alleviate copyright-infringement and unauthorized-use problems. In order to do so, DRM techniques have implemented a mechanism to lock content and limit distribution to subscribed customers. Current DRM solutions include the description, identification, trading, protection, monitoring, and tracking of all forms of rights usages over both tangible and intangible assets including the management of rights holders' relationships (Iannella, 2001).

DRM systems are supposed to serve markets in which the participants have conflicting goals and cannot be fully trusted, yet need to collaborate and share knowledge content with each other. This adversarial situation introduces interesting new twists on classical problems studied in cryptology and security research, such as key management and access control (Feigenbaum, Freedman, Sander, & Shostack, 2002). Furthermore, novel business models and applications often require novel security mechanisms. Recent research has also proposed new primitives for DRM that make it possible to identify content in an adversarial setting.

Functional Architecture

The overall DRM framework suited to building digital-rights-enabled systems is illustrated in Figure 3. The functional architecture stipulates the roles and behavior of a number of cooperating and interoperating modules under the three areas of intellectual property (IP): asset creation, management, and usage (Figure 3).

The concept of intellectual-property asset creation and capture refers to the key question of how to manage the creation of content so it can be easily traded. This includes asserting rights when content is first created (or reused and extended with appropriate rights to do so) by various content creators or providers. The IP asset-creation and -capture module supports (a) rights validation to ensure that content being created from existing content includes the rights to do so, (b) rights creation to allow rights to be assigned to new content, such as specifying the rights owners and allowable usage permissions, and (c) a rights workflow to allow for content to be processed through a series of work-flow steps for review and/or approval of rights (and content).

IP asset management involves the management and enabling of the trade of content. This includes accepting content from creators into an asset-management system. The trading systems need to manage the descriptive metadata and rights metadata (e.g., parties, usages, payments, etc.).

The IP asset-management module supports repository functions to enable the access or retrieval of content in potentially distributed databases and the access or retrieval of metadata. The metadata cover information regarding parties, rights, and descriptions of the work. The module also supports trading functions that enable the assignment of licenses to parties who have traded agreements for rights over content, including payments from licensees to rights holders (e.g., royalty payments). In some cases, the content may need to go through fulfillment operations to satisfy the license agreement. For example, the content may be encrypted, protected, or packaged for a particular type of desktop usage environment.

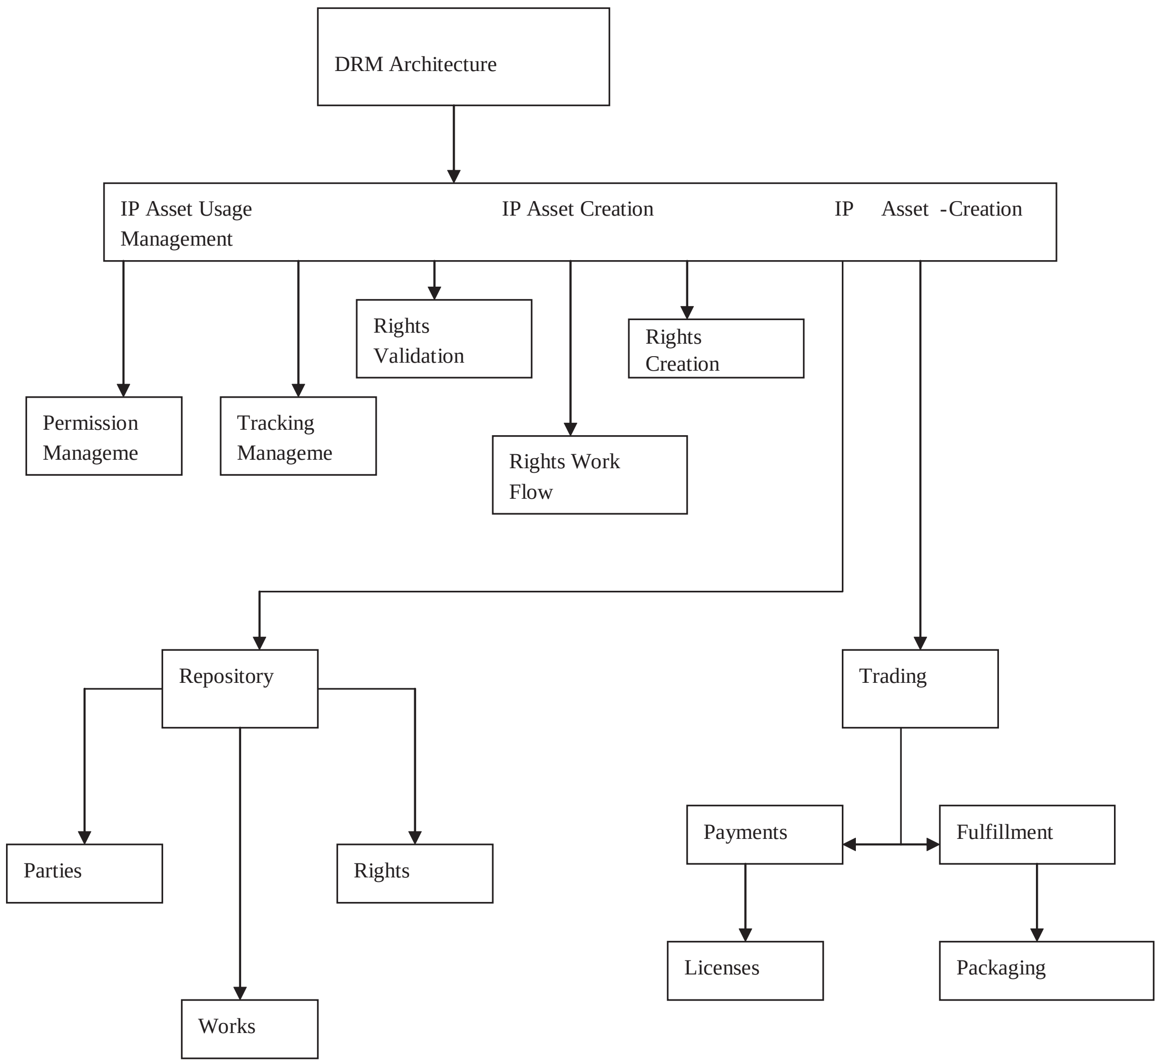
Once the IP asset has been traded, this module focuses on how to manage the usage of content. This includes supporting constraints over traded content in specific desktop systems or software.

The IP asset-usage module supports permissions management to enable the usage environment to honor the rights associated with the content. For example, if the user only has the right to view the document, then printing will not be allowed. It also allows tracking management to enable the monitoring of the usage of content where such tracking is part of the agreed-to license conditions (e.g., the user has a license to play a video 10 times; Iannella, 2001).

SECURE CONTENT MANAGEMENT

The final link in the secure knowledge-management chain is the one that links content and com-

Figure 3. Digital-rights-management architecture



munication, that is, secure content management. The Internet is a tremendous tool for enterprises to share intellectual property with customers, partners, and suppliers. It is an instant distribution network any corporation can use to improve communications while lowering operating costs (Ogren, 2003). The Yankee Group estimates that the market for secure content-delivery products and services amounted to $302 million in 2002 and will grow to $580 million by 2007. It is widely believed that more destructive and harder-to-detect threats, spam, legal liability, employee productivity, and compliance with privacy regulations will continue to fuel the growth of the secure content-management market over the next several years (http://www.csoonline.com/analyst/report1490.html).

The Internet, instant messaging, and the availability of Web content have transformed everyday business activities (Robb, 2003). As a result, CIOs (chief information officers) and IT management are increasingly looking for solutions to help enforce corporate policy, comply with privacy regulations, limit legal liability, increase employee productivity, and reduce network bandwidth consumption. All this is made possible by secure content-management solutions.

Secure content-management tools help to correctly label business-related content. The first generation of SCM products is now beginning to appear on the market. Generally, they consist of the following features: antivirus capabilities, proactive identification to block only malicious code, smart filtering of spam and URLs (uniform resource locators), keyword identification to safeguard against the transmission of proprietary and confidential information via e-mail, and centralized management of all facets to bring simplicity to the task of security administration (Robb, 2003).

Secure Content Delivery

With the advent of the Internet, content that enterprises once closely guarded in private databases is now being placed on the Internet to save distribution costs throughout the supply chain and to increase customer satisfaction. A Web initiative can take multiple forms: for example, an employee portal or Web-enabled self-service partner extranet. Each such initiative involves delivering business value. The Web has been instrumental in expanding communication channels and providing endless opportunities. Globalization has led to increased collaboration among trading partners that require the sharing of confidential information. The quest for cost-effective solutions for secure content delivery is intense since it must not only ensure the privacy of the electronic customers, but also reliably deliver important information only to designated recipients.

The trend has been to centralize identity management and documents in secure server repositories and portals accessed by browsers, and to avoid the complexities of client-side software installations. Content in transit has traditionally been protected by secure-sockets-layer (SSL) communications for browsers, and virtual private networks (VPNs) for application access, encrypted e-mail, and proprietary application solutions.

CONCLUSION

We are moving into a knowledge-based economy in the 21st century. Knowledge-based assets are gaining in importance, and it is becoming extremely important to protect these assets. In the area of national security, the knowledge that must be shared comes from many fields including homeland-defense activities, tactical intelligence missions, diplomatic channels, and direct military support. A range of KMS approaches and technologies and their security features need to be examined to enable critical intelligence gathering. Critical issues in secure knowledge management include content, communication, and collaboration. In this context, SAML, SKQML, circles of trust, DRM, secure content management, and secure content-delivery mechanisms would ensure the security and privacy of knowledge repositories.

Chapter 7.16
Secure Knowledge Discovery in Databases

Rick L. Wilson

Mohammad Saad Al-Ahmadi
Oklahoma State University, USA

INTRODUCTION AND BACKGROUND

Knowledge management (KM) systems are quite diverse, but all provide increased access to organizational knowledge, which helps the enterprise to be more connected, agile, and effective. The dilemma faced when using a KM system is to balance the goal of being knowledge-enabled while being knowledge-secure (Cohen, 2003; Lee & Rosenbaum, 2003).

A recent survey of IT security professions found that over 50% of respondents indicated an increase in the security budgets of their organizations since September 11, 2001, and projected that 2004 IT security budgets would be larger than ever (Briney & Prince, 2003).

The need for increased security is driven by both monetary concerns and legal/regulatory requirements. The goal of any security architecture, and specifically for KM systems, is to reduce the potential loss caused by intrusion, system misuse, privilege abuse, tampering, and so forth. Protection must be provided against external threats and from internal abuse and must include components that address the requirements for preserving the confidentiality of data where appropriate.

A 2002 Jupiter Research Consumer Survey estimates that as much as $24.5 billion in online sales will be lost by 2006 due to consumers' lack of confidence in the privacy of online transactions (E-Compliance Advisor, 2002). While lack of trust is an opportunity cost, security breaches can causes real losses. One study found firms with publicly announced security breaches lose an average of 2% of market capitalization within two days of attack, for an average of $1.65 billion dollars per breach (Cavusoglu, Mishra, & Raghunathan, 2002). On the regulatory side, legislation like the Health Insurance Portability & Accountability Act (HIPAA) and the Gramm-Leach-Bliley Act (GLBA) have forced companies in health care and financial services fields to improve their security measures (Briney & Prince, 2003; Ingrian Networks, 2004). Table 1 summarizes some common security threats.

While most of the major news stories about security breaches involve hackers who steal or access confidential information, infect systems with viruses, and cause trouble with worms or spam, an equally important threat comes from inside organizations. A report from Ingrian Networks (2004) indicated that 50% of security breaches are perpetrated by internal staff (see Lee & Rosenbaum, 2004). Internal threats represent a bigger risk than those from outsiders due to the difficulty in quantifying and counteracting the attacks. But while the risk of insider intrusions

Table 1. Security threats

Information Source	Ingrian, 2004	Briney, 2000	Boren, 2003
General	Poor security policies, human error, dishonesty, abuse of privileges, introduction of unauthorized software	Viruses, malicious code, executables, electronic theft, disclosure of proprietary data, use of resources for illegal / illicit activities	Storage threats: theft of servers, desktops, hard drives, tape backups, information, malicious software installed on server
Identification / Authorization	Internal / external attackers posing as valid users / customers		
Reliability of Service	Natural disasters, equipment failures, denial of service	Denial of service, buffer overflows	
Privacy	Eavesdropping, unauthorized monitoring of sensitive data		
Integrity / Accuracy	Modification or damaging of information		
Access Control	Password cracking, backdoors, security holes	Protocol weakness, insecure passwords, attacks on bugs in servers	Authentication credentials stolen / not properly managed, users given access to unnecessary information

Table 2. Selected security measures

Security Policies / Security Education Programs	X	X	X
Identification/ Classification of Sensitive Data	X		
Determination of acceptable threat level	X		X
Passwords	X	X	X
Firewalls	X	X	X
Encryption	X	X	X
Backup / Recovery	X		X

looms large, many IT security professionals still seem to be externally focused (Briney & Prince, 2003).

With the increased focus on security, both internally and externally, a method that seems to be gaining popularity is a layered security approach (e.g., Kolluru & Meredith, 2001; Clark, Croson, & Schiano, 2001). The layered approach proposes using multiple, overlapping forms of security measures. A representative list of such security measures is summarized in Table 2. The layered security approach is a good way to prevent breaches, because if one measure fails, it is possible that other measures employed can stop the attack.

While many network security texts discuss network related hardware and software that are relevant for protecting the IT and KM system infrastructure (e.g., Panko, 2004) from external threats, this article illustrates a complimentary approach. Data perturbation focuses on protecting confidential data primarily from unauthorized internal data snoopers. This approach can be used alone or in conjunction with other methods.

Data perturbation involves modifying confidential attributes using random noise, with the objective being to prevent disclosure while maximizing access to accurate information (Muralidhar, Parsa, & Sarathy, 1999). Thus, a KM system can maintain and allow access to masked representative confidential data while preventing exact data disclosure.

To illustrate the different ways that perturbation techniques can be utilized, consider an example scenario where two divisions of a company are sharing information, some of which is considered confidential, and the sharing of data is done electronically. A layered approach to security would be the use of both data perturbation and encryption to secure the data. Data perturbation can be done before the transfer to mask or hide confidential attributes. During the transfer of data, encryption can be used to prevent attackers from accessing the data. By using the layered approach, the sending division protects its confidential data, obtains security during the transfer, and gives the receiving division full access to the perturbed data on the back end.

Data perturbation also can be used as a stand-alone technique to prevent unauthorized access from snoopers and hackers. If the data that users have access to is masked, then the impact of either an internal or external security breach is minimized. All attributes that are confidential (and numerical) can be masked, so their true values are hidden. In this way, even if there is a breach of security, no confidential information will be exposed.

Of all the different hardware and software security measures that are well documented for use in all information systems, data perturbation techniques are uniquely equipped to be one of the most useful and specifically applicable security techniques for knowledge management systems due to their focus on the data (and, therefore, on knowledge contained in the data). Thus, understanding how such perturbation techniques work and the implications on knowledge workers in the organization is extraordinarily applicable and very important for today's knowledge worker. Since this area is relatively new, organizations that learn about perturbation could gain considerably from increased protection of confidential data. Thus, the article's focus on perturbation techniques, rather than a general discussion of all possible (well-documented) hardware and software techniques that "might" be applicable to KM, is definitely warranted.

SECURITY AND ACCURACY USING DATA PERTURBATION

Data Perturbation Techniques

Database, security, and KM administrators face a problematic balancing act regarding access to shared organizational data. Confidentiality might be a requirement for some data elements due to legal or competitive reasons, but using KM tools (such as data mining and knowledge discovery algorithms) to find patterns in data can lead to increased profits or improved processes for the organization. Thus, limiting access to data will hamper these important organizational efforts. Nonetheless, the need to protect individual confidential data elements in databases from improper disclosure is critical.

Data perturbation techniques are sophisticated, yet easily implemented, statistically based methods that protect confidential data by adding random noise to original data values. These approaches prevent exact disclosure of confidential data, add a degree of inferential security, and, most importantly from a KM perspective, allow complete data access and analysis flexibility. This flexibility provides significant benefits to the organization using the database in their KM activities. These techniques mask individual confidential data elements while maintaining underlying aggregate relationships of the database.

Note that these techniques are not encryption techniques, where the data is modified, transmitted, and then returned back to its original form. Once data is perturbed, it stays (and is accessed) in its perturbed form.

The Generalized Additive Perturbation Process (GADP) has emerged as the de facto standard in the data protection research area. Thus, we focus on it exclusively. Past studies have shown that today it is the best way to protect confidential data in this manner. No doubt, future research will find additional techniques that will improve upon GADP. But for now, it serves as the most appropriate example.

GADP possesses no statistical biases and preserves statistical relationships in a dataset (Sarathy & Muralidhar, 2002). The GADP process is briefly explained next, and Table 3 compliments the discussion by showing the differences between a dataset with confidential attributes and its perturbed compliment.

In a database, the confidential attributes that data administrators want hidden will be called set X, and all other non-confidential attributes set S. A database U has i instances with attributes

Table 3. GADP method details

Original Data Set				Perturbed Data Set		
Confidential Attributes	Non-Confidential Attributes	Class Variable		Confidential Attributes	Non-Confidential Attributes	Class Variable
Original values	Original values	Original values		Values are perturbed (masked) here	Same as original values	Same as original values

Mean (x)
COV (xx)

Mean (x)
COV (xx)

Statistical relationships unchanged

X+S. The GADP process creates a perturbed database P, based on U, also with i instances and attributes X+S.

For all attributes in S, the attribute value for instance i in database P will equal the corresponding value of that instance. Thus, GADP does not alter non-confidential attributes. However, for all X, the attribute values for instance i in database P will be perturbed, making it different from the value in the corresponding instance i in database U.

The perturbation process preserves the original statistical relationships of database U. These relationships include the mean values for attributes X, the measures of covariance between attribute sets X and S (i.e., a measure of how the two sets of attributes are related), and the canonical correlation between the attribute sets X and S, which is how well the actual values of attribute set X can be predicted by knowing the actual values of attribute set S.

Given these statistical properties of U, a multivariate normal distribution function is constructed for each instance i. Then, a multivariate random number generator generates the new X attribute values for the ith entry in the perturbed database P. This is repeated for all i instances.

Illustrating Data Perturbation

To illustrate the method and its analysis implications, a 50,000 record fictitious bank customer database was used. The data has five numerical attributes (Home Equity, Stock/Bonds, Liabilities, Savings/Checking, and CDs) and a sixth binary categorical class variable indicating whether a customer has been granted special service privileges or not (1 if yes, 0 if no). The means, standard deviations and correlation among these variables are shown in Table 4.

When the dataset was constructed, a decision tree format relating the five numeric attributes to the one class variable was used to assign the 50,000 records to the two classes equally (25,000 cases to each class). The choice of this format is arbitrary and just one of many structures that could represent the database's knowledge. The database was created with different degrees of

Table 4. Original database information

Descriptive Statistics	Home Equity	Stocks/Bonds	Liabilities	Savings/Checking	CDs	Class Variable
Mean	20.000	50.000	100.000	50.000	80.000	0.500
Standard Deviation	5.000	10.000	20.000	10.005	19.981	0.500
Correlation Matrix	Home Equity	Stocks/Bonds	Liabilities	Savings/Checking	CDs	Class Variable
Home Equity	1.000					
Stocks/Bonds	0.440	1.000				
Liabilities	0.501	0.218	1.000			
Savings/Checking	0.357	0.137	0.631	1.000		
CDs	0.237	0.112	0.756	0.723	1.000	
Class Variable	0.353	0.129	0.018	0.068	-0.161	1.000

"noise" in the assignment of class variables, representing different degrees of knowledge "crispness" (i.e., how well the five variables truly differentiate among the two classes of bank customers). We report the results for the 0% noise case, even though knowledge in practice would typically not be this easily defined. Nonetheless, the results will remain representative for the sake of our example.

Additionally, for example's sake, the variables representing Stock/Bonds, Liabilities, and Savings/Checking were deemed confidential, and the others, non-confidential. Thus, the perturbation process will mask the actual values of these three variables but will still preserve the linear relationships between the six variables.

Statistical Relationship Preservation

To check for the proper implementation of perturbation, the means, standard deviations, and variable correlations of the dataset before and after perturbation can be examined (see Tables 4 and 5). We see that the GADP process does preserve these important statistical relationships while masking or hiding the confidential data.

Thus, the knowledge worker can perform analyses on the protected database, and in terms of aggregate statistical measures, suffer no loss of accuracy. Given the confidential attributes have been masked, there is also no chance for the specific confidential data fields to be discovered by a data snooper or unauthorized user.

Table 5. Perturbed database information

Descriptive Statistics	Home Equity	Stocks/Bonds	Liabilities	Savings/Checking	CDs	Class Variable
Mean	20.000	49.906	100.011	49.966	80.000	0.500
Standard Deviation	5.000	9.995	20.046	10.031	19.981	0.500
Correlation Matrix	Home Equity	Stocks/Bonds	Liabilities	Savings/Checking	CDs	Class Variable
Home Equity	1.000					
Stocks/Bonds	0.435	1.000				
Liabilities	0.498	0.000	1.000			
Savings/Checking	0.355	0.132	0.633	1.000		
CDs	0.237	0.106	0.758	0.724	1.000	
Class Variable	0.353	0.124	0.018	0.067	-0.161	1.000

Knowledge Discovery Preservation

Using only simple statistical measures (means, variances, covariances, etc.) to measure the retained information and/or knowledge in a perturbed database is certainly a limited view of the usefulness of data. Knowledge discovery (KD) techniques (i.e., data mining) can identify underlying patterns in a database, which provide decision-makers deeper knowledge about that database, and, therefore, the organization. In this continuing example, we explore how perturbation impacts the ability for KM tools to discover the relationships (if any) between the five quantitative variables and the special services classification designation.

There are innumerable knowledge discovery tools. We choose two basic tools from two "common" families of knowledge discovery approaches. Multiple discriminant analysis (MDA) and logistic regression (LR) are the two traditional parametric approaches utilized, while an inductive learning approach—Classification and Regression Tree (CART)—and a feed-forward neural network (NN) approach were the two non-parametric tools utilized. All four approaches are readily available in software packages like SPSS, and our implementation was performed with SPSS using default values.

Classification accuracy of the knowledge discovery tools was measured to provide a measure of knowledge retention. Ten-fold cross-validation was used to ensure a robust measure of tool classification accuracy (Weiss & Kulikowski, 1991). An instance was labeled correctly classified when the tool classification matched the actual class value of the database instance. The correct number of classifications was assessed both for the training (development) and testing partitions. Because of the large size of the database, the accuracy of the tools for the training and testing sets were nearly identical. For simplicity, the results of only the testing sets are reported.

Table 6 shows the results of the analysis. Not surprisingly, CART, an inductive learning algorithm that discovers database knowledge in the format of a decision tree, correctly classified 100% of the cases in the original database. One would expect this approach to discover database knowledge in a precise manner because its structure matches the method in which the original knowledge was artificially created.

The level of performance of the other three approaches on the original data is also interesting. The NN performs almost as well as CART (98.6% accuracy), while the two parametric approaches, MDA and LR, perform quite poorly (72.55% and 72.85%, respectively). This suggests that the relative performance of knowledge discovery tools is a function of matching the underlying structure of the knowledge in the database. Unfortunately, this structure is not known until the data is analyzed.

Table 6. Classification accuracy

	Tool	Mean	Standard Deviation
Original Dataset	Decision Tree	100.000	0.000
	Artificial Neural Network	98.640	0.237
	Logistic Regression	72.850	0.836
	Multiple Discriminant Analysis	72.550	0.759
Perturbed Dataset	Decision Tree	90.240	0.470
	Artificial Neural Network	90.010	0.438
	Logistic Regression	71.800	0.978
	Multiple Discriminant Analysis	71.740	0.956

This example also indicates the potential utility of NN's as a general-purpose knowledge tool regardless of the knowledge structure.

When using our decision-making tools with the perturbed data, we can see a "loss" in classification accuracy for all tools used. CART and ANN correctly classify about 90% of the cases, a loss in accuracy of about 8 to 10%. The parametric tools had classification accuracy rates that were statistically similar between the original and perturbed data. This was due primarily to their relative inability to differentiate among the two customer classes in the original database.

This loss of accuracy stems from the perturbation process changing the values of the confidential data. While it preserves the statistical relationships, the masking of confidential data does destroy some of the crispness of the underlying knowledge.

Summarizing the results, the use of perturbation to mask confidential data in a KM-enabled database provides good inferential disclosure security and perfectly preserves aggregate statistical relationships, but appears to cause a loss in accuracy in discovering deeper relationships (knowledge) in the database.

Decision-Maker Implications

The results in the previous section have shown that using data perturbation as a means to secure confidential data shows promise. However, the GADP method could not perfectly preserve underlying knowledge in the database as it did the aggregate statistical relationships. A database administrator, or security policy maker, would need to assess whether a small reduction in predictive accuracy from a representative knowledge discovery tool is tolerable given the inferential disclosure security provided in the perturbation procedure.

There may be other measures of successful knowledge discovery beyond classification accuracy. Even with an 8 to 10% drop in accuracy, the rules discovered from the perturbed database might be the same or similar to the rules for the original data. If that were true, the accuracy loss would be irrelevant because the knowledge discovered would be equivalent.

Some practical implementation issues also are worthy of mentioning. The manner in which updates are made to the database is important. Most, if not all, organizational databases are dynamic (not static), and data would need to be perturbed on an ongoing basis. Certainly, coordination of this update would be an important implementation issue.

The costs to implement data perturbation techniques appear to be minimal, so from an economic standpoint, a database administrator would have no trouble justifying its use. In this article, for example, the authors used Microsoft Excel and a free spreadsheet add-in to accomplish the perturbation. For larger databases, similar libraries of code could be utilized to automatically update the databases appropriately. Since frequent updates to databases cause the need for ongoing perturbation, procedures would need to be put into place so that perturbation would occur on a regular (daily) basis and not interfere with employee use of the data. An automated routine can be written such that the perturbation process could occur nightly with little need for human supervision, so the only implementation costs would be in the form of computing time. It is our estimation that the additional cost that would accrue to an organization implementing this as part of their KM security process would be well worth the increase in confidential data protection.

As organizations continue to increase the degree of KM system sophistication, the difficult tradeoffs between data access, protection, and confidentiality must be considered. There are many security issues involved, and a layered, multi-faceted approach has obvious merit.

FUTURE TRENDS

This article has shown how data protection techniques can be used to help mask confidential attributes in an organization's database, which is a part of the overall KM system. The GADP method, a standard in the data protection literature, was used to illustrate the impact on the database attributes of the perturbation (very little) and the impact on the ability of knowledge discovery tools to accurately find important knowledge (somewhat impacted).

The findings indicated that GADP-protected databases have desirable characteristics but cannot perfectly maintain knowledge relationships to the same level as the statistical relationships are preserved. Therefore, some loss of knowledge accuracy is sacrificed when organizations employ this form of data protection technique. The benefits, though, are reduced disclosure risk and full access to data for analysis. These benefits are not found in any query reduction technique or other methods in which access to confidential data is restricted.

Future research will no doubt continue to look at techniques that go beyond GADP in their sophistication and ability to preserve additional relationships (such as knowledge) in databases. There also will be increased emphasis on sharing data between organizations in the future, and the promise of data perturbation will play a key role in dealing with the dilemma of protecting the unauthorized sharing of confidential data.

The focus of this article on one specific technique should not be viewed as myopic. Present research has shown that this technique cannot be matched. Of course, future modifications and variations will occur and these techniques will further mitigate "knowledge lost" that the example application in this article showed could occur. The future is promising for the use of perturbation as part of the layered security techniques in data-centric organizations.

CONCLUSION

The use of data perturbation techniques as a component of KM system security shows great promise, even as a stand-alone approach to protecting confidential data. Future research will continue to enhance our ability to simultaneously keep confidential data secure while making it available and useful to our KM systems. The continued importance of data and knowledge in business will spur further advances in this new innovative, effective, and economical area of data perturbation.

Chapter 7.17
We've Got a Job to Do – Eventually:
A Study of Knowledge Management Fatigue Syndrome

Richard L. Wagoner
The University of Arizona, USA

ABSTRACT

The implementation of knowledge management systems at universities can be tremendously costly in terms of both human and capital resources. One reason for this cost is the extended time period, generally measured in years, not months, over which they are implemented. This qualitative study presents data on the implementation of one such project at a Research I university in the southwestern United States. The analysis focuses on the concept of knowledge management fatigue syndrome and the increase of technological bloat and academic technocracy as a result of the project.

INTRODUCTION

Unforeseen costs and consequences of knowledge management projects at universities frequently are cited in the press. For example, the California State University system began a $400 million overhaul of its administrative information system in 1998. By 2003, there were many questions about the appropriateness and efficiency of the system, and it was clear that it has caused numerous unintended consequences to numerous administrative functions from accounting to student advising (Olsen, 2003). Similarly, an unforeseen problem with a management software upgrade at the University of Florida led to a delay in the processing of paychecks of more than 400 hundred graduate teaching assistants for nearly a month (Carnevale, 2004). These are just two examples of the problems universities face when implementing knowledge management systems. Given such problems, one wonders why a university would choose to implement these large-scale "enterprise" systems and what that process entails. This study illuminates one such implementation demonstrating knowledge management fatigue syndrome (Hakken, 2003). Further, the case study shows how knowledge management implementation can lead to technological bloat and academic technocracy (see Chapter IV).

This chapter is concerned with how such a long term project has affected the units of the university that have been directly involved in the first rounds of implementation, how users have responded to the system, and how the overall structure of units have changed. I will explore these questions by presenting data from e-mails, informal interviews and participant observation in one of the units that have been directly involved with the first round of the system's implementation. Before presenting data, I will discuss the conceptual framework that guided my inquiry.

CONCEPTUAL FRAMEWORK

Many organizations, including universities, in the 1990s chose to use knowledge management systems to improve the efficiency and service quality of their operations. As indicated in Chapter IV, these intended gains in efficiency and quality have remained elusive at best. Why, then, have organizations continued to pursue such goals? The concept of an academic technocracy presented is central to my analysis. In the previous chapter, my colleagues and I discuss three consequences of higher education institutions' efforts to respond to the pressures of academic capitalism and technocracy: the digital restructuring of academic labor, the unproven efficiency argument of academic technology, and the emergence of "technological bloat." Each of these phenomena may be giving rise to an "academic technocracy." In part, this chapter will present data that helps to support these hypotheses, but, more importantly, the chapter will incorporate Hakken's (2003) idea of "knowledge management fatigue syndrome" as an explanation of how an institution-wide knowledge management implementation project could continue for more than a decade.

More than 10 years ago a Research I university in the southwest (Southwest University) proclaimed in a strategic planning document for information technology that it would "leap forward utilizing information technology to fulfill the University's goal of becoming the best land grant institution in the country." Certainly, the goals of this project were grand. While it is not necessarily shocking to see a university desiring to improve its status in the U.S. higher education system, the study university does demonstrate a new dimension in how it intends to create this increased prestige. "Southwest University" intended that an information technology system would create the change needed to achieve the goal. Initially, the implementation process was intended to take only two years; today, after more than a decade, the project has yet to be fully realized. As discussed above, Southwest University envisioned a knowledge management system that would allow students and staff alike the ability to access essential data at any time, from any place. This access, of course, would be attainable because of the Internet and other advanced information technology. Hakken (2003) suggests that the early to mid 1990s was the prime time for such assertions because at that time knowledge management was the "killer application" that would justify the massive organizational investment in automated information technologies: "It [knowledge management] fed (and fed off) the media hype about the 'knowledge society'" (p. 55). In the early 1990s, it was reasonable to assume that a university attempting to improve its ranking would look to an all-encompassing, integrated knowledge management system to achieve its goals, as was the case for Southwest University. Hakken (2003) adds that as a result of the rhetoric of the information society, the New Economy, and globalization, "it was not difficult to convince the typical manager that highly touted information technology, as it got more complex, would provide an infrastructure for 'sharing the knowledge' among distributed staff" (p. 65).

Given the initial enthusiasm and high expectations that a new knowledge management system would solve all of the university's data access, manipulation, storage, and, particularly, integration problems, it is surprising that Southwest did not complete the project reasonably close to its initial two-year timeline. It can be argued, however, that the failure to complete the project in a timely manner was the result of knowledge management fatigue syndrome (Hakken, 2003). As conceptualized by Hakken, knowledge management fatigue syndrome results when enthusiasm for knowledge management solutions evaporates, projects are stalled, and discussion about them is stifled. Hakken offers five technical and conceptual explanations for the emergence of knowledge management fatigue syndrome in organizations: (a) the short shelf life of automated information technology slogans; (b) the overselling of products in a crowded marketplace; (c) continuing technical difficulties in using Web-based interfaces to merge complex information databases; (d) the inappropriateness of IT products designed for one purpose being sold for another; and, (e) the failure of many KM projects to take sufficient account for the social. Generally, technical explanations tend to be more apparent from outside an organization, while the conceptual explanation is more easily viewed from inside an organization.

Hakken's first technical explanation evokes Birnbaum's (2000) concept of management fads in higher education, where higher education institutions adopt popular management trends from the private sector before they have been proven effective. According to Birnbaum, by the time higher education organizations have adopted such practices, private businesses already have moved on to a new strategy because the initial one has lost its luster. In combining these two ideas, the first technical explanation for knowledge management fatigue syndrome would be understood as short-term information technology fads. Hakken (2003) explains that although knowledge itself still might be important to organizations, the term "knowledge management" can cease to have any importance and is, therefore, no longer "fashionable."

Over-competitiveness in a potentially lucrative market defines Hakken's (2003) technical explanation for knowledge management fatigue syndrome. That is, technology firms in their desire to capture market share with the appearance of "cutting edge" technology would simply repackage data and information networking products—without substantive modifications—as "knowledge management" products. Knowledge management in name only, these products were not designed to "address the problems of creating the trust, commitment, and community-life feel of teams/thick knowledge networking, on greater, more complex scales" (p. 65). Once again, this technical explanation for knowledge management fatigue syndrome is also related to Birnbaum's (2000) conception of higher education management fads. Too often higher education organizations seek easy answers in a new management style or system for what is a complex human issue. In the case of knowledge management, this second explanation illuminates the problem that information technology is unable to offer an easy solution to complex problems involving both data and human responses to it and to each other through it. Hakken (2003) suggests that too often inappropriate products were sold as knowledge management solutions.

The third technical explanation is mirrored in the dot com bust at the turn of the century. Initially, the Internet (and networking itself) was championed as the new, efficient model for all businesses and organizations. Unfortunately, that promise was found to be lacking in many instances. One such problem was the relative inability of Web-based products to always integrate large and complex sets of data; let alone doing it instantaneously from remote locations. Each of these three technical explanations, then, gives rise to the fourth. No technology—hardware or software—can be a panacea, the correct and efficient answer to all problems.

Hakken (2003) also offers one overarching conceptual explanation for knowledge management fatigue syndrome: "the failure of many KM projects to take sufficient account for the social" (p. 66). This conceptual explanation is closely related to the second technical explanation. Not only a means to integrating vast amounts of data into useful knowledge, knowledge management systems also need to integrate and coordinate various units in an organization, units which are often territorial about the data they control and the power and leverage such data grants them. To function properly, a knowledge management system must foster a real sense of cooperation and teamwork among units that may have no history of such interactions. This human function is much more complex than even the technical challenges facing knowledge management systems. Through both technical and conceptual frames, Hakken (2003) offers a means to examine the implementation of a fully integrated student information system at Southwestern University.

DATA AND METHODS

This study was a qualitative analysis of the experiences of one student services unit at a southwest university as it worked to implement a new student information software during the 2003/2004 school year. Data for the study included: informal interviews, participant observation, and most importantly for this chapter, analysis of two forms of documents—e-mail communications and historical documents concerning the development of the student information system—based on Hakken's (2003) explanations for knowledge management fatigue syndrome. Initially, I collected unit e-mails regarding the implementation process for a sixth month period, January 2004 – June 2004. After the data were collected, I coded them by Hakken's five explanations—technical and conceptual. I then analyzed the coded e-mail data to look for additional themes based on the challenges presented and discussed in the e-mails (Miles & Huberman, 1984). The informal interviews and my own observation during this period offered a means of triangulation for the e-mail data analysis. That is, the interviews and observations allowed a means of comparison to findings from the document analysis, which increases the validity and reliability of the findings (Creswell, 1994; Marshall & Rossman, 1989; Merriam, 1988) either by confirming patterns found in the document data or presenting contradictions to it.

ANALYSIS

Introduction

Before presenting findings from the study, I will briefly discuss the history of the implementation of the new student information system at "Southwest University." From its inception more than a decade ago, the student information system at Southwest University was intended to be Web-based and available to students, faculty, administration, and any other interested parties. This "anytime, anyplace" access was emphasized as one way that the university could improve its prestige. The new system would integrate data and reporting from all of the university's major academic and administrative units, including student financial aid, student billing, admissions and recruiting, curriculum and registration, and a student Web system.

The student information system project began in the spring of 1994 with the formation of a team to create an information planning study. This initial phase of the project moved quickly, with a report focused on strategic directions for the year 2000 completed by fall of the same year. That fall, a planning team was created to refine the recommendations made in the original strategic directions document. By March of 1996, the planning team had completed more intensive research into the technological needs and aspirations at Southwest. The result of this research phase was to support all of the major recommendations of the original strategic planning document and to suggest that the "initial reengineering" project begin immediately.

Based on evidence found in historical documents, it is unclear what happened with the project between 1996 and 1999. Whatever the cause, there was little action taken during this three-year period. During that period, a request for proposals (RFP) for the new student information software was issued. The RFP stipulated that the module for student prospecting and admissions should be in use by May 1999, with all system components implemented by December 2000. Other than this RFP and its suggested project timeline, there is little evidence of other activity during this period. What is clear is that this timeline was never close to being met.

The university had signed agreements with three corporate partners by March 2000, including a contract with the software company that had won the bid from the RFP. These partnerships were discussed in a March 2000 press release that also claimed that initial testing for the system would begin in July of that year, with complete implementation in three years (spring of 2003). A project newsletter from February 2001 indicated that the spring 2003 timeline was still on target while offering a revision of the project history by indicating that the project had achieved what had seemed impossible "two years ago." This accomplishment was simply completing the initial testing of the system which was still two years from scheduled implementation. The newsletter makes no reference to the RFP which called for full implementation by December of the previous year, let alone the original plan from 1994.

As of the summer of 2004, the project had finally implemented the first of its major modules, but it had not yet completed full implementation. While it may be reasonable to assume that full implementation should be achieved by 2005, that date would be two years after the spring of 2000 projection, five years after the RFP projection, and 11 years after the original strategic plan. The rest of this section seeks to illuminate how this process has taken so long.

Technical Explanations

In this study, I found ample evidence in both the historical documents about the project and in the e-mails concerned with its implementation of knowledge management fatigue syndrome (Hakken, 2003) and how it indicates increased technological bloat and academic technocracy.

The historical documents associated with the development of the student information system were of particular importance for finding evidence for Hakken's (2003) first technical explanation. In documents from 1994-2000 the need for students, faculty, and staff to access information "at any time and from any place" is repeated in all documents. This 24 hour-a-day, 365 day-a-year need for access to information was one of the mantras of 1990s technology enthusiasts. Certainly it would have been used as a major selling point and justification for any information technology project from the time. Beyond this any time, any place access for those associated with the university, the system was also frequently described as a means to share and capture data with "business partners, high schools, community colleges, the state, and the world." A concern with sharing and capturing data with business partners and, particularly, the world also echo the slogans of the New Economy. Finally, these early project documents also promised "information services [that] are automated, knowledge-based, and easily adapted to changing campus and external requirements." Again, the language of the need for constant adaptation of the New Economy is a central premise of the original project documents. From the beginning of the project, then, it is obvious information technology slogans (fads) were influential in the development of the new student information system project.

The historical documents also show a desire on the part of the university to foster partnerships with major technology corporations, including both hardware and software manufacturers. Specifically, the university created a hardware partnership with a major computer manufacturer and operation software corporation that made changing hardware and software platforms virtually impossible because of the nature of the agreements. It is important to note that neither of these companies was known in any way as leaders in the higher education administrative technology systems market; however, they did offer considerable in-kind donations to the university project, allowing the university to decrease its initial capital investment, while allowing the products of both companies to become entrenched in the system. The other major partnership was with the software company that would provide the actual information system software. While this company had worked with several major research universities, it was relatively small and from the beginning of the project it was clear that its software modules would need tremendous customization to fit the university's needs. All three of the partnerships were critical in the initial development of the student information system project at Southwestern University. But, as predicted by Hakken (2003), none of these partners actually had experience with meeting the exact needs of the university. By partnering with these firms, the university put itself in a position to be constrained by the technical limitations of the partners and to be left without viable alternatives when problems arose because of the nature of these exclusive partnerships.

While historical documents were important in establishing the relevance of the first two technical explanations, the experience of student services system analysts and staff members as documented by e-mail communications demonstrate the importance of the third technical explanation (Hakken, 2003). At the most basic level, the continuing technical difficulties in using Web-based interfaces to merge complex information bases is witnessed by the fact that since 2001 there have been three updates to the system minimum requirements for computer hardware and operation system software needed to use the student information system program. In other words, even at this basic level, the technical requirements for the program remain a moving target, demanding continual investments in technology infrastructure for the university. Related to these basic hardware and software changes, in July 2004 the student information system software, which had yet to go live in all units of the university, itself was upgraded. That is, the student information system, although it was not yet in campus-wide use, was already experiencing upgraded versions.

Beyond these continual changes in infrastructure, there were three general problems during the opening months of 2004 that demonstrate the challenges of using a complex Web-based system. Data has been lost, there have been problems with properly synchronizing data from units and central computing, and there was a potential data security problem. While there were only two instances mentioned in e-mails during the first half of 2004, student data was lost in the information system for unknown reasons. The second incidence left "no audit trail at all." Clearly, lost data, especially when there is no indication why it was lost, is a critical problem in such an information system. While not as critical as lost data, improperly synchronized data files were much more frequent than lost data. According to one e-mail, the system was "experiencing an inordinate number of file synchronization errors." With both data loss and data synchronization problems, data-entry and data-processing staff members were required to retrace steps taken with lost or improperly synchronized files and report to two different system analysts, one for the unit itself and one for the central information technology unit. It would take analysts from both units to correct these problems. Finally, because of the net-based nature of the system, users were instructed to "dump their browser cache (including offline content)" because of a "potential" security "issue." Each of these examples amply demonstrates the challenges of using a Web-based interface to manage complex data files among various organizational units and the labor intensive solutions required to remedy such problems.

The fourth technical explanation for knowledge management fatigue syndrome is closely related to the first three: it is particularly challenging for an organization to easily and successfully implement a new knowledge management system when the system was not originally designed for that purpose. The experience of Southwestern University clearly demonstrates this point. In the historical documents, the student information system was described as a product that already had been developed and implemented at several other higher education institutions and would only need to be customized to fit the university's needs. By the spring of 2004 the system was described in an e-mail from the student services director as "a software product that has not been used anywhere else in the world." So, what had been billed as an off-the-shelf product needing some minor modifications was later trumpeted as a unique system. In the same e-mail, the director also described the information system as having "a mind of its own."

Conceptual Explanation

The evidence from the section above provides a clear picture that each of Hakken's (2003) four technical explanations for knowledge management fatigue syndrome manifested themselves during the implementation of the student information system at Southwest University. Beyond these four explanations, there is evidence of a conceptual explanation at Southwest as well. The need for input and cooperation from all members of the university community was stressed throughout both the historic documents and unit e-mails. The planning stages of the project were highlighted by numerous university-wide committees that were intended to work cooperatively together to create a description of a single information system that would meet the needs of all units. These cooperative workgroups themselves would certainly be an example of Birnbaum's (2000) management fads, but more importantly they demonstrate how disparate and sometimes competitive units were expected to define and solve problems together throughout the entire process. The historical documents present technical reasons for why this needed to happen, but there was no suggestion as to how members from these units would be able to work together to accomplish the project's goals. The complex social interactions required of such a process are virtually ignored in the historical documents, leaving one to assume that it was a matter of faith that the promise of an advanced knowledge management system would unite all units of the university with a minimum of problems.

By the spring of 2004, one method of achieving unification became clear. In an e-mail, the director of the department in this study explained to all of its members that the systems personnel from the study's department along with their counterparts in both the financial aid and the curriculum and registration offices were "being merged into one Enrollment Management Information unit. In an effort to improve life for all of the systems people and to improve the service [the student information system] provides to the offices." So, what had originally been envisioned as a means to increased cooperation and information distribution between units finally had become a wholesale reorganization of student services departments at Southwestern University. While all data indicates that this was not an intended result of the new student information system, the system itself had caused the reorganization and redefinition of key student services units.

Ironically, the explanation given for the reorganization of the systems personnel emphasizes the centralized power of experts (as in a technocracy) over the independence and interconnectedness of individual units at the university. In the same e-mail, the unit director explains that "the new unit will expand the resources available to address any one problem in any of the units to a group of 20+ people instead of the limited personnel resources of each unit." Essentially, the use of technology and the information available to each unit would now be controlled by one central group whose individual members would have no direct connection or allegiance to any particular student services unit. It is possible to imagine that without personal ties to the needs of individual units, this new systems unit might be concerned with what it deems best from a technological standpoint without considering the human needs of the various student services units it is intended to serve—a serious sociological consequence of the implementation of the new student information system.

CONCLUSION

In this study, I was concerned with two central questions. First, can Hakken's (2003) concept of knowledge management fatigue syndrome be used to analyze and understand the implementation of the student information system at Southwest University? And, does the implementation of the system show evidence of technological bloat and academic technocracy? The data from this study clearly present evidence of each of Hakken's (2003) descriptions of knowledge management fatigue syndrome and those descriptions provide a means to interpret the long process of the student information system's implementation. Given this evidence one other question arises: Why continue with the project if there is knowledge management fatigue syndrome? The answer to this question is at once simple and complicated. The university is heavily invested in the technology infrastructure demanded by the project—there are tremendous sunk costs. They cannot simply ignore the project; they must forge ahead. At Southwest University, as at other higher education institutions, there may be fatigue, but such labor and capital intensive projects must be completed. Interestingly, there has been little fanfare about the project during the last two school years. A project that was heralded as a means to achieving prominence for the university is now quietly nearing completion. Although understated, the project's implementation has led to a complex reorganization of several student services units into a single enrollment management systems unit.

The new enrollment management systems unit shows evidence of technological bloat and academic technocracy. This new unit is centered on ever-changing advanced technology, and many of its positions which were originally defined as temporary for the project have become institutionalized—clearly a form of bloat. With this new unit, technocrats have assumed an increasingly important role in student services and administrative strategic planning. This increased prominence of "experts" will increase their influence at Southwest—a precursor of academic technocracy.

It is possible to view this technological bloat and academic technocracy as a consequence of knowledge management fatigue syndrome. Because the project has taken an inordinate amount of time to complete, the resulting fatigue has caused institutional stakeholders to be less concerned about efficiency and long-term consequences of decisions than they are about finding ways to complete the project—at 10 years and counting, it is easy to understand why.

Chapter 7.18
Knowledge Calibration

Ronald E. Goldsmith
Florida State University, USA

Kishore Gopalakrishna Pillai
Florida State University, USA

INTRODUCTION

The purpose of this article is to describe the concept of knowledge calibration within the context of knowledge management. Knowledge calibration is a concept borrowed from the psychology of decision making. It refers to the correspondence between knowledge accuracy and the confidence with which knowledge is held. Calibration is a potentially important concept for knowledge management because it describes one of the subtle errors that can lead to poor decisions. Where the correspondence between the accuracy of one's knowledge and the confidence in that knowledge is high, decisions are described as well calibrated; but poor correspondence implies miscalibrated decisions. Since one concern of the field of knowledge management is the best use of knowledge for decision-making purposes, this topic is relevant.

BACKGROUND

A variety of scientists, including meteorologists, statisticians, and psychologists, have been interested in measuring and in explaining judgments of confidence and their relation to accuracy (e.g., Harvey, 1997; Yates, 1990). Most of these studies report that people are systematically overconfident about the accuracy of their knowledge and judgment. In fact, scholars have even considered overconfidence as a stylized fact of human cognition.

The construct "calibration of knowledge" refers to the correspondence between accuracy of knowledge and confidence in knowledge (see Figure 1). High accuracy and high confidence in knowledge promote high calibration; confidence in these decisions is justified. Low accuracy and low confidence also promote high calibration. In this case, decision makers are aware of their

Figure 1. Accuracy-confidence matrix

	Confidence	
Accuracy	High	Low
High	Good calibration	Miscalibration
Low	Miscalibration	Good calibration

ignorance and are unlikely to overreach. A lack of correspondence between accuracy and confidence means miscalibration. Miscalibrated individuals are either overconfident or underconfident—situations that can result in costly mistakes in decision making.

For example, a description of the difficulties Xerox had in successfully bringing their new inventions to market (Carayannis, Gonzalez, & Wetter, 2003) reveals that, among other problems, managers placed great faith in their knowledge of the market, technology, and future trends that was subsequently proved to be misplaced. One could argue that the Bush Administration's decision to go to war with Iraq in order to destroy weapons of mass destruction that did not exist, but were claimed to exist on the basis of high confidence in flimsy evidence, is also an example of miscalibration and its influence on decision making.

Although several approaches to improving knowledge calibration have been suggested, little effort has been made to integrate them into the field of knowledge management. A new dimension of the discourse on knowledge management can be added by examining the implications of the construct of knowledge calibration to knowledge management. In the subsequent paragraphs, we elaborate on how this can be achieved and why it is important.

MAIN FOCUS

Literature on knowledge management has focused on: (a) defining the constructs of knowledge and knowledge management; (b) describing processes associated with knowledge creation, storage and retrieval, transfer, and application; and (c) developing and implementing systems to facilitate these processes. Implicit in these tasks is the idea that knowledge is embedded in individuals, groups, as well as in physical structures (Alavi & Leidner, 2001; Brown & Duguid, 2000). These discussions implicitly assume that knowledge available in the organization will be used in decision making and that such use will enable users to make better decisions. As research has noted, however, knowledge, which as commonly used refers to accurate or correct knowledge, is not the sole factor affecting decision quality. Users have to access and wisely use the knowledge in decision making before KM systems can be said to improve management activity. One instance of this can be found in the "knowledge/use-reuse" situation where knowledge is developed and stored for reuse by its creators later on or by other subsequent users (Markus, 2001). If the knowledge is not well recorded, stored, or made easily retrievable, users will be few and their effectiveness compromised. A further problem is described by the impact of new technologies on marketing management, where Tapp and Hughes (2004, p. 293) argue that "…KM systems have increased the supply of knowledge 'objects' (explicit, recorded, packets of knowledge), but that usage of these 'objects' by other workers (the crucial added value) remains elusive." The skill with which users and re-users take advantage of knowledge depends on many factors, including capturing, packaging, and distribution of the knowledge (Markus, 2001). Moreover, the confidence with which the decision maker accepts that knowledge also affects the way he/she uses the knowledge to make decisions. In other words, knowledge calibration affects the quality of decision making.

Ideally, organizations are better served if all individuals have high calibration, arising from high accuracy and high confidence in the knowledge. This is not to deny that there could be cases where overconfidence can be justified as a functional adaptation to motivate the implementation of decisions (Russo & Schoemaker, 1992). Investigation of subtleties in the context of knowledge management can be the focus of later research. At this stage, the critical issues pertaining to knowledge calibration in the context of knowledge management are: (a) What factors contribute to miscalibration? (b) How can they be reduced or eliminated? and (c) What organizational practices can help promote calibration through knowledge management systems?

Factors Contributing to Miscalibration

Where does miscalibration come from? Although miscalibration is likely due to multiple causes and their interactions, two principal sources can be identified for our purposes: internal (personal) and external (structural). That is, miscalibration can arise from cognitive causes as well as from the quantity of information provided and how it is presented to the user.

Alba and Hutchinson (2000, pp. 139-142) summarize the main cognitive causes. These first include failures of memory due to distortion or incompleteness. Memory is often biased in the direction of a prior judgment, thus increasing overconfidence. Memory might be incomplete when decision-consistent facts are more easily recalled, better decision options fail to be considered, or where other aspects of the knowledge interfere with recall and consideration. Underconfidence can also arise when the consequences of decisions fail to be considered. The difficulty and frequency with which outcomes can be imagined reduces the perceived likelihood of an outcome. A second cognitive source of miscalibration comes from misweighting evidence, thereby not optimally incorporating decision inputs into the decision process. For example, decision makers often fail to use base rates in solving problems. They rely on available cues instead of valid ones. They overemphasize extreme instances, irrelevant data, and easy-to- understand information. Overconfidence can come from poor appraisal of the diagnosticity of information where diagnosticity varies with its ease of use. Motivational factors may induce decision makers to fail to consider hypothesis-disconfirming evidence, accept confirmation uncritically, or limit their search to supportive evidence only. Having some familiarity or expertise with the decision task might induce overconfidence where the decision tasks are inordinately difficult, as in turbulent environments where it is difficult for everybody to see the future. Finally, overconfidence arises where expertise is not helpful to the decision.

Alba and Hutchinson (2000, pp. 142-144) and others describe some of the ways in which information is presented (inappropriate decision inputs) that can also induce sub-optimal levels of confidence. Too much information, where the assumption is made that greater amounts of information yield better decisions, or non-diagnostic information can cause overconfidence. Misattribution of information, as when fragments of retrieved information are interpreted as having been recalled from prior knowledge so that inference is interpreted as recall, can induce miscalibration. The number of operations needed to get an answer, familiarity with judgments, and the ease with which information can be retrieved may play a role. Another example of misattribution can be found in the "sleeper effect," where the source of information is forgotten over time, but the information itself is remembered; confidence in even poor information may increase if its provenance is lost.

Empirical evidence from the literature on information systems suggests that the design of both the information dimensions (quantity, form, format, etc.) and the inquiring system play key roles in user calibration. Oskamp (1965) used clinical psychology case studies to discover that increasing the quantity of information provided to decision makers produced miscalibration because it increased their decision confidence, but did not improve their decision quality. More information caused the confidence to soar out of proportion to the actual correctness of their decisions. Chervany and Dickson (1974) studied the effects of information overload on decision confidence, quality, and time. They found that decision makers using statistically summarized data outperformed those using raw data, but took longer and were less confident in their decisions. Familiarity with the decision task can promote overconfidence, as can the illusion of control, where decision makers come to believe that they have more influence on decision outcomes than they really do.

Ways to Improve Calibration

In general, it can be stated that calibration can be improved by promoting (1) accuracy of knowledge and (2) optimal levels of confidence in the knowledge. While accuracy can be viewed in monotonic terms, in as much as more of it is better, the knowledge management system should strive to promote optimal levels of confidence. Overconfidence and underconfidence mean miscalibration, and research has recorded the widespread prevalence of the former (Einhorn & Hogarth, 1981; Tversky & Kahneman, 1974). Hence, there is a need to build checks into the knowledge management system to promote optimal levels of confidence.

Bell (1984) compared different forms of presenting information and found a convergence between decision confidence and decision quality. Decision confidence based on information presented as text was greater than that for information presented in numeric form, but subjects found it easier to identify inconsistencies when the information was presented in numeric form rather than in textual form.

Literature also suggests that that using decision support systems—and by extension, knowledge management systems—also affects calibration. McIntyre (1982) found that the calibration of subjects using a DSS was worse than that of their unaided counterparts. He speculated that the DSS might have contributed to miscalibration (in the form of underconfidence) because it led subjects to believe that much better decisions existed than those from which they had selected.

Design features of a knowledge management system can also influence user calibration. Studies have examined the effects of design features on user calibration in the context of decision support systems. Davis, Kottemann, and Remus (1991) and Davis and Kottemann (1994) hypothesized that the use of a "what-if" inquiry design creates an illusion of control, causing users to overestimate the effectiveness of the what-if DSS design. Their results supported this hypothesis. Despite performance effects to the contrary, and the availability of tools whose recommendations would have led to much better decisions, subjects continued their use of the what-if design feature. That is, subjects maintained their overconfidence in the efficacy of the what-if inquiry design feature despite negative feedback and the availability of better tools. Davis and his coauthors concluded that an illusion of control was created by using the what-if feature of the DSS and that this illusion overwhelmed any negative feedback, including poor performance, in formulating the subject's attitude about the efficacy of the what-if DSS design feature.

Aldag and Powers (1986) also have suggested the illusory benefits of using a DSS. In their study, subjects analyzed strategic management cases and, assuming the role of a consultant, made written recommendations. Although the recommendations of those who used the DSS were judged no better than their unaided counterparts, the DSS-aided subjects reported more confidence in their recommendations than did those that were unaided, again resulting in miscalibration (Kasper, 1996). These illusory benefits were also found when the aid is an expert system. Faust (1986) provides a series of rules or necessary conditions for improving calibration. In summary form, his rules are: (1) decrease information overload and misleading illusory data; (2) present evidence that disconfirms and refutes one's position; (3) distinguish between knowledge and speculation, between knowledge and metaknowledge; and (4) generate competing alternative hypotheses. Kasper (1996) reviews relevant literature on decision support systems and opines that the design of both the information (overload, misleading, disconfirming, speculative) and the inquiring system (generate competing alternative hypotheses) plays key roles in user calibration. Thus, basic research into reducing miscalibration suggests ways in which knowledge management systems can incorporate features to improve calibration.

Knowledge Management and Knowledge Calibration

How then can knowledge management systems be applied to improving knowledge calibration to enhance decision making? Knowledge is described as consisting in two forms. Tacit knowledge can be summarized as personal or subjective knowledge (mental models, know-how, skills), and explicit knowledge is "articulated, codified, and communicated in symbolic form and/or natural language" (Alavi & Leidner, 2001, p. 110). Miscalibration can arise from overconfidence in both tacit and explicit knowledge. Accounts of the sources of overconfidence that stress the role of expertise and familiarity (Alba & Hutchinson, 2000) imply that the interaction of tacit and explicit knowledge can result in overconfidence as well. While explicit knowledge can be identified more easily, and systems and procedures can be developed to deal with it, for example through feedback and training, dealing with tacit knowledge poses a greater challenge.

When managers access the (explicit) knowledge base prior to decision making, a feature could be added to the retrieval mechanism that explicitly asks them to rate their confidence in the information retrieved. However, for information surrounded by uncertainty, such as strategic decisions for future action, managers could be trained to use such a KM rating system to make them more cautious in their use of this information. Simulations, games, and case studies, where the use of a feedback mechanism can be incorporated to reduce overconfidence, can be developed. By requiring decision makers to explicitly state their level of confidence, this aspect of the decision can be analyzed and critiqued by others involved in the decision process, and the decision maker can gain insight into his/her style of information use. Information sources can also be evaluated by these rating systems, leading to their modification and to improvement.

Calibration of explicit knowledge involves an implicit calibration of tacit knowledge as well, but dealing with miscalibration arising from tacit knowledge requires additions to the existing systems. The system should be capable of tapping into the tacit knowledge base of the user, and in an interactive manner, gauge the level of miscalibration. Obviously, this presupposes a tacit knowledge base within the system, which might go against the very notion of tacit knowledge itself (as something that cannot be made explicit). Still, we feel that at least some dimensions of such knowledge will lend itself to assessment of calibration. For example, evaluating the outcomes of using tacit knowledge by comparing them with the performance people expect of themselves could improve some aspects of decision making (cf. Alba & Hutchinson, 2000, p. 133). Decision making simulations could be designed to deliberately confound experts so as to make them more cautious in their conclusions, training them to pay attention to their assumptions and consider alternative hypotheses.

In this regard, we bring to attention the concepts of transactive and mechanistic memory that have been discussed (Lynn & Reilly, 2002; Wegner, 1987). Transactive memory refers to the set of individual memory systems in combination with their intercommunications; transactive memory exists as a property of a group as group members share their memories through their interactions with each other and with external memory storage devices. Mechanistic memory refers to information accessed from mechanical systems. A part of transactive memory can be conceptualized as overlapping with tacit knowledge. Codifying such transactive memory and systematizing it will enable the creation of interactive procedures that could assess the level of miscalibration of users (cf. Markus, 2001). While this is an idea at an incipient stage, research can look into its possible developments.

With modern IT advances, an intelligent agent could be developed to serve as a sounding board to evaluate decisions under different confidence conditions. Such systems would have to be developed to realistically challenge managers while not promoting underconfidence as found by McIntyre (1982). Miscalibration is more likely in turbulent rather than stable environments and in emergent knowledge processes (new product development, strategy making) because there is high uncertainty, less time for feedback, and little direct experience (cf. Markus, Majchrzak, & Gasser, 2002). Such scenarios encourage the formation of more tacit and less explicit knowledge. IT could be used to present such scenarios to managers in training sessions to accustom them to their environment and alert them to the dangers of overconfidence as well as ways to reduce its harmful impact.

Some researchers have examined issues that address these questions. Kasper (1996) proposes a theory of decision support systems for user calibration. Kasper's theory utilizes the theory of symbolic representation in problem solving (Kaufmann, 1985) according to which the quality of mental acts (including calibration) depends upon matching the appropriate symbolic representation and reasoning to problem novelty. Hence, the DSS design theory for user calibration is based on the notion that user calibration depends upon designing a DSS so that it effectively supports the users' symbolic representation in problem solving, and it contends that DSS designs for user calibration depend upon problem novelty.

Following the guidelines suggested by Faust (1986) and building on Kasper (1996), it can be suggested that future research and development should be devoted to devising ways to adjust KM systems so that:

- They reduce information overload, perhaps screening information so that irrelevant and illusory data can be removed, and only the most crucial and relevant information delivered.
- They incorporate negative or disconfirming information in the retrieval system so that decision makers are exposed to counter-arguments.
- They rate information to distinguish degrees of speculation.
- They require/suggest competing hypotheses that can be analyzed and rejected or accepted side by side with the favored course of action.

FUTURE TRENDS

Possible avenues for research into knowledge calibration in knowledge management include learning more about how decision makers interact with IT systems if the latter include explicit mechanisms to reduce overconfidence. More should be learned about the best ways to integrate knowledge calibration into training in the use of DSS. Which methods work best in reducing overconfidence? Increasing attention is being devoted to novel IS contexts, such as emergent knowledge processes, organizational activity patterns that exhibit "an emergent process of deliberations with no best structure or sequence; requirements for knowledge that are complex (both general and situational), distributed across people, and evolving dynamically; and an actor set that is unpredictable in terms of job roles or prior knowledge" (Marcus et al., 2002, p. 179). A variety of causes seem to induce miscalibration. Future research could focus on delineating more precisely the relationships among these prospective influences. Do multiple causes lead to the same phenomenon, or are there different types of miscalibration, perhaps with different causes? Recent theories of information foraging (Pirolli & Card, 1999) offer new insights into how humans acquire information; integrating these theories with KC and KM is an exiting prospect.

The challenge is to integrate these ideas into the ongoing dialogue on knowledge management, and formulate a dynamic theory of knowledge management systems for user calibration. Given the rapid increase in the research efforts and output on knowledge management, such a theory is likely to evolve over the course of the next few years.

CONCLUSION

Miscalibration seems to be pervasive feature of decision-making environments. We argue that more study should be devoted to it in KM. "The processes of knowledge creation, storage/retrieval, and transfer do not necessarily lead to enhanced organizational performance; effective knowledge application does" (Alavi & Leidner, 2001, p. 129). This brief outline makes a case for the incorporation of knowledge calibration into knowledge management research and practice as one aspect of improving knowledge application. The stream of research on knowledge management can be enriched by integrating relevant thought streams that have the potential of adding a new dimension to our understanding of knowledge management. For instance, Meso, Troutt, and Rudnicka (2002) recently highlighted how naturalistic decision-making research can enhance knowledge management. In the same fashion we hope that the idea outlined above catalyzes the synthesis of thoughts on knowledge calibration into the body of knowledge management research.

Chapter 7.19
Aristotelian View of Knowledge Management

David G. Schwartz
Bar-Ilan University, Israel

INTRODUCTION

Defining and understanding knowledge is a rather broad and open-ended pursuit. We can narrow it considerably by stating that we are interested in defining and understanding knowledge as it pertains to knowledge management (KM) rather than tackling the entire realm of epistemology. This article takes the theory of knowledge espoused by Aristotle and views it through the lens of knowledge management.

The writings of Aristotle have proven to be fertile ground for uncovering the foundations of knowledge management. Snowden (2006) points to Aristotle's three types of rhetorical proof as a basis for incorporating narrative in knowledge management. Buchholz (2006) traces the roots of ontological philosophy forming the basis of current KM ontology efforts back to Aristotle's work. Butler (2006), in his antifoundational perspective on KM, following Dunne (1993), argues that Aristotle's phrónésis and téchné need to be at the core of knowledge-management efforts, and while they cannot be directly applied to IT applications, they must be among the elements upon which knowledge management is based.

It is instructive to seek theoretical foundations for our treatment of knowledge in organizational settings and knowledge-management systems. By doing so we increase the likelihood that our solutions are complete and that we have considered all relevant forms of knowledge that we may desire to manage. Rather than start with modern differentiators of knowledge such as tacit vs. explicit (Nonaka & Takeuchi, 1995), descriptive vs. procedural (Holsapple & Winston, 1996), local vs. global (Novins & Armstrong, 1997), and declarative vs. procedural (Minsky, 1975), we will take a step back to first principles.

Aristotle (n.d.), in his Nicomachean Ethics, presents five virtues of thought that can be mapped to levels of knowledge.

- Epistémé: Factual or scientific knowledge
- Téchné: Skills-based technical and action-oriented knowledge
- Phrónésis: Experiential self-knowledge or practical wisdom based on experience
- Noûs: Intuition
- Sophía: Theoretical knowledge of universal truths or first principles

Other learned traditions and cultures give us similar and related elements, such as the Talmudic philosophical tradition (Luzzatto, 1988; Maimonides, 1966) and Eastern religion and philosophy (Gier, 2004).

As a starting point, we are concerned with the processes shown in the first ring of Figure 1.

1. Knowledge that can be acquired in an organizational setting
   a. creation
   b. discovery
   c. gathering
   d. validation
2. Knowledge that can be organized, categorized, and stored
   a. modeling
   b. classification
   c. calibration
   d. integration
3. Knowledge that can be distributed to some point of action
   a. sharing
   b. reuse
   c. maintenance
   d. dissemination

Without the abilities to acquire, represent, store, retrieve, and apply knowledge in a way that positively affects the operation of our organizations, we are not engaging in knowledge management. Conversely, any form of knowledge to which the aforementioned cannot be applied, while of theoretical importance and interest, cannot be managed. True, as argued by Butler (2003, 2006), the knowledge foundations defined by Aristotle might not be transparently converted into IT-based systems, but that should not prevent us from designing our KM systems and processes to support those knowledge foundations to the greatest extent possible.

Consider the view presented in Figure 1 giving a holistic view of knowledge management and its foundations. The central core of philosophies (the middle) must inform our choice of practical knowledge-management processes (the first ring). These processes must be implemented and adapted to address managerial, social, and organizational needs (the second ring). Finally, the implementation of KM processes to meet our organizational needs must be supported by and implemented through a set of relevant information technologies (the outer ring).

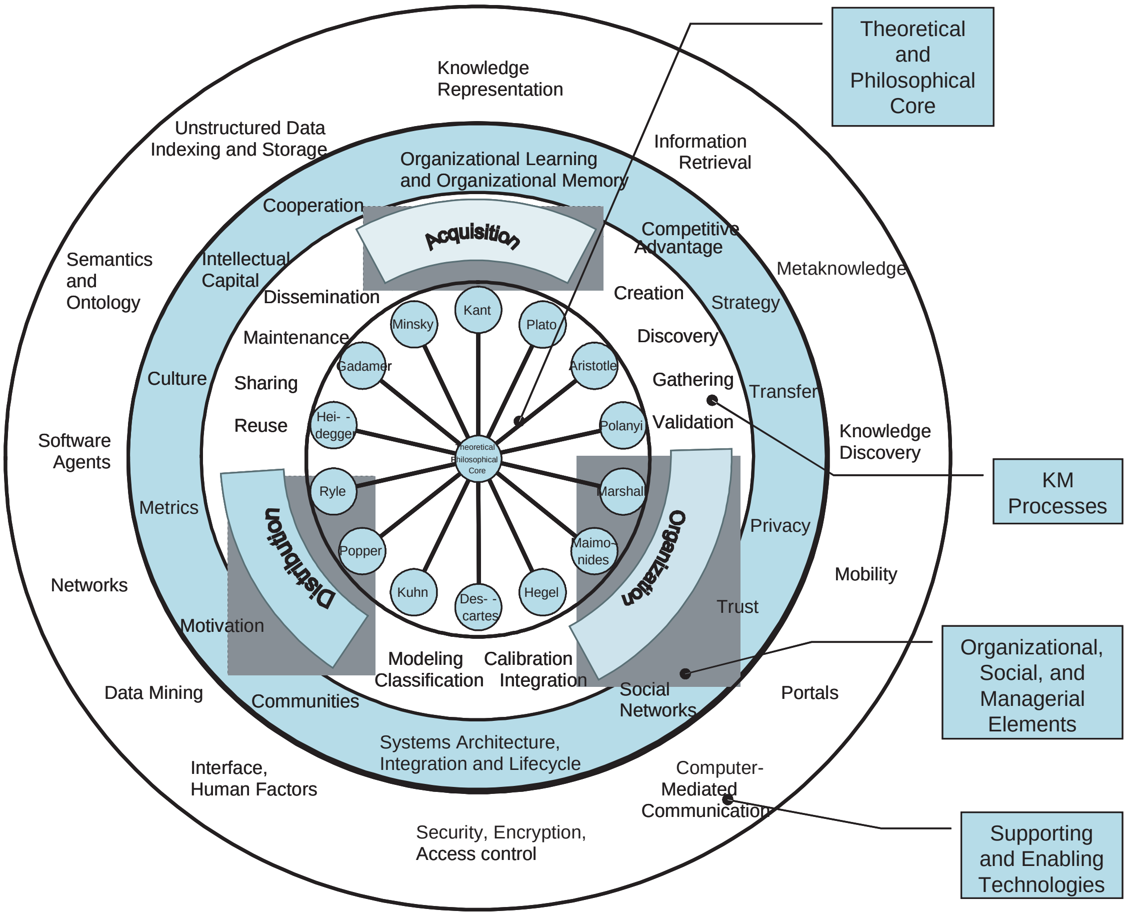
But how do we get from the central core to the first ring? In this article we will examine the definition and understanding of knowledge as a meeting between the Aristotelian classification and the requirements of practical knowledge-management processes.

BACKGROUND

The KM-process ring of Figure 1 shows the three bases of acquisition, organization, and distribution (Schwartz, Divitini, & Brasethvik, 2000), and it is but one of many viable characterizations of process-oriented knowledge management. It represents an emphasis on praxis, taking as a starting point the question, What do we need to do with knowledge in order to make it viable for an organization to use, reuse, and manage it as a tangible resource, and apply it toward specific actions?

By taking this perspective, we avoid to a certain extent the knowledge-information-data (KID) debate regarding the granularity of knowledge. We

Figure 1. Layer upon layer of knowledge management



argue that the distinction between data, information, and knowledge can be conveniently ignored: not treated as irrelevant for a philosophical debate, mind-body discussion, or a metalevel, object-level analysis, but not essential to the fundamental mission of knowledge management.

Arguing that information technologies process data and not information or knowledge, Galliers and Newell (2003) seek to refocus the KM-IT effort on the better management of data. They suggest that since an IT system cannot deal with the fundamental elements of truth and knowledge, it can be counterproductive to create IT-centric knowledge-management initiatives. Holsapple (2002) provides an excellent introduction to different aspects of knowledge and its attributes, including perspectives based on representational issues, knowledge states, production, and the KID debate as well.

Knowledge management, however, does not need to get bogged down in the KID debate. What it does need is to become knowledge centric. Becoming knowledge centric does not necessitate a resolution to the KID debate. Rather, it means that the field of knowledge management could benefit from taking cues from its philosophical lineage—the theories of knowledge—and not only from the praxis that has driven KM over the past two decades. The heavily practice-oriented roots of organizational knowledge management (Davenport & Prusak, 1998; Senge, 1990) have largely developed independent of any relationship to a theory of knowledge. The necessary KM processes have not evolved from any declared need to find an applied outlet for theories of knowledge. While that in no way invalidates KM processes or practice, it does leave open a very broad question as to how knowledge management relates to its epistemological roots.

Aydede's (1998) analysis of different possible interpretations of Aristotle's epistémé and noûs provides some intellectual breathing room to shape our own interpretation of those concepts in directions most amenable to knowledge management.

Hanley (1998) helps provide insights into the applicability of Aristotle to knowledge management by presenting the work of Heidegger, who takes the basic Aristotelian approach to knowledge and presents it from an applied pragmatic view. While Hanley's work does not explicitly consider the discipline of knowledge management, the perspectives drawn from Heidegger's interpretation of Aristotle will appear familiar to knowledge-management researchers.

Let us begin by examining each level of knowledge as envisioned by Aristotle, and see how each relates to certain elements of knowledge management.

AN ARISTOTELIAN VIEW OF MANAGING ORGANIZATIONAL KNOWLEDGE

The Aristotelian virtues are not hierarchical in nature. They are presented as discrete forms of knowledge intended to cover all possible acts of knowing.

Epistémé: Factual or Scientific Knowledge

Epistémé may be the most controversial element of knowledge for knowledge management. It is pure knowledge, such as that of mathematics or logic. Attempting to pin down epistémé is the essence of the knowledge-information-data debate that we discussed, and chose to dismiss, earlier. As scientific knowledge, epistémé is most relevant to our pursuit, and it encompasses knowledge of cause and effect, and deduction (Parry, 2003). A stated goal of information technology is to represent those facts and relationships known as epistémé in digital form, and leverage that representation in different applications as declarative knowledge. In addition, data-mining techniques seek to help identify epistémé that is buried within an organization and bring it to the surface. In parallel, IT seeks to do the same for procedural knowledge, which maps very well to Aristotle's téchné.

Téchné: Skills-Based Technical and Action-Oriented Knowledge

Téchné deals with things that change rather than the constant relationships found in epistémé. Harnessing téchné is at once one of the most challenging and most fruitful of knowledge-management pursuits. To begin with, an organization is the primary place where one would find the bearer of téchné relevant to that organization, and it is precisely that knowledge that we seek to encapsulate and reuse. Téchné reflects the dynamic nature of knowledge. Furthermore, and perhaps most difficult in practice, it is the téchné that artificial intelligence and decision-support systems seek to automate. So, from that perspective, Aristotle has given us a clearly defined and delimited type of knowledge that can be addressed by information technologies.

Phrónésis: Experiential Self-Knowledge or Practical Wisdom Based on Experience

Phrónésis is practical knowledge dealing with action and getting things done. In Aristotle's view, phrónésis is acquired through hands-on training and experiencing the actions being learned. From a learning-through-action perspective, phrónésis differs from téchné in terms of the way each type of knowledge can be shared. The Aristotelian view would be that téchné can be taught from practitioner to student, whereas phrónésis can only be shared through actual mutual experience. In terms of the value of knowledge, Sveiby's (1997) focus on the knowledge-action value chain can find relevant roots in phrónésis. In terms of knowledge management, phrónésis leads us in the direction of simulation, rich media, e-learning, and other forms of the experiential presentation of knowledge or immersion in a virtual environment in which the experience yielding phrónésis can be achieved.

Noûs: Intuition

Noûs is perhaps the least understood of all elements necessary for knowledge management. Noûs not only embodies the intuitive side of knowledge, it also subsumes a large part of what we have come to refer to as tacit knowledge (although clearly there can be tacit knowledge of téchné and phrónésis). Noûs is not restricted to knowledge of first principles, but is viewed by Aristotle as a manner in which one can become aware of first principles. Observing the relationship between noûs and tacit knowledge, we note that there are two fundamental approaches to dealing with tacit knowledge in knowledge management. The first approach is to attempt to externalize the tacit knowledge through interventions and representation methods in order to create explicit knowledge. This, in essence, is attempting to transform the noûs into the epistémé. The second approach is to recognize that the tacit will and should remain tacit, but that the goal of knowledge management is to enable the organization to identify and reach the owner of the tacit—the bearer of the noûs—in an efficient and effective manner. This leads us to employ information technologies to support organizational communications, forums, communities, relationship networks, and the abundance of Internet-enabled interactions that have developed over the past decade.

Another interpretation of noûs is that it emerges from our familiarity with phrónésis and téchné. In other words, by nurturing our support for phrónésis and téchné, we strengthen our ability to exhibit noûs. Butler (personal communication, 2005), based on Bruner's observation (1962, p. 18) that "the act that produces effective surprise…[is] the hallmark of the creative enterprise," suggests that noûs can come about as a result of the processes in which phrónésis and téchné are applied to repairing breakdowns (and to a certain extent epistémé as well). In other words, what we know and how we intuit noûs comes about in part from our reflections on téchné and phrónésis. Therefore, it would appear that support for the noûs within knowledge management may in fact be derived from our treatment of these two contributing types of knowledge.

Sophia: Theoretical Knowledge of Universal Truths or First Principles

We argue that sophía, representing the universal and necessary characteristics of knowledge, has little place in understanding knowledge specific to organizational knowledge management. While universal and necessary truths are surely important to any analysis and treatment of knowledge, they are firmly in the domain of the philosophical and theoretical. Scientific discovery (which we may wish to manage postdiscovery), argumentation, and proof of theorems are all in the realm of the sophía, but still not within the knowledge-management mandate.

Discussion

The first step in bridging the gap between Aristotle's theory of knowledge and knowledge management is to envision how each Aristotelian virtue can be addressed in each phase of knowledge management. Table 1 illustrates.

We can see that the acquisition, organization, and distribution process demands of knowledge management will differ for each of Aristotle's types of knowledge. By understanding this categorization of knowledge, we can achieve greater clarity of thought in our attempts to develop knowledge-management processes for application in organizational settings.

Finally, we can take the analysis one step further by considering which of the 12 specified processes of knowledge management can be reasonably performed on each type of knowledge, as shown in Table 2.

Consider the noûs, for example. We would argue that while noûs cannot be acquired by an IT-based KM system, it can in fact be discovered, modeled, and classified through the use of social network-mapping tools. True, from a philosophical purist perspective, the noûs itself

Table 1. Mapping Aristotle's knowledge virtues to knowledge management stages

	Acquisition	**Organization**	**Distribution**
Epistémé	By gathering facts and relationships known about the organizational knowledge domain and its human participants	Knowledge bases, databases, data warehouses, documents, and diagrams	Enabled and enhanced by information technologies and computer-mediated communications
Téchné	Through interaction, interviews, and discussions with practitioners who have exhibited acquired téchné	Extensive cross-referencing of skills and activities across the organization	Potentially replicated and implemented through information technologies, artificial intelligence, and decision-support systems.
Phrónésis	By recording lessons learned and case studies in the ongoing organizational experience	Case books, project retrospectives, and narratives	Stored, replicated, and delivered through rich media-based computer technologies
Noûs	By determining paths to those people who have exhibited relevant noûs within the organization By increasing support for phrónésis and téchné	Social networks guided by metaknowledge describing participants and their capabilities	The network through which noûs is uncovered is enabled by computer-mediated communications, forums, and online communities.
Sophía	Not a goal of knowledge management	Not a goal of knowledge management	Not a goal of knowledge management

Table 2. Mapping Aristotle's knowledge virtues to KM processes

Process	*Noûs*	*Epistémé*	*Téchné*	*Phrónésis*	*Sophía*
Acquisition					
creation	no	yes	no	no	n/a
discovery	yes	yes	yes	yes	n/a
gathering	no	yes	yes	yes	n/a
validation	no	yes	yes	yes	n/a
Organization					
modeling	yes	yes	yes	yes	n/a
classification	yes	yes	yes	yes	n/a
calibration	yes	yes	yes	yes	n/a
integration	yes	yes	yes	yes	n/a
Distribution					
sharing	yes	yes	yes	yes	n/a
reuse	no	yes	yes	yes	n/a
maintenance	no	yes	yes	yes	n/a
dissemination	yes	yes	yes	yes	n/a

will always remain within its bearer; however, the sharing and dissemination of knowledge within an organization considers both knowledge and metaknowledge. Having a digital representation of where noûs can be found and how it might be applied is as important for some aspects of knowledge management as building a lessons-learned database is for others. Thus, the values for noûs shown in Table 2 relate to a metalevel reference to the noûs.

Knowledge of the types téchné and phrónésis, while they cannot be created through KM processes, can indeed be discovered, gathered for storage by representational systems, organized, and distributed. While phrónésis and téchné may be the core constituents of practical knowledge (Butler & Murphy, 2006), we can enhance noûs within the organization by increasing accessibility to téchné and phrónésis, leveraging the relationship between these different types of knowledge discussed earlier. Here there would seem to be an important role to be played by metaknowledge describing the téchné and phrónésis within the organization to create some form of organizational noûs, which may effectuate to some degree Heidegger's hermeneutical circle (Sampaio, 1998) or Gadamer's (1975) circle of understanding.

With epistémé we can go a step further and utilize data mining, text mining, neural networks, information resource discovery, and other advanced pattern-recognition technologies to create new knowledge based on the patterns of data that exist within our extensive organizational information systems.

FUTURE DIRECTIONS

For knowledge management to advance, it must continue to explore different theories of knowledge and how those theories will affect both the representation and use of knowledge in organizations.

Viewing knowledge as something that we want to manage forces us to narrow down the realm of epistemology to something we can handle in an applied manner. The analysis shown in this article can also be fruitfully applied to other philosophies of knowledge that differ from the Aristotelian view.

The choice of processes presented in Table 2 is by no means definitive: There are many KM frameworks and models proposing equally attractive alternative sets of processes. However, we should seek the broadest possible matching or coverage between our proposed KM processes and the core knowledge virtues. Subjecting a model of KM processes to some form of "Aristotle test" can help us evaluate the completeness of that model.

CONCLUSION

Understanding and defining knowledge can lead us to an open-ended philosophical debate, or it can lead us to a pragmatic characterization aimed at enabling the organizational goals of knowledge management. By choosing the latter, we are able to focus on those elements of knowledge that truly make a difference in practice: in this case, a mapping of the Aristotelian view to managing knowledge in organizations.

Knowledge can be debated at an epistemological and theological level as seen from Aristotle down to Heidegger and beyond. It can be debated at an implementation and representational level as seen in the ongoing knowledge-information-data discussions. We need to understand and appreciate both debates if we are to engage in the management of knowledge, but we should not let the lack of resolution in either debate hinder our advancement. The pragmatic, process-oriented view of defining and understanding knowledge is what we need to embrace, while the insights from both knowledge debates will continue to inform our activities and enrich our understanding. Examining the philosophical bases of knowledge will enable us to move outward from the philosophical core of Figure 1, to relevant KM processes that can then be moderated by and applied to organizational settings.

Each type of knowledge has different applied value and different challenges in acquisition, organization, and distribution. Aristotle's five core intellectual virtues or types of knowledge can even today serve as a base from which we launch our knowledge-management initiatives, and understanding them will help guide us.

Chapter 7.20
Anti-Foundational Knowledge Management

Tom Butler
University College Cork, Ireland

INTRODUCTION

Under the influence of Enlightenment epistemological thought, the social sciences have exhibited a distinct tendency to prefer deterministic1 explanations of social phenomena. In the sociology of knowledge, for example, "foundational" researchers seek to arrive at objective knowledge of social phenomena through the application of "social scientific methodolog[ies] based on the eternal truths of human nature, purged of historical and cultural prejudices" and which also ignore the subjective intrusions of social actors (Hekman, 1986, p. 5). This article argues that "foundationalist" perspectives heavily influence theory and praxis in knowledge management. "Foundationalist" thinking is particularly evident in the posited role of IT in creating, capturing, and diffusing knowledge in social and organisational contexts. In order to address what many would consider to be a deficiency in such thinking, a constructivist "antifoundationalist" perspective is presented that considers socially constructed knowledge as being simultaneously "situated" and "distributed" and which recognizes its role in shaping social action within "communities-of-practice." In ontological terms, the constructivist "antifoundational" paradigm posits that realities are constructed from multiple, intangible mental constructions that are socially and experientially based, local and specific in nature, and which are dependent on their form and content on the individual persons or groups holding the constructions (see Guba & Lincoln, 1994; Bruner, 1990). One of the central assumptions of this paradigm is that there exist multiple realities with differences among them that cannot be resolved through rational processes or increased data. Insights drawn from this short article are addressed to academics and practitioners in order to illustrate the considerable difficulties inherent in representing individual knowledge and of the viability of isolating, capturing, and managing knowledge in organisational contexts with or without the use of IT.

BACKGROUND: WHAT KNOWLEDGE IS AND WHAT IT IS NOT?

The point of departure for the present treatise on the concept of "knowledge" is a definition that is in good standing within the IS field and which is congruent with extant perspectives across the social sciences (e.g., Grant, 1996). In their book Working Knowledge, Davenport and Prusak (1998) posit that:

Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organisations, it often becomes embedded not only in documents and repositories but also in organisational routines, processes, practices, and norms. (p. 3)

While this definition is, on the surface, all-embracing and without contradiction it does, however, possess certain weaknesses that can only be illustrated by a consideration of taken-for-granted issues of ontology. This involves a description of the relationships that exist between the individual and his social world; that is between the knowing social actor and the social groupings and contexts in which he or she participates and exists, and in which knowledge is socially constructed. In terms of the present analysis, this task begins with a brief consideration of the constructivist, "antifoundational" philosophies of Martin Heidegger and Hans Georg Gadamer in order to sketch out the ontological basis of knowledge. This undertaking is particularly timely given the recent emphasis on knowledge management, which is described "[as] an integrated, systematic approach to identifying, managing, and sharing all of an enterprise's information assets, including databases, documents, policies, and procedures, as well as previously unarticulated expertise and experience held by individual workers."2 Whereas the ability of organisations to identify, manage, and share, databases, documents, and codified procedures using IT is not in question, identifying, managing, and sharing tacit knowledge using IT is questionable, as the following treatise on knowledge illustrates.

An Anti-Foundational Perspective on Knowledge

In response to the question "What is knowledge and what is it not?" we argue that knowledge cannot ever become "embedded…in documents and repositories [and] also in organisational routines, processes, practices, and norms." Why? Precisely because it is impossible to isolate and represent objectively "a fluid mix of framed experience, values, contextual information, and expert insight." Certainly, as Bruner (1990) points out, a social actor's knowledge resides not only in his head, but also in the notes, underlined book passages, manuals, and guides he consults, and in the computer-based data he has access to. This is, in many respects, a shorthand description by Bruner. Social actors use such sources because of their inability to recall every source of data they have interpreted and laid down in memory (see Goleman, 1996)—hence they are considered sources of personal information only for the actor who has painstakingly sought out, collated, and put into context the data contained in each personal artefact. Accordingly, contextual, temporally based data makes the transition to knowledge only when an actor interprets (or subsequently reinterprets) them in order to inform his or her understanding of some phenomenon or other. This is a fairly straightforward task for the individual who has, over time, constructed a personal database of the type described. However, others who access the personal "notes, underlined passages, manuals, etc." that constitute such databases may interpret their content differently and not come to the same understanding, as they may not have the same pre-existing ground of understanding and knowledge of the phenomenon in question as the original author3. All this is indicative of the "situated" and "distributed" and "temporal" nature of knowledge4 (hence the origins of Hermeneutics in biblical studies and philosophy): But how does it relate to the social context and ground of knowledge?

As part of the interpretive process that characterizes all understanding, meaning is attributed to data within the context of the actor's constantly evolving "lived experience" and under the sway of a "tradition" (Gadamer, 1975). Heidegger (1976) and Gadamer (1975) illustrate that the "lived experience" of social actors arises out of the web of encounters and dialogues that characterize individual existence or "Being-in-the-world." The concept of "lived experience" describes the relationship between social actors and other beings that populate the tradition or culture in which they are embedded (in a Heideggerian sense, the term "beings" refers not only to other humans but all social phenomena). In delineating the constitution of "lived experience," Heidegger (1976) points out that social actors are "thrown" into a "life-world" where their existence has, from the outset, been "tuned" or "situated" to be a specific existence with other beings, within a specific "tradition," and with a specific history. However, in order to cope with their "throwness" social actors come ready equipped with a "fore-knowledge" or, in Gadamerian terms, a "prejudice"-laden "effective-historical consciousness," that enables them to interpret, make sense of, and partake in their social world. "Fore-knowledge" is, in many ways, knowledge of the "ready-to-hand" (Zuhanden) that constitutes an actor's "life world." Thus, the "ready-to-hand" possess a degree of familiarity that effectively sees them dissolved into the unreflective background of the actor's daily existence. If, however, something happens that results in a "breakdown" in understanding, social phenomena become the object of "theoretical" reasoning and acquire the ontological status of being "present-at-hand" (i.e., a Vorhanden) until the "breakdown" has been repaired. As Gadamer illustrates, social actors must give recognition to the influence that "effective-historical consciousness" exerts if they are to work out their "prejudices."

The process of "working out" prejudices and of repairing breakdowns in understanding is governed by what Gadamer called the hermeneutic "circle of understanding." Here, the "whole" that constitutes a phenomenon is apprehended by the cyclical interpretation of its constituent "parts" as they relate to each other and to the "whole." In so doing, an actor interprets relevant data as "present-at-hand" using a form of question and answer called the dialectic (Socratic, Hegelian, and Analytic-Reductionist—see Butler, 1998). Thus, the actor's understanding of constituent "parts" will be consolidated, and in so doing the horizons or perspectives of interpreter and interpreted will gradually fuse. Thus, in repairing breakdowns, a "fusion of horizons" (of understanding) takes place between interpreter and interpreted.

The pivotal role of language in the interpretive process of understanding has been noted by Gadamer (1975). Accordingly, Bruner (1990) argues that institutional contexts are socially constructed through the narratives of constituent actors. Thus, over time and through highly complex and ill-defined social processes constituted by a polyphonic dialectic, there evolves a shared understanding that constitutes a culture and tradition. In addition, it is clear from Gadamer (1975) that the authoritative impulse to conform, as indicated by the existence of Heidegger's "das Man," is testimony to the resilience of a shared "world view" among actors in institutional contexts and the unwillingness to accept "new" knowledge (e.g., Leonard-Barton, 1995; Pfeffer & Sutton, 2000). This brief ontological view of knowledge has profound implications for those who examine the nature of knowledge and its diffusion in institutional contexts, as will be seen in the following subsection.

IT AND THE SOCIAL CONSTRUCTION OF KNOWLEDGE

If the key to understanding social action lies in explicating the influence of shared "weltanschauungen," "lived experience," and "tradition," as socially embedded institutional knowledge, then the representation of such knowledge must be the goal of all who propose to manage it. However, the impossibility of this task is underlined by Dreyfus (1998), who cites Husserl's exasperation at trying to give a detailed account of the experience of the everyday lives of social actors. Husserl (1960) termed social actors' representations of their experiential knowledge the noema. However, after devoting his life's work to its delineation, he concluded in the face of the noema's "huge concreteness" that the "tremendous complication" in its representation made it an impossible task (Husserl, 1969, p. 244 and p. 246). Significantly, Minsky (1981) commented on the enormity of attempting to represent commonsense experiential knowledge using computer-based systems. This point is underscored by Bruner (1990) who argues that:

Information processing cannot deal with anything beyond well-defined and arbitrary entries that can enter into specific relationships that are strictly governed by a program of elementary operations. (p. 5)

Thus, in Bruner's Acts of Meaning, the message is clear: The experiential knowledge and skills of social actors cannot readily, if ever, be embedded in IT (see Boland, 1987). However, this is not surprising as Dreyfus (1998) notes that philosophers from Socrates to Husserl have wrestled with the problem of knowledge representation without much success. Nevertheless, additional arguments are now adduced to convince the skeptical.

The socially constructed nature of knowledge is described by Berger and Luckmann (1967) who posit that:

The primary knowledge about institutional order is knowledge on the pretheoretical level. It is the sum total of 'what everyone knows' about a social world, an assemblage of maxims, morals, proverbial nuggets of wisdom, values and beliefs, myths, and so forth, the theoretical integration of which requires considerable intellectual fortitude in itself, as the long line of heroic integrators from Homer to the latest sociological system-builders testify. (p. 65)

This point is indicative of the nature of institutional and organisational reality. For example, it indicates why there exists a high degree of rigidity in and immutability of the social stock of knowledge, especially if beliefs are strongly held, or of a religious nature5. This is why "das Man" exerts such a strong influence in fostering resistance to the acceptance of new knowledge and understanding and why those who articulate it often receive the opprobrium of "true believers."

Berger and Luckmann's insights also are congruent with the perspectives of Heidegger and Gadamer articulated previously. Hence, pretheoretical knowledge, as the articulated (present-at-hand) and unarticulated (ready-to-hand) components of Aristotelian phronesis (experiential "self-knowledge") and techne ("skills-based" knowledge), plays a formative role in establishing canonical modes of behaviour (habitualised social action or organisational routines, if you will) and in the transmission of social behaviours among actor networks (Gadamer, 1975; Dunne, 1993). To underscore the points made here, Dreyfus (1998) turns to Heidegger to argue that "the everyday context which forms the background of communications is not a belief system or a set of rules or principles…but is rather a set of social skills, a kind of know-how, any aspect of which makes sense only on the rest of the shared social background" (p. 285). What then of the IS researchers and practitioners who assume that it is possible to describe and codify social contexts as objective facts and who therefore consider unproblematic the transfer of knowledge in organisations? Dreyfus (ibid.) again draws on Heidegger to reject the notion that "the shared world presupposed in communication could be represented as an explicit and formalized set of facts" (p. 283). All this implies that social knowledge cannot be objectified and exist outside the "heads" of knowers (or the social relationships in which knowledge is constructed and maintained); furthermore, it renders fruitless any attempt to codify it objectively. It also casts doubt on those who speak authoritatively about knowledge transfer mechanisms and who ignore the social contexts that gives rise to such knowledge.

The Aristotelian Perspective on Knowledge

In Book 6 of Nicomachean Ethics, Aristotle focuses on practical and technical reason—phronesis and techne. The importance and relevance of this work to any treatment of knowledge is underscored by Dunne (1993). Hence, an understanding of phronesis and techne is essential to the present project as it brings into sharp focus the situated nature of individual knowledge and, as Gadamer (1975) illustrates, adds to the ontological description already offered. To begin, it must be noted that in reading the Ethics in the context of the Metaphysics one is led to conclude that both phronesis and techne are, ultimately, forms of practical knowledge. However, in the Ethics Aristotle distinguishes between praxis and poiesis. The conduct of social affairs in a thoughtful and competent manner Aristotle refers to as praxis. This involves the application of phronesis, that is, a social actor's experientially based "self-knowledge." Poiesis, on the other hand, Aristotle involves the activities of "making" or "production." Here techne is the kind of knowledge possessed by the expert craftsmen and involves the understanding and application of the principles governing the production of social phenomena—both tangible and intangible. It is important to note that Dunne (1993) in his extensive treatment of the topic interprets phronesis as being practical knowledge and techne as being skills-based knowledge. However, he (ibid.) states, in regard to poiesis and praxis, that: "To these two specifically different modes of activity, techne and phronesis correspond, respectively, as two rational powers which give us two quite distinct modes of practical knowledge" (p. 244). Thus, a social actor's "self-knowledge" or "practical wisdom" (phronesis) is a synthesis of his temporal experience of social phenomena with an ability to perform practical actions in relation to such phenomena. According to Gadamer's (1975) interpretation of Aristotle's phronesis, experiential or "self-knowledge" cannot be learned or forgotten; it is ethical and moral in character and, as such, it is the supreme influence on an individual's actions. It is clear that skill-based knowledge (techne) and theoretical knowledge (as theoria, sophia, or episteme) are informed by the "self-knowledge" (phronesis) of relevant social actors. In so doing, self-knowledge embraces, as Gadamer indicates, both the means and ends of social action. Because of its unique constitution, self-knowledge does not often lend itself to linguistic expression. The same could be said of techne, which provides the expert or craftsman with an understanding of the why and the wherefore, the how, and with-what of the production process. Thus, techne, in providing a rational plan of action, also embraces both the means and ends of production activities.

FUTURE TRENDS: IMPLICATIONS OF PHRONESIS AND TECHNE FOR KNOWLEDGE MANAGEMENT

This article argues that an understanding of phronesis and techne as the two primordial components of individual practical knowledge is vital for researchers and practitioners who involved in creating knowledge management systems (KMS), yet studies on information systems development and the field of knowledge management pay scant attention to the ontological ground of knowledge. Consider the assertion by Checkland and Holwell (1998) that "the core concern of the IS field [is] the orderly provision of data and information within an organisational using IT" (p. 39)—clearly this involves the development of IS and their use.

So what of the posited role for IT in the management of knowledge? Can phronesis and techne be embedded in IT? And can such systems account for all contingencies in their application? As Orr (1990) illustrated in his study of photocopier repair technicians, the attempted codification of a fairly well defined techne proved a failure; here phronesis proved the more influential of the two types of individual knowledge. Why? Because of the contextual nature of the Heideggerian breakdowns encountered and the experiential knowledge of the repairmen, some of which was vicariously acquired through the Brunerian narratives they engaged in while constructing their "community of knowing." How then can IT capture adequately the experiential and interpretive nature of the phronesis required for this type of problem-solving? As Dreyfus (1998) concludes, the answer to this question is "It cannot."

Consider also the IT-enabled techne of processing a business transaction. It is evident that the experiential knowledge of the business person managing the transaction plays a major role in dictating the questions posed and details taken in efficiently executing a transaction, irrespective of the routines and activities embedded in an IT-based business information system. Why? Because information systems are "closed" in the sense that they cannot ever capture all aspects of a business problem domain. In different spheres of organizational activity, the data required to resolve a breakdown might be of a more comprehensive nature (e.g., a report or narrative aimed at informing task-based problem-solving) while targeting a problem-solving techne. In this scenario, the context-dependent experiential knowledge of both the author and the recipient(s) will be of special import and will depend on the actors' unarticulated, shared social background. If, for example, the author and recipient belong to a particular socially constructed "community-of-practice" (Brown & Duguid, 1991), then each will participate in a shared tradition with similar phronetic and technic backgrounds. However, even with this shared background, Boland and Tenkasi (1995) indicate that the support available from conventional systems will be limited to well-defined user needs. Echoing Boland and Tenkasi (1995), McDermott (1999) argues that the important "technical challenge is to design human and information systems that not only make information available, but help community members think together" (p. 116); However, McDermott (1999) cautions that "[t]he great trap in knowledge management is using information management tools and concepts to design knowledge management systems" (p. 104).

Given all that has been said here, it is doubtful that the futuristic "electronic communication forums" suggested by Boland and Tenkasi (1995) will be anymore successful than their data processing predecessors in supporting knowledge transfer and management within "communities of knowing," despite shared phronetic and technic backgrounds. Echoing Dunne (1993), practical knowledge (as phronesis and techne) is a fruit that can grow on the fertile soil of individual experience; however, experience of the world occurs within a web of social relationships, and individual knowledge develops within the historical context of a tradition under the influence of significant others. But what are the implications in this for the IS field?

Consider, for example, that extant perspectives on IT capabilities chiefly operate from resource-based view of the firm6, which, with certain exceptions, is chiefly positivist in its orientation and focuses on the outcomes of the application of capabilities rather than the process by which they come into being (Butler & Murphy, 1999; cf. Wade & Hulland, 2004). It is clear from the literature that the resultant applications of this theory of the firm are not sensitive to the type of ontological issues described herein and, accordingly, fail to capture the social and historical nature of knowledge in institutional contexts. On this point, future studies on the development and application of IT capabilities should, we believe, take an interpretive stance and focus on how phronesis and techne are developed and applied in institutional contexts and not just on outcomes of their application.

CONCLUSION

This article joins calls within the IS field for a reassessment of its position on the important topic of knowledge (see Galliers & Newell, 2001). True, the fundamental ideas presented herein are not new, but the manner of their presentation and argument is. In any event, given the recent feeding frenzy on the topic of knowledge and the unquestioning acceptance of the nostrums proposed by some of those championing the cause, a timely injection of commonsense is called for. To recap, this article's main argument is that knowledge of social phenomena, which is enmeshed in a web of social relationships and contexts, defies objectification and cannot be comprehensively and unambiguously represented due to the uncertainty that arises from interpretations that are informed by divergent "worldviews" and different "horizons of understanding." Institutional knowledge does not therefore exist as an objective phenomenon outside of the heads of the knowers and their "communities-of-practice," where it exists primarily in the intersubjective understandings of social actors.

Having illustrated why knowledge cannot be represented objectively, a question is raised as to the status of information. Following a constructivist logic, Introna (1997) points out that information is "hermeneutic understanding" and is acquired through an interpretive process by an "already-knowing" individual. Hence, if information also is abstract and ambiguous in its depiction, data is all that can be represented, stored, transferred, and manipulated by IT. It must be emphasized that the primary mode of informing is the narrative: Narratives serve to define the canonical, and help construct and maintain institutionalised patterns of behaviour. Nevertheless, narratives, written or oral, consist of data, not knowledge or information—hence, the need for dialogue and dialectic. Therefore, if information technology is to be utilized to give voice to organizational narratives, then it must be recognized that it will be a conduit for data only. And, because gaps in comprehension will always exist, no matter how sophisticated the technology and its power of representation, IT must enable a dialectic to take place between social actors and the phenomena they wish to understand. These points are reflected in the capabilities of the latest generation of Internet/Intranet-enabled knowledge management tools7. Although the vendors of such products argue that they are capturing the knowledge of customers, employees, and domain experts, the inputs to and outputs from such applications tend to be well-defined and constitute significant abstractions from the phronesis and techne of social actors (again in the form of data). Hence, considerable interpretation is required, and while knowledge base inference engines are limited in this respect (Butler, 2003), human beings are well adapted to this process, even though their interpretations of phenomena rarely concur with those of other actors, except in situations where the data in question is well delimited. That such systems are of limited value in helping social actors communicate and repair the breakdowns they encounter is not at issue; they do not, however, help social actors manage knowledge in organisations.

Chapter 7.21
Social Philosophy, Communities, and the Epistemic Shifts

Angela Lacerda Nobre
ESCE-IPS, Portugal

INTRODUCTION: DOMINANT AND PERIPHERICAL INFLUENCES

It is critical to distinguish between mainstream traditional management theory and the myriad of complementary approaches that have contributed to the development of alternative approaches to organisational and management theory. The dominant stream of management theory is still largely influenced by the command and control paradigm developed over a century ago by early theorists such as Weber, Taylor, and Fayol. Though the control paradigm today is closely connected to a technocratic and functionalistic perspective of management science, there is a growing awareness of the dangers of assuming a reductive and limited view of organisational complexity. In other words, it is important to recognise the role of bureaucratic, functional, and procedural-like aspects of organisational life, though it is critical to complement these perspectives with richer and more human-centred interpretations of organisational reality. This critical role is performed by, among others, communities of practice theory (Lave & Wenger, 1991; Wenger, 1999; Wenger, McDermott & Snyder, 2002; Brown & Duguid, 1991). In order to better understand the developments in terms of management thinking, it is relevant to revise the sequence of the different schools of thought that influenced the social sciences throughout the 20th century.

BACKGROUND

At the end of the 19th century, the spreading and dissemination of the use of electricity for industrial and domestic use implied profound changes in the way people lived and organised their lives. In parallel with this technologic development, there was a radical change in mentalities. The confident and self-assuring concept of human beings as rational, independent, and autonomous individuals had been the product of the Enlightenment movement of the 17th and 18th centuries, which followed from the 15th and 16th centuries' scientific revolution. Opposing the rationalist and utilitarist perspective, there emerged the idea that humans present different forms of rationality, some of which imply conflicting perspectives; that human beings are not that independent from the social structures in which they are immersed; and that there are hidden inner processes which undermine their apparent autonomy (Foucault, 1972). Following this process, holistic and systemic perspectives had to be incorporated and integrated into social sciences in order to acknowledge this complexity.

At the end of the 20th century, or rather throughout the whole century but more visible in the last quarter of the century, a similar move has occurred which has intensified the previous development. This development is still going through, and may go unnoticed if we fail to recognise the need for a change in perspective and of point of view. This change places its focus and its epicentre on the intrinsic and inherent nature of all human action and thought as socially embedded phenomenon. In order to grasp the importance of this change, it is critical to point out that this notion of social embeddeness has surpassed the traditional binary opposition between individual and social issues which still permeates current and mainstream management and organisational perspectives. Instead of opposing or separating psychological and sociological issues, it treats the individual and the collective, the internal and the external, the inner and the outer world as a unique single reality. In other words, it does not partition and divide, study each isolated part, and then take the result of this process for the whole. Rather, it takes the whole from the start.

Several contemporary organisational theories follow this pragmatist approach. Pragmatism was developed by Peirce who, at the end of the 19th century and together with Saussure, created the two large schools of semiotics that have been largely influential throughout the 20th century. Among these non-dualistic, post-cognitivist, and post-structuralist thinking approaches are Stacey's complex responsive processes (2001), Checkland's soft systems methodology (1984, 1999), Eijjnatten's chaordic systems thinking (2003), Alvesson and Skoldberg's reflexive methodology (2000), and Weick's organisational sense-making (1995, 2001).

MAIN FOCUS: THE EPISTEMIC SHIFTS

The importance of the concept of communities of practice at an organisational level is parallel to the growth in the interest of management approaches such as organisational learning and knowledge management. At a broader level, this development reflects the reactions from the management and organisational areas to the reality of the knowledge economy of the information age (Kearmally, 1999). This movement may be considered as the tip of an iceberg, as the culmination of a long process of development that is still going on.

Social philosophy is a valuable reading matrix for the interpretation of the current complexity of an organisation's environments. If we want to understand the work of Aristotle, we have first to grasp what issues and questions he was trying to answer—his context. In order to understand how to implement organisational practices such as collaborative work and learning, or knowledge creation and sharing, we first have to grasp the necessary conditions for them to work—that is, the relevant community of practice, of learning, or of interest. Communities refer to the form and context of human interaction, to the situated and embodied character of human action and thought. The community concept brings up the social, cultural, and historical underpinnings of individual embeddeness. The hidden part of the iceberg includes a myriad of threads which the philosophy of the social sciences may help to untangle.

Applying this line of reasoning to the field of communities of practice is equivalent to trying to unveil the hidden influences and underpinnings that condition its development, as well as its potential for action: the exploration of the full capacity of the communities of practice theory and practice within organisational settings, the thought-possibilities and action-possibilities of communities of practice as such.

The argument is that social sciences, as a whole, frame and condition the emergence of theories and concepts such as, for example, communities of practice theory. Foucault did a historical analysis of social sciences, or the "human sciences" as he called them (Foucault, 1970; Delanty, 2003; McHoul & Grace, 1993). He looked at the structure of knowledge of a time, at its way of establishing order. He starts long before the existence of the human sciences, and examines the development of the fields known in the seventeenth and eighteen centuries as general grammar, natural history, and the analysis of wealth. He considers the question of what marks the shift into the modern world and claims that before the 18th century, man did not exist. Of course human beings existed before that, and may even have looked at themselves as the centre of the universe. But they were central because God had made them that way. Man was then left with only himself at the centre, as the sole source of knowing, and thus turned to intense examination of what this knowing being was. The Human Sciences sprang up as old fields were re-examined, with a new notion of Man as both the object and the subject of study.

From empiricism and positivism, through rationalism, structuralism, interpretativism, pragmatism, post-structuralism, and post-modernism, the development of the philosophy of social sciences presents a broad array of trends and approaches. Though each one of them may still be present today through the influence it had in the development of specific knowledge areas, when taken as a whole it is possible to differentiate four epistemic shifts throughout the 20th century (Delanty & Strydom, 2003). The first and second shifts developed in the first part of the century, and the third and fourth on the second part. These divisions are not to be taken as once and for all changes, as each one of them still persists today. They mutually influenced and reacted against each other from the start.

The first is the logical turn, in early 1920s, originating in the work of the Vienna Circle, which reacted against 19th century's positivism and promoted logical positivism. Authors such as Schlick and Carnap are examples of this period. Wittgenstein travels at the time connected with Cambridge and Vienna thinkers.

The second shift is the linguistic turn, which developed out of the works of Saussure and Peirce at the turn of the century, and then it was further developed by Wittgenstein, Morris, and many others throughout the first half of the century. Levy-Strauss developed structuralism by applying Saussure's thought to culture in general. The interest in language included not only the syntax and semantic aspects, the structure and meaning, but also and above all the pragmatics of language use.

The third epistemic shift is the context turn, from post-war to the 1970s, and refers to an extension of the linguistic turn into a full historical-cultural revolution which radically contextualised science. Kuhn's work on the conflict of paradigms reflects this change. This development implied also a relativist turn. Further examples of this movement are the feminist standpoint epistemology, radical hermeneutics, constructivism, poststructuralism, and postmodernism, as well as the works of Foucault, Derrida, Rorty, and Bourdieu.

The fourth shift is the knowledge turn during the last quarter of the century; it is an attempt to deal with the problem of the inherent ambiguity and diffuseness of context. It is the turn towards knowledge in the discourses of the human and social sciences.

…knowledge recovers from the full implications of the historical-cultural turn…Knowledge is less about knowing reality than about emergent forms of the real and reflexive relation to the world in which reality is shaped…. (Delanty & Strydom, 2003, p. 10)

Apel, Habermas, and Fuller's work are examples of this shift. Delanty and Strydom call attention to the cognitive practices, structures, and processes that are constitutive of knowledge creation, that in turn occurs within research programs, traditions, and scientific communities. These authors refer that in parallel with the rise of cognitivism, and the interest in reflexivity, new controversies emerged such as the constructivist versus realism dilemma.

From this broad spectrum of approaches related to the historical development of social philosophy, we will situate the emergence of the communities of practice theory.

FUTURE TRENDS AND INFLUENCES

Marginally ignorant and indifferent to the logical, linguist, context, and knowledge epistemic turns of the social sciences, the vast majority of dominant theories and approaches within the fields of management science and organisational theory grew out of the influence, and still remain today largely influenced, by positivist, Cartesian, rationalist, mechanist, and utilitarian philosophical approaches, which developed out of the European Enlightenment. The sophistication of management theory and practice often remains secured within the broad positivist umbrella. This influence is usually subtle and pervasive so that more often than not it remains invisible, thus unquestioned and uncriticised.

Under this perspective, none of the epistemic turns directly and fundamentally influenced the core and functionalistic approach of mainstream management science, as it still remains constitutively determined by pure rationalist influences. Simultaneously to this core-functionalistic management centre, there is a minority and peripheral development which has long invested in non-orthodox and non-traditional management and organisational studies, ranging from cultural and sociological analysis, to the study of organisational development. It is critical to acknowledge these contributions, though still today, they are far from attracting the attention that they deserve. Even within the relatively recent fields of organisational learning and knowledge management, there are still prescriptive, linear, reductionist, and immediatist trends. The holistic, complex, and interpretative perspective of organisational reality is more an ideal than a widely disseminated reality.

These comments are not a dualistic, black-and-white analysis, but rather they aim at calling attention to the immense importance and the critical role of the communities of practice concept. By definition, this concept is intrinsically and inherently non-positivist. It is dynamic, flexible, and open, because it does not stand on rigid rules, clear-cut definitions, quantitative rationale, and universal laws. Its focus is on the particular and not on the general, on the local and not on the universal, on quality and not on quantity. This implies that the theory of the communities of practice potentially embodies every single contribution of all different epistemic turns which occurred in the social sciences during the 20th century.

A second aspect of analysis and directly related to this discussion is what Delanty and Strydom (2003) referred to as the fourth epistemic shift, the knowledge turn. Under their view, there is a radical importance given to cognitivism which becomes as if the new centre of the universe. However, cognitivism is still under a Cartesian and dualistic influence, focusing on the passive observer; on the rational, autonomous, and independent subject;, and on the mind as the centre and single focus of all rationalisation processes. Here, once again, the communities of practice theory implies a 180-degree shift as it calls attention to the intrinsic social nature of knowledge creation, and to the cultural, social, and historical embeddeness of every single human activity, from the external, visible interaction to the internal and invisible thought processes.

CONCLUSION

This somewhat harsh and direct discussion needs a devil's advocate comment. Both positivist and cognitivist approaches represent extremely valuable contributions to humankind and to science in general. The extraordinary development of science and technology, as well as the direct gains obtained from cognitivist research, are overwhelmingly important. At a different level, and within the management field, the functionalistic and mechanistic approaches are crucial in defining routines and procedures. No organisation could survive if it completely ignored its basic and repetitive tasks, and its rigid and bureaucratic structures. The issue that we have been referring to goes beyond these contributions and relates to the urgent and drastic need to pay as much attention to the visible, individual, immediate, repetitive, and standardised issues as to the invisible, collective, complex, subtle, and dynamic aspects of organisational life. Communities of practice theory corresponds to this effort which implies a hidden and subtle thought revolution. Referring again to the epistemic shifts, this thought revolution takes aspects of all previous contributions and integrates them within the fourth knowledge turn, which then becomes not solely restricted, reduced to, and limited by a cognitivist approach. And this is the greatest challenge and potential contribution that may be expected from communities of practice theory.

Chapter 7.22
Phenomenon of Duality:
A Key to Facilitate the Transition From Knowledge Management to Wisdom for Inquiring Organizations

Nilmini Wickramasinghe
Cleveland State University, USA

ABSTRACT

"Wisdom is what you learn after you think you know it all" - unknown

In today's knowledge-based economy, sustainable strategic advantages are gained more from an organization's knowledge assets than from its more traditional types of assets, namely, land, labor, and capital. Knowledge, however, is a compound construct, exhibiting many manifestations of the phenomenon of duality such as subjectivity and objectivity as well as having tacit and explicit forms. Overlooking this phenomenon of duality in the knowledge construct has not only led many knowledge management initiatives to stumble but has also resulted in the discussion of the apparent contradictions associated with knowledge management in the IS literature as well as numerous discussions and debates regarding the "nonsense of knowledge management." It is the thesis of this chapter that a full appreciation of the phenomenon of duality is indeed necessary to enable inquiring organizations to reach the state of wisdom and enlightenment.

INTRODUCTION

Throughout the ages, the nature of knowledge has been central to many debates between philosophers, scientists, academics, and practitioners. In fact, it was the forbidden fruit from the Tree of Knowledge of Good and Evil that caused

Adam and Eve to be dismissed from the Garden of Eden; in addition, interestingly enough, the understanding of Good and Evil, a duality, was to lead Adam and Eve to wisdom. A key underlying and recurring theme in some shape or form with respect to knowledge in all these discussions is the phenomenon of duality as it relates to the knowledge construct and its management. Duality, or the principle of duality, refers to the existence of two irreducible aspects or perspectives that tend to complement each other, as in the example of Adam and Eve, the Tree had knowledge of good and evil. The key to the understanding of duality is that given the existence of duality, one must take a holistic perspective and realize that there is a harmonious balance between these duals. In contrast, taking a singular or one-dimensional perspective will lead to an incomplete understanding and consequently decisions and/or judgments based on such an incomplete view will then be suboptimal or less sound.

Webster's Dictionary defines wisdom as accumulated learning that provides knowledge, the ability to discern inner qualities and relationships, that is, insight and leads to sound judgment. Succinctly stated then, wisdom requires knowledge and is concerned with understanding principles and then being able to make sound decisions and/or judgments based on such an understanding. Knowledge is not a homogenous construct, rather it is a compound complex construct. One of the reasons knowledge is compound in nature is because it exhibits numerous duals at many levels. This chapter contends that by understanding the phenomenon of duality and how it relates to the knowledge construct, not only will inquiring organizations firstly be able to better understand the compound knowledge construct and its management, but also this will facilitate their moving from knowledge management to wisdom.

In this chapter, many specific manifestations of the duality phenomenon as it relates to knowledge and its management are highlighted, such as the subjective and objective perspectives, the consensus versus disensus perspective, the Lockean/Leibnizian aspects of knowledge versus the Hegelian/Kantian aspects, and the people versus technology dimensions. Throughout the chapter, no one perspective is singled out as correct or incorrect, rather the emphasis is on the fact that these respective duals not only underscore the duality phenomenon at different levels but are all useful, necessary, and important for an inquiring organization to fully appreciate the compound quality exhibited by the knowledge construct and thereby embrace superior knowledge management strategies, techniques, tools, and processes. In addition, a sound understanding of the duality phenomenon as it relates to knowledge will not only facilitate a better understanding of how to embrace knowledge management, an important strategy in today's knowledge economy (Drucker, 1993), but also address key needs such as identified by Nonaka that "few managers grasp the true nature of knowledge creating companies--let alone how to manage it" (Holsapple & Joshi, 2002, p. 47) and Ann Stuart that "[m]any managers would be hard pressed to explain precisely and concisely, what this evolving business trend (knowledge management) means" (Holsapple & Joshi, 2002, p. 47). The following then, serves to address this duality phenomenon with respect to the knowledge construct and thereby highlight that a true appreciation of this duality phenomenon with respect to knowledge and knowledge management, more specifically, should enable "the getting of wisdom" for inquiring organizations.

The chapter is structured as follows: first a background section which gives a brief description of key terms required for an inquiring organization to move from knowledge management to wisdom is presented as well as a brief synopsis of inquiring organizations and the integral role of knowledge and its management for these organizations. In addition, this section discusses the compound nature of knowledge and why knowledge as opposed to its related cousins, data, and information, exhibits this duality phenomenon. Then, a discussion of knowledge management, the knowledge construct as well as the major philosophical perspectives for understanding knowledge management is presented. This is followed by a discussion of the key perspectives of knowledge creation. Next, some specific dualities are highlighted and discussed in turn. Finally, conclusions are drawn and avenues for future research highlighted.

BACKGROUND

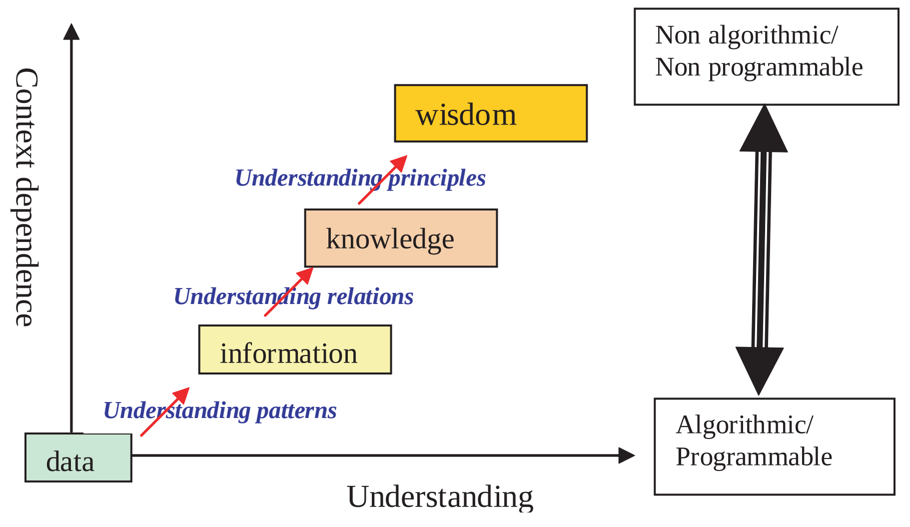
This sections serves to define knowledge and why it is a compound construct. In so doing, it also discusses other relevant terms, including data, information, wisdom, and understanding. The section will also summarize the integral nature of knowledge and knowledge management for inquiring organizations.

From Data to Wisdom

In today's knowledge economy, data can be viewed as an abundant, vital, and necessary resource. It is then possible to tap into this reservoir and by utilizing new ways to channel raw data into meaningful or processed data to form information. This information, in turn, can then become knowledge that ultimately with further understanding leads to wisdom (Alberthal, 1995). Thus data, information, knowledge, and ultimately wisdom are not just connected, but it is also possible to generate knowledge from data, thereby making data and information valuable raw materials in the knowledge economy.

Data can be defined as a series of discrete events, observations, measurements, or facts in the form of numbers, words, sounds, and/or images. In organizations, much of the useful data is in the form of transaction records, stored in data bases and generated through various business

Figure 1. Data to wisdom



processes and activities. Today organizations generate large amounts of various types of data. Given its discrete form, data is not very useful as it is and needs to be processed. When this data is processed and organized into a context, it becomes information. In transforming data into information, five important Cs have taken place as noted by Davenport and Prusak (1998), as follow:

1. Contextualized: the purpose surrounding the data collection/gathering is known.
2. Categorized: the key units of analysis and key factors relating to this data are known.
3. Calculated: mathematical and/or statistical analyses have been performed on this data.
4. Corrected: errors in this data have been corrected or accounted for.
5. Condensed: the data has been summarized and distilled.

There exist many plausible definitions of knowledge. For the purposes of this chapter, the definition of knowledge given by Davenport and Prusak (1998) will be used because it is not only broad and thus serves to capture the breadth of the construct but also and, perhaps more importantly for this discussion, it serves to underscore that knowledge is not a simple homogeneous construct, rather a compound construct:

"Knowledge is a fluid mix of framed experiences, values, contextual information, and expert insights that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it is often embedded not only in documents or repositories but also in organizational routine, processes, practices and norms." (p. 5)

In transforming information to knowledge, the role of people is integral. Furthermore, such transformations take place with four key C activities identified by Davenport and Prusak (1998), including:

1. Comparison: information in one scenario is compared and contrasted with another.
2. Consequences: what implications does the information have for decision making?
3. Connections: how does this bit of information and/or knowledge relate to another?
4. Conversation: what do people think of this information?

What is important to note about these four C activities is that they require human cognitive processes to take place, which are all concerned, to a greater or lesser degree, to the understanding of relations and tend to be subjective in nature, unlike the five C activities associated with information which require more mechanistic or objective functions of understanding patterns. Herein lies the reason for why knowledge as opposed to its cousins of data and information can exhibit the phenomenon of duality, while the more simplistic constructs of data and information do not.

Understanding is an interpolative and probabilistic process where one can take knowledge and synthesize new knowledge from the previously held knowledge. The difference between understanding and knowledge is the difference between learning and memorizing (Wickramasinghe & Sharma, in press). Finally, wisdom is an extrapolative and nondeterministic, nonprobabilistic process (Wickramasinghe & Sharma, in press). It calls on all the previous levels of consciousness, and specifically on special types of human programming (moral, ethical codes, etc.). Given this explanation of wisdom coupled with Webster's definition of wisdom presented in the introduction, what becomes apparent is that to obtain wisdom in addition to knowledge, the understanding of principles is required, and a holistic rather than a singular inquiry system is necessary but not sufficient to the achievement of such a state. Furthermore, such a state of wisdom will lead to sound decision making and judgments.

From Figure 1, several aspects are important to note with respect to the progression from data to wisdom. First, as we move from left to right in the figure, or as we move from data to wisdom, we also move from constructs that are algorithmic and programmable to constructs that are nonalgorithmic and nonprogrammable. This means that while data is highly programmable and algorithmic, wisdom is almost nonprogrammable and nonalgorithmic. Further, we can see from Figure 1 that data is highly context independent while wisdom is highly context dependent. Therefore, the specific context becomes an integral component in the managing of wisdom, and while it is possible to generate a precise prescription for managing data, it is very difficult to generate a similar prescription for facilitating an organization to manage wisdom. The key then to achieving wisdom lies in the understanding and consequent application of principles, that is, making sound judgments and decisions based on a solid understanding of key underlying principles. One such principle is the principle of duality as it relates to the knowledge construct and knowledge management.

Synopsis of Knowledge and Its Management for Inquiring Organizations

In trying to understand knowledge, knowledge management, and related concepts, such as organizational learning and organizational memory, numerous researchers have employed the structure of an inquiring organization (Churchman, 1971; Courtney, 2001; Courtney, Croasdell & Paradice, 1998; Hall, Guo & Davis, 2003; Malhotra, 1997). By doing so, they are able to view knowledge creation and thereby examine knowledge, its management, as well as organizational learning and organizational memory through a systems lens. Since inquiring organizations employ inquiring systems consisting of interrelated processes, procedures, and other measures for producing knowledge on a problem or issues of significance (Courtney, Chae & Hall, 2000; Mitroff & Linstone, 1993), knowledge and its management then become integral to all major activities of inquiring organizations. To be successful today, the modern organization must be a learning organization (Senge, 1990). By viewing such a learning organization as an inquiring system and thus an inquiring organization, it is not only possible but useful to do so in order to identify knowledge creation, in particular, valid knowledge produced (Courtney et al., 1998; Courtney, 2001; Hall, Paradice, & Coutrney, 2003; Malhotra, 1997).

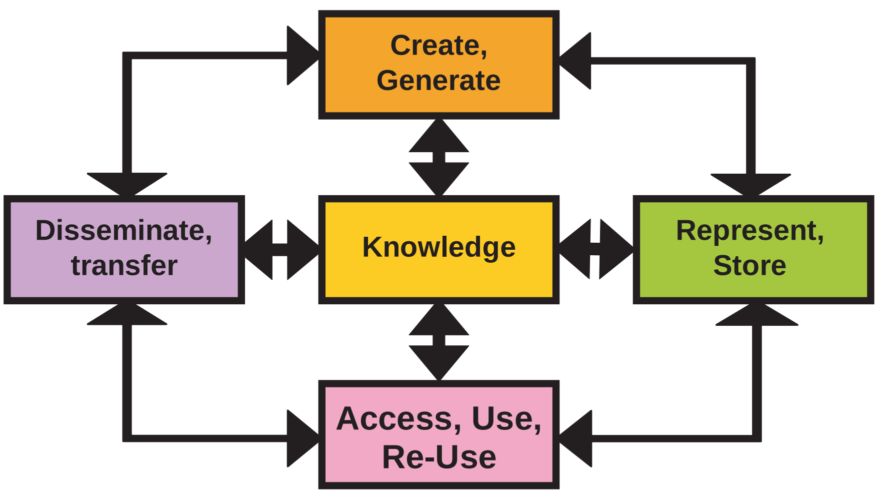
These inquiring organizations have typically been discussed as different types, corresponding to the different types of inquiring systems first identified by Churchman (Courtney et al., 2000) where Churchman's Leibnizian inquirer has led to the Leibnizian inquiring organization, his Lockean inquirer has led to the Lockean inquiring organization, his Hegelian inquirer has led to the Hegelian inquiring organization, his Kantian inquirer has led to the Kantian inquiring organization, and his Singerian inquirer has led to the Singerian inquiring organization, respectively. Such a singular perspective, however, appears limiting given the compound nature of knowledge itself. In this way, knowledge as a construct is set apart from related constructs of data or information because, unlike its distant cousins, it does in fact display instantiations of the phenomenon of duality. Hence, this chapter proposes an embracing of the phenomenon of duality into such inquiring systems and corresponding inquiring organizations as a necessary step to the acquiring of wisdom. Duality with respect to the knowledge construct and some of its manifestations will now be presented.

KNOWLEDGE MANAGEMENT

Knowledge management is a key approach currently being embraced by many organizations, irrespective of their industry to solve problems, such as competitiveness and the need to innovate, which are key challenges faced by businesses today. The premise for the need for knowledge management is based on a paradigm shift in the business environment where knowledge is central to organizational performance (Swan, Scarbrough & Preston, 1999). This macro-level paradigm shift also has significant implications on the micro-level processes of assimilation and implementation of knowledge management concepts and techniques (Wickramasinghe & Mills, 2001), that is, the Knowledge Management Systems (KMS) that are in place. In essence then, knowledge management not only involves the production of information but also the capture of data at the source, the transmission and analysis of this data as well as the communication of information based on or derived from the data to those who can act on it (Davenport & Prusak, 1998). Hence, knowledge management consists of four key steps (create/generate, represent/store, access/use/reuse, and disseminate/transfer) as depicted in Figure 2.

From Figure 2, it is important to notice that these steps are all interrelated, continuous, and impact each other and the knowledge itself throughout the organization. Furthermore, a full appreciation of the knowledge construct, the central component in Figure 2, has far reaching implications on the well functioning of all four steps and the sustainability of sound knowledge management practices. In order to better understand this knowledge construct, it is first important to identify the types of knowledge that exist. Given that the inquiring systems within inquiring organizations result in knowledge creation (Courtney et al., 1998), knowledge management becomes a necessity for inquiring organizations while a fuller understanding of the knowledge construct itself becomes a vital pursuit, and such a fuller understanding should incorporate an understanding of the various dualities that exist and the need

Figure 2. Four key steps of knowledge management



for achieving a harmonious balance of these duals in all their manifestations.

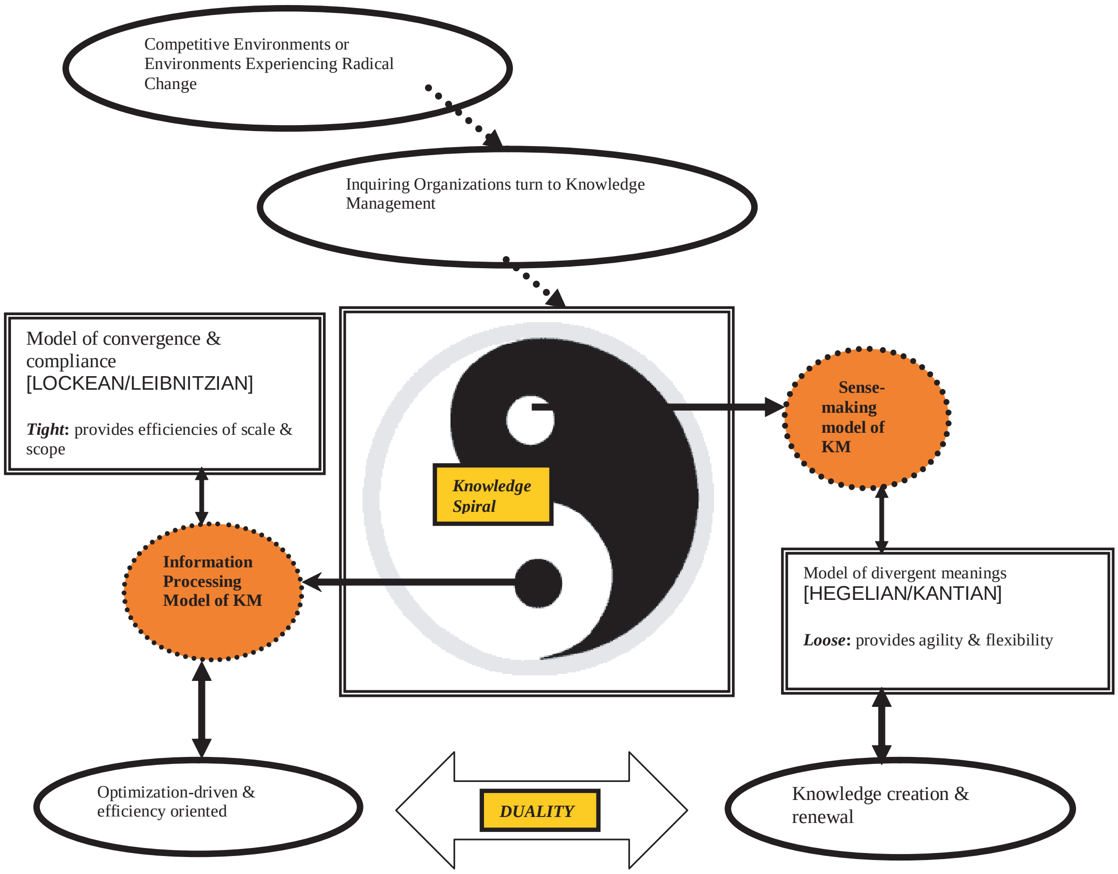
Types of Knowledge

In trying to understand the knowledge construct, it is necessary first to recognize the binary nature of knowledge, namely, its objective and subjective components (Wickramasinghe & Mills, 2001; Alavi & Leidner, 2001; Schultze & Leidner, 2002; WIckramasinghe & Lamb, 2002). Knowledge can exist as an object, in essentially two forms: explicit or factual knowledge and tacit or know-how (Haynes, 1999, 2000; Polyani, 1958, 1966). It is well established that while both types of knowledge are important, tacit knowledge is more difficult to identify and thus manage (Nonaka, 1994; Nonaka & Nishiguchi, 2001). Of equal importance, though perhaps less well defined, knowledge also has a subjective component and can be viewed as an ongoing phenomenon being shaped by social practices of communities (Boland & Tenkasi, 1995). The objective elements of knowledge can be thought of as primarily having an impact on process while the subjective elements typically impact innovation. Both effective and efficient processes as well as the functions of supporting and fostering innovation are key concerns of knowledge management. Thus, we have an interesting duality in knowledge management that some have called a contradiction (Schultze, 1998) and others describe as the loose-tight nature of knowledge management (Malhotra, 2000).

The loose-tight nature of knowledge management comes to being because of the need to recognize and draw upon some distinct philosophical perspectives, namely, the Lockean/Leibnizian stream and the Hegelian/Kantian stream. Models of convergence and compliance representing the tight side are grounded in a Lockean/Leibnizian tradition. These models are essential to provide the information processing aspects of knowledge management, most notably by enabling efficiencies of scale and scope and thus supporting the objective view of knowledge management. In contrast, the loose side provides agility and flexibility in the tradition of a Hegelian/Kantian perspective. Such models recognize the importance of divergence of meaning which is essential to support the sense-making subjective view of knowledge management. Figure 3 depicts the Yin-Yang model of knowledge management (Wickramasinghe & Mills, 2001). The principle of Yin-Yang is at the very roots of Chinese thinking and is centered around the notion of polarity or duality not to be confused with the ideas of opposition or conflict (Watts, 1992). By incorporating this Yin-Yang concept of duality and the need to have or recognize the existence of both components present, yet not necessarily in equal amounts, is appropriate for describing knowledge management from a holistic perspective. Further, by recognizing the manifestations of duality that exist with the knowledge construct as identified in Figure 3 and thereby taking such a holistic perspective, not only are both sides of these duals recognized (i.e., the loose and tight perspectives, subjective/objective, consensus/disensus, Lockean/Lebnizian vs. Hegelian/Kantian) but also, and more importantly, both are required (at least to some extent) in order for knowledge management to truly flourish.

Specifically, Figure 3 shows that given a radical change to an environment or given a highly competitive environment, an organization needs knowledge to survive; implicit in this model is the fact that the organizations that are being described are in fact inquiring organizations in today's competitive business environment. From the Yin-Yang depiction of knowledge management, we see that knowledge is required for the organization to be effective and efficient, but new knowledge and knowledge renewal is also necessary, thereby making both forms of knowledge (i.e., both sides of the duality) important for an organization to capture in order to truly benefit from knowledge

Figure 3. Yin-Yang model of knowledge management (adapted from Wickramasinghe & Mills, 2001)



management. The knowledge spiral represents the transformations that take place in knowledge creation (Nonaka, 1994; Nonaka & Nishiguchi, 2001) as well as a dynamic equilibrium between key dualities.

Such a holistic perspective then strongly suggests that focusing on only one component or having a singular perspective of an inquiring system without any regard for the other side of any given dual is limiting and likely to lead to a less complete picture of knowledge creation, hence, the need to recognize the duality phenomenon for inquiring organizations. The importance for inquiring organizations then, becomes twofold: (a) to recognize and understand this underlying principle of duality and (b) to utilize it by, in essence, finding the right mix of the duality or harmonious balance between these duals for the specific context, given the context-dependent nature of wisdom. Thus, the Lockean inquiring organization grounded in a Lockean inquiring system should not totally ignore aspects of a

Hegelian or Kantian inquiry system in order to create a fuller picture of valid knowledge. It is important to note here, however, that unlike the case with data, this right mix is neither programmable nor algorithmic and thus requires a deep understanding of the duality principle as well as the organization's specific context and what is key in that specific context; in this way, valid knowledge should be resultant and hence a state of wisdom achieved.

The Knowledge Spiral

Knowledge is not static; rather it changes and evolves during the life of an organization. What is more, it is possible to change the form of knowledge, that is, turn tacit knowledge into explicit and explicit knowledge into tacit or to turn the subjective form of knowledge into the objective form of knowledge (Wickramasinghe & Mills, 2001). This process of changing the form of knowledge is known as the knowledge spiral (Nonaka, 1994; Nonaka & Nishiguchi, 2001). Integral to this changing of knowledge through the knowledge spiral is that new knowledge is created (Nonaka, 1994), and this can bring many benefits to organizations. In the case of transferring tacit knowledge to explicit knowledge, for example, an organization is able to capture the expertise of particular individuals; hence, this adds not only to the organizational memory but also enables single-loop and double-loop organizational learning to take place (Huber, 1984). Implicit in this is the underlying dualities and a dynamic equilibrium or right mix between dualities that is determined by context. In the process of creating valid knowledge, inquiring organizations are in fact enacting these transformations and thus experiencing these dualities; however, it is unconscious and, to a great extent, much of the knowledge that potentially could be acquired is never captured by ignoring the underlying dualities and taking a singular focus, such as only a Lockean inquiring system as the lens to view knowledge creation.

Knowledge Creation

The processes of creating and capturing knowledge, irrespective of the specific philosophical orientation (i.e., Lockean/Leibnizian versus Hegelian/Kantian), has been approached from two major perspectives, namely, a people-oriented perspective and a technology-oriented perspective, another duality.

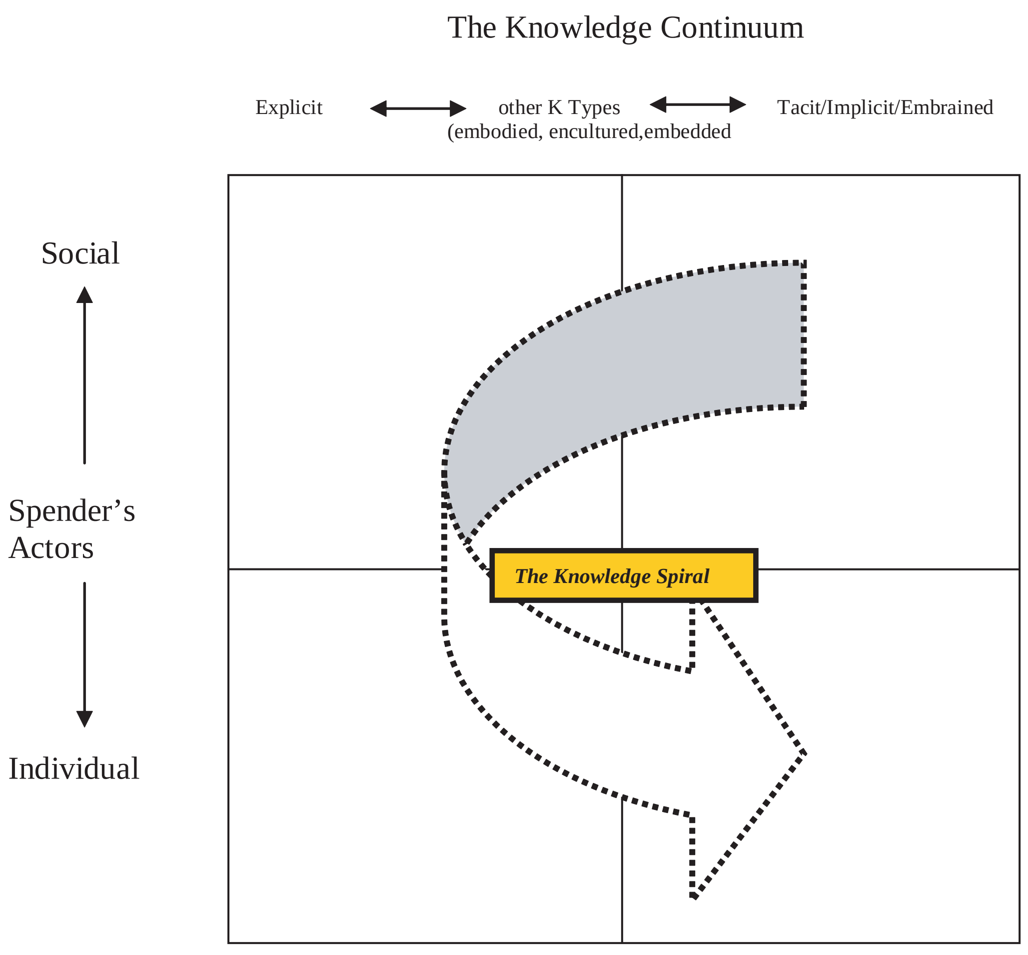
People-Oriented Perspective to Knowledge Creation

This section briefly describes three well known people-oriented knowledge creation frameworks: namely, Nonaka's Knowledge Spiral, Spender's and Blackler's respective frameworks.

According to Nonaka (1994): (1) Tacit to tacit knowledge transformation usually occurs through apprenticeship type relations where the teacher or master passes on the skill to the apprentice. (2) Explicit to explicit knowledge transformation usually occurs via formal learning of facts. (3) Tacit to explicit knowledge transformation usually occurs when there is an articulation of nuances; for example, as in healthcare if a renowned surgeon is questioned as to why he does a particular procedure in a certain manner, by his articulation of the steps, the tacit knowledge becomes explicit. (4) Explicit to tacit knowledge transformation usually occurs as new explicit knowledge is internalized; it can then be used to broaden, reframe, and extend one's tacit knowledge. These transformations are often referred to as the modes of socialization, combination, externalization, and internalization, respectively (Nonaka & Nishiguchi, 2001).

Spender draws a distinction between individual knowledge and social knowledge (yet another duality), each of which he claims can be implicit or explicit (Newell et al., 2002). From this framework, we can see that Spender's definition of implicit knowledge corresponds to Nonaka's tacit knowledge. However, unlike Spender, Nonaka doesn't differentiate between individual and social dimensions of knowledge; rather he just focuses on the nature and types of the knowledge itself. In contrast, Blackler (Newell et al., 2002) views knowledge creation from an organizational perspective, noting that knowledge can exist as encoded, embedded, embodied, encultured, and/or embrained. In addition, Blackler emphasized that for different organizational types, different types of knowledge predominate, and highlights the connection between knowledge and organizational processes (Newell et al., 2002). Blackler's types of knowledge can be thought of in terms of spanning a continuum of tacit (implicit) through to explicit with embrained being predominantly tacit (implicit) and encoded being predominantly explicit while embedded, embodied, and encultured types of knowledge exhibit varying degrees of a tacit (implicit)/explicit combination. Figure 4 depicts an integrated view of all the three frameworks.

Figure 4. Integrative framework of the main people-oriented perspectives

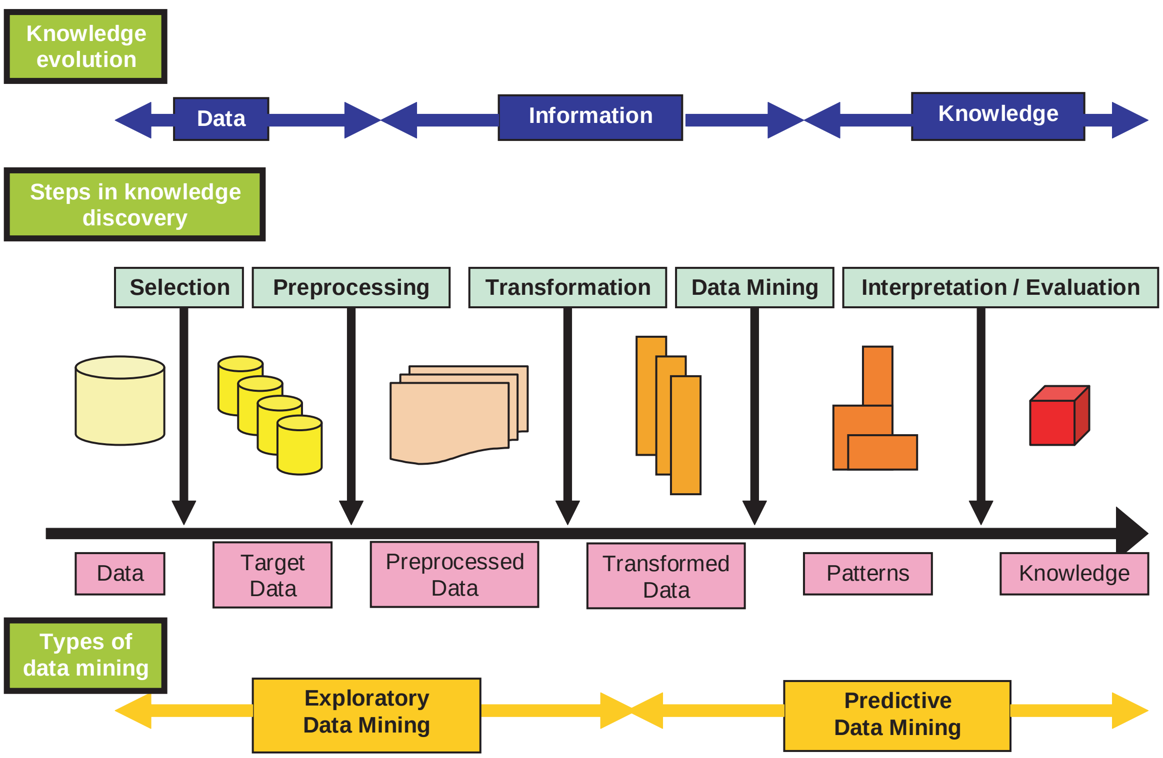


Specifically, from Figure 4 we can see that Spender's and Blackler's perspectives complement Nonaka's conceptualization of knowledge creation and, more importantly, do not contradict his thesis of the knowledge spiral wherein the extant knowledge base is continually being expanded to a new knowledge base, be it tacit/explicit (in Nonaka's terminology), implicit/explicit (in Spender's terminology), or embrained/encultured/embodied/embedded/encoded (in Blackler's terminology). What is important to underscore here is that these three frameworks take a primarily people-oriented perspective of knowledge creation. In particular, Nonaka's framework, the most general of the three frameworks, describes knowledge creation in terms of knowledge transformations as discussed above that are all initiated by human cognitive activities as well as the enacting of at least one of the four Cs relating to knowledge discussed earlier. Needless to say that both Spender and Blackler's respective frameworks also view knowledge creation through a primarily people-oriented perspective. Typically, Hegelian and Kantian inquiring systems would incorporate knowledge creation that is consistent with these people-oriented perspectives (Malhotra, 1997).

Technology-Oriented Perspective to Knowledge Creation

In contrast to the above primarily people-oriented perspectives pertaining to knowledge creation,

Figure 5. Integrative framework of the technology-oriented perspectives



knowledge discovery in databases (KDD) (and, more specifically, data mining), approaches knowledge creation from a primarily technology-oriented perspective. In particular, the KDD process focuses on how data is transformed into knowledge by identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad, Piatetsky-Shapiro & Smyth, 1996). KDD is primarily used on data sets for creating knowledge through model building or by finding patterns and relationships in data. How to manage such newly discovered knowledge and other organizational knowledge is at the core of knowledge management. Figure 5 summarizes the key steps within the KDD process; while it is beyond the scope of this chapter to describe in detail all the steps which constitute the KDD process, an important duality to highlight here is that between exploratory and predictive data mining. Typically, Lockean and Leibnizian inquiring systems would subscribe to a technology-oriented perspective for knowledge creation (Malhotra, 1997).

The preceding discussions then have highlighted some key aspects of knowledge creation from both a people-oriented perspective as well as a technology-oriented perspective. Irrespective of which knowledge creation perspective the concept of duality is reflected in, the knowledge creation process both between the people-oriented and technology-oriented perspectives as well as within each respective perspective; for example, within the people-oriented perspective we have the dualities of social versus individual and tacit versus explicit, while in the technology-oriented perspective we have the duality of exploratory versus predictive data mining. Unlike the dualities identified in the Yin-Yang model of knowledge management though, these dualities represent instantiations of the duality principle at the micro-level. So it is possible then to have the manifestations of dualities with respect to the knowledge construct at both the macro- and micro-levels, yet another reason why the knowledge construct is compound in nature. The following section elaborates on these dualities at both the macro- and micro-levels with respect to the knowledge construct and the impact they have on knowledge management.

DUALITIES IN THE KNOWLEDGE CONSTRUCT

The previous section highlighted several dualities with respect to the knowledge construct and knowledge creation at both a macro- and micro-level. In so doing, we can see that in fact many dualities manifest themselves when we begin to understand the knowledge construct and its management. It would make sense then that our inquiring systems, which are creating knowledge through their activities, should also be viewed in such a light and embrace such a perspective. Before discussing the benefits of embracing such a perspective, it is first useful to summarize the key dualities discussed and their benefits to knowledge management. Table 1 highlights these key dualities and why each side of the duality has importance with respect to knowledge management.

As noted in the introduction, any duality represents the existence of two irreducible aspects or perspectives. By recognizing both sides of a specific dual then, be it tacit/explicit, individual/social, Lockean/Leibnizian versus Hegelian/Kantian, subjective/objective, consensus/disensus, loose/tight or people/technology, a more complete and richer picture of knowledge is created and hence the impact to knowledge management, be it in terms of sharing knowledge, creating knowledge or enhancing the knowledge context, in turn is superior. On the other hand, taking a one-dimensional view, which is more often than not what too many organizations tend to do with respect to their knowledge management initiatives, for example, only recognizing the technology side of knowledge creation (and not being cognizant

Table 1. Key knowledge management dualities

Duality	Impact on KM	Benefits of Recognizing the Dual
Tacit/Explicit	Knowledge creation	From Nonaka's knowledge spiral both tacit and explicit knowledge as well as the transformations of tacit to explicit and vice versa are important to KM. Only focusing on tacit (or only focusing on explicit) provides an incomplete picture with respect to knowledge creation.
Individual/Social	Knowledge sharing	Spender and Blacker, in particular, highlight the significance of both sides of this duality. Only focusing on individually constructed knowledge limits us to a much narrower domain of knowledge creation. Especially given the gregarious nature of humans socially constructed knowledge should also form an important part of the total knowledge created.
Lockean/Leibnitzian vs. Hegelian /Kantian	Knowledge context	These fundamental philosophical perspectives all highlight important facets of the knowledge context (a key dimension of wisdom) and thus when taken together facilitate the understanding of the full spectrum for knowledge management.
Subjective/Objective	Knowledge capture	The sides of this duality highlight both the complexities of knowledge capture relative to the knowledge type being captured as well as the importance of capturing all types of knowledge.
Consensus/Disensus	Knowledge sharing/dissemination	While the consensus side of this duality emphasizes convergence of thought the disensus side emphasizes the need for divergence; however both are reflections of group dynamics that are important for knowledge sharing/ dissemination.
Loose/Tight	Knowledge context	This duality also highlights the need for considering both internal and external organizational context in the framing of KM issues for supporting activities that lead to optimization as well as activities that lead to knowledge creation and renewal
People/Technology	**Knoweldge creation**	This duality underscores the need for a socio-technical approach to knowledge creation because it highlights that knowledge can be created by technologies and people as well as it also being embedded in processes.

of the people side of knowledge creation, i.e., the Lockean and/or Leibnizian inquiring organization) or disregarding the existence of explicit knowledge (and only recognizing the existence of tacit knowledge; i.e., the Hegelian and/or Kantian inquiring organization), in a knowledge creation will lead to a much narrower and limited resultant body of knowledge as well as an inferior and most likely less useful or appropriate knowledge management initiative. Hence, we should not be surprised by the many discussions prevalent in the literature regarding the "nonsense of knowledge management" (Wilson, 2002).

Two key characteristics of inquiring organizations are (1) accuracy of the system basis and (2) continual review of the stored knowledge for accuracy in changing environments (Hall et al., 2003). Surely, a partial picture of knowledge would never be able to provide a similar level of accuracy as a fuller richer picture, hence, the benefit to inquiring organizations of understanding the duality principle and incorporating the many manifestations of these duals both macro and micro with respect to the compound knowledge construct.

Understanding the duality principle necessitates an understanding of the right mix or dynamic equilibrium for the given context. Given this connection with the context and the nonprogrammable nature of the knowledge construct, such an understanding becomes a necessary albeit not sufficient step for transforming inquiring organizations from knowledge to wisdom.

CONCLUSION

This chapter has served to highlight several instances of the duality principle as it relates to knowledge and its management. These instances represented dualities at both the macro- and micro-levels. By so doing, the pervasive nature of the duality principle to knowledge as well as to knowledge management was emphasized. In presenting the duality principle as it relates to knowledge and its management, it is important to recognize its macro and micro aspects because these aspects are characteristics of any organizational setting. Furthermore, an appropriate mix of these dualities is determined by the specific organizational, environmental, technological, and situational context and is necessary but not sufficient in the formulation of an appropriate knowledge management strategy; while the understanding of the underlying principles is important for the achievement of wisdom.

Integral to inquiring organizations is the creation of knowledge; however, as discussed in this chapter, these inquiring systems have tended to focus on a singular line of inquiry, be it Lockean, Leibnizian, Hegelian, Kantian, or Singerian and thus do not recognize or explicitly capture the dualities as connected with knowledge and its management.

Underlying the Yin-Yang model of knowledge management is the recognition of the need to take a holistic view, and thus a fuller richer perspective to knowledge and its management is achieved by understanding the duality principle. Given the importance of knowledge and its management to inquiring organizations, such an understanding would then appear to be essential. Wisdom was defined as the understanding of principles which in turn lead to the making of sound decisions and judgments. Thus, the understanding of the duality principle, in its many manifestations as it relates to knowledge and its management, represents a transition to wisdom or, at the very least, a key step for inquiring organizations trying to attain a state of wisdom. This chapter has severed to create the awareness and appreciation of the existence of the duality principle with respect to knowledge and its management for inquiring organizations; future research will focus on identifying the right mix or equilibrium point for specific inquiring organizations to reach the harmonious balance with respect to these many duals.

Chapter 7.23
Postmortem Reviews

Torgeir Dingsøyr
SINTEF Information and Communication Technology, Norway

INTRODUCTION

Postmortem reviews are collective learning activities which can be organized for projects either when they end a phase or are terminated. The main motivation is to reflect on what happened in the project in order to improve future practice—for the individuals that have participated in the project and for the organization as a whole. Projects are the typical way of working in most knowledge-intensive organizations, and postmortems provide a possibility to learn from the projects with little effort, which makes it ideal as an initial knowledge management activity in a company.

This type of process has also been referred to as "after action reviews," "project retrospectives," "postmortem analysis," "post-project review," "project analysis review," "quality improvement review," "autopsy review," "Santayana review," and "touch-down meetings."

Researchers in organizational learning sometimes use the term "reflective practice," which can be defined as "the practice of periodically stepping back to ponder on the meaning to self and others in one's immediate environment about what has recently transpired. It illuminates what has been experienced by both self and others, providing a basis for future action" (Raelin, 2001). This involves uncovering and making explicit results of planning, observation, and achieved practice. It can lead to understanding of experiences that have been overlooked in practice.

There are a number of methods to conduct postmortems which we will describe in more detail in the following. The methods rely on collecting information from project participants either through interviews, group processes, or a meeting (preferably where participants meet physically). The outcome of a meeting is a postmortem report.

BACKGROUND

In the knowledge creation model of Nonaka and Takeuchi (1995), postmortems are a combination of learning through socialization and through externalization. In listening to others you employ socialization, and in reflecting and sharing your own experience you externalize your tacit knowledge. Postmortems are also a method for leveraging knowledge from the individual level to the organizational level.

In a survey on essential practices in research and development-companies, "learning from post-project audits" are seen as one of the most promising practices that could yield competitive advantage (Menke, 1997).

A survey on post-project reviews in research and development companies show that only one out of five projects received a post-project review (Zedtwitz, 2002). Also, the reviews tend to focus on technical output and bureaucratic measurements. Process-related factors are rarely discussed.

As a knowledge management tool, postmortem reviews are simple to organize. The process focuses on dialogue and discussion, which is a central element in knowledge transfer. Von Krogh, Ichijo, and Nonaka (2000) write:

It is quite ironic that while executives and knowledge officers persist in focusing on expensive information-technology systems, quantifiable databases, and measurement tools, one of the best means for knowledge sharing and creating knowledge already exists within their companies. We cannot emphasize enough the important part conversations play.

An example of postmortem reviews are "after action reviews" conducted by the U.S. army since after the Vietnam war, focusing on a "professional discussion of an event" to provide insight, feedback, and details about the event (Townsend & Gebhart, 1999).

Conducting Postmortem Reviews

There are several ways to perform postmortem reviews. Apple has used a method (Collier, DeMarco, & Fearey, 1996) which includes designing a project survey, collecting objective project information, conducting a debriefing meeting and a "project history day," and finally publishing the results. At Microsoft they also put much effort into writing "postmortem reports." These contain discussion on "what worked well in the last project, what did not work well, and what the group should do to improve in the next project" (Cusomano & Selby, 1995). The size of the resulting document is quite large: "Groups generally take three to six months to put a postmortem document together. The documents have ranged from under 10 to more than 100 pages, and have tended to grow in length."

Kerth (2001) lists a total of 19 techniques to be used in postmortems, many focusing on creating an atmosphere for discussion in the project. Kerth recommends taking three days to discuss projects in detail. (For a more complete overview of methods and purpose of postmortem reviews, see Dingsøyr, 2005)

METHODS FOR CONDUCTING POSTMORTEM REVIEWS

Postmortems can differ in length from activities that takes weeks, to an activity that can be done as a half-day group process. In the following, we present two methods for conducting postmortems, and also present example results from one type of postmortem.

Two techniques are used in both types of postmortems: For a focused brainstorm on what happened in the project, a technique called the "KJ Method," named after Japanese Ethnologist Jiro Kawakita (Scupin, 1997), is used. For each of these sessions, the participants are given a set of Post-It notes and asked to write one "issue" on each note. Five notes are handed out to each person. After a few minutes, the participants are asked to attach one note to a whiteboard and say why this issue is important. Then the next person presents a note and so on until all the notes are on the whiteboard. The notes are then grouped, and each group is given a new name.

Root cause analysis, also called Ishikawa or fishbone-diagrams, are used to analyze the causes of important issues. A process leader draws an arrow on a whiteboard, indicating the issue being discussed, and attaches other arrows to this one like in a fishbone, with issues the participants think are causing the first issue. Sometimes, underlying reasons for some of the main causes are attached as well.

Postmortem Review as a Large-Scale Process

Collier et al. (1996) describe postmortem reviews through five activities:

1. Project Survey: Define a set of questions you would like project participants to answer, such as "Did schedule changes and related issues involve the right people?" and "Were the right tradeoffs between features, quality, resources, and schedule done for the product developed in the project?" Analyze the results of such a survey, and complement with gathering objective data.
2. Collect Objective Information: Objective information related to resources spent, products developed, and other objective information that is valuable for a project.
3. Debriefing Meeting: Give project participants the opportunity to give direct feedback about the project. Use survey results to guide the topics to be covered in the meeting. Organize a series of meetings if more than 30 people participated in the project. Use a facilitator for the meetings in order to ensure a balanced discussion.
4. Project History Day: Formulate a problem statement to focus activities based on findings from the previous steps. An example is: "What are the root causes that determined or affected resources, schedule, and quality?" Invite key project participants, use a facilitator to discuss the problem statement, and use techniques such as root-cause-analysis. Limit participation to six or eight people. Ask participants to read the information gathered from the project, discuss deviations from the project schedule, and perform root-cause analysis on major deviations. Take note of the top 20 "root causes," and categorize using the KJ process.
5. Publish the Results: The leadership summarizes its findings and publishes it in an "open letter to project teams," which should be readable for project management and participants in the organization. It consists of four parts: (1) a description of the project, (2) a summary of positive findings ("the good"), (3) a summary of negative findings ("the bad"), and (4) issues that need to be improved ("the ugly").

Postmortem Review as a Half-Day Group Process

Birk, Dingsøyr, and Stålhane have used postmortem reviews as a group process (Birk, Dingsøyr, & Stålhane, 2002; Dingsøyr, Moe, & Nytrø, 2001; Stålhane, Dingsøyr, Moe, & Hanssen, 2003), where most of the work is done in one meeting lasting half a day. They try to get as many of the persons working in the project as possible to participate, together with two process consultants—one in charge of the postmortem process, the other acting as a secretary. The goal of this meeting is to collect information from the participants, make them discuss the way the project was carried out, and also analyze causes for why things worked out well or did not work out.

The "requirements" for this process include that the project should not take much time for the project team to participate, and it should provide a forum for discussing and analyzing the most important experience from the project. The main findings are documented in a report.

The postmortem meeting has following steps:

1. Introduction: First, the consultants introduced the agenda of the day and the purpose of the postmortem review.
2. KJ Session 1: Consultants hand out Post-It notes and ask people to write down what went well in the project, hear presentations, group the issues on the whiteboard, and give them priorities.
3. KJ Session 2: Consultants hand out Post-It notes and ask people to write down problems that appeared in the project, hear presentations, group the issues on the whiteboard, and give them priorities.
4. Root Cause Analysis: The process consultant leading the meeting draws fishbone diagrams for the main issues, both from the things that went well and the things that were problematic.

Birk et al. use a Dictaphone during the presentations and transcribe everything that is said. The consultants write a postmortem report about the project; the report contains an introduction, a short description of the project analyzed, how the analysis was carried out, and the results of the analysis. The result is a prioritized list of problems and successes in the project. Statements from the meeting are used to present what was said about the issues with highest priority, together with a fishbone diagram to show their causes. In an appendix, everything that was written down on Post-It notes during the KJ session is included, as well as a transcription of the presentation of the issues that were used on the Post-It notes. Such reports are usually between 10 and 15 pages in length.

The day after the meeting, the consultants present the report to the people involved in the project to gather feedback and do minor corrections.

Example Results from a Postmortem

We now present results from one review. First, we present the company, then the project where the review was carried out, and finally extracts from the postmortem report (see Dingsøyr et al., 2001, for more information).

The company makes software and hardware for stations receiving data from meteorological and Earth observation satellites.

The postmortem was organized for a project which had developed a software system for a satellite that was recording environmental data. The project had developed a module that was to analyze data from this satellite from European Space Agency specifications. The project lasted for approximately one year, and employed six people full time and two people part-time—a total of eight man-years. Five people participated in the postmortem review including the project manager.

One result from the KJ session was two Post-It notes grouped together and named "changing requirements." They are shown in the upper left corner of (some of) the results from the KJ process in Figure 1.

Participants made the following statements about "changing requirements":

Another thing was changes of requirements during the project: from my point of view—who implemented things, it was difficult to decide: when are the requirements changed so much that things have to be made from scratch? Some wrong decisions were taken that reduced the quality of the software.

Unclear customer requirements—which made us use a lot of time in discussions and meetings with the customer to get things right, which made us spend a lot of time because the customer did not do good enough work.

Figure 1. Post-It notes showing some of the problems in a software development project

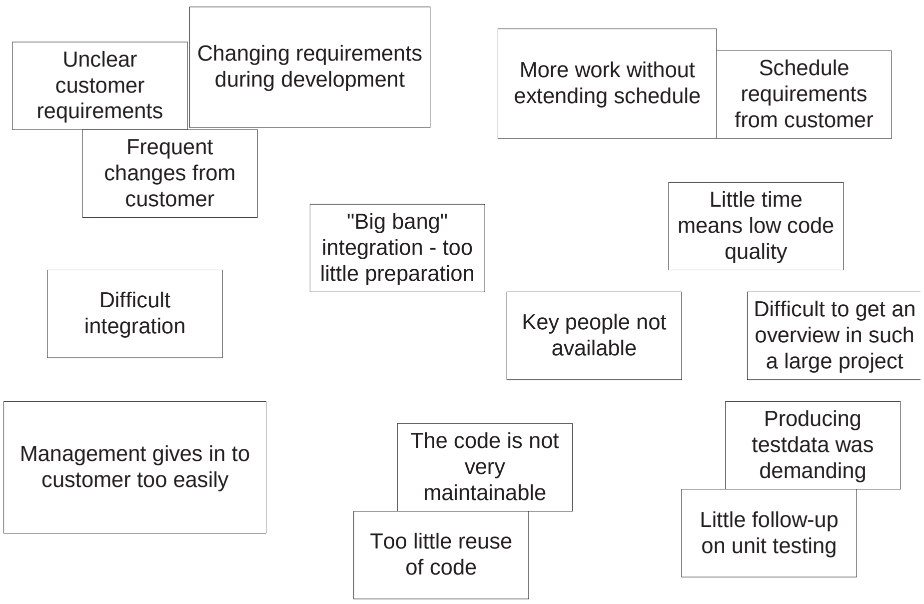

Figure 2. Ishikawa diagram for "changing requirements"

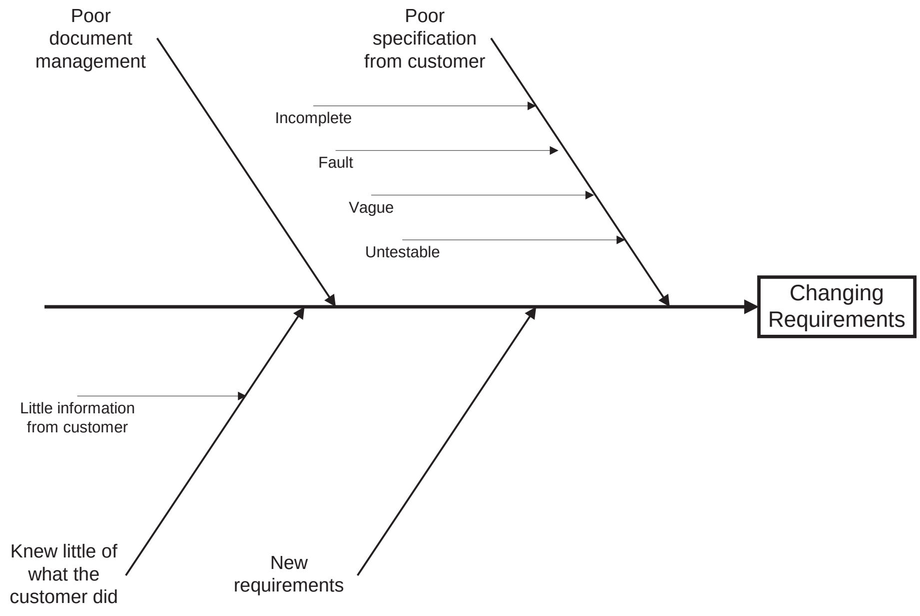

When we later brought this up again and tried to find some of the root causes for "changing requirements," we ended up with the fishbone diagram in Figure 2.

The root causes for the changing requirements, as the people participating in the analysis saw it, was that the requirements were poorly specified by the customer, there were "new requirements" during the project, and the company knew little of what the customer was doing. Another reason for this problem was that documents related to requirements were managed poorly within the company. In Figure 2, we have also listed some sub-causes.

The postmortem helped surface problems and successes that people were already aware of, but was not systematically presented in any way. It helped to focus on some important issues to improve and to sustain in future projects. The report was readable for people who were working on other projects in the company.

FUTURE TRENDS

In a study of 19 companies across Europe on project-based learning practices, Keegan and Turner (2001) found that "project team members frequently do not have the time for meetings, or for sessions to review lessons learned. Often, project team members are immediately reassigned to new projects before they have had time for lessons learned sessions or after action reviews." They did not find a single company where employees expressed satisfaction with the postmortem process.

We think there is a need for simple and practical descriptions of how to conduct postmortems, in order to stimulate knowledge-intensive companies to do it more often. The benefit of conducting postmortem reviews is mainly that it provides a learning forum where discussions are relevant to the project and to the company. It can also be a way for management to show that they listen to what the employees say, and are willing to discuss improvement efforts.

CONCLUSION

We have described postmortem reviews as a simple knowledge management technique, along with two particular methods to conduct postmortem reviews as a group process. We have also presented example results from a postmortem report.

Section 8
Emerging Trends in Knowledge Management

This section highlights research potential within the field of knowledge management while exploring uncharted areas of study for the advancement of the discipline. Introducing this section is research that sets the stage for future research directions and topical suggestions for continued debate. Providing an alternative view of knowledge management are chapters that research the cultural dimension of knowledge management systems, particularly the relationship of learning and culture in knowledge management projects. The inevitable increase in complexity and quantity of the information that is available for students is also considered in this final section. Found in these 21 chapters concluding this exhaustive multi-volume set are areas of emerging trends and suggestions for future research within this rapidly expanding discipline.

Chapter 8.1
The Emerging Discipline of Knowledge Management

David G. Schwartz
Bar-Ilan University, Israel

ABSTRACT

This article presents some of the findings from the editorial process of creating an Encyclopedia of Knowledge Management. The global view of knowledge management (KM) research made available by this process provides interesting insights into the state of knowledge management research today and raises some questions regarding future directions for knowledge management as a discipline. The popularity and interaction between the different foundations of KM research is discussed, and specific attention is given to the discipline of social epistemology as a frame of reference for knowledge management research.

INTRODUCTION

After more than 40 years of information systems research, there remains great divergence and diversity in how to accurately define this important discipline. Banville and Landrey (1989), Backhouse, Liebenau, and Land (1991), Vessey, Ramesh, and Glass (2002), Adam and Fitzgerald (2000), Baskerville and Myers (2002), and Avison (2003) are but six of the many attempts to reach a broadly accepted definition. Fortunately, the lack of acceptance of any such definition has in no way hampered the development of the field. On the contrary, some, such as Frank (1998), question whether a common profile for information systems research is even desirable.

One is tempted to apply this same sort of qualification process to the endeavor of knowledge management (KM) and ask what constitutes the field of KM, what common profile can be ascribed to KM researchers, and if, in fact, knowledge management can be considered a discipline in its own right. Jennex and Croasdell (2003) have called for a determination that knowledge management be considered a discipline. As they discuss, meeting

Kuhn's (1996) criteria for the establishment of a discipline may be a necessary step—it is clearly not sufficient. The actual nature, characteristics, behavior, and interaction of those researchers identifying themselves as KM researchers will ultimately determine whether we emerge as a discipline or not. The analysis presented in this article moves us a step forward in that direction by taking a broad analytical view of KM research underway from both departmental and geographic standpoints.

This article will present some of the initial findings from the editorial process and draw insights regarding the global knowledge management community. We will present a number of findings based on the initial response to a Call for Papers (CFP) for the Encyclopedia of Knowledge Management that was issued in October 2003 (Schwartz, 2003, 2005). We will present some descriptive statistics that form what in essence is a profile of the self-described knowledge management community. Our discussion of these findings will address the question of whether KM should be considered a discipline and raise number of additional provocative questions.

Reviewing the extant KM-related literature, and examining the various research forums in which KM is addressed, one is inexorably drawn toward a conclusion that KM is an increasingly important subfield of information systems research. And, in fact, it was from that perspective that the creation of an Encyclopedia of Knowledge Management (EKM) was initiated. The early stages in the process of creating such a volume have shed light on how KM is viewed around the world.

In this article I will respectfully suggest that most of the IS community, myself included, has it backwards. KM is not an important area of IS research, rather IS research is an increasingly important part of the discipline of knowledge management. In doing so, I will proffer a holistic definition of the field of knowledge management, placing it within, or perhaps replacing it with, the discipline of applied social epistemology.

BACKGROUND AND MOTIVATION

If the field of knowledge management can be considered a meta-level pursuit in which we create and collect knowledge about organizational knowledge and how it can be created, captured, organized, and reused, then the creation of an Encyclopedia of Knowledge Management must be a meta-meta-level task.

Attempting to manage the knowledge of knowledge management means creating an overall map of research being conducted that impacts KM both directly and indirectly. It means reaching out to practitioners and academics in a wide range of disciplines to elicit their views on what makes KM the pursuit that it is (acquisition of knowledge management knowledge). And it means attempting to organize that knowledge in a meaningful way (organization of KM knowledge) so that it can be delivered to and made use of by KM researchers and practitioners in the future (delivery of KM knowledge). In essence the same Acquire-Organize-Distribute model (Schwartz, Divitini, & and Brasethvik, 2000) that can be used to manage the knowledge of a single enterprise is being modified and applied to a multi-organizational and multi-party knowledge management task.

In an attempt to provide as broad coverage as possible for KM, the call for papers including a detailed list of topics and subtopics (Figure 1), prepared in consultation with the international Editorial Advisory Board (faculty.biu.ac.il/~dgk/ekm/EAB.htm). It was through the interactions of the EAB that the CFP metamorphosed from what was originally a very IT-centric world view, to the knowledge- and organization-centric view of its final form. Further modifications (shown

Figure 1. Detailed major topics from the Encyclopedia of Knowledge Management CFP, each of which will have multiple sub-topic entries

Theoretical Aspects of Knowledge Management	**Legal Aspects of Knowledge Management**
Defining and Understanding Knowledge	Intellectual Property/Capital
Types of Knowledge	Privacy Issues
Philosophical underpinnings	Digital Rights Management
Ontologies of Knowledge Management	Liability and the Reliance upon KM Systems
Historical Underpinnings	*Ethics*
Organizations and the Inquiring Organization	**Technological Aspects of Knowledge Management**
The People Perspective	Knowledge Representation
Knowledge Management Models	Knowledge Organization and Indexing
Processes of Knowledge Management	Meta-knowledge and Metadata
Knowledge Creation	Storage and Retrieval
Knowledge Discovery	Presentation and Application Integration
Knowledge Acquisition	Artificial Intelligence in KM
Knowledge Classification	*Computational Experimentation*
Knowledge Verification and Validation	Data Mining in KM
Knowledge Codification	Other specific technologies impacting KM
Knowledge Calibration	**Application-specific Knowledge Management Issues**
Modeling Knowledge	Biomedical Knowledge Management
Knowledge Integration	Commercial and Financial KM
Knowledge Sharing	Industrial Knowledge Management
Knowledge Dissemination	Military Knowledge Management
Knowledge Maintenance	*Mobile Knowledge Management*
Organizational and Social Aspects of Knowledge Management	*Safety-Critical Systems*

KM Systems Analysis and Design	
KM Systems Management and Lifecycle	
Human Resource Management	
Operational KM	
Managing the Knowledge Environment	
Metrics, Milestones, and Measurement	

in italics) were the result of feedback from potential contributors subsequent to the release of the CFP.

Soliciting Contributions

Proposals for contributions to the EKM were solicited through five main channels:

1. the ISWORLD mailing list,
2. the DBWORLD mailing list,
3. the Knowledge Acquisition/Modeling/Management (KAW) mailing list,
4. the publisher's (IGI) master mailing list, and
5. the editorial advisory board—each member of the Editorial Advisory Board was asked to distribute the CFP through his or her personal mailing list of relevant researchers.

RESPONSE TO THE CFP

The initial response to the Call for Papers resulted in more than 170 relevant proposals from 249 co-authors for articles in the encyclopedia. Many of the proposals needed to be divided (in editorial consultation with the authors) into multiple articles in order to maintain a reasonable level of granularity for each article (i.e., a situation in which an author proposed covering multiple related topics in a single article).

Departmental Affiliation

One place to start understanding the directions being taken in knowledge management research is the departmental affiliation of those authors working in an area that they themselves identify as relevant to knowledge management.

Authors affiliated with 29 distinct disciplines found it relevant to contribute article proposals. Table 1 shows the Main Departmental Affiliation of proposal authors from the preliminary round of submissions to the Encyclopedia of Knowledge Management. Where an author indicated multiple affiliations, the first affiliation listed was used.

The top four affiliations show an overwhelming concentration in the fields where knowledge management has been actively addressed over the past decade.

These top four affiliations reflect what may be expected from most of the knowledge management community. Of greater interest, perhaps, is the participation in KM research in what can be termed "non-traditional" KM affiliations.

A second point of interest from Table 1 is the wide range of departmental participation, lending strength to the interdisciplinary nature of KM, and providing an indication as to what types of courses a form program Knowledge Management Studies might need to include.

Also of note is the complete lack of any departmental affiliation specific to knowledge management. While a number of authors were associated with KM research labs or facilities, these were clearly research-oriented initiatives and not teaching initiatives or programs.

Geographic Distribution

A second area of interest is that of geographic distribution. Here we show concentrations of KM research by country and geographic region.

Table 3 presents the total number of authors by country in which they work (i.e., main university/employer affiliation).

BIASES

Obviously the venues in which the CFP was posted to solicit articles had a significant impact on the departmental affiliation of the contributors. This effect was mitigated to a certain degree by the efforts by each Editorial Board member to distribute the CFP to his/her own colleagues in multiple fields.

Table 1. Departmental affiliation of responding authors

Rank	Main Departmental Affiliation	*Count*	%
1	Information Systems	111	44.58%
2	Computer Science	39	15.66%
3	Information and Library Science	15	6.02%
4	Management	12	4.82%
5	Communications	6	2.41%
6	Economics	6	2.41%
7	Marketing	6	2.41%

26	Cultural Studies	1	0.40%
27	Real Estate	1	0.40%
28	Science and Technology	1	0.40%
29	Statistics	1	0.40%
		249	100%

The absence of certain terminology from the CFP may also have had an effect on response—for example, including social epistemology as a topic may have elicited an increased response from with the philosophy or information science communities.

As an edited volume, the EKM will also include a number of invited articles based on the decisions of the Editorial Board to include topics that may not have been addressed by the response to the CFP. The scope and quantity of these ad-

Table 2. Division of respondents into traditional and non-traditional IS/management fields

"Traditional" Information and Management related fields		Non-traditional fields	
Information Systems	44.6%	Economics	2.4%
Computer Science	15.7%	Marketing	2.4%
Information Science	6.0%	Cognitive Science	2.0%
Management	4.8%	Philosophy	2.0%

		Real Estate	0.4%
		Science and Technology	0.4%
		Statistics	0.4%
Total	82.3%	Total	17.7%

ditional contributions has not been considered in this article.

DISCUSSION

I believe that one of the more significant results of this exercise in managing the knowledge of knowledge management is to be found not in the top 10 departmental affiliations shown in Table 1, but rather in the middle 10. Starting from philosophy through to the study of innovation, passing social psychology, sociology, and other non-IS disciplines along the way.

As stated in the introduction, I began this process from an information systems perspective. It is the depth and breadth of non-IS contributions that I have found most enlightening. I fear that in this shortcoming I am not alone amongst knowledge management researchers—a fear reinforced by the overwhelming number of contributions (over 50%) that came from the two fields of information systems and computer science.

The appearance of information and library science in the third spot mitigates those fears somewhat. This field, though viewed by many as ancillary to information systems research, has provided one of the most powerful directions of research for the field of knowledge management, as we will soon discuss.

Episteme

Consider the following definition of knowledge management research:

"The theory or science that investigates the origins, nature, methods, and limits of knowledge in organizations."

Table 3. National affiliation of responding authors

Rank	Author Affiliation by country	Count	Percent
1	United States	76	30.52%
2	England	26	10.44%
3	Italy	17	6.83%
4	Germany	16	6.43%
5	Netherlands	16	6.43%
6	Israel	15	6.02%
7	Australia	13	5.22%
8	France	13	5.22%
9	Ireland	10	4.02%
10	Spain	10	4.02%
11	Canada	9	3.61%
12	Brazil	5	2.01%
13	Singapore	4	1.61%
14	Switzerland	4	1.61%
15	Denmark	2	0.80%
16	Hong Kong	2	0.80%
17	India	2	0.80%
18	Norway	2	0.80%
19	South Korea	2	0.80%
20	Austria	1	0.40%
21	Greece	1	0.40%
22	Japan	1	0.40%
23	Macau	1	0.40%
24	South Africa	1	0.40%
		249	100.00%

Table 4. Regional affiliation of responding authors

Geographic - by region	Count	Percentage
EMEA	98	39%
North America	85	34%
UK	36	14%
Asia Pacific	25	10%
South America	5	2%

- Origin—to cover issues related to knowledge acquisition and creation.
- Nature—to deal with types of knowledge, be it textual, visual, oral, tacit, or explicit.
- Methods—to understand and develop processes to enhance the management and use of such knowledge.
- Limits—to deal with metrics, ROI, accepted use, privacy, and cognitive limitations.

But we already have a field that deals with the theory or science that investigates the origins, nature, methods, and limits of knowledge in organizations. Well, we do if you drop the last two words "in organizations," for what you are left with is the precise definition of a word that appears in Webster's New Twentieth Century Dictionary (Webster, 1970, p. 614)—that word is epistemology.

Well, one might argue, classical epistemology deals with the individual attempting to ascribe knowledge or beliefs to an individual agent. Dealing with organizations requires much more than adding two words to the end of a definition—it requires an essentially different discipline. Even if one were to accept such an argument, one needs to look no further than to a major subfield of epistemology known as "social epistemology."

"Social epistemology is the study of the social dimensions of knowledge or information." (Goldman 2001)

While Goldman (2001) traces elements of social epistemology back to Plato, he brings a modern definition from Shera (1970), which appears to be finely tuned to today's field of knowledge management:

"Social epistemology is the study of knowledge in society…the focus of this discipline should be on the production, flow, integration, and consumption of all forms of communicated thought throughout the entire social fabric." (Shera, 1970, p. 86)

In identifying the "new" challenges in the management of knowledge, Shera (1961) states:

"We are here concerned with an epistemological discipline, a body of knowledge about knowledge itself. The manner in which knowledge has developed and has been augmented has long been a subject of study, but the ways in which knowledge is coordinated, integrated, and put to work is, as yet, an almost unrecognized field for investigation." (emphasis added)

Shera's stated goal (1961) for the proposed discipline of social epistemology is:

"From such a discipline should emerge a new body of knowledge about, and a new synthesis of, the interaction between knowledge and social activity."

Budd (2002) cites the first known reference to social epistemology as being by Egan and Shera (1952, p. 132) in which they state that it is "the study of those processes by which society as a whole seeks to achieve a perceptive or understanding relation to the total environment—physical, psychological, and intellectual."

Back to Information Systems

Let's return for a moment to our starting point—the IS perspective. From an information systems perspective, what is missing from the definitions of Goldman and Shera is the element that turns the study of knowledge into the management of knowledge. It is the element that turns science into engineering. It is the element of the applied (Banville & Landry, 1992) that has driven and differentiated information systems research since its inception.

Thagard (2000) attempts to apply epistemological techniques and standards to the Internet as a corpus of knowledge and foundation for scientific discovery. His analysis focuses primarily on how

Internet technologies (and not information systems and technologies in general) can contribute to scientific research. The relevance of Thagard's work (2000, 1997, 1993) is in its attempt to tie classic epistemology to current technological tools—not unlike our focus in IS-based knowledge management.

There are other attempts to more formally tie information systems and information science to philosophical underpinnings, most notable that of Floridi (2002; Herold, 2001). He proposes and develops a "Philosophy of Information" as "a normative branch of philosophy primarily concerned with the conceptual and foundational investigation into the nature of information, its dynamics, and utilization." A clear definition to be sure, but bearing no obvious advantage to that of Egan and Shera's social epistemology.

The bridge from social epistemology to knowledge management was most recently crossed by Fuller, who in Knowledge Management Foundations (2002) builds a solid basis for the discipline upon the foundations of social epistemology—which, it may come as no surprise, was the focus of his earlier books of the same title (1986, 2002).

Where is all this leading? Based on the above chain of research, and on the specific editorial experiences from the Encyclopedia of Knowledge Management, I suggest that knowledge management as we know it today is in fact applied social epistemology.

So what, you ask? What does it matter what we call it as long as we all know what we are talking about? A rose by any other name would smell as sweet, would it not? Well, it does matter. It matters because what we call it has a direct impact on our perspective and on the directions that we look for related and relevant research upon which to build.

Social epistemology—or social knowledge management—has much to offer our field of organizational knowledge management. At a minimum, the treatment of organizations as social entities opens a wealth of relevant literature.

In terms of a historical progression, it may be useful to consider the following:

Individual Epistemology → Social Epistemology → Applied Social Epistemology

Becoming a Discipline

Where does all this leave us in terms of an agenda for knowledge management research and teaching? First, it tells us that we need to look far beyond the castle walls of information systems in our pursuit of knowledge management. Second, it tells us that a discipline of knowledge management, or a formal academic program of knowledge management, needs to draw from at least 10, and perhaps as many as 20, contributing disciplines. Finally, a glance at Table 4 tells us that while 82% of the respondents to the CFP came from classic information and management-related departments, 18% did not. If the 80-20 rule is any indicator, one can be sure that the "other 18%" will prove to be as challenging, difficult, important, and elusive as the "core 82%."

CONCLUSION

Before having to fend off questions regarding the validity of the statistics reported in this article, let me preempt by pointing out that this was in no means meant to be a formal scientific study into the nature of the knowledge management community and KM research. That being said, in the course of editing the Encyclopedia of Knowledge Management, the sheer scope of interactions between myself and KM researchers has had a formative effect on my own view of the field. This article has been an attempt to share that experience with you and raise some introspective questions in your mind.

Has KM reached the point that it should be considered a discipline in its own right? Is it sufficiently distinct from those component research streams from which it has evolved, or is it in fact applied social epistemology? Should an interdisciplinary undergraduate degree program in knowledge management find its rightful place alongside degrees in information technology management?

I suggest that although we, in the information systems community, have become accustomed to seeing and participating in KM tracts at major IS conferences, by doing so we have reinforced the backward approach. What we should really be doing is attending IS tracts at major KM conferences—developing the true heritage of applied social epistemology, in which we take the science of the applied that information systems research excels at, and systematically apply it to the philosophical and sociological foundations of this exciting emerging discipline.

Fern Universität Hagen, Germany

INTRODUCTION

The success of industrial and scientific research has always been dependent on new discoveries and innovations, but tighter budgets and increasing global competition push the pace with which innovation must happen nowadays. Bringing new products to the market before competitors do constitutes a crucial competitive advantage for many companies and organizations. Accelerating discovery and innovation is increasingly dependent on the use of advanced information and knowledge technology for building environments that support the innovation process systematically and efficiently (cf. Specht, Beckmann, & Amelingmeyer, 2002; Amidon, 2002). Such environments depend on a number of advanced knowledge management technologies and have to adapt to the wide variety of innovative practices, innovation cultures, organizational context, and application areas where innovation takes place. It is essential that the functionalities of such are aligned with the needs of innovators and their context.

Innovation starts with an adequate identification of goals including an appropriate problem description and ends with the successful exploitation of the problem solution. Therefore, innovation is understood as dealing with complex problem-solving processes in whose activities knowledge of different types is applied and created. Systematic support of innovation processes requires efficient management of knowledge with respect to activities like acquisition, creation, enrichment, retrieval, reuse, and combination of such knowledge.

When taking a closer look at innovation activities in different areas, a common core innovation process can be identified that consists of six overlapping but distinguishable phases. The specific characteristics of the innovation process imply an innovation-specific, multi-stage knowledge lifecycle and knowledge management support that reflects the dependency on the innovation environment and the characteristics of the innovation process.

BACKGROUND

Innovation is the successful exploitation of new ideas which can be products or processes. It happens in the scientific domain (development of new scientific approaches, theories, methodologies, etc.) and organizations (new products, processes, marketing campaigns, etc.). Innovation is used by many scientific disciplines in many different shades. Nevertheless the core understanding of innovation can be identified as mentioned above (cf. Specht et al., 2002; Rogers, 1998; OECD, 1997).

Independent of the domain, innovation is a knowledge-intensive process. This means that proper knowledge management is necessary to support the innovation process successfully. To achieve a basis for this, a knowledge lifecycle model can be applied as a means of supporting externalization and application of innovation process and resource knowledge while following the general baseline of all approaches of knowledge management that knowledge is more useful if it does not reside in the minds of individuals, but is applied and made available to others (c.f. Alavi & Leidner, 1999), and that this is even crucial for the creation of new knowledge (Borghoff & Pareschi, 1998; Spiegler, 2000). Revisiting KM theory, several models for knowledge flow and knowledge lifecycles have been proposed that capture the dynamics of knowledge, its transformation and relationship to the respective application context (e.g., Nonaka & Takeuchi, 1995; Borghoff & Pareschi, 1998; Fischer & Ostwald, 2001). In the case of this article, the specific application context in the focus of our work is innovation processes. Therefore, the knowledge lifecycle model discussed here focuses on the specific needs of innovators with regards to managing their innovation resources in an appropriate way. The research work in which this model was developed was almost entirely performed in the context of the European project INNOVANET (IST-2001-38422).

Innovations lead to problem solutions which can differ in the degree of novelty of the solution and the amount of change implied. The terminology of TRIZ (Theory of Inventive Problem Solving, an algorithmic approach for solving difficult technical and technological problems) suggests five levels of innovation (Shulyak, 1977). This ranges from small evolutionary changes implementing improvements of existing systems or products on the lowest level to revolutionary changes on the highest level that offer solutions outside the confines of contemporary scientific knowledge. As discussed later, the partition into an evolutionary and a revolutionary type of innovation has an important impact on the activities in the knowledge lifecycle and on adequate process support.

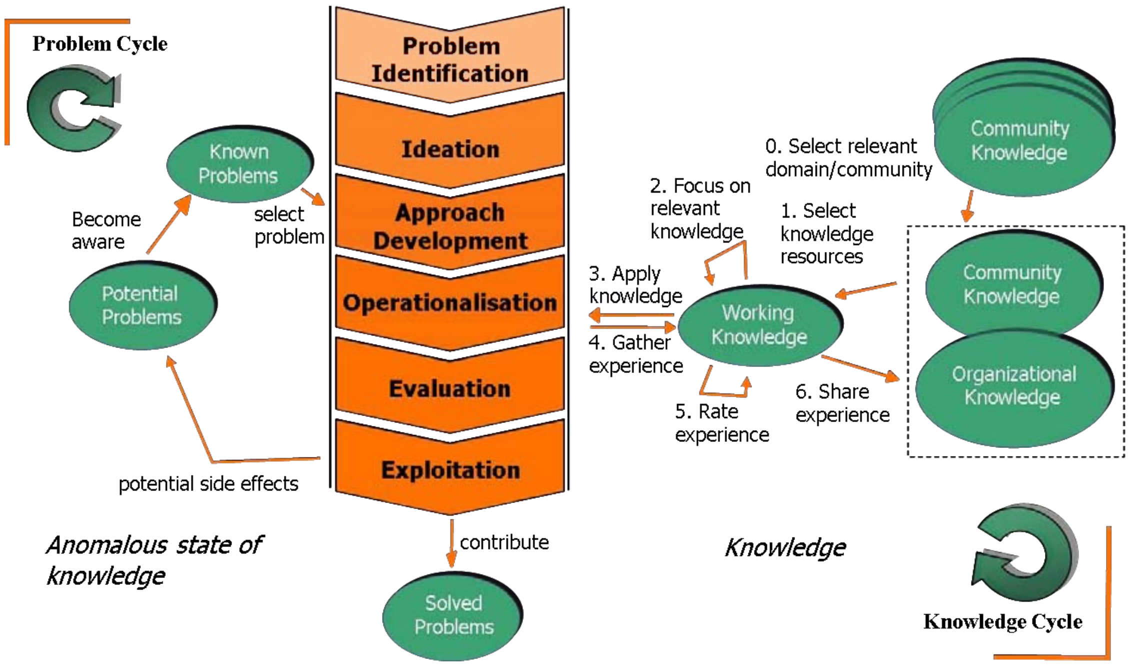
In the remainder of this article, the innovation knowledge lifecycle model is introduced and framed as a representation medium supporting a conceptual basis for externalization, management, and optimization of application of knowledge and knowledge resources in the context of innovation processes. The model is based on a thorough study of the state of the art in both innovation management and knowledge management theory. Within this article, an innovation-focused approach to represent and apply a knowledge management methodology is implemented. However, readers can also benefit from the general discussion around the proposed view of knowledge management activities and practices, while considering innovation as one contextual condition within which knowledge is applied. Finally, the IKLC model as introduced can also be considered as a valuable instrument that enables better understanding and better documentation of innovation processes during their preparation as well as during their execution. In turn, the model is the formal basis for achieving greater transparency, control, and efficiency within knowledge-intensive innovation processes.

MAIN FOCUS OF THE ARTICLE

The Innovation Knowledge Lifecycle (IKLC) is a domain-independent metamodel. It describes the phases of the innovation process in the Innovation Process Model, validated by Paukert, Niederée, Muscogiuri, Bouquet, and Hemmje (2003), and the knowledge flow in each of the innovation phases on an abstract level (Knowledge Lifecycle Model, mentioned above). The Knowledge Lifecycle itself includes a problem cycle and a knowledge cycle (see Figure 1).

The problem cycle (left side of Figure 1) is connected with the innovation process as a whole:

Figure 1. Innovation knowledge lifecycle (IKLC)



- Become aware: In a specific domain, there is a pool of actual and potential problems. By certain dynamics—changes in the environment, personal interests, and so forth—specific problems gain awareness and they receive the status of known problems.
- Select problem: The set of known problems is the starting point for innovation. Selecting a problem is a crucial step that is driven by various factors like market needs, innovation strategies, available resources, and so forth. The choice of the “right” problem is an essential precondition for successful innovation.
- Contribute: If the innovation process is successful, it provides a solution for the problem it was triggered by. The innovation process provides a contribution to the set of solved problems. When exploited, innovation also changes its environment, which in turn may lead to new challenges and problems, triggering further innovation (thus closing the cycle). The problem cycle complements the knowledge cycle and can be compared to the anomalous state of knowledge (a user’s inability to describe and articulate a problem), as discussed by Belkin, Oddy, and Brooks (1982) for the area of information retrieval.

The knowledge cycle (right side of Figure 1) models the knowledge flow in the innovation process, with a special focus on knowledge application. Especially, it follows the argument of Fischer and Ostwald (2001) that knowledge creation should be integrated into the work process and is not a separate activity. The knowledge cycle distinguishes three basic knowledge types: community knowledge; organizational knowledge, shared by a specific community or within an organization; and working knowledge, the knowledge at hand in a concrete working or task context. In the case of an individual activity, this is the personal knowledge of an individual, whereas in the case of a team effort, the working knowledge is the relevant joint knowledge of the members. The knowledge cycle indicates a linear process of seven steps—nevertheless, feedback loops in-between are possible:

- Step 0: Select Relevant Domain/Community: An innovation process is embedded into an application domain with an associated community, whose knowledge is applied. While this knowledge is sufficient for minor scale innovations, facing problems of a totally new kind requires radically new solutions and knowledge. For these revolutionary developments exploring knowledge of different domains/communities is needed. The identification of one or more relevant knowledge domains is an iterative process that requires the exploration of different knowledge domains, the development of an understanding of this knowledge, and assessment of the relevance for the current task.
- Step 1: Select Knowledge Resources: After identifying relevant domains/communities, adequate knowledge resources for the innovation task are selected. This can be a knowledge object, a collection of knowledge objects or an expert; selected and acquired knowledge becomes working knowledge. Identifying knowledge objects also includes internalization of the knowledge (Nonaka & Takeuchi, 1995).

  Selecting domains and focusing on knowledge resources is only necessary if the existing working knowledge is not sufficient. Typically, revolutionary innovations require more new knowledge and also knowledge from different domains. Thus, more effort will be put into these first two steps.
- Step 2: Focus on Relevant Knowledge: Only a small part of the knowledge is relevant for solving the problems in a specific situation.

The process of focusing on relevant knowledge objects may be a mental process if an individual has enough background knowledge to judge the knowledge resources. In case one individual does not have enough knowledge to focus on the relevant knowledge, negotiation and cooperation with others become necessary.

- Step 3: Apply Knowledge: The selected knowledge has to be applied in a specific task in the innovation process, for example, deciding on a certain evaluation method or choosing a specific representation language. Before the knowledge can be applied, it may require adaptation to the context of use. The effort to be spent depends on the match of the current task context and the context the knowledge was learned from.
- Step 4: Gather Experience: By applying knowledge to a task, experiences are made to what kind of result this application leads by observing the performance and the emerging results. For sharing the insights from this knowledge application, at least a minimum of externalization is necessary.
- Step 5: Rate Experience: The gathered experience is set into relationship with the goals of the innovation process or the current activity, and it is rated in this context. This rating provides the basis for the decision about further actions. The rating provides the basis for further applications of the same knowledge. Depending on the rating it may be considered more often or it may be neglected because it was not helpful. Cooperative activities require rating negotiation between team members.
- Step 6: Share Experience: Gathering and rating of experiences producing new knowledge. Ideally, the rated experience and the resulting knowledge are made explicit as knowledge objects, so they can be shared with others, thus closing the knowledge cycle. This requires extra effort, which has to be well motivated (Fischer & Ostwald, 2001). Even negative experiences represent knowledge that might become valuable at a later point in time (Ruggles & Little, 1997).

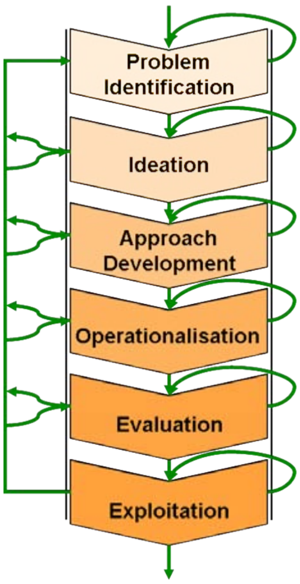
The model described above takes into account another fundamental dimension related to the IKLC, called the contextual dimension. Many studies from philosophy (e.g., Kuhn, 1962), organization science (e.g., Boland & Tenkasi, 1995), cognitive science (e.g., Fauconnier, 1985; Johnson-Laird, 1992), and knowledge representation (cf. Giunchiglia, 1993; McCarthy, 1993) stress the fact that knowledge cannot be viewed simply as a collection of "objective facts" about reality, as any "fact" presupposes a context which contributes to give it a definite meaning. Assuming that each community has its own shared context, which facilitates communication and knowledge sharing, it must be taken into account that communication and knowledge sharing across different communities presupposes a process of "perspective taking" (Boland & Tenkasi, 1993), which is qualitatively different from the process of "perspective making," which means building and using the shared perspective within a single community (Bouquet, Serafini, & Zanobini, 2003). This has an important impact on many of the described phases. For example, the way a community acquires another community's knowledge is not a simple step of incorporation, but may require a "translation" from one language to another, from a conceptual schema to another, and so forth. Analogously, the perception of how relevant a problem is depends also on a community's context, as many examples show that relevance is relative to what is implicitly assumed (cf. Paukert et al., 2003).

Model of the Innovation Process

As outlined earlier, the following model is based on a study of theories in the innovation domain as well as in the KM domain. It has been validated within an intensive evaluation procedure (Paukert et al., 2003). In the following, the model is presented without introducing its derivation to give priority to explaining the innovation domain as a KM application context. Understanding the properties of the introduced exemplar application domain is crucial for fully taking advantage of the IKLC model, even for transferring its generic properties into other KM application domains. Considering the wide variety of possible innovation forms and innovation application domains, generalizations are difficult. However, on an abstract level it is possible to identify six basic phases of an innovation process. They are described in the following innovation process model whose phases are common to most innovation processes (Paukert et al., 2003). The phases are depicted in Figure 2.

There is basically a sequential order between these phases. But there are also overlaps and loops between the phases, where, due to (intermediate) results or external events, revisiting earlier phases becomes necessary. This need for feedback is also stressed by Pérez-Bustamente (1999). In the following, the six phases are described in detail.

Figure 2. Innovation process model (IPM)



Problem Identification Phase

Each innovation is started by a problem that the innovative process is expected to solve. Systematically, two forms can be distinguished (Pérez-Bustamente, 1999):

- proactive forms, which include trend setting, recognition of market opportunity, need creation, and identification of research opportunity; and
- reactive forms, which include open problems in production or processes, changed requirements, and reaction to changed environments.

Regardless of how the innovation is started, the problem needs a proper description. The more people are involved, the more detailed and explicit the problem representation has to be. A first validation of the problem checks the adequacy of the description with respect to the targeted problem as well as the novelty of the problem. Further, a first estimation about the feasibility and the relevance of the problem has to be conducted to reduce the risk of investing resources into further steps. Clearly, these considerations are influenced by the innovation strategy of the involved organization.

Ideation Phase

In the Ideation phase, ideas are generated and collected which are thought to contribute to a possible solution to the described problem. These activities form the core of the innovation process since the subsequent phases are directly dependent on the decisions made at this point. There are several (systematic) ways to discover ideas for solving the problem such as analogy, data mining, paradigm shift, and luck. These all involve the exploration and selection of the current state of the art. The amount of needed knowledge in this phase increases, the more revolutionary the innovation is supposed to be since new domains may be required to find an appropriate solution to the problem.

For negotiating factors like adequacy for the problem, novelty, and feasibility, the ideas have to be formalized and described.

Approach Development Phase

Approach Development is the first step towards solidifying the idea towards an implemented solution. In this phase a conceptual model for the implementation is developed which describes its planned solution on a conceptual level. This phase takes the description, the problem, and the idea as input.

The first set of activities in this phase involves the identification of a useful approach for conceptually describing the implementation of the idea. This involves exploration, selection, application, and creation of related knowledge in terms of technologies, methodologies, and formalisms. The approach and the conceptual model have to be validated for adequacy, novelty, and feasibility of operationalization before they can be considered a valid input for the operationalization phase.

Operationalization Phase

In the Operationalization phase, the developed approach is actually implemented according to the developed model. The goal during operationalization is to achieve results which show that the selected approach adequately resolves the initial problem. This may require a number of iterative steps that are conducted to increase the quality of the solutions to achieve a maximum outcome. Operationalization can become quite resource consuming, making the validation in the preceding phase a crucial activity.

Validating the activities in this phase checks the adequacy of the operationalization with respect to the chosen approach. Also, it checks if it is possible to scale up the developed approach from, for example, a prototype production to a mass production process and with respect to exploitation.

Evaluation Phase

In addition to the validation activities which conclude each developmental cycle during operationalization, there is a separate Evaluation phase which tests the results produced during the innovation process. Negative evaluation results can lead to revision of individual decisions, or they can even lead to cancellation of the entire innovation process. The evaluation requires careful planning of the experimental design and analysis to ensure representative and valid results. The evaluation criteria and methods depend on the domain and intended application area. For revolutionary innovation activities, the evaluation phase is much more challenging than for evolutionary innovation, since revolutionary innovation often also invalidates the traditional best-practice methods of evaluation applied so far.

Exploitation Phase

In this integral part of innovation, the results of the prior phases are distributed in order to gain benefit from them and to meet the goals of the innovation request it was triggered by: a company takes the newly developed product and will try to market it as profitable as possible, or a new process is implemented and integrated into the operational workflow for its improvement and to obtain more cost-effective performance. In the scientific domain, innovations—new insights, methodologies, theories—are disseminated via publication into scientific communities of interest.

Depending on the type of innovation—evolutionary or revolutionary—the demands towards the knowledge lifecycle vary. In an evolutionary innovation scenario—like selling soft drinks in green bottles instead of brown plastic bottles—less knowledge is required than in a revolutionary innovation scenario—like opening new power resources.

An evolutionary innovation requires no knowledge from external domains; the domain knowledge is well known and so are the knowledge resources. Only small shifts of focus have to be made. Applying, gathering, rating, and sharing the knowledge are well-understood operations, although the motivation of systematic knowledge sharing is a challenge in many organizations.

A revolutionary innovation demands knowledge which is out of the main domain of the innovator. Domains will have to be identified which are thought to hold the necessary knowledge. Being unacquainted within these domains, innovators are missing the prerequisite knowledge to decide about the important knowledge resources at first. Also, the process of focusing on the relevant knowledge may take longer since the criteria for these activities are not familiar yet. Applying, gathering, and rating knowledge may require new methods and strategies, whereas sharing the acquired knowledge is less of a problem since this activity is domain-independent.

FUTURE TRENDS

Future steps will concentrate on developing a framework for systematic innovation support. Such innovation support and the knowledge management tools applied in innovation have to be flexible and adaptable in order to take into account that:

- the different phases of the innovation process have specific requirements;
- innovating organizations and teams have their own specific innovation practices, and innovation culture and requirements; and
- requirements and cultural characteristics of innovation culture can change over time (Paukert, Niederée, & Hemmje, in press).

For an Innovation Engineering Environment (IEE) for systematic innovation support by knowledge technology, the following four core technology areas were identified:

- Innovation Process Management: This component is necessary to support the general management of innovation processes. Even though innovation processes present peculiar aspects, an innovation process is first of all a process, and as such it must be managed. This component contains tools that allow innovation managers to plan, log, and monitor the phases and the related activities and resources.
- Generic Innovation Support Components: This core component's sub-components provide classes of functionalities which are intrinsic to knowledge management functionality of any innovation process, independently from domain and application. Examples include: adequate representation, intelligent matchmaking, discovery, and interaction support.
- Application-Specific Support Components: Effective innovation support also requires tools that are domain-specific. This is especially true for approach development and operationalization. Examples of such tools are design and simulation tools. In the design of the IEE, it is important to enable the flexible integration of existing and newly developing application-specific tools.
- Innovation Environment Configuration Support: This functionality has to be specialized for the different phases. This may include method and tool selection, tool configuration, and user interface design. IEE specialization results in a system architecture that provides specific support based on the

generic tools and functionalities suggested by the IKLC.

These four core technology areas have been identified and validated within the resulting research roadmap work (see www.innovanet.eu.com). Implementing solutions to these technology challenges within ongoing knowledge technology R&D will promote and support a more systematic approach to managing innovation. Following a meta design approach (Fisher, 2000), tools for the customization step can finally be part of the overall knowledge-based innovation management framework itself, increasing the flexibility of the approach and enabling involvement of the innovators themselves into the customization process. This allows the adaptation of the system to the requirements of individual organization sand teams, as well as the evolution of the system when the innovation factors change or the environment changes.

CONCLUSION

Although it is generally understood that innovation is a knowledge-intensive process with specific requirements, the work on systematic support of the innovation process by an Innovation Engineering Environment is still in an early state. This article lays a conceptual foundation for the further work in building tools and systems for more systematically supporting the innovation process by information and knowledge technology, with the final aim of contributing to the acceleration of innovation.

In designing and building IEEs that are applicable in different domains, the wide spectrum of existing innovation processes (mostly deviations from the presented innovation process model) is a large challenge and requires flexible and adaptable solutions. However, aiming for a common core of innovation support functionality reduces the overall effort, keeps the R&D activities in this area focused, and eases the adoption of successful innovation cultures and practices across the borders of individual organizations and domains.

Some of the current trends in information and knowledge technology promise to be supportive of the successful development of information technologies:

- the success of service-oriented architectures implemented by Web services can be exploited for building adaptive IEEs, where (Web) services in support of specific innovation activities can be easily and dynamically integrated;
- the Semantic Web activities resulted in widely accepted approaches and exchangeable formats for describing innovation resources and the process itself; and
- the currently increased activities in the area of ontology development and exploitation, which is triggered by the Semantic Web activities, will result in pragmatic and scalable approaches for intelligent decision making and for the interoperable mediation of innovation resources, especially also across the borders of domains as it is required for revolutionary innovation activities.

In spite of the large challenges of this task, it is expected that there will be considerable progress in more systematic and efficient innovation support in the near future.

Chapter 8.3
Experiential Perspective on Knowledge Management

V. P. Kochikar
Infosys Technologies Ltd., India

J. K. Suresh
Infosys Technologies Ltd., India

INTRODUCTION

The last few decades have seen a growing proportion of organizational wealth being represented by intangible assets, i.e., assets with value that cannot be measured in terms of any physical attribute. Management thinking, conditioned over centuries to extract the greatest value out of physical assets, has had to bring within its ambit the leveraging of these intangible assets in building the capabilities required to deliver superior products and solutions. The discipline of knowledge management (KM) was born and came to encompass the gamut of organizational processes, responsibilities, and systems directed toward the assimilation, dissemination, harvest, and reuse of knowledge. In simpler terms, KM is the answer to the question, "How can the organization update and use its knowledge more effectively?" (Kochikar, 2000).

Some of the world's most successful organizations, be they corporate, academic, or government, invest considerably in KM. McKinsey & Co. spends at least 10% of revenues on managing knowledge. The World Bank's annual KM budget is $50 million. IBM has one of the oldest formal KM initiatives, dating back to 1994.

Substantial benefits have been reported across industries. Johnson & Johnson has implemented KM for speeding up the FDA application process and reported savings of $30 million on one product alone (Berkman, 2001). British Petroleum has estimated savings of $400 million a year, while Chevron has discovered operational cost savings of $2.5 billion over 8 years (Infosys, 2002). Tufts University's school of medicine has used KM to integrate its curricula and has been hailed as a national model for medical education (Genusa, 2001). KM is, however, not an unmixed blessing, as Storey and Barnett (2000) noted. Each organization must fashion a KM strategy that takes cognizance of its unique competencies, aspirations, and business context.

Infosys Technologies (NASDAQ: INFY) has conceived, developed, and deployed internally an elaborate architecture for KM that aims to empower every employee with the knowledge of every other employee. The company's success on the knowledge-sharing front has been affirmed by the fact that the company has been a Global MAKE (most admired knowledge enterprises) winner in 2003 (Chase, 2003) and Asia MAKE winner for 2002, 2003. Key elements of the KM architecture include the Knowledge Currency Unit scheme, a comprehensive mechanism for reward, recognition, and measurement of KM benefits; KShop, the corporate knowledge portal built in-house; and the knowledge hierarchy, a four-level taxonomy of 1800 subject areas that constitute knowledge in the Infosys context.

Along the KM journey, we also accumulated a sizeable body of thought on what organizations need to do in order to implement KM successfully, and it is the intention of this article to communicate some of that thought.

BACKGROUND—THE BUSINESS CASE FOR KM

In achieving its goal, KM needs to percolate into every corner of the organizational mind and create a culture of sharing within the organization. The following definitive statement of Lew Platt, Hewlett-Packard's former CEO, sums up the case for KM: "If HP knew what HP knows, we would be three times as profitable." A strong focus on KM has paid undeniable dividends to leading organizations wordwide. This year's Global MAKE winners have delivered a total return to shareholders of 19.6%, twice the Fortune 500 median of 9.1% (Chase, 2003). Similarly, these leading KM practitioners have shown a return on capital employed of 30.4% versus a Fortune 500 median of 18.5%. These winners also figure prominently in other honor lists, such as Fortune magazine's Most Admired Companies list (Hjelt, 2003) and Business Week magazine's list of the world's top brands (Business Week, 2003).

Chard (1997) and Bartlett (1998) have identified the following drivers for KM: the pace of change in a knowledge-driven age, which makes constant learning an imperative; globalization, which means acquiring knowledge about new environments and cultural and economic issues; the emergence of new technologies that offer new leverage if used well; the increase in virtual work, which needs much better knowledge sharing; rising expectations from all stakeholders, to meet the companies that need to be proactive and agile; and growth, which accentuates the challenge of leveraging the knowledge of individuals for corporate advantage.KM Review magazine's survey of 400 global corporations revealed that the following are key objectives of KM programs (KM Review, 2002):

1. Increasing organizational communication
2. Gaining competitive advantage
3. Increasing collaboration among employees
4. Improving customer relationships
5. Becoming more efficient
6. Innovating
7. Learning from previous mistakes and successes
8. Capturing and retaining tacit knowledge

Using the framework of Nahapiet and Ghoshal (1998), the above objectives can be classified as improving financial capital (2, 5); improving social capital (1, 3, 4), and improving intellectual capital (6, 7, 8). While KM activity, as enumerated below, focuses strongly on the social and intellectual capital aspects, the success of KM must necessarily be measured in terms of improving financial capital. As our extracts from Chase (2003) above demonstrate, successful KM adopters have found that this is the case.

BUILDING AN ORGANIZATIONAL KM ARCHITECTURE: CHALLENGES

An organizational architecture for KM must exhibit the following properties:

- Motivation: It must make people want to share knowledge.
- Facilitation: It must make it easier for them to do so.
- Awareness: It must make people aware of the KM architecture that has been created, and their roles in using it.

Figure 1 depicts conceptually the relative organization-wide effort required to be devoted to each of the above as the KM initiative evolves over time.

KM success hinges on an architecture that is designed specifically to suit each organization's business and cultural context. Such an architecture must address four key dimensions: people, process, content, and technology. Figure 2 outlines the key considerations to be addressed by a KM architecture along these four dimensions.

Enumerated below are a few key challenges on the people, process, content, and technology

Figure 1. Relative organization-wide effort devoted to motivation, facilitation, and awareness, as a KM initiative evolves over time

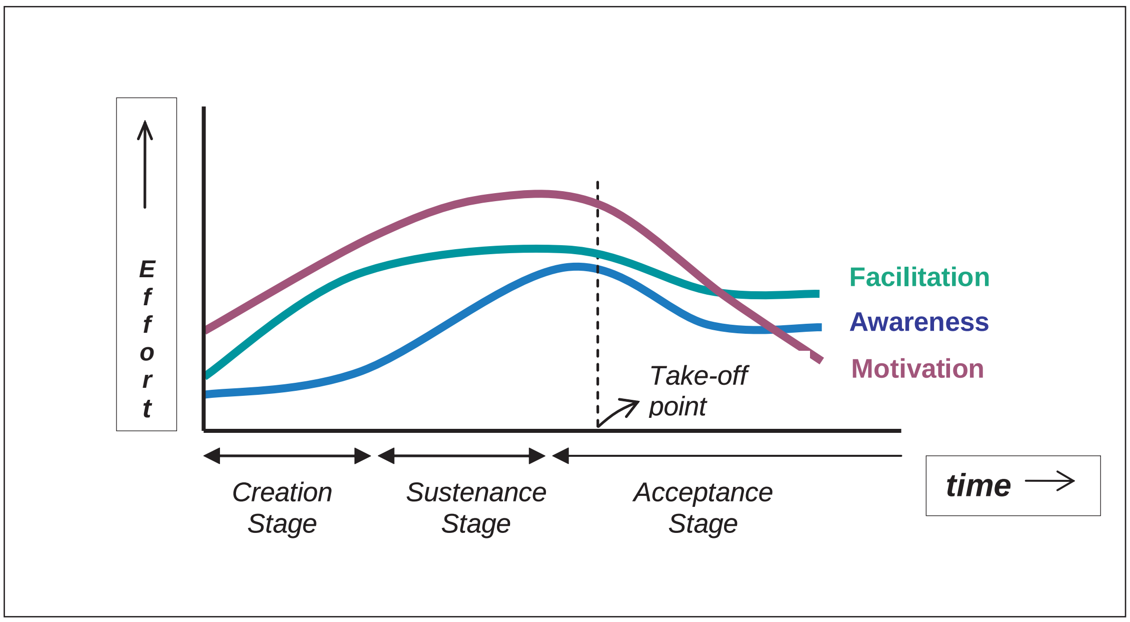

Figure 2. Sample people, process, content and technology considerations to be addressed by a KM architecture

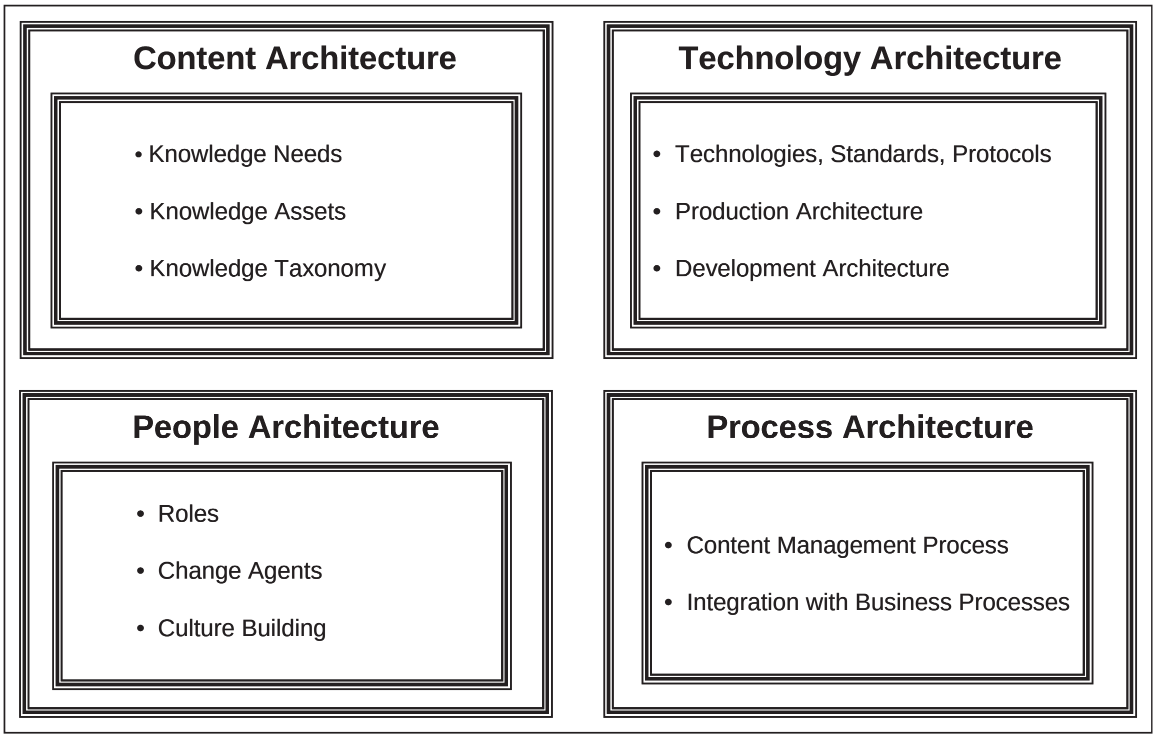

dimensions that must be addressed when creating a KM architecture.

Deciding How Much Effort Should be Devoted to Technology

As its name implies, information technology (IT) is a mechanism for classifying, storing, and presenting information, as well as ensuring its speedy and effective flow across the organization. Because these capabilities are so critical for KM, it is difficult to conceive of any successful KM implementation that does not lay significant emphasis on the use of IT.

It is, however, necessary to guard against excessive reliance on IT—a tendency that has been liberally fostered by vendors of various hues. Clearly, the use of IT must be judicious, appropriate, preferably ROI-driven, and most importantly, backed by a clear strategy and ownership within the organization (Kochikar, 2000).

A popular yardstick is that not more than a third of the effort and investment of implementing KM should go into technology (Davenport & Prusak, 1998)—any excess makes it highly likely that the “softer” issues related to people, content, and process are being neglected. The extent of IT focus is governed by the target audience’s familiarity with, and willingness to use, IT tools.

Table 1. Typology of technologies for KM

Collaboration Technologies Stable Collaboration Technologies: Electronic mail Newsgroups/discussion forums/list servers Chat and instant messaging Expertise management systems Audio, video, and desktop conferencing E-learning technologies Mobile devices Emerging Collaboration Technologies: Whiteboarding and application sharing Virtual workspaces **Enabling Technologies for Collaboration** XML (extensible markup language) WAP (wireless application protocol) and WML (wireless markup language) WebDAV LDAP DSL (digital subscriber line) IP Telephony (VoIP) Streaming media
Enterprise Technologies Application servers Enterprise portals Business intelligence Emerging enterprise technologies Voice portals: Peer-to-peer (P2P) technology
Presentation Technologies Portlets Visualization technologies Personalization Dashboards and Web parts **Enabling Technologies for Presentation** Dynamic HTML (hypertext markup language): Applets Cookies *Source: Infosys Research*.

In the Infosys experience, because KShop has been built internally by the central KM group's technology team without the use of any special hardware or software products, the monetary investment in IT for KM has been extremely small. In terms of effort, the investment hovers around the one-third mark.

Table 1 provides a classification typology of technologies for KM and summarizes some of the key technologies.

Deciding the Degree of Centralization of Responsibility

A key question related to the people architecture for KM is, whose responsibility is it to make KM happen? Although every individual and group in the organization must work to make KM successful, there must clearly be an identified group of some form that will "own" KM in the organization. At the same time, this argument must not be taken to the absurd extreme of saying that this central group will have complete responsibility for all aspects of making KM happen. The question thus reduces to, what is the most appropriate position to occupy on the centralization–decentralization spectrum?

The answer to this question is, of course, dependent on issues deeply embedded in the organization's specific context. The extent of senior management's willingness to commit resources for KM is a key determinant. Expectations of KM in the organization also strongly determine the degree of centralization; in general, as more "guarantees" are expected, the more the onus shifts onto the central group.

In our experience, a "facilitated decentralized approach" works best: the technology architecture management for KM—development, deployment, and maintenance—is done by a central KM group. All stages of the content management process are anchored by the KM group; however, creation of internal content must happen in the field and is facilitated by the KM group. The conception and implementation of the KM strategy is also anchored by the central KM group.

This approach entails considerable investment in training and development of staff in the central KM group and in orienting all other roles in the organization to their knowledge-sharing aspect. One practice that we have found useful has been to "catch them young"—sensitize every fresh employee joining the organization to the mechanics of using the organizational KM infrastructure, within the first 2 weeks. In this manner, they learn the KM ropes at a time when their need to acquire knowledge about the organization is very high.

The "Buy versus Build" Decision

There is an abundance of packaged IT solutions for KM on the market. Some of these have been conceived by their vendors with the KM paradigm in mind, and thus support organizational KM requirements to a fair degree. Others are existing products repackaged with a "KM" label, and thus, they meet only a subset of an organization's requirements.

Organizations interested in reaping the full benefits of KM must, as said earlier, invest in designing a customized KM architecture that fits their context. For the technology dimension then, the "build" route becomes inevitable, as the technology solution must fit well into the people, process, and content dimensions of the KM architecture. Clearly, the economics of the buy versus build decision are also influenced in significant degree by relative costs.

In the Infosys experience, the decision to build was influenced largely by the fact that our proprietary knowledge hierarchy referred to earlier was a central mechanism for accessing content and expertise, and it needed to be supported by the technology system. Similarly, the unique knowledge currency unit (KCU) mechanism needed to be supported. The system was required to compute and use composite KCU ratings (a quality measure for documents) and provide interfaces for users of documents to award KCUs and manage their individual KCU accounts. Further, the system needed to exchange data with a number of existing corporate databases that store employee and project data in disparate schemas. A key requirement, the ability to control access based on organizational role, needed to be supported. Another strong need was for the technology architecture to evolve in response to changes in the other KM architectural elements, and an extraordinary degree of flexibility was a must.

Deciding the Degree of Centralization of Content

From a practical angle, the degree of distribution of content is another challenge to be surmounted. Does all content need to be centralized in one repository, or does it live and evolve in different pockets across the enterprise? The former choice appears attractive, because it offers features such as simplicity of architecture, administration, usage, change management, etc. However, the fact that specialized knowledge continues to develop in pockets—and that the responsibility (and pride) associated with ownership is the best driving force for its continued currency and relevance—indicates a distributed content architecture.

Using Synchronous versus Asynchronous Mechanisms for Knowledge Sharing

Another important aspect is the relative focus on direct, people-to-people collaborative sharing vis-à-vis sharing through codification of knowledge. Collaboration is characterized by its reliance on bringing people "in touch" for knowledge transfer through synchronous mechanisms. The latter approach (also called content management) is asynchronous, depends on repositories, and emphasizes defined ways of explicating knowledge. Conventional KM wisdom associates collaboration with the potential for tacit knowledge transfer and content management with explicit knowledge transfer. However, our experience suggests that technology, used innovatively, can help blur the boundaries between the two. For example, collaboration through technology systems is largely synchronous, and yet, as for example in the open source movement, is capable of creating exciting possibilities for knowledge transfer in virtual teams. The knowledge represented by the content can also be viewed as providing the live context for the exchange of implicit knowledge. It may, therefore, be said that the conversion of the implicit knowledge of the organization into content is a property of mature KM programs. Technology systems that sit atop the e-mail system, and content mining agents on collaborative forums, are further examples indicating the blurring distinctions between collaboration and content management.

Measuring the Benefits of KM

As KM implementations mature, it becomes imperative that mechanisms to evaluate the benefits must emerge. A complete treatment of KM metrics is beyond the scope of this article, and the interested reader may refer to Skyrme (2003).

In our experience, there are three forms of evidence that can be used in assessing the benefits of a KM program, in increasing order of reliability and difficulty: anecdotal, survey-based, and metrics-based (Kochikar & Suresh, 2003). Anecdotal evidence—"Thanks to using good KM, my project saved 12 weeks and saved 15% of cost to the customer"—although it may represent the viewpoint of a few opinion leaders, can be used to great effect. Surveys are generally more convincing, as they represent the view of a sample carefully chosen to represent the views of the entire target population. For example, an internal survey at Infosys found that more than 99% of the respondents believed KM is essential for the company, and 70% said good knowledge-sharing practices had helped in delivering tangible benefit to customers.

The metrics-based approach is the most powerful, and yet the most difficult to implement, demanding a high degree of maturity of the KM implementation. Our approach has been to measure in quantitative terms the impact of knowledge sharing on traditional indicators of project performance, using the KCU mechanism. Several projects have been able to quantify savings in dollar terms, and also report various other benefits, such as improved quality, faster turnaround times, etc.

FUTURE TRENDS

A heartening trend observed over the past few years is the increasing geographical uptake of KM. Of the 1998 MAKE winners, 73.3% were from North America, 17.7% from Europe, and 4.4% from Asia. In the 2003 MAKE study, North America's representation had dropped to 55%, Europe's had risen to 22.4%, while Asia's had surged to 20.4%. Clearly, Europe's and Asia's acceptance of KM has grown at the expense of North America, and this is likely to be a continuing trend.

Over the coming years, KM will continue to be imperative for organizational effectiveness. There is likely to be greater focus on tacit knowledge sharing, evolution of standards for KM solutions, and sharing through communities of practice. These developments will continue to be supported by evolving technologies: the integration of content management and collaboration products, development of agent technologies to provide proactive services, increased role for multimedia content, automated knowledge capture in collaboration products, automatic content classification, and enterprise-level support for mobile application access (reducing the reliance on speech and voice recognition systems).

CONCLUSION

Creating a culture of sharing is governed by principles that have much in common with Metcalfe's law—as more people grow convinced of the benefits of participating in the knowledge-sharing movement, it becomes easier to convince still more people to buy in. Thus, as long as steady progress is made on the road toward achieving greater sharing, the pace of adoption accelerates with time. Once a "critical mass" of users has been reached, the movement reaches a take-off stage (Figure 1), beyond which it becomes self-sustaining, without significant effort being devoted toward building up the motivation and awareness properties. Until this point is reached, it is crucial to understand and manage KM adoption as a process of organizational change.

Chapter 8.4
Strategic Experimentation and Knowledge Management

V. K. Narayanan
Drexel University, USA

INTRODUCTION

Historically, the focus of IT infrastructure has been to capture the knowledge of experts in a centralized repository (Davenport & Prusak, 1998; Grover & Davenport, 2001). These centralized databases contained knowledge that was explicit and historical (e.g., competitor pricing, market share), and the IT infrastructure served to facilitate functional decision-making or to automate routine tasks (i.e., in re-engineering). The users of technology approached the repository to obtain data in a narrowly defined domain (Broadbent et al. 1999). Consequently, IT originally played a significant yet ultimately limited role in the strategy creation process. Management information systems (MIS) arguably generated information that was less applicable to strategy creation, as noted in early writings on the linkage between MIS and strategic planning (Holmes, 1985; Lientz & Chen, 1981; Shank et al., 1985).

The active management of knowledge was similarly underdeveloped. Despite the fact that strategic decision makers had always emphasized the role of tacit knowledge, the actual importance of knowledge was not explicitly recognized. Formalized knowledge management (KM) (Davenport & Prusak, 1998), with its associated terminology and tools, is a recent development and, as such, did not inform the strategic planning process.

However, the shifts that have taken place in IT infrastructures over the last decade and the recent developments in knowledge management have brought them closer to the creators of strategy. Indeed, both IT and knowledge management are increasingly enablers in the contemporary strategic management practice.

1. IT infrastructure is transitioning in its focus from the functional work unit to a process orientation. Whereas computer systems were once the focal point, the new infrastructure is network-centric, with an emphasis on business knowledge (Broadbent et al., 1999). For example, traditional search engines utilized rule-based reasoning to identify elements matching specific search criteria; the "state-of-the-art" knowledge management systems employ case-based search techniques to identify all relevant knowledge components meeting the user's request (Grover & Davenport, 2001).
2. IT now takes into account contexts that include cross-functional experts that are knowledgeable in a wide variety of potentially relevant issues. Additionally, there is a greater emphasis on the integration of infrastructure with organization, structure, culture (Gold et al., 2001), and organizational roles (Davenport & Prusak, 1998). In many ways, the newer IT infrastructures have enabled the garnering of explicit knowledge throughout the organization improving the speed of strategy creation.

The objective of this article is to outline how the developments in IT and KM are facilitating the evolution of strategic management to strategic experimentation in order to create quantum improvements in strategy creation and unprecedented developmental opportunities for the field of IT.

BACKGROUND

Information Technology (IT)

For the purposes of this chapter, IT is defined as physical equipment (hardware), software, and telecommunications technology, including data and image and voice networks employed to support business processes (Whitten & Bentley, 1998). The overarching plan for IT deployment within an organization is called the IT architecture. Technology infrastructure refers to the architecture as including the physical facilities, the services, and the management that support all computing resources in an organization (Turban et al., 1996).

Knowledge Management (KM)

As used in this chapter, data are objective, explicit pieces or units; information is data with meaning attached; and knowledge is information with an implied element of action.

Knowledge is the fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms (Davenport & Prusak, 1998, p. 5).

KM is "a set of business practices and technologies used to assist an organization to obtain maximum advantage from one of its most important assets—knowledge" (Duffy, 2000, p. 62). In other words, it is actively capturing, sharing, and making use of what is known, both tacitly, informally, and explicitly, within the organization. IT often facilitates knowledge management initiatives by integrating repositories (e.g., databases), indexing applications (e.g., search engines), and user interfaces. Davenport and Prusak (1998) note that KM also incorporates traditional management functions: building trust among individuals, allocating resources to KM, and monitoring progress.

Strategic Management

The concept of "strategy" explicated in strategic management is one of marketplace strategy (i.e., winning in the marketplace against competitors, entrenched or incipient). The underlying premise is that "to enjoy continued strategy success, a firm must commit itself to outwitting its rivals" (Fahey & Randall, 2001, p. 30). A large body of literature on strategic management has persuasively argued that effective strategy creation and execution are central to a firm's performance (Covin et al., 1994).

Strategy creation involves both goal formulation—defined in terms of external stakeholders rather than operational milestones—and crafting of the strategic means by which to accomplish these goals (Hofer & Schendel, 1978). The means typically include business scope, competitive posture, strategic intent, and the organizational mechanisms for implementation. In practice, the process of strategy creation has often taken the form of strategic planning. Comprehensive strategic planning (Gluck et al., 1978) has historically been practiced in large corporations. A celebrated example is the use of scenarios by Royal-Dutch Shell. Planning usually consisted of several sequential stages of decision-making involving diagnosis, alternative development, evaluation and choice, and implementation. In each step, the strategic planners emphasized deliberate juxtaposition of "objective data" and careful analysis with top management judgment, thus highlighting the role of tacit knowledge.

Strategic planning has evolved over the years. Writing in the 1970s, Gluck et al. (1978) identified four phases of evolution: budgeting, long-range planning, strategic planning, and strategic management. Each phase of evolution incorporated the lessons from the earlier phases, but also took into account the emerging realities faced by corporations. Gluck et al. (1978) noted that during the 1980s the "strategic management" phase would represent the cutting edge of practice in the world.

TOWARD STRATEGIC EXPERIMENTATION

The 1990s witnessed a revolution in organizational environments often characterized as "hypercompetition" (D'Aveni, 1994). These environments have created three major imperatives for organizations: time compression, globalization, and technology integration (Narayanan, 2001). The increased environmental dynamism also contributes to an increase in the degree of uncertainty confronted by strategic managers, calling into question traditional planning practices. Consequently, a new type of strategy creation process is evolving, which is termed "strategic experimentation." With this evolution, the relationship between strategy creation, knowledge management, and IT is undergoing a profound shift.

All four phases of strategic planning documented by Gluck et al. (1978) incorporated a sequential approach to strategy creation and execution, leading to the identification of one winning strategy that has the highest probability of success. Consequently, firms found it logical to commit the maximum available resources to the implementation of one wining strategy. The goal was to obtain a sustainable competitive advantage vis à vis the firm's rivals, and to reduce uncertainty ex ante using analytical forecasting techniques as well as market research. This approach to planning seems to have been effective during the 1980s when the environment was moderately dynamic.

In hypercompetitive environments, market participants frequently confront great uncertainty over technological possibilities, consumer preferences, and viable business models. This high level of ambiguity often results in a situation where (a) traditional methods of ex ante uncertainty reduction (e.g., market research) fail, and (b) the costs and risks of the traditional "big bet" strategic management approach outweigh the advantages in terms of focus, decisiveness, and concentrated resource commitment. It is in this situation that the emerging strategic experimentation approach holds significant promise.

Strategic experimentation (Brown & Eisenhardt, 1998; McGrath, 1998; McGrath & MacMillan, 2000) draws on real-options reasoning (McGrath, 1997), discussions of exploration vs. exploitation, and trial-and-error learning (Van de Ven & Polley, 1992).

1. Companies engaging in strategic experimentation continually start, select, pursue, and drop strategic initiatives before launching aggressively those initiatives whose values are finally revealed (McGrath & MacMillan, 2000).
2. Strategic initiatives serve as low-cost probes (Brown & Eisenhardt, 1998) that enable the discovery of product technology and market preferences. They also serve as a stepping stone option for future competitive activity in that particular product-market domain.
3. The role of the strategic manager is to administer a portfolio of strategic initiatives that represent an appropriate mix of high and low uncertainty projects, and to maximize the learning from these real options (McGrath & MacMillan, 2000).

Strategic experimentation represents a fundamentally different view of the practice of strategic planning and the path to competitive advantage. Movement is emphasized over position in this approach. Thus, competitive advantage is viewed as temporary at best, and hence, innovation and learning are considered crucial to success. Strategic experimentation is especially appropriate for high velocity environments such as emerging product markets with high uncertainty surrounding both technology and customer preferences (e.g., the early Personal Digital Assistant, Internet appliance, and satellite-based telephony markets). Here, low-cost probes can be very effective in gaining knowledge and reducing uncertainty while minimizing exposure to the results of faulty assumptions.

THE ROLE OF IT AND KNOWLEDGE MANAGEMENT IN THE ERA OF STRATEGIC EXPERIMENTATION

Since strategic experimentation represents the cutting edge of ideas in strategic management, we should expect significant advances in tool development and utilization in the next few years that will enable us to move the idea towards normal organizational practice.

Strategic experimentation necessitates several major functions that should be performed by an organization. KM is critical in strategic experimentation; therefore, it is not surprising that many of the tools currently moving into practice have emerged from KM. Following are the four major strategic experimentation functions and the associated KM tools.

Rapid Decision-Making

The ability to quickly garner tacit knowledge in all phases of decision-making is a central requirement in strategic experimentation. Current KM tools to support this include visualization and prototyping, group decision facilitation, and knowledge representation. Each method attempts to reduce the time needed for a group to progress from problem identification to solution implementation. These tools help to coordinate the use of data, systems, tools, and techniques to interpret relevant information in order to take action (Little, Mohan, & Hatoun, 1982).

Integration of Learning from Experiments

Organizational learning, another core concept in strategic experimentation, requires that appropriate learning be distilled from each experiment. This orientation combines decision-making and learning. Initiatives judged to be failures are not merely weeded out; they become occasions for discovery of root causes. Nor are successes simply alternatives to back financially; successes often generate potential best practices. Current KM tools in use for this purpose include learning histories (Roth & Kleiner, 1998), group brainstorming, and shared communication platforms.

Diffusion of Learning

Organizational learning has to be diffused throughout the organization. Since formal organizational channels may stifle transmission of tacit knowledge, diffusion may require interactions among "communities of practice" (Grover & Davenport, 2001; Davenport & Prusak, 1998). An organizational architecture incorporating relevant tools and IT infrastructure has to be designed to support theses interactions. KM tools such as knowledge maps identifying the experts in specific areas and repositories of case histories, are evolving to include dynamic updating of repositories and focused search tools to reduce information overload.

Managing a Portfolio of Strategic Experiments

Finally, unlike in previous eras, strategic experimentation requires maintenance and management of a portfolio of initiatives (Narayanan et al., 2001). This has three major implications. First, the knowledge base for decisions has to be broader and richer, simply due to the increase in the number of initiatives. Second, the knowledge base becomes much more complex, since the initiatives themselves differ in terms of the mix of tacit and explicit knowledge. Thus, newer initiatives are likely to be more dependent on tacit knowledge, whereas mature ones can be augmented by explicit knowledge. Finally, the sheer number of people involved in the process will be larger, given specialized pockets of tacit knowledge that would have grown up around specific strategic initiatives. DSS and other rich data applications, including cognitive mapping, can be used to capture the knowledge and feedback.

IT can accelerate the development of strategic experimentation by designing infrastructures that accommodate the new KM demands imposed by this new mode of planning. Consider how each of the following functions can be enhanced by IT infrastructure development.

1. Future developments can significantly reduce the time expended in solution development through real time displays, and expand opportunities for geographically dispersed collaboration. Also, advanced multimedia and communication capabilities increase the benefits of GSS and DSS tools.
2. Learning from experiments can be enriched by qualitative database construction, multimedia enhancements to communication applications, and open platforms to permit the sharing of knowledge over various communication channels, including wireless media.
3. Today, diffusion is hampered by information overload that has intensified competition for the user's attention (Hansen & Haas, 2001). To solve the problem, search tools should include separate parameters for content, rationale, and purpose of the query in order to isolate salient responses. Additionally, knowledge repositories must be maintained to ensure the contents are accurate and of high quality. Maintenance, currently pro-

vided by intermediaries (Markus, 2001), might be performed by faster automated systems.

4. Expert systems or neural networks may be developed to manage and track portfolios, promoting reuse of the knowledge captured.

The significant implication for IT infrastructure from our discussion is the need for technology integration (Narayanan, 2001) with both hard and soft technologies. IT infrastructure should exploit the potential for integration with other hard technologies such as telecommunications to enhance the organizational capacity for speed and the carrying capacity for tacit knowledge. Similarly, IT should seek to interface with decision sciences to embed AI-based processing tools, and with cognitive theorists to capture the tacit knowledge pervasive in organizations.

CONCLUSIONS AND IMPLICATIONS

We have argued that the technological changes of the 1990s have ushered in the need for strategic experimentation as the metaphor for planning practice. Strategic experimentation involves (a) maintaining a portfolio of strategic thrusts, (b) rapid decision-making so that successful experiments are backed and failures are weeded out quickly, (c) learning from both successes and failures, and (d) diffusion of both explicit and tacit knowledge throughout the relevant segments of an organization. This phase requires fundamental shifts in our view of knowledge management—its significance, use, and tools. Finally, we have argued that the shift to strategic experimentation requires fundamental shifts in the development of IT infrastructure. Instead of developing in relative isolation to other disciplines, IT should focus on technology integration by working in close collaboration with the telecommunication technologies, artificial intelligence community, and managerial cognition scholars.

Chapter 8.5
Competitive Intelligence Gathering

Kevin R. Parker
Idaho State University, USA

Philip S. Nitse
Idaho State University, USA

INTRODUCTION

Knowledge management (KM) is the process through which organizational performance is improved through better management of corporate knowledge. Its goal is to improve the management of internal knowledge processes so that all information required for corporate decisions can be made available and efficiently used. Competitive intelligence (CI) is a process for gathering usable knowledge about the external business environment and turning it into the intelligence required for tactical or strategic decisions. The two are strongly connected because gathered CI has no long-term value unless an effective KM process is in place to turn the information into something usable. Although most information collected during a CI investigation is used in immediate decision making, it must be integrated into the internal knowledge systems to provide a long-term resource when companies attempt to detect trends or adapt to changes in their environments (Aware, 2004).

Both KM and CI systems are designed to enhance the information resources of an enterprise, but often target different information types and sources. While CI is concerned with gathering information from the external environment to enable the company to gain competitive advantage (Williams, 2002), most investigation into KM has focused on capturing the knowledge stored within the minds of individual employees (Nidumolu, Subramani, & Aldrich, 2001). Bagshaw (2000), Johnson (2000), Rubenfeld (2001), and Williams (2002) all focus on the use of KM for collecting, managing, and sharing internally generated knowledge.

Restricting the focus to internal data severely limits the potential of KM systems. The vast wealth of knowledge outside the traditional boundaries of the company may prove just as useful to organizations seeking a competitive advantage (Gold, Malhotra, & Segars, 2001). Fortunately, some studies indicate an awareness of the value of external information. Abramson (1999) notes that KM enables companies to create and systematically use the very best internal and external knowledge that they can obtain. Grzanka (1999) notes that KM provides a methodology to leverage and manage all knowledge, whether external or internal. Other researchers take it a step further and recognize the synergies between KM and CI. Johnson (1999) states that KM and CI are two parts of the same whole because both are designed to apply enterprise knowledge of the internal and external environment for long-term competitive advantage. KM and CI "have similar goals and are natural extensions of one another (e.g., manage information overload and timely/targeted information delivery, provide tools for data analysis, identify subject matter experts, enable collaboration)" (Meta Group, 1998). Davenport (1999) even goes so far as to take the stance that CI can be viewed as a branch or subset of KM.

A major difference between KM and CI is the much broader scope of KM compared to the more clearly focused CI: rather than applying knowledge to the entire firm and its complete set of objectives, CI focuses on defending the firm from competitive threats, while at the same time proactively working to acquire market share from competitors (Johnson, 1999). Further, while KM often falls under the purview of the information technology department, more often than not CI activities are found within strategic planning, marketing, or sales (Fuld, 1998).

While it is difficult to simplify the relationship between CI and KM (Johnson, 1999), it is important to note that the two approaches complement each other. The goal of both disciplines is to evaluate current business decisions, locate and deliver appropriate knowledge from the environment, and ultimately help to give it meaning so that decision makers better understand the options available to them (Johnson, 1999). The synergies between KM and CI indicate that greater convergence between the two approaches is inevitable.

BACKGROUND

Each organization has associated with it a particular context pertaining to such issues as customer attitudes, competitors' actions, regulatory patterns, and technological trends. Environmental scanning tools collect information from the environment to assist in developing strategies that help the organization formulate responses to that environment.

Environmental scanning was first defined by Aguilar (1967) as the process of gathering information about events and relationships in the organization's environment, the knowledge of which assists in planning future courses of action. It entails perceiving and interpreting both the internal and external environment with the objective of making appropriate operational, tactical, and strategic decisions that help insure the success of the firm (Elofson & Konsynski, 1991). Any organization that fails to monitor its environment in order to determine the conditions under which it must operate courts disaster (Mitroff, 1985). Identification of key economic, social, and technological issues that affect the organization, its lifecycle stages, and their relevance to each other helps managers allocate attention and resources to them (McCann & Gomez-Mejia, 1992). Scanning is a fundamental, early step in the chain of perceptions and actions that permit an organization to adapt to its environment (Hambrick, 1981).

Aguilar (1967) stresses the close relationship between strategic planning and scanning, noting that scanning is the acquisition of external strategic information that is useful for making decisions about company strategy and long-term plans. The objectives of environmental scanning vary with the business strategy employed by an organization (Jennings & Lumpkin, 1992). Differentiation strategy is associated with a systematic scanning activity to alert the organization to market opportunities as well as indications of innovations (Miller, 1989). Cost leadership strategy involves scanning for more efficient methods of production as well as innovations made by the competition (Miller, 1989). Reactive strategy is associated with scanning the external environment for problems (Ansoff, 1975), while low-cost strategy directs the scanning effort toward solving specific problems regarding product cost (Hrebiniak & Joyce, 1985). An organization's strategy determines whether environmental scanning is used to search for opportunities or to forewarn of threats (Snyder, 1981). The goals of an organization are continuously evolving, and as they are changing, so too are the pertinent threats and opportunities that must be monitored (Elofson & Konsynski, 1991). Environmental scanning systems are dependent on the identification of pertinent factors, both external and internal, to be scanned.

Many tools can be used to perform environmental scanning, including CI, business intelligence, knowledge acquisition, knowledge discovery, knowledge harvesting, enumerative description, knowledge engineering, information retrieval, document management, and enterprise information portals. This article focuses on the approach most widely used in business, CI.

MAIN FOCUS OF THE ARTICLE

Miller (2001) defines CI as the process of monitoring the competitive environment. This competitive environment includes but is not limited to competitors, customers, suppliers, technology, political and legal arenas, and social and cultural changes. Kahaner (1996) explains that CI is a systematic and ethical program for gathering, analyzing, and managing information about competitors' activities and general business trends that can affect a company's plans, decisions, and operations. Note the distinction of CI as an ethical process, unlike business espionage, which acquires information by illegal means like hacking (Malhotra, 1996). CI enables management to make informed decisions about a wide variety of tactical and strategic issues. Outcomes from a formal CI program should enable strategists to anticipate changes in the company's marketplace and actions of its competitors. CI should also uncover the existence of new competitors, new technologies, products, laws, or regulations that will have an effect on business. CI can help a business learn from the successes and failures of other enterprises, make better mergers and acquisitions, and enter new business arenas. From an internal viewpoint, CI can help a company assess its own business practices from a more open and objective perspective while helping implement new management tools (Kahaner, 1996).

The CI process is becoming even more important as the pace of business both at home and abroad continues to accelerate. CI also helps managers deal with the rapid change in the political, legal, and technical environments (Kahaner, 1996). A key goal of CI is to provide early warnings or timely alerts that allow decision makers to proactively position the company to maintain or gain a competitive advantage. Management must be able to detect changes in the market early enough to place the company in the most strategically advantageous position possible. A key feature of CI is the analysis process, which organizes and interprets raw data to uncover underlying patterns, trends, and interrelationships, thereby converting it into actionable intelligence. Data thus transformed can be applied to the analytical tasks and decision making that form the basis for strategic management (Miller, 2001).

Lackman, Saban, and Lanasa (2000) propose a model of the CI process that consists of several processes, including Identify Users, Assess Intelligence Needs, Identify Sources of Information, Gather Information, Interpret Information, and Communicate Intelligence. In the Interpret Information step, they propose an Intelligence Library that is closely related to KM since the Library serves as a repository for intelligence and secondary data with a user-friendly retrieval system designed to encourage its use. The inputs into the Library could come from CI departments and their activities or from more traditional KM activities designed to capture and disseminate tacit knowledge as explicit knowledge regardless of the organizational structure of the business. This model of CI thus incorporates features of KM.

The classic intelligence cycle has four stages—collection, processing, analysis/production, and dissemination—which is closely mirrored by knowledge management's four-step cycle of capture, transformation, communication, and utilization (Nauth, 1999). Kahaner (1996) describes a four-step CI cycle consisting of planning and direction, collection activities, analysis, and dissemination, while Miller (2001) adds feedback as a fifth step. Planning and direction requires working with decision makers to discover and hone their intelligence needs. Based on the vast array of directions that CI can take as illustrated above, this is one of the most difficult and ill-defined tasks, especially for managers not accustomed to using the CI process. Collection activities involve the legal and ethical gathering of intelligence from various public and private sources, both internal and external to the company. Two major approaches used in information collection are responding to ad hoc requests and continuously monitoring key intelligence areas. Proactive requests can be answered with available data, perhaps in a KM system, while reactive requests require a search process to uncover pertinent intelligence (Breeding, 2000). Several resources can be searched, including pay-for-use services such as Dow Jones, Hoover's Company Data Bank, Standards & Poor's, NewsEdge, as well as free information sources such as company Web sites, SEC's Edgar system, and corporateinformation.com (Breeding, 2000).

There are also specialized databases from third-party vendors (Dialog, Lexus/Nexus), press release and newsfeed collections (WavePhore's Newscast Access or NewsEdge's NewsObjects), product literature, competitor Web sites, archived design specifications, company profiles and financial statements, and numerous other sources that are databased, searchable, and categorized (Johnson, 1998). Monitoring key intelligence areas falls under the purview of environmental scanning. While many of the same information sources can be used, this approach allows critical intelligence to be pushed directly to the desktops of those decision makers who most need it without their having to do any searching through newspapers, Web sites, or other resources on their own, and it heightens awareness about the competition, making users aware of the competition in many of their day-to-day activities (Breeding, 2000). Analysis involves interpreting data and compiling recommended actions. The analysis, like the collection process, is driven by the planning stage to answer specific questions or concerns that managers are dealing with at the time. These questions or concerns will range from very tactical to very strategic in nature.

Dissemination involves presenting the findings to decision makers. This again is directed by the planning stage where the question of how to disseminate the findings is determined and agreed to prior to the start of the project. It is important to insure that decision makers get the types of reports that they want, rather than what the CI personnel find most interesting. That means that if the decision maker wants a simple, direct-to-the-point report rather than a long, involved presentation, then he/she should get it. Feedback involves soliciting responses from decision makers about the quality, timeliness, and accuracy of the intelligence and their needs for continued intelligence reports. Whether we are contemplating the classic intelligence cycle, the knowledge management cycle, or the competitive intelligence cycle, the cycle is a circular, iterative process. Note that unlike internal knowledge management, CI's focus is on both internal and external events and trends, with a strong focus on competitors' and others' activities and likely intentions.

While all phases of the CI cycle may be equally critical, planning and direction—and the needs identification process involved therein—are pivotal. No information-gathering approach can be successful unless it is provided with an adequate specification of the variables that need to be monitored. A great deal of research has been devoted to studying how to look for information, while overlooking the equally vital issue of what information to look for. A recent review of software marketed toward the online intelligence community clearly illustrates that the ability of most software to determine what information to gather is clearly deficient (Fuld, 2001).

Many tools for gathering intelligence are profile based, designed to sift information through a profile of intelligence needs (Berghel, 1997). These profiles are often made up of a set of topics that describe specific interests (Foltz & Dumais, 1992), and are developed early in the CI cycle and modified throughout the course of the intelligence operations. Each topic can be expressed in terms of a keyword or concept. The primary weakness of this type of approach is its reliance on the completeness and accuracy of a one-dimensional or single-class profile. If the profile is insufficient in any way, the effectiveness of the filtering process is seriously diminished. For example, if the profile is too narrow in scope or omits critical intelligence topics, the competitive intelligence process will overlook much of the pertinent available information, leaving managers unaware of vital facts. Thus, decision makers may consistently make crucial decisions based on faulty information. If, on the other hand, the profile is too broad or general, the intelligence gathering process may be capturing irrelevant information, overwhelming the decision makers and convincing them that the CI process is ineffective. In short, the profile of information needs is the pivotal element in determining how well the CI process performs.

Needs identification requires a structured approach that takes into account multiple dimensions, or classes. Such an approach helps to insure that the process of identifying an organization's intelligence needs considers each of the categories that make up those needs. Stadnyk and Kass (1992) propose the development of knowledge bases of description categories over which individual models of interests can be defined. Herring (1999) proposes the concept of Key Intelligence Topics (KITs) to help identify intelligence requirements by considering strategic decisions, early-warning topics, and key players. Based on Herring's prior work with both the government and Motorola, the KITs process helps management to identify and define critical intelligence needs. CI programs often operate under the direction of upper management, which generally delineates the objectives or needs that CI must attempt to meet.

However, CI activity should not be restricted to the upper management level because it can assist all organizational levels. Further, CI needs vary by company and by project. Therefore, an analysis of the information needs of an enterprise requires consideration of the types of information required by decision makers at all levels of management. Many management models, including Anthony's Managerial Pyramid (1965), represent organizations as having various levels of decision making—operational control, tactical control, and strategic planning—each of which has different information needs.

The multi-class interest profile (M-CLIP), first proposed in 2001 (Parker & Nitse, 2001), addresses these shortcomings. It provides a strategically aligned framework based on the various types of information needs in order to insure that key items within each critical intelligence area are accounted for. Thorough needs identification guided by a structured, multi-dimensional framework increases the likelihood of a successful CI effort. The classes that make up the M-CLIP were derived by taking into consideration such information-intensive activities as project management, strategic planning, competitive analysis, and environmental analysis, and then acknowledging the correlation between the information needs of those activities and the decision-making levels described in the Managerial Pyramid. The project class consists of interest areas intended to target the information necessary for the execution of current projects, including both long-term activities such as tracking the daily or weekly actions of an overseas competitor, as well as shorter-term specialized projects such as the investigation of a possible acquisition or alliance prospect. The enterprise class includes internal and external interest areas, such as technological factors, investment issues, corporate news, operating expenses, and so forth, that are necessary for tactical decision making. The industry class targets information needs that stem from the type of industry or organization performing the investigation and helps the CI process supply intelligence related to the general external environment of the company.

The M-CLIP spans all decision-making levels and provides a structured, expanded set of intelligence topics. The M-CLIP system also provides specialized templates to aid in the identification of critical intelligence needs, an expansion mechanism to help insure that no key concepts are overlooked, and an adaptive mechanism to handle the removal of unproductive topics automatically.

A complete set of intelligence topics encompasses a wide spectrum of corporate interests, thus providing the means to access a greater percentage of relevant online information. A more complete information set makes the analysis and dissemination efforts more likely to succeed, insuring that the CI process provides decision makers with a more complete set of information, enabling them to assess domestic and international issues in an efficient, accurate, and timely manner.

FUTURE TRENDS

As noted above, the KM and CI functions complement each other. There is a great deal of overlap between the two, and KM systems will become more robust as KM workers recognize the benefits of adjusting their focus to include not only internal, but also external sources of information. At the same time, CI efforts will benefit by making greater use of KM. One statistic indicates that as much as 80% of the competitive knowledge that a firm requires to compete successfully is already present somewhere within the company and can be gathered by probing internal sources (Johnson, 2001). Competitive intelligence should be an integral part of knowledge management, and vice versa. Knowledge management can be improved by actively gathering competitive intelligence, and competitive intelligence can be improved by accessing the internal information gathered by knowledge management. The convergence of these two disciplines can be realized only when strategic planners are able to define more completely the relationships between CI and KM, and their specific role in delivering decision support (Johnson, 1998).

CONCLUSION

Effective CI requires an effective KM process. Without KM, gathered CI information is useful for only a brief period. CI data is highly time sensitive and is often useless unless acted upon immediately (Johnson, 1998). However, if CI is integrated into the internal knowledge processes, it will begin to have some long-term value to a firm (Aware, 2004). This integration will enable companies to detect trends and markets in which competitors act, as well as to identify latent and parallel competitors. This intelligence can then be of long-term use to decision makers at all levels (Johnson, 1998).

One measure of organizational effectiveness is the creation and continuance of a measurable competitive advantage (Gupta & McDaniel, 2002). KM and CI share that common goal, and a convergence of these two approaches will enable organizations to use the synergies between the two to take advantage of changes in both the internal and external environment.

Chapter 8.6
An Integrative Knowledge Management System for Environmental-Conscious Construction

ABSTRACT

This chapter introduces an integrative knowledge management prototype named E+ for environmental-conscious construction based on a comprehensive integration of current environmental management (EM) techniques and tools in construction. The overall objective is to apply the theory of knowledge management (KM) in EM in construction, and the authors will achieve it though developing the E+ model and its tools for dynamic EM in construction. The approaches applied in this chapter include system analysis and development, literature review, questionnaire survey and interview, and case study. The results from this chapter include the E+, a comprehensive review of EM tools adopted in construction, and a demonstration of the implementation of

the E+. Furthermore, the authors hope that the adoption and implementation of the E+ can effectively improve contractors' performance in EM and reduce adverse environmental impacts in construction.

LEARNING OBJECTIVES

Due to the purpose of the integrative methodology of KMS for EM in construction, this chapter mainly contributes to existing theory for EM in construction in the area of quantitative analytical approaches and their integrative implementation. According to the literature review and questionnaire survey for this research, the lack of effective, efficient, and economical (E3) quantitative analytical approach is one of obstacles to implementing EM in construction. Therefore, there are four points of contribution of this research to the existing theory or practice for EM in construction:

1. This research has developed an integrative methodology (E+) to implementing EMS and KM in construction, with a rigorous dynamic Environmental Impacts Assessment (EIA) model based on various functional-different approaches to EM in a construction cycle. The E+ prototype was originally created in both the theory and practice for EM in construction, and it is open to further integration of various functional-different approaches for EM in construction other than the three EM tools presented in this chapter. Because the E+ is both EMS oriented and process oriented in construction, it can thus help contractors to implement EM from a messy situation to a normalised system, and to effectively share EM knowledge and information internally and externally.
2. The CPI method integrated in the E+ model is a quantitative approach to predicting and levelling complex adverse environmental impacts potentially generated from construction and transportation due to the implementation of a construction plan. As a result, the CPI method has been integrated into E+ EM Toolkit A, one functional section of the E+ system, to carry out the task in environmental-conscious construction planning.
3. The IRP method is a quantitative approach to reducing the waste of construction materials on a construction site, and it is designed to effectively be implemented by using a barcode system. The IRP is then integrated in the E+ EM Toolkit B, another functional section of E+, as a basic component.
4. The Webfill method is an e-commerce model designed for the trip-ticket system to effectively reduce, reuse, and recycle C&D waste. Although there is a lack of data to prove the efficiency in reality, the computer simulation results and a questionnaire survey from another research (Chen, 2003) have proven that the Webfill system can effectively realise the design function. As a result, the Webfill is also integrated in the E+ model as an important component of the E+ EM Toolkit C.

Readers can obtain the socio-technical perspectives from the introduction of the E+ prototype and its toolkits, and know how E+ can work for a dynamic EIA process in construction with integrated supports from E3 quantitative analytical approaches in the toolkits.

INTRODUCTION

The adverse environmental impacts of construction—such as construction and demolition waste, noise and vibration, dust, hazards emissions and odours, soil and ground contamination, water pollution, wildlife and natural features demolition, and archaeological destruction —have been of concern since the early 1970s, and received more and more academic and professional attention in the construction industry especially after the ISO 14000 series of EM standards was enacted. In this regard, quantitative analytical approaches to EM in construction are currently not as available as qualitative approaches such as regulations and practical guides due to the difficulties in the transformation of practical data to abstraction data that are needed in the calculation for EM. However, it is hard to accept an environmental management system (EMS) without adequate support from EM tools and knowledge warehouse (KW), which is the essential component of an enterprise's knowledge management system (KMS) where knowledge is developed, stored, organised, processed, and disseminated (SAP INFO, 2004). From this point of view, the overall objective of this chapter is to put forward a methodology of an integrative KMS based on the developed holistic approach for environmental-conscious construction project management, which can facilitate knowledge management (KM) initiatives for improved competitiveness of construction enterprises in EM. This objective will be achieved step by step though four sub-objectives. They are: (1) to illustrate an integrative KM prototype to capture and reuse data, information, and knowledge for dynamic EM in construction project management; (2) to describe quantitative EM tools that can be integrated into the integrative KM model for dynamic environmental-conscious construction project management; (3) to describe the interaction among the quantitative EM tools within the integrative KM model and key information techniques to develop the integrative KMS for dynamic EM in construction project management; and (4) to demonstrate the implementation of the integrative KMS through a case study.

BACKGROUND

EM in construction has received more and more attention over the past 30 years. For example, studies on noise pollution (USEPA, 1971), air pollution (Jones, 1973), and solid waste pollution (Skoyles & Hussey, 1974; Spivey, 1974) from construction sites were all individually conducted in the early 1970s. Although the expression of EM in construction came out in the early 1970s, after the U.S. National Environmental Policy Act of 1969 was enacted (Warren, 1973), the concept of EM in construction was introduced later in the '70s, when the role of environmental inspector was defined in the design and construction phases of projects to provide advice to construction engineers on all matters in EM (Spivey, 1974; Henningson, 1978). However, there has been little enthusiasm for establishing an EMS in construction organisations until two main important standards, BS 7750 (released by the BSI Group in 1992) and the ISO 14000 series (released by the International Organisation for Standardisation (ISO) in 1996) were promulgated to guide the construction industry from passive CM on pollution reduction to active EMS for pollution prevention.

Implementation of EM

In the 1990s, the Construction Industry Research and Information Association (CIRIA) conducted a series of socio-technical reviews on environmental issues and have undertaken initiatives relevant to the construction industry after the introduction of BS 7750 (Shorrock et al., 1993; CIRIA, 1993-95; Guthrie & Mallett, 1995; Petts, 1996). Thereafter, research works on EM have also been led to the implementation of EMS and the registration of ISO 14001 EMS by authoritative institutions in the construction industry, such as the CIOB (Clough & Antonio, 1996), the FIDIC (1998), the Construction Policy Steering Committee (CPSC) (1998), and the CIRIA (Uren & Griffiths, 2000).

To assess the implementation of EMS in construction, several socio-technical investigations have been conducted independently by researchers in different countries since 1999. For example, Kein, Ofori, and Briffett (1999) conducted a field study in Singapore to assess the level of commitment of ISO-9000-certified construction enterprises to EM. They found that contractors in Singapore were aware of the merits of EM, but were not instituting systems towards achieving it. Ofori, Briffett, Gang, and Ranasinghe (2000) then conducted a survey to ascertain the perceptions of construction enterprises on the impact of the implementation of the ISO 14000 series on their operations. Major problems were identified, such as the shortage of qualified personnel, lack of knowledge of the ISO 14000 series, indistinct cost-benefit ratio, disruption and high expenses on changing traditional practices, and resistance from employees. The CIRIA (1999) led a self-completion questionnaire survey of the state of environmental initiatives within the construction industry and of sustainability indicators for the civil engineering industry in the United Kingdom.

Tse (2001) conducted an independent questionnaire survey in the Hong Kong construction industry to gain a further understanding of the difficulties in implementing the ISO 14000 series. Lo (2001), also in Hong Kong, made an effort to identify nine critical factors for the implementation of ISO 14001 EMS in the construction industry based on critical factors drawn from an investigation in another industry. The CPSC (2001) in Australia conducted a questionnaire survey of the New South Wales construction industry on EM with industry leaders. Chen, Li, and Wong (2000) conducted a questionnaire survey of main contractors in five main cities in mainland China and found that there are five classes of factors influencing the acceptability of the ISO 14000 series including governmental regulations, technology conditions, competitive pressures, cooperative attitude, and cost-benefit efficiency. In addition, Zeng, Tam, Deng, and Tam (2003) conducted a questionnaire survey of the mainland China construction industry to discover the conditions of implementation of the ISO 14000 series. All these questionnaire surveys clarified real situations in adoption and implementation of the ISO 14000 series in the local construction industries, and provided relative perspectives on how to conduct EM of the construction industry.

In addition to the questionnaire survey, case studies are further applied to investigate the acceptability of the ISO 14000 series in the construction industry. For example, Valdez and Chini (2002) conducted a literature review and case study of a construction contracting firm certified for the ISO 14001 EMS in the United States. They concluded that the positive aspects of certification outweigh the negative aspects, and recommended adding government support and the combined use of the ISO 14000 series with other EM and matrices.

Conflicts with EIA

The Environmental Impacts Assessment (EIA) is a process to identify, predict, evaluate, and mitigate the biophysical, social, and other relevant environmental effects of development proposals or projects prior to major decisions and commitments being made (IAIA, 1997). Although the EIA has been accepted by the construction industry in different countries under governmental regulations to evaluate environmental impacts of construction projects, the implementation rate of ISO 14001 EMS accreditation is normally much lower than the implementation rate of EIA in the construction industry. For example, a remarkable disagreement/deviation between the rate of ISO

14001 EMS accreditation and EIA implementation in some countries indicates that contractors there have not really implemented EM and accepted the ISO 14000 series (Chen, 2003). According to the Official Report on the State of the Environment in China 2001 (China EPB, 2002), the annual implementation rate of EIA for construction projects was 97% in 2001 in mainland China. In addition, a further investigation on the implementation rate of EIA in mainland China indicates that the average EIA rate from 1995 to 2001 is 88%, with an increasing rate of 23% (China EPB, 2002). By contrast, the percentage of the construction enterprises that have been awarded environmental certificates versus total governmental registered construction enterprises in mainland China is as low as 0.083%, and statistical figures also indicate that most construction enterprises have not yet adopted or accepted the ISO 14000 series in mainland China (Chen, 2003). Because of the disagreement between the implementation rates of EIA and EMS, there may be little coordination between the EIA process and EMS implementation in construction projects, and thus the EIA may not really serve as a tool to promote EM in the construction industry in those countries. For that reason, adverse environmental impacts such as noise, dust, waste, and hazardous emissions still occur frequently in construction projects in spite of their EIA approvals prior to construction. As a result, the failure to implement mitigation measures adequately or monitor environmental impacts following the approval of projects is often cited as a major shortcoming of the EIA process, and the contents and recommendations of EIA are often disregarded when EMS are implemented (Sánchez & Hacking, 2000).

KM Will

The growing consciousness, requirements, and initiatives of KM are existent in order to manage the intellectual capital and get benefits from previous construction processes and projects (Zyngier, 2002; & Zarli, Rezgui, & Kazi, 2003). For example, the C-Sand project (c-sand.org.uk) has been conducted in the United Kingdom to foster organisational practices that enable knowledge creation for subsequent sharing and reuse, and to promote sustainable construction (Khalfan, Bouchlaghem, Anumba, & Carrillo, 2003). As one of the largest contracting companies in the United States, Centex Construction Group (centex-construction.com) faces some knowledge-related business challenges that are not always associated with the construction industry. For instance, they have a technology infrastructure in place where all professionals in the company have computing power, that is, laptops and/or desktops. All offices and job sites are connected to a nationwide WAN via dial, ISDN, and Frame. Remote access is Web based and available from anywhere to lead some initiatives to increase knowledge sharing and provide better information access across the company's diverse landscape (Velker, 1999). Beyond the development of knowledge warehouse (KW) in the construction industry, socio-technical research also reflected that there was a majority of agreement to the statement that KM is an extension of IT (Zyngier, 2002). The progress of KM in construction also reflects the trend of construction enterprises away from traditional blue-collar operations towards a more knowledge-based CM.

According to the survey results, EMS implementation requires practical approaches for contractors to conduct EM. That is, although the governmental regulations have been identified as a major factor influencing the implementation of the EMS and the EIA in the construction industry, the construction industry is still a negative receiver if there are not enough technology conditions to support EMS implementation, especially the techniques or tools that can help contractors to conduct EM in construction projects where most of the negative environmental impacts are generated. Even the positive bodies in the construction industry have high willingness to implement EM; the E3 EM tools are essential to them (Chen, 2003). Based on this consideration, the authors of this chapter will integrate several EM tools and an EMS-based dynamic EIA process developed previously into an environment of KM, entitled E+, for E3 EM in construction project management.

THE E+

Methodology

The E+ is an integrative methodology for E3 EM in construction projects in which an EMS-based dynamic EIA process is applied within a knowledge support system for active knowledge capture and reuse about environmental-conscious CM during construction. The successful implementation of an EMS in a construction project requires far more than just the apparent prevention and reduction of adverse or negative environmental impacts in a new project and its construction process development cycles during pre-construction stage, continuous improvement of the EM function based on institutionalisation of change throughout an onsite organisation to reduce pollution during construction stage, or efficient synergisms of pollution prevention and reduction such as waste recycle and regeneration during construction and post-construction stages. It necessitates a complete transformation of the CM in an environmentally conscious enterprise, such as changes in management philosophy and leadership style, creation of an adaptive organisational structure, adoption of a more progressive organisational culture, revitalisation of the relationship between the organisation and its customers, rejuvenation of other organisational functions (i.e., human resources engineering, research and development, finance, and marketing) (Azani, 1999). In addition to the transformation for the EM in construction enterprises, the E+ for the E3 implementation of the EM in all phases of construction cycle—including the pre-construction stage, the construction stage, and the post-construction stage—is necessarily activated, together with other rejuvenated CM functions such as human resources, expert knowledge, and synergetic effect.

There are already some approaches to effectively implementing the EM onsite at different construction stages. For example, the CPI approach, which is a method to quantitatively measure the amount of pollution and hazards generated by a construction process and construction project during construction, can be utilised by indicating the potential level of accumulated pollution and hazards generated from a construction site at the pre-construction stage (Chen et al., 2000), and by reducing or mitigating pollution level during construction planning stage (Li, Chen, & Wong, 2002). In addition to the CPI approach, an analytic network process (ANP) approach to construction plan selection (Chen, Li, & Wong, 2003), a life-cycle assessment (LCA) approach to material selection (Lippiatt, 1999), and a decision programming language (DPL) approach to environmental liability estimation (Jeljeli & Russell, 1995) also provide quantitative methods for making decisions on EM at the pre-construction stage. For the construction stage, a crew-based incentive reward program (IRP) approach, which is realised by using a bar-code system, can be utilised as an onsite material management system to control and reduce construction waste (Chen et al., 2002a). For the post-construction stage, an online waste exchange (Webfill) approach, which is further developed into an e-commerce system based on the trip-ticket system for waste disposal in Hong Kong, can be utilised to reduce the final amount of construction and demolition (C&D) waste to be landfilled (Chen et al., 2002b). Although these approaches to EM in a construction project have been proven effectively, efficiently, and economically applicable in a corresponding construction stage, it has also been noticed that these EM tools can be further integrated for a total EM purpose in construction project based on the interrelationships among them. The integration can bring about not only a definite utilisation of current EM tools, but also an improved environment for contractors to maximise the advantages of utilizing current EM tools due to sharing EM-related data, information, and knowledge in construction project management.

As mentioned above, the EMS is not as acceptable as the EIA at present in some countries and areas such as mainland China partly due to the lack of E3 EM approaches in construction, besides the governmental regulations; the tendency of practical EM in construction is to adopt and implement the EMS when the EIA report/form of a construction project has been approved. As a result, the E+ for contractors to enhance their environmental performance, which integrates all necessary KW and EM tools, simply appropriates to the occasion.

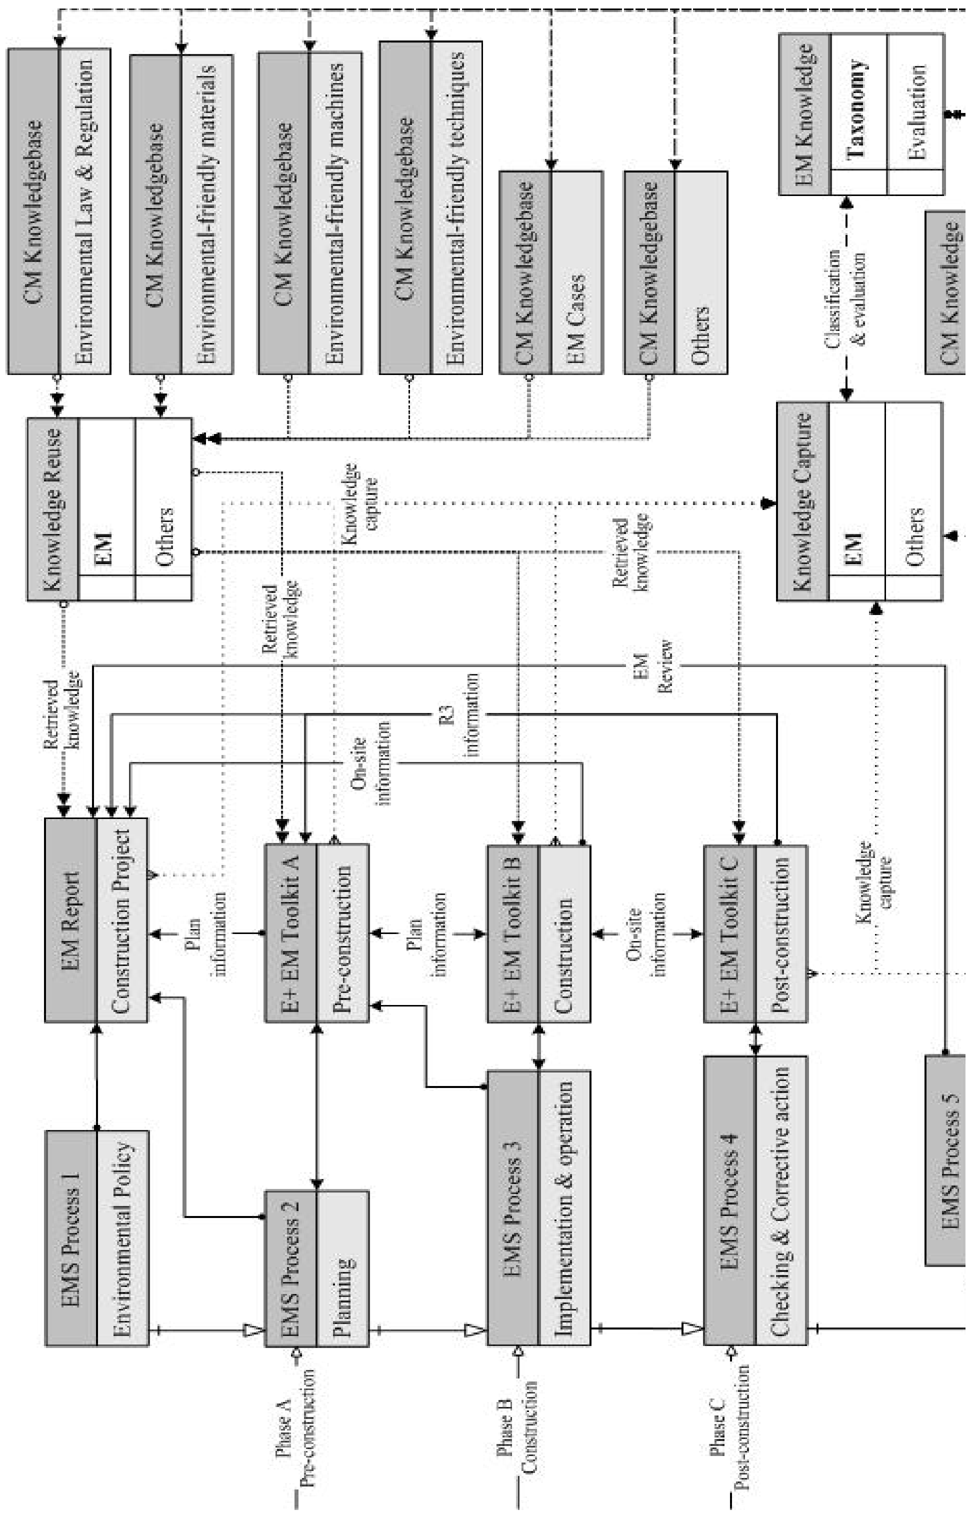
The proposed E+ aims to provide high levels of insight and understanding regarding the EM issues related to the project management in a construction cycle. In fact, current EIA process applied in construction projects is mainly conducted prior to the pre-construction stage when a contractor is required to submit an EIA report/form based on the size and significance of the project, and the EIA process for the construction stage is seldom conducted in normalised forms. Due to the strong alterability of the environmental impacts in the construction cycle, commonly encountered static EIA process prior to construction cannot accommodate the implementation of the EMS in project construction, and a dynamic EIA process is thus designed for the E+. In addition, several EM tools are to be combined with the ISO 14000 Model (ISO, 2002), which is a frame for implementation of the ISO 14000 series, according to their interrelationships with which various EM-related data, information, and knowledge in construction can be captured, organised, and reused (see Figure 1). Because the main task of the EM in the construction cycle is to reduce adverse environmental impacts, the dynamic data transference in the framework is the prime focus of the E+ methodology. Thus, a prototype of the E+ is put forward in Figure 1.

Operation

Operation of the E+ model needs an integrative software environment in which various EM tools can work together with the EMS process. There are three main steps to develop the E+ system (software environment) as follows:

1. Feasibility study. The feasibility study is conducted not only prior to the establishment of the E+ model, but also before the system analysis and realisation of the E+ software environment. First of all, it is important to analyse whether such an E+ system is necessary for the EMS-based dynamic EIA process in project construction, and this is to be done prior to the establishment of the E+ model. Next, if the E+ system is necessary, it is required to search for enough quantitative EM tools to support the E+ system, and this is to be done before the system analysis and development of the E+ system. The feasibility study is essential for both a practicable E+ model and an E3 E+ system.
2. System analysis and realisation. The system analysis and realisation is to be conducted after the E+ model has been established. The aim of this step is to realise the E+ system from a model to a software environment with computer programming. Being limited by the length of this chapter, no further discussion is presented here to illustrate the development of the E+ system.

Figure 1. The prototype of the E+



3. Application test. The application test is a trial process for the developed E+ system. There is also no further discussion related to this step due to the under-construction of the E+ system. However, an experimental case study is conducted to demonstrate the E3 EM function of the E+ system.

The following discussions focussed on several core EM tools adopted in the E+ model, and inter-relationships among these EM tools as to working for the EMS-based dynamic EIA process. The EM tools selected for the E+ model in this chapter include: the CIP approach for adverse environmental impacts indicated at the pre-construction stage, the IRP approach for material management onsite at construction stage, and Webfill approach for residual and waste material and equipment exchange at post-construction stage; no further EM tools will be discussed here.

EM TOOLS FOR THE E+

CPI

The Construction Pollution Index (CPI) (Chen et al., 2000) is an approach to quantitatively measure the amount of pollution and hazards generated by a construction project or a construction process during construction. Because the value of CPI reflects the accumulated amount of adverse environmental impacts generated by a construction project within its project duration, its utilisation in construction planning is easily realised though a CPI histogram, similar to the resource histogram in a Gantt chart used in construction scheduling. By integrating the concept of CPI into a commonly used tool for construction project management such as Microsoft Project, a system to neatly combine EM with project management is then formed, and project managers can use the CPI histogram to identify the periods in which the project will generate the highest amount of pollution and hazards, and reschedule the whole project to level extremely high CPI (Li et al., 2002).

In the E+ prototype, the CPI approach is set to the E+ EM Toolkit A for construction planning at the pre-construction stage (see Figure 1). The E+ EM Toolkit A captures data from three kinds of sources:

- Source one: EMS Process, including EMS Processes 2 and 3.
- Source two: E+ EM Toolkits, including Toolkits B and C.
- Source three: KW of EM, including knowledgebase of environmental law and regulation, environmental-friendly construction materials, environmental-friendly construction machines, environmental-friendly construction techniques, and EM cases.

Meanwhile, the E+ EM Toolkit A transfers data to these three kinds of data sources and the EM report, such as the EIA report of a construction project.

IRP

The Incentive Reward Program (IRP) approach (Chen et al., 2002b) is an approach to quantitatively measure the amount of material waste generated by a construction project or a process during construction.

In the E+ prototype, the IRP approach is set to the E+ EM Toolkit B for construction at the construction stage (see Figure 1). The E+ EM Toolkit B captures data from three kinds of sources:

- Source one: EMS Process 3.
- Source two: E+ EM Toolkits, including Toolkits A and C.
- Source three: KW of EM, including knowledgebase of environmental law and regulation, environmental-friendly construction

materials, environmental-friendly construction machines, environmental-friendly construction techniques, and EM cases.

Meanwhile, the E+ EM Toolkit B transfers data to these three kinds of data sources and the EM report, such as the EIA report of a construction project.

Webfill

The Webfill approach (Chen et al., 2002b) is an e-commerce method to increase the amount of construction and demolition waste exchanged for reuse and recycle among different construction sites and material regeneration manufacturers. As a matter of fact, disposal of C&D waste to landfills usually comes with a monetary charge in many countries (Chen, 2003). For example, to dispose of C&D waste in an orderly manner to disposal facilities by trucks, a trip-ticket system (TTS) was conducted of the Hong Kong construction industry in 1999, which requires contractors to pay for the disposal of their C&D waste in terms of waste disposal receipts issued to them. The Webfill approach sets a TTS-based e-commerce model conforming to the external requirement, and simulation results indicate that the Webfill-enhanced TTS can apparently reduce the total amount of the C&D waste through encouraging the increase of waste reuse and recycle.

In the E+ prototype, the Webfill approach is set to the E+ EM Toolkit C for post-construction work at the post-construction stage (see Figure 1). The E+ EM Toolkit C captures data from three kinds of sources:

- Source one: EMS Process 4.
- Source two: E+ EM Toolkit B.
- Source three: KW of EM, including knowledgebase of environmental law and regulation, environmental-friendly construction materials, environmental-friendly construction machines, environmental-friendly construction techniques, and EM cases.

Meanwhile, the E+ EM Toolkit C transfers data to these three kinds of data sources and the EM report, such as EIA report of a construction project.

Interrelationships

The interrelationships among the EMS process, the EIA process, the EM Toolkit, and the knowledge capture and knowledge reuse processes can be put up in agreement with EM-related data transfers. There are six kinds of EM-related data transfers in the E+ system. The first kind occurs between the EMS process and the EIA process; the second kind occurs among the EM toolkits and the EIA process; the third kind occurs among the various EM toolkits; the fourth kind occurs from the knowledge reuse entity to the EM toolkits and the EIA process; the fifth kind occurs from the EM toolkits, the EIA process, and the EMS process to the knowledge capture entity; and the sixth kind occurs from the knowledge capture entity to the knowledge reuse entity through several essential KWs such as knowledgebase of environmental law and regulation, environmental-friendly construction materials, machines, techniques, and EM cases. Because all these data are generated from different construction stages, integrative data transfer in the E+ system can thus provide up-to-date information to the EIA process, and the dynamic EIA process is realised accordingly. In order to completely clarify the interrelationship potentially existing in the E+ system, some of the EM-related data and their transfers are summarised in Table 1.

AN EXPERIMENTAL CASE STUDY

The experimental case study conducted here combines data such as wastage at different

Table 1. Interrelationship among EM-related data in the E+ system

Data Host	Data Name	Transfer to	Captured from	Usefulness
CPI Host (Toolkit A)	*CPI* and CPI_i	EIA Host and KW	-	Data update for EIA report
	CPI_i	EMS Process 1 and KW	-	Construction planning
	CPI_{waste}	IRP Host and KW	-	Quantity survey of waste

	undefined	-	EMS Process 2 and KW	Data update for EIA report

Note:
1. CPI_{waste} represents the CPI_i that involves waste impact only;
2. Q_{sold} is the quantity of C&D waste a contractor sold; and
3. Q_{bought} is the quantity of regenerated materials or reusable material a contractor bought.

construction stages (Vaid & Tanna, 1997) from several separated cases (Chen et al., 2000, 2002) and authors' experiences with a virtual construction project because there are no data available at present to demonstrate the utilisation of the E+ system from only one construction project. In this case, the aim of this experimental case study focuses mainly on the utilisation of the E+ model. Data adopted are for reference only, although there is practical background to support them. Case studies for real construction projects can be further conducted in the future when the E+ software environment has been realised.

The experimental case study conducted in Table 2 demonstrates the process of the E+ model. The process of the EMS-based dynamic EIA in the experimental case study is divided into three stages corresponding with the construction cycle, including pre-construction stage, construction stage, and post-construction stage (see Table 2). The EM-related data for the EMS-based dynamic EIA provided by the E+ system are different from

Table 2. Case study of the E+ implementation for a dynamic EIA in a construction cycle

stage to stage. At the pre-construction stage, there are two kinds of data for the EIA including the original set of CPIi and the Qbought requested by each crew; at the construction stage, there are four kinds of data for the EIA including the relay set of CPIi, the Qi(j), the Qsold, and the Qbought; and at the post-construction stage, there are three kinds of data for the EIA including a final set of CPIi, a total Qsold, and a total Qbought. Because the functions of current EM tools integrated in the E+ model are different, for example, the CPI approach deals with total adverse environmental impacts of construction processes, while the IRP approach and the Webfill approach deal with the C&D waste only; the CPIi in this case study is thus represented by a CPIwaste, which represents the CPIi that involves waste impact only (see Table 1).

Moreover, the case study puts forward and utilises the concepts of original CPIwaste, relay CPIwaste, and final CPIwaste to demonstrate the process of the EMS-based dynamic EIA, and looks at these three kinds of CPI as essential data in an EIA report. The original CPIwaste means the CPIwaste that is valued before a construction process, the relay CPIwaste means the CPIwaste that is devalued during a construction process, and the final CPIwaste means the CPIwaste that is finally valued after a construction process. Because the value of the CPIwaste is regarded as one important data in an EMS-based EIA process, the changing process of the three kinds of CPIwaste appropriately incarnates or reflects the process of a dynamic EIA. Thus an EMS-based dynamic EIA process is realised.

It is necessary to notice that in order to value each CPIwaste, expert experiences have to be used corresponding to changed amounts of Qsold and Qbought. The expert experiences required are stored in the knowledge reuse entity, which is distilled from crude data in KW including knowledgebase of environmental law and regulation, environmental-friendly construction materials, machines, techniques, and EM cases. Therefore the EM-related construction knowledge effectively supports the process of the EMS-based dynamic EIA.

The result of this experimental case study indicates that the implementation of the E+ system can finally reduce the adverse environmental impacts of project construction. For example, the total value of the original CPIwaste of all construction tasks in the experimental case study is 2.57, the total value of the relay CPIwaste of all construction tasks in the experimental case study is 2.08, and the total value of the final CPIwaste of all construction tasks in the experimental case study is 1.85. That is, the E+ system draws support from several EM tools such as the CPI approach, the IRP approach, and the Webfill approach, and realises an EMS-based dynamic EIA process, while the benefits of various EM tools can be shared within the E+ environment through EM-related data transfer and integrative data, information, and knowledge utilisation.

FUTURE TRENDS

Recommendations on the integrative KMS for environmental-conscious construction come from the usefulness, efficiency, and benefit of the E+ prototype and EM tools, which have been demonstrated in this chapter. However, due to the limitations of current research, it is thus recommended that further research be conducted on both the development of the E+ software environment and the development of more E3 EM tools for the E+ system.

First of all, the E+ model can be further developed to Web-based environmental information and KMS for a contractor to implement EM in construction project management. According to the essential theory and practice of EM in construction, the environmental information is required in construction planning, construction material management, and C&D waste exchange, whilst the EM knowledge in construction is essential to support decision making by using various EM tools. Because both environmental information and EM knowledge are needed in the E+ system, and the Internet is particularly suitable to implement effective and flexible CM by mobile site management units, the key issues of the development of such an E+ system are: how to establish a Web-based software system and enable managers in different construction sites to use and share environmental information and knowledge on the same platform of E+; and how to capture, transfer, and reuse necessary data between the E+ system and current CM system. Moreover, additional functional components such as E+ EIA—besides the E+ toolkits—are also under consideration.

Besides the development of the E+ system, further research is also needed in the development of fully user-oriented EM tools and their integration in the E+ system. The fully user-oriented EM tools can enable a contractor or construction manager to use the EM toolkits easily, without the help of the tool developers. For example, the fully user-oriented tool of CPI can enable them to define the CPI of each construction process in a construction plan and then level the extremely high CPI, whilst the fully user-oriented tool of EnvironalPlanning (Chen, 2003) can enable them to transfer necessary data from construction plan alternatives to an ANP environment and thus select the most environmental-friendly construction plan. In addition to the development of the fully user-oriented EM tools, improvements in the functional-different approaches for EM in construction are also necessary, focusing on the innovation of these approaches. For example, the CPI of a construction process is currently defined by experts' experience, and this treatment is definitely practicable; however, in order to receive a wide recognition and minimise the arbitrary decision or subjective error on the definition of the CPI of each construction process, we suggest development of an objective calculation method to define the CPI of each possible construction process a contractor may use in construction planning. So both the development of the fully user-oriented EM tools and the consummation of current functional-different approaches for EM in construction are required in further research.

Beyond the consummation of the E+ system and its components, additional functional-different approaches for EM in construction are also necessarily to be developed in order to improve the performance of the E+ system. Currently, the potential functional-different approaches to implementation of EM in construction include the life cycle analytical (LCA) approach and risk analytical approach for E+ EM Toolkit A, and the EIA template for the new E+ EIA Toolkit.

Although this research project has been accomplished with satisfying results, there are some limitations not only within the research but also in the duplicate implementation of the EM tools developed in the research. The limitations of the research exist in the following areas:

- This research has not accomplished an E+ software environment to further demonstrate its usefulness, efficiency, and benefit for EM in construction.
- The CPI method has not been developed into a fully user-oriented tool to help contractors deal with any CPI problem in construction planning.

As a conclusion, it is recommended that further research and development for the E+ system focus on the development of a Web-based E+ system, the consummation and innovation of current EM tools in construction, and the development of new EM approaches for the E+ system.

CONCLUSION

This chapter presents an integrative prototype to knowledge-based dynamic EM in construction, which integrates various EM approaches and knowledge bases with a general EMS process throughout all construction stages in a construction project. The EM approaches integrated in the E+ are divided into three categories, including EM Toolkit A for pre-construction, EM Toolkit B for construction, and EM Toolkit C for post-construction. These EM toolkits are further integrated with an ISO 14001 EMS and EM knowledge capture and reuse entities for an integrative KMS for environmental-conscious construction. In addition to the proposed E+ prototype, an experimental case study has also been conducted to demonstrate the usefulness, efficiency, and benefit of the E+ system. The E+ is expected to effectively, efficiently, and economically assist contractors in enhancing both their EM techniques and environmental performances in construction project management, and to overcome the weakness of static EIA formally applied in the construction industry in some countries by the dynamic EIA process where the necessary data for an EIA report can be updated in the construction cycle.

PRACTICAL TIPS AND LESSONS LEARNED

For the efficient management of environment-related knowledge, it is essential to integrate data and information from various dispersed tools and applications. In order to promote the implementation of the E+ model, further research is needed to transfer the E+ model to a computer software environment, improve current EM tools, and develop more EM approaches as subsidiary components of the E+ system to deal with all adverse environmental impacts of construction on the purpose of total EM in construction project management. Although the software environment of the E+ has not been presented in this chapter, the demonstration of the E+ model in the experimental case study enabled a closer understanding of how the E+ system can be effectively applied for EM in construction, and it also unveiled that the E+ methodology is flexible in the integrative implementation of functional-different quantitative approaches to EM in construction.

Chapter 8.7
MNE Knowledge Management Across Borders and ICT

Jürgen Kai-Uwe Brock

Yu Josephine Zhou
International University of Applied Sciences, Bad Honnef-Bonn, Germany

INTRODUCTION

Firms are consumers, producers, managers, and distributors of information (Egelhoff, 1991; Casson, 1996) and as such a repository of productive knowledge (Winter, 1988). Consequently the ability to generate, access, and utilize relevant knowledge is an essential organizational activity in order both to reduce uncertainty about the firm's external environment and improve the efficiency of its internal operations.

Particularly for multinational enterprises (MNEs), efficient implementation of knowledge management processes is of competitive importance. In contrast to their set of indigenous competitors, MNEs face liabilities of foreignness (Zaheer, 1995) and a more complex organizational structure that transcends cultures and countries.

Advances in location insensitive information and communication technology (ICT), in particular the Internet's marketspace (Rayport & Sviokla, 1994), could significantly facilitate MNEs' knowledge management efforts. Ease of information gathering, communication, and knowledge management is no longer a strict function of geographical proximity. As a result of the Internet, the location specificity of knowledge (von Hayek, 1945) is becoming less location dependent, and thus less costly. Despite this, the role of the Internet in knowledge management has its limits due to its inherent media characteristics and the aforementioned liabilities particular to the operations of MNEs.

This article explores the possibilities and limitations of the Internet in supporting knowledge management in the specific context of MNEs. It is structured as follows. First we will provide a background to the article by discussing and defining the specifics of MNEs, MNEs' knowledge management challenges, and the specifics of the Internet. Subsequently the article will analyze and explore the potential impact of the Internet on MNEs' knowledge management processes. A discussion of future trends and an overall conclusion close the article.

BACKGROUND

Global trade has grown 16-fold since the 1950s, by far outstripping the growth in GDP (Economist, 1998). A key driving force behind this trend is foreign direct investment (FDI), whereas FDI is defined as an acquisition of an asset in a foreign country (host country) made by an investor in another country (home country) with the intention to manage this asset (WTO, 1996). MNEs are the main driver behind FDI. Although definitions vary, an MNE can be defined as a firm that is engaged in FDI in several countries outside its home country (for a more detailed discussion the reader might refer to, e.g., Vahlne & Nordström, 1993; Rugman & Verbeke, 2004).

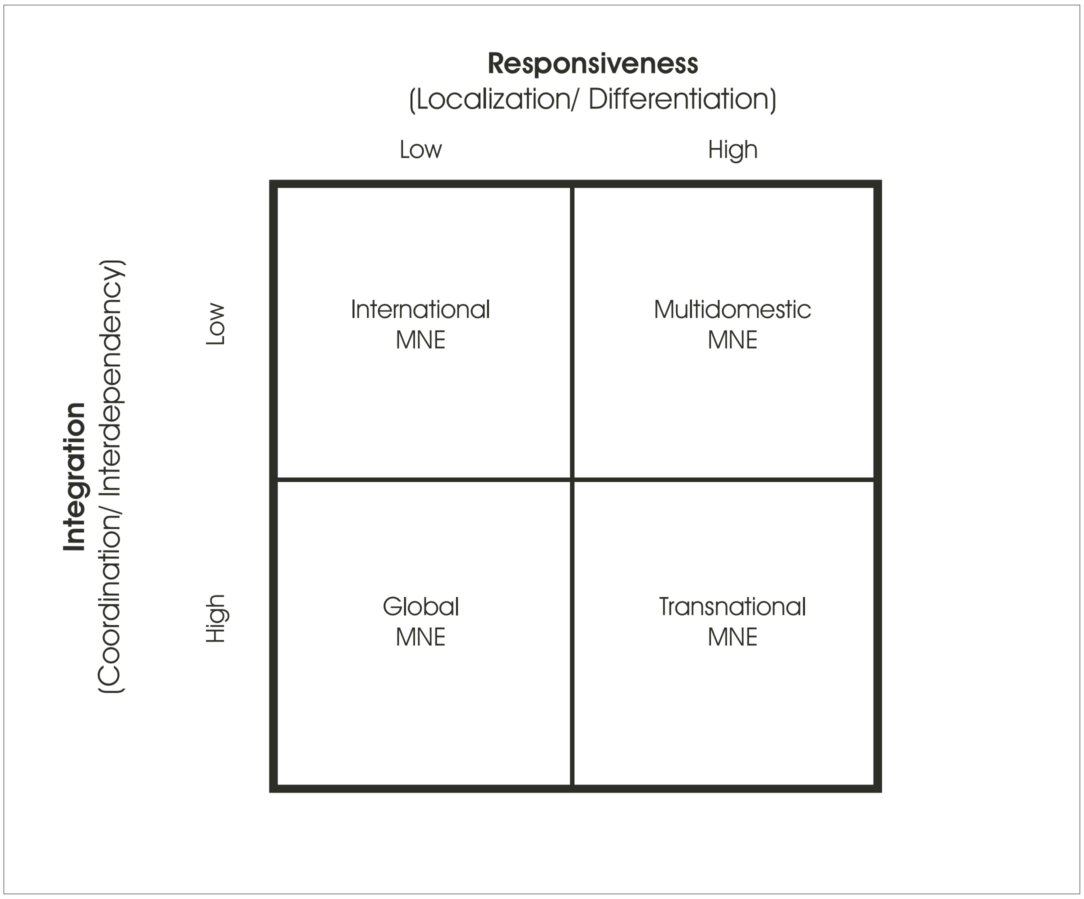
Before discussing the specific knowledge management challenges of MNEs and the role of the Internet therein, it is vital to understand why MNEs exist at all. International business theory has addressed this. The core idea of international trade theory—the idea of market imperfections—was utilized by international business researchers to explain international activities at the firm level by projecting these imperfections into the firm. This helped to explain the emergence and existence of MNEs, as opposed to firms only trading with each other by means of importing and exporting. In 1960 (published in 1976), Hymer's market imperfections theory in essence postulated that firm specific advantages like technology and management skills are the core source enabling firms to successfully operate abroad, offsetting cost and information advantages enjoyed by indigenous firms. Hymer's idea was then further refined and developed by Buckley and Casson (1976) to become internalization theory. Buckley and Casson conceptualized the MNE as a firm that responds to pre-product or intermediate-product market imperfections by internalizing these markets (like components, semi processed goods, knowledge, skills, and technology) across national boundaries (via FDI). Internalization means that a firm makes use of its organizational hierarchy and in-house resources to manage a specific business transaction as opposed to buying it on the market. By internalizing the transfer of a firm's assets and capabilities, firms mitigate transfer problems and at the same time exploit their internal advantage(s) internationally.

At the heart of internalization is the management of knowledge-related imperfections (Kogut & Zander, 1993), which makes effective knowledge management a central task for MNEs. Knowledge management within MNEs is about two interrelated tasks:

1. Knowledge management within the MNE (intra-MNE) which focuses on continuous knowledge creation, transmission, use, and retention between and within headquarters and subsidiaries.
2. Interface knowledge management (extra-MNE) which is about the continuous identification of the MNEs' external knowledge environment, its scanning, the collection of relevant external knowledge, and synthesis with existing intra-MNE knowledge.

This categorization can be related to types of MNEs (see Figure 1). Intra-MNE knowledge management mainly relates to the integration di-

Figure 1. Types of MNEs



Source: Derived from Harzing's MNE typology synthesis (Harzing, 1997)

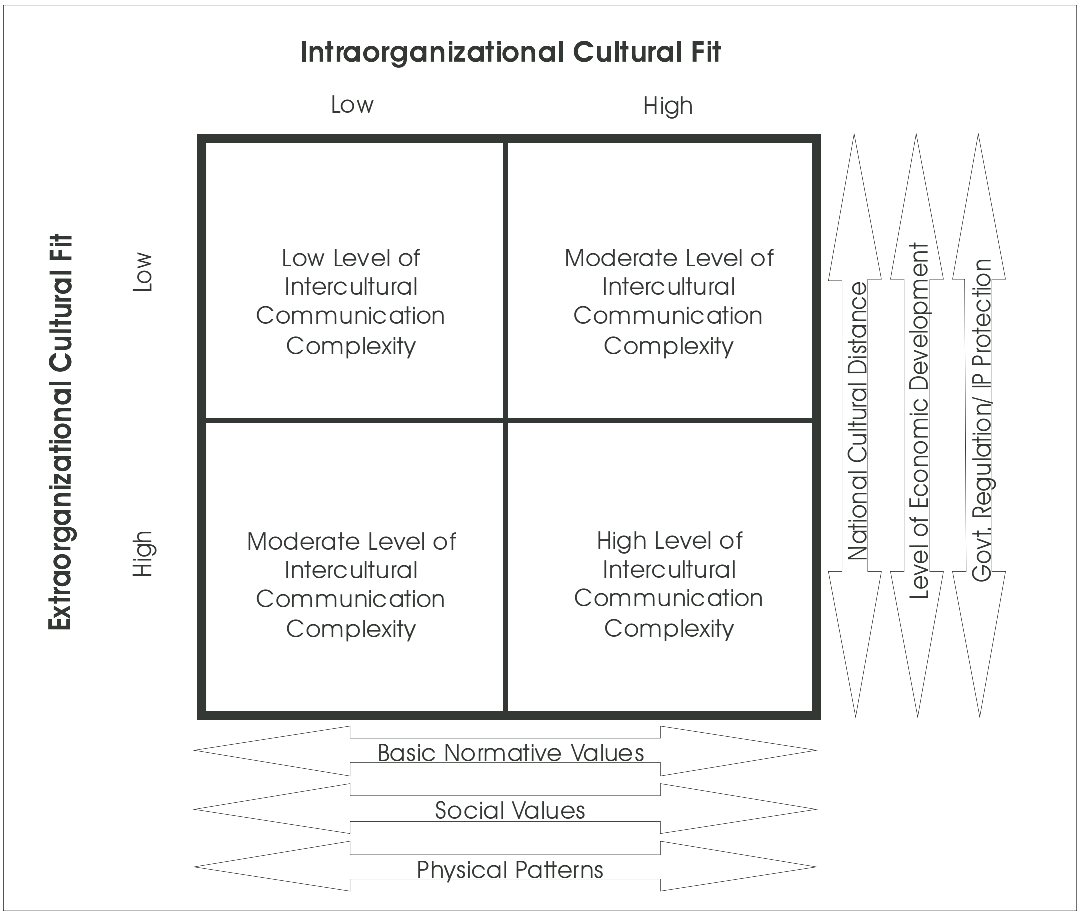
mension, and extra-MNE knowledge management mainly relates to the responsiveness dimension. Obviously, as an MNE moves from low to high on both dimensions, knowledge management (intra- and extra-MNE) requirements increase.

This article will focus on the first knowledge management task (intra-MNE knowledge; integration), because it is unique to MNEs.

The key challenge for intra-MNE knowledge management is knowledge transmission (Kogut & Zander, 1993). Transmitting knowledge is costly (Teece, 1977). The more tacit—or personal (Polanyi, 1958)—and complex the information, the more difficult and expensive it will be to transmit it. This is so because the codification and teaching costs in the transmission process increase as tacitness and complexity increases. Transmitting knowledge across different cultures and countries further increases the costs due to different norms, habits, languages, and interpersonal processes that can inhibit communication flows (Johanson & Vahlne, 1977). These differences operate at two levels, the intra-organizational level and the extra-organizational level, both defining the communication complexity in the knowledge transmission process (see Figure 2). While the former refers to differences between the different organizational cultures within MNEs (mainly headquarters to subsidiary/-ies), the latter refers to differences at the national level (home country to host country/-ies). However, the intra-MNE transfer of knowledge can be eased by the development of a common understanding and of capabilities—combinative capabilities according to Kogut and Zander (1993)—how to manage this transmission. Such development emerges—via repeated interactions—over time in the form of organizational routines.

Before analyzing how the Internet's marketspace could impact the intra-MNE knowledge management process, an evaluation of the marketspace is required.

Figure 2. Intercultural MNE communication matrix



Source: Derived from Harvey and Griffith (2002)

Whereas the marketplace represents the physical world of resources, the marketspace represents the virtual world of digitized information (Rayport & Sviokla, 1994). The most evident and widely known manifestation of the marketspace is the Internet. Following key elements of December's (1996) definition, the Internet can be defined as:

- Computer-mediated communication, including
- information dissemination and
- information retrieval that
- involves data (bits) exchanges taking place on the
- global collection of computer networks using
- the TCP/IP protocol suite for data transfer.

The information content can involve a broad range of data types (text, graphics, images, sound, video), and various forms of open and closed (in the case of intranets and extranets) information processes (one-to-one, one to many; asynchronous, synchronous) are possible. The Internet can thus be used by organizations such as MNEs to process, distribute, and retrieve codified knowledge, and it can be used to interact (communicate) with others. To express this, the terms "information pull," "information push," and "interaction" are introduced. Information pull refers to organizational activities related to synchronously or asynchronously pulling information from the Internet (or intranet, extranet). Information pull can be active or passive, with, for example, searching the Web referring to the former and subscribing to mailing lists referring to the latter. Subscribing to corporate mailing lists is a passive, non-specific information pull activity, because the subscriber does not know exactly what specific kind of information he or she receives prior to subscribing.

On the other hand, information push refers to organizational activities related to pushing information onto the Internet (or intranet, extranet). Active information push refers to organizations actively marketing their information push activities. In contrast, passive information push refers to organizations setting up Web sites without any internal or external promotions.

Interaction is the Internet's third potential use for organizations. The main difference between information push/pull and interaction is that interaction involves non anonymous, asynchronous or synchronous personal exchange of information between known communication parties. Both information pull and information push is at least partially anonymous. Interaction as understood here means mediated personal interaction between known users or parties. When an organization pushes corporate information onto the Internet, it does not know ex ante who might actually retrieve and read its content. The same applies for posting non personalized messages to newsgroups or mailing lists, because the sender does not know in advance who will read his message and who will not. In addition, the sender does not know the identity of all the receivers, unless he is the initiator and owner of the mailing list requiring subscribers to reveal their identity during the subscription process. The same applies in the case of information pull. Although users accessing a Web page or Internet-based databases leave "digital fingerprints" (Drèze & Zufryden, 1997) and Web sites can send so-called "cookies" to users accessing a Web page, users pulling information from the Internet can remain anonymous if they wish to by refusing cookies or by using anonymizer software. In contrast, interaction as defined here involves the one-to-one or one to many exchange of information between pre-specified and known parties. The defining element of interaction is value exchange between known parties.

All of the aforementioned three use categories are interrelated, with information pull activities potentially being influenced by and leading to information push activities and interaction activities, and vice versa. Also, the three uses relate to similarly interrelated activities taking place in the non mediated marketplace.

MAIN FOCUS OF THE ARTICLE

Although the role of ICT in organizations in general has been the focus of studies since the 1970s (e.g., Pfeffer & Leblebici, 1977), little is known about the specific role of ICT in cross-cultural contexts (e.g., St.Amant, 2002; Weisinger & Trauth, 2002) and MNE operations (e.g., Petersen & Welch, 2003). With the background provided in the previous section, it is possible to explore possible effects of the Internet's marketspace on intra-MNE knowledge management.

Knowledge management scholars have identified four dynamically interacting processes how organizational knowledge is created and transmitted (Nonaka, 1991). The first process—termed "socialization"—is about tacit-to-tacit knowledge transfers. The traditional German apprenticeship system is an example of such a transfer. An apprentice learns via observation, imitation, and practice. In this process he or she "imports" the tacit knowledge base of the master which becomes his or her own tacit knowledge. The second knowledge transfer process is "articulation," whereby explicit or codified knowledge is directly transferred to become explicit knowledge elsewhere. An example of such a process would be an individual recombining a set of coded knowledge such as a financial report into a different document. The third and fourth processes are about transformative transfers, whereby explicit knowledge in turned into tacit knowledge or vice versa. The tacit-to-explicit transfer is called "combination." Combination takes place when an individual articulates his or her tacit knowledge base, thereby converting it into explicit knowledge that can be shared with others. Finally, "internalization"—a technical term in the knowledge management literature that has a different meaning to the one in the international business context—is the explicit-to-tacit process of knowledge transfer. This process takes place when employees use the explicit organizational knowledge available, for example in the form of a database, to extend their own tacit knowledge.

How could the Internet support or enhance these four processes in the case of intra-MNE knowledge management?

On the one hand, the answer lies in an understanding of the differences between mediated and unmediated communication. On the other, an appreciation of cultural differences in communication is required. With regards to the former, rational media choice theories, such as social presence theory (Short, Williams, & Christie, 1976) and media richness theory (Daft & Lengel, 1986) postulate that an individual determines his or her choice of media by rationally assessing the requirements of a communication task and selecting an appropriate medium matching these requirements. Media is categorized along a continuum based on the channel's information richness, which depends on the medium's ability for immediate feedback, the number of carried cues, the number of channels utilized, its language variety, and its level of personalization capable of reducing equivocality. This set of theories postulates that the higher the perceived need for social cues and equivocality reduction in a communication situation, the higher the likelihood of face-to-face communication, the richest mode of information exchange with the highest degree of social presence. This would, for example, be the case in tacit-to-tacit knowledge transfers ("socialization"). In contrast, the Internet is considered less information rich. It follows that the reduction in channel capacity on the Internet compared to face to face communications makes knowledge transfers more difficult despite its cost-reducing properties in general.

Mixed empirical findings regarding the predictive validity of the rational media choice theories (e.g., Markus, 1994; Walther, 1996; Ngwenyama & Lee, 1997) have led to the development of social influence models of communication technology use (e.g., Ngwenyama & Lee, 1997). The social influence models of communication technology use all regard information richness or leanness in communications not as attributable to the properties of the communication medium alone, but as emerging from the interaction between people and contexts. According to this school of thought, media choice is influenced by the attitudes and behaviors of others, as well as norms that have developed within a group, within organizations, or across organizations. Hence, media perception is not fixed, but it varies across people, organizations, situations, tasks, time, and user experience with the medium. Because these models make no a priori assumption about any direct relationships between communication richness and the quantity of social cues (Ngwenyama & Lee, 1997), they in essence detach the message from the medium. Any message can be rich (or lean) relatively independent of the medium, more dependent upon the users' experience with the medium, their experience with the communication topic, and their experience with the communication partner or the communication context (Carlson & Zmud, 1999). Communication richness is therefore an outcome of social behavior, not solely an outcome of the nominal, rationally determined media richness of the communication channel. All this implies that although the amount of social information per communication act via the Internet is lower compared to face to face communication, it is more the rate of social information exchange than the amount of social cues exchanged that constitutes the key difference between the two forms of communication (Walther, 1996). Compared to non mediated communication, the exchange of social cues is "just" temporally retarded. Hence, informal, interpersonal communication can take place over computer-mediated communication channels, as user experience with the medium, the topic, the communication partner, and the communication context accumulates and increases. This phenomenon has been termed the "channel expansion effect" (Carlson & Zmud, 1999). But when first exposed to new media such as the Internet, it is likely that people's need for unmediated, face-to-face interactions increases (Nohria & Eccles, 1992).

A similar, albeit media-independent expansion effect can be observed within the organizational context of the MNE. As described by Kogut and Zander (1993), the personnel of the MNE must share a similar background and organizational culture in order to be able to encode and decode messages—in any of the four processes described above—correctly, otherwise misunderstandings will arise. Such capability, constituting the MNEs' transactional ownership-advantage (Dunning & Rugman, 1985), is MNE specific and only emerges over time through repeated interactions.

Considering communication differences across cultures is the second aspect that requires attention to understand how the Internet could support or enhance the four processes of intra-MNE knowledge management (see Figure 2). Hall's work on intercultural communication (Hall, 1976, 1983) provides a suitable framework that has been applied widely in similar research contexts, especially its contextual dimension (e.g., St.Aman, 2002; Zakaria, Stanton, & Sarker-Barney, 2003; Matveev & Nelson, 2004). The contextual dimension in Hall's framework represents the ways in which information is perceived, exchanged, and used by people from different cultures. Hall categorized cultures on a high- to low-context continuum. Low-context cultures such as those in the United States, Germany, and Scandinavian countries tend to present and exchange information in an explicit and direct manner. The implicit assumption is that little or no contextual overlap with the receiver is required, because all necessary information is vested in the explicit code (i.e., words) used. In contrast, high-context cultures such as those in Japan, China, Russia, and Latin America tend to rely less on coded, explicit communication. In such cultures most of the actual information content resides within the physical and situational context, as well as inside the communication parties. Less explicit information exchange is the natural consequence. Research has shown that such cultural differences also impact the way people go about their information pull, push, and interaction tasks, whether ICT mediated or unmediated (e.g., Straub, Keil, & Brenner, 1997; Pook & Füstös, 1999; Kersten et al., 2003; Pauleen, 2003; Zakaria et al., 2003).

Considering these different aspects, it becomes evident that it is likely that the relative role of Internet versus face-to-face-based knowledge management processes depends on the type of knowledge transfer process; the MNEs employees' experience with the Internet and its three generic uses; the employees' experience in transferring, absorbing, and using intra-MNE knowledge; and the intercultural communication complexity. Table 1 provides an overview.

For tacit-to-tacit transfers, the role of the Internet is the most limited, and only one of the three generic uses apply. Unmediated face-to-face interactions will play the dominant role with the highest base level, particularly in complex communication situations that require very personal communication strategies (Harvey & Griffith, 2002). Only over time, as the previously mentioned expansion effects occur and the emergence of an organizational communication culture reduces communication complexity, will the interac-

*Table 1. Knowledge management aspects, culture, ICT, and MNEs**

Process	Culture		Role of the Internet#			Face-to-face#	Relevance for MNE Type				Hypothesized, Stylized Relationship
			Pull#	Push#	Interaction #		International	Multidomestic	Global	Transnational	
Tacit-to-Tacit ("socialization")	Intercultural Communication Complexity	High	–	–	Low	High	Low	Low – Medium	Medium – High	High			Low	–	–	Low → Medium	High → Medium					
Explicit-to-Explicit ("articulation")	Intercultural Communication Complexity	High	Medium	Medium	Medium	Medium	Low	Low – Medium	Medium – High	High			Low	Medium → High	Medium → High	Medium → High	Low → Low					
Tacit-to-Explicit ("combination")	Intercultural Communication Complexity	High	–	Low	Low	High	Low	Low – Medium	Medium – High	High			Low	–	Low → Medium	Low → Medium	High → Medium					
Explicit-to-Tacit ("internalization")	Intercultural Communication Complexity	High	Low	–	Low	Low	Low	Low – Medium	Medium – High	High			Low	Low → Medium	–	Low → Medium	Low → Low					

tion use of the Internet increase and the role of unmediated interactions decrease. An exception to this trajectory is a surmised initial increase in face-to-face interaction (Nohria & Eccles, 1992). The overall shift over time will be of a complementary rather than fully substitutive nature (Kraut, Steinfield, Chan, Butler, & Hoag, 1998), especially in high-context cultures (Zakaria et al., 2003). A video conference over the Internet with an instructor practically demonstrating procedural knowledge is an example of a tacit-to-tacit knowledge transfer.

Explicit-to-explicit transfers are the stronghold of the Internet. All three generic uses apply, the frequency of use is the highest, and the face-to-face base level is the lowest. Codified organizational knowledge such as a blueprint stored in an Internet-enabled database is an example. Here, the need for unmediated communication is rather low, with the exception of complex intercultural communication situations. In addition, the need for unmediated communication might increase initially to achieve source credibility and trust.

For tacit-to-explicit transfers, only the push and interaction use of the Internet applies and its relative role lies somewhere between the two processes previously discussed. Turning uncodified, personal knowledge into codified knowledge requires richer, unmediated communication, particularly initially and in culturally dissimilar contexts. However, similar to tacit-to-tacit transfers, expansion effects might reduce the relative importance of unmediated interactions over time. As previously mentioned, an initial increase in face-to-face interactions (Nohria & Eccles, 1992) might be an exception to this. An example of such a transfer over the Internet would be an employee who publishes (pushes) an installation guide that incorporates his experience in installing the described piece of machinery on an MNE's best practice intranet site.

In the case of explicit-to-tacit transfers, both media play a limited role, with the influence of the Internet's pull and interaction use likely to increase over time as users gain expertise in pulling the right set of information from the medium and in interacting with colleagues from different countries. Here the relative role of the Internet for the MNE is similar to its role in the tacit-to-explicit transfer. The two differences are that the pull use of the Internet applies while the push use does not and that the overall use frequency of both media is lower. Internalization is more of a media-independent internal human learning process where mainly the source—face-to-face or mediated—matters. An example would be an employee in a subsidiary who downloads a new manual containing work rules that he or she will subsequently use in the daily work. Over time the explicit, codified knowledge is absorbed and becomes part of the employee's personal, tacit knowledge base.

As indicated in Table 1, the importance of these effects depends on the MNE type and the associated importance of intra-MNE knowledge management (see Figure 1 and Table 1). If integration is low, the relevance and role of the Internet is limited. If integration is high, the Internet can facilitate intra-MNE knowledge management as described above. In addition, the MNE's overall strategic intent regarding knowledge management matters. If a personalization strategy rather than a codification strategy is followed (Hansen, Nohria, & Tierney, 1999), the role of the Internet will be more limited.

FUTURE TRENDS

The importance of knowledge management in MNEs will increase in the future. As economies' value add shifts to services and knowledge becomes the key asset for firms, productive use of organizational knowledge becomes the main challenge (Drucker, 1999). Moreover, as the international integration of economies increases, cross-cultural communication competence becomes an increasingly important aspect in knowledge management. Research has demonstrated its positive impact on performance (Matveev & Nelson, 2004). What is less clear is how the role of the Internet will change in the future and how this relates to knowledge management within MNEs. Even its present role in knowledge management processes is not well understood. The Internet is a very dynamic and innovative medium, and its capabilities have significantly improved over time, including faster network connections. Therefore one could speculate that the role of the Internet will expand further. As mobile access to the Internet improves, individuals' and organization's skills in using it improve, and its bandwidth further expands richer information can be transmitted. This will reduce—albeit not completely substituting—the need for unmediated communication in the knowledge transmission process. Real time, virtual reality conferencing between headquarters and subsidiaries is but one example. Additionally, as global Internet diffusion further increases, cultural differences might matter less and lead to the emergence of a meta-culture that transcends location-bound aspects of culture in communication.

Yet it is important to understand that the Internet is "only" an infrastructure technology available to every MNE. In other words, it is a competitive necessity, not a source of competitive advantage per se. Only if the MNE integrates the Internet seamlessly into its culturally sensitive knowledge management processes, leveraging its resource-related and transaction-related advantages, will the Internet enable MNEs to sustain their competitive advantage. An understanding of the Internet's limitations and strengths as discussed above will help.

CONCLUSION

This article explored the possibilities and limitations of the Internet in supporting intra-MNE knowledge management. As was shown theoretically, the Internet can support such management tasks, assuming that personal relationships among employees and a joint understanding of the organizational context and culture have developed. Over time, as experience with the medium, the exchange partner, and the exchange context increases, this role becomes more prominent. Despite this, unmediated communication remains of importance. Especially in complex intercultural communication situations, in the early phases of knowledge transmission processes, and in cases where tacit knowledge is dominant, the Internet's current role is more limited. In addition, the nature of the MNE matters. Especially for MNEs that manage a highly interdependent network of subsidiaries with a high level of integration, efficient use of the Internet is imperative to stay competitive. With this in mind, a more differentiated role of the Internet in intra-MNE knowledge management processes emerges. Neither will it completely obsolete distance and the location-dependency of knowledge, nor will it play no role in knowledge management (for the latter argument see, for example, McDermott, 1999).

Although this middle-of-the-road position might be logically appealing, future research should test these conclusions. Thus far, empirical evidence in this area is scant and mainly anecdotal. Can the hypothesized relationship be found in MNEs? What are the antecedents and consequences of face-to-face versus Internet-mediated knowledge management processes? Does intercultural complexity moderate or mediate antecedents and consequences of media use in knowledge management processes? What overall organizational impact could be expected? Will it lead to—or be the result of—smaller MNEs and/or more decentralized MNEs and/or more integrated MNEs (for such findings in general, see Brynjolfsson, Malone, Gurbaxani, & Kambil, 1994; Dewan, Michael, & Min, 1998)? So far, these questions have not been answered.

Chapter 8.8
Knowledge Management in Tourism

Daniel Xodo
Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina

Héctor Oscar Nigro
Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina

INTRODUCTION

Management greatly depends on knowledge, and its detection, creation, transmission, and number of intangibles play a fundamental role in success.

In tourism, information systems must work on immaterial concepts and take steps to satisfy the expectations of multiple potential customers. These systems require complex models of reality and suitable conceptual tools to work out strategies.

This article expounds the use of different mathematical and management techniques that can be applied to the modeling, application, and control of strategic and operative management.

BACKGROUND

Data, Information, and Knowledge

These three concepts, which are frequently used as synonyms, are different representation stages of reality and its apprehension enables us in different ways.

Data, as simple representations, do not tell us much about themselves unless they are related to other data. It is from this relation that we get information.

Information is useful because of the possibility of intervention (e.g., cause–effect relationships), which is provided by knowledge.

What is knowledge? Knowledge can be understood as representation, production or estate

(Marakas,1999). In relation to this definition, any of the aforementioned concepts are, generically, knowledge. The definition of knowledge will depend on the usage and application of the term.

If we consider knowledge as "behavior support" (Lopez, 1999)—sharing perceptions in a socioeconomic system by means of the knowledge of goals, means, and evaluation of accomplishments—it will be easier to accomplish it effectively and efficiently.

If we consider knowledge taxonomically, we could derive, by means of appropriate processes, a linguistic and assimilative level of conceptualization and shared understanding from a primary level (descriptive, procedural, and rational). Hence, the possibilities of organization management success will be improved. Concepts such as "mission" are hard to explain, as its vagueness facilitates a certain mission to be attractive to many people who, at the same time, give their own meaning to it that does not always coincide with that of the others. The same happens with the comprehension of different functions, qualities, or behaviors, which must be shared by numerous actors.

The information systems meant to communicate knowledge vary according to what we want to transmit. However, it is always necessary to reduce ambiguity and unify concepts.

The following four types of formal systems can be distinguished (Simon, 1995):

a. of beliefs
b. of limit setting
c. of diagnosis control
d. of interactive control

In any of these, knowledge can be represented, generated, or established in different states, according to its usage, relationship, and application. For example, a certain number of guests in a hotel may be rather meaningless, but if we add the capacity, the date, and the category of the hotel to the number of people, it will have different meanings for the owner, the competitor or a new guest. These meanings will be influenced by, among other factors, the vision, the knowledge, and the expectations of the people involved. In this way, we will build up representation models, whose complexity will favor or damage our decisions according to our ability to deal with them.

Knowledge as Representation: The Indicators

If we take the concept "intellectual capital" to mean useful knowledge, which we develop "increasing the human capital" (Olve, Roy, & Wetter, 2000), it is obvious that people's knowledge varies from individual to individual. It is necessary to "translate the vision and the strategy into goals and indicators, through a well-balanced set of perspectives" (Kaplan & Norton,1999). The indicators will give the necessary homogeneity to the perceptions of those who have to make decisions in relation to the reality given by the indicator as well as its interpretation (i.e., people's subjective judgment).

Knowledge as Production

The occurrence of events, their measuring by means of indicators, and their processing provide elements of judgments, references, parameters, and interpretation of the reality on which decisions are made. In the dynamic of measuring and evaluating reality, we will "produce" new knowledge that will modify the evaluation as well as our behavior. A clear example is to study the environmental impact produced by tourist activity through intensity measures, and its extension and importance over the socioeconomical system (Coccossis & Parpairis, 1992).

Knowledge as State

According to its relevance, knowledge can be perceived in different ways: data, information, structured information, perceptions, judgments, and decisions (van Louizen, 1996). We are constantly changing the knowledge from one level to another until we get to the culmination of the knowledge, the decision. It is in this process that the precision and meaning of the information increases

At the same time, in the same process, we must reconcile material factors and goals with cultural and subjective factors (e.g., information, computing projects planning, information management with system of thoughts, learning systems, activity systems; Espinoza & Molina, 1999).

KNOWLEDGE MANAGEMENT IN TOURISM

Considering knowledge management as the process of managing immaterial assets explicitly, we immediately come to know that management in tourism (either private or public) is an especially fertile field. The aims of the service are mostly experiences, individual or group acquired knowledge, emotions, and personal transformations (Gunn, 1994). Likewise, the possibility of offering the service properly depends on the physical infrastructure and its usage as well as on the ability of interpreting expectations and needs, evaluating subjectivities and, getting ahead of them, understanding customs, likes and dislikes, preferences, and cultural and social guidelines (Tissen, Andriesen, & Lekanne, 2000) and from the offer of services and hiring until arrival time, staying, leaving, and even the memories and the will to come back (Organización Mundial de Turismo, 1997).

The challenge is to make the tourist destination offer the guests the desired utility, getting as a reward a successful operation of the system. To achieve this, the prodigal nature or the large investments are not enough. There are other elements that should be considered, such as proper management concepts directed towards constant learning and innovation, service processes, orientation to the customers, and the proper application of the economic–financial resources (Inskeep, 1991; Wisniewski & Dickson, 2001).

Service Profit Chain

Among the diverse approaches and strategies to increase the quality of the provision facilities, the customers' satisfaction, and, as a consequence, the increase in the incomes and the final profitability, it is useful to mention the "utility chain in services" (Heskett, Sasser, & Schlesinger, 1998).

The utility chain links different concepts that have an effect on the improvement of services, related to the ability of the ones whose mission is to carry them out. Almost all of them are related to knowledge, individual and shared knowledge of

a. structures
b. processes
c. needs
d. motivations for choice
e. service complementarity
f. demand complementarity
g. development of special packages for different segments
h. customers satisfaction
i. vision
j. personnel loyalty and satisfaction
k. investments in relevant aspects

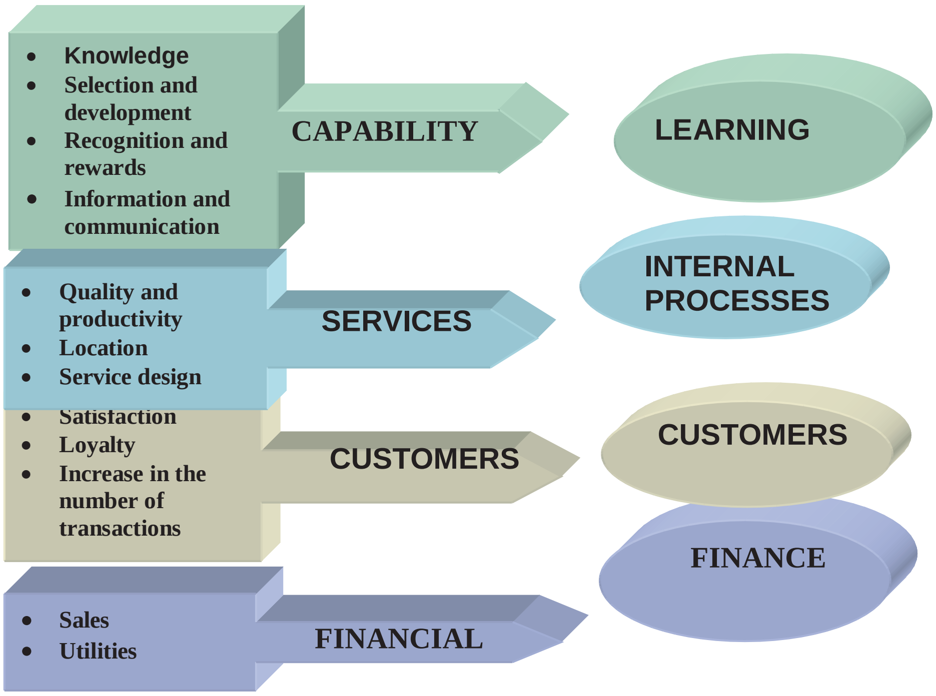
These concepts can be appreciated in the "value equation" (see equation below).

$$\textit{Value equation} = \frac{\textit{Results} + \textit{Process quality}}{\textit{Price} + \textit{Cost of access to a service}}$$

The keys for its application would be in

a. understanding the client needs
b. responding or covering needs
c. investing in key aspects, such as clients' restrain
d. developing value packages for different markets

Figure 1. Service profit chain and balanced scorecard



e. developing value conscience (Heskett et al.,1998; Ho & McKay,2002)

The service profit chain and its correspondence to the balanced scorecard is shown in Figure 1.

The service profit chain (Heskett et al., 1998) shows the relationship between different fundamental factors of tertiary activities such as tourism. This shows that the successful results in a certain administration come out as a result of the employees' capability, loyalty, satisfaction and productivity; generating high value services due to quality and low costs. Hence, not only do clients' satisfaction and loyalty rise, but so do growth and utilities.

Higher value is bounded to major commitment and people's training (growing perspectives). As a result, there will be better performed processes (internal process perspective) with more effective results (customer perspective), and thus better financial results (financial perspective). There is an important correspondence between the utility chain and the balanced scorecard perspectives.

Balanced Scorecard as a Tool of Knowledge Management

We can focus on knowledge in relation to two principal theories: information or people management (Probst, Raub, & Romhardt, 2000).

In information management, all the information is included at its different levels and support systems. In people management, its equivalence in the complex dynamic of human behavior takes particular significance. Both concepts should be considered within the frame of the structure in which they are developed or used. Therefore, we have three different elements at our disposal: information, people, and structure.

It is at this stage when the balanced scorecard functions as a knowledge management tool: the choice, diffusion, and application of the chosen strategy in the selected reference system. The data the BSC put together are useful to those people who are responsible for the application and control of the strategy. For example, the hotel reservation rate is useful to foresee the ticket sales to a certain tourist destination. In addition, the rate will be the result of the advertising and service strategies chosen and it will allow service providers to measure its efficiency (Miyake, 2002).

Need for Knowledge in Tourism

The basic knowledge in the sector are based on

a. physical assets
b. knowledge processes in tourist services (intangible assets)
c. strategies:
   - choice
   - diffusion
   - application

This knowledge is detected, elaborated, and transmitted through ratios, outcome measures and performance drivers whose substantial value is to reflect the cause–effect relationship of the items they are linking (Baud-Bovy, 1998; McIntyre,1992).

Balanced Scorecard as a Means for Managing Knowledge

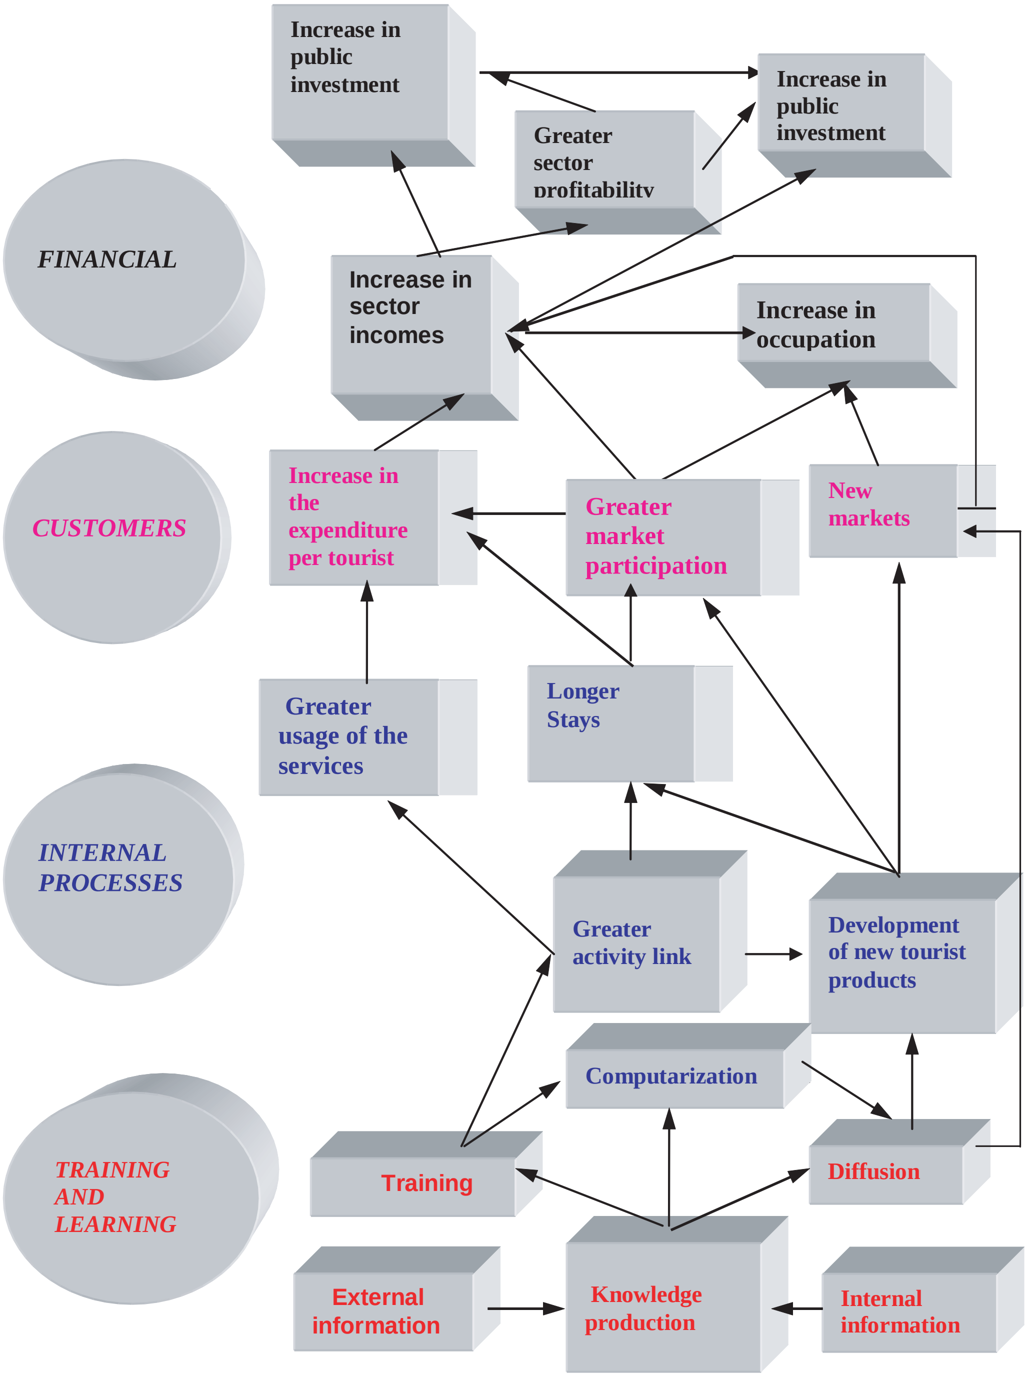
The balanced scorecard studies different aspects in the knowledge management of an organization and combines cultural, structural, and strategic aspects by causality relationships through

a. mission and vision
b. strategies
c. responsibilities
d. application
   - modeling of tasks
   - modeling of performance
e. transformation

Balanced Scorecard Advantages with Regard to Knowledge Management

a. it considers intangible assets
b. it makes use of linked outcome measures and future performance drivers
c. it makes the mission and the strategy more comprehensive by means of action
d. it is a cyclical process
e. it considers intellectual factors: creativity, innovation
f. its main utility is communication
g. it is multidimensional
h. it allows selecting indicators and inductors
i. it transfers the strategic outcome to quantitative measures
j. it transforms the strategy into action
k. it quantifies qualitative variants
l. it links cause–effect relationships to strategic activities
m. it is prospective
n. it allows measuring, simulating and evaluating alternatives

Figure 2. Some cause–effect relationships in tourism



o. it can be quickly modified (Kaplan & Norton, 2001; Malina & Selto, 2001; Neidorf, 2002)

The balanced scorecard (see Figure 2) outlines the tourist activity showing diverse cause–effect relationships.

Indicators

Outcome measures and performance drivers. The detection and selection of the indicators and inductors must be taken into account as diverse aspects to materialize the balanced scorecard.

a. cause–effect relationships
b. the possibility of obtaining, storing, and updating information
c. feasible control and processing
d. facility for diffusion and interpretation

FUTURE TRENDS

Informatic Applications in Tourist Knowledge Management

Data Warehouse, Data Mining, and Online Analytical Processing (OLAP) Applications and Use

Applications of these techniques (Fayyad, 1996, 1997) include

a. detection
b. selection of detection tools
c. integration of tools
d. application–organization
e. computerization and oversight

Data Warehouse as an Organization Process of the BSC

Data warehouse is a collection of data aimed at the matter—integrated, not volatile, thematic, and historical—organized to support a decision-making helping process. (Inmonn, 1996).

Useful Data Warehouse Characteristics for a BS

- Integrated: The data stored in the data warehouse are integrated in a structure; therefore, any existent inconsistency among the diverse operational systems must be eliminated. The information is often arranged into different detail levels for its adjustment to the users' needs.
- Thematic: Only the data essential for the knowledge generation process is integrated from the operational environment. The data is organized by topics to facilitate their access and understanding to the final users. For example, customers' data can be compiled in a unique data warehouse board. Consequently, the requests of information about customers will be easier to answer.
- Historical: Time is an implicit part of the information compiled in a data warehouse. In operational systems, data usually show the state of business activity at present. The information stored in a data warehouse can be used, among other purposes, to do trend analysis.
- Nonvolatile: The data of a data warehouse are meant to be read, no to be modified. Therefore, the information is permanent. Updating the data warehouse is the incorporation of the latest values the different variables it contains have taken without taking any kind of action on what already existed (Inmonn, Glassey, & Welch, 1997).

OLAP Tools for a Balanced Scorecard Information Analysis

We shall add the multidimensional information analysis by means of OLAP tools and consider OLAP systems as parts of the executive information systems (EIS), which are used to provide the strategic level with the necessary information for decision making (Codd, Codd, & Salley, 1993).

In an OLAP data model, the information is perceived as cubes that consist of descriptive categories (dimensions) and quantitative values (measures). The multidimensional data model makes it easier for the users to formulate complex queries, correct the mistakes in a report, change summed-up data for detailed data, and "filter" the data in meaningful subsets.

Applying Data Mining Tools in a Balanced Scorecard

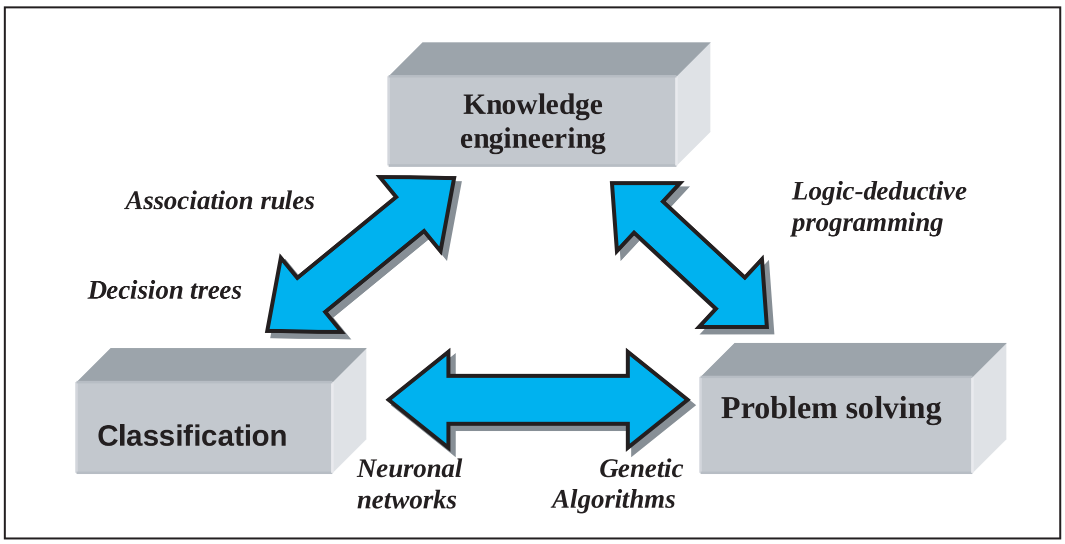
Data Mining Definition

Data mining is an analytical process that has been designed to explore large quantities of data and to search for consistent models and the systematic relationships among variables so as to validate the results of applying the discovered models to the new data subsets.

The process consists of three steps: exploration, construction or definition of the model, and validation/verification.

If the nature of the available data allows, we repeat it interactively until we identify a "strong" model. However, in business practice, the pos-

Figure 3. Learning algorithms



sibilities to validate the model in the analysis phase are usually limited. Consequently, the initial results often have the heuristic condition which might influence in the decision-making process.

There are three main working areas: knowledge engineering, classification, and problem solving. Each learning technique places itself in this three-dimensional space. No learning or pattern recognition technique is considered the best. An environment of knowledge databases discovery must bare these different types of techniques (hybrid environment, Indurkhya & Weiss, 1998).

Different Learning Algorithms Compared to Different Types of Tasks in the Application Inside a BSC

Any of the three techniques (i.e., knowledge engineering, classification, and problem solving) can be applied in a balanced scorecard to analyze and predict indicators or to take part in the indicators' building process (see Figure 3).

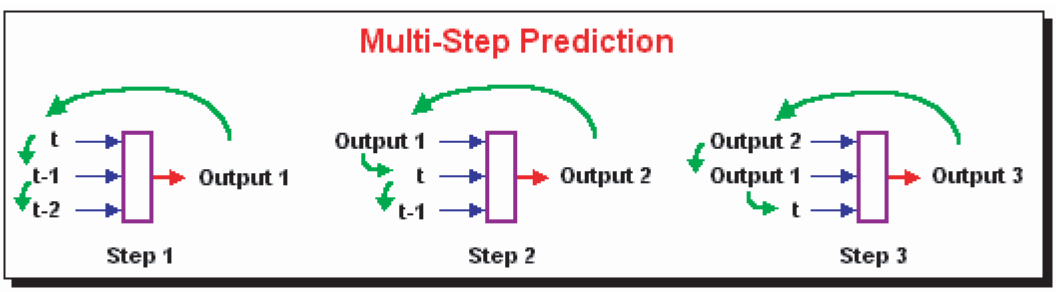
Structure and Application to the Proposed Indicators

Neuronal Networks Application in the Prediction of an Indicator. If we take a resulting indicator as the increase in the percentage of the average stay, we will get, in addition to this current indicator and its historical trajectory (i.e., applying temporal series), an indicator of the potential average stay for the following 6 months. The source of information of this indicator can be build up from (a) hotel and outing databases, and (b) sample interviews considering hotels and outings.

A temporal series represents the evolution of a magnitude in time. The factor of highest interest will be the correlation between different events along time. If such a correlation exists and can be modeled, predictions of the future behavior of the temporal series can be made.

The temporal series are build-up on a feed-forward architecture, such as multilayer perception (MLP) or radial basis functions (RBF). Alternatives include feed-forward networks, with a fixed-entry window and recurrent networks with unique entries.

Figure 4. Sequence of steps in the prediction



There are two types of models that can be applied to predict the next value in a temporal series:

a. single-step prediction, in which the inputs to the model are always known values taken from the temporal series, and
b. multi-step prediction, in which the result of the first prediction is fed back as a new entry in the network (see Figure 4).

Studying Techniques

There are two ways of studying temporal series:

a. finding out patterns to explain the past behavior of the temporal series, and
b. evaluating the effect of a fact that intervenes and changes the behavior of the temporal series.

Cycle Development: Preproject → Data Gathering → Data Preparation → Design → Training and Testing → Implementation and Maintenance

Between the design, and training and testing stages there is an interactive stage that corresponds to optimization.

Preparation of Data

The data employed in the application consisted of the following five fields registered (or calculated) in the T instant:

a. An increase in the percentage of the average stay (result indicator)
b. Quantity of necessary consultancies to define the trip
c. Increase in the number of options of tourist packages
d. Quantity of innovations in the Web site
e. Information availability in service centers

The last four items are guiding indicators.

Design

Selection of neuronal processing tools, model structure, and initial conditions.

a. Data input tool
b. Time series window
c. Time series plot

Data Input Tool

The data input tool allows the specifying of the variables to be included in the input window and also the ones that will go in the target window (prediction).

Time Series Windows

Time series windows allow the making of two kinds of predictions: single-step prediction and multi-step prediction.

Time Series Plot

Time series plot shows the results of an application as a two-dimensional graphic as a function of time. It shows the temporal comparison between the actual and predicted outputs and the actual outputs with inputs.

INDICATORS GROUPING TO GENERATE ANOTHER GUIDING INDICATOR

An example of this is taking into account the customers' level and Kohonen network.

The generated guiding indicator is "type of customer," with the following characteristics:

a. A varied passengers' origin
b. Percentage of reiteration of visits
c. Percentage of provenances
d. Segments diversity
e. Number of visitors
f. Total expenditure per tourist

Kohonen Auto-Organized Maps

These are based on evidences found at brain level. They associate entry vectors with output patterns and are able to make cluster analysis (i.e., to project a high-dimensioned space onto a smaller one).

The learning process is nonsupervised competitive. The neurons compete with each other to carry out a given task. When there is just one input, only one neuron activates (i.e., the winning neuron).

- Goal: "Cluster" the data introduced to the network.

SOFM Architecture: Connections

Each entry memory i is connected to each of the output neurons of j by means of weight (Wij). Each output neuron has a weight vector associated to it (Wij) as a reference vector, which represents the average vector of this category. Among the neurons of the output layer there are implicit lateral connections of excitement or inhibition (del Brío, 1997; see Figure 5).

Learning Stage

This stage aims to establish, by means of the presentation of a training pattern set, the different categories that will be employed during the working stage to classify new input patterns. A set of patterns is presented repeatedly in the network, until the different reference vectors are tuned to one or more input patterns. If the input space is divided into groups, each neuron will specialize in one of them, and the essential operation of the network will be interpreted as a "cluster analysis" (see Figure 6).

Figure 5. SOFM architecture

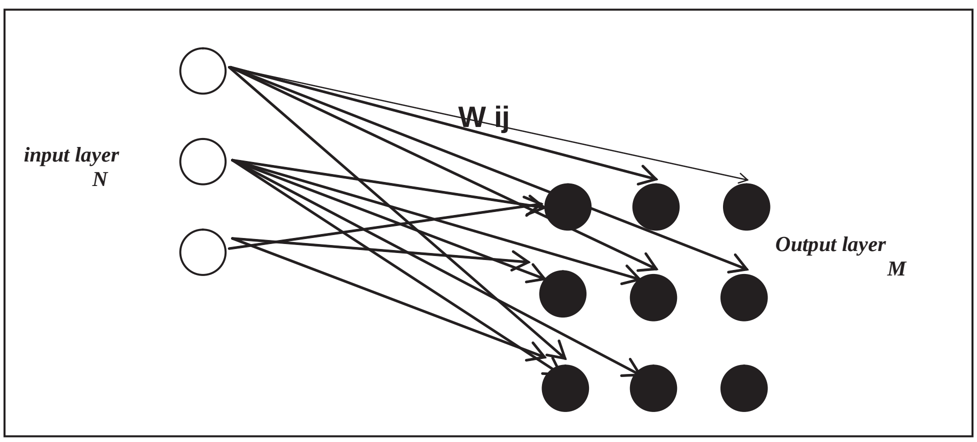


Figure 6. Bidimensional map sample

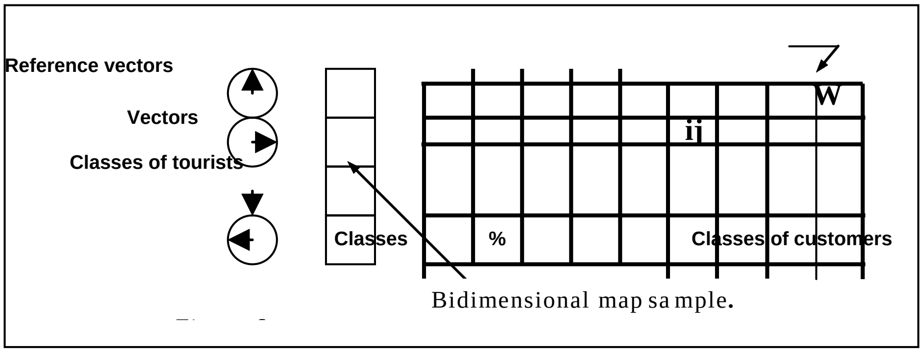


Working Stage

In the output layer, each neuron estimates the similarity between the input vector (Xp) and its own weight vector (Wij). Simulating a competitive process, the winning neuron will be the one whose weight vector resembles the input vector. The activated output neuron represents the class the input belongs to. When the input is a similar pattern, the same neuron, or a neighbor neuron, is activated.

Application of the Fuzzy Decision Theory as a Financial Indicator of the Future Investment in the Area

Fuzzy logic deals with imprecise information (such as the acceptance of a tourist package, the proper customers' attention, or an uncomfortable means of transport to the city) in terms of fuzzy sets (Lazzari, Machado, & Pérez, 1998). These fuzzy sets are turned into rules to define actions, such as "if the quality of a service is not good, the amount of tourists will decrease 50% in the following 6 months."

Control systems based on fuzzy logic combine input variables (which are defined in terms of fuzzy sets) by means of rules that produce one or several output values (Kasabov,1996). The fuzzy set theory comes from the classic set theory and adds a belonging function to the set, which is defined as a real number between 0 and 1.

The concept of fuzzy sets or subsets is introduced in association with a determined linguistic value, defined by a word, adjective, or linguistic label A.

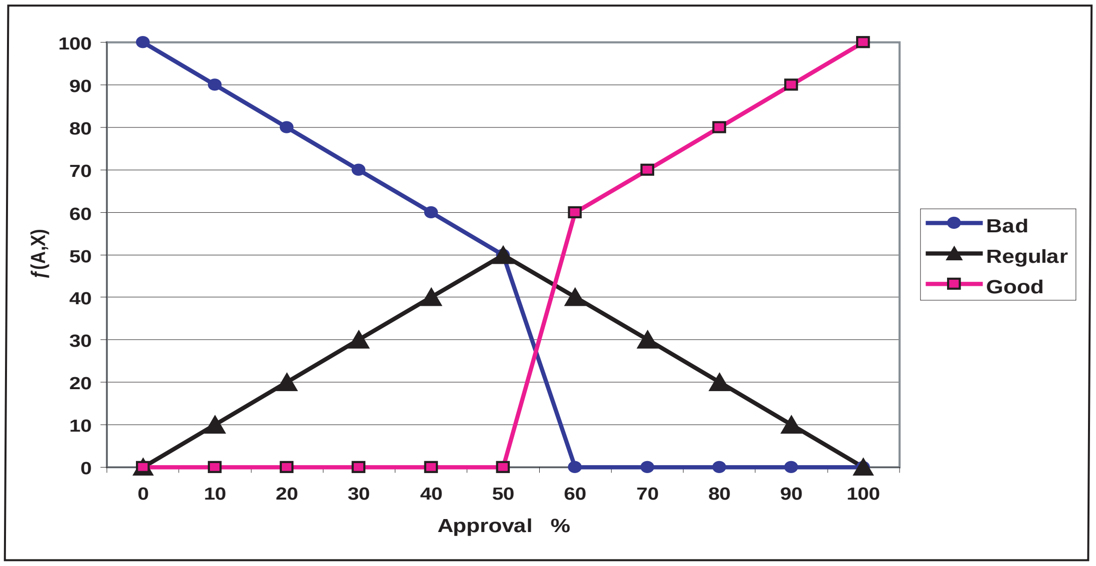
For each fuzzy set or subset there is a belonging or inclusive function ƒa(t) that indicates the degree in which the t variable is included in the concept that label A represents (Hilera & Martínez, 1995). For example, the linguistic value customers' attention may represent the acceptation degree in percentage to the attention of a specific tourist place expressed through interviews. Then, we can define three fuzzy sets, each one identified with a label (Bad, Regular, or Good) and with a belonging or inclusive function.

{ƒBad (t), ƒRegular (t),ƒ Good (t)}.

The outcome would be a distribution, as shown in Figure 7.

An economic–financial indicator to apply to the scorecard may be the amount of acquired packages for a specific tourist program. We will apply the fuzzy decision theory mechanisms to deduce different decisions about the acquisition of those packages and the future profits linked to

Figure 7. Fuzzy sets



each option (e.g., for each travel agent), according to the ways of searching information, the attitudes towards risk, the decision criteria, the total uncertainty, or others.

For these purposes, the concept of fuzzy logic may be applied, estimating the number of package tours to be sold, who will make decisions about the amount of reservations periodically booked in a specific excursion program. These decisions will have an initial capital investment intended to establish booking cost for each package to estimate the profitability.

CONCLUSION

Management has powerful formal tools at its disposal to optimize decisions. The computational decision systems (e.g., management information systems, decision support systems, executive information systems) are samples of the growing trend to eliminate empiricism, to go deeply into the analysis, to release from duty those who decide on routines, thus allowing them to adopt approaches of greater conceptual amplitude. Among these approaches are the ideals of understanding, vision, and quality, whose scope broadens the deterministic and quantitative approaches. Within this frame, the methods of proximal reasoning (in which we tend to include as an essential element the typical uncertainty that the social sciences constitute), together with computational algorithms, is a promising path in search of knowledge, which is a human concern for all people at all times.

Chapter 8.9
Multidisciplinary Project Teams

Patrick S. W. Fong
Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Knowledge in designing a product or rendering a service does not form a complete and coherent body of knowledge that can be precisely documented or even articulated by a single individual. Rather, it is a form of knowing that exists only through the interaction among various collective actors (Gherardi & Nicolini, 2000). Existing literature (Kanter, 1988; Nonaka, 1994; Spender, 1998; Starbuck, 1992) has highlighted a need for the development of a diverse workforce if knowledge creation is to be promoted and sustained within organisations. This literature suggests that a diverse set of resources (experts with different backgrounds and abilities) provides a broad knowledge base at the individual level, offering greater potential for knowledge creation.

Conceptually, a team can be viewed as a socially constructed phenomenon or linking mechanism that integrates individuals and organisations (Horvath, Callahan, Croswell, & Mukri, 1996). A multidisciplinary team is defined by Nonaka and Takeuchi (1995, p. 85) as "a self-managed, self-organised team in which members from various functional departments, and/or areas of expertise work together to accomplish a common goal." The primary goal of the multidisciplinary composition is to marry diverse bodies of knowledge in a way that produces a synergistic knowledge outcome that is innovative, contextualised, and, as such, has strategic value. For the most part, project team tasks are nonrepetitive in nature and involve considerable application of knowledge, judgement, and expertise.

The advantage of adopting multidisciplinary project teams is that they are quicker in integrating the expert knowledge of different functions, for example, design, construction, marketing, maintenance, and accounting. Cross-functional project teams with mutual accountability and collective work products have been found to decrease development time and increase product quality (Ancona & Caldwell, 1992; Dougherty, 1992; Van de Ven, 1986; Wheelwright & Clark, 1992). Multidisciplinary project teams create a "task culture," facilitating the necessary close linkages and direct personal contacts between different functions (Cohen & Levinthal, 1990). These close connections are necessary, as new product development by its very nature includes uncertainty about potential market response and about new technology (Henke, Krachenberg, & Lyons, 1993). This transformation process is a team-level phenomenon. It emerges through "heedful interrelationships" (Weick & Roberts, 1993) and interdependencies between team members, their actions and interactions, and the enmeshment of their individual knowledge paradigms. If creating new collective knowledge is indeed a team-level phenomenon, then the multidisciplinary team is considered the greenhouse where such a phenomenon can be best cultivated.

This article views the multidisciplinary project team as an unusual team arrangement, primarily because it is composed of professionals from various disciplines who take pride in their fields of expertise. They are committed to the basic assumptions of their paradigms and they perceive their roles in the team as representing their knowledge bases in the best possible way. In addition, a project on which a multidisciplinary team works can metaphorically be seen as an experiment, a vehicle for knowledge creation, with knowledge being created through the process of executing the project.

Examining knowledge creation from a microscopic view, it can be further subdivided into knowledge development and knowledge acquisition. The former develops knowledge that is made available through internal resources, whereas the latter acquires required knowledge by external means. Knowledge development involves the development of knowledge through internal effort after identifying the difference between required and available knowledge. Developing knowledge internally can be achieved via personnel in-house, or through research and development efforts, education and training, creativity techniques like brainstorming, or customer satisfaction surveys. Knowledge acquisition entails the acquisition of knowledge from external sources if developing knowledge internally is not possible. This is done through employing specifically qualified personnel, by merging or acquiring firms, by purchasing e-learning training, by forming joint-venture companies, or by employing an external company to conduct market research.

The relationship between knowledge creation and knowledge management is like the metaphor of the chicken and the egg, that is, it is hard to say which one should come first. If we imagine just managing existing knowledge without creating new knowledge, we can foresee what kind of world we would be living in—probably just a highly effective society without much technological advancement or improvement in living standards. Alternatively, if we kept on creating new knowledge or innovating without properly managing our existing knowledge, we would end up going round and round in circles and repeating the same mistakes time after time. In order for a society to flourish or a new product to be successful when it is launched, knowledge should not simply be managed: The creation of new knowledge also should be possible. In essence, knowledge creation should go hand in hand with knowledge management, as without one or the other, our knowledge journey will be futile.

BACKGROUND

The issue of knowledge has been debated for several centuries. Knowledge has only recently been viewed as a collective phenomenon in organisational contexts. Two conflicting theoretical perspectives about knowledge emerge. The first, as highlighted by Prahalad and Hamel (1990) and Wernerfelt (1984), focuses on the resource-based view where knowledge is considered to be a set of strategically important commodities that exist independent of their creators and are context-independent (i.e., the firm's primary role is as knowledge applicator). The second perspective, from Berger and Luckmann (1966) and Nonaka and Takeuchi (1995), perceives knowledge as a set of shared beliefs that are constructed through social interactions and embedded within the social contexts in which knowledge is created (i.e., the firm's primary role is as knowledge creator). This view of knowledge embodies the social construction perspective held by this article of trying to understand knowledge creation processes in multidisciplinary project teams.

The present framework for examining the knowledge creation processes within multidisciplinary project teams is based on Nonaka and Takeuchi's (1995) organisational knowledge creation theory. Nonaka and Takeuchi's theory is utilised because it is one of the few knowledge creation theories available that examines the interrelationships between explicit and tacit knowledge. Further, Nonaka and Takeuchi's (1995) theory was inductively developed using case studies of product development projects, so the focus on technical knowledge creation is appropriate for this study. However, Nonaka and Takeuchi's (1995) knowledge creation model has some limitations that lessen the model's suitability for the study of knowledge creation in multidisciplinary project teams. Their primary distinction between tacit and explicit knowledge is problematic as tacit or unarticulated knowledge is always a precondition for explicit knowledge (Engeström, 1999). Tuomi (1999) also criticises the model for taking culture and language for granted. The difficulty of discussing the role of language as a "repository of culturally shared meaning" (Tuomi, 1999, p. 340), critical for any knowledge creation theory, may make its use difficult for multidisciplinary project teams. It also is not clear what happens when the knowledge-creating spiral expands outside a team: Is knowledge still created in the same way (Tuomi, 1999)? As pointed out by Tuomi (1999, p. 328), "There is no model of social activity within the [knowledge creation] model□the motives for knowledge creation, and their relations to individual or organisational needs, remain obscure. Why some knowledge is created, and why some knowledge is not, remains an open question." Furthermore, Tuomi (1999) finds that though Nonaka and Takeuchi (1995) stress that the process of knowledge creation is "social", their underlying focus is on individual and intrapersonal knowledge. He adds that "as their concept of knowledge is intrapersonal, truth becomes a necessary aspect of knowledge, grounding intrapersonal knowledge into interpersonal reality" (Tuomi, 1999, p. 333).

In order to overcome some of the shortcomings in Nonaka and Takeuchi's knowledge creation model, if one accepts the social construction perspective of knowledge as a set of shared beliefs constructed through social interaction amidst certain social circumstances, then both individual and social levels require acknowledgement and integration.

Two multidisciplinary project teams, working on two different construction projects at the design stage, were selected for study. In this article, a construction project also can be treated as a product because at the end of construction a facility will exist, with consumers using it to fulfill their needs. The selection of a residential development project recognises the large reservoir of idiosyncratic knowledge developed by the owner company over the years. It also recognises the crucial innovating dynamics behind the need to compete on the market with other residential developments. The infrastructure project presented alternative opportunities for knowledge creation and learning, unique in several respects. First, it was a complex operation, distinguished by an extraordinary multiplicity of consultants employed. Second, it is rare to find such a project, usually managed by government, in private hands. Finally, the technical challenges presented in this project made it an interesting arena for knowledge creation and absorption within the team.

MAIN FOCUS OF THE ARTICLE

Beyond modifying Nonaka and Takeuchi's (1995) model of knowledge conversion processes, a major and significant finding is that the collaborative nature of multidisciplinary project teams is essential in creating new knowledge. With a traditional focus on professional specialisation, many new development projects may be managed with tasks being executed in parallel or in sequence, or by certain project team members in isolation. This is often counterproductive when projects are so designed that the success of creating new knowledge among diverse disciplines may suffer, with optimal value possibly not being achieved.

The first process in knowledge creation involves boundary crossing, with two types of boundaries identified as affecting the progress and success of multidisciplinary knowledge creation. The importance of boundary crossing is reflected in solving the "boundary paradox" (Quintas, Lefrere, & Jones, 1997), where team members are able to exchange and combine knowledge (Nahapiet & Ghoshal, 1998). The interactions across these boundaries can either foster or hinder knowledge creation. The first boundary identified was between team members of different disciplines. The second existed between different stakeholders. The expertise boundaries could be crossed, not only through knowledge redundancy among team members, but also through boundary objects. The most prominent project boundary objects were drawings and personal conversations among team members. The second hierarchical boundaries could be crossed through team members consciously breaking down any barriers by valuing the expertise of others. It must be stressed that crossing boundaries does not necessarily guarantee the creation of knowledge. It is seen, however, as a prerequisite for the four remaining processes to occur.

The second process relates to knowledge sharing, with project team members of differing knowledge domains more likely to discuss their uniquely distinct information and knowledge than those who possess information in common. It seemed to be an advantage to have a diverse pool of knowledge for team members to access and share in discussion. Despite the existence of little competition among team members, external competition could act as a double-edged sword in the knowledge sharing process. Sharing important market or design knowledge could lead to imitation by competitors, possibly even resulting in project poaching. In addition, the type of communication appeared more influential in the transfer of tacit rather than explicit knowledge. For tacit knowledge to be effectively transmitted, interpersonal communication seemed of the utmost importance.

The third process to be considered is that of knowledge generation, in which teams create knowledge by generating new or "emergent" knowledge through interaction and communication. New or emergent knowledge, not possessed before discussion, can develop through group discussion and interaction (Kogut & Zander, 1992). The development of emergent knowledge is vital for creativity and innovation. It is generated through various means, including those of social networks, printed sources, and customer and competitor feedback.

Social networks were identified as the most important vehicle for information and knowledge exchange, with team members heavily reliant upon colleagues, friends, and ex-colleagues as rich resources for generating design knowledge. The use of printed data in the design process appeared to be limited: It was viewed as time-consuming and used mainly to cross-check the solutions offered. Social networks tended to recommend published materials, helping to reduce research time and enhance usability. Comprehension of customer needs, insight into competitor products, and an inspection of completed facilities all seemed to stimulate knowledge generation. Time and motivation were identified as two very significant influences, and it is interesting to note that both of these impacted on the sharing of knowledge, as well as the generation of new knowledge.

Fourth is knowledge integration, realised by marrying the differing perspectives and knowledge of various disciplines in the design decision-making process. This enables different stakeholder views to be incorporated so that they can be considered and integrated. New product design requires multidisciplinary skills and knowledge input. Various team members brought different sets of assumptions about optimal ways to proceed, prioritising different values and perspectives to ultimately best meet stakeholder requirements as well as arrive at satisfactory design solutions. Project documentation as well as various design objects were used as tools to integrate the range of knowledge input from project participants.

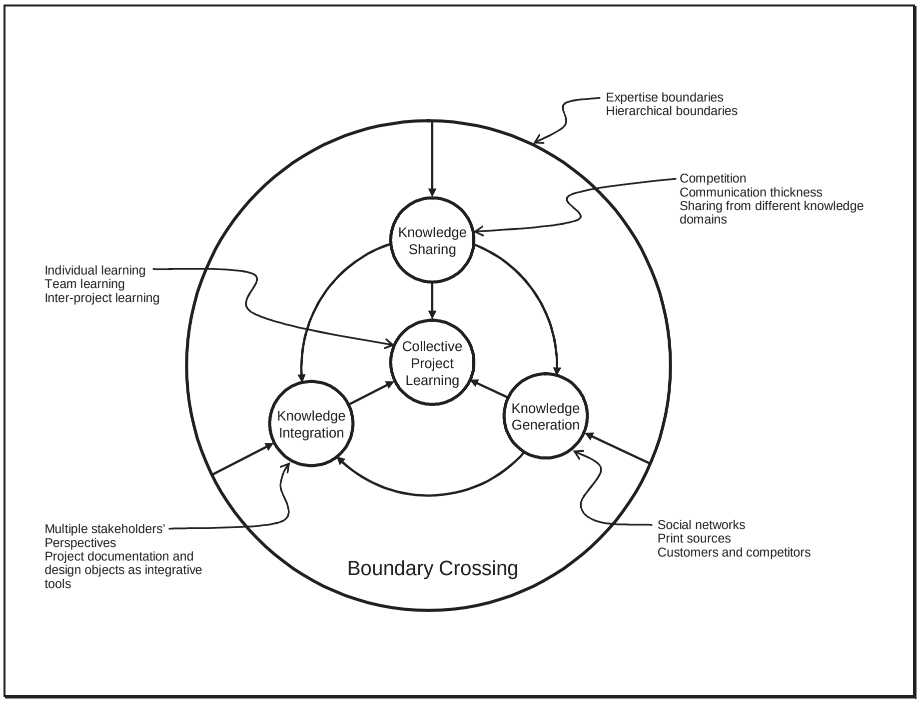
The fifth process involves collective project learning, in which professionals with extensive experience in self-directed learning learn from the projects they are engaged in. Project team members had to constantly absorb new technology and techniques in order to remain competitive. Experts in self-directed learning, they created an environment maximising opportunities for individual inquiry and learning. Problem-solving being central to their work, they also recognised that failure was an opportunity for learning and understanding. Understanding failure is a primary mechanism in learning how new technology and systems operate, optimally avoiding repetitive mistakes. Therefore, considerable effort should be made to support an individual's critical problem-solving and reflection processes. Individuals then develop personal strategies based on their own thinking and learning preferences.

The project teams themselves encouraged team learning activities, independent of any directives. Small sub-teams typically pooled their resources for learning, acquiring the necessary skills and knowledge to solve problems in an open and permissive environment. Individuals shared their information seeking strategies so that the sub-team might learn in as many different ways as possible. The larger project teams followed more formal processes and procedures for sharing and interacting. The smaller teams contributed directly to the work of the larger project teams, but they were not formally recognised in the organisational structure of the projects. They spontaneously grouped and regrouped, navigated by the team members themselves. Most formations were temporary, lasting only until the immediate goals were accomplished.

Inter-project learning can be seen as gaining knowledge from a project and transferring it directly or indirectly to other subsequent or concurrent projects. Interproject learning can happen both concurrently or sequentially. In concurrent transfer, a new project begins to transfer knowledge from a base project before it has completed its task. Sequential transfer happens when knowledge and experience are transferred from an initial project to a new one upon the original's completion. A central prerequisite for interproject learning is a certain degree of repetitiveness between projects, with the similarity of aspects enabling construction and refinement of procedures, whereas the total uniqueness of a project can slow learning, possibly hindering immediate progress. The most widely observed strategy in interproject learning involved personalisation rather than codification.

Through studying two multidisciplinary project teams working on two facilities projects during their design phase, this article has arrived at a new model of knowledge creation within multidisciplinary project teams, differing from the organisational knowledge creation theory developed by Nonaka and Takeuchi (1995). The new model of knowledge creation within multidisciplinary project teams is proposed and illustrated in Figure 1, with the interrelationships among different processes highlighted. It is emphasised that these processes are not linear in nature but intertwined with one another.

Figure 1. The interrelationships between multidisciplinary knowledge creation processes



FUTURE TRENDS

As more organisations employ multidisciplinary teams to sustain or improve their competitive advantage through innovative products or services, more attention should be directed to highlighting their unique features and understanding how to turn such teams into an effective knowledge creation force.

Though project teams with diverse workforces can be seen as essential units in promoting and sustaining knowledge creation within organisations (Kanter, 1988; Nonaka, 1994; Spender, 1998; Starbuck, 1992), the diversity of team members can be problematic, placing demands on the team to manage divergent thinking paradigms and basic assumptions, as well as the "professional egos" of team members (Dougherty, 1992). This would suggest a need for proper management before the benefits of knowledge creation can be harvested. This would require the joint effort of teams and their management. Four key lessons for multidisciplinary project teams and management are suggested here:

- The support of intra- and interorganisational social networks
- The enhancement of cooperative teamwork
- Mechanisms for easing tension among project team members

- Concentration on project value maximisation

Although this article has made some theoretical and practical contributions, it has limitations that call for further research. Several research agendas emanating from this model are:

First, only a specific type of team was included in the research data. The research site provided an excellent opportunity to explore the processes, interrelationships, and contributory factors to knowledge creation within a multidisciplinary setting. However, the experience of these teams cannot be extrapolated to all teams. It is suggested that future research could attempt to conduct similar studies in more diverse settings. Since different team structures and cultures could influence the knowledge creation processes in different ways, future research could contribute to the development of a pluralistic, rather than normative, view of team knowledge-creation capability. This might include comparative studies of information-intensive teams vs. production-oriented teams, and research- vs. product-oriented teams. Future studies could examine teams in more complex interdisciplinary circumstances (e.g., biotechnology, genomics, etc.) where teams are brought together, even from quite different fields and industries. These teams might work on complex problems, pooling their diverse backgrounds and training, possibly to solve a complex business problem, design a new system, product or service, or to reorganise a company.

Second, the research on knowledge creation extends across multiple theoretical boundaries. However, this study emphasised primarily the areas of knowledge creation and team processes. Though other related literature has been discussed, their review was not the main thrust. The ample information management and information systems literature, devoted to knowledge management or organisational knowledge, was not incorporated into the study. This limitation can be explained by the study's focus on the processes of knowledge creation within multidisciplinary project teams, rather than the effects of information systems on these processes. Such a limitation represents a major research opportunity through exploring the impact of information systems on knowledge creation.

Finally, the study did not measure the effectiveness or quality of the knowledge created by the multidisciplinary project teams. Such a measurement could facilitate a clearer understanding of any organisational competitive advantage that might result from knowledge creation. Clearly, future research aiming to tackle these issues might enable project teams and management to better understand and evaluate the potential impact of multidisciplinary project teams on knowledge creation.

CONCLUSION

This article has arrived at a new model of knowledge creation within multidisciplinary project teams, differing from the organisational knowledge creation theory developed by Nonaka and Takeuchi (1995). It places primary emphasis on the processes rather than the outcomes of multidisciplinary knowledge creation as put forward by previous researchers.

The underlying processes of knowledge creation in multidisciplinary project teams are different to those proposed in the organisational knowledge creation theories. A new model of knowledge creation within multidisciplinary project teams is proposed. In the model, the five processes of knowledge creation are identified, including the processes of boundary crossing, knowledge sharing, knowledge generation, knowledge integration, and collective project learning. The interrelationships of these five processes are elaborated to enable their thorough understanding. It must be stressed that that these knowledge creation processes within multidisciplinary teams are not linear. Instead they are interwoven, occurring throughout the projects. In addition, there is a need for proper management of multidisciplinary project teams before the benefits of knowledge creation can be harvested and recognised.

Chapter 8.10
Boundaries in Communities

José Córdoba
University of Hull, UK

INTRODUCTION AND BACKGROUND

This article suggests a way of complementing the notion of boundary objects from communities of practice to enable learning: That of extending the notion of boundary objects to account also for boundary people. There are some people whose participation in a community could provide benefits for them and the community. Although it has been suggested that in a community of practice there are different types of membership, little is mentioned about how learning could be fostered by developing inclusive membership. This could be a way of bringing relevant experience to the attention of a community.

BOUNDARIES AND MEMBERSHIP

In a community of practice, there are two main elements that constitute learning: experience and competence (Wenger, 1998). A community can be seen as a recurrent encounter between people who share interests with this permanency generating their competence, participation, and own identity. The community feeds itself from the experience of its members, including newcomers.

According to Wenger, McDermott, and Snyder (2002), cultivation of communities of practice requires establishing first a domain of competence, something that members care about. Nurturing this requires organizing activities of a community and roles for participants. It also requires establishing ways of dealing with contingencies (i.e., conflict). The result of this will be generating knowledge, which can be explicit (i.e., documents).

Although in the theory of communities of practice, it is acknowledged that communities have boundaries that define who is in and who is not part of it, there is very little guidance on how communities can deal with the resulting exclusion of individuals. It is assumed that members share interests that lead them to become part of a community and to define their engagement. Individual motivation is a condition for the formation of communities of practice, and the theory's main thrust is to provide guidance for the adequate development (or nurturing) of communities. An issue that remains unexplored is how to facilitate inclusion of those whose interest is (or might not be) developed to belong to a community, but who could greatly benefit from participating in it as well as benefiting the community.

CRITIQUE ON BOUNDARIES: BRINGING PEOPLE TO A COMMUNITY

The notion of what constitutes a boundary has been explored in management science, more particularly, in the literature of critical systems thinking (Midgley, 2000; Ulrich, 1983). A boundary is a social construction by which knowledge and people to be considered relevant in a situation are defined (Churchman, 1968). This notion presents a similarity with that of a boundary object of the theory of communities of practice (mentioned elsewhere in this encyclopedia). A boundary object helps people from a community to communicate with the rest of the world and to coordinate activities (Wenger, 1998).

This concept of an object could be extended to account for people who may be excluded from participation in a community of practice. Therefore, the idea of boundary people can be put forward. Midgley (1992) suggests that in any situation, reflection on people and issues which become marginalized from any decision could help those deciding to foster inclusion and participation. In a community, this type of reflection could also help members define their identity by acknowledging who they are and what they do, or who they could become. Often, Wenger (1998) argues, defining what and who constitutes a community helps individuals to define their own identity.

Non-participation and marginality are two issues that are accounted for in the theory of communities of practice. The first refers to a non-intensive engagement (i.e., when people are new to a community). The second refers to situations where there are barriers for people to become full members of a community. This situation may be problematic for the development of a community. In this aspect, reflection on boundaries and marginalization of both objects and people could help potential participants and community members identify issues that need to be addressed to facilitate inclusion and learning.

Midgley (1992) suggests that the definition of a boundary brings value judgments about what and who is to be included and marginalized from decisions. These value judgments could be subject to debate to enable a community to debate on possibilities of including some peripheral and marginalized members and their experience as a core element of their practice. The following questions could help a community to reflect on issues of inclusion and marginalization:

- Who is to be included within this community?
- What can constitute knowledge within the community?
- What and whose value judgments are supporting the above definitions?
- What and who is to be marginalized from activities? Why?
- From the above questions, what barriers for inclusion and learning could be identified?

CONCLUSION

In this article, a perspective to facilitate inclusion in a community of practice has been developed. This perspective takes the notion of a boundary object and extends it to account for the possible existence of people in the margins of boundaries whose participation in a community of practice could bring benefits for learning. In the dynamics of a community, it is inevitable some people and their knowledge could be marginalized. Reflecting on the implications of maintaining their marginality or avoiding it by including them into community's activities could be seen positively as a way of fostering learning and competency.

Chapter 8.11
Representation Languages for Narrative Documents

Gian Piero Zarri
University of Paris IV/Sorbonne, France

INTRODUCTION

A big amount of important, "economically relevant" information, is buried into unstructured "narrative" information resources: This is true, for example, for most of the corporate knowledge documents (memos, policy statements, reports, minutes, etc.), for the news stories, the normative and legal texts, the medical records, many intelligence messages as well as for a huge fraction of the information stored on the Web. In these "narrative documents," or "narratives," the main part of the information content consists in the description of "events" that relate the real or intended behavior of some "actors" (characters, personages, etc.)—the term "event" is taken here in its more general meaning, also covering strictly related notions like fact, action, state, and situation. These actors try to attain a specific result, experience particular situations, manipulate some (concrete or abstract) materials, send or receive messages, buy, sell, deliver, and so forth. Note that in these narratives, the actors or personages are not necessarily human beings; we can have narrative documents concerning, for example, the vicissitudes in the journey of a nuclear submarine (the "actor," "subject," or "personage") or the various avatars in the life of a commercial product. Note also that even if a large amount of narrative documents concerns natural language (NL) texts, this is not necessarily true. A photo representing a situation that verbalized could be expressed as "Three nice girls are lying on the beach" is not of course an NL text, yet it is still a narrative document.

Because of the ubiquity of these "narrative" resources, being able to represent in a general, accurate, and effective way their semantic content—that is, their key "meaning"—is then both conceptually relevant and economically important: Narratives form, in fact, a huge underutilized component of organizational knowledge. This type of explicit yet unstructured knowledge can be, of course, indexed and searched in a variety of ways, but it requires, however, an approach for formal analysis and effective utilization that is neatly different from the "traditional" ones.

BACKGROUND

Usual ontologies—both in their "traditional" and "Semantic Web" versions (see the "Knowledge Representation" and "RDF and OWL" articles in this Encyclopedia)—are not very suitable for dealing with narratives. Basically, ontologies organize the "concepts"—that we can identify here with the important notions to be represented in a given application domain – into a hierarchical structure, able to supply an elementary form of definition of these concepts through their mutual generic/specific relationships ("IsA" links). A more detailed definition of the concepts is obtained by associating them with a set of binary relationships of the "property/value" type (e.g., a "frame"). The combination of these two representational principles is largely sufficient to provide a static, a priori definition of the concepts and of their properties.

Unfortunately, this is no more true when we consider the dynamic behavior of the concepts, that is, we want to describe their mutual relationships when they take part in some concrete action or situation ("events"). First of all, representing an event implies that the notion of "role" must be added to the traditional generic/specific and property/value representational principles. If we want to represent adequately a narrative fragment like "NMTV (an European media company) … will develop a lap top computer system…," besides asserting that NMTV_ is an instance of the concept company_ and that we also must introduce an instance of a concept like lap_top_pc, we have to create a sort of "threefold" relationship; this relationship includes a "predicate" (like DEVELOP or PRODUCE), the two instances, and a third fundamental component, the "roles" (like SUBJECT or AGENT for NMTV_ and OBJECT or PATIENT for the new lap top system) used to specify the exact function of these two instances within the formal description of the event. Moreover, in an event context, we also must deal with those "connectivity phenomena" like causality, goal, indirect speech, co-ordination, and subordination that link together the basic "elementary events." It is very likely, in fact, that dealing with the sale of a company, the global information to represent is something like: "Company X has sold its subsidiary Y to Z because the profits of Y have fallen dangerously these last years due to a lack of investments," or, returning to our previous example, that "NMTV will develop a lap top computer system to put controlled circulation magazines out of business," or, that dealing with the relationships between companies in the biotechnology domain, "X made a milestone payment to Y because they decided to pursue an in vivo evaluation of the candidate compound identified by X." In computational linguistics terms, we are here in the domain of the "Discourse Analysis" which deals, in short, with the two following problems: (1) determining the nature of the information that in a sequence of statements goes beyond the simple addition of the information conveyed by a single statement; (2) determining the influence of the context in which a statement is used on the meaning of this individual statement or part of it.

It is now easy to imagine the awkward proliferation of binary relationships that sticking to the traditional ontological paradigm it would be necessary to introduce to approximate high-level notions like those of "role" and "connectivity phenomena."

Solutions for representing narratives in computer-usable ways that could move beyond a strict "binary" framework have, therefore, already been proposed in the past. In the context of his work—between the mid 1950s and mid 1960s—on the set up of a mechanical translation process based on the simulation of the thought processes of the translator, Silvio Ceccato (Ceccato, 1961, 1967), proposed a representation of narrative-like sentences as a network of triadic structures ("correlations") organized around specific "correlators" (a sort of roles). The correlators (100 or 200 in all, according to the different natural languages) included conjunctions and prepositions, punctuation marks, and syntactic/semantic relationships like subject-predicate, substance-accident, apposition, development-modality, comparison, and so forth. Ceccato also is credited to be one of the pioneers of the semantic network studies, even if the "official" beginning of this discipline is traditionally associated with the first publication, in 1966, of the Ross Quillian's thesis on "Semantic Memories" (Quillian, 1968). Basically, semantic networks are directed graphs (digraphs) where the nodes represent concepts, and the arcs represent different kinds of associative links, not only the "classical" IsA and property-value links, but also "ternary" relationships derived from Case Grammar in Linguistics (see Fillmore, 1966), and labeled as Actor, Object, Recipient, Instrument, and so forth. A panorama of the different conceptual solutions proposed in a semantic network context can be found in Lehmann (1992). In the 1970s, a sort of particularly popular semantic network approach was represented by the Conceptual Dependency theory of Roger Schank (1972). In this theory, the underlying meaning ("conceptualization") of narrative-like utterances is expressed as combinations of "semantic predicates" chosen from a set of 12 "primitive actions" (like INGEST, MOVE, ATRANS, the transfer of an abstract relationship like possession, ownership and control, PTRANS, physical transfer, etc.) plus states and changes of states, and seven role relationships ("conceptual case") in the Case Grammar style. Conceptual Graphs (CGs) is the representation system developed by Sowa (1984, 1999) and derived from Schank's work and other early work in the Semantic Networks domain. CGs make use of a graph-based notation for representing "concept-types" (organized into a type-hierarchy), "concepts" (which are instantiations of concept types) and "conceptual relations" that relate one concept to another. CGs can be used to represent narratives in a formal way, like "A pretty lady is dancing gracefully," and more complex, second-order constructions like contexts, wishes, and beliefs. CYC (see Lenat, Guha, Pittman, Pratt, & Shepherd, 1990) concerns one of the most controversial endeavors in the history of artificial intelligence. Started in the early 1980s as a MCC (Microelectronics and Computer Technology Corporation, TX) project, it ended about 15 years later with the set up of an enormous knowledge base containing about a million of hand-entered "logical assertions" including both simple statements of facts and rules about what conclusion can be inferred if certain statements of facts are satisfied. The "upper level" of the ontology that structures the CYC knowledge base is now freely accessible on the Web (www.cyc.com/cyc/opencyc). A detailed analysis of the origins, developments and motivations of CYC can be found in Bertino, Catania, and Zarri (2001, pp. 275-316).

NARRATIVE KNOWLEDGE REPRESENTATION LANGUAGE (NKRL)

With the exception of CYC and (very partially) of the Conceptual Graphs, the greater part of the solutions evoked in the last section concern mainly pure academic work, implying very sketchy forms of implementation. Narrative Knowledge Representation Language (NKRL) (Zarri, 1997, 2003) represents an up-to-date, fully implemented, and relatively complete solution to the problem of representing narratives without a too important loss of the original "meaning." NKRL innovates with respect to the usual ontology paradigm by associating with the traditional ontologies of concepts an "ontology of events," that is, a new sort of hierarchical organization where the nodes correspond to N-ary structures called "templates."

Instead of using the traditional object (class, concept)—attribute—value organization, templates are generated from the combination of quadruples connecting together the symbolic name of the template, a predicate, and the arguments of the predicate introduced by named relations, the roles. The quadruples have in common the "name" and "predicate" components. If we denote then with Li the generic symbolic label identifying a given template, with Pj the predicate used in the template, with Rk the generic role and with ak the corresponding argument, the NKRL core data structure for templates has the following general format:

(Li (Pj (R1 a1) (R2 a2) … (Rn an))) (1)

See the example in Table 1. Predicates pertain to the set {BEHAVE, EXIST, EXPERIENCE, MOVE, OWN, PRODUCE, RECEIVE}, and roles pertain to the set {SUBJ(ect), OBJ(ect), SOURCE, BEN(e)F(iciary), MODAL(ity), TOPIC, CONTEXT}. An argument of the predicate can consist of a simple "concept" (according to the traditional, "ontological" meaning of this word) or of a structured association ("expansion") of several concepts.

In turn, templates are included in an inheritance hierarchy, HTemp(lates), which implements

Table 1. Deriving a predicative occurrence from a template

```
name: Move:TransferOfService

 var3  =     <service_>
 var4  =     <human_being_or_social_body>
 var6  =     <human_being_or_social_body>
 var8  =     <process_> | <sector_specific_activity>
 var9  =     <sortal_concept>
 var10 =     <situation_>
 var2, var5, var7 = <geographical_location>

c1)     MOVE  SUBJ   british_telecom
        OBJ    payg_internet_service
        BENF   (SPECIF customer_ british_telecom)
        date-1: after-1-september-1998
        date-2:
```

the new "ontology of events," (see Figure 1); they represent then formally generic classes of elementary events like "move a physical object," "be present in a place," "produce a service," "send/receive a message," and "build up an Internet site." When a particular event pertaining to one of these general classes must be represented, the corresponding template is "instantiated" to produce what, in the NKRL's jargon, is called a "predicative occurrence."

To represent then a simple narrative like "British Telecom will offer its customers a pay-as-you-go (payg) Internet service in autumn 1998," we must first select in the HTemp hierarchy the template corresponding to "supply a service to someone," represented in the upper part of Table 1.

This template is a specialization (see the "father" code) of the particular MOVE template of HTemp corresponding to "transfer of resources to someone" (see Figure 1). In a template, the arguments of the predicate (the ak terms in (1)) are represented by variables with associated constraints—which are expressed as concepts or combinations of concepts, that is, using the terms of the NKRL standard "ontology of concepts" (HClass, "hierarchy of classes"). The constituents (as SOURCE in Table 1) included in square brackets are optional. When deriving a predicative occurrence (an instance of a template) like c1 in Table 1, the role fillers in this occurrence must conform to the constraints of the father-template. For example, in occurrence c1, british_telecom is an individual instance of the concept company_: this last is, in turn, a specialization of human_being_or_social_body. payg_internet_service is a specialization of service, a specific term of social_activity, and so forth.

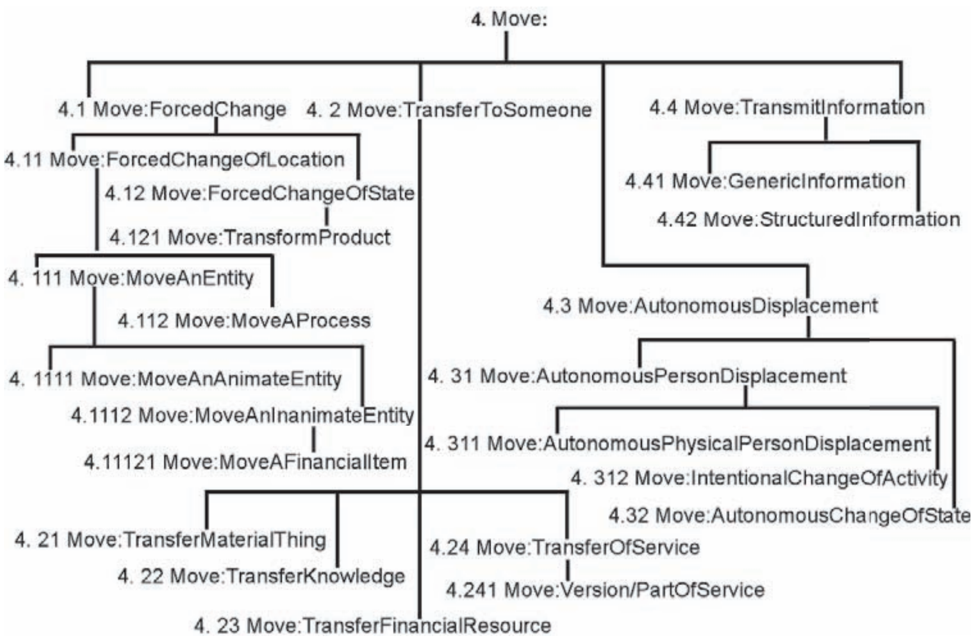
The meaning of the expression "BENF (SPECIF customer_ british_telecom)" in c1 is self-evident: The beneficiaries (role BENF) of the service are the customers of—SPECIF(ication)—British Telecom. The "attributive operator," SPECIF(ication), is one of the four operators that make up the AECS sub-language, used for the set up of the structured arguments (expansions); apart from (SPECIFication = S), AECS also includes the disjunctive operator (ALTERNative = A), the distributive operator (ENUMeration = E), and the collective operator (COORDination = C). The interweaving of the four operators within an expansion is controlled by the so-called "precedence rule" (see Zarri, 1997, 2003).

In the occurrences, the two operators date-1, date-2 materialize the temporal interval normally associated with narrative events; a detailed description of the methodology for representing temporal data in NKRL can be found in Zarri (1998).

About 150 templates are permanently inserted into HTemp; Figure 1 reproduces the "external" organization of the actual state of the MOVE branch in HTemp; this branch includes the Move: TransferOfService template used in Table 1. HTemp, the NKRL ontology of events, corresponds then to a sort of "catalogue" of narrative formal structures that are very easy to "customize" in order to derive the new templates that could be needed for a particular application. This approach is particularly advantageous for practical applications, and it implies, in particular, that: (1) a system-builder does not have to create himself the structural knowledge needed to describe the events properly to a (sufficiently) large class of narrative documents; (2) it becomes easier to secure the reproduction or the sharing of previous results.

What we have expounded until now illustrates the NKRL solutions to the problem of providing a coherent and complete representation of elementary (simple) events. To deal now with those "connectivity phenomena" that arise when several elementary events are connected through causality, goal, indirect speech etc. links, the basic NKRL knowledge representation tools have been complemented by more complex mechanisms

Figure 1. 'MOVE' branch of the HTemp hierarchy



that make use of second order structures created through reification of the predicative occurrences' conceptual labels (see Zarri, 1998, 2003). For example, the "binding occurrences" are NKRL structures consisting of lists of symbolic labels (ci) of predicative occurrences; the lists are differentiated making use of specific binding operators like GOAL and CAUSE. Let us suppose that in Table 1 we would now state that: "British Telecom intends to offer to its customers a pay-as-you-go (payg) Internet service…," where the elementary event corresponding to "British Telecom … (will) offer to its customers a pay-as-you-go (payg) Internet service…" is represented by the occurrence c1 in Table 1. We must first introduce an additional predicative occurrence labeled as c2 that we will represent here, in a very simplified way, as: "c2) BEHAVE SUBJ british_telecom." c2 means: "at the date (date-1) associated with c2, it can be noticed that British Telecom is (mentally) acting in some way." We will then add a binding occurrence c3 to link together the conceptual labels c2 (the intention) and c1 (the intended result); c3 will have the following form: "c3) (GOAL c2 c1)." The global meaning of c3 is: "the activity described in c2 is focalized toward (GOAL) the realization of c1"—c1 is represented in Table 1.

Reasoning in NKRL ranges from the direct questioning of an NKRL knowledge base making use of "search patterns" (the formal NKRL equivalents of natural language queries) that try to unify the predicative occurrences of the base, to high-level inference procedures employing complex inference engines.

For example, the "transformation rules" try to "adapt," from a semantic point of view, the original query/queries (search patterns) that failed to the real contents of the system knowledge base. The principle employed consists in using rules to automatically "transform" the original query (i.e., the original search pattern) into one or more different queries (search patterns) that are not strictly "equivalent" but only "semantically close" to the original one. In this way, an original query posed, for example, in terms of "searching for evidence of having lived in a given country" will be replied in terms of "searching for evidence of an original school/university diploma delivered in that country."

"Hypothesis rules" allow building up "reasonable" answers according to a number of predefined reasoning schemata, such as "causal" schemata. For example, after having directly retrieved information like "Pharmacopeia, an USA biotechnology company, has received $64,000,000 from the German company Schering in connection with an R&D activity," we could be able to automatically construct a sort of "causal explanation" of this information by retrieving in the knowledge base information like (1) "Pharmacopeia and Schering have signed an agreement concerning the production by Pharmacopeia of a new compound" and (2) "in the framework of the agreement previously mentioned, Pharmacopeia has actually produced the new compound."

FUTURE TRENDS AND THE IMPORTANCE OF NKRL IN KNOWLEDGE MANAGEMENT

In these last years, knowledge has been recognized as one of the most important assets of an enterprise and a possible success factor for any industrial organization, on the condition that it could be controlled, shared, and reused in an effective way. Accordingly, the core of the organization can then be conceived the form of a general and shared "corporate memory," (see van Heijst, van der Spek, & Kruizinga, 1996; Brooking, 1998; Beckett, 2000), that is, of an online, computer-based storehouse of expertise, experience, and documentation about all the strategic aspects of the organization. The construction and practical use of corporate memories then becomes the main activity in the knowledge management of a company. As already stated, this corporate knowledge is mainly represented under the from of narrative documents; the possibility of having at one's disposal a tool in the NKRL style becomes then an essential condition for the concrete setup and for the "intelligent" exploitation of non-trivial corporate memories.

In this context, we can remark that the different working groups managed by the W3C are not, apparently, very interested in the problem of dealing in an appropriate way with everyday life and complex narratives. W3C (the World Wide Web Consortium) is coordinated by MIT (USA), ERCIM, the European Research Consortium for Informatics and Mathematics, and the Keio University (Japan), and includes all the main bodies on earth interested in the developments of Internet and the Web. As an at least partial exception to this attitude, we can mention a recent paper from the W3C Semantic Web Best Practices and Deployment Working Group (SWBPD WG) about defining N-ary relations on the Semantic Web (Noy & Rector, 2005). After having recognized that the Semantic Web languages promoted by the W3C, like RDF and OWL, can only support binary relations (properties) between individuals (see the "RDF and OWL " article in this encyclopedia) the authors try to propose some extensions to these languages that could be able to deal with narratives like: "Christine has breast tumor with high probability," "Steve has temperature, which is high, but failing," or "John buys a Lenny the Lion book from books.Example.com for $15 as a birthday gift," which, obviously, cannot be represented, making use only of IsA and property-value relationships. The solutions proposed range from the introduction of fictitious individuals to represent the n-ary relations to the rediscovery of some semantic networks solutions of the 1970s. Interestingly enough, the authors state that "The SWBDP WG does not expect this document to become a Recommendation (i.e., a W3C Recommendation)" (Noy & Rector, 2005, p. 2). In NKRL, the two first examples—"Christine has breast tumor…" and "Steve has temperature…"—are translated as simple instantiations of the template Experience: NegativeHuman/SocialSituation (3.211), and the example about "John buys…" as an instantiation of the template Produce:Buy (6.361).

CONCLUSION

In this article, we have recalled first the importance, from an economic point of view, that "narratives" have in the context of the corporate knowledge. We have then shown that the usual ontological tools, both the "traditional" (frame-based) ones and the new ones proposed in a Semantic Web context, are unable to offer complete and reliable solutions to the problem of a non-trivial representation and exploitation of narratives. After having recalled the existence of early proposals in this field, we have supplied some details about NKRL (Narrative Knowledge Representation Language), a fully implemented, up-to-date knowledge representation and inferencing system especially created for an "intelligent" exploitation of narrative knowledge. The main innovation of NKRL consists in associating with the traditional ontologies of concepts an "ontology of events," that is, a new sort of hierarchical organization where the nodes correspond to N-ary structures called "templates." Templates—150 at present, but new templates can be easily created on the model of the existing ones—represent formally generic classes of elementary events like "move a physical object," "be present in a place," "produce a service," "send/receive a message," and "build up an Internet site." More complex, second order tools based on the "reification" principle allow to encode narratives characterized by the presence of elementary events linked by relationships like causality, goal, indirect speech, co-ordination, and subordination. After having evoked the query/answering and inferencing tools associated with NKRL, the article ends by mentioning the importance of having at one's disposal tools in the NKRL style for the actual setup of non-toy corporate memories.

Chapter 8.12
Culture-Free or Culture-Bound? A Boundary Spanning Perspective on Learning in Knowledge Management Systems

Robert M. Mason
Florida State University, USA

ABSTRACT

Knowledge management systems (KMSs) have been criticized as having a North American bias. The cultural dimension of KMSs, particularly the relationship of learning and culture in KM projects, are rarely discussed. This paper addresses these concerns in a review of the conceptual foundations for KM and by examining implementations of KM projects. Despite the evolutionary changes in how KM is viewed, KMSs, as they have been designed, implemented, and reported, do not appear to provide for cultural diversity among users. Instead, the reports of KMSs indicate that such systems seek to create and maintain a homogeneous organizational culture, and the adoption of such a shared culture appears to be a prerequisite for success. The paper discusses KMSs as systems that exhibit boundary spanning objects and processes in three different categories, and an analysis of reported projects reveals that boundary spanning across national and ethnic boundaries is rare.

INTRODUCTION: INFORMATION TECHNOLOGY AND KNOWLEDGE MANAGEMENT

Global enterprises increasingly turn to knowledge management systems (KMSs) to raise productivity and remain competitive. Although there is considerable evidence that applications of information technology (IT) for storage and improved access of information help create value, some observers believe that KMSs are limited in their utility because they have been designed with a North American bias (Nonaka, 1995). To understand why this bias may be of concern, it is useful to consider KM programs in the context of the resource-based view (RBV) of the firm (Penrose, 1959).

The dynamic economic environment and the ever-increasing innovative capabilities of global organizations have renewed interest in the RBV. In the opinion of many writers, the RBV has had a significant impact on how information systems and strategy are viewed. The RBV is closely linked with strategy and sustainable competitive advantage (Barney, 1994, 1996), plays a major role in how the modern economic theory of the firm has developed (Madhok, 2002), and perhaps has become the most influential framework for the theory of strategic management and sustained competitive advantage (Barney et al., 2001). The knowledge-based view (KBV) of the firm, foreseen by Drucker (1988), is a special case of the RBV with a focus on knowledge as an organizational resource (Grant, 1996a,1996b; Spender, 1996).

As in the more general case of the RBV's influence on strategic management and competitive advantage, the KBV provides the conceptual foundation for much of the research and design efforts that link information technology (IT) and systems, strategic IT, organizational learning, and knowledge management systems. The KBV has shaped the discussion of KMSs and the role of information technology in strategy and competitive advantage (Huber, 1991; Mata, 1995; Kogut, 1996; Alavi, 2001). While the KBV is the foundation for IT support of knowledge management, most observers agree that knowledge by itself is not the source of a competitive advantage. Instead, organizations use knowledge to gain a competitive advantage through learning (Stata, 1989), by the development of competencies (Rebentisch & Ferretti, 1995; Alavi, 2001), and through knowledge integration (Grant, 1996b; Kogut, 1996). In other words, the value of KM programs depends not only on the application of IT but on the individual and organizational learning and knowledge integration that comes from revealing and using all the intellectual assets of the organization. This requires a mix of technology and organizational processes.

From the perspective of the KBV, a global enterprise that has members from distinct ethnic and cultural backgrounds would appear to have a potentially large asset in the rich source of tacit and experiential knowledge of its members. KM efforts would be one way to access this potential asset. This paper addresses the question of how and to what extent firms may be taking advantage of the knowledge asset represented by having members with diverse backgrounds.

In the remainder of the paper, we will use the terms "KM" and "KMS" interchangeably; both will refer to the set of activities directed toward knowledge asset management. Our approach is in the spirit of socio-technical systems, thus KM and KMS include physical resources (e.g., computers and communication infrastructures), conceptual resources (e.g., repositories of expressed knowledge, tacit knowledge), and the social and organizational processes associated with the use of these resources.

The paper contributes to the discussion of KM by drawing attention to the importance of culture in KM efforts and proposing that KMSs may be viewed as boundary spanning systems. The cultural boundary is important for two reasons. First, ethnic backgrounds and national cultures represent a potential knowledge asset of the enterprise. Second, culture is a significant factor in how people learn, and learning is required for the organization to take advantage of the potential intellectual assets in the organization. The paper uses Carlile's boundary spanning framework (Carlile, 2002) to review the functions of KMSs and to examine how these systems handle culture.

In the following three sections, this paper provides a synopsis of knowledge management approaches and learning from three perspectives:

a) a summary of the goals and expected benefits of KMSs; b) the role and importance of culture and ethnic background in learning; and c) reports on the implementation and use of KMSs and the role of culture in these implementations. The fourth section reviews these KMS implementations using Carlile's framework of practical boundary spanning systems to gain a better understanding of the relative importance of culture in the design and use of a KMS in a particular organization. Based on this review, most KMSs appear to fulfill the boundary spanning role primarily at two of Carlile's three levels. The KM activities at the third level are not directed at spanning boundaries between or among national or ethnic cultures but rather at spanning hierarchical boundaries. As a consequence, benefits that might accrue from the surfacing of differences in tacit cultural knowledge are unlikely to be realized. The final two sections discuss the contribution of this paper, its limitations, and its potential significance for research and practice.

KMS DIRECT AND INDIRECT BENEFITS: THE VALUE OF CULTURE AND LEARNING

Early studies of KMSs viewed such systems as the application of IT to improve the information value chain (Rayport, 1995) by providing an organizational memory (Walsh & Ungson, 1991) and supporting organizational learning (Huber, 1991). A recent review of KM elaborates on this basic value chain model and summarizes prior studies as being focused on four basic processes in knowledge work: creating, storing/retrieving, transferring, and applying knowledge, with each of these processes being subjected to more detailed analyses (Alavi, 2001, p. 114). This conceptual model views KMSs as systematic attempts to make visible the collective and individual knowledge in an organization, develop a knowledge-intensive culture, and support this culture through an IT-enabled infrastructure (Davenport & Prusak, 1998; Alavi, 2001). Specifically, a KMS is viewed as a class of information systems applied to managing knowledge (Alavi, 2001), and IT is seen as an enabler of the basic processes of creating-storing/retrieving-transferring-applying knowledge.

While much effort is devoted to creating repositories of explicit knowledge, KM efforts also seek to identify sources of tacit knowledge, to surface and improve access to this knowledge, and to enable collaborative learning and integration across functional areas (Alavi, 2001; Leonard, 2002; MacCormack, 2002; Fulmer, 2003). In their study of 31 KM projects, Davenport et al. (1998), identified four broad types of objectives: (1) create knowledge repositories, (2) improve knowledge access, (3) enhance knowledge environment, and (4) manage knowledge as an asset.

Reports of tangible benefits have included cost savings (arising from, among other things, reduced time required for knowledge access by having ready access to needed information) and increased revenue and profit. These benefits are recognized as both direct and indirect. Direct benefits are those associated with having the collective knowledge readily accessible to all organizational members: a corporate memory (e.g., best practices, repositories of projects, compilations of data about clients and suppliers, etc.) and the facilitation of communication among the organization's members (a shared structure and communication infrastructure, meta-information that enables members to locate others that may have the information they require), and knowledge transfer (Fulmer, 2003). These direct benefits are antecedents to indirect benefits: knowledge creation and innovation in products and processes, improved collaboration and the synthesis of tacit knowledge from multiple entities in the organization, the creation and maintenance of core competencies, and improved competitiveness. The indirect benefits require learning and knowledge integration across functional boundaries and may be even more valuable than the direct benefits.

However, as noted by many of the cases, it is easier to see the impact of KM efforts on the direct benefits, and firms are able to assign values to these direct benefits more easily than to indirect benefits (Alavi, 1997; Davenport et al., 1998; Hansen, 2002; MacCormack, 2002; Ng, 2002; Soo, Devinney, et al., 2002). The difficulty of measuring indirect benefits may be overcome by measuring their impact. For example, Soo et al. (2002) suggest measuring changes in the innovative outputs that arise from the KM effort.

A global firm comprises organizations that have individuals from many different ethnic and cultural backgrounds. From the KBV, knowledge from this diverse set of employees represents a potential intellectual asset. Appropriating the benefits from this asset, however, requires learning. The next section reviews the relationship between culture and learning.

LEARNING: THE ROLE OF CULTURE

Learning is defined as "a relatively permanent change in the ability to exhibit a behavior; this change occurs as the result of a successful or unsuccessful experience'' (Klein & Mowrer, 1989, p. 2). This definition is consistent with the experiential learning model (Kolb, 1984) and with a prevailing view in the IT field that "an entity learns, if, through its processing of information, the range of its potential behaviors is changed" (Huber, 1991, p. 89). Although these definitions are consistent—each relates to ability or capability to demonstrate behavior, for example—they have differences: Klein and Kolb emphasize experience as the basis of learning; Huber, as an IS researcher, views the learner as an information (or knowledge) processing entity. Huber also posits that an organization learns if "…any of its units acquires knowledge that it recognizes as potentially useful to the organization" (Huber, 1991, p. 89).

Although a discussion of the similarities and distinctions between individual and organizational learning could be interesting and enlightening (e.g., Dixon, 1994), this paper accepts that individual learning is critically important to (if not, as Huber posits, equivalent to) organizational learning. Consequently, the following discussion focuses on individual learning and looks particularly at contemporary theories about culture-based learning.

The study of learning processes has provided a rich field for psychologists for well over 100 years (Mowrer, 1989). Earlier views of learning focused on the stimulus-response relationship and later (particularly Skinner's work) associated reinforcement (rewards) with behavior. Contemporary learning theory, in contrast, has moved away from global theories and looked more closely at concept formation, problem solving, language, and other cognitive aspects of learning. Even the biological aspects of learning are getting new attention (LoLordo, 1989; Mowrer, 1989; Zull, 2002).

Because learning is related to language and language use, and language rules may be "hardwired" as Chomsky proposed in the 1980s (see Baker, 2001, for recent renewal of these arguments), one might conclude that the basic biological foundation for learning is genetic and therefore would not vary from culture to culture. A common biological base does not prevent the development and evolution of learning skills and abilities along different paths in distinct ethnic groups and cultures.

Indeed, for over 70 years researchers have examined the link between culture (and ethnicity) and learning. Hall (1959) summarizes the relationship between learning and culture by saying, "once people have learned to learn in a given way, it is extremely difficult to learn in any other way […C]ulture reflects the way one learns." In 1930, Vygotsky and Luria proposed a culture-centered approach to learning, and others developed this approach further (Vygotsky et al., 1987; Forman et al., 1993; Kozulin, 1998). In this perspective, culture is a source of differences in cognition as cognitive processes are formed through sociocultural activities. Cole and others developed this into a contextual theory of cognitive functions (Cole, 1971), which has as a foundation the idea that different cultures have different systems of mediated learning experience (MLE). Such systems are important to cognitive development, and differences in development (which can arise from different MLEs) become evident when a learner makes a transition from one system to another.

Some have argued "cross-cultural differences tend to disappear under the influence of systematic exposure to formal schooling" (Kozulin, 1998, p. 110, citing Cole, 1990). However, recent research confirms Hall's general statement and provides empirical evidence for Cole's theory that individual cognitive abilities can develop differently in different cultures. Even within the U.S., studies have indicated that some groups exhibit distinct behavioral styles through which they express their abilities to learn. Individuals who have experienced culturally distinct environments while growing up tend to use the skills gained in these environments even after they are adults (Hilliard, 1992). In studies of young adults who have completed schooling in one culture and move to another culture, the results indicate that the nature of the initial formal schooling makes a difference. This difference is not simply a difference in knowledge base, but rather is associated with the basic skills by which one learns new concepts. The young adults exhibited specific difficulties associated with coding schema, concepts, and graphic and symbolic devices used in communication of ideas (e.g., tables, ordering, plans and maps). The difficulties extend to cognitive activities such as the ability to identify or define problems (that is, the ability to apply their knowledge to a set of data and infer the implicit question or issue), the ability to work with multiple sources of information, etc. In short, the young adults are missing cognitive antecedents that would enable them to excel in their new environment (Kozulin, 1998). Kozulin concludes, "…cross-cultural differences in cognition are most probably related to learning practices characteristic of different cultures and subcultures…" and "Two major determinants of cognitive prerequisites are conceptual literacy and facility with other symbolic psychological tools, and a mediated learning experience responsible for the integration of these tools into the cognitive system of the student" (Kozulin, 1998, p. 129). His work showed that intervention could help learners develop the basic skills that would enable them to learn effectively in the new environment.

Research on western-style education has included considerable recent interest in problem-based learning (PBL) as a distinct pedagogy. The potential benefit of PBL is that it provides a better match of formal learning experience with environmental demands after the completion of formal schooling. While some research reports mixed results, there is considerable enthusiasm for this approach in the sciences and medicine (Culatta, 1994; Boud & Feletti, 1998; Jones et al., 2001). The use of PBL to develop competencies—abilities that enable persons to continue to learn—is suggested by Tien, et al. (2003), who compare the competencies identified as goals by the educational systems in Australia, the UK, the U.S., Canada, and Taiwan. Significantly for this review, the competencies in different countries are similar but not identical in wording. For example, Australia and the UK emphasize instrumental competencies more so than the U.S., Canada, and Taiwan. Taiwan lists "self-understanding and potential development" as one of its ten competencies, a skill not articulated by any of the other countries' educational systems (Tien, 2003). Tien's study illustrates that even with many shared goals, the educational objectives of even industrialized countries have differences; the differences across a wider range of countries might be even greater.

Kozulin's studies suggest that cultural backgrounds can perform a critical role in the development of problem definition and problem solving abilities. Moreover, intervention to develop missing skills may be required for a learner to make a successful transition from one learning system to another. Since many KMSs are intended to support group problem solving and learning across functional boundaries, a PBL approach may be a useful way to bridge cultural differences, as suggested by Tien (2003). However, there are practical difficulties in designing PBL interventions for non-western and non-English speaking students (Walker, 1996; Allen & Rooney, 1998).

KMS IMPLEMENTATIONS AND CULTURE

This study examined published reports of KMSs in the literature and focused particularly on the role of culture in KMS and KM project success. For individual cases, this section draws heavily on teaching cases (business school cases of individual implementations) and other summaries of actual implementations (e.g., Davenport et al., 1998). Table 1 summarizes the findings, including this author's summary of what appear to be critical success factors in each case. Table 2 provides additional examples of the implementations summarized by Davenport et al. (1998).

The results of the studies summarized in Tables 1 and 2 are striking in three ways. First is the emphasis by so many of the implementations on standardization, both technical standards and the format of the content. Second is the frequent mention that an organizational culture of knowledge sharing is a correlate of success. Third is the prevalent, though not universal, use of incentives to change behavior and encourage system use. National culture and ethnic background of the users are rarely mentioned.

Only one case directly discusses the importance of national culture. In the Buckman Laboratories case, national culture and non-English speakers were handled explicitly (Fulmer, 2003). K'Netix, as it evolved, encouraged contributions to the knowledge base in whatever language the contributor felt most comfortable. A key component of the system was a group of translators hired by the firm. The translators translated into English the contributions selected by the forum monitors, making these contributions more accessible to employees whose native language was not English. As the system evolved, separate regional forums began, including a Spanish language case database on best practices. In 1997 there were 1,787 cases in English and 685 in Spanish (Fulmer, 2003). At the last report, however, the firm had standardized on English as the common language for contributions, rather than having separate language forums (Fulmer, 2000). Consequently, the only case that gave attention to national culture appears to have "regressed to the mean" and decided on a standardized approach to knowledge sharing.

This review of KM contrasts with the attention paid to culture in studies of other information systems, (e.g., Walsham, 2002) and in other studies of international management, (e.g., Erez & Earley, 1993). The tendency to ignore cultural background in KM efforts suggests that KMS designers may be implicitly adopting the "culture-free" hypothesis as a basis for design. The culture-free hypothesis expresses the thought that there is universality to organizational design and structures—that organizations are micro social entities that can exist without reference to their immediate societal environment. This is in contrast to the culture-bound view that organizations match their structures to fit their societal environment (Maurice, 1976). For a wide range of production firms, the culture-free hypothesis is supported by a meta-analysis (Miller, 1987). There is some evidence supporting the culture-free hypothesis in banks (Birnbaum, 1985), but research that examines this hypothesis in other professional service work is missing. Perhaps the

Table 1. Characteristics and critical success factors (CSFs) of sample KMSs

Source	Context/Users	Technology and Methods	CSFs (author's summary)	Support for multiple cultures?

National Semiconductor	Intranet Lotus Notes	Engineers preferred Intranet; sales and marketing preferred Notes
TelTech Resource Network	Referral of experts (technology not specified) Customer feedback Records of K resources used in proposals and projects compared with "wins"	Basis for business model
Sematech	Formal K transfer practices • K transfer organization • K transfer sessions • Client "assignees"	Face-to-face most effective for K transfer
Consulting firm	Structured K base	Contributions to K base a significant factor in compensation (not entirely successful)
Automobile co.	Specific K application guidelines Decision audits to assess use of Knowledge	Success not established
Automobile co.	Grapevine: interprets, stores, routes competitive intelligence to managers	
Skandia	Intellectual capital audit	
Dow	Review and manage patents	Expect $100 million more in licensing revenue

lack of attention to (national) culture in KM efforts is understandable, particularly given the experience and decision of Buckman Laboratories, but there is no research that supports "culture-free" as a normative approach to knowledge work (or other professional service work).

KMSS AS BOUNDARY SPANNING SYSTEMS

Boundary spanning has been recognized as a necessary component in processes that require coordination and translations among diverse groups (Star & Greisemer, 1989) and different functional groups or "thought worlds" (Dougherty, 1992). Product development is an example of a process requiring such coordination. KM and learning are often discussed in the context of new product development (NPD) processes; (Chapman & Hyland, in press; Verganti, 1998; Ramesh and Tiwana, 1999; Alavi, 2001).

Carlile's (2002) study of boundary spanning objects in an NPD process suggests a useful framework for examining the functions of KMSs. Carlile looked at the four primary functions involved in the creation of a new product (sales/marketing, design engineering, manufacturing engineering, and production) and examined how the new product development team dealt with the specialized knowledge of each area. Each of the four functional areas had different and specialized (in Carlile's terms, "localized and embedded") knowledge, structured in a way that made sense to the group. This knowledge specialization presented a barrier to the effective operation of the NPD team—the team found it difficult to exchange and synthesize knowledge as necessary for the successful development of a new product. Carlile observed that the team overcame this barrier by using boundary spanning objects that operated at three different levels: syntactic, semantic, and pragmatic.

At the syntactic level, repositories enabled communication of facts and agreed-upon tasks and actions. At the semantic level, standardized forms and methods enabled not only communication of facts, but also provided a way for the different groups to clarify differences in meaning. The objects at this semantic level (standard forms and methods) enabled the team to translate the knowledge embedded in one group so that other groups contributing to the product development could understand it. At the pragmatic level, objectives, maps, and models enabled each group to transform embedded knowledge into knowledge that the team (and others not in the group) could understand.

Earlier, Brown and Duguid (1998) pointed out different roles of boundary spanning activity, noting particularly the need for translators between communities. In commenting on Carlile's model, Brown (2002) suggests that Carlile's three levels correspond to three different levels of knowledge ambiguity among communities of practice. At each level, different types of boundary objects are necessary for communication, knowledge transfer, and learning.

At the syntactic level, the differences across the boundaries are explicit, clear, and stable. A shared syntax is a necessary (but not necessarily sufficient) condition for knowledge sharing under these conditions. Taxonomies and classification (e.g., shared databases) provide this syntax and enable the sharing and transfer of knowledge among groups that have a clear understanding of their differences and understand that these differences are relatively stable.

At the semantic level, the differences are neither clear nor necessarily stable (Brown, 2002), and the solution is to provide a means of translating meanings across boundaries. At this level, Carlile (2002) observed the use of standardized forms and methods as boundary objects.

At the pragmatic level, Brown (2002) notes that the knowledge of one group is not neutral to another's. The communities may have different values and/or power relationships, and this level of difference requires boundary objects that provide additional capability beyond the first two levels. At this level, the groups must transform their knowledge and create new (shared) knowledge rather than simply exchanging or transferring knowledge. Resolution of the group differences requires objects such as models and maps, objects that enable the sharing of methods of thinking and the surfacing of assumptions and values. Only when both groups understand these differences can the two communities be co-creators of knowledge that did not exist before the differences were discussed. It is at this level that one might observe the kind of knowledge integration and synergy anticipated by the KBV of the firm.

Considering KM efforts and KMSs as processes to span the boundaries of groups that have different knowledge and experience, one can map the examples from Tables 1 and 2 onto Carlile's framework. At the syntactic level, shared databases (e.g., repositories of best practices, evident in all the cases) provide a way for groups to transfer knowledge. At the semantic level, standard forms and practices (highlighted in Nortel, Siemens, PwC, EYKnowledgeWeb, KPMG's KWeb and Andersen's Knowledge Xchange) provide the means of representation of different knowledge in familiar formats and a means of learning from groups that have a different knowledge base.

At the pragmatic level, where differences in value would be apparent, Tables 1 and 2 provide fewer examples. The use of principles (Buckman Laboratories) as a boundary-spanning object between upper management (the owner) and employees could be considered a pragmatic level object, helping transform the owner's values into practice. An interesting distinction is that the principles are not developed in collaboration with the employees but rather presented to them as a standard—a codified set of behavioral principles that enable them to understand the goals and objectives of the firm. Similarly, one may consider the incentives and efforts to change corporate culture as boundary spanning activities at the pragmatic level.[1] These activities may also be viewed as

Table 3. Levels and functions of boundary spanning processes with KMS examples

Level (Carlile, 2002)	**Community Differences (Brown, 2002)**	**Boundary Object Function or Solution—adapted from (Brown, 2002)**	**KMS Boundary Objects**	**Example KMS**
Pragmatic	Knowledge is not neutral; values and power may differ across boundaries	Transformation Exercise of power	Objectives Maps Models Incentives Forums	Buckman Labs Siemens Andersen E&Y KPMG Others (Davenport, Long et al. 1998) Buckman Labs NASA/JPL

** Only this boundary spanning object/process specifically recognizes cultural distinctions; other pragmatic level objects span top executive and employee communities and may relate more to power than to sharing of knowledge* procedures and routines that serve to translate values from the executive level to managers and other employees—procedures that might also be viewed as semantic. In other words, these processes span a hierarchical boundary, not an ethnic or national cultural boundary.

Table 3 summarizes Carlile's levels, Brown's (2002) view of the community differences for which spanning is required, and the corresponding boundary spanning techniques used by KMSs. Note that all of the KM efforts report use of syntactic boundary objects (repositories).

Table 4 presents the examples in Table 1 in terms of the different boundary objects in Carlile's model. Most objects and processes span communities of practice (e.g., different functional groups) at the syntactic or semantic level, and the majority are operating at the syntactic level—that is, most of the KMSs are set up to facilitate the exchange of knowledge at the level where the knowledge differences are, in Brown's (2002) words, "clear and stable." (The leadership development process at NASA/JPL, assuming it includes dialogue among individuals with different values, is an example of a process operating at the pragmatic level, but the literature provides little detail.) All behavioral change processes and exercise of power (incentives, top management support, etc.) are classified as "pragmatic" processes that span the boundary between executives and other employees—a hierarchical boundary spanning process. Only the forums of Buckman Labs explicitly recognize the role of national culture and provide the opportunity for knowledge to be shared across ethnic boundaries and national backgrounds. The latest report suggested that these forums now are using a single language (English) for sharing knowledge.

CONCLUSIONS AND DISCUSSION

The intellectual foundation for KM is the KBV of the firm. For global enterprises, the tacit and experiential knowledge of staff from different cultures is a potential knowledge asset, one that a KM effort might seek to exploit. However, reviews of KMSs and KM efforts revealed little attention directed toward the cultural or ethnic backgrounds of staff. National and ethnic culture are not important considerations in most KM efforts. There is, however, a universal emphasis on creating and maintaining an organizational culture that supports knowledge exchange and the use of the KMS. Indeed, the success of these KM efforts seems linked to establishing and rewarding a shared organizational culture. The research identified only one system—Buckman Labs—that explicitly recognized the potential value in different national cultures. The latest report on this system indicates that the decision has been made to emphasize English and thus provide a common language base for all employees, so the sole example of a KM that had national culture as a significant dimension has discarded this factor in its latest incarnation.

When examined using the lens of Carlile's pragmatic view of boundary objects, current KMSs and knowledge management efforts have emphasized the syntactic (knowledge transfer) and semantic (knowledge translation) levels of boundary spanning. Boundary spanning at the pragmatic (knowledge transformation and learning) level has focused on internal cultural and behavioral change (related to administrative power) rather than capturing and exploiting knowledge from diverse national or ethnic cultures.

Present-day KM efforts are richer in vision and technique than earlier KM implementations that had a primary emphasis on computer-based repositories of readily available data and knowledge—they include processes and forums in which people exchange knowledge face to face, for example. However, even current KM efforts have not explicitly recognized the potential value of objects and processes that operate at the pragmatic level to span cultural boundaries. It may be that boundary spanning at this level is required to realize the full potential of knowledge integration and co-creation of new knowledge from culturally diverse groups.

Based on this review, it appears that current KM efforts have developed consistent with the "culture-free" hypothesis. That is, by not taking into account multiple national cultures or ethnic backgrounds, these KM efforts tacitly adopt the position that a single organizational culture is appropriate without regard for the societal environment.

This finding raises several issues. The "culture-free" hypothesis is not consistent with other studies that examine culture in IT applications such as group support systems (Watson, 1994) and software production (Walsham, 2002). This raises the question of whether KM is going through a temporary phase and will evolve to a more culturally sensitive form of management, or if KM, as organizational processes and structures seem to be doing for production organizations, will appear the same regardless of cultural environment or the cultural composition of the organization. The stated goal of KM efforts is to achieve knowledge integration and benefit from the collective knowledge of the organization through learning. Because learning is so dependent on cultural experience, it remains an open question if the current culture-free approach is better. Can a culture-free approach enable a KM effort to effectively surface, or otherwise benefit from, the tacit knowledge of its staff from different cultures, the component of the "collective knowledge assets" that comes with the staff? More fundamentally, if KM is intended to exploit the entirety of the organization's intellectual assets, why do current systems appear to have ignored this ethnic and cultural component of the organization's collective knowledge? If organizations truly value all components of the collective knowledge, then KM efforts should pay more explicit attention to the use of objects and processes at the pragmatic level to span cultural boundaries.

By reviewing contemporary learning theory and showing the relationship of culture to learning in the context of knowledge management and knowledge management systems, this paper contributes to the KM discussion by directing attention to the cultural aspects of KM. The paper also highlights what may be a limitation of current KM efforts by viewing them as boundary-spanning systems that often operate at two of the levels in Carlile's model—the syntactic and the semantic—but not always at the pragmatic level.

The research in this paper has been limited to secondary reports of KM efforts taken from the management and information systems literature. Consequently, it has all the limitations that come with depending on the reports of others. Constraints of time and space, and the author's judgment on dealing with these constraints mean that the research may have missed significant reports from other fields. The paper also is limited by the scope of the reviewed literature. It represents a review of the recent KM literature and, while it examined the strategic links of KM to the KBV of the firm, the paper did not critically examine the fundamental assumptions in knowledge ontology and epistemology. The paper did not review, for example, ERP systems and other strategic systems that impose structure on entire organizations. A comparison of such systems with KM efforts might lead to different conclusions and different insights. Moreover, the paper did not examine the philosophical, linguistic, and semiotic foundations for the "syntactic, semantic, and pragmatic" levels in Carlile's boundary spanning model. Such an investigation might provide a richer set of explanations and models with which to improve our understanding of the complex practice of sharing and developing knowledge in organizations.

IMPLICATIONS FOR KM RESEARCH AND PRACTICE

The findings raise several questions about the current designs of KMSs and the evolution of KM. Missing in current discussions of KMSs is a discussion of the potential knowledge assets represented by culturally diverse staff in global organizations. Despite the KM goals of tapping into all parts of the collective knowledge in the firm, this cultural aspect of the organization's knowledge appears, from published reports, to be neglected. Without research on its value, one cannot say that this culturally based set of assets has sufficient value to deserve more formal recognition in KM efforts.

KM efforts appear to be adopting, without debate or research support for its efficacy, a culture-free design. Research is needed to determine if this culture-free approach is most appropriate for KM, or if other, more culturally sensitive approaches to KM would enable an organization to realize even greater benefits than it can realize using current practices. As researchers, we may want to look toward the critical review of our models of KM (e.g., (Schultze, 2002), and to consider the suggestion that we re-frame our systems as supporting emergent knowledge (Markus et al., 2002), in order to think "outside the box" of the prevailing view of KM as applications of IT to improve the information value chain. If a culture-free approach is judged to be appropriate, then research is needed to understand if an intermediate step is necessary to enable individuals from non-western (non-North American) cultures to adapt to these approaches.

From a practical viewpoint, the research suggests that current KM efforts may need to give added attention to the learning dimension of their portfolio of activities. Contemporary learning theory shows a strong relationship between learning and cultural experience—individuals learn based on how they have learned in the past, and early ethnic and cultural experiences provide a base of models and abilities that enhance and constrain an individual's capabilities in new situations. The implication of these theories for KM practice is two-fold. First, staff from different ethnic and cultural backgrounds will not necessarily share a basic set of models when they begin with their new firm, and these staff may benefit from efforts to bridge the gap in meta-learning skills and models. The frequent reports of KM efforts to reward use of a KMS (conform to a corporate norm) may reflect one approach to bridging this gap, but typically these have been reported simply as efforts for corporate cultural change. Second, if a firm is to benefit from the tacit knowledge these staff members bring with them, it may need to incorporate processes and techniques that are not evident in current examples of KM efforts.

ACKNOWLEDGMENTS

This paper is significantly different from an earlier version, and the author thanks Roberto Evaristo and three anonymous reviewers for thoughtful and insightful comments that led to this revision.

INTRODUCTION

In this article, we will develop a framework for educational software development teams that recognizes the conflicts and tensions that exist between the different professional groups and will assist software teams to recognize the intellectual capital created by individuals and teams. We will do so by recognizing the inherent relationship between the tangible elements of intellectual property and the intangible organizational assets that form the basis of intellectual capital and by discussing how knowledge generated by a project team can become an explicit asset.

BACKGROUND

Universities are increasingly becoming developers of complex software-based applications. In-house development ranges from teaching aids and online learning resources to large information systems products that could ultimately become successful commercial ventures. Increased product complexity is easily recognized, yet research shows that the organizational aspects of a software development project are more likely to affect performance and outcomes than technical issues (Xia & Lee, 2004). Successful development and deployment of today's complex educational systems and environments comes with an imperative for an array of different and unique skill sets for the various stages of each project. One can view a software development team as a microcosm of the wider community of practice of software development professionals who work in information and knowledge management in higher education. As Wenger (1998) observes, such communities of practice are not random but constructed around required skills and through a process of negotiation based on mutuality and accountability.

Workforce mobility has increased: academic staff members regularly and easily move between institutions; development and design staff have many opportunities for contract-based work, move to other academic institutions or into the private sector. The ideas that lie behind a successful process or product are increasingly drawn from a wider pool of talent and, as people move around, these ideas are being taken with them and disseminated through informal and new work practices into a wider community of practice. How then does a team, formed to design and develop a technology-rich educational or systems environment, manage and control issues of intellectual capital and intellectual property such that all of those who contribute throughout the life of a project are acknowledged and rewarded fairly and appropriately for that contribution, even after they have left the project?

Team Formation and Relationships

Additional complexity leads to specialization (Jacobson, Booch & Rumbaugh, 1998). New ways of working bring with them a shift in power, where the academic expert will often lack the technical skills, time or resources to turn ideas into reality. Instead, they must rely on a team of experts from other disciplines to interpret their ideas, evolve them, and deliver the finished product. As complexity increases, communication between team members becomes paramount; specialist educational designers are required to translate pedagogy into functional specifications that can be understood by software developers and graphic designers. Modern software teams are project-based, where resources come and go as required.

Software development communities of practice exist within a larger organizational context. Roles and responsibilities will vary and are negotiated depending on the toolset and architecture used, the size of the project, and the culture of the organization (Phillips, 1997; Williamson et al., 2003). Project team members can be full- or part-time employees (academic or non-academic) or contractors retained specifically for the project. As such, these roles exhibit complex relationships and interfaces between each other and the project. In Figure 1, a range of typical roles and relationships found in a tertiary education software development project are shown.

During the various stages of the development process, various players move into prominent roles. One way to illustrate this shifting set of work responsibilities is to list the main players at each stage of the process. We will do this using the classic instructional systems design (ISD) model (Dick & Carey, 1990) as it is so well known. (There are many other models, many of which are discussed in Bannan-Ritland, 2003.) The key players at each stage of the ISD model are listed

Figure 1. Intra-project relationships in software development teams (Williamson et al., 2003, p. 345)

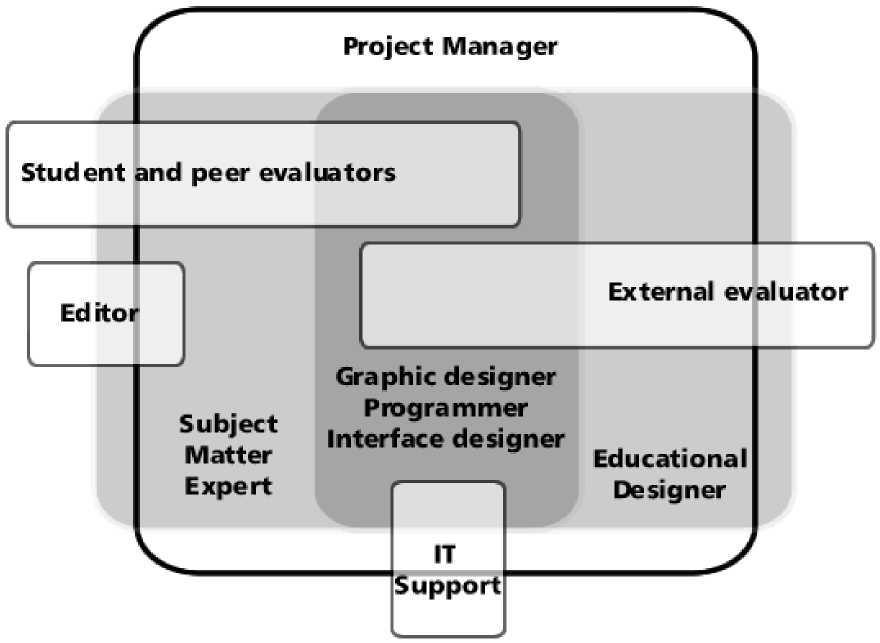

Table 1. Key players at each stage of the ISD model

Stage of the ISD model	Key players
Needs assessment	Subject matter expert
Analysis	Subject matter expert, Educational designer
Design	Subject matter expert, Educational designer, Project manager
Development	Project manager, Graphic designer, Programmer, Interface designer, Editor
Formative evaluation	Student and peer evaluators, Subject matter expert, Educational designer
Revision	Project manager, Graphic designer, Programmer, Interface designer, Editor
Implementation	Subject matter expert, IT support
Summative evaluation	External evaluator
Maintenance	IT support, Subject matter expert (Interface designer)

in Table 1. In reality, each team parcels out the work depending on the skill set of individuals in the team.

It is important to be aware of the different communities of practice that exist in this field and ensure that the role of individual team members is able to be promoted appropriately. Professional recognition can come through either publication, a portfolio of work or through the finished product, and the importance of a successful project to the career development of individuals should not be underestimated. It is important to ensure that academic dissemination of successful projects through publication recognizes the contribution made by all team members, including the non-academic members. Many myths persist in relation to acknowledging the veracity of contribution with regard to educational software, and these often have the potential to leave team members feeling their effort and ideas have gone unrecognized and, at worst, feeling they have been exploited (Williamson et al., 2003). In the second half of this article, we will develop a framework that ensures appropriate outlets for reward and recognition of individual contributions within academic software development teams. Before doing this, we will define what is meant by intellectual capital and intellectual property.

Defining Intellectual Capital and Intellectual Property

Florida (2002) argues that the principal factors for successful software development are talent, knowledge, and intellectual capital (IC). The connection of new ideas and existing knowledge within an organizational context leads to the creation of IC. Stewart (1999) defines IC as the sum of everything everybody in a company, organization, or team knows and which provides some advantage over their competitors. Davidson and Voss (2001) agree, describing individual IC as "the sum of individual imagination, intelligence and ideas" (p. 60). They then extend this definition to encapsulate a model for organizational IC that is based on the talent of individuals (human capital), the knowledge that is captured within systems and processes (structural capital), and the characteristics of relationships with customers and suppliers (customer/supplier capital). Organizational IC comes from the "interplay of all three (structural capital augments the value of human capital, leading to an increase in customer/supplier capital)" (p. 61). In terms of this discussion as it relates to the appropriate recognition and acknowledgement of individual contributions within software development teams, human capital is our primary focus. Human capital is "what walks out of the door at the end of the day" (p. 68); it is a vital intangible.

If IC is the intangible but invaluable contribution of human talent to a project, then Intellectual Property (IP) is a formal measurable subset. It is the tangible product that results from the idea. The UK Patent Office (United Kingdom Patent Office, n.d.) defines four formal types of IP:

- patents for inventions;
- trademarks for brands;
- designs for product appearance; and
- copyright for material (including software and multimedia).

This definition is then extended to cover a much broader and often more intangible grouping that extends to trade secrets, plant varieties, geographical indications, and performers rights. While many see copyright as a way of protecting IP, it is only a subset. Copyright provides recognition of their invention to the creators of software or multimedia products in order for them to be able to obtain economic rewards for their efforts (Macmillan, 2000). Historically, comparisons have been drawn between software development and the traditional arts, such comparisons reinforcing an argument that IP law is focused on the protection of software such that others are not able to modify the source product (White, 1997). It is important to note that copyright extends only to a tangible product, it does not lend protection to the more intangible areas of IC such as ideas and individual contribution. Since copyright has a primarily commercial imperative, it is a limited and perhaps inappropriate mechanism for acknowledging contribution. This is of greater importance in higher educational settings since copyright of educational materials can reside with the institution (particularly with off-campus courses), rather than the individual, and very few educational software products developed for specific content domains in higher education are ever commercialized (Alexander, McKenzie & Geissinger, 1998).

The Relationship between IC and IP

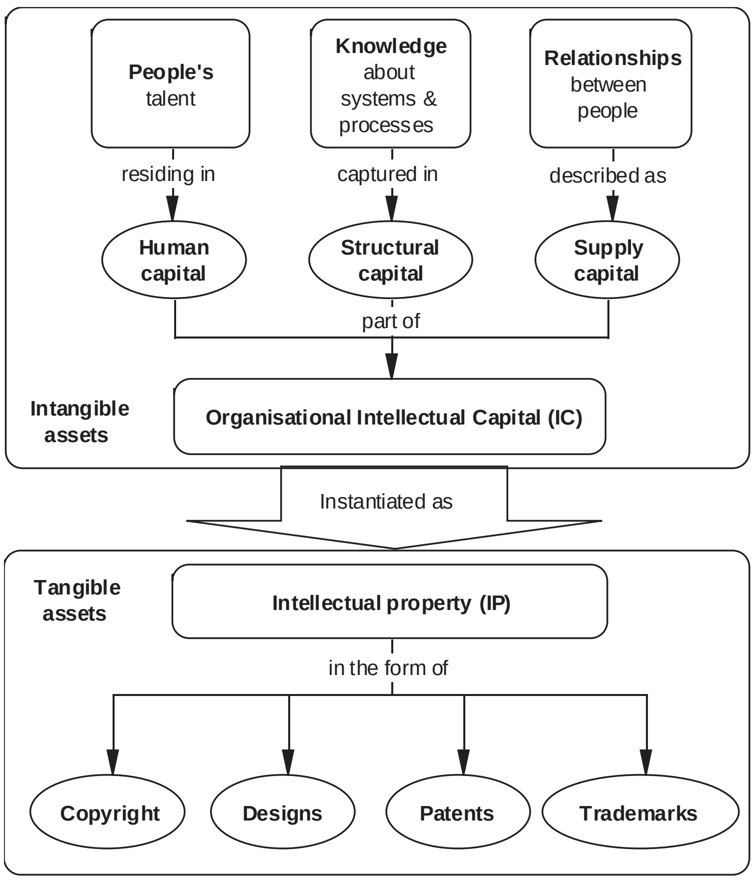
A relationship exists between the tangible elements of intellectual property and the three forms of intellectual capital (the intangible organizational assets) discussed in the preceding section. These are shown in Figure 2.

IC/IP Management Framework

Having addressed the complexity of educational software development teams and defined IC and IP within an educational software context, we will now develop a framework that can be used to ensure proper recognition and reward for individual and collective ideas in such a setting.

Given the critical value of IC in software development (Florida, 2002), it is important that the processes used within educational software development are strengthened and formalized through the adoption of a strong project man-

Figure 2. Intellectual capital and intellectual property (Williamson et al., 2002, p. 342)



agement framework. Project management is a key role in any project involving information and communication technologies and interactive multimedia software, and it requires specific skills and attributes. These include both the hard skills of contract negotiation, budgeting, scheduling, project definition, and scoping as well as the soft skills of human relations, team building, and facilitation (Burdman, 2000; Schwalbe, 2000). Successful teams work well together because they have clear roles and relationships and because the terms of engagement within the team and with external parties are well defined, understood, and agreed by all. This provides a solid platform for the explicit incorporation of IC and IP policies into project documentation so that such issues can be considered early on, preferably during the project scoping phase.

A process and framework are required to recognize knowledge as it is created so that it becomes explicit. Without doing so, knowledge remains tacit and cannot be rewarded or acknowledged, that is, credited to the appropriate team members in the future. Extending this concept, knowledge that is explicit within the team can remain tacit beyond team boundaries if no process is in place to ensure appropriate recognition of contribution. It is, therefore, necessary for teams to negotiate clear, up-front delineation of roles, responsibility, and ownership of both tangible and intangible outputs from the project. This does not prejudge what that ownership might be, merely that the agreement takes place before the project commences. It is important to consider how IC/IP generated during the project's life will be disseminated, in what form, and by whom. Such a clear articulation of roles and responsibilities has the benefit of helping to make the process of dissemination more visible. By doing so, it is hopefully the case that team members will recognize the significance of the different sources of acknowledgment. This in turn will result in up-front agreement on potential opportunities for dissemination of original ideas among the team.

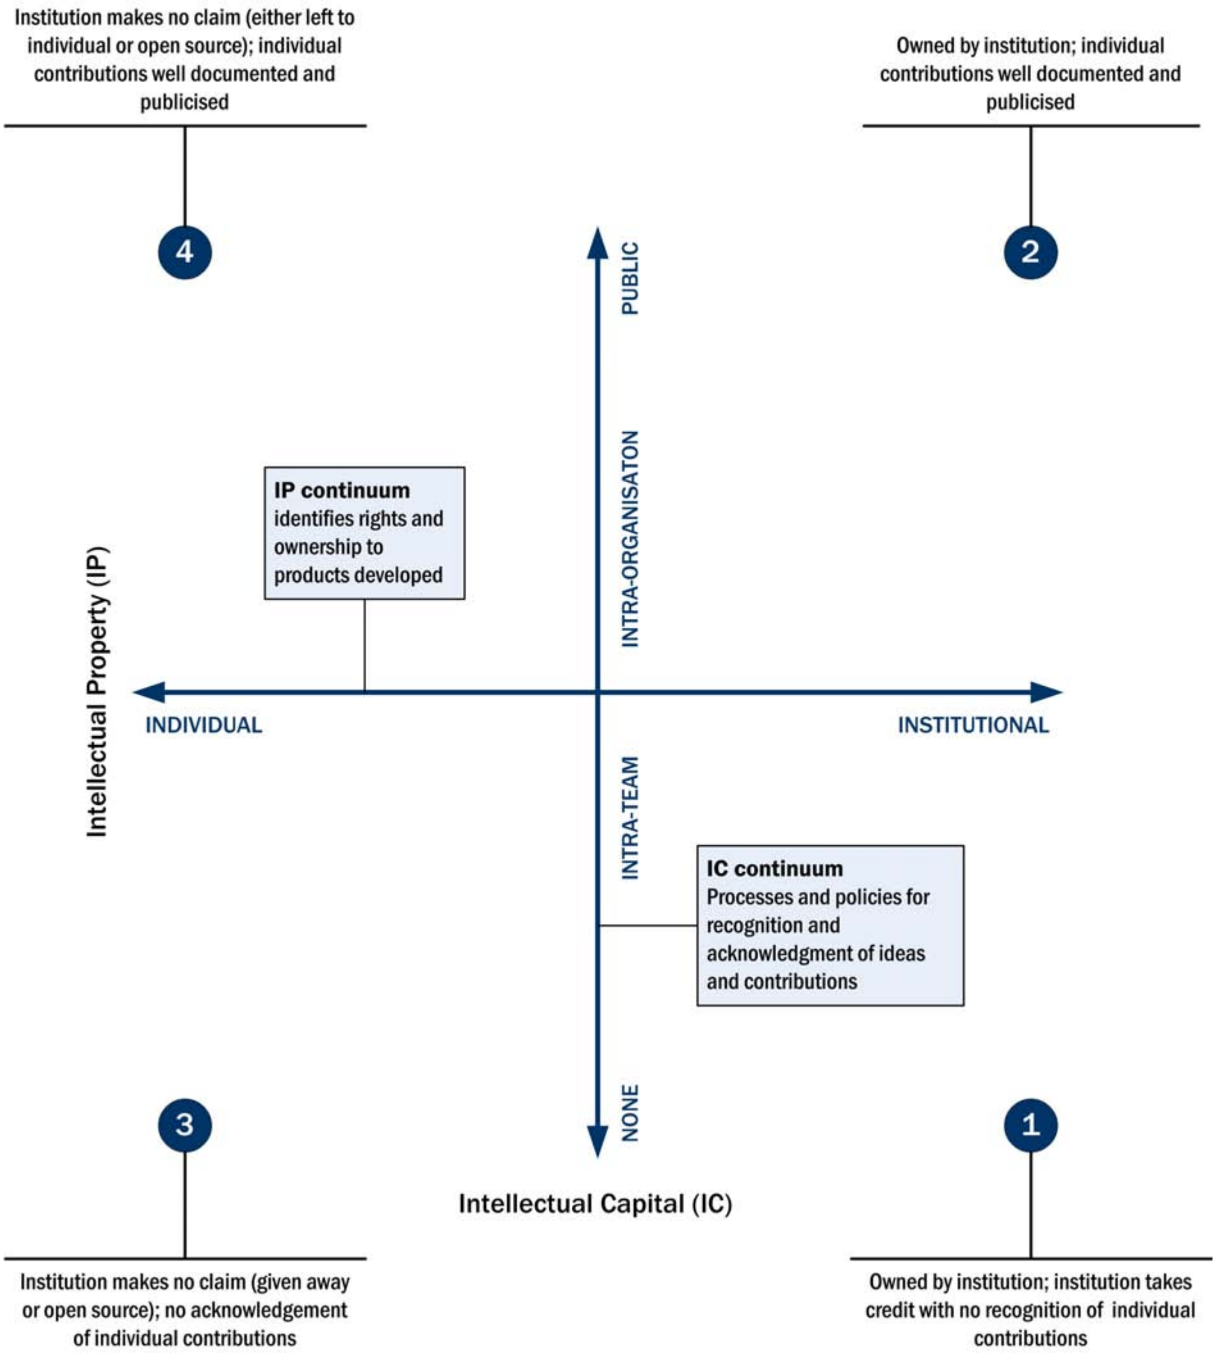
A seldom discussed aspect of the manner in which ideas might be disseminated (and credit obtained) is the potential synergy between individual team members. For example, among academic staff involved in the project, there is a possibility for cross-disciplinary publications.

This framework, shown in Figure 3, maps out two axes: the horizontal axis representing formal ownership of the tangible IP, the vertical axis representing a continuum of recognition for the IC generated during a project, ranging from no acknowledgment of individual effort and contribution to a full public acknowledgment. Intermediate steps include recognition at the team and institutional level.

Enacting the IC/IP Framework

Our discussion so far has shown that, regardless of the nature of the IP ownership, academics and professionals working in software development teams need appropriate recognition for their contributions, but certain factors can prevent this from happening. The challenge, therefore, is to identify a set of project attributes that can be used to inform project management practices such that institutions are cognizant of the need for appropriate recognition. In the following section, we identify seven key attributes of, or processes within, a successful project. The model is developed from a review of the authors' own experiences of software development teams where problems had occurred. This review led to the identification of which weaknesses in the process had resulted in these problems (Williamson et al., 2003). By ensuring that these seven attributes are recognized and actively negotiated by newly forming teams and enacted throughout the life of the team, this model can assist projects in identifying

Figure 3. IP/IC management framework



and filling gaps in the structure of development teams, hence future risk can be mitigated.

In essence, the IC embedded in the members of the project team is articulated in terms of the various IP contributions made by these team members. However, if the focus is exclusively on the tangible products of the process (e.g., software and papers) through only considering the IP, then the worth of ideas (IC) can be underplayed, and their potential may not be realized. We are suggesting that explicit application of these seven guidelines can ensure more successful project outcomes and positive professional outcomes for all members of the team.

The nature of an effective community of practice for software development teams is discussed in terms of Figure 3. The two major axes and the four examples in Figure 3 are used to frame the seven attributes.

Intellectual Property: Individual Affirmation to Institutional Affirmation

Have an IP Acknowledgement Strategy

Highly successful projects exhibit a strong team dynamic which arises when the expertise and knowledge of individual team members can be communicated and shared with others. Part of this process involves ensuring that ideas are fairly acknowledged within and outside the team, whether by portfolio (graphic artists), publication (academics), or product (project managers and programmers).

Have an IP Review Strategy

It does not matter for the purposes of academic critical review whether the subject of study is a written paper, a software product, or a portfolio. Contribution from individual team members needs to be acknowledged through an inclusive authorship policy which is regularly revisited in team meetings. This process can strengthen collegiality and reinforce mutual valuing between team members.

Have a Strategy to Separate IP from IC

The IP might be owned by an organization or institution, but the IC remains with the individuals in the team. Formal acknowledgment of where the ownership of IP lies is important and needs to be negotiated ahead of the commencement of the project. In many higher education institutions, this has become standard practice and involves retaining a competitive advantage and protecting the resources produced by employees of the organization. There are risks associated with key project contributors leaving (for example, a lead programmer) and either taking intellectual property with them or holding a software development team or institution to ransom by withholding access to code or other resources. In some organizations, the IC also remains with the organization via means of a nondisclosure agreement. Communities of practice might consider using a confidentiality agreement as part of a contract or offer of employment in order to keep this issue open and transparent.

Longevity Strategy: Ideas Remain

When a person leaves a team, they cede their IC to the project team or institution, and that contribution should continue to be recognized and acknowledged in project documentation, appropriate publications, and authorship in any finished product. In some projects, this may also involve ceding formal IP to the project (e.g., in the case of commercialization).

Intellectual Capital: No Formal Acknowledgment to Public Acknowledgment

Recognize the Emergent Nature of the Software Development Process and Its Impact on IC/IP for all Team Members

As software becomes more complex, it becomes less and less likely that the original academic imperative that led to the idea for the product will be instantiated in a form initially envisaged by the academic or the organizational unit that initiated the project. The development process and the end result will be strongly influenced by a wide range of individual and group contributions to the process and the product.

Ideas are Perishable

Software has a shelf-life, hence the IC that led to that product is also of limited use. The idea will become superseded and outdated as new ideas and new technologies emerge. For example, there are any number of commercial or free customizable online survey instruments (such as Survey Monkey, http://www.surveymonkey.com) that now exist. Learning Evaluation Online (LEO) was an early system that explored how customizable educational surveys could be developed online using an entirely Web-based interface (Kennedy & Ip, 1998). At the time this was an innovative approach, but it has since been superseded by more robust software. Thus, the IC for LEO has long since expired. The idea behind LEO has been

Table 2. Implications for IP and IC

#	Scenario	Implications for IP and IC
1	IC and IP is owned by institution; institution takes credit with no contribution of individual creativity and effort.	This is a very poor scenario for developing the IC of an institution. Without affirmation, individuals will seek employment elsewhere and take their IC with them.
2	IP and IC are owned by the institution; individual contributions are well documented and publicized.	This is the scenario in a number of institutions worldwide, particularly those involved in distance education. This scenario is problematic when commercial aspects enter the situation as in the case of patents.
3	Institution makes no claim (software is given away or open source); no acknowledgment of individual contributions.	This is often the result of small student projects (although many institutions claim the IP of all undergraduate student work, not postgraduate) undertaken during a course of study). Most software of this type has a very limited life although there are some exceptions (Gunn, 1995).
4	Institution makes no claim (either left to the individual or open source community); individual contributions are well documented and publicized.	This applies to postgraduate work in universities. In many institutions, postgraduate (especially doctoral) students own their IP, and it is up to the student and supervisor to disseminate the details of the project. This aspect is changing as universities try to gain a competitive advantage, and many postgraduate students working in a large research department would do well to consider how the results of their studies might be retained, negotiating with the university in the early phases of the project. For example, some student projects (see moodle.org and moodle.com) have become very high profile products (Dougiamas & Taylor, 2003).

taken up by others and reproduced using different software code. The code is the instantiation of the idea and is the only part of the project subject to IP rights.

Public Acknowledgment of IP/IC Requires the Source Material to be in the Public Domain

Acknowledgment of unpublished work or work not publicly available is not sufficient to acknowledge IC and IP issues in a publication. In the case of academics where affirmation and professional career progress is at least partially a result of publication in accredited arenas such as books and journals, this is clearly not sustainable. Graphic artists, on the other hand, have their portfolios of work with iterations of visual designs that they take with them to the next project or job; and programmers have compilations of code: for these professionals, the publication is less important or substantive in career development. A key issue for an institution is providing the process by which academic publications can be developed without compromising the IP of the individual or trade advantages in the marketplace.

In summary, the implications for the four scenarios in Figure 3 are shown in Table 2.

THE FUTURE: APPLICATION OF THE SEVEN ATTRIBUTES OF THE IC/IP FRAMEWORK

In order to see how these attributes can be enacted in practice, the example of a major Australian multimedia project, An@tomedia, will be used. An@tomedia was designed to support problem-based learning (PBL) of anatomy in the Faculty of Medicine at the University of Melbourne (http://www.anatomedia.com). A number of academic evaluations on the role of An@tomedia in this PBL learning environment have been published (e.g., Kennedy, Eizenberg & Kennedy, 2000; Kennedy, Kennedy & Eizenberg, 2001).

The software has been successfully commercialized by the four subject matter experts (core SMEs or core authors) after other members of the development team ceded any personal commercial claims to the group by means of a legal document to that effect.

Affirmation and acknowledgment involving publishing for academic members (Kennedy et al., 2000; Kennedy et al., 2001), contributions to portfolios for non-academic members, and public acknowledgments in the An@tomedia Web site for every person who contributed in any significant way to the project were not affected by this written agreement. The public affirmation (particularly important for non-academic members of the project team) is illustrated by the observation made by a reviewer of An@tomedia in The Lancet (Marušiæ, 2004) where she mentions the extensive list of credits for all the members of the team (over 60) involved with the project. This process was accomplished quite simply because matters of IP had been previously discussed in the course of project meetings, and the “prior art” that existed and underpinned the educational approach was well known to all project members. Table 3 summarizes the way in which the seven attributes worked in this project.

CONCLUSION

While formalized tools exist for capturing IP generated during a project, most software development teams lack formal explicit processes for ensuring that the IC generated is accurately and adequately apportioned. This article has raised issues relating to how software development project teams are recognized for their contribution and a simple framework for measuring recognition

Table 3. Example of the application of the seven attributes of the IP/IP framework

#	Attribute	Enactment
1	Have an IP acknowledgment strategy	The acknowledgment of IP was never an issue within the project group. Individual contributions were always acknowledged by the core development team, becoming part of the documentation of the project. The extensive documentation ensured that no one was left off the credits on the *An@tomedia* Web site.
2	Have an IP review strategy	The existence of "prior art" was established in the early phases of the project. While the final product did not resemble the initial designs, it was always clear in the project meetings that the team was involved in the instantiation of the educational vision of the project leader (one of the core SMEs).
3	Have a strategy to separate IP from IC	The strategy to separate IP from IC was undertaken by the four principal authors as *An@atomedia* was moved from an interesting project to a commercial product. The documentation resulting from meetings included discussions of commercialization of *An@atomedia* and the associated need to separate IP from IC. The strategy adopted involved consultations with the university's legal advisors and the project team. The IP for the sale and commercial rights to *An@tomedia* were ceded to the four key authors by the other team members; however, the IC remained with members of the project team to use as they required.
4	Longevity strategy: Ideas remain	The credits list contains a list of all members who contributed to the project over a period of many years, including those individuals who either retired (in one case) or moved to other institutions (a number of people). It is possible for all members of the project team to include evidence of contributions to *An@atomedia* by reference to either the Web site or the CD-Roms (the form in which *An@tomedia* is published and sold).
5	Recognize the emergent nature of the software development process and its impact on IC/IP for all team members	The development of *An@tomedia* occurred over a considerable period of time. The genesis of some the clinical approaches adopted in the project were developed by the project leader and occurred well before *An@tomedia* commenced (Eizenberg, 1988, 1991). The use of technology followed as a consequence of the need to develop more effective and engaging approaches to the teaching of anatomy (Driver & Eizenberg, 1995). As the final design of the software emerged, it was always clear in meetings and associated documentation that other members of the project team were involved in the instantiation of prior concepts and developments in new and innovative ways, but the underlying concept derived from the earlier work in paper-based media.
6	Ideas are perishable	*An@atomedia* received a number of awards for innovation and excellence after the first release (see http://www.anatomedia.com/credits.shtml). However, as people come and go from the project, the initial ideas will be superseded or altered to reflect teaching evaluations, changes in the medical curriculum, and improvements in technology. Solutions developed in 1999 or 2000 may not be suitable in 2005. What was once a good idea may not be appropriate in the future, but the three major methods of affirmation remain—publication, portfolio, and vitae for all contributions.
7	Public acknowledgment of IP/IC requires the source material to be in the public domain	The *An@atomedia* Web site provides definitive acknowledgment of the specific contributions of individuals, including the evaluators, programmers, educational consultants, photographers, medical consultants, project managers, dissectors, illustrators, interface and graphic designers, and research assistants, to name a few.

of contribution has been presented. Seven key project attributes or processes have been identified to assist project teams develop an awareness of how project roles and structures can be negotiated so that tacit ideas and knowledge generated can become explicit. Such a model must recognize that the requirements for, and process of, recognition will differ within different multiskilled teams. The application of the framework to one major multimedia project has been discussed.

ABSTRACT

The technological pace and the advent of the knowledge society will set in the next years the new context for e-learning evolution: The convergence of learning and daily life of citizens worldwide will be evident in new services and transparent technologies. Pervasive or ubiquitous learning will be a critical cornerstone and an ultimate achievement of the e-learning research community. Additionally, worldwide efforts will define the social responsibility character of e-learning. In this short visioning paper, we try to address two critical questions: How will knowledge management and relevant technologies affect e-learning in the forthcoming six years? and What are the critical research questions for the new period of e-learning evolution? Many of these aspects could initiate interesting PhD research.

INTRODUCTION

In recent years, the knowledge society has been referred to as our new context of living. Knowledge and learning are anticipated as integrative parts of our strategy toward the promotion of our society. Unfortunately, several obstacles limit the potential value of this new context and its evidence for every citizen.

From this perspective the e-learning research agenda will in the next years realize a qualitative shift in issues that promote the role of e-learning in the context of the knowledge society. The convergence of e-learning and knowledge management will be evident in worldwide initiatives that will foster a constructive, open, dynamic, interconnected, distributed, adaptive, user-friendly, socially concerned, and accessible wealth of knowledge. This seems to be an interesting answer from the scientific community to a volatile world where differences are characterized by points of tension.

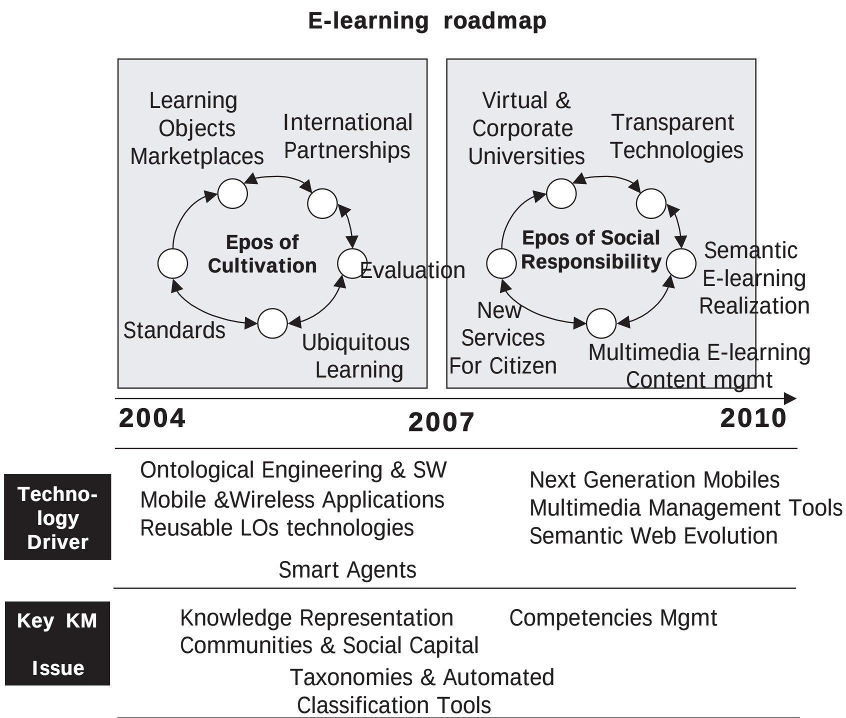
In this short paper, we will provide our point of view for the emerging new era of e-learning. We have decided to distinguish two periods: The epos of cultivation and the epos of social responsibility.

EPOS OF CULTIVATION

In Figure 1, a roadmap for e-learning is presented, where a number of critical milestones provide the significant path for the evolution of the discipline. Toward this direction, knowledge management is a critical enabler. In the following section, we will discuss in more detail the arguments for the presented milestones.

In the first period, 2004-2007, we have classified five important achievements for e-learning:

Figure 1. E-learning roadmap: 2004-2010



- Justification and Communication of Standards: Nowadays, several standardization bodies work toward the specification of standards that refer to different aspects of e-learning, such as technologies, annotation, and interoperability. In the forthcoming years, standardization will include in its agenda themes like quality, semantic annotation and instructional design.
- Development and Exploitation of Learning Objects Marketplaces: In the past years, several initiatives and excellent research works has promoted the discussion of the establishment of distributed marketplaces of learning objects. This trend will continue in the next years. The emphasis will be on the (semi-) automated assembly of learning objects and the extensive development of ontologies that will guide the representation and retrieval of distributed learning content.
- International Partnerships: A challenging milestone for the promotion of e-learning will be the intensive collaboration of academia and industry through several large-scale international partnerships. Several top IT companies will develop important interest in the e-learning market, which will cause an extraordinary effort for the development of several transparent technologies and services that will promote the ubiquitous learning vision. From a knowledge management perspective, this cornerstone will require the exploitation of theories that refer to the networked organization.
- Ubiquitous Learning: Ubiquitous learning stands for the new era of learning services that will be promoted through transparent new technologies and services. The debate in this area has started already, and, from this perspective, e-learning will exploit further new communication medias as well as new instructional models. The ubiquity of knowledge will be an interesting research theme.
- Evaluation of E-Learning: Another interest research stream in the forthcoming years will be the specification of new approaches for the evaluation of the learning outcomes in e-learning. New insights will be based mainly on knowledge management and especially on the codification of the e-learning journey that each learner selects in an adaptive e-learning system. Additionally, knowledge management literature and communities of practice will provide scalable considerations for the evaluation profile, which will constitute qualitative features like social interaction and learner-led semantic annotation of content.

A stream of four technologies will guide this new era of e-learning:

- Ontological Engineering and Semantic Web: The exploitation of ontological engineering and semantic Web, in the context of e-learning, will support new systems and new approaches on content codification as well as new reference models.
- Mobile and Wireless Technologies: These technologies will provide extraordinary challenges for learning content diffusion. The great challenge for knowledge management and e-learning will be to exploit theories of multimedia content management, and, from this perspective, we will face an increased share of synchronous learning content delivery: To go a step further, we believe that the distinction of synchronous and asynchronous delivery mode will be eliminated.
- Reusable Learning Object Technologies: The quest for the development of adaptive and personalized e-learning systems in the last five years was at the top of the e-learning

research agenda. The bet of researchers for the new period is to embed instructional elements in revealing learning objects and to value ingredients that new knowledge management techniques will support. A vision in this direction is the automated argument markup of learning content as well as its semantic annotation.

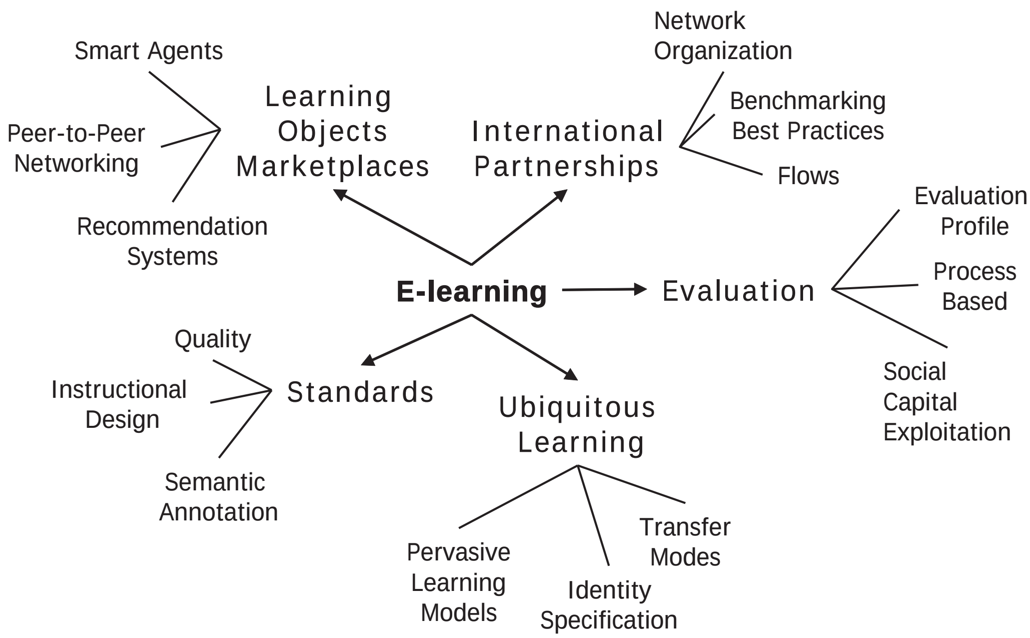
- Smart Agents: The sophistication of e-learning systems and the promotion of value adding services to learners will require an extensive boost on the role of smart agents for e-learning. The critical theme in this context is the practical interpretation of several interesting conceptualizations on agents.

EPOS OF SOCIAL RESPONSIBILITY

Undoubtedly, the advent of the knowledge society reveals the importance of learning as the major process for the formation of a high performance economy. Thus, the second period in our horizon is characterized by a systematic strategy to justify the societal value of e-learning. In this direction, five critical pillars will promote the societal role of e-learning in the context of the knowledge society:

- Virtual and Corporate Universities: It is true that in the last decade several virtual and corporate universities have emerged. In the new e-learning landscape, these institutions

Figure 2. The milestones and critical issues in the epos of cultivation

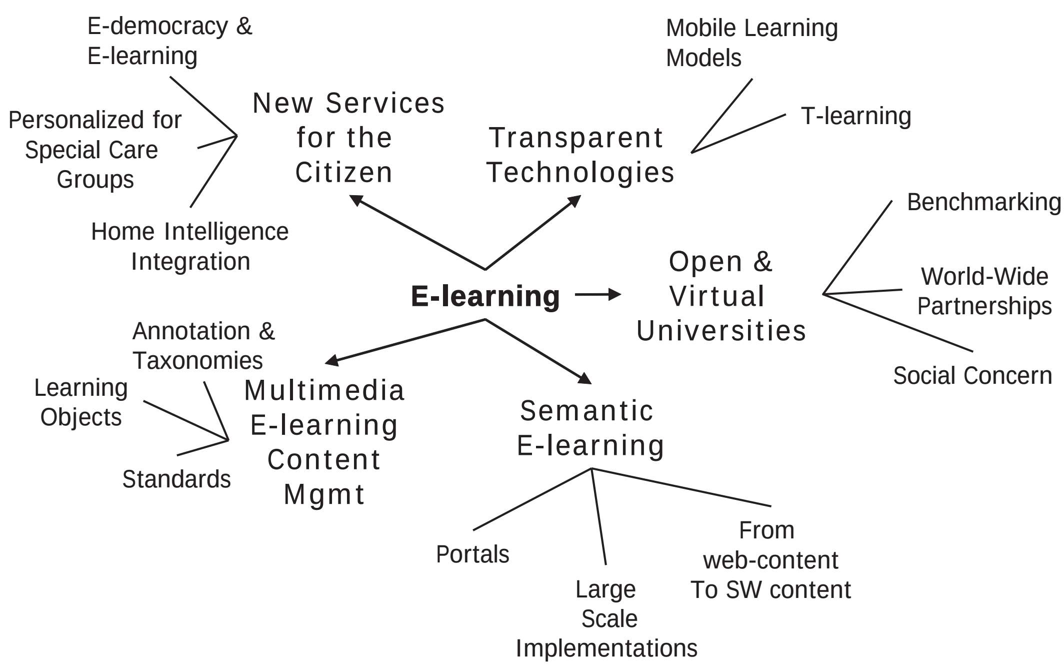


will promote worldwide initiatives that will extend the learning possibilities. Moreover, they will be directed in two general dimensions: academia and industry collaboration; and government funding for targeted e-learning to specific populations.

- Semantic E-Learning Realization: The evolution of the Semantic Web promoted by W3C in terms of standards, languages, and tools will require extensive work in specific scientific fields for the exploitation of its contribution to specific contexts. From this perspective, the semantic Web propositions will provide fertile ground for interesting research concerning the annotation of learning content as well as the provision of Semantic Web-enabled services for learners.
- New Services for the Citizen and Transparent Technologies: Semantic Web evolution, as well as the promotion of mobile and wireless networks worldwide, will help the provision of new services that will incorporate the perception that learning is inevitable in any aspect of human life.
- Multimedia E-Learning Content Management: Within the epos of social responsibility, the interest in multimedia content knowledge management will continue to trigger enormous research effort. At the end of the period, we will realize fully automated tools for natural language semantic Web-enabled recognition, and this will support transformation of multimedia content types (e.g., from speech to text, from text to speech, from video to text, argumentation, etc.).

The key characteristics of this period will be the automation of argumentation, the fully person-

Figure 3. The milestones and critical issues in the epos of social responsibility



alized and adaptive systems, and the move from PC-based e-learning facilitators to mobile smart devices and home intelligence systems. The critical milestone for this second period of e-learning evolution will be the integration of information systems that in previous stages have supported e-learning (e.g., PCs, mobile systems, wireless applications, videoconferencing, etc.) to a single multimedia semantic-enabled and ubiquitous learning environment. This technological pace will subsequently support several value adding services for learners worldwide.

EMERGING KM-ENABLED E-LEARNING RESEARCH AGENDA

The previous discussion of the roadmap on e-learning can be used to outline some critical research questions for e-learning. We have decided to provide a short list through a careful selection of issues in order to help readers, especially readers interested in undertaking research on the convergence of knowledge management and e-learning.

A. Epos of Cultivation

1. Standards
   - Integration of instructional design principles with e-learning content standards
   - Exploitation of peer-to-peer networking as an enabler of learner centric standardization
   - Multimedia e-learning content standardization
2. Learning Objects Marketplaces
   - Automated assembly of distributed knowledge objects toward the provision of e-learning unique experiences
   - Ontology-driven e-learning engineering
   - Data and flow modeling of learning activities
3. Ubiquitous Learning
   - Pervasive learning models toward the integration of multi-channel content delivery
   - E-learners identity specifications
   - Modes of ubiquitous e-learning transfer / learning bouquet
4. Evaluation of E-Learning
   - Justification of the evaluation profile from a social capital perspective
   - Process-based evaluation
5. International Partnerships
   - Benchmarking of e-learning practices
   - Models of network integration in e-learning international partnerships

B. Epos of Social Responsibility

1. New Services for Citizens
   - E-democracy and e-learning convergence: a multifold analysis of managing learner profiles
   - Personalized e-learning services for people with disabilities / special care groups
2. Open, Virtual, and Corporate Universities
   - Open and virtual universities as networks: a knowledge management perspective
   - Benchmarking and best practices
3. Multimedia E-Learning Content Management
   - Annotation of multimedia content management
   - Multimedia learning objects and standards
   - Taxonomies and automated classification tools

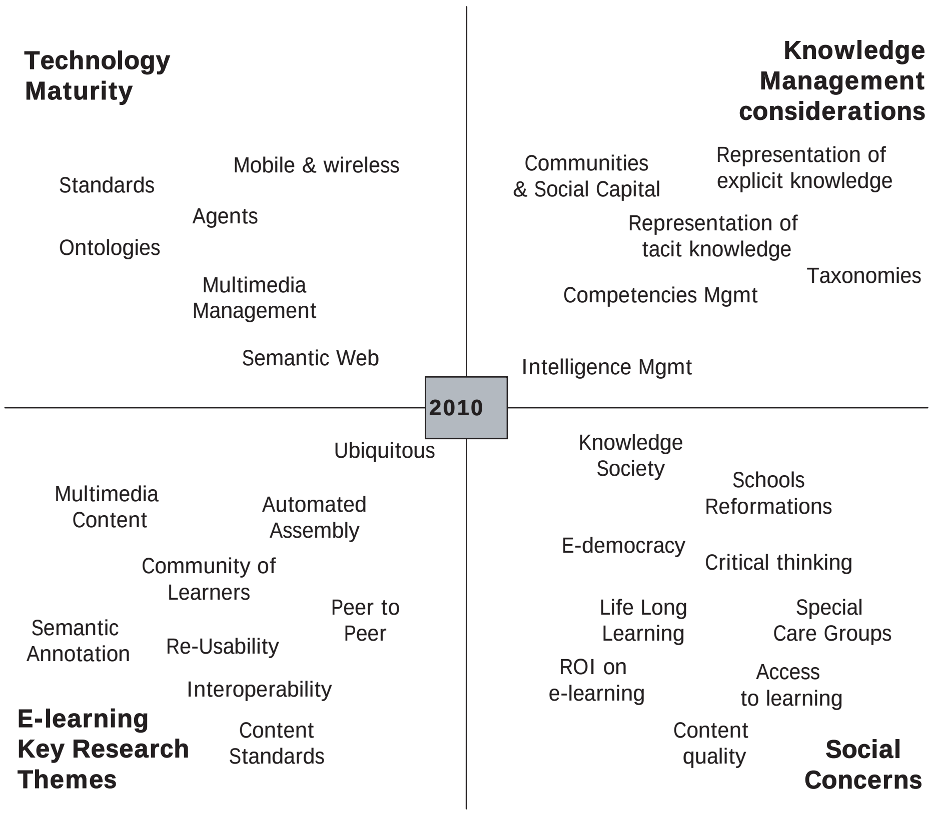
4. Semantic E-Learning Realization
   - Semantic Web portals specifications
   - Methods for the upgrade of Web-based e-learning content to Semantic Web e-learning content

CONCLUSION

This special issue themes relates to an inevitable aspect of e-learning. Knowledge management will continue to develop more and more interest in e-learning for two basic reasons: (1) there is a solid linkage between these two fields, since they represent two critical aspects of human identity; and (2) e-learning as a context is an excellent research field for researchers coming from the KM research community, since learning challenges the representation and the exploitation of knowledge for learning purposes and provides an excellent test bed for experiments and qualitative research.

In Figure 4, we provide our visionary view for the evolution of e-learning. Four dimensions — technology maturity, knowledge management considerations, social concerns, and e-learning key research theme — summarize important shifts and milestones for e-learning. The ultimate depicted objective in 2010 is the realization of a knowledge society with the characteristics of

Figure 4. The challenging new research context of e-learning and knowledge management convergence



ubiquitous learning and the facilitation of intelligence management through the tools and services of the transparent semantic Web.

Toward this direction, we have planned a corresponding issue to this special publication: In early 2005, we will publish with IDEA Group Publishing the edited book, Intelligent Learning Infrastructures for Knowledge Intensive Organizations: A Semantic Web Perspective.

PROBLEMS OF EDUCATION IN KNOWLEDGE SOCIETY

Since technological changes are touching many aspects of today's society, education cannot stay behind; in a world where information is the key to progress, the education of its citizens should not be based on expositive means alone (Adell, 1997). The inevitable increase in complexity and quantity of the information that is available and necessary has led to a need for continuous learning. Information handling requires a profound transformation of learning and teaching methods: from a model in which the teacher is the monopolizing agent and the authorized representative of knowledge, we must move towards a model that offers the student room for individual exploration and self-learning. The student needs to build relations, discover the process from within, and feel stimulated to draw his own roadmap (Piaget, 1999). This way, he will not only learn, but learn to extract the relevant information, that is to say, he will "learn to learn" in actual society.

This kind of learning can only be obtained through action strategies that are not perceived as restricting obligations, but rather as interesting learning options. Content, for instance, should be represented not as an object of study, but rather as necessary elements towards a series of objectives that will be discovered in the course of various tests.

Another characteristic of actual education is that students come from different environments and have different ages and education backgrounds, which make it more complicated to integrate them into one single group. Real personalized attention would require many more teachers and much more time. Add to that the increasing demand for continuous education, with flexible timetables and subjects, and it becomes clear that the current programs are much too rigid.

Tele-education platforms try to meet these needs by providing individualization, physical and temporal flexibility, and a higher level of student implication. However, the contents of these platforms remain the same as those of traditional systems, even if their presentation format is adapted, and therefore they do not substantially contribute to the improvement of the learning process (Martínez, 2002).

KNOWLEDGE MANAGEMENT IN EDUCATION

The learning process consists of a modification of our conduct that, by extracting knowledge from acquired experience, enables us to tackle problems (Wiener, 1967). This definition highlights the two basic aspects of all learning processes: knowledge acquisition, and the experience that leads to it (see Table 1).

The way we can access knowledge strongly depends on how it is stored. According to this criterion, three types of knowledge can be distinguished (Wiig, 1995):

- Tacit Knowledge: Knowledge that is so much embedded in the individual's brain that he himself cannot explain it. Since this kind of knowledge is only accessible by observing

Table 1. Summary of current systems for the representation, management, and storage of information

Representation System	Stored Information	Applied Transformations	Obtained Information
Knowledge Management Systems	Explicit knowledge plus mechanisms to share and acquire tacit knowledge	Meetings, put in common knowledge, relations between knowledge	Explicit knowledge as object and process Possibility of acquiring tacit knowledge
Data Mining	News	Relations that can obtain rules or categories	Explicit knowledge as object and process
Knowledge-Based Systems	Data, news, and relations	Rules for making deduction Transformations of frames	Explicit knowledge as object
Databases	Data	Consults: filters with data	News

the individual's behavior (Nonaka & Takeuchi, 1995), at present we cannot physically store it.

- Implicit Knowledge: Knowledge that is embedded either by the organization, which locates it in procedures, models, and techniques, or by individuals who store it in their brain. In this case, the knowledge can only be accessed, located, and communicated by means of questions and discussions.
- Explicit Knowledge: Knowledge that is easily accessible and documented in normal knowledge sources, frequently well organized. One can typically find this knowledge in books and in digital format, and it must be formalized in order to be significant. Actually, only formalized knowledge can be electronically stored, shared, and effectively applied.

After studying the representation, storage, and information management systems that are currently in use (including databases, data mining, knowledge-based systems, and knowledge-management systems, illustrated in Table 1), we have reached the conclusion that the best currently available approach is knowledge management, which issues from the business environment and has proven its success on many occasions (Tissen, Andriessen & Deprez, 2000). A knowledge management system not only stores information in the shape of news, it goes further by making the users a part of the system itself. In addition, this type of system incorporates mechanisms that allow us to share tacit knowledge: meetings, pieces of advice, examples, and so on. In this way, one can say that these mechanisms facilitate the acquisition of every kind of knowledge.

Knowledge management has obtained positive results in the business world and could very well be applied in the educational sector. Apart from being the best currently available way of handling large amounts of knowledge and knowledge interrelations, knowledge management allows the user to personalize the acquisition of knowledge, improving the current systems.

Unfortunately, the intent to include knowledge management in learning systems (Calés, 2002) has so far been limited to including only certain aspects such as lists of "Frequently Asked Questions," or mechanisms for the exchange of tacit knowledge, but without including these contents in the knowledge base or allowing the feedback of the student's experiences.

To improve the learning process, e-learning models should have the following characteristics:

1. Provide individual attention, taking into account the student's preferences about learning strategies, different kinds of materials, their previous knowledge, and so forth.
2. Facilitate all the available information, in different formats coming from different sources, for the students to learn how to choose the most relevant elements for their learning.
3. Join strategies to get and raise students' motivation and encourage their inquisitiveness, relating the available information with the students' interest, proposing the possibility of exploring deeper the same or related subjects and using the computer games strategies that give rise to investigation.
4. Propose an apprenticeship approach by means of works and problems to solve, so that the students' knowledge grows as they go on with the resolution of their works.
5. Provide information from different sources, to allow seeing different points of view of the same realities.

These characteristics can be achieved with the use of actual technology. In short, it is proposed that the use of a knowledge management system—which, using a global ontology, allows us to establish the highest quantity of relationships between the available information and its classification at different levels. From this support of knowledge, we will establish the apprenticeship by means of the task proposal, using computer game strategies, and the system will interact with the student in order to motivate him, to stimulate his capacity of raising questions, and it will show him the information according to his preferences.

A PROPOSAL FOR A MODEL

Tools for the Sharing of Tacit Knowledge

To get an adequate enrichment and working of this system, there must be (synchronous and asynchronous) "meetings" with the following participants:

- Students interested in a series of related subjects
- Tutors meeting in related subjects
- Students and tutors in related subjects

In addition, the same groups may participate in meetings on any subject.

The reason for the proposal of all these sorts of meetings is that, this way, the ideas posed in each one can be quite different. Students talk with more freedom without tutors, and vice versa, but there are points that can interest both groups together.The reason for meeting people interested in different subjects is that from sharing ideas, understandings, and so on, new knowledge is gained through group work which could not be obtained separately.

In a telematic model, where the predominant communications are asynchronous and technology based, there must also remain room for personal meetings (e.g., videoconferencing), and for the revision of already held meetings.

Institutional Memory

Most of works and examples of knowledge management systems in education focus on the philosophy of knowledge sharing and on communications to circulating tacit knowledge. In order to get a more complete system, content should be included in it, to facilitate students to acquire new skills and knowledge. That is to say, there should be an explicit knowledge base or institutional memory, which comprises knowledge and facilities for learning.

This institutional memory must contain thematic units and the processes that the student is supposed to control in each of the units, detailed down to the most basic level of the course and real problems related to each process. In order to implement the relations between elements, we will have to use a global ontology with the aim of separating the conceptual structure from the storage structure (Gruber, 1993). XML or java classes offer different possibilities for the implementation of the ontology.

Help Tools

The student accesses a series of help tools that are structured according to the knowledge management instructions:

- Yellow Pages, which include documents of different formats: images, videos, texts; recommended bibliographies; lists of experts in the field; students that have achieved a similar level; examples of solutions of similar tasks; related or similar tests; links to related subjects.
- Learned lessons including best practices, worst practices, and false maneuvers.
- Frequently asked questions (FAQs).
- Communication tools: e-mail, discussion, chats, videoconferencing.

- Basic material to resolve the tests in various formats.

Personalization

We propose a method that allows us to store and access the knowledge in a progressive way, to embrace the non-linear structure of the information and the experience-based active learning (Pedreira, 2003). Instead of directly presenting the contents that are to be studied, we present tests that, in order to be carried out, require the aimed knowledge. If the student cannot carry out these tests, they will be divided into easier subtests. By using the help tools, the student gradually constructs his own knowledge through practice. Once he finds the solution to a problem, he will be confronted with more complicated tasks that require the previously acquired knowledge. In the course of the learning process, he will be able to use the available communication tools and thus increase the information that is stored in the system.

The design of the tasks follows computer game strategies, whose characteristics stimulate motivation and action. Like in a game, the student knows the final aim, but not the intermediate steps, which keeps his interest level constant. There is a high level of interaction; errors and successful actions are detected immediately; the rhythm of the study is self-regulated; the classical user manual is replaced by an interactive demonstration of the rules; and the student will also have access to information on related subjects, depending on his preferences.

PRACTICAL CASE STUDY

At the Computer Sciences Faculty of the University ORT Uruguay, the Programming I course has carried out an experiment that links learning-through-experimentation to the support of a knowledge management system, with a simplified prototype developed in Java which incorporates basic programming concepts in its knowledge base (Friss de Kereky, 2004). The ontology was implemented with a class scheme and establishes various knowledge types, each with its corresponding attributes. As the experiment was carried out as an addition for attending classes, tacit knowledge can be shared by means of personal communications.

The experiment divided the students into three arbitrary groups: the first group (A) followed the usual theoretical-practical classes, the second group (B) worked on problem solving, and the third group (C) also worked on problem solving, but received the additional help of the developed environment.

The statistical tests carried out analyze: (1) problem comprehension, (2) search for new ways to solve familiar problems, and (3) the ability to apply already known strategies to new problems (transfer of knowledge).

The results reveal the following: (a) none of the cases presents any significant changes in the problem comprehension, and (b) the group that used the environment obtained the best results in the search for new ways to solve problems, followed by the problem-solving group. Both the use of the environment knowledge and the usual classes favor the transfer of knowledge. The comprehension of the problem seems to improve by the use of the environment or the usual classes.

The School for Industrial Design of the University of A Coruña is carrying out a complementary experiment in its Basic Computer Sciences course. This first phase did not make use of a specific system; it used a standard platform of Web-based e-learning that functions as an information repository and incorporates the necessary communication mechanisms for the circulation of the tacit knowledge. The results of this experiment are very positive. At first, the students are puzzled about the problem, but by making use of the information that is available in the system, of the search hints for more information in the Internet, or of the division into sub-problems, they are able to find the solutions within a reasonable time span and they feel motivated to tackle more problems. Half of 140 students were arbitrarily selected to use the platform and follow the proposed tasks; the rest assisted the habitual classes. From the first half, 74% passed the course, in front of the 61% in the second half.

This first approach requires the control and advice of the teacher, but we are working on the development of a system that allows autonomous and personalized learning, in which the biggest workload of the teacher lies in the tasks before the learning process; afterwards, the teacher becomes a tutor who lets the student manage his own learning process.

CONCLUSION

Knowledge management can be an interesting approach to the implementation of a learning system, because it can maintain the existing interrelations of the information, it provides explicit knowledge, and it circulates the tacit knowledge.

The proposed model incorporates the contents in its institutional memory to improve their assimilation, and possesses an ontology that maintains the information and its categorization independently. It also proposes learning through action, while guaranteeing that the acquired knowledge is used in the execution of the tasks. The approximations with reduced prototypes show that the use of the environment allows the student to extend or improve his problem-solving methods and his abilities to transfer knowledge.

Chapter 8.16
Incentive Structures in Knowledge Management

Hamid R. Ekbia
University of Redlands, USA

Noriko Hara
Indiana University, USA

INTRODUCTION

The role of incentives in organizational behavior has long been recognized and studied (Whyte, 1955; Hertzberg, 1959). This role becomes ever more paramount in knowledge management (KM), where users also become creators and contributors: The voluntary sharing of knowledge by individuals is a key element in the implementation and success of any knowledge-management endeavor. Having gradually recognized this, the KM community has theorized, examined, and implemented various incentive structures to promote knowledge sharing and system use in organizations. This article investigates some of these incentive structures, their underlying assumptions, as well as the issues and questions that they raise for KM theory and practice in general.

The article continues in the next section with a brief history and a general discussion of incentives in organizations. It then discusses the theoretical underpinnings of different approaches to KM as they relate to issues of incentive, and provides examples of practical incentive structures used by organizations. Next, it presents an analysis of the examples in the previous section, discusses possible future trends, and finally draws conclusions in terms of appropriate incentive structures for knowledge sharing.

BACKGROUND: THE CENTRAL DILEMMA OF KNOWLEDGE MANAGEMENT

Organization and management scientists have long studied the role of incentives in organizational behavior. Whyte (1955), for instance, provides a classic study of "the 5 M's of factory life: men, money, machines, morale, and motivation" (p. 1). The dominant scientific management view, which held sway in the incentive systems of the time, was based on an economic model of rational human beings who seek to maximize their individual material gains. Whyte challenged this model and replaced it with a socioeconomic model that studies human reaction to incentives in the context of their relationships with other human beings (fellow workers, work groups, managers, etc.). He argued that incentives can be symbolic and much broader in character than purely material and monetary, and emphasized that "we change sentiments and activities through changing interaction" (p. 227). The lessons of the latter half of the last century, including those of KM, seem to support Whyte's model as a more realistic picture of human organizational behavior.

The situation in knowledge management is obviously different from the factory-floor situation studied by Whyte (1955). Not only are we dealing with a different work environment in terms of organization, management, culture, technology, and so on, we are facing a new type of economic agent, usually referred to as a knowledge worker in the literature. Although this term implies a different type of economic activity from earlier ones (e.g., factory work), it does not necessarily mean that knowledge workers have a totally novel psychology in their reaction to incentives. To the contrary, we argue that Whyte's original insights are by and large true of the current work environments as well. To demonstrate this, we introduce what might be called the central dilemma of knowledge management.

A widely studied phenomenon in the social studies of cooperative behavior are the situations known as social dilemmas: namely, those where individual rationality (trying to maximize individual gain) leads to collective irrationality (Kollock, 1998; cf Cabrera & Cabrera, 2002). Well-known examples of social dilemmas are the tragedy of the commons, where overuse of a shared resource (such as land) by beneficiaries (such as herders) would result in its ultimate depletion (Hardin, 1968), and the phenomenon of free ride, where individuals are tempted to enjoy a common resource without contributing to it (Sweeney, 1973). It has been suggested that knowledge sharing can be understood as a special case of a social dilemma (Cabrera & Cabrera; Connolly, Thorn, & Heminger, 1992). That is, if we consider knowledge as a common resource of an organization, individual workers are often faced with the questions of whether or not, to what extent, and under what circumstances should they use, relate to, and contribute to this common property. Although there are clear differences between a natural resource, which is physically constrained in the extent of its use, and knowledge, which is not depleted by use, this conceptualization of knowledge sharing as a social dilemma is rather useful. One way to understand this dilemma is through the fact that contribution to a KM system involves cost (in terms of time, expertise, job security, etc.) that may not be accounted for or paid off by the organizational incentive structures. This is the essence of the central dilemma of KM, which can be articulated as follows:

Why should a knowledge worker contribute to the shared knowledge of the organization if the cost of doing so for the individual is higher than its benefits?

This dilemma gives rise to a tension that is inherent in almost any knowledge-management effort. Incentive structures could therefore be broadly understood as attempts to resolve or reduce this tension. Such attempts should at a minimum address the following questions (Cabrera & Cabrera, 2002, p. 691).

- Why do people share or not share information with coworkers?
- What motivates a person to give up personal knowledge to a third party?
- What are the main barriers that an organization may face when trying to foster knowledge sharing among its employees?
- What can an organization do to overcome those barriers?

The ubiquity of the above dilemma turns these into central questions in the theory and practice of KM. The following discussion demonstrates that various approaches to KM partly diverge on the basis of the answers that they give to the above questions.

INCENTIVES IN KM THEORY

There are different ways to classify KM approaches. For our purposes here, we are going to distinguish among three different views of KM: the techno-centric, human-centric, and socio-technical.

The Techno-Centric View

Roughly speaking, the techno-centric or product-oriented view emphasizes knowledge capture as the main objective of KM. This involves two major dimensions: a cognitive dimension that takes knowledge as something that can be codified, organized, stored, and accessed on the basis of need, and a technical dimension that emphasizes the role of new information and communication technologies in the knowledge-capture process. As such, the techno-centric view tends to formulate and answer the above questions in mainly cognitive and technical terms: People share their knowledge to the extent that they can elicit it and their technologies can capture it. The main barriers to such capturing are therefore either cognitive or technical in character, as are the solutions to overcome the barriers.

As we see, the techno-centric view does not pay much attention to issues of incentive and motivation. Nonaka's (1994) well-known quadrant model might be a rough example of this view: Capture and codify knowledge with expert systems, share knowledge with groupware and intranets, distribute knowledge with databases and desktop publishing, and create knowledge with CAD, virtual reality, and so on. Organizationally, the techno-centric view gives rise to an information-systems model of KM (cf Huysman & de Wit, 2002), concentrating KM efforts within IT departments. It might be fair to say that the techno-centric view, in its purest forms, belongs to the early days of KM and does not have much currency today, although its cognitive component is deep rooted and still holds a strong influence on KM thinking.

The Human-Centric View

The human-centric or process-oriented view, on the other hand, emphasizes the social processes that are needed for the development of trust and reciprocal relationships among individuals. As such, it focuses on person-to-person communication and highlights social constructs such as communities of practice as the main vehicles of KM implementation. According to this view, people are driven toward knowledge sharing by their need for knowledge (Lave & Wenger, 1991). Reciprocity and recognition are, therefore, major motivations for them. Knowledge sharing is often emergent, informal, and hard to create top-down. The barriers to knowledge sharing are often issues of trust, and they can be overcome by building and expanding the right social relationships. Organizationally, the human-centric view is associated with the human-capital view of the firm, and leads to a human-resource-management model of KM (Huysman & de Wit, 2002; see, for example, Desouza & Awazu, 2003). The human-centric view has gained some momentum in recent years, especially around the literature on communities of practice (Lave & Wenger).

The Socio-Technical View

Finally, the socio-technical view thinks of KM as people sharing their knowledge with IT-enabled applications. It considers KM as an integrated socio-technical intervention with coordinated efforts to enroll participants, reward high-quality participation, and resolve issues of trust and commitment. This is the view advocated, among others, by the proponents of social informatics (Kling, 2000). Unlike the techno-centric view, social informatics does not consider IT as a silver bullet that automatically energizes knowledge sharing, and in contrast to the human-centric view, it regards best practices as contextual frames rather than isolated practices. It also puts a large emphasis on power relationships in KM practice (Ekbia & Kling, 2003).

Organizationally, the socio-technical view considers knowledge sharing as an orchestrated process that needs to be supported by both top-down managerial interventions and bottom-up employee and practitioner involvement. Although there seems to be a growing enthusiasm for the socio-technical view, it might take a while before the KM community comes to grips with the full complexity of KM as a socio-technical intervention. As the next discussion illustrates, current practices of KM, even when they involve some kind of incentive structure, are still dominated by either the techno-centric or the human-centric views.

INCENTIVES IN KM PRACTICE

Having recognized the importance of incentives in KM, firms and organizations have devised various schemes to support and motivate knowledge sharing among their employees. The following examples are illustrative of some of the more common schemes. Stevens (2000, p. 54) reports various cases of "innovative strategies that encourage knowledge sharing." Briefly, these included examples range from companies that incorporate this into their hiring process to those that try to develop trust by creating a code of ethics; implementing reward systems on the basis of employee contributions; encouraging knowledge sharing through conferences, classes, and mentoring programs; establishing communities by expanding networks of contacts; or creating role models and KM advocates who keep the ball rolling. It is to be noticed that many of these incentive schemes are under the strong influence of either the techno-centric or the human-centric views.

Other studies of incentive structures report more or less similar attempted schemes (Angus, 2000; Ward, 2002; Wright, 1998). Generally speaking, current schemes often take the form of extrinsic incentives such as monetary rewards, recognition, and promotion. Popular accounts of incentive systems also tend to focus on similar schemes and, as a result, often portray a rosy picture of the impacts of incentives on employee performance. A rather different picture emerges, however, when employees' opinions are probed. In a survey conducted on a group of knowledge workers, Rupp and Smith (2003) found that 58% of their respondents feel that there is a discrepancy between their merit increase and performance rating. The authors suggest that in order to improve this situation, organizations need to give more responsibilities to employees.

Austin (1996) introduces the phenomenon of "incentive distortion" to demonstrate some of the complications that arise when incentive systems are not built upon employee responsibility. An example comes from a government organization whose task is to help people find jobs. An incentive system, which rewarded employees on the basis of the number of interviews they conducted, actually resulted in a significant rise in the number of interviews, but it also made employees spend little time on finding referrals. Ideally, for the process to be fruitful, the time spent on conducting interviews and finding referrals should be equally divided. To move toward this ideal, management changed the measure of the reward as the ratio of the number of interviews to the number of referrals, only to find out later that employees were deleting the record of interviews in order to distort the ratio.

Barth (2000) introduces some examples of dysfunctional mismatch between incentives and performance measurement. For instance, as part of their performance reviews, IBM employees were asked to contribute their project experience to a company-wide KM system. However, many employees did not submit their contributions until the very last month preceding the reviews. This can be understood in light of the additional burden of the activity, which would take away employees' time and resources from tasks with more direct returns or from what they probably considered more important tasks. Faced with this situation, IBM management introduced a quality-control component that incorporated a kind of expert peer review to evaluate the content and quality of the submissions in terms of their usefulness to other employees. Aside from employee competition, this introduces issues of overhead and cost efficiency for the whole company. The use of selective incentives such as the above incurs a cost for the organization in terms of the monitoring of participation (in addition to the rewards themselves), and this needs to be taken into account in the evaluation of the KM initiative (Cabrera & Cabrera, 2002).

DISCUSSION: FACING THE DILEMMA

"A man always has two reasons for doing anything—a good reason and a real reason." (J. P. Morgan)

The above examples raise a set of questions. How can incentive structures be tailored to improve employee satisfaction? How can managers and KM practitioners prevent incentive distortions from proliferating? At what point are the costs of selective schemes in terms of company overhead, employee time, and employee satisfaction going to tip off the benefits? These (and our earlier) questions should be taken seriously in order for KM efforts to work, and to answer them, the KM community has largely turned to economic theory for a source of ideas.

Davenport and Prusak (1998), for instance, discuss the idea of a "knowledge market" where buyers and sellers of knowledge negotiate a mutually satisfactory price for the exchange. According to this idea, the perceived gain from the exchange in terms of reciprocity, repute, and altruism serve as an incentive for knowledge sharing. As Ba, Stallaert, and Whinston (2001a) have argued, however, it is difficult to quantify these gains into monetary values so that a benefit can be assigned by the organization. Furthermore, knowledge has the characteristics of a public good in that it is nondepletable, and economic theory itself warns us that treating a public good as a private good leads to the underprovision of knowledge and, hence, to organizational loss (ibid; cf Samuelson, 1954). This is related to the free-rider problem and what we called the central dilemma of KM. Ba, Stallaert, and Whinston (2001b) have applied economic theory to discuss an incentive-aligned market mechanism to optimize investment in KM within a firm, but their account focuses almost exclusively on extrinsic motivations such as monetary rewards. To find about intrinsic motivations such as commitment and job satisfaction, however, we need to look elsewhere outside of economic theory.

Social psychologists distinguish intrinsically, vs. extrinsically, motivated activities as ones for which "there is no apparent reward except the activity itself" (Deci, 1976, p. 23). These are behaviors that a person engages in "to feel competent and self-determining" (p. 61). Therefore, they could be either sought as a means of stimulation or as a way of conquering challenges or reducing incongruities (ibid). Furthermore, industrial psychologists have shown that motivation is a rather fluid and dynamic phenomenon: What motivates one person may not motivate another, what motivates a person may change over time, and people might be always motivated but not necessarily toward organizational goals (Champagne & McAfee, 1989). Similar observations have been made in information-systems research: For example, the report by Constant, Kiesler, and Sproull (1994) reveals that people share knowledge because of their altruistic preferences. These theories and findings might indeed be useful in reducing the tension that arises due to the central dilemma of KM. In her study of a consulting firm with a strong KM initiative, Orlikowski (2000) explains consultants' reluctance to contribute knowledge in terms of the perceived incompatibility between the collaborative nature of the technology, and the individualistic and competitive nature of the organization. Under such circumstances, paying attention to intrinsic motivations might be a key to more effective systems.

What this discussion illustrates is not only that incentive structures are important for KM efforts, but also that they are multifaceted phenomena, the understanding of which requires different levels of analysis from different perspectives: the psychological, social, economical, technical, and so on.

FUTURE TRENDS

Given the multifaceted nature of incentive issues, it would seem that a socio-technical approach, such as proposed by social informatics, holds a stronger promise in addressing them, a trend that is emerging in different quarters of KM theory and practice.

Huysman and de Wit (2002) suggest that, following a first wave where organizations were prone to fall into one of three traps (overemphasis on the role of ICT, individual learning, and managerial needs), KM is moving toward a second wave where the focus is on collective knowledge (social capital) that is routinely shared through personal and electronic networks. Gold, Malhorta, and Segars (2001, p. 187) also introduce an organizational capabilities perspective of knowledge management based on three key infrastructures: the structural (which "refers to the presence of norms and trust"), cultural ("shared contexts"), and technical. Ba et al. (2001a) propose to add an incentive-alignment dimension to the current software-engineering and user-acceptance dimensions of the design and implementation of information systems in organizations.

Cabrera and Cabrera (2002), from the perspective of social dilemmas discussed earlier, suggest a number of interventions with a strong socio-technical character: for example, reducing the cost and increasing the benefits (direct or perceived) of contributing through gain-sharing plans that reward the combined efforts of individuals; increasing the efficacy of contributions through training, feedback mechanisms, and advanced technologies; enhancing group identity and personal responsibility by frequent communication and interaction; and so on.

As these examples indicate, there is a growing trend toward a socio-technical approach that integrates heterogeneous interventions (technical, cultural, structural, etc.) at different levels (micro and macro) of organizational life.

CONCLUSION

The global economy went through a serious transformation in the second half of the 20th century, one aspect of which is the move toward what some analysts call a knowledge economy. Knowledge management is an organizational manifestation of this trend that incorporates novel elements of economic and organizational activity. It would be wrong, however, to conclude from this that everything about the knowledge economy and about knowledge management is novel and unprecedented. There are stable and enduring aspects to all forms of economic activity, and the social psychology of incentive, motivation, and cooperation is one such aspect. Those 21st century factory workers who are unwilling to share their special knowledge (Aeppel, 2002) can probably be explained in similar terms to those that Whyte (1955) used to explain the behavior of their mid 20th century fellow workers, that is, in terms of their material and symbolic relationships to other human beings. By the same token, the reaction of knowledge workers toward incentive structures can also be understood in similar terms.

In this article, we have suggested that KM can be best understood as a socio-technical intervention rather than a purely technological system. A key aspect of this intervention is to motivate individuals to share their knowledge and skills with their fellow workers. This is what turns incentive structures into an indispensable component of any KM effort. The question is how best to implement such structures. To be sure, there is no general answer to this question as particular contexts shape the character of the intervention and structures. But a common lesson that seems to be emerging is that extrinsic motivations alone are not always sufficient and that human beings are often driven by intrinsic motivations such as job satisfaction. It is becoming increasingly clear that even nonmonetary rewards, such as social recognition, can be effective so long as they are public, infrequent, credible, and culturally meaningful (Lawler, 2000). Similar findings are reported in the literature on communities of practice (Lave & Wenger, 1991; Orr, 1996; Schwen & Hara, 2003). The growing phenomenon of free and open software development, which works through the voluntary contribution of very many individuals, is also a case in point.

In summary, a common recognition of the key role of incentive structures in knowledge management and an associated increase of enthusiasm for socio-technical perspectives seem to be shaping. This does not mean that the path of the future is clear, straightforward, and uncontroversial. There are still many outstanding issues in terms of our understanding of the interplay between various elements and levels: the individual and the social, the cognitive and the technical, the material and the symbolic, the intrinsic and the extrinsic, and so on. A good part of the answer to these questions should inevitably come from outside knowledge management, from the social, organizational, and cognitive sciences as well as technical fields such as computer science. The knowledge-management community can greatly contribute to our better understanding of the above issues by its efforts to integrate those insights in its theory and practice. Organizational incentive structures provide a good starting point for such efforts.

Chapter 8.17
e-Health with Knowledge Management:
The Areas of Tomorrow[1]

ABSTRACT

The main purpose of this chapter is to bring out and discuss the central facts pertaining to the importance of incorporating knowledge management in the area of e-health. This is accomplished by focusing on the application of knowledge management in e-health and its effects.

INTRODUCTION

The evolution of the "Information Age" in medicine is mirrored in the exponential growth of medical web pages, increasing number of online data sources, and growing services and publications available on the World Wide Web. The Internet started with a few computers linked by the predecessor in 1969 and has grown to more than six million web sites today, of which at least 2% have health-related content. More than 150 million people currently communicate over the Internet with medical information being amongst the most retrieved information on the web. Health information providers on the web mostly consist of private companies offering medical information, individual patients and health professionals, patient self-support groups, non-governmental organizations, universities, research institutes and governmental agencies. Thus, the importance of e-health has grown tremendously these days and providing e-health coupled with the concept of knowledge management will only serve to enhance the efficiency of e-health initiatives.

E-HEALTH

E-health is a very broad term that encompasses many different activities related to the use of the Internet for healthcare. The rate at which health professionals are using the Internet as a source of consumer information about health and medicine is rapidly increasing. It has been reported by healthcare professionals that large numbers of patients arrive at their offices either with questions related to online medical information or a large variety of health products on the Internet. Some of this content may prove extremely helpful to the health and recovery of a patient. Prior to 1999, e-health was barely in use. Now it seems to be a general "buzzword," used to characterize not only "Internet medicine," but also virtually everything related to computers and medicine (E-Health in the Medical Field, 2003).

Intel, for example, has referred to e-health as "a concerted effort undertaken by leaders in healthcare and hi-tech industries to fully harness the benefits available through convergence of the Internet and healthcare." As the Internet has created new opportunities and challenges to the traditional healthcare information technology industry, the use of this new term to address these issues seems appropriate. The latest challenges for the healthcare information technology industry with respect to e-health fall primarily into the following categories:

1. Institution-to-institution data transmission possibility (B2B = "business to business");
2. Consumers' capability to interact with their systems online (B2C = "business to consumer"); and
3. Peer-to-peer consumer communication possibility (C2C = "consumer to consumer").

E-health can be described as an emerging field at the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies (Eysenbach, 2001). In a broader sense, the term characterizes not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking to improve healthcare locally, regionally, and worldwide by using information and communication technology (ibid).

The E's in e-Health

The preceding definition of e-health is broad enough to apply to the dynamic environment of the Internet and at the same time acknowledge that e-health encompasses more than just "Internet and Medicine" (Eysenbach, 2001). It is useful to think of the "e" in e-health not just standing for "electronic," but also a number of other "e's," which together perhaps best characterize what e-health is all about. Specifically, we now present some of the "e"s that serve to represent the "e" in the e-health that have been identified by Gunther Eysenbach, editor, Journal of Medical Internet Research in his editorial comments on what is e-health, as follows:

Efficiency – E-health aims to increase efficiency in healthcare, thereby decreasing costs, in particular transactions costs. This can be realized by avoiding redundant or unnecessary diagnostic or therapeutic interventions, through enhanced communication possibilities between healthcare establishments, and through patient involvement.

Enhancing Quality of care – Increasing efficiency improves quality along with reducing costs. In addition, e-health provides a vehicle for trying to decrease the myriad of medical errors which in turn naturally impact the quality of healthcare treatments in a positive fashion.

Evidence Based – E-health interventions should be evidence-based thus they should be proven by rigorous scientific evaluation and thus no assumptions need be made in this area with respect to treatments.

Empowerment of Consumers and Patients – E-health facilitates patient-centered medicine, and supports wiser patient choice. This is accomplished by making the knowledge bases of medicine and personal electronic records accessible to consumers over the Internet.

Education of not only physicians but also consumers – Today's healthcare sector is complex and physicians must contend with continually updating of their medical knowledge base to keep abreast with new treatment protocols etc e-health offers an effective avenue for this. Education however is not just limited to physicians but all medical and healthcare professional as well as healthcare consumers.

Extending the scope of healthcare in both a geographical sense as well as in a conceptual sense – Via e-health, it is possible for patients to access key knowledge and reach experts who maybe located in different countries for primary or even second opinions. In addition, the area of telemedicine in particular helps to provide needed and a broad range of healthcare services to remote and typically inaccessible areas.

Ethics – E-health involves new forms of patient-physician interaction and poses new challenges and threats to ethical issues such as online professional practice, informed consent and privacy issues. It is important that many of the ethical dilemmas presented by e-health initiatives are to some extent no different to the ethical dilemmas generally created by e-commerce technologies with which all organizations must contend.

Equity – To make healthcare more equitable is one of the promises of e-health, but at the same time there is a considerable threat that e-health may deepen the gap between the "rich" and "poor" and increase the digital divide (Journal of Medical Internet Research, 2001).

THE ROLE OF CONSUMERS

Today, a large number of patients and consumers already use the Internet to retrieve health-related information, to interact with health providers and even to order pharmaceutical products. Physicians mainly use the web to access science databases like PUBMED or MEDLINE, but they lag behind other professions in their use of online information. On the other hand, consumers have taken the lead in adopting the Internet media for the retrieval and exchange of health information. Informed and Internet-savvy patients will play a crucial role in being a major driving force for clinicians to "go online" and for evidence-based medicine. Patients will undoubtedly increase the pressure on physicians to use timely evidence by accessing online information. They also will encourage them to adapt themselves to information technology in order to deliver high quality health services. For the first time in the history of medicine, consumers have equal access to the knowledge bases of medicine — and they are heavily using this access. It has been noted that "the number of Medline searches performed by directly accessing the database at the National Library of Medicine increased from 7 million in 1996 to 120 million in 1997, when free public access was opened; the new searches are attributed primarily to non-physicians" (Sieving PC Factors Driving the Increase in Medical Information on the Web, 1999). Thus, the Internet will act as a catalyst for evidence-based medicine in two ways: First, it enables health professionals to access timely evidence. Second, it enables consumers to draw information from the very same knowledge base, leading to increased pressure on health professionals to actually use the evidence (PricewaterhouseCoopers Healthcare Practice, 2003).

By 2005, 88.5 million adults will use the Internet to find health information, shop for health products and communicate with affiliated payers and providers through online channels, according to Cyber Dialogue (Online Health Information Seekers Growing, 2003). Today, the e-health consumer demands include the need for specific health services, such as obtaining information when faced with a newly established diagnosis.

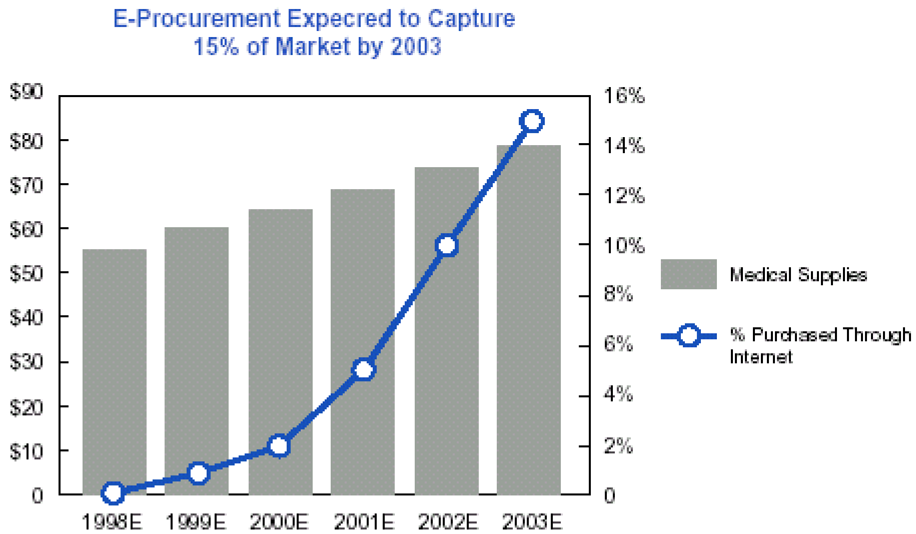
Some key challenges must be met to develop optimal partnerships between consumers and other groups of decision-makers. Some of these include the need for:

- Meaningful collaboration with patients,
- Preparation for upcoming technological developments,
- Efficient strategies to monitor patterns of Internet use among consumers,
- Balance between connectivity and privacy factors,
- Better understanding of the balance between real and virtual interactions, and
- Equitable access to technology and information across the globe.

E-HEALTH ISSUES

Three important issues must be carefully considered in the field of e-health (The Higher the Connection Speed, 2001). These issues tend to be similar to all aspects of e-commerce and typically comprise the areas of procurement, connectivity, and benefits. We discuss each in turn briefly.

Figure 1. e-Procurement market sales



Source: Odyssey Research, 2003

e-Procurement

Health systems must begin to consider how their organizations are going to adapt and leverage Internet-based tools to manage their medical supplies.

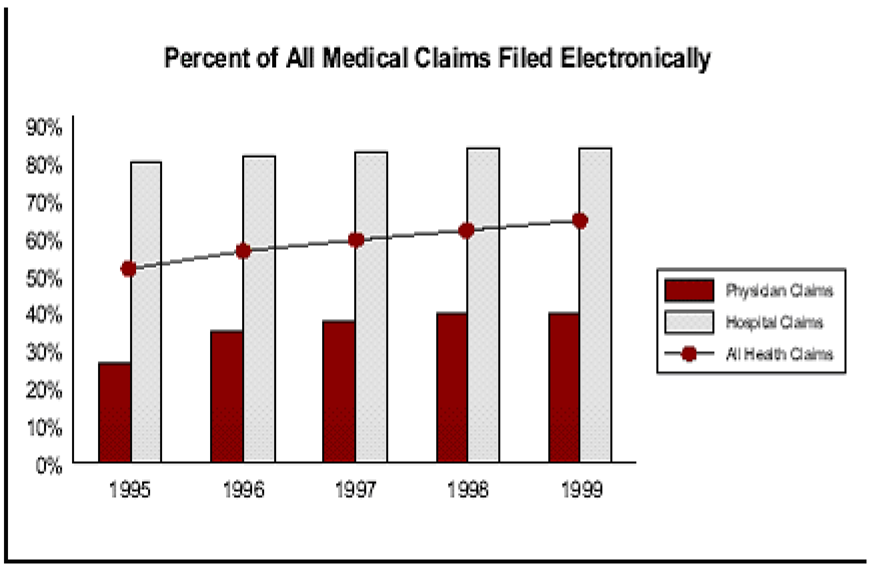
Procurement in healthcare products must move toward an online business platform for data interchange. Producers and consumers also must work together toward standardization, including a universal product numbering system. As shown in Figure 1, in the US, e-procurement of medical supplies is estimated to grow to 15% of medical supply spending in the US by 2003, according to Deutsche Banc Alex Brown (PricewaterhouseCoopers Healthcare Practice, 2003).

e-Connectivity

Healthcare is local, and so is connectivity. Finding that they can not boil the ocean, connectivity companies must pragmatically assess what the industry can reasonably move to on a step-by-step basis. Technology is a tool, but it will not pay for itself unless organizations deploy it in practice and track how their clinicians and administrative workers are using it. To do so, managers must design processes and metrics for productivity. Otherwise, it's like expecting someone to drive a car when his previous experience is limited to a 10-speed bicycle. However, healthcare organizations will find that getting this work stream web-enabled offers the most opportunity now, and that other functions like disease management and demand management can also be Internet-enabled.

Health plans and hospitals are beginning to migrate to the web for claims-related transactions as the first step of a broader Internet strategy. This can be clearly depicted by Figure 2. Because many organizations continue to use Electronic Data Interchange (EDI) for claims submissions, transactions surrounding claims — eligibility,

Figure 2. Increase in the percent of electronically filed claims



Source: Odyssey Research, 2003

referrals, etc., they will be the first to be adopted for e-health connectivity. Those health plans that are adopting Internet connectivity for these functions view them as the foundation upon which to build other Internet-enabled partnerships with patients and providers.

The critical need for automation has risen as the number of healthcare transactions is outpacing the growth of health spending. The number of claims submitted increased by about 7% during the past five years, according to the Health Data Directory. In contrast, healthcare spending has increased at between 5% and 6% during the past five years. Many of the functions associated with claims submissions and payment are repetitive tasks that are more efficiently done by computers. The most expensive processes are not the claims submissions themselves, but the tasks surrounding the claims process, such as eligibility checks and referrals. Coupling that with increasing labor shortages, the onus is on organizations to re-engineer (PricewaterhouseCoopers Healthcare Practice, 2003).

Health plans must understand physicians' needs when designing Internet-based solutions. First-mover advantage is not as important as a system that works. Many e-business companies have benefited from a first-mover advantage, which means they get the most capital, the best partners and brand recognition. However, healthcare is a "show-me" business and successful models will replicate market by market.

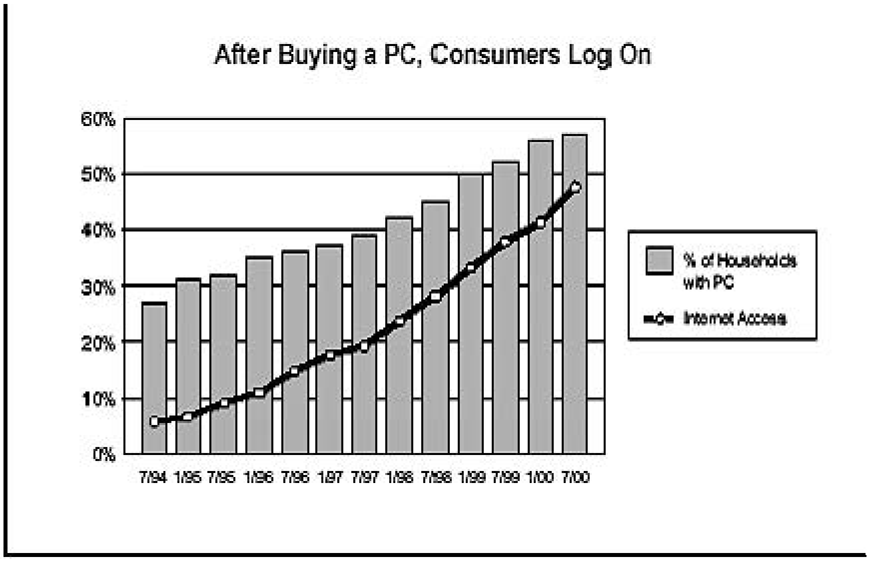
e-Benefits

The health industry has discovered the benefits of online business. Like the conundrum of the chicken-and-the-egg, many employers and health plans are awaiting the development and implementation of e-benefits and e-insurance products. Health plans don't want to deliver web-based products if employees are not ready to use them. Employers can not deliver e-benefits products until health plans develop them. However, starting with online benefits enrollment, e-health is evolving in incremental stages. A by-product of this evolution is the combination of employee responsibility and authorization. Paternalistic urges aside, employers will gradually grant more control for health benefits to employees themselves. One of the primary drivers of e-benefits is the possibility of self-service tools through which employees can customize their own insurance plans and have ready access to them, just as they do with their other online accounts. Employees may become more fiscally responsible about their benefits once their insurance information is made more easily available to them. Finally, they may want complete exposure over all the issues of their benefits.

The process of moving toward an online system cannot be an all-at-once process. Employers will gradually shift responsibility to their employees and proceed further depending on how the new system is being adopted and implemented. The national research conducted by PricewaterhouseCoopers (PricewaterhouseCoopers Healthcare Practice, 2003) indicates that few employers are willing to adopt self-directed, otherwise known as defined contribution, health plans today. However, as they adopt more web-enabled functions, they will move more responsibility for choices to employees. As that balance of responsibility shifts, some employers will need to determine how ready their workforce is to accept increasing levels of responsibility.

Physicians are among the first ones to be directly and adversely affected when a significant portion of the healthcare insurance market moves to self-directed, Internet health benefits accounts. Some defined contribution health plans have medical savings accounts as a centerpiece. In these, employees pay out of a medical savings account for routine expenses up to $1,500 or $2,000. Physicians must be prepared to deal with patients who are paying cash for their visits and who may shop around for the best value. Figure 3 shows the

Figure 3. Internet usage among customers



Source: Odyssey Research, 2003

statistics of the probability of customers using the Internet when they have access to a PC (Odyssey Research, 2003).

The insurers should come up with new e-quote products to assist consumers using the Internet for healthcare benefits. They also must follow the growing and changing needs of people and develop products that assist consumers going through the online process.

Standardization can be chosen as the ascendant theme of Healthcare in the near future. Proper steps are to be taken to penetrate this e-business niche so that employees and employers can make apples-to-apples comparisons. Offering more options without proper insight into the standard benefits may just add more confusion.

E-HEALTH: A CASE EXAMPLE[2]

Let us take the e-health department at a large healthcare organization in the Midwest of North America (ABC Healthcare Organization) as an example to see how the Internet can be used for healthcare and the benefits that can be derived. The ABC Healthcare Organization is one of the world's largest and busiest health centers. It was founded in the early 1920s as a not-for-profit group practice, integrating clinical and hospital care with research and physician education. The ABC Healthcare Organization has more than 1,000 salaried physicians on staff, representing approximately 120 specialties and subspecialities. Last year, they provided for almost 2 million outpatient visits and almost 50,000 hospital admissions. Patients came to ABC Healthcare Organization from across America and from more than 80 nations.

The demand for web-based health will increase rapidly as the Internet is branching out its roots into common households. From 1999 to 2001, there was a 67% increase in the number of people who had requested health information via ABC Healthcare Organization's web site. In 2001, they received an average of 1,500 web mail inquiries per month, including an average of 270 requests for appointments. People requested various types of information online, including second opinions, general health information, and appointment requests.

Many e-mails and phone calls were received by the clinic staff requesting quality second opinions from the famous physicians at ABC Healthcare Organization. Looking at the high volume of requests for second opinions, the organization decided to enter into the e-market.

E-health is one of the important divisions in the Information Technology Department of ABC Healthcare Organization. It has the primary responsibility of making sure that secure and trustworthy information is presented online. It also has to ensure that online patients are getting the same amount and quality of information that regular patients receive.

e-Health Second Opinion

When patients are faced with a serious medical problem, obtaining a second opinion has long been an accepted medical practice. With the rise of consumerism since the late 70s, both patients and healthcare providers adopted the practice of second opinions to get maximum satisfaction from the treatment. Consider this accepted practice juxtaposed against the technology advances with computers, coupled with the phenomenal growth of the Internet. In 2000, 52 million American adults, or 55% of those with Internet access, sought health information online, many of these people seeking specific information about their own or a family member's condition (Efficient Knowledge Making, 2003). As the use of these online medical resources continues to grow exponentially, healthcare organizations have a unique opportunity to leverage consumer interest in the Internet to advance e-market services. Specifically, the demand for medical second opinions, coupled with the acceptance of the Internet, created an opportunity to develop and offer a web-based second opinion service that meets the public's demand for convenient access to credible, quality, patient-directed healthcare while also increasing the efficiency of the physicians who provide these services. In February 2002, ABC Healthcare Organization, launched its e-health Second Opinion Program, an Internet-based service for patients with a life-threatening or life-altering diagnosis who wish to obtain a second opinion from physicians at ABC Healthcare Organization.

The Development

Development of the operational plan for the Internet-based second opinion program was facilitated by the experience of ABC Healthcare Organization with an 80-year history for providing specialty consultations and second opinions. For approximately 65 years, the only portal to the doctor was through the front door of the hospital and clinic and these patients came primarily from the Midwest and its contiguous states.

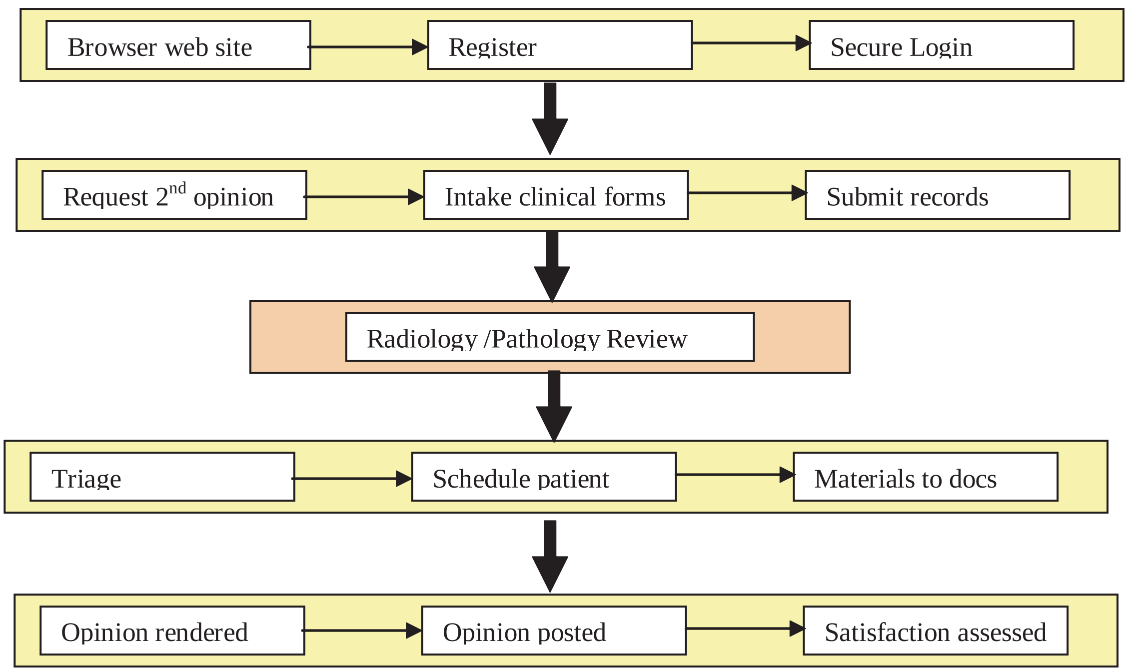
A fundamental shift occurred in the mid-1990s. Patients and potential patients began using technology to gain greater access to healthcare information and healthcare providers, bypassing traditional geographic barriers to service. Additionally, many patients in other countries expressed a desire to have ABC Healthcare Organization physicians render a second opinion when they were faced with a new diagnosis or medical problem. Typically, these requests and the data were sent by fax and overnight courier service. Although connectivity at home is increasing and getting faster — 18% of e-health users have broadband connections (The Higher the Connection Speed, 2001) — the ability to respond to this demand for health information was challenged by the many different methods used for responding to remote patient's inquiries that also integrated existing operational processes and information systems.

E-health second opinion represents in its basic form the transformation of a traditional medical service into an e-health service. The program was designed to handle only second opinions and to require the data upon which the primary diagnosis was based. Each clinical department and the physicians identified the diagnoses in their practices for which second opinions were requested. Since rendering a second opinion is considered by the regulations of most state medical boards as the practice of medicine, an early decision in the development of the second opinion program was to license those physicians who were to participate in the program throughout the States. Since ABC Healthcare Organization is a multi-specialty group practice in which the physicians are credentialed through a single office, this office facilitated the licensing of the ABC Healthcare Organization physicians participating in the e-health program in each state in which the program was being offered.

Integration of Online Second Opinions with the Existing System

ABC Healthcare Organization has a vigorous information system for fast and convenient access to patient information. This makes it necessary

Figure 4. Logical design of the online second opinion



that the integration of the e-health second opinion program into current operational systems should be efficient and seamless. To achieve this, any patient's visit through the Internet is handled in the same way as a physical visit at ABC Healthcare Organization.

Integration of e-health second opinion should not cause any kind of efficiency and response time problems to the current IT system. To ensure this, the same methods of online registration, appointment, e-mail, results reporting, statistical reporting and financial reporting systems are integrated with the online second opinion request forms and requester contact information gathering process. Hence the overall infrastructure is not disturbed. Figure 4 provides a schematic of the logical architecture for the e-health second opinion program.

During the process of requesting a second opinion online, the patient can stop the process at any stage and resume at a later time. The information is saved so that the patient need not start from the beginning when returning within the specified time interval. This feature also gives the patient the ability to talk to experienced nurse practitioners on the team. This has proven to be very useful to the patients and allows them to submit complete and informative second opinion requests. The patients are given the full list of the nurses and their e-mail and telephone contacts to contact at any point during the e-consult process if they have any questions. A registered nurse contacts the patient directly by telephone one to two days following completion of the consultation to ensure the patient understands the content of the second opinion information and that all questions have been answered. Should the patient have further questions, the clinical staff facilitates the discussion with the physician who completed the second opinion. Once all of the steps of the process are completed, the medical records are filed with the Health Data Services department for further action.

Online Healthcare Provision to Patients

With the entrance of the health industry into the World Wide Web, the ability of patients to communicate with physicians or healthcare providers changes radically. In a time of great need, such as when patients have been diagnosed with a life-threatening or life-altering diagnosis, quality information from a trusted source is paramount. Second opinions offer the reassurance and peace of mind that a prescribed course of treatment is the best for each individual. Most importantly, second opinions provide a safeguard against unnecessary or inappropriate treatment.

Various factors both externally and internally were considered before launching second opinion requests in e-space. Integration of the second opinion process into existing operational and information technology systems at ABC Healthcare Organization minimized the operational impact of a new clinical offering. In fact, adding the web expression to already existing services permitted consolidation of many different processes into a unified method by which a second opinion could be rendered remotely for selected diagnoses. By incorporating e-appointments into the physician's routine medical practice, by complying with disparate state licensing regulations, and by communicating the program's features and benefits to providers and patients, ABC Healthcare Organization has launched a second opinion program that satisfies internal constituents whiles responding to external market demands for quality service and convenience. When the consultation is real and the visit is virtual, greater access and value is created for all concerned. Future developments will continue the integration of technology into existing healthcare processes, in addition to the creation of new processes that will more effectively address the clinical needs of patients.

DRAWBACKS OF USING E-HEALTH AND POSSIBLE SOLUTIONS

At the core of the e-health debate is the tension between access and quality assurance. Access to healthcare becomes less hierarchical and nonlinear with e-health as it destroys the single-point, gatekeeper model of access, allowing multiple entry points. Thus on the surface it seems that these technologies should decrease costs and improve access. But, in reality heath information online poses serious issues for quality assurance systems. Systems based on licensure or malpractice law are premised on a single point of entry identifiably located in physical space. These systems will be ineffective to police a delivery system that is no longer based on physicality or the preeminence of the traditional patient-physician relationship.

Lack of physicality can be considered as a major problem in the e-health world. Physically meeting a patient will give the physician a better chance to interact and find out more about the problem. For example, consider the online second opinion: For each diagnosis, sets of questions are predefined and the patient has to fill in the answers. But sometimes some further questions may arise depending on a given answer. Physically, the physician changes his questions depending on the response of the patient, but this is not possible when the patient is being asked questions online. Even if it is made interactive, it cannot be as efficient as asking the patient in person.

As e-health provides more choice and communication (aided by the promise of extracting administrative costs from the healthcare delivery system), access should be dramatically improved. Yet, e-health's lack of physicality, its depersonalization, anonymity, and even coldness challenge usual conceptions of competence and compassion. Further, multipoint entry into the delivery system makes continuity difficult to achieve, while health advice sites based on e-commerce paradigms involve considerable conflicts of interest. Finally, e-health marketing practices and privacy concerns frequently seem to involve the commodification of patients and patient data.

Despite the challenges discussed above, e-health has great potential for good. Highly efficient national medical markets, around-the-clock service and the seamless integration of products and services no longer should be the stuff of dreams. The ability to heavily personalize computer-mediated relationships may rehabilitate patient-physician relationships eroded by years of managed care, while the web's ability to deliver rich information directly to consumers could reverse centuries of damaging informational asymmetry between patient and physician.

To achieve the promise of e-health, ethical and legal structures must be refurbished to further demand the provision of quality medical information, untainted by patient-sorting costs or provider self-interest. Regulatory systems must be changed so that they are no longer premised on ties with some physical place. Legal and ethical constructs must be informed by e-health codes of conduct and computer-mediated data quality solutions.

The US Department of Health and Human Services has sought valiantly to reconcile cost extraction and patient rights in its privacy regulations. This is a positive sign for e-health. In the e-health environment, as information, diagnosis, treatment, and care are delivered through inconversant channels, serious challenges posed by e-health should not be underestimated. However, there is still time to re-engineer legal and ethical codes to marry increased access to quality assurance and avoid the abyss of a computer-mediated sequel to the worst and most dehumanizing aspects of managed care.

INCORPORATING KNOWLEDGE MANAGEMENT IN E-HEALTH

Incorporating the concepts, looks, and strategies of Knowledge Management (KM) can only reveal the full value of e-health. In order to understand this, we now introduce KM before discussing how KM helps e-health. Specifically, we provide the context for why knowledge management is now necessary and briefly discuss the value of knowledge management as well as seven basic considerations for embracing knowledge management in any organizational setting.

Quality of Medical Information

Sometimes the information displayed on the Internet will not be of good quality. This is a major setback, as both the consumers and healthcare providers will not be ready to use and rely on such a system. Studies assessing the quality of health-related web sites, newsgroups or evaluating interactive venues using the method of posing as a fictitious patient have demonstrated that important aspects of quality — like reliability, accessibility, and completeness of information and advice on the Internet — are extremely variable. Though this problem also exists in media which are not web-oriented, like magazines, newspapers, and television, some extra problems — such as the originators of messages and their credibility — are difficult to assess by readers and are more troublesome when it comes to the use of the Internet. Solutions for these concerns — such as the widespread use of evaluative meta-information — have been proposed (Alberthal, 1995) and will, once adopted, help to make the web a more useful tool for patient education. Furthermore, the Internet will open new ways for professional medical education (Knowledge Management, 2003). Knowledge management will provide a great way to achieve good quality, as all the actions will become organized using it.

The e-Knowledge Market as an Enabler of e-Health

The e-knowledge market concept can be a powerful, next generation platform for enabling e-Healthcare.

Knowledge management offers ideas and approaches that can be valuable to disability researchers and service providers. A consumer or patient — centered orientation, a belief that "healthcare is an information business," and a focus on obtaining maximum value from information resources are all important concepts with broad applicability.

In an era of user involvement, consumer empowerment, and the wide dissemination of information on health and health services, it is important that we identify who the consumers of online health information are, what their information needs are, and understand why and how they seek information online. Following this method will enable information to be provided in ways that will have benefits from the worldwide to the individual level. It will also inform current debates over the quantity and quality of information that is provided and issues of privacy and security. Using knowledge management in this process will obviously improve the way in which the data is shown to customers online and thus increases customer satisfaction, which is one of the primary concerns of e-health sites.

Health Knowledge Management

So far, most (if not all) of the technology-based applications to promote knowledge management in health have been a mere transition from paper-based to electronic-based means to process and distribute information in text form. Most of the efforts to date have been developed for and by healthcare providers. The belief remains that in the future the bandwidth of knowledge management will increase and this will allow consumers to communicate more effectively. With these developments one will be to go beyond text to more "natural" or primal ways of representing and exchanging knowledge.

To make knowledge management grow to its full extent and be more useful, projects and applications that will explore innovative ways to synthesize, distill, package, integrate and deliver different types of information (e.g., clinical data, anecdotes, rules of thumb, or intuitive statements) in more engaging and more efficient ways need to be developed.

CONCLUSIONS

From the above discussion we highlight that knowledge management can be a tremendous factor in developing the infrastructure and outcome of e-health. Using the Internet as one of the media to promote health conditions can be of great use if proper security and other issues are taken care of.

The second opinion e-health program at ABC Hospital discussed earlier, also points out the ease with which healthcare is reachable to people using the Internet. Adding web applications to an existing healthcare organization's activities will increase awareness among patients and also spread the news faster and in a more convenient way. Given the rate at Internet use is increasing, it is definitely useful to provide health information online. However, e-health also brings with it many challenges. Knowledge management, when incorporated into e-health applications, can serve to make e-health better and make the process even faster with its efficient organization of critical information and relevant knowledge, thereby providing solutions to many of the current challenges facing e-health initiatives.

The Internet will not be the same in the next millennium. Important developments are likely to improve not only the speed but also the quality of information and retrieval possibilities. The web could evolve into a global medical knowledge base, where diverse medical Internet applications and resources are interconnected and integrated beyond manual "linking." Moreover, the Internet will revolutionize science itself by opening new ways of scholarly communication and electronic publishing. The Internet and related new communication technologies will enable health professionals to reach larger populations with interactive applications, which in turn will open enormous opportunities and challenges. The need for research is clear. "Cyber medicine" research should go beyond the mere development and provision of technical solutions. It should also address social and human factors and evaluate the impact of the Internet on society, healthcare, and public health. As researchers, one has the responsibility not to follow blindly the general Internet hype, but to help physicians and consumers to maximize the use of the Internet by carefully evaluating our interventions and revealing determinants that influence the effectiveness and efficiency of Internet communications in healthcare. Many of these evaluation methods are yet to be developed.

Chapter 8.18
Hybrid Knowledge Networks Supporting the Collaborative Multidisciplinary Research

Stanislav Ranguelov
University of the Basque Country, Spain

Arturo Rodríguez
University of the Basque Country, Spain

INTRODUCTION

Virtual networks are becoming increasingly important instruments for knowledge and collaboration management. In addition, research, development, and innovation performances are among the most important activities in modern organisations. These two issues deal with complex problems that companies, universities, and other organisations can only face with multidisciplinary, geographically widespread teams.

This article describes the setup of a model of a hybrid knowledge network that can group and connect together universities and researchers and enable them to collaborate. The proposed model for the virtual network is based on the conjunction of the personal and organisational aspects of collaboration. Due to this union within the organisational structure, two main levels of collaboration have been envisaged, namely the institutional one and the individual one.

BACKGROUND

Nowadays, it is claimed that the main source of sustainable competitive advantage is based on the possession of valuable information and the capacity to exploit, produce, and obtain new knowledge.

Networks in general, and virtual networks in particular, have gradually become more and more important instruments for knowledge management. Early references in this field can be found in the research made by Drucker (1989), Savage (1990), Keen (1991), Donaht (1998), and Koch, and Wörndl (2001). A huge number of definitions have been identified to characterise collaborative networks and the organisation of communities of practice (Koschtzky, 2001), but it has been quite difficult to define a clear border between the different types of knowledge networks that exist.

In the research and development (R&D) process, there is no doubt that communities of practice as specific forms of such networks have become the most important tools to implement knowledge management and to accelerate the transference of innovation. They bring together people with common goals and interests who are physically remote and are working in different types of organisations. Using new technologies they can join together and work as a team towards the objectives set.

This article deals with a new form of knowledge network which, on one side, groups together elements from the traditional virtual community of interest and from the more sophisticated communities of practice, and on the other side, promotes collaborative multidisciplinary research that produces high-quality research results and stimulates their transfer.

MAIN FOCUS—KNOWLEDGE NETWORKS: CONCEPT AND APPROACHES

The main concept treated in the networks economy theory is the cooperation between organisations based on the mutual trust, without hierarchical structures, and that considers knowledge networks as an intermediary stage between the free market and the rigid organisation. In their theoretical approach to the concept of knowledge networks, Seufert, Krogh, and Bach (1999, p.182) define them as structures established between individuals, groups, and organisations in which not only bilateral relations, but also all activities carried out by the knowledge network are important.

From the socio-economic viewpoint, networks are interpreted as a specific set of linkages between a defined set of actors, with the additional property that the characteristics of these linkages as a whole may be used to interpret the social behaviour of the involved actors (paraphrased from Mitchell, 1969, p. 2, as cited by Alba, 1982, p. 40). Therefore, the term "network" covers strong social relationship and includes players who may be individuals, groups, or even whole companies. From this viewpoint, networks can be structured formally or informally. The relationships that can be identified within them are interpreted as long-term connections, which may be personal/organisational or technological/organisational.

Knowledge networks usually share a series of characteristics among which, most important according to Seufert et al. (1999) and Real Communities Inc. (2000), are the following:

- Networks exist to create and disseminate new knowledge.
- They are structured and operate to increase the rate of creation of new knowledge.
- They provide clear, recognisable benefits to all participants.
- Network membership is by invitation, based on merit or prior review of the purposes of the project.
- Networks are usually inter-disciplinary, and cross over the frontiers between sectors of activity and areas of knowledge.
- Through networking, a transfer between the tacit knowledge of individuals and the explicit knowledge held at organisations takes place.

COMMUNITIES OF PRACTICE

The term "communities of practice" was presented first by Lave and Wenger (1991). These communities are groups of people who share an interest in a domain of human endeavour and engage in a process of collective learning that creates bonds between them. A basic characteristic of the community of practice is the specific way in which learning takes place, through a process of "legitimate peripheral participation" (LPP). Therefore it is not exclusively based on practical teaching, but also comprises a process of development of knowledge based on experience. The elements of legitimacy, participation, and peripheral define specific characteristics of communities of this type (Wenger, 1999).

Communities of practice therefore have the role of integrating specific knowledge¾that is, turning individual knowledge into collective knowledge according to the capabilities of the team involved. In short, the creation of "team knowledge" is the result of interaction between individual and collective knowledge, and between tacit and explicit knowledge, according to the development of the "knowledge spiral" (Nonaka & Takeuchi, 1995).

There are certain features that distinguish communities of practice from formally configured teams (see Table 1).

Some Key Factors for Success of the Communities of Practice

- The knowledge network should be focused on the needs of its members. In line with this, management should seek to study the profiles of members: what knowledge they possess and what they need.
- The knowledge network must invest in content. Much of the effort put in must go into the generation of new content and new contributions, as this is the only way to increase the knowledge of the organisations.
- Adopt the assumption that the community cannot operate on its own. This means that members must identify who can act as informal moderator and lead the remaining

Table 1. Differences between communities of practice and formal teams (Lesser & Storck, 2001)

Communities of Practice	Formal Teams
Relationships are formed around one practice	Relationships are formed when a team is assigned
Authority relationships emerge through interaction around expertise	Authority in teams are organisationally determined
Communities are responsible to their members	Teams have goals which are established by people not involved in the team
Communities develop their own procedures	Teams have processes that are organisationally defined
High flexibility provided by the absence of any hierarchical dependences	Rigid structure with less possibilities to reorganise the work
Bidirectional relations between the members of the community	Unidirectional relations with the organisational structure
Less bureaucracy defined by the absence of contractual arrangements between the members	Strong bureaucracy processes defined by the hierarchical structure

members towards the problems to be dealt with and provide basic working methods.

- External factors like the organisational culture are extremely important. One of the main aims of group moderators must be to achieve a common culture so that knowledge sharing is a natural activity, not a special effort.
- The understanding that the activities of knowledge network are not limited to discussion groups. Communities are much more complicated than that.

As a concluding remark for this section, online communities can be said to hold clear advantages for research groups.

HYBRID KNOWLEDGE NETWORKS

The process of creating a virtual network supporting collaborative multidisciplinary research has its roots in the project "Knowledge Management at a Public University: The Process of Research, Development, and Transfer of Scientific and Technical Knowledge," which was set up in 2000 at the University of the Basque Country in Spain with a three-year timeframe. The project brought together a multidisciplinary group of 22 researchers with the purpose of drawing up a model for knowledge management that could cover the whole process from pure research to the transfer of scientific and technical knowledge from the university to businesses and institutions.[1]

The idea of organising virtual research centres has come a step closer to reality with major advances in technology and the need for researchers to respond to rapid changes in the socio-economic environment and the increasing uncertainty that they bring. Several attempts are currently under way to set up non-physical centres, but doubts remain as to the management method best suited to creating and structuring them so that they are capable of providing an open climate for cooperation. Some schemes in Japan and the U.S. have shown the benefits of cooperation by large groups of researchers from different organisations (Echeverri-Carroll, 1999; Jin, 1999). Many of these knowledge networks were set up with short-term aims, but others are structured as long-term alliances.

The development of these networks has also been fostered by the arrival of the age of cooperation for innovation. The cost of innovation and the speed of change create a major need for cooperation to achieve progress. The promotion of research and pre-competitive cooperation between organisations of different types is an essential factor in reducing R&D&I costs and bringing new products, processes, and services to the market as quickly as possible.

Another aspect is the break-up of the old research process. The frontiers between basic and applied research and between research and innovation are disappearing. The time lapse between obtaining basic research results, developing applications in a specific sector, and marketing those applications is becoming ever shorter, making it harder to distinguish the different phases of the process.

FUTURE WORK

Based on these elements, the idea of developing a new type of network of universities for knowledge management is radically different from the way in which the process is currently organised. First of all, a change is introduced in the purpose of applied research: it no longer has to be contained within a specific framework of action, but can instead be carried on in various areas hitherto untouched, but related to particular topics. Furthermore, this network must bring together people of very different types from different branches of science, public administration, and interested companies.

In view of the foregoing, a virtual research network should set itself the following immediate goals:

- To organise the resources needed for research at the lowest possible cost and the greatest possible speed.
- To attract renowned researchers by offering them broad cooperation, flexibility, and new concepts of organisational culture, along with a policy of openness.
- To promote the principle of blending team spirit with individual creativity to increase competitiveness and create the conditions for a substantial increase in technological development.

The model that we propose for a virtual network of universities for knowledge management is fully in line with this approach. The research is broad in its purpose and can take place in different areas concerned with management of the transfer of knowledge from universities to companies and to society. Furthermore, the scope and variety of the group of researchers and universities who make up the network provides a multidisciplinary outlook on problems with multiple possibilities for cooperation and the appearance of innovative ideas.

We propose to establish two distinct levels for the collaboration, with different names: a "networked virtual centre for universities for knowledge management" and a "virtual network of university personnel for knowledge management."

Membership of the higher level (i.e., the "networked virtual centre") would be restricted to research centres committed to carrying out knowledge management projects concerned with the process of research, development, and transfer of scientific and technical knowledge. Their basic purpose would be to exchange and share information, knowledge, and experience in regard to knowledge management at universities through an online structure, with particular reference to the managing of the transfer of scientific and technical knowledge to businesses and institutions. On this basis, forums, seminars, joint projects, and so forth on the relevant topics can be arranged.

The second level is the virtual network of university researchers for knowledge management (though the possibility of including non-university researchers might be considered, depending on their level of involvement) interested in going deeper into the field of knowledge management in general, and knowledge management at universities in particular, with special emphasis on managing the transfer of scientific and technical knowledge from universities to companies and institutions. This network would work mainly as a forum for discussion and for the exchange of information, ideas, and knowledge online, without excluding the possibility of joint projects and face-to-face meetings.

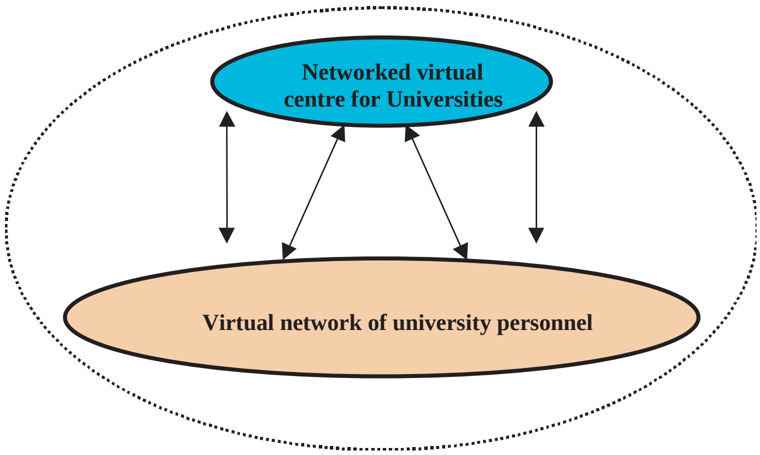
Figure 1 shows the structure of the two-level model proposed.

As can be observed, our proposal to some extent contains elements from both types of knowledge network considered.

Like communities of practice, they have distinct levels of participation, but the distinction in levels is not based, as it is in those communities, on the degree of involvement in tasks, but on such characteristics as the personality of members (individual or institutional), their degree of commitment (drawing up of a knowledge management project or mere commitment to confidentiality), and the type of tasks to be performed (exchange of ideas, knowledge, and experience on projects and even joint projects, or merely a forum for debate and exchange on topics).

Our proposal could therefore be said to envisage two levels of network. As in communities of practice, there may be some process of learning and gradual integration, as researchers from a university may first come into contact with a topic in the virtual network and then undertake a project under the auspices of their university which raises

Figure 1. Model of a virtual network of universities for knowledge management (Rodríguez, Araujo & Ranguelov, 2001)



them to the higher level of the network (i.e., the virtual centre).

CONCLUSION

This article introduced a project that develops a new model of virtual knowledge management network, which groups together universities and research teams, and enables them to exchange information and knowledge, and share their experience in the R&D area.

The proposed model for an innovative virtual network presents two levels of integration, namely a "networked virtual centre for universities for knowledge management" and a "virtual network of university researchers for knowledge management." This hybrid knowledge network includes characteristics of both types of virtual communities considered in the article. The two levels are not based on the degree of involvement in the activities, but on the personality of members, their degree of commitment, and the type of tasks to be performed. Our proposal could therefore be said to envisage two different but connected virtual communities linked by a common theme, though a learning process is possible which would enable movement from one to the other.

On that basis, the presented model introduces four important innovation elements in the field of R&D and network communities. The first element is the creation of mutual trust and adaptation of members' activities and to promote the interdisciplinary research. The second element is the development of an information network, along with virtual and interactive work methods between universities and individual university researchers. The third point considers the development of an exchanging mechanism of knowledge, good practices, and experiences in the field of managing knowledge in the research, development, and transference process. And the fourth element is about the joint management of the knowledge produced inside the knowledge network.

Chapter 8.19
Intelligence and Counterterrorism Tasks

Antonio Badia
University of Louisville, USA

INTRODUCTION

At the end of the Cold War, the intelligence situation (characterized in the past by a confrontation among equals and information scarcity) changed radically to the current situation of today, characterized as an asymmetric threat: On one side, there is still a nation, but on the other, there is a relatively small group of individuals brought together by a common ideology, usually with ethnic and religious elements. These individuals can only confront their opponent by using subterfuge, deception, and terrorist acts. They try to disguise their activities by infiltrating society at large and seeking refuge in anonymity. This kind of conflict has long been analyzed in the military literature under names like low-intensity conflict (LIC) or operation other than war (OOTW; for more on this perspective, the reader is referred to the classic work by Kitson, 1971). The task of the nations under terrorist threat is to detect the group's individuals and their intentions before they can carry out destructive actions. For this, their intelligence services count with large amounts of raw data obtained from many different sources: signal intelligence, open sources, tips from informants, friendly governments, and so forth. However, this data is not always reliable and almost never complete, and the truly interesting events are usually to be found hidden among large amounts of similar looking facts. To deal with this situation, intelligence officers use sophisticated information technology tools. Several authors have pointed out that this task is not at all dissimilar from the task that strategists in business intelligence (BI) and knowledge management (KM) face: As in KM, in intelligence the challenge is that "the right knowledge must get to the right people at the right time" (Pappas & Simon, 2002). Therefore, intelligence experts may learn something from studying BI and KM, and their history and milestones, while business strategists may also be enlightened by the history and lessons of military intelligence (after all, military intelligence is an ancient discipline; in contrast, KM can be considered a newcomer). In this article, we describe the intelligence analysis cycle and compare it with the KM cycle (we assume the reader is familiar with KM, but not with intelligence tasks). We point out the similarities (and the differences) between the two, and highlight several ways in which military intelligence may benefit from the hindsights and techniques developed by KM practitioners. We also briefly describe tools and methods from military intelligence that KM practitioners may find illuminating. We close with a discussion of future trends and some conclusions.

BACKGROUND: INTELLIGENCE ANALYSIS

The ultimate goal of intelligence analysis is to provide a customer, military or civilian, with the best possible information to help in making policy, strategic, and tactical decisions that affect national security[1]. In this task, intelligence is used to refer to knowledge and information, the basic end product of the analysis. Such analysis is carried out by highly trained analysts who work in a continuous process involving the following steps[2].

- Need Analysis: Customers (policy makers and others) make requests that the analyst must translate to specific requirements and tasks in order to make sure that the final product answers the needs of the customer. Customer demands often need interpretation or analysis before they can be expressed as an intelligence requirement (Krizan, 1996). The customer may have additional constraints on the intelligence product; the request may have time constraints (short term vs. long term) or scope constraints (broad or strategic vs. narrow or tactical).
- Collection: This refers to the gathering of raw (uninterpreted) data. Nowadays, there is an abundance of data due to the variety and richness of sources:
  - Signal intelligence (SIGINT) includes information from radar, telemetry, and intercepted communications.
  - Imagery intelligence (IMINT) refers to images delivered by electronic means, mostly satellites.
  - Measurement and signature intelligence (MASINT) is data produced from sensors (chemical, acoustic, etc.) other than SIGINT and IMINT.
  - Human-source intelligence (HUMINT) refers to data provided by informants, either through clandestine means, official contacts with allied nations, or diplomatic missions.
  - Open-source intelligence (OSINT) refers to publicly available information (radio, television, newspapers, commercial databases, etc.); this is in contract with all previous sources, which are usually classified and not open.
- Processing and Exploitation: In this stage, the raw data is converted to a form suitable for further analysis. This includes the translation of documents in foreign languages, analysis of sensor data, decoding of messages, and so forth. These tasks consume a large amount of resources from intelligence agencies since many of them are labor intensive, and specialized personnel are needed to carry them out. Moreover, in this phase, the evaluation of the accuracy, reliability, and meaning of the raw data (which continues in the next step) gets started.
- Analysis and Production: In this stage, the processed data are integrated, interpreted, and evaluated. In this crucial phase, the analyst must assess how reliable and complete the data pieces are, how distinct pieces of

data can be interpreted, and how they fit in an overall picture. The first task is needed since many times the sources of information are not trustworthy, and an adversary may leave indications that actually mislead an intelligence agency in order to disguise real intentions. The second task is needed since raw data is rarely unambiguous; the same act (for instance, buying fertilizer) may signal completely different intentions depending on the context (to work on a farm or to prepare explosives). The last task is needed since data is rarely complete; after all collection is done, analysts usually have only fragmented and sometimes unrelated evidence. Finally, even after some conclusion is reached, there are two tasks left. First, analysts try to verify their work by correlating finished intelligence with data from other sources, looking for supporting evidence and/or inconsistencies. Because the process is far from exact, and is based on partial, tentative evidence, all conclusions reached are by necessity also tentative, best estimate interpretations. Note that in this step we go from facts to interpretation and judgment; hence, it is in this step that the danger is greater for presumptions, biases, and other problems to arise. Second, the created intelligence must be tailored to the customer, and an effort must be made to make sure that the product answers the customer's needs. In particular, the information produced must be relevant to the original answer, as accurate as possible (and, if uncertain, accompanied by some measure of its certainty), objective, usable (i.e., actionable), and timely.

- Dissemination: This is simply the process of delivering the finished product to the consumer. Sometimes, this is followed by the consumers providing feedback to the intelligence analyst so that the process can be improved.

While some intelligence is produced in response to a specific demand from a consumer, other intelligence is produced simply in order to keep track of ongoing events, to detect trends and patterns, or to be aware of events that may develop. As a result, finished intelligence can be of one of several categories, depending on its origin, subject, type of analysis, and/or intended use. With regard to origin, intelligence may be analyst driven, event driven, or scheduled (periodical). With regard to subject, intelligence may be economic, geographic, political, scientific, and so forth. With regard to the type of analysis, intelligence can be descriptive or inferential; in the latter case, it can be about the past, the present (warnings), or the future (forecasts; Waltz, 2003).

In the United States alone, there are several intelligence agencies that are collectors of data and/or producers of finished intelligence based on several departments. Collaborations among these agencies have been notably absent in the past.

KM IN INTELLIGENCE ANALYSIS

The idea that KM has a role to play in intelligence analysis is not new. In a seminar paper, Brooks (2000) already stated our main thesis, namely, because of similarities in goals, issues, and tasks, KM could lend significant insight when analyzing intelligence work and vice versa. The book by Waltz (2003) has this very same thesis at its core. Moreover, the 9/11 Commission has stated that some of the most serious failures in intelligence that had been observed (the lack of communication between the FBI and CIA, and the obsolete information technology deployed at the FBI) stem from not having an adequate knowledge management strategy in place: "In essence, the agency didn't know what it knew." Also, the book by Krizan (1996) starts with a prologue under the subtitle "National Intelligence meets Business Intelligence." But the most revealing proof of the influence of KM in intelligence work may be the creation, by the Central Intelligence Agency, of a nonprofit enterprise (In-Q-Tel) devoted to identifying promising technologies and funding companies developing them. In this article, we focus on the influence of KM on intelligence work, concretely on techniques and tools of KM that could have an impact on intelligence tasks. We will also briefly mention aspects in which intelligence work is influencing KM, although this is not our main topic.

In order to achieve our goal, we start by listing similarities and differences between KM and intelligence as this will help us understand which methods may transfer.

- Relationship with a Customer: Both BI and intelligence have the need to satisfy a customer (the policy maker or military command in the intelligence case, the company executive in the BI case). Furthermore, in both cases, customers may not articulate the exact needs in terms conducive to the intelligence task, but in terms that make sense to themselves. Also, in both cases, the customer requires actionable intelligence, that is, information that supports decision making and planning. It is up to the analyst to ensure that the final product of analysis has, at least to some degree, several characteristics that will make it useful to the customer: It is to be accurate, objective, usable, relevant, and timely. Finally, because we live in an era where access to information is easy, both BI and intelligence analysts need to add value, going beyond what the customer already knows (which may be quite a lot) by offering analytical skills.
- Data Analysis: Both in the BI and intelligence cases, analysts have at their disposal large amounts of raw data (usually from open sources); however, the information sought is usually hidden within this massive set of uninterpreted, unconnected set of facts. Both BI and intelligence rely on IT to deal with this large amount of data (Waltz, 2003). However, there is no procedure that will yield the needed results on each case. Several techniques must be used in the analysis, and many times the analysis relies also on the intuition and experience of the analyst. Another similarity is the fact that scenarios under analysis have widened considerably. In BI, it is routine now to watch data on many different fields, from technology to politics to the weather. Also in intelligence, routine political analysis is being complemented by historical, economical, and other analyses.
- Transformation of Tacit Knowledge: Both companies and intelligence organizations have a large deal of tacit (implicit) knowledge in the heads of senior personnel and in the informal networks developed over time as a byproduct of work processes. Analysts, either in business or intelligence, absorb and internalize information; this manifests itself externally in social interaction (meetings, memos, etc.; Waltz, 2003). In both cases, it is very important to leverage (by making explicit, recording, and cataloguing) as much as possible this internal knowledge. This is a difficult task but it offers the possibility of a large payoff in the form of expertise that is kept in house when people leave the organization (Von Krogh, Ichijo, & Nonaka, 2000).

An important difference is the adversarial nature of the intelligence scenario. Each party tries to protect information about itself by hiding it and by deception. While in industry there is also a need and a practice for a certain amount of secrecy, there is usually no need for deception (at least not on a large, organized scale). Hence, intelligence must deal with information that may not be trustworthy; the sources must be carefully considered and the information has to be cross-checked with other available information. BI does not have to bother itself with these issues. As a consequence, the amount of what we called processing and exploitation is much smaller in BI than it is in Intelligence. The analysis phase also takes on a different character. Because of the need to evaluate the reliability of sources in intelligence work, evaluating and selecting evidence is an important part of the analysis; this step is rarely needed in BI.

Another important difference is the reserved nature of sources in intelligence work. This has consequences throughout the intelligence cycle: Sometimes it is not possible to go back to the source for additional information, and sometimes results cannot be disseminated as this would compromise the source of some data. This is why sometimes the intelligence process has been described as "the process of the discovery of secrets by secret means" (Waltz, 2003, p. 2).

Finally, a crucial difference is the extreme need for security in intelligence work. While companies are more and more aware of the need for security (due to industrial espionage, market competition, and malicious attacks to their networks), in the intelligence world there are a series of long standing procedures to restrict access, usually based on credentials (clearance levels) and on policies like need-to-know.

KM TECHNIQUES IN INTELLIGENCE

Based on our previous analysis, we can sketch a list of KM techniques that are bound to be beneficial for intelligence analysis.

- Creation of an Organizational Memory, including a Best-Practices Repository: Since much work by the analyst relies on his or her experience and intuition, such experience and intuition are great resources that must be kept and shared. Best-practices repositories do just that. Such repositories help not only to improve ongoing analysis, but they aid in the purpose of training (Clift, 2003; Pappas, & Simon, 2002). The intelligence community has recognized the importance of this approach and has tried to incorporate it into its practice, for instance, by collecting best practices (called tradecraft in the intelligence world); however, this has been done mainly in print (Product Evaluation Staff, Directorate of Intelligence, Central Intelligence Agency, 1996) without the support of IT tools that would facilitate searching and dissemination (Watson, 2002).
- Creation of Communities of Interest and Communities of Expertise: Many times, intelligence analysis requires considerable expertise in more than one area: Economical, political, military, and historical knowledge may be needed for a single task. No person is likely to possess all the knowledge so the analyst must frequently consult experts. Connecting analysts to the right person to consult for a given task would increase the quality of the analysis. Note that, in creating such communities, the intelligence agencies face the same problems that companies do, for instance, the common good problem (the cost of the effort to providers outweigh the benefit to consumers since the provider does not benefit). Several solutions applied in business may be useful here, too: Reduce the cost to providers (make it as easy as possible to give advice, etc.) and/or reward them. Ultimately, one should strive to achieve equilibrium (mutual reciprocity) as providers also become consumers; at this point, the problem goes away. However, starting may be difficult since communities need critical mass: They are only good if enough people use them. In fact, bootstrapping the com-

munity may be the hardest part (Clawson & Conner, 2004).

- Information Management Tools: KM has special information management needs that databases do not fulfill, so certain tools and techniques are of special interest in KM. The same tools could be very useful to the intelligence analyst. Among them, we point out the following:
- Document Management Tools: A considerable amount of information accessed by the analyst is disseminated in documents of several types: memos, reports, and so forth. Clearly, one of the challenges in the intelligence process is to find the relevant facts from among all the data available from different sources. Databases can easily index, sort, and access with efficiency-structured data, that is, data that has been entered in a certain format, usually specified in advance by a database designer. However, data in documents tend to be semistructured (i.e., they have irregular, dynamic structures) or unstructured (i.e., any structure is implicit and not known beforehand), and databases tend not to deal well with this sort of data. On the other hand, information retrieval (IR) systems deal well with such data, but usually offer only limited search capabilities (keyword-based processing). A new generation of tools, however, is emerging around information extraction (IE) technology to specifically address the challenges of managing document-based information. Such tools can be a valuable aid for the analyst, especially since often the information in documents (e-mails, memos, etc.) may lead to tacit knowledge (Asprey & Middleton, 2003). As an example, what people write in e-mails, memos, and so forth gives strong clues as to what their expertise is. In the context of intelligence work, though, such tools must include sophisticated access control (separate privileges for viewing, versioning, annotating, and printing, for instance) in order to deal with security issues (Mena, 2004).
- Collaborative Tools: Due to the complexity of today's intelligence analysis, most analysts are experts in a well-defined domain. This specialization means that complex problems that are best attacked from several angles must be tackled by groups, not individuals. However, successful teams require good organization, effective communication, cooperation, and a shared mental model or at least vocabulary. Therefore, collaborative tools (groupware, communication tools, etc.) could be used in this regard. Intelligence agencies are well aware of this situation: Collaborative tools using commercial web technologies are being developed through the Joint Intelligence Virtual Architecture program to assist today's analyst in locating and accessing valuable data, assessing such data, producing an informed analytic product, and moving that product to where it will be of value. (Clift, 2003) Common in KM, such tools are only recently being adopted by the intelligence community, probably because of concerns about security and access. However, the potential payoff of such systems is high, especially if the dissemination of information (based on predefined profiles or dynamic requests) is added to the process being modeled.
- Work Flow Management (WM) Tools: Because each step in the intelligence process (see above) is likely to be given to a different expert, the final product is the result of a collaborative process, a true team effort. The members of this team must communicate easily and effectively; the better the communication, the more likely the final product will be of high quality. WM tools help control collaborative processes and

therefore are very relevant in this area. Thus, just like collaborative tools address collaboration at the process level, work flow management tools support collaboration at the analysis level.

- Intelligent Indexing and Search Tools for Multimedia Data: Due to the variety of sources, intelligence analysts work with data in several formats. The need to link all available data, unearthing unknown connections, means that all data should be indexed and tagged to facilitate further analysis. These tools are especially important nowadays because they help combat information overload and because with abilities like push-pull (subscribe query) dissemination and intelligent text processing (sometimes in multilingual environments), the tools support the knowledge exchange cycle, facilitating the transformation between tacit and explicit knowledge (Waltz, 2003).
- Cognitive or Analytical Tools: Used especially in the analysis and production phase, these tools focus on the reasoning process itself: keeping track of hypotheses, goals, and their interrelationships, choosing among alternatives, and performing what-if analysis. The importance of these tools is that they help counteract natural biases and shortcomings of the analyst's mental model. Because these are part of internalized knowledge, such biases are difficult to identify and deal with, and they constitute a serious problem in intelligence work (Heuer, 1999) where dealing with deception and hard-to-interpret information is part of everyday work (Waltz, 2003).

Note that the above list relies heavily on IT tools and techniques. Clearly, there is more to KM than IT. In fact, it is well known that managerial and organizational changes are needed in order to support KM (Davenport & Prusak, 1998; O'Leary, & Studer, 2001). Therefore, strategies to make the tools work within the organization are an integral part of KM. Some authors state that real KM is not achieved until there is a culture change in the organization (Brooking, 1999; Davenport and Prusak). To support organizational learning, collaboration, and team problem solving, businesses have adopted a variety of strategies (Choo & Bontis, 2002). Such experiences are another source of knowledge from which intelligence agencies may greatly benefit since historically they have worked on a very different mindset-one that encouraged secrecy.

INTELLIGENCE IN KM

As it is often the case, the adoption of KM techniques in intelligence (and in the military at large) has resulted in the adaptation of old techniques to new circumstances, or even the development of new ones. As a result, intelligence officers have also contributed some concepts that are useful to KM at large. It is notable, in this context, that military strategy has recently become trendy in business circles, with books like the classic Art of War by Sun-Tzu being recommended literature for executives. Another notable trend is the adoption of KM techniques in the military at large; in fact, the Army has declared "information superiority" as one of the key concepts of the Army of the future in the "Joint Vision 2020," a report from the U.S. Joint Chiefs of Staff issued in 20003. One area where intelligence leads the way is the emphasis on security. As stated above, in a business environment, the situation is not openly adversarial but is competitive nonetheless. Malicious network attacks by hackers, disruptive tactics used by competitors in other countries (industrial espionage, etc.), and the fact that a country's economy is also a target in terror warfare have made businesses more and more aware of the need for strict security policies and methods. Data mining techniques, common in business to better understand clients and the market, are also being used to protect from internal and external threats: "To protect from insider threat, an organization could mine employee's information to learn about travel patterns, emails, phone conversations, work habits, computer usage, [and] Web usage" to determine if an individual is likely to betray the organization (Thuraisingham, 2003, p. 359). Measures like compartmentalization, access based on clearance levels, and need-to-know policies will help in this regard, although they must be carefully implemented so that they do not restrict the flow of information or collaborative efforts.

Another area in which intelligence agencies are well versed is the need for appropriate training. Because analysts must have a thorough formation phase to be useful to their agency, several practices (including mentoring from senior analysts) have been adopted that should be considered in a business setting.

Finally, some concrete techniques seem to have great potential for transfer. For instance, the institution of postmortem analysis, especially of failures, facilitates the creation of an institutional memory and is a great resource for further analysis, like "meta-analysis of the causes and consequences of analytical success and failure" (Heuer, 1999). Such practices, therefore, should be readily adopted in the business world, although resistance to them should be expected and will have to be dealt with through managerial measures. Another particular technique developed in the intelligence community is link analysis: the search for relationships among seemingly unrelated pieces of information in order to uncover previously unknown connections. This technique forms the basis for social network analysis (Sageman, 2004) and could prove very useful in BI. Finally, there are tools like modeling and simulation tools (especially in the modeling and simulation of the analysis process) and data visualization tools, which are already in use in the intelligence community but are still not as common in BI. It is very likely that such tools will become more and more important in the latter.

FUTURE TRENDS

There is no doubt that the future will see still further interaction between the KM and intelligence communities. Their similarities mean that they will continue learning from each other and influencing each other. On the intelligence side, as the commoditization of sensors and other data acquisition technologies means that all parties will have access to most of the same data, the emphasis will shift to analysis and synthesis (Waltz, 2003). Also, a fast changing environment means that the ability to cope with change will be needed by the intelligence community. The business world, having recognized this need some time ago, has already addressed the problem (although not all techniques from the business world will be readily applicable, like sharing information with business partners and suppliers, due to security concerns; Bennet & Bennet, 2003). Overall, KM processes and methods will become more and more relevant. Thus, it is likely that, in the near future, each area surveyed in this article will continue to be developed and lead to further interaction.

Some areas that will require further attention in the near future include how to share data securely; it will be necessary to track how information is being accessed and used in order to make sure that security is not compromised. Thus, collaboration tools will have to add this ability. Also, the stress on information access and dissemination means that new techniques for personalization, profiling, and distribution (like push-pull systems; Glance, Arregui, & Dardenne, 1998) will become more and more appealing to intelligence organizations.

Finally, the introduction of collaboration and other tools will foster the development of informal communities in intelligence organizations. Efforts in the business world to nurture and sustain such communities will provide guidance to the intelligence community (Clawson & Conner, 2004).

CONCLUSION

There is a strong connection between knowledge management and intelligence work that only now has begun to be explored with the depth it deserves. Several authors have already pointed out that intelligence organizations need KM due to the size and complexity of the data being processed, the level of expertise needed to process the data, and the sophistication of the final product, which must have the qualities of actionable knowledge. Here we have provided only a short introduction to this line of work. Some preliminary conclusions can be drawn already: The parallelisms this analysis unearths are resulting in a cross-pollination of techniques and tools that can only be beneficial to professionals on both sides, and there are still many parallelisms to be uncovered. Thus, it is important to continue work in this direction, especially in times of need like the present one.

ENDNOTES

[1] In this article, we will not distinguish between national and military intelligence (Waltz, 2003) as we are interested in a high-level analysis for which this distinction is not very productive.

[2] Our description of the intelligence cycle is, out of necessity, highly summarized; the interested reader is referred to A Consumer's Guide to Intelligence (1998), Krizan (1996), and Waltz (2003).

[3] As an example of KM tools already in use in the U.S. Army, the Program Executive Office Command, Control and Communications Tactical (PEO C3T) has developed a knowledge-center Web portal that has served as a precursor and model for the service-wide Army Knowledge Online (AKO) Internet site. The portal has a variety of technology products and capabilities, such as project-management tools, repositories, work-flow applications, and similar tools, and it serves as the daily operations center of the workforce for PEO C3T and other

Army agencies. This tool has put recent emphasis on externalizing tacit knowledge. Efforts to capture knowledge and create communities of practice among subject-matter experts have also been extended (Donnelly, 2003). Outside the Army, the FBI has recently developed the Secure Collaborative Operational Prototype Environment for Counterterrorism (SCOPE), a data mart with more than 34 million documents related to counterterrorism, in which several knowledge-management tools (like collaboration tools) are being used.

Chapter 8.20
Knowledge Management in Smart Organizations

Shirley Chan
The University of Hong Kong, Hong Kong

ABSTRACT

This chapter looks at the deployment of appropriate information and communication technologies in helping smart organizations to manage knowledge. Taking a management perspective, smart organizations can be regarded as those that can make smart strategic decisions and put into practice such managerial principles as value creation, continual learning, embracing uncertainty, and empowerment. Making good decisions would involve gathering and synthesizing the appropriate knowledge—knowledge about the market, products, suppliers, customers, competitors, and others. Different schools of knowledge management theories and the related technologies will be discussed. The author hopes that understanding the knowledge management technologies and related practices would assist researchers and practitioners in gaining some insights into managing the knowledge required for making smart decisions in organizations.

INTRODUCTION

The 21st century witnesses innovative organizational or work arrangements such as digital factory, virtual, or smart organizations. This kind of organization is like a network of independent production units working together, and is flexible and responsive to the challenges and uncertainty of the ever-changing business environment. The increasingly popular deployment of information and communication technologies facilitates these organizations in establishing unconventional work arrangements, networking with fellow co-workers or business partners, and seizing the opportunities as offered by the uncertainty in the current business climate.

Whether these organizations are forming innovative work arrangements, networking with stakeholders, or tapping into new opportunities, they are making strategic decisions in the Knowledge Age. The common thread running through such activities is knowledge—the ability to find, use, store, share, and retrieve the relevant organizational knowledge to make the right move and gain a competitive edge.

The term "smart organization" is used for organizations that are knowledge-driven, internetworked, dynamically adaptive to new organizational forms and practices, learning as well as agile in their ability to create and exploit the opportunities offered by the new economy (Filos & Banahan, 2000).

This chapter focuses on the knowledge sharing, network, and management in smart organizations. It will look closely at the management aspects of smart organizations and how knowledge management fits into the overall organizational management. Taking a management-oriented approach, the notion "smart organizations" appears to be originated from the book Smart Organisation: Creating Value through Strategic R&D (Matheson & Matheson, 1998). The authors consider "smart organizations" as those organizations that develop world-beating products on a continuing basis at prices that establish value leadership. They also regard "being smart" as making good decisions.

We are in the era of the Knowledge Economy. The basis of competition is "knowledge." Mastery of the relevant, crucial, and up-to-date knowledge would enable businesses and organizations to survive well and gain a competitive edge in this age. As stated above, "being smart" means making good decisions. Making good decisions would involve gathering and synthesizing the appropriate knowledge—knowledge about the market, products, suppliers, customers, competitors, regulatory environment, and other aspects. Such knowledge, if well utilized, would facilitate making good decisions so that the related organizations can develop world-beating products and services—befitting to be regarded as "smart organizations."

It would therefore be imperative to look at knowledge management in the context of smart organizations. This chapter will start off by introducing to the readers the general theoretical framework and the nine principles of smart organizations as indicated by Matheson and Matheson (1998), with the focus on how knowledge could be seen as a common thread running through these nine principles. This will be followed by an elaboration of the development and theory relating to knowledge management. It will then focus on how knowledge management helps realize the potential of smart organizations by implementing each of their nine principles. The relevant knowledge management technologies will also be discussed.

BACKGROUND

Smart Organizations

There are different definitions of "smart organization." Some take a broader perspective, while others may be based on a narrower context. These definitions may have some differences according to the field of approach—such as management, information technology, or human resources. A management-oriented definition of "smart organization" can be found in Matheson and Matheson (1998), which will be elaborated immediately below. This chapter focuses on knowledge management in smart organizations as seen from this management-oriented approach.

The term "smart organization" appears to be originated from the title of the book The Smart Organisation by David Matheson and Jim Matheson (1998). They regard smart organizations as those companies that develop world-beating products and services and deliver them at prices that can establish value leadership. They are also of the opinion that "being smart" and "acting smart" would guarantee businesses to succeed in this fast-changing and increasingly competitive market.

They define "being smart" as making good strategic decisions. The authors consider "acting smart" as "the activity of effectively carrying out those decisions." Having said that, what are qualities expected of smart organizations? They conducted a benchmarking of best practices for strategic decision-making in R&D (research and development) in the early 1990s identified organizational characteristics determining whether companies would be successful in adopting best practices. They name these characteristics the "nine principles of the smart organisation" (Matheson & Matheson 2001). These nine principles about smart organizations as indicated in Matheson and Matheson (1998) are as follows:

- Value Creating Culture: The purpose of the organization should be maximizing the value created for customers and captured by the enterprise.
- Creating Alternatives: Choice means that several good alternatives should be created and that the related organization would choose the best one.
- Continual Learning: One of the main objectives of an organization should be learning continually about what would create value and how to deliver it.
- Embracing Uncertainty: People should endeavour to understand all sources of uncertainty and use that knowledge when making decisions.
- Outside-in Strategic Principle: The organization aims at understanding the dynamics of its industry and customers and using this perspective to frame and evaluate strategic decisions at all levels.
- Systems Thinking: It is advisable that the organization answers complex questions by thinking through cause-and-effect relationships in the context of the whole business and identifying leverage points, feedback loops, and key factors.
- Open Information Flow: It is crucial that in the organization, information is available to whomever wants it and that it is used to create value. Such flow of information should cross functional boundaries.
- Alignment and Empowerment: The people involved are empowered and trusted to pursue value creation and that the organization is guided by a shared understanding of its strategies for creating value.
- Disciplined Decision Making: This refers to a decision-making process that identifies strategic choices, involves the relevant people and information, and selects alternatives based on the highest value.

Smart organizations demonstrate most, if not all, of the above nine principles (Matheson & Matheson, 2001), which would enable them to make good strategic decisions. One could therefore argue that a common thread running through these nine principles is knowledge—gathering, utilizing, and understanding the relevant knowledge—knowledge about the industry, market, products, suppliers, customers, competitors, and other related issues to facilitate the organization in making good strategic decisions, rendering them to be considered as "smart." It is therefore imperative for smart organizations to understand the practices of knowledge management and the related enabling technologies so that they could make the best use of such practices and technologies to implement each of the nine principles.

Knowledge Management

Some wonder what is meant by "knowledge" and how it is different from information and data.

Schoderbek, Schoderbek, and Kefalas (1985) regard "data" as " … unstructured, uninformed facts so copiously given out by the computer. Data can be generated indefinitely; they can be stored, retrieved and updated and again filed…." They are also of the view that "information" refers to facts with meaning or evaluated data. One of the world's leading experts in knowledge management, Karl-Erik Sveiby, stated that information simply exists and is all waiting to be interpreted, to have meaning attached by people, and becomes knowledge at the moment of its human interpretation (Miller, 1999).

One of the management gurus, Earl (2001), is of the opinion that theoretical insights into how knowledge might be managed are available from several disciplines, including economics (Silberston, 1967), philosophy and epistemology (Kuhn, 1970), computer science (Hayes-Roth, Waterman, & Lenat, 1983) and sociology (Polanyi, 1958; Polanyi, 1966).

One of the world-renowned knowledge management gurus, Yogesh Malhotra, stated that the term "knowledge management" has been appearing in information systems literature over the past two decades, since the 1980s. This is because the knowledge management systems were traditionally included into the information systems research domain, with a heavy artificial intelligence and expert systems emphasis (Malhotra, 1999).

Throughout the 1990s, knowledge management as a discipline received more attention as managers in the post-Industrial Age had become more aware of the phenomenon that knowledge may be the most critical resource, rather than land, machines, or capital (Drucker, 1993). From a more practical perspective, knowledge management was considered to be central to product and process innovation and improvement, to executive decision-making, and to organizational adaptation and renewal (Earl, 2001). Different schools of thought regarding knowledge management emerged during the 1990s, which will be discussed immediately below.

IT Track and People Track

Karl-Erik Sveiby concurred with the above view that knowledge management has a technology-oriented origin. His observation was that during the 1990s and leading up to 2000, knowledge management specialists were from the "IT track." They were researchers and practitioners that have their education in computer and/or information science, and were involved in constructing information management systems, artificial intelligence, reengineering, and groupware. This "IT track" went through three rapid phases: (1) The first phase started around 1992 and focused on productivity issues such as "How can we use IT systems to prevent reinventing the wheel?" (2) The second phase had a customer focus addressing such concerns as "How can we leverage what we know about our customers to serve them better?" and (3) The third phase was sometime around 1999 to 2001, coinciding with the dot.com boom and there was much discussion about interactive IT Web pages, e-business, and online transactions (Sveiby, 2001).

During the knowledge management evolution along this IT track, there was the emergence of various schools of thought focusing more on the non-technical aspects of knowledge management, or one could name that as the "people track" (Sveiby, 2001)—that knowledge is an organizational resource and that people play a key role in the process of creating, utilizing, and managing knowledge. One of these is the "intellectual capital" school of thought led by Leif Edvinsson. He is probably the world's first corporate director in intellectual capital. In his capacity as the intellectual capital director of Skandia, the Swedish insurance and financial services company, he engineered the publishing of the world's first intellectual capital annual report (Anonymous, 1997). He advocated that such intangible assets as intellectual capital (like an employee with a PhD) could be measured, and the resulting value

Table 1. Knowledge management schools of thought: IT track and people track

IT or People Track?	Development Phase or Focus	Main Issue
IT Track	First Phase – Productivity Focus	How can we use IT systems to prevent reinventing the wheel?
	Second Phase – Customer Service Focus	How can we leverage what we know about our customers to serve them better?
	Third Phase – Dot.com Boom	Discussion about interactive web pages, e-business and online transactions.
People Track	Market Value and Competitive Advantage	Organisations can understand, analyse, measure and manage their intellectual assets and turn their organizational knowledge into market value.
	Knowledge Creation	SECI Model – Organisational knowledge creation process involves four stages: socialization, externalization, combination and internalization.
	Narrative and Context	We manage knowledge as a flow and not as a thing.

could be included in the annual financial statements (Edvinsson & Malone, 1997).

Advocates of the "people track" of knowledge management tied in knowledge management with business strategy and generating value. Thomas Davenport and Larry Prusak drew on their work with more than 30 knowledge-intensive organizations and examined how different kinds of companies can effectively understand, analyse, measure, and manage their intellectual assets, turning corporate knowledge into market value (Davenport & Prusak, 1997). Two Japanese experts, Nonaka and Takeuchi, offered a refreshing approach to knowledge management when they published their book The Knowledge-Creating Company: How Japanese Companies Create the Dynamics of Innovation in 1995 (Nonaka & Takeuchi, 1995). They proposed a SECI model for understanding the organizational knowledge creation process, which involves four stages: socialization, externalization, combination, and internalization (Nonaka & Takeuchi, 1995; Ursin, 2000). They further commented that the traditional Western view, emphasizing the organizational importance of knowledge that is codified and stored through such technical means as the databases, should be broadened to include tacit knowledge, which is knowledge based on experiences, insights, hunches, and perspectives, and often remains in human brains. Dave Snowden advocates that we should grow out of managing knowledge as a thing, but rather as a flow—which means we should focus more on narrative and context when sharing or managing knowledge, rather than just the content. This emphasis on narrative suggests that we can always know more than we can tell and we will always tell more than we can write, because the process of writing reflective knowledge is time consuming and involves loss of control over its subsequent use (Snowden, 2002).

Technocratic, Economic, and Behavioural Approaches

The "IT track" and "people track" approaches as proposed by Sveiby (2001) could be one way of viewing the developments of the knowledge management field. Earl (2001) suggested an alternative model of viewing such developments—three approaches consisting of seven schools. The first three schools are labelled "technocratic," as they are based on the premise that information technology supports and, to various degrees, conditions employees (or knowledge workers) in their daily tasks. The first school is the systems school, whose fundamental idea is to capture specialist knowledge in knowledge bases (from conventional databases through CD-ROMs to expert systems), which other specialist or "qualified" people can access. The second school is the cartographic school, which is concerned with mapping organizational knowledge and aiming at recording and disclosing who in the organization knows what by building knowledge directories to ensure that knowledgeable people in the organization are accessible to others for advice and consultation. The third school is the process school, which is a derivative or outgrowth of business process engineering. There are two ideas driving this school:firstly, performance of business processes can be enhanced by providing operating personnel with knowledge relevant to their tasks, and secondly, management processes are more knowledge-intensive than business processes (Earl, 1994,2001).

While the first approach emphasizes the "technocratic" aspect, the second approach is "economic" in nature because it has a business orientation explicitly creating revenue streams from the exploitation of knowledge and intellectual capital. It is perhaps what Davenport, De Long, and Beers (1998) described as "managing knowledge as an asset," where knowledge or intellectual assets consist of patents, trademarks, copyrights, and know-how (Earl, 2001).

The third approach is "behavioral" in nature, as it seeks to stimulate and orchestrate managers or managements to be proactive in creating, sharing, and using knowledge as a resource, and there are three schools of thought under this head. The organizational school emphasizes using organizational structures or networks to share or pool knowledge. They are often described as "knowledge communities," which are groups of people with common interests, problems, or experiences. These communities are designed and maintained for a business objective, and could be either interorganizational or intraorganizational in terms of arrangement. Although such communities may be supported by technology, this school is still under the "behavioural" approach because the essential feature of these communities is that they exchange and share knowledge interactively and often in nonroutine, personal, and unstructured ways, as an interdependent network. Another school is the spatial school, which centers on the use of space—or spatial design—to facilitate knowledge exchange or sharing. Typical examples include the metaphors quoted in modern management journalism—such as the water cooler as the meeting place, the kitchen as a "knowledge café" or the open-plan office as a "knowledge building." These are essential "spaces" for knowledge transfer within modern organizations, as most people are social beings who like human contact and often prefer conversation to documents or information systems. Tacit knowledge is most likely to be discovered and exchanged when people socialize within such spaces—and an alternative label for this school could be social school, because the rationale is to encourage socialization as a means of knowledge exchange.

Finally, the strategic school is primarily concerned with raising consciousness about the value creation possibilities available from recognizing knowledge as a resource, and this explains why some corporate mission and purpose statements embrace knowledge as an important item on the organizational agenda (Earl, 2001).

KNOWLEDGE MANAGEMENT PRACTICES AND TECHNOLOGIES: IMPLEMENTING THE NINE PRINCIPLES

As stated above, there are generally nine principles characterizing an organization to be a smart organization and that one could argue that knowledge is the common thread running through these nine principles, as smart organizations need to make good strategic decisions in the knowledge age. Below will be a discussion on how common knowledge management practices and technologies would help implement or realize each of the nine principles, rendering an organization smart. During the discussion, current knowledge management theories and schools of thought will be included as appropriate.

Value Creating Culture

It is crucial for a smart organization to aim always for value creation. Within such organization, it would be ideal if every person saw his or her final job as creating the greatest value. There could be changes or exceptions to rules if these rules stand in the way of creating value. In respect to organizational culture, it aims at rewarding those who work to create more value and encourages different functions to collaborate to create value. In case there are disagreements within the organization, the policy is that they should be resolved in favor of attaining the greatest value (Matheson & Matheson, 1998).

Table 2. Different schools of thought regarding knowledge management

Approach	**School of Thought**	**Main Issue**
Technocratic	Systems	Capture specialist knowledge in knowledge bases (e.g. databases) which specialist people can access.
	Cartographic	Map organizational knowledge by building knowledge directories so that others in the organisation can consult them.
	Process	Business processes can be enhanced by providing operating personnel with relevant knowledge. Management processes are more knowledge-intensive than business processes.
Economic	Economic	It has a business orientation explicitly creating value streams from the exploitation of knowledge.
Behavioural	Organisational	It emphasizes using organizational structures or networks to share or pool knowledge such as “knowledge communities”.
	Spatial	It centres on the use of space to facilitate knowledge exchange or sharing.
	Strategic	It is concerned with raising consciousness about the value creation possibilities available from recognizing knowledge as a resource.

The conventional way of understanding "value creation" in the past two decades has been influenced by the notion of industrial logic, in which value is added in sequential stages based on the premise that each part can be optimized individually and therefore contributing to the overall organizational value creation (Ramirez, 1999; Roberts, 2000; Skoog, 2003). During the past two decades, nonlinear models have been challenging this traditional value creation framework (Heskett, Jones, Loveman, Sasser, & Schlesinger, 1994; Simons, 1995; Ramirez, 1999; Roberts, 2000; Skoog, 2003). These new perspectives emphasize the role of different actors (stakeholders) as coproducers or creators of organizational value. They appear to stress the significance of combinations and connectivity among the related actors or stakeholders and assert that a significant part of the value creation cannot be expressed in mere monetary terms (Heskett et al., 1994; Simons, 1995; Ramirez, 1999; Roberts, 2000; Skoog, 2003) because "value," or the currency in the current knowledge economy is "knowledge," which is an intangible asset not normally measured in terms of money.

Our knowledge economy is characterized in terms of the nature of its products and services being knowledge-based. Value creation in the knowledge age is therefore very much related to strategically leveraging an organization's intellectual or knowledge capital. It is important for an organization to have the capacity to coordinate, orchestrate, and deploy its knowledge resources toward creating value in the pursuit of its future vision. In fact, the nature and rationale of intellectual capital is about creating value through developing and deploying knowledge-based competitive advantages faster than the competitors or the pace of change in the industry (Rastogi, 2003). Knowledge and its exploitation for creating value are the conjoint outcomes of organizational learning (Senge, 1990; Rastogi, 2003). During this process, an organization may have to meet many challenges and exploit various opportunities in its quest for value creation (Rastogi, 2003). Effectively managing knowledge would help organizations to overcome such challenges and make the best use of such opportunities so as to achieve the ultimate goal of creating value.

Extranets

Our current business environment is becoming more competitive, with customers having a wide variety of consumption choices, each alleging to be offering high-quality products or services with a relatively lower price. In this context, "value'" can be seen in the context of the relationship between supplier offerings and customer purchases by identifying how the supplier fulfils the customer's needs (Band, 2000; Porter, 1998; Clarke, 2001). Mastering the knowledge about the customer's needs or requirements would be of utmost importance in creating value for a smart organization.

The knowledge management technology of extranets could help organizations better understand customers' needs and deliver a better service and thereby create value. Extranets are secure Internet protocol-based networks linking the information infrastructures of various extranet participants—in the business context, usually one or more of the following parties: suppliers, vendors, customers, and business partners (Bushko & Raynor, 2001). Extranets are a result of the evolution of electronic document exchange (EDI) technology, which has been used for many years to connect organizations together for supply chain integration. EDI used the automated exchange of simple, highly structured electronic forms over private networks, whereas extranets dramatically extend the benefits of interorganizational integration through the intertwining of EDI with Internet technologies. Since the Internet is a public and international network based on the Internet protocol (IP) and related standards, it provides a standard of interconnecting networks so that any system can communicate with any other system. Hence, extranets have the advantage of allowing various organizations having different hardware and software to communicate given extranets' use of the Internet's open standards (Yen & Chou, 1999, 2000).

One of the common purposes of extranets is to allow various organizations to share their information resources and knowledge storage, facilitate their knowledge flow, and work with their suppliers, customers, distributors, and other businesses to reach a common goal. The knowledge flow could be in relation to the customers' knowledge about the vendors' products and services, or business partners sharing their knowledge about certain target markets with the view of setting up joint ventures there. The essence of the extranets, from a knowledge management perspective, is allowing each of the extranet partners to access certain permitted areas of their business partners' networks in order to gain access to the requisite knowledge.

Such knowledge management could add value to the service delivered to the clients. For instance, extranets linking an organization with its customers or clients are instrumental in strengthening client relationships and creating value for clients. An example would be Deloitte Consulting's UK practice developing a highly technologically sophisticated extranet to link up a client firm in respect of a major strategy project. It uses the extranet to communicate sensitive information to a select audience (in this case, the client firm), keep the clients and other stakeholders informed of the strategy formulation process, and allow the clients access to the detailed information about the project as the project goes on (Bushko & Raynor, 2001). The added "value" as exemplified in this case is enhanced client service quality—in the sense that in addition to Deloitte providing high-quality consulting service, the client firm can actually get access to the relevant information sources at Deloitte to keep track of the internal workings of the project and thereby facilitate consultant/client relationship.

Customer Relationship Management Systems

While extranets connecting an organization's networks to its customers may have the potential of enhancing the service quality, the technology of customer relationship management systems would help manage knowledge about customers' needs and customer relationships and enable the organization to create value. Customer relationship management is about using information technology in implementing relationship marketing strategies. Berry (1983) first introduced the term "relationship marketing," which is concerned with how organizations manage and improve their relationships with customers for long-term profitability (Ryals & Payne, 2001). He defined relationship marketing as "attracting, maintaining, and … in multi-service organizations … enhancing customer relationships" (Berry, 1983). Since then, the field of relationship marketing has generated much interest and attention (Sheth, 2000). The longer the customer relationship lasts, the more profitable customers are shown to be, and therefore the focus of customer relationship management is on the lifetime value of the customer, rather than the profitability in any single period (Reichheld, 1996). Relationship marketing advocates view the customer relationship as an asset that can be managed and that requires investment. Technology can help organizations manage the information that they need to understand customers, so that appropriate relationship marketing strategies can be formulated (Ryals & Payne, 2001). This is where customer relationship management systems play a role.

Kutner and Cripps (1997) contend that customer relationship management is based on four premises: (1) manage customers as important assets; (2) customer profitability varies, and not all customers are equally desirable; (3) customers vary in their needs, preferences, buying behaviour, and price sensitivity; and (4) by understanding customers drivers and profitability, organizations can tailor the products and services they offer in order to maximize the overall value of their customer portfolio (Ryals & Payne, 2001). Kotler (1990) is of the view that organizations should make the best use of technology to manage their customer relationships. They could build and use customer databases to keep track of what customers are buying and what they are interested in, therefore utilizing such information to serve customers better (as quoted in Caruso, 1992; Ryals & Payne, 2001).

Such information can be used to strengthen the relationship with the customer and increase customer value over time (Gronroos, 1997). For instance, First Direct bank uses the data from a previous transaction in a proactive way in order to strengthen the relationship by personalizing a later transaction. The customer, who wishes to use his First Direct bank card in an American ski resort, asks for information about automated teller machines there. In a subsequent transaction, a different call center operator uses this information to check whether this customer had a satisfactory experience. External data sources can also be added to the store of knowledge about customers. Market research results or information from other databases can also be added to this customer knowledge store (Ryals & Payne, 2001).

As mentioned above, creating value requires knowledge and understanding of the customers, their needs and requirements, and other related factors. These factors could be the market, competitors, and regulatory environment, which could impact the customers' needs. Such an understanding would help the organization evaluate alternatives and the business environment, find the appropriate strategic position, and make a wise decision rendering the organization to add value to the customers.

Creating Alternatives and Disciplined Decision-Making

Disciplined decision-making is a process identifying strategic choices, engaging the right information and people and selecting alternatives based on the highest value. People working in smart organizations should understand the nature, importance, and process of decision quality and initiate the appropriate process in addressing the strategic decisions. Part of the culture of the smart organizations is that a quality decision is applied to every important decision, including portfolio, technology, and R&D project strategy (Matheson & Matheson, 1998).

As disciplined decision-making involves identifying strategic choices, there would be a preceding step, which is creating alternatives. The notion of creating alternatives is about looking for high-value alternatives that are desirable, safe, and rewarding. It also requires committing to evaluating alternatives honestly and without prejudice, if possible. Generating alternatives would pave the way and allow for more choices when it comes to the stage of identifying strategic choices. Choice means creating various good alternatives and selecting the best one as appropriate for the situation (Matheson & Matheson, 1998).

The processes of alternative creation and disciplined decision-making—generating, identifying, and evaluating options and selecting the most appropriate one—would be facilitated by knowledge sharing and retrieval. This is because one that is well-equipped with the requisite knowledge would be in a position to generate the relevant alternatives and make an informed decision. Sharing knowledge among people concerned and retrieving knowledge from databases or other knowledge storage places would help maximize the knowledge base on which an organization or each individual within that organization can create alternatives and make a good strategic decision. The knowledge base could be in relation to the knowledge about the industry, markets, customers, suppliers, competitors, and other stakeholders.

Knowledge sharing and knowledge retrieval can be enabled by the related knowledge management technologies. Part of the organizational knowledge generation process consists of sharing knowledge in the first place and surfacing current knowledge and assumptions, making it available for critical scrutiny (Despres & Chauvel, 2000). Knowledge can also be retrieved from where it is stored for understanding, analysis, and utilization. The knowledge management technologies of intelligent agents could enable the knowledge sharing and retrieval processes, providing the knowledge base for generating alternatives and engaging in disciplined decision-making.

Intelligent Agents

An "agent" in the legal sense is empowered to act on behalf of another (Feldman & Yu, 1999). An "intelligent agent" is one that can learn the behavioural patterns or the rules concerning certain actions and transactions, and then act accordingly on behalf of its "boss" (Feldman &Yu, 1999) or user. While there would be various definitions of "intelligent agents," most current researchers agree that agents have the following characteristics: autonomy, adaptiveness, collaborative behaviour, and mobility (Feldmand & Yu, 1999).

Agents have knowledge retrieval, profiling, and filtering capacities. They can search and retrieve information brokers or document managers (Stenmark, 2003). They often play a collaborative roleproviding information and expertise on a specific topic by drawing on relevant information from other information agents. The architecture of an agent is that each agent contains a domain model (providing descriptions of the classes of objects in the domain, relationships between these classes, and other domain-specific information) and information resource models (providing descriptions of both the contents of the information sources and the relationship between those models and the domain model) (Knoblock, Arens, & Hsu, 1994).

The system uses these mappings for transforming a domain-model query into a set of queries to the appropriate information sources. Information retrieval query processing requires developing a plan for obtaining the data. This includes selecting the information sources to provide the data, the processing operations, the sites where the operations will be performed, and the order of performing (Ambite & Knoblock, 1997). The organization of agents needs a common communication language and protocol to interact and collaborate. A common content language is the Loom knowledge representation language (MacGregor, 1990), which is a language for representing hierarchies of classes and relations, as well as efficient mechanisms for classifying instances of classes and reasoning about descriptions of object classes (Knoblock et al., 1994).The knowledge query and manipulation language (KQML) is a common protocol to organize the dialogue between agents (Ambite & Knoblock, 1997), as explained above.

Knowledge Interchange Format

While the intelligent agents are looking for the relevant information, they may have to communicate or establish links with databases or knowledge sources residing in disparate computer systems. Knowledge interchange format is a language designed for use in the interchange of knowledge among disparate systems, which could be those created by different programmers, at different times or in different languages. The purpose of knowledge interchange format is quite analogous to that of Postscript, which is commonly used by text and graphics formatting systems in communicating information about documents to printers. Postscript is a programmer-readable representation facilitating the independent development of formatting programmes and printers. While knowledge interchange format is not as efficient as a specialized representation for knowledge and not as perspicuous as a specialized display, it is a programmer-readable language capable of facilitating the independent development of knowledge-manipulation programmes (Genesereth, 2004).

The features essential to the design of knowledge interchange format include: (1) The language has declarative semantics so that it is possible to understand the meaning of an expression in a language without appeal to an interpreter for manipulating that expression; (2) The language is logically comprehensive in the sense that it provides for the expression of arbitrary logical sentences; and (3) The language provides for the representation of knowledge about knowledge, allowing the user to make knowledge representation decisions explicit and permitting the user to introduce new knowledge representation constructs without changing the language (Genesereth, 2004).

As explained above, intelligent agents with information retrieval and filtering abilities have a major characteristic distinguishing them from search engines: its proactive nature. Search engines such as Yahoo! and Google are inherently reactive (an information seeker has some query in mind, puts in some keywords, and the programme reacts to such query by displaying the search results). Retrieval and filtering agents are proactive in the sense that they keep watching a user's environment (usually a computational environment such as e-mail or a Web page that a user is reading) and present information to the user without requiring any continual action of the part of the user (Rhodes & Maes, 2000).

Creating alternatives and engaging in disciplined decision-making would need the decision-makers to align the organizational goals, because any alternative created or decision made without the possibility of ultimately attaining organizational goals would not lead to success for the organizations concerned. Such alternative creation and disciplined decision-making processes could also employ systems thinking involving the consideration of various factors or possibilities before reaching a final decision.

Alignment, Empowerment, and Systems Thinking

Smart organizations encourage participation in the decision-making process to achieve alignment of goals and the understanding required to make empowerment effective. The organization is guided through a shared sense of understanding of its strategies for creating value, and that people are empowered and trusted in pursuing value creation. Employees in the organization should feel empowered to act and take on the responsibility of acting, as well as for maintaining a shared sense of purpose. The organizational culture should be encouraging strategic decisions to be through a participative process and horizontal and vertical dialogue in realigning the organization through various periods of change (Matheson & Matheson, 1998).

While the organization is going through the decision-making process to achieve alignment of goals, it would be advisable that it deploys systems thinking—considering various factors before making a strategic decision. Systems thinking involves answering complex questions by thinking through cause-and-effect relationships from the perspective of the whole business and identifying leverage points, feedback loops, and key factors (Matheson & Matheson, 1998). The system approach can be described as a method to assemble and organize information, knowledge, and activities to attain greater efficiency (Vallee, 2003).

Systems thinking also requires an agile mind and a keen appreciation of how various parts of the world (the system) are linked together. Employees in an organization promoting systems thinking are expected to understand how their jobs and their actions are part of a larger system, and work to incorporate multiple and whole-system approaches into their thinking. Decision-makers in this kind of organization expect people to think through the full implications of their proposals and bring multiple perspectives to each important choice (Matheson & Matheson, 1998).

Organizational Decision Support Systems

The knowledge management technology of organizational decision support systems may be able to help organizations utilize the collective knowledge of various individuals within the organization, encouraging participation in decision-making and deploying systems thinking by considering various factors before making a strategic decision. Decision support technologies, including decision support systems, are computer-based tools developed to provide managers with the relevant information about internal operations and its business environment, together with experts' knowledge and models to facilitate their decision-making (Cascante, Plaisent, Bernard, & Maguiraga, 2002). Given that alignment of goals, one of the characteristics of smart organizations, involves encouragement of participation in the decision-making of the organization, organizational decision support systems that aim to support organizational decision-making that cuts across functional boundaries (Kim, Graves, Burns, & Myung, 2000) appear to be most suitable among various other kinds of decision support technologies.

The key notions in the organizational decision support systems frameworks are distributed problem-solving by human and machine knowledge processes, communication among these problem-solvers or decision-makers, and coordination of interrelated problem solving or decision-making efforts in the interest of solving an overall decision problem (Holsapple & Winston, 1996; Kim et al., 2000). Organizational decision support systems refer to a collection of individual decision support systems that communicate with each other to support collective organizational decision-making. Each constituent decision support system depends on the while but capable of supporting local decision-making. While the objective of an individual decision support system is to improve the performance of individual decision-making, the goal of organizational decision support systems is to improve the performance of collective organizational decision-making (Kim et al.) by having the systems take into account the collective knowledge sources and organizational goals, and assisting the decision-makers to reach an optimum decision compatible with such goals.

While there may be variations from one type of organizational decision support system to another, a typical organizational decision support system architecture consists of four components: (1) organizational participants; (2) language subsystem; (3) messaging subsystem; and (4) public resource management subsystem (Kim et al., 2000). The organizational participants are either human or machine processors, which communicate with each other to solve overall organizational problems (Kim et al.). The Language Subsystem provides the user with the interface to accept requests from participant nodes and to display the results of the request (Holsapple & Whinston, 1996; Burns, Rathwell, & Thomas, 1987). The Messaging Subsystem involves communication among participant nodes, such as notification of actions of a participant node to others (Holsapple & Whinston, 1996; Swanston & Zmud, 1989; Burns et al., 1987). The Public Resource Management System manages the public resources, including data and models such as a directory of the participant nodes' names and operators' names that each decision support system wants to be available to (Burns et al., 1987; Kim et al.).

One example of how an organizational decision support system assists with collective decision-making is an organizational decision-making system helping a television station to forecast television viewership, which helps formulate its marketing and planning strategies. Factors influencing television viewership are closely related to the relevant knowledge in respect of sociocultural factors affecting viewership such as different lifestyles, the viewers' ages and program preferences, and weather conditions. Forecasts for the television viewership done manually relied on the experience of the people doing such forecasts, and producing such results was a very long process based on individual subjective assessments. The results were inaccurate because there was no quest for supporting evidence and the person who did the forecasting might have had all types of prejudices and limitations that usually appear in judgmental forecasting (Patelis, Metaxiotis, Nikolpoulos, & Assimakopoulos, 2003).

An organizational decision support system called FORTV was proposed, which can help decision-makers identify various factors affecting television viewership and the competitive environment, such as total viewership, market share of each TV channel, viewership of each TV station, the program's viewership and the commercials' viewership, and to have such relevant body of knowledge incorporated into the analysis process. The system can perform the function like a knowledgeable human being by forecasting television viewership in the future to help the organization plan its programs and devise its strategies (Patelis et al., 2003).

Empowering individuals within an organization to align organizational goals and deploy systems thinking in reaching a strategic decision would also require taking an outside-in perspective—appreciating the impact of the business environmental circumstances and the uncertainty they often represent, and evaluate how such external circumstances and uncertainty could affect the organization and its success.

Outside-in Strategic Perspective and Embracing Uncertainty

The essence of an outside-in strategic perspective is to see and act on the "big picture," appreciate its importance for strategy, and distance oneself from his or her personal circumstances. The organization would need to understand the dynamics of the industry and customers and use this perspective to frame and evaluate strategic decisions at all levels. The organizational culture should encourage actively seeking information about what is outside of the organization and use it in decision-making, and view inside-out frameworks with suspicion (Matheson & Matheson, 1998).

If gaining knowledge about the world outside of the organization is crucial for strategic decision-making, the organization would also need to have the qualities to embrace uncertainty given that the environment in which businesses operate these days is characterized by uncertainty and the only constant is change. Perceived environmental uncertainty exists when decision-makers are not confident about understanding what the major events or trends are in an environment, or that they feel unable to accurately assign probabilities to the likelihood that particular events and/or changes will occur (Miliken, 1987). Scanning the environment could also be a difficult organizational process because the environment is complex (Cyert & March, 1963) and becoming more uncertain.

People of a smart organization should seek to understand all sources of uncertainty and apply such knowledge when making decisions (Matheson & Matheson, 1998), as strategic action depends on perceptions and interpretations of the environment (Schneider & De Meyer, 1991), and the environment is a major source of uncertainty for managers (Elenkov, 1997). It has been said that strategies are formulated in light of the perceived environmental conditions (such as uncertainties about the competitors, customers, and the environment) as well as internal capabilities (Parnell, Lester, & Menefee, 2000).

Research has identified multiple dimensions of the environment, such as dynamism, complexity, munificence, and uncertainty (Dess & Beard, 1984; Sharfman & Dean, 1991). Uncertainty has been defined as a combination of such perceived dynamism and complexity as they are held by the managers (Duncan, 1972; Koberg, 1987). Members of the organization are recommended to recognize that amid such uncertainty, decisions can be controlled but outcomes cannot. They need to understand uncertainty within their area of expertise, communicate such uncertainty accurately, and articulate it in terms of possibilities and probabilities with a realistic understanding of what they can influence and what may be beyond their control. The related organizational culture is one that promotes treating uncertain information as ranges or probability distributions. Forecasts are never turned into commitments because of the awareness of the uncertainty factor in the forecasts, and the decision-making process requires explicit consideration for risk and return (Matheson & Matheson, 1998).

Taking an outside-in strategic perspective requires knowledge about the external environment (such as knowledge regarding the customers, suppliers, and competitors) and embracing uncertainty calls for utilizing such knowledge to frame an analytical framework from which solutions and ideas in managing such uncertainty come up. Knowledge about customers, supplier, competitors, and industry may be gathered from various information sources within the organization, such as customer records and customer service survey results, market segmentation analysis, suppliers' order records, competitors' intelligence reports, and industry forecast. These various pieces of information may be scattered in different sections of the organization—for example, in customer service, marketing, logistics, and strategy planning departments respectively. The organization cannot have a complete picture of the external environment if it possesses knowledge of only one or two aspects of the environment—for instance, just the competitors and the industry. It needs knowledge of all relevant aspects of the environment, and this is where the knowledge management technology of enterprise informal portals comes in.

Enterprise Information Portals

An enterprise information portal can be defined as a single point of access for the pooling, organizing, interacting, and distributing of organizational knowledge (Aneja, Brooksby, & Rowan, 2000; Kendler, 2000; Schroeder, 2000). Enterprise portals have quite complex structures and features, but their basic functions and elements are relatively easy to define (Raol, Koong, Liu, & Yu, 2002). Firstly, from an operational point of view, the strength of enterprise portals lies in its ability to provide Web-based access to the organizational information, applications, and processes (Raol et al., 2002). Secondly, from a functional perspective, enterprise portals leverage existing information systems, data stores, networks, workstations, servers, and applications, as well as other knowledge bases, to give each individual within the organization immediate access to an invaluable set of organizational data anytime and anywhere (Kendler, 2000; White, 2000). As mentioned above, it is important for the organization to have knowledge about all relevant aspects of the environment when it takes an outside-in strategic perspective, and this function of enterprise portals being able to gather an integrated set of relevant information would help the organization in gathering the related knowledge in taking such perspective.

Enterprise portals could help an organization tap into not only its internal knowledge bases, such as the customer records, market segmentation reports, and industry forecasts, but also external sources about the environment, and therefore assist with the organization to take an outside-in perspective. In addition to ubiquity and ease of use of the Web browser interface, one of the important features of the enterprise portals is the availability of innumerable new data sources on the public Internet, in addition to the data sources across the organization (Kim, Chaudhury, & Rao, 2002). This has to do with the two-layered architecture of many enterprise portals, as explained below.

Aneja et al. (2000) comes up with a generic framework of an enterprise portal showing some of the major applications, entities, capabilities, tools, and their relationships, which was reproduced in Raol et al. (2002). The enterprise portal framework essentially contains two primary layers. At the core of any enterprise portal framework are the applications that it purports to support, which can range from unit-specific to organizational-wide capabilities, staff to administrative support functions, and individual to system-wide inquiries. Examples of such applications are office documents, decision support systems analysis/reporting, business content such as marketing and human resources information, personal or group Web sites, as well as collaboration facilities like e-mail and calendar (Aneja et al., 2000). The second layer consists of various Web-based drivers (Raol et al., 2000) leading to external information sources such as Web sites, news feeds, stock and weather information, or travel reservations (Aneja et al., 2000). These drivers are the means for the openness and easy access capabilities to the disparate databases and reports generated. Some of the core enterprise portal software functions include customization and personalization, collaboration and community, content management, ease of use, dynamism, and security (Raol et al., 2000).

The current political, business, and social environment is characterized by constant change. Individuals and organizations that are able to rise to the challenge of taking an outside-in perspective and appreciating the uncertainty of such an environment are those that engage themselves in learning about new events, circumstances, ideas, and people. Open information flow as a way for individuals within the organizations to gather new knowledge, as well as continual learning, are of crucial importance in this context.

Open Information Flow and Continual Learning

The purpose of having an open information flow in an organization is to "inform and be informed." The flow of information crosses functional boundaries, with virtually all information available to whomever that wants it. Information is routinely captured, packaged, shared, and applied, and used in various ways to create value. People in a smart organization feel safe sharing what they know, and feel obliged to contribute to information sharing systems and are excited about learning and teaching. The prevailing organizational culture should support an ethic of both "giving and getting" in relation to information sharing, and this would hopefully discourage information hoarding (Matheson & Matheson, 1998). The organizational culture drives the overall value system, providing norms for information sharing and reaching a consensus on its meaning (Sinkula, 1994). Such information sharing is essential for the organization to learn continually, so as to address and overcome various challenges arising from operating in this increasingly complex and ever-changing business environment.

A smart organization should have the purpose of learning continually about what creates value and how to deliver it (Matheson & Matheson, 1998). Learning would enrich the intellectual capital of both individuals and organizations, and such capital is a significant resource in generating value in today's knowledge economy. For a number of years, some of the world's most proactive observers of societal change have predicted the emergence of a new economy in which intellectual prowess, not machine capability as valued in the industrial economy, would be the critical resource (Graham, 1996).

It would be ideal if people in a smart organization were not only excited about learning and growing, but also willing to accept constructive comments and new ideas and apply the same to themselves and their organization (Matheson & Matheson, 1998). All individuals within the organization are continually engaged in learning, helping each other to learn, and sharing their learning (Lawler, 1988) to the extent that it would become a "learning organisation." A learning organization is an organization that purposefully adopts structures and strategies that encourage learning (Dodgson, 1993). When such an organization emphasizes continual learning, the organizational culture would be viewing change as important, emerging, and profitable, and as something routine leading to improvements (Matheson & Matheson, 1998). The organization should also adopt a critical attitude questioning organizational myths and assumptions, and even welcoming "bad news," which will be used to initiate improvements (Matheson & Matheson, 1998).

Learning occurs when organizations seek not just to synthesize but also institutionalize people's intellectual capital and learning, their memories, cultures, routines, and core competencies. Though people may come and go in an organization, its memories preserve the individuals' behaviour, norms, and values as accumulated over time, and gradually build an organizational structure that will become the repository for lessons learned as the organization addresses and solves its problems on its way. As the members of the organization leave and new ones join, it is crucial that the knowledge and competence of the former staff can be transferred to the new ones across generations of learning (O'Keeffe, 2002). The related knowledge management practices and technologies could facilitate this cross-generational learning process.

Communities of Practice

Knowledge management advocates support the idea of forming communities of practice in facilitating organizational learning process. The idea of a community of practice was developed by Lave and Wenger (1990) as a theory for practice-based learning in which one could undertake "legitimate participation" to serve a kind of apprenticeship with a group of "insiders" in an organization, organizations consisting of a range of different disciplinary groups or collectives, each charged with specific areas of responsibility. Wenger and Snyder (2000) later depicted a community of practice as a "group of people informally bound together by shared expertise and passion for a joint enterprise," with members inevitably sharing knowledge in order to solve problems in their organization (Russell, Calvey, & Banks, 2003).

Wenger (1998) incorporated both informational and interactive elements of knowledge into his community of practice theory through the concepts of reification and participation. Reification is "the process of giving form to our experience by producing objects [including symbols and texts] that congeal this experience into 'thingness'" (Wenger, 1998, p. 58). Reification represents the concreteness apparent in the informational view of knowledge. Participation gives the active and social element of knowledge through engagement in the activity. Reification and participation together form a duality interacting in the process of knowing (Iverson & McPhee, 2002).

Wenger (1998) further identified three characteristics of communities of practice: (1) mutual engagement, (2) negotiation of a joint enterprise, and (3) a shared repertoire. Mutual engagement involves interaction with other members within the community of practice during which members are motivated to negotiate their practices and the meanings of their actions. By being mutually engaged with one another, knowledge is shared and enacted. Members can offer to each other insights, adopt others' practices, critique practices, and share frustrations, and hopefully the members will learn from each other through open flow of information during such interaction. Negotiation of a joint enterprise gives a sense of purpose and coherence to the community of practice. It can be said to be the common purpose binding people together and providing a unifying goal and coherence for their actions. Wenger states that this negotiation process creates more than "just a stated goal but creates among participants relations of mutual accountability that become an integral part of the practice (Wenger, p. 76). The third characteristic is shared repertoire, which refers to the community's set of resources for negotiating meaning. Knowing the shared repertoire such as jargon, stories, and other forms of a stock of understood information and techniques as utilized by the community members can be a proof of membership (Iverson & McPhee, 2002).

Intranets

Intranets incorporating the feature of online discussion would be a useful knowledge management technology helping communities of practice to share knowledge and promote open flow of information and continual learning.

An intranet is an "internal corporate Internet," or a private network inside a company or organization allowing colleagues to communicate with each other and access corporate information (Chan, 2000). It is also possible to view the

Table 3. Knowledge management (KM) technologies/practices in smart organizations (SO)

SO Principle	**KM Technology/Practice**	**Features**
Value Creating Culture	Extranets	Secure Internet protocol-based networks linking the information infrastructures of various extranet participants.
	Customer Relationship Management Systems	They help manage customer relationships and facilitate relationship marketing.
Creating Alternatives and Disciplined Decision-Making	Intelligent Agents	They can learn the users' behavioural patterns and can have knowledge retrieval, profiling and filtering capacities.
	Knowledge Interchange Format	It is a language designed for interchanging knowledge among disparate systems.
Alignment, Empowerment and Systems Thinking	Organisational Decision Support Systems	They are systems providing managers with the relevant internal and external to facilitate their decision-making.
Outside-in Strategic Perspective and Embrace Uncertainty	Enterprise Information Portals	A portal is a single point of access for the pooling, organizing, interacting and distributing of organizational knowledge.
Open Information Flow and Continual Learning	Communities of Practice	Groups of people are informally bound together by similar expertise for sharing knowledge.
	Intranets	An intranet is an internal corporate Internet for communication and accessing corporate information.

intranet as a shared knowledge space for content, communication, and collaboration (Choo, Detlor, & Turnbull, 2000; Stenmark, 2002), as it provides a private space giving the employees in the organization the ability to organize information, readily access that information, manage documents, and enable efficient collaboration, all in a Web-based environment (Intranets.Com, 2004). From a knowledge-sharing point of view, an intranet provides a context where the essence of knowledge-sharing—dialogue, reflection, and perspective-making—could happen (Stenmark, 2002).

Intranets are said to facilitate collaboration, communication, and change mechanisms within organizations, achieving rapid transitions when the pace of change is critical (Ali, 2001). Recent research has shown that an interorganizational virtual team adapted to the use of a collaborative technology (an intranet) and achieved its objective of manufacturing a highly innovative product (Majchrzak, Rice, Malhotra, King, & Ba, 2000). The intranet serves newsgroups that facilitate exchanges of information between members, resulting in a corporate "knowledge base." The organization's members could subscribe to and view a screen with subject lines, authors, and news articles numbers. Each of these items serves as the beginning of a "thread" that started when someone sent out an article or e-mail; readers can then trace these threads deeper as they wish. In these ways, individuals with the organization can share knowledge and enhance the communication in the community of practice. Employees remain faithful to the informal social networks of "community of practice" as the principal mode of sharing and developing knowledge (Ali, 2001).

CONCLUSION AND FUTURE DIRECTION

As argued above, the common thread running the nine principles characterizing a smart organization is knowledge. In order to become smart, an organization needs to have knowledge about the customers' needs and how it can better satisfy their needs in order to create value. Extranets linking the information networks of the organization and the customers could help enhance customer service quality and deliver better value.

Creating alternatives and engaging in disciplined decision-making requires acquiring the knowledge about possibilities and probabilities, evaluating each of them, and selecting the most appropriate option. The proactive intelligent agents facilitate the knowledge discovery and sharing processes, maximizing the knowledge base on which creative ideas are formed and informed decisions are made. Alignment of goals and empowering individuals to act on a shared sense of purpose and deploy systems thinking would be achieved if the individuals within the organization managed complex issues by looking at the cause-and-effect relationships and examining the implications in relation to the big picture. Decision support systems would be able to help by weighing different factors, taking into account the goal and making the optimum choice.

Taking an outside-in strategic perspective and embracing uncertainty would involve gathering knowledge about such environmental factors as the suppliers, competitors, industry, and customers, and utilizing the same to make an appropriate strategic decision. Enterprise portals acting as a single gateway to organizational knowledge sources, both internal and external, would help with collecting information about the uncertain business environment to enable taking an outside-in strategic perspective. Open information flow and continual learning are essential if an organization wants to gain a competitive advantage in the knowledge age, because "knowledge" is the basis of competition; the technology of intranets would facilitate the process.

While there has been a substantial body of literature on knowledge management, as summarized above, recent literature search shows that little research has been done on knowledge management in the context of various aspects of smart organizations such as operations, strategy, human resources, and marketing. What has been proposed above—how knowledge management practices and technologies could help realize each of the nine principles characterizing smart organizations—is based on a theoretical perspective and personal insights rather than empirical evidence. It is based on the author's understanding of and insights into the theories relating to both knowledge management and smart organizations.

This could be regarded as the beginning of setting a future research direction—conducting empirical studies on proving, disproving, extending, or criticizing these theoretical insights to fill in the knowledge gap relating to how knowledge management could make a worthy contribution to smart organizations. For instance, one would look at how the related knowledge management technologies impact recruitment procedures in organizations from a human resources perspective. Another possibility would be examining how knowledge management technologies could innovate supply chain processes. Such studies would make a worthy contribution to the practitioners so that the latter could have a better understanding of how knowledge management technologies generate business value. They would also contribute to academia because little has been done on synergizing knowledge management theories with theories of other management or business disciplines, such as human resources, marketing, or finance. As we are in an era where boundaries are breaking down in various ways—politically, economically, and geographically, for instance—an interdisciplinary approach crossing academic disciplinary boundaries to understand knowledge management and other business disciplines would be timely.

Chapter 8.21
Knowledge Management Metrics:
A Review and Directions for Future Research

A. Kankanhalli
National University of Singapore, Singapore

B. C. Y. Tan
National University of Singapore, Singapore

ABSTRACT

Metrics are essential for the advancement of research and practice in an area. In knowledge management (KM), the process of measurement and development of metrics is made complex by the intangible nature of the knowledge asset. Further, the lack of standards for KM business metrics and the relative infancy of research on KM metrics points to a need for research in this area. This article reviews KM metrics for research and practice, and identifies areas where there is a gap in our understanding. It classifies existing research based on the units of evaluation such as user of knowledge management systems (KMS), KMS project, KM process, KM initiative, and organization as a whole. The article concludes by suggesting avenues for future research on KM and KMS metrics based on the gaps identified.

INTRODUCTION

Knowledge management (KM) has become an accepted part of the business and academic agenda. Organizations have high expectations for KM to play a significant role in improving their competitive advantage (KPMG, 2000). Measuring the business value of KM initiatives has become imperative to ascertain if the expectations are realized.

Metrics are measures of key attributes that yield information about a phenomenon (Straub, Hoffman, Weber, & Steinfield 2002). Metrics are key to advancement of research and practice in an area. In research, they provide comparability of studies between individuals, time periods, organizations, industries, cultures, and geographic regions (Cook & Campbell, 1979). They also provide a basis for empirical validation of theories and relationships between concepts. Measures that are reliable and valid enable accumulation of research in a topic area, and free subsequent researchers from the need to redevelop instruments (Boudreau, Gefen, & Straub, 2001).

For practitioners, metrics are a way of learning what works and what does not. In fact, measuring business performance is the focus of the entire field of management accounting. In KM, performance measures serve several objectives including securing funding for KM implementation, providing targets and feedback on implementation, assessing implementation success, and deriving lessons for future implementation. Measures can assist in evaluating the initial investment decision and in developing benchmarks for future comparison.

Measurement is typically a complex process fraught with errors. What is easy to measure is not always important and what is important is often difficult to measure (Schiemann & Lingle, 1998). KM metrics are particularly distinct from other metrics due to the intangible nature of the knowledge resource (Glazer, 1998). Something such as knowledge that is difficult to define and has multiple interpretations is likely to be difficult to value and measure. Due to such considerations and the complexity of assessing organizational initiatives in general, research (Grover & Davenport, 2001) and practice (Bontis, 2001) on the assessment of KM initiatives and knowledge management systems (KMS) is not well developed.

In light of the above motivations, this study seeks to review metrics in practice and research and identify areas for further investigation. Previous research on metrics for KM and KMS is classified based on the elements of evaluation such as user of KMS, KMS project, KM process, KM initiative, and organization as a whole.

In the next section, some basic definitions of metrics and KMS are provided. This is followed by the review of practice KM metrics, classification of research on KMS and KM metrics, and finally a discussion of areas for further investigation.

DEFINITIONS

Metrics and Measures

At the outset it is important to distinguish what is meant by a metric and a measure. The IEEE standard glossary of software engineering provides the following definitions of measures and metrics. A measure is a standard, unit, or result of measurement (IEEE, 1983). A metric is a quantitative measure of the degree to which a system, entity, or process possesses a given attribute (IEEE, 1990). An example of a measure is a patient's temperature value of 99 degrees Fahrenheit. Without a trend to follow or an expected value to compare against, a measure gives little or no information. It especially does not provide enough information to make meaningful decisions. A metric is a comparison of two or more measures, for example, body temperature over time. It allows a trend or pattern to be seen in the measure. Therefore, a measure by itself doesn't provide much understanding unless it is compared with another value of the measure—that is, it becomes a metric. Hence the focus of our review is on metrics for KMS and KM initiatives.

KM and KMS

KM involves the basic processes of creating, storing and retrieving, transferring, and applying knowledge. The ultimate aim of KM is to avoid reinventing the wheel and leverage cumulative organizational knowledge for more informed decision making (Alavi & Leidner, 2001). Examples of ways in which knowledge can be leveraged include: transfer of best practices from one part of an organization to another part, codification of individual employee knowledge to protect against employee turnover, and bringing together knowledge from different sources to work on a specific project.

Information technology (IT) is recognized as a key enabler of KM (although there are many other factors that are necessary for KM success). Without the capabilities of IT in terms of both storage and communication, leveraging of knowledge resources would hardly be feasible (Alavi & Leidner, 2001). A variety of tools are available to organizations to facilitate the leveraging of knowledge. These tools (KMS) are defined as a class of information systems applied to managing organizational knowledge. That is, they are IT-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application (Alavi & Leidner, 2001). Common KMS technologies include intranets and extranets, search and retrieval tools, content management and collaboration tools, data warehousing and mining tools, and groupware and artificial intelligence tools, like expert systems and knowledge-based systems.

Two models of KMS have been identified in information systems research (Alavi & Leidner, 1999), both of which may be employed by organizations to fulfill different needs. These two models correspond to two different approaches to KM—the codification approach and the personalization approach[1] (Hansen, Nohria, & Tierney, 1999). The repository model of KMS associated with the codification approach focuses on the codification and storage of knowledge in knowledge bases. The purpose is to facilitate knowledge reuse by providing access to codified expertise. Electronic knowledge repositories (EKRs) to code and share best practices exemplify this strategy (Alavi & Leidner, 2001). A related term, organizational memory information system (OMIS), refers to any system that functions to provide a means by which knowledge from the past is brought to bear on the present in order to increase levels of effectiveness for the organization (Stein & Zwass, 1995).

The network model of KMS associated with the personalization approach attempts to link people to enable the transfer of knowledge. One way to do this is to provide pointers to location of expertise in the organization, that is, who knows what and how they can be contacted. This method is exemplified by knowledge directories, commonly called "yellow pages" (Alavi & Leidner, 2001). It has been noted that in order to access the knowledge in an organization that remains uncodified, mapping the internal expertise is useful (Ruggles, 1998).

A second way is to link people who are interested in similar topics. The term communities of practice (COPs) has come into use to describe such flexible groups of professionals informally bound by common interests who interact to discuss topics related to these interests (Brown & Duguid, 1991). KMS that provide a common electronic forum to support COPs exemplify this approach (Alavi & Leidner, 2001). The two models of KMS allow us to make sense of existing KMS metrics (since metrics for a particular type of KMS are similar) and identify directions for further evaluation of KMS.

KM AND KMS METRICS IN PRACTICE

KM Metrics

Most practice metrics of KM initiatives focus on measuring knowledge assets or intellectual capital (IC) of a firm, assuming the outcome of a KM initiative is its impact on IC. The majority of respondents of practice surveys think that IC should be reported and knowledge measurement would improve performance (Bontis, 2001). Even the process of measuring IC is considered important, whether as an internal management tool or for external communication on financial balance sheets.

Three general-purpose approaches to measuring the impact of KM initiatives include House of Quality (Quality Function Deployment or QFD), Balanced Scorecard, and American Productivity Center (APQC) benchmarking approach (Tiwana, 2000). The House of Quality (Hauser & Clausing, 1988) method involves the development of a metrics matrix (house). The desirable outcomes of KM initiatives are listed on the left wall of the house, the roof consists of the performance metrics, the right wall consists of the weights (relative importance of the outcomes), and the base of the house consists of targets, priorities, and benchmark values. By looking at the correlations within the body of the matrix, management can decide to focus on those areas of KM that are most likely to affect overall firm performance. A number of software tools such as QFD designer are available to automate the analysis process.

The Balanced Scorecard technique developed by Kaplan and Norton (1996) aims to provide a technique to balance long-term and short-term objectives, financial and non-financial measures, leading and lagging indicators, and internal and external perspectives. Typically four views—customer, financial, internal business, and learning and growth—are used to translate high-level strategies to real targets. Within each view, the goals, metrics, targets, and initiatives are listed. Relationships between views must also be considered. The views (dimensions) can be suitably adapted to assess the current state of KM and evaluate the impact of initiatives in this area. Here also software tools are available, though in general the balanced scorecard is more difficult to develop than QFD. However, it is likely to yield more "balanced" goals with a built-in consideration of the causal relationships.

The APQC process classification framework (PCF) provides a detailed taxonomy of business processes derived from the joint effort of close to 100 U.S. businesses (APQC, 1998). The PCF can be employed to benchmark and assess impact on business processes as a result of introduction of KM initiatives. Other general measures of firm performance such as Economic Value Added (EVA) and Tobin Q can also be used for evaluating IC (Stewart, 1997).

Three other metrics specific to KM are the Skandia Navigator, IC index, and Intangible Assets Monitor. The Skandia Navigator (Edvinsson & Malone, 1997) consists of 112 IC and traditional metrics (with some overlap between metrics) in five areas of focus (financial, customer, process, renewal and development, human). These areas are similar to the balanced scorecard views, except for the additional human focus area in the Skandia metric (more areas can also be added in Balanced Scorecard as desired, though a limit of seven areas is suggested). Out of all the indicators, the monetary indicators are combined into a single dollar value C, while the remaining percentage completeness measures are combined into an efficiency indicator I which captures the firm's velocity or movement towards desired goals. The overall IC measure is a multiplication of I and C.

The IC index (Roos, Roos, Dragonetti, & Edvinsson, 1998) is an extension to the Skandia IC metric that attempts to consolidate measures into a single index and correlate this index with changes in the market, that is, it focuses on monitoring the dynamics of IC. It consists of monitoring both IC stock and IC flow. A third technique is the Intangible Assets Monitor (Sveiby, 1997). Intangible asset value is defined as the book value of the firm minus the tangible assets and the visible debt. Three components of intangible assets are external structure (brand, customer, and supplier relations), internal structure (management, legal, manual, attitude, software), and individual competence (education, experience, expertise). For each intangible asset component, three indicators focus on growth and renewal, efficiency, and stability of that component. Other KM-specific techniques include Technology Broker (Brooking, 1996) and Citation-Weighted Patents (Hall, Jaffe, & Trajtenberg, 2000).

Whether it is the more general purpose or the more KM-specific techniques for business performance evaluation, the efficacy of all techniques depends on the competence of management in applying these techniques. Although the above-mentioned techniques attempt to provide systematic and comprehensive indicators, there are a number of subjective judgments to be made in applying these techniques, including determining which objectives are more important than others and which indicators need to be given greater weight. As pointed out in previous studies (Bontis, 2001), a further limitation on these IC techniques is that many of them use different terms to label similar measures. A lack of standards leads to proliferation of measures and difficulty in comparison. Also, since most of the evidence on KM assessment is on a case-by-case basis, there is a lack of generalizable results on this topic.

KMS Metrics

Organizations employ a variety of metrics to assess their KMS (Department of Navy, 2001). System-level measures for EKR include number of downloads, dwell time, usability surveys, number of users, and number of contributions and seeks. Measures for electronic COPs include number of contributions and seeks, frequency of update, number of members, and ratio of number of members to the number of contributors. System-level measures have been used for evaluating and monitoring particular KMS implementations. Here also the literature is mainly in the form of individual case studies (e.g., Wei, Hu, & Chen, 2002), and generalizable measurement techniques are lacking.

PREVIOUS RESEARCH ON KM AND KMS METRICS

Grover and Davenport (2001) suggested a pragmatic framework for KM research based on the knowledge process and the context in which the process is embedded. The knowledge process can be divided into generation, codification, transfer, and realization. The elements of the embedded context include strategy, structure, people/culture, and technology. The framework can be applied for processes at individual, group, and organization levels. We adopt a similar classification for categorizing previous research on KM and KMS metrics based on elements of evaluation (user, system, project, process, and organization level).

The previous research articles have been selected based on the following criteria. First, they are empirical articles that have proposed and tested metrics for evaluating KMS users, KMS project, KM process, or organizational outcomes. Second, they are chosen from reputed journals such as MIS Quarterly, Management Science, Information Systems Research, ACM Transactions, IEEE Transactions, Journal of the American Society for Information Science and Technology, Journal of Management Information Systems, Organization Science, Administrative Science Quarterly, Journal of Strategic Information Systems, Decision

Support Systems, Information and Management, Harvard Business Review, Sloan Management Review, and California Management Review, as well as established IS conferences such as the International Conference on Information Systems, Hawaii International Conference on Systems Sciences, and Americas Conference on Information Systems. The articles span the period from 1998 to present, with the exception of the Constant, Sproull, and Kiesler (1996) article that is one of the first research articles in its area.

User Evaluation

The articles on user evaluation are tabulated according to the type of user (contributor or seeker), type of KMS, and the sample of the empirical study (Table 1). The bulk of previous research at the user level has been studies to evaluate the motivation of users to contribute to or seek knowledge from different types of KMS, and in a few studies the consequent usage of KMS. Research has investigated both contributor and seeker motivations for using both repository and network model KMS. Most of the samples for the studies have been drawn from one organization or one online forum.

KMS Evaluation

The articles on KMS evaluation are tabulated according to the type of KMS, performance criteria suggested, and the sample of the empirical study (Table 2). It can be seen that a variety of performance criteria have been proposed focusing on user, task, KM process, and organizational outcomes for different KMS. The samples in these studies have been drawn both from single organizations as well as multiple organizations.

Table 1. Selected studies on KMS users

Study	User	KMS	Sample
Constant, Sproull, & Kiesler 1996	Contributor factors on seeker	Email distribution list	Tandem Computers, 48 seekers & 263 contributors
Goodman & Darr 1998	Contributor and seeker	Repository + electronic COP	Office equipment distributor, 1500 respondents
Kankanhalli, Tan & Wei 2001	Seeker	Repository	128 knowledge workers
Wasko & Faraj 2000	More emphasis on contributor	Electronic COP	3 Usenet groups, 342 participants
Kuo, Young, Hsu, Lin, & Chiang 2003	Contributor and seeker	Electronic COP	264 teachers in an online forum
Zhang & Watts 2003	Seeker	Electronic COP	145 participants in a travel forum
Jarvenpaa & Staples 2000	Contributor and seeker combined	All electronic media	1 University, 1125 employees
Bock & Kim 2002	Contributor	All electronic media	4 Public organizations

Table 2. Selected studies on KMS evaluation

Study	KMS	Performance Criteria	Sample
Ackerman 1998	Answer Garden Knowledge Repository (FAQ) + Electronic COP (via email)	• Usage - heavy, intermittent, tire-kicker • User evaluation in seeking answer • Expert evaluation of providing answer	2 univ lab sites, 49 users (seeker), 7 experts (contributor)
Baek & Liebowitz 1999	Knowledge repository	Contributor • Simplicity, richness, flexibility of creation • Ease of consistency checking, ease of knowledge change management Seeker • Ease of knowledge navigation and searching Both • Awareness, timeliness, fairness	2 multimedia design teams (3 members & 4 members)
Jennex, Olfman, Panthawi & Park 1998	Organization memory information system	• Individual job time, number of assignments, completeness of solutions, quality of solutions, complexity of assignment, client satisfaction • Organizational unit capability (problem correct) Unplanned scrams (problem solve)	120 engineers in 2 nuclear power plants
Jennex & Olfman 2002	Organization memory information system	• Integration • Adaptation • Goal attainment • Pattern Maintenance	83 engineers
Hendriks & Vriens 1999	Knowledge based system (expert system)	Assessment of current knowledge • Establishment of strategic value of knowledge • Comparison of knowledge to competition • Establishment of required knowledge • Creation of new knowledge • Distribution of knowledge • Application of knowledge • Evaluation of knowledge	17 organizations (government, bank, insurance, manufacturing)
Nissen 1999	Koper Knowledge based system	KM effects • Knowledge capture, organization and formalization • Knowledge distribution and application • Analytical consistency and completeness • Knowledge integration	Large multisite enterprise
Gottschalk 2000	Data warehouse, executive IS, expert system, enterprise wide system, intranet	IT support for KM • Generating knowledge • Accessing knowledge • Transferring knowledge • Sharing knowledge • Codifying knowledge	73 law firms in Norway
Ruppel & Harrington	Intranet implementation	Level of implementation for knowledge sharing	44 organizations (different industries)
Maier 2002	Knowledge management system	DeLone and McLean IS success model based criteria	73 organizations

Project Evaluation

Relatively fewer articles were found on KM metrics related to project evaluation (Table 3). These articles are tabulated based on the nature of the project, the performance criteria, and the sample of the study. The projects include software development, new product development, and process improvement projects. In the first study of the table, the performance criteria are in terms

Table 3. Selected studies on project evaluation

Study	Project	Performance Criteria	Sample
Verkasalo & Lappalainen 1998	Hypertext annual plan project	Efficiency index for knowledge utilization • Process width = number of employees • Process delay = time taken to spread / distribute • Process effort = time to document, distribute, and perceive use (not collect and compile)	Nokia telecom factory
Hansen 1999	New product development project	Project completion time (conception to market)	120 projects in a large electronics company
Mukherjee, Lapre, &Wassenhove 1998	Total quality management project	Project performance, goal achievement, ability to specify impact, change in attention rules	62 projects in a Belgian multinational steel wire manufacturer

Table 4. Selected studies on organizational-level KM evaluation

Study	Impact of	Performance Criteria	Sample
Khalifa, Lam, & Lee 2001	Overall KM initiative	KM effectiveness (organizational performance impacts)	185 KM practitioners from discussion forums
Becerra-Fernandez & Sabherwal 2001	Knowledge internalization, externalization, combination, socialization + all KM tools use	KM satisfaction (availability, effectiveness of knowledge, KM at task, directorate, across organization, knowledge sharing)	Kennedy Space Center, 159 employees from 8 sub-units
Gold, Malhotra, & Segars 2001	KM capability: Knowledge infrastructure, Knowledge process	Organization effectiveness • Innovation and commercialization, coordination of unit • Anticipate and identify opportunities • Speed and adaptation to market • Avoid redundancy and streamline	323 executives, finance and manufacturing, large organizations
Tanriverdi 2002	IT Knowledge relatedness	Market based performance Tobin's Q	315 firms, manufacturing and service

of the knowledge process, whereas in the other two studies, knowledge processes (sharing and creation) appear as mediators. All these studies are tested on single or multiple projects within a single organization.

KM Process and Organizational-Level Evaluation

A relatively popular area of research on KM and KMS metrics has been at the KM process and organizational level. Similar to the practice business performance metrics, the research metrics at this level also attempt to tease out the relationships between KM initiative, process, or capability, and firm performance, albeit with a theoretical emphasis. Literature in this area is tabulated based on the independent variables, performance criteria, and the sample (Table 4). Effectiveness outcomes have been studied in single and multiple organizational settings.

DIRECTIONS FOR FUTURE RESEARCH

From our literature review we can infer certain gaps in research on KM and KMS metrics in terms of unit or level of study. At the intersection of user and system level, most research tends to investigate motivations of users. There is a lack of research on usability of KMS and limited studies on usage of KMS. Both usability and usage studies, if well designed, can provide a good indicator of user acceptance of KMS. For example usability studies of both interactive and integrative KMS may be undertaken. Also, comparative studies of KMS usability may prove fruitful. Studies across multiple organizations or forums can add to existing studies.

At the system level, the majority of studies appear to focus on EKR, OMIS, knowledge-based systems, and overall KM technologies. There appears to be a lack of evaluation studies on electronic COPs since the majority of studies on COPs appear to be anecdotal in nature. Therefore future research can investigate suitable metrics for evaluating electronic COPs, an integral part of the network model of KMS. Further, review studies can help to infer commonalities and differences among the metrics for different forms of KMS.

There appears to be a relative paucity of KM evaluation studies at the group and team levels, except for a few virtual team studies (e.g., Alavi & Tiwana, 2002). Although there have been studies at the project level (Table 3) which could be interpreted as group-level evaluations, these studies did not investigate group characteristics and team dynamics in relation to evaluation of KM. This area presents an opportunity for future research on team effectiveness in terms of KM. For example, studies of how effective KMS are in terms of facilitating group, team, and project KM may be useful. Additionally, a greater variety of projects can be studied to draw inferences about what metrics are useful for particular types of projects. Alternatively, metrics for a particular type of project can be compared across different organizations.

In relation to Grover and Davenport's (2001) framework, there appears to be a lack of studies focusing purposefully on evaluation of KM strategy and KM structure. Considering that both elements can be vital to the success of KM initiatives, research on these elements is required. Additionally there is a gap between the micro-level assessment studies (user and system level) and the macro-level assessment studies (organization level). Possibly more research on team, project, and business unit level KM evaluation may serve to bridge this gap. Aggregation from user and system-level evaluation to team, project, and business unit-level evaluation—and subsequently to organization-level KM evaluation—could provide a worthwhile avenue for future research.

Although limited by the fact that a complete review of literature cannot be claimed, this study sheds light on the existing research on KMS and KM metrics. It also serves to identify potential areas where further evaluation research would be useful. Given that organizations are expending significant resources towards implementing KM initiatives and KMS, more research on metrics in these areas is warranted.
