Library of Congress Cataloging-in-Publication Data

Knowledge management : concepts, methodologies, tools and applications / Murray Jennex, editor.
p. cm.
Summary: "This is the defining reference source for all theories, concepts, and methodologies within the KM discipline. It includes chapters on Implementing KM in Organizations; KM Systems Acceptance; KM Communication; Knowledge Representation; Knowledge Sharing; KM Success Models; Knowledge Ontology; and Operational KM, and provides libraries with the defining reference to the field"--Provided by publisher.
Includes bibliographical references and index.

VOLUME I

Section 1: Fundamental Concepts and Theories in Knowledge Management

This section serves as a foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of knowledge management. Research found in this section provides an excellent framework in which to position knowledge management within the field of information science and technology. Excellent insight into the critical incorporation of learning systems into global enterprises is offered, while basic, yet crucial stumbling blocks of information management are explored. With 43 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring knowledge management discipline.

Section 2: Knowledge Management Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures and knowledge management frameworks to provide the reader with a comprehensive understanding of the emerging technological developments within the field of knowledge management while offering research fundamentals imperative to the *understanding of research processes within the knowledge management discipline. On a more global scale, many chapters explore cultural and infrastructural issues related to the management of knowledge in developing countries. From basic designs to abstract developments, this section serves to expand the reaches of development and design technologies within the knowledge management community. Included in this section are 45 contributions from researchers throughout the world on the topic of information development and knowledge sharing within the information science and technology field.*

VOLUME II

Section 3: Knowledge Management: Tools and Technologies

This section presents extensive coverage of various tools and technologies available in the field of knowledge management that practitioners and academicians alike can utilize to develop different techniques. Readers are enlightened about fundamental research on one of the many methods used to facilitate and enhance the knowledge sharing experience while exploring the intrinsic value of technology and knowledge management. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of knowledge management. With more 28 chapters, this section offers a broad treatment of some of the many tools and technologies within the knowledge management community.

Section 4: Utilization and Application of Knowledge Management

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective knowledge management programs and processes. This section includes more than 50 chapters, some of which review knowledge management literature published in top-tier journals, offering findings on the most popular trends researched within the academic community. Other chapters discuss the utilization of knowledge management within the governmental realm. Also considered in this section are the challenges faced when utilizing knowledge management with healthcare systems. The adaptability of governmental agencies in response to disasters is given consideration as well through research which investigates major hurdles faced in knowledge sharing in the face of disasters, spanning the globe. Contributions included in this section provide excellent coverage of today's global community and how knowledge management research is impacting the social fabric of our present-day global village.

VOLUME IV

VOLUME V

Section 6: Managerial Impact of Knowledge Management

This section presents contemporary coverage of the social implications of knowledge management, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Core ideas such as training and continuing education of human resources in modern organizations are discussed through these more than 35 chapters. Also discussed is strategic planning related to the organizational elements and knowledge sharing program requirements that are necessary to build a framework in order to institutionalize and sustain knowledge management systems as a core business process. Equally as crucial, are the chapters which address the gap between theory and practical implementation within the knowledge sharing community. Directing the reader's focus forward, the final chapters found within this section help to establish a basis for assessing the value of knowledge management while evaluating its results within business enterprises.

VOLUME VI

Section 7: Critical Issues in Knowledge Management

This section contains 25 chapters addressing issues such as intellectual capital and knowledge management, communities of practice and critical social theory and ontology-supported web service composition. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study while developing an excellent model for researchers and practitioners as attempts are made to simultaneously ease and expedite the transfer of knowledge from the private to the public sector. Forming frameworks in which to position the issues faced in this growing field are provided by research found in chapters that take the core psychological paradigms of sociology and translate them into applicable ideas within the exploding realm of information sharing. Crucial examinations serve to reinforce the ideas presented in this section while simultaneously enticing and inspiring the reader to research further and participate in this increasingly pertinent debate.

Section 8: Emerging Trends in Knowledge Management

This section highlights research potential within the field of knowledge management while exploring uncharted areas of study for the advancement of the discipline. Introducing this section is research that sets the stage for future research directions and topical suggestions for continued debate. Providing an alternative view of knowledge management are chapters that research the cultural dimension of knowledge management systems, particularly the relationship of learning and culture in knowledge management projects. The inevitable increase in complexity and quantity of the information that is available for students is also considered in this final section. Found in these 21 chapters concluding this exhaustive multi-volume set are areas of emerging trends and suggestions for future research within this rapidly expanding discipline.

Preface

Emphasis on knowledge and information is one of the key factors that differentiate the intelligent business enterprise of the 21st century. In order to harness knowledge and information to improve effectiveness, enterprises of the new millennium must capture, manage, and utilize information with rapid speed in an effort to keep pace with the continually changing technology. Knowledge management is an important means by which organizations can better manage information and, more importantly, knowledge. Not easily defined, knowledge management embodies a plethora of categories within the field of information science and technology.

Over the past two decades, numerous researchers have developed a variety of techniques, methodologies, and measurement tools that have allowed them to develop, deliver, and, at the same time, evaluate the effectiveness of several areas of knowledge management. The explosion of these technologies and methodologies have created an abundance of new, state-of-art literature related to all aspects of this expanding discipline, allowing researchers and practicing educators to learn about the latest discoveries in the field of knowledge management.

Rapid technological changes, combined with much greater interest in discovering innovative techniques to manage knowledge in today's modern organizations, have led researchers and practioners to continually search for literature that will help them stay abreast of the far-reaching effects of these changes, as well as to help develop and deliver more innovative methodologies and techniques utilizing new technological innovation. In order to provide the most comprehensive, in-depth, and recent coverage of all issues related to knowledge management, as well as to offer a single reference source on all conceptual, methodological, technical, and managerial issues, as well as the opportunities, future challenges, and emerging trends related to this subject, *Information Science Reference* is pleased to offer a six-volume reference collection on this rapidly growing discipline, in order to empower students, researchers, academicians, and practitioners with a comprehensive understanding of the most critical areas within this field of study.

This collection, entitled *Knowledge Management: Concepts, Methodologies, Tools, and Applications*, is organized in eight distinct sections, providing the most wide-ranging coverage of topics such as: (1) Fundamental Concepts and Theories; (2) Development and Design Methodologies; (3) Tools and Technologies; (4) Utilization and Application; (5) Organizational and Social Implications; (6) Managerial Impact; (7) Critical Issues; and (8) Emerging Trends. The following provides a summary of what is covered in each section of this multi-volume reference collection:

Section 1, ***Fundamental Concepts and Theories***, serves as a foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of knowledge management. Chapters such as, "Knowledge Management Success Models" by Murray E. Jennex, as well as, "Knowledge Synthesis Framework" by Kam Hou Vat provide an excellent framework in which to position knowledge management within the field of information science and technology. "Beyond Knowledge Management:

Introducing Learning Management Systems" by Audrey Grace and Tom Butler offers excellent insight into the critical incorporation of learning systems into the global enterprises, while chapters such as, "Knowledge Management, Communities of Practice, and the Role of Technology: Lessons Learned from the Past and Implications for the Future" by Wee Hin Leo Tan, Thiam Seng Koh, and Wei Loong David Hung address some of the basic, yet crucial stumbling blocks of information management. With 43 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring knowledge management discipline.

Section 2, ***Development and Design Methodologies,*** provides in-depth coverage of conceptual architectures and knowledge management frameworks to provide the reader with a comprehensive understanding of the emerging technological developments within the field of knowledge management. *"Supporting Research and Development Processes Using Knowledge Management Methods"* by Thomas Hahn, Bernhard Schmiedinger, and Elisabeth Stephan offers research fundamentals imperative to the understanding of research processes within the knowledge management discipline. On a more global scale, Adekunle Okunoye and Nancy Bertaux's**, "**KAFRA: A Context-Aware Framework of Knowledge Management in Global Diversity" explores cultural and infrastructural issues related to the management of knowledge in developing countries. From basic designs to abstract development, chapters such as "Stages of Knowledge Management Systems" by Peter Gottschalk and "Autopoietic Approach for Information System Development" by El-Sayed Abou-Zeid serve to expand the reaches of development and design technologies within the knowledge management community. This section includes over 45 contributions from researchers throughout the world on the topic of information development and knowledge sharing within the information science and technology field.

Section 3, ***Tools and Technologies***, presents an extensive coverage of various tools and technologies available in the field of knowledge management that practioners and academicians alike can utilize to develop different techniques. Chapters such as Tobias Mueller-Prothmann's, "Use and Methods of Social Network Analysis in Knowledge Management" enlightens readers about fundamental research on one of the many methods used to facilitate and enhance the knowledge sharing experience whereas chapters like, "Technology and Knowledge Management: Is Technology Just an Enabler or Does it also Add Value?" by Helen Mitchell explore the intrinsic value of technology and knowledge management. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of knowledge management. With more 28 chapters, this section offers a broad treatment of some of the many tools and technologies within the knowledge management community.

Section 4, ***Utilization and Application***, discusses a variety of applications and opportunities available that can be considered by practioners in developing viable and effective knowledge management programs and processes. This section includes more than 50 chapters such as "Knowledge Management and the Leading Information Systems Journals: An Analysis of Trends and Gaps in Published Research" by Todd Peachey, Dianne J. Hall, and Casey Cegielski which reviews knowledge management literature published in top-tier journals, offering findings on the most popular trends researched within the academic community. Additional chapters such as Hyung Seok Jeong and Dulcy M. Abraham's, "Knowledge Management in Civil Infrastructure Systems" discuss the utilization of knowledge management within the governmental realm. Also considered in this section are the challenges faced when utilizing knowledge management with healthcare systems as outlined by Martin Orr's, "The Challenge of Privacy and Security and the Implementation of Health Knowledge Management Systems." The adaptability of governmental agencies in response to disasters is given consideration in chapters such as, "Knowledge Management and Hurricane Katrina Response" by Tim Murphy and Murray E. Jennex which investigates the major hurdles faced in knowledge sharing in the face of disasters, spanning the globe. Contributions included in this section provide excellent coverage of today's global community and how knowledge management research is impacting the social fabric of our present-day global village.

Section 5, ***Organizational and Social Implications***, includes a wide range of research pertaining to the social and organizational impact of knowledge management technologies around the world. Introducing this section is Daniel L. Davenport and Clyde W. Holsapple's chapter entitled, "Knowledge Organizations" providing a comprehensive introduction of the modern-day knowledge organization. Additional chapters included in this section such as "The Role of Culture in Knowledge Management: A Case Study of Two Global Firms" by Dorothy Leidner, Maryam Alavi, and Timothy Kayworth explore the difference in the community approach versus the process approach to knowledge management within two cultural paradigms. Also investigating a concern within the field of knowledge management is Bendik Bygstad's, "*Some Implementation Challenges of Knowledge Management Systems: A CRM Case Study*" which provides a study of the varying challenges when implementing knowledge management systems. The discussions presented in this section offer research into the integration of technology to allow access for all.

Section 6, ***Managerial Impact***, presents contemporary coverage of the social implications of knowledge management, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Core ideas such as training and continuing education of human resources in modern organizations are discussed through these more than 35 chapters. "*Networks of People as an Emerging Business Model*" by Lesley Robinson discusses strategic planning related to the organizational elements and knowledge sharing program requirements that are necessary to build a framework in order to institutionalize and sustain knowledge management systems as a core business process. Equally as crucial, chapters such as "*Bridging the Gap from the General to the Specific by Linking Knowledge Management to Business Processes*" by John S. Edwards and John B. Kidd address the gap between theory and practical implementation within the knowledge sharing community. Concluding this section is a chapter by Catherine C. Schifter of Temple University, "*Faculty Participation in Distance Education Programs*". Directing the reader's focus forward, the final chapter of this section, "*Outcomes of Knowledge Management Initiatives*," by Vittal S. Anantatmula riteria helps to establish a basis for assessing the value of knowledge management while evaluating its results within business enterprises.

Section 7, ***Critical Issues***, contains 25 chapters addressing issues such as intellectual capital and knowledge management, communities of practice, and critical social theory and ontology-supported Web service composition. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study. Franz Hofer's, "*Knowledge Transfer Between Academia and Industry*" develops an excellent model for researchers and practioners as attempts are made to simultaneously ease and expedite the transfer of knowledge from the private to the public sector. Forming frameworks in which to position the issues faced in this growing field are provided by research found in chapters such as, "*Communities of Practice and Critical Social Theory*" by Steve Clarke and "*Aristotelian View of Knowledge Management*" by David G. Schwartz—both chapters that take the core psychological paradigms of sociology and translate them into applicable ideas within the exploding realm of information sharing. Crucial examinations such as that presented in Richard L. Wagoner's chapter, "*We've Got a Job to Do - Eventually: A Study of Knowledge Management Fatigue Syndrome*" serves to reinforce the ideas presented in this section while simultaneously enticing and inspiring the reader to research further and participate in this increasingly pertinent debate.

The concluding section of this authoritative reference tool, ***Emerging Trends,*** highlights research potential within the field of knowledge management while exploring uncharted areas of study for the advancement of the discipline. Introducing this section is David G. Schwartz's, "*The Emerging Discipline* *of Knowledge Management*" which sets the stage for future research directions and topical suggestions for continued debate. Providing an alternative view of knowledge management is the chapter, "*Culture-Free or Culture-Bound? A Boundary Spanning Perspective on Learning in Knowledge Management Systems*" by Robert M. Mason. This chapter researches the cultural dimension of knowledge management systems, particularly the relationship of learning and culture in knowledge management projects. Another debate which currently finds itself at the forefront of research within this field is presented by Nieves Pedreira, Julián Dorado, Juan Rabuñal, and Alejandro Pazos' research, "*Knowledge Management as the Future of E-Learning*" which explores the inevitable increase in complexity and quantity of the information that is available for students of all backgrounds postulating that we must move towards a model that offers the student room for individual exploration and self-learning. Found in these 21 chapters concluding this exhaustive multi-volume set are areas of emerging trends and suggestions for future research within this rapidly expanding discipline.

Although the primary organization of the contents in this multi-volume is based on its eight sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore to ensure that the scholar, researcher, and educator have access to the entire contents of this multi volume set, as well as additional coverage that could not be include in the print version of this publication, the publisher will provide unlimited multi-user electronic access to the online aggregated database of this collection for the life of edition, free of charge when a library purchases a print copy. This aggregated database provides far more contents than what can be included in the print version in addition to continual updates. This unlimited access, coupled with the continuous updates to the database, ensures that the most current research is accessible knowledge seekers.

Knowledge management as a discipline has witnessed fundamental changes during the past two decades, allowing knowledge seekers around the globe to have access to information which two decades ago, was inaccessible. In addition to this transformation, many traditional organizations and business enterprises have taken advantage of the technologies offered by the development of knowledge management systems in order to expand and augment their existing programs. This has allowed practioners and researchers to serve their customers, employees, and stakeholders more effectively and efficiently in the modern virtual world. With continued technological innovations in information and communication technology and with on-going discovery and research into newer and more innovative techniques and applications, the knowledge management discipline will continue to witness an explosion of information within this rapidly evolving field.

The diverse and comprehensive coverage of knowledge management in this six-volume authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field, resulting in a greater understanding of the fundamentals while fueling the research initiatives in emerging fields. We at Information Science Reference, along with the editor of this collection, and the publisher hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of knowledge management.

Introductory Chapter: Contemporary Research in Knowledge Management

Murray E. Jennex
San Diego State University, USA

INTRODUCTION

Knowledge management (KM) is a hot topic in academia and the business community. KM can be viewed as an evolution of decision support systems, DSS, and information systems, IS, that is helping organizations overcome the "productivity paradox" and to ensure that "IS matters." This six volume set presents current KM research that investigates the many facets of KM. Although, the title 'knowledge management' itself might suggest a rather simple definition, KM is a complex discipline with many different focuses. This introductory chapter presents the foundation of KM and places the research from these six volumes into the unified context of the KM discipline by presenting an overview of fundamental KM concepts and theories and then discusses the many technologies, applications, managerial and organizational implications, trends, and issues in KM.

FUNDAMENTAL CONCEPTS AND THEORIES IN KNOWLEDGE MANAGEMENT

Knowledge

Davenport and Prusak (1998) view knowledge as an evolving mix of framed experience, values, contextual information and expert insight that provides a framework for evaluating and incorporating new experiences and information. They found that in organizations, knowledge often becomes embedded in artifacts such as documents, video, audio or repositories and in organizational routines, processes, practices, and norms. They also say that for knowledge to have value it must include the human additions of context, culture, experience, and interpretation. Nonaka (1994) expands this view by stating that knowledge is about meaning in the sense that it is context-specific. This implies that users of knowledge must understand and have experience with the context, or surrounding conditions and influences, in which the knowledge is generated and used for it to have meaning to them. This also implies that for a knowledge repository to be useful it must also store the context in which the knowledge was generated. That knowledge is context specific argues against the idea that knowledge can be applied universally, however it does not argue against the concept of organizational knowledge. Organizational knowledge is considered to be an integral component of what organizational members remember and use meaning that knowledge is actionable.

Polanyi (1967) and Nonaka and Takeuchi (1995) describe two types of knowledge, tacit and explicit. Tacit knowledge is that which is understood within a knower's mind and which cannot be directly expressed by data or knowledge representations and is commonly understood as unstructured knowledge. Explicit knowledge on the other hand is that knowledge which can be directly expressed by knowledge representations and is commonly known as structured knowledge. Current thought has knowledge existing as neither purely tacit nor purely explicit. Rather, knowledge is a mix of tacit and explicit with the amount of explicitness (only one dimension needs to be measured) varying with each user. This is the knowledge continuum where purely tacit and purely explicit form the end points with knowledge existing somewhere on the continuum between the two end points. Smolnik, et al. (2005) have an individual position knowledge on the continuum through context explication where context explication reflects the experience and background of the individual. Nissen and Jennex (2005) expand knowledge into a multidimensional view by adding the dimensions of reach (social aggregation), life cycle (stage of the knowledge life cycle), and flow time (timeliness) to explicitness. Research is continuing to refine the concept of knowledge and its dimensions.

Knowledge transfer in an organization occurs when members of an organization pass tacit and explicit knowledge to each other. Nonaka and Takeuchi (1995) propose four modes of knowledge creation and transfer.

- Socialization is the process of sharing experiences and thereby creating tacit knowledge such as mental models and technical skills. Tacit knowledge can be obtained without using language through observation, imitation, and practice.
- Externalization is the process of articulating tacit knowledge in the form of explicit concepts, taking the shapes of metaphors, analogies, concepts, hypotheses, or models.
- Combination is the process of systemizing concepts into a knowledge system by combining different bodies of explicit knowledge. Explicit knowledge is transferred through media such as documents, meetings, email, and/or phone conversations. Categorization of this knowledge can lead to the generation of new knowledge.
- Internalization is the process of converting explicit knowledge to tacit knowledge and is closely related to learning by doing.

These four modes or processes show that the transfer of knowledge is dependent upon the transfer of a common understanding from the knower to the user of the knowledge. Common understanding consists of the context (the story behind the knowledge, the conditions and situations which make the knowledge understandable) and the experience (those activities which produce mental models of how the knowledge should be used) expressed in a culturally understood framework.

What is culture and context? The United Nations Educational, Scientific and Cultural Organization, UNESCO, states that culture is the "set of distinctive spiritual, material, intellectual and emotional features of society or a social group and that it encompasses, in addition to art and literature, lifestyles, ways of living together, value systems, traditions and beliefs" (UNESCO, 2002). The American Heritage Dictionary (2000) defines context as the part of a text or statement that surrounds a particular word or passage and determines its meaning and/or the circumstances in which an event occurs. Culture forms the basis for how we process and use knowledge by providing belief frameworks for understanding and using the knowledge, context provides the framing for the knowledge explaining how it is created and meant to be used. Both are critical to the transfer and reuse of knowledge. We normally expect explicit knowledge to be easily transferred while we expect issues with transferring tacit knowledge. However, we are finding that transfer of either dimension of knowledge in a multicultural environment is not easy.

Jennex and Zakharova (2006) discuss why we need to consider culture and issued a call for further research into the impact of culture on KM. This discussion is based on Hofstede (1980, p. 25) who refines the definition of culture as: "Culture consists in patterned ways of thinking, feeling and reacting, acquired and transmitted mainly by symbols, constituting the distinctive achievements of human groups, including their embodiments in artifacts; the essential core of culture consists of traditions (i.e. historically derived and selected) ideas and especially their attached values." His work focuses on identifying cultural differences between nations and illustrates that value systems are not the same the world over. The key to the impact of culture on knowledge transfer is how values impact how different social groups will externalize metaphors, analogies, hypotheses, and models; how groups will systemize concepts; how groups internalize concepts; and how groups understand experiences. Differences in culture, and Hofstede (1980, 2001) show that there are significant differences between national cultures, can lead to differences between national groups within the same organization, which can cause those groups to either understand knowledge differently, or have significant barriers to participating in the sharing of knowledge. We must understand that culture is a unique component that is so deeply imbedded into peoples' lives that our ignorance of it usually leads to failures. Knowledge management systems (KMS) as well as other systems created to improve organization's performance should use all possible information about culture to escape system's mistakes due to lack of cultural awareness and understanding. Probably no theory ever will be capable to capture all or even full knowledge about a specific culture but there are enough theories (as discussed above) to establish a process and methodology for including cultural parameters in the design of KM initiatives and the system analysis and design activities.

Along with concerns about how national cultures affect the use and understanding of knowledge is the impact of organizational culture on knowledge use. Organizational culture impacts the flow of knowledge through the organization as well as the willingness of its members to share and reuse knowledge. Jennex and Olfman (2005) synthesized literature and research into a set of twelve critical success factors. Organizational culture was found to be a key critical success factor by several researchers (Alavi and Leidner, 1999, Bock and Kim, 2002, Chan and Chau, 2005, Davenport, et al., 1998, Forcadell and Guadamillas, 2002, Jennex and Olfman, 2000, Sage and Rouse, 1999, and Yu, et al., 2004). Issues related to organizational culture include organizational reward, incentive, and personnel evaluation systems and management and leadership styles and support for KM.

Why consider context? Davenport and Prusak (1998, p.5) found that for knowledge to have value it must include the elements of human context, experience, and interpretation. Nonaka (1994) expands this view by stating that knowledge is about meaning in the sense that it is context-specific. This implies that users of knowledge must understand and have experience with the context (surrounding conditions and influences) in which the knowledge is generated and used for it to be meaningful. This suggests that for a knowledge repository to be useful it must also store the context in which the knowledge was generated. The suggestion that knowledge is context specific argues against the idea that knowledge can be applied universally.

Context is the collection of relevant conditions and surrounding influences that make a situation unique and comprehensible to the users of the knowledge, Degler and Battle (2000). Context can be stored with knowledge and/or can be possessed by knowledge users. When a system's knowledge users are known, the knowledge that is captured is used to support specific activities. KMS users are readily known when the KMS is built to support a specific team, project, or process and the users are those involved with that team, project, and/or process. These users tend to possess a high degree of shared understanding where understanding incorporates context and experience. Experience is what knowledge users use to generate mental models of how to use or apply the knowledge, Degler and Battle (2000). Experience comes from the individual's own experience with the knowledge domain, other's shared experience with the knowledge domain, and/or a collective experience with the knowledge domain, Degler and Battle (2000). Combined, this means that knowledge users in teams, projects, or even processes understand the organizational culture, the structure of organizational documents, organizational terminology and jargon, and how the organization works and are able to use posted knowledge, even if it does not include context, as they implicitly understand the context in which the knowledge was created and have experience in using this knowledge. On the other hand, when KMS users are not known it is not possible to assume these users possess a common understanding or experience associated with the generation of the knowledge. This means the KMS will have to capture this context and experience for users to be able to utilize the captured knowledge effectively.

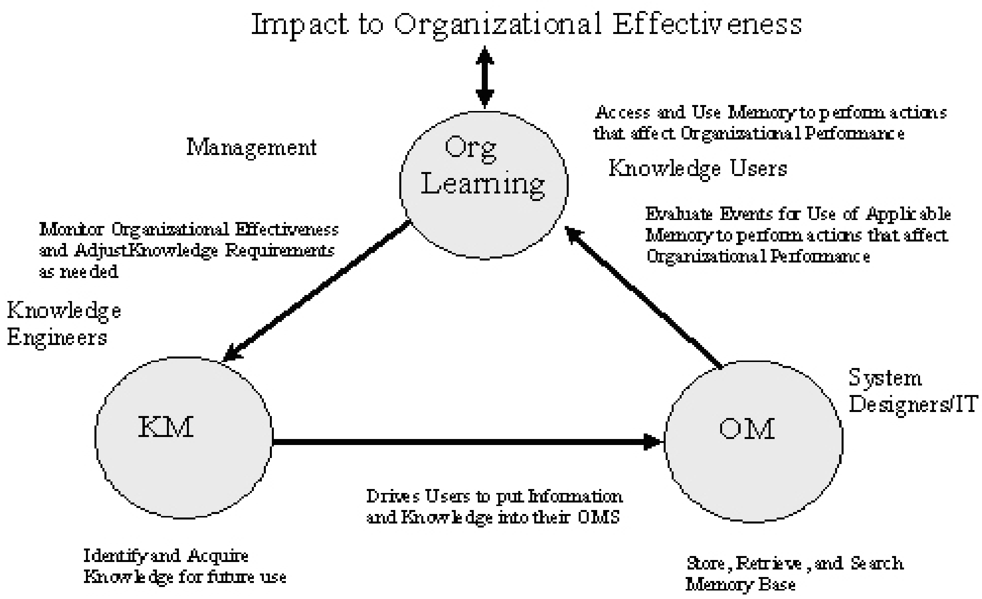
This section has presented current thought on what knowledge is, but the definition of knowledge is far from agreed upon. Knowledge is a difficult construct to define as most knowledge is context, culture, and time specific and is rarely viewed as universal, leading individuals to define knowledge uniquely. It is expected that the definition of knowledge will be debated for quite a while, perhaps as long as KM is researched. Ultimately I agree with Keen and Tan (2007) who believe that while it is important to understand what knowledge is, it is unproductive for researchers to get focused on trying to precisely define knowledge at the expense of furthering KM research.

Knowledge Management

Jennex (2005) utilized an expert panel, the editorial review board of the *International Journal of Knowledge Management* (IJKM), to generate a definition of KM as the practice of selectively applying knowledge from previous experiences of decision making to current and future decision making activities with the express purpose of improving the organization's effectiveness. Another key definition of KM includes Holsapple and Joshi (2004) who consider KM as an entity's systematic and deliberate efforts to expand, cultivate, and apply available knowledge in ways that add value to the entity, in the sense of positive results in accomplishing its objectives or fulfilling its purpose. Finally, Alavi and Leidner (2001) concluded that KM involves distinct but interdependent processes of knowledge creation, knowledge storage and retrieval, knowledge transfer, and knowledge application. Taken in context, these definitions of KM focus on the key elements of KM: a focus on using knowledge for decision making and selective knowledge capture. This is important as the selective focus on knowledge capture separates KM from library science which attempts to organize all knowledge and information and the decision making focus emphasizes that KM is an action discipline focused on moving knowledge to where it can be applied. Ultimately, KM may best be described by the phrase "getting the right knowledge to the right people at the right time" and can be viewed as a knowledge cycle of acquisition, storing, evaluating, dissemination, and application.

KM is better understood when the concepts of organizational memory (OM) and organizational learning (OL) are incorporated. Jennex and Olfman (2002) found that the three areas are related and have an impact on organizational effectiveness. Organizational effectiveness is how well the organization does those activities critical to making the organization competitive. OL is the process the organization uses to learn how to do these activities better. OL results when users utilize knowledge. That OL may not always have a positive effect is examined by the monitoring of organizational effectiveness. Effectiveness can improve, get worse, or remain the same. How effectiveness changes influences the feedback provided to the organization using the knowledge. KM and OM are the processes used to identify and capture

Figure 1. The KM/OM/OL model (Jennex & Olfman, 2002)



critical knowledge. Knowledge workers and their organizations 'do' KM; they identify key knowledge artifacts for retention and establish processes for capturing it. OM is what IT support organizations 'do'; they provide the infrastructure and support for storing, searching, and retrieving knowledge artifacts. Figure 1 illustrates these relationships and the following sections expand on these concepts.

Organizational Learning

Organizational Learning is defined as a quantifiable improvement in activities, increased available knowledge for decision-making or sustainable competitive advantage (Cavaleri, 1994; Dodgson, 1993, Easterby-Smith, 1997; Miller, 1996). In this view organizations learn through individuals acting as agents for them. Individual learning activities are seen as being facilitated or inhibited by an ecological system of factors that may be called an organizational learning system. Learning in this perspective is based on Kolb's (1984) model of experiential learning where individuals learn by doing. Huber, Davenport, and King (1998) believe an organization learns if, through its processing of information, its potential behaviors are changed. Huysman, Fischer, and Heng (1994) as well as Walsh and Ungson (1991) believe organizational learning has OM as a component. In this view, OL is the process by which experience is used to modify current and future actions. Huber (1991) considers four constructs as integrally linked to OL: knowledge acquisition, information distribution, information interpretation, and organizational memory. In this case, OM is the repository of knowledge and information acquired by the organization. Organizational learning uses OM as its knowledge base.

A different perspective on OL from Sandoe, et. al. (1998) is that organizations do not learn; rather only individuals learn. During work, people gain experience, observe, and reflect in making sense of what they are doing. As they analyze these experiences into general abstractions, their perceptions on how work should be done changes. As these individuals influence their co-workers, the "organization" learns and the process is gradually changed. Learning in this perspective is also based on Kolb's (1984) model of experiential learning.

Organizational Memory

Stein and Zwass (1995) define OM as the means by which knowledge from the past is brought to bear on present activities resulting in higher or lower levels of organizational effectiveness. Walsh and Ungson (1991) define OM as stored information from an organization's history that can be brought to bear on present decisions. OM, like knowledge, can be viewed as abstract or concrete. It is comprised of unstructured concepts and information that exist in the organization's culture and the minds of its members, and can be partially represented by concrete/physical memory aids such as databases. It is also comprised of structured concepts and information that can be exactly represented by computerized records and files. Sandoe and Olfman (1992) and Morrison (1997) describe these two forms of OM as having two functions, representation and interpretation. Representation presents just the facts (or knowledge or expertise) for a given context or situation. Interpretation promotes adaptation and learning by providing frames of reference, procedures, guidelines, or a means to synthesize past information for application to new situations. Comparing to the definition of knowledge, it is obvious that knowledge and OM are related through experience and learning. We consider knowledge to be a subset of OM and the processes of KM a subset of OM processes.

Knowledge Management Systems

Jennex (2005) views a KM system, KMS, as that system created to facilitate the capture, storage, retrieval, transfer, and reuse of knowledge. The perception of KM and KMS is that they holistically combine organizational and technical solutions to achieve the goals of knowledge retention and reuse to ultimately improve organizational and individual decision making. This is a Churchman (1979) view of KM that allows KMS to take whatever form necessary to accomplish these goals. Alavi and Leidner (2001, p. 114) defined a KMS as "IT (Information Technology)-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application." They observed that not all KM initiatives will implement an IT solution, but they support IT as an enabler of KM. Maier (2002) expanded on the IT concept for the KMS by calling it an ICT (Information and Communication Technology) system that supported the functions of knowledge creation, construction, identification, capturing, acquisition, selection, valuation, organization, linking, structuring, formalization, visualization, distribution, retention, maintenance, refinement, evolution, accessing, search, and application. Stein and Zwass (1995) define an organizational memory information system (OMS) as the processes and IT components necessary to capture, store, and apply knowledge created in the past on decisions currently being made. Jennex and Olfman (2006) expanded this definition by incorporating the OMS into the KMS and adding strategy and service components to the KMS.

KMS Classifications

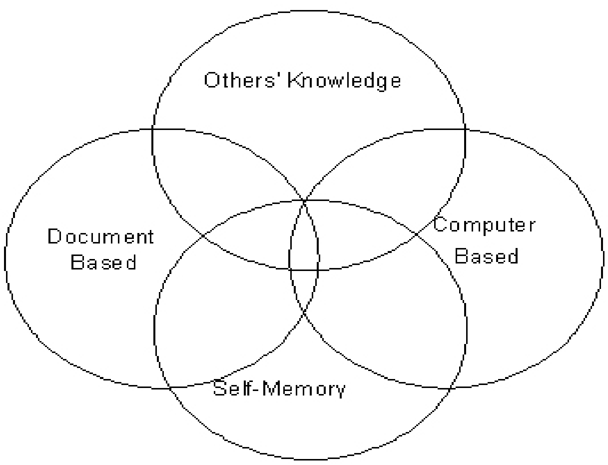
There are different ways of classifying a KMS and/or KMS technologies where KMS technologies are the specific IT/ICT tools being implemented in the KMS. Alavi and Leidner (2001) classify the KMS based on the Knowledge Life Cycle stage being predominantly supported. Marwick (2001) uses the mode of Nonaka's (1994) SECI model being implemented. Borghoff and Pareschi (1998) classifications are based on the class of the KM Architecture being supported. This architecture has 4 classes of components: repositories and libraries, knowledge worker communities, knowledge cartography/mapping, and knowledge flows. Hahn and Subramani (2001) classify by the source of the knowledge being supported: structured artifact, structured individual, unstructured artifact, or unstructured individual. Binney (2001) uses the Knowledge Spectrum. The Knowledge Spectrum represents the ranges of purposes a KMS can have. Zack (1999) classifies a KMS as either Integrative or Interactive. Integrative KMS support the transfer of explicit knowledge using some form of repository and support. Interactive KMS support the transfer of tacit knowledge by facilitating communication between the knowledge source and the knowledge user. Jennex and Olfman (2004) classify the KMS by the type of users being supported. Users are separated into two groups based on the amount of common understanding they have with each other resulting in classifications of: process/task based KMS for groups that have a common understanding and a generic/infrastructure KMS for groups that do not share a common understanding. An example of a group with a common understanding is a community of practice, CoP, which is a set of people who share a concern, a set of problems, or a passion about a topic (Wenger et al., 2002).

Knowledge Repositories

Key to the KMS is knowledge repositories. There are three types of knowledge repositories: paper documents, computer based documents/databases, and self memories:

- Paper documents incorporate all hard copy documents and are organization-wide and group-wide references that reside in central repositories such as a corporate library. Examples include reports, procedures, pictures, video tapes, audio cassettes, and technical standards.
- Computer based documents/databases include all computer-based information that is maintained at the work group level or beyond. These may be made available through downloads to individual workstations, or may reside in central databases or file systems. Additionally, computer documents include the processes and protocols built into the information systems. These are reflected in the interface between the system and the user, by who has access to the data, and by the formats of structured system inputs and outputs. New aspects of this type of repository are digital images and

Figure 2. Knowledge repositories



audio recordings. These forms of knowledge provide rich detail but require expanded storage and transmission capacities.

- Self-memory includes all paper and computer documents that are maintained by an individual as well as the individual's memories and experiences. Typical artifacts include files, notebooks, written and un-written recollections, and other archives. These typically do not have an official basis or format. Self-memory is determined by what is important to each person and reflects his or her experience with the organization.

Repositories have overlapping information and knowledge as shown in Figure 2. Paper documents are indexed or copied into computer databases or files, self memory uses paper and computer based documents/databases, computer databases or files are printed and filed. Spheres for self-memory and others' memory reflect that organizations consist of many individuals, and that the knowledge base contains multiple self-memories. Finally, the relative size of each sphere depends on the nature of the organization. Organizations that are highly automated and/or computerized would be expected to have a greater dependence on computer-based repositories while other organizations may rely more on paper or self-memory based repositories.

Use of Knowledge Repositories

Should organizations focus more on computerized repositories or on self-memory repositories? Computerized repositories provide a measure of permanence coupled with better tools for searching and retrieving knowledge. However, organizations should consider the transience and experience level of their workers when selecting repositories. Sandoe and Olfman (1992) found that the increasing transience of organizational workers requires a shift in the location of knowledge. Organizations that have large numbers of transient workers are at risk of losing knowledge if it is allowed to remain in self memories. These organizations need to capture and store knowledge in more concrete forms such as paper or computer-based repositories. They also suggest that stronger attempts should be made to capture the unstructured, abstract information and knowledge in concrete forms. Additionally, Jennex and Olfman (2002) found that new organizational workers have trouble using the document and computer-based repositories and rely on the self-memories of longer-term members. This continues until the new member gains sufficient context and culture to understand and use the information and knowledge in the paper and computer-based repositories. While these guidelines are contradictory because transient organizations will tend to have more new members, they do emphasize that organizations should minimize reliance on self-memories for the retention of concrete, structured knowledge while using self-memories as the mechanism for teaching organizational culture and passing on unstructured, abstract knowledge.

KM/KMS Success

Jennex, Smolnik, and Croasdell (2007) found KM success to be a multidimensional concept defined by capturing the right knowledge, getting the right knowledge to the right user, and using this knowledge to improve organizational and/or individual performance. KM success is measured using the dimensions of impact on business processes, strategy, leadership, efficiency and effectiveness of KM processes, efficiency and effectiveness of the KM system, organizational culture, and knowledge content.. KM success is considered the same as KM effectiveness and KM success is also equated to KMS success when the Churchman (1979) view of a KMS is used.

While these measures are useful for measuring success, it is also important to understand what is needed to have successful KM/KMS. Jennex and Olfman (2005) summarized and synthesized the literature from 17 studies on over 200 KM projects on KM/KMS critical success factors, CSFs, into an ordered set of twelve KM CSFs. The below twelve CSFs were ordered based on the number of studies identifying the CSF:

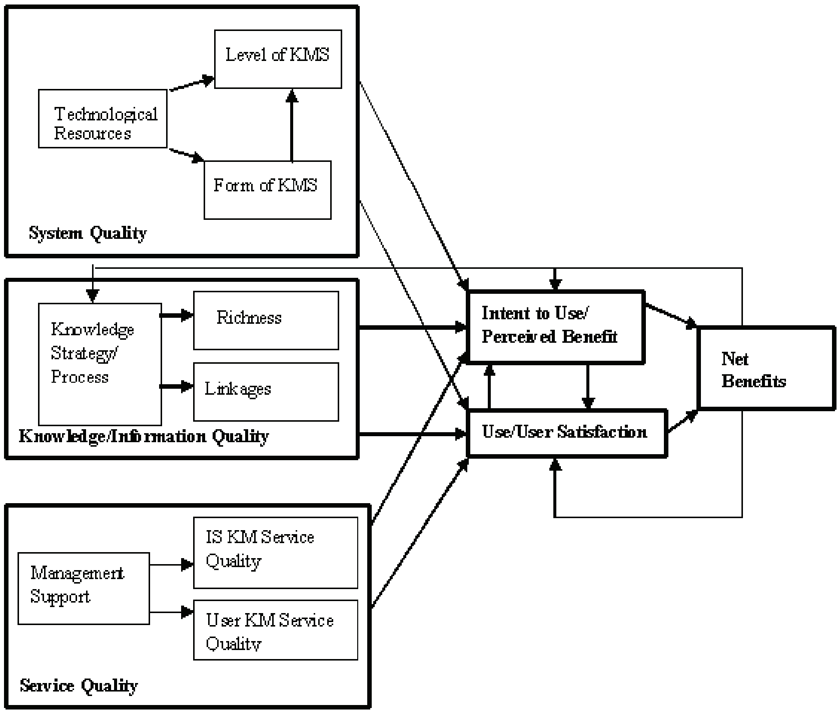
- A knowledge strategy that identifies users, sources, processes, storage strategy, knowledge and links to knowledge.
- Motivation and commitment of users including incentives and training
- Integrated technical infrastructure including networks, databases/repositories, computers, software, experts
- An organizational culture and structure that supports learning and the sharing and use of knowledge
- A common enterprise wide knowledge structure that is clearly articulated and easily understood
- Senior management support including allocation of resources, leadership, and providing training
- Learning organization
- There is a clear goal and purpose for the KMS
- Measures are established to assess the impacts of the KMS and the use of knowledge as well as verifying that the right knowledge is being captured
- The search, retrieval, and visualization functions of the KMS support easy knowledge use
- Work processes are designed that incorporate knowledge capture and use
- Security/protection of knowledge

While it is useful to identify the KM CSFs, it is more useful to express the CSFs in a model that relates them to KM success. The Jennex Olfman (2006) KM success model (Figure 3) is a causal model based on the DeLone and McLean (1992, 2003) IS Success Model. The Jennex Olfman (2006) KM Success Model is discussed because it has been shown to relate KM CSFs to KM success. It has three basic dimensions as antecedents to KM success: system quality which deals with the technical infrastructure; knowledge/information quality which deals with KM strategy for identifying critical knowledge and then how that knowledge is stored; and service quality which deals with management support and allocation of resources. The model also has the dimensions of perceived benefit, user satisfaction, and net benefits. These dimensions deal with ensuring that the KM initiative meets the needs of the users and the organization and ultimately expresses KM success in terms of impacts on organizational and individual work processes.

Of course other KM success/effectiveness models exist. Jennex and Olfman (2005) summarized and described these models and related them to KM success factors. The following is a listing of these models:

- Bots and de Bruijn (2002) The Knowledge Value Chain KM Success Model, based on the value chain approach to determining key processes.
- Massey, Montoya-Weiss, and Driscoll (2002) KM Success Model, a process-based KM success model derived from their Nortel case study.
- Lindsey (2002) KM Effectiveness Model, based on combining Organizational Capability Perspective theory (Gold, 2001) and Contingency Perspective Theory (Becerra-Fernandez and Sabherwal, 2001).
- Maier (2002) KMS Success Model, based on DeLone and McLean (1992) IS Success Model

Figure 3. Jennex Olfman (2006) KM success model



KNOWLEDGE MANAGEMENT DEVELOPMENT AND DESIGN METHODOLOGIES

Traditional information systems (IS) are developed and designed through the well known systems analysis and Design (SAD) process. This process is based on application of a systems development life cycle approach that based on identifying user requirements, designing and implementing the requirements into an IS, verifying the IS meets the requirements, then maintaining these requirements over the life of the system. While this process has been modified through the application of Extreme Programming and Agile Methods, the basic SAD process still remains focused on user requirements. A KMS is different than an IS. The incorporation of knowledge into a system adds complexity forcing system designers to consider using a process that Tauber and Schwartz (2006) label as the knowledge integrated systems analysis (KISA) process. KISA basically has system designers use parallel process, IS personnel use traditional SAD techniques to design the user and technical components of the KMS while the KM group analyzes for knowledge requirements. SAD techniques are well known and documented in the SAD literature. Knowledge analysis techniques are not. The key to knowledge analysis is understanding knowledge flow and usage. The following paragraph discusses current trends in knowledge process modeling techniques. It should be noted that these techniques, while based on IS methodology, include the modeling of organizational needs and are not just technology focused.

Knowledge process modeling is a key activity in the design of a KMS. Two new approaches come from Kim, et al. (2006) who proposes using Unified Modeling Language, UML, to model knowledge intensive processes; and from Froming, et al. (2006) who proposes a specification for a Knowledge Modeling and Descriptive Language, KMDL, that also assists in modeling knowledge intensive processes. Another aspect of knowledge process modeling understands the flow of knowledge. Social Network Analysis, SNA, is a technique used to determine key knowledge flow nodes. Cheuk (2006) applied SNA to an organization as a diagnostic tool for understanding knowledge flows through the organization. It is also important to be able to elicit information from KMS users. SAD uses standard interview techniques and approaches such as joint application development (JAD) to accomplish this. Taylor (2005) proposes the use of the critical decision interview method to help identify knowledge used in knowledge intensive processes. Finally, in the earlier discussion on knowledge the importance of culture and context were mentioned. Understanding how context and culture impacts the social, technical, and political environment in which a KMS operates is also essential. Okunoye and Bertaux (2006) propose the use of KAFRA, Kontext Aware FRAmework, as a means for developers to understand and analyze these issues.

UTILIZATION AND APPLICATION OF KNOWLEDGE MANAGEMENT

The following are examples of KM implementations in organizations. Two classes of approaches are used, Internet and enterprise based approaches. In general these examples are initially discussed based on the technology used to support the KMS. However, this chapter takes a Churchmanian approach to systems so the examples also include discussion of social and organizational issues that affected the example systems. The examples are not an all inclusive or exhaustive set. Their purpose is to illustrate how KM is being implemented in organizations and to provide context for how social and technical approaches are combined to create KMS and KM solutions.

Internet Based KMS

One of the most commonly cited KMS success factors (Jennex and Olfman, 2005) is having an integrated technical infrastructure including networks, databases/repositories, computers, software, and KMS experts. KM designers are using the Internet to obtain this integrated network and are using browsers as common software. Various approaches are being utilized by KMS designers to achieve common databases and repositories. Common taxonomies and ontologies are being used to organize storage of unstructured knowledge files and to facilitate knowledge retrieval while other Internet based KMS serve as interfaces to large enterprise databases or data warehouses. Some Internet KMS are being used to facilitate communication and knowledge transfer between groups. Knowledge portals are being used by organizations to push knowledge to workers and be communities of practice (COP) to facilitate communication and to share knowledge between community members. The following section describes some examples of Internet based KMS.

Internet networks can be scaled to fit any size KMS. Browsers can be tailored to fit processes as desired. Taxonomies can be created that support unstructured knowledge sharing for any size KMS. The following examples illustrate this flexibility as the examples include a project KMS, an industry wide project KMS, and enterprise KMS. Knowledge Portals can be scaled to fit either form of KMS but are more commonly used for enterprise KMS. Community of Practice KMS is a variation of process/task KMS.

Examples of Internet Based KMS

Project Based KMS for a Single Organization

Jennex (2000) discussed an Intranet based KMS used to manage knowledge for a virtual Y2K project team. This KMS used two different site designs over the life of the project. The purpose of the initial site was to facilitate project formation by generating awareness and providing basic information on issues the project was designed to solve. The design of this site was based on Jennex and Olfman (2002) that suggested a structure providing linkages to expertise and lessons learned were the knowledge needed by knowledge workers. This was accomplished by providing hot links to sites that contained Y2K knowledge, a project team roster that indicated the areas of expertise for each of the project team members and additional entries for individuals with expertise important to the project, and some basic answers to frequently asked questions. The site did not contain guidelines and accumulated knowledge as reflected in test plans, test results, inventories of assets referenced to the division who owned them, and general project knowledge such as project performance data, meeting minutes and decisions, presentations, and other project documentation. This information had not been generated at the time the site was implemented. Once generated, this information was stored on network servers with shared access to acknowledged project team members.

As the project team formed and began to perform its tasks the requirements for the Intranet site changed from generating awareness to supporting knowledge sharing. The site was redesigned and expanded to include detailed frequently asked questions (FAQs), example documents, templates, meeting minutes, an asset database, guidelines for specific functions that included lessons learned, etc. The knowledge content of the site was distributed into the other components of the site and persons were identified as being responsible for the information and knowledge content of their responsible areas. Additionally, access to the site was enhanced by the addition of a hot link to the Y2K site placed and prominently displayed on the Corporate Intranet home page. The basic layout of the site provided for access to seven specific sub-sites: Major Initiatives, Contacts, Documents, What's New, Hot Links, Issues and Questions, and Y2K MIS.

The effectiveness of the two sites was considered good. The first site was successful in generating interest and starting the project. The second site succeeded in taking a project that was performing in the bottom third of projects to being a leading project within six months after its release. Effectiveness of the sites was established using the model in Figure 3 and by ensuring the Information Quality was high and the System Quality, especially the search, retrieval, and infrastructure, was good.

KMS as a Knowledge Portal

This example, from Cross and Baird (2000) is an Intranet site built by Andersen Consulting. Consulting firms have had a long tradition of brokering their knowledge into business. In the early 1990s, Andersen Consulting began to produce global best practices CDs for distribution to project personnel. This evolved into the development of a Intranet site called KnowledgeSpace that provided consultants with various forms of knowledge including methodologies and tools, best practices, reports from previous like engagements, and marketing presentations. Support was also provided for online communications for online communities of practice and virtual project teams. The site was effective for personnel with access to the Internet and adequate bandwidth. It should be noted that current modem technology and improved dial in access, as well as the proliferation of broadband connections, have made sites such as this much more effective for field or remote personnel.

The second example, from Bartczak (2005), describes the system used by the United States Air Force to support the Material Command called the AFKM Hub. The AFKM Hub is the primary Web site for the AF Lessons Learned utility. Although the Website has evolved, Lessons Learned is still the centerpiece of the Hub. Lessons Learned have been captured and categorized by subject area and provide valuable knowledge about past processes and events. The AFKM Hub also acts as a portal for all other AFKM components and serves as the default AFKM home page. The AFKM Hub provides a conduit to select relevant information and knowledge resources and provides an avenue for creating a knowledge-sharing organization. The AFMC Help Center of the AFKM Hub allows AFMC customers to perform a natural language or keyword search of over 130 AFMC Websites and selected databases. It connects AFMC customers throughout the Air Force and Department of Defense with the appropriate AFMC information source or point of contact. The CoP Workspace supports the growing number of Air Force CoPs. CoP workspaces are virtual environments where members can exchange information to complete work tasks and solve problems. Each CoP serves a specific customer set. The AFKM Hub provides workspaces for a variety of CoPs and supports over 1300 active CoPs. The effectiveness of the AFKM Hub has also been mixed. Air Force leadership sees the value in KM and many examples of successful uses of knowledge have been recorded. However, articulating a knowledge and KM strategy has been difficult and has allowed for wasted effort in supporting Air Force KM needs.

KMS as a Topic Map

The last examples come from Eppler (2001). There are five types of knowledge maps: source, asset, structure, application, and development. A multimedia company Intranet site is used to illustrate a knowledge source map. This site provides graphical buttons representing individuals with specific expertise color-coded to indicate the expert's office location. The Knowledge Asset map provides a visual balance sheet of an organization's capabilities of a skills directory or core competency tree. Colors are used to indicate knowledge domains while the size of symbols indicates level of expertise. Knowledge Structure maps divides knowledge domains into logical blocks that are then broken into specific knowledge areas. The Knowledge Application map breaks an organization's value chain into its components parts and then indicates what knowledge, tools, or techniques are needed to implement the component part. The last example is a Knowledge Development map. This map is used to plot the activities needed to acquire the indicated knowledge competence. Clicking on the displayed competence displays the steps needed to develop the competence. Effectiveness of these maps has only been determined for the Knowledge Asset map. This map, developed for a telecommunications consultant firm, was found to be very useful for the planning of training activities and for identifying experts quickly when required during an emergency. IT should be noted that knowledge maps enhance the linkage aspects of information quality.

Enterprise System Support for KMS

As organizations strive to improve their competitive position/advantage, they are implementing enterprise wide systems. These systems integrate processes and data/information/knowledge across the enterprise and in many cases with suppliers and customers to improve efficiency and effectiveness (Koch 2002). This usually results in lowered operating costs and improved response times, economies of scale, and user satisfaction. Typical examples of these systems are enterprise resource planning (ERP), customer relationship management (CRM), supply cChain management (SCM), and data warehouse implementations. As these systems are refined and improved organizations are finding that incorporating knowledge and KM improves system performance. Unfortunately, there are also several issues involved in successfully using enterprise systems to support KM; chief among these are organizational culture issues. Many enterprises suffer from fragmentation, meaning that many organizations within the enterprise own and use their own data and systems. Enterprise systems seek to integrate these systems but to be successful they must overcome issues of ownership and a reluctance to share data, information, and knowledge. This issue is usually characterized by the presence of "silos" in the enterprise. Corral, Griffen, and Jennex

(2005) discuss this issue with respect to integrating data warehouses and KM. The following examples describe how enterprise systems and KMS are being fused together.

ERP and KMS

Li, et al. (2005) describe an ERP implementation in a Chinese paper manufacturing company. The ERP was implemented to help the company respond to market and customer changes more rapidly by integrating enterprise data information and knowledge and centralizing process control. Unfortunately, China lacked experience with ERP implementation and is not overly familiar with western concepts of centralized data, information, and knowledge management. This was an issue in getting the ERP implemented and utilized. Once this was accomplished, decision making was greatly enhanced through improved knowledge transfer provided by the ERP's integration of organizational data, information, and knowledge into a single accessible location. Other issues faced in implementing the ERP was management support for the various sub organizations being integrated into the ERP and creating a culture that used data, information, and knowledge in the expected way.

White and Croasdell (2005) describe ERP implementations in Nestle, Colgate-Palmolive, and Chevron-Texaco. Each of these implementations was performed to improve data, information, and knowledge integration with an expectation of improved decision making and transfer of key knowledge such as lessons learned and process improvements. All three implementations were ultimately successful after initial difficulties including cost overruns due to unrealistic project estimates of schedule and cost and overcoming employee resistance to changing to new processes and merging data, information, and knowledge ownership. These examples also incorporated the KMS success factor of metrics for measuring success and illustrate the importance of measuring KMS performance.

CRM and KMS

Al-Shammari (2005) describes a knowledge-enabled customer relationship management, KCRM, system in a large middle-eastern telecommunications company. The KCRM was composed of three major parts: Enterprise data warehouse (EDW), operational CRM, and analytical CRM. The KCRM initiative was designed to automate and streamline business processes across sales, service and fulfillment channels. The KCRM initiative was targeted at achieving an integrated view of customers, maintaining long-term customer relationship, and enabling a more customer-centric and efficient go-to-market strategy. The driver for the initiative was that the company faced deregulation after many years of monopoly. The company initiated a customer-centric KM program, and pursued understanding customers' needs and forming relationships with customers, instead of only pushing products and services to the market. Unfortunately, the KCRM program ended as an ICT project. The company didn't succeed in implementing KCRM as a business strategy, but did succeed implementing the KCRM as a transactional processing system. Several challenges and problems were faced during and after the implementation phase. Notable among these is that the CRM project complexity and responsibilities were underestimated, and as a result, the operational CRM solution was not mature enough to effectively and efficiently automate CRM processes. Changing organizational culture was also a tremendous effort in terms of moving towards customer-centric strategy, policy and procedures, as well as sharing of knowledge in a big organization with lots of business 'silos'. Employee resistance to change posed a great challenge to the project. Ultimately, this project failed to achieve to expectations.

Data Warehouse, Enterprise Databases, and KMS

White and Croasdell (2005) describe Xerox use of an enterprise database to facilitate the sharing of experience knowledge across the company. Xerox had difficulty in fostering best practice among its group of printer maintenance employees. The problem centered on an inability to circulate employee expertise using existing organizational infrastructure. To help the maintenance technicians share their experience and expertise, Xerox created a database to hold top repair ideas in order to share those ideas with other technicians in all areas. This strategy called for only the most favored ideas to be kept within the database as it often occurred that what one person thought useful others found the same the idea absurd or redundant. Xerox also realized that many databases had been created by managers who filled the databases with information they thought would be useful for their employees. However, most of those databases were rarely used by the employees. When Xerox created the Eureka database it also formed a process for entering and updating the ideas within the database. The process is based on a peer-review system. Within this practice the representatives, not the organization, supply and evaluate tips. In this way a local expert would work with the representative to refine the tip. Representatives and engineers evaluate the tips, calling in experts where appropriate. As of July of 2000 the Eureka database held nearly 30,000 ideas and was being utilized by 15,000 Xerox technicians who answered a quarter-million repair calls per year. The shared knowledge in Eureka saved Xerox about $11 million in 2000 and customers also saved money in terms of the reduction in downtime.

Eureka later extended the role of the Eureka Database to collect, share, and reuse solutions to software and network problems as well as those involving hardware.

KNOWLEDGE MANAGEMENT TOOLS AND TECHNOLOGIES

Although there is strong support for using the Internet as a Knowledge infrastructure, there are concerns. Chief among these concerns is the difficulty in organizing, searching, and retrieving unstructured knowledge artifacts. Ezingeard, et al. (2000) points out that Ernst & Young UK in the beginning of 2000 had in excess of one million documents in its KMS. Another concern is the tendency to not to use the system. Cross and Baird (2000) discusses this tendency but comes to the conclusion that repositories are essential. Jennex (2007a) found that use and importance for knowledge do not correlate suggesting that use is not a true measure of the value of a KMS. Jennex and Olfman (2002) found that voluntary use is enhanced if the system provides near and long term job benefits, is not too complex, and the organization's culture supports sharing and using knowledge and the system. Stenmark (2002) found that if the Internet is visualized as a system for increasing awareness of knowledge and the KMS, a system for retaining and sharing knowledge, and as a system for enhancing communication and collaboration between teams and knowledge experts and users; then it should be successful as a KMS. In all cases, researchers are experimenting with technologies that improve the handling of unstructured knowledge. These are discussed in the following paragraphs.

Newman and Conrad (2000) propose a framework for characterizing KM methods, practices, and technologies. This framework looks at how tools can impact the flow of knowledge within an organization, IT's role in manipulating knowledge artifacts, and the organizational behavior most likely to be affected. The framework also looks at the part of the KM process the tool works in. The Activity phase looks at the utilization, transfer, retention, and creation of Knowledge. This framework can be used to show that Internet and Browser based KMS tools are effective.

Gandon, et al. (2000) proposes using XML to encode memory and knowledge, and suggest using a multi-agent system that can exploit this technology. The proposed system would have improved search capabilities and would improve the disorganization and poor search capability normally associated with Internet systems. Chamberlin, et al. (2001) and Robie, et al. (1998) discuss using XML query language to search and retrieve XML encoded documents.

Dunlop (2000) proposes using clustering techniques to group people around critical knowledge links. As individual links go dead due to people leaving the organization, the clustered links will provide a linkage to people who are familiar with the knowledge of the departed employee. This technique would improve the reliability of the links to knowledge called for in Figure 2. Lindgren (2002) proposes the use of Competence Visualizer to track skills and competencies of teams and organizations.

Te'eni and Feldman (2001) propose using task-adapted Websites to facilitate searches. This approach requires the site be used specifically for a KMS. Research has shown that some tailored sites, such as ones dedicated to products or communities have been highly effective. This approach is incorporated in the examples in this paper with the exception of the use of dynamic adaptation.

Abramowicz, et al. (2002), Eppler (2001), and Smolnik and Nastansky (2002) discusses the use of knowledge maps to graphically display knowledge architecture. This technique uses an Intranet hypertext clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as Topic Maps and Skill Maps. Knowledge maps are useful as they create an easy to use standard graphical interface for the Intranet users and an easily understandable directory to the knowledge.

The use of ontologies and taxonomies to classify and organize knowledge domains is growing. Zhou, et al. (2002) propose the use of ROD, Rapid Ontology Development, as a means of developing an ontology for an undeveloped knowledge domain.

Making sense of seemingly unrelated structured data, information, and knowledge can also be difficult. Data mining is being used as a method for identifying patterns in this data, information, and knowledge that can then be assessed for meaning. Zaima and Kashner (2003) describe data mining as an iterative process that uses algorithms to find statistically significant patterns in structured data, information, and knowledge. These patterns are then analyzed by business process experts to determine if they actually have meaning in the business process context. CRM tends to use this technology the most as illustrated by the example from Al-Shammari (2005).

Organizing and visualizing data and information into usable knowledge is a challenge that digital dashboard technologies are seeking to solve. Few (2005) describes dashboards as providing single screen summaries of critical data and information. Key to developing effective dashboards is the use of KM to identify critical knowledge for key decision making and then linking it to the appropriate context data and information that indicates the status of the key knowledge. Dashboards can be used with a Internet browser or any other KMS infrastructure.

ORGANIZATIONAL AND SOCIAL IMPLICATIONS OF KNOWLEDGE MANAGEMENT

KM is about capturing and sharing knowledge, capturing knowledge from knowledge creators and possessors and sharing knowledge to knowledge users. KM success hinges on several factors but some of the key CSFs that impact organizations and society are (Jennex & Olfman, 2005):

- A knowledge strategy that identifies users, sources, processes, storage strategy, knowledge and links to knowledge
- Motivation and commitment of users including incentives and training

- An organizational culture and structure that supports learning and the sharing and use of knowledge
- Learning organization
- Work processes are designed that incorporate knowledge capture and use

These CSFs impact organizations and society by changing expected behavior of individuals from being that of knowledge hoarders to that of knowledge sharers. This is an obviously disruptive discipline in the organization. However, as organizations find they must better utilize their knowledge in order to compete, they will do what is necessary, including changing their organizational culture, to ensure they better utilize and share their knowledge. Case study research on the implementation of KM in a variety of organizations is finding the issue of changing organizational culture is not a trivial or easy task. Several cases in this set explore this issue. Additionally, this is leading to two other impacts on society. The first is the impact of national culture on knowledge sharing and transfer. The second is the growing movement towards open source KM.

National culture impacts what we have to include with knowledge in order to make it useful to users from cultures other than the culture where the knowledge was created. This was previously discussed in the section discussing knowledge. A further consideration is how national culture affects organizational culture and the ability of an organization to transfer and share knowledge. Research investigating KM in various cultures has been recently published and it shows that this is a consideration that impacts the ability of an organization to implement KM successfully. The key societal implication of culture is this impact and its potential to increase the "digital divide" between those countries with cultures that support knowledge sharing and those whose culture inhibits knowledge sharing.

Open source KM is a new term (Jennex, 2006a) used to describe the concept of community cooperation. Open source KM is a form of KM where communities manage knowledge in a leaderless or semi-leaderless environment and tend towards using open source tools and systems. In other words, the communities are not focused on tightly bound business organizations; rather, they are focused on loosely bound social networks. Also, this KM is not necessarily focused on improving organizational performance. In many cases it is focused on improving social conditions. An example is the development and growth of Wikipedia, an open source, collaborative encyclopedia free to all to use. Another example is the various academic initiatives aimed at providing free access for publication and dissemination of research using online academic journals. A final example is the use of open source tools such as Wikis to facilitate community participation in disaster or emergency response such as PeopleFinder and ShelterFinder following Hurricane Katrina (Murphy & Jennex, 2006).

MANAGERIAL IMPACT OF KNOWLEDGE MANAGEMENT

KM is a disruptive influence in organizations and society as mentioned in the previous section. This is particularly true for management. KM is about improving decision making (Jennex, 2005) and this helps improve management's decision making. KM is also about collaboration and knowledge sharing. Organizations implementing KM increase the amount of knowledge sharing between their members, this also improves decision making but creates potentially uncontrolled knowledge flows and new social networks. Management that implement's a KM initiative does so with the expectation that they will better utilize their knowledge resources, make better decisions, and ultimately improve their competitive position. However, automating knowledge processes allows for decision making to be pushed to lower levels as knowledge becomes easier to find and access. This allows organizations to flatten out and decentralize as decision making is pushed closer to where the decision is. This can lower the power of managers and can cause tension in organizational cultures that aren't prepared to adjust their power structures.

Additionally, KM requires adjustment in corporate governance and management support. Jennex and Olfman (2006) include a management support dimension to KM success. This dimension focuses on management's role in establishing the direction and support an organization needs to provide to ensure that adequate resources are allocated to the creation and maintenance of KM, a knowledge sharing and using organizational culture is developed, encouragement, incentives, and direction is provided to the work force to encourage KM use, knowledge reuse, and knowledge sharing; and that sufficient control structures are created in the organization to monitor knowledge and KM use (Jennex & Olfman, 2006). Zyngier (2006) describes these functions along with risk management and leadership as KM governance. While Management Support or governance provides the leadership and risk management direction for the organization, it is the KM Strategy/Processes construct that provides the information needed to guide the KM initiative implementation. Jennex and Addo (2005) discuss the functions of KM strategy as including identifying knowledge to be captured, sources and users of knowledge, knowledge storage strategies, and processes for using and capturing knowledge. Zyngier, et al. (2006) establishes the relationship between KM governance, KM strategy implementation, and KM success or as in the case of the Jennex and Olfman (2006) KM Success Model, the relationship between the Management Support and the KM Strategy/Process constructs to KM success. Both are necessary for KM success and both are necessary for incorporating security into KM initiatives.

Ultimately, the managerial impact from KM is a loosening of knowledge control as organizations create more ways of collaborating and knowledge sharing. This can be disruptive to rigid and/or hierarchical management structures but will empowering to those management structures willing to embrace its enhanced flow of knowledge coupled with decision making being pushed to lower organizational levels.

CRITICAL ISSUES IN KNOWLEDGE MANAGEMENT

KM is growing in its importance and application to solving business problems. However, there are some critical issues that need addressing. These are discussed in the following paragraphs.

Perhaps the most critical issue facing KM is the incorporation of security and risk management into KM strategy and governance. Jennex (2007) discussed the importance of security to KM and issued a call for research. The key issue with respect to security and KM is that it isn't recognized as being needed, in fact, it is almost counter to the precepts of knowledge sharing and flow. Jennex and Olfman (2005) found that security was the lowest ranked KM CSF. While not emphasized as much as it should be, it is promising that KM security is recognized as a CSF. Key issues with respect to KM security are the identification of security policies and an emphasis on risk management through KM strategy. KM risk management looks at using standard risk management techniques to analyze KM strategy to identify where there are risks of not capturing or losing potentially critical knowledge. KM security policies focus on an establishing appropriate levels of confidentiality, integrity, and availability to knowledge stored in a KMS and recognize the need to address issues such as privacy, identity theft, data/knowledge retention, disposal of old knowledge, and secure transfer of knowledge. A final note on this issue is that KM security is less focused on developing new security technologies while more focused on identifying how to apply existing security technologies to implement KM security policies. Currently conferences such as the Secure KM workshop and the KM and risk management minitrack at the *Hawaii International Conference on System Sciences, HICSS*, are beginning to address this issue and future calls for the KM track at IRMA include this as a requested research paper topic.

KM and KMS success and measurement is another issue needing to be explored. It is imperative that managers and practitioners understand how to build successful KMS and how to define, measure, and recognize when their KM initiatives are successful. It is also important for the credibility of the KM discipline that we be able to define and measure KM success. Additionally, from the perspective of KM academics and practitioners, identifying the factors, constructs, and variables that define KM success is crucial to understanding how these initiatives and systems should be designed and implemented. This issue is receiving attention with the KM Success minitrack at HICSS addressing this issue, other conferences such as AMCIS and IRMA soliciting papers on the topic, several articles being published by the *International Journal of Knowledge Management* (IJKM) and with an outstanding call for this research by the IJKM. Additionally, several models that attempt to ground KM success in theory are being developed and tested (Jennex & Olfman 2005, 2006).

An ongoing set of issues that has been and still is critical is the identification of the social and organizational factors that influence the flow and transfer of knowledge between individuals and across organizations. Key aspects of these issues are the impact of national and organizational culture, incentive programs, barriers to knowledge flow, and stickiness of knowledge (stickiness refers to the tendency for knowledge to get locked up in individuals and not transferred.) These issues are more difficult to research, understand, and overcome than the technical issues in KM. These issues also seem to have a greater impact on KM success than the technical issues. This chapter has spent a great deal of discussion on the technical issues and this should not be construed as indicating that technical issues are more important. The research in these volumes will show that by far the hardest and most important issues to overcome are the social and organizational factors that influence the flow and transfer of knowledge between individuals and organizations.

The formulation and implementation of KM strategy is listed by Jennex and Olfman (2005) as the most mentioned CSF. This implies that this CSF is seen as the issue most often recognized in research as leading to successful or failed KM initiatives. What makes this a critical KM issue is that what this strategy needs to entail is still not completely understood. Jennex and Addo (2005), as discussed above, list the functions of KM strategy as including identifying knowledge to be captured, sources and users of knowledge, knowledge storage strategies, and processes for using and capturing knowledge. However, other researchers are postulating that KM strategy should include other issues and it is expected that future research is needed to fully define this CSF.

The final issue to be discussed in this chapter is the persistence of knowledge. Jennex (2006b) discusses issues related to the storage and retrieval of knowledge. In particular changing formats and media are causing knowledge to be lost. Organizations rarely update archived knowledge to new formats or new media if it hasn't been recently used. The result is that this knowledge may not be retrievable when needed. This has happened in the United States space program, specifically in relation to lunar exploration, and may happen to many organizations should they not have a strategy (see the above critical issue) for dealing with changing formats and media. A last concern focused on media is that storage media are not permanent. Compact Discs, tape, floppy disks, fixed disks; all have a discreet life span and will ultimately fail, probably within five years from start of use. This is an issue organizations definitely need to address as essentially current storage media will not survive as well as traditional paper.

EMERGING TRENDS IN KNOWLEDGE MANAGEMENT

KM is a young and evolving discipline. The last section of this chapter looks at some of the emerging trends affecting our discipline. Many of these trends have been discussed in relative detail in previous sections so they will just be summarized. The first trend is towards more formal measurement of KM success and performance. This is an indicator of discipline maturity, organizations are moving from "it's a good idea to do KM" to "KM has this impact on our performance."

A second trend is the growing interest in using KM to empower knowledge groups such as communities of practice, CoPs. KM was initially viewed as a formal process for managing organizational knowledge, this is still true but it is also being recognized that KM can enable groups and teams to self manage their knowledge. CoPs are groups who may or may not be in the same organization. What makes them a CoP is a shared common interest in a knowledge domain. CoPs have a shared context of understanding and may or may not share culture. CoPs self identify critical knowledge and transfer it to those in the CoP that need it. Finally, CoPs need technology that facilitates CoP communication and collaboration. Wikis and other open source tools as well as knowledge portals are examples of technology used by CoP. Murphy and Jennex (2006) illustrate how these tools in the hands of a CoP can lead to leaderless development in times of emergency and the quick creation of KM enabled systems.

This leads to growing use of KM in crisis/emergency response. KM is used to create knowledge bases that can be used to facilitate decision making and response generation in times of stress. Additionally, KM and CoPs are being used to help groups of predetermined and self organizing groups of experts collaborate and respond to the needs of crisis response managers. Organizations such as the International Society for Crisis Response and Management, ISCRAM, recognize this trend and are incorporating KM sessions in their international conferences.

As mentioned earlier, Risk Management is just being incorporated into KM. This is tool to be used by organization to assess the risk associated with use of knowledge, with not having the right knowledge, and with losing critical knowledge. This is management function that will be incorporated into KM governance.

Additionally, the Internet itself is changing. Efforts to improve the Internet's ability to facilitate collaboration and handle unstructured data, information, and knowledge, both by users and by software agents, is leading to the development of the Web 2.0 and Web 3.0/semantic web. Web 2.0 refers to improving the Web to handle social networking sites and collaborative technologies such as Wikis, blogs, and other community based sites (such as Craigslist, Skype, etc.). Web 3.0/semantic Web is predicted to be an environment where data, information, and knowledge can be understood and used by any user and software agent. Technologies used include Resource Description Framework, RDF, Web Ontology Language, OWL, and the Extensible Markup Language, XML. Both of these developments will improve the ability of the Web to store, search, and retrieve knowledge and to facilitate knowledge transfer.

Finally, there is a growing trend towards international KM and KMS by multinational organizations. This increases the impact of national culture on the use of knowledge and is increasing pressure on organizations to be aware of the national cultures impact on their KM users, those that create knowledge and those that use it. Organizations are finding that national cultures impact knowledge use and it is becoming critical to incorporate national culture concerns into KM strategy.

CONCLUSION

This chapter has attempted to summarize the state of the KM discipline. This is not an easy task. The six volumes of this research set do a better job of doing this. However, this chapter does establish a foundation to assist the reader in utilizing the research in this six volume set. To conclude this chapter it is stated that KM is a vital discipline. It aids organizations in utilizing the knowledge of its members and in building organizational knowledge. KM has an impact on organizational performance. Organizations that utilize their knowledge well tend to perform better and are more successful. It is hoped that users of this six volume research set will be able to better design and implement KM in their organizations.

About the Editor

Murray E. Jennex is an associate professor at San Diego State University, editor-in-chief of the *International Journal of Knowledge Management*, editor-in-chief of IGI Global's Knowledge Management book series, and president of the Foundation for Knowledge Management (LLC). Dr. Jennex specializes in knowledge management, system analysis and design, IS security, e-commerce, and organizational effectiveness. Dr. Jennex serves as the Knowledge Management Systems track co-chair at the Hawaii International Conference on System Sciences. He is the author of over 80 journal articles, book chapters, and conference proceedings on knowledge management, end user computing, international information systems, organizational memory systems, ecommerce, security, and software outsourcing. He holds a BA in chemistry and physics from William Jewell College, an MBA and an MS in software engineering from National University, an MS in telecommunications management and a PhD in information systems from the Claremont Graduate University. Dr. Jennex is also a registered professional mechanical engineer in the state of California and a Certified Information Systems Security Professional (CISSP).

Section 1
Fundamental Concepts and Theories in Knowledge Management

This section serves as a foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of knowledge management. Research found in this section provides an excellent framework in which to position knowledge management within the field of information science and technology. Excellent insight into the critical incorporation of learning systems into global enterprises is offered, while basic, yet crucial stumbling blocks of information management are explored. With 43 chapters comprising this foundational section, the reader can learn and chose from a compendium of expert research on the elemental theories underscoring the knowledge management discipline.

Chapter 1.1
An Overview of Knowledge Management

Jatinder N. D. Gupta
University of Alabama in Huntsville, USA

Sushil K. Sharma
Ball State University, USA

Jeffrey Hsu
Fairleigh Dickinson University, USA

ABSTRACT

One of the key factors that distinguishes the intelligent business enterprise of the 21st century is the emphasis on knowledge and information. Unlike businesses of the past, the fast, high-tech, and global emphasis of businesses today requires the ability to capture, manage, and utilize knowledge and information in order to improve efficiency, better serve customers, manage the competition, and keep pace with never-ending changes. Knowledge management is an important means by which organizations can better manage information and, more importantly, knowledge. Unlike other techniques, knowledge management is not always easy to define because it encompasses a range of concepts, management tasks, technologies, and practices, all of which come under the umbrella of the management of knowledge. This chapter takes a broad view of the topic of knowledge management and aims to provide a comprehensive overview of knowledge management — the technologies, processes, and concepts involved, and the challenges and future of this important area.

INTRODUCTION

Rapid changes in both personal computer technology and electronic communications during the past decade have given us the ability to create, gather, manipulate, store, and transmit much more data and information than ever before. It is now a fact that large amounts of information are transmitted via the Internet and other means on a daily basis (Chase, 1998; Sistla & Todd, 1998). In addition, the enhanced speed and capacity of communication has enabled the existence of a global market for many industries and business sectors (Chase, 1998). Moreover, the pressures of competition within the 24-hour global marketplace have greatly increased demands for better quality, less costly production, more accountability to both customers and shareholders, and improved information about materials, processes, customers and competitors (Chase, 1998; Drucker, 1993). This highly competitive, global environment has fostered the growth of management trends like total quality management, customer satisfaction, benchmarking, re-engineering, re-structuring, downsizing and outsourcing, strategic planning, organizational learning and, of course, knowledge management (Skyrme, 2001). Many emerging models of knowledge exchanges represent harbingers of extra-organizational collaborations that will be needed for the execution of an organization's knowledge work. In the 21st century, successful organizations have to be competitive, fast paced, first-to-market, and global in nature. Creating strategic advantage requires a new type of organization that has the capability to create knowledge to maximize organizational competitiveness and strategic success. Knowledge, like any other resource, is viewed as a resource that is critical to an organization's survival and success in the global market. Organizations should have mechanisms to create knowledge and manage knowledge as an asset. However, the bulk of organizations still have not approached knowledge management (KM) activity formally or deliberately. The cause of this inattention could be that most organizations are struggling to comprehend the KM concept. KM is still defining itself because the body of theoretical literature and research in this area is small, but growing (Skyrme, 2001). It is estimated that worldwide spending on knowledge management services will grow from US$776 million in 1998 to more than US$8 billion by 2003 and, as the industry moves into the so-called "second generation" phase, managers are being challenged to have in-depth understanding of the issues and need to demonstrate business performance and learning gains from investing in knowledge-based projects and initiatives. The New Wealth of Organizations is total quality management, re-engineering, and intellectual capital, and the companies that will succeed in the 21st century are those that master the knowledge agenda (Skyrme, 1997, 2000). While most business leaders appreciate the strategic value of knowledge and the need to manage their knowledge assets, many of them seem unable to derive real benefits from their efforts. Creating knowledge-based organizations will not be an easy exercise as organizations have to overcome tremendous hurdles in bringing disparate enterprise data sources into a cohesive data warehouse or knowledge management system (Allee, 1997). This chapter describes the overview of knowledge management concepts that may be required for creating knowledge-based organizations. The chapter has four sections. The first section describes the overview of knowledge management. The second section details the evolution of knowledge management. The next few sections describe knowledge representation, creation and generation and sharing. The next two sections describe the concepts of the learning organization and organizational memory that are useful for creating knowledge-based organizations.

OVERVIEW OF KNOWLEDGE MANAGEMENT

The importance of knowledge to the complex, competitive and global business environments which exist in the 21st century cannot be overemphasized, and those businesses that know how to effectively acquire, capture, share, and manage this information will be the leaders in their respective industries. We have moved into a period where competitive advantage is gained not just merely through access to information but, also — more importantly — from new knowledge creation (Drucker, 1994; Davenport & Prusak, 1997). Knowledge management is an emerging, interdisciplinary business model dealing with all aspects of knowledge within the context of the firm, including knowledge creation, codification, sharing, and using these activities to promote learning and innovation. It encompasses both technological tools and organizational routines of which there are a number of components. These include generating new knowledge, acquiring valuable knowledge from outside sources, using this knowledge in decision making, embedding knowledge in processes, products, and/or services, coding information into documents, databases, and software, facilitating knowledge growth, transferring knowledge to other parts of the organization, and measuring the value of knowledge assets and/or the impact of knowledge management. Knowledge management is becoming very important for many reasons. To serve customers well and to remain in business, companies must reduce their cycle times, operate with minimum fixed assets and overhead (people, inventory and facilities), shorten product development time, improve customer service, empower employees, innovate and deliver high quality products, enhance flexibility and adaption, capture information, create and share knowledge. None of these actions are possible without a continual focus on the creation, updating, availability, quality and use of knowledge by all employees and teams at work and in the marketplace (Leonard, 1998). Seven knowledge layers are possible in organizations as described in Table 1 (Skyrme, 1999, 2001).

There are many definitions of knowledge management. At a generic level, it can be defined as the collection of processes that govern the creation, dissemination, and utilization of knowledge. It involves creation of supportive organizational structures, facilitation of organizational members, putting IT instruments with emphasis on teamwork and diffusion of knowledge (e.g., groupware) into place. Knowledge is the full utilization of information and data coupled with the potential of people's skills, competencies, ideas, intuitions, commitments and motivations. A holistic view considers knowledge to be present in ideas, judgments, talents, root causes, relationships, perspectives and concepts. Knowledge is stored in the individual brain or encoded in organizational processes, documents, products, services, facilities and systems. Knowledge is action, focused innovation, pooled expertise, special relationships and alliances. Knowledge is value-added behavior and activities (Pfeffer & Sutton, 2000). Knowledge encompasses both tacit knowledge (in people's heads) and explicit knowledge (codified and expressed as information in databases, documents, etc.). Knowledge is not static; instead, it changes and evolves during the life of an organization (Skyrme, 2000, 2001). What is more, it is possible to change the form

Table 1. Seven knowledge levels

Lever	Key Activities
Customer Knowledge	Developing deep knowledge sharing relationships. Understanding the needs of your customers' customers. Articulating unmet needs. Identifying new opportunities.
Stakeholder Relationships	Improving knowledge flows between suppliers, employees, shareholders, community, etc. using this knowledge to inform key strategies.
Business Environment Insights	Systematic environmental scanning including political, economic, technology, social and environmental trends. Competitor analysis. Market intelligence systems.
Organizational Memory	Knowledge sharing. Best practice databases. Directories of expertise. Online documents, procedures and discussion forums. Intranets.
Knowledge in Processes	Embedding knowledge into business processes and management Decision making.
Knowledge in Products and Services	Knowledge embedded in products. Surround products with knowledge e.g. in user guides, and enhanced knowledge-intensive services.
Knowledge in People	Knowledge sharing fairs. Innovation workshops. Expert and learning networks. Communities of knowledge practice.

Table 2. Knowledge transformations

From/To	Tacit Knowledge	Explicit Knowledge
Tacit Knowledge	Socialization (Sympathized Knowledge) Where individuals acquire new knowledge directly from others.	Externalization (Conceptual Knowledge) The articulation of knowledge into tangible form through dialogue.
Explicit Knowledge	Internalization (Operational Knowledge) Such as learning by doing, where individuals internalize knowledge from documents into their own body of experience.	Combination (Systematic Knowledge) Combining different forms of explicit knowledge, such as that in documents or on databases.

of knowledge, i.e., turn existing tacit knowledge into new explicit knowledge and existing explicit knowledge into new tacit knowledge or to turn existing explicit knowledge into new explicit knowledge and existing tacit knowledge into new tacit knowledge. These transformations are depicted in Table 2.

The KM architecture and KM process model that could be used for knowledge capture, creation, distribution and sharing is shown in Figures 1 and 2.

Knowledge management draws from a wide range of disciplines and technologies. These include cognitive science, artificial intelligence

Figure 1. KM architecture

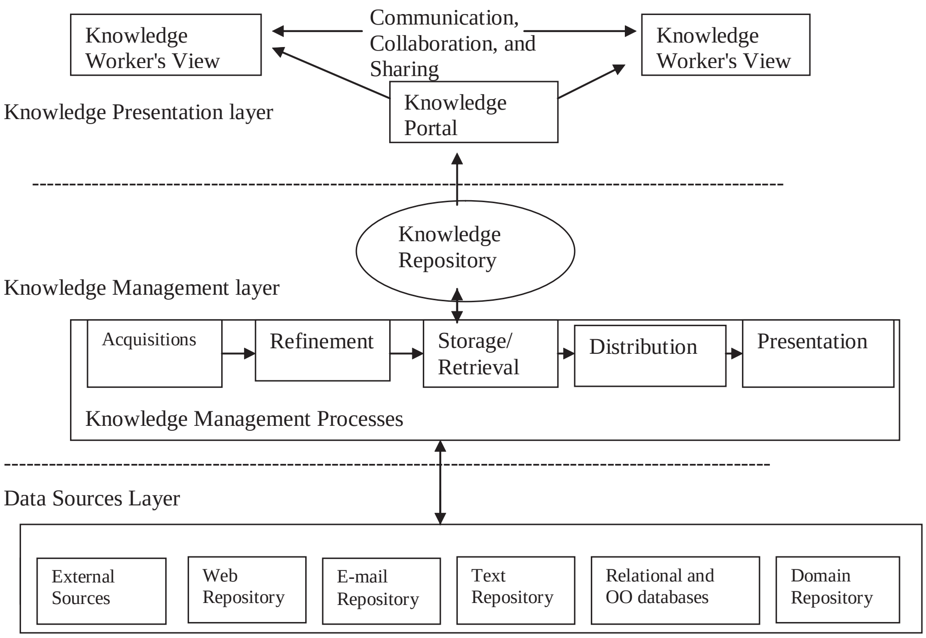

Figure 2. Knowledge management process model

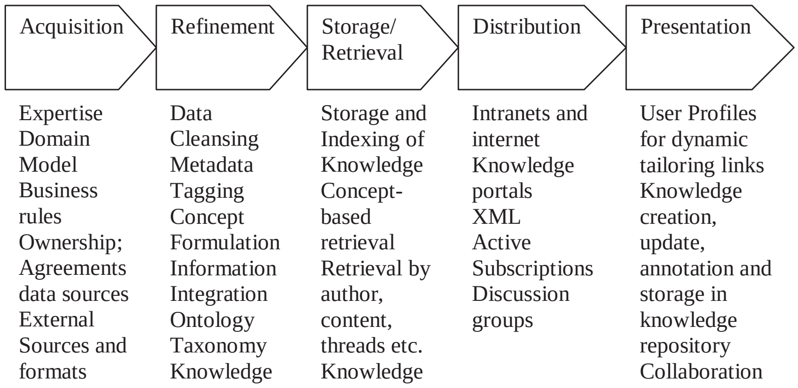

and expert systems, groupware and collaborative systems, and various other areas and technologies as described in Table 3.

So in summary, we can describe knowledge management as an audit of "intellectual assets." Knowledge management complements and enhances other organizational initiatives such as total quality management (TQM), business process re-engineering (BPR) and organizational learning, providing a new and urgent focus to sustain competitive position. A wide variety of practices and processes are used in knowledge management. Some of the more common ones are shown in Table 4.

Over time, considerable knowledge is also transformed to other manifestations such as books, technology, practices, and traditions within organizations. Knowledge management for the organization consists of activities focused on the organization gaining knowledge from its own experience and from the experience of others and on the judicious application of that knowledge to fulfill the mission of the organization. These activities are executed by marrying technology, organizational structures, and cognitive- based strategies to raise the yield of existing knowledge and to produce new knowledge. Critical in this endeavor is the enhancement of the cognitive system (organization, human, computer, or joint human-computer system) in acquiring, storing and utilizing knowledge for learning, problem solving, and decision-making.

EVOLUTION OF KNOWLEDGE MANAGEMENT

The history and evolution of knowledge management has not always been that clear or straightforward given that the field has evolved from so many different disciplines and domains. A number of management theorists have contributed to the evolution of knowledge management, among them Peter Drucker, Paul Strassmann and Peter Senge in the United States. Drucker and Strassmann have stressed the growing importance of information and explicit knowledge as organizational resources, and Senge has focused on the "learning organization," a cultural dimension of managing knowledge. Chris Argyris, Christoper Bartlett and Dorothy Leonard-Barton of Harvard Business School have examined various facets of managing knowledge. In fact, Leonard-Barton's well-known case study of Chaparral Steel, a company which has had an effective knowledge management strategy in place since the mid-1970s, inspired the research documented in her book *Wellsprings of Knowledge — Building and Sustaining Sources*

Table 3. Wide range of disciplines and technologies for knowledge management

Disciplines and Technologies	Description
Cognitive science	Since knowledge management is related to how we learn and know, the study of cognitive science certainly has a usefulness towards gathering and transferring knowledge.
Expert systems, artificial intelligence and knowledge base management systems (KBMS)	AI and related technologies are directly applicable to knowledge management. Expert systems, for example, have as its goal the capture of knowledge within a computerized knowledge base
Computer-supported collaborative work (groupware)	K*nowledge management* is often closely linked with and in some cases is almost synonymous with *groupware and* Lotus Notes. Sharing and collaboration are clearly vital to organizational knowledge management — with or without supporting technology.
Library and information science	The body of research and practice that encompasses libraries, information science, and knowledge organization can be applied to management of knowledge. These include tools for thesaurus construction and controlled vocabularies.
Document management and technical writing	Originally concerned primarily with managing images, document management has moved on to making content more accessible and usable. Early recognition of the need to associate "metainformation" with a document object suggests a connection between document management and knowledge management. Technical writing (often known as *technical communication*) forms a body of theory and practice that is directly relevant to effective representation and transfer of knowledge.
Decision support systems	Decision Support Systems (DSS) have brought together insights from the fields of cognitive sciences, management sciences, computer sciences, and operations research, in key cognitive tasks, including organizational decision-making. The emphasis here is on quantitative analysis, and on tools for managers.
Semantic networks	Semantic networks are formed from ideas and the relationships among them — sort of "hypertext without the content," but with far more systematic structure according to meaning. Often used for such tasks as textual analysis, semantic nets are now in use in mainstream professional applications, including medicine, to represent domain knowledge in an explicit way that can be shared.
Relational and object databases	Currently, relational databases are used primarily as tools for managing "structured" data, and object-oriented databases for "unstructured" content. Of particular interest are the models on which they are founded, which relate to representing and managing knowledge resources.
Simulation	Knowledge Management expert Karl-Erik Sveiby suggests "simulation" as a component technology of knowledge management, referring to "computer simulations, manual simulations as well as role plays and micro arenas for testing out skills."
Organizational science	The science of managing organizations increasingly deals with the need to manage knowledge — often explicitly. Other technologies include: object-oriented information modeling; electronic publishing technology, hypertext, and the World Wide Web; help-desk technology; full-text search and retrieval; and performance support systems. (Barclay and Murray, 1997)

of Innovation (Harvard Business School Press, 1995). Everett Rogers' work at Stanford in the diffusion of innovation and Thomas Allen's research at MIT in information and technology transfer, both of which date from the late-1970s, have also contributed to our understanding of how knowledge is produced, used, and diffused within organizations. By the mid-1980s, the importance of knowledge as a competitive asset was apparent even though classical economic theory ignores knowledge as an asset, and most organizations still lack strategies and methods for managing it. Recognition of the growing importance of organizational knowledge was accompanied by a need to deal with exponential increases in the amount of available knowledge and the increased complexity of products and processes. The computer technology that contributed so heavily to this "information overload" started to become part of the solution in a variety of domains. Doug Engelbart's Augment (for "augmenting human intelligence"), which was introduced in 1978, was an early hypertext/groupware application capable of interfacing with other applications and systems. Rob Acksyn's and Don McCracken's knowledge management system (KMS), an open distributed hypermedia tool, is another notable example.

The 1980s also saw the development of systems for managing knowledge that relied on work done in artificial intelligence and expert systems, giving us such concepts as "knowledge acquisition," "knowledge engineering," "knowledge-base systems," and computer-based ontologies. The phrase "knowledge management" finally came into being in the business community during this decade. To provide a technological base for managing knowledge, a consortium of U.S. companies started the Initiative for Managing Knowledge Assets in 1989. Knowledge management-related articles began appearing in journals like *Sloan Management Review*, *Organizational Science*, *Harvard Business Review*, and others, and the first books on organizational learning and knowledge management were published (for example, Senge's *The Fifth Discipline* and Sakaiya's *The Knowledge Value Revolution*). By 1990, a number of management consulting firms had begun in-house knowledge management programs, and several well-known U.S., European, and Japanese firms had instituted focused knowledge management programs. Knowledge management was introduced in the popular press in 1991 when Tom Stewart published "Brainpower" in *Fortune* magazine. Perhaps the most widely read work to date is Ikujiro Nonaka's and Hirotaka Takeuchi's *The Knowledge-Creating Company: How Japanese Companies Create the Dynamics of Innovation* (1995). By the mid-1990s, knowledge management initiatives were flourishing, thanks in part to the Internet. The International Knowledge Management Network (IKMN) that began in Europe in 1989 went online in 1994 and was soon joined by the U.S.-based Knowledge Management Forum and other KM-related groups and publications. The number of knowledge management-based conferences and seminars is growing as organizations focus on managing and leveraging explicit and tacit knowledge resources to achieve competitive advantage. In 1994 the IKMN published the results of a knowledge management survey conducted among European firms, and the European Community began offering funding for KM-related projects through the ESPRIT program in 1995. Knowledge management, which appears to offer a highly desirable alternative to less successful TQM and business process re-engineering initiatives, has become big business for such major international consulting firms as Ernst & Young, Arthur Andersen, and Booz-Allen & Hamilton. In addition, a number of professional organizations interested in such related areas as benchmarking, best practices, risk management, and change management are exploring the relationship of knowledge management to their areas of special expertise (Lipnack & Stamps, 2000).

KNOWLEDGE REPRESENTATION

Knowledge representation—explicit specification of "knowledge objects" and relationships among those objects—takes many forms, with variations in emphasis and major variations in formalisms. Knowledge representation allows computers to reconfigure and reuse information that they store in ways not narrowly pre-specified in advance. *Concept mapping, semantic networks, hypertext, information modeling,* and *conceptual indexing* all exemplify knowledge representation, in somewhat different ways. **Concept mapping** seems to be rooted primarily in educational techniques for improving understanding, retention, and as an aid to writing. A concept map is a picture of the ideas or topics in the information and the ways these ideas or topics are related to each other. It is a visual summary that shows the structure of the material the writer will describe. **Semantic networks** are often closely associated with detailed analysis of texts and networks of ideas. One of the important ways they are distinguished from hypertext systems is their support of semantic typing of links, for example, the relationship between "murder" and "death" might be described as "is a cause of." The inverse relationship might be expressed as "is caused by." Semantic networks are a technique for representing knowledge. As with other networks, they consist of nodes with links between them. The nodes in a semantic network represent concepts. A concept is an abstract class, or set, whose members are things that are grouped together because they share common features or properties. The "things" are called instances of the concept. Links in the network represent relations between concepts. Links are labeled to indicate which relation they represent. Links are paired to represent a relation and its inverse relation. For example, the concept Femur is related to the concept Upper Leg with the relation has-location. The inverse of has-location is the relation location-of, which relates Upper Leg to Femur. Hypertext (an expanded semantic network), known to most people these days by its implementation in the World Wide Web, is sometimes described as a semantic network with content at the nodes. But the content itself, the traditional document model, seems to be the driving organizational force, not the network of links. In most hypertext documents, the links are **not** semantically typed, although they are typed at times according to the medium of the object displayed by traversing the link. **Information modeling** is concerned with precise specification of the meaning in a text and in making relationships of meaning explicit, often with the objective of rapid and accurate development of new software applications for business requirements. Some of the essence of information modeling is expressed in the following definition: "The process of eliciting requirements from domain experts, formulating a complete and precise specification understandable to both domain experts and developers, and refining it using existing (or possible) implementation mechanisms." **Conceptual indexing** is rarely discussed in the same breath as hypertext, conceptual maps, and semantic networks, perhaps because indexers themselves sometimes relish the aura of "black art" surrounding indexing, but the connection is fundamental. Conceptual indexes traditionally map key ideas and objects in a single work. An index is a structured sequence, resulting from a thorough and complete analysis of text, of synthesized access points to all the information contained in the text. The structured arrangement of the index enables users to locate information efficiently. The organization of topics into parent-child, synonym, and "see also" relationships is a critical part of an effective professional index. Good indexes are not flat lists of names and ideas.

Knowledge Sharing/Information Sharing

The terms *knowledge sharing* and *information sharing* are often used in conjunction with discussions of *ontologies* and *knowledge representation*. In the context of the following quote, the primary concern of information sharing is precision of expression and access in order to meet the objective of rapid product development. Information sharing and decision coordination are central problems for large-scale product development. This chapter proposes a framework for supporting a knowledge medium (Stefik, 1986): "a computational environment in which explicitly represented knowledge serves as a communication medium among people and their programs." The framework is designed to support information sharing and coordinated communication among members of a product development organization, particularly for the tasks of design knowledge capture, dynamic notification of design changes, and active management of design dependencies. The proposed technology consists of a shared knowledge representation (language and vocabulary), protocols for foreign data encapsulation and posting to the shared environment, and mechanisms for content-directed routing of posted information to interested parties via subscription and notification services. A range of possible applications can be explored in this framework, depending on the degree of commitment to a shared representation by participating tools. A number of research issues fundamental to building such a knowledge medium are introduced in the chapter.

Metadata/Meta-information/ [Document] Profile Information/ [Subject] Classification/Key Words/ "Attributes"

Metadata is simply information added to a document (or a smaller unit of information) that makes it easier to access and reuse that content. It's also referred to as simply "data about data." You'll find metadata in many different forms including key words in a software help system, the document profile information attached to documents in a document management system, and the classification information in a library card catalog. There are, of course, distinctions in how these various disciplines and technologies implement metadata, in substance as well as in formalisms. But the value of metadata for critical information is widely accepted as a basic element of knowledge management implementations.

Ontologies [Computer-based]

Computer-based *ontologies*, formal, structured representations of a domain of knowledge, are commonly associated with artificial intelligence technology where they were originally designed to serve as the raw material for computer reasoning and computer-based agents.

ACQUIRING AND GENERATING KNOWLEDGE

Critical to managing knowledge is the generation and dissemination of information, followed by shared interpretation of the processed information into “knowledge.” In order for an organization to be able to manage knowledge, it must have knowledge to work with in the first place. There are a number of ways in which to acquire and generate new knowledge for your firm. One of the most obvious ways to acquire new knowledge is either to acquire an organization with the knowledge which you desire, or alternately, to hire people who possess the same knowledge. While, in the case of acquiring a firm, it is not guaranteed that the knowledge (or people who possess it) will necessarily stay with the company, it is possible to retain a significant portion of it. It should also be noted that political and cultural aspects may come into play, affecting how well a new acquisition can be integrated into the parent firm (Nonaka & Takeuchi, 1995).

Another possibility is to “rent” knowledge through the hiring of outside consultants or to help generate new knowledge by supporting (financially or otherwise) the research being conducted at universities and research centers, with the promise of future benefits in terms of developing the technologies for commercial use (Davenport & Prusak, 2000).

Aside from the method of obtaining or generating knowledge externally, it is also possible to do it “in-house.” One way is to set up a research center within the auspices of a company with the specific purpose to generate new ideas, technologies and, eventually, commercial products. Notable examples of these include the Xerox PARC (Palo Alto Research Center), which among other things was where the concept of the GUI (graphical user interface), including menus, the mouse, and the use of icons originated. These were later incorporated into various models of the Apple Computer. Firms which have developed their own research centers include IBM, Motorola, and Sharp Electronics (Davenport & Prusak, 2000).

There are a number of other methods by which knowledge can be acquired or brought into an organization. These include data mining, text mining, and knowledge elicitation. Data mining is not a single technique or technology but a group of related methods and methodologies which are directed towards the finding and automatic extraction of patterns, associations, changes, anomalies and significant structures from data (Grossman, 1998). Data mining is emerging as a key technology which enables businesses to select, filter, screen, and correlate data automatically. Data mining evokes the image of patterns and meaning in data, hence the term which suggests the mining of “nuggets” of knowledge and insight from a group of data. The findings from these can then be applied to a variety of applications and purposes including those in marketing, risk analysis and management, fraud detection and management, and customer relationship management (CRM). With the considerable amount of information which is being generated and made available, the effective use of data-mining methods and techniques can help to uncover various trends, patterns, inferences, and other relations from the data which can then be analyzed and further refined. These can then be studied to bring out meaningful information which can be used to come to important conclusions, improve marketing and CRM efforts, and predict future behavior and trends (Han & Kamber, 2001). The possibilities for data mining from textual information are largely untapped, making it a fertile area of future research. Text expresses a vast, rich range of information, but in its original, raw form is difficult to analyze or mine automatically. As such, text data mining (TDM) has relatively fewer research projects and commercial products compared with other data mining areas. As expected, text data mining is a natural extension of traditional data mining (DM) as well as information archeology (Brachman et al., 1993). While most standard data mining applications tend to be automated discovery of trends and patterns across large databases and datasets, in the case of text mining, the goal is to look for patterns and trends like nuggets of data in large amounts of text (Hearst, 1999). Knowledge elicitation is the process of extracting information from an expert source, such as interviewing an expert in a given subject area, so that it can then be coded and otherwise stored in a form which can be accessed by others. Closely related to the term knowledge acquisition in the expert systems field, knowledge elicitation is a difficult process and is often referred to as a "bottleneck" in the acquisition of knowledge. Experts cannot often explain or express their reasoning and thought processes which causes the problem known as the "paradox of expertise."

As discussed above, there are a number of ways in which knowledge can be acquired or brought into an organization. These can include the acquisition of firms and organizations which hold the knowledge which is desired, the hiring of professionals who possess this knowledge, the hiring of outside consultants, or the derivation of new knowledge from such sources as data mining, text mining, and knowledge elicitation. All of these can enhance your firm's capabilities by the introduction of new knowledge into your organization.

CODIFYING KNOWLEDGE

Knowledge which is obtained needs to be captured and stored in a form which would allow it to be accessed by others or to be referenced when needed. This would allow the knowledge to be retained within a firm rather than having it be "carried in the heads" of the company founders or employees, which might result in it being lost if the person was to leave, die, or be otherwise unavailable. A number of different methods and technologies can be used with regards to codifying knowledge, and the specific method used could vary according to the specific type of information which is being coded. According to Davenport and Prusak (2000), the goal of codifying knowledge is to "convert knowledge into accessible and applicable formats." Included within this broad definition are steps and methods such as describing, categorizing, modeling, and mapping knowledge in a "coded" form. Coded knowledge is often put into a computerized form although the word "coded" does not always or necessarily mean coded into a computerized format. The important concepts to keep in mind include the need to decide what business goals the coded information will serve, how a certain set of knowledge will be used to meet these goals, how to select the right knowledge to be coded (form and content) and, finally, what is the medium or method which is to be used to code this information effectively. To start, there are different kinds of knowledge. Knowledge may be as straightforward as a set of rules or definitions (explicit knowledge) or as complex as the skills involved in something like playing a violin or hitting a baseball in the major leagues. This latter form of knowledge, called tacit knowledge, is one of the challenging areas of knowledge management in that it is very difficult to codify this kind of knowledge on paper or in a database. Tacit knowledge can be more formally defined as *"Knowledge that enters into the production of behaviors and/or the constitution of mental states but is not ordinarily accessible to consciousness."* The distinction between tacit knowledge and explicit knowledge has sometimes been expressed in terms of knowing-how and knowing-that, respectively (Ryle, 1949/1984, pp. 25-61), or in terms of a corresponding distinction between embodied knowledge and theoretical knowledge. On this account, knowing-how or embodied knowledge is characteristic of the expert who acts, makes judgments, and so forth without explicitly reflecting on the principles or rules involved. The expert works without having a theory of his or her work; he or she just performs skillfully without deliberation or focused attention. Knowing-that, by contrast, involves consciously accessible knowledge that can be articulated and is characteristic of the person learning a skill through explicit instruction, recitation of rules, attention to his or her movements, etc. While such declarative knowledge may be needed for the acquisition of skills, the argument goes, it no longer becomes necessary for the practice of those skills once the novice becomes an expert in exercising them and, indeed, it does seem to be the case that, as Polanyi argued, when we acquire a skill, we acquire a corresponding understanding that defies articulation (Polanyi, 1958/1974). Now that the differences between the two main types of knowledge have been explained, attention can be given to a method of codifying knowledge using knowledge maps. A knowledge map is not a collection of the knowledge or information itself but rather is a kind of roadmap or index to the knowledge. This is an important component to have, since a large mass of knowledge may be difficult to understand or manage if there is not some kind of map to guide the user.

TRANSFER OF KNOWLEDGE

The transferability of information and knowledge is a critical determinant of an organization's capacity to confer sustainable competitive advantage. The issue of transferability is paramount in both intra- (such as between functional units and management levels) and inter-organizational settings (such as supply chains, strategic alliances, and joint venture development). Critical to the flow of information and knowledge is the knowing how (tacit knowledge) and the knowing about (explicit knowledge) distinction of knowledge transferability. Knowledge transfer is an important aspect of knowledge management because knowledge, once captured or obtained by an organization, must be able to be shared from and by persons and groups within the organization. There are a number of techniques in which organizations transfer (and related to this, share) information. According to Nancy Dixon (2000), there are five main types of knowledge transfer/sharing. These include serial transfer, near transfer, far transfer, strategic transfer, and expert transfer. Each of these differs according to the purpose, method, and ways in which they are implemented. Serial transfer is a form of knowledge transfer where knowledge (both explicit and tacit) which is gained in one context or setting is then transferred to the next use when it is performed in a different setting. In general, this applies to the same team applying their knowledge from an earlier similar task to a slightly different context at a later date. This involves the management of both explicit and tacit knowledge and usually involves regular meetings, participation by all of the team members, and an emphasis on brief meetings. An example of this might be a team replacing an air conditioning system in an office building and then doing the same task in a different setting, such as an apartment complex. Knowledge gained from the one setting can be used in the new setting (Dixon, 2000). Near transfer differs in that the type of knowledge being transferred is basically explicit in nature, and the specific information which is key to doing a task by one team is then transferred to another team that will be doing a very similar task. This type of transfer is best suited for tasks which are generally routine, frequent, and generally similar when repeated. Often, this information is distributed through electronic means, and the information is both explicit and somewhat brief and concise in nature. For example, one team at the corporate headquarters has perfected a method of doing a certain kind of installation. The methods and steps can be recorded electronically (in e-mail or PDF file or other electronic means) and then distributed to other offices and teams throughout the organization, which can bring about better performance and productivity by the receiving teams. Far transfer focuses on the sharing of tacit knowledge between teams in an organization and often results in the collaboration between the teams, whether face-to-face or using other means. Because the information involved here is tacit, it cannot be easily recorded and transmitted as with the near transfer method. Far transfer of information is best suited to information which is non-routine in nature and for tasks which are likely to be frequently performed. Both teams can collaborate by mutually offering and receiving information. For instance, if a team has been tasked to work on a new and unique project, they may bring another team who has worked on similar projects in the past so that they can share and exchange information and come up with a viable solution to the problem (Dixon, 2000).

Strategic transfer focuses on the transfer of knowledge which can impact the organization as a whole. Involving both explicit and tacit knowledge, it is designed for situations which are neither frequent, nor routine and could involve tasks which are high-level within an organization, such as the knowledge required for corporate mergers and acquisitions. Strategic transfer frequently involves the identification of key knowledge needed by corporate executives and senior-level managers and then the collection and interpretation completed by knowledge specialists. Finally, there is expert transfer, which involves the gaining of explicit knowledge from experts when the scope of a task is outside of the knowledge of a team working on a task. The information in this case, because of its explicit nature, can be transmitted via electronic forums or networks and can be in the form of "bulletin boards," where a question can be posted and various knowledgeable experts who know the answer can then respond with the required knowledge. Having such a network in place can be extremely useful, since problems can occur at any time, and having a network of experts available when problems arise is a valuable resource (Dixon, 2000).

Another useful method of sharing and transferring information is through Communities of Practice (CoPs). A definition of a community of practice is "a group of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in an area by interacting on an ongoing basis" (Wenger et al., 2002). Although the term "Community of Practice" is new, CoPs are not. Such groups have been around ever since people in organizations realized they could benefit from sharing their knowledge, insights, and experiences with others who have similar interests or goals. The concept of a community of practice is an extension or a variation of the concept of special interest groups, clubs, medieval guilds, and even regions for certain industries (Silicon Valley for high-tech and Detroit for the automobile industry). One of the best-known examples of a CoP was one formed by the copy machine repair technicians at Xerox Corporation. Through networking and sharing their experiences, particularly the problems they encountered and the solutions they devised, a core group of these technicians proved extremely effective in improving the efficiency and effectiveness of efforts to diagnose and repair Xerox customers' copy machines. The impact on customer satisfaction and the business value to Xerox was invaluable (Wenger, 1999).

TECHNOLOGIES FOR KNOWLEDGE MANAGEMENT

As mentioned previously, knowledge management is an area which is not always easily defined because it is broad and spans various disciplines. The field encompasses the use of management techniques and methods, collaborative concepts and techniques, as well as the use of various computer and related technologies. The purpose of this section is to examine some of the important technologies which are used in the area of knowledge management.

The *computer-supported collaborative work* (CSCW) community has been addressing issues of shared development of knowledge for many years. *Groupware* is sometimes used as a synonym for CSCW, and Lotus Notes often appears to be the defining CSCW application, even though there are other groupware products including Netscape's Collabra Share. Recent developments in corporate *intranets* are likely to dramatically increase the

Table 5. Summary of various tools and technologies available for knowledge management

Technologies & Tools	Description
Expert systems	An expert system is regarded as the embodiment within a computer of a knowledge-based component from an expert skill in such a form that the system can offer intelligent advice or make an intelligent decision about a processing function. Expert systems are computer-based programs which are designed to record human expertise (knowledge) and then apply this knowledge to applications in a certain domain.
Distributed hypertext systems	*Distributed hypertext systems* have been concerned with the generation and leveraging of organizational knowledge for more than a dozen years. Theodor Holm Nelson coined the term "hypertext" in the 1960s, and his writings about representation, access, and management of knowledge -- embodied in his vision for Project Xanadu, a global "docuverse" that pre-figured the World Wide Web – are useful for managing information and knowledge.
Document management	*Document management* systems originally were primarily concerned with providing online access to documents stored as bit-mapped images. Document management technology -- already in widespread use in large, information-intensive companies-- is likely to become an integral part of virtually every "intranet" in one form or another.
Geographic information systems	*Geographic information systems*, a term associated with knowledge management, is used as a graphic tool for *knowledge mapping.* Known by the acronym GIS for short, the technology involves a digitized map, a powerful computer and software that permits the superimposition and manipulation of various kinds of demographic and corporate data on the map.
Help desk technology	*Help desk technology* is primarily concerned with routing requests for help from information seeker to the right technical resolution person within an organization
Intranets	*Intranets* -- intra-corporation networks that use the Internet's IP (Internet Protocol) standard -- not only permit sharing of information, but they also view the organization's information (including structured resources like relational databases as well as unstructured text) through Web browsers like Internet Explorer and Netscape Navigator.
Concept mapping	*Concept mapping* seems to be rooted primarily in educational techniques for improving understanding, retention, and as an aid to writing. A concept map is a picture of the ideas or topics in the information and the ways these ideas or topics are related to each other. It is a visual summary that shows the structure of the material the writer will describe
Semantic networks	*Semantic networks* are often closely associated with detailed analysis of texts and networks of ideas. One of the important ways they are distinguished from hypertext systems is their support of semantic typing of links -- for example, the relationship between "murder" and "death" might be described as "is a cause of." The inverse relationship might be expressed as "is caused by." Semantic networks are a technique for representing knowledge.
Hypertext (an expanded semantic network)	*Hypertext*, known to most people these days by its implementation in the World Wide Web, is sometimes described as a semantic network with content at the nodes. But the content itself -- the traditional document model -- seems to be the driving organizational force not the network of links. In most hypertext documents, the links are **not** semantically typed, although they are typed at times according to the medium of the object displayed by traversing the link.

Table 5. Summary of various tools and technologies available for knowledge management (continued)

Technologies & Tools	Description
Information modeling	*Information modeling* is concerned with precise specification of the meaning in a text and in making relationships of meaning explicit -- often with the objective of rapid and accurate development of new software applications for business requirements. Some of the essence of information modeling is expressed in the following definition "The process of eliciting requirements from domain experts, formulating a complete and precise specification understandable to both domain experts and developers, and refining it using existing (or possible) implementation mechanisms."
Conceptual indexes	*Conceptual* (or "back-of-the-book") *indexes* are rarely discussed in the same breath as hypertext, conceptual maps, and semantic networks -- perhaps because indexers themselves sometimes relish the aura of "black art" surrounding indexing -- but the connection is fundamental. Conceptual indexes traditionally map key ideas and objects in a single work. An index is a structured sequence -- resulting from a thorough and complete analysis of text -- of synthesized access points to all the information contained in the text. The structured arrangement of the index enables users to locate information efficiently.
Metadata	*Metadata* is simply information added to a document (or a smaller unit of information) that makes it easier to access and re-use that content. It's also referred to as simply "data about data." You'll find metadata in many different forms, including key words in a software help system, the document profile information attached to documents in a document management system, and the classification information in a library card catalog.

level of interest in CSCW as IP-based technologies replace or complement proprietary products like Notes.

Table 5 is a summary of various tools and technologies available for knowledge management.

LEARNING ORGANIZATION

In recent years, an increasing amount of global business school research and literature has focused on concepts such as the "knowledge-based economy," "organizational learning," "knowledge workers," "intellectual capital," "virtual teams," and the like in order to make sense of this "new discipline" (Gittell & Vidal, 1998). Organizational learning is a fairly recent way to think about learning in organizations. In a time of less organizational change (technological, societal, and economic), it was possible for an organization to develop a strategy for functioning and, assuming the strategy was initially effective, maintain that strategy for several decades. Current organizations, however, must change constantly in order to survive for even one decade. But change in and of itself is not sufficient. The change must be based on appropriate data gathered externally from the environment and internally from lessons learned. Both are a part of organizational learning, and both are critical to effective organizations (Skyrme, 1998, 2000, 2001). Learning organizations or organizational learning are defined in many different ways. A few selected definitions are:

"The essence of organizational learning is the organization's ability to use the amazing mental capacity of all its members to create the kind of processes that will improve its own" (Dixon, 1994);

and

"Organizations where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning to learn together" (Senge, 1990).

In general, we can define learning organizations as those that have in place systems, mechanisms and processes that are used to continually enhance their capabilities and those who work with it or for it to achieve sustainable objectives, both for themselves and for the communities in which they participate. Companies are seeking to improve existing products and services (continuous improvement) and innovation (breakthrough strategies). This has resulted in a plethora of initiatives such as TQM (Total Quality Management) and BPR (Business Process Re-engineering). But companies are finding that such programs succeed or fail depending on human factors, such as skills, attitudes and organizational culture (Garvin, 2000).

Types of Learning

A learning organization is not about "more training." While training does help develop certain types of skill, a learning organization involves the development of higher levels of knowledge and skill. There could be four different levels of learning. (See Table 6.)

Organizations need to follow different steps to convert themselves into learning organizations.

- **Learning Culture:** An organizational climate that nurtures learning. There is a strong similarity with those characteristics associated with innovation.
- **Management Processes:** Processes that encourage interaction across boundaries. These are infrastructure, development and management processes as opposed to business operational processes (the typical focus of many BPR initiatives).
- **Tools and Techniques:** Methods that aid individual and group learning, such as creativity and problem-solving techniques.
- **Skills and Motivation:** To learn and adapt.
- **Free Exchange and Flow of Information:** Systems are in place to ensure that expertise is available where it is needed and individuals network extensively, crossing organizational boundaries to develop their knowledge and expertise.
- **Commitment to Learning, Personal Development:** Support from top management;

Table 6. Four different levels of learning

Level of Learning	Description
Level 1.- Learning facts, knowledge, processes and procedures	Applies to known situations where changes are minor.
Level 2.- Learning new job skills that are transferable to other situations	Applies to new situations where existing responses need to be changed. Bringing in outside expertise is a useful tool here.
Level 3 - Learning to adapt	Applies to more dynamic situations where the solutions need developing. Experimentation and deriving lessons from success and failure are the mode of learning here.
Level 4 - Learning to learn	Is about innovation and creativity; designing the future rather than merely adapting to it. This is where assumptions are challenged and knowledge is reframed.

people at all levels encouraged to learn regularly; learning is rewarded. Time to think and learn (understanding, exploring, reflecting, developing).

- **Valuing People:** Ideas, creativity and "imaginative capabilities" are stimulated, made use of and developed. Diversity is recognized as a strength. Views can be challenged.
- **Fostering a Climate of Openness and Trust:** Individuals are encouraged to develop ideas, to speak out, to challenge actions.
- **Learning from Experience:** Learning from mistakes is often more powerful than learning from success. Failure is tolerated, provided lessons are learned.

Tools and Techniques

Tools and techniques include a wide range of learning and creativity skills in the following groups:

- **Inquiry:** interviewing, seeking information
- **Creativity:** brainstorming, associating ideas
- **Making Sense of Situations:** organizing information and thoughts
- **Making Choices:** deciding courses of action
- **Observing Outcomes:** recording, observation
- **Reframing knowledge:** embedding new knowledge into mental models, memorizing

Collective (team and organizational) learning requires skills for sharing information and knowledge, particularly implicit knowledge, assumptions and beliefs that are traditionally "beneath the surface." Key skills here are:

- Communication, especially across organizational boundaries
- Listening and observing
- Mentoring and supporting colleagues
- Taking a holistic perspective — seeing the team and organization as a whole
- Coping with challenge and uncertainty

ORGANIZATIONAL MEMORY

Organizational memory is the record of an organization that is embodied in a set of documents and artifacts. Organizational memory has become a hot topic recently due to the growing recognition that it appears to be so thoroughly lacking in contemporary organizations. The problem is not a scarcity of documents and artifacts for the organizational memory but rather the quality, content, and organization of this material. For example, an effective organizational memory would be able to answer such often-asked questions as, "Why did we do this?" and "How did such and such come to be the case?" Rarely is this possible now (Conklin, 1996).

Basically, the goal of an organization memory is to remember and learn a firm's past. Contemporary organizations seem to have only a weak ability to do this and are thus seeking to gain the capacity for "organizational memory." Networked computers might provide the basis for a "nervous system" that could be used to implement the capacity for organizational memory, but the technology (software and hardware) must provide for easy capture, recall, and learning. Moreover, for an organization to augment its memory, it must shift from the currently pervasive document- and artifact-oriented paradigm (or culture) to one that embraces process as well. This process-oriented paradigm requires the use of a system that integrates three technologies: hypertext, groupware, and a rhetorical method. Groupware allows the organizational record to be built in the course of everyday communication and coordination.

Hypertext provides the ability to organize and display this rich informational web. And a rhetorical method, such as IBIS, structures the memory according to content, not chronology. In addition to the computer technology, a shift in organizational culture toward an appreciation of process is required to implement organizational memory (Conklin, 1996).

Organizational memory is perhaps most clearly missing in industries where large numbers of people engage in the design and construction of large, complex systems over long periods of time such as defense, aerospace, utilities, pharmaceuticals, and telecommunications. Engineering organizations in these industries have serious limitations in transferring previous learning to current problems. The design rationale of large, complex systems is thoroughly and systematically lost. Such phrases as "reinventing the wheel," "going in circles," and "having the same discussion over and over," often heard in large engineering organizations, point to a striking phenomenon: while organizations don't seem to learn or remember very well, this limitation was, until recently, regarded as normal and inevitable. It is thus highly desirable to increase the capacity of organizations to remember and to learn. This means capturing more of the "documents and artifacts" of the organization in a way that they can be effectively recalled and reinterpreted. The growth of networked computers for all phases of information work creates the infrastructure – (i.e., the "nervous system") to support this increased capture and reuse of organizational memory (Conklin, 1996).

Three Tools For Organizational Memory

The most immediate barrier to capturing more of the process of work and making it part of organizational memory is that it seems to present an insurmountable and onerous documentation burden on the people doing the work. The key to overcoming this perception is to shift the notion of capturing the process data from being an additional documentation burden to "tapping into" the flow of communication that is already happening in an organization. Not surprisingly, this shift is also a shift from an artifact-oriented to a process-oriented perspective (Conklin, 1996).

The first element of the computer technology is hypertext, because the nature of the process-oriented approach is essentially non-linear, so the representation for capturing and organizing it must also be that rich. Moreover, as time goes by and the organizational record grows more convoluted and complex, the unlimited flexibility of hypertext as a representational medium is essential for ongoing restructuring and summarization.

The second element is groupware, for the same reason that e-mail is a natural first step toward easy capture of organizational process. An MCC/NCR field study showed clearly that it is critical that the technology used to capture rationale be as transparent as possible and that it must closely fit the existing practices and tools of the organization. Groupware by its very nature is not focused on capture, but rather on communication and coordination. The secret to capturing organizational memory then is to "tap into" the existing flow of process interactions between the members of the organization and to crystallize this on an ongoing basis into the key elements of the organizational memory. Groupware can provide the medium for organizational dialogues which, because they occur via the computer, create a computable record of semi-structured documents. The ability then exists to manipulate, distribute or share this information and intelligence throughout the organization or team effectively and on an ongoing basis, creating a memory and learning tool.

The third element of the technology for capturing organizational memory is the use of a rhetorical method, or conversational model, for structuring the conversations occurring with the technology. The reason for this is two-fold. A simple rhetorical method provides a structure for discussing complex problems that can immediately improve the quality of the dialogue process. The IBIS (Issue-Based Information System) method (Kunz & Rittel, 1970) provides this kind of structure and process improvement. IBIS organizes planning and design conversations into issues (stated as questions), positions which offer possible solutions, and arguments which support or object to the positions. Such a model provides a basis for structuring the conversational record which is not simply chronological (as in an e-mail or bulletin board type system). For example, conversations in the IBIS method are structured according to the issues being discussed, providing a content-based index within which the cumulative record of the organizational process is preserved and organized.

Taken together, the technologies of hypertext, groupware, and the IBIS method combine synergistically to form a communication device for teams and teamwork and the ability to create an effective organizational memory for an organization. Thus, the technology for organizational memory must, at a minimum, incorporate hypertext, groupware, and a rhetorical model. But this computer technology alone is not sufficient to create an effective organizational memory. While the technology must be very good and the user interface transparent, the organization must also shift to making capture and use of organizational memory an important and natural practice. This shift towards a process-oriented paradigm and culture requires organizational commitment, and it is the most challenging part of establishing a capacity for memory and learning in an organization.

CONCLUSION

Knowledge management, in an age where there is an overwhelming amount of information and perhaps not sufficient resources or understanding to manage all of it, is a critically important area of concern to 21st century organizations. The basic, yet important, terms and concepts associated with knowledge management and organization memory for learning organizations are discussed in this chapter. Extracting knowledge that already exists in the minds of employees is a difficult process for generating knowledge. Future knowledge extractors will focus on rewards for knowledge, hiring good knowledge creators and providing easy-to-use tools for capture. In the future, categorization and organization of knowledge will be a core competence for every firm. This will require strategic thinking about what knowledge is important, the development of a knowledge vocabulary, prolific creation of indices, search tools and navigation aids, and the constant refinement and pruning of knowledge categories. Knowledge editors will have to combine sources and add context to transform information into knowledge (Prichard et al., 2000).

Chapter 1.2
Theoretical and Practical Aspects of Knowledge Management

London School of Economics and Political Science, UK

INTRODUCTION AND BACKGROUND

The last decade of the 20th century saw the emergence of a new discipline within the realm of information systems, which became known as knowledge management (KM). As such, it has become one of the most discussed issues amongst academics and practitioners working in the information systems and human resource management arenas (Prusack, 2001). Amongst academics it has become an area of specialisation with research projects, journals, conferences, books, encyclopaedias, and numerous papers devoted to the topic. Businesses are investing heavily in buying or developing KM supportive systems. However, predominately researchers and practitioners in this area have tended to see (see for example, Alavi & Leidner, 2001; Baskerville, 1998):

1. consider the context in which knowledge management takes place as teams of knowledge workers in communities of practice, whose performance and the performance of their organisation, can be enhanced by knowledge sharing;
2. focus on the process—the creation and application of knowledge management programmes and systems as an organisational resource—neglecting, with some exceptions (Alvesson & Karreman, 2001; Swan & Scarborough, 2001; Schultze, 1999), the wider context in which knowledge management takes place and the fact that resources can be used in ways that can be both creative and destructive, facilitating and manipulative; and
3. stress the role of technology as the enabling agent for KM.

OBJECTIVES AND FOCUS

This article proposes to broaden the KM discourse by re-examining some of the foundations of knowledge management in order to show that much of the current discussion—including by those who are critical of the conceptual basis of KM—neglects or underplays some otherwise well-known aspects of the topic. Two aspects in particular need to be considered:

a. the notion that knowledge is managed for a purpose—it is used as an instrument to achieve some objective, sometimes explicit, but often hidden or tacit. We note that the purpose is not necessarily benign, and that this, the darker side of knowledge management, includes knowledge and information manipulation.
b. that knowledge has been managed since mankind invented speech, and that few purposeful activities do not include some elements of knowledge management. Examples are provided to illustrate the point.

The article is presented from the perspectives of the IS scholar in particular, and organisational studies in general, as both face KM as a new area of study. The article is intended to act as a warning to both scholars and practitioners interested in KM, and suggests that the rhetoric emerging from the KM field should be treated with caution.

The article concludes with some reflections on the ethical dimensions stemming from KM practices.

Outline Argument

The argument presented in the article may be briefly summarised as follows: knowledge is not some benign resource which is only managed for the good of the individual, the team, and the organisation. Knowledge can be, and is, used instrumentally to achieve a range of objectives, ranging from the criminal, the mischievous, to the constructive and benign. The argument focuses on the relationship between the provision, acquisition, and dissemination of information, and the formation and creation of knowledge. It is argued that information, as a building block of knowledge, can be, and in practice is, guided, managed, controlled, or manipulated for a desired outcome. The practice of research is cited in order to demonstrate the argument. Finally, by drawing on some familiar institutional canons of our culture such as education, marketing, (scientific) management, and law, the article takes the first steps in broadening the KM discourse looking at control, instrumentality, and power relations.

The Argument Expanded

There is almost complete unanimity in the academic literature that KM is an essential activity for a modern enterprise to flourish in a global competitive economy, and many practicing managers share this view. Two assumptions underlie the KM literature:

- that there is a positive relationship between knowledge and truth; and
- that knowledge is the sum of beliefs, values, insights, and experiences.

Both assumptions serve to hide the instrumentality of knowledge. The article notes that underlying the management of knowledge are the notions of purpose and control. One purpose of providing software to facilitate knowledge sharing may be to improve the productivity of the group. But a second purpose may be to control the way the group works, for example, by determining who can share in the knowledge. Again the purpose of a marketing campaign may ostensively be to provide knowledge for the consumer, but also to mislead the consumer and ultimately to control the consumer's behaviour.

Both assumptions raise questions about the ethical implications and the power dynamics of knowledge management. How do these assumptions work and what are their implications?

Assumptions

KM, as a concept, is a good example of "reification" (Thompson, 1990)—the use of various ideological strategies for the purpose of maintaining a particular order of things—of what is essentially a very old idea, that we can work/live together much more harmoniously and productively, if only we communicate better (and more) with each other. Naturalisation takes place by supporting that it is always good and desirable to communicate and exchange knowledge with each other. The notion has been provided with an agenda: that through technological development, we can create an infrastructure that enables us to communicate and exchange (share) knowledge more effectively. Finally, the ideas are given a label—KM—and presented as a natural development of historical events, such as the emphasis on knowledge work and the capabilities provided by ICT.

Nevertheless, it is well known that the above does not completely capture reality. The tools provided by the technology and by organisational architecture are as much used to manipulate or hide knowledge, as to reveal and share it. The activity of exclusion and inclusion, of amplification and distortion of data, can be strategic, and no amount of technical sophistication can prevent that. Indeed, the technology can be harnessed to assist in these activities. White-collar crime is a good case in point. The literature on white-collar crime does not use the terms 'knowledge management' or 'knowledge manipulation' in describing the various manifestations of the crime, but it is clear that these activities are central to the expansion taking place in that type of crime and ICT can play major role in facilitating criminal activity.

In the process of reifying knowledge as something to be harnessed and exploited, there is also a tendency in the literature to reify the organisation, and therefore to think about organisational knowledge in terms of the benefit derived by the organisation, where organisation usually refers to top management. The ensuing power dynamics and the politics of knowledge production and use are all too clear. Knowledge and organising are not the privilege of the few, but the "processes" (Hosking & Morley, 1991) that occur in spaces where individuals form and un-form social relations, and carry out formal and informal practices across the organisation. Entering into this space, whether as a researcher or as a KM "manager," or indeed any other stakeholder, has implications for the dynamics of that space.

Implications

The implications are explored by examining the practice of research looking at the notions of bias, involvement, and lay/expert knowledge.

An individual approaching anything will be doing so from a particular position, be that theoretical, methodological, historical, or political, consciously or unconsciously. Past experiences tend to inform future actions by constraining as well as enabling one's movements. As such, the assumption about the positive relationship between knowledge and truth is unfounded because of the natural bias—by virtue of our unique experiences—that we all have. For example, in the context of organisational research, the study may be intended to gain understanding (knowledge) of some aspect of the organisation's activity. The choice of research methodology, a facet of knowledge management, guides and constrains the researcher.

Exactly the same applies to the design, implementation, and development of any organisational system or project. For example, the choice of development tool, as Actor Network Theory suggests (Nijland, 2004), plays a key role in determining both what knowledge is utilised and the way that knowledge is used. Furthermore, ignoring the 'power' dimensions of the situation being studied gives the impression that organisational space is neutral, and that the action of entering the space is also neutral. For example, in the case of 'resistance to change' to new technology, it may not be so much an instance of resisting the technology, per se, but a form of protest against those (usually superiors) who implement new technology for the benefit of the organisation as a whole, with little knowledge or understanding of the actuality at subordinate levels of the organisation (Land, 1992).

Lessons drawn from different forms of research—from observational to action research—teach us that the moment of interaction or engagement with our subject of research is never without its power dynamics. Access to the organisation and acceptance of the research in the first place is dependent on some form of hierarchical 'buy-in'—that is, the support of people who are senior enough in the organisation and who have the power to 'open doors' for the researchers. But problems arise, particularly if a researcher is forced to choose between access and compromise in research design; following the management's agenda does not necessarily reflect the organisation's concerns. The knowledge that is produced is likely to benefit the particular group in question and the organisation as a whole, but only in so far as management (or the sub-class of management involved) represents the organisation. As such, one of the most obvious dangers involved in working with pre-selected groups in an organisation is perpetuation of a hierarchy of knowledge. Similarly, it may be said that KM initiatives and systems are yet another management tool designed to enhance the working of the management; the old "panopticon" (Foucault, 1979) in a new packaging.

Lessons from research demonstrate that the processes of knowledge production are far from neutral. This can be explored with respect to the so-called 'lay/expert' knowledge debate. According to Shenav's analysis (1999), scientific management was introduced into the organisation as a way of neutralising the political/power dimensions of organisational life. Furthermore, when this was done, engineers had a special role of "redefining industrial conflict as a mechanical problem rather than as a result of political struggles" (p.3; cited in Grint, 2002, p. 173). It would seem that in the case of KM, the 'K' neatly replaces the 'scientific' and the role of the KM system designer or manager is taking over from the engineer. In both the case of the engineer and the knowledge manager, the problem is one of manipulation of 'expert' knowledge.

The problem is manifest at both internal and external levels. At the internal level the assumption is that managers know—in other words, managers are experts, and subordinates follow. Stories from senior management are more likely to be taken as authoritative and representative of the organisation than stories told by lower-level employees. Yet experience suggests that on important issues, knowledge is more evenly distributed than the authority structure implies (Land, 1992), and that at the micro level those at the coal face have more knowledge than those in positions of authority. At the external level, the 'expert' problem is manifest in the form of the consultants' guides which are often based on a pre-designed, standardised formula. Expert knowledge uses "formal theories [that] are often developed by powerful and/or socially elite individuals who use the theory to influence and control others. Some elements of formal theory may be based on scientific research, but others are based upon unsupported assumptions" (Whyte, 1990. p. 13). The problem arises when 'unsupported assumptions' become equated with being 'objective' knowledge in order to uphold positions of control. So long as the KM literature continues to refer to knowledge in terms of beliefs, values, and experience, the 'knowledge' will be susceptible to control and manipulation.

In the following section we will give examples of other areas, beyond the research context, which can help us to broaden the discourse on knowledge management.

Examples

The introduction to this article suggested that manipulation of knowledge takes place at the interface between information and knowledge. Information can be guided, managed, controlled, or manipulated for a desired outcome. The following examples have been selected in that they illustrate both the instrumental use of information and knowledge, and the wide variety of human activity in which knowledge is an indispensable component subject to management and manipulation. They are given from a non-expert position and are intended as triggers for thinking about how the knowledge management discourse could be broadened.

EDUCATION

Education, a major institutional force in the socialisation of the individual, is at least in part about managing the transfer of information for the creation of knowledge between teacher and pupil(s). Let us consider the teacher-pupil interaction for a moment. A teacher is a trained expert in a particular field and uses different resources (books, articles) in order to teach a, usually, national curriculum. The different resources form the link between what the teacher needs to convey and what the pupils need to learn. This is an informational link on the one level. On another level, however, it intends to 'form' the pupil's knowledge of a particular subject. We know that education—whether at the level of the curriculum, school, or individual teacher—is not objective, and the information intended to form pupils' knowledge can be managed for a desired effect. The subject of history is a case in point. There are good criticisms of this form of education. The Socratic dialogue is probably the oldest form of criticism; more recent, and widely cited, is the work of Brazilian educator Paolo Freire (1970). The criticism is against individuals as "repositories" of information, and instead encourages the active questioning and dialogue between teacher, pupil, curriculum. Control is a central theme in this questioning.

MARKETING

Marketing, embracing advertising and public relations, is another area redolent of KM. Marketing, widely taught as a core discipline in business schools, epitomises the use of knowledge management to provide consumers with product or service knowledge in order to enable them to make informed choices on what to buy. In the domain of marketing, the manipulative aspect of KM is widely recognised—its use to manipulate information in an instrumental way designed to provide consumers with a very partial or even distorted picture of the goods or service on offer and those offered by the competition. Advertising and public relations are constrained to some extent by regulations, in recognition that left unregulated organisations will manage knowledge in an unprincipled way for competitive advantage and maximum profit. Organisations like the Consumer Association exist to redress the balance between vendor and consumer, and try to offset the sometimes tacit, but often explicit knowledge management of the vendor.

(SCIENTIFIC) MANAGEMENT

Taylor's (1911) "scientific management" provides a further source of ideas with regards to the control aspect of KM. The advocates of scientific management believe firmly in the need to manage knowledge in order not to clutter up the minds of employees and to distract them from the limited tasks they are assigned to. Hence someone of higher authority always determines, on the principle of providing knowledge on a strict 'need-to-know' basis, what information and knowledge is to be provided for the employee. Whilst the KM movement espouses the reverse view, in reality Taylorism is deeply embedded in managerial practices, for example so called modern ideas of industrial reorganisation such as Business Process Reengineering (Hammer, 1990; Hammer & Champy, 1993; Davenport, 1993, 1996). Practical implementations of KM suffer a similar fate by carefully defining what knowledge can be shared and with whom sharing is permitted.

LAW

The law itself, and its study, provides another perspective on KM. The law relating to intellectual property rights, for example, defines and limits the way knowledge about intellectual property can be shared. The controversy about the human genome illustrates the relationship of intellectual property rights to KM. One group of scientists working on the human genome project took their discoveries to be knowledge that they were entitled to treat as a commodity not available to anyone except as they determined and for a price. Another group of scientists working on a human genome project reached a very different conclusion. They held that their discoveries were not an 'invention', but merely knowledge derived from the decoding of a natural phenomenon and as such could not be regarded as a commodity, and hence freely available to all (Sulston & Ferry, 2002; Wickelgren, 2002). Debates about intellectual property rights, data retention, and privacy (Hosein, 2001; Tsiavos & Hosein, 2003; Drahos & Braithwaite, 2003) provide concrete examples around the discourse of ownership and control of information and knowledge.

The instruments that support KM in its benign or destructive forms are varied. They include organisational architectures such as the authority structure, organisational provisions such as social clubs, technology-based provisions such as data warehouses, expert systems, case-based reasoning, web facilities, the intranet, and many others and, as ENRON demonstrated, the humble shredder as a potent weapon of KM.

FUTURE TRENDS

Given the argument presented in this article, two trends are noted in particular. The first is the growing realisation that technological developments provide ever widening opportunities for the dark side of knowledge management to flourish, and hence that there is a need to develop both awareness of the potential problems and defence mechanisms. Such mechanisms will need to emerge out of critical research that no longer relies on linear, fixed representations of reality, but which allows for the representation of uncertainty and the unexpected. For an example, see Land, Amjad, and Nolas's approach (in another article in this encyclopedia, titled "Knowledge Management Processes").

The second is the growing awareness of the political aspects of organisational processes driving the use of information and knowledge. There is a need to take an ethical stance both in the design of KM systems, as well as in research about the KM systems and their relationship with and effects on organisational processes. This requires a more interdisciplinary approach that permits the researcher and practitioner to both learn from the past and critically engage with the future.

CONCLUSION

The article has shown that it is possible and insightful to trace notions that might be interpreted as knowledge management to a broad range of older disciplines, and that a study of these provides us with a richer picture and deeper understanding of

KM. It is as if—to use a metaphor—the study of KM in the literature of the subject has focused a light on an iceberg so that we can see it in its full glory, but omits to note that there is more under the water than above it. What this article has set out to do is to expose some of the underside of the iceberg.

It is clear from studies in KM that whilst management can create the conditions for the beneficial aspects of KM—for example, knowledge sharing by the provision of tools, or by providing the conditions for relationships to develop, or both—the outcomes are dependent on a range of other factors such as organisational culture (Ackerman, Pipek, & Wulf, 2003). On the other hand, knowledge sharing can and does take place without any management intervention at all—without a conscious KM.

Despite its eminence and the notion of KM as a subject of study, critiques around the notion do exist and have evolved around the definition of knowledge and the choice of tools to support KM, those being either technological or human. But neither the technology, nor the relationship-oriented models have specially noted that KM involves power dynamics, as well as ethical issues. We need to look elsewhere for the discourse with which to address power dynamics and ethical issues (Foucault, 1980; Sussman, Adams, & Raho, 2002).

Knowledge management is not a chimera. KM has been helpful in drawing attention to the value of knowledge and how it can be utilised for the benefit of organisations, individuals, and society. But much of the work currently defined as being about KM takes a one-eyed stance. The Mafia principle of 'omerta' is also a form of knowledge management, albeit at its most malign, and companies like ENRON prompt us to question the ethical problems for society as a whole, but also for the individual, whether in the role of employee, outside observer (for example, journalist), or researcher, in the management of knowledge.

If the study of KM is to have an enduring future, it must take a more dynamic and contextual approach, recognising that its antecedents come from many more disciplines than those which are cited in the literature. Of course, research into the part of the iceberg above water is easier, in the sense that the stories that are told about it reflect the views of those who want to extol its beauty. Diving into the cold water below the iceberg and explaining what is there is more difficult. The dark side of KM is protected against exposure. It is perhaps not surprising that it requires more than auditors or academic researchers to reveal what lies under the iceberg. But students, researchers, and practitioners alike have to recognise the instrumentality of which drives action and the problems it gives rise to in terms of values, truth, and ethics.

In presenting these arguments we have followed the advice of two very distinct views of scientific progress. On the one hand we follow Popper (1972) in believing that one function of the researcher is to provide warnings about the fallibility of current orthodoxies. The evidence provided by the examples goes some way to throw doubt on the interpretation of KM as set out in much of the current literature. The second source of advice comes from Foucault (1980) and critical theory, which alerts us to power and politics implicit in the process of knowledge creation and utilisation.

Chapter 1.3
Knowledge Management Success Models

Murray E. Jennex
San Diego State University, USA

INTRODUCTION

Alavi and Leidner (2001, p. 114) defined knowledge management systems (KMSs) as "IT-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application." They observed that not all KM initiatives will implement an IT solution, but they support IT as an enabler of KM. Maier (2002) expanded on the IT concept for the KMS by calling it an ICT system that supported the functions of knowledge creation, construction, identification, capturing, acquisition, selection, valuation, organization, linking, structuring, formalization, visualization, distribution, retention, maintenance, refinement, evolution, access, search, and application. Stein and Zwass (1995) define an organizational memory information system (OMIS) as the processes and IT components necessary to capture, store, and bring to bear knowledge created in the past on decisions currently being made. Jennex and Olfman (2004) expanded this definition by incorporating the OMS into the KMS and adding strategy and service components to the KMS.

Additionally, we have different ways of classifying the KMS and/or KMS technologies, where KMS technologies are the specific IT and ICT tools being implemented in the KMS. Alavi and Leidner (2001) classify the KMS and KMS tools based on the knowledge life-cycle stage being predominantly supported. This model has four stages: knowledge creation, knowledge storage and retrieval, knowledge transfer, and knowledge application. It is expected that the KMS will use technologies specific to supporting the stage for which the KMS was created to support. Marwick (2001) classifies the KMS and KMS tools by the mode of Nonaka's (1994) SECI model (socialization, externalization, combination, and internalization) being implemented. Borghoff and Pareschi (1998) classify the KMS and KMS tools using their knowledge management architecture. This architecture has four classes of components—repositories and libraries, knowledge-worker communities, knowledge cartography or mapping, and knowledge flows—with classification being based on the predominant architecture component being supported. Hahn and Subramani (2001) classify KMS and KMS tools by the source of the knowledge being supported: a structured artifact, structured individual, unstructured artifact, or unstructured individual. Binney (2001) classifies the KMS and KMS tools using the knowledge spectrum. The knowledge spectrum represents the ranges of purposes a KMS can have and include transactional KM, analytical KM, asset management KM, process-based KM, developmental KM, and innovation and creation KM. Binney does not limit a KMS or KMS tool to a single portion of the knowledge spectrum and allows for multipurpose KMS and KMS tools. Zack (1999) classifies KMS and KMS tools as either integrative or interactive. Integrative KMS or KMS tools support the transfer of explicit knowledge using some form of repository and support. Interactive KMS or KMS tools support the transfer of tacit knowledge by facilitating communication between the knowledge source and the knowledge user. Jennex and Olfman (2004) classify the KMS and KMS tools by the type of users being supported. Users are grouped into two groups based on the amount of the common context of understanding they have with each other, resulting in the classifications of process- or task-based KMS and KMS tools, or generic or infrastructure KMS and KMS tools.

Regardless of the classification of the KMS, once a KMS is implemented, its success needs to be determined. Turban and Aronson (2001) list three reasons for measuring the success of a knowledge management system.

- To provide a basis for company valuation
- To stimulate management to focus on what is important
- To justify investments in KM activities

All are good reasons from an organizational perspective. Additionally, from the perspective of KM academics and practitioners, the measurement of KMS success is crucial to understanding how these systems should be built and implemented.

To meet this need, several KM and/or KMS success models are found in the literature. Models of KM success are included as a Churchman (1979) view of a KMS can be defined to include the KM initiative driving the implementation of a KMS (also, the counterview is valid as looking at KM can also include looking at the KMS).

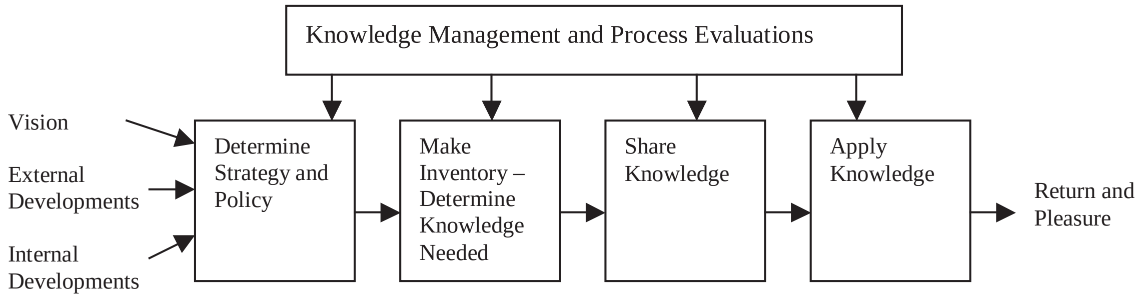
What is KM or KMS success? This is an important question that has not been fully answered as researchers are finding it difficult to quantify results of KM and KMS efforts. This article presents several KM and KMS success models. Two basic approaches are used to determine success. The first looks at the effective implementation of KM processes as the indicator of a successful implementation, with the expectation that effective processes will lead to successful knowledge use. These models identify KM processes by looking at KM and KMS success factors. The second approach looks at identifying impacts from the KM or KMS implementation, with the expectation that if there are impacts from using knowledge, then the KM or KMS implementation is successful. These models consider success a dependent variable and seek to identify the factors that lead to generating impacts from using knowledge. The following models, found through a review of the literature, use one or both of these approaches to determine KM or KMS success.

KNOWLEDGE MANAGEMENT SUCCESS MODELS

Bots and de Bruijn: Knowledge Value Chain

Bots and de Bruijn (2002) assessed KM and determined that the best way to judge good KM was through a knowledge value chain. Good KM

Figure 1. Bots and de Bruijn (2002) KM value chain



is defined as using KM to improve organizational competitiveness. However, measuring the KM impact on competitiveness is considered difficult, so ultimately it was concluded that good KM is when the KM initiative matches the model provided in Figure 1 and the KM processes are implemented well. KM is assessed for effectiveness at each step of the knowledge process and is good if each of the indicated activities is performed well with the ultimate factor being that the KM enhances competitiveness. Figure 1 illustrates the KM value chain. The model was developed by viewing and contrasting KM through an analytical (technical) perspective and an actor (user) perspective. These perspectives are conflicting, and KM assessment occurs by determining how well the KMS meets each perspective at each step.

Massey, Montoya-Weiss, and O'Driscoll KM Success Model

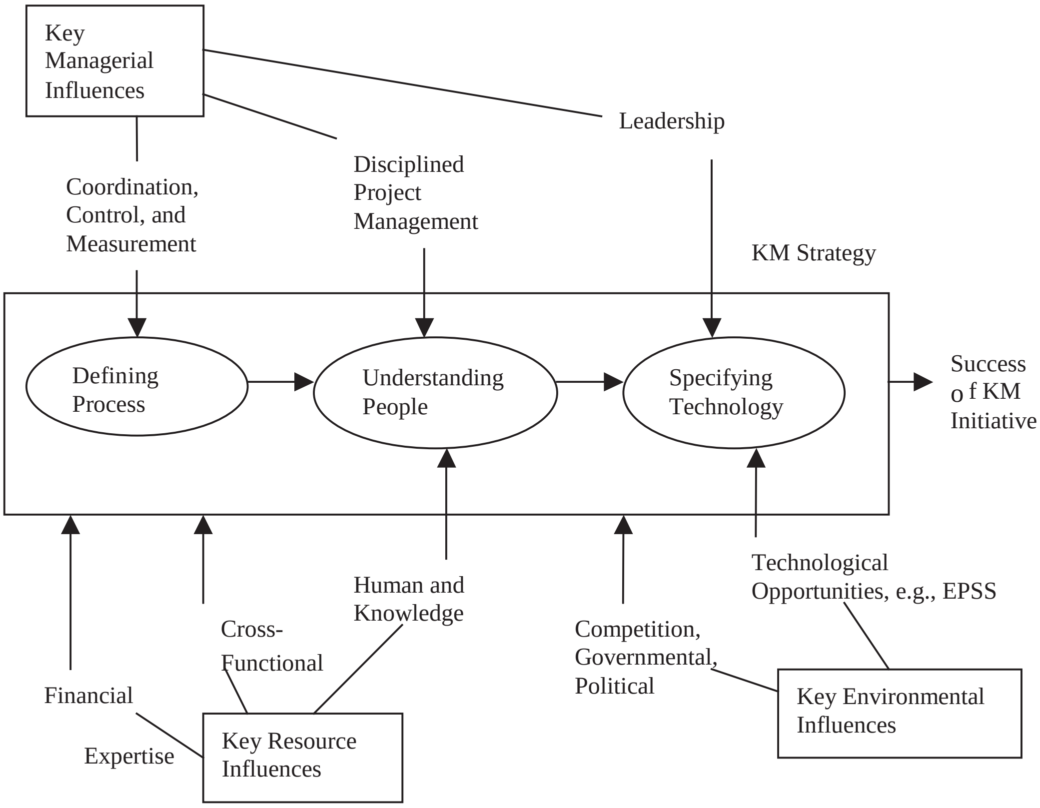
Massey, Montoya-Weiss, and O'Driscoll (2002) present a KM success model based on their Nortel case study. The model is based on the framework proposed by Holsapple and Joshi (2001) and reflects that KM success is based on understanding the organization, its knowledge users, and how they use knowledge. It recognizes that KM is an organizational change process and KM success cannot separate itself from organizational change success, with the result being that KM success is essentially defined as improving organizational or process performance. The model is presented in Figure 2. Key components of the model are the following.

- **KM Strategy:** The processes using knowledge and what that knowledge is; the sources, users, and form of the knowledge; and the technology infrastructure for storing the knowledge
- **Key Managerial Influences:** Management support through leadership, the allocation and management of project resources, and the oversight of the KMS through the coordination and control of resources and the application of metrics for assessing KMS success
- **Key Resource Influences:** The financial resources and knowledge sources needed to build the KMS
- **Key Environmental Influences:** The external forces that drive the organization to exploit its knowledge to maintain its competitive position

Lindsey KM Success Model

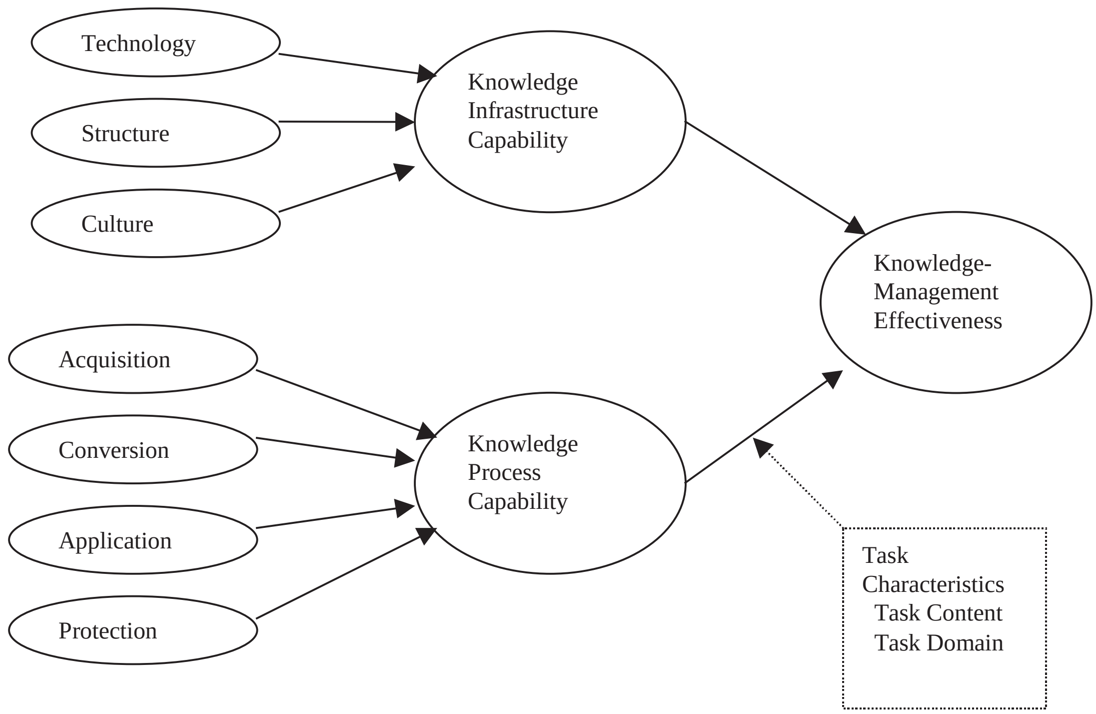
Lindsey (2002) considered KM success as being defined by Kaplan and Norton's (1992) balanced-

Figure 2. Massey et al. (2002) KM success model



scorecard approach and proposed a KM effectiveness model based on combining the organizational capability perspective theory (Gold, Malhotra, & Segars, 2001) and the contingency-perspective theory (Becerra-Fernandez & Sabherwal, 2001). The model defines KM effectiveness in terms of two main constructs: knowledge infrastructure capability and knowledge process capability, with the knowledge process capability construct being influenced by a knowledge task. The knowledge infrastructure capability represents social capital and the relationships between knowledge sources and users, and it is operationalized by the technology (the network itself), structure (the relationship), and culture (the context in which the knowledge is created and used). The knowledge process capability represents the integration of KM processes into the organization, and it is operationalized by acquisition (the capturing of knowledge), conversion (making captured knowledge available), application (degree to which knowledge is useful), and protection (security of the knowledge). Tasks are activities performed by organizational units and indicate the type and domain of the knowledge being used. Tasks ensure the right knowledge is being captured and used. KM success is measured as a combination of the satisfaction with the KMS and the effectiveness of KM processes. Figure 3 illustrates the Lindsey model.

Figure 3. Lindsey (2002) KM effectiveness model

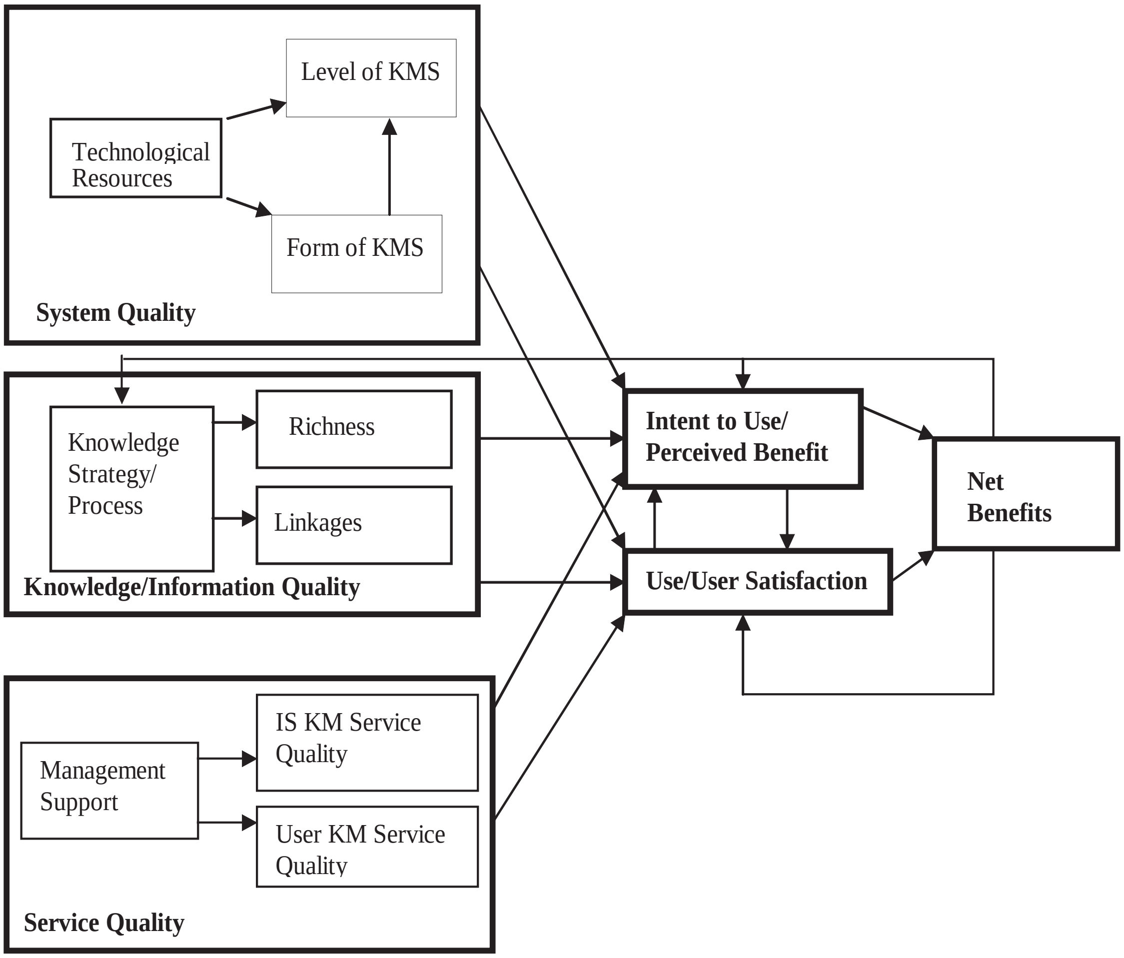


Jennex-Olfman KMS Success Model

Jennex and Olfman (2004) present a KMS success model that is based on the DeLone and McLean (1992, 2003) IS success model. Figure 4 shows the KMS success model. This model evaluates success as an improvement in organizational effectiveness based on the use of and impacts from the KMS. Descriptions of the dimensions of the model follow.

- **System Quality:** how well the KMS performs the functions of knowledge creation, storage and retrieval, transfer, and application; how much of the OM is codified and included in the computerized portion of the OM; and how the KMS is supported by the IS staff and infrastructure.
- **Knowledge and Information Quality:** ensures that the right knowledge and OM with sufficient context is captured and available for the right users at the right time.
- **Use and User Satisfaction:** indicates the actual levels of KMS use as well as the satisfaction of the KMS users. Actual use is most applicable as a success measure when the use of a system is required. User satisfaction is a construct that measures satisfaction with the KMS by users. It is considered a good complementary measure of KMS use when use of the KMS is required, and the effectiveness of use depends on users being satisfied with the KMS.
- **Perceived Benefit:** measures perceptions of the benefits and impacts of the KMS by users and is based on Thompson, Higgins, and Howell's (1991) perceived-benefit model. It is good for predicting continued KMS use when use of the KMS is voluntary, and the amount and/or effectiveness of KMS use

Figure 4. KMS success model of Jennex and Olfman (2004)



depends on meeting current and future user needs.

- **Net Impact:** An individual's use of a KMS will produce an impact on that person's performance in the workplace. Each individual impact will in turn have an effect on the performance of the whole organization. Organizational impacts are typically not the summation of individual impacts, so the association between individual and organizational impacts is often difficult to draw; that is why this construct combines all impacts into a single construct. This model recognizes that the use of knowledge and OM may have good or bad benefits, and allows for feedback from these benefits to drive the organization to either use more knowledge and OM or to forget specific knowledge and OM.

Maier KMS Success Model

Maier (2002) also proposes a KMS success model based on the DeLone and McLean IS success model (1992). This model is similar to the Jennex-Olfman model. A breakdown of the dimensions into constructs is not provided, but specific measures for each dimension are identified. This model is illustrated in Figure 5 and uses the following dimensions.

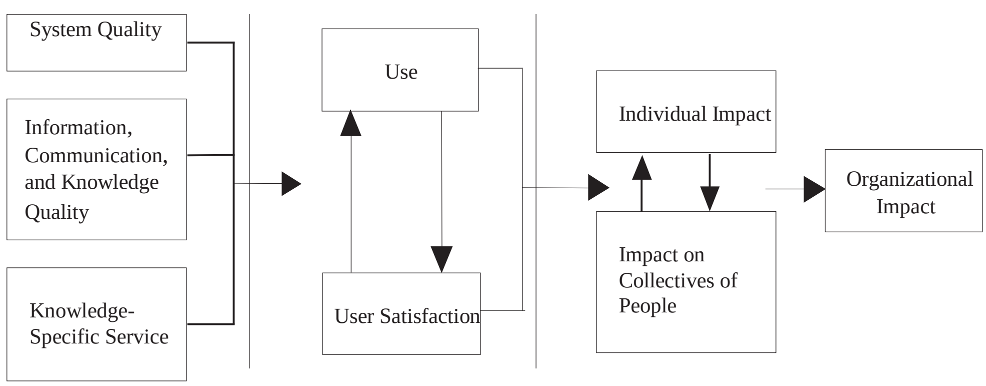
- **System Quality:** taken directly from DeLone and McLean (1992) and refers to the overall quality of the hardware and software
- **Information, Communication, and Knowledge Quality:** the quality of the stored data, information, and knowledge, and the quality of knowledge-flow methods
- **Knowledge-Specific Service:** how well subject-matter experts and KMS managers support the KMS
- **System Use and User Satisfaction:** taken directly from DeLone and McLean (1992) and refers to actual KMS use and the satisfaction users have with that use
- **Individual Impact:** taken directly from DeLone and McLean (1992) and refers to the impacts KMS use has on an individual's effectiveness
- **Impact on Collectives of People:** the improved effectiveness within teams, work groups, and/or communities that comes from using the KMS
- **Organizational Impacts:** taken directly from DeLone and McLean (1992) and refers to improved overall organizational effectiveness as a result of KMS use

FUTURE TRENDS

There are two areas needing research. The first is in defining KM and KMS success and quantifying the factors that define or reflect this success. Two promising approaches are in identifying success measurements with respect to DeLone and McLean's (2002) IS success model, or to Kaplan and Norton's (1992) balanced-scorecard approach.

The second area is to improve the generalizability of the models by establishing quantitative support across a broad range of organizations and users. This is necessary for showing that the models are not just reflective of the conditions observed in the case study leading to their generation.

Figure 5. Maier (2002) KMS success model



CONCLUSION

Many KM and KMS success and effectiveness models have been proposed. Most are based on case study research that looked in depth at KM or a KMS in an organizational setting. This type of research yields good insight into organizational and user processes and mechanics, giving researchers an excellent perspective from which to build models that explain their observations. Additionally, all of these models have some level of theoretical foundation. The use of established theory coupled with observation yields useful models. The models presented in this article are all useful to researchers exploring KM and KMS success and effectiveness. Also, these models are useful to practitioners and KMS designers as they provide guidance into what to look at when determining KM and KMS success, and what to include in a KMS.

Chapter 1.4
Technology and Knowledge Management

Helen Mitchell
Unitec, Auckland, New Zealand

INTRODUCTION

Rapid and extensive advances in technology, particularly in the area of communications, have had a considerable impact on the way organizations operate and opened pathways to access vast amounts of information. Information, however, is static unless knowledge is applied to translate it into something meaningful and with the potential to be actionable. From the time organizations commence business, they accumulate information about the markets in which they operate, yet often, knowledge is not applied in a way that it can be exploited to bring benefit. The ability to share knowledge, to develop ideas, and to become more innovative is increasingly important for businesses, and the range of technologies now available provides a conduit for knowledge to flow through the organization to enable sharing to occur. Technology is frequently referred to as "just an enabler," but it can also be identified as a value-adder.

INFORMATION AND KNOWLEDGE

In their paper, Evans and Wurster (1997, p. 71) referred to changes that had taken place over the previous 10 years as organizations adapted their "operating processes" to "information technologies," recognizing that accessing information was going to have an important bearing on where industries would be going in the future. During this period, technology was moving forward at a rapid rate, and organizations were investing huge sums of money in information technology.

Information is defined as facts and data organized to describe a particular situation or problem. The definition used for knowledge is that by Davenport and Prusak (1998):

Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms. (p. 5)

Connectivity, it is suggested by Evans and Wurster (1997), provided the most important change in the information revolution: "What is truly revolutionary about the explosion in connectivity is the possibility it offers to unbundle information from its physical carrier" (p. 73). Amidon (1997) referred to the major change from information processing to knowledge processing that has taken place, "which includes the concepts of learning tools, intelligent electronic coaching, decision-making systems, and more" (p. 87). The availability of such tools, and their ongoing development, add considerable value to an organization by providing a means through which more efficient and effective management techniques can be introduced. This evolving of expectations indicates that organizations are not only anticipating more from technology but are also becoming more reliant upon it.

As interest grows beyond information per se, organizations are looking to technology to progress toward the development of knowledge management systems. Bhatt (2001) referred to business managers who believe computers and communication technologies provide an avenue for the harvesting of knowledge from data repositories of organizations, while other managers say knowledge "resides in human minds, and therefore, employee training and motivation are the key factors to knowledge management" (p. 68). The development of technology has taken the drudgery out of searching, analyzing, and converting data into information to which knowledge can be applied.

Technology and knowledge, however, do not stand in isolation. There are many interacting factors, not least of which is the environment in which the organisation operates. According to Bhatt (2001), the "…pattern of interaction between technologies, techniques and people is unique to an organization" (p. 69). Such uniqueness is important, because it is not easy to replicate. The organisation that promotes the value of the knowledge, skills, and competencies of its people, and recognizes the importance of technology, is providing well for its future (Carneiro, 2000; Bhatt, 2001).

From a productivity perspective, Grant (2000) indicated the value of digital technology. He referred to knowledge no longer being held exclusively by people. Codification and use of technology provides the opportunity for knowledge replication. While costly to create, replication and distribution can be reduced to almost "zero marginal cost" (Grant, 2000, p. 32). In the long term, and with the arrival of new technologies, the rate of productivity growth is likely to accelerate (Grant, 2000). People have skills and knowledge, but it is technology that enables them to access in a timely manner huge amounts of data available both internally and externally to the organization. While technology enables people to access data, the added value comes in its ability to allow the data to be assembled in a meaningful way for the purpose of decision making.

SHARING KNOWLEDGE

An environment in which knowledge sharing is encouraged leads to the creation of new knowledge, but as Marshall, Prusak, and Shpilberg (1996) indicated, it is not easy to encourage voluntary sharing of knowledge by employees. An organisation that develops a knowledge-sharing environment increases opportunities for the creation of new ideas that have the potential to add value to it.

Barriers to sharing knowledge exist, and for managers advocating knowledge sharing, they should examine the existing practices within the organization. It is possible that somewhere in the organization, the "knowledge is power" syndrome exists, and if so, it does not auger well for knowledge sharing. There may also be concern over job security, "if I share my knowledge, I am no longer of value to the organization, and therefore, my job will be in jeopardy." A barrier to knowledge sharing may simply rest on the premise that a person may not realize that knowledge acquired in another situation could be of value to the organization. Managers may need to look to changing the organizational culture to one that recognizes, and acknowledges, the value of shared knowledge.

Bhatt (2001), referring to the need for the distribution and sharing of knowledge throughout the organisation, suggested that interactions among technologies, techniques, and people have a direct bearing on the effectiveness of the distribution of knowledge.

RANGE OF TECHNOLOGIES

According to Frappaola and Capshaw (1999): "Knowledge management refers to the practices and technologies that facilitate the efficient creation and exchange of knowledge on an organizational level" (p. 44).

From the literature, it appears that there are a number of applications specifically designed for sharing knowledge (Davenport, 1997; LaPlante, 1997; Fahey & Prusak, 1998). The benefits of applications, such as groupware, data warehousing, knowledge maps, client server systems, and chat rooms, are recognized as providing the means through which knowledge can be shared. A useful aspect of such applications is that they allow for interaction and sharing of information that is highly unstructured in nature (Shani, Sena, & Stebbins, 2000). Research carried out by Mitchell in 1999 indicated that people are finding groupware applications useful mechanisms for sharing knowledge.

A number of writers, Allee (1997), Amidon (1997), Marshall (1997), Watt (1997), and Davenport and Prusak (1998), refer to the intranet as providing channels through which organizational knowledge can flow. E-mail is now well accepted as a useful and valuable medium of communication, and for knowledge to flow through an organization (Bontis, Fearon, & Hishon, 2003). The advent of electronic conferencing provides an avenue through which people geographically dispersed can interact without the time and cost involved in traveling. Networking, bulletin boards, and the establishment of virtual teams also provide opportunities for people to interact over distances and to share knowledge.

Reference is made by Beckett (2000) to the "Data warehousing knowledge set" containing reference data, defined as market trends, operational data, and customer performance needs. From this knowledge set, actions can be taken that ultimately benefit stakeholders and customers. While the knowledge set may be considerable, ideally, its value only becomes realistic when there is in place the means to allow for the "free" flow of knowledge throughout the organisation and when there are people who can recognize that value can be gained from it. It is most unlikely that organizations allow for a free flow of knowledge, because issues such as privacy and confidentiality, "need to know," and other constraints restrict access to knowledge. However, providing access to knowledge that can be made available should be the aim of organizations wanting to encourage a knowledge-sharing environment.

Technology has opened avenues to the customer to search for opportunities and products that may better serve their needs. The opportunity, however, is also open to the organization to exploit the potential of technology to create greater value for its customers.

KNOWLEDGE MANAGEMENT STRATEGY

Hansen, Nohria, and Tierney (1999) identified management consultants as being among the first to recognize the potential of information technology for the capture and dissemination of knowledge. It was found that organizations tend to employ two very different strategies for the management of knowledge. One is the "codification strategy," where maximizing the use of technology shows a strong focus on codifying knowledge and storing it in databases for access by anyone in the company. The second approach viewing knowledge being shared through person-to-person contacts is identified as the "personalization strategy" (Hansen, Nohria, & Tierney, 1999, p. 107).

From their research, Hansen et al. (1999) found that organizations pursuing "an assemble-to-order product or service strategy emphasized the codification and reuse of knowledge. Those that pursued highly customized service offerings, or a product innovation strategy, invested mainly in person-to person knowledge sharing" (p.112). Whichever strategy is used, there is inevitably the inclusion, as a support mechanism, of an element of the other strategy. Hansen et al. suggest an 80:20 split, that is, "80% of their knowledge sharing following one strategy, 20% the other." They go on to say that "Executives who try to excel at both strategies risk failing at both" (p. 112).

In his article, Beckett (2000) referred to the fastest knowledge-transfer vehicles, relating them to the work of Nonaka and Takeuchi (1995). The tacit/tacit transfer is fast, "because people use multiple sensors in working together in teams" (p. 317). Using electronic media for the transfer of explicit/explicit transfer can also be fast. However, there is evidence that "tacit/explicit transfers are slow, as specialist skills are needed to draw out and carefully enunciate tacit knowledge" (p. 317). Becket indicated that explicit/tacit transfers are similarly positioned, and provides the example of formal education.

Giving consideration to the perspectives of Hansen et al. (1999) and Beckett (2000), and others, such as Ericsson and Avdic (2003), Mockler and Dologite (2002), Jentzsch and Prekop (2002), and Frappaolo and Capshaw (1999), determining a knowledge management strategy needs careful thought if it is to meet the requirements of the organization.

TECHNOLOGY: ENABLER OR VALUE-ADDER?

Lloyd (1996) referred to the use by organizations of worldwide networks and said that new technology is "the catalyst which is forcing all organizations to re-evaluate what they know, what they do with that knowledge, and how they continually add value (or not) to that knowledge in meeting changing customer needs" (p. 576). Technology has advanced considerably since Lloyd made this comment, and it will continue to evolve in the years ahead, providing for greater enrichment of organizational operations. While the cost of "keeping up" with technological developments has always been a problem for organizations that have made a strong commitment to technology, others recognize that they need to work smarter with what they have.

If technology is just an enabler, what is it that adds value to the organisation? Binney (2001, p. 33) addressed the question of knowledge-management (KM) investments. What has emerged is the KM spectrum, in which he identifies KM applications and places them into "six common categories to establish the elements of the KM spectrum" (p. 34). Binney identified from the literature six categories to provide the elements of the KM spectrum: transactional, analytical, asset management, process, developmental, and innovation and creation. He then mapped KM applications to the elements:

1. Transactional—Order entry applications; help desk applications
2. Analytical—Data warehousing, customer relationship management, DSS, MIS
3. Asset management—Document management, intellectual property

4. Process—TQM, process automation, benchmarking
5. Developmental—Skills development, training
6. Innovation and creation—Communities, virtual teams, networking

The next stage of the process added to the various elements, enabling technologies:

1. Transactional—Expert systems, probability networks
2. Analytical—Intelligent agents, data analysis and reporting tools
3. Asset management—Document management tools, knowledge maps
4. Process—Workflow management, process-modeling tools
5. Developmental—Computer-based training, online training
6. Innovation and creation—Search engines, voice mail, groupware

The KM spectrum provides organizations with the means to identify their present positions and to make use of the framework to map their future investments in knowledge management. The examples given above illustrate the wide range of applications available to organizations, and their potential and value emerges through maximizing their use for the purpose of effective decision-making in an increasingly competitive environment.

Technology has provided the impetus for the growth of the information age, but it should not be regarded as a dominant partner. As Pemberton (1998) commented, "The IT exponents of KM tend to downplay the central role of human factors in KM…IT doesn't itself create knowledge any more than does a library, an office, or a classroom" (p.60). But, as Carneiro (2000) indicated, the combining of knowledge and information technology is a major success factor in strategic planning formulation. The future will bring ever more sophisticated advancements in technology providing new avenues of exploration for seeking, creating, and sharing knowledge.

CONCLUSION

Is technology just an enabler, or is it also a value-adder? From the literature, technology, while recognized as being important, tends to be regarded as an enabler rather than a value-adder. Yet the continual movement in technological progress, as shown in Binney's KM spectrum, clearly identifies the developments that have taken place in technology to enhance the operation of business. People provide value through the application of their knowledge, but their ability to do so is considerably enhanced by the availability of technology. Technology enriches opportunities for disseminating and sharing knowledge, and through providing the means to access information for decision making. While the role of technology may be seen as that of enabler to access information, value is added through the ability to assemble data, put it into meaningful information, and manipulate it into various scenarios before determining the best decision. Technology is adding value by allowing organizations to do this. Without the range of technology available to organizations, they would be considerably restricted in their ability to effectively manage their business. Therefore, technology should be identified as an adder of value.

Chapter 1.5
Smart Organizations in the Digital Age

Erastos Filos
European Commission, Belgium

ABSTRACT

The chapter aims to present and explain the concept of the smart organization. This concept arose from the need for organizations to respond dynamically to the changing landscape of a digital economy. A smart organization is understood to be both internetworked and knowledge-driven, and therefore able to adapt to new organizational challenges rapidly. It is sufficiently agile to respond to opportunities of the digital age. The three networking dimensions of smart organizations, ICT-enabled virtuality, organizational teaming, and knowledge hyperlinking, are elaborated. This networking capability allows smart organizations to cope with complexity and with rapidly changing economic environments. The paper also shows how managing the smart organization requires a more "fuzzy" approach to managing smart resources: people, information, knowledge, and creativity. Research is also presented, mainly from the European perspective. It has been key to creating the conditions for organizations to become smart.

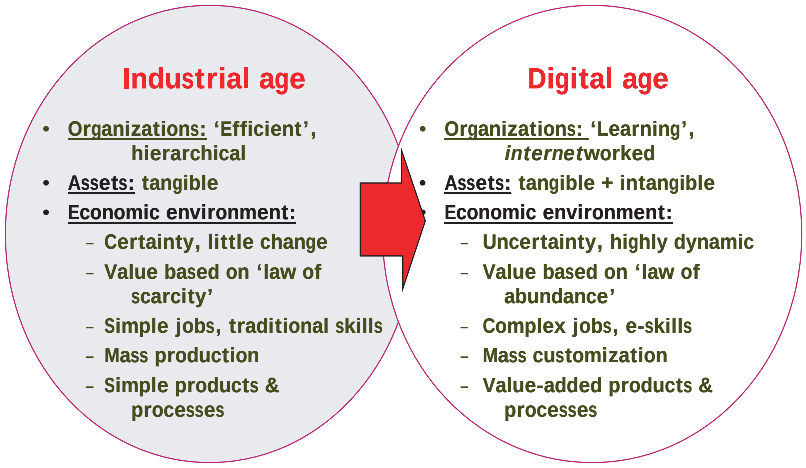
CHARACTERISTICS OF THE DIGITAL AGE

Over the last decades, information and communication technologies (ICT) have been the enabling factor in organizational change and innovation, and there is now evidence of their impact on industrial value chains. Organizations today strive to become agile and to operate profitably in an increasingly competitive environment of continuously and unpredictably changing markets.

The digital age is different from the industrial age in various ways (Figure 1). For example, today ICT represent a substantial—and increasing—part of the added value of products and services. ICT-intensive sectors include manufacturing, automotive, aerospace, pharmaceuticals, medical equipment, and agro-food, as well as financial services, media, and retail. In the automotive sector, for instance, an estimated 70% of innovations that happened over the last 20 years were related to ICT.

According to recent studies, more than half of the productivity gains in developed economies

Figure 1. Industrial vs. digital age characteristics



can be attributed to ICT (OECD, 2003; O'Mahony & van Ark, 2003). The gains stem both from the production of innovative, high-value goods and services based on ICT, as well as from improvements in business processes through a wider diffusion, adoption and use of ICT across the economy. Their impact on the economy and on society at large has led to remarkable changes.

A "Hyperlinked" Economy

The increased networking in a global economy is due to the pervasiveness of ICT and the Internet. Since business success depends on the ability to innovate, and since innovation comes from a clash of ideas, networks provide a natural environment for this. The Internet not only facilitates a hyperlinking of documents, but also a hyperlinking of people and of organizations (Levine, Locke, Searls, & Weinberger, 2000). The internetworked economy (Ticoll, Lowy, & Kalacota, 1998) is about the right set of connections between people and organizations in whatever role they may be in. In relationships that are fostered via networks, roles become blurred: The seller becomes the "buyer" of valuable feedback on his product. Smart business organizations today see customers, suppliers, regulators, and even competitors as stakeholders who can make valuable contributions to their success.

"Value" Redefined

Individuals and organizations today understand value as something different from value in its traditional sense—that is, not only attributable to something that is unique or scarce. Value in a networked economy grows with the number of intermediation opportunities (e.g., relationships). Network theory predicts an exponential growth of interactions with a growing number of involved members ("nodes"). The more nodes there are in a network community, the more each node becomes an intermediary to all others (Kelly, 1999).

Another reason for the new perception of value is the fact that economic value is no longer derived from tangible assets alone—for example, from investments in labor, plants, and machinery. "Smart" resources—such as information, content, software, knowledge, brands, and innovation capability—contribute increasingly to value creation in today's economy.

Intangible Assets

Brands and knowledge are becoming a source of value, not unlike capital. Brands, for example, represent accumulated surplus value turned into client loyalty, which translates into lower marketing costs, higher prices, or larger market share for the owner organization (Davis & Meyer, 1998). In digital markets, brands are an invaluable source of trust and orientation to consumers who are looking for quality and security. Many organizations invest heavily in building a reputation that is conveyed through a brand. Some businesses have even outsourced almost all other activities just to maintain their focus on managing the brand. In an internetworked economy, knowledge is a key intangible asset that requires effort to develop and to protect.

The Growing Need for Trust

A key question in the digital economy is: "How can you do business with somebody that you do not see?" (Handy, 1995). As business relies more and more on technologies and infrastructures that reduce geographical distance, open communication networks and associated information systems become vulnerable to integrity and security threats. Technologically, trust and dependability must be established and maintained through security technologies such as cryptography and electronic authentication (biometrics, electronic signatures, etc.) and by technologies that enhance privacy and help protect and manage intellectual rights, digital assets, and identities. In the socio-organizational context, trust becomes an essential element of management.

THE SMART ORGANIZATION

Most organizations are not designed—they evolve. This is why biological analogies may provide an appropriate means to describe organization phenomena. But not all organizations adapt equally well to the environment within which they evolve. Many, like dinosaurs of great size but with little brains, remain unchanged in a changing world. In a digital economy, the law of survival of the fittest will evidence its relevance to organizations as it does in the biological domain.

Handy (1999) sees the old understanding of alliances with suppliers, consultants, retailers, and agents changing into a new type—that is, stakeholder alliances with suppliers, customers, and employees, as well as alliances with competitors. As no organization today can afford to remain an "island entire unto itself," every organization is a network of other organizations. No discussion of structure can therefore rest content with the inside of the organization.

Some organizational metaphors include terms like adhocracy (Mintzberg, 1980), cluster organization (Mills, 1991), network organization (Foy, 1980; Imai & Itami, 1984), and organizational marketplace (Williamson, 1975). All these concepts share certain common characteristics, like flatter hierarchies, dynamic structures, empowerment of individuals, and high esteem of individuals' capabilities, intellect, and knowledge. However, although they may gain importance in the digital age, they cannot be considered a panacea to cure all management ills.

Despite the proposed new models, the basic duality between a hierarchical (bureaucratic) and a networked structure remains. In The Knowledge-Creating Company, Nonaka and Takeuchi (1995) argue that while for most of the 20th century organizational structures have oscillated between these two basic types, what is necessary for knowledge-driven organizations today is a smart combination of both. They propose the concept of the hyperlinked organization, which is able to maximize corporate-level (hierarchical) efficiency and local flexibility (networked teams) as it grows in scale and complexity while maintaining its basic capability to create value.

The implications of the above trends for organizations have led to a proliferation of adjectives applied primarily to enterprises—among others, the agile enterprise, networked organization, virtual company, extended enterprise, ascendant organization (Wickens, 1998), knowledge enterprise (Nonaka & Takeuchi, 1995), learning organization (Senge, 1990), ambidextrous organization (O'Reilly & Tushman, 2004). The definitions all have their nuances, deriving from the emphasis on one or another combination of the aspects above. Ultimately, however, they all point to the need to respond to the changing landscape of the digital economy in dynamic and innovative ways.

Within the European Commission's research program Information Society Technologies (IST, 2002), the term "smart organization" was coined for organizations that are knowledge-driven, internetworked, and dynamically adaptive to new organizational forms and practices, learning as well as agile in their ability to create and exploit the opportunities offered in the digital age. Smart organizations involve more than the capability of setting up and exploiting a digital infrastructure or the ability to enter into a virtual collaboration with other partner organizations (Filos & Banahan, 2001b).

The Three Networking Dimensions of Smart Organizations

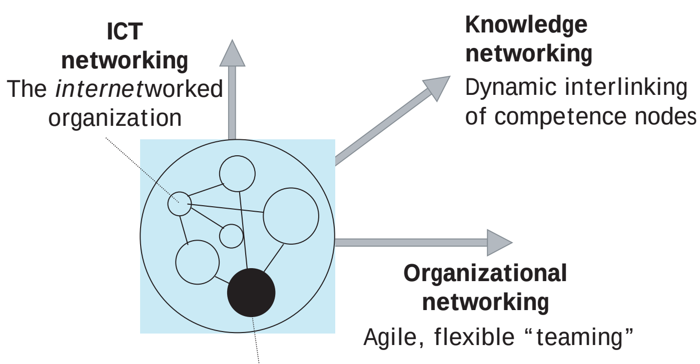
Smart organizations are networked in three dimensions: the ICT dimension, the organizational dimension, and the knowledge dimension (see Figure 2).

Networking at the ICT level enables organizations to move into extended or virtual organizational forms. This may not be enough, though, since the organizational structure and management cultures may need to move beyond steep hierarchies toward leaner business processes organized around flexible cross-functional teams. A further step lies in involving the knowledge dimension into the networking by empowering the individuals in those teams to become dynamically linked to each other and to share information and knowledge (Savage, 1996).

ICT-Enabled Virtuality

Smart organizations have the capability to enter into a virtual collaboration with other organizations. Virtual organizational forms are thus an essential characteristic of smart organizations in the digital age (Filos, 2005).

Figure 2. Smart organizations are networked in three dimensions (Filos & Banahan, 2001a)



While in the past the aim for organizations was to integrate the supply chain as tightly as possible, the focus is now shifting from vertical integration toward internetworked organizational forms. One characteristic is a focus on "core business", while noncore activities are "outsourced" over the Internet and through e-business exchanges to partners that may have the capability to perform specific tasks better or more cost-effectively.

Organizational Teaming

For businesses, large and small, collaborative partnerships have become central to competitive success in fast-changing global markets. Since many of the skills and resources essential to an organization's competence lie outside its boundaries, and outside management's direct control, partnerships are no longer an option but a necessity. Organizations today have to be "smart" in their ability to conceive, shape, and sustain a wide variety of collaborative partnerships. Hence the challenge: The "capacity to collaborate" becomes a core competence of an organization.

Collaborative partnerships are held together because of the added value they offer. Organizations that enter into a cooperation with others do so because of a variety of strategic goals they may pursue (Doz & Hamel, 1998). These can be:

- Resource optimization (sharing investment with regard to infrastructure, R&D, market knowledge and the sharing of risks, while maintaining the focus on one's own core competences)
- Creation of synergies, by bundling complementary competences and by offering customers a solution rather than a mere product or a service
- Attaining critical mass in terms of capital investment, shared markets, and customers
- Achieving increased benefits in terms of shorter time-to-market, higher quality, with less investment

Goldman, Nagel, and Preiss (1995) have described four strategic dimensions of agile behavior that are crucial to smart organizations. These are customer focus, commitment to intra- and inter-organizational collaboration, organizing to master change and uncertainty, and leveraging the impact of people (entrepreneurial culture) and knowledge (intellectual capital).

Knowledge Hyperlinking

Nonaka and Takeuchi (1995) see as a basic precondition for the growth of organizational knowledge the creation of a "hyper-text" organization, which is made up of three interconnected layers or contexts, such as the business system, the project teams, and the (corporate) knowledge base. The key characteristic of the knowledge-creating company is this capability to shift contexts. The bureaucratic structure efficiently implements, exploits, and accumulates new knowledge through internalization and combination. Project teams generate (via externalization) conceptual and (via socialization) synthesized knowledge. The efficiency and stability of the bureaucracy is combined in this model with the effectiveness and dynamism of the project team. But, according to Nonaka and Takeuchi, these two elements are not sufficient without the third context, the knowledge base, which serves as a "clearinghouse" for new knowledge to be generated inside both the enterprise and the project team contexts.

This hyperlinked organization has the organizational capability to convert knowledge from outside the organization by being an open system that features also continuous and dynamic knowledge interaction with partners outside the organization.

With the evolution of new organizational forms, such as networks, communities, and partnerships, the focus shifts from an ICT-centered to a human-centered perspective of knowledge management (KM). The knowledge sharing process is driven by people who work in a community that shares common interests and objectives. Evans and Roth (2004) elaborate on the basic premises and working principles of collaborative knowledge networks, which link communities together by providing a technical and social infrastructure for collaboration and knowledge management. Organizations that have implemented such environments report significant benefits in terms of knowledge transfer efficiency, response time, and innovation (Deloitte, 2002).

Lessons Learned from the Science of Complexity

The digital age is characterized by uncertainty and unpredictability, and organizations have to cope with it. This factor is radically changing the ways in which organizations relate to each other, and to the individuals who provide their core competence, and to their environment.

Sustainable innovation is the result of persistent disequilibrium between chaos and order. The internetworked economy resembles an ecology of organisms, interlinked and coevolving, constantly in flux, deeply tangled, ever expanding at its edges.

In their book The Complexity Advantage, Kelly and Allison (1999) discuss how six concepts derived from complexity science can be applied to business:

- In nonlinear dynamics, small differences at the start may lead to vastly different results. The so-called "butterfly effect" may prove valuable for business, particularly at turning points, such as the launch of a new product, the starting of a new division or investment in a new line of research.
- An open system is one in which the boundaries permit interaction with the environment. A good example for this is the living cell in a biological organism. Many organizations seem only partially open. Businesses, teams, leaders often shut out certain kinds of information and are open only to information that matches the way in which they see the world. However, it is critical for business organizations to also see the changing nature of their customers, markets, and competition in order to be able to offer genuine value.
- A feedback loop is simply a series of actions, each of which builds on the results of prior action and loops back in a circle to affect the original state. The final action either reinforces or changes the direction of the status quo. For example, although innovation is an important aspect of business success, an amplifying feedback loop might exaggerate the amount of innovation to the point at which nothing is ever produced or brought to the market. It is essential to identify such amplification and counterbalance it. Feedback loops, whether functional or dysfunctional, are a key part of the self-organization that emerges in all business.
- Fractal structures are those in which the nested parts of a system are shaped into the same patterns as the whole. Fractals do not define quantity but quality. This self-similarity applied to organizations can make them agile and responsive. For example, in an organization in which self-similarity of values and processes has emerged at all levels and in all geographic areas, effective teams can be assembled very quickly to take advantage of sudden opportunities or handle unexpected threats.
- In evolutionary theory, those species survive that are most capable of adapting to the environment as it changes over time. In rapidly changing global markets, the actions of one player trigger actions and reactions

of other players whose actions feed back on the actions of the former. This coevolution is the reason why companies today must run as fast as they can just to maintain their current position.

- Group self-organization enables a unity to emerge from individual diversity. Like individuals, work teams and organizations too can develop behavioral patterns.

Organizational Ecosystems

Like complex organisms, smart organizations have a "nervous system" which enables them to thrive on chaos and to guide them through turbulent times. Organizational nervous systems provide the functions of sensing and learning, communications—internal and external—coordination, and memory. In fast-moving, unpredictable digital environments, "nervous system" functions are essential to provide the organization with anticipatory, filtering, empathic, learning, and adaptive capabilities in real time (Por, 2000).

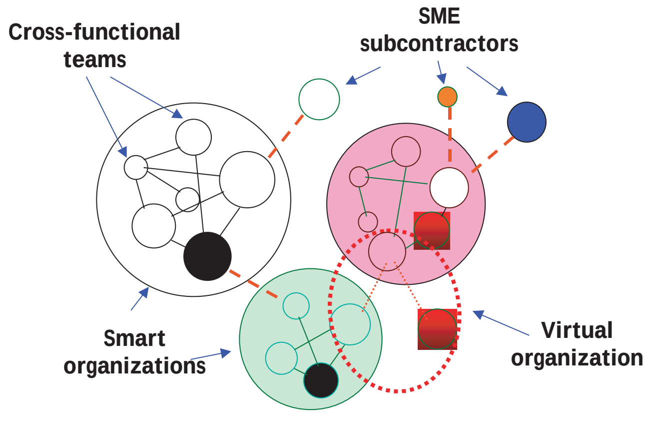
Second, economic activity is fractal, in that it shows the same structure and obeys the same rules for creating value at the level of the economy, the organization, and the individual. Therefore, smart organizations will need to be adaptive to their economic environment—that is, open with permeable boundaries, operating at the edge of chaos (Warnecke, 1992; Davis & Meyer, 1998).

Third, the fittest will survive. Smart organizations become fit through variety and diversity of thought, old and new ideas, that breed innovation. Cross-functional, multidisciplinary teams capable of creativity are an essential element to this. Combined with openness, through ideas from the market and interorganizational exchanges, organizational fitness grows.

Fourth, by being big and small at the same time. The essence of ecosystems is the balance between big and small organisms dependent on one another. Likewise, smart organizations must be big to afford large-scale investments, but they also must be small, nimble, unified around a purpose, and capable of paying attention to the details of important relationships (ecosystems of smart organizations, see Figure 3).

The smart organizations depicted in Figure 3 are composed of teams (dots) that are linked via ICT-enabled business processes between individuals and teams inside or outside the organization (connecting lines).

Figure 3. Ecosystem of smart organizations



MANAGING THE SMART ORGANIZATION

Organizations in the digital age, unlike industrial age ones, will not seek to control their environments. Rather, they will adapt to them, since they recognize that any attempt to control would at best fail, and at worst stifle the creativity and imagination necessary to support innovation. In a globally networked economy, participants are free to focus and re-focus their commitment as they see fit. With this in mind, management style is evolving from one, which used to place emphasis on planning, organizing, and controlling, to one, which emphasizes providing vision, motivation, and inspiration (Kostner, 1996).

Also, in the internetworked economy, the roles of "superior" and "subordinate" are becoming blurred and management becomes fuzzy—that is, more laid-back, less controlling, and trust-based (Filos & Banahan, 2001a).

A bureaucracy is an efficient organizational scheme for tackling recurring tasks in a sequential way. Its static structure guarantees stability and reliability. However, team-based (networked) organizations are better able to handle tasks that are nonroutine and which demand a high degree of flexibility and adaptability. They are also able to link expertise that is distributed throughout the organization. The flexible structure of teams thus guarantees a dynamic and competent response to ad hoc tasks (Figure 4).

The organization of work in the internetworked economy is shifting from stable, physically co-located functions to dynamic, competence-based virtual teams that create value by synthesizing information across geographical and organizational boundaries. As a consequence to this, organizational culture and management change as well.

The Self-Organizing Distributed Team

The face of work is changing, too. As the business world becomes more complex due to demands for flexibility and shorter response times, the nature of work has to keep pace with organizational change. Work in smart organizations is therefore marked by concurrent work practices, flexible and versatile teamwork, and creativity and intelligent use of ICT (Figure 5).

A virtual organization is a collection of geographically distributed, functionally, and/or

Figure 4. Organizational culture of the industrial vs. the digital age

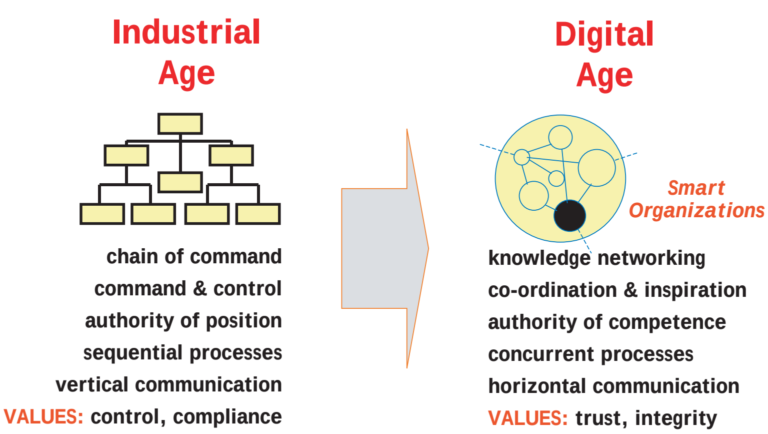


Figure 5. The evolution of collaborative work and the impact of organizational forms

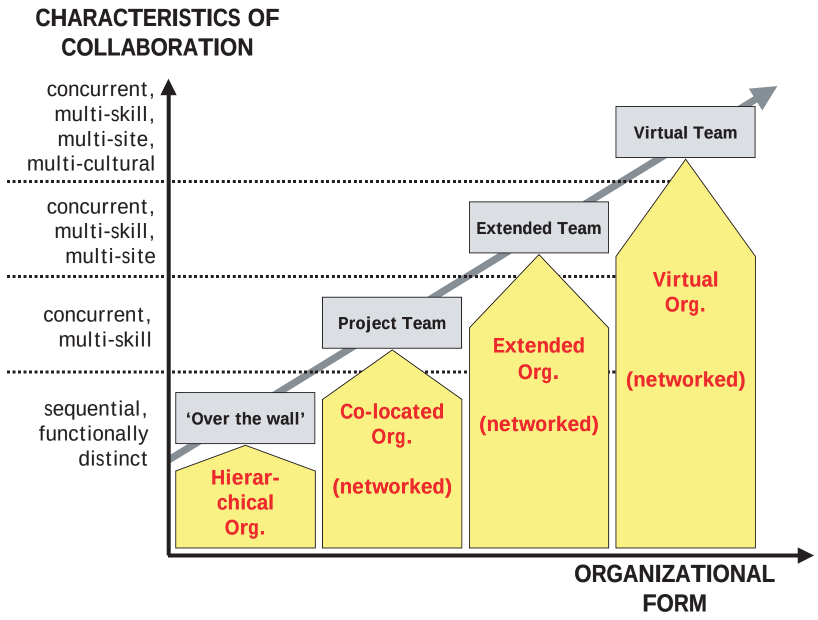


culturally diverse entities that are linked through ICT and rely on lateral, dynamic relationships for coordination (Camarinha-Matos & Afsarmanesh, 1999; Filos & Ouzounis, 2003). Despite its diffuse nature, a common identity holds the organization together in the minds of its constituents. The virtual organization is managed via teams consisting of geographically dispersed employees, forming a "company without walls," a collaborative network of people working together, regardless of location or who "owns" them (DeSanctis & Monge, 1998). A major distinction between virtual and other organizational models consists in that the former are networked (via ICT), transcend organizational boundaries (Grabowski & Roberts 1998), and should therefore be viewed as metaphors of organization design that is held together, literally, by communication.

A virtual team is defined as a temporary, culturally, and/or functionally diverse, geographically dispersed, ICT-mediated communicating work group (Jarvenpaa & Leidner, 1998). As virtual teamwork is fast becoming a dominant way of working with many organizations, successful management of virtual teams constitutes a key component to managing virtual organizations. As virtual teams are made up of individuals with human needs for belonging, communicating, and togetherness, a radically new approach to and interdisciplinary understanding of virtual team management is required in order to harness the benefits and to develop the potential of this new socioeconomic paradigm.

Virtual Team Communication

When individuals are working together toward a common goal, the success of their undertaking depends, to a large extent, on the information exchanged, which is heavily dependent on the quality of communication between those involved. As communication between human beings involves far more than merely an exchange of information at a rational level, factors such as the emotional atmosphere, the social and cultural context, as well as nonverbal aspects may not be neglected. Contrary to earlier reservations, computer-mediated communication needs do not necessarily have a reductionistic impact on team work, but may rather contribute to "revolutionizing" its potential (Lipnack & Stamps, 1997; Devine & Filos, 2001).

In the traditional team environment, in which individuals are colocated, communication happens via conventional means, such as oral or written forms of interpersonal discourse. While written communication is almost exclusively perceived as formal and legally binding, oral communication is differentiated according to the informational settings (formal meetings or informal social events) in which it is embedded.

On the other hand, communication between individuals of remote teams has to rely almost exclusively on ICT. The distinction between the oral and the written, and with it the distinction between formal and informal discourse, may become blurred. Ong (1982) thus speaks of the "secondary orality" of the digital age. As a result, other distinctive features are likely to become important, such as ease of use, interactivity (which allows the user to feel involved), and even the noninteractivity of asynchronous communication tools (e.g., e-mail).

The Impact of Organizational Culture

The very technologies that offer individuals the freedom to work anytime and anywhere may also fray the ties that bind organization members to each other and to their employer. In particular, the cues that pull team members together in traditional organizational settings include dress codes, shared language, shared organizational culture (e.g., routines and processes), office buildings, and colocation. Consequently, since all these factors are less readily available and less indicative of meaning in the virtual context, the links between virtual team members may be less tangible, and thus more social and psychological in nature. Wiesenfeld, Raghuram, and Garud (1998), in their study on the effects of different communication media on the organizational identification of virtual workers, found that electronic media are particularly important to maintaining organizational identification due to the strong correlation of the frequency of use with it, whereas face-to-face contact may be more critical for creating it. Research on new organizational forms needs to consider the "system of work" and the "system of meaning." the institutional facets of the organization, specifically the values attached to the work engaged in (Scott, 1991). Organizational identification is a part of the larger construct that has to do with the creation and preservation of the "system of meaning" in new work forms.

Trust in the Virtual Context

Handy remarks (1995) that virtual teams are run on trust rather than on control. Indeed, the effective coordination and management of the virtual team seem to pose a real challenge. Although team cohesion may suffer from a lack of immediacy in team members' interactions due to geographical dispersion, divergence of expertise levels, or a socio-organizational heterogeneity, research results suggest that in cross-cultural virtual teams, trust takes on a form of "swift trust" that is based on clear role divisions among members who have well-defined specializations (Jarvenpaa & Leidner, 1998). Communication mediated by ICT provides the virtual platform for an informal and open sharing of thoughts, expectations, assumptions, and values. It offers an opportunity to form alliances of collective responsibility that may be different from the formal hierarchies of management relationships within the parent organizations. The virtual context may thus prove advantageous in providing clarification, sense making, and motivation for the individuals involved. This way, the value of team members' contributions is recognized and used better for the good of the community. In the end, high levels of virtually enabled trust, established between team members, may pioneer a strengthening of links between the member organizations partaking in a virtual collaboration (Grabowski & Roberts, 1998).

Leadership Conventions

Virtual teams enjoy the freedom to define for themselves the management and task assignment schemes that best suit their specific situation. Indeed, each team can build its own project culture, which can be tailored to its needs and goals, and it is certainly less "bureaucratic" than the culture in team members' organizations. Since the virtual context requires lateral communication and active involvement from each individual, it undeniably demonstrates a flat organizational structure, participatory management practices, and novel schemes of shared responsibility (e.g., management tasks performed in rotation).

In traditional teams, the focus on the team leader's role is prone to downgrade the position of the other team members. In that context, the most senior, most experienced, member is appointed as team leader. This hierarchical management scheme, as well as the assumption that teams require a single leader, is called into question in the virtual context, as teams here benefit from having different types of leaders performing complementary tasks, depending on project stage. In the virtual team, each member is empowered and responsibility is shared. Also, since there is no one person or institution to which all team members are accountable, penalties for noncompliance to the rules are imposed by the team members themselves (Jarvenpaa & Shaw, 1998).

Coping with Overabundant Information

In the digital age, the great problem may turn out not to be lack of information access but rather an overabundance of information. As Herbert Simon said, "the wealth of information creates a poverty of attention" (Shapiro & Varian, 1999). Even as passive partakers in the Information Society, people unconsciously become active contributors to this surplus of information. This is because ICT can make people vulnerable to accessing more information than they can "digest," and this can amount to a threatening drawback for organizational efficiency. Smart organizations will therefore need to manage relationships on the basis of techniques that help win the attention of people.

Weiser and Brown (1998) use human optical vision as an analogy to explain information overload and discuss possibilities to avoid it. ICT through their ubiquitous and voluminous provision of information, must engage a richer periphery. In trying to catch up with an increasing "volume of bits," users may be helplessly overwhelmed. The tools developed and used need to engage the periphery as well as the center. A balanced view must be sought continuously.

Nurturing the Knowledge Process

Managing knowledge is a core competence of the "smart" organization. In the digital economy knowledge becomes the primary raw material and result of economic activity.

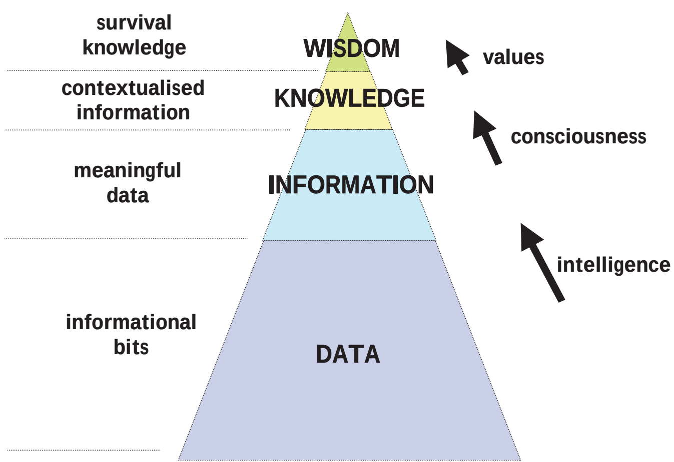
The initial challenge in moving toward organizational smartness, and in order to leverage the power of knowledge, one must know where to find it and once found, know what to do with it. Knowledge can be either explicit or tacit (Polanyi, 1966). In the case of the former, knowledge is formal and systematic and thus easy to capture, store, and communicate. Tacit knowledge on the other hand is personal, a combination of experience and intuition, and as such the organization's ability to capture and communicate it is heavily dependent on the individual owner's commitment to the organization and to its need to generate value from it. In this sense, a great deal of trust and loyalty between the individual and the organization is necessary to leverage organizational knowledge, including its tacit dimension.

It is therefore essential to make a proper distinction between the terms "data," "information," and "knowledge" (Figure 6). The interchangeable use of "information" and "knowledge" tends to obscure the fact that while it can be easy and quick to transfer information from one place to another, it may often involve a very difficult and slow process to transfer knowledge. Knowledge is a human capability that can be acquired and expanded through learning. In trying to define knowledge it can be helpful to realize that the human mind is considered capable of two kinds of knowledge, the rational and the intuitive.

In Western thinking, intuitive knowledge has been devalued in favor of rational scientific knowledge. In Eastern thinking however, the tradition has been to recognize the importance of the intuitive. Chinese philosophy has emphasized the complementary nature of the intuitive and the rational and has represented them by the archetypal pair yin and yang.

Recognition of the difficulties inherent in transferring knowledge from one person to another has tended to highlight the importance of tacit knowledge. This heuristic, subjective, and internalized knowledge is not easy to communicate and is learned through practical examples, experience, and practice. Where explicit, articulate knowledge may be stored in the form of a patent or as documented know-how, tacit, nonarticulate knowledge is communicated in social networks, or know-who. Debates over the meaning of knowledge are ongoing, and do not seem likely to end for some time to come. Similarly, there is no agreed definition of knowledge management. The term is used loosely to refer to a broad collection of organizational practices and approaches related to generating, capturing disseminating know-how, and other content relevant to an organization's business. Knowledge is thus not an explicit, tangible "thing", but information combined with experience, context, interpretation, and reflection. Also, knowledge involves the full person, integrating the elements of both thinking and feeling. Knowledge management is thus increasingly seen as signaling the development of a more organic and holistic way of understanding and exploiting the role of knowledge in the process of managing and doing work, and an authentic guide for individuals, teams, and organizations in

Figure 6. The knowledge pyramid: A tentative approach to explaining "slippery" terms



coping with the increasing complexity of modern business environments.

Stewart (1998) uses the term "intellectual capital" to denote intellectual material—knowledge, information, intellectual property, experience—that can be put to use to create wealth. Intellectual capital is to be seen as an asset for every organization residing in its people (human capital), its structures (structural capital), and its customers (customer capital).

Achieving and Maintaining a High Level of Creativity

Smart organizations embody cross-functional, multidisciplinary teams. Their creativity is based on knowledge networking within and across the organization's boundaries. This openness to ideas drives the creativity of the whole organization.

As Toffler (1981) illustrates, the distinction between producer and consumer diminishes as consumers begin to play an important role, such as in the development or the further improvement of a product. Mass customization enables smart organizations to see customers, suppliers, regulators, and even competitors as stakeholders with meaningful contributions.

Redundancy Frameworks

Building redundancy is a way to support creative teams. Redundancy comes from intensive communication on a common cognitive ground and the facilitation of tacit knowledge transfer. While team members share "overlapping" information, they can sense what others are struggling to articulate.

One way to achieve redundancy is to organize teams in competition with each other. In one sense, such internal competition is wasteful. However, when responsibilities are shared, information proliferates, and the organization's ability to develop and implement efficient concepts is accelerated.

Another way to enable redundancy is through rotation, especially between different functions such as R&D and marketing. Rotation helps employees understand the business from a multiplicity of perspectives. Changing roles and responsibilities helps create and maintain team spirit and commitment to the team objectives, but most importantly, it may drive innovation within the team, as a result of augmented lateral thinking and knowledge sharing.

Active Knowledge Sharing

Metes, Gundry, and Bradish (1997) propose a computer-mediated approach to facilitating knowledge management and creativity of distributed teams. The tool they propose is computer conferencing, also known as "chat" tool. They argue that in contrast to teams using the telephone, fax, e-mail, or audio and video conferencing, teams that use computer conferencing create a permanent shared record of their communication. This is specifically important because information is transmitted in its proper contextual setting, including situations, relationships, assumptions, expectations, and history. Adding context to information transforms it into knowledge (see Figure 6).

Investments in intellectual assets, unlike investments in physical assets, increase in value with use. Properly stimulated, knowledge and intellect grow exponentially when shared. If two people exchange knowledge with each other, both gain information and experience. And if both then share their new knowledge with others—each of whom feeds back questions, suggestions, and modifications—the benefits can grow exponentially. Once an organization gains a knowledge-based competitive edge, it becomes ever easier for it to maintain its lead and ever harder for competitors to catch up.

Professional intellect (Nonaka & Takeuchi, 1995) of an organization operates on four levels:

- Cognitive knowledge (know-what), the basic mastery of a discipline, achieved through extensive training and certification.
- Advanced skills (know-how), the ability to apply the rules of a discipline to complex, real-world problems.
- Systems understanding (know-why), a deep knowledge of the interlinked cause-and-effect relationships underlying a discipline.
- Self-motivated creativity (care-why), which consists of will, motivation, and adaptability for success. Here lies the reason why highly motivated creative teams often outperform teams with greater physical or financial resources. This level depends on the organizational culture.

The value of professional intellect increases when moving up the intellectual scale from cognitive knowledge to self-motivated creativity. Unfortunately, most organizations focus their training efforts on developing basic skills and only very few invest in developing systems and creative skills.

RESEARCH ON THE SMART ORGANIZATION

Research and development (R&D) has contributed substantially to the emergence of smart organizations. In Europe for example, successive research framework programs in the last 12 years have supported the development of technologies that facilitated electronic commerce and digital business. In the early 1990s, research focused on concurrent engineering (Fan & Filos, 1999), on computer-supported collaborative work and product and process data modeling. The work program of the European Strategic Program in Information Technologies (ESPRIT,1997), in the domains high-performance computing and networking, technologies for business processes, and integration in manufacturing supported R&D relevant to the virtual enterprise. Between 1994 and 1998, more than 50 industry-led projects were set up with around 100 million-Euro funding (shared cost funding with 50% industrial contribution). In addition to regular consultations with industry, a number of projects were established which brought together major industrial users of information technology (IT) and the vendor community. The common aim of these projects was to set long-term research targets for the IT industry in order to meet well-formulated industrial needs. The Advanced Information Technology initiative, for example, dealt with the automotive and aerospace industries (AIT, 2001). It comprised 22 R&D projects that also had a major impact on standardization developments. All these projects were operating concurrently within a harmonization framework (Garas & Naccari, 2001). Forty percent of organizations participating in ESPRIT were industrial user enterprises. In total, 65% of participants in ESPRIT were industrial companies. Until 1999, R&D support for the "virtual enterprise" in Europe was mainly through ESPRIT and its international cooperation activities under the Intelligent Manufacturing Systems (IMS, 2005) framework.

In 1999, the Information Society Technologies program (IST, 1999) emerged as an integrated program from previous programs ESPRIT, Advanced Communications Technologies and Systems (ACTS, 1998), and Telematics (TAP, 1998). In the work program of IST, the perspective had changed from "virtual enterprise" to any type of "virtual organization". Under the new program's Key Action II (New Methods of Work and Electronic Commerce), several calls for collaborative research proposals were launched under topics such as "dynamic networked organizations", "smart organizations", and "dynamic value constellations". In parallel, research in learning and cognition had led to the introduction of a new research field, "organizational knowledge management".

All these R&D efforts have contributed to a strong research foundation for the development of smart organizations in Europe (Filos & Ouzounis, 2003; Wagner et al., 2004).

Research on the Virtual Organization

In parallel to these European research activities, research relevant to the virtual organization in the United States was undertaken mainly under defense contracts funded by the Defense Advanced Research Projects Agency (DARPA) and through grants of the National Institute for Standards and Testing and the National Science Foundation (Goranson, 1999).

Between 1999 and 2002, under the European IST program, more than 200 R&D projects were launched on organizations research and on research in e-business and e-work, with a total funding of about 450 million Euro. These fall into three subareas: ICT; work, business and organizational aspects; and socioeconomic issues (Zobel & Filos, 2002; Filos, 2005; Camarinha-Matos et al., 2005).

ICT Aspects of Virtual Organizations

The part of the project portfolio dealing with activities related to the design and development of generic infrastructures to support collaborative business in a networked environment involved issues such as safe communications, interoperability and tools integration, information and knowledge sharing, repositories, coordination mechanisms, and collaborative environments. These projects worked towards the emergence of a general "plug-and-do-business" architecture for interoperability (Bacquet & Naccari, 2002; Doumeingts & Chen, 2003). Project GLOBEMEN aimed at creating an IT infrastructure to support globally distributed and dynamically networked operations in one-of-a-kind industries (Karvonen et al., 2003), COMMA and BUSINESS ARCHITECT made extensive use of modeling and knowledge sharing to support virtual enterprise process integration.

As far as the characteristics and requirements regarding interoperability and information exchange are concerned, innovative approaches were required. Interoperability was to become a "design principle" while aiming to preserve the diversity, autonomy, and heterogeneity of components and environments. For example, project ECOLNET sought to validate different business strategies for independent small- and medium-sized enterprises (SME) focusing on their national market, E-COLLEG investigated an infrastructure to establish a backbone for collaborative engineering (Witczynski & Pawlak, 2002), CO-OPERATE focused on coordination of manufacturing, planning, and control activities in supply chain management, and WHALES developed a planning and management infrastructure for distributed organizations working as networks on large-scale engineering projects.

The projects portfolio was strong in demonstrating the feasibility of operating the virtual organization. The technologies used involved the Java framework, CORBA, XML, Web services, multi-agents, and modeling tools based on UML. The general aim was to use standards whenever possible. This aspect is particularly clear with respect to de facto standards being proposed by industry groups such as the Object Management Group, the Workflow Management Coalition, the World Wide Web Consortium (W3C), and the UN Center for Trade Facilitation and Electronic Business (ebXML).

The significance of virtual organization modeling and interoperability of applications arose from the need to model the virtual organization as a means to properly understand and manage it. A problem with existing business process modelers lies in how to translate one model based on one proprietary modeling technique into an equivalent model represented by another. One strategy pursued in Europe was in agreeing on a basic language that makes such transformations possible. Consensus was reached and the Unified Enterprise Modeling Language was defined (UEML, 2004).

Some projects dealt with ontologies, conceptual information models that describe things that exist in a domain, whose purpose was

- To support human understanding and organizational communication.
- To be machine-processable and thus facilitate content-based access, and communication, and integration across different information systems.

A decade of international research has led to the creation of ontology languages, editors, reasoning techniques, and development guidelines. Various languages for ontology specification and implementation are now available. These languages have built-in reasoning techniques, and they also allow developing special purpose reasoning services.

An area of impact is the Semantic Web, in which computers "find the meaning" of data in automated Web services such as functional agents. The DARPA Agent Markup Language (DAML) and the Ontology Inference Layer (OIL) that was developed by the World Wide Web Consortium and the European OIL community (W3C, 2001), provide a rich set of constructs with which to create ontologies and to mark up information so that it becomes machine-readable. A significant number of European projects addressed knowledge technologies in the context of the virtual organization and business collaboration (Filos, 2002).

Work, Business, and Organizational Issues

This subarea involved reference models and architectures,such as the specification of logical reference architectures for new and emerging cooperative organizations by identifying the main functional blocks, interactions, actors and their roles, resources, and value systems, as well as the definition and the characterization of collaborative business models, the forms of cooperation in networked environments and means to assess the effectiveness of virtual organizations. Work involved virtual organization reference models, collaborative business models (and related case studies), cooperation methodologies and performance measurement. The projects addressed centralized support services as well as services that are distributed across the virtual organization (Hartel, Sonderegger, Kamio, & Zhou, 2002; Kazi, Hannus, & Ollus, 2002; Katzy & Sung, 2003).

Some projects addressed business functions of the various parts of the life cycle of a virtual organization. Research activities included partner registration and search, marketplace management, e-procurement and negotiation, distributed business process planning and management, and so forth, with a particular focus on domain-independent services covering the various phases of the life cycle of a virtual organization. They also comprised supervision and monitoring, as well as specialized services, such as contract modeling and negotiation, a support infrastructure to help virtual enterprises to address the legal issues involved, as well as a Web-based infrastructure for alternative online dispute resolution for SME (Gouimenou, 2001).

Through its IST program, the European Commission also supported a range of projects that aimed to accelerate e-business technology take-up in SME. The concept behind these projects was to transfer leading-edge technologies to industry and other end-users. Under Key Action II, between 1998 and 2002, more than 70 take-up projects were launched, which demonstrated the relevance of e-business, e-commerce, and e-work technologies for SME. Hundreds of SME throughout Europe participated together with so-called "catalysts"—local or regional organizations that worked with them to help them adapt their business processes toward better ICT use. The SME were able to "rethink" and adapt emerging technologies to their business needs by sharing development effort and jointly achieved results among one another. These take-up projects thus became a means to leverage the results of IST research and to contribute to the implementation of the European Commission's eEurope (2005) initiative at local level, by supporting SME directly or indirectly.

The 70 million Euro invested in this take-up project's pilot activity represent only a small fraction of the total European investment in e-business. They were essential, however, in demonstrating that investment in R&D and technology transfer can be a useful instrument to help increase SME competitiveness in today's global market places. Twenty-two showcases are presented in a book (eBiz, 2003). They complement European Member States' efforts, such as those under the GoDigital initiative (2002).

The Socioeconomic Perspective

Between 1999 and 2002, socioeconomic research within IST was a significant nontechnological research activity that aimed at complementing technology activities. It was implemented through a series of calls for proposals. The primary scope of this research was in methods and tools and in understanding the impact of ICT on the economy and on society at large. The main beneficiaries were the program's research community, industry, and policy makers (Hayfa & Filos, 2003). More than 40 projects addressed socio-organizational or socioeconomic issues: industrial and organizational aspects of the digital economy (e-business, e-work), as well as societal aspects; e-business models and intangible assets; impact assessment, mainly at microlevel; corporate social responsibility; statistical indicators. Also, a number of key legal and regulatory issues emerged as a result of this research activity. Some of them were explicitly addressed; for example, legal aspects of virtual enterprises, contract law (intra-/inter-organizational or that of individuals), alternative dispute resolution, digital rights management, intellectual property rights, consumer protection, and related legal aspects (Merz et al., 2001; Hassan, Carter, Seddon, & Mangini, 2001; Van Schoubroeck, Cousy, Droshout, & Windey, 2001; Carter, 2002). All these activities contributed to the definition of a virtual organizations framework (Camarinha-Matos et al., 2004).

Research in Knowledge Management

The European Commission has supported research in knowledge management since the late 1980s, long before knowledge management itself was a recognized term. Early contributions were made in areas such as information management, quality management, and the social sciences. The first formal initiative was launched in 1998 under the research theme "Learning and Training in Industry" (LTI), as part of the ESPRIT program. Under the LTI initiative 16 research projects were launched involving more than 100 research and user organizations. Although the situation has evolved considerably since then, many current projects have their roots in this initial incursion into the realities of organizational learning.

As knowledge management concepts and practices caught the attention of organizations across Europe, European-funded research moved squarely toward supporting the development of solutions that enable individuals to share knowledge within and among organizations as part of the innovation process. The main focus of research has been on supporting multidisciplinary solutions and practices for individuals and corporations to manage knowledge within networked organizations and communities of practice. Specifically, this included aspects such as:

- Integrated ICT platforms, including mobile, to manage the full lifecycle of knowledge (i.e., its capture, organization, maintenance, mining, sharing and trading) in support of both intra- and inter-organizational activities

- Personalized, context-, task- and role-sensitive functionality for the dynamic provision and sharing of timely and relevant knowledge.
- Solutions to organize and exploit heterogeneous, unstructured information sources, using ontologies, self-organization paradigms as well as semantic cross-lingual search, in support of e-work and e-commerce applications.
- Tools and environments for knowledge sharing, collaboration, and socialization within and among organizations which build on methodologies from areas such as organizational behavior, cognitive psychology, human factors, man-machine dialogue, as well as social and management sciences.

The research activities focused not just on technology development but also on its application. In addition to R&D projects, the European Commission also funded a variety of take-up and

Table 1. Knowledge management research in the IST (2002) program

Projects funded under the IST Program reflect a broad spectrum of KM approaches and theories. They can be classified broadly as follows:

First Generation KM

Information portals - tools and methodologies integrating to a greater or lesser extent information necessary for back and front office processes in organizations. These projects mainly originated from the first call for proposals in IST (1999).

Second Generation KM

Knowledge processes to business processes - tools and methodologies linking knowledge and business processes;

Assessment or measurement-type projects - which attempt to measure and benchmark knowledge management implementation within and between organizations and to manage and measure impact of knowledge lifecycles within the enterprise;

Collaboration and innovation spaces - tools, methodologies and good practices to accelerate creative exchanges between people working within and across organizations. The end objective of such projects is to support the transition of organizations into knowledge-based communities.

Third Generation KM

Knowledge and innovation ecologies - tools, methodologies and good practices which identify contextual barriers and enablers of absorptive and innovative capacities of organizations and attempt to replicate co-creation abilities across the enterprise or network;

Human-centered knowledge management - focus on people as unique holders of knowledge, and exchanges between people as primary generators of new knowledge for innovation.

Networks and working groups - which attempt to build critical mass within and outside the IST program.

support activities designed to help make knowledge management better known and accepted notably in small and medium enterprises.

Under the IST program, the "Knowledge Management Made in Europe" (KMME) initiative was launched after the start of the Fifth Framework Program (1999-2002), with an aim to "create a strong brand for European KM research and practice" and to "bring into the portfolio quality proposals". The overall goal of the initiative at the outset was to increase European competitiveness, to improve the working life of European individuals, and to build on European strengths of languages, cultural diversity, and industrial leadership.

One of the major epistemological directions the initiative declared was to pursue the challenge of complexity as a key factor in the knowledge economy, using a holistic approach. The initiative involved 58 research, take-up, and cluster projects with a total public investment of approximately 65 million Euro. Projects funded fell into the three categories outlined in Table 1.

The first category, or first set of projects to be funded, were denoted "first generation KM" (under LTI in 1998) and concentrated on themes and concepts such as information portals, tools and methodologies integrating to a large or lesser extent information necessary for back and front office processes in organizations.

The second wave, from 1999 to 2000, aimed at a more holistic treatment of primarily tacit knowledge in organizations and funded projects with concepts and themes such as linking knowledge processes to business processes, assessing KM implementation and collaboration and innovation spaces.

The third generation KM (2001-2002) represented a movement away from the classical knowledge management engineering approach, and aimed at funding projects with concepts and themes such as knowledge and innovation ecologies and human-centered KM.

One of the most conspicuous and most mentioned projects with the largest international profile is the European Knowledge Management Forum (EKMF), a cluster project which attempted to "build a sustainable network of Knowledge Management theoreticians and practitioners who are interested in Europe's journey into the knowledge economy, and what Knowledge Management methods and tools can contribute to this journey." (KnowledgeBoard, 2005).

An assessment of the KMME initiative (Sage, Stanbridge, & Shelton, 2004) to date shows that projects funded in the first wave are indicating a focus on classical, engineering approaches to knowledge management. This concentration is typical of early projects in knowledge management programs. The same phenomenon was observed in the U.S. in knowledge management research. Many of the projects in the first phase were industry- or sector-specific and helped to solve problems specific to the sector or industry, without addressing issues that were of benefit to different sectors or with impact on the industry value chain.

The second wave marks a shift from the engineering approach to a more centralist, best-practice approach. In the third wave, a significant number of projects were funded that are advanced on the mathematical complexity scale and address concepts such as intelligent agents and the Semantic Web.

However, only a few projects address the area of social complexity, which has high potential for KM that is related to the European context of linguistic and cultural diversity. The subject of complexity is not widely recognized within the KnowledgeBoard community.

The phenomenon of divergence between focus areas in knowledge management research in Europe, and a false dichotomy between human-centered approaches and engineering/mathematical approaches has been observed in the U.S. as well. The opportunity for Europe is to fund and initiate more research that is related to the human-centered approach, but also looks at social complexity.

CONCLUSION

This chapter aimed to draw a picture of the changing organizational paradigm in the digital age. Successive European R&D programs played a significant part in developing the technologies and concepts that are key to those developments. The research efforts aimed at understanding and improving knowledge management, the virtual organization and digital business processes. While many of the features of digital age organizations are not yet fully understood, there is hope that organizations in the future will become "smart" in various respects. The unprecedented opportunities offered by Information Society for individuals to relate with one another, to work, and to do business in digital environments will change the ways organizations relate to each other and to the individuals that are key to their core competences.

Chapter 1.6
Knowledge Sharing

William R. King
University of Pittsburgh, USA

INTRODUCTION

Knowledge sharing (KS) is critical to organizations that wish to use their knowledge as an asset to achieve competitive advantage. Knowledge management systems (KMSs) can be primary enablers of knowledge sharing in an organization.

A major focus of knowledge sharing is on the individual who can explicate, encode, and communicate knowledge to other individuals, groups, and organizations. In particular, the employment of some KMSs requires individuals to contribute their knowledge to a system rather than keeping it to themselves or sharing it only through personal exchanges.

Another major focus of knowledge sharing is on knowledge sharing in teams since teams have become so prominent in management thought and practice, and because some of the long-presumed benefits of teams such as "higher labor productivity, a flatter management structure and reduced employee turnover" have been validated (Glassop, 2002, p. 227).

A major distinction between knowledge sharing and knowledge transfer (terms that may sometimes be used interchangeably) is that transfer implies focus, a clear objective, and unidirectionality, while knowledge may be shared in unintended ways multiple directionally without a specific objective (see article titled "Knowledge Transfer").

Of course, knowledge may also be shared in intended ways, such as when a team attempts to develop mutual knowledge, a common ground, or knowledge that the parties know they share in common (Cramton, 2001).

BACKGROUND

Some people presumably have a tendency to share knowledge just as some people have a tendency to be talkative. Others follow the "knowledge is power" dictum, probably learned in organizational settings; these people may hoard knowledge and be reluctant to share it.

Knowledge sharing may occur between and among individuals, within and among teams, among organizational units, and among organizations. Sharing among individuals within teams is a particularly important focus whether the teams are temporary sets of interdependent individuals bound by a collective aim, problem-solving groups (also usually temporary in nature), self-managing teams, or cross-functional teams (Glassop, 2002). Virtual teams, those in which individuals primarily communicate using electronic means, are becoming a more important focus of KS.

Sharing behavior may be differentiated in terms of the sharing of explicit knowledge (that which is written down or encoded in some fashion) vs. the sharing of tacit knowledge (that which exists in the mind of an individual; Nonaka, 1994), or some combination of the two varieties. Individuals may have different propensities to share explicit and tacit knowledge. They may consider explicit knowledge, such as reports and memos that are in their possession, to be owned by the organization that paid them to produce the documents, whereas they may consider that knowledge that is in their heads belongs to them (Constant, Kiesler, & Sproull, 1994).

Knowledge-management systems of two general varieties are both driven primarily by knowledge sharing. The two types are referred to as repositories and networks, or as the codification and personalization types of KMS strategies (Kankanhalli, Tanudidjaja, Sutanto, & Tan, 2003). Repositories are databases of knowledge usually contributed by individuals, teams, or organizations for potential use by others. The best example is a best-practices repository. Networks facilitate communications among team members or among groups of individuals who are not necessarily identified a priori.

Information technology can enable both types: in the former case, enabling sharing across widely dispersed elements of an organization, and in the latter case, enabling communities of practice involving people who discover that they have common practices or interests to form and share knowledge either within an organization or among various organizations. Probably the best known interorganization community is that which develops and maintains the open-source Linux system (Lee & Cole, 2003).

ISSUES IN KNOWLEDGE SHARING

Organizations have taken different views on knowledge sharing. Some, believing that there is a danger in giving away secrets or viewing sharing as a diversion from individuals' primary work, have not encouraged sharing. Others, believing that there is great potential benefit in disseminating knowledge within an organization and perhaps beyond its boundaries, support it. Of course, the tenets of knowledge management presume that sharing is generally both beneficial and necessary if an organization is to realize its potential.

Many researchers and those organizations and managers that wish to encourage knowledge sharing have focused on how they might best motivate individuals to share their most valuable personally held knowledge. The concept of knowledge as a public good can serve to illustrate this issue.

Knowledge as a Public Good

A fundamental issue of KMS is demonstrated by the notion of knowledge as a public good. A public good is something that is available to all members of a community or organization regardless of whether they contributed to the constitution of the good. A fundamental problem with public goods is that they are subject to the free-rider problem whereby an individual enjoys the benefits without contributing to the institution or maintenance of the common asset, which may result in an undersupply of the good.

Thorn and Connolly (1987) conducted research that conceptualized information in a database as a public good. They identified cost as a factor for individuals considering sharing their valuable personally held information in terms of sharing cost: the time and/or effort that is required from the individual to share knowledge through a computer-based system. They concluded that this cost is something that is considered by the potential sharer when making the decision of whether to contribute.

Constant et al. (1994) identified positive motivators for individuals to contribute, even when the personal costs may be high. These include the enhancement of self-esteem, the reinforcement of an individual's understanding of their own knowledge, and the shared values of organizational citizenship (Bolino & Turnley, 2003).

Goodman and Darr (1999) identified the contextual conditions in the organization affecting an individual's decision to share his or her knowledge through a KMS. They determined that a sharing culture is necessary prior to the implementation of such a system. They also identified shared rewards as an important element in producing such a culture. Such intangible and cultural variables may well constitute the accepted wisdom among KMS practitioners.

Motivating Knowledge Sharing

Organizations generally rely on either formal supervisory controls or more general organizational support to motivate knowledge sharing. Examples of the former are guidelines that specify what is appropriate sharing behavior and the monitoring of the knowledge that individuals provide to a KMS. Illustrative of the latter is the development of cultural norms that promote sharing.

These quite-different views of how knowledge sharing can be motivated are illustrated in studies conducted by Perlow (1998) and Alvesson (1993).

Perlow (1998) studied knowledge workers in a software-development group where the management of the organization instituted a stringent means of controlling the employees. The company imposed strict demands by monitoring employees, standing over them, and routinely checking up on them. Management instituted mandatory meetings, deadlines, and extra work to ensure that the employees were working in the best interest of the firm. This approach is referred to as supervisory control.

Alvesson (1993) performed a case study of a computer consulting company. The study found that management felt that the company operated efficiently because management strove to have a strong interpersonal culture in the organization. This culture was based on focusing on the organization as a community instead of viewing it as merely a collection of individuals. This approach reflects a general approach referred to as social exchange.

Supervisory Control

Organizations can operate in formal ways that encourage knowledge sharing, for example, by using employment contracts that specify that knowledge and information that is collected or generated in the course of work belongs to the organization. However, such legalistic approaches are difficult to enforce.

However, other forms of supervisory control may have an impact on an individual's willingness to share his or her knowledge through a KMS (Loebecke, Van Fenema, & Powell, 1999). Supervisory control is defined as efforts by management to increase the likelihood that individuals will act in ways that will result in the achievement of organizational objectives (Stajkovic & Luthans, 2001).

Supervisory control is important because an assumption in agency theory, and in some other management literature, is that the goals of the employer and the employee are, to some degree, divergent, necessitating a need for control in order to align the goals of the two actors (Flamholtz, 1996). The exact nature of the supervisory-control mechanisms needed to produce goal congruence is unresolved because of the widely varied types of control mechanisms that have been utilized and studied. For example, supervisory-control mechanisms may consist of the use of power, leadership, building clans, or information processing.

Social Exchange

Social-exchange theory posits that people contribute to others commensurate with the contributions that they perceive are being made by others to them. This theory views the contributions that individuals make to an organization as reciprocal arrangements. Reciprocal arrangements occur when an individual performs some type of action for another individual, group, or organization. The action is performed without a specific economic contract that ensures that the action will be repaid. Rather, the individual who performs the action does so because he or she believes that the action will be reciprocated at some future time, though the exact time and nature of the reciprocal act is unknown and unimportant (Turnley, Bolino, Lester, & Bloodgood, 2003).

This exchange relationship develops from a series of mutual exchanges between two actors until such time as a relationship exists whereby mutual exchanges become a normative behavior. Unlike an economic-exchange relationship, in the social-exchange relationship, the potential result of any behavior is based on a trust that the relationship will proceed as in past exchanges (Meyer, Stanley, Herscovitch, & Topolnytsky, 2002).

This relationship of mutual exchange may exist between individuals or between an individual and an organization. Over a period of time, an individual may develop opinions about the exchange relationship between himself or herself and the organization by observing the relationship, the organization, other employees and their relationship with the organization, and individuals who are external to the organization. In this way, employees personify the organization through the actions of their supervisors and coworkers.

Research has demonstrated the relationship between social exchange and positive outcomes in organizations (Allen, Shore, & Griffeth, 2003). Social exchange has been found to be important in exploring why individuals have high feelings of loyalty to their organization. It has also been found to be important in explaining why individuals exhibit positive behaviors in their organizations when these positive behaviors are not formally required (Liao & Chuang, 2004).

Perceived Organizational Support

The emphasis on social exchange from an individual to an organization and vice versa was used by Eisenberger, Huntington, Hutchison, and Sowa (1986) in developing the concept of perceived organizational support (POS) to explain how individuals in organizations can become committed to their organizations. They proposed that "employees develop global beliefs concerning the extent to which the organization values their contributions and cares about their well-being" (p. 501). They developed a reciprocal view of the relationship between employee and employer in which the employee shares a strong level of commitment to his or her organization if he or she perceives that the organization has a strong commitment in return. They surmised that high levels of POS will create a feeling of obligation in the employee, whereby the employee will feel obligated to support organizational goals.

Other research supports this conclusion. Eisenberger, Fasolo, and Davis-LaMastro (1990) showed that POS demonstrated a positive relationship to conscientiousness in the performance of job-related responsibilities and a commitment to making the organization a better place through fostering innovation. Lynch, Eisenberger, and Armeli (1999) found a positive relationship between a high level of POS and a high level of extra-role behaviors, and that the reverse was also true; that is, if there is a low level of POS, there is a low level of extra-role behaviors from individuals in an organization. POS has become a much-used construct in various areas of social science and business (Fuller, Barnett, Hester, & Relyea, 2003).

The Effects of Supervisory Control and Organizational Support

Numerous studies have identified the differences between theories of economics (e.g., supervisory control) and theories of sociology (e.g., organizational support), and their impacts on the achievement of organizational goals. Often, these studies propose that the theories of economics and sociology rely on differing assumptions and therefore cannot be considered to be similar (Adaman & Madra, 2002). In fact, some even contend that the cross-pollination of the disparate theories is inappropriate and should be avoided (e.g., Oleson, 2003).

Modern consideration of rational man as a utility maximizer and social man as a conglomeration of complex motivational forces in an organization trace back to Barnard (1938), who recognized the importance of the "willingness of persons to contribute efforts to the cooperative system" (p. 83). This willingness was considered to be different than the tangible and more easily measurable elements of motivation derived from a supervisory-control system. He emphasized that if individuals in organizations were only concerned with a direct relationship with the structured control system as a means of dictating the exact amount of work that they would accomplish, then the organization would be unable to function. He posited that the helpful behaviors exhibited by employees that are difficult to measure acted as the glue that allowed operations in organizations to run relatively seamlessly.

Katz and Kahn (1966) further developed this idea by distinguishing between in-role behaviors and "innovative and spontaneous behaviors," positing that innovative and spontaneous behaviors make an organization "intrinsically cooperative and interrelated" (p. 339). They proposed that these behaviors are so ingrained in the fabric of the organization that they are seemingly transparent to management and thus are often taken for granted. However, these behaviors ought not to be so taken since much of the work that is accomplished in organizations is difficult for management to specify.

March and Simon (1958) approached organizations from the perspective of social psychology. They acknowledged that individuals make their decisions on much more than purely economic bases and presented propositions that allude to the vast array of influences in an organization that impact the decision-making processes of individuals. Specifically, they focused on the effects that group norms and expectations have on individuals. These norms and expectations are not easily measurable in an economic framework; however, they are important in an organization that is attempting to accomplish specific objectives.

Davis, Schoorman, and Donaldson (1997) contributed to this economics-vs.-sociology discussion by recognizing that viewing individuals as utility maximizers may not account for the complex set of factors that can motivate individuals to accomplish things that do not always seem to directly maximize their utility. They stressed that other motivational elements that are not based on economic assumptions of utility maximization are necessary to account for the motivational elements in individuals and organizations.

FUTURE TRENDS

The issue of how best to motivate individuals to share their most valuable personal knowledge is not completely resolved. The conventional wisdom is that the creation of a knowledge-sharing culture is the best way, although that is not empirically well validated (Goodman & Darr, 1999).

Among the other research findings related to knowledge sharing that appear to have value are the following:

a. Knowledge sharing involves both costs and benefits (not necessarily economic; Constant et al., 1994; Thorn & Connolly, 1987).
b. Contrary to some popular wisdom, supervisory control appears to be more important than perceived organizational support in terms of both the frequency of submissions and the perceived effort expended in contributing to a KMS (King & Marks, in press; since this study was done in a military organization, the results may be limited to similar contexts).
c. Concern with self-interest has a negative effect on sharing-related attitudes (Constant et al., 1994). This might suggest that an organization that creates a highly competitive culture, such as by having the policy of attempting to counsel 10% of the lowest performers out of the organization each year, might have difficulties in motivating knowledge sharing.
d. Dispersed (not colocated) computer-mediated teams have difficulties in knowledge sharing that are greater than those experienced in colocated teams in part because of the difficulties in establishing social presence—the degree to which the medium facilitates the awareness of other people and the development of interpersonal relationships (Cramton, 2001).
e. Systems variables, such as use and usefulness, appear to have important moderating effects on individuals' sharing behavior through a KMS (King & Marks, in press).

CONCLUSION

Economic, behavioral, and social factors must be considered when assessing the issue of how to motivate individuals to contribute their most valuable personally held knowledge to others who they may not even know, as in contributing to a KMS.

Most interest and research in knowledge sharing has focused on this supply-side issue: that is, how to motivate people to share. However, some researchers have focused on the demand side: individuals' knowledge-seeking and knowledge-acquisition behavior. This perspective addresses potential users of knowledge and how they search for it when they have a question or problem. Expert networks have been established in organizations such as Microsoft to enable such search, and of course, communities of practice also facilitate this demand-side viewpoint of sharing.

Chapter 1.7
Knowledge Management on the Web

Ruidong Zhang
University of Wisconsin-Eau Claire, USA

INTRODUCTION

The importance of knowledge management has been recognized both in academia and in practice. In recent years, corporations have started talking about knowledge management, organizational learning, organizational memory, and computerized support. A few years ago, Microsoft®'s awareness of knowledge management and corporate memory was demonstrated by Bill Gates through his keynote speeches in the second and third Microsoft's CEO summits that attracted quite a few CEOs and other corporate executives from Fortune 1000 companies. Gates (1998) outlined his vision through a term he coined "digital nervous system," which is an integrated electronic network that can give people the information they need to solve business and customer problems. An effective digital nervous system should include access to the Internet, reliable e-mail, a powerful database, and excellent line-of-business applications, and should transform three major elements of any business: the relationships to customers and business partners—the e-commerce element; the information flow and relationships among workers within a company—the knowledge management element; and the internal business processes—the business operations element. The recent release of Windows® Tablet PC® edition is an example of a Microsoft tool that supports the concept of digital nervous system.

Even though knowledge management as a conscious practice is still young (Hansen et al., 1999), using information technology to support knowledge management is being explored and is well under way in many organizations. The Web technologies are not only changing the landscape of competition and the ways of doing business but also the ways of organizing, distributing, and retrieving information. Web-based technology is making effective knowledge management a reality, and Web-based knowledge management systems have been developed and deployed.

Currently, Web-based technology is enabling the management of knowledge at the document management level, in contrast to the traditional record-level data management. The record-level data management is basically the focus of traditional database management systems. The document level is higher than the record level. For example, we generally handle daily problems through communicating with each other by using documents and exchanging ideas or perspectives about an issue, rather than dealing with database fields or records. Document-level information management is generally viewed as a lower level of knowledge management.

In this chapter, Web-based knowledge management is explored. Four representative types of Web-based knowledge management models are identified and studied. The study of these models would shed light on the effective management of organizational knowledge, what should be contained in a knowledge management system, the levels of knowledge management support, and how knowledge management support systems can be technically implemented. This chapter is organized as follows. In the next section, some theoretical issues about knowledge management are reviewed. Then, it is justified why Web technology is an enabling technology to the effective knowledge management and why Web-based knowledge management is desirable. Then, the four types of Web-based knowledge management models are discussed and compared. Finally, the conclusion section summarizes the results of this chapter and discusses future directions of Web-based knowledge management.

BACKGROUND

Traditional Information Systems vs. Knowledge Management Systems

Traditional information systems were developed to capture data about daily business transactions (transaction-processing systems), and to access, process, and analyze those internal and external data to generate meaningful information to support management [management information system (MIS), decision support system (DSS), or enterprise integration system (EIS)]. These traditional systems help make an organization operate smoothly. However, they were developed at a time when the importance of knowledge management was not recognized. They all emphasize quantitative data processing and analysis. But an effective organization does not rely on quantitative analysis alone to deal with its problems. The nonquantitative side, such as knowledge creation and management, mental models, document sharing, human communications, information exchange, and meaning making, play a great role in an organization's growth and development. Thus, the nonquantitative areas also need to be supported. Knowledge management systems are supposed to fulfill this role. In other words, knowledge management systems should complement traditional systems in providing nonquantitative side support. A difficult task is to define what needs to be contained in the knowledge management system. A lot of existing studies provide only theoretic suggestions. A study described and discussed 10 knowledge management frameworks (Holsapple & Joshi, 1999). These frameworks are generally concentrated on conceptual knowledge creation or knowledge-building activities. They may be useful in deciding what functions a knowledge management system should eventually provide, but they fall short in suggesting what should be contained in a knowledge management system and how such a system may be implemented. In this chapter, the study of four types of Web-based knowledge management models should provide some practical advice about the content of a knowledge management system.

Knowledge vs. Information vs. Data and Knowledge Management

Commonly agreed, data is often defined as the raw facts, and information as the processed data. Davenport and Prusak (1998) defined knowledge as "a combination of experience, values, contextual information, and expert insight; and knowledge provides a framework for evaluating and incorporating new experiences and information." On the other hand, Applehans and coresearchers (1999) defined knowledge as the ability to turn information and data into effective action, which brings desirable outcomes for an organization. In this chapter, we follow a compromised approach to define knowledge: it is about the application of data and information for a given task so that the given task can be effectively performed.

The traditional view about the relationship between knowledge, information, and data is that knowledge is above data and information; data is a prerequisite for information; and information is a prerequisite for knowledge. This theory can be simply illustrated by the following diagram:

Data → Information → Knowledge

The second view, also a different view, is called a reversed knowledge hierarchy, which suggests that we first need to have the knowledge about what information we want, and then we will know what data to look for (Tuomi, 1999). In other words, data emerge only after we have information, and that information emerges only after we already have knowledge. This view can be simply illustrated by the following diagram:

Knowledge → Information → Data

The third view is also possible. We have a large amount of data collected but fail to make use of the data to create information because of our lack of relevant knowledge. An historical example is at point, which is about the making of the everyday weather map. For a long time in history, weather data were collected, and there were rich data available. But the usefulness was limited when these data are not combined with a map (Monmonier, 1999). Once we have the relevant knowledge about how to process data, how to visualize data, the boring data start making sense and generating meanings. In this situation, the knowledge is the catalyst that transforms data into information. This process can be simply illustrated by the following diagram:

Data → Knowledge → Information

These differing logics and understandings about the relationships and the sequences between data, information, and knowledge are meaningful, depending on the context. The development of the traditional information systems (TPS, MIS, DSS) basically follows the traditional view of data, information, and knowledge, while scientific research and inference statistics generally follow the second view (the reverse hierarchy) on data, information, and knowledge. In terms of knowledge management, the third view bears more impacts and implications. This third view suggests a fundamental fact in many organizations—there are a lot of documents (data) accumulated over years, and we need to know what to do to turn them into information to support a given task. All knowledge is tacit in nature and largely resides in the human mind, and to articulate knowledge is to create information about knowledge (Stenmark, 2002). The document is one place where information about knowledge can be found. Another place is the human mind, and the identification of the right human mind (expert) for a given task must be a responsibility of knowledge management. This help explains why the awareness of corporations to identify and utilize inside expertise for a given task has increased in recent years.

To summarize, knowledge management is concerned about how documents (data) may be organized, associated, and retrieved so that meaningful information can be produced for a certain task. This also includes identifying experts whose expertise can immediately help a given task. In other words, the following understanding about knowledge management is used in this chapter: Knowledge management is about meaningful organization of data (documents) and people who have expertise about a task, so that for a given task, meaningful information can be uncovered, associated, and retrieved, and experts with matching expertise can be identified.

THE WEB TECHNOLOGY

The content of a knowledge management system is not created by one individual. The content collection and the access of the content is a collective behavior. Therefore, the technological infrastructure installed must be able to facilitate the collective behavior of knowledge management. In a study where 31 knowledge management projects in 24 companies were examined, eight factors were identified to characterize a successful project (Davenport et al., 1998). One of these factors was the use of a technology infrastructure that includes common technologies for desktop computing and communications. Web technology has provided a common technological infrastructure to support the collective knowledge management, which is justified by the following observations in a separate study conducted by Zhang and Chen (1997):

- Web-based technology uses standard transmission-control protocol/Internet protocol (TCP/IP), which is mature and is supported by almost every vendor (Panko, 1997; Telleen, 1996; Strom, 1995).
- Information can be collected, retrieved, and shared through popular browsers like Netscape Navigator and Internet Explorer.
- A home page can be quickly developed, deployed, and shared.
- There are languages specially developed for Web-based applications, such as Java or VB script. Java applets can be embedded in Web home pages. The applets are executed on the client's PC and make it possible to develop interactive home pages with instant user responses and with multimedia features.
- With Web technologies, an organization enjoys platform independence or cross-platform operation. JAVA applets do not have to be rewritten to work with PC browsers, Macintosh browsers, and UNIX browsers (Panko, 1997).

In addition to the common technical infrastructure feature offered by Web technology, there are several major reasons why Web-based knowledge management is desirable:

1. The basic unit of knowledge is at the document level, which is equivalent to the level at which human beings normally communicate. Documents are usually created to deal with particular issues, and we live our everyday lives by dealing with issues. Different from an expert system, a document-based knowledge management system cannot automatically derive solutions. Instead, its usefulness lies in its large repository of classified documents, its multi-indexed powerful searching capabilities, the links between documents, the links within a document, and the potential of including other advanced features (e.g., animation). The interpretation of the documents provided by a knowledge management system largely lies with the users. The function of a document-based knowledge management system is largely to support relevant information for a task.
2. The intranet, which is based on Web technology, is the driver for new business applications. As one study has found, corporate intranets and the Internet have made the process of finding the right expert for a given task more feasible than ever before (Yiman & Kobsa, 2000). Another study has shown that intranets can provide useful and people-inclusive knowledge management environments (Stenmark, 2002).
3. The association between documents and tasks can be easily established by creating

hypertext links. Hypertext links can be created between documents and within a document. Hypertext links make explicit the meaningful documents relevant for a given task.

4. The collective behavior of knowledge management can be supported. A Web site can be easily configured to allow multiple users or contributors to edit existing documents or add new documents. When talking about the knowledge management architecture, Morey (1999) suggested that successful knowledge management architecture must have the following characteristics: be available, be accurate, be effective, and be accessible. Web-based technology has made it possible to have effective knowledge management architecture.

THE WEB-BASED KNOWLEDGE MANAGEMENT MODELS

Four Web-based knowledge management models are identified in this section. These models represent the current level of Web-based knowledge management. Nonetheless, these four types of models may not represent all of the Web-based knowledge management models. These four representative models are as follows:

- Library model
- Attachment/association model
- Directory model
- Press center model

Library Model

This model enables content-based document searches. Under this model, a large collection of documents is established. Both the attributes and the content of a document are indexed, in contrast to the traditional method where only the attributes of a document are indexed. The attributes of documents may include title, subject, author name(s), publication (creation) date, number of pages, and so on. Under this model, powerful search functions are provided, where not only these attributes (title, subject, etc.) are searched, but also the contents of documents are searched.

An example was provided by the ITKnowledge.com Web site, which is a large repository of information technology (IT)-related books. The contents of the books are fully available. The chapters in a book are hypertext-linked, and a book is essentially a set of hypertext documents. Not only the attributes of the books are classified and indexed and can be searched easily, but also the chapter titles (the content) are indexed by keywords and can be searched. This makes it possible to find a document with attributes (title, subject) that do not meet a search criterion but that may contain chapters that are relevant to the search criterion. In Figure 1, the ITKnowledge.com search screen is displayed. In Figure 2, a search result is returned. As can be seen in Figure 2, a chapter in the book Handbook of Data Management that is relevant to the search criterion "knowledge management" has been returned. If the book is only indexed by its title, this search result should not have been possible.

Attachment/Association Model

Under this model, information is organized around topics. If we search for a particular topic, all information associated with the topic will be returned. New information can be attached to a topic once it becomes available. In fact, anyone at any time can attach new information to a topic. The attachment creation is an ongoing process.

An example of this model is Amazon.com, which is also an example of successful e-commerce. Bookselling is its major business. Amazon.com maintains a large database of book titles. To help sell a book faster and to make users understand a book better, all information relevant to a book title is stored and organized around a book

Figure 1. IT Knowledge.com expert search screen

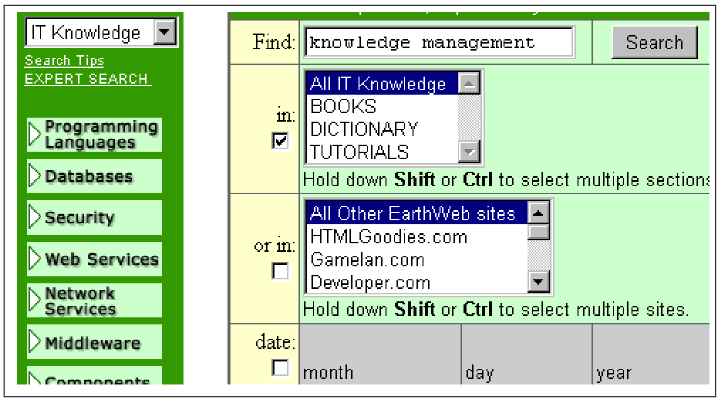

Figure 2. Search results returned

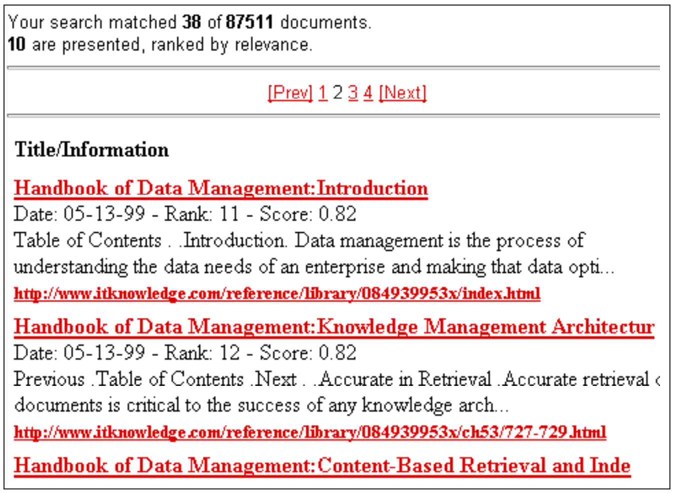

title. Therefore, essentially, the book database is more than just a collection of book attributes. Amazon.com provides users more than book titles. Suppose we want to find books that are relevant to "knowledge management."

After a title that matches the search criterion is returned, other relevant titles, and what other customers often purchase together with the current title, are returned and displayed. In addition, one can learn more about a book by reading the reviews attached to or associated with the book and other customers' comments attached to the book. If a reader wants, he or she can write comments about a book and easily attach his or her comments to the existing pool of information about this book.

Directory Model

Under this model, the experts in different areas are identified, and a directory of experts is created. The areas of expertise of these experts are classified and organized. A directory of experts, together with their areas of expertise, is provided.

A representative example of this model is the Round Table Group (round.table.com). Round Table Group (RTG) was founded in 1994 with a vision of being a virtual consulting firm where business leaders, management consultants, and litigation attorneys could shop for answers to critical questions from world-class thinkers, anywhere in the world, in Internet time (STVP, 1999). According to an STVP case study, RTG has formed a worldwide network of over 3,000 Round Table scholars—professors, researchers in well-known think tanks, and other experts. Essentially, RTG's most valuable competitive asset is its directory of professors from around the world who were available to consult with clients on demand. RTG provides answers-on-demand services to its clients. In Figure 3 below, the classified area of expertise by topic is displayed.

Press Center Model

Under this model, any information that can possibly be collected, including news, relevant articles, solution providers, publications, and discussions about a task is collected. A representative model is Kmworld.com, where a rich collection of relevant information about knowledge management can be found. If one is interested in knowledge management, a good starting point would be to visit a site like Kmworld.com. One could be overwhelmed by the information available, such as discussions, news, and solution providers. But, by spending some time and effort, one could figure out what is going on with a task, the current status, the issues, and history information on some issues.

A Comparison of the Models

The four types of Web-based knowledge management models as discussed above reflect the current level of Web-based knowledge management, which can be summarized as the content-based information retrieval and topic-oriented information organization.

These four models share the following common characteristics:

- Are basically document-based and content-indexed
- Have powerful searching capabilities

Figure 3. The identification of expertise by topic

Table 1. Key characteristics of Web-based knowledge management models

Model	Key Characteristic
Library	Content-based document retrieval
Association/attachment	Topic-oriented information organization/attachment
Directory	A well-organized directory of experts that can be searched for a given task
Press Center	A clearinghouse with rich organized information

- Focus on a specific application area (task-specific: IT knowledge, bookselling)
- Offer anytime, anywhere access
- Have potential to have more advanced features (e.g., multimedia, animation)
- All have an external orientation and are customer focused

On the other hand, the four models discussed above also have unique characteristics, which are indicated in Table 1.

FUTURE TRENDS AND CONCLUSIONS

Current Web-based knowledge management is essentially at the document management level—a lower level of knowledge management, but indeed beyond pure document management (pure classified collection of documents in a central file cabinet) to allow content-based retrieval, distributed access, and topic-oriented information organization and association. In this chapter, four different Web sites that represent four different models of Web-based knowledge management are discussed. But it is believed that a Web site could employ multiple models at the same time. For example, a Web site can be constructed based on the library model while supporting the association and attachment model. As a matter of fact, ITKnowledge.com is planning to include the association and attachment model in its site. It is expected that a sophisticated Web site will provide a menu of knowledge models for its users to choose from so that the potential of a Web site can be fully utilized.

A study, conducted by Hansen, Nohria, and Tierney (1999), discussed two strategies of knowledge management, based on the authors' studies on the practice of knowledge management in consulting firms, with computer vendors, and with health care providers. One strategy is called the personalization strategy, where knowledge is closely tied to the person who developed it and is shared mainly through direct person-to-person contacts. The computer information systems are used mainly to help people communicate knowledge, not to store it. Other examples like the use of groupware products to support the knowledge management process also fall into this category. This may be called the communication-based knowledge management level.

Another strategy, from the same study conducted by Hansen, Nohria and Tierney (1999), is called codification strategy, where knowledge (actually, a variety of documents) is codified and stored in databases to be used by anyone in the company. The knowledge is extracted from documents and may take the forms of interview guides, work schedules, benchmark data, or market segmentation analysis. These knowledge forms are codified and stored into a database with search capabilities. This is may be called the document-based knowledge management level.

The existing Web-based knowledge management, as evidenced by the four types of models identified and discussed in this chapter, basically corresponds to the knowledge management levels (especially the second). However, these levels are considered as lower levels of knowledge management, because they do not consider the support of meaning interpretation or sense making, they are generally text based, and they do not challenge whether the knowledge inherent in the document is accurately transmitted (knowledge transfer). But, after all, good steps on the right track have been made.

As future research directions about Web-based knowledge management, the higher levels of knowledge management may need to be addressed. Other functional areas should get involved, such as sales and marketing, customer support, and research and development. Other models about Web-based knowledge management may also need to be identified. Automatic and intelligent knowledge extraction and retrieval (knowledge agents) should also be studied for Web-based knowledge management.

Chapter 1.8
Business Process Outsourcing to Emerging Markets:
A Knowledge Management Approach to Models and Strategies

Jurgis Samulevičius
Vilnius Gediminas Technical University, Lithuania

Val Samonis
Cornell University, USA, & Vilnius University, Canada

ABSTRACT

A major phenomenon of globalization, outsourcing is a complex and controversial issue. It occurs when companies contract out activities previously performed in-house or in-country to foreign (usually offshore) companies globally. Couched in the terms of a SWOT analysis and using a modified Harvard-style case study that was subjected to the SWOT analysis, the chapter analyzes business process outsourcing (BPO) to emerging markets, frequently called outsourcing or offshoring in short. The overarching advantage of outsourcing is that it allows a business to focus on core activities as called for by core competence, strategic alliance, and competitive advantage theories of international business. Such a global restructuring of production has been sometimes called the true WMD (weapon of mass destruction) of jobs in the developed world. However, a more balanced approach could borrow the term "creative destruction" from the prominent Austrian economist Josef Schumpeter and emphasize the all-important transformational aspect of outsourcing. A transformational aspect of outsourcing is evidently very important for emerging markets but also for many companies in the developed world; therefore, BPO is sometimes called BTO (business transformational outsourcing). The global digital/knowledge economy offers unprecedented opportunities to produce and sell on a mass scale, reduce costs, and customize to the needs of consumers, all at the same time. Whether you live in a large country such as the U.S. or China, mid-sized country such as Canada or a smaller country such as Lithuania, your potential market is of the same global size. And you can source (netsource) inexpensively wherever you wish. Added to that are immensely increased opportunities to access new knowledge and technologies, driving productivity and living standards further up. BPO to emerging markets is *or should be driven by those fundamental reasons having to do with rapid organizational change, reshaping business models to make them viable in the long term, and launching new strategies. This is the essence of transformational outsourcing. In this chapter, BPO is used in the broader, integrated, and comprehensive understanding of changes in the company's business models and strategies but first of all the company's changing core competencies and competitive advantages: partnering with another company to achieve a rapid, substantial, and sustainable improvement in company-level performance. A knowledge management approach is advocated in this research that is to be continued in the future. The chapter concludes that outsourcing is a wave of the future. Postcommunist and other emerging markets countries are well advised to jump to these new opportunities as they represent the best chance yet to realize the "latecomer's advantage" by leapfrogging to technologies and models of doing business which are new for Western countries as well. The chapter analyzes and outlines some of the ways in which contemporary and future business models are deeply transformed by the global digital/knowledge economy. Global outsourcing provides a compelling platform to research the issues of upgrading competitive advantage in developed countries and contract out non-core competencies to emerging markets. Therefore, suggestions for further research are included in the chapter as well.*

INTRODUCTION: WHAT DO WE KNOW ABOUT THE NATURE OF BUSINESS PROCESS OUTSOURCING?

Business process outsourcing (BPO) is generally defined as the transfer of the control of the business process to external suppliers. BPO deals with differentiated activities, such as finance and accounting, procurement and supply, customer relations' management, human resources, security and so forth.

BPO implies a more comprehensive — or business process oriented — approach to outsourcing information technology (IT) services, which is the original and narrower term. BPO contracts are seen as being more inclusive, covering a great deal of process redesign work, redeployment and retraining of the people doing the work, and almost always include the information and communication technology (ICT) or information and telecommunication technology (ITT) that enables and supports the business process. The goal is to provide an even greater opportunity for generating innovation, efficiency and speed in reaching markets and, ultimately, shareholder value through this more comprehensive, integrated approach. In this research, BPO is used in this broader, integrated, and strategic sense of changes in the enterprise's management models and strategies but first of all the enterprise's changing core competencies and competitive advantages.

Under the dual pressures of global competition and shareholder expectations, Western companies are driven to reduce operating costs and focus on core competencies. To accomplish this in the global economy, companies are turning to business process outsourcing (BPO), outsourcing or offshoring in short. BPO can be defined as the practice of turning over the operation of an internal business process, like customer care or transaction processing, to a third party service provider. Service providers use their process expertise, human resources, and available technologies to provide the required services. The client company ("client") manages and compensates the service provider by defining measurable performance metrics and then evaluating the service provider's performance using those agreed metrics. Service providers can be located onshore, nearshore or offshore. Companies assessing a service provider usually compare different service provider locations, as differences in culture, business strategies/models, and technical infrastructure affect price and other performance parameters.

Global outsourcing provides a compelling platform to research the issues of upgrading competitive advantage in developed countries and contract out non-core competencies to emerging markets. Such a global restructuring of production has been sometimes called the true WMD (weapon of mass destruction) of jobs in the developed world, especially so in America. However, a more balanced approach could borrow the term "creative destruction" from the famous Austrian economist Josef Schumpeter and emphasize the all-important transformational aspect of outsourcing. A transformational aspect of outsourcing is evidently very important for emerging markets but also for many companies in the developed world. While global executives began outsourcing substantial portions of their operations more than a decade ago to offload activities regarded to be non-core to cut costs and refine their strategies, in modern outsourcing companies are looking around globally for more fundamental reasons — to facilitate rapid organizational change, to launch new strategies, and to reshape business models. In essence, they are engaging in transformational outsourcing, that is partnering with globally scattered companies to achieve rapid, substantial, and sustainable improvements in performance.

According to The McKinsey Institute (Agrawal & Farrell, 2003), on a practical level BPO can be executed through several business models depending on the process and the company's business strategies:

- Conventional outsourcing: where a company contracts with a service provider for services over a defined time period.
- Joint ventures: where a Western company partners with an offshore company to provide outsourcing services to the Western company and/or third parties.
- Build operate transfer (BOT): where a Western company engages with a service provider to establish an offshore facility, hire and train employees, transition the onshore process to the offshore operation and then run the facility and manage the workforce. The Western company then has the option, after a pre-defined time period, to purchase the offshore operation.

In conventional outsourcing and joint venture models, a company may transfer an entire functional area to a service provider on start up (transfer of assets).

STATE OF KNOWLEDGE ASSESSMENT: LITERATURE REVIEW AND THEORETICAL UNDERPINNING

There is no established body of literature dedicated to the business process outsourcing (BPO) per se. By 2005, what we have are fragmentary contributions to the understanding of the BPO process that is rapidly changing, evolving, and providing new empirical material. This is due to the novelty of the issue.

However, the proposition of this chapter is that, in deeper essence, the theoretical background of this research is based on the multinational production body of knowledge (Dunning 1996, 1998), especially the international alliance formation literature, foreign direct investment literature, and related contributions.

There exist different theories and models that are relevant to the study of BPO in general. Research on strategic alliances between firms has received increasing attention in the literature during the last decade, reflecting the increasing frequency, diversity, and importance of strategic alliances in regional and/or global business and finance. The main theoretical explanation for why firms form strategic alliances is offered by the transaction cost perspective. According to Williamson (1985, 1991), internalization is the strategy here and it can take different forms.

Two main streams of literature can be identified; one stream is mainly concerned with examining the underlying conditions favoring alliance formation (motivation for alliance formation or intent) (Harrigan, 1985; Teece, 1986; Contractor & Lorange, 1988; Hennart, 1988; Kogut, 1988; Oliver, 1990; Williamson, 1991), the other stream is occupied with investigating alliance outcomes and the impact of alliances on the partner firms (Kogut, 1989; Blodgett, 1992; Dussage & Garette, 1995; Doz, 1996; Mitchell & Singh, 1996; Park & Russo, 1996; Nakamura, Shaver, & Yeung, 1996). Recently, researchers have begun exploring issues related to alliance dynamics and related knowledge management issues (Singh & Mitchell, 1996; Gulati, 1998; Koza & Lewin, 1998). For more insights, please consult the structured and annotated references section.

Methodological Approaches

In this chapter, the researchers attempted to approach the subject using statistical and legal/institutional research couched in the SWOT analysis terms as well as using a modified Harvard-style case study that was also subjected to the SWOT analysis. The researchers also attempted to study broader actual empirical/practical processes, as they have been experienced in transition economies such as Lithuania, thus bringing important evidence and empirical insights into the subject of the analysis.

BACKGROUND, TRENDS, INTERPRETATIONS

By 2005, the debate about outsourcing focused upon its impact on the U.S. and other Western countries' jobs. But it is important to take a broader and longer-term view of what best serves the interests of the U.S. and Western countries in general. The West stands to gain tremendously by promoting a healthy and stable global economy, particularly important and challenging is the integration of emerging markets into the integral global economy. This is something that eluded globalization efforts in the 20th century.

No doubt, specific groups of workers in the West might lose out from outsourcing. Emerging markets do pose a competitive threat to some Western companies that stand to lose market shares due primarily to the shortage of their thinking and action about moving to new business models and strategies. But the costs to those specific companies are outweighed by the benefits to Western consumers, a much larger group. In case after case, they enjoyed far lower prices, and often more choice and better goods, after markets were opened to globalization, including BPO. Outsourcing to emerging markets will increase sharply as companies there develop a critical mass of competitive advantages due to restructuring, organizational learning, and organizational change in general. By 2005, skill-intensive Western sectors such as pharmaceuticals and auto parts have not shifted production overseas but are likely to feel the brunt of this next wave of outsourcing. By 2015, manufacturing imports from emerging markets to the United States could increase to more than 50% of total U.S. manufacturing imports, up from 42% in 2002 — a shift worth hundreds of billions of dollars (Agrawal & Farrell, 2003).

The benefits are substantial to emerging markets as well. The price of passenger cars in China, for instance, fell by more than 30% from 1995 to 2001, years when Ford Motor, General Motors, and Honda Motor entered the market. In Mexico, the "everyday low prices" of Wal-Mart stores ended a long history of hefty margins for leading domestic retailers and reined in fast-rising food prices so much that some analysts credit the company with helping to reduce the country's inflation rate. In

India, the price of air conditioners, television sets, and washing machines fell by roughly 10% in 2001 alone after foreign companies entered the market. Similarly, prices for cars declined by 8 to 10% a year during the 1990s after the government opened the sector, and the number of models available has now risen from a handful to more than 30. Lower prices have unleashed demand, and India's auto sector has grown by 15% a year.

Outsourcing IT and business processes generates more than $10 billion a year for India and gives employment to half a million of Indian workers. Suppliers to the companies that provide outsourced services employ another half million people. With wages in the sector 50 to 100% higher on average than those for other white-collar occupations, a new middle class of educated workers is being formed. Foreign direct investment played a key role in the creation of these industries: the fast-growing Indian companies that now dominate the global sector got started only after multinational companies pioneered the approach, showed the world that India was a viable outsourcing destination, and trained a critical mass of local employees. Foreign companies continue to provide healthy competition that forces Indian companies to improve their operations continually. They hone the efficiency and productivity of the local industries by bringing in new capital, technology, new business models, and management skills. Equally important, they increase the level of competition, forcing less efficient domestic companies to improve or go out of business (transformational aspect).

BPO is thus held in this chapter to be both very complex and very important to the realization of the benefits of transformation and global integration at both micro and macro levels in emerging market economies and in developed economies. A Schumpeterian "creative destruction" and micro foundations of growth perspective and approach is important in this research, as this approach is more and more relevant to processes in today's global (knowledge) economy. While there are, admittedly, theoretical controversies as to why firms grow (e.g., Romer's new growth theory) and how the growth process works specifically, it is the restructuring and outsourcing processes that shape the impact of corporate behavior and investment on economic performance via capital productivity and new competitive advantage building through technological and organizational innovations, adaptability, Schumpeterian change in general.

As a first stage of a larger research effort, the chapter attempts to contribute to the understanding of the theory and practice of BPO processes as they occur in the direction developed economies-emerging markets, with special reference to Central and Eastern Europe, Lithuania in particular, see the case study below. The authors tried to identify and define key policy areas and measures aimed at improving corporate governance, finance, and competitive advantage building in enterprises with regard to requirements of effective participation in BPO. They also tried to collect other theoretical and empirical evidence pertaining to the impact of the post-communist transformation (esp. privatization, enterprise restructuring, financial sector reform) and new information and communication technologies (ICT) on enterprise strategies/models, with special reference to further restructuring and competitive advantage building via BPO.

RESEARCH METHODOLOGY: THE ANALYTICAL FRAME

Given the complex nature of modern research topics, different aspects need to be analyzed and evaluated, not unlike in the biological systems that are very complex by nature. The Strengths-Weaknesses-Opportunities-Threats (SWOT) analysis lends itself very well to the study of such complex living or human-devised systems. The broader explanation and rationales for using the SWOT analysis are as follows.

SWOT Stands for: Strengths, Weaknesses, Opportunities, Threats

Strengths, Predominantly Internal

Every organization or country has some strengths. In some cases this is obvious; for example, dominant market shares. In other cases, it is a matter of perspective, for instance, a country is small and hence has the ability to move fast using certain strategic moves, like BPO. It is important to note that countries that are in a weak competitive position also have strengths. Whether these strengths are adequate is an issue for analysis.

Weaknesses, Predominantly Internal

Every organization or country also has some weaknesses. In some cases, this is obvious; for example, a stricter regulatory environment. It is important to note that companies or countries that are extremely competent in what they do (that stick to their core competencies) also have weaknesses. How badly these weaknesses will affect them is a matter of analysis.

Opportunities, Predominantly External

All organizations and countries have some opportunities that they can utilize by certain strategic moves. Identifying hidden opportunities is the matter of analysis.

Threats, Predominantly External

No organization or country is immune to threats in the global economy that is characterized by increased competitive pressures. These could be partially internal, such as falling productivity due to outdated technologies, or they could be almost entirely external, such as lower priced international competition.

TOWARDS A KNOWLEDGE BASE OF BUSINESS PROCESS OUTSOURCING

As stated above, due to the novelty of the topic of business process outsourcing to (and from) emerging markets, especially transition economies, there is no body of dedicated literature. However, the chapter looks for theoretical and empirical clues in some of the broadly relevant Western and Eastern literature, for example, on enterprise restructuring, corporate governance and finance, turnaround management, core competencies, competitive advantage building and so forth. The chapter takes a look at enterprise restructuring in Central and Eastern Europe (with special reference to Lithuania) and argues that the transformation from a state-owned enterprise into a truly capitalist firm involves more than reacting to economic stimuli. Enterprises need access to capital markets to finance investment and they have to acquire new capabilities (esp. identify and define core competencies, "polish" Porter's Diamond, etc.) to be able to grow and compete successfully in Europe and in the global knowledge economy (GKE). In the crucial areas - human resource development, investment capital including new technologies, new models of corporate governance and finance, overall competitive capability building — interaction with Western businesses can make a key contribution to transformations, within the European Union and globally. In general, global outsourcing provides a compelling platform to research the issues of upgrading competitive advantage in developed countries and contract out non-core competencies to emerging markets so that a new and modernized global economic architecture is achieved.

Some broad hypotheses relating to common elements of the restructuring and BPO processes include a shift to flatter, less hierarchical organization structures within Williamson's markets-hierarchies dichotomy and related schemes; the adoption of Western knowledge management and financial/accounting practices, and the introduction of Kornai's hard(er) budget constraints; the evolution of the marketing function and the rationalization of product ranges in light of rapidly changing and increasingly global market needs. Moreover, in the global knowledge economy (GKE), what needs essential redefinition is the enterprise (firm) itself; one obvious point of departure here is the transaction cost theory and the Ronald Coase theorem. Below is a modern take on the Coase theorem relevant changes brought about by the Internet and the global knowledge economy in general (with special reference to emerging markets).

Why Firms Exist?

Ronald Coase's answer was that, due to a number of impediments (e.g., distance, shortage of information, coordination costs, etc.), it is many times difficult and/or costly to conduct such transactions. Consequently, it is a useful and cost-reducing proposition to "internalize" such transactions within a firm. A "transaction cost" model and strategy of business was born.

The Internet Revolution

How does the advent of the Internet change business models under the new paradigm of the global digital economy (GDE)?

The Death of Distance

The geographical distance used to play a very important role in the world economy, for example, expressed operationally in the gravitational models of international trade. Now distance is (almost) dead. Anybody on the Internet can collaborate or do business with any other Web-based individual or business at a small fraction of costs incurred in the pre-Internet era. This is true especially for the service sector but increasingly for the goods sector as well. Consequently, irrespective of whether one operates in small Lithuania or huge China or the U.S., the market is the same: the globe; anybody on the Internet faces a fully global competition, not just local/domestic or regional/international competition.

The Collapse of Time

The instant interactivity brought about by the Internet is fuelling change. Companies have to accept a strong culture of constant change known as the Schumpeterian "creative destruction" because in a world of instantaneous interactivity and connection there is a big premium on fast response and learning and adapting quickly to clients needs.

The Undoing of Old Paradigms:

The New Nature of Business and Comparative/Competitive Advantage

The old "bricks and mortal only" model of corporations is dead in a much shorter run than most people are inclined to think. In the global digital village, to paraphrase Marshall McLuhan, every individual or small business can go global and directly compete with any company. At the professional level, there will be fewer traditional 9-to-5 jobs and more outsourcing/contracting with free-agent skilled workers Web-based globally. Competition in the goods and services markets has been brought to new, higher levels, and permanently so.

Developed countries can no longer hide behind politically motivated barriers, physical or other walls to protect themselves from competition from developing countries or emerging markets. Rather than clinging to old models, individuals and corporations in developed and (increasingly) in developing or transition nations need to upgrade their competitive advantages through more education and training. It is far more important to improve human capital (human resources) than it is physical capital (buildings, machines, etc.) or "natural" capital (raw materials, geographical position, etc.).

New information and communication technologies (ICT), especially the Internet (increasingly wireless), bring new opportunities to concentrate on core competencies, specialize and increase trade and investment flows. For these gains to occur, however, what needs essential transformation is the corporation itself.

Corporations need to change the ways they do business; they must become less hierarchical and flatter. Above all, they must be more focused on their core competencies albeit see them dynamically (as constantly changing) and not statically (as, for example, "natural" gateways in trade). Also, they must rely less on their locally available "jack-of-all-trades" workforce and increasingly distribute tasks (outsource or "netsource" them) to other contributors Web-based globally. These new contributors (or teams of contributors) may or may not be full-time employees, but they will generally be equally or better qualified, more willing to learn, and offer greater flexibility, all of which will increase economic efficiency and create new competitive advantages that will become more sustainable.

The above means that corporations need to become much more flexible, amorphous networks of international professionals and knowledge managers working on particular projects. How such corporations should be governed is a new challenge before the managers working in the global knowledge economy. It is postulated in this chapter that a knowledge management (KM) approach should be adopted in trying to solve the above problems. Specifically, three elements of this KM approach are relevant: models and strategies of modern business, human resources, and underlying technologies, especially the Internet technologies.

CONCLUSIONS AND RECOMMENDATIONS

Under the dual pressures of global competition and shareholder expectations, Western companies are driven to reduce operating costs and focus on core competencies. To accomplish this in the global economy, companies are turning to business process outsourcing (BPO), outsourcing or offshoring in short. BPO can be defined as the practice of turning over the operation of an internal business process, like customer care or transaction processing, to a third-party service provider. Service providers use their process expertise, human resources, and available technologies to provide the required services. The client company ("client") manages and compensates the service provider by defining measurable performance metrics and then evaluating the service provider's performance using those agreed metrics. Service providers can be located onshore, near-shore or offshore. Companies assessing a service provider usually compare different service provider locations, as differences in culture, business strategies/models, and technical infrastructure affect price and other performance parameters.

Global outsourcing provides a compelling platform to research the issues of upgrading competitive advantage in developed countries and contract out non-core competencies to emerging markets. Such a global restructuring of production has been sometimes called the true WMD (weapon of mass destruction) of jobs in the developed world, especially so in America. However, a more balanced approach could borrow the term "creative destruction" from the famous Austrian economist Josef Schumpeter and emphasize the all-important transformational aspect of outsourcing. A transformational aspect of outsourcing is evidently very important for emerging markets but also for many companies in the developed world. While global executives began outsourcing substantial portions of their operations more than a decade ago to offload activities regarded to be non-core to cut costs and refine their strategies, in modern outsourcing companies are looking around globally for more fundamental reasons — to facilitate rapid organizational change, to launch new strategies, and to reshape business models. In essence, they are engaging in transformational outsourcing, which is partnering with globally scattered companies to achieve rapid, substantial, and sustainable improvements in performance.

Couched in the terms of the SWOT analysis, the chapter concludes that outsourcing is a wave of the future. Outsourcing can create wealth both for the countries that send jobs offshore and for those that receive them.

Outsourcing is a major part or aspect of globalization. No longer can a company stay in its country of origin and remain competitive. Companies are roaming the globe (increasingly digitally) in search of the location(s) that will provide them with the economies of scale that will ensure efficiency with cost reduction and increased productivity. The U.S. economy gains more then $1 in new wealth for every dollar of corporate spending that U.S. companies outsource abroad. The primary objective of outsourcing should be to create added value. Value is added by providing the product at a lower price and maintaining or improving quality.

The U.S. and other Western countries will always have a competitive advantage in something. That something is shifting, however, up the ladder of competitive advantage towards higher value added activities (Americans want higher wages than those in China or India, for example), like research and development as opposed to IT, simple manufacturing or even the main elements of the business process that gets outsourced to emerging markets. In order to get up the ladder of competitive advantage, more Americans will need to upgrade their skills/education. The Internet technologies are making that possible through the lifelong process learning processes, especially online education of executives and other working professionals.

In the last few years, outsourcing has moved from "traditional outsourcing" to the next generation called "strategic outsourcing." Using the strategic outsourcing approach, many companies have reaped the benefits of improved performance, increased access to international markets, access to leading edge technologies, enhanced responsiveness to customer needs, contributed to organizational goals of increased productivity and efficiency, reduced costs, reduced cycle time, and improved quality of the goods and services in their organizations. In today's economy, the outsourcing approach is considered a viable option for achieving the best possible results, that is, in-depth business transformation.

In the future, outsourcing will be an even more effective and globally available model to reduce costs, boost productivity and exports, and increase profits. Thus, outsourcing will continue to be a viable business strategy, and even to the greater extent in the decade to come.

Business Process Outsourcing: Suggestions For Further Research and Knowledge Building

What is a corporation and how corporations should be structured and governed is a new challenge before the managers working in the global knowledge economy of the 21st century. It is postulated in this chapter that a comprehensive knowledge management (KM) approach should be adopted in trying to solve the above problems. Specifically, three elements of this comprehensive KM approach are most relevant: models and strategies of modern business, human resources, and underlying technologies, especially Internet technologies.

In the crucial areas — human resource development, investment capital including new technologies, new models of corporate governance and finance, overall competitive capability building — interaction with Western businesses can make a key contribution to transformations, within the emerging markets and globally. Global outsourcing provides a compelling platform to research the issues of upgrading competitive advantage in developed countries and contract out non-core competencies to emerging markets. In this context, outsourcing should be studied in connection with mergers and acquisitions (M&A) and foreign direct investment (FDI) as the two engines of global restructuring. Global financial institutions should be more active in research, explanation, and promotion of such a global restructuring. For the insights, please consult the structured and annotated reference section.

There are several promising lines of further research and fruitful approaches to outsourcing. One of them is the cluster method and strategy for modern growth developed at Harvard by Prof. Michael Porter (1990). The cluster method fosters high levels of productivity and innovation and lays out the implications for competitive strategy and economic policy. Economic geography in an era of global competition poses a paradox that is not well understood, needs further research. On one hand, location should no longer be a source of competitive advantage. Open global markets, rapid transportation, and high-speed communications should allow any company to source anything from any place at any time. But on the other hand, claims Prof. Porter, location remains important to competition. The global economic map is characterized by clusters: critical masses in one place of linked industries and institutions — from suppliers to universities to government agencies — that enjoy unusual competitive success in a particular field or fields. Porter explains how clusters affect competition in three broad ways: first, by increasing the productivity of companies based in the area; second, by driving the direction and pace of innovation; and third, by stimulating the formation of new businesses within the cluster. Geographic, cultural, and institutional proximity provides companies with special access, closer relationships, better information, powerful incentives, and other advantages that are difficult to tap from a distance, according to Porter. The more complex, knowledge-based, and dynamic the global economy becomes, the more this is true, claims Porter. Competitive advantage lies in local things - knowledge, relationships, and motivation — that distant rivals cannot replicate very efficiently, Prof. Porter continues. However, the advent of the Internet, knowledge management, and the global knowledge economy seems to be changing that and profoundly affecting the essence of "thinking globally but acting locally".

On top of more theoretical research (e.g., based on new growth theories) and the relevant argumentation advanced, there is a need to critically analyze outsourcing experience from a number of old and new and cases, etc, in such leading countries as China, India, Finland, Poland, U.S., Canada. Case-study type insights need to be presented on specific approaches that worked well within specific institutional/systemic settings called policy environments. Such policy environments (their parameters) are created mainly on the interaction of business, government (various levels), and other elements of a civil society in particular countries or integration groupings. Apparent failures in this regard are to be studied as well. By going deeper into the nature of policy environments (especially incentives they create), we need to refine the discussion on this issue and thereby build the knowledge base. The case study below is such an attempt.

THE CASE STUDY: LITHUANIA

Introduction

Full member of NATO and the EU since 2004, Lithuania is offering excellent business opportunities in a stable political, economic and social environment. Lithuania is strategically located in the gateway between the EU and the CIS. Being on a sea and land route, Lithuania is serving as an arterial road between the East and the West, the North and the South. In fact, one of geographical centers of Europe is located just north of Vilnius.

In spite of the heavy burden of the Soviet occupation legacies after regaining its independence in 1990, Lithuania embarked on a path of determined, radical, and sustained reforms aimed at re-establishing democracy and a functioning market economy. It succeeded remarkably and is now regarded Europe's transformation success story.

Lithuania in the European Union: Implications for Business Process Outsourcing

The widening and deepening of the European integration (especially the introduction of the euro) markedly increased competitive pressures, so companies began looking for new, sustainable and dynamic advantages. Given that the continent is aging pretty rapidly and immigration presents a problem for a number of reasons, a shortage of qualified labor is developing that can be best addressed by taking advantage of the digital/knowledge revolution and of the potential of new EU members such as Lithuania. Under these circumstances, a better use of the continent's resources has become critical to winning the competitive game or even survival in the unified Europe and the integrated world.

Large European and multinational corporations (e.g., BT, Buckman Labs, Nokia, Siemens, etc.) are the early adopters of new thinking. They first realized that high initial costs of research, human/intellectual capital costs, etc., are efficiently spread only over longer periods and larger geographical areas. The vision they have, specifically their new-frontier mentality and the ability to develop integrative thinking across functional areas of business, not only at the highest management levels but, what is even more important, at lower management levels resulted in knowledge-sensitive enterprise cultures and the resultant organizational learning regarding new business models and strategies. Also, such issues are pretty high on the EU institutions' agenda (e.g., Lisbon Strategy). The unique European competitive advantage (e.g., compared to the U.S.) is that EU institutions are able to give push and pull to many continent-wide initiatives that fall within the public goods category (e.g., earlier adoption of continent-wide standards for mobiles, knowledge management practices, etc.).

The chief criterion of readiness to become a full member of the EU is the capability to withstand the European competitive pressures. While in the first period lower labor costs do provide certain competitive advantages pretty much across the branches of economic activity, this factor is of rather short duration in the case of Lithuania or other transition economies. Lithuania will need to develop higher added-value market niches that will precisely call upon the Lithuanian capabilities to create an entrepreneurial economy that is integrated continentally and globally. BPO provides such opportunities especially in the context of knowledge and innovation in the European and global business.

Knowledge industries in Lithuania are still not very advanced, compared to global leaders. But some pioneering firms that were created around research institutes do have histories going back a decade or so, esp. those in biotechnology, laser research and so forth. A national political consensus was reached and the national agreement was signed calling for Lithuania to become a knowledge-based economy. Further development of the knowledge economy infrastructure (e.g., better access to high-speed Internet) is needed. That will necessitate a better public sector-private sector collaboration so as to arrive at innovative management models and strategies underpinning the knowledge economy in Lithuania. One such innovative scheme is the Sunrise Valley in Vilnius, deliberately modeled after the Silicon Valley, California. There are other such schemes at different stages of implementation. Among Lithuania's corporate leaders are SICOR Biotech, Fermentas, Alna, Sonex, Omnitel, Bite GSM, Ekspla, Laser Research Institute. They are members of The Knowledge Economy Forum of Lithuania.

The dominant challenge before Lithuania is how to use a considerable theoretical research (e.g., biotech, lasers, semiconductors, game theory) potential of the Lithuanian research institutes, universities, and industry. There is a need to develop a practice-oriented strategy for knowledge-based economy in Lithuania. The theory-practice gap has been something of a problem inherited from the communist period, as are the inter-institutional collaboration shortcomings. One important aspect of that challenge is the interdisciplinary and cross-disciplinary nature of modern business models that mandates integrative thinking and puts a premium on those managers who are able to integrate functional perspectives. Educational institutions in European countries are still somewhat attached to the subject-based teaching/learning; and this problem is therefore more pronounced in Europe than in North America. It could well be that BPO is that vehicle and that frame of mind that can help overcome such shortcomings.

Business Process Outsourcing: Lithuania's Strengths

Availability of Well-Trained, Competitive Labor Force

The annual number of university graduates per 1000 inhabitants is one of the highest in the region. The cost of labor is among the lowest. The average monthly wage in the manufacturing sector in Lithuania is about one tenth that of industrialized countries, including those in the EU.

Attractive Operating and Living Costs, Lifestyle

Utilities, rent, building, overhead, service and living costs are among the lowest in the EU. Thus, Lithuania has significant cost advantages while offering geographical proximity to the Eastern markets. Lithuania's modern European life style is predicated on its long national and statehood history and a largely unspoiled natural environment.

Well Developed Transportation Networks

The EU Transport Commission designated Lithuania as the region's transport hub, with two out of the 10 priority corridors in Europe intersecting in Lithuania.

A network of European-standard four-lane highways links major industrial centres. By most standards, Lithuania has a well-developed transportation system. Road construction is underway for connecting with the trans-European transportation network. It will be part of the transportation system around the Baltic Sea and a transportation axis linking Russia and the Baltic Sea. The country offers four international airports and an ice-free seaport on the eastern Baltic Sea.

Free Economic Zones and Industrial Parks

Lithuania's Free Economic Zones and Industrial Parks boast excellent infrastructure and trans-shipment facilities, highly qualified labor force, and offer investors very attractive incentives. There is also plenty of industrial land with direct access to ports, railroads, and highways available.

World Standard Export Production

Most foreign businesses invest in Lithuania for export production purposes. Many local producers have already obtained ISO 9000, ISO 14000, GMP and other standards. Lithuanian exports in 2004 wee 7.5 billion and growing.

Multinational Investor Satisfaction

Siemens, Telia, Philips, Motorola, Mars/Masterfoods, Sonera, Kraft Food International, Festo, Lancaster Steel, Partec, Kemira, Danisco, SEB, Carlsberg and Marzotto are among the multinationals that have chosen to locate production facilities in Lithuania.

Strong FDI Growth

Foreign investment in Lithuania has been steadily increasing and reached close to Euro 5 billion as of the end of 2004. There are attractive "greenfield" and privatization projects in infrastructure, transport, energy, to name a few sectors.

There are some forward-looking initiatives in Lithuania (e.g., Window to the Future, The Knowledge Economy Forum) that in some ways lead the Central and Eastern Europe. With regard to outsourcing, Outsource2Lithuania is a project worth a closer analysis.

Outsource2Lithuania: A Business Process Outsourcing Project

Outsource2Lithuania is a new project aimed at uniting Lithuania's information technology and telecommunications (ITT) corporations, who are potential exporters of products and/or services within the European and global outsourcing models and strategies. The goal of the Project is for the Lithuanian ITT corporations to take the leading positions among the providers of ITT outsourcing services in Europe and globally. It also seeks to develop Lithuanian ITT products and services, promote exports to international markets, and contribute to the establishment of a positive image of the Lithuanian ITT market. According to Gartner Inc. experts' evaluation, the growth of the Lithuanian ITT outsourcing market reached some 40% over 2003 alone. Lithuania is rated as one of the most attractive providers of this type of service in Eastern Europe.

The project is open for participation by member corporations of the Association Infobalt (grouping Lithuania's ITT and other high-tech companies), pursuing business related to cross-border activities, promotion of exports and so forth. It is expected that up to 40 Lithuanian ITT corporations could be attracted within the first stage of the project, working in such fields as system integration, software development, data center operation, as well as education establishments, marketing organizations, training facilities, etc; thus covering a major part of the entire BPO spectrum. According to the project's policy, any strategic decision on the project's activity shall be taken through a consensus of all the project members. Particular implementation task of the project are to be carried out by the Infobalt staff.

For achievement of the goals of the project, efficient international marketing efforts are to be employed including dissemination of the information on the Web portal, through international exports Web sites, specialized publications, presentation of the Lithuania's ITT potential at various ITT offshore services forums internationally, enticement of potential partners, as well as through relevant governmental institutions and agencies. The participants of the project are offered training courses, including topics like the management of outsourcing, marketing, exports, public relations in international business, participation in business missions and so forth.

Participation in the project is based on a fee. Each corporation willing to participate shall be charged a membership fee assessed in relation to it's sales, ranging from 1000 to 3000 litas (LTL) a year. Membership fees, however, shall by no means be the sole source of funding the project. Additional sources of financing shall be sought to expand the value added by the project.

Each member of the project is offered a Web space for the placement of its corporate information and sales pitch on the portal (www.outsource2Lithuania.com) and on a compact disk to be distributed to potential partners in outsourcing services in Europe and Asia. The information on the undertakings of the participating businesses, their services and products are to be distributed by the Association Infobalt and it's partners including The Lithuanian Development Agency, International Chamber of Commerce, and the Lithuanian Ministry of Foreign Affairs, as well as at international ITT events. Each project member is entitled to use the service mark "Member of the Project: Outsource2Lithuania".

BPO to Lithuania: Services

"Outsource2Lithuania" companies provide a substantial range of enterprise solutions. They help to plan, analyze, design, develop, deploy and sustain solutions in high business impact areas like:

- **B2B:** Business Intelligence, Customer Relationship Management, Enterprise Resource Planning, Document and Content Management, Supply Chain Management, Product Data Management, Enterprise Application Design and Development, Enterprise Application Integration, Enterprise Application Testing;
- **Development Services:** Software Development, Testing, Data Warehousing, Content Delivery Network, Digital Signal Processing, Embedded Software, Engineering Services, Middleware Verification and Validation Services;
- **ICT Infrastructure and Solutions:** Internet Infrastructure, IT Infrastructure Services, Hardware Design, Security Solutions, Storage Area Network, Voice over IP, Wireless Technologies, Broadband, Multimedia;
- **ICT-Enabled Services:** Process Support Services, Contact/Call Centers, Sales and Marketing Support.

Business Process Outsourcing to Lithuania: A SWOT Analysis

The World Trade Organization and the International Trade Centre (WTO&ITC, Geneva) team of experts carried out extensive consultations with the Lithuanian Ministry of the Economy, Ministry of Internal Affairs, Ministry of Transport and Communications, Communications Regulatory Authority, Committee on Development of Information Society, Association of Lithuanian Chambers of Commerce, The Lithuanian Development Agency, Infobalt, the Information Technology Centre, the Lithuanian Standards Board, the Internet Service Providers Association, leading ICT companies, leading banks, customs authorities and others. The purpose of these consultations was to assess and help develop a knowledge-based industry in Lithuania and the Baltic region so that it gains a major share of the global ICT marketplace.

The WTO&ITC team compared Lithuania's ICT industry with similar industries of countries in the region. The conclusion was that the industry is developing and expanding its activities across the region. In the EU market, activities related to sub-contracting or onshore software application were taking place. Although the Lithuanian ICT industry is relatively small compared to the ICT market of Poland, for example, it has good growth potential driven by niche areas and niche products.

Box 1 shows the results of the WTO & ITC team's and others' research on Lithuania's ICT industry based on analysis of its strengths, weaknesses, opportunities and threats (SWOT).

Box 1. The SWOT analysis of the Lithuanian ICT and other high tech industry: Summary and outline

STRENGTHS	**WEAKNESSES**
Human resources suitable for innovative activities and knowledge-based production; Healthy economy, growing most rapidly among the CEE (5-6% for 2001-2005); Well-developed high tech & other universities producing over 500 specialists in ICT and other disciplines annually; Other well-trained & low-cost human resources available; Modern telecom infrastructure with a digitalization ratio of 100% and mobile penetration of some 50%; Labor force versatile in English, German, Russian, and Polish; Open economy with rule-based system aligned to the EU & WTO – economic stability; Developed financial institutions & intermediaries; Location between the EU, Nordics, Commonwealth of Independent States (CIS); Capacity to promptly adapt to rapidly changing ICT & knowledge based economy; Full scale privatization accomplished; industry re-structured based on comparative advantages; Institutional support to SME development; Well developed IT infrastructure across the region; Sound linkages between academia and industry for development of applications EU and NATO integration to provide large market opportunities for ICT-enabled services.	Manpower adequately skilled but needs re-training on project management and quality management of ICT projects; Slow drafting and implementation strategies of ICT & other high tech; Vague long-term vision for ICT development including action plans or prioritization of funds; Comparatively small market - small investment by MNCs; Foreign economic relations still to be formulated on the basis of national and EU interests; Capital market in the development stage; ICT penetration not sufficient to give a substantial boost to e-commerce and e-business development; Logistics management poor - railway transport system physically inadequate; Public-private partnerships weak & cooperation among economic entities underdeveloped; Insufficient incentives for R&D by business.
OPPORTUNITIES	**THREATS**
Development of labor-intensive sectors like computer science and knowledge-based sectors to serve a larger market of EU and CIS; Availability of structural funds from the EU to provide support to business modernization, employment promotion, improvement in quality of life, etc; Industrialization processes based on FDI, advanced technology and international management experience to enhance competitiveness and leverage advantages to achieve export-led growth; EU accession to expand sales markets and provide preconditions for foreign trade; Globalization of financial resources will provide alternative possibilities for financing; Use of digital technologies will open wider markets and provide conditions for more efficient cooperation with advanced economies in ICT, BPO, R&D, and other IT enabled services; Possibility to establish positions in the transport service markets of continental Europe, with logistic centres in Kaunas, Klaipeda and Vilnius; Free movement of IT and high tech personnel to provide opportunities for application development and onshore software development;	Emigration weakens the intellectual potential of Lithuania; Potential closures of domestic ICT companies due to fierce competition unless they develop sustainable niche markets; Fear of becoming a center of higher cost production because of alignment with the high-cost EU and trade distortions imposed by third countries; Loss of General Preference Systems discounts for exports to North America and Japan; International environmental obligations may lead to higher costs of production; Advanced ICT countries may wrongly see Lithuanians as consumers and not as developers/partners for modern products and services thereby leaving Lithuania out of BPO networks; Lack of coherent vision of the Lithuanian industry; Inconsistent policies and inadequate communications may lead to fragmented growth of IT and other high tech industry.

Chapter 1.9
Keeping the Flame Alive:
Sustaining a Successful Knowledge Management Program

Eliot Rich
University of Albany, USA

Peter Duchessi
University of Albany, USA

EXECUTIVE SUMMARY

This case study looks at how to keep a knowledge management initiative going after it has been successful for a couple of years. This organization found that continuously measuring benefits from the knowledge management system and keeping the knowledge in the system fresh and relevant were key to long-term success. However, achieving this was difficult as improving quality added more work to the already-busy managers and measuring worth was difficult.

INTRODUCTION

Michelle Johnson was in a reflective mood. As director of System Management Solutions International's (SMSI) knowledge management staff, she had led a two-year project to turn the firm's experimental use of groupware into a viable and important corporate asset. Her vision of a technology-driven resource for sharing the corporation's expertise was in operation.

These first two years focused on the start-up issues that had stymied the knowledge management (KM) projects of others. Her team had managed to find a combination of formal and informal incentives that stimulated hundreds of staff members to share their experience with others around the firm. The technology architecture to connect the firm's worldwide offices was in place. Finally, senior management support for the effort was, for the moment, sufficient to fund the current effort.

Now she needed to consider what was next for the program. The satisfaction Ms. Johnson felt over the successful integration of KM techniques into the company was tempered by concerns about the program's future. Surveys showed that staff satisfaction and participation was quite high, and user feedback about the quality and breadth of the KM system was positive, though not as high as earlier in the year. There was particular uncertainty about the attitude of SMSI's partners, who paid for the program but did not receive the direct knowledge benefits seen by the field workers.

The planning for future KM activities at SMSI needs to focus on sustaining the momentum and effectiveness of the program as the firm moved from a booming consulting industry to one where projects were becoming more scarce. Thus, the critical issue becomes maintaining the current success of its KM initiatives and system, given both external and internal changes.

BACKGROUND

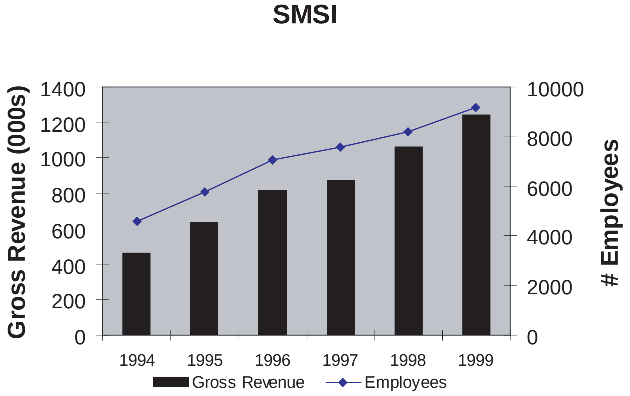
SMSI, founded in the early 1970s, is a publicly held business consulting and IT services firm. During the last three decades, the firm has completed tens of thousands of engagements, ranging in intensity from a few staff weeks to hundreds of staff years. While technology implementations were still the main focus of the firm, its expertise in change management and specialized content areas (e.g., human resource management, government operations, financial reporting) have become an important part of the firm's portfolio. By most measures, the firm has been very successful. Gross revenues of the firm have grown steadily since its founding, reaching $1 billion in the late 1990s. In parallel, staffing has grown from about 4,500 employees in 1994 to almost 9,000 by the end of 1999 (Figure 1).

SETTING THE STAGE

The Resource Structure of SMSI

SMSI is organized around lines of business and geographic regions. Within each region, it followed what is more or less a prototypical staffing model, consisting of three professional levels. Consultants are the "worker bees" responsible for the execution of specific tasks. Managers, the next level in the organization, organize, instruct, and review consultant work as well as develop work that requires more experience. Partners, at the high end of the structure, are responsible for leadership of major projects, define strategy for the firm, develop business opportunities, and maintain client relations. These three roles are "the grinders, the minders, and the finders" of the consulting business (Maister, 1997). These professional roles are backstopped by a support organization that sustains the day-to-day operations of the firm.

Figure 1. SMSI revenues and staffing



The Role of KM

Consulting is fundamentally a knowledge-based business. Clients use consultants to provide hard-to-develop skills, retaining them for short periods, the duration of a project, or sometimes longer. Over the last decade a transition has occurred in the consulting business, away from treating every problem as a unique opportunity, and toward rapid leverage of experience. This creates a new perspective on the role of the consultancy, where consultants act as information brokers, using connections across industries and projects to identify classes of problems, and applying their collective skills to solve them (Sarvary, 1999). Consulting firms act as a resource hub, with networks of staff that can reuse their knowledge for multiple clients. Finding the right skills within the consultancy and bringing them to bear quickly is a key selling point. Therefore, consulting firms need to find techniques for sharing their experience quickly, and creating the linkages and team structures that attract clients.

Staffing and Knowledge Retention

Every year consulting firms organize hiring plans based on their projected project demand. Many recruit from undergraduate and graduate programs, preferring to train staff in their unique approach to business and clients. New consultants face a great deal of work pressure and competition for managerial positions, and a large proportion of them leave before moving to the managerial ranks. The combined effects of long work hours, uncertain career paths, and competitive pressure for recognition all exert adverse pressure on junior staff. Similarly, there is churn in the managerial ranks as experienced professionals try to develop the client relationships required to support promotion to partner. A small proportion of managers achieve partner status; the remainder may change firms or launch other opportunities. There is something of an "up-or-out" structure, similar to that seen in law firms.

Concern about turnover is of greater concern during upswings in the market, as there is more competition for talented staff. In these times, firms must replace staff recruited away by competitors as well as recruit new consultants to meet swelling demand for services. These two forces have generated hiring rates as high as 40% per year for some large companies, which in turn create a great strain on the firms to train and integrate these new employees into the firm.

Turnover also affects the knowledge available to the firm. When experienced staff leave the firm, they take their knowledge with them. Rather than risk the loss of this knowledge, consulting firms actively collect and codify project-based materials, write practice guides and methodologies, and synthesize their experience in written, oral, and multimedia forms. When new inexperienced staff arrive, these codified assets provide significant leverage. The "push" model of individual training and mentoring of juniors by seniors has given way to a "pull" model, where experience is made available on demand through databases and communications networks.

KM in Consulting Companies

The staggering rate of change in the volume of information has accelerated the need for information and knowledge management. Individuals and companies that have their fingers on the pulse of the newest and most useful information can command a high price for their knowledge, if they can bring it to their clients quickly. This, in turn, means that the experts must access and leverage their own knowledge acquisition and retention, so that they always have the best information for their clients.

The consulting environment has always required mobility and flexibility, and the knowledge resources of the firm must be at the fingertips of consultants in the field. As one manager put it, "We're all road warriors now." It's not clear if staff spend more time on the road than in the past, or if they are just expected to be available and productive whether in or out of the office. Consultants are expected to use technology, primarily e-mail, and to remain connected to the corpus of the firm. In these firms, successful knowledge management implementations mean that the road warriors can bring the intellectual resources of the firm with them to client sites. It is not surprising that large consulting firms were also early adopters of knowledge management technologies (e.g., Alavi, 1997; Bartlett, 1996; Chard, 1997; Reimus, 1997). Knowledge management is a competency of interest to consulting clients, and the ability to demonstrate internal implementation competence and benefit validates the credentials of the firm to potential clients.

CASE DESCRIPTION

For SMSI, the ability to leverage its existing experience through KM technology came none too soon. The late 1990s were very busy times for technology and management consultants, and SMSI rode the leading edge of the boom. To meet customer demand, SMSI hired staff at an unprecedented rate. At the same time, staff turnover was very high, peaking at about 20% per year, as the combination of work pressure and opportunities in a skill-seller's market makes retaining staff difficult. Much of the turnover was among staff with experience in the most current software platforms. As new skills were learned, many staff left SMSI to chase better offers. This staff churn created a continuing outflow of knowledge from the firm's resources.

Surging growth, technical change, and high turnover created great pressure within the firm to capture and disseminate knowledge and experience. Lessons learned in one project might be immediately useful elsewhere, and certainly would provide value to someone else in the firm. When the firm was smaller, staff with questions could discuss them with others in the same office; now, expertise was more scattered and less available. Individuals did not know each other as well as they did in the past, and there has been a sense of reluctance to contact individuals outside the immediate workgroup.

Long-time employees are concerned about the effects of rapid growth on the organization's culture of information sharing. One termed the effect "intellectual sprawl," where consultants in different business units were re-creating the same work products and techniques independently. In their view, there was not enough sharing of the lessons of technology and engagement management, at a time when the proportion of inexperienced staff grew. While the knowledge management program attempts to facilitate sharing, there was still a sense that the best ideas were not always available, and that human contacts were superior to the use of an information system.

Developing SMSI's KM Program

The development of a formal KM program at SMSI was facilitated by the firm's history in information systems consulting. From a practical standpoint, the firm was well positioned to implement the complex technological infrastructure associated with KM. The firm's leadership committed to solve the technical success and the cultural and social challenges that KM presents. This recognition allowed SMSI to avoid some of the stumbling blocks that less sophisticated firms faced.

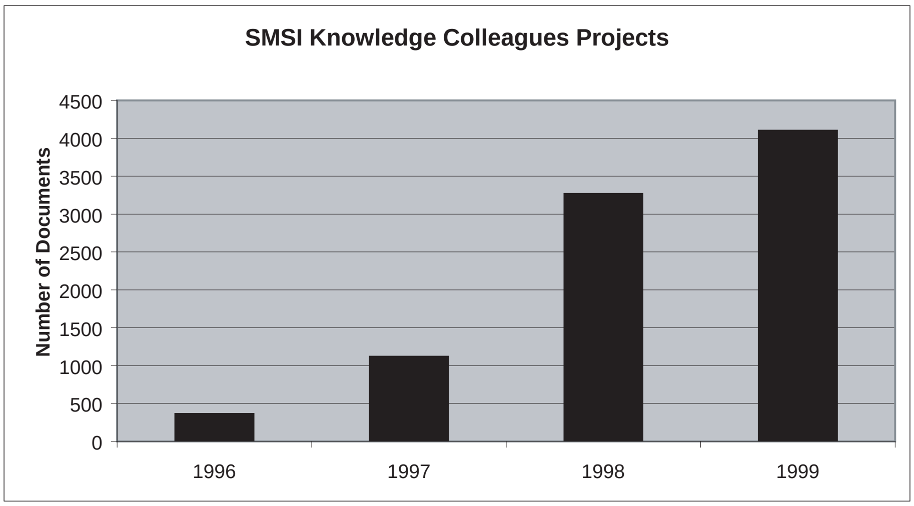
Experimentation with KM technologies started in 1992, with the introduction of Lotus Notes as a groupware tool. By 1998, almost 100 Notes servers were in place, and all office-based personnel had desktop access to the tool; most field personnel had shared access through one or more Internet-enabled computers. When the tool was adopted as a firm-wide standard, a number of special interest groups (SIGs) were established, and used Lotus Notes as a tool to facilitate discussions across offices on topics of mutual interest as well as an e-mail backbone. Most were informal discussions on emerging technologies; these discussions rarely lasted more than a few months as individual knowledge needs changed. Often they became places to ask direct questions from individuals across the firm, with additional follow-up through telephone calls. Occasionally some synthesized databases stimulated working papers or, eventually, encapsulations of SMSI's best practices.

To stimulate further development and sharing of information, SMSI established a Knowledge Colleagues program. Staff working in business units proposed short-term technology experiments or projects, resulting in the development of a paper or prototype to share throughout the firm. Individuals were released from their project work for two weeks to work on their tasks, with the expectation that they would also contribute additional time to complete their work. A series of activities dealing with knowledge sharing was established in late 1996, facilitating transfer of information across several core disciplines around the firm. The initial series included systems development, business process reengineering, customer value management, engagement management, change management, advanced technologies, and decision analytics. Knowledge management and electronic commerce were added in 1998, along with the firm-wide rollout of the technology platform.

During these first few years, the list of completed contributions grew from 400 to over 4,000 topics (Figure 2). This growth was a mixed blessing. Ms. Johnson noted that the more recent documents were not as useful as earlier ones. The initial topics tended to be of more general interest, and later ones were more specialized to particular problems and industries, and less relevant to the general population. In addition, there was less review of the contents as the number of documents grew.

SMSI's KM program extended beyond the development of the Colleagues program. A small headquarters-based unit acted as a clearinghouse for the firm's current and past activities. Databases of current activities across the firm, model

Figure 2. SMSI knowledge colleagues projects



deliverables, and frequently asked questions were made available. They were representative samples of well-received project materials, client proposals, templates, and general advice on the topics at hand. Experts and thought leaders in the topic area were identified, and their particular expertise highlighted. Discussion databases, where questions may be posed to these experts, received several postings a day. These discussion databases could be initiated by anyone in the firm, and there were literally thousands of them. No central repository was maintained, and the contents were often informal and somewhat wild and wooly.

SMSI's Knowledge Colleagues also agreed to participate in the discussion databases and make themselves available for ad hoc questions around the firm. Through their responses, the Colleagues extend the informal information network that corporate growth was dissolving. The time they spend in this role was not billable to any project, and went largely unmonitored. Here, more than anywhere, the altruistic nature of the knowledge-sharing experiment was seen, as individuals who answered questions were often contacted off-line for further explanations.

CURRENT CHALLENGES

The success of the SMSI KM program was quite remarkable. Almost all of SMSI's staff used the KM system in some fashion. The most pleased were the junior and mid-level consultants, who found ready reference for their project needs and routine questions about the firm. Managers and partners used the system to locate experts for use in proposals and to fill staffing gaps for projects. This was particularly valuable when there were few available resources, and there seemed to be a constant scramble to match client needs with experienced consultants.

Of all the various facets, Ms. Johnson was proudest of the Knowledge Colleagues program. Here, more than 800 members of the professional staff, almost 10% of the firm's employees, were volunteering time to share their experience with others around the firm. This was the essence of the cultural change that SMSI needed to leverage its knowledge capital. The program's participants were eager to add new materials to the collections available across the firm, as their contributions were noted in their annual performance reviews as an important contribution to the culture of the firm. While not a large measure, there was clearly some recognition in the review process that was felt to factor into raises and promotions.

Now that the program is in place, Ms. Johnson's challenge is to establish that SMSI's KM can continue to provide value. Will the KM system continue to provide useful information? She considered the primary driver of the KM program's success to date: the perceived positive effect on users and the firm.

User value is subjective, resting in how the user applies the knowledge to the problem at hand. A KM system may provide a specific answer to a direct question, or it may provide some insights into an issue that add value in a new context. In a knowledge-intensive industry, the results of answers may be easy to measure (such as the foregone cost for work that could be borrowed, rather than repeated), or may be very difficult to quantify (as with the value of a confirming perspective prior to taking a decision).

To facilitate the acceptance of the KM program, there was no cost to using the system. It was hoped that a free system to share knowledge would demonstrate its value organically, rather than through a pricing mechanism. It was expected that the free system would demonstrate particular deliverables (i.e., training courses) that might be subject to internal development charges.

With KM systems, as with other types of decision support tools, users who do not like the tool may choose to ignore it or not contribute to it. Thus one measure of user value is the level of participation. In traditional transaction-oriented

IT systems, users have little choice about using the technology. They may love it, or they may hate it, but the computer is still integral to performing their jobs, and users are compelled to make do with the system. Thus continued participation and inquiry of a KM system may be used as a surrogate for satisfaction.

In turn, satisfaction with a KM system often generates additional demands for knowledge. The more value users found with the information contained in the system, the more likely staff were to come back with additional requests and inquiries (and the higher the costs of the system to develop new materials). The evidence that requests were growing was the major justification for continued funding of KM efforts at SMSI.

A more formal measure of effect was still elusive. In manufacturing environments, it is possible to identify the value of knowledge through reductions in defects, worker productivity, or other production-based metrics. In consulting, the results of learning and transferred experience through the use of KM tools tended to be a better quality of ideas, rather than simply finishing work more quickly. One consultant noted, tongue-in-cheek, that finishing work more quickly might even be against the firm's principles, particularly if the client was paying by the hour. The senior managers reviewing the effects of KM on the organization were asked to think about softer and more anecdotal measures than they were used to, with user satisfaction being a primary indicator of continued success.

Of course, reasoned Ms. Johnson, this would likely work in reverse as well: A KM system that did not address the needs of the users would get less use. Requests would taper off, starting a possible downward spiral toward obsolescence. Such a spiral would be hard to identify beforehand, and would be difficult to reverse. Thus sustaining a KM program requires several critical adjustments to the KM program to maintain the positive momentum and continually demonstrate the KM system's value to users and the firm. Yet, Ms. Johnson thought, how does SMSI (or any firm for that matter) meet these challenges?

Encouraging the collection of knowledge from a large number of contributors had several unanticipated consequences. The most concrete was a large accumulation of materials, not all of which were adding to the available knowledge for several reasons. First, redundant materials have little incremental impact. At the outset of the Knowledge Colleagues program all contributions were welcome. In response, staff posted their planning tools, interim deliverables, and project documents for use by others. Over time, though, the incremental value of these postings to others decreased. When searching for a topic, many users looked only at the first few hits. Having seven or eight or 15 examples of a project schedule made little difference in outcome, but they do consume resources.

Second, collected materials become obsolete, and their effects on the organization decrease. The collection of project materials and examples permitted the dissemination of new information quickly. Over time, though, the older materials became less useful as techniques change and market requirements shift. In the fast-changing world of information technology consulting, some materials were really only useful for a few weeks or months. After that, they might be misleading or just plain wrong. If users of the KM system find that materials are not current, their satisfaction will drop, and they are less likely to ask for information in the future.

Third, the "core knowledge" needed by the firm was about to change because the marketplace was about to change as well. When SMSI's KM program was launched, the firm was struggling with integrating thousands of newly hired employees into the fabric of the firm. When a new hire arrives, the KM system gives him or her a ready source for contacts around the firm and exposure to SMSI's project portfolio. This eased the transition into the firm, and made these new hires much more productive.

With the slowing of the consulting marketplace, however, the firm may not be hiring staff as quickly, and the value of indoctrination-focused knowledge falls. In a declining market, emergent needs revolve around developing and maintaining customers and looking for new opportunities, rather than sharing knowledge about techniques to complete projects. The SMSI partners, who made up the firm's marketing and management teams, needed support in their quest to obtain work. Internal data sources, while providing information on the firm's existing project and resource portfolios, provided limited value in their search.

SMSI was willing to pay for the KM infrastructure and support participation in knowledge activities. This senior management support came from the desire to retain and reward key employees, and less from any formal calculation of the knowledge benefits to the firm. In a time of high turnover, any reasonable technique to retain staff through formal and informal recognition was deemed useful. Even in the absence of financial value, the firm's partners and senior executives believed that the program was helping the firm manage its growth in a time of technical change and rapid expansion of staff.

The belief in the potential of KM to sustain the company through this period of growth was most manifest in the recognition of Knowledge Colleagues. Participation in the program was specifically considered during staff personnel reviews, and Colleagues were given special business cards that identified them as participants. This provided both financial and psychological incentives to participate.

As she considered these observations, Ms. Johnson saw that they interacted in a complex way. Firm growth stimulated demand for knowledge, and the programs she developed helped to meet that need. The internal programs and incentives created an active knowledge-sharing environment. Was there more "knowledge sharing" than could be maintained while preserving quality? Should there be additional screening or reviews put in place? What effects would such changes have on the culture of the firm and incentives to provide knowledge?

Forces external to the firm would also affect what direction KM should take. SMSI had benefited from the explosive growth in e-commerce paired with the millennial-driven Y2K systems revisions. The suddenness of these industry changes created an extreme demand for information and solution reuse, which provided great leverage from the collected knowledge assets of the firm. There was little expectation that this type of work would continue at the same pace, and much of this previously valuable information would no longer be needed. The cost of keeping existing materials is small, as long as they are correct.

What new knowledge needs would emerge when markets start to decline? Integrating new staff was going to be less important. What knowledge will be needed to maintain SMSI's revenue and opportunities for growth? Are there unmet internal markets for knowledge that might still be exploited? This is another area Ms. Johnson wanted to explore.

The internal KM program at SMSI needed to shift its focus from creating a knowledge-sharing organization to one that manages its knowledge as an asset that depreciates over time. The success of the program would be based on maintaining the value and quality of its contributions to its users. In addition, a somewhat shaky forecast for SMSI's services would affect the willingness to support programs that do not demonstrate bottom-line contributions. Was there a way to directly demonstrate the value of knowledge sharing to the partners of the firm?

She believed that ongoing investment is needed, but was not sure how should it be applied. Is the development of new knowledge more important than cleaning up and review of older information? Are the incentives in place adequate to keep the internal knowledge channels open? What about developing new markets for KM? What should be the focus of her team's activities?

EPILOGUE

The Manager's Actions

In late 1999, Ms. Johnson unveiled her plans for creating a sustainable KM program for SMSI. There were two major threads to her plan. First, she believed that it was necessary to maintain the KM resource as a source of reliable, solid information. While the Knowledge Colleagues program had engaged thousands of people in the firm, some of the materials were not well regarded. Second, she needed to establish the worth of the program in a formal manner.

To meet the first objective, she revised the Colleagues program's structure. Starting in 2000, all new contributions were reviewed by senior managers of the firm to ensure their applicability and accuracy before they were accepted for distribution. In addition, all the existing materials were reread for continuing value, with revisions or deletions as required. A cap of 500 new topics per year was put in place, roughly the same number of contributions as in the first year of the program. Ms. Johnson felt that this was about the maximum number of documents that could be adequately reviewed each year.

At first, limiting the number of contributions did increase the quality of the contributions, as there was now a need to weed out weaker materials. This had a secondary effect, however, as rejected materials discouraged participation in other aspects of knowledge sharing among previously enthusiastic junior staff.

The increased emphasis on quality necessarily also increased the workload on the managers and partners who participated in the Colleagues program. These staff had the experience and breadth of knowledge to evaluate the usefulness of contributions to the firm, and their applicability beyond a particular project. The change of their role from creator to reviewer was unwelcome, and their enthusiasm for the voluntary nature of the program was shaken. To counter this anticipated shift in collegial spirit, SMSI agreed to maintain the formal (i.e., financial) recognition for those staff still participating in the program.

The second goal, establishing the worth of the KM program, remained elusive. Throughout the program's introduction, the KM staff was careful to collect any anecdote about the financial worth of materials obtained through its offices. War stories of projects working on opposite sides of the globe shared information and materials were disseminated. A set of user surveys were conducted to ask for estimates of value from users; these yielded highly suspect results, particularly one that estimated that the KM program yielded half the net revenue of the firm for 1998. The continuing internal support of the program was still largely based on the belief that it was working, and that competitors were doing it as well, rather than concrete value.

Longer-Term Results

The emergent recognition of the need to balance volume of collected knowledge and maintaining quality and was disrupted by forces outside the control of Ms. Johnson and the KM staff. The postmillennial slowdown in IT consulting drastically changed the SMSI workplace, and in turn, the KM program. The initial changes came from a drastic drop in new project work. As projects completed, there were fewer new assignments, and more staff went unassigned. By late 2000, hiring was frozen, and the turnover rate dropped to about 2% as competitors no longer hired skilled staff away.

In an attempt to shore up their finances, SMSI stopped funding all activities that did not directly contribute to revenue. Development of knowledge materials for training and indoctrination work was curtailed, particularly as virtually no new staff was joining the company. KM programs, while believed important, were carried as an overhead expense to the firm, and the financial support was withdrawn.

The nonfinancial incentives for participating dried up as well, as staff became more concerned about maintaining their own positions than assisting others for the good of the firm. There was great pressure to "tend to one's own garden," and use whatever time was available to develop leads for potential projects, rather than participating in the Colleagues program. Indeed, this was a rational perspective, as a series of layoffs dropped the payroll to 7,200 by 2001.

By mid-2001, much of the KM program, including the Knowledge Colleagues program, had been dismantled. Ms. Johnson left SMSI to join a new consultancy firm that specialized in knowledge management, along with many of her staff. The KM program continued at a much smaller scale, focusing on market intelligence and skill building for the SMSI staff.

Lessons Learned

The final straw for the KM system was the weakness in SMSI's markets, and the reaction of its management to reduce funding. This was not in the scope of control of the KM managers. Nevertheless, there are several elements that may be taken away from the case.

- More is not always better. Developing a community of knowledge-sharing staff was a particular concern to SMSI's KM managers. To this end, their program emphasized a broad-based, inclusive approach that encouraged participation and knowledge sharing. After some time, however, the quality of the knowledge shared was not equal to the quantity that was available. This perception of dropping quality may have contributed to the program's later weakness. This problem would become more visible as the collection of accepted knowledge grew. A more selective process for accepting contributions, along with a process of vetting and reviewing the content of the system, might have mitigated.
- Monitoring usage. Integrating a usage or rating scale into the knowledge system would have assisted in identifying materials that were outdated or not widely applicable. More modern KM systems than that available at SMSI recognize this need, and assign weights to materials that have been evaluated by the users as useful or not. Examples where this is present include the customer service sites at Symantec and Microsoft, which ask users to rate the usefulness of retrieved items.
- Recognizing the stakeholders. While the SMSI program clearly recognized the needs of junior consultants and managers, it was less successful in developing the same kind of respect among partners, who ultimately paid for the system. For this group, the anecdotal evidence that the KM program was useful was not sufficient to continue its funding as the financial position of SMSI worsened. In comparison, a competitor firm spent considerable effort developing marketing and prospect management knowledge bases for the partners. When faced with the same declining market, this competitor continued to fund its own KM system, in large part because it provided direct benefits to those making financial decisions about its future. The axiom "Follow the money" continues to ring true.

Chapter 1.10
Knowledge Transfer

William R. King
University of Pittsburgh, USA

INTRODUCTION

The term knowledge transfer (KT) is often used in a generic sense to include any exchange of knowledge between or among individuals, teams, groups, or organizations, whether intended or unintended.

However, knowledge transfer, as it has been formally studied, reflects intended unidirectional exchange, as when an enterprise resource planning (ERP) systems consultant transfers implementation knowledge to a potential user of a system, or when a franchiser's training team transfers knowledge about how to operate a franchise to a franchisee's team. Such knowledge transfers are between a clearly defined source and a recipient, have a focus, and have a clearly identified objective.

Although this unidirectional, focused, objective-oriented view is widely held among those who have a professional or academic interest in the KT process, there are different schools of thought concerning exactly when transfer can be said to have taken place between a source and a recipient. Some adopt the view that knowledge must both be communicated and applied before it has been transferred; others take the view that if the recipient of knowledge has the capacity to apply it, transfer has occurred. Still, others assume that if it has been cognitively transferred (e.g., understood), it has been transferred. Each of these viewpoints appears to be useful in certain circumstances, so there is no universal agreement on which is best.

However, there is agreement that knowledge transfer is different from knowledge sharing, which may be an unfocused exchange among individuals or groups who have little intention to send or receive knowledge (see article titled "Knowledge Sharing" in this encyclopedia). Of course, knowledge sharing may also have a focus as when persons engage in a brainstorming group session in order to generate new ideas or enhance creativity.

Perhaps the best way to conceptualize knowledge transfer and knowledge sharing is that they are at two ends of a spectrum. The knowledge transfer end is formalized, with a clearly defined purpose, and is unidirectional. The knowledge-sharing end is multidirectional, informal, and has no clear objective and few rules. Between these extremes lies a wide range of possible combinations involving individuals, teams, groups, organizational units, and organizations. Different people may use different terminology to describe these possible situations, but the end points are well grounded in theory and in practice.

BACKGROUND

Knowledge that is transferred may be either tacit, explicit, or a combination of both (Nonaka, 1994). When a master craftsman works to develop the skill and knowledge of an apprentice, he is transferring tacit knowledge. When a physician highlights a finding in a medical research paper and sends it to an associate, she is transferring explicit knowledge. When an ERP consultant shows a potential system user how to use tools and tables to implement a system, he or she is transferring a combination of tacit and explicit knowledge.

Knowledge transfer is very important because without it, every problem-solving approach or operating skill would have to be reinvented each time that the knowledge is needed. Indeed, it may not be overstating the case to say that knowledge transfer is a fundamental process of civilization. Certainly, it is a focus of learning, which is critical to all advancement.

As treated here, knowledge transfer is the communication of knowledge from a source so that it is learned and applied by a recipient (Argote, 1999; Darr & Kurtzberg, 2000). The source and recipient may be individuals, groups, teams, organizational units, or entire organizations in any combination.

Knowledge is usually defined as a justified belief that increases an individual's capacity to take effective action (Alavi & Leidner, 2001). Explicit knowledge is transmittable in formal, systematic language. Tacit knowledge "dwells in a comprehensive cognizance of the human mind and body" (Nonaka, 1994).

One of the central tenets of KT relates to the ease of transfer across individuals, groups, and organizations. Codified knowledge may be transferred in the form of documents and manuals. When the codified knowledge is of the know-what (concerning the state of the world) variety, the passage of the materials may complete the transfer. However, when the codified knowledge is of the know-how (competence) variety, complementary discussion or practice involving both the source's and recipient's tacit knowledge is often necessary to complete the transfer (Edmondson, Pisano, Bohmer, & Winslow, 2003).

When the knowledge to be transferred is tacit, the proximity of the source and recipient and their interpersonal interactions influence the likelihood of successful KT. Some tacit knowledge may be verbalized, explicated, codified, and communicated to others. This is an important mechanism of knowledge transfer, although many other processes are valid and useful as well. Some tacit knowledge may not be transferable, or at least will require demonstrations by the source and practice by the receiver.

Commercial knowledge, which may be either explicit or tacit, "... is not truth, but effective performance; not right, but 'what works' or even 'what works better'" (Demarest, 1997). Commercial knowledge is an important focus of practical knowledge transfer in organizations. It is exemplified by the implementation knowledge—sets of rules, tools, guidelines, and ways to effectively employ them—that is conveyed by a consultant who is aiding a client in implementing or customizing a complex information system in the client's organization. For instance, in this context, consultants may transfer knowledge about testing procedures to clients who learn and apply this knowledge as evidenced by the clients developing test scripts, conducting tests of individual modules, and running integration tests to ascertain whether data are correctly passed between modules.

ISSUES IN KNOWLEDGE TRANSFER

The best way to measure KT has not been uniquely determined. First, there are the conceptual issues, noted earlier, concerning when transfer shall be deemed to have taken place. Whichever definition is adopted, transfer is usually measured through surrogates. For instance, Szulanski (1996) measures "stickiness": the difficulty in transferring knowledge in an organization. A few studies (e.g., Ko, Kirsch, & King, 2005) have used direct measures for specific contexts, for instance, by observing a recipient's ability to perform tasks that are related to the objectives of the transfer. However, most studies have not used behavioral measures of successful KT.

A major issue in knowledge transfer has to do with the antecedents, or determinants, of effective KT. In other words, what factors most importantly influence successful knowledge transfer?

Argote (1999) depicts four categories of antecedents for knowledge transfer between organizations: characteristics of the relationships among organizations, characteristics of the knowledge transferred, characteristics of the organizations, and characteristics of the transfer process. After examining a number of such factors, Szulanski (1996) identified two categories of antecedent factors: knowledge barriers and motivational barriers to the transfer of best practices between sets of individuals in an organization. Ko et al. (2005) added communications factors because such factors have been found to be important in KT in information systems implementation processes (Hartwick & Barki, 2001).

Knowledge-Related Factors

An arduous relationship, causal ambiguity, shared understanding, knowledge observability, and absorptive capacity are widely believed to be important knowledge-related antecedent factors for successful KT. These factors are related to the source's and/or recipient's knowledge base or ability to acquire knowledge when it is needed, as well as to their knowledge relationship. An arduous relationship refers to the quality of the relationship between the source and recipient. Successful transfer usually requires many interactions for the knowledge to be successfully transferred. An arduous relationship, one that is emotionally laborious and distant, is likely to adversely influence knowledge transfer (Faraj & Sproull, 2000).

Causal ambiguity refers to "ambiguity about what the factors of production are and how they interact during production" (Szulanski, 1996, p. 30). Taken literally, this refers to the production of goods, but it may also apply to the production of knowledge. Although this interpretation is untested, it is not unreasonable to posit that if the source and recipient understand how knowledge has been produced and to what it relates, this relative absence of ambiguity might facilitate transfer.

Shared understanding represents the extent to which a source's and recipient's work values, norms, philosophies, problem-solving approaches, and prior work experience are similar. Studies suggest that having similar heuristics and similar shared experiences are important to knowledge transfer (Hansen, Nohria, & Tierney, 1999). Without shared understanding, there is a tendency for the source and recipient to disagree, which leads to poor outcomes. Shared understanding probably removes barriers to understanding and acceptance between the two parties and enhances their ability to work toward a common goal.

Knowledge observability leads to more effective transfer. Knowledge observability is "how easy it is to understand the activity by looking at and examining different aspects of the process or final product" (Zander, 1991, p. 47). The basic premise underlying this concept is that knowledge may be a sticky asset, making it difficult to transfer (Szulanski, 1996). Knowledge observability makes knowledge less sticky, which should enable better transfer (Birkinshaw, Frost, & Ensign, 2002).

Absorptive capacity is the ability of a recipient to recognize the value of the source's knowledge, assimilate it, and apply it. This capacity is largely a function of the recipient's existing stock of knowledge prior to the transfer, which enables a recipient to value, assimilate, and apply new knowledge successfully (Galbraith, 1990).

Motivational Factors

Factors such as a lack of incentives, a lack of confidence, "turf protection," and the "not-invented-here" syndrome are considered to be motivational factors that may influence knowledge transfer. Not all of these have been extensively studied, but motivation in general has been shown to be a positive factor in transfer. For instance, in a technological transfer context, knowledge-acquiring firms were found to accelerate the speed of KT when other companies were perceived to be developing similar products (Zander & Kogut, 1995).

For practical purposes, it is useful to distinguish between intrinsic and extrinsic motivation. Intrinsic motivation exists when the activity "... is valued for its own sake and appears to be self-sustained" (Calder & Shaw, 1975, p. 599). In contrast, extrinsic motivation comes from external sources. Intrinsic motivation in an organizational setting can be influenced by appropriate personnel selection. Extrinsic motivation can, on the other hand, be influenced by specific rewards for transferring knowledge, the inclusion of knowledge transfer as an element of personnel evaluations, and other explicit forms of reward or recognition.

A best-practices repository is a good illustration. Technically, this involves knowledge sharing since one person or unit contributes a practice to be shared by initially unidentified others. However, once a best practice has been identified by a potential user, the source is typically contacted with questions and requests for complementary tacit knowledge. At that point, it becomes a KT process. In such instances, it has been found that careful screening of the ideas that are submitted provide the best results. Many firms have a committee that carefully evaluates each best-practice submission. Only those that are the best of the best actually get put into the repository. The submitter's name is prominently displayed on the best practice, thereby conferring status on those whose ideas have passed this rigorous test. Similar recognition is given to those who make significant contributions to the well-known open-source Linux software (Lee & Cole, 2003).

Communications Factors

The information systems literature has identified various communications factors as impediments to successful system implementation (e.g., Hartwick & Barki, 2001). Among the most important are source credibility and communications competence.

Source credibility is a communications factor that reflects the extent to which a recipient perceives a source to be trustworthy and an expert (Grewal, Gotlieb, & Brown, 1994). When source credibility is high, the knowledge presented is perceived to be useful, thereby facilitating transfer. When source credibility is low, recipients tend to be less-readily persuaded and may heavily discount the value of the knowledge that is the focus of the intended transfer. The transfer of knowledge between departments in a firm has been found to be importantly influenced by the credibility of the source (Slaughter & Kirsch, 2000).

Communications competence is the ability to demonstrate the appropriate communications behavior in an organizational setting. Communications within a dyad requires both the encoding and decoding of messages. Encoding competence is the ability to clearly put ideas into words or symbols, have a good command of language, and be easily understood. A study of communications encoding competence suggests that subordinates form either positive or negative perceptions about their supervisor based on this ability (Berman & Hellweg, 1989).

Decoding competence refers to a recipient's ability to listen, be attentive, and respond quickly. This capability has also been shown to affect working relationships and to create opportunities to improve relationships.

Many studies have shown that communications competence is important for resolving conflicts, having effective teams, and providing opportunities to improve the quality of relationships; all of these outcomes are correlated with successful knowledge transfer.

FUTURE TRENDS

The KT source and recipient model appears to be a powerful analytic tool for many situations in which knowledge must be communicated and learned by someone who is less experienced and is less qualified than the source.

A major need that is beginning to be filled is for measures of successful knowledge transfer that incorporate the impact aspect of transfer whether it is cognitive or behavioral.

Some research results that are either widely accepted or recently developed are the following:

1. An arduous relationship between the source and recipient negatively affects KT (e.g., Szulanski, 1996).
2. Shared understanding between the source and recipients is particularly important to successful KT (Ko et al., 2005).
3. Absorptive capacity has long been believed to be important in influencing effective KT (e.g., Galbraith, 1990).
4. Knowledge observability is important to successful KT (e.g., Birkinshaw et al., 2002).
5. Intrinsic motivation may be more important than extrinsic motivation in KT.
6. Source credibility is important in KT, while the source's encoding competence may not be so important (e.g., Ko et al., 2005).

CONCLUSION

Knowledge transfer is done more efficiently when the knowledge to be transferred is relatively more explicit and relatively less tacit. Most organizations use structures and processes such as routines and standard procedures to codify as much of the knowledge that is to be transferred as is possible (Cohen & Bacdayan, 1994; March & Simon, 1958).

This is important because in the general situation of transferring knowledge, there is the assumption that meaning is universal and that the contexts of the sender and receiver are relatively homogeneous. In fact, the meaning that is given to knowledge is situational, cultural, and contextual. Thus, knowledge transfer should be more successful when these factors are similar for the sender and receiver. This is why the transfer of knowledge in complex systems implementation and in franchisee training is based on so many standard procedures, routines, and documented knowledge, and why individuals are chosen to offer and receive such training that come from the same backgrounds. For example, the trainers have invariably served in the operating capacities for which they are instructing the trainee.

Of course, some tacit knowledge cannot be explicated, so it can only be transferred through demonstrations, as in apprentice training. This is a very expensive and time- consuming process, so the goal in most organizational settings is to put knowledge that needs to be transferred into as explicit a form as is feasible.

Other practical guidelines involving successful knowledge transfer are the following: (largely derived from Ko et al., 2005).

1. It is important to create situations where the source and recipient can interact frequently, thereby nurturing their relationship and enhancing the flow of knowledge.
2. Individuals who have the least need for new knowledge should be selected to be the initial recipients of knowledge (because the recipient's absorptive capacity is so important for effective KT). This means that KT in a professional setting should not initially be viewed as training.
3. When widespread training is necessary, a two- stage strategy may be useful. First, have those with the least need (those that are already best qualified) take part in the KT process; then have them transfer knowledge to those that are more in need of the new knowledge.
4. Personnel with the highest level of intrinsic motivation should be assigned to KT; extrinsic rewards are not effective, except perhaps in the earliest stages of KT.
5. Consulting firms and others who are being evaluated as potential sources of knowledge should be required to commit to the use of specific individuals in the KT process since the abilities of the individuals' sources are critical.

Chapter 1.11
Knowledge Management

Petter Gottschalk
Norwegian School of Management BI, Norway

Knowledge is an important organizational resource. Unlike other inert organizational resources, the application of existing knowledge has the potential to generate new knowledge. Not only can knowledge be replenished in use, it can also be combined and recombined to generate new knowledge. Once created, knowledge can be articulated, shared, stored, and re-contextualized to yield options for the future. For all of these reasons, knowledge has the potential to be applied across time and space to yield increasing returns (Garud & Kumaraswamy, 2005).

The strategic management of organizational knowledge is a key factor that can help organizations to sustain competitive advantage in volatile environments. Organizations are turning to knowledge management initiatives and technologies to leverage their knowledge resources. Knowledge management can be defined as a systemic and organizationally specified process for acquiring, organizing, and communicating knowledge of employees so that other employees may make use of it to be more effective and productive in their work (Kankanhalli, Tan, & Wei, 2005).

Knowledge management is also important in interorganizational relationships. Interorganizational relationships have been recognized to provide two distinct potential benefits: short-term operational efficiency and longer-term new knowledge creation. For example, the need for continual value innovation is driving supply chains to evolve from a pure transactional focus to leveraging interorganizational partnerships for sharing information and, ultimately, market knowledge creation. Supply chain partners are engaging in interlinked processes that enable rich (broad-ranging, high-quality, and privileged) information sharing, and building information technology infrastructures that allow them to process information obtained from their partners to create new knowledge (Malhotra, Gosain, & El Sawy, 2005).

CHARACTERISTICS OF KNOWLEDGE

Knowledge is a renewable, reusable, and accumulating resource of value to the organization when applied in the production of products and services. Knowledge cannot, as such, be stored in computers: it can only be stored in the human brain. Knowledge is what a knower knows; there is no knowledge without someone knowing it.

The need for a knower in knowledge existence raises the question as to how knowledge can exist outside the heads of individuals. Although knowledge cannot originate outside the heads of individuals, it can be argued that knowledge can be represented in and often embedded in organizational processes, routines, and networks, and sometimes in document repositories. However, knowledge is seldom complete outside of an individual.

In this book, knowledge is defined as information combined with experience, context, interpretation, reflection, intuition, and creativity. Information becomes knowledge once it is processed in the mind of an individual. This knowledge then becomes information again once it is articulated or communicated to others in the form of text, computer output, spoken or written words, or other means. Six characteristics of knowledge can distinguish it from information: knowledge is a human act, knowledge is the residue of thinking, knowledge is created in the present moment, knowledge belongs to communities, knowledge circulates through communities in many ways, and new knowledge is created at the boundaries of old. This definition and these characteristics of knowledge are based on current research (e.g., Poston & Speier, 2005; Ryu, Kim, Chaudhury, & Rao, 2005; Sambamurthy & Subramani, 2005; Tanriverdi, 2005; Wasko & Faraj, 2005).

Today, any discussion of knowledge quickly leads to the issue of how knowledge is defined. A pragmatic definition defines the topic as the most valuable form of content in a continuum starting at data, encompassing information, and ending at knowledge. Typically, data is classified, summarized, transferred, or corrected in order to add value, and become information within a certain context. This conversion is relatively mechanical and has long been facilitated by storage, processing, and communication technologies. These technologies add place, time, and form utility to the data. In doing so, the information serves to inform or reduce uncertainty within the problem domain. Therefore, information is united with the context, that is, it only has utility within the context (Grover & Davenport, 2001).

Knowledge has the highest value, the most human contribution, the greatest relevance to decisions and actions, and the greatest dependence on a specific situation or context. It is also the most difficult of content types to manage, because it originates and is applied in the minds of human beings. People who are knowledgeable not only have information, but also have the ability to integrate and frame the information within the context of their experience, expertise, and judgment. In doing so, they can create new information that expands the state of possibilities, and in turn allows for further interaction with experience, expertise, and judgment. Therefore, in an organizational context, all new knowledge stems from people. Some knowledge is incorporated in organizational artifacts like processes, structures, and technology. However, institutionalized knowledge often inhibits competition in a dynamic context, unless adaptability of people and processes (higher order learning) is built into the institutional mechanisms themselves.

Our concern with distinctions between information and knowledge is based on real differences as well as technology implications. Real differences between information and knowledge do exist, although for most practical purposes these differences are of no interest at all. Information technology implications are concerned with the argument that computers can only manipulate electronic information, not electronic knowledge.

Business systems are loaded with information, but without knowledge.

Davenport and Prusak (1998) define knowledge as a fluid mix of framed experience, values, contextual information, and expert insights that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories, but also in organizational routines, processes, practices, and norms. Distinctions are often made between data, information, knowledge, and wisdom:

- Data are letters and numbers without meaning. Data are independent, isolated measurements, characters, numerical characters, and symbols.
- Information is data that are included in a context that makes sense. For example, 40 degrees can have different meaning depending on the context. There can be a medical, geographical, or technical context. If a person has 40 degrees Celsius in fever, that is quite serious. If a city is located 40 degrees north, we know that it is far south of Norway. If an angle is 40 degrees, we know what it looks like. Information is data that make sense, because it can be understood correctly. People turn data into information by organizing it into some unit of analysis, for example, dollars, dates, or customers. Information is data endowed with relevance and purpose.
- Knowledge is information combined with experience, context, interpretation, and reflection. Knowledge is a renewable resource that can be used over and over, and that accumulates in an organization through use and combination with employees' experience. Humans have knowledge; knowledge cannot exist outside the heads of individuals in the company. Information becomes knowledge when it enters the human brain. This knowledge transforms into information again when it is articulated and communicated to others. Information is an explicit representation of knowledge; it is in itself no knowledge. Knowledge can both be truths and lies, perspectives and concepts, judgments and expectations. Knowledge is used to receive information by analyzing, understanding, and evaluating; by combining, prioritizing, and decision making; and by planning, implementing, and controlling.
- Wisdom is knowledge combined with learning, insights, and judgmental abilities. Wisdom is more difficult to explain than knowledge since the levels of context become even more personal and thus, the higher-level nature of wisdom renders it more obscure than knowledge. While knowledge is mainly sufficiently generalized solutions, wisdom is best thought of as sufficiently generalized approaches and values that can be applied in numerous and varied situations. Wisdom cannot be created like data and information, and it cannot be shared with others like knowledge. Because the context is so personal, it becomes almost exclusive to our own minds, and incompatible with the minds of others without extensive transaction. This transaction requires not only a base of knowledge and opportunities for experiences that help create wisdom, but also the processes of introspection, retrospection, interpretation, and contemplation. We can value wisdom in others, but we can only create it ourselves.

These are the definitions applied in this book. Grover and Davenport (2001) calls these definitions pragmatic, as a continuum is used, starting from data, encompassing information, and ending at knowledge in this book. The most valuable form of content in the continuum is knowledge. Knowledge has the highest value, the most human contribution, the greatest relevance to decisions and actions, and the greatest dependence on a specific situation or context. It is also the most difficult of content types to manage, because it originates and is applied in the minds of human beings.

It has been argued that expert systems using artificial intelligence are able to do knowledge work. The chess-playing computer called Deep Blue by IBM is frequently cited as an example. Deep Blue can compete with the best human players because chess, though complex, is a closed system of unchanging and codifiable rules. The size of the board never varies, the rules are unambiguous, the moves of the pieces are clearly defined, and there is absolute agreement about what it means to win or lose (Davenport & Prusak, 1998). Deep Blue is no knowledge worker; the computer only performs a series of computations at extremely high speed.

While knowledge workers develop knowledge, organizations learn. Therefore, the learning organization has become a term frequently used. The learning organization is similar to knowledge development. While knowledge development is taking place at the individual level, organizational learning is taking place at the firm level. Organizational learning occurs when the firm is able to exploit individual competence in new and innovative ways. Organizational learning also occurs when the collective memory—including local language, common history and routines—expands. Organizational learning causes growth in the intellectual capital. Learning is a continuous, never-ending process of knowledge creation. A learning organization is a place where people are constantly driven to discover what has caused the current situation, and how they can change the present. To maintain competitive advantage, an organization's investment decisions related to knowledge creation are likely to be strategic in nature (Chen & Edgington, 2005).

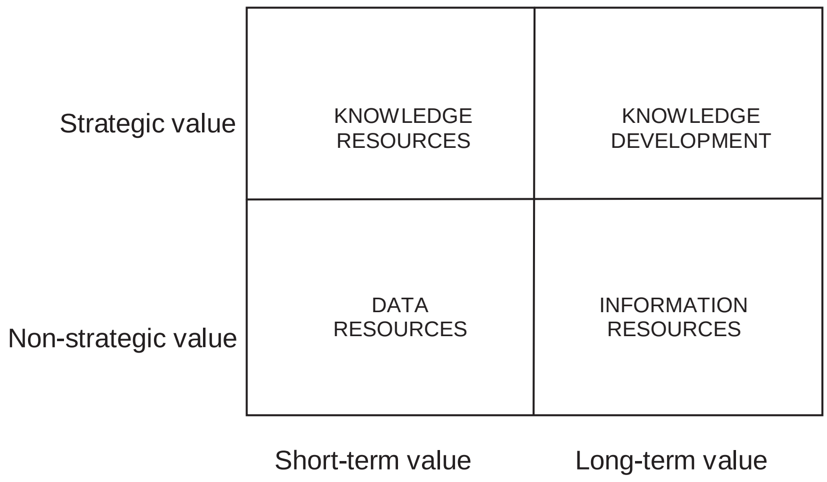
Alavi and Leidner (2001) make the case that the hierarchy of data-information-knowledge can be of a different nature. Specifically, they claim that knowledge can be the basis for information, rather than information the basis for knowledge. Knowledge must exist before information can be formulated and before data can be measured to form information. As such, raw data do not exist: the thought or knowledge processes that led to its identification and collection have already influenced even the most elementary piece of data. It is argued that knowledge exists that when articulated, verbalized, and structured, becomes information that when assigned a fixed representation and standard interpretation, becomes data (Alavi & Leidner, 2001, p. 109):

Critical to this argument is the fact that knowledge does not exist outside an agent (a knower): it is indelibly shaped by one's needs as well as one's initial stock of knowledge. Knowledge is thus the result of cognitive processing triggered by the inflow of new stimuli. Consistent with this view, we posit that information is converted to knowledge once it is processed in the mind of individuals and the knowledge becomes information once it is articulated and presented in the form of text, graphics, words, or other symbolic forms. A significant implication of this view of knowledge is that for individuals to arrive at the same understanding of data or information, they must share a certain knowledge base. Another important implication of this definition of knowledge is that systems designed to support knowledge in organizations may not appear radically different from other forms of information systems, but will be geared toward enabling users to assign meaning to information and to capture some of their knowledge in information and/or data.

KNOWLEDGE VALUE LEVEL

It is not difficult to agree with this reasoning. In fact, our hierarchy from data via information to knowledge is not so much a road or direction as

Figure 1. Value levels of resources in the organization



it is a way of suggesting resource value levels. Knowledge is a more valuable resource to the organization than information, and information is a more valuable resource than data. This is illustrated in Figure 1. The figure illustrates that it is less the knowledge existing at any given time, per se, than the organization's ability to effectively apply the existing knowledge to develop new knowledge, and to take action that forms the basis for achieving long-term competitive advantage from knowledge-based assets.

According to Grover and Davenport (2001), knowledge processes lie somewhere between information and the organization's source of revenue: its products and services. This process can be generically represented in three subprocesses: knowledge generation, knowledge codification, and knowledge transfer/realization. Knowledge generation includes all processes involved in the acquisition and development of knowledge. Knowledge codification involves the conversion of knowledge into accessible and applicable formats. Knowledge transfer includes the movement of knowledge from its point of generation or codified form to the point of use.

One of the reasons that knowledge is such a difficult concept is because this process is recursive, expanding, and often discontinuous. According to Grover and Davenport (2001), many cycles of generation, codification, and transfer are concurrently occurring in businesses. These cycles feed on each other. Knowledge interacts with information to increase the state space of possibilities, and provide new information that can then facilitate generation of new knowledge. The knowledge process acts on information to create new information that allows for greater possibilities to fulfill old or possibly new organizational needs. This process is often discontinuous, where new needs and their fulfillment mechanism could be created.

In our resource-based perspective of knowledge, data is raw numbers and facts, information is processed data, and knowledge is information combined with human thoughts. Knowledge is the result of cognitive processing triggered by the inflow of new stimuli. Information is converted to knowledge once it is processed in the mind of individuals, and the knowledge becomes information once it is articulated and presented to others. A significant implication of this view of knowledge is that for individuals to arrive at the same understanding of information, they must share the same knowledge framework.

In Figure 1, we can imagine that data are assigned meaning and become information, that information is understood and interpreted by individuals and becomes knowledge, and that knowledge is applied and develops into new knowledge. We can also imagine the opposite route. Knowledge develops in the minds of individuals. This knowledge development causes an increase in knowledge resources. When the new knowledge is articulated, verbalized, and structured, it becomes information and causes an increase in information resources. When information is assigned a fixed representation and standard interpretation, it becomes data and causes an increase in data resources.

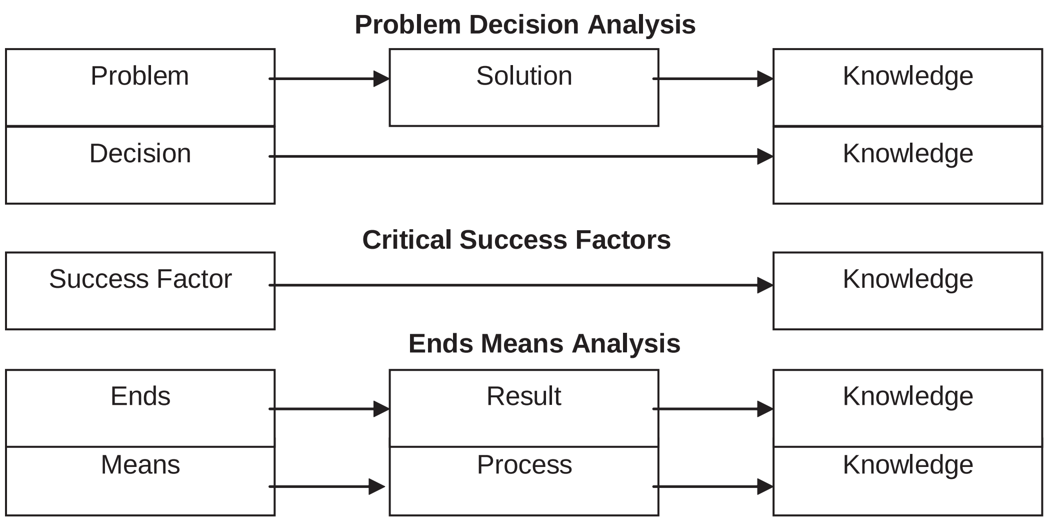
There are alternatives to our perspective of knowledge as a resource in the organization. Alavi and Leidner (2001) list the following alternatives: knowledge is state of mind, knowledge is an object to be stored, knowledge is a process of applying expertise, knowledge is a condition of access to information, and knowledge is the potential to influence action.

This book applies the resource-based theory of the organization, where the knowledge-based perspective identifies the primary role of the organization as integrating the specialist knowledge resident in individuals into goods and services. The task of management is to establish the coordination necessary for this knowledge integration. The knowledge-based perspective serves as a platform for a view of the organization as a dynamic system of knowledge production and application.

IDENTIFICATION OF KNOWLEDGE NEEDS

To classify knowledge as a resource, there has to be a need for that knowledge. Hence, identification of knowledge needs in an organization is important. Three supplementary methods exist

Figure 2. Methods to identify knowledge needs



to identify needs for knowledge, as illustrated in Figure 2:

- Problem decision analysis. This method aims at identifying and specifying problems that knowledge workers have, solutions they can find, decisions they have to make, and what knowledge they need to solve problems and make decisions. For a lawyer, the problem can be an insurance claim by a client, the decision can be how to approach the insurance company, and the knowledge need can be outcomes of similar cases handled by the law firm.
- Critical success factors. This method aims at identifying and specifying what factors cause success. Success can be at firm level, individual level, or individual case level. For a lawyer, critical success factors at the individual case level can be quality of legal advice and service level of advice delivery. Critical knowledge in this case includes legal knowledge as well as procedural knowledge.
- Ends means analysis. This method aims at identifying and specifying external demands and expectations to goods and services from the firm. For a lawyer, the client expectation might be that she or he wins the case. The end is winning the case. Knowledge needs associated with winning a case includes legal, procedural, and analytical knowledge of successful cases in the past. The means for winning a case might be access to resources of various kinds, such as client documents and client funds. Knowledge needs associated with means include historical records and analysis of legal client practice.

KNOWLEDGE CATEGORIES

Many researchers have tried to define categories and dimensions of knowledge. A common distinction is made between explicit and tacit knowledge. Explicit knowledge can be expressed in words and numbers and shared in the form of data, scientific formulae, specifications, manuals, and the like. This kind of knowledge can be readily transmitted between individuals, both formally and systematically. Tacit knowledge is, on the other hand, highly personal and hard to formalize, making it difficult to communicate or share with others. Subjective insights, intuitions, and hunches fall into this category of knowledge. Tacit knowledge is deeply rooted in an individual's actions and experience as well as in the ideals, values, or emotions he or she embraces. Tacit knowledge is embedded in the human brain and cannot be expressed easily, while explicit knowledge can be easily codified. Both types of knowledge are important, but Western firms have focused largely on managing explicit knowledge (Grover & Davenport, 2001).

Tacitness may be considered as a variable, with the degree of tacitness being a function of the extent to which the knowledge is or can be codified and abstracted. Knowledge may dynamically shift between tacit and explicit over time, although some knowledge always will remain tacit. Nonaka et al. (Nonaka, Toyama, & Konno, 2000) have suggested that knowledge creation is a spiraling process of interactions between explicit and tacit knowledge. This spiraling process consists of socialization, externalization, combination, and internalization, as we will see later in this chapter.

The concept of tacit knowledge corresponds closely to the concept of knowledge with a low level of codification. Codification is the degree to which knowledge is fully documented or expressed in writing at the time of transfer between two persons. The complexity of knowledge increases with lower levels of codification. A similar distinction, which scholars frequently make, is between practical, experience-based knowledge and the theoretical knowledge derived from reflection and abstraction from that experience.

A distinction is sometimes made between codification and personalization. This distinction is related to the tacit vs. explicit concept. It involves an organization's approach to knowledge transfer. Companies using codification approaches rely primarily on repositories of explicit knowledge. Personalization approaches imply that the primary mode of knowledge transfer is direct interaction among people. Both are necessary in most organizations, but an increased focus on one approach or the other at any given time within a specific organization may be appropriate (Grover & Davenport, 2001).

Explicit knowledge is sometimes called articulable knowledge (Hitt, Bierman, Shumizu, & Kochhar, 2001). Articulable knowledge can be codified, and thus can be written and easily transferred. Tacit knowledge is not articulable, and therefore cannot be easily transferred. Tacit knowledge is often embedded in uncodified routines and in a firm's social context. More specifically, it is partially embedded in individual skills and partially embedded in collaborative working relationships within the firm. Tacit knowledge is integral to professional skills. As a result, tacit knowledge is often unique, difficult to imitate, and uncertain. It has a higher probability of creating strategic value than articulable knowledge.

Distinctions can be made between core, advanced, and innovative knowledge. These knowledge categories indicate different levels of knowledge sophistication. Core knowledge is that minimum scope and level of knowledge required for daily operations, while advanced knowledge enables a firm to be competitively viable, and innovative knowledge is the knowledge that enables the firm to lead its industry and competitors:

- Core knowledge is the basic knowledge required to stay in business. This is the type of knowledge that can create efficiency barriers for entry of new companies, as new competitors are not up to speed in basic business processes. Since core knowledge is present at all existing competitors the firm must have this knowledge, even though it will provide the firm with no advantage that distinguishes it from its competitors. Core knowledge is that minimum scope and level of knowledge required just to play the game. Having that level of knowledge and capability will not assure the long-term competitive viability of the firm, but does present a basic industry knowledge barrier to entry. Core knowledge tends to be commonly held by members of an industry and therefore, provides little advantage other than over nonmembers (Zack, 1999).

In a law firm, examples of core knowledge include knowledge of the law, knowledge of the courts, knowledge of clients, and knowledge of procedures. For a student in the business school, core knowledge includes knowledge of what subjects to study this term and where the lectures take place.

According to Tiwana (2002), core knowledge is the basic level of knowledge required just to play the game. This is the type of knowledge that creates a barrier for entry of new companies. Since this level of knowledge is expected of all competitors, you must have it, even though it will provide your company with no advantage that distinguishes it from its competitors. Let us take two examples: One from the consumer electronics (hard product) business and one from Internet programming (soft product). To enter the modem manufacturing market, a new company must have extensive knowledge of these aspects: a suitable circuit design, all electronic parts that go into a modem, fabricating surface mount (SMD) chip boards, how to write operating system drivers for modems, and familiarity with computer telephony standards. Similarly, a company developing Web sites for, say, florists, needs server hosting capabilities, Internet programming skills, graphic design skills, clearly identified target markets, and necessary software. In either case, just about any competitor in those businesses is assumed to have this knowledge in order to compete in their respective markets; such essential knowledge, therefore, provides no advantage over other market players.

- Advanced knowledge is what makes the firm competitively visible and active. Such knowledge allows the firm to differentiate its products and services from that of a competitor through the application of superior knowledge in certain areas. Such knowledge allows the firm to compete head on with its competitors in the same market and for the same set of customers. Advanced knowledge enables a firm to be competitively viable. The firm may have generally the same level, scope, or quality of knowledge as its competitors, although the specific knowledge content will often vary among competitors, enabling knowledge differentiation. Firms may choose to compete on knowledge head-on in the same strategic position, hoping to know more than a competitor. They instead may choose to compete for that position by differentiating their knowledge (Zack, 1999).

In a law firm, examples of advanced knowledge include knowledge of law applications, knowledge of important court rulings, and knowledge of successful procedural case handling. For a student in the business school, advanced knowledge includes knowledge of important articles and books that are compulsory literature in subjects this term.

According to Tiwana (2002), advanced knowledge is what makes your company competitively viable. Such knowledge allows your company to differentiate its product from that of a competitor, arguably, through the application of superior knowledge in certain areas. Such knowledge allows your company to compete head on with its competitors in the same market and for the same set of customers. In the case of a company trying to compete in modem manufacturing markets, superior or user-friendly software or an additional capability in modems (such as warning online users of incoming telephone calls) represents such knowledge. In case of a Web site development firm, such knowledge might be about international flower markets and collaborative relationships in Dutch flower auctions that the company can use to improve Web sites delivered to its customers.

- Innovative knowledge allows a firm to lead its entire industry to an extent that clearly differentiates it from competition. Such knowledge allows a firm to change the rules of the game by introducing new business practices. Such knowledge enables a firm to expand its market share by winning new customers, and by increasing service levels to existing customers. Innovative knowledge is that knowledge that enables a firm to lead its industry and competitors, and to significantly differentiate itself from its competitors. Innovative knowledge often enables a firm to change the rules of the game itself (Zack, 1999).

In a law firm, examples of innovative knowledge include knowledge of standardizing repetitive legal cases, knowledge of successful settlements, and knowledge of modern information technology to track and store vast amounts of information from various sources. For a student in the business school, innovative knowledge includes knowledge of important topics within subjects, links between subjects, typical exam questions, and knowledge of business cases where theory can be applied.

According to Tiwana (2002), innovative knowledge allows a company to lead its entire industry to an extent that clearly differentiates it from competition. Innovative knowledge allows a company to change the rules of the game. Patented technology is an applicable example of changing the rules. Innovative knowledge cannot always be protected by patents, as the lawsuit between Microsoft and Apple in the 1980s should serve to remind us. Apple sued Microsoft for copying the look and feel of its graphical user interface (GUI). The Supreme Court ruled that things like look and feel cannot be patented; they can only be copyrighted. Microsoft won the case since it copied the look and feel, but used entirely different code to create it in the first place.

Many more categories and dimensions of knowledge have been suggested by researchers. The problem with most of these classifications is that they do not seem to satisfy three important criteria for classification. The first requirement is that a classification should always be complete, there should be no category missing. The second requirement is that each category should be different from all other categories, that is, there should be no overlap between categories. The final requirement is that each category should be at the same level, there should be no category including another category. Consider the following categories suggested by researchers: formal knowledge, instrumental knowledge, informal knowledge, tacit knowledge, metaknowledge, and context-independent knowledge. These categories seem to violate some of the classification rules. For example, there seems to be an overlap between informal knowledge and tacit knowledge. Maybe Long and Fahey's (2000) classification into human knowledge, social knowledge, and structured knowledge satisfy our requirements:

- Human knowledge. This constitutes the know-what, know-how, and know-why of individuals. Human knowledge is manifested in individual skills (e.g., how to interview law firm clients) or expertise (e.g., why this case is similar to a previous case). Individual knowledge usually combines explicit and tacit knowledge. This type of knowledge may be located in the body, such as knowing how to type touch on a PC or how to ride a bicycle. This type of knowledge may be cognitive, that is, largely conceptual and abstract.
- Social knowledge. This kind of knowledge exists only in relationships between individuals or within groups. For example, high-performing teams of tax lawyers share certain collective knowledge that is more than the sum of the individual knowledge of the team's members. Social or collective knowledge is mainly tacit knowledge, shared by team members, and develops only as a result of team members working together. Its presence is reflected by an ability to collaborate effectively.
- Structured knowledge. This is embedded in an organization's systems, processes, tools, routines, and practices. Knowledge in this form is explicit and often rule based. A key distinction between structured knowledge and the first two types of knowledge is that structured knowledge is assumed to exist independently of individual knowers. It is, instead, an organizational resource. However, to be complete, this knowledge has to be in the heads of individuals.

Two dimensions have been introduced to classify knowledge. The first dimension is concerned with whether an individual knows. The second dimension is concerned with whether an individual knows whether he or she knows. This is illustrated in Figure 3. I can either have the knowledge (I do know) or not have the knowledge (I do not know). I can either be aware of it (I know it) or not be aware of it (I do not know it).

Some researchers have argued that the real tacit knowledge is found in the right upper quadrant. In this dimension, I do know, but I do not know that I know. Tacit knowledge in this sense is also called hidden knowledge or nonaccessible knowledge. In this book, we do not use this extremely

Figure 3. Dimensions of individual knowledge

I do know	I know that I know	I don't know that I know
I don't know	I know that I don't know	I don't know that I don't know

limited definition of tacit knowledge. We define tacit knowledge as personal and difficult, but not impossible to communicate.

Classification of knowledge into categories and dimensions may depend on industry. For example, there are likely to be different knowledge categories in a bank compared to a law firm. At the same time, there will be certain generic knowledge categories such as market intelligence and technology understanding in most companies, independently of industry. When classifying knowledge in a firm, it is important to do the analysis without the organization chart. If you classify knowledge into technology knowledge, production knowledge, marketing knowledge, and financial knowledge, it may be because the firm, according to the organization chart, consists of a development department, production department, marketing department, and financial department. It might be more useful to introduce new knowledge categories, such as product knowledge, that include knowledge of development, production, marketing, and finance. By identifying cross-sectional knowledge categories and dimensions, solutions for improved knowledge flows in the organization will emerge.

A law firm is a good example. A law firm is organized according to legal disciplines. Some lawyers work in the tax department, while others work in the department for mergers and acquisitions. The types of knowledge involved in the practice of law can be categorized as administrative, declarative, procedural, and analytical knowledge (Edwards & Mahling, 1997):

- Administrative knowledge, which includes all the nuts and bolts information about firm operations, such as hourly billing rates for lawyers, client names and matters, staff payroll data, and client invoice data.
- Declarative knowledge, which is knowledge of the law, the legal principles contained in statutes, court opinions, and other sources of primary legal authority; law students spend most of their law school time acquiring this kind of knowledge.
- Procedural knowledge, which involves knowledge of the mechanisms of complying

with the law's requirements in a particular situation: how documents are used to transfer an asset from Company A to Company B, or how forms must be filed where to create a new corporation. Declarative knowledge is sometimes labeled know-that and know-what, while procedural knowledge is labeled know-how.

- Analytical knowledge, which pertains to the conclusions reached about the course of action a particular client, should follow in a particular situation. Analytical knowledge results, in essence, from analyzing declarative knowledge (i.e., substantive law principles) as it applies to a particular fact setting.

Classification of knowledge into categories and dimensions has important limitations. For example, the classification into explicit and tacit knowledge may create static views of knowledge. However, knowledge development and sharing are dynamic processes, and these dynamic processes cause tacit knowledge to become explicit, and explicit knowledge to become tacit over time. Tacit and explicit knowledge depend on each other, and they influence each other. In this perspective, Alavi and Leidner (2001) argue that whether tacit or explicit knowledge is the more valuable may indeed miss the point. The two knowledge categories are not dichotomous states of knowledge, but mutually dependent and reinforcing qualities of knowledge: tacit knowledge forms the background necessary for assigning the structure to develop and interpret explicit knowledge.

According to Alavi and Leidner (2001), the linkage of tacit and explicit knowledge suggests that only individuals with a requisite level of shared knowledge are able to exchange knowledge. They suggest the existence of a share knowledge space that is required in order for individual A to understand individual B's knowledge. The knowledge space is the underlying overlap in knowledge base of A and B. This overlap is typically tacit knowledge. It may be argued that the greater the shared knowledge space, the less the context needed for individuals to share knowledge within the group and, hence, the higher the value of explicit knowledge. For example in a law firm, lawyers in the maritime law department may have a large knowledge space so that even a very limited piece of explicit knowledge can be of great value to the lawyers. Alavi and Leidner (2001, p. 112) discuss knowledge space in the following way:

Whether tacit or explicit knowledge is the more valuable may indeed miss the point. The two are not dichotomous states of knowledge, but mutually dependent and reinforcing qualities of knowledge: tacit knowledge forms the background necessary for assigning the structure to develop and interpret explicit knowledge. The inextricable linkage of tacit and explicit knowledge suggests that only individuals with a requisite level of shared knowledge can truly exchange knowledge: if tacit knowledge is necessary to the understanding of explicit knowledge, then in order for Individual B to understand Individual A's knowledge, there must be some overlap in their underlying knowledge bases (a shared knowledge space). However, it is precisely in applying technology to increase 'weak ties' in organizations, and thereby increase the breadth of knowledge sharing, that IT holds promise. Yet, absent a shared knowledge space, the real impact of IT on knowledge exchange is questionable. This is a paradox that IT researchers have somewhat eschewed, and that organizational researchers have used to question the application of IT to knowledge management. To add to the paradox, the very essence of the knowledge management challenge is to amalgamate knowledge across groups for which IT can play a major role. What is most at issue is the amount of contextual information necessary for one person or group's knowledge to be readily understood by another.

It may be argued that the greater the shared knowledge space, the less the context needed for individuals to share knowledge within the group and, hence, the higher the value of explicit knowledge and the greater the value of IT applied to knowledge management. On the other hand, the smaller the existing shared knowledge space in a group, the greater the need for contextual information, the less relevant will be explicit knowledge, and hence the less applicable will be IT to knowledge management.

Some researchers are interested in the total knowledge within a company, while others are interested in individual knowledge. Dixon (2000) was interested in the knowledge that knowledge workers develop together in the organization. Employees gain this knowledge from doing the organization's tasks. This knowledge is called common knowledge, to differentiate it from book knowledge or lists of regulations or databases of customer information. Some examples of common knowledge are what medical doctors in a hospital have learned about how to carry out certain kinds of surgery, what an organization has learned about how to introduce a new drug into the diabetes market, how to reduce cost on consulting projects, and how to control the amount of analysis in maritime law cases. These examples all include the how-to rather than the know-what of school learning. Moreover, it is know-how that is unique to a specific company. In the law firm example, procedural knowledge was classified as know-how.

Chapter 1.12
Enhancing Performance Through Knowledge Management:
A Holistic Framework

ABSTRACT

Knowledge management (KM) has gained increasing attention since the mid-1990s. A KM strategy involves consciously helping people share and put knowledge into action. However, before an organization can realize the promise of KM, a fundamental question needs to be asked: What performance goal(s) is the organization trying to achieve? In this paper, we develop and offer a framework that provides a holistic view of the performance environment surrounding organizational knowledge work. We illustrate the KM framework using two organizational case studies. Then, based on the KM framework and further insights drawn from our case studies, we offer a series of steps that may guide and assist organizations and practitioners as they undertake KM initiatives. We further demonstrate the applicability of these steps by examining KM initiatives within a global software development company. We conclude with a discussion of implications for organizational practice and directions for future research.

INTRODUCTION

Knowledge management (KM) is a topic that has gained increasing attention since the mid-1990s. Knowledge about customers, products, processes, past successes, and failures are assets that may produce long-term sustainable competitive advantage for organizations (Huber, 2001;

Leonard & Sensiper, 1998; Stewart, 2001). KM proponents argue that these assets are as important as managing other organizational assets like labor and capital. A survey conducted by Knowledge Management magazine and the International Data Corporation suggests that KM is evolving from a discrete undertaking to a strategic component of business solutions (Dyer & McDonough, 2001).

A KM strategy entails consciously helping people share and put knowledge into action by creating access, context, and infrastructure, and by simultaneously shortening learning cycles (Alavi & Leidner, 2001; Davenport, DeLong & Beers, 1998; Davenport & Prusak, 1998; O'Dell & Grayson, 1998). It takes place within a complex system of organizational structure and culture and is often enabled through information technology (IT) (Alavi, 2000; Alavi & Leidner, 2001). While technology drove the initial interest in KM, both academics and practitioners have begun to realize that effective KM initiatives and solutions will be based on a more holistic view of the knowledge work environment (Grover & Davenport, 2001; Holsapple & Joshi, 2002; Massey & Montoya-Weiss, 2002; Rubenstein-Montano et al., 2001). Specifically, before an organization can realize the promise of KM, a fundamental question needs to be asked: What performance goal(s) is the organization trying to achieve? Addressing this question will direct the organization to what knowledge should be managed and how it should be managed.

Improving customer service, shortening product development cycles, growing revenues, and improving profits are commonly cited as goals motivating KM initiatives. If the intent of a KM initiative is to enhance organizational performance, organizations first need to understand the performance environment surrounding and driving the underlying knowledge work. For example, improving customer service and shortening product development cycles require that firms look to their processes, which may be reengineered to capitalize on or to expand organizational knowledge resources and capabilities (Gold, Malhotra, & Segars, 2001; Hammer & Champy, 1993; Maier & Remus, 2001). Generating performance improvements via a KM initiative thus requires a deep understanding of how process work is organized, what knowledge is inherent to and derived from it, what factors influence knowledge workers, and how all of these factors relate to an organization's business environment (Massey & Montoya-Weiss, 2002).

In this paper, we offer a framework that provides a holistic view of the performance environment surrounding organizational knowledge work. The framework provides a useful means to identify, define, analyze, and address knowledge-based problems or opportunities relative to multi-level (business, process, and knowledge-worker) performance goals and requirements. Our perspective responds to a current call in the literature for KM frameworks that take a holistic, systems-oriented perspective by considering problems and opportunities in their entirety (Rubenstein-Montano et al., 2001; Senge, 1990). We draw from and integrate literature concerned with approaches to dealing with complexity and purposeful (i.e., performance-oriented) systems (Checkland & Howell, 1998), business process reengineering (Hammer & Champy, 1993), and human performance (Stolovich & Keeps, 1999). Rather than suggesting that KM requires a whole new perspective with its own special laws, our framework purports that KM sits well within our current understanding of what drives performance (Soo, Devinney, Midgley, & Deering, 2002).

We illustrate the efficacy of our framework to KM using case studies conducted at IBM and Nortel Networks. In addition, based on the framework and the insights we drew from our case studies, we offer a series of steps that can help direct organizations as they undertake KM initiatives. Finally, we illustrate the generalizability of these steps by demonstrating them in context of the software development process, using insights gained from a study with a software development firm. We conclude our paper with a discussion of broader implications for organizational practice and directions for future research.

BACKGROUND AND MOTIVATION

The general goal of KM is to capitalize on knowledge assets in order to achieve maximum attainable business performance (Barney, 1991; Becerra-Fernandez & Sabherwal, 2001; Davenport & Prusak, 1998). Organizations are faced with two key questions: What should an organization consider before undertaking a KM initiative? and How can KM become a strategic asset?

In a review of existing KM frameworks, Rubenstein-Montano and colleagues (2001) suggest that most frameworks to date have been prescriptive and focused primarily on knowledge flows. As such, they do not provide a comprehensive, holistic approach to integrate KM practices with strategic goals of the organization to realize potential for improving performance. Moreover, they do not consider non-task-oriented aspects that ultimately influence knowledge workers as they carry out business process activities. A further review of the literature suggests that KM has considered a broad array of issues and approaches, addressing things such as capturing and sharing best practices, building databases and intranets, measuring intellectual, establishing corporate libraries, installing groupware, enacting cultural change, and fostering collaboration (Ackerman, Pipek, & Wulf, 2003; Alavi & Leidner, 1999, 2001; Fahey & Prusak, 1998; Grover & Davenport, 2001; O'Dell & Grayson, 1998; Stewart, 2001). Thus, while no generally accepted framework has been adopted, it seems that KM has involved all kinds of approaches, practical activities, measures, and technologies.

In order to make KM a strategic asset and to realize the potential for improving performance, there is a need for a unifying framework that considers KM relative to the entirety of the organizational system as well as its subcomponents (i.e., the business, its processes, and knowledge workers) (Soo et al., 2002). Such a framework should provide a general sense of direction (i.e., be prescriptive) for KM initiatives in order to ensure that the same general requirements are addressed across the organization, but it also should be descriptive in that it considers factors that ultimately influence KM success or failure (Rubenstein-Montano et al., 2001; Tsoukas, 1996).

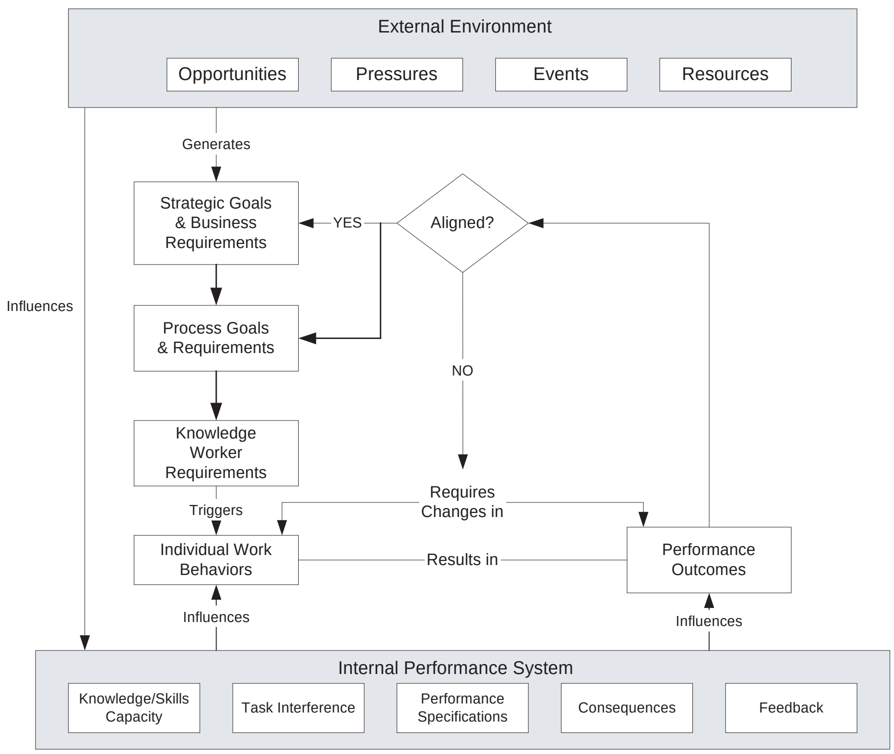
A systems approach to KM can ensure a holistic and purposeful (performance-oriented) consideration of the interrelationships between the business, its processes, and knowledge workers (Ackoff & Emery, 1972). The objective is to enhance understanding of and responsiveness to a problem by examining relationships between various parts of the system (Checkland, 1981; Checkland & Howell, 1998; Gao, Li & Nakamori, 2002). A systems approach can enhance KM initiatives by examining and depicting the complex relationships among components such that an organization can ascertain where and how KM might respond (Rubenstein-Montano et al., 2001). In the following section, we develop and offer a holistic KM framework that considers the complex interdependencies among the business, its processes, and knowledge workers surrounding organizational knowledge work. When applied, the framework offers a systematic way to identify, define, and analyze performance problems or opportunities and their drivers and causes at multiple levels (business, process, and individual). By doing this, desired performance outcomes at all levels can be described, and behaviors that will produce those outcomes can be identified (Gordon, 1996). With this robust understanding, organizations can more precisely specify and implement interventions to address problems or capitalize on opportunities and ultimately improve performance (Gery, 1997; Massey & Montoya-Weiss, 2002; Rosenberg, 1995; Stolovitch & Keeps, 1999).

A HOLISTIC FRAMEWORK FOR KM

In Figure 1 we offer a framework to ensure that KM initiatives and multi-level requirements are addressed in a similar vs. an ad hoc fashion across the organization. Described next, the framework draws from and integrates literature concerned with approaches to dealing with complexity and purposeful (i.e., performance-oriented) systems (Checkland & Howell, 1998), business process reengineering (Hammer & Champy, 1993), and human performance (Rummler & Brache, 1992; Stolovich & Keeps, 1999). It possesses both prescriptive (task-oriented activities) and descriptive (consideration of factors that influence success or failure) elements, which, in turn, facilitate a holistic perspective. Importantly and consistently with a systems approach, the framework does not imply that the same methodologies will be used for all situations; rather, the framework facilitates a method to KM that is adaptive and responsive to different situations.

Since knowledge is context-specific, and since KM will be most powerful when applied to a specific domain (Sviokla, 1996), a component of our framework is its focus on core business processes. Thus, at the process level, we draw from the business process reengineering (BPR) literature, which is concerned with a fundamental rethinking of and redesign of business processes in order to achieve performance improvements (Hammer & Champy, 1993). Although BRP involves the analysis and design of workflows, it does not explicitly consider the complex environment that influences knowledge workers (Davenport & Short, 1990). Without consideration of the human element in

Figure 1. A holistic framework for knowledge management (adapted from Rummler & Brach, 1992; Stolovich & Keeps, 1999)



knowledge-intensive processes, BPR rarely will be successful. Therefore, by leveraging literature concerned with human performance (Stolovich & Keeps, 1999; Rummler & Brach, 1992), our KM framework includes factors that influence individual work behaviors and performance. It is likely that a KM initiative that only considers isolated subcomponents of the overall system will not enhance performance. Rather, success will hinge on understanding how each part — strategic goals, business process, knowledge workers — influences and interacts with other parts.

As illustrated, the external environment presents an organization with opportunities, pressures, events, and resources (Holsapple & Joshi, 2000, 2002). In response, an organization generates business and process requirements — a set of actions that allows the organization to capitalize on external opportunities and/or respond to threats. For example, to remain competitive, a strategic business performance goal may be to increase market acceptance of new products (Moorman & Rust, 1999). In a software-related business, the business-level requirement may be to increase the rate of new software introduction into the marketplace. This business requirement generates process-level requirements (e.g., the new product development process must produce a stream of continuous new products or services).

Gaps between current process capabilities and defined requirement(s) may force the organization to reengineer the business process such that the process performs at the required level of performance (Davenport, 1993; Hammer & Champy, 1993; Teng, Grover & Fiedler, 1994). Recognizing that processes are knowledge-intensive (Davenport, DeLong & Beers, 1998; Massey & Montoya-Weiss, 2002), reengineering efforts should focus on decomposing and structuring the process such that data, information, knowledge activities, and workflows between activities are clearly defined (Davenport & Short, 1990; Hammer & Champy, 1993; Teng et al., 1994). Importantly, structuring the process and identifying knowledge exchange activities inherent to the process will assist in identifying knowledge worker requirements (Leonard & Sensiper, 1998; O'Dell & Grayson, 1998). In particular, this involves defining what knowledge and what types of knowledge (i.e., tacit or explicit) are needed to accomplish activities. It also involves identifying who or what are the sources and receivers of knowledge (e.g., human, archives, etc.) as well as defining desired performance outcomes of process-level work. A purposeful and seamless flow of data, information, and knowledge — a defined knowledge cycle — then can occur among collaborating knowledge workers tasked with various process activities.

In addition to rethinking how a process work should be done via reengineering (Davenport, 1993; Hammer, 1990), it is important to consider the knowledge worker(s) who will be tasked with carrying out process activities. Thus, in addition to specifying the knowledge cycle, we must consider factors that influence the behaviors and performance of knowledge workers at the task/activity level (Checkland, 1981; Rubenstein-Montano et al., 2001; Rummler & Brache, 1992). As shown in Figure 1, the task/activity level factors are referred to as a knowledge worker's internal performance system. Here, it becomes important to recognize that individual (or often team) performance is not simply a function of knowledge, skills, or capacity. Rather, other factors influence performance, including: the nature and clarity of the business process work tasks and whether anything (e.g., lack of resources) interferes with task completion, clarity of performance specifications and goals, positive and negative work consequences, and performance feedback (Rummler & Brache, 1992). By taking a broader view of knowledge workers, cause(s) of poor performance and/or opportunities to enhance performance (beyond knowledge, skills, and capacity) can be identified.

As described previously, the framework enables a holistic examination of the interrelationships among multi-level goals and requirements that allows for the identification of problems or opportunities that should be addressed in order to enhance performance (Senge, 1990). In the following section, we illustrate the framework based on our work with IBM and Nortel. Our purpose is not to provide detailed case studies; rather, our intent is to illustrate key elements and interrelationships (see Massey, Montoya-Weiss, & Holcolm, 2001; and Massey, Montoya-Weiss & O'Driscoll, 2002 for further in-depth case studies).

PERFORMANCE-DRIVEN KM INITIATIVES

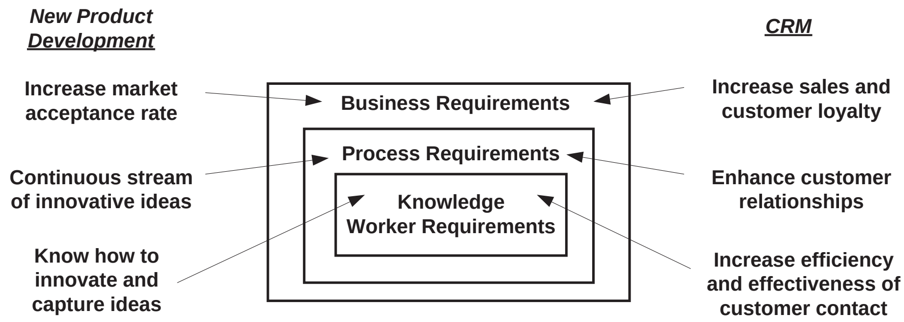
In the latter half of the 1990s, both IBM and Nortel Networks were facing significant external pressures. With regard to IBM, from 1986 to 1992, its market share dropped from 30% to 19%, with each percentage point representing $3 billion in revenues. Rather than paying attention to customer needs, IBM focused on its own financial needs and tried to reduce costs by cutting customer service staff and levels of support. In the end, customers were driven away. Thus, by the mid-1990s, the changing market environment and downsizing necessitated that IBM rethink the basic way they serviced customers in order to reduce customer defections and to increase sales. Throughout the 1980s and early 1990s, IBM's primary points of contact with its customers were through business partners, direct catalog, and the traditional "blue suits." Given that these points of contact were not supporting the business-strategic goals and requirements to remain competitive, an internal task force was charged with reengineering IBM's customer relationship management (CRM) process.

CRM involves attracting, developing, and maintaining successful customer relationships over time (Berry & Parasuraman, 1991; Day, 2000, 1994). At the core of CRM is the development of a learning relationship that engages customers in a two-way collaborative dialogue that is effective and efficient for both customers and the firm (Peppers, Rogers, & Dorf, 1999). When effective, this knowledge-based process leads to a relationship that gets smarter and deeper through every interaction. The task force charged with addressing the business problem recognized that advanced information technology, the burgeoning Internet, and the emerging network-centric environment presented great opportunities for reengineering IBM's CRM process and leveraging its knowledge assets.

Similarly, at Nortel Networks, the Telecommunications Reform Act of 1996 produced intense competition in the telecom industry, yielding an explosion in the development of innovative telecommunications technology. The new rules of the deregulated telecommunications marketplace forced Nortel to recognize that differentiation through innovation was one of the few strategies that might allow the company to continue to succeed. Like IBM, an internal group was charged with the task of addressing this strategic business goal and requirement. After preliminary research, the group discovered that the generation and existence of innovative ideas within Nortel was not the issue. Rather, Nortel's existing new product development (NPD) process had no formal mechanism to systematically capture, develop, and manage internally generated ideas (i.e., ideas that could be developed into product or service concepts and evaluated for funding). Developing ideas and evaluating concepts is knowledge-intensive work based on the individual and collective expertise of employees. The Nortel task force set out to reengineer its NPD process in order to leverage its knowledge assets. As described, the efforts of both the IBM and Nortel initiatives were guided by strategic business goals and requirements that, in turn, led to them to focus on business processes most relevant to achieving desired performance (Figure 1).

As shown in Figure 2, core business processes like CRM and NPD represent the fundamental link between business and knowledge workers performance. The reality for both IBM and Nortel

Figure 2. Examples of interdependent multi-level performance requirements



was that their respective business requirements would be achieved through processes, and both organizations were only as good as its processes, which ultimately depended on the behaviors of knowledge workers. Driven by this performance reality, IBM's reengineered CRM process was designed to enhance the customer relationship, while Nortel's reengineered NPD process was designed to produce a continuous stream of products and services. Although the specific details of the process reengineering efforts are beyond the scope of this paper (details are available upon request), both organizations structured their new processes by decomposing the process into knowledge-based activities, simultaneously identifying the required flows of data, information, and/or knowledge among activities and knowledge workers. The analysis led to the specification of the knowledge-based drivers (types, sources, and receivers) of each activity, decision, or information flow. In their reengineering efforts, both task forces went through several process prototype iterations (Davenport & Short, 1990), simultaneously considering whether (or not) the new process could, in fact, support business goals and requirements. As one IBM task force member put it:

We had done things the same way for so long. We realized early on that any changes to our [CRM] process had to demonstrate they would, in fact, improve business performance or nobody — our reps or our customers — would buy in. We continually asked ourselves whether the new process supported our business [level] goals.

This quote illustrates the strong link between business and process levels shown in Figure 1 and how important it is not only to decompose the levels but to integrate them, as well.

The reengineering of IBM's CRM process and Nortel's NPD process created new knowledge worker performance requirements, triggering requisite changes to individual work behaviors. As one Nortel task force member observed:

While we believed our new [NPD] process could perform as desired, we were not sure if our people could or would actually carry out the new process. We needed to gain a better understanding of their capabilities and motivations.

Given this, both organizations sought to understand the internal performance system of its various knowledge workers in light of the reengineered processes and requirements (see Figure 1). Specifically, did they possess the knowledge/skills/capacity to carry out reengineered or new process activities? Did they possess and/or understand the inputs required to carry out process tasks? Did anything exist that would interfere with task requirements? Did they understand the desired performance outcomes intended to support business and process requirements? What contextual factors would motivate or demotivate knowledge workers to share knowledge and carry out the new process (i.e., consequences and feedback)?

Answers to these questions enabled a collaborative learning relationship between IBM representatives and customers and a more collaborative relationship between the engineers and managers involved in the NPD process at Nortel. For example, Nortel's NPD process called for idea generators (often engineers) to develop a raw product or service idea into a robust concept along the lines of marketing, business, technology, and human factors (areas used by managers to make funding decisions). While engineers are technically knowledgeable, they typically do not possess sufficient knowledge in the other areas required in the new NPD process. This drove Nortel's team to consider interventions to support the specific knowledge gaps of workers engaged in this process activity. Similarly, IBM's team considered the factors that would influence the behavior of CRM knowledge workers. For example, IBM sales representatives felt threatened by the CRM reengineering effort, due to their perception that the customer relationships would be transferred largely from human contacts to technology. In response, IBM undertook efforts to show sales representatives that the new CRM process would, in fact, allow them to more proactively sell and market products and services.

Ultimately, both IBM and Nortel designed and implemented technology-based interventions to support the performance of knowledge workers. Drawing from the disciplines of KM and CRM, IBM developed an Internet-based system called Inside IBM. The system allowed customers to link directly to IBM's intranet and back-end, cross-functional, knowledge-based resources. Inside IBM was subsequently adopted as a corporate standard leading to IBM's e-Services as it is known today. Deploying artificial intelligence, information systems, and user-centered design, Inside IBM aggregated IBM's accumulated product support knowledge into a single system and enabled collection of information about its customers. IBM's efforts facilitated a collaborative and learning relationship between IBM and its customers. This led to improved decision making for both the customer and the organization's sales and service workforce, leading to increased sales and customer loyalty. IBM estimated that $525 million of incremental revenue and $50 million of productivity savings were realized over a three-year period as a result of this initiative (see Massey et al., 2001, for further details concerning IBM's initiative).

Similarly, Nortel developed a KM system called Virtual Mentor. Virtual Mentor supported both the performance of knowledge workers (engineers) engaged in developing raw ideas into robust concepts and decision makers (managers) tasked with making funding decisions. Virtual Mentor subsequently was integrated into a broader corporate time-to-market strategy that is in place today. Nortel's efforts led to decreased time-to-market, increased time-to-market acceptance, and improved funding decisions. Over a three-year period, Nortel's new product introduction rate increased by over 50% (see Massey et al., 2002, for further details concerning Nortel's initiative).

Clearly, the bottom line for IBM and Nortel was to increase profitability, sales, share, and return on investment by leveraging and managing its knowledge assets. As evidenced, IBM and Nortel's KM initiatives were guided by a holistic understanding of interdependent multi-level (business, process, knowledge-worker) performance goals and requirements. This facilitated problem/opportunity identification and definition, diagnoses of the changes required, and the subsequent design of suitable interventions needed to affect the performance of knowledge workers tasked with process activities. Addressing what to do from a performance perspective drove the reengineering of two knowledge-intensive business processes. Both processes called for improvements to cross-functional coordination, collaboration and learning, and knowledge exchange in business, technology, and marketing (and other relevant areas). Considering how to do it and simultaneously understanding the behavioral factors that influenced knowledge workers informed the development and implementation of interventions designed to enhance performance. In the end, both IBM and Nortel were directed by a deep understanding of the complex interdependencies inherent to their organizational systems. In their respective efforts, they not only decoupled the organizational environment into its smaller parts (business, process, knowledge worker), but also continually considered how the parts were linked in hierarchies to form the whole performance environment.

In the following section, we present a series of steps that underlie our framework and provide direction for KM initiatives. We then illustrate the efficacy of our approach in a software engineering context. Our data in this context are based on interviews with managers and developers regarding KM systems currently in use at TechCo (a pseudonym), a well-known Indian software development firm that has several centers certified at Level 5 of the Capability Maturity Model (Paulk, Weber, Curtis, & Chrissis, 1995).

STEPS FOR KM INITIATIVES

Step 1: Select a Target Business Process

Once an organization has identified its business goals and requirements, a KM initiative then must identify the firm's key leverage points for achieving business results. As noted earlier and as evidenced at IBM and Nortel, since knowledge is context-specific (Sviokla, 1996), KM likely will be most powerful when it addresses a particular domain, such as new product development, operations, sales, and customer service. Organizations should start where advocacy exists for doing something different. Processes such as those targeted for improvement by the organizations we studied is where work is accomplished. Once the process is identified, establish a process and project owner and ensure that the new initiative is managed as a business change project, not an information technology project (as many early KM projects were managed). In this step, it is also important to establish performance measures for the business case. Demonstrating success with a single process may lead to acceptance for other processes.

Step 2: Model the Process

This step requires that the inherent, underlying process structure be found or defined in order for an initiative to move forward. Oftentimes, process activities and the data, information, and knowledge flows among activities are poorly defined. Clarifying activities and promoting an integrative view of the whole process is the starting point for managing knowledge and improving performance. For example, in the front end of the NPD process, idea-to-concept development and concept selection activities often are called the fuzzy, because they involve ill-defined activities and ad hoc decisions carried out by multiple and diverse stakeholders (Cooper & Kleindschmidt, 1995). Via careful analysis and benchmarking, Nortel reengineered and enhanced the front end of its NPD process by defining a consistent and structured approach for developing, screening, and cataloging new product ideas.

Step 3: Identify Activity-Based Knowledge Exchange Processes

This step requires understanding the context of work (i.e., the knowledge needs associated with each process activity defined in Step 2). For example, in IBM's CRM process, in order for customer representatives to target sales and marketing proactively, they had to determine how to acquire knowledge concerning customer requirements. Similarly, at Nortel, different knowledge workers and functions had different pieces of data, information, and knowledge relevant to the NPD process. These pieces needed to be exchanged in order to create a common and logically organized bank of knowledge about a product or service concept. The objective of this step is to identify the knowledge exchange processes that are or must be in place to support value-creating activities.

Step 4: Identify Desired Knowledge Exchange Performance Outcomes

When individuals or teams exploit knowledge in a business process, it is reflected in the quality of a valued outcome that benefits the organization. This step involves specifying the performance outcomes that should be derived from the knowledge exchange processes identified in Step 3. For example, in Nortel's NPD process, one desired outcome was that a decision maker (manager) could make an informed decision regarding further funding for product development. Another was when the right combination of product-related data (e.g., marketing, business, and technology) needed to be readily accessible in the right format for different tasks and functional areas. Alternatively, in IBM's CRM process, a desired outcome was that the right people, information, and services would be readily accessible to the customer.

Step 5: Identify the Knowledge Drivers of Each Process Activity, Decision, and Information Flow

This step requires the identification of the types of knowledge required, the sources of that knowledge (internal and/or external people, archived data), and the receivers of knowledge (people, other databanks). In Nortel's case, this step required identification of the specific knowledge required by an idea generator (i.e., an engineer or knowledge worker source) so he or she could develop a raw idea into a robust concept in the areas of marketing, business, human factors, and technology. With this knowledge, a raw idea could be developed into a complete and robust concept so that decision makers (i.e., manager or knowledge worker receiver) could evaluate the concept and make a funding decision.

Step 6: Identify and Develop Interventions

In concert, Steps 2 through 5 specify the knowledge inputs, exchange processes, sources and receivers, and desired outcomes associated with the targeted and defined business process. The factors that influence individual work behaviors (i.e., the internal performance system of knowledge workers) also must be considered to ensure that desired performance outcomes are achievable. With this holistic understanding available, an organization now can specify more precisely its KM interventions or solutions in order to support individual and/or teamwork. Interventions reflect both responses to identified causes of performance problems and opportunities for improving performance. Potential interventions could include the development of individuals or teams (e.g., training) or solutions that focus on rewarding performance (e.g., incentive/reward systems). Interventions also may include information technology-based KM systems (Alavi, 2000; Alavi & Leidner, 2001; Gery, 1997; Hinds & Pfeffer, 2003; Rosenberg, 1995). Intervention selection should be done in light of appropriateness (internally and externally), economics, feasibility (given organizational constraints or barriers to implementation), and acceptability to the organization and knowledge workers. Again, by taking a holistic view and understanding the performance environment first rather than starting with a solution looking for a problem, interventions can be identified more appropriately and precisely.

One key issue to be considered when supporting activities within a business process context is the issue of language translation. Knowledge workers deploy local languages relative to their areas of expertise. Thus, successfully enabling the flow of data, information, and knowledge between process activities and diverse knowledge workers may require language translation. For example, as noted earlier in our Nortel case, we found that idea generators (engineers) did not speak the language of decision makers (managers). Nortel's KM solution, Virtual Mentor, thus was designed to depict and translate knowledge in forms that were appropriate for different audiences (engineers, managers, process owners). For example, through concept development and rating forms designed in the language of engineers, idea generators provided knowledge concerning a new concept and its potential application(s). Virtual Mentor then translated the contextual structure of this concept information into a form so decision makers could conduct a SWOT—strengths, weaknesses, opportunities, threats—analysis. Virtual Mentor enabled collaboration by supporting the local languages of disparate knowledge workers who must exchange knowledge in order to improve decision making. Another issue that needs to be dealt with is the differential navigational needs of the various stakeholders. As an example, the navigation needs of a customer representative in the CRM process seeking to acquire customer requirements differs significantly from the needs of a customer seeking information.

AN APPLICATION OF THE STEPS FOR KM INITIATIVES

In this section, we provide further evidence that demonstrates the validity of our holistic framework and underlying steps identified in the previous section. Here, we describe the path taken by TechCo in arriving at the KM solutions in use today. TechCo is one of the leading software services and consulting organization in Southeast Asia, providing systems development and integration services to Global Fortune 500 clients.

During the 1990s, TechCo saw a significant increase in competition in the offshore software development arena. With a business goal of maintaining its position as one of the market leaders in this arena, TechCo sought to gain a competitive edge by focusing its efforts on improving the quality of its core software development processes. This effort was very similar to Nortel's efforts described earlier, which focused on enhancing its NPD process.

Software development, by its very nature, is a knowledge-intensive process that involves many people working on several different activities and phases (Rus & Lindvall, 2002; Ward & Aurum, 2004). Success hinges on the creation, acquisition, identification, adaptation, organization, distribution, and application of knowledge within and between projects. It is also a dynamic process, evolving with technology, organizational culture, and development practices (Ward & Aurum, 2004). Inherent to software development is knowledge embedded in products and meta-knowledge concerning not only the products but also the development processes (Rus, Lindvall, & Sinha, 2001). While individuals engaged in software development projects make decisions based on personal knowledge, the sharing of this knowledge historically has been limited to informal means (Rus & Lindvall, 2002) (see Rus et al., 2001, for a review of KM and software engineering).

TechCo's focus on process improvement initiatives was driven by a desire to provide a measure of control and accountability within complex software development projects. Example processes that could be targeted in a software lifecycle context include the requirements analysis, software development and software maintenance processes, as well as more managerial processes, such as the project management or change management process (Jalote, 2000; Rus et al., 2001). TechCo sought to address several of these processes through its efforts to achieve the Carnegie Mellon Institute's Capability Maturity Model Level 5 certification (Paulk et al., 1995).

Having identified a set of target processes to reengineer (Step 1 of our checklist), TechCo began to specify and document the standard activities and information flows for each major process in the software development life cycle. This activity (a requirement in order to be certified at Level 3 of the CMM) helped TechCo to achieve the objectives stated in Step 2 of our KM checklist. Each process was broken down into stages consisting of activities that, in turn, were divided into subactivities. Key participants for each stage also were identified as part of the process definition. For example, the requirements analysis process was divided into the activities of preparation, eliciting requirements, analyzing requirements, and so forth. Examples of subactivities that were identified for the requirements analysis activity included the creation of logical data models and process models.

Steps 3 and 4 of our KM initiative checklist were achieved as a natural consequence of TechCo's efforts to detail the activities that comprised each process. TechCo used the ETVX (Entry, Task, Verification, and eXit) model (Radice, Roth, O'Hara & Ciarfella, 1985) to define the details of each stage in a process. The entry criteria and input specification together defined the primary knowledge inputs to each activity, while the exit criteria and associated metrics defined the knowledge exchange outcomes associated with each activity.

Step 5 of our checklist deals with the identification of the knowledge sources and receivers for each activity. At TechCo, the knowledge sources and receivers for each activity were defined in the process definition handbooks. These handbooks contained generic guidelines for performing activities such as group reviews, defect prevention, and so forth, as well as detailed checklists for accomplishing activities such as high-level design, functional design, code review, and so forth. In addition, TechCo created a series of templates for producing various types of documents generated during the software development process (e.g., requirements specification, unit test plan, and acceptance test documents). Specifying these items to a sufficient level of detail such that every project could follow the guidelines as well as produce documents in a standardized fashion was a key step in helping TechCo achieve Level 5 certification. These templates represented a codification of knowledge that then could be exchanged among the various sources and receivers.

Having defined in detail its software engineering processes, TechCo began to examine the best mechanism by which it could support the activities of the knowledge workers executing these processes (Step 6 of our checklist). It is well known that software development requires coordination and collaboration among various stakeholders (Kraut & Streeter, 1995) (i.e., project leaders, module leaders, analysts, developers, and members of quality assurance groups). Armed with an understanding of the individual tasks performed by each knowledge worker, the types of knowledge exchanged among the various stakeholders and the coordination and communication needs of knowledge workers during each phase of the life cycle, TechCo was able to design a project level KM system, the Project Reporting and Management System (PRMS). PRMS facilitates efficient knowledge sharing among the workers by providing support for essential collaborative activities, such as (1) configuration management of work products (e.g., documents and code); (2) division, scheduling, and assignment of subactivities to various knowledge workers; (3) support for testing and problem reporting; and (4) change management. In addition, PRMS captures various metrics relating to defects per stage, effort spent per stage, and so forth. In essence, PRMS is a project-level KM that serves as a one-stop shop for sharing key knowledge related to a given project, including informal knowledge generated during the course of the project.

By achieving the high level of process maturity and control over its software development processes and the use of tools such as PRMS, TechCo was able to maintain its competitive edge in the marketplace. However, it still did not have any organization-wide mechanism in place to facilitate knowledge sharing across various projects. This often resulted in wasted effort and costly mistakes in personnel and time estimation. For example, there was no easy mechanism to solve the problems related to the "who knows what" issue that plagues large organizations. Moreover, no mechanisms for sharing knowledge regarding best practices and processes were in place.

To address these problems, TechCo developed and deployed an organization-level KM system in the form of an electronic knowledge asset library (KAL). This system served as a repository for knowledge about its software development process (i.e., guidelines, checklists, templates, etc.). TechCo organized knowledge generated from prior projects based on two criteria: industry vertical (e.g., manufacturing, pharmaceutical) and technology characteristics (e.g., languages, tools, databases). Detailed knowledge from each project (captured in the PRMS) in the form of all final documents produced during the various phases of the lifecycle (e.g., requirements documents, high-level design documents, program code, and records of quality assurance reviews, was stored in this system. Furthermore, because of its highly mature processes, TechCo was also able to capture quantitative information (e.g., effort and defects per stage) in the system. This system also served as a forum for posting white papers and tutorials on emerging technology topics. Each knowledge item in the system had associated with it a contact person's information, thus creating knowledge about where expertise resides within the organization.

The knowledge captured in KAL is accessible to all users in the organization. Access to the library is provided through a groupware system based on Lotus Notes® technology. Common navigation functionality, such as ability to search projects based on keywords and other criteria, is provided. Thus, using this system, a project leader initiating a project using J2EE technology in the financial industry can retrieve documents related to prior J2EE projects in the financial industry and use the knowledge in the system to estimate the manpower and time needed to execute the new project successfully. The project leader is able to find and communicate with other project leaders with experience in that domain and to make requests for software engineers, who have performed well in a specific domain. At the same time, a developer can read tips on how to develop wireless applications using J2ME. Similar systems (i.e., the process asset database [PDB] and Knowledge Map) are in use at Infosys, one of TechCo's chief competitors (Ramasubramanian & Jagadeesan, 2002). To encourage the sharing of knowledge via these KM systems, TechCo linked knowledge worker financial incentives to systems use, which TechCo believes led to performance improvements.

Through the use of these KM systems, TechCo has been able to deliver consistently high-quality software products by reducing the barriers of time and space associated with virtual software development (Carmel & Agarwal, 2001). It is worth noting that the process of accomplishing the six steps has taken more than five years. TechCo's efforts were spent on defining and refining the details of the software development processes (Steps 1 through 5) and the needs and motivations of its knowledge workers prior to considering and designing the subsequent technology-based KM system interventions. In the end, TechCo's efforts reflect its response to external competitive pressures and desire to improve interdependent, multi-level (business, process, and knowledge worker) performance (Figure 1). The fact that TechCo has been able to maintain its leadership position in an extremely competitive IT outsourcing/offshoring space provides evidence of the value of the KM initiatives. Thus, the TechCo case reiterates the importance of taking a holistic, performance-centric view of KM.

IMPLICATIONS FOR PRACTICE AND RESEARCH

Successful organizations like IBM, Nortel, and TechCo are searching for ways to improve performance by leveraging knowledge assets more effectively. New products, services, and customer relationships are key drivers of growth for sales and profitability, particularly for firms facing intense competition and rapid technological change (Alavi, 2000; Huber, 2001). Viability often hinges directly upon the competitive quality and exploitation of a firm's underlying knowledge base. Relative to their own environment, every organization will respond differently to the fundamental question posed earlier in this paper: What performance goal(s) is the organization trying to achieve by managing its knowledge assets? While KM cannot be applied generically, we have provided an overseeing framework and underlying steps that may assist organizations in addressing this question (Rubenstein-Montano et al., 2001; Tsoukas, 1996).

For practice, our perspective is both adaptive and responsive to different situations. Importantly, our approach considers the entire KM process — strategic objectives, operational factors, the role of technology, and people/culture — as well as underlying knowledge types, flows, tasks, and learning that must to be considered when considering the fit of a KM initiative to a particular organization. As evidenced in our cases, any KM initiative must be aligned with the existing strategic environment (Liebowitz & Beckman, 1998). An organization should assess the relationship of the initiative to current value chain processes, the level of change, the resources required to implement the envisioned solution, and the level of senior management support. Senior level support establishes an appreciation of knowledge assets and is essential for the ongoing funding and investment for necessary human and technical resources (Holsapple & Joshi, 2000). A KM initiative must fit with the operational environment. Interventions may change workflow and interpersonal relationships and thus may necessitate new roles and/or skills for knowledge workers. Deploying information technology in the form of a KM system also requires consideration of the existing technical environment (Flanagin, 2002; Holsapple & Joshi, 2002; Huber, 2001). The solution must be compatible with networks and platforms, and the organization must be ready to deal with the level of investment and change necessary to implement desired technical functionality. Perhaps the most challenging issue is the assessment of the fit between a KM initiative and the cultural environment. Creating a culture of knowledge sharing is critical to success (Davenport et al., 1998; Fahey & Prusak, 1998; Grover & Davenport, 2001). Given this, an organization needs to assess incentive and reward systems and identify internal inconsistencies. Understanding the internal performance system of a knowledge worker will assist in identifying factors that positively or negatively influence the behavior of knowledge workers.

For researchers, while we recognize the limits of a case study approach to generalizability, we maintain that the very nature of our framework requires holistic study of its application. This suggests a need for additional qualitative case studies conducted in collaboration with organizations that have engaged in or that are considering KM initiatives. It is only when a sufficient amount of systematic qualitative case study research has been conducted that themes and relationships inherent to our framework can be validated further via quantitative research methods.

CONCLUSION

A KM strategy entails developing a portfolio of strategically focused initiatives required to achieve business results. Organizations must prioritize these initiatives based on business value, enterprise support, and funding. As such, holistically and systematically understanding the performance environment surrounding organizational knowledge work takes on heightened importance (Massey & Montoya-Weiss, 2002; Rubenstein-Montano et al., 2001). With both prescriptive and descriptive elements, the framework and associated steps developed and offered in this paper should guide future research and assist organizations interested in undertaking and leading KM initiatives.

ACKNOWLEDGMENTS

The authors gratefully acknowledge the research funding provided by the Advanced Practices Council of the Society for Information Management (SIM) and the Center for Innovation Management Studies, as well as the practical insights of their respective members. We also acknowledge the input and support of IBM, Nortel, and TechCo personnel.

Chapter 1.13
Taxonomies of Knowledge

Phillip Ein-Dor
Tel-Aviv University, Israel

INTRODUCTION

Knowledge management has become a major application of information technology (IT) and a major focus of IT research. Thus, it becomes increasingly important to understand the nature of the knowledge object and knowledge engineering processes. The assumption underlying this article is that in order for knowledge to be managed by technological means, it must first be represented in the relevant technology. As Sowa (1999) puts it:

Knowledge engineering can…be defined as the branch of engineering that analyzes knowledge about some subject and transforms it to a computable form for some purpose.

The purpose assumed here is the management of knowledge for organizational aims. The other key term is "analyzes knowledge"; to analyze an object, one must first describe it, and taxonomies are intended to facilitate description and analysis. A useful analogy is that of taxonomies of living creatures which employ multiple characteristics such as size, number of legs, blood temperature, and many more to assign specimens to categories.

As different kinds of knowledge require different modes of representation, taxonomy becomes the central link between knowledge engineering and knowledge management. For example, accounting data are represented as data records; routine manipulation of the data is performed employing accounting knowledge embedded in programs. Organizational use of accounting data may be mediated by expert systems, which are generally realized as a special form of rule-based programs. Thus, in order to effectively design a knowledge management system, one must first classify the types of knowledge to be embedded in it. Hence the importance of a taxonomy of knowledge. A definition of knowledge is itself knowledge; thus, this article deals essentially with knowledge about knowledge—that is, meta-knowledge.

Knowledge is a highly multidimensional phenomenon and can be studied from many points of view. Thus, Sowa's (1999) book titled Knowledge Representation is subtitled Logical, Philosophical, and Computational Foundations. The approach taken here is largely a computational one, since knowledge management is generally discussed, though not necessarily in the context of computer-based systems. Given a computerized knowledge management system, questions also arise of eliciting the knowledge to be embedded in the system; some of these are also addressed here.

BACKGROUND

Attempting to understand the nature of knowledge has been a major theme of philosophical enquiry for thousands of years. Thus, Aristotle (384-322 BC) argued that knowledge objects are made accessible to thought by assigning them to categories. This approach still underlies much of knowledge management in specific areas. It applies especially to library classification systems—for example, The Dewey Decimal Classification (Dewey et al., 2003) for organizing all published knowledge. The classic Yahoo search engine was based on the same principle.

However, not all knowledge management relates to knowledge by content area; many other classifications are possible, and it is the purpose of this article to elaborate those. Because of the multidimensionality of knowledge, many taxonomies are possible. A well-known attempt to

Table 1. Knowledge taxonomies and examples (Alavi & Leidner, 2001)

Knowledge Types	**Definitions**	**Examples**
Tacit	Knowledge is rooted in actions, experience, and involvement in specific context	Best means of dealing with specific customer
Cognitive tacit:	Mental models	Individual's belief on cause- effect relationships
Technical tacit:	Know-how applicable to specific work	Surgery skills
Explicit	Articulated, generalized knowledge	Knowledge of major customers in a region
Individual	Created by and inherent in the individual	Insights gained from completed project
Social	Created by and inherent in collective actions of a group	Norms for inter-group communication
Declarative	Know-about	What drug is appropriate for an illness
Procedural	Know-how	How to administer a particular drug
Causal	Know-why	Understanding why the drug works
Conditional	Know-when	Understanding when to prescribe the drug
Relational	Know-with	Understanding how the drug interacts with other drugs
Pragmatic	Useful knowledge for an organization	Best practices, business frameworks, project experiences, engineering drawings, market reports

survey taxonomies of knowledge in the context of knowledge management systems is that of Alavi and Leidner (2001); they present 10 categories of knowledge gleaned from the knowledge management literature; their summary is cited as Table 1. This article uses the Alavi and Leidner (2001) categories as a basis, while extending and rationalizing them.

In general, taxonomies of knowledge may be ordered by their degree of generality; one may deal with knowledge at the highest level of abstraction, as Sowa (2000) does, while at the other extreme there are taxonomies of knowledge within specific fields (i.e., subsets of the general scheme of classification by content). The approach taken here is something of an amalgam of these two extremes. As it is impossible within the confines of an encyclopedia article to cover the entire gamut of types of knowledge, the emphasis here is on some higher level categories that we consider most relevant to practical knowledge management.

THE FOCUS: DIMENSIONS OF KNOWLEDGE

In discussing types of knowledge, one can think of the characteristics of knowledge items as unique points, each representing a class of knowledge. In this approach, for example, tacit and explicit knowledge are two different types. Most taxonomies to date have adopted this view. However, these two categories are also opposite poles of a single dimension along which there may well be types of knowledge that are combinations of the extreme points: for example, a given item of knowledge may be partly tacit and partly explicit. It therefore seems useful to think of the dimensions as having two extremes and to juxtapose those to depict characteristics of any given knowledge object.

The dimensions of knowledge discussed here are the tacit-explicit, individual-social, procedural-declarative, commonsense-expert, and task-contextual; three additional dimensions—true-false, certain-uncertain, and private-public are also briefly introduced. As the reader will note, there is considerable, but not complete, overlap with the Alavi and Leidner (2001) typology. The dimensions are also consistent with, but broader than, Nichols' (2000) identification of tacit, explicit, declarative, and procedural knowledge.

Given the multidimensional nature of knowledge, the ontology of an item of knowledge must refer to its location on all relevant dimensions in order to provide a complete specification. Such a specification should provide guidance in building systems to manage knowledge.

The Tacit-Explicit Knowledge Dimension

Tacit knowledge is knowledge that is possessed by an individual, but which he or she is unable to express verbally. At the other extreme of this dimension is explicit knowledge—knowledge that can be fully verbalized and so is available to any enquirer. An extreme statement of the tacit knowledge problem is that of Wittgenstein (1922): "The limits of my language are the limits of my mind. All I know is what I have words for." This might seem to imply that there can be no tacit knowledge. If we cannot put things into words, we cannot know them. "Whereof one cannot speak, thereof one must be silent" (Wittgenstein, 1922). This position, however, does not consider the possibility of assistance to explicate tacit knowledge, and it seems likely that there are varying degrees on the tacit/explicit dimension.

One of the best known philosophical treatments of tacit knowledge is that of Polanyi (1983), who distinguishes between tacit and "focal" knowledge. Polanyi characterizes tacit knowledge in the statement, similar to Wittgenstein's, that "…we can know more than we can tell." But knowledge that "we cannot tell" can sometimes be elucidated with appropriate help; for example, Police Identikits aid witnesses to crimes to concretely describe physiognomies of persons glimpsed under poor conditions and which they cannot describe verbally. However, some deeper level still remains unfathomable. This might derive from the fact that words cannot express all the detail of a physical entity or concept—a problem of granularity of language.

We may regard Polanyi's tacit knowledge as inchoate cognitive sensations for which we have not yet found words. In that case, this is knowledge about "whereof one cannot speak." However, with assistance, one may be able to find the words and so make the knowledge explicit. That would render much tacit knowledge potentially explicable. Thus, in principle, there is nothing we know that we cannot tell; practically, however, there may be things we know that we have not yet developed the ability to tell.

Tacit knowledge is, among other things, the knowledge of experts who intuitively know what to do in performing their duties, but find it difficult to express. Such knowledge is frequently based on intuitive evaluations of sensory inputs or gestalts of smell, taste, feel, sound, or appearance. Eliciting such knowledge was a major problem in early attempts to automate production processes such as brewing beer, manufacturing paper, or making wine, which were traditionally managed by master craftsmen who acquired their knowledge from long apprenticeship and experience. Eliciting such knowledge can be a major obstacle in attempts to build expert systems, as will be elaborated in discussing the commonsense-expert dimension.

The Individual-Social Knowledge Dimension

The process of converting tacit knowledge into explicit knowledge has been dealt with in great depth by Nonaka (1995). The emphasis there is on explicating tacit individual knowledge and converting it into social knowledge at ever higher levels. Alavi and Leidner (2001) include individual and social knowledge as separate categories in their list of taxonomies; Nonaka, however, sees a continuum from individual knowledge through group, organizational, and inter-organizational levels. He envisions the process as a spiral in which the expansion of explicit knowledge permits the creation of knowledge at higher levels of organization: "A spiral emerges when the interaction between tacit and explicit knowledge is elevated dynamically from a lower ontological level to higher levels" (Nonaka, 1995, p. 57).

This dimension is well nigh synonymous with what has also been referred to as the objective artifact-socially constructed perception (Davenport & Prusac 1998): this view relates to the manner in which knowledge is attained—whether through personal experience or by social interaction.

The Procedural-Declarative Knowledge Dimension

Declarative knowledge consists of facts and figures. Procedural knowledge is knowledge about means for achieving goals. At first blush, it might not seem clear why the two are considered poles of a single dimension. There are, however, a number of reasons for this juxtaposition.

Psychologists have studied the interaction in humans between declarative and procedural knowledge for some time. There is disagreement over whether procedural knowledge develops from declarative knowledge (Anderson, 1996), or whether declarative knowledge plays a role in the development of procedural knowledge but does not evolve into procedures (Nichols, 2000). In any case, some procedures (e.g., facial recognition) are developed without recourse to declarative intervention.

Beginning with human knowledge, in many cases there is a tradeoff between knowing facts and knowing how to compute those facts. Thus, one may learn the multiplication table by heart, or one may compute a multiplication when needed. In fact, most people know the multiplication table for relatively small numbers, but must compute the outcomes for larger numbers. One may remember telephone numbers as facts, or one may have a procedure for recovering them from a repository of such numbers.

From the computer point of view, declarative knowledge (data) and procedures (programs) are indistinguishable. Both reside in digital memory in the same format and possibly intermingled. In some programming languages (e.g., LISP), programs are themselves data that can be manipulated by the program itself. As with humans, computer resident knowledge may be stored as the facts themselves, or as procedures for computing the facts. However, the degree of flexibility in deciding which form of representation to adopt is much greater for machine resident knowledge because of the far greater computing power of the machine. For example, it would be impractical to re-compute account balances for every access required to manually maintained bank records. However, a strategy of re-computation might be adopted in machine maintained accounts if the tradeoff between maintaining balances digitally and re-computing them is in favor of the latter.

Furthermore, declarative and procedural knowledge are increasingly intertwined in modern information systems. Thus, markup documents (HTML, XML, etc.) contain both declarative knowledge (the content) and procedural knowledge (the controls) that dictate the presentation of the declaratives. Spreadsheet cells may contain declarative knowledge or procedures that compute and display the declarative values.

The conclusion from this discussion is that design of a knowledge management system must take into consideration whether any knowledge item is optimally represented declaratively, procedurally, or both.

The Commonsense-Expert Knowledge Dimension

Commonsense knowledge is what every member of a society is expected to know. This includes socially approved behavior, how to conduct simple commercial transactions (Ein-Dor & Ginzberg 1989), and naïve physics (Hayes, 1978, 1979). Expert knowledge is that which imbues recognized experts with their status. Implicit in the recognition of experts is the understanding that their number is severely limited. When experts' knowledge is diffused to the population at large, it becomes commonsense knowledge. One example of this is driving automobiles; when they first appeared, automobiles were driven by professional drivers who were considered experts. Eventually, the majority of people in advanced economies learned to drive and that knowledge is now close to commonsense. Another example is writing, once the domain of expert scribes; with the advent of universal education, knowing how to write has become commonsense. The examples of driving and writing also exemplify the existence of a continuum between commonsense and expert knowledge.

This dimension of knowledge is one which poses severe problems for knowledge management (Buchanan et al., 1983; Feigenbaum, 1993), often related to the fact that expert knowledge is frequently tacit in nature. Expert systems are embodiments of expert knowledge. One of the reasons that expert systems have not realized the potential once projected for them is that it has proven extremely difficult, in many cases, to elicit the requisite knowledge from the relevant experts. Feigenbaum (1993) gives this as one of the reasons for the delay in expert systems achieving the expectations from them. Furthermore, once the knowledge has been elicited, it may be difficult to represent in digital form. The representation is usually as a set of rules determining the action to be taken for a given input set.

As for commonsense knowledge, one might first ask why is it necessary to represent such knowledge, given that it is possessed by all? There are several reasons to digitally represent commonsense knowledge. First, if it is desired to automatically process natural language texts—for example, newspaper items, professional reports, or voice recordings—commonsense knowledge is necessary in order to interpret the texts. Second, commonsense knowledge is common to a culture, but not necessarily outside that culture; much has been written, for example, concerning the different negotiating styles of Western and Asian businessmen and the difficulties this can cause. Such problems increase in intensity with the spread of globalization. Formal representation of the commonsense of cultures might help alleviate these problems.

Unfortunately, representing commonsense knowledge is an extremely difficult undertaking. There are numerous reasons for this (see Ein-Dor & Ginzberg, 1989). In spite of great efforts, much work still remains to compile a general commonsense knowledge base. One consolation is the presumption that once such a knowledge base has been compiled, it should be useable by all, with adaptation required perhaps to specific cases. A large project, known as Cyc, with the objective of building a commonsense knowledge base has been underway since 1984 (see Cycorp, 2004; Guha, Lenat, Pittman, Pratt, & Shepherd, 1990; Lenat & Guha, 1990; Lenat, 1995).

The Task-Context Knowledge Dimension

Organizational knowledge is generally utilized to perform tasks of various kinds from the most routine to the highest level strategic decision making. Many of these tasks, however, require some context for their performance (Pomerol & Brézillon, 2001). That context may be intra-organizational or external. Building on this definition, what we refer to here as "task knowledge" is also called "organizational knowledge."

The knowledge to perform a given organizational task may be exclusively internal to the organization (e.g., where to store inventory items) or it may require much contextual knowledge (e.g., devising a marketing program). Note however that while the low-level task of storing inventory may be dictated by organizational procedures, those procedures may themselves be influenced by contextual knowledge concerning the frequency of and size of requests for items.

Thus, the knowledge for performing a given task may vary from high to low task-context combinations. The import of this fact for knowledge management is that task information is internal to the organization and is relatively easier to acquire and maintain. But note the discussion of expert knowledge above, which suggests that even internal knowledge may be difficult to manage, partly because of the contextualization required. Van Leijen and Baets (2004) discuss the way business processes are affected by the contextual knowledge patterns of the individuals responsible for their execution.

Contextual knowledge external to the organization poses severe acquisition problems, as sources need to be identified and the organization's environment changes constantly, requiring that the knowledge be constantly updated. Such contextual knowledge is either commonsense or expert in nature and is consequently subject to the problems discussed for the commonsense-expert dimension.

Additional Dimensions of Knowledge

As noted, the dimensions of knowledge outlined above are those considered particularly relevant to knowledge management. However, some additional dimensions of knowledge have been identified, beyond those discussed above. These may be relevant to some knowledge management systems and are here noted very briefly.

- True-False: Certain things we know are true; others things we think we know are probably false. Much knowledge lies between the extremes of truth and untruth and may be closer to one extreme or the other. Thus, in recording knowledge, knowledge items will be of varying degrees of veracity. For example, respondents to a survey may give their exact years of experience, slightly overstate or understate it, or exaggerate wildly. A computerized knowledge management system cannot evaluate veracity, except perhaps by triangulation of different representations of the same knowledge item or by logical inference from a number of items. Thus, evaluating veracity is a function primarily of those who collect and use the knowledge.
- Certain-Uncertain: Things can be known with different degrees of certainty from accurately measured physical properties to estimations of an opponent's intentions based on evaluation of relevant facts, which may themselves be subject to high uncertainty and low veracity. Again, a computerized knowledge management system cannot evaluate degrees of certainty unless programmed to do so, with the quality of the determination depending both on the accuracy of the data and the correctness of the evaluation parameters. Thus, controlling for certainty is again the responsibility of the knowledge collector and user.
- Private and Individual-Public and Shared Dimension (Aarons, 2005): This dimension is linked to the objective artifact-socially constructed perception above. The latter deals with the way in which knowledge is constructed, the former with the current state of construction.

FUTURE TRENDS

Managing knowledge efficiently and effectively requires a deep understanding of the nature of knowledge and its embedding in computerized systems. Thus, it is reasonable to assume that greater efforts will be invested in research to improve our understanding of knowledge. In the context of this article, that presumes a full mapping of all the dimensions of knowledge and establishing relationships between knowledge, as mapped on these dimensions, and the technological implications for the management of that knowledge. Understanding knowledge, studied in the past primarily by philosophers and psychologists, is an area in which the Information Systems field might make a profound contribution.

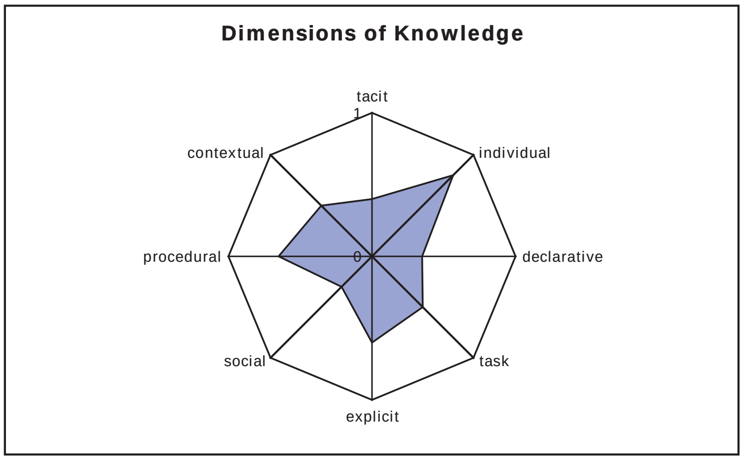
CONCLUSION

Knowledge is a multidimensional artifact, and cognizance of the various dimensions is useful for understanding the nature of a body of knowledge and is required in order to completely specify an item of knowledge. The principal dimensions of knowledge recognized here are tacit/explicit, individual/social, declarative/procedural, and task/context. The categorizations of a knowledge item may be graphically displayed as in the example in Figure 1.

Additional dimensions have been suggested—for example, the categories recognized in Alavi and Leidner (2001) as conditional, relational, and pragmatic; these are not included here because, while they may describe certain aspects of knowledge items, they are not generally recognized as basic dimensions of knowledge. The specification of knowledge to be represented computationally is important in choosing the computational solution to be employed.

A major conclusion from the multidimensional view of knowledge presented here is that the distinctions usually made in the IS literature

Figure 1. Example of dimensions of knowledge for a hypothetical knowledge item



between data, information, and knowledge are largely irrelevant (Ein-Dor, 1986). A data item in an organization's information systems is simply a piece of knowledge that is generally explicit, declarative, social, and organizational. A manager's knowledge of an aspect of the marketplace is probably to a large extent implicit, individual, declaratively and procedurally mixed, and contextual. Any knowledge item may be classified on these dimensions as a basis for analysis and implementation. This view can lead to greater integration of the various kinds of knowledge embedded in information systems.

Chapter 1.14
Understanding Organizational Memory

Sajjad M. Jasimuddin
University of Dhaka, Bangladesh and University of Southampton, UK

Con Connell
University of Southampton, UK

Jonathan H. Klein
University of Southampton, UK

INTRODUCTION

It is generally recognized that Walsh and Ungson (1991) "provided the first integrative framework for thinking about organizational memory" (Olivera, 2000, p. 813). Within the field of knowledge management (KM), there has been interest in a variety of issues surrounding organizational memory (OM), which is understood to involve processes of storage and retrieval of organizational knowledge of the past for use in both the present and the future. The recognition of the importance of OM has implications for practice. For example, Argote, Beckman, and Epple (1990) suggest that the effective use of OM can protect an organization from some of the negative effects of staff loss, while Stein (1995, p. 19) asserts that an appreciation of OM can facilitate the solution of problems associated with the retention and utilization of knowledge within organizations.

Although the need to preserve knowledge in organizations is now recognized, organizational theorists still disagree on a number of issues relating to OM. Existing literature exhibits contradictory arguments regarding OM which can make the relevance and application of OM concepts to KM difficult to understand. This article describes some of the disagreements surrounding OM in order to provide a deeper understanding of how OM might help to manage knowledge.

BACKGROUND

The topic of OM has received a great deal of attention from researchers across a wide range of disciplines, most notably organization theory, psychology, sociology, communication theory, and information systems. In a detailed exploration of OM, Stein (1995, p. 17) suggests that "there are three major reasons to explore this concept in more detail: (1) memory is a rich metaphor that provides insight into organizational life; (2) OM is embedded in other management theories; (3) OM is relevant to management practice."

Most of the literature on OM tends to focus on definitions of the term, the content and types of OM, its location, and the processes associated with the acquisition, storage, retrieval, and maintenance of memory (Walsh & Ungson, 1991; Stein & Zwass, 1995; Casey, 1997). Walsh and Ungson (1991, p. 61) provide an overall definition of OM as "stored information from an organization's history that can be brought to bear on present decisions." This corresponds closely with the definition given by Stein (1995), who regards OM as the way in which organizational knowledge from the past is brought to bear on present activities.

Some studies have addressed the role of information technology in developing OM systems (OMS) which support OM processes (Sherif, 2002). Several researchers have highlighted the barriers to the implementation of OMS, the ways in which they might be overcome (Sherif, 2002), and the influence of OM on organizational effectiveness (Olivera, 2000).

OM occupies a significant place within management literature. However, Walsh and Ungson (1991, p. 57) argue that "the extant representations of the concept of OM are fragmented and underdeveloped." Examination of the existing literature reveals frequent divergence of understanding of the notion of OM (Corbett, 1997). Indeed, earlier researchers (most notably Ungson, Braunstein, & Hall, 1981; Argyris & Schon, 1978) denied the existence of OM. Generally, organizational theorists disagree about a variety of issues surrounding OM. Ackerman and Halverson (1998, cited by Schwartz, Divitini, & Brasethvik, 2000, p. 3) are concerned that a clear and universally accepted definition of what an OM should do appears to be lacking:

After nearly 10 years of research, the term organizational memory has become overworked and confused. It is time for a re-examination. The term is burdened with the practical wish to reuse organizational experience, leading researchers to ignore critical functions of an organization's memory and consider only some forms of augmenting memory.

CONTROVERSIES IN OM

The field of OM exhibits many controversies in which researchers seem unable to agree about fairly fundamental features. The literature regarding these issues tends to be somewhat sparse and inconclusive. Some of the most notable of these issues, on which we focus in subsequent sections, are:

- Can organizations be said to have memories, or is OM essentially anthropomorphism?
- What is the relationship between the research fields of OM and KM?
- Does OM reside in the minds of individual organizational members, or elsewhere?
- Is OM appropriately modeled in terms of static storage bins, or should it be treated as a dynamic socially constructed process?
- How are OM systems operationalized?
- Is OM functional or dysfunctional in terms of organizational performance and effectiveness?

IS OM ANTHROPOMORPHISM?

Some researchers question whether OM can truly exist at all. They argue that, unlike an individual human being, an organization cannot be said to have a memory. Walsh and Ungson (1991) suggest that the idea of OM raises possible problems of anthropomorphism: Attributing characteristics that may be uniquely human to organizations may be an everyday convenience, but may obscure rather than clarify research issues. Argyris and Schon (1978), for example, contend that organizations cannot memorize knowledge of the past. Others, however, argue the contrary. Weick (1979, p. 206), for instance, asserts that organizational memory is implicated in the production of organizational personality, and that organizations must accept and live with their memories.

WHAT IS THE RELATIONSHIP BETWEEN OM AND KM?

The relationship between OM and KM is another issue of contention. Knowledge management encompasses the management of organizational knowledge to enhance competitive advantage and implies an integrated approach to identifying, capturing, preserving, and retrieving the knowledge associated with the activities of an organization. Davenport and Prusak (1998), for example, define KM as the process of capturing, preserving, and distributing organizational knowledge. But are OM and KM fundamentally distinct fields of enquiry, or do they possess substantial commonality? This question is unresolved. Recent KM literature has either identified OM as an element of KM or appears to have used the terms, whether by accident or design, interchangeably. Unfortunately, however, there has been little attempt to systematically address the nature of the differences and similarities between them. There is little agreement as to what, if indeed anything, distinguishes OM from KM.

OM and KM seem to have evolved, at least, into close partners (Schwartz et al., 2000). Most researchers, including Kuhn and Abecker (1998), view OM as an important component of the KM perspective. The argument is that OM, being concerned with the preservation of knowledge for present and future use, must be integrated with KM. Similarly, Randall, Hughes, O'Brien, Rounefield, and Tomie (2001) consider OM to be a sister concept to KM, and the two are in practice used interchangeably. Hoog and Spek (1997, p. v) acknowledge the close relationship between OM and KM when they state that an important problem in KM is "insufficient use of knowledge possibly stored in badly organised corporate memories."

However, some researchers hold the view that OM and KM are not the same and should not be confused. Marsh and Morris (2001), for example, draw attention to temporality, arguing that KM is of the present, while OM is of the past. They regard KM as relating to the management of knowledge that is currently in use, while OM is concerned with the storage of past knowledge for future use.

Given that a central aspect of KM is the preservation and retrieval of organizational knowledge and that OM is the mechanism by which knowledge from the past is brought to bear on the present and future, it seems legitimate to regard OM as a constituent of KM. The two terms are not synonymous: KM, which addresses the entire issue of managing organizational knowledge, is a far broader area than OM. The storage and retrieval of organizational knowledge is just a part, albeit a crucial part, of the whole job.

WHERE DOES MEMORY RESIDE?

The memories held by an organization constitute a record of its past that may contain a vast amount of knowledge. The literature recognizes a variety of types of devices that may store knowledge (Table 1).

Where organizational memory resides, however, is controversial. The traditional view is that organizational knowledge is brought into being by people within the organization, and that it is located within the human mind (El Sawy, Gomes,

Table 1. Knowledge storage devices

Knowledge storage devices
Formal and informal behavioral routines, procedures, and scripts (Nelson & Winter, 1982)
Standard routine procedures (Stein, 1995)
Managerial technical systems and capabilities (Leonard-Barton, 1992)
Individuals (El Sawy et al., 1986)
Culture (Cook & Yanov, 1992)
Products (Olivera & Argote, 1999)
Physical artefacts of an organization (Campbell-Kelly, 1996)
Computer-based information systems (Stein & Zwass, 1995)

Table 2. A storage bin model of organizational memory (Walsh & Ungson, 1991)

Storage bins
<u>Internal retention bins:</u>
1. Individuals (and their own memory aids, such as files);
2. Culture;
3. Transformations (procedures, rules, and systems that guide the transformations of inputs into outputs);
4. Structures (in particular, organizational roles);
5. Ecology (the physical structure of the workplace); and
<u>External bin:</u>
6. External bin (external archives).

& Gonzalez, 1986; Olivera, 2000). Others place it in the organization itself (Galbraith, 1977). Walsh and Ungson (1991) suggest that memory resides in many different organizational locations, and adopt a "storage bin" analogy, in which OM is structured in six bins which underpin processes of knowledge acquisition and retention (Table 2).

SHOULD OM BE VIEWED AS A SOCIALLY CONSTRUCTED PROCESS?

The storage bin model of OM is typical of a perspective that regards OM as centered around "sets of knowledge retention devices, such as people and documents, that collect, store, and provide access to the organization's experience" (Olivera, 2000, p.

815). However, this is not a universal perspective. The typology of OM constructed by Nissley and Casey (2002) contrasts the storage bin view with that of OM as a socially constructed process, and this is an approach adopted by many researchers (Conklin & Star, 1991; Randall, O'Brien, Rounefield, & Hughes, 1996; Casey, 1997; Randall et al., 2001; Nissley & Casey, 2002; Ackermann & Halveson, 1998). For example, Nissley and Casey (2001) regard collective memory as a socially constructed shared interpretation of the past, and Randall et al. (1996) suggest that considerations of memory should acknowledge "social context," which is relevant not only to retention and transfer of knowledge but also to how it becomes useful to people in the course of their work.

Similarly, Conklin and Star (1991) regard OM as a facilitator of organizational learning. OM is more than the aggregate of the memories of the members of the organization—it is a social phenomenon. Randall et al. (1996, p. 29) emphasize that:

OM should be seen as a collection of socially organized activities done by persons in organizations; that is, remembering as a feasible achievement verb. To put it another way, the 'organizational memory' metaphor fails to distinguish the kinds of social remembering that might take place in organizational life, and provides few examples of the 'remembering how,' 'remembering who,' and 'remembering what' that we are interested in.

HOW ARE OM SYSTEMS OPERATIONALIZED?

Existing literature tends to either neglect the operationalization of OM systems, taking them for granted, or describe it in the context of a technology-based or a people-focused approach. Technologies do indeed play an important role in how organizations preserve their knowledge. Anand, Manz, and Glick (1998) consider technology-based OM systems to fully acknowledge technologies as forms of OM, and several researchers (e.g., El Sawy et al., 1986; Te'eni & Weinberger, 2003) conceptualize IT-supported OM.

Computer-mediated IT, such as Lotus Notes, databases, and Intranets, provide mechanisms for retaining and accessing electronic archives. Stein and Zwass (1995) stress the role of technology in actualizing OM and provide a model for an OM system, of which information systems are a vital component. Meanwhile, some researchers recognize the importance of non-IT-based processes in operationalization of OMS (Walsh & Ungson, 1991). Organizational members may be the most effective means to operationalize storage and retrieval of knowledge.

IS OM FUNCTIONAL OR DYSFUNCTIONAL?

It is perhaps surprising that there are arguments not only for, but also against, the desirability of making the knowledge of the past available in knowledge storage repositories (Paper & Johnson, 1996). Some do indeed argue that OM is functional (Walsh & Ungson, 1991; Stein 1995). Walsh and Ungson (1991, pp. 73-74), for instance, identify three important organizational roles occupied by OM: (1) an informational role; (2) a control function; and (3) a political role. Other benefits that have been identified include increased organizational learning (Te'eni & Weinberger, 2003), improved coordination (Yates, 1989), rapid product development (Moorman & Miner, 1997), and the facilitation of knowledge sharing (Te'eni & Weinberger, 2003). Stein (1995, pp. 31-32) contends that OM can benefit organizations in several ways, including strengthening its identity and providing new personnel with access to the expertise of their predecessors.

However, some authorities (e.g., Walsh & Ungson, 1991; Stein & Zwass, 1995) have pointed to dysfunctionalities. In their view, organizations should discard old practices and develop new ones. Argote (1999) provides evidence which indicates the significance of such policies. Stein (1995) argues that organizational memory is not necessarily a good thing for individuals or organizations, and that, at the other extreme, it can become a constraint that threatens organizational viability.

FUTURE TRENDS

This discussion of OM has focused on a number of key controversies in the field. The contention of the authors of this article is that exploration of these controversies will be valuable to the development of OM theory and practice, and that resolving and accommodating the disagreements will lead to substantial advance. Some research has been directed at such resolution and accommodation, and it is in this direction, the authors consider, that the future lies.

OM, as currently depicted, describes the ways in which organizations can learn and memorize knowledge of their past, through their members, by means of both mental and structural artefacts. As such, OM may be seen as a significant element of KM (Schwartz et al., 2000): KM addresses organizational knowledge holistically, while OM focuses on the storage of past or current knowledge for present and future use. The article presents divergent perspectives—static storage bin or dynamic socially constructed process—on an appropriate model of OM, with the bulk of the literature apparently favoring the former. In the future, we may expect to see some integration of these perspectives, perhaps moving toward a "dynamic socially-constructed storage bin" model which captures valuable aspects of both.

In parallel to this, the technological view of OM that many adopt has been challenged by some researchers. Anand et al. (1998) argue that in order to implement KM initiatives and to manage OM in particular, it will be crucial to understand the nature of the relationships between technology and other organizational features and, in particular, people. We can expect to see more even-handed approaches to human and technical elements in future OM developments.

Although the arguments pointing to the dysfunctionality of OM, potential or otherwise, should not be ignored, we would suggest that the Markovian organization—the organization with no memory—is a foolhardy goal. Indeed, we suggest it might be an impossible one and that organizations need to address the issue of OM, if for no other reason than managed memory is likely to be more functional (or, to put it more pessimistically, less dysfunctional) than unmanaged memory. The functionality of OM lies in the contribution it can make to the effective management of the future of the organization—to organizational decision-making. However, it is essential to ensure that the knowledge available in the repositories of OM is relevant to that activity.

CONCLUSION

Organizational memory is the function of the organization in which organizational knowledge is stored and retrieved for present and future use, and thus contributes importantly to the processes of designing and creating the future of the organization. Although it has interested researchers for several years, many aspects remain unclear and contradictory. The authors hope that this article has provided insight into these aspects and recommend a pluralistic stance to them.

Chapter 1.15
Inquiring Organizations

Dianne Hall
Auburn University, USA

David Croasdell
University of Nevada, Reno, USA

INTRODUCTION

In order to manage knowledge and operate successfully in today's information-intensive business environments, various organizational forms have emerged (e.g., Mintzberg, 1979; Nonaka, 1994; Nonaka & Takeuchi, 1995). The form that an organization takes has consequences for communication and dissemination of information, and thereby the ability to engage in organizational learning. Some of these forms compress knowledge at the root level of the organization, while others facilitate the search for useful knowledge within the organization. Other forms are capable of supporting organizational members who must synthesize knowledge from diverse sources. If a firm begins to reconfirm that knowledge management and core competencies are at the heart of organizational performance, the demand on organizations to develop core competencies and to create and manage knowledge intensifies. Even after realizing the critical role of knowledge in the present competitive environments, firms are struggling with managing and creating knowledge.

Growing interest in a firm's intellectual capital and collective knowledge have led to ways in which organizations improve knowledge (organizational learning), store knowledge (organizational memory), and share knowledge (knowledge transfer). Although often discussed separately, these three concepts are tightly interwoven, and all must be considered when an organization strives to move toward a knowledge-based competency. These aspects fall under the broad and complex umbrella of knowledge management. In a review of knowledge management literature, Schultze and Leidner (2002, p. 218) suggest a definition of knowledge management as being the "generation, representation, storage, transfer, transformation, application, embedding, and protecting of organizational knowledge." While their definition is not the only one, nor may all researchers or practitioners agree with its appropriateness, it does demonstrate the incredible complexity that knowledge management presents. The authors note that research in knowledge management is a complex interdependency of collaboration (both in knowledge/information sharing and work), organizational memory, and organizational learning.

An organization striving toward knowledge management competency may be best served by incorporating an organizational form that facilitates learning and thus the expansion of organizational memory. However, choosing one form may not be supportive of the multiple types of learning required by such an organization. These organizations should adopt the form of an inquiring organization (Courtney, Croasdell, & Paradice, 1998) and use it to structure flexible subforms that facilitate the learning process.

This article describes inquiring organizations and considers the appropriateness of applying philosophical perspective to organizational form. The next section provides a background to inquiring organizations. The latter part of the article focuses on how inquiring organizations can take on multiple forms. The article concludes with a discussion of areas for future investigation.

BACKGROUND: INQUIRING SYSTEMS, INQUIRING ORGANIZATIONS AND LEARNING

Inquiring systems are characterized by properties described by Churchman (1971), who develops five inquirers based on the writings of five Western philosophers Leibniz, Locke, Kant, Hegel, and Singer. While an in-depth discussion of the inquirers is not within the scope of this article, each of the inquirers is briefly introduced in the following sections on inquiring organization subforms.

Inquiring systems create and manage knowledge, and provide a component called a guarantor that promotes accuracy and reduces redundancy in organizational memory (Hall, Paradice, & Courtney, 2003). They can provide the basis for a knowledge-oriented organization by facilitating the creation of new organizational knowledge and the adaptation of existing knowledge in wickedly changing situations (Hall et al., 2003). Inquiring organizations are based on inquiring systems (Courtney et al., 1998).

Inquiring organizations and learning organizations are terms that are often used interchangeably; however, there is one critical difference between the two. To be an inquiring organization, the organization's philosophical foundation must be laid on the principles of inquiring systems as discussed by Churchman (1971). Both the learning organization and the inquiring organization aspire to learn. Learning organizations primarily engage in double-loop learning (e.g., reacting to a problem by both fixing the problem (single-loop learning) and making changes to underlying norms that may have contributed to the problem) (Argyris & Schön, 1996) and often approach knowledge management in a reactive manner rather than the proactive process of the inquiring organization. However, an inquiring organization inquires—that is, it continuously searches and investigates its environment and engages in behavior that examines the learning process itself with an end goal of increasing learning efficiency (triple-loop learning). In this manner, the organization challenges the assumptions on which its behavior is based, effectively examining not the most effective means to an end, but examining the foundation of means themselves (Isaacs, 1993). This provides the capacity to routinely check organizational memory for inaccuracies, redundancies, or information that is no longer relevant (Hall et al., 2003).

Given the complexity of any organization moving toward knowledge competency, one can see that its support needs go beyond managerial style, technology, or process design. A knowledge-based organization must be considered in its entirety; however, providing an adequate foundation that can support such an organization is not easy. Churchman's (1971) inquirers, and the inquiring organization in particular, provide a basis for that foundation.

THE MAIN FOCUS: THE INQUIRING ORGANIZATION

The inquiring organization is a mesh of integrated inquiring systems that operate singly or together depending on the complexity of the environment in which the organizational unit finds itself operating. Each of the inquirers discussed by Churchman (1971) has specific strengths that allow it to operate efficiently in specific contexts, and together the inquirers have the ability to handle the complexity and the chaotic environment in which many modern organizations operate. Each of the inquirers is suited to a particular organizational form and environment. For instance, the Leibnizian inquirer is suited to a hierarchical form where knowledge is pushed throughout the organization. Lockean inquiry is more suited to a network form where information is pulled into the network; knowledge is created specifically for that network's context.

Inquirers in the Churchmanian tradition embody different organizational subforms, but integration of the forms into the inquiring organizational metaform allows homeostasis to survive against the elements, and in doing so, supports the characteristics of an inquiring organization. We therefore define the inquiring organizational metaform as a complex structure of multiple organizational subforms working together for the benefit of the organization. We now discuss the subforms in terms of their architecture and learning characteristics.

The Leibnizian Subform

The Leibnizian inquirer is the most basic of the inquirers and provides the inquiring organization with its initial set of facts (fact nets) and axioms derived from formulas that comprise the foundation of organizational memory. These fact nets are created by identifying and testing a hypothesis using basic axioms stored in the system (Churchman, 1971). This inquirer is considered a closed system; that is, it functions within a limited set of relationships. Learning that is attributed to the Leibnizian inquirer is primarily based in the theory of autopoiesis which is the ability to self-perpetuate and produce through a series of relationships in a closed, stable environment. Organizations or organizational units that exist in an environment of stability and routine do well to adopt the Leibnizian inquirer as their organizational form.

This structured environment requires adherence to rules and regulations; learning within the organization is a push rather than pull process. Learning occurs at the top of the organization and is pushed downward throughout the organization by processes such as demonstration workshops. Because of the explicit nature of the information being passed downward throughout the organization, teaching is not generally a necessary means of information dissemination; the printed rules and handbooks of the organization serve the function well.

The Lockean Subform

The Lockean inquirer is a well-suited system for a relatively stable, but highly social environment. This inquirer is founded on principles of agreement embedded in classification of observations. The Lockean inquirer's members share a common belief and vision, culminating in shared mental models of the organization's environment, tasks, and strategies. Learning is a group effort and does not occur without consensus. Thus, relationships and communication are integral facets of this inquirer (Churchman, 1971).

The learning here is both a push process (e.g., guidelines) and an assimilation process (e.g., the collective observation of senior sales personnel). Rather than demonstrate techniques, formal teaching is likely to involve storytelling by top producers, combined with tried-and-true heuristics generated by those experts to react to specific situations, such as an irate customer.

The new salesperson will strive to assimilate actions and processes that are observed to have favorable outcomes for senior sales personnel. This pull process is encouraged through informal indoctrination and by extrinsic motivation factors such as commission percentages.

The Kantian Subform

The Kantian inquirer is designed to incorporate both multiple perspectives and facts to determine models that are appropriate for the situation. Using Leibnizian fact nets to support its data analysis, this inquirer performs modeling techniques to detect causal relationships between perspectives. After a model is chosen as being most appropriate for the particular context through a process known as best-fit analysis, the Kantian inquirer performs an analysis to determine whether that model continues to produce satisfying results; when a model fails to satisfy, it is removed from consideration (Churchman, 1971). This form is most suitable in environments where there is some structure and some ability to formally analyze data, but where a clear solution may not be evident or possible.

Learning in this inquirer is a combination of theoretical and empirical analysis, and is disseminated through the organization via the group members. The nature of the knowledge will affect whether formal or informal teaching applies. Learning may take place in the explicit form (e.g., a change in a process) that would likely be disseminated through a push process as well as being represented in the organization's memory. A new goal, mission, or cultural change may be disseminated less formally through narrative indoctrination.

The Hegelian Subform

The Hegelian inquirer is a more advanced form that seeks to create knowledge through a dialectic process (Churchman, 1971). At its foundation are opposing Leibnizian fact nets that contain the thesis and antithesis perspectives of the question under consideration. Each of these perspectives is examined for their underlying assumptions; these are then paired (one from each side) and examined. As each pair is examined, the assumption with the most applicability to the situation at hand is synthesized into a new perspective that draws on the strength of each of the underlying perspectives (Churchman, 1971). Communication is critical in this form where learning occurs during the synthesis process and a greater understanding of the context is obtained.

Learning in this form is the outcome of the dialectic. Lessons are disseminated throughout the form itself by communication among the members. Little formal teaching or observing is required because members of these organizations are active in the learning process; however, when this form interacts with other forms, the teaching process would be selected in accordance with the receiving form (e.g., formal workshops for the Leibnizian form).

The Singerian Subform

The Singerian inquirer is the most complex of Churchman's (1971) inquirers. Its primary purpose is to seek out inconsistencies throughout the organization and resolve the inconsistencies through a process of measuring, partitioning, and refining. During this process, the Singerian inquirer "sweeps in" variables and perspectives from as many stakeholders as possible, sometimes using the other inquirers for support. When there are no problems to be solved, the Singerian inquirer challenges the status quo and again enters the measurement process. A subcomponent of the inquirer reruns the models associated with the measurement process to ensure replication throughout the system. This inquirer is appropriate for all environments, but is most appropriate for tumulus environments where fast, efficient action is required and little experience with the problem context is available.

The learning associated with this inquirer is complex in both breadth and depth, and is designed to enlarge the "natural image" with multiple perspectives, partitions, and refinements that allow an organization and its members to engage in a wider variety of innovative and creative tasks. The Singerian organizational form produces knowledge on all levels, and therefore all of the aforementioned learning approaches may be appropriate.

MULTIPLE APPROACHES: THE INQUIRING ORGANIZATIONAL METAFORM

The subforms described above are contained within the inquiring organizational metaform. Rarely does an organization consist of a homogenous set of processes, individuals, cultures, or environments. One common thread that does run throughout the organization, however, is the need for an accurate and dynamic organizational memory. As contributions from any organizational member or unit are stored in organizational memory, other organizational components, such as knowledge discovery components, may develop relationships between the new information and existing information that will be beneficial to another, possibly unrelated, unit, thereby facilitating organizational learning. Growth of organizational memory may be further enhanced in this organizational metaform by the use of a system designed to discover and distribute information, particularly from the external environment. Organizational memory may then be used within the organization to facilitate new or innovative knowledge creation.

Just as the components of an organization may differ vastly, so too may the tasks, environment, and decision-making strategies of different units. These characteristics play an important role in determining an appropriate organizational form to adopt. Because the focus of the inquiring organization is learning and the accompanying growth of organizational memory, care must be taken to structure each organizational unit in a way that provides appropriate structure for the task and environment, but does not limit learning potential. The following examples help clarify how the inquiring organizational metaform may translate into its subforms, all working together to provide proper support to the organization.

Manufacturing firms provide an example that illustrates the existence of varying organizational forms in inquiring organizations. Factory floor workers following standard operating procedures and highly routinized tasks are representative of the Leibnizian form. Team members working together to analyze and reengineer business processes to improve efficiencies and productivity represent the Lockean form. Matching product development and production to market needs and developing strategy to meet consumer needs require model fits typified by the Kantian form of inquiry. Labor talks and negotiated contracts are representative functions of the Hegelian form. Finally, organizational metrics that are used to inform productivity measures, assign performance bonuses, or modify existing practices would be typical of the Singerian inquirer. New knowledge from these process (e.g., new consumer needs strategy or new productivity measures) are added to organizational memory.

Another organizational form that can be considered is the academic community that exists in higher education. Each form of organizational inquiry exists within the community. Staff members within a given area function at the Leibnizian level using formal mechanisms and routines. The academic work environment is typically stable, and relatively few administrators carry out centralized high-level decision making. Researchers working together through the processes of research and publication are functioning in Lockean communities; committee and service commitments are also Lockean in nature. Kantian forms of inquiry are active when decisions such as budgeting or admissions standards are considered. These tasks are moderately formal, more complicated in nature, and typically include more autonomy in the decision-making process. Hegelian forms of inquiry may exist between students and faculty, and between faculty and the board of trustees. The tenure and promotion process would be typical of Singer inquiry, with the emphasis on measuring output by the number and quality of publications, student evaluation metrics, and quantified contributions to the referent discipline. Individuals go through a process of refining "research" to a specific number of publications, journal quality, contribution matrices, and so forth. These measures may vary by department. The newly created knowledge that arises from this decision scenario may consist of new journal rankings, new productivity measures, and new ratios of service to research. Again, these are added to organizational memory.

Five organizational subforms have been presented in this article. Discussion has included how each of the subforms may be implemented by or within a given organization, and exemplified how they may work together within an organization under the inquiring organization metaform. Each of the subforms has strengths in particular environments or contexts, but as the metaform, they support the underlying philosophy of the inquiring organization. Managers considering these perspectives can apply the basic principles of each subform as appropriate. Table 1 summarizes the discussion.

FUTURE TRENDS FOR INQUIRING ORGANIZATIONS

Over the last several years, researchers have searched for a unifying theory for knowledge management and the complexities it presents. Clearly, such a theory must support adaptability, flexibility, and the construction of social processes. Two often suggested for the task are Open Systems Theory and Weick's ESR model.

Adaptability is a goal of open systems theory (OST) (Morgan, 1997; von Bertalanffy, 1950, 1968). OST examines an organization for its ability to look beyond its boundaries for information and material, making changes in response to environmental input and learning. These changes are based not only on what it has experienced, but also by combining new information with human experiential knowledge as in an inquiring organization. Weick's (1979, 1995, 2001) Enactment-Selection-Retention (ESR) model of organizing is also concerned with flexibility and

Table 1. Organizational structure of Churchman's (1971) inquirers

Form C	Characteristics P	Primary Learning Style
Leibnizian and Lockean	Formal, routine tasks, stable environment	Top-down dissemination (Leibnizian) Observant assimilation (Lockean)
Kantian	Moderately formal, more complicated tasks, moderately stable environment	Lateral dissemination
Hegelian and Singerian	Informal and often temporary, complicated tasks, turbulent environment	Dialectic (Hegelian) Any of the above (Singerian)

information sharing. One of the main premises of ESR is that an adaptive organization is a collective action, and that influence comes not from positional individuals, but from the pattern of communication and relationships inherent in any social organization.

Churchman's (1971) inquirers, OST, and the ESR model each stress the need for communication and information sharing, and propose that an effective organization is a product of its environment, enacts on its environment, and ultimately shapes its environment. Thus, each of these systems is suitable for both stable and unstable environments, and is a potential knowledge management foundation theory. The inquiring organizational metaform described herein goes a step beyond OST and ESR by facilitating knowledge creation within a framework of multiple perspectives.

It is likely that research into a foundational theory for knowledge management will continue. Further development and testing of organizational structures and technologies developed on the foundation of Churchman's (1971) inquiring theory may provide insight into the applicability of this theory as a foundational one. Churchman's (1971) theory has been used as a foundation for organization memory systems and knowledge management systems. Chae, Hall, and Guo (2001) suggest that using Churchman's (1971) inquirers as a foundation for an organizational memory information system can support Huber's (1991) four assumptions about organizational learning: existence, breadth, elaborateness, and thoroughness.

One conceptualized knowledge management system founded on the principles of Churchman's (1971) inquiring systems is proposed to enable organizations to create, manage, and store reliable information that may then be used to support decision making (Hall et al., 2003). This system not only provides technological and social support for an inquiring organization, but places particular emphasis on information acquisition and discovery, a requirement for organizations embroiled in a fast-paced environment. This model was later found to be applicable to Mintzberg, Raisinghani, and Theoret's (1976) seven-stage systems approach to decision making (Hall & Paradice, 2005).

Future research opportunities into inquiring organizations exist in further development and testing of this knowledge management system and its decision-making components. Further, this system was developed using the design theory espoused by Walls, Widmeyer, and El Sawy (1992), which provides yet another research opportunity. For instance, one may ask what advantages and disadvantages exist when a comprehensive theory such as the inquiring systems theory is overlaid on a framework designed to work with focused theories.

To our knowledge, the metaform discussed in this article is unique in the research realm. Thus, many opportunities exist for researchers interested in organizational form. For instance, can heuristics be generally developed to indicate when an organizational unit should invoke a particular subform? Should the lesser subforms be eliminated in favor of the Hegelian and Singerian forms? Is the learning style of a given subform as effective as another? If new and innovative organizational forms are not routinely considered, developed, and tested, will knowledge management fail to reach its full potential?

CONCLUSION

A flexible organizational form such as that underlying an inquiring organization will provide organizations with the ability to withstand tumulus environments and succeed in establishing themselves as knowledge-based systems. The form that supports inquiring organizations allows them to confront different domains, contexts, and environments with an appropriate form, supports knowledge creation and social processes when appropriate, and provides support for quick action.

Organizations adopting this flexible and comprehensive form will achieve better advancement toward their knowledge-based goals.

We propose that no one form, process, or system will transform an organization into one with a knowledge orientation. Careful examination of social and technological processes, including the importance of a dynamic organizational memory accessible to all organizational members, is critical. This foundation for viewing the whole organization as a knowledge manager contributes to the future of knowledge management.

INTRODUCTION

The work done by some authors in the fields of computer science, artificial intelligence, and multi-agent systems foresees an approximation of these disciplines and those of the social sciences, namely, in the areas of anthropology, sociology, and psychology. Much of this work has been done in terms of the humanization of the behavior of virtual entities by expressing human-like feelings and emotions.

Some authors (e.g., Ortony, Clore & Collins, 1988; Picard, 1997) suggest lines of action considering ways to assign emotions to machines. Attitudes like cooperation, competition, socialization, and trust are explored in many different areas (Arthur, 1994; Challet & Zhang, 1998; Novais et al., 2004). Other authors (e.g., Bazzan et al., 2000; Castelfranchi, Rosis & Falcone, 1997) recognize the importance of modeling virtual entity mental states in an anthropopathic way.

Indeed, an important motivation to the development of this project comes from the author's work with artificial intelligence in the area of knowledge representation and reasoning, in terms of an extension to the language of logic programming, that is, the Extended Logic Programming (Alferes, Pereira & Przymusinski, 1998; Neves, 1984). On the other hand, the use of null values to deal with imperfect knowledge (Gelfond, 1994; Traylor & Gelfond, 1993) and the enforcement of exceptions to characterize the behavior of intelligent systems (Analide, 2004) is another justification for the adoption of these formalisms in this knowledge arena.

Knowledge representation, as a way to describe the real world based on mechanical, logical, or other means, will always be a function of the systems ability to describe the existent knowledge and their associated reasoning mechanisms. Indeed, in the conception of a knowledge representation system, it must be taken into attention different instances of knowledge:

- The Existent Knowledge: It will not be known in all its extension because it characterizes all the circumstances of the universe of discourse, known or unknown.
- The Observed Knowledge: Acquired by the experience, it must be noticed that it may depend upon the observer education, state of mind, and prejudices (to state a few).
- The Represented Knowledge: With respect to a certain objective, it may be irrelevant to represent a given set of data. This is the information that must be represented and understood.

In a classical logical theory, the proof of a question is made in terms of being true or false, or in terms of representing something about which one could not be conclusive. In spite of that, in a logic program, the answer to a question is only of two types: it can be true or false. This is due to the fact that a logic program shows some limitations in terms of knowledge representation. (It is not allowed explicit representation of negative information.) In addition, in terms of an operational semantics, it is applied the Closed World Assumption (CWA) to all the predicates.

The generality of the programs written in logic represents implicitly negative information, assuming the application of reasoning according to the CWA. An extension of a logic program may comprise negative information (Alferes et al., 1998; Neves, 1984), as well as directly describe the CWA for some predicates. Consequently, it is possible to distinguish three types of conclusions for a question: true, false or, when there is no information inferring one or another, the answer will be unknown.

In this work, the subject related with the qualitative knowledge is discussed behind the assumption that, when a system needs to reason about the real world, it must have the ability to infer upon imperfect knowledge. Hence, this knowledge imperfection may have an important role in the quality of the whole system when considered as a part of a wider community of virtual entities with a rich knowledge component, having sophisticated properties such as planning, reactivity, learning, cooperation, communication, and argumentation. Agent societies may mirror a great variety of human societies with emphasis on behavioral patterns and predefined roles of engagement and obligation.

PRELIMINARIES

Knowledge and belief are generally incomplete, contradictory, or error sensitive, being desirable to use formal tools to deal with the problems that arise from the use of incomplete, contradictory, ambiguous, imperfect, nebulous, or missing information. This work is supported by the developments in Analide (2004) where the representation of incomplete information and the reasoning based on partial assumptions is studied, using the representation of null values (Analide & Neves, 2000; Neves, 1984) to characterize abnormal or exceptional situations. The ELP language presents itself as a formal and flexible tool to obtain a solution for the problems just referred.

Null Values

The identification of null values emerges as a strategy for the enumeration of cases, for which one intends to distinguish between situations where the answers are known (true or false) or unknown (Analide & Neves, 2000; Traylor & Gelfond, 1993).

The representation of null values will be scoped by the ELP. In this work, two types of null values wil be considered: the first will allow the representation of unknown values, not necessarily from a given set of values, and the second will represent unknown values from a given set of possible values.

Consider the following as a case study to show some examples of how null values can be used to represent unknown situations. Consider the implementation of a time table to express the departure of trains through the predicate:

connect: City × Time

where the first argument denotes the city of departure and the second represents the time of arrival (e.g., connect(guimarães,17:00) denotes that the Guimarães's coming train is expect to arrive at 17 o'clock, Program 1).

Program 1

Extension of the predicate that describes arrivals at the train station:

connect(guimarães,17:00)
¬connect(C,T) ←
    not connect(C,T)

In Program 1, the symbol ¬ denotes the strong negation, denoting what should be interpreted as false, and the term not designates negation by failure.

Unknown

Following the example given by Program 1, one can admit that the connection from Oporto has not yet arrived. This situation will be represented by a null value of the type unknown that should allow the conclusion that the connection exists but to which it is not possible to be affirmative with respect to the arrival time (Program 2).

Program 2

Information about Oporto connection with an unknown delay:

connect(guimarães,17:00)
connect(oporto,⊥)
¬connect(C,T) ←
    not connect(C,T) ∧ not exception(connect(C,T))
exception(connect(C,T)) ←
    connect(C, ⊥)

Symbol ⊥ represents a null value of an undefined type, in the sense that it is a representation that assumes that any value is a potential solution but without given the clue to conclude about which value one is speaking about. Computationally, it is not possible to determine from the positive information, the arrival time of the Oporto's connection; by the description of the exception situation (fourth clause from Program 2, the closure of predicate connect), the possibility to be assumed as false any question on the specific time of arrival of that connection is discarded.

Unknown but Enumerated

Consider now the example in which the time of arrival of Lisbon's connection is foreseen as 18 o'clock but is 15 minutes delayed. It is not possible to be affirmative regarding the arrival at 18:00 or at 18:01 or even at 18:15. However, it is false that the train will arrive at 16:16 or at 17:59. This example suggests that the lack of knowledge may only be associated to an enumerated set of possible values.

Program 3

Representation of the connection with a 15-minute delay:

connect(guimarães,17:00)
connect(oporto,⊥)
¬connect(C,T) ←
    not connect(C,T) ∧ not exception(connect(C,T))
exception(connect(C,T)) ←
    connect(C, ⊥)
exception (connect(lisbon,T)) ←
    T ≥ 18:00 ∧ T ≤ 18:15

The exception occurs to the time interval 18:00…18:15. It is unknown that Lisbon's connection will arrive at 18:05 or at 18:10; it is false that it will arrive at 17:55 or at 18:20.

Interpretation of Null Values

To reason about the body of knowledge presented in a particular knowledge, set on the base of the formalism referred to above, let us consider a procedure given in terms of the extension of a predicate called demo, using ELP as the logic programming language. Given a question, it returns a solution based on a set of assumptions. This meta-predicate will be defined as:

demo: Question × Answer

where Question denotes a theorem to be proved, and Answer denotes a truth value: True (T), False (F), or Unknown (U) (Program 4).

Program 4

Extension of meta-predicate demo:

demo(Q, T)   ← Q
demo(Q, F)   ← ¬Q
demo(Q, U)   ← not Q ∧ not ¬Q

The first clause of Program 4 sets a question to be answered with appeal to the knowledge base positive information; the second clause denotes the question is proved to be false with appeal to the negative information presented at the knowledge base level; the third clause stands for itself.

COMPUTING THE QUALITY OF KNOWLEDGE

Based on the assumptions presented previously, it is possible to establish mechanisms to analyze and process the information available in a way that turns feasible the study of the behavior of virtual entities in terms of its personification. Situations involving forgetfulness, remembrance, learning, or trust can be analyzed in the way proposed in this work; that is, the description of abnormal situations, declared as exceptions to a predicate extension, made one's goals possible.

Characterization of a Problem

Consider the following example, built up to illustrate the practical application of what is the main contribution of this work.

Program 5

Excerpt of an extended logic program, representing knowledge at a time ti:

parent(carlos,joão)
¬parent(P,S) ←
    not parent(P,S) ∧ not exception(parent (P,S))

In Program 5, there is an axiom stating that Carlos is a parent of João. Assuming that this is all the knowledge available at instant ti, the second clause of Program 5 enforces that all other situations where there is a lack of information and that are not being treated as exceptions must be considered false.

Suppose that, an instant later, tj, the knowledge evolves in such a way that it may be represented as shown in Program 6.

Program 6

Knowledge base excerpt at instant tj:

¬parent(P,S) ←
not parent(P,S) ∧ not exception(parent (P,S))
exception(parent(carlos,joão))
exception(parent(luís,joão))
exception(parent(pedro,joão))

At a third instant of time, tk, the knowledge base is shown as Program 7.

Program 7

Excerpt of the program that shows how the knowledge base evolves between instants tj and tk:

parent(⊥,joão)
¬parent(P,S) ←
not parent(P,S) ∧ not exception(parent(P,S))
exception(parent(P,S)) ←
parent(⊥,S)

Looking to the way the knowledge base evolved, between instants tj to tk, one may say that the information has been losing specificity. In the beginning, it was known that Carlos was a parent of João (ti); after that, it was only known that the parent of João was Carlos, Luís, or Pedro (tj); finally, in a third instant, the system only knows that João has a parent but cannot be conclusive about who such a person is; it is also not possible to state that João does not have a father.

Consequently, in terms of the temporal axis ti → tj → tk, one may say that the knowledge evolution has taken a form of forgetfulness, leading to the emptying of the knowledge base knowledge. However, taking the knowledge evolution the other way around, that is, tk → tj → ti, a similar analysis leads to the conclusion that the knowledge base learned something, showing that the knowledge base evolves in a way that secures its information.

The System Semantics

Last but not least, it is now possible to pay some attention to the human-like attributes to be represented at a system level, considering the ELP as the language to describe its knowledge bases or theories. Consequently, the objective here is to define those mechanisms that will allow the advent of computational agents at the system level with human-like properties and behaviors, making the way to a certain kind of personification of those computational entities.

Let us consider Program 5, referred to above, that describes the state of the system at instant ti, where who is João's parent is questioned. In terms of the demo meta-predicate, one may have:

i. "(P): demo(parent(P,joão),T)?
∠ successful
"(P): demo(parent(P,joão),F)?
∠ unsuccessful
"(P): demo(parent(P,joão),U)?
∠ unsuccessful

This question is answered in terms of the knowledge base positive information that states that Carlos is João's parent. It is now possible to determine the amount and quality of the information that was used in this round. In other words, one intends to find the set of all the solutions that could contribute to solve the question referred to above, namely:

ii. "(P,S): findall(P,demo(parent(P,joão),T),S)?
∠ S = [carlos]

Let us now consider Program 6, referred to above, and in this context, endorse the same question as in (i). One may have:

iii. "(P): demo(parent(P,joão),T)?
∠ unsuccessful
"(P): demo(parent(P,joão),F)?
∠ unsuccessful
"(P): demo(parent(P,joão),U)?
∠ successful

That is, the question is solved but the answer is vague. This means that endorsing the question as in (ii) will give rise to an empty set of solutions when invoked in terms of the meta-predicate demo. One may have:

iv. "(P,S): findall(P,demo(parent(P,joão),U),S)?
∠ S = [ ]

This situation denotes there are clauses defined as exceptions to the extension of predicate parent, allowing the solution to be unknown, U. One may now turn to the exceptions in order to evaluate the answer. One may have:

v. "(P,S): findall(P,exception(parent(P,joão)),S)?
∠ S = [carlos, luís, pedro]
"(S,N): length(S,N)?
∠ N = 3

In this case, attending to the fact that there are three exceptions to the predicate extension, the vagueness of the data is set to 1/3.

Finally, let us consider the case described by Program 7, referred to above. By the application of the same procedures as in (i), one may have:

vi. "(P): demo(parent(P,joão),T)?
∠ unsuccessful
"(P): demo(parent(P,joão),F)?
∠ unsuccessful
"(P): demo(parent(P,joão),U)?
∠ successful

That is, the solution to the question is undefined. In this case, acting as in (ii), one is presented with a specific result:

vii. "(P,S): findall(P,demo(parent(P,joão),U),S)?
∠ S = [⊥]
"(S,N): lenght(S,N)?
∠ N = ∞

That is, the evaluation of the truth value to assign to the solution falls back upon a mechanism that starts from an unlimited set of possible solutions. It is to be understood that the cardinality of such a set tends to be infinite.

CONCLUSION

The dissemination of computational systems with the ability to live in a virtual community is an open subject for discussion, attaining increasing relevance when the debate relates to the assessment of human-like attitudes and behaviors to virtual entities. The ability to represent and infer upon an entity body of knowledge built around the need to manage imperfect information is an advantage and a virtue explored in this work. This benefit is used to reason about the quality of the information that characterizes such body of knowledge. ELP proved to be an adequate tool for knowledge representation and reasoning, in particular, when one intends to endorse situations where the information is vague, imperfect, or incomplete, which is the case when representing properties and attitudes at the agent's level, only found in humans. The use of these techniques, in particular, in intelligent systems, are flexible to endorse problems where the knowledge of several agents has to be diffused and integrated, and the agents reason about the knowledge or the behavior of their peers in a competitive and/or collaborative way.

Chapter 1.17
Knowledge Management, Communities of Practice, and the Role of Technology:
Lessons Learned from the Past and Implications for the Future

Wee Hin Leo Tan

National Institute of Education, Singapore

Wei-Loong David Hung
National Institute of Education, Singapore

ABSTRACT

This chapter reviews the current work in knowledge management (KM) and attempts to draw lessons from research work in situated cognition about the nature of knowledge which can be useful to the field of KM. The role of technologies and the issues of literacy in technology are discussed in the context of communities of practice (CoPs) and the KM framework with some examples described for K-12 settings. Implications are drawn in terms of how teachers and students can be a community of learners-practitioners through technologies which support their work and learning processes.

INTRODUCTION

As countries in the world compete globally in a knowledge and technology-driven environment where national and global business boundaries continue to dissolve at an unprecedented rate, education is seen as one of the key strategies in meeting the challenges ahead. Educating citizens with attributes such as innovation, creativity, and enterprise has become the rallying call of many governments to make their economies competitive. In order for K-12 schools to produce citizens with such attributes to meet the challenges ahead, school leaders and teachers must be able to fully exploit and share critical pedagogical knowledge with one another. Knowledge management (KM) is a key enabler of a successful school today. In this chapter, KM is discussed in the context of teachers sharing knowledge as a community of practitioners, and when such a community can be facilitated through technologies, the technology literacy levels of teachers are developed in the process. This chapter will begin with a discussion of KM and how lessons from situated cognition can be drawn to inform the field of KM and the issues of CoPs, and technology literacy in K-12 schools are drawn as implications to KM as found in the later parts of this chapter. As the field of KM may be new to many readers of this book, a relatively large section of this chapter will be devoted to the discussion of KM.

In essence, KM is an attempt to understand what works in organizations and institutions such as K-12 schools—their best educational practices, expert practitioners' thinking, and other processes that seem obvious to the experienced school leaders and teachers, but would be alien to beginning teachers. In the past, knowledge management practices focused primarily on the management of data and information. But, more recently, KM practices increasingly revolve around facilitating dialogue and forming collaborative groups within the organization that leverage on innovative information technology (IT) tools to create, capture, and use that information to facilitate communication among individuals to meet organizational goals (Duffy, 2000; Petrides & Guiney, 2002). Thus, the appropriate adoption of technologies in KM in schools should increase the technology literacy levels of teachers. Much of the difficulty in KM for schools lies in the fact that these KM processes may be very much hidden as tacit or implicit knowledge. The difficulty with tacit knowledge is that there is only an extent through which that knowledge can be made explicit. Take for example the case of riding a bicycle. If someone were to ask you to describe the process of riding a bicycle (or how to ride it), you would probably begin to tell about how to balance, how to position the steering, how to pedal, and so forth. However, this merely describes the how-to procedure of bicycle riding. You would probably agree that there is more to riding than the procedure of how-to. Even if we could articulate all about our experiences of riding a bicycle, it is still not the same as the actual skill of riding one. There is a fundamental difference between descriptions of experiences and the actual experience. In other words, tacit knowledge may not necessarily be fully described in explicit terms. The irony is that even if one can fully describe the tacit knowledge, you would not know if what is articulated is the fullest description ever possible.

Tacit knowledge about teaching and learning processes is thus the knowledge gained through experience of managing K-12 schools and designing appropriate learning opportunities for students. Expert teachers and school leaders gain a whole wealth of tacit knowledge as they encounter numerous cases and problem-solving experiences during the course of their work. In the past decade, artificial intelligence (AI) attempted to create expert systems such as intelligent tutoring systems by trying to make explicit the tacit knowledge of expert teachers through codifying this knowledge in the form of computer programs. Two decades of research yielded the fact that expert systems (containing the rules of expert thinking) are not isomorphic or equivalent to experts. Polyani (1964) stressed that we know much more than we can say. Expert teachers and school leaders, in others words, know much more than they can tell or articulate what they know. For example, reading a book written by a successful school leader in turning around a poorly performing school is still miles apart from what the person actually knows from the wealth of his personal experiences in turning around such a school.

KM is an attempt to make explicit what is implicit. Of course, not all implicit or tacit knowledge is useful to a school. A school's tacit knowledge is probably better known as the collective wisdom of the school (c.f., Choo, 2001). Taking a corporate example, "…what HP knows which it cannot even describe as best practice and transfer these processes" to another HP plant (Brown & Duguid, 2000). The explicit knowledge of a school would include, among other things, routines, rules, standard operating procedures, strategic planning documents, and curricular-related materials such as schemes of work and syllabuses. In essence, KM's intent should be to make the school a more effective educational organization by attempting to make explicit as much of what "works best" in terms of practices and processes, and to consciously formulate them, either into documentations and/or through imparting the knowledge to others by explicit sharing.

APPROACHES TO KNOWLEDGE MANAGEMENT

This chapter explores the application of the situated cognition concepts and principles (Lave & Wenger, 1991) to KM within a K-12 school context. It highlights fundamental issues on translating the tacit to explicit and institutional knowledge in a school context. It is important to appreciate that not all tacit knowledge about educational practices and processes can be made explicit. In developing KM within a school, there should be a consideration of context (the work environment or learning environment in relation to persons, tasks, functions, and others) to understand the limit to which there is meaningful translation of tacit knowledge to explicit knowledge—that is, to be mindful of the socio-cultural perspective. While it may not always be possible to fully extract out the tacit knowledge residing in an expert teacher or school leader, it should be possible to engineer processes within a school that could eventually lead to the distillation of key tacit knowledge for the purpose of either "training" (codified knowledge—explicit or established knowledge) or improving educational practices. We suggest that there are two approaches that could be adopted in KM within a school context:

- Approach 1: In situations where the tacit knowledge could be understood and clarified, it should be, as far as possible, be made explicit through the process of externalization such as dialogue, reflection, abstraction, and so forth. This extracted knowledge could be improved upon through appropriate re-packaging with the aim of 'imparting' them to practitioners. This 'imparting' process could be through training, documented in descriptions such as books, or reified into the form of artifacts (Choo, 2002, 2003).
- Approach 2: In situations where the tacit knowledge is difficult to codify (or made objective), the alternative approach is to design a social setting or environment for apprenticeship (imitation and modeling) where experts and novices could interact and where novices could be mentored. Through such a process, tacit knowledge is "internalized" (both tacit and explicit) through enculturation. Through such an enculturation process, members interact on the basis of problems encountered, stories or narratives of situations and cases experienced, and the co-production of artifacts (Brown & Duguid, 2000).

As not all dimensions of tacit knowledge within a school context could be fully understood objectively, we can never be certain that the first approach is always the better approach. We suggest that KM (in its current state of understanding as a field) move towards the second approach of "designing for knowledge stealing" (as it were), and in the process of communities of practice (CoPs) engage in a systematic process of understanding the known processes (first stance). The two stances can be adopted in tandem. Before we elaborate on the two approaches, we reiterate that Approaches 1 and 2 can be adopted for any generic model of training and learning where technology literacy is a topical issue that teachers and students need to address explicitly or whether CoPs can be fostered around issues of literacy where tacit knowledge is negotiated. If technology literacy is not the subject-context or content, teachers and students could be engaged in issues of concern through the facilitation of technologies, and as a consequence, heighten their technology literacy levels in K-12 contexts.

Approach 1 is commonly known as the objectivist worldview, where the assumption is that knowledge is objective and that there is a one version of truth in reality out there. The entire thrust would be to try to find out scientifically what is the truth (in the form of explicit knowledge) and represent it in some codified form. The worldview assumes that there is a singular perspective to "truth" or reality and thus could be represented into forms of language—albeit through multimodal means.

From an expert system point of view, AI has, in the past, attempted to distil or make explicit in the form of programmable rules and language the behavior, skills, and thinking of experts. By and large, much of this knowledge is well-structured knowledge, whereas what is considered as ill-structured remains difficult to make explicit. In a sense, one can say that attempts at understanding the well structured or well defined is noteworthy. By doing so, we could improve educational practices by "automating" what is well understood through, for example, off-loading what is well defined from teachers and letting them concentrate on what are more ill-structured demands in the classroom. This approach would make them more efficient.

The situated cognition view taken in Approach 2 above differs from the objectivist worldview. The situated view espouses that knowledge is deeply contextualized, and any attempt to decontextualize knowledge from either the person or context makes that knowledge meaningless. Such a deep interwovenness of context to knowledge makes the argument of abstraction problematic. In addition, the situated cognition view claims that because knowledge is contextualized, all knowledge is deeply influenced by one's interpretation of a reality or phenomena, giving rise to multiple perspectives (of which all perspectives are valid). In other words, even in KM's attempt to codify knowledge, this codified knowledge is via a perspective—the perspective prevalently held by the interpreters of the phenomena. Hence, the situated view is "against" notions or attempts at over-representing knowledge; rather it favors the perspective of designing situated contexts where improvement in educational practices occurs between teachers in schools through interactions such as negotiations of meanings, apprenticeship, and other methods espoused by social-cultural psychology.

Importance of Product and Process in KM

There is much that KM can learn from the lessons of the last two decades—the work of AI arising from the objectivist view, and the subsequent attempts by situated cognition. Our sense is that clearly both views (Approaches 1 and 2) are at the two ends of the knowledge continuum—one espousing that there is one singular objective view, and the other where multiple views exist—and that all these views may be equally valid. On one end, all attempts made are to codify knowledge as products, and on the other end, knowledge codification is not emphasized, but rather process-interactions are.

Both product and process are important. KM's attempts at putting structures in place within organizations to promote sharing and collaborations, and rewarding process-oriented activities are noteworthy. Such a perspective is very much aligned with the situated cognition view. In addition to facilitating sharing, KM could focus on the design of learning environments or rather the design of workplace environments to facilitate apprenticeship forms of learning and social interactions. The examples of studies done on Xerox engineers by Julian Orr (1996) and others are good examples of such design. John Seely Brown relates the example of how the coffee brewer, once fresh coffee is made, sends a signal to all staff via the Web, and members in the organization flock to the coffee corner (space for informal interactions) where informal knowledge is transacted. However, all these interactions assume that knowledge remains in the organization, as they are held by the individuals and processes within the community. But when these 'experts' leave, the collective knowledge held by these teams within the organizations would most likely be leaked out of the organization as well.

Problem Formulation for KM

Hence, the key issue for schools would be to adopt certain KM practices or processes to ensure that knowledge of best educational practices and tacit knowledge about teaching and learning are retained within the school as far as possible. With an understanding of these practices, knowledge can then be institutionalized (in the form of cultural knowledge) and formalized procedures can then be made explicit. However, when educational contexts change, these institutional norms/practices would have to change accordingly. The challenge for any school is really to know when and how to change.

In summary, the problem of KM can be formulated as an attempt to: (a) understand practice through putting structures in place for knowledge sharing and interactions (still largely explicit knowledge made overt); (b) improve practice by knowing what it knows, retaining as much of what it knows, and by changing what it knows based on changing demands and contexts (establishing and adjusting cultural knowledge); and (c) design community interactions that would facilitate members to appropriate or "steal" knowledge (particularly tacit knowledge).

For this chapter, we would like to concentrate on point (c) that is concerned with the design of community interactions. Based on KM literature, we recognize that this is one significant area of which the literature on situated cognition and the work in education and learning can inform the field of knowledge management (Choo, 2001, 2002, 2003).

DESIGNING COMMUNITY INTERACTIONS

The concept of communities is not new (Vygotsky, 1978). The earliest communities were tribal in nature, where people form societies underpinned by traditions and beliefs of varied orientations. Communities include all kinds of professional practices, religious communities, networks of people, and so forth. More recently the concept of communities of practice (CoPs) is a prevalent concept that has dominated the field of learning, education, and business management. CoPs arise based on professional practices such as the scientific, mathematics, engineering, law, or accounting practices. CoPs are a community of people who practice a profession oriented towards a code of conduct, ethics, history, and peculiar culture. This community of people shares similar concerns and passions, allowing them to collectively evolve the necessary structures and processes to deepen their expertise and knowledge through engaging one another on an ongoing basis (Barab & Duffy, 2000). So, when we try to model the concepts and strategies of CoPs into schools and learning contexts, we have "CoLs" or communities of learners. Similar to CoPs and CoLs is the concept of schools as learning organizations. Within this concept, Fullan (1999) suggests collaborative organizations to: (a) value diversity, (b) bring conflicts into the open, (c) value the quality of relationships as being central to success, (d) accept emotional responses as a complement to rationality and logic, and (e) recognize the value of quality ideas. These tenets are in the same vein as the kinds of orientations CoPs aim to foster.

Principles for Growing and Sustaining Communities

Four principles are observed to be necessary for growing and sustaining communities. These principles, derived from CoPs, would have to find their counterpart-principle in a community of learners.

First, within CoPs there ought to be mutuality, where members share overlapping histories, values, and beliefs. Because of mutual benefits to one another, interdependence of actions is crucial to sustain activities within the CoP.

Second, the community has to, over time, develop a repertoire of artifacts for mutual enterprise. These artifacts represent the knowledge and skills of the members in that community. Over time, the CoP develops increasingly efficient and innovative mechanisms of production and reproduction, giving rise to common practices.

Third, the CoP has to be organized in ways where there would be plenty of opportunities for interactions, active participation, and meaningful relationships to arise. Within these relationships, respect for diverse perspectives and views would be necessary. In other words, CoPs are connected by intricate, socially constructed webs of beliefs and ways of thinking. The authentic activities arising from CoPs are framed by their culture and demands—usually mooted by society needs. Meanings are socially constructed within CoPs through negotiations among present and past members.

Lastly, within CoPs, there has to be a growth and renewal process of new members with past and present persons within the community. Throughout the history of CoPs, one important phenomena observed is new members joining as legitimate peripheral participants (Lave & Wenger, 1991) where they act as novices elbowing experts (or older members) of the CoP. This process begins with peripheral participants (as novices) appropriating an identity through observing masters at work. After extended opportunities of practicing the trades of the community, these novices begin to behave and think like the experts in the community of practice (Wertsch & Rupert, 1993). Lave and Wenger (1991) espoused that by exposing a newcomer to the practices of a community and providing him or her with the opportunities to engage in those practices, the newcomer would move from peripheral participation to a more central participation. In other words, there are levels of participation and contribution through which members in a community make advancements over time. The hypothesis is that, through each advancement, members appropriate a fuller identity similar to the central participants of that particular community of practice. Gradually, over time, these members become significant members in the community and take on central participation within these CoPs.

To summarize the principles underpinning CoPs, Brown and Duguid (2000) characterize learning to be: (a) demand driven, as CoPs create needs of mutual interdependency and outcomes; (b) a social act, as members interact and relate to one another with specific roles and functions in order to achieve the CoP's goals; and (c) an identity formation, where members develop "ways of seeing" meanings, beliefs, and ethics according to the professional practice, for example, mathematicians see patterns in numbers.

The Role of Technology in a CoP Framework

First, within the CoP framework as articulated above, we believe technology can play a crucial role in enhancing learning in the context of relationship-building—that is, technology as a collaborative tool (not just for task collaboration, but socializations). The basic question to ask is how technology can bridge the mutual enterprise of members within the CoPs that involves interdependency of engaging in joint tasks and projects for learning among one another. A key question for research in technology is how to develop scaffolds and structures in collaborative applications where it would help members to co-develop mutual interdependency with one another. Today we have examples of online communities which capitalize on the Internet to establish environments where members are always dependent on each other. One such example is the "Tapped In" Community (http://tappedin.org/tappedin/), a community of education professionals established since 1997. This community is an online forum where groups of teachers are brought together to engage one another based on their specific needs and demands. Professionals participate in sites such as "Tapped In" because there is a rather quick way of receiving some (personal) benefit such as having some query answered by someone, somewhere in the Internet world. Members bother to answer questions, and when their answers are unique and "stand out" from others, these "experts" rise to fame and indirectly receive consultancies and celebrity. It all works on the principles of mutual gain and benefit. Within these thriving online communities, members begin to adopt an online identity and sense of belonging to this community of like-minded people with similar interests and passion. Learning occurs as a consequence of participation in these online communities.

Second, a significant use of technology within the community context is what we are all familiar with—technology as a productivity tool. We are all familiar with how technology enables us to maximize our outputs and production of resources and artifacts for teaching, to communicate with one another either synchronously or asynchronously, to search for information, and to automate our administrative tasks. There is no need to further elaborate on this point.

Thirdly, technology can be used to support a learning community by assisting learners in seeing meanings and concepts without which it would be difficult. Here, we have technology as a (collaborative and individual) sense-making tool. In science, the microscope is an example of a technology which enables learners and scientists to see cells beyond the naked eye. When learners are engaged in meaningful discovery of concepts, technology can open up new vistas of concept visualizations. Computer graphics today can simulate phenomena which traditional media of 2-D charts are unable to do. Chemical bonds and molecular structures can be visualized through appropriate simulations. Simulations are also useful in dangerous or very expensive situations where actual use of equipment may prove unwise.

Thus far, the examples mentioned above described the role of technology in communities. Communities can be formed around teachers who are interested in its use for enhancing their professional practices. In order to leverage on such professional communities to enhance learning, there would be a need to adapt the KM approach to capturing, understanding, and retaining the knowledge and insights gained from the interactions arising from within these communities.

For example, in an ongoing professional development program for Heads of Department for Information Technology (HoDs in IT) in Singapore schools, we had a group of HoDs (IT) who became interested in knowledge-building pedagogies (Hung, Tan, Hedberg, & Koh, 2005; see Scardamalia, 2002 for knowledge-building pedagogies) using computer-supported collaborative learning (CSCL) systems, and who decided to collaborate and support one another in the implementation of knowledge-building activities in their respective schools. One of the HoDs (IT) who was initially observed to be rather passive both during face-to-face sessions and online sessions (when these teachers were attending a heads of department course at the National Institute of

Education) developed into an active participant at the end of the program. She mentioned in an interview that she was the least knowledgeable of the three members in her knowledge-building team in terms of the use of CSCL systems for teaching and learning. She described how the other members in the group, more experienced in knowledge-building activities and CSCL systems, supported her during the planning and implementation stages, sharing ideas with her and helping her solve technical problems. Through this enculturation process, she developed from being a peripheral participant (Lave & Wenger, 1991) at the beginning of the program into a more central participant. She has since presented in two sharing sessions to other HoDs (IT), an ICT conference, as well as a school cluster (a group of schools within a particular district) sharing session. She has plans to implement this knowledge-building concept to more levels in her school and tried to tie up with other schools in implementing knowledge-building activities using CSCL systems.

In this example, we could see the development of this HoD (IT) in identity formation, from a peripheral participant at the beginning of the program to a central participant after one year into the program. This process of transformation is facilitated by the use of online discussion tools, used at the beginning of the program for the members to raise issues on teaching and learning using technology, and using e-mail for discussion when the HoDs (IT) were back in school during the implementation period. Such identity formation in a community arose from uncertainty in the use of technology for innovative use of technology in teaching and learning. The KM approach, had it been adapted for use in the above example, would have yielded more useful learning that could be used to grow and sustain other similar communities.

The above roles of technology are not exhaustive, but indicative of technology as an enabler to facilitate learning interactions within communities of learners. We emphasize that educational technology is a means to an end, and not an end in itself. They can be used effectively to enhance social relationships in learning, assist learners in their projects, and help learners explore and deepen their conceptual understanding through simulations and visualizations.

A summary of the role of technology in forming and sustaining communities discussed thus far is provided in Table 1. From Table 1, it is obvious that there is a lack of technology tools for identity formations such as the learning or enculturation of beliefs and shared values.

The ability of members such as teachers within a CoP to adopt technology in the above ways

Table 1. Synthesizing CoP principles with technology tools

CoP-CoL Principles	3 principles of Learning	Technology Tools
Shared Beliefs and History	Learning is an identity formation	*Gap area*
Mutual enterprise & production of joint artifacts	Learning is demand-driven (based on needs to understand); Learning is a social act	Technology as a productivity tool; Technology as a sense-making tool Technology as a collaborative tool
Interactions, activities, and relationships-building (mutual trust)	Learning is a social act	Technology as a collaborative tool
Cycle of renewal—new members joining the community	Learning is a social act; Learning is an identity formation	Technology as a collaborative tool *Gap area*

enhances their literacy levels with regards to: (1) using language, symbols, and text for knowledge creation and dialogue; (2) interacting between their knowledge-understanding and the information they receive from others and elsewhere; and (3) adopting different technology tools whenever they need to achieve goals at hand (Istance, 2003).

FUTURE DIRECTIONS FOR KM: INVOLVING THE LARGER COMMUNITY

The approach taken by the CoP framework is clearly more process than product oriented from the KM perspective. So, what's next? Knowledge from Polanyi's perspective is largely tied to context and the person. In other words, knowledge differs from "information" because when information is applied to a context, it becomes contextualized, and the person applying that knowledge gained personal experiences and knowledge. If that person leaves the community (or organization), knowledge leaves with that person(s). We offer one recommendation to KM: invest heavily on person and context-process development. There is a need to form networks of teams across organizations and communities, and expand the global process of knowledge management. Technology today can mediate and connect people and expertise (not just information), and knowledge can still be managed across networks of people. We recommend a community of communities suggestion.

Academia serves as a good example of these community of communities networks. In academia, professors and practitioners belong to different universities and organizations, but generally many are affiliated to societies and professional bodies. Yearly, many of these societies organize activities such as conferences where expertise is being shared. In addition, many of these societies have dissemination means such as Web sites, e-mail communications, journals, and others. The unique part of universities in terms of their rewarding mechanisms to their faculty members is that academics are rewarded when they contribute to new knowledge to the larger community (and not just to the university). And this recognition mechanism is common across most universities. Thus knowledge leaks (as it were, when individuals move out of these respective institutions or organizations) are contained to within the larger communities and mediated by societies and communication means (such as journals). Importantly, in academia, the reward criteria for academics are relatively consistent across universities. These networks of networks represent the non-linearity of interactions that are needed for knowledge creation and management—denoting "complex forms of negotiation and interaction between people, some of whom will offer different kinds of knowledge" (Southworth, 2000, p. 290).

Technologies have in the past supported attempts at codifying knowledge, and these efforts can be seen in databases being created to manage information. More recently, technologies that support processes of knowledge creation and sharing include computer-supported collaborative environments and computer-supported communication tools. These technologies support the process rather than the product-oriented views of knowledge. Similarly, authoring or constructive tools enable individuals to engage in the process of knowledge creation and meaning making rather than receiving knowledge. Increasing, technology must now support the process of story creation or narrative creation as we recognize that storytelling is one effective tool in KM. Moreover, how can technologies support the social construction process of story creation, refining, and reconstruction—the process of which enables individuals to construct a coherent understanding of "what they are doing in practice"? The commonly told accounts of Xerox's technicians constructing stories of the machine problems they encounter, by relating to one another pieces of troubleshooting data, account for their experimentations on certain problems, getting more data to support their conjectures and co-constructing their "story," attempting to being coherent to their "story," and defending that their stories are all part of the social construction process.

CONCLUSION

The fundamental issue of KM is to understand the "ways things work," improve on them, establish and formulate processes, and possibly scale up and sustain these so-called good practices. Within this whole process of attempting to understand practice, we expect dimensions of tacit, explicit, and cultural (or institutional) knowledge to be interwoven and to manifest in various forms. Moving from "if only an organization knows what it knew" to "knowing as much of what it knows and setting processes to sustain its better processes" and "knowing when to change its processes when needed" seem to be what the business of KM is all about. All these attempts presume the assumption that we tease out as much of the tacit (individual and organizational levels) to the explicit (individual and organizational), and formulate cultural knowledge (organizational level) to improve ways of thinking and doing.

We need to recognize that there is a limit to what KM can achieve. Social relations, cultural and contextual underpinnings (or overpinnings), and knowledge as tied to persons are part of the capital of what distinguishes one organization-individual from another. The key lies in striking a balance between codifying knowledge and creating the processes which support knowledge creation, sharing, and transfer. Technology can only facilitate the processes enabled for both and enhance the KM efforts. The CoP frameworks are efforts to create such process-oriented KM processes, but as in any approach, there would be advantages and disadvantages. Certainly, we recognize that both process- and product-oriented KM is necessary, and we see both as dialectically informing each other. We envisage that in the near future, this concept of CoPs will pervade the teaching profession and educational community as its popularity increases (Gee, 2000; Hung et al., 2005). Technology will inevitably be an integral part of CoPs—both as a content-issue to be dialogued upon by members of the CoPs and thus heighten technology literacy, and as a means through which members engage in interactions within CoPs and across disciplines through knowledge brokering. As a result of such adoptions, teachers will become more technology competent both in terms of its awareness and in terms of its use as a tool. Issues in the adoption of technology in learning are dialogued upon as a "product" and adopted as a tool in the "process" of being members in CoPs. CoPs and the concepts of KM can transform our traditional notions of pedagogy and radically shift our mindsets from transmission notions of learning to transformative possibilities where knowledge for the learner (both students and teachers) is not only an entity-product to be absorbed, but as an emerging-process to be constructed and understood both individually and socially.

Schools can no longer afford to be structured in entrenched hierarchical structures, but must be able to respond quickly to the external environment in order to meet the increasingly competitive demands of the global society. Fostering members into CoPs, where every member contributes to others and receives from others within a KM framework, would enable knowledge to flow dynamically within a school (or across schools) (Wenger, McDermott, & Snyder, 2002). In this way, members of CoPs need to assume increased responsibility, ownership, and accountability to the school organization and to knowledge. Inevitably, we believe that schools would have to be "transformed" into dynamic communities and sub-communities. Information technologies would be an integral part of the knowledge flow processes, and as a consequence, literacy levels rise in tandem. Through such a transformative stance, schools become "knowledge-creating schools" (Hargreaves, 1999) where learning is understood as a collaborative effort, and in the process, artifacts are developed within a KM framework which could be knowledge-products, practices, and ideas—both conceptual and material (Paavola, Lipponen, & Hakkarainen, 2004).

Finally, summarizing the entire chapter, we recognize that (as we think through the issues of KM, CoPs, CoLs, and the related underlying theoretical foundations of situated cognition) CoPs and/or CoLs can be seen as ways of organizing teachers (or professionals) for continuous (organizational) learning and for propagating good professional practices. The tools of CoPs/CoLs are frameworks or strategies available to facilitate interactions among members in some structured manner to give focus and to achieve goals and results. KM is a product and process methodology that captures and retains the knowledge and insights gained for future mining to minimize possible mistakes (which were done in the past) and lower the entry of learning needed to participate in the community (that is, to speed up the process of learning within the community—from novice to expert). Technologies (including AI) are enablers to facilitate KM, CoPs/CoLs, and the implementation of derived framework-strategies to facilitate interactions and processes more conveniently.

Chapter 1.18
Customer Knowledge Management

Scott Paquette
University of Toronto, Canada

INTRODUCTION

As companies begin to develop competence in managing internal knowledge and applying it towards achieving organizational goals, they are setting their sights on new sources of knowledge that are not necessarily found within the boundaries of the firm. Customer knowledge management comprises the processes that are concerned with the identification, acquisition, and utilization of knowledge from beyond a firm's external boundary in order to create value for an organization. Companies can utilize this knowledge in many different forms of organizational improvement and change, but it is especially valuable for innovation and the new product development function.

The notion of working with partners to share information was first discussed in 1966 where the possibility of transferring information between a company and its suppliers and customers was identified. Kaufman (1966) describes the advantages to a business that include reduced order costs, reduced delivery time, and increased customer "confidence and goodwill" (p. 148).

Organizations have since been viewed as interpretation systems that must find ways of knowing their environment (Daft & Weick, 1984). Through this environmental learning, a firm's ability to innovate can improve by going beyond a firm's boundaries to expand the knowledge available for creating new and successful products. Some organizations conduct ongoing, active searches of the environment to seek new and vital information. Such organizations become the key innovators within an industry. Other, more passive organizations accept whatever information the environment presents and avoid the processes of testing new ideas and innovation. Marketing literature refers to this concept as market orientation (Kohli & Jaworski, 1990; Slater & Narver, 1995).

More recently, many organizations have realized the value of information about their customers through customer relationship management and data mining strategies, and have used this information to tailor their marketing efforts (Berson, Smith, & Thearling, 2003; Blattberg, Getz, & Thomas, 2001; Davenport, Harris, & Kohli, 2001). The idea of using information from suppliers to accurately manage inventory levels within the supply chain (Lin, Huang, & Lin, 2002) also reflects this notion. However, what is missing from these theories and strategies is the realization of the value of knowledge residing within customers, and not information about customers.

Iansiti and Levien (2004) describe an organization's environment as an ecosystem, where networked organizations rely on the strength of others for survival. Within this ecology, they identify certain "keystone organizations" that "simplify the complex task of connecting network participants to one another or by making the creation of new products by third parties more efficient" (p. 73). This increase in overall ecosystem productivity is accomplished though the incorporation of technological innovations and niche creation through innovative technologies. Through recognizing customer knowledge as a key component to a firm's ability to innovate, and actively searching for sources of knowledge within the business environment, a firm is able to augment its innovation capabilities and position themselves as a keystone organization.

BACKGROUND

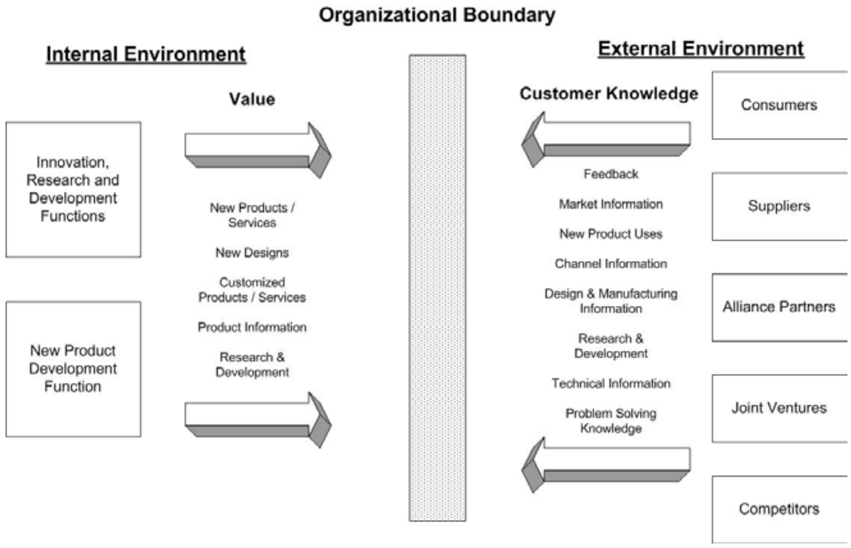
In examining the role of external knowledge in an organization's internal processes, customer is broadly defined as an organization's stakeholders such as consumers, suppliers, partners, joint ventures and alliances, and competitors. In some cases, a customer may not have a current relationship with the organization, but one is likely to develop in the future. Knowledge in this context refers to the model presented by Cook and Brown (1999), where it can be explicit or tacit, and individual or group knowledge. Explicit knowledge is easily codified, transferred, and understood by multiple individuals, where tacit knowledge requires experience and practice in order to flow from one individual to another. Both of these forms of knowledge can reside at the individual level, or be created and transferred between different groups.

Knowledge derived from these relationships through an interactive and mutually beneficial process is referred to as customer knowledge. Customer knowledge can be composed of a combination of consumer knowledge, supply chain knowledge, joint venture specific knowledge, and so forth. This knowledge is created within a two-way flow of knowledge which creates value for both parties. It goes beyond information identifying and classifying customers, to knowledge that is resident within the external organization that has been developed through industry and market experience. Examples can be consumer preferences of new product features, newly recognized uses for current products, knowledge derived from joint research and development, design improvements from suppliers intended to reduce the cost of manufacturing, and knowledge regarding trends within the business environment.

An important aspect of customer knowledge is that it is knowledge not owned by the firm, but by others who may or may not be willing to share such knowledge. The processes that a firm employs to manage the identification, acquisition, and internal utilization of customer knowledge are collectively referred to as customer knowledge management. It is within these processes that an organization and its customers collectively work together to combine their existing knowledge to create new knowledge. This new knowledge is a key input into a company's ability to innovate, which is reflected in their research and development function. Furthermore, the ability to design and improve new products is also impacted by the level of customer knowledge flows. A depiction of customer knowledge flows is shown in Figure 1.

Many studies have used customer knowledge and customer information interchangeably, causing confusion between the two terms. Blosch (2000) states that understanding "how each customer interacts with business processes is to gain

Figure 1. Summary of customer knowledge



knowledge about that customer" (p. 266). Gibbert, Leibold, and Probst (2002) would describe this only as customer information, as it is knowledge about the customer and is gained without a predetermined close interaction or partnership. Dennis, Marsland, and Cockett (2001) also examine the use of customer information within a retail environment, and look at how data mining can contribute to an organization's understanding of the customer. Once again, the emphasis is on acquiring information about the customer, without interaction or joint knowledge creation.

Davenport et al. (2001) begin to argue that knowledge about the customer is only the first step, and organizations should create processes to better manage the relationships they discover with this information to create profitable interactions. The focus they present remains with learning about the customer's needs through different channels. However, the customer's involvement in the knowledge process is still passive, and not participatory.

Recently, an emphasis on customers as partners in the knowledge creation process has been presented (Sawhney & Prandelli, 2000). Customers co-create knowledge with an organization in order to create value for both parties by sharing knowledge residing within customers in order to create better products. Here, the two entities work together with a shared goal in mind, and the customer becomes an active and key participant in the knowledge creation process. Gibbert et al. (2002) examined a set of organizations that have implemented this idea into their customer relationship strategy, and described the types of CKM they observed.

CUSTOMER KNOWLEDGE AND INNOVATION

Henry Chesbrough (2003) states that most innovations fail when brought to the marketplace. However, if companies do not continually innovate, they die. This is in part due to the key role innovation plays in value creation and profitable growth (Prahalad & Ramaswamy, 2003). Innovation creates advantages in the marketplace over competitors, leads to and supports other competitive advantages such as cost savings, and differentiates the organization in the marketplace through the eyes of its customers.

Innovation relies on the creation of new knowledge by the organization, and this is derived from many sources. Companies can identify new and usable knowledge within their employees (Bontis, Crossan, & Hulland, 2002; Leonard & Sensiper, 1998), convert this existing tacit knowledge to easily shared explicit knowledge (Nonaka & Takeuchi, 1995), purchase or acquire knowledge from other organizations, or look to the external environment for new sources of knowledge such as their customers. This is where customer knowledge can significantly contribute to a firm's ability to innovate.

An organization is continually challenged to create new knowledge, and transform this knowledge (i.e., into solutions to problems, new products, etc.) through the integration of knowledge from different sources (Carlile & Rebentisch, 2003). Firms are constantly striving to identify valuable information and disseminate it to the appropriate areas of the organization in order to make informed decisions and create a competitive advantage. More and more, firms are looking beyond external boundaries for new sources of knowledge, and in many cases this points them towards their customers. An organization will be able to stimulate its new product development process and create well-received products if it can collaborate via a knowledge sharing strategy with its customers. A successful knowledge partnership with the most valuable and important customers can not only strengthen these business relationships, but also create a competitive advantage that is difficult for the competition to duplicate.

Customer knowledge can establish a competitive advantage for the organization through increased organizational learning and innovation. The competitive advantage gained through knowledge acquisition can either be temporary, as other competitors will follow and learn the new skills, processes, products, and so forth, or it can be more permanent if the competition is prevented from gaining this knowledge. Customer knowledge can be a barrier to knowledge acquisition for the competition by building a close relationship with the customer that cannot be duplicated. This barrier is strengthened if the customer perceives an intrinsic benefit that cannot be duplicated by other competitors. For example, as Amazon.com learns a customer's buying preferences and is able to offer valuable recommendations, that customer will be reluctant to switch retailers and begin the learning process over. In some cases this is referred to as customer learning (Stewart, 1997), where the two-way exchange of knowledge allows the customer to gain new knowledge and use this to his or her benefit. The knowledge sharing partnership acts both as a facilitator of knowledge transfer and sharing, and a barrier to the competition.

Types of Customer Knowledge

Customers can provide unique knowledge that allows an organization to learn and acquire knowledge to improve its internal operations, including innovation. In turn, the organization provides to the customer knowledge of its products and services which improves the functionality to the customer. This two-way flow of knowledge provides the basis for a competitive advantage through a strong relationship or partnership. Gibbert et al. (2002) discuss the five basic forms of customer knowledge which are prosumerism, team based co-learning, mutual innovation, communities of creation, and joint intellectual property development (Table 1). Each form of customer knowledge originates from a relationship between the organization and a customer source, and can be derived from multiple sources.

The first version of customer knowledge is prosumerism, a term derived from Toffler's (1980) 'prosumer', which describes a customer filling the dual role of consumer and producer. In this

Table 1. Summary of the five forms of customer knowledge

Knowledge Form (Gibbert et al., 2002)	**Typical Relationship Form**
Prosumerism	Firm—Producer/Manufacturer
Team-Based Co-Learning	Firm—Consumer/Joint Venture
Mutual Innovation	Firm—Supplier/Joint Venture
Communities of Creation	Firm—Consumer/Joint Venture
Joint Intellectual Property	Firm—Consumer

instance, knowledge co-production is generated from role patterns and interactivity. For example, Bosch develops engine management systems with Mercedes-Benz who then creates and assembles the finished product, a car. Bosch's customer, Mercedes-Benz, is allowed to share value-creating ideas and facilitates the development of new initiatives and products.

The second form of customer knowledge management is team-based co-learning. This involves intense interactions with the customer to gain their knowledge on processes and systems to facilitate systematic change. A prominent example of this is Amazon.com. By restructuring their organization from being an online book retailer to a seller of many varieties of goods, they accomplished many co-learning interactions with their customers (i.e., suppliers) to design a new value chain. Amazon.com uses this value chain as a competitive advantage against other online retailers, as it allows for quick movement of goods at competitive prices. This strategy has the added value of creating an even closer relationship with their suppliers that other online retailers will not be able to duplicate. A second illustration is Toyota, who has created knowledge-sharing networks with its suppliers, with the common goal of learning through combining each other's knowledge to create efficiencies in the production process (Dyer & Nobeoka, 2000). Toyota and a supplier will create a team, co-populated with employees from each organization who together study organizational processes and create new customer knowledge.

Mutual innovation was initially identified by von Hippel (1988), who discussed that most product innovations come from the end-users of the product, as they have specific product knowledge derived from use and their own needs. Mutual innovation is more than just asking for future requirements, but constructing knowledge that comes from closely integrated innovation practices. Rider Logistics developed complex and extensive logistical solutions for its customers through close examination of their manufacturing operations and supply chain strategies, then designed services that fit and added value to these processes. This may convert Rider from a basic trucking company towards a logistics solutions provider (Gibbert et al., 2002).

Communities of creation occur when companies organize their customers into groups holding similar expert knowledge and encourage interaction in order to generate new knowledge. These groups are characterized by working together over a long period of time, sharing a common interest, and wanting to create and share valuable knowledge. Unlike traditional communities of practice (Wenger, 1998), these groups span organizational boundaries and develop value for multiple organizations. Microsoft beta testing with customers is an example where groups of targeted customers test products together with the Microsoft product development engineers to jointly create a product that provides value for Microsoft and its participating customer organizations. These communities also form through informal relationships which are capable of producing valuable knowledge.

The final form of CKM is joint intellectual property, which may be the most intense form of cooperation between a company and its customers. Here, the company takes the view that it is owned by its customers and they have ownership in product development. This notion goes beyond normal customer relationships and co-creates new businesses based on customer education and co-development. Skandia Insurance is an example where a company and its valued consumers created new businesses owned by both. They have proven this strategy especially successful in emerging markets where the company initially lacks customer knowledge, yet gains a great deal from its local customers.

Challenges for Customer Knowledge Management

Many of the discussions on internal knowledge transfer deal with the challenges of sharing knowledge at the individual, group, or organizational level. These challenges remain true for sharing customer knowledge across an external boundary. Initially, firms may experience a cultural challenge of perceiving customers as a source of knowledge, not just revenue. This is reflected in the 'not invented here' concept, which demonstrates an organization's unwillingness to accept externally generated ideas. Other companies fear showing internal processes to customers such as suppliers or alliance partners in case a poor perception develops. It is common for heavily brand-based companies who want to control what the customer sees to be afraid of giving away strategic secrets to the marketplace (Gibbert et al., 2002). A further case is resistance to sharing proprietary knowledge with suppliers. Questions of how to control the flow of this knowledge to competitors arise, and the effectiveness of confidentiality agreements are doubted when a firm must reveal or share proprietary technology that is part of a firm's competitive advantage (Ragatz, Handfield et al., 1997).

Besides cultural influences, a firm may not have the competency required to absorb and utilize the external knowledge. Cohen and Levinthal (1990) state that a firm's absorptive capacity, or its ability to absorb new knowledge, is a function of the firm's prior knowledge that allows it to recognize and synthesize new knowledge. Also, information systems may not be able to handle the transfer of knowledge from external sources, as most knowledge sharing support systems are only designed for internal use. Organizations can be quite reluctant to open up these systems, as technical challenges occur without a universal integration and security mechanism that interfaces with both parties' systems. Control of content may be lost, as external knowledge transfer can push the locus of control beyond a firm's boundaries which for some may cause apprehension (Gibbert et al., 2002).

A further obstacle exists when the customer can solely derive innovations from their knowledge and the need for a partner becomes insignificant. Von Hippel (1988) argues that innovators must have a poor ability to gain from their knowledge regarding innovations in order to share this information with others, or else they would capitalize on their knowledge independently and realize higher revenues. Factors such as manufacturing capability, geography, market knowledge, or supply chain requirements can increase an innovator's ability to bring their development to market, and prevent the opportunity for a formalized knowledge sharing alliance.

A key question an organization may ask is how do they know the customer is supplying correct information or that it is representative of the entire market? Although some knowledge sharing partnerships may only be able to encompass the knowledge of one customer, market researchers have techniques to ensure enough customers were consulted to recognize trends or significant findings. However, customer knowledge management still depends on the assumption that an environment exists where useful knowledge can be provided to the company. This may indicate that the potential value to be realized by a customer knowledge management initiative is equal to the ability of the external environment to provide such knowledge, and customer knowledge management may be more effective in some industries over others.

To further this point, companies should realize the limitations of focusing on their current customers and markets, and look beyond their range to products that cannot be foreseen or their value realized by current customers. These new ideas, sometimes called disruptive technologies (Christensen, 2000), go against the axiom of staying close to your customer (Prahalad & Ramaswamy, 2000) and encourage innovators to develop innovative ideas that disrupt a customer's process and patterns to introduce new products that leap the product lifecycle and replace current paradigms and technologies. They may even target new markets that do not exist or satisfy customers' needs today, and therefore cannot be currently used to gain customer knowledge, but possibly will in the future.

FUTURE TRENDS

The concept of customer knowledge is relatively new to the field of knowledge management, yet it continues to develop as more organizations embrace the idea and put it into practice. It is becoming quite common to observe knowledge-sharing agreements between separate firms, and in some cases joint ventures for the specific purpose of creating new knowledge.

As competency in utilizing customer knowledge increases, more companies will conduct new product development through a web of businesses capable of enhancing the process with their unique core competencies. By working as a team, each firm's internal knowledge will contribute to the creation of a new set of shared knowledge. This new knowledge will be the driver for innovative product ideas and advancements. Developing the ability to learn from external organizations will become a key objective in organizational knowledge management strategies. Firms will take the best practices of sharing knowledge over external boundaries, and apply these skills towards improving internal knowledge transfer between different teams, departments, units, and subsidiaries. A cyclical learning cycle of improving knowledge management practices by learning through internal and external knowledge transfer only strengthens a firm's knowledge management abilities.

The definition of customer can be broadened even further to include those entities that may not have a transactional relationship with the firm, yet contain pertinent knowledge of an organization's business environment. Lobby groups, government organizations, legal entities, activist groups such as environmental awareness associations, professional associations, and standards boards all influence the business environment and a firm's ability to operate within it. Each should be considered a valuable source of external knowledge a firm requires to not only understand the environment, but flourish in it (Paquette, 2004). Expanding the range of sources providing customer knowledge will transform this knowledge set into external knowledge management, encompassing all stakeholders' knowledge available to the firm.

CONCLUSION

Facilitating knowledge sharing between internal individuals and groups can be a daunting task for any organization. The challenges of this endeavor multiply when the knowledge sharing involves an external entity possessing knowledge that is not owned by the firm.

However, the benefits of creating social structures, business processes, and technologies to facilitate customer knowledge flows can have a substantial impact on the performance of the organization, and in particular its ability to innovate. By actively involving customers in creating a two-way flow of knowledge that supports innovation, an organization leverages a new source of knowledge which can improve its standing in the marketplace. Determining the correct combination of valuable customer knowledge sources and customer knowledge management forms can create a sustainable competitive advantage through the introduction of products that satisfy a market's latent needs. A firm's acknowledgement of the importance of customer knowledge will encourage the expansion of its current knowledge management practices to beyond the organizational boundary. This creates an improved ability to identify, acquire, and utilize valuable knowledge that an organization requires to be successful.

Chapter 1.19
A Survey of Internet Support for Knowledge Management/ Organizational Memory Systems

Murray E. Jennex
San Diego State University, USA

ABSTRACT

Studies of organizational memory/ knowledge management, OM/KM, systems have found that using a common infrastructure to facilitate access to and utilization of knowledge and memory increases the usability and success of these systems. The solution to this is for organizations to have an integrated network. This paper discusses using the Internet as the integrated network. Several systems are described that use the Internet for the OM/KM infrastructure. Theoretical support from case study research for using the Internet as a common knowledge infrastructure is provided through DeLone and McLean's IS Success Model modified and analyzed for knowledge/memory based systems.

INTRODUCTION

Organizations are building and maintaining systems for managing organizational knowledge and memory. Users of these systems may not be at the same location. In many cases, they are distributed across large geographical distances and multiple offices. Key to this task is developing an infrastructure that facilitates distributed access and utilization of the retained knowledge and memory. Connectivity and easy-to-use interfaces are main concerns. Jennex (2000) found that using the Internet as a common communications platform (either as an Intranet or an Extranet) and web browsers as an interface is a viable, low cost solution. Newell et al. (1999) found that Intranets not only supported distributed knowledge processes, but also enhanced users' abilities to capture and control knowledge. Stenmark (2002) proposes that using a multiple perspective of the Internet—information, awareness, and communication—allows developers to build successful Internet-based Knowledge Management Systems, KMS. The purpose of this paper is to illustrate how the Internet can be effectively used as an infrastructure for Knowledge Management/ Organizational Memory Systems, KMS/OMS. This is based on an intensive analysis of a KMS/OMS, an action research study of a KMS, and a literature review of KMS/OMS studies. For simplicity, this paper assumes that knowledge is a subset of Organizational Memory, OM, and the term OMS includes KMS, however, the term KMS will be used to generically refer to a KMS/OMS. This relationship will be illustrated later.

The paper begins by defining concepts used in the paper. This is followed by a discussion on the two types of KMS and the presentation of an assessment model based on DeLone and McLean's (1992) IS Success Model. The presented assessment model is used to assess the success of Internet-based KMS. This is followed by a discussion on enabling factors for a KMS and other tools and research for building an Internet-based KMS. This culminates in the presentation of examples of Internet-based KMS's followed by conclusions and limitations.

BACKGROUND

Organizational Learning

Organizational Learning, OL, is identified as a quantifiable improvement in activities, increased available knowledge for decision-making, or sustainable competitive advantage (Cavaleri, 1994; Dodgson, 1993; Easterby-Smith, 1997; Miller, 1996). Another definition refers to OL as the process of detection and correction of errors, Malhotra (1996). In this view, organizations learn through individuals acting as agents for them. Individual learning activities are seen as being facilitated or inhibited by an ecological system of factors that may be called an organizational learning system. Learning in this perspective is based on Kolb's (1984) model of experiential learning, where individuals learn by doing.

An organization can also learn if, through its processing of information, its potential behaviors are changed, Huber et al. (1998). This incorporates the concept of OM into OL (Huysman et al., 1994; Walsh, Ungson, 1991). In this view, OM is the process by which experience is used to modify current and future actions.

Organizational Memory and Knowledge

Organizational Memory is variously viewed as abstract or unstructured concepts and information that can be partially represented by concrete/physical memory aids, such as databases, and as concrete or structured concepts and information that can be exactly represented by computerized records and files. This paper views OM as a combination of abstract and concrete, where the concrete is the history and trend data collected in the memory and the abstract is the experience gained by the organizational member over time. Definitions by Stein and Zwass (1995) and Walsh and Ungson (1991) support this. Additionally, all agree that OM can include everything within the organization that is retrievable, including the set of documents and artifacts that forms the corporate record and the collection of shared and stored understandings and beliefs that forms the basis for organizational sense-making and social construction of reality.

OM has two principle goals: to integrate information across organizational boundaries and to control current activities and, thus, avoid past mistakes. OM functions are perception, acquisition, abstraction, recording, storage, retrieval, interpretation, and transmission of organizational knowledge (Stein, Zwass, 1995). OM retention facilities are individuals, transformations, structure, ecology, and culture (Walsh, Ungson, 1991).

Davenport and Prusak (1998) view knowledge as an evolving mix of framed experience, values, contextual information and expert insight that provides a framework for evaluating and incorporating new experiences and information. They found that in organizations knowledge often becomes embedded in documents or repositories and in the organizational routines, processes, practices, and norms. Nonaka (1995) expands this definition by stating that knowledge is about meaning in the sense that it is context-specific.

This paper considers OM and knowledge to be constructs and attributes of organizational learning. Also, knowledge is a subset of OM and the acquisition and use of OM includes the acquisition and use of knowledge.

Knowledge Management

Knowledge Management, KM, as a discipline has not been clearly agreed upon. KM is defined as that process established to capture and use knowledge in an organization for the purpose of improving organizational performance (Malhotra, 1998). Organization refers to any acknowledged business group, from a small team to the total enterprise. Also, this process is not restricted to the IS/IT organization and is better done in the organizations that create and use the knowledge. Personnel performing these functions are referred to as Knowledge Workers.

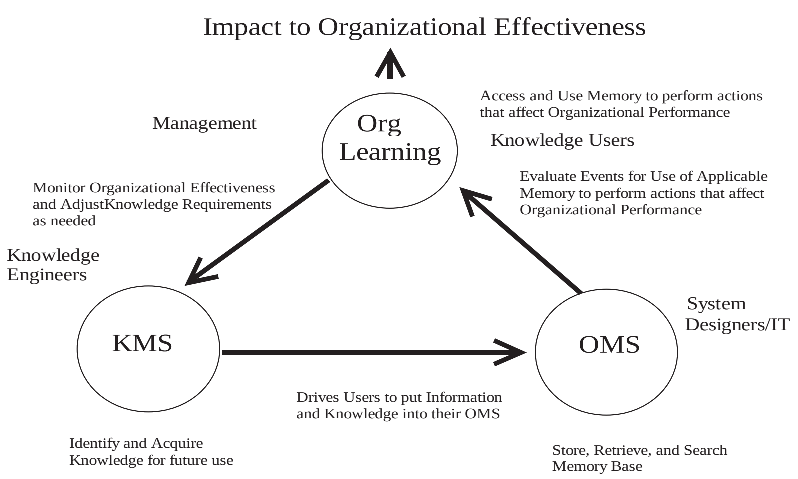
Organizational Memory and Knowledge Management Systems

The OMS is the processes and IS components used to capture, store, search, retrieve, display, and manipulate OM. The KMS consists of the tools and processes used by knowledge workers to identify and transmit knowledge to the knowledge base contained in the OM. Knowledge is managed and used through a combination of the KMS and OMS. Jennex and Olfman (2002) presented the KMS-OMS model in Figure 1 as a model illustrating the relationships between OM, KM, and OL. As mentioned earlier, to simplify terms, the rest of the paper will refer to these combined systems as a KMS.

Types of Knowledge Management Systems

There are two approaches to building a KMS as discussed by Hansen et al. (1999) and Stenmark (2002). These can be described as a project/pro-

Figure 1. The KMS-OMS model



cess/task-based approach, henceforth referred to as the project-based approach, and an infrastructure/generic system based approach, henceforth referred to as the infrastructure-based approach. The project-based approach focuses on the use of OM by participants in a process, task or project in order to improve the effectiveness of that process, task or project. This approach identifies information and knowledge needs, where they are located, and who needs them. The KMS is designed to capture OM unobtrusively and to make OM available upon demand to whoever needs it. Many Y2K projects used project-based KMS.

The infrastructure-based approach focuses on building a base system to capture and distribute OM for use throughout the organization. Concern is with the technical details needed to provide good mnemonic functions associated with the identification, retrieval, and use of OM. The approach focuses on network capacity, database structure and organization, and information and knowledge classification. Context is captured with the knowledge. The key difference is that the project-based approach has known users with a common context of understanding, while the infrastructure-based approach does not.

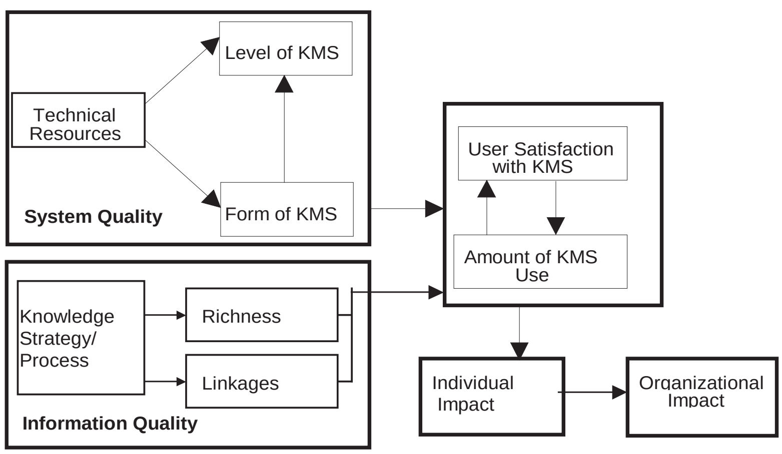
It is hypothesized that both approaches are necessary to create a complete organization-wide OM and KMS. Morrison and Weiser (1996) support the dual approach concept by suggesting that an organizational KMS be designed to combine an organization's various project/task/process-based KMSs into a single environment and integrated system.

Assessing KMS Success

Jennex and Olfman (2002) generalized assessment of KMS success by adapting DeLone and McLean's (1992) IS Success Model to a KMS. The DeLone and McLean model is based on a review and integration of 180 research studies that used some form of system success as a dependent variable. It identifies six system success constructs and shows how they are related. Figure 2 is the model adapted for KMS. The model is a block-recursive one that includes five blocks. Block descriptions are as follows:

System Quality – is defined by the technical characteristics of the KMS as described by three constructs: the technical resources of the organization, the form of the KMS, and the level of the

Figure 2. The KMS modified IS success model



KMS. Technical resources define the capability of an organization to develop and maintain a KMS. The form of KMS refers to the extent to which it is computerized and integrated, explicitly, how much of the accessible information/knowledge is on-line and available through a single interface. The level of the KMS refers to its ability to bring past information to bear upon current activities. Given the effectiveness of information technology to provide timely information, it is expected that a more fully computerized system utilizing network and data warehouse technologies will result in the highest levels of system quality.

Information Quality – Davenport and Prusak (1998) discuss two primary types of knowledge, links to experts who serve as sources of knowledge and rich, detailed knowledge. Jennex and Olfman (2002) found that KMS users new to an organization utilized knowledge linkages more than any other aspect of the KMS, while more experienced members of the organization relied on retrieving detailed, accurate, and timely information. The third construct, KM Strategy and Process, reflects that the knowledge needs of the KMS users change over time. KM Strategy is needed to determine what information/ knowledge should be in the knowledge base, where it is located, and how it is to be acquired. The KM Process ensures that knowledge requirements are reviewed on an ongoing basis.

Use - Information/knowledge use refers to the utilization of the outputs of the system. This construct is most applicable as a success measure when use is required. User satisfaction measures perceptions of the users. It is considered a good surrogate for measuring system use when use is voluntary. Jennex and Olfman (2002) used a perceived benefit model adapted from Thompson, Higgins, and Howell (1991) to measure user satisfaction and predict continued use of the KMS. This measure was found to work well and is included in the user satisfaction construct.

Individual and Organizational Impact – An individual's use of a system will produce an impact on that person's performance. DeLone and McLean (1992) note that an individual 'impact' could also be an indication that an information system has given the user a better understanding of the decision context, has improved his or her decision-making productivity, has produced a change in user activity, or has changed the decision maker's perception of the importance or usefulness of the information system. Each individual impact will, in turn, have an effect on the performance of the whole organization. Organizational impacts are typically not the summation of individual impacts, so the association between individual and organizational impacts is often difficult to draw.

Enabling Factors for KMS/OMS

Jennex and Olfman (2001) developed a set of design recommendations for enabling KM/OM in systems. The recommendations, Table 1, are based on the research previously discussed and on the blocks of the KM/OM modified IS Success Model. It should again be noted that the model is recursive and that enhancing one factor enhances succeeding factors. System Quality recommendations call for use of a common infrastructure. The Internet is suggested for this due to its widespread availability, open architecture, and developed interfaces. This also assists in standardizing software across the organization through the use of browsers and web applications. Information Quality recommendations include one for security. This topic is not discussed in this paper due to length considerations, not lack of importance.

The Internet meets several of these recommendations. It provides a common network that is global. Use of common browsers aids in standardizing software. Ease of use of browsers and in building and maintaining Internet-based systems empowers users (Newell et al., 1999) and simplifies incorporating the KMS into everyday processes. Ease in handling unstructured data,

Table 1. KMS enabling recommendations

Factor	Recommendation
System Quality	Use a common network structure, such as the Internet.
	Add KM/OM skills to the tech support skill set
	Use high end PCs and/or clients.
	Standardize hardware and software across the organization.
System and Information Quality	Incorporate the KMS into everyday processes and IS
	Use an Enterprise wide data dictionary to design knowledge base
	Allocate maintenance resources for KMS
	Train users on use and content of the KMS
Information Quality	Create and Implement a KM Strategy/Process for identifying/ maintaining the knowledge base
	Expand system models/life cycles to include the Knowledge process
	Assess system/process changes for impact to the KMS.
	Automate data capture.
	Design security into the knowledge base
Use	Incorporate KM into personnel evaluation processes
	Implement KMS use/satisfaction metrics
	Identify organizational culture concerns that could inhibit KMS usage.

as well as databases, simplifies knowledge representation, capture, and dissemination. Tools and research that expand the ability of the Internet to serve as the infrastructure for a KMS are discussed in the next section.

Other Tools/Research

Although there is strong support for using the Internet as a Knowledge infrastructure, there are concerns. Chief among these concerns is the difficulty in organizing and searching for knowledge. Ezingeard et al. (2000) points out that Ernst & Young UK in the beginning of 2000 had in excess of one million documents in its KMS. Another concern is the tendency to not use the system. Cross (2000) discusses this tendency, but comes to the conclusion that repositories are essential. Jennex and Olfman (2002) found that voluntary use is enhanced if the system provides near and long-term job benefits, is not too complex, and the organization's culture supports sharing and using knowledge and the system. Stenmark (2002) found that if the Internet is visualized as a system for increasing awareness of knowledge and the KMS as a system for retaining and sharing knowledge, and as a system for enhancing communication and collaboration between teams and knowledge experts and users, then it should be successful as a KMS.

Newman and Conrad (2000) propose a framework for characterizing KM methods, practices, and technologies. This framework looks at how tools can impact the flow of knowledge within an organization, its role in manipulating knowledge artifacts, and the organizational behavior most likely to be affected. The framework also looks at the part of the KM process the tool works in. The activity phase looks at the utilization, transfer, retention, and creation of Knowledge. This framework can be used to show that Internet and browser-based KMS tools are effective.

Gandon et al. (2000) propose using XML to encode memory and knowledge, and suggest using a multi-agent system that can exploit this technology. The proposed system would have improved search capabilities and would improve the disorganization and poor search capability normally associated with Internet systems. Chamberlin et al. (2001) and Robie et al. (1998) discuss using XML query language to search and retrieve XML encoded documents.

Dunlop (2000) proposes using clustering techniques to group people around critical knowledge links. As individual links go dead due to people leaving the organization, the clustered links will provide a linkage to people who are familiar with the knowledge of the departed employee. This technique would improve the reliability of the links to the knowledge called for in Figure 2. Lindgren (2002) proposes the use of Competence Visualizer to track skills and competencies of teams and organizations.

Te'eni and Feldman (2001) propose using task-adapted websites to facilitate searches. This approach requires the site be used specifically for a KMS. Research has shown that some tailored sites, such as ones dedicated to products or communities, have been highly effective. This approach is incorporated in the examples in this paper with the exception of the use of dynamic adaptation.

Eppler (2001), Smolnik and Nastansky (2002), and Abramowicz et al. (2002) discuss the use of knowledge maps to graphically display knowledge architecture. This technique uses an Intranet hypertext-clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as Topic Maps and Skill Maps. Knowledge maps are useful, as they create an easy-to-use standard graphical interface for the Intranet users and an easily understandable directory to the knowledge.

The use of ontologies and taxonomies to classify and organize knowledge domains is growing. Zhou et al. (2002) propose the use of ROD, Rapid Ontology Development, as a means of developing an ontology for an undeveloped knowledge domain.

EXAMPLES OF INTERNET KMS

Jennex (2000) discussed an intranet-based KMS used to manage knowledge for a virtual Y2K project team. This KMS used two different site designs over the life of the project. The purpose of the initial site was to facilitate project formation by generating awareness and providing basic information on issues the project was designed to solve. The design of this site was based on Jennex and Olfman (2002), who suggested that a structure providing linkages to expertise and lessons learned was the knowledge needed by knowledge workers. This was accomplished by providing hot links to sites that contained Y2K knowledge, a project team roster that indicated the areas of expertise for each of the project team members and additional entries for individuals with expertise important to the project, and some basic answers to frequently asked questions. This site was accessed from the corporate Intranet site through the special projects section of the IT division page. This made the site hard to find for those who did not know where to look, forcing the project team leadership to provide direction to the site through e-mail directions. The site did not contain guidelines and accumulated knowledge as reflected in test plans, test results, inventories of assets referenced to the division who owned them, and general project knowledge, such as project performance data, meeting minutes and decisions, presentations, and other project documentation. This information had not been generated at the time the site was implemented. Once generated, this information was stored on network servers with shared access to acknowledged project team members. This was done due to a lack of resources allocated to the initial site. No dedicated personnel or special technologies were allocated for the design or maintenance of the site. This site was in effect from early 1998 through mid 1998.

As the project team formed and began to perform its tasks, the requirements for the Intranet site changed from generating awareness to supporting knowledge sharing. The site was redesigned and expanded to include detailed, frequently asked questions (FAQs), example documents, templates, meeting minutes, an asset database, guidelines for specific functions that included lessons learned, etc. The knowledge content of the site was distributed to the other components of the site and persons were identified as being responsible for the information and knowledge content of their responsible areas. Additionally, access to the site was enhanced by the addition of a hot link to the Y2K site placed and prominently displayed on the Corporate Intranet home page. The basic layout of the site provided for access to seven specific sub-sites: Major Initiatives, Contacts, Documents, What's New, Hot Links, Issues and Questions, and Y2K MIS.

Access to this site was granted to all the employees, however, several of the sub-sites were password protected for restricted use. Most of the knowledge contained on the site was contained in these protected sub-sites. The knowledge from the initial site was rolled over into the Hot Links and Contacts sub-sites. Additionally, information that had been previously stored on network servers was left on those sites, but access was provided through the Intranet site. The network structure was expanded to include more sub-structures for storing more documents, information, and knowledge.

The effectiveness of the two sites was considered good. The first site was successful in generating interest and starting the project. The second site succeeded in taking a project that was performing in the bottom third of all projects, to being a leading project within six months after its release. Effectiveness of the sites was established using the model in Figure 2 and by ensuring the Information Quality was high and the System Quality, especially the search, retrieval, and infrastructure, was good. Use of both sites was established by ensuring the sites met the needs of the project team and the company.

The second example is the Extranet site used by the utility industry for Y2K (Jennex, 2000). Its purpose was to facilitate information/knowledge sharing between industry members. It initially provided documents, procedures, and guidelines for getting projects started. It also provided an electronic forum for questions and answers. As projects progressed, more test data became available and this information was posted. Finally, this site provided links to other important sites and sources of information.

The effectiveness of the site was limited. A great deal of knowledge was stored on the site, but searching was difficult and time consuming, reducing system quality. The consensus of the Nuclear and Non-Nuclear Generation Y2K project personnel was that the site provided little benefit, as many companies did not post test results, thus reducing information quality. The Substation Controls Y2K project personnel also found it limited, except they did use the knowledge to put together a statistically valid test sample as requested by the North American Electric Reliability Council (NERC). Industry consensus was that the site had limited knowledge value. A redesign of the site with more emphasis on knowledge search and retrieval was not available until after most projects were complete. It was anticipated the new site would be available for the expected onslaught of lawsuits following the roll over to 2000 which, of course, did not happen. A further inhibitor to effectiveness was that the member companies did not categorize equipment and system information in the same format. This lack of a shared ontology contributed to the search and retrieval difficulties and made understanding the posted information and knowledge more difficult for users from other companies.

The third example, from Cross (2000), is an Intranet site built by Andersen Consulting. Consulting firms have had a long tradition of brokering their knowledge into business. In the early 1990s, Andersen Consulting began to produce global best practices CDs for distribution to project personnel. This evolved into the development of a Intranet site called KnowledgeSpace that provided consultants with various forms of knowledge, including methodologies and tools, best practices, reports from previous like engagements, and marketing presentations. Support was also provided for online communications for online communities of practice and virtual project teams. The site was effective for personnel with access to the Internet and adequate bandwidth. It should be noted that current modem technology and improved dial-in access, as well as the proliferation of cable modems and digital subscriber lines, DSL, have made sites such as this much more effective for field or remote personnel.

The last examples come from Eppler (2001). There are five types of knowledge maps: source, asset, structure, application, and development. A multimedia company Intranet site is used to illustrate a knowledge source map. This site provides graphical buttons representing individuals with specific expertise, color-coded to indicate the expert's office location. The Knowledge Asset map provides a visual balance sheet of an organization's capabilities of a skills directory or core competency tree. Colors are used to indicate knowledge domains, while the size of symbols indicates level of expertise. Knowledge Structure maps divides knowledge domains into logical blocks that are then broken into specific knowledge areas. The Knowledge Application map breaks an organization's value chain into its components parts and then indicates what knowledge, tools, or techniques are needed to implement the component part. The last example is a Knowledge Development map. This map is used to plot the activities needed to acquire the indicated knowledge competence. Clicking on the displayed competence displays the steps needed to develop the competence. Effectiveness of these maps has only been determined for the Knowledge Asset map. This map, developed for a telecommunications consultant firm, was found to be very useful for the planning of training activities and for identifying experts quickly when required during an emergency. It should be noted that knowledge maps enhance the linkage aspects of information quality.

CONCLUSIONS

The conclusion is that the Internet is an effective infrastructure for a KMS. However, there are issues associated with using the Internet that KMS designers need to be aware of. Chief among these are knowledge representation and search. Several tools, such as Knowledge Maps, XML, adaptive websites, clustering, and examples of effective Internet based KMSs, were discussed that addressed these issues. However, as knowledge bases grow, designers need to be aware of increasing search times, as well as a variety of knowledge artifacts. This is perhaps the most important area for future research. Developing ontologies and taxonomies to aid in classifying and structuring knowledge domains is critical.

Maintaining a site is critical. User, organizational, and/or project needs for knowledge change over time, requiring the KMS to change its knowledge content. Also, knowledge has a life cycle and eventually reaches a point where it is no longer useful. Organizations must allocate resources to update and maintain every KMS.

Securing the KMS is also critical, as knowledge is valuable. This paper did not address security issues or technologies, but KMS designers need to ensure the security of captured knowledge. This may be the greatest impediment to the development of Internet-based KMSs.

The final issue is the tendency of people not to use the computer portion of a KMS. Jennex and Olfman (2002) found that this is a tendency of new members and suggest that this is a matter of context. New members do not understand the context under which the knowledge was created and stored, so they don't know how to retrieve and use the knowledge. As these members gain experience, they gain context and rely more upon the computer and less upon their peers.

Browsers are not discussed in the paper, except that the mentioned sites were designed to work with Internet Explorer and Netscape. Use of a browser is mandatory for the Jennex (2000) examples with the inference that effectiveness of these sites supports the use of browsers. A potential issue for KMS designers is deciding which browsers to support. Knowledge representation can include rich context information and documents designed to store this information may not display or function properly on all browsers.

LIMITATIONS

The examples used in this paper are limited in number and scope. They may not be indicative of the actual effectiveness of the Internet when used to develop a KMS. Insufficient research has been performed to verify that the Internet is the best approach for a KMS infrastructure. However, sufficient evidence exists to suggest this may be the case. The external validity is limited and is left to the reader to determine if sufficient evidence exists to warrant the claims of this paper.

The examples have limitations as discussed in the references. In general, all used reliable methods to reach their conclusions.

Chapter 1.20
Information Technology Assessment for Knowledge Management

ABSTRACT

New technologies, increasingly demanding customers, new aggressive competitors, and innovations in products and value now characterize our current competitive environment. Organizations of the 21st century have no choice but to invest in new technologies, especially knowledge management tools to enhance their services and products in order to meet the demands of today's information-driven, globally competitive marketplace. Knowledge embedded in systems, brains and technology has always been the key to economic development. However, knowledge management is increasingly being viewed as a strategy to leverage a firm's knowledge and best practices to serve customers and to be competitive. Several organizations have already started experimenting with knowledge management initiatives to capture and capitalize on knowledge assets and thereby claim the enormous benefits afforded by such endeavors, including improved profitability and transformation of their businesses into new generation businesses. This chapter develops a technology assessment model for knowledge management indicating what kinds of computing and communication systems any organization needs in order for it to have a sound knowledge management approach.

INTRODUCTION

Any 21st century organization faces a dynamic, new competitive environment consisting of numerous opportunities, possibilities and challenges.

As economies are becoming more knowledge-based, consumers' expectations are rising day by day. While new technologies threaten to make present systems and networks obsolete, new competitors threaten to upset existing markets and infrastructures. Global deregulation, allowing new competitors to enter previously guarded national monopolies, and hyper-competition are forcing organizations to offer services and products as a one-stop solution to meet customers' increasingly demanding expectations (Housel & Bell, 2001). To tackle such a global competitive environment, organizations have to invest in new technologies such as knowledge management tools that can contribute to enhance services and products that are offered in information technology-driven marketplaces.

The rules of business are undergoing radical change and these impact the competitive strategies of many businesses. The old laws of production, distribution, and consumption are evolving into new theories of e-businesses. Many organizations have an abundance of data and information but they starve for knowledge (Dean, 2001). Global markets are expanding rapidly, thus capturing new customers and retaining existing ones are becoming daunting tasks for organizations. Organizations are becoming more knowledge intensive in order to learn from past experiences and from others to reshape themselves and to change in order to survive and prosper (Brown & Duguid, 2000). New Web-based technologies have the capabilities to prepare organizations for knowledge management. The recently published report Knowledge Management Software Market Forecast and Analysis 2000/2004 estimated that the total KM software market would reach $5.4 billion by 2004 (Duffy, 2000). While extensive literature exists to describe the developments in the knowledge management area, little work has been done on the assessment of IT for knowledge management. This chapter endeavors to address this void by developing an IT assessment model for knowledge management. Concisely stated, IT assessment means focusing on the availability and capability of computing and communication resources. Specifically, our model will enable organizations to answer such questions as: What kinds of computing and communication systems does our organization need for knowledge management to be successful? Such questions are critical for organizations as they try to incorporate knowledge management and move to become knowledge-based enterprises.

KNOWLEDGE MANAGEMENT (KM)

Arguably, the most valuable resource available to any organization today is its knowledge that is stored in patents, copyrights, corporate data warehouses, employees' brains, processes and information systems (Duffy, 2001). Knowledge management focuses on how to identify, manage, share, and leverage all information assets, such as databases, policies and procedures, content, and staff and members' expertise and experience to serve the organization (Shepard, 2000). These knowledge assets or repositories are stored in unstructured data formats (i.e., document and content management, groupware, e-mail and other forms of interpersonal communication) and structured data formats (i.e., data warehousing, databases, etc.). KM is the process of creating value from an organization's intangible assets. Organizations are realizing that their human capital (people power) and structural capital (databases, patents, intellectual property and related items) are the distinguishing elements of their organizations (Liebowitz, 2000). KM consists of systems, information and processes that take information and turn it into structured knowledge to support specific and general business purposes. Early attempts at KM included the use of data warehouses and data marts to help to predict future patterns in form of data mining, but now the KM domain is recognized to be much more than mere data warehousing and data mining (Srikantaiah & Koeing, 2000).

KM's major objective is to connect people with people and stimulate collaboration (Lee, 2000). Knowledge management benefits significantly from real-time communication between individuals that encompasses information exchange and provides a shared workspace (e.g., application sharing and videoconferencing). Such communication accommodates shared creation of work products — documents, group decision support, networked virtual meetings, etc. — and provides the ability to link immediately to experts if they are online (Alavi & Leidner, 2001). To support both explicit and tacit knowledge, KM solutions are built with content and collaboration technologies. Data technologies are structured and typically numerically oriented; knowledge technologies deal most often with text. Knowledge technologies need more human interactions than data technologies.

FACILITATING FOR E-COMMERCE AND INTELLIGENT ENTERPRISES

E-business and e-commerce is growing fast and becoming the popular way of doing business. E-business mandates that organizations use new technological tools, have new sharing cultures, incorporate new sets of values and new strategies appropriate for the new knowledge-based economy (Brown & Duguid, 2000). Many experts today believe that e-business is one of the three pillars of the new economy, along with knowledge management and partnering strategies (Moore, 2000). Today, organizations want to know more about their customers, partners and suppliers. Companies are willing to invest in technologies that enable them to track patterns in customers and other partners' transactions (Davenport et al., 2001). Companies are interested in creating an integrated data repository about customers, policies, procedures, suppliers and partners so that the concerned user in one location can learn everything about a customer, procedure or suppliers by accessing information with one click (Davenport et al., 2001).

Knowledge management is becoming a key determinant of value in the marketplace, of an organization's success, and a competitive edge in this e-commerce era. Many organizations leverage the efficient flow and transfer of knowledge across the organization (Silver, 2000) for enhancing markets, revenues and growth opportunities for e-business. Today, many companies compete not only on the basis of product, service and operational superiority, but also through KM assets to drive their competitive edge.

In this e-business era, organizations that offer e-business solutions have a number of automated systems that generate valuable data. But many of these automated systems are disparate systems that do not integrate and relate the stored data, leaving the consolidation and analysis of the data to the end-user (Hammond, 2001). Despite their strength, these systems do not help end-users to make better business decisions. End-users need business intelligence (BI) derived from the systems that provide the in-depth analytical capabilities to analyze the situations and prepare strategies accordingly to compete in a global environment (Hammond, 2001). The growth of Web technologies provides an opportunity to build portal-type applications that integrate a firm's knowledge in the form of KM assets and can be accessed from anywhere through dynamic, end-user-driven querying tools for report distribution and data analysis (McMillin, 2000). Such features of a portal will add value to an enterprise's strategy by improving analysis of interdepartmental data by delivering relevant enterprise data to a greater number of knowledge consumers. Furthermore, such a KM infrastructure would help organizations to improve customer service and partner relationships and to create marketable knowledge products from an enterprise's own internal data (Hammond, 2001). Organizations can allow their customers to view dynamic reports displaying their purchasing habits and identifying areas where they can consolidate purchases from different suppliers to take advantage of volume discounts. Another indirect benefit of implementing a KM solution exists in the capability of an enterprise to package and resell its own internal data to other companies.

Knowledge management is an intelligent process by which raw data is gathered and transformed into information elements. These information elements are assembled and organized into context-relevant structures that represent knowledge (Onge, 2001). It has become necessary for organizations to have their business information stored in databases, file servers, Web pages, e-mails, ERP (enterprise resource planning), and CRM (customer relationship management) systems integrated into a repository which can be accessed by various users. These integrated repositories, which act as knowledge management systems, can cut the time wasted on searching for particular data and allowing better business decisions. Having such knowledge management systems can turn a company into an intelligent enterprise (Hammond, 2001).

A knowledge-based view of the firm identifies knowledge as the organizational asset that enables a sustainable competitive advantage, especially in hyper-competitive environments (Alavi, 1999; Davenport & Prusak, 1998; Kanter, 1999) or in environments experiencing radical discontinuous change (Malhotra, 2000). This is attributed to the fact that barriers exist regarding the transfer and replication of knowledge (Alavi, 1999). Knowledge and knowledge management have strategic significance (Kanter, 1999). Knowledge management addresses the generation, representation, storage, transfer and transformation of knowledge. Therefore, knowledge architecture, designed to capture knowledge and, thereby, enable the knowledge management processes to be efficient and effective (Wickramasinghe & Mills, 2000).

Underlying the knowledge architecture is the recognition of the binary nature of knowledge, namely its objective and subjective components. Knowledge can exist as an object in essentially two forms: explicit or factual knowledge and tacit or "know how" (Polyani, 1958; Polyani, 1966). It is well established that while both types of knowledge are important, tacit knowledge is more difficult to identify and thus manage (Nonaka, 1994). Furthermore, objective knowledge can be located at various levels, e.g., the individual, group or organization (Kanter, 1999). Of equal importance, though perhaps less well defined, knowledge also has a subjective component and can be viewed as an ongoing phenomenon, being shaped by social practices of communities (Boland et al., 1995). The objective elements of knowledge can be thought of as primarily having an impact on process while the subjective elements typically impact innovation. Both effective and efficient processes as well as the functions of supporting and fostering innovation are key concerns of knowledge management.

The knowledge architecture recognizes these two different yet key aspects of knowledge and provides the blueprint for an all-encompassing KMS. Clearly, the knowledge architecture is defining a KMS that supports both objective and subjective attributes of knowledge. Thus, we have an interesting duality in knowledge management that draws upon two distinct philosophical perspectives, namely, the Lockean/Leibnitzian stream and the Heglian/Kantian stream (Wickramasinghe & Mills, 2001). This duality can be best captured in the Yin-Yang of knowledge management (refer to Figure 1) (ibid). The principle of Yin-Yang is at the very roots of Chinese thinking and is centered around the notion of polarity, not to be confused with the ideas of opposition or conflict, thereby making it most apt for describing these two sides of knowledge management because both are necessary in order for knowledge management to truly flourish (ibid).

Models of convergence and compliance that make up one side are grounded in a Lockean/Leibnitzian tradition (Wickramasinghe & Mills, 2001). These models are essential to provide the information processing aspects of knowledge management, most notably by enabling efficiencies of scale and scope and thus supporting the objective view of knowledge management. In contrast, the other side provides agility and flexibility in the tradition of a Hegelian/Kantian perspective (ibid). Such models recognize the importance of divergence of meaning which is essential to support the "sense-making," subjective view of knowledge management. Figure 1 depicts this Yin-Yang view of knowledge management. This figure shows that, given a radical change to an environment or given a highly competitive environment, an organization needs knowledge to survive. From this Yin-Yang depiction of knowledge management we see that knowledge is required for the organization to be effective and efficient, but new knowledge and knowledge renewal is also necessary. The ultimate challenge for KMS is to support both these components of knowledge management. The pivotal function underlined by the knowledge architecture is the flow of knowledge. The flow of knowledge is fundamentally enabled (or not) by the knowledge management tools adopted.

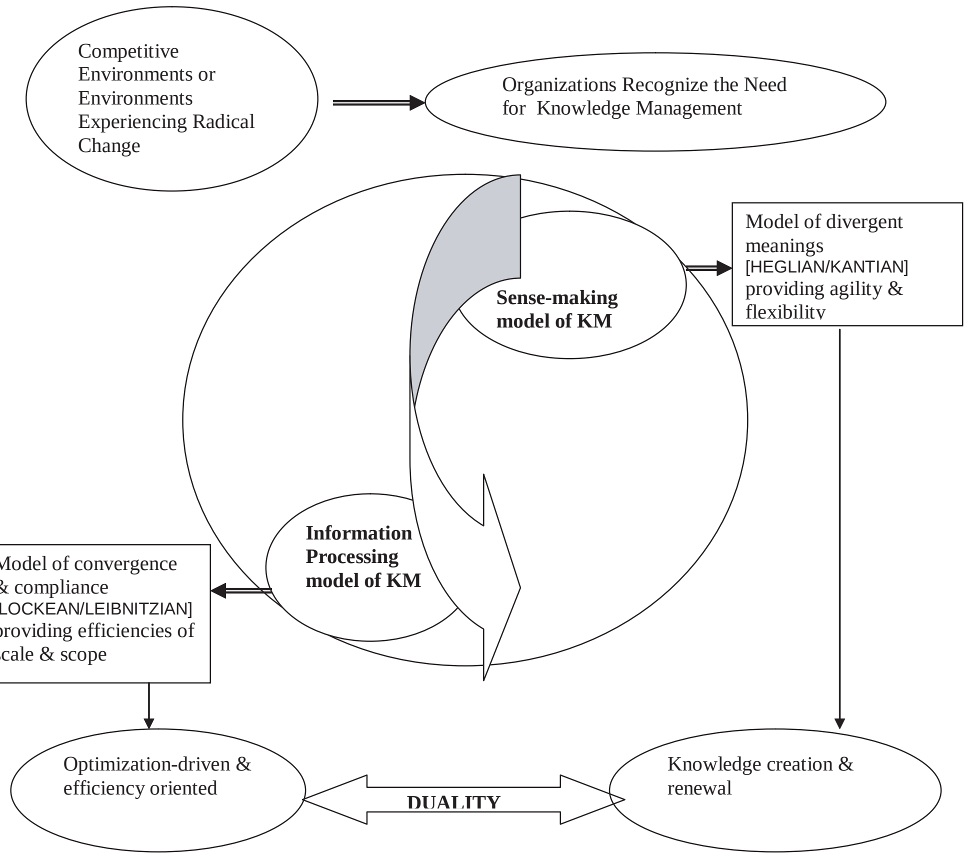
TECHNOLOGY ASSESSMENT MODEL FOR KNOWLEDGE MANAGEMENT

Today's organizations offer e-commerce and conduct business on a 24-hour-seven-day-a-week basis through their own offices as well as with the help of their business partners located geographically in dispersed locations worldwide. Organizations have their databases, people, and technology infrastructure dispersed in many different locations. Organizations need a single database and e-commerce systems of all their activities that allows their customers, staff and business partners to have real-time information for their use (Shepard, 2000). Furthermore, organizations need knowledge by integrating all data stored in these disparate systems. Organizations typically have various systems such as database systems, intranets, groupware, document management, data warehousing, e-mail and ERP systems. The first step in actualizing the knowledge management systems architecture is concerned with integrating all these systems so that these various formats can be integrated to create a uniform format for users (Nissen et al., 2000).

The first major step needed for embracing KM often includes overcoming hierarchies and building environments in which knowledge sharing and collaboration become a routine way of doing business. This requires a technology infrastructure that encourages collaboration and facilitates knowledge capture and access (Duffy, 2001) as well as changes in business rules, procedures and policies. While organizations generate much data during transactional phases, its systems do not document much of the generated data. The undocumented data potentially could be quite useful for generating business intelligence. Therefore, one of the biggest problems faced by an organization is the need to bring disparate enterprise data sources into a cohesive data warehouse. Data abstraction from databases of enterprises of data storage requires skills to map the actual database fields and tables into the intuitive query tools that end-users will eventually see on their desktops for extracting intelligence or knowledge. This is just one of many instances where a technology assessment model would be beneficial.

The technology assessment model can be divided into five layers (Duffy, 2000) or groups

Figure 1. Yin-Yang model of KM



in the typical enterprise systems architecture model. The layers and their purpose are shown in Figures 2, 3 and 4.

Communication Systems Layer

The basic foundation layer for knowledge management is the communication systems layer that represents all the communication systems involved. There are varieties of communication systems such as local area network (LAN) or intranet, extranet and World Wide Web or Internet. The organizations would have connectivity to Internet service providers (ISPs) through various "last-mile technologies" options. The communications systems are used for communicating across or exchanging information through various groupware systems for the creation of knowledge. Organizations should have their communication systems in place before they opt for knowledge management. It is required that communication systems should support appropriate bandwidths for effective information exchange. It has been experienced that many times organizations have low bandwidth links that restrict effective groupware applications supports.

The next major wave of communication systems would be to deliver the information and experience on demand, in the right form, at the right time and at the right price to fixed or mobile

Figure 2. Technology assessment model for knowledge management

Layers	Domain
End User Application Layer	Represents the user interface into the applications and data used regularly
Middleware Layer	Integrates the internal knowledge to easy to user interface.
Knowledge Repository layer	Consists of repositories for unstructured data (i.e., document and content management) and structured data (i.e., data warehousing, generation, and management), groupware for supporting the collaboration needed for knowledge sharing as well as e-mail and other forms of interpersonal communication required for the efficient, time and location-independent exchange of information
Enterprise Data Source layer	Consists of databases, file servers, Web pages, e-mails, ERP (enterprise resource planning), and CRM (customer relationship management) systems
Communication Systems layer	Made up of local area network, Intranet, extranet and Internet Systems

terminals anywhere. Bandwidth, distance and time will ultimately no longer be significant. Service and access will become the dominant features of the changing demands and knowledge-focused society.

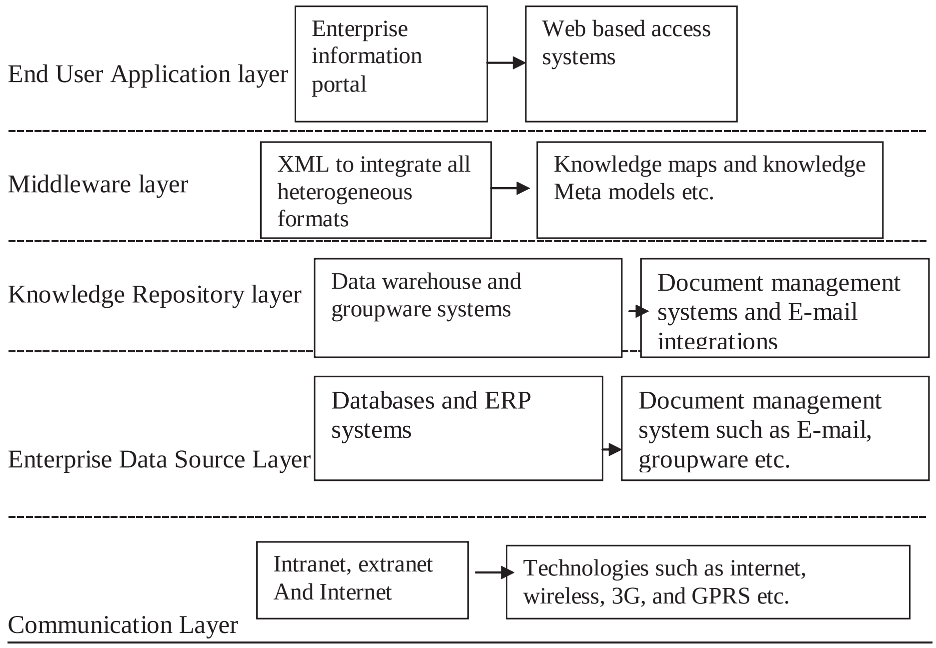
Using communication systems would ensure more information and more transparency for customers, suppliers and users. In the world of knowledge management, everybody will know everybody else's business. Advances in communications technology are being driven by the relentless spread of e-commerce. The latest developments in communications technology promise that it will soon be possible to receive up-to-the-second information about the flow of goods from manufacturer to customer with a small and compact handheld device. And in the next two years, developers are promising communications devices that are small and light enough to be worn as jewelry or clothing. Much is riding on the next generation of networks, the so-called "third generation" (3G), which will allow moving pictures and data to be transmitted much more easily to handheld devices.

Network and handset operators are also pinning their hopes on another variant of transmission technology, which allows a mobile device to be continually connected to a network. The technology is known as general packet radio service (GPRS). Today's mobile devices have to dial into a central server and download electronic information and translate it into a voice or digital message. Devices that use GPRS are known as "always on" because they do not need to be switched on and off.

Enterprise Data Source Layer

The enterprise data source layer provides the base or platform upon which KM solutions are built. It consists of repositories for unstructured data (i.e., document and content management)

Figure 3. Components of each layer of KM solutions



and structured data (i.e., databases, e-mail) and groupware, etc. (Duffy, 2001). Companies use databases and ERP systems for structured data and varieties of document management systems for unstructured data.

This layer acts as a foundation for KM solutions. At this layer data is captured in various databases or document management systems. The technological tools used include relational database management systems, document management systems, messaging technologies (like e-mails systems), groupware, and work flow systems.

The enterprise data source layer represents different types of data (textual data, video, and audio) stored in databases, file servers, Web pages, e-mails, ERP (enterprise resource planning), and CRM (customer relationship management) systems. Enterprise data sources can be fileservers, database servers, groupware servers, document management systems, e-mail servers or web sites. Each repository's structure will depend on the content or knowledge it stores and manages. Although each is a separate physical repository, together they form a single, virtual knowledge repository (Duffy, 2000).

Knowledge Repository Layer

The knowledge repository layer consists of a data warehouse for structured data and document content management and a groupware system for unstructured data. The knowledge repository layer mainly consists of repositories for unstructured data (i.e., document and content management), structured data (i.e., data warehousing, generation, and management), and groupware for supporting the collaboration needed for knowledge (Duffy, 2001).

The knowledge stored may be either created inside an organization or acquired from external sources and then added to the enterprise's knowl-

Figure 4. Technologies and systems of knowledge management

Layer	Tools and Technologies
End User Application Layer	Enterprise information portal (EIP) and web based access system
Middleware layer	XML technology and various routing and retrieval algorithms
Knowledge Repository layer	Data warehouse, data marts, document management systems, groupware applications
Enterprise Data Source layer	Databases, ERP, Groupware, document management systems, and E-Mail etc.
Communication Systems Layer	Systems: LAN, Intranet, Extranet and internet Technologies: Internet, 3G, GPRS, Bluetooth etc.

edge base. There are a variety of tools needed to capture the knowledge at the knowledge repository layer. Traditional tools for capturing knowledge include word processing, spreadsheets, e-mail, and presentation software. Increasingly, newer technologies such as voice recognition, shared workspaces, and video conferencing are also used to support the knowledge-capture process.

This layer is also known as the data abstraction layer and represents the processes through which data is extracted from the enterprise data source layer or operational form of data layer and converted into summarized data. Data abstraction involves suppression of irrelevant data. The relevancy depends on the task and the use of information, thus it changes with the context. There are six main abstraction mechanisms used such as classification, generalization, aggregation, contextualization, materialization and normalization.

Data Warehouse and Data Marts

The data warehouse is the main component of KM infrastructure. Organizations store data in a number of databases. The data warehousing process extracts data captured by multiple business applications and organizes it in a way that is meaningful to the business for any future references in the form of knowledge (Duffy, 2001).

The data warehouse process has two components of data warehousing software to support KM. One component transfers operational data to the warehouse (i.e., data extraction, cleansing, transformation, loading, and administration) and the second component supports warehouse management or utilities for supporting data mining (Shaw et al., 2001).

Collaborative Applications

Collaborative applications' core functions include e-mail, group calendaring and scheduling, shared folders/databases, threaded discussions, and custom application development. Collaborative applications provide the capabilities needed for identifying subject matter experts who can give answers to knowledge seekers (Skyrme, 1999). Collaborative applications systems are the major component of KM systems because it is through these systems that an interaction of experts and users take place.

Content Management

Content management software represents the convergence of full-text retrieval, document management, and publishing applications. It supports the unstructured data management requirements of KM initiatives through a process that involves capture, storage, access, selection, and document publication. Content management tools enable users to organize information at an object level rather than in binary large objects or full documents. The information is broken down by topical area and usually tagged via extensible markup language (XML). Both capabilities dramatically increase the opportunity for re-use.

Middleware Layer

The middleware integrates the applications of the knowledge repository and enterprise information portals. Middleware supports intelligent message routing, business rules that control information flow, security, and system management and administration.

Users like to have information or knowledge without getting into complexities of how knowledge is stored or structured. Thus, there is a need for the middleware layer which can keep the complexities of knowledge repositories hidden from users who want easy access to knowledge. Some authors refer to this layer as the "knowledge about the knowledge" layer (Duffy, 2001) that represents the entire collection of knowledge objects, regardless of category or location, and helps to identify the links between existing islands of information. This layer has two components, i.e., knowledge maps and knowledge meta-model. Thus, the middleware layer is the heart of a knowledge management system. The information about each knowledge object in the repository includes such items as the identity of the person who created the knowledge and the time it was created, the knowledge object's format and media, the knowledge object's purpose, actions and sequences of events surrounding its existence, and linkages with other knowledge objects. The knowledge map (K-map) is the navigational system that enables users to navigate to find the answers they seek (Duffy, 2001). The K-map is the front end of an integrated knowledge management system and helps to create an interactive user interface.

KM uses XML technology as a standard for middleware. Knowledge management technologies have to follow open standards so that they can support a heterogeneous environment on the Internet and foster interoperability among various operating systems and software applications. These standards will promote a common platform that simplifies integration and furthers connectivity between diverse sources of information. XML (extensible markup language) is emerging as a fundamental enabling technology for content management and application integration. XML is a set of rules for defining data structures, thus making it possible for key elements in a document to be categorized according to meaning.

End-User Application Layer

The end-user application layer represents the user interface into the applications and knowledge. Because the Web is used as a medium for interface, it uses Web-based interactive tools to access knowledge from knowledge management systems. In many instances, portals similar to those used to access the Internet (e.g., Yahoo!, Lycos, Excite, or Plumtree) represent the user interface layer (Duffy, 2001). A user interface should be easy to use, interactive and valuable to the users. It should hide all the internal complexities of KM architecture and should respond to users' requests through easy-to-use features.

The end-user application layer has two components, enterprise information portal and Web-based access systems. These two components are supported by varieties of various other tools such as presentation, distribution and Web-mining tools.

Enterprise Information Portals

Enterprise information portals (EIPs) are evolving as a single source of knowledge-based systems (Silver, 2000). They integrate access to knowledge and applications. EIPs provide a single point of entry to all the disparate sources of knowledge and information both within and outside an organization, usually through the Internet or a company intranet (Ruppel & Harrington, 2001). EIPs have to be fully integrated with legacy systems of the organization. Through these EIPs, companies serve their customers, interact with business partners and suppliers, and offer employees access to online tools and the right content and knowledge for decision making. EIP functionality ranges from access to structured data used in classifying and searching unstructured data to supporting collaborative processes. EIPs are poised to integrated access to heterogeneous types of data (Morris, 2000).

Web-Based Access System

The Web has created a noble opportunity for easy access to data from any geographic location. KM supports Web-based access system having thin client architecture for end-user applications. Thin client architecture requires no software installation on the client end.

The KM Web-based access system uses many tools like Text and Web Mining Tools for Query system (Duffy, 2001). Text mining is used to automatically find, extract, filter, categorize and evaluate the desired information and resources. Text mining applies to Web content mining, which is the automatic retrieval of information and resources, filtering and categorization. End-user query and reporting tools are designed specifically to support ad hoc data access and report building by even the most novice users.

Information extraction utility pulls information from texts in heterogeneous formats — such as PDF files, e-mails, and Web pages — and converts it to a single homogeneous form. In functional terms, this converts the Web into a database that end-users can search or organize into taxonomies (Adams, 2001).

CONCLUSION

As we move into the 21st century, the need for rapid access to relevant knowledge has never been greater. The business world is becoming increasingly competitive, and the demand for innovative products and services is growing. Organizations that compete in such an intense competitive environment need to leverage their knowledge assets so that they do not lose markets, revenues and growth opportunities. The importance of KM technology and the role it will play in organizational success cannot be over emphasized. This chapter has discussed a myriad of technologies and tools for knowledge management that are at the disposal of organizations. The importance of addressing both the subjective and objective perspective of KM as well as outlining the significance of the knowledge architecture was highlighted. Necessary technology components that need to be considered by any organization as part of the sound knowledge architecture were discussed. The proposed knowledge assessment model will provide organizations with a useful framework in order for them to successfully embrace KM.

Chapter 1.21
Practice-Based Knowledge Integration

Glenn Munkvold
Norwegian University of Science and Technology, Norway

INTRODUCTION

For organisations, the tension between integration and specialisation has become a key issue as the knowledge of work is becoming increasingly fragmented through specialisation (Becker, 2002; Grant, 1996; Kogut & Zander, 1992). Specialisation, as knowing more about less, distributes the overall accomplishment of work on several entities (Aanestad, Mørk, Grisot, Hanseth, & Syvertsen, 2003; Becker; Berg, 1997; Hutchins, 1995) with the consequent need for the integration of different competencies and types of expertise. Becker (p. 3) provides the following definition of knowledge integration:

By knowledge integration we mean solving problems raised by specialisation: Specialisation leads to a dispersion of specialised bodies of knowledge that are held by different specialists...Knowledge integration refers to how this drawing on different bodies of specialised knowledge is organised.

The capability of relying upon specialisation and the ability to integrate specialised knowledge have been identified as critical factors in the competitiveness of an organisation (Grant, 1996; Kogut & Zander, 1992). Because of this, integration has become a theme for numerous research efforts.

A first line of research looks at knowledge integration as the transferring of knowledge to where it is supposed to be used (Berends, Debackere, Garud, & Weggeman, 2004). By transferring knowledge to someone who is able to use it and combine it with his or her own work practice, knowledge is integrated. If we are able to capture and model the content of knowledge, we can disseminate it and make it usable across contexts. As an integration mechanism, transfer is problematic because "it is costly and counters the necessary specialisation of organisation members" (Berends et al., p. 4). Moreover, the notion of knowledge as something that can be externalised and combined is problematic in itself (Blackler, 1995; Walsham 2001, 2004).

Current discourse on knowledge is filled with ambiguities and varying conceptualisations (see, e.g., Alvesson, 2001; Blackler; Boland & Tenkasi, 1995; Carlsen, Klev, & von Krogh, 2004; Cook & Brown, 1999; Davenport & Prusak, 1998; Fitzpatrick, 2003; Gherardi, 2000; Walsham, 2001), and a detailed discussion of this issue is beyond the scope of this article. For this article, we will recall that the underlying tenet grounding most of the existing views is a distinction between explicit and tacit knowledge. Explicit knowledge refers to knowledge that is movable and easy to convey, while tacit knowledge is intimately connected to our identity and is thus hard to formalize (Polanyi, 1966). Nonaka and Takeuchi (1995, p. 61) claim that the conversion between tacit and explicit knowledge is "a 'social' process between individuals and not confined within an individual." While popular, their view on tacit knowledge as something to be externalised and combined has been criticized (see, e.g., Blackler, 1995; Walsham 2001, 2004). As human interaction is always mediated by representations, our experiences and the way we perceive the world can never be replicated perfectly. Hence, Walsham (2001) argues that the knowledge-management discourse in general, and knowledge-management systems in particular, should pay closer attention to the contextual sides of knowledge.

This different understanding of knowledge leads to a second line of research on knowledge integration: one that is first and foremost paying attention to the relational and situated nature of knowledge (Brown & Duguid, 1991; Lave & Wenger, 1991; Suchman, 1987). Rather than trying to single out the knowledge entities and how they could merge, the focus is on understanding how knowledge is deeply embedded in situated practices and closely connected to people's ability to act (see, e.g., Carlsen et al., 2004; Cook & Brown, 1999). In this article, we discuss research in this direction. In particular, we elaborate on the practice-based perspective on knowledge integration to understand better the role of artefacts. In our opinion, it is not enough to look at the practice in terms of human interaction; we also need to look at the overall system where integration takes place. Our perspective is illustrated with an example from the health care domain. We will look in particular at the patient list, an A4 format template created by nurses to support their everyday activities and used in different settings in the hospital ward. We illustrate how the patient list serves various functions within the ward and how it, along with other actors, helps the integration of different aspects of work. For the ongoing efforts of introducing information technology in health care, understanding the implicit roles of existing material arrangements is essential as it helps us identify how technology might be better designed.

The article is organised as follows. In the next section we discuss research on knowledge integration and the relevance of adopting a practice-based perspective, paying attention to the artefacts used within practices. The section after introduces health care as a relevant domain to study integration and presents a concrete example on how the patient list integrates different aspects of work. The last section sums up the contribution of this article.

KNOWLEDGE INTEGRATION

While the literature abounds in diverse classifications on how to coordinate the efforts of specialists (see, e.g., Becker, 2002; Berends et al., 2004; Ditillo, 2002; Willem & Scarbrough, 2002), we remain at their common reference point: the work of Grant (1996). Grant identifies four different organising mechanisms for integrating knowledge: (a) rules and directives, (b) sequencing, (c) routines, and (d) group problem solving. Rules and directives are standards that regulate interaction between workers (e.g., policies and rules). These standards or artefacts can be said to accumulate knowledge. In health care, for example, the transition from paper-based to electronic health records (EPR) has imposed new rules and directives on how to handle EPRs (e.g., security and privacy). Sequencing is a mechanism for coordinating efforts across time and space. For instance, a procedure is a sequence of actions that should be undertaken to do a certain task. In terms of work, sequencing can be said to be a mechanism for minimising communication and maximising specialisation. In health care there are diverse types of procedures ranging from clinical (e.g., how to perform an operation) to administrative (e.g., how to refer a patient to a specialist). Routines are habitual procedures embedded in work practices. They are beneficial in that they enable complex interaction in the absence of other coordinating mechanisms. For example, experienced surgeons do not search for a procedure before performing a standard operation as it has become an embodied routine. Group problem solving is different from the previous three mechanisms in that it requires personal and communication-intensive forms of integration. In this sense, group work in itself is a mechanism for integrating knowledge.

Of the four mechanisms, the latter (group) has been recognised as fundamental for knowledge creation (see, e.g., Becker, 2002; Ditillo, 2002). Ditillo (p. 11), claiming that "knowledge integration is best achieved through direct involvement," suggests a group-based approach to knowledge integration. In a similar vein, Fitzpatrick (2003, p. 106) contends that "strategies to supporting knowledge sharing, even in large scale communities cannot discount for the interactional human-to-human processes through which it is nurtured in local settings or across settings." The fundamental view grounding these perspectives is that no individual can possess all knowledge, and thus a group or community, where knowledge is naturally distributed, becomes an effective mechanism for integration. In this sense, knowledge is not treated as a transferable entity, but rather knowledge integration is considered to be a collective and interactive process. Understanding integration thus implies unfolding human interaction.

A Practice-Based Perspective on Knowledge Integration

Based on the assumption that we know more than we can express, Polanyi (1966) points out that we sometimes act according to our feelings without being able to give rational explanations for our conduct. In this sense, the notion of tacit knowledge has become an important aspect of the way we understand work (Levin & Klev, 2002). Empirically assessing knowledge thus implies attending to the everyday practices constituting organisational performances. Practice implies doing and is the situation of all human action (Suchman, 1987).

In a practice-based perspective, emphasis is on the active and productive processes of knowledge (see, e.g., Carlsen et al., 2004; Cook & Brown, 1999). Practices are driven by, but not limited to, tacit knowledge; they are improvised, spontaneous, and hallmarked by responses to changing and unpredictable environments (Brown & Duguid, 2000). Emphasis is on communities of practice (CoPs) in which knowledge sharing and integration takes place rather than on individuals, methods, or particular systems. In this sense, the traditional view on knowledge integration needs elaboration. Boland and Tenkasi (1995, p. 359) provide an interesting perspective:

...the problem of integration of knowledge...is not a problem of simply combining, sharing or making data commonly available. It is a problem of perspective taking in which the unique thought worlds of different communities of knowing are made visible and accessible to others.

Our experiences and the way we perceive the world can never be replicated perfectly, but to be able to make visible different world views, we need common denominators: that is, entities that are interpreted differently in different social worlds, but still remain common enough to be recognisable (Star & Griesemer, 1989). These entities are what Star and Griesemer call boundary objects. In a practice perspective, these boundary objects are means of representing, learning about, and transforming knowledge (Carlile, 2002). They enable collaborative work across social worlds (i.e., different CoPs).

We would like to emphasise that these social worlds consist of both people and artefacts. Knowledge is distributed among actors, and no actor has the complete picture of the collaborative work process (Berg, 1997; Hutchins, 1995).

Activating the Artefacts

Practice, then, as knowing in action, implies unfolding the joint activity performed by interrelated elements. In this perspective, activity does not take place solely in people's heads. Hutchins (1995) would contend that it is the system that knows. Looking at the practice of navigating ships, Hutchins develops a methodological and analytical framework for understanding how cognitive achievements can be conceptualised as a joint accomplishment. Hutchins maintains equality between people and artefacts in structuring practice. One expects to find a system that can dynamically configure itself to bring subsystems into coordination to accomplish various functions (Hollan, Hutchins, & Kirsh, 2000). Thus, the centre of attention in work activities is the interdependencies between people, and between people and artefacts.

In the same way, Berg (1996, 1997) illustrates each minute part of a work process aiming at documenting a hospital patient's fluid balance, which is a sum of what fluid goes in and what comes out. In observing and recording each minute detail of a particular process, the separate elements are identified. This hybrid comprises everything that is needed for the activity to proceed including several people, various artefacts, routines, and experiences. The formal tools come to life only as part of the real-life activity. In Berg's (1996) and Hutchins' (1995) terminology, integration implies looking at how work is distributed, delegated, coordinated, and communicated across time and space (Ellingsen & Monteiro, 2003).

In this article, artefacts are provided an active role in integrating knowledge. Artefacts not only mediate human action, but rather, they play an active role in shaping that same action. Furthermore, there is a relational interaction between artefacts and humans. Knowledge, then, is not a group of entities that can be merged, but rather a distributed system of cognitive elements whose integrative potential lies in the collective ability to perform.

INTEGRATION IN PRACTICE: AN EXAMPLE FROM HEALTH CARE

Below we provide a short example on how an artefact, the patient list, is produced and used in a hospital ward. By going beyond the concrete representational aspects of the list, other aspects of work become visible, for instance, the informal and implicit coordination and interaction among the people that populate the ward. The description and analysis of the patient list described below is based on observations from a 4-week stay at a hospital ward working as a nursing assistant.

The Patient List

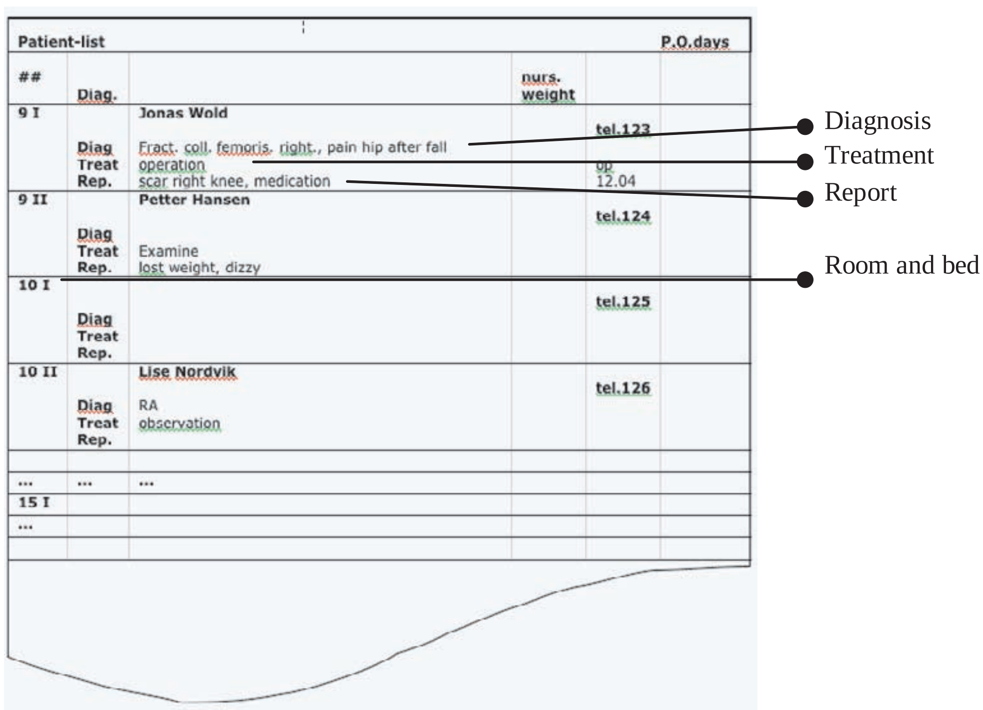
Medical records take many forms. Information from the electronic patient record, clinical-specific systems, and other systems are often printed out on paper and copied to become usable in everyday work. Representations of patients are found on walls, in circulation, in copies, in annotated copies, on computers, in people's heads, in letters, on Post-It notes, in pockets, and so forth. In this article, we analyse one of these artefacts: the patient list. The patient list is a sheet of A4 paper listing all admitted patients, arranged after which room they are lying in. Every nurse on watch carries a copy of the list. The patient list summarizes information about the patient's diagnosis, type of treatment, and report, that is, recent information that might be relevant for nurses (as shown in Figure 1). It is a tool for planning, coordinating, distributing, delegating, and communicating.

A new list is assembled during each night watch. A fresh copy of the patient list is given to all nurses starting a new watch. During their watch, the nurses use the patient list to record information regarding things that happen. Upon change of watch, in order to hand over tasks and information, a briefing meeting is held with the nurses ending their watch and those starting a new watch. Nurses actively use the patient list during these meetings (sometimes supported by other documents). Nurses finishing the watch use their personal patient list as a reference. Nurses starting their watch take notes on their own blank copy while listening to the brief. All the patients at the ward are reported on, and at the end of the brief, all nurses have information about the patients. Moreover, they all have written down the distribution of responsibility on the patient list. Afterward, they go about doing their duties in the ward with the patient list nicely folded into their pockets. Frequently during the watch, they pick up the list to make sure that they are on schedule. Furthermore, the list is used as a reference point during discussions, meetings, and so on.

Constructing Knowledge by Interplaying, Tinkering, and Enacting

The patient list itself seems like a rather poor representation of patients. It is assembled from

Figure 1. A section of the patient list (fabricated for visualisation purposes only)



a myriad of different, richer representations. What, then, makes its way from these richer representations into the patient list? During the night watch, a software program assembles the list. This program delegates the task of providing information to the nurses. It determines what information the nurses are expected to provide. Still, it presents a limited number of fields to fill. Once the nurses have provided the software with the required information, the patient list is assembled. Knowledge is in this sense distributed between the nurses, the software, and the patient list. What is it then that decides what information is extracted from the different representations? Is it the fields provided by the software? Is it the nurses who determine what goes into these fields? There is an interplay between the nurses and the software: in effect, an integration process. In deciding what should go into the different fields, the nurses fluctuate between glimpsing into the patient record, asking colleagues, and memorising. In this sense, filling out the form is a process of tinkering (searching, combining, reducing, and writing down). Furthermore, what eventually becomes engraved into the patient list is based on a process of enactment based on different knowledge representations. According to Ellingsen and Monteiro (2003), in rendering knowledge credible, relevant, and trustworthy, knowledge representations have to be enacted.

Reconstructing Meaning by Telling Stories and Circulating

In the briefing meeting, the reporting nurses (accompanied by the patient list) are themselves highlighting certain parts of what has happened during their watch. The report takes form as a story, structured by the list and told by the nurse. Stories, the patient lists remade by the nurse, act as repositories of accumulated wisdom, and it allows people to keep track of the sequence of behaviour and their wisdom (Brown & Duguid, 1991; Orr, 1996). Storytelling thus serves as a mechanism for integrating knowledge. Furthermore, the stories are not only shared in the briefing meeting, but they circulate, partly by means of the patient list, partly by means of nurses' encounters and so forth.

Circulation can also be seen as the way the patient list travels as a template among the nurses. The list is easy to replicate and thus easy to circulate. In this way, knowledge about nursing, as manifested in the patient list, can circulate and spread. Furthermore, the list has an organising effect, having the power to organise a large number of workers (see Turnbull, 1993).

Knowing as a Sociotechnical Interaction

In the latter part of this analysis, we look closer into the details of the list (see Figure 1). What does the patient list know? By taking a brief look at it, the list can tell nurses which rooms and bed are available. In the figure, the list tells us that Bed 1 in Room Number 10 is available. Furthermore, the list does not give Petter any diagnosis, but tells us that the he is waiting for an examination. For Lise Nordvik, the situation is more clear-cut: The list tells us of a diagnosis and that the patient is admitted to the hospital for observation.

The way that the nurse interacts with the patient list regulates and coordinates the action that can be taken. For example, a new patient should be admitted to Bed 1 in Room 10. The list tells nothing about Petter's diagnosis. The nurse might want to consult a physician before giving him any medication. The patient list tells nurses that Lise has been here before and that this patient knows her way around, but that the nurses must keep an eye on her regularly. All three cases illustrate that interaction does not solely take place between people mediated by artefacts. Rather, interaction can often be identified as something happening between humans and artefacts. Artefacts and humans have knowledge about different aspects of the ward and its patients, and it is in the interaction that this knowledge becomes usable. Action is the result between the social and the material, and the integration is not observable in itself, only the resulting practice.

CONCLUSION

This article has addressed the concept of knowledge integration. We have described how a practice-based perspective provides an extension of the seminal work on knowledge integration by Grant (1996). In our practice-based approach, we have emphasised the role of artefacts not only as mediators of human action, but as active participants in shaping that same action. By providing an example from health care—the patient list, an A 4-format template created by nurses and used in different settings at a hospital ward—we have highlighted the relational interplay between artefacts and humans in work performance. Tinkering, enacting, storytelling, circulation, and sociotechnical interaction have been identified as mechanisms for integrating knowledge.

The main contribution of this article is the proposal for a practice-based perspective on knowledge integration where specialisation, as traditionally being located only within humans, is challenged. We have emphasised the need to look beyond the pure representational aspects and also attend to the interactive roles of tangible arrangements (e.g., paper). This makes it imperative to be explicit on the role of artefacts in work performance because it plays such an important part in our understanding of collaboration and work. As we have demonstrated, the patient list plays an active role in structuring and coordinating work (see also Fitzpatrick, 2000). Furthermore, paper in itself provides rich support for collaborative work: It can help us gain knowledge of how technology might be better designed (Sellen & Harper, 2002). In health care, for instance, any move to introduce IT impacts the very nature of that care, so if we do not have a profound understanding of the richness and complexity in the accomplishment of that work, we will not be able to design effective systems that will fit with the work (Fitzpatrick, 2000).

Traditionally, when specifying requirements for knowledge management systems, conventional interview techniques are employed to portray existing work arrangements. In other words, work is specified as presented by the human workers. The problem then is that they (the human workers) are not consciously aware of the interactive role artefacts play in performing work. As artefacts do not talk back, conventional interview techniques need to be supplemented with additional ethnographic techniques to enable technology designers to look beyond the pure representational aspects of tangible arrangements. However, technology designers do not have the professional competence of ethnographers, so there is a need to provide them with guidelines to simplify the effort needed.

Another issue that naturally comes out of this article is the understanding of how users themselves actually design their own work practices in the usage of artefacts. For instance, in health care, organisational decisions on what kind of general types of information systems to implement have already been made (e.g., the electronic patient record, picture archive and communication system, etc.). Thus, future research needs to attend to the domestication of technology, that is, how to effectively integrate it into different work environments. This implies not only an understanding of how technology needs to be designed, but also of how existing work arrangements need to be adjusted.

Chapter 1.22
Knowledge Representation

Gian Piero Zarri
University of Paris IV/Sorbonne, France

INTRODUCTION

In 1982, Allen Newell introduced the "knowledge level" principle (Newell, 1982) and revolutionized the traditional way of conceiving the relationships between knowledge management and computer science. According to this principle, the knowledge level represents the highest level in the description of any structured system: Situated above and independent from the "symbol level," it describes the observed behaviour of the system as a function of the knowledge employed, and independently of the way this knowledge is eventually represented/implemented at the symbol level. "The knowledge level permits predicting and understanding behaviour without having an operational model of the processing that is actually being done by the agent" (Newell, 1982, p. 108). An arbitrary system is then interpreted as a rational agent that interacts with its environment in order to attain, according to the knowledge it owns, a given goal in the best way; from a strict knowledge level point of view, this system is then considered as a sort of "black box" to be modeled on the basis of its input/output behaviour, without making any hypothesis on its internal structure. To sum up, the knowledge level principle emphasises the why (i.e., the goals), and the what (i.e., the different tasks to be accomplished and the domain knowledge) more than the how (i.e., the way of implementing these tasks and of putting this domain knowledge to use).

BACKGROUND

The emergence of the knowledge principle produced a shift of emphasis, in the (computerized) knowledge management domain, from a pure "representational" attitude to a "modeling" one, that is, a shift from the production of tools for implementing the knowledge a system will use to that of tools for building up models of the behaviour of the system in terms of that knowledge. An example of this is the Knowledge Acquisition and Design Structuring (KADS) methodology (Schreiber, Wielinga, & Breuker, 1993; Schreiber, Akkermans, Anjewierden, de Hoog, Shadbolt, Van de Velde, & Wielinga, 1999). A fundamental step in the KADS approach is, in fact, the set up of a general "conceptual model" of the system, which an observer (a knowledge engineer) creates by abstracting from the problem-solving behaviour of some experts. According to the knowledge principle, the conceptual model does not include any detailed constraint about the implementation level. This last function is assigned to the "design model," which corresponds to the (high level) specifications of the final knowledge-based system (KBS), and which represents the transformations to be executed on the conceptual model when we take into account the external requirements (e.g., specialised interfaces, explanation modules, etc.). The conceptual model is built up according to a four-layer structured approach: Each successive layer interprets the description given at the lower layer. A first layer concerns the "static domain knowledge," that is, the domain concepts and their attributes, the domain facts, the structures representing complex relations, and so forth. The static knowledge can be viewed as a declarative theory of the domain. A second type of knowledge concerns the "knowledge sources" and the "metaclasses." A knowledge source is defined as an elementary step in the reasoning process (an inference) that derives new information from the existing one; KADS presupposes the existence of a set of canonical inferences such as "abstraction, association, refinement, transformation, selection, computation." Metaclasses describe the role that a group of concepts plays in the reasoning process (e.g., observable, hypothesis, solution, etc.). The third layer contains knowledge describing how inferences can be combined to fulfill a certain goal, that is, how to achieve operations on metaclasses. The most important type of knowledge in this category is the "task": A task is a description of a problem-solving goal or subgoal, as "diagnose a patient with these particular symptoms." The fourth category of knowledge is the "strategic knowledge," which settles the general goals that are relevant to solve a particular problem; how each goal can be achieved is determined by the task knowledge.

One of the main attractions of this structured, analytical approach to the automation of knowledge management resides in the fact that all the methodologies based implicitly or explicitly on the knowledge level principle embrace the idea that the set up of KBSs can be facilitated by the development of libraries of reusable components. These pertain mainly to two different classes, (1) reusable "ontologies" (see also Zarri, "RDF and OWL" in this Volume) and (2) reusable problem-solving methods, which define classes of operations for problem-solving. Chandrasekaran (1990) is one of the first to suggest the development of reusable components under the form of "generic tasks," where a generic task defines both a class of application tasks with common features, and a method for performing these tasks.

An additional manifestation of this general tendency toward generalisation, abstraction, and reuse in the knowledge management domain are the activities aimed at the construction of general and reusable "corporate memories," (see van Heijst, van der Spek, & Kruizinga, 1996; Brooking, 1998; Beckett, 2000). Knowledge has been recognised as one of the most important assets of an enterprise and a possible success factor for any industrial organization, on the condition that it can be controlled, shared, and reused in an effective way. Accordingly, the core of the organization can then be conceived under the form of a general and shared organizational memory, that is, of an online, computer-based storehouse of expertise, experience, and documentation about all the strategic aspects of the organization. The construction and practical use of corporate memories becomes then the main activity in the knowledge management of a company, a focal point where several computer science and artificial intelligence disciplines converge: knowledge acquisition (and learning), data warehouses, database management, information retrieval, data mining, case-based reasoning, decision support systems, querying (and natural language querying) techniques, and so forth.

A clear discrimination between "knowledge" and "symbol" level is often not so easy to attain. For example, some methodologies that make reference to the knowledge level principle go in reality against Newell's approach because the structure they impose on the knowledge is a function of how a specific class of applications is implemented and dealt with, and the models they produce are then valid only in a very specific context. On a more pragmatic level, reuse can be very difficult to obtain, because there is often a significant semantic gap between some abstract, general method, and a particular application task. Moreover, discovering and formalising a set of elementary tasks independently from any specific application domain is a particularly hard endeavour which meets all sort of embarrassing problems, ranging from the difficulties in defining the building blocks in a sufficiently general way to the ambiguities concerning which aspects (the model or the code) of the blocks can really be reused. This explains why a (not trivial) number of "pure" knowledge-level proposals are still theoretical proposals, characterised by a limited implementation effort.

Indiscriminate use of the "modeling" approach risks forgetting that the basic technological support for implementing effective knowledge management is nevertheless provided by the knowledge representation (and processing) techniques. The building blocks, the generic tasks, the reusable modules, the shareable ontologies, and so forth must be formalised using one or more of the ordinary knowledge representation techniques developed in the last 50 years such as rules, logic, or frames. In this article, knowledge management will then be seen essentially as an application of the usual knowledge representation (and processing) techniques: creating and using, for example, large corporate memories requires that, first off all, the knowledge be represented, store,d and computer-managed in a realistic and efficient way.

TYPES OF KNOWLEDGE REPRESENTATION SYSTEMS

"Knowledge is power!" according to the well-known slogan spread abroad by Edward Feigenbaum—more precisely, Feigenbaum stated that: "...the power...does not reside in the inference method; almost any inference method will do. The power resides in the knowledge" (Feigenbaum, 1984, p. 101). Reviewing the different solutions for representing knowledge proposed in these last 50 years, we can isolate two main groups:

- The "symbolic" approach. This is characterised by (1) the existence of a well-defined, one-to-one (bijective) correspondence between all the entities of the domain to be modeled (and their relationships) and the symbols used in the knowledge representation language, and (2) by the fact that the knowledge manipulation algorithms (inferences) take explicitly into account this correspondence.
- The "soft programming" approach. Here, only the input and output values have an explicit, bijective correspondence with the entities of a given problem to be modeled. For the other elements and factors of the problem, (1) it is often impossible to establish a local correspondence between the symbols of the knowledge representation system and such elements and factors; (2) the resolution processes are not grounded on any explicit correspondence notion; (3) statistical and probabilistic methods play an important part in these resolution processes.

Given the present popularity of "ontologies" (a sort of symbolic approach) in all the domains requiring the concrete application of knowledge representation tools—including the knowledge management context, (e.g., Staab, Studer, Schnurr, & Sure, 2001)—it is very likely that knowledge management specialists will have to make use of symbolic (ontological) tools in the practice of their discipline. On the other hand, (1) information about soft systems is, apparently, less omnipresent than its symbolic counterpart in the knowledge management literature, and (2) bio-inspired intelligent information systems are broadly seen as one of the next frontiers of computer science. We will then supply here some (very limited) information about soft systems and an essential bibliography. For an in-depth discussion of the symbolic approach (see Bertino, Catania, & Zarri, 2001, p. 105-170; Zarri, "RDF and OWL" in this Volume).

THE SOFT PROGRAMMING PARADIGM

Neural Networks

Neural networks represent probably the most well-known example of soft programming paradigm. As genetic algorithms, their inner model can be considered as (loosely) "biologically inspired." More than on a loose analogy with the organisation of the brain—in this contest, only the (very simplified) concepts of "neuron" and "synapse" have been preserved—the biological foundations of neural networks reside in the self-organising principles that are characteristic of living systems. When a threshold number of interconnections (synapses) have been established between a set of neurons—and if the network has been carefully "programmed"—a form of self-organising activity appears that allows an external observer to affirm that the network "learns": it learns, for example, to associate a pattern with another, to synthesise a common pattern from the set of examples, to differentiate among input patterns and so forth where "pattern" must be understood here according to its more general meaning.

A neural network is made up of several "layers," where any number of neurons (processing units) can be present in each of the layers. Each neuron maps the inputs received from all the other neurons situated in a lower layer (or some external stimuli) to a one-dimensional output. This last is a function, among other things, of the "weights" associated with the connections (synapses) between the neurons in layer n and neurons in layer n-1, that is, of the "strength" of these connections. "Learning" is normally implemented by modifying the weights of the connections: For example, the "backpropagation method" consists in adjusting the weights making use of the difference, for a given distribution of input values, between the desired output values of the network and the values really obtained. Using then a training set made up of couples of input-output patterns, the weights are cyclically modified so that the differences are eventually minimised according, for example, to a least-squares sense. See Wasserman (1989) and Anderson (1995) for a detailed account of neural networks' theory.

Neural networks are particularly useful for capturing associations or discovering regularities within a set of patterns, especially when (1) the number of variables or the diversity of data is very great, and (2) the relationships between the variables are not well understood and, therefore, are difficult to describe using traditional (symbolic) methods. Accordingly, "classical" applications of neural networks concern banking (credit scoring, recovery scoring, forecasting the behaviour of new costumers, identifying "good risks"), financing (predicting share prices and volatilities, portfolio and asset management), industry (predicting demand for a product or a service, servo-control for machines or chemical reactors), marketing (marketing and mailing targeting, turnover prediction, data mining), public administration (analysis and prediction of crime, tax fraud detection, economic forecasting), and so forth. In these domains, neural network present, with respect to the corresponding "symbolic solutions," the fundamental advantage of freeing the knowledge engineer from the necessity of constructing a faithful "model" of the situation at hand, and of formatting correspondingly the data: with neural networks, the model is already there, even if it must be appropriately tuned (learning). Moreover, at the difference of many symbolic solutions, neural networks are relatively insensible to missing or erroneous values. On the other hand, neural networks—because of the lack of a one-to-one correspondence between entities to be modeled and symbols—are "black boxes" that do not explain their decisions. Moreover, their possible domains of applications are surely limited in number with respect to those where a symbolic approach can be appropriate.

Genetic Algorithms

Darwinian evolution—based on the principle of the "only the strongest survive strategy"—characterises the biological metaphor that is behind the creation of the genetic algorithms (GAs). According to this strategy, individuals compete in nature for food, water, and refuge, and for attracting a partner: The most successful individuals survive and have a relatively large number of offsprings. Their (outstanding) genetic material will then be transmitted to an increasing number of individuals in each successive generation; the combination of such outstanding characteristics ("chromosomes" or "genotypes") will be able to produce individuals whose suitability ("fitness") to the environment will sometimes transcend that of their parents. In this way, species can evolve—John Holland (Holland, 1975) and his colleagues of the University of Michigan are unanimously recognized as the first researchers to have envisaged the utilization of this strategy to solve the usual computer science problems.

The first step in the utilisation of the GAs approach consists then in the creation of a "population" of individuals (from a few tens to a few hundreds) that are represented by "chromosomes" (sometimes called "genotypes"). From the point of view of the problem to be solved, each chromosome represents a set (list) of parameters that constitutes a potential solution for the problem: for example, in a problem requiring a numerical solution, a chromosome may represent a string of digits; in a scheduling problem, it may represent a list of tasks; in a cryptographic problem, a string of letters, and so forth. Each item of the list is called a "gene." Traditionally, the parameters (genes) are coded using some sort of binary alphabet (i.e., a chromosome takes the form of a string of n binary digits).

The initial population is then modified and "improved" making use of two genetic operators, "crossover" and "mutation." Crossover takes two selected individuals, the "parents," and cuts their gene strings at some randomly (at least in principle) chosen position, producing two "head" and two "tail" substrings. The tail substrings are then switched, giving rise to two new individuals called "offsprings," which inherit some genes from each of the parents: The offsprings are then created through the exchange of genetic material. Mutation is applied to the offsprings after crossover, and consists into a random modification of the genes with a certain probability (normally a small one, e.g., 0.0001) called the "mutation rate." Note that mutation—that can be conceived, in biological terms, as an error in the reproduction process—is the only way to create truly new individuals (crossover makes use of already existent genetic material).

Genetic algorithms are part of a wider family of biologically inspired methods called in general "evolutionary algorithms," which are search and optimisation procedures all based on the Darwinian evolution paradigm evoked here, and consisting then in the simulation of the evolution of particular individuals through the application of processes of selection, reproduction, and mutation. Apart from GAs, other evolutionary methodologies are known under the name of “Evolution Strategies,” “Evolutionary Programming,” “Classifier Systems,” and “Genetic Programming.” Genetic Programming domain has emerged in these last years as particularly important. Genetic Programming can be seen as a variation of GAs where the evolving individuals are computer programs instead of chromosomes formed of fixed-length bit strings; when executed, the programs supply then a solution of the given problem (see Koza, 1992). In Genetic Programming, programs are not represented as lines of ordinary code, but rather as “parse trees” corresponding to a coding syntax in prefix form, analogous to that of LISP. The nodes of the parse trees correspond then to predefined functions (“function set”) that are supposed to be appropriate for solving problems in general in a given domain of interest, and the leaves (i.e., the terminal symbols) correspond to the variables and constants (“terminal set”) that are proper to the problem under consideration. Crossover is then implemented by swapping randomly selected sub-trees among programs; mutation, normally, is not implemented.

The classical reference in the GAs field is still Goldberg (1989); a good introductory book is Mitchell (1998).

Fuzzy Knowledge Representation Techniques

The fuzzy logic paradigm also is based on some sort of biologically inspired approach, even if the analogy looks less evident. It is related to the fact that fuzzy logic intends to simulate the way humans operate in ordinary life, that is, on a continuum, and not according a crisp “nothing-or-all” Aristotelian logic. Humans use some forms of gradually evolving linguistic expressions to indicate that, with respect to a given thermal environment, they are “comfortable,” “cold,” or “freezing.” Fuzzy logic allows to quantify such “fuzzy” concepts, and to represent then our sensations about temperature making use of numeric values in the range of 0 (e.g., “comfortable”) to 1 (e.g., “freezing,” with 0.7 representing then “cold”).

More precisely, according to the “fuzzy sets” theory—this theory, introduced by Zadeh (1965) makes up the core of the fuzzy logic paradigm (see also, in this context, Zimmerman, 1991; Kosko, 1992)—every linguistic term expressing degrees of qualitative judgements, like “tall, warm, fast, sharp, close to,” and so forth corresponds to a specific fuzzy set. The elements of the set represent then different “degrees of membership,” able to supply a numeric measure of the congruence of a given variable (e.g., temperature) with the fuzzy concept represented by the linguistic term.

Knowledge representation according to the fuzzy logic approach consists then in the computation, for a collection of input values, of their degree of membership with respect to a group of fuzzy sets. For a fuzzy application dealing with a temperature regulation system, the fuzzy sets to be considered for the variable “temperature” will be “cold,” “cool,” “comfortable,” “warm,” and “hot.” The process allowing us to determine, for each of the inputs, the corresponding degree of membership with respect to each one of the defined sets is called “fuzzification”; the degrees are calculated making use of appropriate “membership functions” that characterise each one of the sets. In this way, an input value of 83° F will be translated into two fuzzy values, 0.2 which represents the degree of membership with respect to the fuzzy set “hot,” and 0.8 representing the degree of membership with respect to the fuzzy set “warm,” (see Viot, 1993 for the technical details). Imprecise, approximate concepts like “warm” and “hot” are then translated into computationally effective, smooth, and continuous terms.

The fuzzy logic paradigm is widely used in industrial applications, especially for systems without a precise mathematical model and characterised by a high level of uncertainty. These applications range from household appliances such as dishwashers and washing machines that make use of fuzzy logic to find out the optimal amount of soap and the correct water pressure, to self-focusing cameras and embedded micro-controllers. Fuzzy logic also is used in special kinds of expert systems like decision support systems and meteorological forecast systems.

The Symbolic Paradigm

Knowledge representation systems that follow the symbolic approach range between two possible basic forms (as usual, mixed forms are possible):

- Pure rule-based representations supporting inference techniques that can be assimilated to first order logic procedures (inference by resolution). Within this first pole, is at least pragmatically useful to distinguish between the systems developed in a logic programming context and the simplest Expert Systems based on the standard production rules paradigm.
- Pure frame- or object-based representations supporting inference by inheritance, and also admitting defaults and procedural attachment. A particular class of inheritance-based systems that are today particularly fashionable are the ontology-based systems and their formal counterpart, the description logics (terminological logics) systems.

The Rule-Based Approach

Expression (a) below represents a so-called “Horn clause” (named after Alfred Horn, who first investigated their properties), that is, a kind of well-formed formula (wff) of the first-order predicate calculus characterised by the fact of having at most one positive “literal,” ‘A.’ Horn clauses are particularly important in artificial intelligence because they represent the basis of the logic programming paradigm and constitute the formal framework of programming languages like PROLOG and DATALOG.

$$A \vee \neg B1 \vee \neg B2 \ldots \vee \neg Bn \qquad n \geq 0 \qquad (a)$$

Applying to (a) a series of logical transformations based, inter alia, on the well-known de Morgan’s laws, formula (a) can be transformed into (b)—(see Bertino, Catania, & Zarri, 2001, pp. 112-113)—where ‘∧’ represents now the “conjunction” or “logical and” symbol, and ‘⊃’ is the “implication” symbol.

$$(B1 \wedge B2 \ldots \wedge Bn) \supset A \quad n \geq 0 \qquad (b)$$

Making use of the standard notation for representing implication, we can write (b) as (c), where the arrow ‘→’ is the connective “if” representing the implication and a “comma” still represents a “logical and”:

$$B1, B2, \ldots Bn \rightarrow A \qquad n \geq 0 \qquad (c)$$

In (c), B1 … Bn is now the “antecedent,” or the “conditions,” of the implication, and A is the “consequent” or the “conclusion.” Therefore, formula (c) states that, if the different conditions B1, B2, …, Bn are all verified (TRUE), they imply the conclusion A; we can write (c) succinctly as:

If B Then A. (d)

Formula (d) corresponds to the well-known notation used for the “production rules” that still constitute one of the basic operational tools used in all sort of artificial intelligence, cognitive science, knowledge management and Semantic Web applications. Their derivation from “classical” first order logic sketchily outlined is very important, given that the theory of production rule can then be easily brought back to the well-known formal context proper to theorem proving (resolution principle) and logic programming, (see Bertino, Catania, & Zarri, 2001, p. 107-122). Note, however, that production rule systems can only implement a reduced subset of the full first order logic.

The functioning of a typical "expert system" (ES) that makes use of production rules can be described as follows:

- The system includes a "rule base," that is, an unordered collection of production rules having the format of (c). We give now to the Bi the meaning of "conditions" (facts) that must be satisfied, and to A the meaning of the "action/actions" that must be performed if the conditions are satisfied. The Bi represent the "left-hand side" (LHS) of the rule r, A the "right-hand side" (RHS).
- The system also includes a "working memory" (WM) where the facts submitted are stored as input to the system or automatically inferred during its functioning.
- During its functioning, the system repeatedly performs a "recognise-act" cycle, which can be characterised as follows in the case of "condition-driven" or "forward-chaining" ESs:
    - In the "selection phase," for each rule r of the rule base, the system: (1) determines whether LHS(r) is satisfied by the current WM contents, that is, if LHS(r) matches the facts stored in the WM ("match subphase") and, if so, (2) it adds the rule r to a particular rule subset called the "conflict set" (CS) ("addition subphase"). When all the LHS are false, the system halts.
    - In the "conflict resolution phase," a rule of the CS is selected for execution. If it is impossible to select a rule, the system halts.
    - In the "act phase," the actions included in RHS(r) are executed by the interpreter—this is often called "firing a rule." Firing a rule will normally change the content of WM and, possibly, the CS. To avoid cycling, the set of facts ("instantiation") that has instantiated the LHS variables of the fired rule becomes ineligible to provoke again the firing of the same rule, which, of course, can fire again if instantiated with different facts.

A way of schematising the recognise-act cycle is represented in Figure 1. The name of "conflict set" is due to the fact that, amongst all the competing selected rules that are in agreement with the current state of WM, it is necessary to choose the only rule to be executed by the interpreter in the current cycle—choosing and executing multiple rules is possible, but more complex. The specific procedures to be implemented for performing the resolution of the conflicts depend on the application, and can be very complicated, given that the execution of a rule may lead other rules to "fire," or on the contrary, prevent their firing and so forth. It is then possible to make use of user-defined priorities: The user is allowed to choose a particular strategy, such as giving preference to rules that operate on the most recent information added to WM, or that match the highest number of items, or the most specific rule, the one with the most detailed LHS that matches the current state of WM. It is also possible to make use of predefined criteria for ordering the rules, which may be static (i.e., a priority ordering is assigned to the rules when they are first created) or dynamic.

Production systems can be classified into two different categories according to the way rules are compared with data of WM. When the comparison is between LHS(r) and WM as illustrated in Figure 1, we have the "condition-driven" or "forward-chaining" systems). But it is also possible to compare RHS(r) with WM ("action-driven," or "backward-chaining" systems). An example of a backward-chaining system is given by MYCIN, a software designed to perform medical diagnosis (prescribe antibiotic therapy) in the field of bacterial infections that represents one of the best known and historically important expert system (see Shortliffe, 1976). More details can be found in Bertino, Catania, & Zarri (2001, p. 125-131).

The Inheritance-Based Approach

Inheritance is one of the most popular and powerful concepts used in the artificial intelligence and knowledge representation domains. It represents, at the same time:

- Static: A static structuring principle that allows to group together similar notions in classes, and to economise in the description of some attributes of the entities of the low-level classes because these descriptions can be inherited from the entities of the high-level classes;
- Dynamic: A dynamic inferencing principle that allows to make deductions about the properties (attributes) of the low-level entities that are a priori unknown because these properties can be deduced from those that characterise the high-level entities—with the well-known problems linked with the fact that, for example, "penguins" and "ostriches" pertain to the class "birds," but they cannot inherit from the description of this general class the property "can_fly";
- Generative principle: A generative principle that allows to define new classes as variants of the existing ones: The new class inherits, in fact, the general properties and behaviours of the parent class, and the system builder must only specify how the new class is different.

The inheritance principle is normally used to set up hierarchies of "concepts"—"ontologies" or "taxonomies," where the first are differentiated from the second because they add to the plain description of the hierarchical links among the concepts also an explicit definition/description of these concepts. Ontologies/taxonomies are then structured as inheritance hierarchies making use of the well-known IsA link—also called AKindOf (Ako), SuperC, and so forth (see Figure 2). A relatively unchallenged—see however, Brachman,

Figure 1. The "recognise-act" cycle

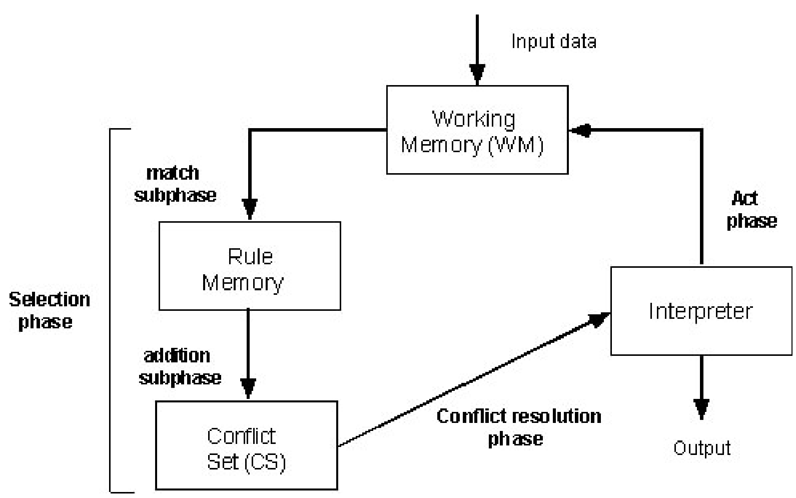

Figure 2. A simple inheritance hierarchy

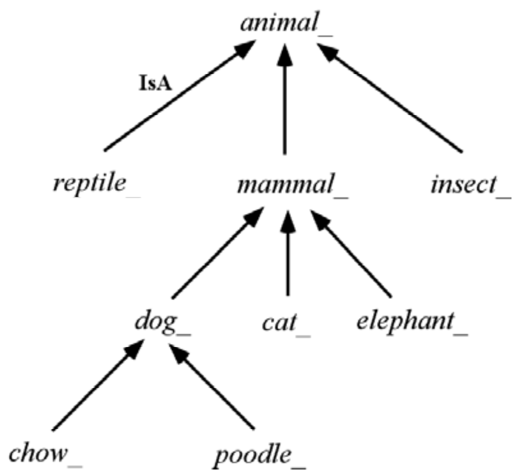


(1983)—semantic interpretation of IsA states of this relationship among concepts, when noted as (IsA B A), means that concept B is a specialisation of the more general concept A. In other terms, A subsumes B. This assertion can be expressed in logical form as:

$\forall x\ (B(x) \rightarrow A(x))$; (e)

(e) says that, if any elephant_ (B) IsA mammal_ (A), and if clyde_ is an elephant_, then clyde_ is also a mammal_—as usual, the concepts_ are written down in italics, and their instances_ (e.g., clyde_, an "individual") in roman characters. When (e) is interpreted strictly, it also implies that a given concept B and all its instances must inherit all the features (properties) and their values of all the concepts Ci in the hierarchy that have B as a specialization; we speak in this case of "strict inheritance." Note that, under the strict inheritance hypothesis, totally new properties can be added to B to differentiate it (specialize it) with respect to its parents.

Relation IsA is transitive: This means that, for example, having both $\forall x\ (C(x) \rightarrow B(x))$ and $\forall x\ (B(x) \rightarrow A(x))$, we can deduce from this that $\forall x\ (C(x) \rightarrow A(x))$. This property is particularly important because it allows, in an inheritance hierarchy like that of Figure 2, to represent explicitly only the IsA relationships that associate directly two nodes (i.e., without the presence of intermediary nodes). All the residual IsA relationships are then explicitly derived only when needed: For example, from Figure 2 and from the transitive property of IsA, we can explicitly assert that (IsA chow_ mammal_).

The necessary complement of IsA for the construction of well-formed hierarchies concerns some form of InstanceOf link, used to introduce the "instances" (concrete examples) of the general notions represented by the concepts. The difference between (IsA B A) and (InstanceOf C B) is normally explained in terms of the difference between the two options of (1) considering B as a subclass of A in the first case, operator '$\subset$', and (2) considering C as a member of the class B in the second, operator '$\in$'. Unfortunately, this is not sufficient to eliminate any ambiguity about the notion of instance, which is much more controversial than that of concept. Problems about the definition of instances concern: (1) the possibility of accepting that concepts (to the exclusion of the root) could also be considered as "instances" of their generic concepts; (2) the possibility of admitting several levels of instances, that is, instances of an instance. For a discussion about these problems and the possible solutions, see Bertino, Catania, and Zarri (2001, p. 138).

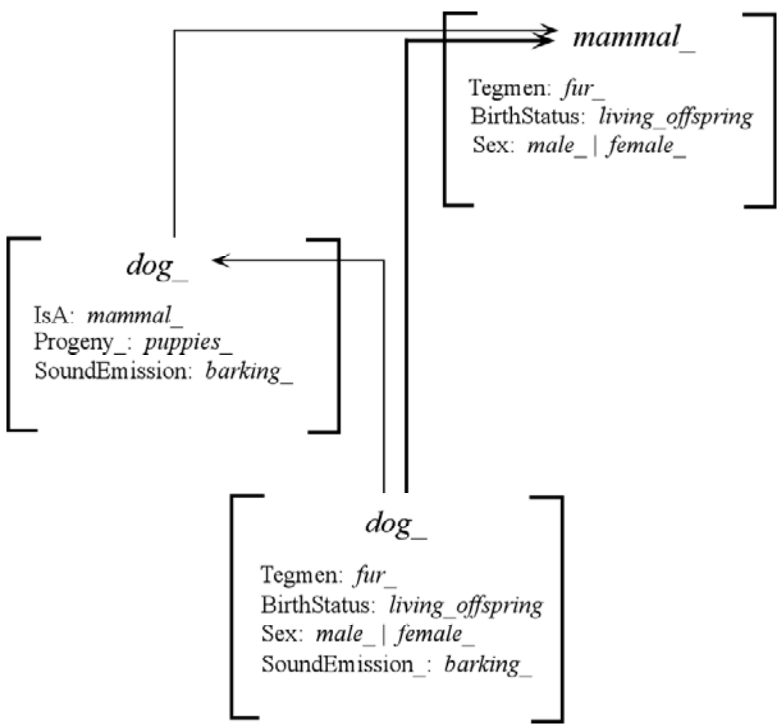
We can now associate to any concept a "structure" (a "frame") to reflect the knowledge human beings have about (1) the intrinsic properties of these concepts and (2) the network of relationships, other than the hierarchical one, the concepts have each other. As already stated, we are now totally in the "ontological" domain, and this sort of frame-based ontologies can be equated to the well-known "semantic networks" (see Lehmann, 1992).

Basically, a "frame" is a set of properties, with associated classes of admitted values, that is linked to the nodes representing the concepts. Introducing a frame corresponds then to establishing a new sort of relationship between the concept Ci to be defined and some of the other concepts of the ontology. The relationship concerns the fact that the concepts C1, C2 … Cn used in the frame defining Ci indicate now the "class of fillers" (specific concepts or instances) that can be associated with the "slots" of this frame, the slots denoting the main properties (attributes, qualities, etc.) of Ci. There is normally no fixed number of slots, nor a particular order imposed on them; slots can be accessed by their names.

Figure 3 (an "ontology") reproduces a fragment of Figure 2 (a "taxonomy") where the concepts are now associated with their (highly schematized) defining frames—note that the two fillers male_ | female_ also could have been replaced by their subsuming concept sex_. This figure makes explicit what "inheritance of properties/attributes" means: Supposing that the frame for mammal_ is already defined, and supposing now to tell the system that the concept dog_ is characterised by the two specific properties Progeny and SoundEmission, what the frame dog_ really includes is represented in the lower part of Figure 3.

Even if, under the influence of the Semantic Web work (see Zarri, "RDF and OWL" in this Volume), the "classic" frame paradigm sketched here is moving toward more formalized, logic-based (and XML/RDF-based) types of representation, nevertheless this paradigm still constitutes the foundation for the setup of a large majority of knowledge repositories all over the world;

Figure 3. A simple example explaining the "inheritance of properties/attributes"



often, a knowledge base is nothing more than a "big" ontology formed of concepts/individuals represented under the form of frames. The most well-known tool for the setup of large knowledge bases making use of the frame model is Protégé-2000, developed for many years at the Medical Informatics Laboratory of the Stanford University (California, USA) (e.g., Noy, Fergerson, & Musen, 2000; Noy, Sintek, Decker, Crubezy, Fergerson, & Musen, 2001). Protégé-2000 represents today a sort of standard in the frame-based ontological domain.

FUTURE TRENDS

Knowledge representation systems that follow the "soft programming" paradigm are expected to evolve into the new "bio-inspired intelligent information systems." These are systems capable of extracting meaning associated to complex patterns of sensor stimuli and of generating well coordinated sequences of elementary actions complying with a set of higher level goals. The systems should show autonomous growth in perceptual, motor, and cognitive abilities. Examples can concern the construction (1) of hardware/software "artifacts that live and grow" (ALGs), that is, artifacts that self-adapt and evolve beyond pure programming, and (2) of perception-response systems (PRSs) inspired by the sophistication of solutions adopted by living systems, where "perception" refers to the sensorial, cognitive, and control aspects (covering vision, hearing, or any other modalities) used by the biological organisms to interact with the environment.

With respect now to the "symbolic approach," the most up-to-date rule-based systems are those used in a Semantic Web context (see Zarri, "RDF and OWL" in this Volume). In the inheritance- and frame-based domain, Protégé-2000 is still the de facto standard; on a more theoretical level—and thanks at least partly, once again, to the success of the Semantic Web research—description logics (DLs) have gained particular importance in these last years. DLs (Baader, Calvanese, McGuinness, Nardi, & Patel-Schneider, 2002) are an axiomatized, inheritance-based system characterised by the presence of a mechanism for the automatic classification of concepts as its main reasoning component. One of the main reasons for the introduction of DLs has been the wish to offer a formal and logically-sound foundation for frame-based systems (see Minker & Grant in this Volume).

CONCLUSION

In this article, we started with the fundamental revolution in the relationships between knowledge management and computer science that followed the introduction of the "knowledge level" principle, and of the new emphasis on the "modeling" principles that resulted from that. Notwithstanding the corresponding, indisputable progresses at the theoretical and methodological level, we have then shown that the adoption of the knowledge level principle does not eliminate the need—when creating and using, for example, large organizational memories—for making certain that the required "knowledge" be represented, stored, and computer-managed in a realistic and efficient way. Knowledge representation represents then one of the key, enabling factors for knowledge management.

Confronted with the choice of selecting specific knowledge representation tools, we must choose between two conflicting paradigms, the "symbolic" approach—where there is a precise, one-to-one correspondence between the entities of the domain to be dealt with and the symbol intended to represent them – and the "soft programming" approach, where this correspondence is totally blurred. In a knowledge management context, the symbolic paradigm ("ontologies") seems to be, presently, the predominant one; given, however, the importance that the new "bio-inspired intelligent information systems"—an evolution of the "soft programming" approach—should have in the future, the soft programming techniques (neural networks, genetic algorithms, and fuzzy logic) are of growing importance.

Chapter 1.23
External Knowledge Integration

Jeroen Kraaijenbrink
University of Twente, The Netherlands

Fons Wijnhoven
University of Twente, The Netherlands

INTRODUCTION

As an academic field, knowledge management has concentrated on the creation, storage, retrieval, transfer, and application of knowledge within organizations, while underexposing external knowledge (e.g., Alavi & Leidner, 2001). Although the importance of external knowledge is well recognized (e.g., Cohen & Levinthal, 1990), there remains a need for a better understanding of the organizational processes through which external knowledge is integrated (Grant, 1996; Ranft & Lord, 2002). In particular, we believe that a holistic view on knowledge integration (KI) is both important and lacking. In this article, we address this lacuna in the literature by proposing a process model of KI consisting of three stages—identification, acquisition, and utilization of external knowledge. Our objective is to propose a model consisting of modular subprocesses that parsimoniously reflect the variety of KI concepts in the literature. This model is useful to scholars and practitioners because it provides a better understanding of the various KI subprocesses by putting them together in a coherent way. Such understanding serves as bedrock for solving KI problems and for designing KI solutions (cf. Markus, Majchrzak, & Gasser, 2002).

BACKGROUND

In the current literature, the term KI is used for the integration of knowledge from individuals or departments within an organization (Becerra-Fernandez & Sabherwal, 2001; De Boer, Van den Bosch, & Volberda, 1999; Grant, 1996; Leonard-Barton, 1995; Okhuysen & Eisenhardt, 2002; Szulanski, 1996). Based on the meaning of the word integration ("to incorporate into a larger unit," Merriam Webster Online) we extend the term KI with three stages that model the incorporation of external knowledge. We call the processes associated with the term KI in the current literature utilization. Because external knowledge needs to be acquired before it can be utilized, we include a stage of acquisition in the model that precedes the utilization stage. Correspondingly, to acquire external knowledge it needs to be identified first. Acquisition is therefore preceded in our model by a stage of identification.

Although there is excellent research done on each of the KI stages, we found no contribution that covers them all. For their own reasons, scholars concentrate on one or two KI stages and disregard either identification (e.g., Almeida, 1996; Crossan, Lane, & White, 1999; Tsang, 2002), acquisition (e.g., Galunic & Rodan, 1998; Rosenkopf & Nerkar, 2001), or utilization (e.g., Leifer & Huber, 1977; McEvily, Das, & McCabe, 2000; Shenkar & Li, 1999). Other scholars regard KI as a black box or elaborate on explanatory models of successful KI (e.g., De Boer et al., 1999; Hamel, 1991; Hansen, 2002; Lane & Lubatkin, 1998; Mowery, Oxley, & Silverman, 1996; Szulanski, 1996; Zander & Kogut, 1995). As such, they provide an understanding of the outcome of KI but less so of the process. Holistic approaches are found in literature on knowledge transfer (e.g., Appleyard, 1996; Bhagat, 2002; Duncan, 1972; Gupta & Govindarajan, 2000; Kostova, 1999; Newell & Swan, 2000; Szulanski, 1996, 2000). In this article, however, networks and alliances are the objects of research, which limits its contribution to the understanding of the KI process in a single organization.

Though they do not provide a holistic model, these scholars provide us with all the necessary ingredients for a holistic KI model. In this article, we try to put the pieces of the KI puzzle together. We follow a pragmatic approach in which we borrow relevant concepts from literature and position them in the KI model: an approach similar to what Glaser called "transcending"—taking relevant variables from theories while trying to raise their conceptual level (1978, pp. 14-15).

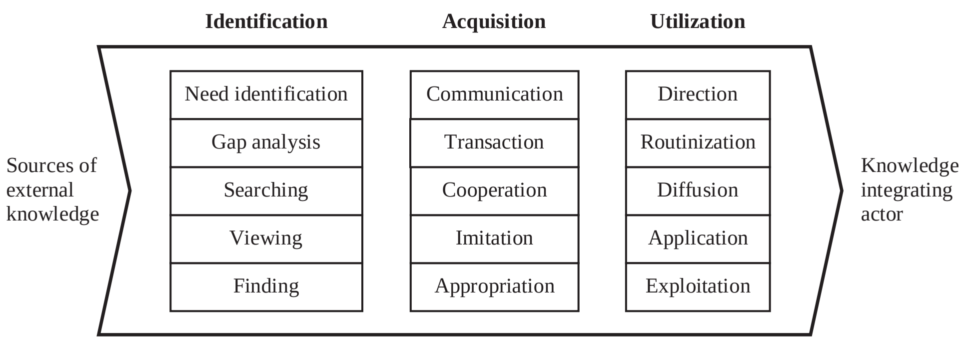
MAIN FOCUS: STAGE MODEL

Although there is no consensus on what constructs form the essential basis of a process model (Curtis, Kellner, & Over, 1992), we define a process as a configuration of connected subprocesses, performed by certain actors. Within this article, we suggest an ordered set of KI subprocesses (see Figure 1) and four views on actors that perform them. An elaboration on the configurations that can be created with these elements is left for future research.

Identification

All subprocesses between initiating a KI process and locating specific external knowledge are considered the identification stage. The apparent relevant theory for this stage is the theory on

Figure 1. Stages and subprocesses of knowledge integration



information seeking. Many information-seeking models follow the process of an information need followed by a successful or unsuccessful search (for an overview, see Case, 2002). These models, however, only partly cover the identification stage, because there are variations in how this stage is initiated. Some seekers start actively from a defined need, while others wait for useful information to appear. Knowledge sources and third parties also can initiate the KI process by pushing an organization to use certain knowledge. Aguilar (1967), Daft and Weick (1984) and Choo (2002) make these distinctions in their work on environmental scanning. At the heart of information-seeking models are information needs. Some authors (e.g., Ellis & Haugan, 1997; Leckie, Pettigrew, & Sylvain, 1996; Wilson, 1999) assume that these needs automatically follow a stimulus or goal. There is, however, substantial evidence that identifying needs is a core problem in information seeking (Choo, Detlor, & Turnbull, 2000; Dervin, 1992; Taylor, 1968). The first subprocess that we propose is therefore need identification, which is defined as finding out to a satisfying degree what knowledge an actor needs at a certain moment for a particular purpose. Closely related to need identification is gap analysis, which we define as finding out what knowledge an actor is lacking at a certain moment for a particular purpose. It can be beneficial to find out whether knowledge is available internally before looking outside since search costs are likely to be lower within an organization (cf. March, 1991; March & Simon, 1958) and in personal files (Taylor, 1968). If no additional external knowledge is needed, available knowledge can be exploited (which we consider part of the utilization stage). Once there are indications for what knowledge is needed, companies can search for it. Therefore, a third subprocess that we propose is searching, which is defined as intentionally striving to find knowledge or sources of knowledge. This definition suggests that searching is an intentional process regardless of its outcome (cf. Marchionini, 1995). Together, these three subprocesses reflect an information seeking procedure. However, knowledge also can be identified without a focused searching process by broadly scanning the environment. Daft and Weick (1984) call this viewing. Daft and Weick do not provide a definition, so we define it as monitoring the existing external knowledge base to detect relevant changes. A final subprocess proposed in the identification stage is finding, which we define as coming across knowledge or across sources of knowledge. Finding is an outcome that can occur without searching or viewing, for example, when knowledge is pushed by another organization.

Acquisition

Although there is a conceptual difference between identification and acquisition (Hansen, 1999), searching is often included in the acquisition process (e.g., Gold, Malhotra, & Segars, 2001; Zahra & George, 2002) or defined as the acquisition of information (Johnson, in Case, 2002). However, in our view, searching does not automatically imply acquisition. Since knowledge that crosses organizational borders implies interactions between two or more organizations, social systems theory is highly relevant for this stage. Kuhn and Beam describe three intersystem interactions that we include as subprocesses within the KI model. (Kuhn & Beam, 1982, p. 14)

- Communication: An interaction analyzed with respect to its information content
- Transaction: An interaction analyzed with respect to its value content
- Organization: An interaction analyzed with respect to its joint effectual content

We propose these three interactions as subprocesses in the KI model, but prefer the term “cooperation” above “organization” because of the broader meaning that is given to “organization” in management literature. The subprocesses differ in the way knowledge is transferred. For example, by communication, knowledge is acquired by talking to somebody; by transaction, it is acquired by buying a document; and by cooperation, it is acquired by working together on a project. These three acquisition subprocesses imply the involvement of both the source and the recipient of knowledge. However, knowledge also can be acquired without the involvement of the source. Disregarding illegal activities, such as stealing and spying, this is achieved by imitating a source's behavior or products (Zander & Kogut, 1995). We propose imitation as a fourth acquisition subprocess and define it as reproducing knowledge by copying objects or actions from another actor, with or without its assent. Imitation without the source's assent is also called "replication" (Nelson & Winter, 1982). Imitation is, however, also carried out with the assent of the source, for example, when a knowledge source demonstrates how to perform a certain task and the recipient imitates this behavior. Related to knowledge transfer is the transfer of a certain form of property rights, such as patents or copyrights. When one organization buys a document from another organization, this usually automatically involves the acquisition of property rights. In other cases, however, the transfer of property rights is not so natural and might even be problematic, for example, during cooperation (Liebeskind, 1996; Teece, 1998). It is important to include the acquisition of property rights in the KI model because they allow for different ways of utilization (Liebeskind, 1996). Some knowledge may only be used once in an unmodified form, while other knowledge may be fully modified and exploited. We propose appropriation as the final subprocess in the acquisition stage and define it as obtaining rights to utilize acquired knowledge in a certain way.

Utilization

As argued in the introduction, knowledge management scholars have extensively researched this KI stage. Researchers on organizational memory (Stein, 1995; Walsh & Ungson, 1991; Wijnhoven, 1999) have distinguished several "mnemonic" processes for utilizing knowledge within an organization. Subprocesses frequently included are acquisition, retention, search, retrieval, and maintenance (Stein, 1995; Walsh & Ungson, 1991). Since acquisition was regarded as a separate stage, we exclude it here.

Grant (1996) observed two primary internal KI "mechanisms"—direction and routinization—which we propose as subprocesses within this stage. Direction involves codifying tacit knowledge into explicit rules and instructions so that it can be communicated at low cost throughout the organization (Grant, 1996: 379). Routinization is the development of a fixed response to defined stimuli in order to simplify choice (March & Simon, 1958: 142). In dynamic environments, where there are few "defined stimuli," adaptation of the repertoire of these routines is crucial (Argyris & Schön, 1978; Levitt & March, 1988). Organizations can facilitate direction and routinization by a third utilization subprocess: diffusing knowledge throughout the organization. Using the image of a jigsaw puzzle, Galunic and Rodan distinguish two forms of diffusion: "A picture on a jigsaw puzzle is distributed when each person receives a photocopy of the picture. The same image would only be dispersed when each of the pieces is given to a different person" (1998: 1198). Like Boisot (1995), by diffusion we not only refer to the active dissemination of knowledge to persons in the organization, but also to the establishment of availability. Therefore, storage of knowledge is included in this subprocess. Unlike routinization, which includes application (Nelson & Winter, 1982), direction and diffusion do not imply that knowledge is applied. A fourth subprocess is therefore distinguished—application—which is defined as using knowledge for the purpose(s) for which it was acquired. Knowledge can be applied for other purposes than those for which it was acquired. Organizations might gain maximum advantage from knowledge by reusing it (Markus, 2001) and recombining it (Galunic & Rodan, 1998). Following March (1991) and Schumpeter (1934), we call this fifth and last subprocess in the utilization stage exploitation.

Actors

The occurrence and interrelationships of the 15 subprocesses will depend upon the roles that their actors play within the organization. Rather than providing specific roles, we discern four general views on the roles that individuals play within collectives.

The first view stems from the gatekeeper theory (Allen & Cohen, 1969; Tushman, 1977) in which individuals are representatives that identify and acquire knowledge for the organization. In the utilization stage, knowledge is elevated to a collective level by direction, routinization, and diffusion into the organizational memory. This view is also central in the information processing perspective (e.g. Daft & Lengel, 1984; Weick, 1979) in which a manager's task is to reduce equivocality within the organization. Although this view might reflect the usual situation in hierarchical organizations, a different situation might well exist in organizations of professionals (cf. Mintzberg, 1979). In such organizations, individuals are professionals that identify, acquire, and utilize knowledge themselves. In this second view, each of the subprocesses can be executed individually as well as collectives, such as by collaborative search, group decisions, and group work. Some researchers on collective mind (Weick & Roberts, 1993), organizational decision-making (Simon, 1997), and organizational learning (Argyris & Schön, 1978; Hedberg, 1981; Kim, 1993; March, 1991) emphasize the mutual influence of individuals and collectives. Collectives, like organizations, influence individual knowledge needs and KI processes, while individuals' knowledge and actions, in turn, influence the organization. This third view suggests that individuals are part of a collective. People can choose to keep knowledge at the individual level (in their head and personal filing systems) and not make it available to the collective, a central issue in knowledge sharing literature and practice. A fourth view emerges when considering that KI processes can cross business processes and organizational units. Knowledge that is identified, acquired, and applied in one business process or unit also can be used within another business process or unit. This occurs, for example, in new product development, where knowledge acquired and used by a production department also is used in the development of a new product by an R&D department. In this view, individuals are specialists that have different areas of expertise.

We believe the proposed stage-model of subprocesses and actors is the most comprehensive of its sort. It extends the most comprehensive existing model that we found (Schwartz, Divitini, & Brasethvik, 2000) with knowledge acquisition and application subprocesses and with an elaboration on the relation between individuals and collectives. The value of these extensions is that the model allows for a more complete analysis of KI than existing models do. This can provide practitioners with a better awareness of the KI process and with an instrument to solve KI problems in their organizations. For example, suppose a company's director notices that his information specialists find and acquire much external knowledge and successfully diffuse it by sending documents to the concerning people in the company. However, he receives many complaints from engineers that this knowledge is not applicable for them. Faced with this problem, the director can use the proposed model to analyze what is going wrong and what can be done to solve this. First, he will observe that application is done by different people than the other subprocesses, which suggests that the information specialists act as representatives of the engineers. Based on this observation, he might decide that it is better to treat the engineers as professionals that can and should identify and acquire the needed knowledge themselves. Second, he can observe that the knowledge is acquired and diffused by means of documents while alternative ways might lead to less loss of relevant details. The KI model makes him aware that imitation and routinization might be alternatives for respectively communication and diffusion. Thus, while the model is descriptive, it can facilitate normative decisions by pointing out alternatives for and relationships between KI subprocesses and roles of actors.

FUTURE TRENDS

In this article, we have proposed an ordered set of KI subprocesses and four views on the relation between individual and collective actors. Very important and still lacking are the KI configurations (combinations of subprocesses and roles of individuals) that can be created with them. We suspect that from the numerous theoretically possible configurations, only few appear in practice. It is a challenge to find out which they are and how they relate to organizational effectiveness. Future research should address these open questions, as well as test the completeness and validity of the proposed model. To this end, further decomposition and operationalization of the model into reliable and valid measurement instruments are challenging but necessary steps. Because of its formal approach, we expect the literature on workflow processes to be very useful to find interactions between subprocesses and to check the KI process on completeness (e.g., Van der Aalst, Ter Hofstede, Kiepuszewski, & Barros, 2003).

Considering the growing interconnectivity of organizations over the world, external knowledge becomes more and more important for them. Because of this growing importance for practitioners, we expect a growing attention to KI and KI-related concepts amongst KM researchers in the near and far future. Looking back at the last decade of KM research, we believe there is indeed a growing attention. We find it, however, hard to estimate whether this trend is merely numerical or whether it also reflects cumulativity of knowledge. Huber already remarked in 1991 on the lack of cumulative work and on the lack of synthesis of work from different research groups on organizational learning (Huber, 1991: 107). We have tried to make a step toward synthesis with respect to the integration of external knowledge. This complete volume shows to what extent the KM research community in general has achieved synthesis and also what research challenges there still are.

With the growing attention for interorganizational connectivity, we also expect research attention to shift from large organizations to small organizations and individuals. In networks of companies and individuals, the concept of organization becomes ambiguous. A revealing example is the development of Linux software (Lee & Cole, 2003). The emergence of such networks, where organizational borders and structures are blurred, has significant consequences for KM research and practice. It imposes unanswered questions on, for example, the remaining value of concepts like organizational learning and organizational memory. Because of the diverging meaning of the term organization, we have not committed ourselves to a single level of collectiveness in this article. Conversely, we have proposed perspectives on interactions of subprocesses on different levels of collectiveness. We believe these perspectives as well as the KI model remain relevant on the level of organizations, networks, and individuals.

CONCLUSION

We started our analysis with the observation that a comprehensive model of the KI process is both important and lacking. In this article, we have proposed a model that consists of 15 subprocesses ordered in three stages—identification, acquisition, and utilization. This model is comprehensive in its coverage of subprocesses that are involved in KI. However, the current model is like a box of LEGOs®—we have proposed bricks (subprocesses) and types of connections (roles of individuals within collectives), but not the designs (configurations) that can be created with them. Although substantial work still needs to be done, we believe the proposed model is a useful instrument for knowledge management practitioners and researchers because a thorough understanding of the KI process is essential to find and design KI solutions (cf. Keen & Scott Morton, 1978). As a process model, the proposed KI model serves as a kernel theory for design of information systems that are to support the KI process (cf. Markus et al., 2002).

Chapter 1.24
Understanding Innovation Processes

Sue Newell
Bentley College, USA

INTRODUCTION

Knowledge integration is a process whereby several individuals share and combine their information to collectively create new knowledge (Okhuysen & Eisenhardt, 2002). Here we are interested in knowledge integration in the context of innovation project teams tasked with developing a new product or organizational practice. Knowledge integration is crucial in relation to innovation, since innovation depends on the generation of new ideas (new knowledge) that leads to the development of new products or organizational practices. Knowledge integration, rather than simply knowledge per se, is important for innovation because it is not simply the possession of new knowledge that will create success in terms of improved practice or new products, but rather, the ability to integrate knowledge across groups and organizations (Gibbons et al., 1994). This is especially the case in relation to radical innovation, which depends on involvement of an increasingly dispersed range of professional groups and organizations (Powell, Koput, & Smith-Doerr, 1996). For example, in the medical domain there are an increasing number of breakthroughs in scientific and technical knowledge that could drastically change medical practice. Achieving such breakthroughs, however, does not necessarily result in performance improvements in medical practice. Major pharmaceutical companies take, on average, 11 years and a minimum of one-third of $1 billion to bring a drug to market, and over 90% of development processes fail (CMR International, 2000). Similarly, in relation to major transformational IT innovation projects in organizations, many do not just fall short of meeting cost, functionality, and scheduling targets, but actually fail outright (Johnson, 1995).

While there are many reasons for such failure, one important reason relates to the problem of integrating knowledge, because breakthroughs leading to radical innovation are highly disruptive (Christensen, Bohmer, & Kenagy, 2000) and potentially “competency destroying” (Henderson, Orsenigo, & Pisano, 1999). For example, the development of the new drug or the new IT system will often cut across established institutionalized domains and structures for the production of knowledge, and therefore require radical shifts in relationships among professional and functional groups. New developments made possible by breakthroughs in science may not align well, for example, with existing professional regimes and medical practices (Christensen et al., 2000).

In this article then, we consider the issue of knowledge integration in the context of innovation projects and relate it to social capital, since understanding the process of knowledge integration involves exploring the "micro-social interactions among individuals" (Okhuysen & Eisenhardt, 2002). It is helpful to explore these micro-social interactions through the lens of social capital since social capital refers to the social networks and the assets that can be mobilized through these networks that enable social action generally and knowledge sharing more specifically (Nahapiet & Ghoshal, 1998). In other words, given that the development of new products and practices typically involves teams of people from different backgrounds (i.e., multi-disciplinary project teams) working together, exploring how individual team members share and combine their respective knowledge in order to generate new ideas to support innovation is important. Specifically, we will consider how different approaches to creating and using social capital leads to different levels of knowledge integration, which in turn influence the innovation achieved, which can be either incremental or radical.

BACKGROUND

The Concept of Knowledge Integration

To reiterate, in this article we are interested in how a project team, tasked with developing a new product or practice, shares and combines the information of the different team members and of other stakeholders who have relevant information in order to create new knowledge that supports innovation. While the Okhuysen and Eisenhardt definition (above) suggests that knowledge integration is a simple process, the reality is that sharing and combining information is often very difficult. This is because knowledge is dispersed (Tsoukas, 1996) and ambiguous (Dougherty, 1992), as well as being potentially competency destroying (Henderson et al., 1999) in the sense that new products or practices may make obsolete the knowledge of particular groups who may then resist involvement in the knowledge integration process and so limit progress.

Teams will differ in terms of what they achieve in relation to knowledge integration. To simplify this we can identify two extremes in the way that knowledge can be taken to be integrated in the context of a project team tasked with developing a new product or service—"mechanistic pooling" (Knights & Wilmott, 1997) versus "generative" (Cook & Brown, 1999) knowledge integration. Mechanistic pooling occurs when each project member works independently on a set of clearly defined tasks or processes with which he/she is familiar and uses his/her existing knowledge to consider the potential of the new scientific/technological breakthrough on the particular problem domain, be this a new drug to help treat cancer or a new IT system to support information integration within an organization. In such circumstances, the new drug or IT system is perceived as simply fitting independent pieces together, like a jigsaw puzzle. This mechanistic pooling of knowledge is likely to result in a new product or service that may have higher performance than current products or services, in which case it may replace what currently exists. However, the innovation is likely to be incremental and is unlikely to lead to any radical change in practice, because radical change is likely to require a more generative and interactive approach to knowledge integration (Newell, Huang, & Tansley, 2004).

Generative knowledge integration occurs when there is joint knowledge production achieved through the combination and exchange of knowledge (Nahapiet & Ghoshal, 1998) and experimentation (Rosenberg, 1982) between individuals from diverse backgrounds (Grant, 1996; Hitt, Nixon, Hoskisson, & Kochhar, 1999). Through this exchange and experimentation, new and novel ways of doing things are identified that could not have been predetermined by the independent parts (Cook & Brown, 1999). In other words, generative knowledge integration occurs when communication and exchange within a group or a team evokes novel associations, connections, and hunches such that new meanings and insights are generated. In this case, knowledge integration involves a process of social construction in which organizational members negotiate, achieve, and refine a shared understanding through interaction, sense-making, and collective learning (Ayas & Zeniuk, 2001; Boland & Tenkasi, 1995). It is this process that provides the basis for creativity, and it is precisely such creative, generative knowledge integration that is much more likely to lead to radical change—for example, radical changes in medicine that many declare is possible with new scientific/technological breakthroughs.

As indicated, exploring knowledge integration processes involves understanding the network relationships and social interactions within and across communities that support this activity (Okhuysen & Eisenhardt, 2002; Grant, 1996). Grant (1996) points out that there is a dearth of empirical research exploring these networking processes supporting knowledge integration. In the next section we consider how these micro-social processes are viewed through the lens of social capital.

The Concept of Social Capital

Effective knowledge integration during an innovation project depends on selecting project team members with an appropriate mix of knowledge, skills, and expertise (Teram, 1999). This will include both organizational and technical/scientific knowledge. This intellectual capital of the team comprises both human and social capital. The human capital of the team refers to the "knowledge and knowing capability of the collectivity" (Nahapiet & Ghoshal, 1998). While important, it is unlikely that team members will have all the relevant knowledge and expertise necessary. Thus, the development of a new drug or a new IT system requires the integration of an extremely broad base of knowledge, but the number of individuals that can be directly involved in the project is necessarily small because of communication and resource constraints (Grant, 1996). So the project team will need to network with others. In doing this they will be drawing upon their collective social capital. Social capital is derived from the network of relationships that connect people together and refers to the "goodwill that is engendered by the fabric of social relations and that can be mobilized to facilitate action" (Adler & Kwon, 2002, p. 17), here to access and integrate knowledge needed for innovation. Social capital would, therefore, appear to be highly relevant in understanding these processes of knowledge integration.

The concept of social capital has become very popular in Management literature, based on the recognition that social networks are useful in a variety of contexts (Coleman, 1988) and can influence a wide range of outcomes (Burt, 1997). Here, we are interested in the ways in which social capital influences knowledge integration during innovation projects. We focus on the antecedent conditions for social capital in such projects (Adler & Kwon, 2002). Thus, networks will vary in their quality and configuration. For example, networks will differ in terms of the extent to which actors' contacts are also connected (Coleman, 1988). They will also differ in the content of the network ties (Uzzi, 1996, 1999), for example the extent to which the connected actors share common knowledge (Nonaka, 1994) and/or beliefs and norms (Portes, 1998). This will influence the development of social relationships and influence the strength of the ties (Granovetter, 1973). As individuals interact with each other, social relationships are built, and goodwill develops (Dore, 1983). This can be drawn upon to gain benefits at some later point in time. While the terms of exchange are not clearly specified, there is a tacit understanding that a 'favor' will be repaid at some time and in some way. This repayment (the outcome of social capital) may be in the form of information, influence, and/or solidarity (Sandefur & Laumann, 1998).

While the concept of social capital is widely used, Adler and Kwon (2002) highlight one central distinction in the way the concept is defined, contrasting the "bridging" from the "bonding" view of social capital. The "bridging" view is focused externally, seeing social capital as a resource inhering in a social network that can be appropriated by a focal actor, based on relations with others in the network (Burt, 1997). Individuals who provide a "bridge" across divided communities are important, since they play a brokerage role. For example, Burt (1997) identifies how there are structural gaps within any given network—individuals and groups who are relatively disconnected from each other. He suggests that people who bridge across these gaps are particularly important to ensure that individuals and groups are not isolated from the larger network. The "bonding" view, by contrast, focuses on the collective relations between a defined group (Coleman, 1988). Social capital relates to the internal structure and relations within this collective. It ensures an internal cohesiveness that allows the collective to pursue shared goals. The source and effects of social capital are, therefore, viewed differently, depending on whether the focus is on bonding or bridging.

Adler and Kwon (2002) note that some definitions of social capital do not distinguish whether the focus is internal (bonding) or external (bridging). They argue that this is preferable because, in practice, both bridging and bonding will influence behavior in all situations, and because bridging and bonding are essentially interchangeable depending upon the unit of analysis considered. They argue against "bifurcating our social capital research into a strand focused on external, bridging social capital and a strand focused on internal, bonding, social capital" (Adler & Kwon, 2002, p. 35). They develop a definition of social capital that does indeed include both internal and external ties. Thus, social capital is "the goodwill available to individuals or groups. Its source lies in the structure and content of the actor's social relations. Its effects flow from the information, influence, and solidarity it makes available to the actor" (Adler & Kwon, 2002, p. 23).

However, given that in this article we are considering the project team as the unit of analysis, we can differentiate between internal bonding within the project team itself, as members collaborate and share and combine knowledge, and external bridging, as team members seek out or are provided with knowledge and information from others outside the project team. Thus, while we agree that in practice both forms of social capital are involved simultaneously in any social activity system and, therefore, adopt Adler and Kwon's definition, we argue that, in relation to innovation projects, it is helpful to maintain the distinction (Newell et al., 2004). This is because while project teams engage in both external bridging and internal bonding activities, they differ in how they undertake these two activities and this influences the way they approach knowledge integration. This article, then, explores how social capital, considered in terms of the bridging and bonding components, is an antecedent to knowledge integration within innovation project teams.

In summary, it is argued that knowledge integration is a key issue during an innovation project. The level of knowledge integration achieved will influence the extent to which the innovation is incremental and simply reinforces the status quo (mechanistic pooling) or is radical, with the potential to create transformational change in a product or a practice (generative knowledge integration). The level of knowledge integration actually achieved depends upon how social capital is used by the project team tasked with designing and implementing the new product or service.

MAIN FOCUS: THE LINK BETWEEN SOCIAL CAPITAL AND KNOWLEDGE INTEGRATION

Table 1 presents a summary of the suggested link between social capital and knowledge integration.

Starting with generative knowledge integration, it is argued that this is necessary for radical innovation, and requires the establishment of strong bonds within the team plus access to diverse stakeholders beyond the team (through bridging relationships). First, developing strong bonds within a project team appears to be critical to facilitate generative knowledge integration. Encouraging the development of strong ties (Granovetter, 1973) increases the closeness and reciprocity between project members who develop strong common or "consummatory" norms (Portes, 1998). Moreover, building a project team where members participate because they are interested in and knowledgeable about the project helps to ensure some 'knowledge redundancy' (Nonaka, 1994)—that is, overlapping knowledge within the team. The development of strong links, common understanding, and norms of trust and reciprocity (i.e., the structural, cognitive, and relational aspects of social capital; Nahapiet & Ghoshal, 1998) leads to high levels of cooperation (Gulati, 1998) that facilitates knowledge sharing and creativity. Team building to enhance the bonding aspect of social capital within the project team is, therefore, crucial for generative knowledge integration. The effect of this bonding is that it allows the team to subsequently share and integrate the dispersed knowledge that they gather during their bridging activities.

In relation to this bridging activity, as already discussed, a project team is unlikely to have all the knowledge necessary for developing the new product or service so that bridging activity with a wider stakeholder community is also important (Coleman, 1988). The ties between the project team members and the wider stakeholder community are likely to be much looser or weaker (Granovetter, 1973) than those ties developed within the project team itself. This is necessary since it will not be possible to develop the dense network, based on a strong sense of common purpose, across so many people. Thus, the network will be open and loose, with others getting involved with the project team for instrumental reasons—to ensure that they had some influence on the new product or service. Such weak ties are sufficient for such information access (Hansen, 1999, 2002). The effect of encouraging this wider involvement is that

Table 1. The link between social capital and knowledge integration

	Social Capital	
Knowledge Integration	**Bonding**	**Bridging**
Generative knowledge integration	Establishment of trust and redundant knowledge allows team to synergistically share and integrate unique knowledge and expertise	Involvement of multiple stakeholders with diverse and conflicting views—resolving conflicts and evaluating different views provides source of new ideas
Mechanistic pooling	Each team member works independently to design his or her part of the new product or service based on existing knowledge and expertise	Minimal involvement of stakeholders, thus restricting access to different views

the team will have access to broader knowledge from across the stakeholder community, which will mean that different perspectives will be surfaced. These differences will need to be discussed in order to develop new products or practices that people will buy-in to. Radical innovation, based on generative knowledge integration, depends on cultivating extensive social networking between the project team and other stakeholders, in order to foster opportunities for the transformation of a product or a practice.

To achieve mechanistic pooling of knowledge, adequate for more incremental innovation, is simpler so that bonding within the team can be weaker and bridging to other stakeholders more limited. This is because incremental innovation does not depend on breakthrough knowledge but rather builds on existing knowledge. For incremental innovation, team members can work independently of each other, and knowledge sharing can be limited because the interfaces between the knowledge domains are already established. Moreover, there is less need to bridge extensively to a diversity of stakeholders because there is no need to identify new knowledge trajectories that may be relevant, nor will stakeholders be required to radically change their existing practices. They do not, therefore, need to be involved in the innovation project in order to ensure that their commitment is built. This mechanistic approach to knowledge integration is therefore more economical and facilitates the introduction of a new product or practice more quickly with limited disruptive change, albeit the new product or practice only improves what currently exists.

The point of making this distinction is that there are some contexts in which a mechanistic approach to knowledge integration to support innovation is likely to be more effective, while there are other contexts in which a more generative approach will be more beneficial. For example, mechanistic pooling will be most efficient where a new product or practice, for example a new medical treatment or a new IT system, simply replaces an existing product or practice. Similarly, mechanistic pooling will be more efficient where there is little need for interaction across professional or functional domains in developing the new product or practice. On the other hand, generative knowledge integration will be necessary where the development of the new product or practice depends upon interactions between professional groups who have not worked together previously or where the innovation results in radical changes to a product or a practice so that the buy-in of stakeholders requires cultivation. In other words, a contingency approach is suggested, which specifies that for incremental innovation, where a mechanistic approach is appropriate, social networking both within the project team and between the project team and the wider stakeholder community can be minimized. Under conditions where a generative approach to knowledge integration is necessary, team bonding and bridging will need to be more intensive and extensive because of the need to engage in the "generative dance" (Cook & Brown, 1999) of sharing and integrating knowledge that underpins innovation processes that lead to radical changes in products or practices.

FUTURE TRENDS

It is likely that radical innovation, requiring a lot of interactivity across professional and disciplinary groups, will become more important as competition intensifies in most industries (Gibbons et al., 1994). This suggests that the need for generative knowledge integration will increase in the future. Below we consider the implications of this for the management and organization of project teams tasked with creating radical new products and practices. More specifically we consider a number of aspects of a project team that will be differentially affected depending upon whether the focus is radical or incremental innovation. It is likely that the aspects that foster radical innovation through generative knowledge integration will become more important:

1. Team Building: Where generative knowledge integration is necessary to foster radical innovation, it will be important to nurture a strong and cohesive project team through, for example, team-building exercises. Where mechanistic pooling is sufficient, there is less need for such team building.
2. Division of Tasks: Where mechanistic pooling is adequate, tasks can be divided up into independent activities that are assigned to different people, since as Becker (2001) identifies, one strategy for dealing with the dispersion of knowledge is to decompose organizational units into smaller ones so that each unit (in this case each individual) is responsible for one part of the larger problem. As Becker notes, this strategy of specialization reduces the opaqueness of complex problems. Where the resulting 'pieces' of work can be put together easily because interfaces between the 'pieces' are pre-established, this is very efficient. For generative knowledge integration, however, this is problematic because these interfaces are not pre-established, since different groups are involved, which have not previously worked together. In this case, tasks are more effectively divided up so that there is considerable overlap and inter-dependency built in.
3. Allocation of Tasks: Where the mechanistic pooling of knowledge is sufficient, it is most efficient to allocate only specialists to tasks. However, where generative knowledge integration is required, the allocation of specialists may not be appropriate because these specialists are likely to have preconceived ideas about how activities should be completed and so will not think about alternative processes that could be supported by the new scientific/technological breakthroughs. As Meacham (1983) states:

   Each new domain of knowledge appears simple from the distance of ignorance. The more we learn about a particular domain, the greater the number of uncertainties, doubts, questions, and complexities. Each bit of knowledge serves as the thesis from which additional questions or antithesis arise. (p. 120)

   The point is that specialists may not get past their "distance of ignorance" because they believe that they already have the solution. Involving non-expert individuals may therefore help in generative knowledge integration because such individuals are more likely to ask the questions that could identify the complexities of the situation and the alternative opportunities afforded by the breakthroughs.
4. Knowledge Redundancy: Generative knowledge integration also requires significant common understanding within the project team where mechanistic pooling does not require this to the same extent because, as already indicated, the interfaces between the different parts of the project are already well established. Bruner (1983) described creativity as "figuring out how to use what you already know in order to go beyond what you currently think" (p. 183). This implies that an important impetus to creativity is knowledge about the issue you are dealing with. So, while existing knowledge can be a barrier to creative thinking, it is also the case that without knowledge there can be no creativity. Without this effort to understand broader issues across different disciplines, individuals will rely on their existing knowledge and so a more mechanistic orientation to knowledge integration is likely to result.

In the future it will be increasingly important for those involved in radical innovation projects to have a broad inter-disciplinary understanding.

5. Stakeholder Involvement: Another important issue relates to the extent of bridging activity. Limiting bridging activity means that the diversity of opinion that exists across the wider stakeholder community will not be voiced. This may be efficient in contexts where incremental innovation is the goal. Yet, as Leonard-Barton (1995) reminds us, bringing together individuals with different views and backgrounds can lead to "creative abrasion" that results in new and innovative approaches being considered. Creative abrasion is necessary to achieve generative knowledge integration. User involvement is likely to be especially important in this respect. Involving users can help to encourage commitment to the project. Additionally, users can be a source of creativity if they are given the opportunity to voice their ideas about alternative processes and practices. Discussion with users may lead to conflicting suggestions, as expected in such novel situations; nevertheless they can also provide a significant source of ideas.

CONCLUSION

In conclusion, there are significant differences in the knowledge integration challenge of a project team that is tasked with developing a radical innovation compared to a team tasked with some kind of incremental innovation. These differences in the knowledge integration challenge have implications for the way the team will need to create and use its social capital. It is suggested that where the focus is on radical innovation, it is important for project teams to develop strong internal ties and develop a sense of a shared purpose to foster generative knowledge integration. The focus is thus on team bonding and the development of a closed network. This allows team members to develop some common or redundant knowledge that is crucial for generative knowledge integration. This team building creates a sense of shared destiny and understanding among the project members, which leads to a normative commitment to the project. However, where the focus is on more incremental innovation, knowledge integration within the team can be more mechanistic. The social capital bonding requirements for the team are then much simpler because within the team, bonds do not need to be as strong since individuals can work more independently.

For generative knowledge integration, once the core project team has developed a shared sense of purpose—a "collective mind" (Weick & Roberts, 1993)—they can begin to bring in ideas and information from individuals across the wider network of stakeholders who will be affected by the innovation. In doing this they are using their bridging social capital to gather information needed for the project. External parties provide the needed information because they can see an instrumental return in doing this. The provision of this information gives the project team an understanding of the likely sources of resistance to the change in practice and so can begin the process of building user commitment to the change. The network focus is on bridging activity, and it is helpful if the network structure is more open to facilitate wider information flow. However, for more incremental innovation projects, the project team can work in a more isolated way from potential users and other stakeholders, with a more restricted network, since there is less need to capture the diversity of views and ideas. Working in this way, the project team will probably be unchallenged by creative abrasion, but this is efficient where the goal is incremental innovation.

Where project teams work towards a common goal in a very mechanistic way, the extent of transformational change that they can anticipate from the new product or practice they develop is likely to be limited. But there are situations in which this is highly appropriate. Where project teams work more collaboratively, this will encourage interaction and the sharing of knowledge more synergistically and creatively so that they are more likely to be able to generate products and practices that can encourage more transformational change. Which approach to knowledge integration is appropriate will depend on the unique circumstances of each innovation project.

Chapter 1.25
Knowledge Management System Success Factors

Murray E. Jennex
San Diego State University, USA

INTRODUCTION

What does it take to build a successful knowledge management system (KMS)? Knowing the essential success factors is useful as it provides researchers and practitioners with the basic requirements for building a successful KMS. Also, if we take a Churchman (1979) view of systems, it can be argued that determining KMS success factors will also help us determine KM initiative success factors as Churchman found it difficult to separate the system from the process requiring the system. However, what is KM or KMS success? The literature does not provide a consensus on this, although two concepts of success can be identified. The first considers KM or KMS a success if knowledge use through the initiative or system improves the organization's ability to compete. The second considers KM or KMS a success if the KM processes implemented through the KMS (discussed later) are implemented effectively. Both success concepts imply that the KMS has to be used. Therefore, KM and KMS success factors are those factors that encourage or help users to use the KMS to effectively perform KM functions.

What is a KMS? Alavi and Leidner (2001, p. 114) define KMSs as "IT-based systems developed to support and enhance the organizational processes of knowledge creation, storage/retrieval, transfer, and application." They observed that not all KM initiatives will implement an IT solution, but they support IT as an enabler of KM. Maier (2002) expanded on the IT concept for the KMS by calling it an ICT system that supports the functions of knowledge creation, construction, identification, capturing, acquisition, selection, valuation, organization, linking, structuring, formalization, visualization, distribution, retention, maintenance, refinement, evolution, access, search, and application. Stein and Zwass (1995) define an organizational memory information system (OMIS) as the processes and IT components necessary to capture, store, and bring to bear knowledge created in the past on decisions currently being made. Jennex and Olfman (2004) expanded this definition by incorporating the OMIS into the KMS and adding strategy and service components to the KMS.

This article uses a literature review to identify these success factors. Studies looking at KM, KMS, OM, and OMS or OMIS were reviewed and the success factors extracted. KM studies were included as a Churchman (1979) view of a KMS can be defined to include the KM initiative driving the implementation of a KMS (also, the same logic can be applied for including OM with OMS studies). OM and OMS studies are included with KM and KMS as Jennex and Olfman (2002) found that KM and OM are essentially the same with the difference being the players. End users tend to use KM where KM is concerned with the identification and capture of key knowledge. Information systems personnel tend to be concerned with OM where OM is the storage, search, retrieval, manipulation, and presentation of knowledge. KMS and OMS are the systems built to support KM and OM, and are essentially systems designed to manage organizational knowledge.

The literature review identified many KMS success factors that are summarized below. To make sense of these factors, they were analyzed for key words and concepts and combined into generic success factors. Definitions for the generic success factors were generated by combining and simplifying the concepts included in the base success factors. The generic success factors are also presented and discussed. The generic success factors were ranked based on the number of articles the base success factors appeared in. The article concludes with a ranked list of KMS success factors.

KMS SUCCESS FACTORS

A successful KMS should perform well the functions of knowledge creation, storage and retrieval, transfer, and application. However, other factors can influence KMS success. Mandviwalla, Eulgem, Mould, and Rao (1998) summarized the state of the research and described several strategy issues affecting the design of a KMS. These include the focus of the KMS (who are the users), the quantity of knowledge to be captured and in what formats, who filters what is captured, and what reliance and/or limitations are placed on the use of individual memories. Additional technical issues affecting KMS design include knowledge storage and repository considerations, how information and knowledge is organized so that it can be searched and linked to appropriate events and use, and processes for integrating the various repositories and for reintegrating information and knowledge extracted from specific events. Some management issues include how long the knowledge is useful, access locations as users rarely access the KMS from a single location (leads to network needs and security concerns), and the work activities and processes that utilize the KMS.

Ackerman (1994) studied six organizations that had implemented his Answer Garden system. Answer Garden is a system designed to grow organizational memory in the context of help-desk situations. Only one organization had a successful implementation because expectations of the capabilities of the system exceeded the actual capabilities. Ackerman and Mandel (1996) found that a smaller task-based system was more effective on the suborganization level because of its narrower expectations. They refer to this narrower system as "memory in the small."

Jennex and Olfman (2000) studied three KM projects to identify design recommendations for building a successful KMS. These recommendations include the following:

- Develop a good technical infrastructure by using a common network structure, adding KM skills to the technology support skill set, using high-end PCs (personal computers),

integrating databases, and standardizing hardware and software across the organization.
- Incorporate the KMS into everyday processes and IS by automating knowledge capture.
- Have an enterprise-wide knowledge structure.
- Have senior management support.
- Allocate maintenance resources for the OMS.
- Train users on the use and content of the OMS.
- Create and implement a KM strategy or process for identifying and maintaining the knowledge base.
- Expand system models and life cycles to include the KMS, and assess system and process changes for impact on the KMS.
- Design security into the KMS.
- Build motivation and commitment by incorporating KMS usage into personnel evaluation processes, implementing KMS use and satisfaction metrics, and identifying organizational culture concerns that could inhibit KMS usage.

Additionally, Jennex and Olfman (2002) performed a longitudinal study of KM on one of these organizations and found that new members of an organization do not use the computerized KMS due to a lack of context for understanding the knowledge and the KMS. They found that these users needed pointers to knowledge more than codified knowledge.

Jennex, Olfman, and Addo (2003) investigated the need for having an organizational KM strategy to ensure that knowledge benefits gained from projects are captured for use in the organization by surveying year 2000 (Y2K) project leaders. They found that benefits from Y2K projects were not being captured because the parent organizations did not have a KM strategy or process. Their conclusion was that KM in projects can exist and can assist projects in utilizing knowledge during the project.

Davenport, DeLong, and Beers (1998) studied 31 projects in 24 companies. Eighteen projects were determined to be successful, five were considered failures, and eight were too new to be rated. Eight factors were identified that were common in successful KM projects. These factors are as follow:

- Senior management support.
- Clearly communicated KMS purposes and goals.
- Linkages to economic performance.
- Multiple channels for knowledge transfer.
- Motivational incentives for KM users.
- A knowledge-friendly culture.
- A solid technical and organizational infrastructure.
- A standard, flexible knowledge structure.

Malhotra and Galletta (2003) identified the critical importance of user commitment and motivation through a survey study of users of a KMS being implemented in a healthcare organization. They found that using incentives did not guarantee a successful KMS. They created an instrument for measuring user commitment and motivation that is similar to Thompson, Higgins, and Howell's (1991) perceived-benefit model, but is based on the self-determination theory that uses the perceived locus of causality.

Ginsberg and Kambil (1999) explored issues in the design and implementation of an effective KMS by building a KMS based on issues identified in the literature and then experimentally implementing the KMS in a field setting. They found knowledge representation, storage, search, retrieval, visualization, and quality control to be key technical issues, and incentives to share and use knowledge to be the key organizational issues.

Alavi and Leidner (1999) surveyed executive participants in an executive development program with respect to what was needed for a successful KMS. They found organizational and cultural issues associated with user motivation to share and use knowledge to be the most significant. They also found it important to measure the benefits of the KMS and to have an integrated and integrative technology architecture that supports database, communication, and search and retrieval functions.

Holsapple and Joshi (2000) investigated factors that influenced the management of knowledge in organizations through the use of a Delphi panel consisting of 31 recognized KM researchers and practitioners. They found leadership and top management commitment and support to be crucial. Resource influences such as having sufficient financial support, a high skill level of employees, and identified knowledge sources are also important.

Koskinen (2001) investigated tacit knowledge as a promoter of success in technology firms by studying 10 small technology firms. Key to the success of a KMS was the ability to identify, capture, and transfer critical tacit knowledge. A significant finding was that new members take a long time to learn critical tacit knowledge, and a good KMS facilitates the transference of this tacit knowledge to new members.

Barna (2003) studied six KM projects with various levels of success (three were successful, two failed, and one was an initial failure turned into a success) and identified two groups of factors important to a successful KMS. The main managerial success factor is creating and promoting a culture of knowledge sharing within the organization by articulating a corporate KM vision, rewarding employees for knowledge sharing, creating communities of practice, and creating a best-practices repository. Other managerial success factors include obtaining senior management support, creating a learning organization, providing KMS training, and precisely defining KMS project objectives.

Design and construction success factors include approaching the problem as an organizational problem and not a technical one; creating a standard knowledge submission process; having methodologies and processes for the codification, documentation, and storage of knowledge; and having processes for capturing and converting individual tacit knowledge into organizational knowledge. Also, organizations should create relevant and easily accessible knowledge-sharing databases and knowledge maps.

Cross and Baird (2000) propose that KM would not improve business performance simply by using technology to capture and share the lessons of experience. It was postulated that for KM to improve business performance, it had to increase organizational learning through the creation of organizational memory. To investigate this, 22 projects were examined. The conclusion was that improving organizational learning improved the likelihood of KM success. Factors that improved organizational learning include the following:

- Supporting personal relationships between experts and knowledge users.
- Providing incentives to motivate users to learn from experience and to use the KMS.
- Providing distributed databases to store knowledge and pointers to knowledge.
- Providing work processes for users to convert personal experience into organizational learning.
- Providing direction to what knowledge the organization needs to capture and learn from.

Sage and Rouse (1999) reflected on the history of innovation and technology and identified the following issues:

- Modeling processes to identify knowledge needs and sources.

- A KMS strategy for the identification of knowledge to capture and use, and of who will use it.
- Incentives and motivation to use the KMS.
- An infrastructure for capturing, searching, retrieving, and displaying knowledge.
- An understood enterprise knowledge structure
- Clear goals for the KMS.
- The measurement and evaluation of the effectiveness of the KMS.

Yu, Kim, and Kim (2004) explored the linkage of organizational culture to knowledge manage-

Table 1. KMS success factor summary

ID	Success Factor	Source
SF1	An integrated technical infrastructure including networks, databases/repositories, computers, software, KMS experts	Alavi and Leidner (1999), Barna (2002), Cross and Baird (2000), Davenport et al. (1998), Ginsberg and Kambil (1999), Jennex and Olfman (2000), Mandviwalla et al. (1998), Sage and Rouse (1999), Yu et al. (2004)
SF2	A knowledge strategy that identifies users, user experience-level needs, sources, processes, storage strategies, knowledge, and links to knowledge for the KMS	Barna (2002), Ginsberg and Kambil (1999), Holsapple and Joshi (2000), Jennex et al. (2003), Koskinen (2001), Mandviwalla et al. (1998), Sage and Rouse (1999), Yu et al. (2004)
SF3	A common enterprise-wide knowledge structure that is clearly articulated and easily understood	Barna (2002), Cross and Baird (2000), Davenport et al. (1998), Ginsberg and Kambil (1999), Jennex and Olfman (2000), Mandviwalla et al. (1998), Sage and Rouse (1999)
SF4	Motivation and commitment of users including incentives and training	Alavi and Leidner (1999), Barna (2002), Cross and Baird (2000), Davenport et al. (1998), Ginsberg and Kambil (1999), Jennex and Olfman (2000), Malhotra and Galletta (2003), Yu et al. (2004)
SF5	An organizational culture that supports learning and the sharing and use of knowledge	Alavi and Leidner (1999), Barna (2002), Davenport et al. (1998), Jennex and Olfman (2000), Sage and Rouse (1999), Yu et al. (2004)
SF6	Senior management support including the allocation of resources, leadership, and providing training	Barna (2002), Davenport et al. (1998), Holsapple and Joshi (2000), Jennex and Olfman (2000), Yu et al. (2004)
SF7	Measures established to assess the impacts of the KMS and the use of knowledge, as well as to verify that the right knowledge is being captured	Alavi and Leidner (1999), Davenport et al. (1998), Jennex and Olfman (2000), Sage and Rouse (1999)
SF8	A clear goal and purpose for the KMS	Ackerman (1994), Barna (2002), Cross and Baird (2000), Davenport et al. (1998)
SF9	A learning organization	Barna (2002), Cross and Baird (2000), Sage and Rouse (1999), Yu et al. (2004)
SF10	Easy knowledge use supported by the search, retrieval, and visualization functions of the KMS	Alavi and Leidner (1999), Ginsberg and Kambil (1999), Mandviwalla et al. (1998)
SF11	Work processes designed to incorporate knowledge capture and use	Barna (2002), Cross and Baird (2000), Jennex and Olfman (2000)
SF12	The security/protection of knowledge	Jennex and Olfman (2000), Sage and Rouse (1999)

ment success. They found that KM drivers such as a learning culture, knowledge-sharing intention, KMS quality, rewards, and KM team activities significantly affected KM performance. These conclusions were reached through a survey of 66 Korean firms.

DISCUSSION

These studies provide several success factors. To summarize them, they have been reviewed and paraphrased into a set of ranked success factors where the ranking is based on the number of sources citing them. Table 1 lists the final set of success factors in their rank order. Additionally, success factors SF1 through SF4 are considered the key success factors as they were mentioned by at least half of the success factor studies.

FUTURE RESEARCH TRENDS

Many of the above KMS success factors were identified through qualitative research with their importance established through bibliographical analysis. Future research needs to consolidate these factors into a single KMS success-factor model. To be useful, the generated KMS success model needs to be quantitatively validated against a variety of organizations. This will improve the validity and general application of the model.

CONCLUSION

Many studies have been performed that have identified KM success factors. The summary of Table 1 is a useful summary of success factors and their importance, and is useful for researchers and practitioners. However, more research into KM and KMS success is needed. The success factors presented in this article were generated from a literature survey. The studies used for this literature survey utilized a variety of methods including surveys, case studies, Delphi studies, and experimentation. A total of 78 projects or organizations were investigated using case studies, and approximately 100 organizations were surveyed. Overall, in addition to the case studies mentioned, four surveys were administered and one Delphi study and experiment were performed. However, this is not sufficient research to definitively state that all KM success factors have been identified and their importance determined. Only a few of the sources were able to conduct any kind of statistical analysis or hypothesis testing, leaving a qualitative analysis basis for most of these success factors. This leaves an opportunity for researchers.

Chapter 1.26
Knowledge Management Systems Acceptance

Fredrik Ericsson
Örebro University, Sweden

Anders Avdic
Örebro University, Sweden

INTRODUCTION

Knowledge management is a set of systematic actions that organizations can take to obtain the greatest value from the knowledge available to it (Davenport & Prusak, 1998). Systematic means that knowledge management is made up of intentional actions in an organizational context. Value means that knowledge management is measured according to how knowledge management projects contribute to increased organizational ability (see for example Prieto & Gutiérrez, 2001; see Goldkuhl & Braf, 2002, on the subject of organizational ability). The motivation for knowledge management is that the key to competitive advantage for organizations in today's business world is organizations' ability to manage knowledge (Nonaka & Takeuchi, 1995; Davenport & Prusak, 1998). Knowledge management as an intentional and value-adding action is not easy to accomplish in practice (Scarbrough & Swan, 1999). Scarbrough and Swan (1999) present several case studies in knowledge management, successful and unsuccessful in their respective knowledge management projects. A major point and lessons learned from the case studies is that prevalent approaches in knowledge management overstate technology and understate how technology is implemented and applied.

To succeed with knowledge management, encompassing development of information technology-based information system, some requirements have to be fulfilled. An important aspect in the development process is system acceptance. Implementation is at large a process of acceptance. Implementation is the process where the system becomes an integrated part of the users' or workers' work practice. Therefore implementation is essential to make a knowledge management project successful in order attain an increased organizational ability and to succeed with knowledge management.

ISSUES OF KNOWLEDGE MANAGEMENT—SYSTEMS AND ACCEPTANCE

In this section we provide broad definitions and discussion of the topics to support our positions on the topics of knowledge management and systems acceptance.

Managing Knowledge

Work in knowledge management has a tendency to omit social or technological aspects by taking on one of two perspectives on knowledge management, the anthropocentric or the technocratic view (Sveiby, 2001; Swan, 1999). The anthropocentric and the technocratic views represent two contradictory views on knowledge management and can be summarized as technology can or technology cannot. The gap between the anthropocentric and technocratic view depends on a difference of opinions concerning the notion of knowledge. The technocratic view conceives knowledge to be some organized collection of data and information, and the anthropocentric view conceives knowledge to reside in humans, not in the collection (Churchman, 1971; Meredith & Burstein, 2000). Our conception of knowledge is that of the anthropocentric view. Taking on an anthropocentric view on knowledge management does not mean that we discard knowledge management technologies; we rather take on a balanced view on the subject. Information technology can support knowledge management in an organization through a number of different technological components, for example intranets, extranets, data warehouses, and database management systems (Borghoff & Pareschi, 1998; Tiwana, 2000; Ericsson & Avdic, 2002). The point in taking on an anthropocentric view of knowledge management is not to lose sight of the knower who gives meaning to the information and data found in IT-based knowledge management systems.

Knowledge Management Systems

Information systems can include either operative or directive and decision support information (Langefors, 1966; Yourdon, 1989). Operative systems provide system users with information necessary in workers' daily work, while directive and decision support systems provide system users with information that improves the quality of decisions workers make in daily work. Knowledge managements systems are systems developed to manage knowledge directly or indirectly to give support for an improved quality of a decision made in workers daily work, and as an extension, an increased organizational ability. A knowledge management system typically includes directive information, for example in guiding a user's choice in a specific work situation. Such systems are often optional in the sense that users can deliberately refrain from using the system and/or refrain from taking the directed action. Accordingly, user acceptance is crucial for the degree of usage of knowledge management systems.

Acceptance of Technological Systems

Technology acceptance has been subject of research by, for example, Davis, Bagozzi, and Warshav (1989), who developed the well-known Technology Acceptance Model (TAM) and later a revised version of the original model, TAM2 (Venkatesh & Davis, 2000). TAM is an explanative model explaining user behavior of computer technologies by focusing on perceived ease of use, perceived usefulness, attitude towards use, and behavioral intentions as determinants of user behavior. TAM2 is an extension of the original model including external factors related to perceived usefulness.

The framework for system acceptance, Requirements of Acceptance Model (RAM) have some resemblances with TAM and the later TAM2.

RAM is in comparison with TAM descriptive in nature. Workers' work practice is treated as an integrated element of RAM, compared with not being treated as a determinant of system use in the original TAM and as an external factor in TAM2. Further, RAM covers acceptance of knowledge management systems, and TAM/TAM2 cover a broad range of computer technologies. RAM systematically acknowledges factors important in implementation of knowledge management systems to gain acceptance of such systems.

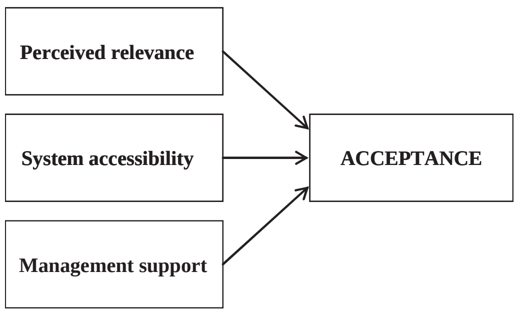
REQUIREMENTS OF THE ACCEPTANCE MODEL

We perceive acceptance to be a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. In this section we present the requirements of acceptance in RAM. The Requirements of Acceptance Model is illustrated in Figure 1.

Perceived Relevance

The workers, who are to use the system, must perceive the knowledge management system as relevant. Since it is possible for workers to work without using the system, it has to be obvious

Figure 1. Requirements of Acceptance Model (Ericsson & Avdic, 2003)



that usage of the system implies adding value to the work result. An additional aspect of relevance related to perceived relevance is how the system should be integrated in running work, that is, to make the system an integrated part of the workers' work practice.

In summary, perceived relevance is about workers, who are to use the system, perceiving the system as (Ericsson & Avdic, 2003)

- adding value to the work results; and
- being integrated in running work.

Accessibility

To obtain acceptance of knowledge management systems, accessibility has to be satisfactory. It must be accessible to the workers who are to use the system. Accessibility is a question of who is to be the user (type of workers concerning organizational position), what action and work the system is to support (daily work, product development, innovation, etc.), where users get access to the system (the physical access), when the system is ready to use, and how the system's interface fulfills the goal of the system.

In summary, systems accessibility is about (Ericsson & Avdic, 2003):

- knowing who the user is;
- systematizing the actions workers perform in the work practice the system is to support;
- deciding the system's physical access;
- securing a certain degree of usage before the system is put into operation; and
- ensuring the system's design meets the goals of the system.

Management Support

Management support is vital according to many models on information systems development, especially when the system is a directive/decision support system (Yourdon, 1989). Knowledge management systems are typically directive systems, and workers have a choice in deciding whether to use the system or not. Management support is important to stress the value for workers to use the system and to make conditions for workers to do so.

Development is a Process of Acceptance

There must be a fit between workers' work practice and technology to get acceptance of knowledge management systems. The technology used to create a knowledge management system must fit the actions workers perform in their work practice. On an overall level there must be a fit between technology and actions performed by individual workers, and between individual workers and the organization as a whole, thus forming a coherent whole. It is in the development of knowledge management systems that the requirements of acceptance are fulfilled. A common conception concerning information systems development is that it constitutes analysis, design, construction, and implementation of information systems (Hirschheim, Klein & Lyytinen, 1996).

The groundwork for acceptance is made during the design, but foremost when implementing the system. Workers who are to use the system should be engaged at an early stage of the development process. The point of including workers at an early stage is to acquaint users with the system and the purpose of the system. Further, this is an opportunity for workers to influence the system's design and content. The most prominent aspect addressed when involving workers at an early stage is that of choosing and determining the meaning of crucial concepts managed by the system. Crucial concepts managed by the system are the knowledge represented in the system, and by determining concepts, knowledge represented in the system takes on a systematized character. Further, by involving the workers in the process of choosing and determining the meaning of crucial concepts managed by the system, the knowledge represented in the system does not lose its origin or meaning. The point is to keep the knowledge represented in the system within a frame of understanding or meaning, as perceived by workers. A knowledge management systems should be seen as a tool developed to support workers in learning and acquiring knowledge about actions taking place at work. This requires closeness between how concepts are perceived by workers and how such concepts are represented in a system.

FUTURE TRENDS

Research on technology acceptance (i.e., Davis et al., 1989; Venkatesh & Davis, 2000) has focused on user behavior of computer technologies. RAM is developed for and is used to assess acceptance of knowledge management systems. Acceptance has not been a crucial issue within the knowledge management area. A problem with knowledge management systems is that they work in theory, but seldom in practice (Wickramasinghe, 2003). A contributing factor to that picture may very well be that of having overlooked usage-related problems connected to knowledge management systems. In that sense, knowledge management systems acceptance can be expected to be an area for further research in the future.

CONCLUSION

Acceptance of knowledge management systems is a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. RAM is summarized in Table 1.

The Requirements of Acceptance Model point towards several important aspects concerning relevance, accessibility, and support. The groundwork for system acceptance is the development process. Development is very much a process of

Table 1. Summary of RAM (Ericsson & Avdic, 2003)

Perceived relevance—Workers, who are to use the system, have to perceive the system as:

- Adding value to work results
- Being integrated in running work

Systems accessibility—System accessibility is about:

- Knowing who the user is
- Systematizing actions workers perform in the work practice the system is to support
- Deciding the physical location where users get physical access to the system
- Securing usage of the system before it is put into operation
- The systems' design must meet up to the goals of the system

Management support—Fundamental because management authorizes development of systems

acceptance as a process of developing the system itself. Through requirements of acceptance, knowledge management systems can remain and continue to be a contributing factor for the organization's ability to do business.

Chapter 1.27
Knowledge Synthesis Framework

Kam Hou Vat
University of Macau, Macau

INTRODUCTION

The last decade of the 20th century saw explosive growth in discussions about knowledge—knowledge work, knowledge management, knowledge-based organizations, and the knowledge economy (Cortada & Woods, 2000). At the center of such discussions are the two notions of process and knowledge. The former represents not only the organization's operations characterized by clearly defined inputs, outputs, and flows, but also management practices which give the organization its depth and means for handling change and turbulence. The latter is represented by a range of complexity and intellectual richness, from Plato's "justified true belief" (Nonaka & Takeuchi, 1995) to a more mundane "the capacity to act" (Sveiby, 1997). How knowledge is characterized, used, and even created within an organization is a very complicated process. Nevertheless, we believe that each member of an organization has his or her own knowledge space, which is subject to some level of description, and thus may be architected, integrated, and designed into an organization (Davenport & Prusak, 1998; Levine, 2001). As the source of wealth shifts from capital to knowledge (Drucker, 1992), it is clear that organizations that actively seek to create their own communal knowledge space from that, which exists among its members, will have a decided advantage over those who do not. One working definition of knowledge is hereby interpreted in terms of its potential for action and its ability to change context and goals—the rules of relevance and adaptation. Yet, what is the means by which a communal knowledge space may be built? And how would an organization use it for advantage? To answer these questions, this article is divided into five sections: The Background of Knowledge Synthesis; Pursuing the Ideal of a Learning Organization; Scaffolding the Knowledge Framework; Future Trends of IS Design for Knowledge Sharing; and Conclusion.

The first provides the foundations on understanding the knowledge phenomenon as it is happening in many an organization today. The second serves as a digest in capturing some basic ideas of the learning organization. The third brings forth our conception of an actionable framework of knowledge synthesis, applicable to the Internet-based development of present-day organizations. The fourth discusses some of the challenges in information systems (IS) design for knowledge work. The fifth concludes the article by reiterating the challenges in doing organizational knowledge synthesis.

The theme of this article is to investigate strategies to enhance knowledge sharing through the idea of a learning organization. Its aim is to conceive appropriate design of IS support so as to expand an organization's capacity to adapt to future challenges.

THE BACKGROUND OF KNOWLEDGE SYNTHESIS

To situate our discussions about knowledge work in an organization, we first resort to the classification scheme of knowledge tasks from Charles Perrow (1970) on the basis of their analyzability (the degree to which search activity is needed to solve a problem) and variability (the number of exceptions—new or unexpected—encountered while performing a task). There are four task subtypes: craft, routine, engineering, and non-routine. Routine tasks are characterized by the combination of low variability and high analyzability. Namely, few exceptions are encountered in the work process, and when an exception does occur, little search behavior is required to handle it. Craft tasks are characterized by the combination of low variability and low analyzability. This means only a narrow range of exceptions being encountered, but a high level of search activity is needed to find a solution to problems. Engineering tasks are characterized by the combination of high variability and high analyzability. Namely, the number or variety of exceptions that workers may encounter in the task is high, but finding a solution is relatively easy because well-understood standard procedures should have been established to handle the exceptions. Finally, non-routine tasks are characterized by the combination of high variability and low analyzability. It is the most complex and least routine of the four tasks in Perrow's classification. These tasks are complex because not only is the number of unexpected situations large, but search activity is high: Each new situation creates a need to expend resources to deal with it. A key goal of management is to analyze and refine what have been craft and non-routine tasks, and transform them into routine and engineering tasks. They constantly seek to reduce the ambiguity and uncertainty by routinizing work and the business rules governing that work. Nonetheless, organizational tasks are increasingly being craft and non-routine. Such knowledge work is not easily subject to process explicitness (clearly defined specifications). As tasks become more unanalyzable (i.e., craft, non-routine), the level of ambiguity increases and requires people with relatively more experience and tacit knowledge, and a certain level of rich information. Similarly, as tasks become more variable (i.e., engineering and non-routine), the level of uncertainty increases thereby requiring people with more training, formal education, explicit knowledge, and high quantities of information. Obviously, such is the backdrop behind which many an enterprise today has been developing their contexts for organizational knowledge synthesis.

In order to develop a communal knowledge space—one that develops new forms of knowledge from that which exists among its members—we must describe how and with what an organization performs its work, say, in terms of its core capabilities (i.e., strategic processes) and core competencies (i.e., knowledge areas applied to capabilities) (Stalk, Evans, & Shulman, 1992). Oftentimes the alignment context is expressed in terms of the dynamics of the people-process-system issue. Namely, we need to design suitable information systems to help people with knowledge to perform the processes involved to produce results of value to the organization. In fact, Zuboff (1988) has written extensively on the interaction of people and information technology (IT), and the all-important shift in management thinking from automating to informating. In practice, automating typically refers to the use of IT during process change to substitute the deployment of humans. Automating serves to lower uncertainty and increase management control. Informating, in contrast, refers to the effect IT may have on the understanding and transparency of a process. Informating makes people more productive through their use of and process integration with IT. It serves to increase the capacity of people to understand the entire value-adding business process. Thus, informating concerns itself with the connection people have with their specific tasks as well as the whole flow of work. Certainly, the notion of knowledge must be incorporated. While informating concerns IT and task integration, the idea of knowledging (Savage, 1996) refers to individual and organizational learning, and is characterized by the process of knowledge creation and the active involvement of the individual with his or her work. Knowledging includes a dynamic interaction between the known (explicit) and the vision (tacit) forms of knowledge. In fact, each context from automating to informating to knowledging may be thought of as a stage, a progression requiring additional alignment threads and trade-off. In particular, the trade-off between individualism and community may impact the movement from informating to knowledging. Individualism drives individual knowledge and rewards, and thus encourages informating, while a community emphasizes sharing and is more closely associated with knowledging, including the interaction of computers, people, lateral relations, business processes, and organizational learning (including knowledge creation). Thereby, in order to create a communal knowledge space for the organization, each successive organizational transformation, from automating to informating to knowledging, requires higher levels of process abstraction and a broad range of process integration and alignment threads.

PURSUING THE IDEAL OF A LEARNING ORGANIZATION

Nowadays, enterprises including educational institutes are challenged to do things faster, better, and more cost effectively in order to remain competitive in an increasingly global economy. There is a strong need to share knowledge in a way that makes it easier for individuals, teams, and enterprises to work together to effectively contribute to an organization's success. This idea of knowledge sharing has well been exemplified in the notion of a learning organization (LO) (Garvin, 1993; King, 1996; Levine, 2001; Senge, 1990; Vat, 2001). Basically, a learning organization could be considered as an organization that focuses on developing and using its information and knowledge capabilities in order to create higher-value information and knowledge, to modify behaviors to reflect new knowledge and insights, and to improve bottom-line results. Based on this characterization of LO, there are many possible IS instances that could be incorporated into a learning organization. The acronym "LOIS" (Learning Organization Information System) (Vat, 2003; Williamson & Lliopoulos, 2001) as applied to an organization is often used as a collective term representing the conglomeration of various information systems, each of which, being a functionally defined subsystem of the enterprise LOIS, is distinguished through the services it renders. For example, if a LOIS could support structured and unstructured dialogue and negotiation among the organizational members, then the LOIS subsystems might need to support reflection and creative synthesis of information and knowledge, and thus integrate working and learning. They should also help document information and knowledge as it builds up, say, by electronic journals. Or, they have to make recorded information and knowledge retrievable, and individuals with information and knowledge accessible. Collectively, a LOIS can be considered as a scheme to improve the organization's chances for success and survival by continuously adapting to the external environment. Consequently, we stand a better chance of increasing social participation and shared understanding within the enterprise, and thus foster better learning. Although we believe that this positioning of LOIS represents a significant vision of a future generation of information systems, there are serious questions to be addressed in connection with knowledge capture and transformation, as well as intellectual asset management within the enterprise. All these have consequences for organization transformation in such areas as strategies, structures, processes, systems, and people. More importantly, the philosophy underlying the LOIS design should recognize that our knowledge is the amassed thought and experience of innumerable minds, and the LOIS helps capture and reuse those experiences and insights in the enterprise. The notion that emerges strongly resembles the classical history paradigm of learning from past events, necessitating the collection of data and repeated re-interpretation of its meaning, significance, and impact for next generations. That is also the idea of organizational learning (Senge et al., 1994), supported by an organizational memory (Conklin, 1996)—the means by which knowledge from the past is continuously brought to bear on present activities. It should possibly result in higher or lower levels of organizational effectiveness (Stein, 1992) in terms of the decision making, organizing, leading, designing, controlling, communicating, planning, and motivating functions of the management process. The cultivation of a communal knowledge space based on the organizational memory is fundamental to enterprises that intend to establish, grow, and nurture a digital learning organization (Hackbarth & Groven, 1999), where individuals grow intellectually and expand their knowledge by unlearning inaccurate information and relearning new information. Oftentimes, there is the essential difference between doing it the way we always did it (single-loop learning) and arriving at an innovative solution that establishes new patterns and relationships (double-loop learning) (Argyris, 1992; Senge et al., 1994).

SCAFFOLDING THE KNOWLEDGE FRAMEWORK

In order to create the communal knowledge space for the entire organization, an organization needs a vision that orients the entire organization to the kind of knowledge it must acquire, and wins spontaneous commitment by the individuals and groups involved in knowledge creation (Dierkes, Marz, & Teele, 2001; Stopford, 2001). It is top management's role to articulate this knowledge vision and communicate it throughout the organization. A knowledge vision should define what kind of knowledge the organization should create in what domains. It helps determine how an organization and its knowledge base will evolve in the long run (Leonard-Barton, 1995; Nonaka & Takeuchi, 1995). On the other hand, the central requirement for organizational knowledge synthesis is to provide the organization with a strategic ability to acquire, create, exploit, and accumulate new knowledge continuously and repeatedly in a circular process. To meet this requirement, we need an actionable framework, which could facilitate the installation of this strategic ability. It is believed that there are at least three major elements constituting the knowledge framework of a learning organization, including the knowledge architecture, the knowledge synthesis process, and the technical knowledge infrastructure. The first, being a component of the overall organizational architecture, is responsible for generating an ever-growing body of organizational knowledge. The second provides the formal methodology for collecting, integrating, and disseminating knowledge. The third, increasingly being virtualized over the Internet in every organization, should allow every individual to gain access to knowledge wherever and whenever it is needed.

The Knowledge Architecture

Following the idea of a learning organization, we suggest the creation of a number of architectural components in the knowledge architecture (Vat, 2001, 2003), which are intended to facilitate learning, and the creation, acquisition, plus distribution of knowledge among organizational members.

- The IL-component: The individual learning (IL) (Kim, 1993) component serves to provide training and education for individuals through the institution of workshops, apprenticeship programs, and the establishment of informal mentoring programs. Typically, an IL component provides free use of the organization's IS infrastructure to access unstructured material in order to pursue an explicit educational path, and to access structured learning material purposely designed for online self-learning. The organization that adopts the IL component in pursuit of a learning organization is betting on its people; namely, enhanced individual learning will translate into improved organizational behaviors and performance.
- The OL-component: The organizational learning (OL) (Grant, 1996; Probst & Buchel, 1997) component focuses on the use of a communities of practice approach, leading to the formation of collaborative groups composed of professionals who share experience, knowledge, and best practices for the purposes of collective growth. The conceptual basis is that group-based organizational competencies and capacities can be developed, refined, and enhanced to enable the organization to adapt to changing circumstances and demands, through such ideas as teamwork, empowerment, case management, or development-centered career paths.
- The IPM-component: This component deals with the issue of intellectual property management (IPM) (Stewart, 1997; Sveiby, 1997; Wiig, 1997) underlying the activities that are involved in leveraging existing codified knowledge assets in the form of patents, brands, copyrights, research reports, and other explicit intellectual properties of the organization. The organization that pursues the IPM component in support of a learning organization may devise a financial incentive that allows individuals and groups to be rewarded for the creation and leveraging of intellectual properties.
- The KM-component: The knowledge management (KM) (O'Leary, 1998) component focuses on the acquisition, explication, and communication of mission-specific professional expertise that is largely tacit in nature to organizational participants in a manner that is focused, relevant, and timely (Grant, 1996; King 1999; van der Spek & De Hoog, 1995; Wiig, 1993). The conceptual basis is that an organization's tacit knowledge can, in part, be made explicit, and leveraged through the operation of KM-related processes and systems developed for knowledge sharing.

The Knowledge Synthesis Process

Knowledge synthesis is a social as well as an individual process. Sharing tacit knowledge requires individuals to share their personal beliefs about a situation with others. At that point of sharing, justification becomes public. Each individual is faced with the tremendous challenge of justifying his or her beliefs in front of others—and it is this need for justification, explanation, persuasion, and human connection that makes knowledge synthesis a highly fragile process. To bring personal knowledge into a social context, within which it can be amplified or further synthesized, it is necessary to have a field that provides a place in which individual perspectives are articulated and conflicts are resolved in the formation of higher-level concepts. In a typical organization, the field for interaction is often provided in the form of an autonomous, self-directed work team, made up of members from different functional units. It is a critical matter for an organization to decide when and how to establish such a team of interaction in which individuals can meet and interact. This team triggers organization knowledge synthesis through several steps. First, it facilitates the building of mutual trust among members, and accelerates creation of an implicit perspective shared by members as tacit knowledge. Second, the shared implicit perspective is conceptualized through continuous dialogue among members. Tacit field-specific perspectives are converted into explicit concepts that can be shared beyond the boundary of the team. It is a process in which one builds concepts in cooperation with others. It provides the opportunity for one's hypothesis or assumption to be tested. As Markova and Foppa (1990) argue, social intercourse is one of the most powerful media for verifying one's own ideas.

Next comes the step of justification, which determines the extent to which the knowledge created within the team is truly worthwhile for the organization. Typically, an individual justifies the truthfulness of his or her beliefs based on observations of the situation; these observations, in turn, depend on a unique viewpoint, personal sensibility, and individual experience. Accordingly, when someone creates knowledge, he or she makes sense out of a new situation by holding justified beliefs and committing to them. Indeed, the creation of knowledge is not simply a compilation of facts, but a uniquely human process that cannot be reduced or easily replicated. It can involve feelings and belief systems of which we may not even be conscious. Nevertheless, justification must involve the evaluation standards for judging truthfulness. There might also be value premises that transcend factual or pragmatic considerations. Finally, we arrive at the stage of cross-leveling knowledge (Nonaka, Toyama, & Konno, 2002). During this stage, the concept that has been created and justified is integrated into the knowledge base of the organization, which comprises a whole network of organizational knowledge.

The Knowledge Infrastructure

The knowledge infrastructure supporting the idea of a learning organization is based on a simple philosophy; namely, various knowledge services, in support of a specific LOIS context (say, the creation of a communal knowledge space), must be interpreted as the essential means to realize the particular synthesis processes for organizational knowledge transfer. And such services could be made available to their users in the form of different distributed Web-based applications, which are each designed and tested incrementally and iteratively according to the purposeful activities of the organizational scenarios. The challenge is how to design the infrastructure to enable spontaneous knowledge capture and transfer so as to turn the scattered, diverse knowledge of individual knowledge workers into well-structured knowledge assets ready for reuse in the organization (De Hoog, Benus, Vogler, & Metselaar, 1996). Accordingly, adoption of a three-tiered configuration—composed of respectively the front-end KM services (KMS), the middle-layer KM architecture (KMA), and the back-end organizational memory (OM)—is suggested (Vat, 2000, 2002).

- The knowledge management services (KMSs): The design of front-end KM services is an attempt to recognize the human assets within the minds of individuals, and to leverage them as organizational assets that can be accessed and used by a broader set of individuals on whose decisions the organization depends. According to Nonaka and Takeuchi (1995), organizational knowledge can be created through the interactions between tacit and explicit knowledge based on the SECI (socialization, externalization, combination, and internalization) process. Consequently, our KM services can be devised based on these four modes of interactions. The 'knowledge socialization' process usually occurs in the form of informal communication when someone raises a question for discussion or an issue that requires a response. The 'knowledge internalization' process occurs when we are actively searching for methods or lessons learned to solve problems at hand. We internalize knowledge by doing, and also by observing what other people have done in a similar context and by example. The 'knowledge externalization' process is aimed at structuring knowledge and making it available to other users. It involves concept mapping, tacit knowledge categorization, and representation. The 'knowledge combination' process involves various knowledge sharing and decision coordination.

- The knowledge management architecture (KMA): The KMA acts as the middle layer supporting the front-end KMS through the back-end OM. Its logical requirements are to satisfy the KM concerns to create, retain, share, and leverage knowledge from the personal level to the team level, the organizational level, and even the inter-organizational level. Its development is conceived from two architectural perspectives: the business architecture and the technology architecture. The former involves the development of management solutions that are related to modeling the business functionality of the organization—namely, business strategies, processes, and structures that enhance and facilitate organization-wide knowledge leveraging. The latter involves the development of information and communications technology (ICT) components within an intranet-based knowledge medium to translate the organization's business vision into effective electronic applications that support the intra- and inter-organizational KM services.
- The organizational memory (OM): The KM processes involved in organizational learning often require iterations of references and modification of the components developed in the business and the technology architectures of the KMA. This requirement implies the importance of a reusable asset repository for storing various business-specific and technology-related components in the form of tacit and explicit knowledge items. The OM could be designed to fulfill this specific requirement. For example, it could be structured into the business repository and the technology repository. Typically the business repository stores knowledge items we can use to standardize definitions of organizational and process models. And we can archive existing process components, which can then be recalled later by coworkers in other departments to be reused or modified for new process models. Similarly, the technology repository stores technology resources such as 'business objects', pre-built and purchased components, developer documentation, and numerous other technology standards.

FUTURE TRENDS OF IS DESIGN FOR KNOWLEDGE SHARING

According to Checkland and Holwell (1995), the main role of an information system is that of a support function. The IS function is to support people taking purposeful action by indicating that the purposeful action can itself be expressed via some activity models, which are called the "human activity systems" (HAS) models from the perspective of soft systems methodology—SSM

(Checkland & Scholes, 1990). The job of providing IS support can then be thought about as entailing a pair of systems, one a system which is served (the people taking the action), and the other a system which does the serving. Thereby, whenever a system serves or supports another, it is a very basic principle of SSM (Checkland, 1983) that the necessary features of the serving system can be worked out only on the basis of a prior account of the system served. This is because the nature of the system served—the way it is thought about—will dictate what counts as service, and hence what functions the system which provides that service must contain (Checkland, 1981, p. 237). Thus, an IS strategy concerning support to an organization, such as a LOIS, can be coherently designed and set up only on the basis of a clear concept of the knowledge sharing context. This is true not only for the IS strategy of the learning organization as a whole, but also for the thinking concerning each detailed system created within that strategy. Consequently, the process of IS development needs to start not with attention quickly focused on data and technology, but with a focus on the actions served by the intended organizational system. Once the actions to be supported have been determined and described (using various HAS-based activity models), we can proceed to decide what kind of support should be provided, say: automating action which is currently being carried out by people; or informating people (providing information support to people) (Zuboff, 1988); or knowledging teams of people (facilitating their social and mental exchange) (Savage, 1996) as they carry out their tasks. In each case, we need to determine what will help people take the desired action, and what will help to monitor the action and make adjustments if desired outcomes are not emerging. Often the monitoring and control needs to be thought about carefully in terms of some declared measures of performance, which should derive from how the purposeful activity is conceptualized. The key point is that in order to create the necessary IS support that serves the intended organizational scenario, it is first necessary to conceptualize the organizational system that is to be served, since this order of thinking should inform what relevant services would indeed be needed in the IS support.

CONCLUSION

This article describes an initiative to develop an actionable framework for knowledge synthesis, paying particular attention to the design issues in support of participatory knowledge construction, in the context of organization transformation in today's prevailing knowledge economy. Our discussion intends to clarify the ideal of a learning organization (LO) which is designed to help transfer learning from individuals to a group, provide for organizational renewal, keep an open attitude to the outside world, and support a commitment to knowledge. In particular, we have elaborated the design issues of the LOIS support that help structure and facilitate knowledge interconnectivity, in terms of a three-tiered technical knowledge infrastructure comprising the front-end knowledge management services, the mid-layer of knowledge management architecture, and the back-end organizational memory. To realize the LOIS support, it is also necessary to examine the underlying processes in which, in a specific organizational context, a particular group of people can conceptualize their world and hence the purposeful action they wish to undertake. We need to understand why, among these people, certain data are selected and treated as relevant items in order to get the best possible definitions of accepted purposes and the intentional action that follows from pursuing them. The examination of meanings and purposes, in support of designing the necessary IS functions, should be broadly based, and its richness will be greater the larger the number of people who take part in it. Nevertheless, the examination should try to home in on the question: If we want to pursue this purpose, which seems meaningful to us, what would we have to do and how could we do it? Remembering the many possible relationships that have to be managed, we have to acknowledge the rarity of complete consensus among different people. What are sought are often the accommodations, which enable some meaningful work to be sustained in undertaking actions relevant to plausible purposes. This consequently provides the basis for ascertaining the organization's communal knowledge space: namely, what IS support is truly needed by those undertaking their actions, and how modern IT can help to provide that support.

Chapter 1.28
Communities of Practice and Organizational Development for Ethics and Values

Jim Grieves
University of Hull, UK

INTRODUCTION AND BACKGROUND

Ethics is the study of moral issues and choices. In organizations, such a study inevitably involves consideration of decision-making practices and interpersonal relationships. This in turn may require the investigation of complex combinations of influences which include personality characteristics, values, and moral principles as well as organizational mechanisms and the cultural climate that rewards and reinforces ethical or unethical behavioral practices. Organizations ignore ethical issues at their peril as we know from recent examples of:

- past claims of brutality, poor wages, and 15-hour days in the Asian sweatshops run by Adidas, Nike and GAP,
- banks that rate their customers by the size of their accounts,
- the race for commercial control by private firms, universities, and charities claiming exclusive development rights over natural processes in the human body and patents sought by organizations, overwhelmingly from rich countries, on hundreds of thousands of animal and plant genes, including those in staple crops such as rice and wheat,
- a lack of people management skills and supervision which was said to be responsible for the falsification of some important quality control data of an experimental mixed plutonium and uranium fuel at the Sellafield nuclear reprocessing scandal which led to cancelled orders and the resignation of its chief executive.

We can all think of other examples that have hit the headlines to indicate that modern business management must recognize its responsibility to provide an ethical framework to guide action. This is the case in respect to human resources policy, health and safety policy, marketing policy, operations management, and environmental management.

Ethical policymaking has become the watchword for both national and local government. Ethics is now taught in the police force in order to be proactive and combat discrimination. Concern is now expressed in all forms of decision making from genetic modification of foods and the patenting of human organs to the ethical decisions of pharmaceutical companies or the marketing dilemmas of global corporations. Despite these developments, we continue to find many examples of decision makers making bad ethical decisions and people who blow the whistle on many of those actions. On the positive side, we have seen how so called green organizations have proved that ethics and profit are not incompatible goals.

COMMUNITIES OF PRACTICE AND SOCIAL RELATIONSHIPS

While many of these issues will engage people at the organizational level, communities of practice need to be aware of ethical issues particularly in relation to social relationships. This is because compromises have often to be made in relation to decision making as well as in the production of products and the provision of services. We can therefore distinguish between deliberate practices which include activities to deceive others such as consumers, employees, or colleagues and stakeholders from actions which are not premeditated to deceive but do, nevertheless, contravene what we might call ethical standards.

There are also many practices that may not be legally defined as unethical but which may result from collusion between subordinates and others who hold positions of power. Such examples are often not perceived as controversial and tend to be rationalized by means of situational expediency. These are related to the five main sources of power articulated by French and Raven (1968) and involves the relative perceptions of the manager and subordinate relationship. The examples below indicate how this can occur when an individual makes decisions that are informed by perceptions and situational circumstances that constrain reflective judgment.

1. Reward power is seen to legitimize actions when a subordinate perceives the manager has the ability and resources to obtain rewards for compliance with directives. These often take the form of pay, promotion, praise, recognition, and the granting of various privileges. While this is quite a natural process, it can give rise to conflicts of interest when the motives of a subordinate are informed by personal gain, and those of the manager seek to achieve instrumental objectives.
2. Coercive power may not legitimize the actions to conform in the eyes of subordinates, but it does explain how collusion is sometimes related to perceived fear of punishment. This may, of course, be extremely subtle since the perception of punishment may be related to desired personal objectives or rewards such as promotion or an increase in pay. The abuse of power occurs when power holders can exercise power to the extent that subordinates fear that non-compliance may lead to the allocation of undesirable tasks or to lost opportunities to progress their careers.
3. Legitimate power reflects the assumptions of subordinates that a power holder as manager or supervisor has a right to expect compliance with a particular course of action. This is fairly typical of the position power that exists within bureaucratic structures. Unless subordinates are extremely knowledgeable about their own rights in relation to a particular manager's legitimate right to command obedience, they are likely to be drawn along by the situation.
4. Referent power occurs when a particular manager exercises influence because of charismatic reasons or because of personal

attributes perceived to be desirable by subordinates. In situations where a conflict of interest may occur, collusion in a course of action may result because subordinates may be over-zealous in their pursuit of particular objectives while failing to reflect on the consequences of their actions. This may often be the motive for group-think, the consequences of which may be disastrous for an organization.

5. Expert power occurs when a leader is perceived to have a special knowledge, expertise, or degree of competence in a given area. In such cases, subordinates and, indeed, other stakeholders are likely to defer to the expertise of a particular individual. Thus, alternative judgments and information can be overlooked.

Because individuals often seek to achieve organizational objectives, their tendency to ignore conflicting value systems can create value dilemmas and ethical conflicts of interest. Many people do report conflict of interest in their work. Examples often cited in relation to overt practices include bribes, gifts, slush funds, concealing information from customers, shareholders, or, more generally, from the market place, engaging in price-fixing, and so on. We can regard these examples as institutionalized practices, but there are also examples where ethical problems emerge because of workplace pressures to achieve results.

How people come to rationalize their judgments is partly explained by the exercise of power but is also informed by the belief that actions are not illegal or unethical. This is illustrated by Gellerman (1986) who argues that there are four commonly held rationalizations that lead to ethical misconduct:

1. The belief that the activity is within reasonable ethical and legal limits—that it is not “really” illegal or immoral.
2. A belief that the activity is in the individual’s or the corporation’s best interests—that the individual would somehow be expected to undertake the activity.
3. A believe that the activity is “safe” because it will never be found out when publicized—the classic crime-and-punishment issue of discovery.
4. A belief that, because the activity helps the company, the company will condone it and even protect the person who engages in it.

LESSONS FROM ORGANIZATIONAL DEVELOPMENT

While ethical issues in organizations can be addressed from a variety of perspectives and raise complex theoretical issues, it would be more instructive for the reader to consider whether a community of practice should address ethical issues separately from the procedures and guidelines identified within their own organizations. Where guidelines and ethical codes for practice exist, as they do in many organizations, then members of a CoP will be obliged to be guided by them. In this respect, employees are likely to be informed by organizational values, rules, and guidelines or by professional codes of practice. However, as a general principle, it is recommended that members of a CoP consider their own activities in relation to the extent to which interventions will be a consequence of their actions.

Some lessons from organizational development (OD) may assist CoP members in meeting their objectives. The first point to be made is that OD is informed by its own value system, and OD consultants accept that they are bound by humanistic and democratic values. These are seen to be essential to building trust and collaboration within an organization. Nevertheless, there are some difficulties here.

The first major dilemma for an OD consultant is the extent to which the pursuit of humanistic values is contradicted or compromised by the desire to achieve organizational effectiveness. As Cummings and Worley (1997) argue, "more practitioners are experiencing situations in which there is conflict between employees' needs for greater meaning and the organisation's need for more effective and efficient use of its resources" (p. 57). As a result, it is important to identify any areas of potential concern at the point of agreeing to a contract with the client system. It should be clear, therefore, that any contract must make it transparent that organizational efficiency and effectiveness will depend upon an open and democratic concern for improvement through the organization's employees. And this, of course, has not always been the case where more programmed approaches to change management (for example, TQM, BPR) have sometimes adopted more instrumental and formulaic approaches to their interventions.

The second dilemma is related to the value conflict that OD practitioners are likely to face in relation to the different perspectives of stakeholder groups. Whereas traditional OD tended to adopt a relatively naive functionalist perspective, contemporary OD practitioners/consultants are much more likely to be aware of the plurality of interests operating within an organization. This inevitably means that different stakeholders will need to be consulted and their views explored in order to arrive at a workable intervention strategy. Each of these potential value conflicts may arise when consultants are not clear about their roles. In other words, role conflict and role ambiguity can give rise to value dilemmas.

A third dilemma relates to technical ability. In other words, a change agent who fails to act with sensitivity to the needs of the client system and who fails to possess sufficient knowledge and skill of underpinning behavioral issues is acting unethically. Thus, the ability to analyze a problem situation and to diagnose a potential solution requires an awareness of the variety of intervention strategies appropriate to the nature of the problem identified.

CONCLUSION AND FUTURE TRENDS: ETHICAL GUIDELINES FOR COMMUNITIES OF PRACTICE

Communities of practice might therefore consider whether they have a helping role in relation to a particular client system. If they do, then they will need to question the following:

1. The needs of the client system in its widest possible sense which, of course, may include all stakeholders and/or different employee groups.
2. The extent to which compromises are possible in relation to organizational efficiency and effectiveness vis-a-vis humanistic values.
3. The clarity of purpose or remit of the CoP in order to achieve its defined objectives.
4. The extent to which members of the CoP possess sufficient knowledge and internal skills in relation to (a) intrapersonal skills; (b) interpersonal skills; (c) consultation skills; (d) knowledge of underpinning organizational behavior.

A useful set of guidelines has been provided by the Human Systems Development Consortium (HSDC). These are stated in-depth in Cummings and Worley (1997) and refer to four main areas that should be addressed. These are (1) responsibility for professional development and competence; (2) responsibility to clients and significant others; (3) responsibility to the profession; (4) social responsibility. The reader is advised to read these issues in more depth and consider their relevance to any CoP activities they are currently undertaking.

As we noted previously, an organization's reward system can compound the problem of ethical dilemmas caused by the pressure for results. Like organizations, a CoP should consider rules for its own ethical climate. A basic framework should include the following:

1. Act as a role model by demonstrating positive attitudes and behaviors that signal the importance of ethical conduct.
2. Develop a code of ethics which (a) is distributed to everyone; (b) refers to specific practices and ethical dilemmas likely to be encountered; (c) rewards compliance and penalizes non-compliance.
3. Where necessary, provide ethics training designed to identify solutions to potential problems.
4. Create mechanisms such as audits to deal with ethical issues.

Social Capital Knowledge

Daniel L. Davenport

Clyde W. Holsapple
University of Kentucky, USA

INTRODUCTION

Organizations have capabilities for creating and sharing knowledge (intellectual capital) that give them their distinctive advantage over other institutional arrangements, such as markets (Ghoshal & Nahapiet, 1998). But, what is the basis of a firm's knowledge development capabilities? At least in part, the answer is that these capabilities stem from the social capital that an organization possesses as a result of bringing people together for extended periods of time, creating interdependence through specialization and integration, forcing interaction, and providing boundaries and directions. Following the resource-based theory of the firm (Conner & Prahalad, 1996), enterprises that cultivate particular forms of social capital are likely to realize competitive advantages (Ghoshal & Nahapiet, 1998).

This article traces the connections between an organization's social capital and the organization's development of knowledge. Understanding these connections is important for leaders of knowledge management initiatives, particularly if they seek to leverage knowledge production into enhanced competitiveness. We begin with a background discussion of the nature of social capital including its structural, cognitive, and relational dimensions. This is followed by a consideration of intellectual capital (i.e., knowledge that can be used to achieve an organization's purpose) and an explanation of the supportive role of social capital in furnishing conditions necessary for developing this knowledge. We describe a model of knowledge conversion processes whereby intellectual capital is developed within a social capital context known as Ba. Some future trends in socially-based processes of knowing by people and organizations are outlined, followed by concluding remarks.

BACKGROUND

Social capital is the "sum of actual and potential resources embedded within, available through, and derived from the network of relationships possessed by an individual or social unit. Social capital thus comprises both the network and the assets that may be mobilized through that network" (Nahapiet & Ghoshal, 1998, p. 243). All social capital constitutes some aspect of social structure and facilitates the actions of individuals within that structure (Coleman, 1990). Social capital is inherent in relationships among persons and is a productive asset facilitating some forms of social action while inhibiting others. It has three dimensions: (1) structural, (2) relational, and (3) cognitive.

The structural dimension of social capital includes three "properties of the social system and of the network of relations as a whole" (Nahapiet & Ghoshal, 1998, p. 244): appropriable organization structure, network ties, and network configuration within a set of relationships. Appropriable organization structure refers to structure created for one purpose which provides a valuable source of resources for another purpose. Network ties are social relations that provide information benefits in the form of access, timing, and referrals. Network configuration refers to the structure of network ties that influence the range of information and the cost in accessing it.

The cognitive dimension of social capital includes those resources providing shared representations, interpretations, and systems of meaning among parties (Cicourel, 1973). Examples are shared language and codes, ontologies, and shared narratives.

- Shared language and codes: The means by which people discuss and exchange information, ask questions, and conduct business. Language and codes organize sensory data into perceptual categories and provide a frame of reference for observing and interpreting our environment. Language and codes filter our awareness. A common language enhances the capacities for sharing knowledge and for combining knowledge.
- Ontologies: Simplified, abstract views of a domain adopted by participants in an organization that characterizes key concepts and offers axioms about them and their relationships (Gruber, 1995). Commitment by participants to an ontology promotes sharing and reuse of knowledge, collaborative exploration of the domain, and development of new knowledge about the domain.
- Shared narratives: Myths, stories, and metaphors that provide powerful means in communities for creating, exchanging, and preserving rich sets of meanings (Denning, 2000).

The relational dimension of social capital includes the kinds of personal relationships that people have developed with each other through a history of interactions (Granovetter, 1992). This dimension stems from, or is conditioned by, an organization's culture and subcultures. It includes the trust, norms, obligations, and identification within a set of relationships.

Trust is a belief that results of an entity's intended action will be beneficial (or at least not harmful) to our interests (Miztal, 1996). Factors that promote trust include open communication, participation in decision-making, sharing valuable knowledge, and sharing viewpoints and attitudes (Mishra & Morrisey, 1990). Where relationships are high in trust, people are more willing to engage in social exchange, in general, and cooperative interaction, in particular (Nahapiet & Ghoshal, 1998). A norm exists when the socially-defined right to control an action is held not by the actor but by others; norms are expectations that bind (Kramer & Goldman, 1995). Norms may have a significant influence on exchange processes involved in knowledge development, opening up access to parties for the exchange of knowledge and ensuring the motivation to engage in such exchange (Nahapiet & Ghoshal, 1998).

Obligations and expectations refer to commitments or responsibilities to undertake some activity in the future. They differ from norms in that they are developed within the context of a particular relationship (Coleman, 1990). Obligations and expectations are likely to influence both access to parties for exchanging and combining knowledge and the motivation to combine and exchange such knowledge (Nahapiet & Ghoshal, 1998). Identification refers to a self perception of belonging within a social group or network, carrying with it an adherence to its culture and an understanding of characteristics or boundaries of that group that distinguish it from other groups.

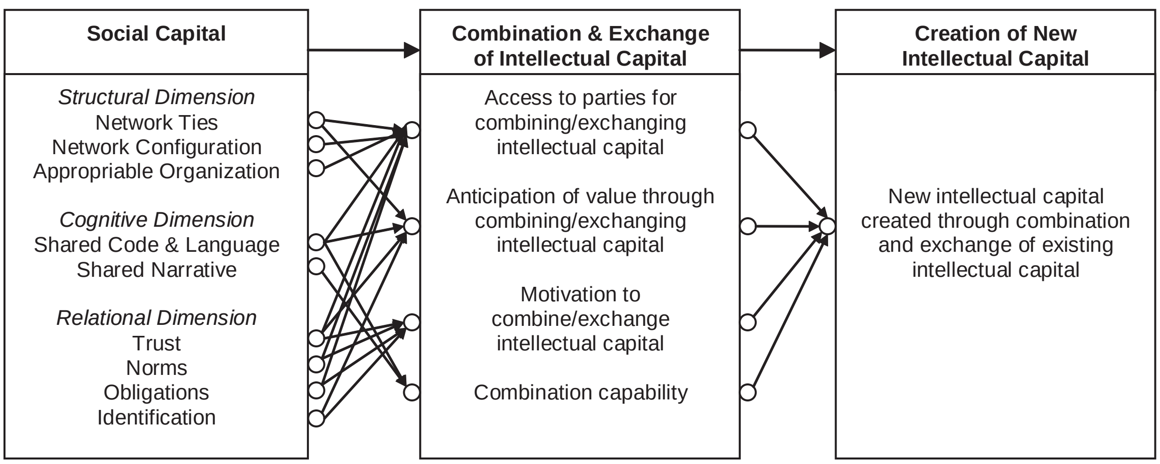
INTELLECTUAL CAPITAL CREATION AND SOCIAL CAPITAL

Intellectual capital (IC) has been defined in many ways. Relative to social capital, IC is defined as the knowledge of an organization's participants that results in a competitive advantage for that organization (Stewart, 1991), or as knowledge and knowing capability belonging to a social collective (Nahapiet & Ghoshal, 1998). Moran and Ghoshal (1996) maintain that all resources, including intellectual capital, are created primarily through the generic processes of combination and exchange of existing resources. (We note that it is unclear whether creation involving discovery, insight, or imagination can be fully described in terms of combination and exchange.) Intellectual capital, then, is developed through processes that combine knowledge and experience of different parties and is therefore dependent on exchange, which implies that knowledge development in an organization is influenced by the organization's social capital.

Because exchange often occurs through social interaction and coactivity permitted by a firm's social capital, firms provide the necessities for creating new intellectual capital through opportunities for the sustained interaction, conversations, and sociability (Nahapiet & Ghoshal, 1998). Thus, a firm can be defined as a "social community specializing in the speed and efficiency in the creation and transfer of knowledge" (Kogut & Zander, 1996, p. 503).

Through their purpose and organizational structure, firms develop social closure and interdependence. Closure is a feature of social relationships that is conducive to the development of high levels of relational and cognitive social capital. Formal organizations such as firms, by definition, imply a measure of closure through the creation of explicit legal, financial, and social

Figure 1. Social capital in the creation of intellectual capital (Nahapiet & Ghoshal, 1998)



boundaries (Kogut & Zander, 1996). Because they promote specialization and integration (i.e., interdependence), firms encourage development of social capital and, hence, intellectual capital as well.

There are four conditions that must exist for the creation of new intellectual capital through exchange to take place: (1) opportunity, (2) expectation of the creation of value, (3) motivation (expectation of realizing and benefiting from some of the newly created value), and (4) capability (Nahapiet & Ghoshal, 1998). The links between the elements and dimensions of social capital and these four conditions are shown in Figure 1. The structural elements of social capital are shown promoting access to participants and anticipation of value. The cognitive elements support access to participants, anticipation of value, and combination capability. The relational dimension elements support access, anticipation of value, and motivation for exchange.

Social Knowledge

In addition to supporting the creation of new intellectual capital through combination and exchange, social relationships become the locus for their own type of intellectual capital, called social knowledge. Social knowledge is knowledge inextricably embedded in complex, collaborative social practices, separate from individual knowledge. This is consistent with the notion of schematic knowledge resources (Holsapple & Joshi, 2004), which exist independent of any organizational participant and include an organization's purpose/vision, strategy, culture, and infrastructure (i.e., roles, relationships, regulations).

Nahapiet and Ghoshal (1998) have identified two modes of social knowledge: explicit and tacit. They define the former as "objectified" knowledge shared across the organization. Social tacit knowledge, on the other hand, is fundamentally embedded in the forms of social and institutional practice; it resides in the tacit experiences and enactment of the collective (Brown & Duguid, 1991). Such knowledge and knowing capacity may remain relatively hidden from individual actors but manifests and is sustained through their interactions (Spender, 1994). The notions of tacit and explicit knowledge play a central role in the SECI model.

The SECI Model and Ba

The SECI model is a conceptualization of how new intellectual capital is developed via processes of socialization, externalization, combination, and internalization (SECI). The SECI model focuses on the perspective of knowledge as existing in two modes: tacit and explicit. Value creation by an organization emerges from using the four processes to convert knowledge between tacit and explicit modes. This conversion happens within Ba, "a shared space for emerging relationships" (Nonaka & Konno, 1998, p. 40). The concept of Ba is a perspective on the idea of social capital as discussed.

Tacit and Explicit Knowledge

One of the many attributes for characterizing knowledge is its mode (Holsapple, 2003). Two modes of knowledge are tacit and explicit. Sometimes, a third mode, called implicit knowledge, also is considered. "Tacit knowledge is highly personal and hard to formalize, making it difficult to communicate or share with others. Subjective insights, intuitions, and hunches fall into this category of knowledge. It is deeply rooted in an individual's actions and experience as well as in the ideals, values, or emotions he/she embraces." (Nonaka & Konno, 1998, p. 42) They go on to contend that there are two dimensions of the tacit mode:

- Technical dimension of tacit knowledge: "The informal personal skills or crafts often referred to as 'know-how.'"

- Cognitive dimension of tacit knowledge: "Beliefs, ideals, values, schemata, and mental models which are deeply ingrained in us and which we often take for granted. It shapes the way we view the world."

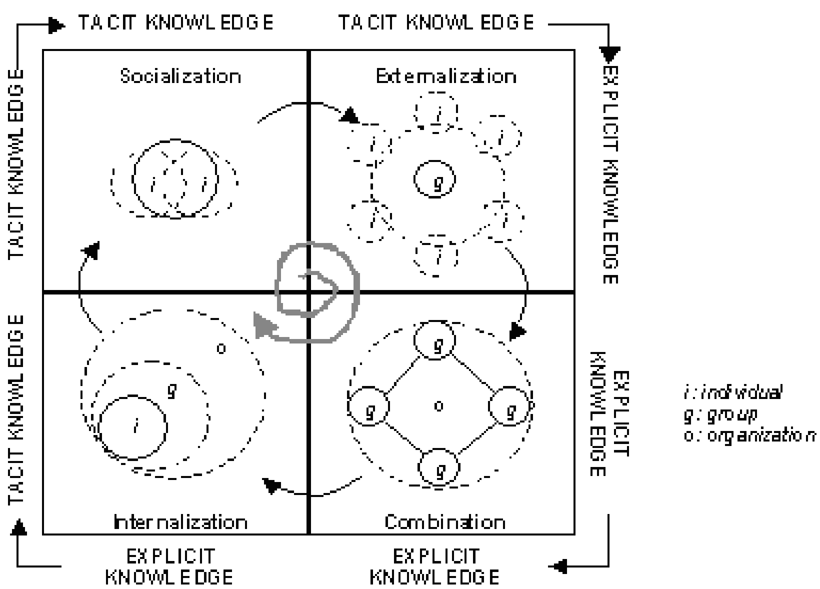
Explicit knowledge is knowledge that can be codified into symbolic representations such as words and numbers. As such, it can be readily transferred among persons in formal, systematic ways.

THE SECI SPIRAL OF KNOWLEDGE CREATION

In the SECI model, knowledge creation is a spiraling process of conversions between explicit and tacit knowledge. The combinations of possible interactions between the two modes lead to four conversion patterns called socialization, externalization, combination, and internalization. These are illustrated in Figure 2 and characterized by Nonaka and Konno (1998) as follows:

- Socialization is the process of individuals sharing tacit knowledge. It is shared through interaction over time, rather than through written or verbal instructions. It involves transcending oneself and empathizing with another.
- Externalization is the articulation into explicit knowledge of previously held tacit knowledge to others within a group setting. In externalization, the individual fuses with the group and transcends their inner and outer boundaries of self.
- Combination is the process of synthesizing explicit knowledge into new, more complex explicit knowledge.

Figure 2. Spiral evolution of knowledge conversion and self-transcending process (Nonaka & Konno, 1998)



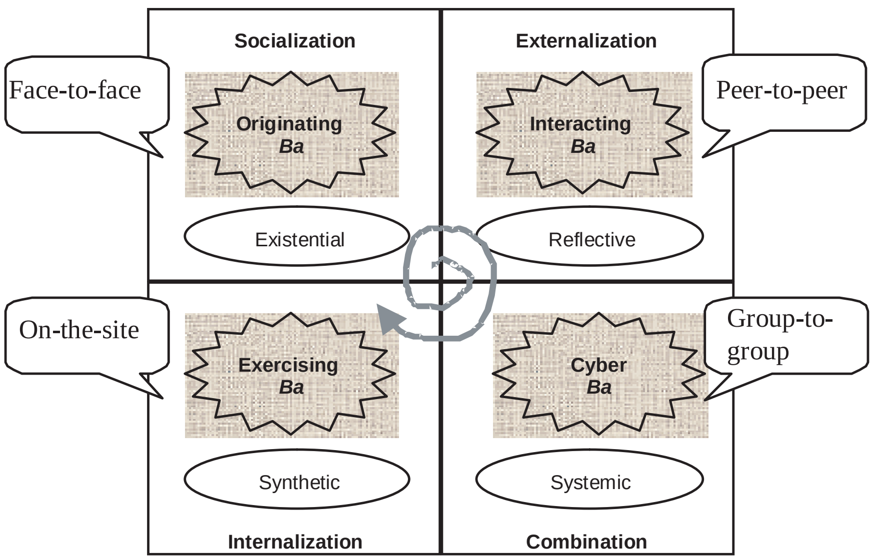
- Internalization is the process whereby new knowledge is shared throughout the organization and various participants convert it to their own tacit knowledge through using it to broaden, extend, and reframe their own tacit knowledge.

The Shared Space of Ba

The four conversion processes for developing knowledge take place in Ba: "a shared space for emerging relationships.…This space can be physical, mental, virtual, or any combination.…It is the platform for the "resource concentration" of the organization's knowledge assets and the intellectualizing capabilities within the knowledge-creation process" (Nonaka & Konno, 1998, p. 40). Organizations manage knowledge creation through nurturing the Ba (i.e., social capital) that provides its context. The four aspects of Ba illustrated in Figure 3 correspond with the four stages of the SECI model: originating, interacting, exercising, and cyber Ba. Each is especially suited to the knowledge conversion process that it supports. Nonaka and Konno (1998, pp. 46-47) describe the four social capital spaces as follows:

- Originating Ba is the "space where individuals share feelings, experiences, and mental models. An individual sympathizes or further empathizes with others, removing the barrier between self and others." Originating Ba produces care, love, trust, and commitment leading to self-transcendence and therefore sharing and new knowledge. It is the primary Ba from which the knowledge creating process begins.
- Interacting Ba is the "shared space where people's mental models and skills are converted into common terms and concepts through dialogue. It is the place where tacit knowledge is made explicit and represents the externalization process."
- Cyber Ba is a "place of interaction in a virtual world instead of real space and time; and it represents the combination phase. Here the

Figure 3. Four characteristics of Ba (Nonaka & Konno, 1998)



combining of new explicit knowledge with existing information and knowledge generates and systematizes explicit knowledge throughout the organization." Cyber Ba supports the combination process.

- Exercising Ba is the space that supports the internalization process. It facilitates the conversion of explicit knowledge to tacit knowledge in the individual. "Rather than learning from teaching based on analysis, it stresses learning through continuous self-refinement via on-the-job training or peripheral and active participation."

Thus, the SECI model identifies four social capital spaces that an organization needs to cultivate as a basis for developing knowledge by way of the four conversion processes. Further information about the SECI model and Ba can be found in Nonaka and Takeuchi (1995, 1996) and Nonaka (1991, 1994). For instance, Nonaka and Takeuchi (1995) indicate that even when there is social capital conducive to knowledge creation, further conditions need to be met: vision, autonomy, fluctuations, redundancy, and variety. The organization needs a clear vision that allows it to evaluate the utility of developed knowledge relative to the organization's purpose and strategy. The condition of autonomy means that participants in the organization should be self-motivated in their quests for new knowledge. Fluctuation refers to the introduction of breakdowns in rigid, stale processes as a means for fostering creative chaos. The redundancy condition refers to having knowledge available beyond what is necessary for supporting short-run operations. Finally, variety is concerned with ensuring sufficient internal diversity to deal with the dynamics and complexity of situations imposed by external circumstances.

The Knowing Organization

Extending the work of Nonaka and colleagues, Choo (1998) advances the notion of a knowing organization as one in which knowledge is developed not only by knowledge conversion processes of the SECI model, but also by knowledge building and knowledge linking. Like knowledge conversion, both knowledge building and knowledge linking are rooted in an organization's social capital, in the social networks that shape an organization's potential for creating knowledge.

The idea of knowledge building comes from Leonard-Barton's (1995) observation that organizations can engage in such activities as experimentation, prototyping, joint problem-solving, adopting new techniques/tools, acquiring knowledge, and acquiring special processing skills (e.g., new participants with some special expertise). These kinds of activities are both enabled and constrained by the structural, relational, and cognitive dimensions of an organization's social capital. They build on an organization's current knowledge base in the sense of expanding its scope and quality, and leave the organization poised to better cope with its future knowledge needs.

The idea of knowledge linking holds that knowledge is developed not only by networks of participants within an organization but also by forming networks of links to external entities (e.g., customers, suppliers, partners) to encourage interorganizational knowledge flows (Badaracco, 1991; Wikstrom & Normann, 1994). That is, the social capital of an organization can be seen as having two components: internal and external. The internal orientation of social capital is concerned with internal networks among core participants in an organization (Tsai & Ghosal, 1998). The external orientation of social capital involves networking across organization boundaries, encompassing knowledge-intensive interactions between core participants and virtual or ancillary participants from outside the organization. As in the internal case, externally- oriented social capital needs to be cultivated to furnish a healthy context for fostering knowledge development.

Thus, knowledge creation can be seen as being developed from other knowledge via processes of knowledge conversion, knowledge building, or knowledge linking, each of which is conditioned by extant social capital. Choo (1998) goes on to point out that there are three kinds of organization knowing: Knowledge is used not only for knowledge creation, but also for sensemaking and decision-making. Here, we contend that both sensemaking and decision-making are knowledge creation processes that are conditioned by social capital.

Sensemaking occurs in situations that are open to multiple interpretations (Weick, 1995). It involves (1) the production or selection of an interpretive scheme to apply to the situation so as to grasp its meaning, thereby giving a basis for determining appropriate responses, and (2) the assimilation of helpful interpretive schemas to be reused or adapted for making sense of future ambiguous situations (Boland & Yoo, 2003). The immediate goal of sensemaking is for the organization's participants to share a common understanding of what the organization is and what it is doing; the longer-term goal is to ensure that the organization adapts and therefore continues to thrive in a dynamic environment (Choo, 1998).

The outcome of sensemaking is shared meanings and intents for the organization. Such sharing implies the pre-existence of social capital, a network of social relationships in which the meanings and intents can incubate and propagate. The meanings and intents are, in essence, knowledge about what is and what is should be. These did not exist before the sensemaking exercise, but rather are the result of it. Thus, sensemaking is a process of developing new knowledge, just as knowledge conversion, knowledge building, and knowledge linking are processes for developing new knowledge.

Results of sensemaking can be important ingredients for decision-making. "All organizational actions are initiated by decisions, and all decisions are commitments to action. In theory decision-making is rational, based upon complete information about the organization's goals, feasible alternatives, probable outcomes of these alternatives, and the values of these outcomes to the organization. In practice choicemaking is muddled by the jostling of interests among stakeholders, idiosyncrasies of personal choice making and lack of information" (Choo, 1996, p. 329). In other words, decision-making processes happen within the context of social networks which have the property of either facilitating/enhancing the process or muddling/obstructing it. This is certainly the case for multi-participant decision-making (i.e., multiple entities participate in the making of a decision). It is also the case, albeit indirectly, for individual decision-making (i.e., the individual's deliberations are affected by the organization's social capital).

Decision-making has long been recognized as a knowledge-intensive activity (Bonczek, Holsapple, & Whinston, 1981; Holsapple, 1995). Knowledge is the raw material, work-in-process, byproduct, and final outcome of decision-making. That is, a decision is knowledge that indicates a commitment to action. Thus, decision-making processes are knowledge creation processes, just as sensemaking, knowledge conversions, knowledge building, and knowledge linking. All five of these approaches to developing knowledge unfold in and as a result of an organization's social capital.

FUTURE TRENDS

Understanding knowledge development and its antecedents, particularly those related to social capital, is an important issue for KM practitioners and remains an area for continuing investigation by researchers. For instance, is there a difference in how social capital manifests in large enterprises vs. small firms? Characterizations of social capital are often made from the standpoint of the large enterprise. Davenport, Graham, Kennedy, and Taylor (2003) are studying how social capital manifests in small firm networks that rely on rapid turnover of projects, as a basis for devising prescriptions about building, maintaining, and refreshing social capital. As another example, consider the constructs that contribute to social capital. One of these is trust. Ford (2003) analyzes trust implications for knowledge processes such as knowledge creation. She poses a series of propositions that give a starting point for future research into the connections between trust and the development of knowledge. Similar analyses and detailed proposition statements wait to be performed for the connections between other social constructs and knowledge development.

At a more macro level, social capital connections to knowledge development are related to several broad topic areas within the KM field. Advances in these topic areas will impact our understanding of better creating the social capital needed for effective knowledge development, and vice versa. One of these topics is communities of practice (Brown & Duguid, 1991; Wenger, 2000). These are social networks (often technologically supported or enabled) that are dedicated to knowledge sharing and development pertaining to some domain of interest/expertise that is common to participants in the community. Another topic area is organizational learning (Bennet & Bennet, 2003) which is concerned with the means whereby organizations learn (i.e., develop greater intellectual capital) and the impacts of that learning. All five of the knowledge development approaches identified in this article can be regarded as variants of organizational learning. For organizational learning to happen, there must be sufficient social capital in terms of communication, interaction, and flexibility (Allard, 2003).

The knowledge management ontology (Holsapple & Joshi, 2004) suggests that we need to better understand techniques and technologies that can foster knowledge development episodes in an organization; specifically how do we lead, coordinate, control, and measure such episodes relative to the organization's present resources and environing situation? These and other questions remain for practitioners and researchers to resolve.

CONCLUSION

An organization's intellectual capital includes the knowledge that it can apply to enhance performance through increased productivity, agility, innovation, and/or reputation. Given the challenges of a dynamic, global, hypercompetitive environment, it is imperative that organizations be actively and consciously engaged in developing knowledge. One prerequisite for doing so is social capital. This article has outlined basic considerations important for cultivation of social capital and described its connections with the development of intellectual capital. It has identified five kinds of knowledge creation: knowledge conversions, knowledge building, knowledge linking, sensemaking, and decision-making. All of these deserve and can benefit from attention by leaders of KM initiatives and by the cultivation of appropriate networks of social relationships. The result is a more competitive organization.

Chapter 1.30
Knowledge Communication

Martin J. Eppler
University of Lugano, Switzerland

INTRODUCTION: THE IMPORTANCE OF KNOWLEDGE COMMUNICATION IN MANAGEMENT

Communicating professional knowledge is a key activity for today's specialized workforce. The efficient and effective transfer of experiences, insights, and know-how among different experts and decision makers is a prerequisite for high-quality decision making and coordinated, organizational action (Straub & Karahanna, 1998). Situations of such deliberate (interfunctional) knowledge transfer through interpersonal communication or group conversations (Gratton & Goshal, 2002) can be found in many business constellations, as the following typical examples illustrate:

Technology experts present their evaluation of a new technology to management in order to jointly devise a new production strategy (McDermott, 1999). Engineers who have discovered how to master a difficult manufacturing process need to convey their methods to engineers in other business units (Szulanski, 1996, 1999). Legal experts brief a management team on the implications of new regulations on their business model (Wilmotte & Morgan, 1984). Experts from various domains need to share their views and insights regarding a common goal in order to agree on a common rating of risks, requirements (Browne & Ramesh, 2002), industries, or clients. Project leaders need to present their results to the upper management and share their experiences of past projects in order to assess the potential of new project candidates (Schindler & Eppler, 2003). Scientists who work as drug developers present new avenues for future products that business unit managers must assess. Market researchers present their statistical analyses of recent consumer surveys to the head of marketing (Boland et al., 2001). Strategy consultants present the findings of their strategic company assessment to the board of directors in order to devise adequate measures (Creplet, Duouet, Kern, Mehmanzapir, & Munier, 2001).

What these diverse situations all have in common is the problem of knowledge asymmetry (Sharma, 1997) that has to be resolved through interpersonal communication. While the manager typically has the authority to make strategic or tactical decisions, he or she often lacks the specialized expertise required to make an informed decision on a complex issue (Watson, 2004). Because of the wide scope of decisions that need to be made, a manager frequently has to delegate the decision preparation to experts who—based on their professional training and previous experience—can analyze complex situations or technological options in a more reliable manner. The results of such analyses then need to be communicated back to the manager, often under considerable time constraints. The knowledge communication challenge, however, begins long before that, at the time when the manager has to convey his or her knowledge needs and decision constraints to the experts in order to delegate the analysis task effectively.

BACKGROUND: THE CONCEPT OF KNOWLEDGE COMMUNICATION

Based on the reasoning described in the previous section, we define knowledge communication as the (deliberate) activity of interactively conveying and co-constructing insights, assessments, experiences, or skills through verbal and non-verbal means. Knowledge communication has taken place when an insight, experience, or skill has been successfully reconstructed by an individual because of the communicative actions of another. Knowledge communication thus designates the successful transfer of know-how (e.g., how to accomplish a task), know-why (e.g., the cause-effect relationships of a complex phenomenon), know-what (e.g., the results of a test), and know-who (e.g., the experiences with others) through face-to-face (co-located) or media-based (virtual) interactions. This type of knowledge communication can take place synchronously or asynchronously.1 The first mode of communication refers to (often face-to-face) real-time interactions, while the latter designates delayed (usually media-based) interactions.

We use the term knowledge dialogues for the first type of (synchronous) knowledge communication, stressing the interactive and collaborative style of knowledge exchange in this communication mode (see Isaacs, 1997; Nonaka, Toyama, & Konno, 2000). Depending on the knowledge-focused goal of such dialogues, we distinguish among Crealogues (that focus on in the creation of new insights), Sharealogues (facilitating knowledge transfer), Assessalogues (focusing on the evaluation of new insights), and Doalogues (e.g., turning understanding into committed action, i.e., 'talk the walk'). Each type of knowledge dialogue requires different behavior and interaction patterns and support measures (e.g., whereas Assessalogues require critical, convergent evaluation tools, Crealogues require an open atmosphere for divergent thinking and rapid idea generation without judgment).

With regard to asynchronous knowledge communication, we refer to the concept of knowledge media (see Eppler, Röpnack, & Seifried, 1999) as enabling knowledge transfer through technology-based communication, collaboration, e-learning, aggregation, retrieval, and archiving services. Knowledge media can be differentiated in terms of their target community, such as scientific knowledge media, public knowledge media, professional knowledge media, and so forth. The concept of knowledge media in general stresses the importance of a community that collaborates regularly using a common platform that consists not only of IT functionalities, but also of common communication norms and (usage) rules.

In this understanding, knowledge communication is more than communicating information (e.g., facts, figures, events, situations, developments, etc.) or emotions (e.g., fears, hopes, reservations, commitment) because it requires conveying context, background, and basic assumptions. It requires the communication of personal insights and experiences. Communicating insights requires the elicitation of one's rationale and reasoning (i.e., one's argumentation structure); of one's perspective, ratings, and priorities; and of one's hunches and intuition. At times it may even be necessary to present an overview of the expert's relevant skills along with his/her previous professional experiences and credentials (Lunce, Iyer, Courtney, & Schkade, 1993) in order to build trust and enable an adequate atmosphere for effective knowledge transfer. Thus, in addition to pure information (and at times emotion), a myriad of other indicators need to be provided in order to transfer knowledge. These indicators help the person who requires insights from another to understand the other's perspective, to reconstruct the other's insights correctly, and to connect them to one's own prior knowledge.

Still, knowledge communication does not only differ in terms of what is communicated (knowledge in context rather than isolated data or information2), but also how one communicates. The transfer of information can often be successful without additional effort beyond an ordinary, everyday communication style. Communicating expertise-based, complex insights, by contrast, calls for didactic tricks and at times sophisticated indirect speech acts and visualization means that help the other side to become actively involved in the communication and engage in a collaborative, goal-directed sense-making process—a prerequisite for the construction of new knowledge (see Weick, 1995). The process of knowledge communication hence requires more reciprocal interaction between decision makers and experts because both sides only have a fragmented understanding of an issue and consequently can only gain a complete comprehension by iteratively aligning their mental models. All of this means that when we communicate knowledge, we are still communicating information and emotions, but we also create a specific type of context so that this information can be used to re-construct insights, create new perspectives, or acquire new skills.

This (interpersonal) communication perspective on knowledge transfer has already been emphasized by other researchers—who explicitly label this view as 'knowledge communication' (Scarbrough, 1995, p. 997; Antonelli, 2000; Harada, 2003; Reiserer, Ertl, & Mandl, 2002)—and by several practitioners (e.g., Watson, 2004). Nevertheless, these authors have often treated knowledge communication as a kind of black box that is described only in broad terms and general traits, such as the major communication goals or steps. By examining the communication problems that often impede knowledge transfer in detail, we can look into this black box and propose pragmatic ways of improving knowledge communication, especially among experts and managers where the chasm between in-depth knowledge and decision authority is particularly apparent.

PROBLEMS IN COMMUNICATING KNOWLEDGE AMONG EXPERTS AND DECISION MAKERS

In order to better understand the problems that can impede the effective transfer of decision-relevant knowledge from experts to managers and from managers to experts, we will review relevant constructs and prior findings from social and engineering sciences, as there are in fact numerous concepts that describe issues related to sub-optimal knowledge transfer. These concepts regard topics such as interdepartmental knowledge transfer, professional communication, decision making, communication technology, or the nature of expert knowledge. By screening these disciplines and topic areas, we can establish a first overview of possible knowledge communication problems and we can create a systematic terminology to speak more explicitly (and consistently) about knowledge communication barriers.

Previously identified barriers of knowledge communication are summarized in Table 1. There are three main criteria for including concepts in this table: First, the concept has to be closely related to problems of interpersonal, professional knowledge transfer.3 Second, the concept has to describe a problem of major impact on the quality of knowledge transfer (rare or very specific issues are not included). Third, the concept has to be influential—that is, it has to be cited with the same construct label by several authors (other than the creator of the concept). The resulting list in Table 1 first includes 'umbrella' concepts that designate a group of closely related problems, such as cognitive biases, decision-making problems, argumentation fallacies, communication biases, or defensive routines, and then concepts that label individual problems, such as the not-invented-here syndrome or the ASK problem.

The problems listed in Table 1 are neither mutually exclusive nor collectively exhaustive. Nevertheless, Table 1 summarizes many of the key pitfalls in communicating knowledge. It is in the nature of the phenomenon that these problems are not isolated, but that they rather interact in many, sometimes unpredictable ways.

Based on the concepts from Table 1, and based on 10 focus groups4 and 10 personal interviews with engineers who frequently collaborate with managers in their companies, as well as interviews with 20 IT managers5 who regularly interact with experts for their decision making, we distinguish among five types of knowledge communication problems. These are briefly summarized below, followed by examples of each type of problem, cited from both experts and managers.

The first type of knowledge communication problems is expert-caused difficulties. These mistakes make it cumbersome for the decision maker to grasp the insights of a specialist. This type of problem also includes issues that make it difficult for the manager to explain his or her own constraints and priorities. Examples of this kind of problem are the use of overly technical jargon, not relating the insights to the manager's situation, starting with details before an overview is given, or lacking interest of the expert in related (but relevant) issues. From the list provided in Table 1, knowledge-sharing hostility and the paradox of expertise clearly belong to this category.

The second type of knowledge communication challenges is manager-caused problems that leave it unclear to the expert what the manager actually expects from him or her (briefing). This makes it difficult for the expert to convey what he or she knows. Management mistakes make it harder for the manager to fully profit from the offered expertise. For example, a manager's reluctance to discuss detailed problems may have major effects on an issue, such as lack of concentration

Table 1. Key research concepts that illustrate knowledge communication barriers

Key Concept/Knowledge Communication Barrier	Description	References
Cognitive biases (confirmation, availability, recency, dichotomized reasoning, framing, anchoring, representativeness, etc.)	Knowledge may not be correctly interpreted or used due to biases in one's reasoning, such as listening only to those insights that confirm one's prior opinion.	Tversky & Kahnemann, 1974
Decision problems (plunging in, shooting from the hip, poor feedback, taking shortcuts, frame blindness, etc.)	The decision maker may for example believe that he/she can make a complex decision right away without looking further at the provided analysis.	Russo & Shoemaker, 1989

Table 1. continued

Key Concept/Knowledge Communication Barrier	Description	References
Communication biases (audience tuning, misattribution bias, saying-is-believing, shared reality)	The knowledge is inadvertently manipulated through communication itself: • *Audience Tuning*: Communicators spontaneously tune their messages to: –the personal characteristics of the audience, or –the situational factors. • *Misattribution Bias:* Communicators tend to consider their audience-tuned messages to be about the topic of the message rather than about the audience. • *Saying-Is-Believing Effect:* Autopersuasion has stronger effects because one does not activate regular mechanisms of critical reflection. • *Shared Reality*: You consider your audience-tuned message to provide objective, accurate information on the message topic because it was shared with others.	Higgins, 1999
Argumentation fallacies (begging the question, overgeneralizing, personal attacks, defective testimony, problematic premise, slippery slope, red herring, etc.)	In demonstrating one's ideas and insights, people fall into argumentative traps, such as begging the question (circular reasoning), over-generalizing, appealing to false majorities or false expertise, reasoning ad consequentiam (what should not be true, cannot be true) or reacting with direct attacks at a person (at hominem) rather than at a knowledge claim.	van Eemeren et al., 1992
Defensive routines (skilled incompetence, learned helplessness, easing-in, etc.)	New knowledge is sometimes not accepted (or provided) due to mechanisms or habits that prevent the identification and acceptance of one's own ignorance. This may lead to a reduced effort to understand complex issues (learned helplessness).	Argyris, 1986, 1990
Knowledge disavowal	A number of factors have been found which limit information use in organizations, such as not spending enough time collecting advice, refusal to share, fear of exposure, and so forth. Knowledge disavowal occurs when reliable and relevant information is not shared among decision makers.	Zaltman, 1983; Deshpande & Kohli, 1989
Knowledge sharing hostility	Knowledge communication fails because the 'knowledge givers' are reluctant to share their insights due to micropolitics, strenuous relationships, or fear.	Husted & Michailova, 2002
Micropolitics of knowledge	The 'knowledge claims' of an expert are discredited by the decision makers due to their differing (hidden) agenda, because of a coalition of people with an alternative view, or due to the expert's lack of formal authority.	Lazega, 1992
Internal knowledge stickiness	Knowledge can sometimes not be transferred because of arduous relationships or casual ambiguities regarding the knowledge, or because of the lack of absorptive capacity of the knowledge receivers.	Szulanski, 1996, 1999

Table 1. continued

Key Concept/Knowledge Communication Barrier	Description	References
Groupthink	A (management) team may not truly listen to the input of an expert because of the team's group coherence, and group dynamics sometimes block outside advice and feel omniscient.	Janis, 1982
Information overload	An individual is sometimes not able to integrate new information into the decision-making process because too much complex information has to be interpreted too quickly.	O'Reilly, 1980; Eppler & Mengis, 2004
Self/other effect	Individuals tend to discount advice and favor their own opinion.	Yaniv & Kleinberger, 2000
Knowing-doing gap/smart talk trap	Sometimes organizations know where a problem resides and how to tackle it, but do not move from knowledge to action (due to unhealthy internal competition or lacking follow-up).	Pfeffer & Sutton, 2000
Absorptive capacity	Limited ability of decision makers to grasp the knowledge of the expert based on lack of prior knowledge.	Bower and Hilgard, 1981; Cohen & Levinthal, 1990
Paradox of expertise	Experts sometimes find it difficult to articulate their knowledge or rephrase their insights in a way that a non-expert can understand. Sometimes experts indicate other rules than they actually apply.	Johnson, 1983
Ingroup outgroup behavior	We tend to interact more with likewise groups than with others, thus reducing our chances to acquire radically new knowledge.	Blau, 1977
Task closure	In our communication, we may choose to use a one-way communication medium because it permits us to close an open task without having to have a conversation. Thus leaner communication channels are used that may be necessary. In other words: We tend to want to close a communication process in order to complete an open task.	Straub & Karahanna, 1998; Meyer, 1962
Set-up-to-fail syndrome	Managers are projecting their initial expectation of an expert's likely performance unto him/her, leading to the self-fulfilling prophecy of (at times) lower performance. This is aggravated by de-motivating feedback to the expert.	Manzoni & Barsoux, 2002
ASK problem	Anomalous State of Knowledge: When a decision maker does not have the knowledge base to really know what to ask for. People need to know quite a bit about a topic to be able to ask or search for relevant information.	Belkin, 1980 ; Chen et al., 1992
Not-invented-here (NIH) syndrome	Knowledge from others is sometimes rejected because it originated elsewhere.	Katz & Allen, 1982
Preference for outsiders	This is the opposite of the NIH syndrome and describes the tendency of managers to value outside knowledge higher than internal knowledge because it has a higher status, it is scarcer (because of difficult access), and it is less scrutinized for errors than internal knowledge.	Menon & Pfeffer, 2003
False consensus effect	We assume others see situations as we do, and fail to revise our framing.	Manzoni & Barsoux, 2002

Table 1. continued

Key Concept/Knowledge Communication Barrier	Description	References
Inert knowledge	The knowledge that the decision maker has acquired from the expert does not come to mind when it is needed or useful for decision making or actions. The transferred knowledge is stuck in the situation where it has been acquired.	Whitehead, 1929
Hidden profile problem	One often does not know other people's background (profile)—that is, what they know and could contribute to a problem's solution. The knowledge that is thus frequently shared in a discussion is what is expected by everyone.	Stasser 1992; Stasser & Stewart, 1992
Common knowledge effect	The tendency of a group to focus merely on commonly shared (rather than unique) pieces of information.	Gigone & Hastie, 1993
Lack of common ground	Common ground refers to the manager's and expert's assumptions about their shared background beliefs about the world. If those assumptions are wrong or inconsistent, communication becomes more difficult.	Clark & Schaefer, 1989; Olson & Olson, 2000
Cassandra syndrome	The decision makers do not give sufficient weight or attention to an expert's warning because they face many other important problems. Only when the situation has deteriorated dramatically do they start taking the expert's advice.	Mikalachki, 1983

and attention or lack of technical know-how. From the list in Table 1, the decision problems, the ASK problem, the Cassandra syndrome, or the inert knowledge problem are typical examples of this group.

The third type of knowledge communication problems are caused by the mutual behavior of experts and managers, including their experiences or attitudes (e.g., reciprocal stereotypes). Examples from the list of concepts that belong to this group are lacking feedback on both sides, the set-up to fail syndrome, groupthink, and ingroup outgroup behavior.

Fourth, we see problems caused by the interaction situation of the expert-manager interaction, such as time constraints, communication infrastructure, distractions, interventions from others, and so forth. The problem of information overload in Table 1 can arise due to the time constraints in a communication situation. But the hidden profile problem can also be due to the communicative situation, where the background of the participants is not fully revealed or discussed at the beginning of a manager-expert interaction.

The fifth and final type of knowledge communication problems includes issues that are caused indirectly by the overall organizational context of managers and experts, such as their organizational constraints and their differing tasks, priorities, and interests. The 'micropolitics of knowledge' concept listed in Table 1 would be an example of the (negative) impact of the organizational context on the transfer of knowledge.

CONCLUSION AND FUTURE TRENDS

Many studies in knowledge management examine the structural, macro aspects of knowledge transfer on an organizational level (Szulanski, 1999). There are also studies that examine the general motivational barriers to such transfers (Husted & Michailova, 2002). The field of knowledge communication, by contrast, examines the micro perspectives of knowledge transfer, thus highlighting the role of adequate or inadequate communication behavior patterns for knowledge transfer. These examined patterns go beyond the question of motivation and encompass issues such as the use of adequate language, timing, group interventions, or media use for knowledge transfer. This article has defined this approach as knowledge communication. It has outlined the various problems that exist when individuals (particularly experts) communicate their knowledge to others (e.g., managers).

Future knowledge management research should examine ways of facilitating and thus improving knowledge communication. This can be achieved through such tools as knowledge visualization suites, dialogue techniques, or knowledge elicitation methods. In doing so, future research should pay particular attention to the influence of (expert and manager) behavior, and to situational and organizational factors that affect the quality of knowledge communication.

ENDNOTES

1 Both modes can be used in one-to-one or one-to-many contexts. Both modes can rely on speech, text, graphics, and other means of communication (i.e., verbal and non-verbal).

2 Our distinction between data, information, and knowledge follows the mainstream conception found in current literature (e.g., Davenport & Prusak, 1998). We view data as isolated recordings that are often generated automatically and cannot be directly used to answer questions. Information is connected, condensed, or generally processed data that allows an individual to answer questions. Knowledge is what enables an individual to ask relevant questions (Newman & Newman, 1985, p. 499). It refers to the capability of an individual to solve problems (Probst, Romhardt, & Raub, 1999). Information only becomes knowledge if a person interprets that information correctly, connects that piece of information with his or her prior knowledge, and can apply it to problems or decisions (see also Alavi & Leidner, 2001).

3 The concept does not have to originate in the context of interpersonal communication research, but its application to it must be obvious and fruitful, as in the example of the ASK problem. The ASK problem was first discussed in the information retrieval community, but it has ramifications for

interpersonal knowledge communication as well.

4 Each focus group lasted for approximately one hour and consisted of 12-20 participants. The focus groups were conducted in 2002 and 2003 in Switzerland and Germany, with engineers and IT specialists from eight companies (each employing more than 1,000 people). Focus group facilitation and documentation was provided by the research team. The topic of the focus group discussion was "communication problems among engineers/specialists and managers."

5 Each interview lasted between 30 minutes and two hours. Interviewees were mostly senior IT managers or chief information officers of medium-sized and large Swiss companies, as well as select line managers with considerable experience. The main topic of the interviews was "problems in the knowledge communication with specialists."

This work was previously published in the *Encyclopedia of Knowledge Management* edited by D. Schwartz, pp. 317-325, copyright 2006 by Idea Group Reference (an imprint of IGI Global).

INTRODUCTION

Knowledge of past activities, discoveries, and events is applied by businesses to support everyday operations in much the same manner that human beings use their personal memories. But the true nature of organizational memory (OM) remains obscure, and information-systems practitioners have no clear definitional model of what they are working toward and have been unable to build a convincing organizational memory system (Olfman, 1998).

Having apparently reached a dead end, OM studies have been subsumed into knowledge management (KM) research as a subsidiary field. OM research is currently focused on the faculties of an organization that are capable of storing knowledge perceived or experienced beyond the duration of the actual event. Researchers and practitioners in the field use a definitional frameworks and models of organizational memory derived from flawed models of aggregate human behavior used in earlier sociological studies (Frost, 1942; Wilson, 1998). Models derived from earlier sociological studies rarely consider the exact nature and sources of commonplace thinking and memory use, and focus on highly visible and significant behavior and activities. Rapid theoretical and technological advances made in psychology research, brought about by the advent of sophisticated technological aids, have disparaged and largely disproved many of the naive systemic models of human cognition developed by earlier social scientists (Dominowski & Bourne, 1994; Sternberg, 1994) and were incorporated into information-systems sciences in the early years.

Before we consign the hope of deeper knowledge of business memory to the "too hard basket," it might be fruitful to examine an alternative path to understanding the nature of organizational memory and its application: The impersonal and generalized models of business activity (and cognitive operations) inherited from social sciences have not proved fertile, but the individual and personal models of memory and cognition found in biological and related sciences offer some promise in light of recent advances.

BACKGROUND

The human mind has always been, and always will be, an area of great interest to the layperson and scientist alike (Luria, 1973). The sheer volume, and constancy, of research attention it receives has inevitably resulted in a plethora of knowledge that enlightens us about various aspects of the human mind, but, on the other hand, it has tended to add a complexity to our view of human cognitive functioning. The modeling theory and conceptual analysis techniques, however, offer a means whereby the complexity and controversies of a topic can be isolated or marginalized in the interest of building a clear overall picture of a concept or phenomenon (Dubin, 1969). This can be particularly valuable in a field of study like human cognition where scholarly research has branched into many unreconciled and introverted schools of thought.

While many gaps still exist in our knowledge of exactly how humans think and remember (Baddeley, 1998), and the mind is shrouded in scientific (and nonscientific) controversy and beliefs, many incontrovertible aspects and fundamental elements of biological memory offer a path to a less controversial understanding of what organizational memory might be.

Biological studies offer some clues as to the purpose memory has been put to and the structure of memory elements (Carlson, 1994). Anthropology offers an indication of how simple behaviors dependent on memory have evolved over time into sophisticated activities of modern man (Hallpike, 1979). Studies of the psychology of memory provide an increasingly vivid breakdown of what happens when people remember (Carter, 1998). Specialist research into cognitive subelements such as consciousness (Dennett, 1991), emotion (Dimasio, 2000), language (Jackendoff, 1992), and perception (Sowa, 1984) offer insight into the essential nature of human ideas and at the same time provide a means for isolating many of the complexities involved in understanding the relationship between thinking and memory. Some of the more interesting ideas that can be gleaned from these research fields in respect to memory phenomena, and which could stabilize and enrich our current model of organization-centered memory, are presented here.

A BIOLOGICAL MODEL OF MEMORY

Organizational Self

Deutsch's (1966) central idea in his influential model of organizational cognition is an "organizational self," which, like a personal human self, has a central role in focusing and directing all organizational behavior. This idea was studiously avoided in subsequent OM research (Stein, 1995) probably because such a concept is problematic in the context of the shifting (and often private) constitutional and motivational elements that focus and direct modern collective business behavior: Deutsch's example was a formally constituted government authority whose purpose and goals were published and generally unchanging.

KM and OM researchers have recognized the efficacy of personalizing organizational knowledge (e.g., Spender, 1995; Tuomi, 1999), but not the power of one integral element—a person—as an organizing device. Dimasio's (2000) work describes how an individual biological body informs all that organism's cognitive function and provides a single point of reference for all its cognitive artifacts.

The critical nature of an executive intervention in the component processes of memory might be a fruitful area for further organizational memory systems studies in view of Dimasio's (2000) work. An executive that guides organizational behavior is not a new concept (see Corbett, 1997; Middleton, 2002), but its potential as a unifying element in organizational cognitive behavior is not fully appreciated.

Ubiquity of Memory Application in Everyday Operations

Memory function is a faculty inherited by humans from organisms of a much lower order of complexity (Monod, 1971/1997), and the advanced nature of human cognitive achievement owes much more to an ability to consciously hold more than one idea at a time (which lower organisms seem unable to do) than it does to any sophistication in the fundamental cognitive equipment used to perceive and remember (Dennett, 1991).

Human memory supports seemingly simple operations as well as complex ones, and in order for an organism to operate independently from moment to moment and across space, such services must somehow be ever present. What we pursue in organizational memory studies is not necessarily a complex and mysterious set of functions and artifacts, but rather a collection of well-tested and refined things that interact seamlessly with one another to deliberately preserve past experiences and make them available to support subsequent and increasingly sophisticated actions. Pilot studies carried out by the authors to test a biological model of memory in an organizational setting suggest that memory of past organizational events may be applied to many seemingly minor, but possibly essential, organizational activities given little attention in the current OM and KM research literature.

OM practitioners recognize the need to support access to organizational memory via e-mail and the Internet (Schwartz, Divitini, & Brasethvik, 2000), but neither the support nor the process is recognized as worthy of attention at an organizational policy level. Often we identify the office culture, traditional business practices, conscientious employees, and common sense as coordinators and directors of a relationship between organizational behavior and the organization's best interests without investigating organizational memory, which underpins them. Many seemingly inconsequential business behaviors are the foundational support for ensuring the best interests of the organization in critical day-to-day operations.

Biological memory offers constant and continual support for its owners' endeavors; similar support might be offered to a wider variety of organizational memory applications if they were recognized as such.

Memory Ownership

The unifying element in organic memory systems is the self: a personal prototype that provides an impetus and steers the various component operations, giving them a fundamental associative fulcrum (Dimasio, 2000)—a fulcrum that might provide the key to the efficiency and power we admire in memory systems.

With this in mind, it is easier to appreciate the significance of the personal nature of memory. Each memory system is inextricably bound to an individual owner with its own individual history, individual interests, individual desires, and individual goals, preserving its individual perceptions for its individual use. This perspective also illustrates that knowledge objects that have not passed through the owner's cognitive processes cannot be added to the memory store.

Organizational memories, if they are to be real memories and not simply information, must be consciously collected and laid down in the store of memories by the organization itself. Having acquired and laid down the memories by its own hand, the organization is best placed to know the contents of its stores and where a particular memory is likely to be found. Just because a document or idea relates to the past events or activities of an organization, it does not mean that it is accessible for application by the organization in subsequent deliberations or activities (see Wilson, 1997; Yates, 1990).

Information-systems and information-management theorists and practitioners generally recognize the value of information ordering (Simon, 1957), but the relationship between the individual who orders and stores the information and the individual who uses it may be underappreciated.

The biological phenomenon memory does not accord with established concepts of systems and mechanics: The input plus the process may not fully describe the product, and vice versa; what goes into memory may not come out; and the cause or stimulus might not result in any discernable effect (Haberlandt, 1997). Many independent functions might provide services to memory operation while appearing to provide diverse and valuable services in their own right (Chomsky, 1968).

Many established and familiar organizational information and knowledge operations and devices might actually serve essential organizational memory functions. OM researchers risk misidentifying (or ignoring altogether) memory components by taking a systemic view of memory. The relationship between a linking and directing executive and such tasks as the archiving and summarization of documents, and document search operations might not be fully appreciated, and the potential in the relationship for ensuring the best interests of the organization might be overlooked.

Memory psychologist Baddeley (1998) and cognitive scientist Ashcraft (1994) detail a number of sustaining functions and operations supporting memory:

- separate short-term and long-term memory stores and functions, immediate postperception memory stores and functions, and separate autobiographical (sequenced) remembrance stores and functions
- an attention system to monitor prospective sources of memories, and a sensory-perception system to search a stimulus for cues and provide raw material for the subsequent creation of memories
- percept construction systems to associate new experiences to previous knowledge
- an encoding process that transcribes sensory perception into proprietary physiochemical neural matter that matches the structure of those previously stored

The concept of divisions of organizational memory faculties is an interesting one given the diversity of OM support functions previously identified by KM, OM, and information-management researchers. Maier (2002) provides a survey of diverse KM tools and systems. Middleton (2002) describes a history of information-management tools and strategies. These comprehensive lists of technological solutions illustrate the diversity of applications that attempt to operationalise OM functions without an overriding coordination by the particular organization. They can be utilized as guides to OM developers when implementing OM solutions. However, this will require a level of integration across applications to ensure that the knowledge objects are all robustly related to an organizational self.

Focusing attention on prospective sources of valuable information is not a new idea, but its dependence on direction and preexisting contents of information stores is not readily appreciated. In order to attend to the most appropriate sources in the biological world, memory owners must give some thought to who and what are the most potentially valuable sources (Bergson, 1907/1975, 1896/1996). Constant monitoring of the environment to discover other better sources of knowledge are readily appreciated everyday tasks of living things (Sternberg, 1994).

Memory Percepts

Hallpike's (1979) investigation into the anthropology of cognition discovers many simple and universal cognitive operations in primitive, and comparatively unsophisticated, societies. More complex and powerful cognitive operations, familiar in modern Western cultures and clearly the product of enlightened public education systems, are possible because of remembered algorithms, strategies, formulas, and models (made up of a finite set of rules or operations that are unambiguous) rather than from ambiguous reflection, contemplation, or remembrance of past events and facts. Moreover, many of these strategies and models have been deliberately refined to allow a lighter cognitive load: That is, we remember the source of information in lieu of carrying the information itself (aides memoires).

Current models of organizational memory used in information-systems sciences presume a file, book, or document prototype for memory artifacts (see Ackerman, 1994; Walsh & Ungson, 1990) rather than a discrete fact or formula, or discrete pictorial or aural representation. Neither is the source of information recognized as having a value equal to that of a whole document or complete file.

Biological memories are based on percepts created in response to an eternal stimulus and can best be compared to the concept of an idea (Baddeley, 1998). Memory artifacts themselves are not unitary but comprise a network of component mental elements, which together can evoke a memory. The current concept of a whole file, a complete document, or a work practice as a unit of organizational memory is unhelpful to OM researchers: Storing whole files, archiving complete documents, and articulating a tacit work practice are expensive and time consuming, and maybe storing, preserving, and articulating underlying ideas might be more cost effective in the long run.

Memory Encoding

The biological model of memory encoding describes the recording of responses to sensory stimuli in a series of mental artifacts (Baddeley, 1998) richer than the mere articulation in language of an idea or perception. Chomsky (1968) and Jackenoff (1992) have illustrated how the flexibility of biological memories (they can be rearranged, reinterpreted, reused, colored, and decomposed ad infinitum) may derive from their insubstantialness beyond the confinement of concrete or specific language representation.

While language is clearly a primary method whereby ideas can be organized, categorized, associated, and communicated, OM theorists' current view of organizational memories as communicable and substantial language-based informational artifacts (Walsh & Ungson, 1991; Yates, 1990) appears restrictive. Memories put into words are a transfiguration carried out more for communication with others than for the preservation of memories themselves, and it necessarily alters the totality of the idea to accord with a set of commonly shared word concepts and categories. Polanyi's (1964) often misconstrued notion of tacit knowledge was a description of many kinds of knowledge artifacts (remembrances) that are inexpressible in words for one reason or another. OM and KM theorists might consider his work was a call not necessarily to articulate tacit knowledge into words, but to consider inexpressible ideas as equally relevant and often more powerful than those expressed in language.

FUTURE TRENDS

The nature and composition of organizational memory remains obscure, while theoretical models derived from outmoded psychology, common sense, and social theory continue to provide a framework for research.

In contrast, the phenomenological model of human memory (and simpler biological memory systems) offers an easily appreciated and robust representation of the totality of the processes, components, and functions that make up memory systems generally.

While it is generally recognized that organizational memory exists, researchers have been unable to make unequivocal discovery of it (Walsh & Ungson, 1991). It appears to be applied in modern business activity, but the mechanism whereby organizations apply it remains obscure.

Organizational learning studies, organizational memory research, and information-systems and information-management theories all offer credible and effective explanations of aspects of organizational cognitive operations, but they are without a consilience of the various terminologies and conflicting theories across the different research disciplines. The model of human memory promises to provide that if we can reconcile the personal aspect of the human organism to the collective and shared superpersonal nature of the organization. Maturana (1970) offers some constructive ideas toward this reconciliation in his description of unity. He suggests that if we distinguish the behavior of an organizational agent, which is applied primarily in the service of a particular organization, from its private behavior, it becomes easier to distinguish between organizational memory and private memory. From that point, a differentiation of aspects of agent behavior might lead to an insight about what constitutes organizational-memory-directed behavior and what does not.

CONCLUSION

The model of memory offered by biological studies is a rich one. Many aspects have not been touched here, but remain to be discovered by researchers provided they have a flexible but robust definitional framework to base their investigations on. Biological sciences indicate to us that memory is applied in the seemingly trivial activities of everyday life, and that many of those seemingly commonplace activities support more profound actions. While our current usage of organizational memory might be supported in respect to major decisions and activities, we might question how well it is supported in more mundane, and quite possibly critical, tasks.

By reconciling the concepts of organizational memory systems research to the familiar model of biological human memory, theorists might offer a reconciliation of many information-systems and information-management concepts based on the idea that the knowledge management they are working toward involves the same common objects.

Chapter 1.32
Internet-Based Spatial Decision Support Using Open Source Tools

G. Brent Hall
University of Waterloo, Canada

Michael G. Leahy
University of Waterloo, Canada

ABSTRACT

In the last half decade, there has been growing interest in the concept of collaborative geographic information systems (GIS) in support of decision making, especially in the context of various domains of planning. This interest has spawned an already substantial literature in what is now becoming popularly known as public participation GIS (PPGIS) or community GIS. A central and general objective of PPGIS is to encourage the use of GIS technology by broadly based and geographically dispersed nonexpert users. In the context of planning decision support, this involves creating software with map-based functionality that is responsive to the needs of user groups that have limited experience with computers and only a rudimentary knowledge of even simple spatial analysis concepts. This functionality should be designed to enable these individuals to communicate and interact with higher level users and agencies on an equal footing so that all participants can be both better informed of each others perspectives and more involved in decision-making processes that involve land and resource use planning and management. This chapter considers the general issue of PPGIS in the context of use of the Internet and the World Wide Web as a means of achieving broad participation and collaboration in decision making among dispersed participants with a diversity of backgrounds and competencies in using spatial concepts and analyses. The chapter also considers the role that open source software tools can play in crafting accessible and highly customizable solutions using an example for assessing the quality of primary-level education in Peru.

INTRODUCTION

Research into supporting human decision-making processes through the use of computer-based applications is well established in many fields. This research includes the spatial data domain that, although relatively young by comparison, has a history of over 10 years of experimentation, which has produced a large literature. Several threads of research are intertwined within and between specific application areas that use spatial data resources (such as health, education, urban planning, resource management, etc.). These threads have persisted in the literature and have recently diverged into several new areas.

Much of the emphasis in spatial decision-support research continues to focus on developing tools, typically using macrolanguage scripting exclusively or scripting linked to compilable programming and commercial geographic information systems software, such as workstation Arc/Info and desktop ArcGIS. More recently, however, there is an emergent trend in developing spatial decision-support tools on other software platforms (see, for example, Andrienko, Andrienko, & Voss, 2003; Rinner & Malczewski, 2002; Voss, enisovich, Gatalsky, Gavouchidis, Klotz, Roeder, & Voss, 2004), and especially using the Internet as a deployment and communications medium (Dragievi & Balram, 2004; Evans, Kingston, & Carver, 2004; Rivest, Bedard, & Marchand, 2001).

The applications that are bound to mainstream commercial GIS are characterised to varying degrees by a number of limitations. These limitations have been itemized by a number of researchers. They include, among others, relatively cumbersome and potentially difficult to use interfaces (due to the relative difficulty of developing common user interface dialogs and menus with scripting languages, especially in the earlier tools); a preponderance to a single-user, single-decision problem orientation, often using proprietary spatial and tabular data formats, but with far less dependence on import and export of nonstandard file formats and nonscenario-based and nonshared (stand-alone) spatial analysis than in the past; limited flexibility and options in the support functions, which are required to address specific types of decision problems (Jankowski & Nyerges, 2003); and steep learning curves in the use of the tools for nonexpert users (Feick & Hall, 1999; Uran & Jensen, 2003).

These problems have plagued the practical use of GIS use in decision support to the point where some researchers have recently reevaluated progress in order to facilitate more constructive use of the technology for this purpose (see, for example, Higgs, 2004; Merrick, 2003; Nyerges, Jankowski, & Drew, 2002; Uran & Jansen, 2003;). This critical reevaluation is in part due to the fact that relatively few cases of deployment of spatial decision-support tools have resulted in successful outcomes beyond the academic arena. Certainly, while many tools have been developed, there are few published or well-documented cases that can be heralded as having clear and continued utility in improving public decision-making processes (for example, while it is possible to develop an Internet map-based tool for broad-based public input into where nuclear waste disposal sites should be located (Evans et al., 2004), it would be quite another matter to have such a tool used by a nuclear power authority to guide actual site choices). This dislocation between academic research and its practical uses is complex, and by no means limited to the domain of spatial decision support. However, it is likely that the relative lack of successful use of spatial decision support tools for actual decision making is in part related to a basic mistrust of academic research by some practitioners, as well as a combination of the factors outlined previously.

New research threads in spatial decision support may offer renewed optimism for this area of investigation. In particular, four strands can be identified. These include, first, interest in facilitating the use of GIS technology by nonexpert members of the general public, more commonly known as public participation or community GIS (PPGIS or simply PGIS), especially within the context of collaboration in decision processes that relate to various forms of planning (Craig, Harris, & Weiner, 2002). Second, the varied dynamics of individual and group participant, colocated and dispersed, facilitated and non-facilitated decision support have also received increased research attention (Hendriks & Vriens, 2000; Jankowski & Nyerges, 2003). Third, the advent and rapid diffusion of open source GIS (OSGIS) and other software have created a surge of innovation that offers many possibilities for crafting nontraditional and, when tightly coupled with Internet-based delivery, highly accessible and flexible software architectures to address spatial decision-support problems. Finally, the possibilities offered by the now widespread (in economically advanced) and rapidly growing (in developing countries) use of the Internet itself as the major global communications medium has revealed many new possibilities (Carver, Blake, Turton, & Duke-Williams, 1997; Dragicevic & Balram, 2004; Dragicevic, 2004).

These four threads of research are closely interrelated, and build upon the existing body of knowledge on decision support within the spatial data domain. They have allowed improvements to be made and new approaches to be developed to address problems that relate to collaboration during decision processes. This chapter focuses specifically on the potential of OS software, the Internet, and the World Wide Web (Web) to liberate access to spatial data and broaden their use through the creation of tools that allow, in principle, any person or group with a connection to the Internet to be able to use spatial data in general, and for supporting decision processes in particular.

The domain of interest in the chapter is primary-level education planning and specifically, the evaluation of education quality at the individual school level in Peru. An application is described that is developed exclusively with the use of Web-based OSGIS software that is freely available for download, enhancement, and deployment with no financial costs in acquisition or licensing. Moreover, the databases and decision-support tools are themselves provided on the Internet with full source code for others to download, modify, and enhance. The approach subscribes to the concept and manifesto of the OS initiative (http://www.opensource.org) and the objectives of PGIS in the sense that the only restrictions placed on either developers or users are those imposed by the limits of their interest and/or willingness to learn.

The approach can equally serve the participatory goals of individuals and/or groups who can be colocated and working together on evaluating education quality with a view to decision making, or dispersed and working independently on the same sorts of issues via the Internet. The groups can be diverse with highly varied computing skills, perspectives, and knowledge bases. For example, in the application discussed in this chapter, participants can include parents seeking to evaluate the performance of neighbouring schools relative to an important choice they have to make for their children about to enter school, or to evaluate performance of the school their children already attend relative to others nearby; school administrators seeking to identify aspects of their school that need to be improved relative to other schools; teachers who are interested in assessing aspects of the education process so they can enhance the learning of their students; and Education Ministry planners at the local, regional, and central government levels who need to make important decisions on resource allocations for schools they are responsible for administering. In addition, the tool is also useful for independent researchers from the academic and nongovernment organization (NGO) sectors as it provides these participants with ready access to clean and well-compiled spatial databases, as well as freely available analysis tools that offer flexibility in problem scoping and decision making support. It is possible for any number of individuals within these groups to collaborate on evaluating education quality and building strategies for improving this.

The chapter is structured as follows. The next section briefly reviews the migration from single user to group collaboration, and from standalone GIS to the Web as a means of facilitating various types of spatial decision support, noting the strengths and weaknesses of the approaches. This discussion also highlights needs that can be filled with the use of OS Web-based software in current spatial decision support applications. The innovation that is made possible through the use of OSGIS-based tools is discussed more fully in Section 3, focusing specifically on the Web. This discussion includes OS Web mapping, object-relational databases that have spatial data capabilities, open Web programming languages, and Web services. The design and functions of the specific decision-support tool developed to assess education quality in Peru using these components is described in Section 4. Section 5 presents a sample application of the tool. The chapter is concluded in Section 6 with a summary of the main points and directions for future application development.

INDIVIDUAL AND GROUP DECISION SUPPORT AND THE INTERNET

One of the four emergent research threads noted above concerns the dynamics of individual vs. group, colocated vs. dispersed, and facilitated vs. nonfacilitated participation. This thread recognizes the important fact that there are many possible forms of participation, and that flexibility in selecting the best form of participation for participants will enhance the success of addressing a decision problem. It is therefore important to create high-level architectures for decision support tools that can be relatively easily modified to accommodate multiple decision approaches that allow for varied practices, preferences, and abilities of the decision participants. Further, it is important to accommodate group collaboration as well as individual participation as, unlike buying a new car or developing an investment strategy, very few decisions in the spatial domain, and especially those in the context of urban or regional planning, are made by a single individual. Hence, independent of the use of the Internet, which is discussed below, it is important to facilitate group interaction in problem scoping and analysis as well as individual use. This expansion of the scope of interest represents a shift from building decision support tools by programming for individuals (and single problems), to consider explicitly how these tools might best be used in facilitating both individual use and group collaboration in a variety of decision contexts. In addition, the cultural and political context of the decision problem needs to be considered, along with the actual tools that are used.

Generic spatial decision support tools that cover all possible end-user needs and forms of participation have yet to be developed, as virtually all instances of the tools reported in the literature are specific to a particular domain and/or to a specific type of user interaction. However, recent research (for example, Peng, 1999; Peng & Zhang, 2004) has investigated and reported on the use of emergent data and open programming standards for the development of tools using the Internet and the Web as a deployment medium. In particular, current research on new and potentially revolutionary "sensor web" technologies, including sensor model language (SensorML) and associated services, seeks to create enabling tools primarily for environmental sensors and applications to connect across the Internet independent of their location (Reichardt, 2004).

These standards, most of which combine the use of OS software tools, herald the introduction of an era that will likely witness new and much more flexible approaches in terms of crafting generic tools that can address individual use as well as group collaboration, colocated and dispersed use, and moderated vs. nonmoderated decision support problems within the spatial data domain.

In this context, scalable vector graphics (SVG), geography markup language (GML), and the Web feature services specifications established by the Open Geospatial Consortium (OGC) offer many possibilities for crafting tools that have the capability to be adapted relatively easily to various types of decision problems, as well as to various forms of use (OGC, 2005). Moreover, in the last 3 or 4 years, the arrival and rapid uptake of OSGIS and other software components, such as those noted in Section 3 that can use the OGC standards, breathes new life into this area of research. However, given the relative recency of these standards and the OS components, their impact on application development will not likely be immediate, but will rather appear incrementally over the coming years.

In addition to experimenting with new data, Web features standards, and OS components, the progression of spatial decision support development has moved increasingly toward the use of languages such as Java, GML, and prehypertext processor (PHP). These new tools provide the needed flexibility in software development that can produce applications for single and group users as well as stand-alone applications and distributed participation via applications deployed on the Web. In this context, the development of the CommonGIS platform (Andrienko et al., 2003) comes close to being generic in its ability to address decision problems, as well as function as a general purpose GIS. The software, which is not open but is fully developed in Java, achieves its Web readiness through the use of Java applets and plug-ins (Voss et al., 2004). In addition, functions already developed in CommonGIS can be used by individuals for selection, prioritization, and integration of decision options. For group decision making, the developers have created a voting interface for interactive ranking and classification options for groups and that can be moderated by a facilitator to survey and analyze submitted votes (Andrienko et al., 2003).

CommonGIS also has the ability to facilitate, in conjunction with a tool named Dito, user communication via asynchronous use of self-guided or moderated messaging, which can be assembled into communication threads created by e-mail or directly on the Web (Voss et al., 2004). This creates the ability for decision participants to communicate using messaging with one another, independent of whether they are colocated, dispersed, and participating either in virtual groups, or working individually on a decision problem via the Internet. In addition to CommonGIS, other proprietary tools such as the Java-developed Web-based mapping software JMap (KHEOPS, 2005) have been developed to support online collaboration that allows individual and group participants in decision problems to communicate asynchronously with each other by annotating and sharing maps in common views.

The conceptual underpinnings of the research thread on participatory decision making is lead especially by the contributions of Nyerges and Jankowski (see, for example, 2001a, 2001b, 2003) and others (Hendriks & Vriens, 2000). Their contributions have focused primarily on developing frameworks and strategies for determining the strengths and weaknesses of various approaches to participatory GIS use and decision support for the general public (see also, Craig et al., 2002; Seiber, 2000a, 2000b; Weiner et al., 2001). In this work it is recognized that in order for spatial (and other) decision support tools to be used to advantage, they must be built not to satisfy the objectives of the developer, but rather to meet the objectives and needs, as well as the preferred practice of participation, that are most useful to the user(s). Moreover, there must be a close alignment between the construction of a tool and the decision process it is intended to support, explicitly taking into account issues that relate to usability and collaboration (Haklay & Tobón, 2003; Merrick, 2003). To achieve this, ease of use and flexibility of architecture in terms of individual use and group collaboration must be recognized as being at least as important as functionality that determines, for example, how decision alternatives get specified and evaluated by participants. This suggests that in the new generation of software the form of user participation in the decision process should take on elevated importance, as should the need to focus on the practice of participation (individual group, colocated vs. Dispersed, etc.), rather than the mechanics of evaluating decision alternatives.

This conceptualization represents a general move toward thinking beyond the traditional single problem, single decision maker focus of early spatial decision support development, where capacities existed for only one person (or potentially one group working on the same machine at the same time) to assess a problem by generating decision alternatives, and then using a ranking mechanism to identify the most suitable option. The new approaches that are required are not only conceptually, but also operationally considerably more complex. They also represent an implicit acknowledgement that system developers must take into account what Hendriks and Vriens (2000) refer to as spatial complexity in helping users navigate the evaluation of a decision problem. Here, rather than pursuing a solitary objective of solving a decision problem by finding a satisfactory outcome, a dual objective of decision support must be to understand better the nature of the problem under discussion through interactive use of spatial data, and through synchronous and asynchronous communication between participants during the decision process.

In the quest to achieve heightened understanding of a decision problem and to create a framework for informed input on the part of a wide spectrum of participants, the objective, therefore, is not to confuse or confound issues through the use of overly complex concepts and procedures (Uran & Jansen, 2003). Rather, the objective is to make the use of spatial data and analysis/evaluation procedures as transparent as possible, so users can link the procedures used to generate an evaluation with the nature of the results they generate. To enhance the possibilities for grassroots-level participation in spatial decision processes, tools should also accommodate a wide range of user needs and skill sets, from the very basic to the very sophisticated, and allow a user to work with the level of complexity that he/she is most comfortable with. However, it is important not to reduce the roles of spatial data and geographical thinking to those of “ghosts in the machine” (Schuurman, 2003) in achieving this level of transparency. That is, rather than analyses being black box-oriented, they must be understandable to users, with the premise that if a user understands the process, then they are more likely to understand the outcomes. Merrick (2003) has shown that this level of understanding can be achieved through the collaboration of participants with varied skill sets, working together and mutually reinforcing each other’s perspectives.

In the above discussion, the role of the Internet and Internet-based GIS is central to realizing the needs that are identified. What Kling (1999) described as recently as 1999 as the “next generation Internet” is already about to be superseded by a second generation of advanced Internet. Social access to the Internet is now broadly supported for ordinary people at home and in public service agencies worldwide, especially in economically advanced countries. Moreover, recent advances in the Internet’s presence in developing countries means that access is not privy only to the economically advantaged, but that local solutions, such as low access cost Internet cabinas (using the Latin American term), have emerged in virtually all communities in response to market-driven demand for access (Fernandez-Maldonaldo, 2001). This has both broadened and intensified the use of the Internet globally.

The pervasiveness of the Internet has had an important spillover effect on the development of online GIS in general and in the domain of spatial decision support in particular (Dragicevic, 2004). Current decision support applications are dominated by Web-mapping extensions developed by the mainstream commercial software vendors (such as ESRI's ArcIMS, Intergraph's Geomedia Web Map, MapInfo's MapXtreme, and Autodesk's MapGuide, among others). Recent research has shown that commercial Web-mapping products can be used constructively for collaborative online decision making with spatial data (for example, Dragicevic & Balram, 2004). However, other noncommercial Web-based GIS products are appearing from within the OS software community.

The possibilities that exist for innovation with the use of OS tools are considerably greater than with commercial products by virtue of the flexibility that is available through the openness of the former for developers. That is, it is possible to experiment with new architectures, new functions, and whole new approaches to decision support that address most if not all of the needs identified in this section. Before describing the design and general implementation of an OS spatial decision support tool developed for use in Peru, it is first necessary to outline the enabling software used, and its genesis within the OS software movement.

INNOVATION AND OPEN SOURCE SOFTWARE

The third thread of research noted in the introduction to this chapter refers to the rapidly growing trend in innovation through the use of OS software development. This approach essentially means that the original source code for software is left "open" and available for those who are interested in viewing the code, using it, and/or modifying it to suit their specific needs. This approach is not a new phenomenon, however it has gained prominence over recent years as the number of developers and users of OS software have steadily increased. In 1998, the Open Source Initiative (OSI, 2005) was established as a nonprofit organization to manage and promote the definition of OS, and to prevent abuse of the name "open source" as a brand or label.

By 1999, the term "open source" had become integrated fully into mainstream computing parlance, but was considered too overly descriptive or general to be registered as a trademark by the OSI. The open source definition (OSD) that was adopted outlines the principles that must be upheld by licenses applied to OS software. First, licenses must not restrict distribution of the software as either source code or in compiled form. Second, OS licenses must permit either derived works based on the original source code, or modifications through third-party patches to change the software. Third, OS software licenses must be unbiased in every sense, such that people, groups, or fields of endeavour are not discriminated against, and such that the license applies equally to all whom the software is distributed. Finally, the OSD also implies neutrality towards technology such that OS licenses may not restrict software to be used with any other software, or restrict the use of other software, nor may it be predicated towards any individual technology or interface (OSI, 2005).

The rapid diffusion of OS software that has taken place since the late 1990s is the outcome of several trends that have converged in recent years. In particular, the efforts made by the OSI have effectively turned around the negative image that "free software" had outside the OS community, and has made the OS concept a viable alternative to standard commercial software. Over the same time period, the expansion of the Internet, in terms of coverage, bandwidth, and usage has increased significantly. This has allowed the geographically dispersed software developers and organizations that volunteer time, or operate in a nonprofit manner based on funding from donations and research grants, to be able to communicate and collaborate in the development of OS projects.

Initially, OS was predominantly associated with high-profile projects such as the Linux operating system, the Apache Web server (which remains the most commonly used Web server in the world), and the Mozilla Web browser. As the principles and benefits of software developed using the OS approach have increasingly become common knowledge, the number of projects and people using them has grown steadily. On the surface, the most commonly identified benefit of using OS software is that it can be used, modified, and distributed by anyone at no financial cost. Yet there are subtler and more significant benefits. In particular, quality control of the software is essentially in the hands of the developer and user communities, since OS projects typically provide avenues for nonaffiliated users to give feedback, report problems, and/or submit their own solutions or upgrades to OS tools. Thus, in a sense, the OS approach can be viewed as a form of public participation in software development. Unlike commercial businesses selling proprietary or "closed source" software, OS projects generally stand to lose nothing by announcing problems or security issues. In fact, OS software benefits from this by enabling the entire user and developer communities to respond immediately and contribute to solutions. In contrast, proprietary software can only be maintained by the original authors or copyright owners, and software upgrades or security patches are only produced and released when it best suits the owners. This dynamic interaction between developers and users within the OS community has led to some of the most successful and highest quality software yet developed (such as those mentioned earlier).

The main challenges associated with the use of OS software generally stem from the fact that it is normally developed to satisfy the needs of developers and, as noted in section 2, this is an approach that is almost guaranteed to fail relative to the goal of developing broad-based and highly usable decision support tools. In addition, OS software is generally distributed "as is," such that its authors or distributors are not liable in any way, nor are obligated to provide documentation, user support, or warranties. Consequently, the use of many OS projects is limited to experts familiar with the use and manipulation of low-level source code. However, where OS software meets the needs of a large enough number of people, members of the user community have contributed considerable effort to produce documentation, enhance the user-friendliness of the software, and provide supplementary support to peers and users.

In addition to major nodes of OS development such as SourceForge.net (the most recent statistics report that SourceForge.net hosts approximately 100,000 OS projects, and has over 1,000,000 registered users (http://www.sourceforge.net)), many well-organized or established OS projects are hosted by independent sites or by community sites that cater to specific themes. In addition, numerous Web sites have been assembled as catalogues of OS projects available from various independent or public sources, usually referring to software related to a particular theme or area of interest. As the OS community has grown in general, so too has the open source GIS (OSGIS) community. While the number of developers and users supporting OSGIS projects is relatively small, several notable projects are under development.

Among the most common requirements among organizations that make use of spatial data is the ability to generate and distribute data as cartographic maps or via interactive mapping tools. The establishment of open standards for spatial data formats, processing, and Internet-based transfer protocols by the OGS was noted earlier. These standards have helped to promote many OSGIS projects, as well as to standardize interoperability between both OS and commercial GIS tools. From this environment of innovation, numerous OSGIS projects have emerged. While it is beyond the scope of this chapter to describe these in any detail, most of these projects can be located on the Internet via the FreeGIS.org (http://www.freegis.org) Web site, which catalogues all forms of OS software related to GIS and spatial data processing. Further, the MapTools.org Web site (http://www.maptools.org), hosted by DM Solutions in Ottawa, Canada, has also emerged as a project-hosting service similar to SourceForge.net (though at a much smaller scale), catering specifically to OSGIS projects.

In general, there are two areas of development in OSGIS that are relevant to this chapter. The first relates to the need to display and interact with spatial data in distributed environments for which the concept of Web mapping has become a standard solution. In this category, MapServer has emerged as a particularly popular OSGIS solution. The plans for development of MapServer began in 1996 with the partnering of the University of Minnesota with the Minnesota Department of Natural Resources (DNR) in the ForNet project funded by NASA (Lime, 2004). Its initial purpose was to deliver remote sensing projects to field forestry staff. Web-mapping solutions at the time were either proprietary (e.g., the Xerox Parc Map Server released in 1994), or relied on commercial tools such as the early ESRI Web-map servers. MapServer 1.0 was first released in 1997 as an independent common gateway interface (CGI) program, taking advantage of existing OS tools for graphics and interaction with GIS data using the ”open” ESRI ShapeFile format (.shp).

MapServer was first released as public OS software in 2000. Since that time it has grown steadily, both in terms of its overall functionality and its acceptance by the OSGIS community (Lime, 2004). The number of contributors has grown from 2 at the time of its OS release to 19 developers and 15 documenters around the world. The various contributors have made significant improvements to MapServer by enhancing its overall functionality, and producing tools to make it easier to use. DM Solutions, for example, has produced a series of tools that make development of MapServer applications much easier. These include a version of the MapScript library that interfaces with MapServer from within server-side PHP code; the Rosa java applet which provides a dynamic Web-based user interface (beneficial for interacting with maps generated by MapServer); MapLab, a PHP-based tool that provides a programming interface for authoring map files for MapServer; and, more recently, Chameleon, a PHP-based system of “widgets” that can be used to produce highly functional and flexible Web-based interfaces for MapServer projects. Contributions such as these have enabled many MapServer users to develop highly functional Web-mapping applications.

Despite its growing success, MapServer is not a fully functional GIS, nor should this be a development objective. Rather, it is a tool that enables the development of visual interfaces primarily via Web pages, based on the most well-known spatial data formats. This leaves a second area of development that had to be filled by other OSGIS projects, namely the storage and processing of spatial data. In 2001 following the OS release of MapServer, Refractions Inc., a company located in Vancouver, Canada, initiated the development of PostGIS, which ultimately reached full maturity when it was released as version 1.0 in April, 2005. PostGIS is an add-on module for the OS PostgreSQL object-relational database management system (ORDBMS) that enables the storage and processing of spatial data in PostgreSQL databases via structured query language (SQL). The SQL that is used in Postgre is based on the OGC simple features for SQL specification (OGC, 2005). PostGIS also relies on two other OS tools, namely the geometry engine open source (GEOS), also developed by Refractions Inc., for spatial topological functions, and the Proj.4 library available from RemoteSensing.org (http://www.remotesensing.org), for projection and transformation of spatial coordinates.

Essentially, PostGIS provides all of the standard functionality expected of any GIS, with the added advantage of advanced functionality available through spatially-enhanced SQL in PostgreSQL. In addition, upon the recent release of PostgreSQL 8.0 in late 2004, major improvements have made it comparable to most commercial enterprise-level database systems. Since the latest releases of both PostgreSQL and PostGIS, contributors have worked to package the software to make it as easy to use as possible (e.g., producing documentation and/or installer programs for MS Windows). Although there are existing commercial equivalents to PostgreSQL such as ESRI's Spatial Database Engine (SDE) and Oracle Spatial, these tend to be very costly and have high-management overhead. Following PostgreSQL, MySQL, an OS ORDBMS with a much larger developer and user community than PostgreSQL, also released a version (version 4.1 in September, 2004) with spatial object support based on the OGC standards. However, the spatial functionality incorporated into MySQL has yet to reach the level of that provided by PostGIS.

Together, the use of the PostgreSQL and PostGIS projects form an excellent starting point for alternatives to commercial GIS software. Recent user trends are a testament to this. Since late 2003, the number of registered users of PostGIS has more than doubled from approximately 230 to approximately 600 as of May 2005. Over the same time period, the number of downloads of the PostGIS source code per month has more than tripled from approximately 350 to 1200 (Ramsey, 2005).

In 2002, not long after the initial development releases of PostGIS, support for the PostGIS data format was added to MapServer. Although optional support has also been added to MapServer for other spatially enabled database systems (namely SDE and possibly also Oracle Spatial), the pairing of MapServer with PostGIS has become an ideal solution for Web-based spatial decision support projects that require highly flexible and scalable architectures. With the option to control both MapServer and PostGIS using application programming interfaces (APIs) available for PHP with MapScript and PostgreSQL functionality included with PHP, it is highly feasible to develop an entirely OS approach to address the design and functionality needs of spatial decision support tools identified in section 2. Combined with tools contributed by the MapServer/PostGIS community (particularly those contributed by the DM Solutions group), all of the requirements for building Web-based tools with highly adaptable and advanced functionality for both individual and collaborative use are available through OS tools.

This combination of OS components was used to develop an operational Web-based tool that uses an intuitive interface for individuals and groups to assess the quality of early childhood education in Peru, and to assist in generating dialogue between stakeholders that will result in planning for systemic improvements. The databases and information derived from use of the tool relate to all levels of the education hierarchy, as well as to locational data on community-based characteristics of school contexts. The approach used is of particular interest as the level of computing skills among users is highly variable: from indigent parents living in very poor urban, rural and jungle areas of Peru, to school teachers and administrators in the same areas, as well as local, regional, and national planners within the Peruvian Ministry of Education and researchers within the NGO and University sectors. The high-level design and a sample application of the tool are presented in the following sections.

DESIGN AND FUNCTIONS OF THE EDUCAL DECISION SUPPORT TOOL

The issue of education development during the formative years of the education process is high on the agenda of many governments, especially in developing nations. This is a function of the recognition that education is a fundamental aspect of the development process, and that access to a good quality education is a prerequisite for the populations of nations to compete and operate in today's globalized marketplaces. Moreover, ensuring fundamental principles of equal access to a quality education independent of gender, religion, ethnicity, wealth, and geographic location (among other things) is a basic human right that must be sought by all nations in the world.

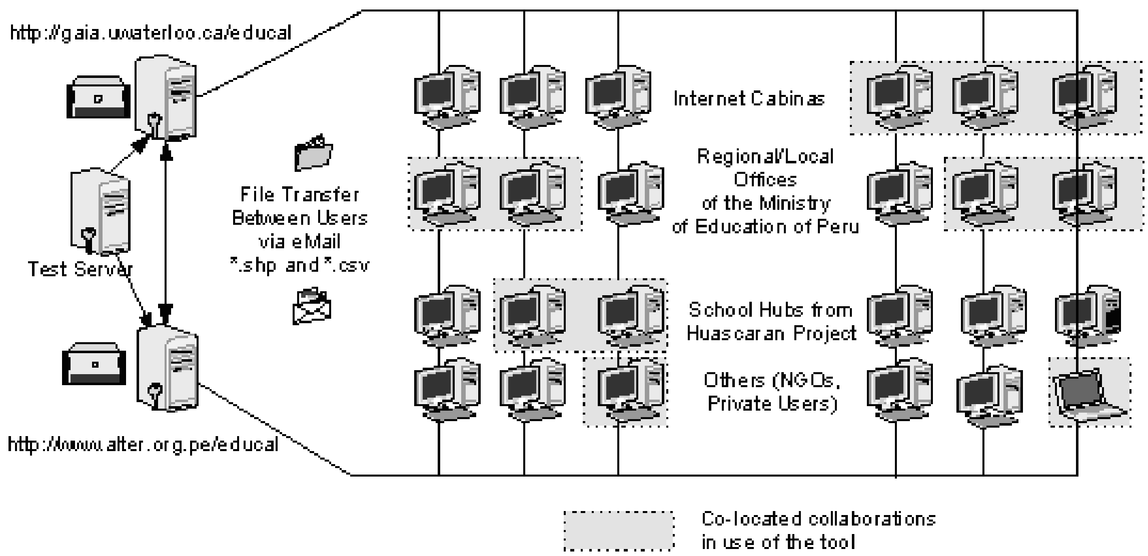
These considerations have been addressed in different ways by different nations. Since 2002 in Peru, for example, the government has passed a number of laws that require decentralized education planning and management, as well as greater transparency in the access of all members of Peruvian society to basic government information (Hall & Peters, 2003; Peters & Hall, 2004). These actions have created in Peru the need for mechanisms that enable data to be returned back to its original collection points, packaged as information. Subsequently, according to the principles of decentralized management and planning, there is a further need for knowledge-generating tools that allow stakeholders in the education sector to dialogue with each other, and to make informed local-level decisions that seek to improve the quality of education.

The required mechanisms and tools are provided in Peru by the EduCal project. The acronym EduCal stands for in English Education Calculations and in Spanish Educación de Calidad, or an education of quality, and it represents both a specific tool as well as an approach to fostering decision-oriented collaboration between stakeholders in the education planning process. In short, EduCal allows stakeholders to use a custom programmed, Internet-based tool developed entirely using OSGIS and other OS software to evaluate school and area-based education quality. The tool uses an intuitive multilingual interface (Spanish and English) with scenario-based methods that function equally well for colocated users as for independent, dispersed users. Use of the tool allows stakeholders to understand better the absolute and relative performance of schools and their geographic contexts according to easily customizable assessments of school-based education quality and community-based indicators of well-being.

The Internet is central to the way that EduCal is conceived and the way that it functions. As noted in the previous section, the pervasiveness of Internet access points in even the most remote corners of many developing countries, including the ubiquitous public cabinas in Peru, provides an infrastructure that facilitates the access of a wide range of stakeholders to participate in education assessment and planning. EduCal allows users to work individually or to collaborate in group, colocated evaluations, as shown in Figure 1. The software and associated databases are served from two mirrored servers, one located in Waterloo, Canada and one in Lima, Peru. Both are PHP-enabled production servers and are linked to a similarly configured test server that is not advertised to users. All servers require authenticated login using a secure socket layer (SSL) certificate. This allows users to save scenarios they have generated to their own userid and password-secured accounts for future recall and comparison or modification. Users can create group and/or individual accounts, depending on the preferred or most practical form of participation identified in Figure 1.

Basically, four types of uses are anticipated with the tool, namely individual or colocated group use for parents, teachers, or administrators working in an Internet cabina; individual or colocated education planners working from the local or regional offices of the Ministry of Education; parents, teachers, or administrators working individually or in groups on networked computers running at schools participating in the Huascarán project (for more information see http://www.huascaran.edu.pe/); and NGO, university, or private users who can also work

Figure 1. High-level architecture of Web-based user interaction of EduCal tool



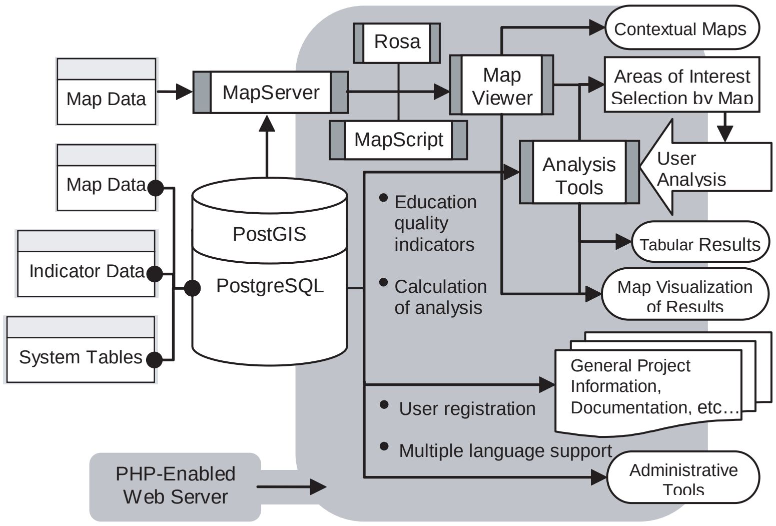
in colocated groups or by themselves. As shown in Figure 1, it is also possible to have vertical or mixed interaction between different access points and types of users to encourage further collaboration and dialogue.

EduCal's object relational database managed by PostgreSQL and PostGIS. The database contains basic map layers including, among others, school points, population centre points for rural areas, city block polygons for urban areas, and all relevant areas of higher spatial aggregation (districts, zones, provinces, departments (recently renamed to regions), and the entire nation). Attached to the school points are detailed normalized and cleaned (parsed for obvious errors and either corrected or flagged as suspect and not analyzed) data from the regularly enumerated (at least every 2 years) censo escolar or school census. In addition, other databases are included on individual student nutrition and height. The education databases are available for approximately all 33,000 state-managed primary schools in the country. Data are keyed on the codigo_modular, which is a unique identifier for all schools.

Approximately 500 variables are available for education quality assessment from the school database. These indicators are sorted into four closely related, yet distinct dimensions of the education process (Peters & Hall, 2004), namely inputs, processes, outputs, and outcomes. In addition, EduCal provides a large database of approximately 150 indicators of contextual variables assembled from the most recent Peruvian census of population and dwellings at city blocks in urban areas and population centres in rural areas. This recognizes that education quality is not simply a function of what occurs during the school day, but also the quality of life of students in their homes.

The conceptual design of the EduCal tool is illustrated in Figure 2. As noted earlier, the Web site runs within the environment of a PHP-enabled Web server that allows server-side programming to generate dynamic Web pages that users interact with. Supporting this Web site is the PostgreSQL

Figure 2. High-level interface diagram of OS components of the EduCal tool

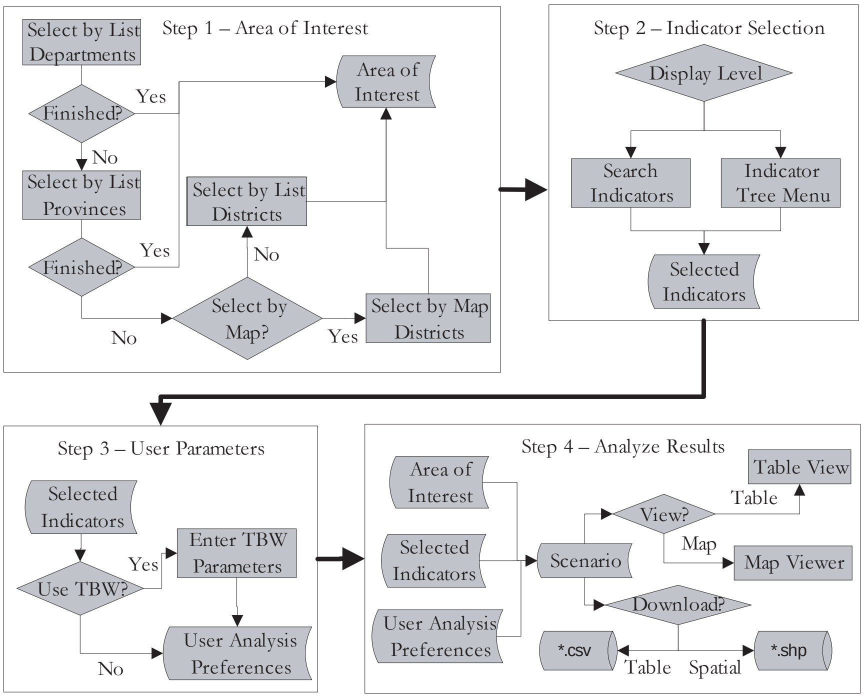


database, described earlier, with the PostGIS extension installed for spatial data handling. The database also contains various system tables that support the Web site's functionality, such as user authentication, and embedded multilingual presentation. These tables can be managed through basic utilities accessible to users with administrative privileges to the Web site. In addition, the database stores the indicator data and associated map layers required for the education quality analysis tool.

The map viewer, also developed in PHP code, utilizes MapScript's API to load dynamic map information, generate a map image with MapServer, and present the map to users. The Rosa Java applet incorporated in the map viewer's output adds a more dynamic mapping interface, improving the user's interaction with the software. The map viewer is configured such that it can operate as a mapping interface alone for presentation of contextual maps using PostGIS map data or other spatial data types. In addition, it enhances the education quality analysis tool by enabling map-based selection of study areas and presentation of assessment results.

The analysis tool is EduCal's main feature for users interested in accessing data and assessing education quality as a basis for making improvements through dialogue between stakeholder groups. The tool is presented to the user in four steps, as illustrated in Figure 3. The first step begins by asking the user to identify a geographical area of interest. Selection of a study area begins by allowing departments/regions, the top level of administration within Peru, to be selected from a scrolling list box. Having selected one or more departments, users may choose to use their selection to define the geographical extent of their analysis, or proceed to select from a list of provinces (the next administrative level) that are nested within the departments/regions. Finally, if any provinces have been selected, districts within the selected provinces may optionally be selected from a list, or selected spatially using one of several methods available on the toolbar within the map viewer.

Figure 3. Four-step procedure for education quality assessment with EduCal



Having completed the first step, the second step prompts users to select a set of indicators for analysis from those available in the database. The indicators are presented in a Java-based expandable tree comprising five categories based on the four dimensions of the education process and the social context. Options are available to select from a basic subset of indicators, an intermediate list including more indicators, or a complete list that allows selection from all available indicators within any category. This leads to the third step, where users may choose to analyze the indicators directly, thus proceeding on to the fourth step. Alternatively, users may choose to assess the indicators selected in the previous step with a target-based weighting (TBW) method. The TBW approach allows users to discuss their perspectives if working together in a group, or if working alone, to use their own perspective of education quality by defining how each indicator should be interpreted. To do this, users must specify a range of acceptable values for each indicator (minimum to maximum), and the ideal value or target within the range. In addition, the relative importance of each indicator can be specified by relative numerical scalar weights assigned by the user(s). These parameters are processed by the EduCal tool to produce an overall index (optionally normalized between 0 and 1) for education quality and social context that can be used to rank cases (i.e., schools, districts, provinces, etc.) in a way that reflects the analyst's perspectives. Further information on this method and its use can be obtained from either the Guided Tour or the Help system within the EduCal Web site (Figure 1).

The fourth step of the analysis process provides options for further dialogue by viewing, evaluating, and saving the output from an analysis.

In this step, users are presented with options to view results in tabular form for various levels of aggregation (depending on the study area selected in step one). In addition, users may select options to view classified thematic maps based on the calculated TBW indices (or based on the unweighted indicators, if TBW is not used). The analysis scenario itself may be saved in a user profile on the Web site so that it may be reloaded and/or modified on the Web site at a later time. Finally, results from the analysis may be downloaded in tabular (*.csv) or spatial (*.shp) file formats, enabling users to save the results locally and examine them off-line using other statistical or spatial analysis software packages. In addition, results in the form of map outputs and attached comma delimited tables can be sent to other participants in a group evaluation by automated e-mail from within the tool. To illustrate better how these functions work, a sample scenario is presented in the following section.

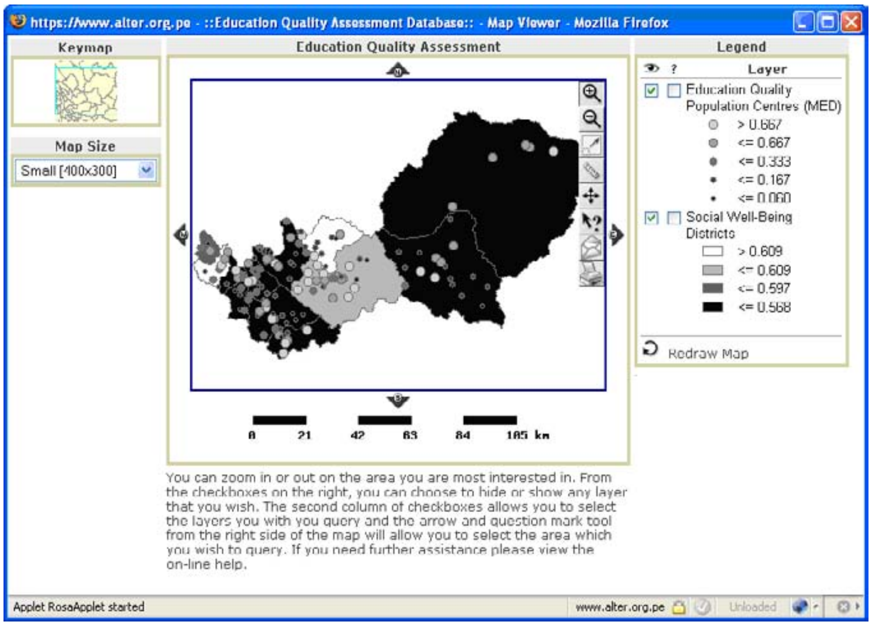
APPLICATION

To illustrate one of the multiple ways in which the EduCal tool can be deployed, consider the perspective of a planner working at the local education management unit (Unidad de Gestión Educativa Local - UGEL) of the Peruvian Ministry of Education in the rural province of Quispicanchi in southern Peru (department/region of Cusco). The general objective is to examine (visually and numerically) education quality at the individual school level based on user-defined indicators. In this case, the net loss of children by grade from schools (desertion) is examined, combined with an analysis of the number of children under the age of 15 who work at the level of the districts within the province. Desertion from school for paid or unpaid family work is a common phenomenon in the Andean highlands, and represents a substantial problem within the Peruvian education sector in general.

To create the scenario, the province of Quispicanchi in the department/region of Cusco is selected to represent the study area in step one. Indicators relating to desertion and youth labour are selected in step two, and parameters are defined in step three using the TBW method to determine how education quality and social context should be represented using these indicators. Desertion rates are selected for both boys and girls for grades 1 and 6. Minimum and target levels for desertion rates are set to zero, indicating that no desertion by grade is the value required for a school to receive a perfect score. As the lower grades in Quispicanchi tend to have higher desertion rates (as revealed by default values from the database in the TBW parameters), the maximum values, at which the indicators would receive the worst (zero) overall scores were set higher for grade 1 (0.25) than in grade 6 (0.10) in order to capture a better range of values. However, the weights for grade 6 are set twice as high as for grade 1, thus making grade 6 desertion rates have twice the influence on the overall education quality index than grade 1 desertion rates.

The youth employment rate is the only indicator selected for the social context, hence its weight is effectively unimportant and therefore left equal to unity. The index for context is therefore entirely determined by the youth employment rate relative to the minimum/target (also set to zero) and the maximum limit of 10%, at and beyond which the context would receive a zero (worst possible) score, whereas cases of zero youth employment would receive a maximum (best case) value of unity. After the scenario is generated, the results can be examined in both tabular and map form, directly within the EduCal tool itself (e.g., Figure 4 shows the results for schools and districts with both indices ranging from 0 to 1, with values nearer 1 being better). In addition, the data from the results can be downloaded from the EduCal tool in tabular form, and analyzed using a spreadsheet program such as Excel to produce general summaries and more advanced statistical analysis

Figure 4. Map view of calculated Indices, Quispicanchi, Cusco, Peru



of results. While this level of analysis is beyond the capacity of most EduCal users (outside the user communities within NGOs, universities, and the regional offices of the Ministry of Education), the basic results that are produced are readily understandable by all users in Peru after basic training in the use of the tool.

It is straightforward to generate a list of schools where desertion appears to be a significant problem. Table 1 shows the results for the 10 worst schools in Quispicanchi as far as desertion is concerned. This list is particularly useful to Ministry planners as well as school administrators, teachers, and parents at the affected schools as it provides a basis for community consultations

that seek to establish why children are leaving school prematurely. Moreover, it allows planners to be able to dialogue with parents over the importance of keeping their children in school, and encourage them to ensure that their children pass beyond primary education to complete at least the required minimum number of years of secondary education (Table 1).

It is important to emphasize that the simple analysis described above could be undertaken by one or more Ministry planners independently within or between local management units (UGEL), as well as for an extended area by planners at the more geographically aggregate regional level of administration. Each participant has the ability to develop his or her own scenario targets and weights for indicators, and then convene either online or in person to discuss and refine their results as part of the education quality improvement process. In addition, a group of parents working together and producing several scenarios with varied parameters that may include additional indicators to those identified by the ministry planners can produce comparator scenarios that promote the perspective of the parents as opposed

Table 1. Results from 10 schools in Quispicanchi with lowest values for education quality

School Name	Education Quality Index	Social Well-Being Index	Male student desertion rate in grade 1	Female student desertion rate in grade 1	Male student desertion rate in grade 6	Female student desertion rate in grade 6	Percent of population that employed under the age of 15
Canchapata	**0**	**0**	0.66	0.55	0.14	0.5	14
Alto Serranuyoc	**0.02**	**0.362**	0.4	0.22	0.33	1	6.38
Huatshua / Huatshua Laguna	**0.06**	**0.646**	0.16	0.55	0.16	0.5	3.54
Ullpo	**0.06**	**0.239**	0.57	0.16	0.66	0.33	7.61
Urin Ccoscco	**0.073**	**0**	0.21	0.18	0.28	0.33	23.83
Pampa Chulla	**0.093**	**0.786**	0.33	0.11	0.12	0.22	2.14

Ccollcca	**0.167**	**0.286**	0	0.44	0.33	0.1	7.14

to the perspective of the Ministry. Clearly, while there are no right or wrong perspectives and/or scenarios in the evaluation of education quality, there are certainly as many perspectives as there are participants.

The EduCal tool facilitates consideration of these multiple perspectives in a flexible manner that accommodates participation independent of whether a user has his or her own computer and /or an Internet connection. By virtue of being accessible through public Internet cabinas, in this case in Peru, the tool promotes true democratic access to and participation in decision processes. Operationally the tool is easy to use and powerful, without requiring a high level of computing knowledge. It is possible that parent associations, administrators, and teachers can each be asked to develop their own analyses using the tool, and then to convene with the explicit objective of developing a common vision and plan for improving the quality of early childhood education. In this context, the integration of mapping and spatial selection functionality in the tool provides a visual and interactive environment that hides much of the complexity of the analysis process from the end user.

CONCLUSION

This chapter has discussed several emergent threads in the literature on decision making with the use of spatial data. Fundamental to these new threads is the fact that spatial decision making, especially in the planning realm, is seldom undertaken by a single individual. Rather, multiple participants are typically involved in collaboration through the course of a decision process. Given this, new approaches within the spatial domain seek to provide greater flexibility in the way that participants can interact and communicate effectively not only with the software that supports decision analysis, but more importantly with each other. Participation in this context must be broad-based or public, and accommodate diverse knowledge bases and computing skills that range from very basic to advanced. This represents a divergence away from previous approaches to achieve the goal of dialogue building and collaboration through the development of easily understandable user interfaces that are flexible in the manner in which they are deployed.

The emergent role of the Internet as the dominant international information and communication technology of the current era makes this medium well suited to facilitate broad-based participation in decision processes. This is especially true in developing countries where Internet uptake is facilitated through publicly accessible Internet cabinas in lieu of personal computer ownership and relatively high Internet access costs. Further, the diffusion of open source software technologies goes beyond the initial popular operating system and server tools to include a wide variety of software products, including conventional and Web-based GIS, and has added further flexibility to the various types of user interaction the Internet makes possible. OSGIS and other OS tools allow experimentation with a variety of software and system architectures de novo, as the availability of source code and the lack of financial burden due to software acquisition are pervasive incentives for innovative research.

The EduCal tool that was described in this chapter represents one example of what is possible without the dependency on commercial GIS or other commercial software products. While the tool, in its current release has been warmly received by the education community in Peru, there are still many areas in which it can be further improved. For example, work currently underway using the same OS tools as EduCal seeks to achieve true collaboration for dispersed individual users and group collaborators through synchronous scenario development, including threaded messaging and shared map views between multiple users. Linkages between text messages and spatial objects allow the construction of a potentially rich integrated database that can subsequently be mined to understand better the process of generating alternatives, and their evaluation in making decisions.

Further, additional functions are being added to the EduCal tool to provide spatial online analytic processing with a three-dimensional temporal data model rather than conventional two-dimensional database tables. This will allow educators to examine temporal trends in education quality for schools, as well as perform spatial drill-down, roll-up, and drill-across operations that ultimately, using natural language spatial queries, seek to identify areas and/or schools that have similar characteristics.

With the flexibility that OS software provides for low-level coding, the possibilities for future enhancement to the EduCal tool are essentially open ended. Certainly, the advent of a flourishing international OSGIS community allows innovation to flourish without the encumbrances of closed code and the proprietary data structures that have constrained research possibilities in the past.

Chapter 1.33
Measuring Knowledge Management Capabilities

Uday Kulkarni

Ronald Freeze
Arizona State University, USA

INTRODUCTION

As business professionals know, creating awareness of a problem and its impact is a critical first step toward the resolution of the problem. That which does not get measured, does not get managed (Redman, 1998). In fact, measurement is a precursor to improvement. This is true for knowledge management (KM) capabilities of an organization. "In today's knowledge-based economy," Alan Greenspan recently said, "70% of organizational assets are knowledge assets." Knowledge assets are intangible capabilities, and there is a recognized need to "make a greater effort to quantify the value of such intangible assets" (Teece, 1998b). How does one measure the worth of an organization's knowledge assets? What does one mean by knowledge assets anyway?

In this article, we afford some formal structure to the idea of measuring knowledge management capabilities of an organization, with the ultimate goal of improving business performance through better management of knowledge assets. We describe a large-scale effort at Intel to assess such capabilities with a view to enhance them. This project started in May of 2002. We describe the different types of knowledge assets identified, the potential capabilities associated with managing knowledge assets, the metrics devised for their measurement, and the assessment methodology that is being standardized across the corporation. We also provide results of the initial validation of the instrument and its ability to ascertain KM capabilities correctly. Hundreds of knowledge workers (Davenport, 2003) have so far participated in this study to benchmark KM capabilities of their units. Some units are already planning the next steps for improving their KM capabilities.

BACKGROUND: WHAT IS KNOWLEDGE?

The direction required to quantify the value of knowledge assets begins to come into focus when one realizes their diversity in an organizational setting. Some knowledge assets are “grounded in the experience and expertise of individuals,” that is, tacit knowledge, while others can be stored as knowledge objects that exist on their own, that is, explicit knowledge (Fahey & Prusak, 1998; Teece, 1998a). Therefore, to describe knowledge assets that exist across organizations, domains that encompass knowledge work and can be studied for improving on-the-job productivity must be identified. For this reason, we start with classifying the whole gamut of knowledge residing in an organization into a knowledge-asset framework.

We categorize institutional knowledge assets into four areas: expertise, lessons learned, knowledge documents, and data. This categorization resulted from the realization that knowledge in each area has a unique (a) mix of tacit and explicit content, (b) method of transfer and contextual value, and (c) life cycle (creation to application), including its shelf life. To contrast the unique nature of each knowledge area, its characterization along these three dimensions needs to be understood.

Expertise

Expertise is high in tacit knowledge. Individuals in an organization are often considered experts within a particular domain. The transfer of expertise occurs via consultation, collaboration, mentoring, and observation, that is, through personal interaction. The shelf life of this type of knowledge depends on the currency of the knowledge in the context of its application, and it can be extended by renewal and learning. The availability of experts and the ability of an organization to locate required expertise for a given situation quickly can result in performance improvement (Dooley, Corman, & McPhee, 2002).

Lessons Learned

Lessons learned are the essence of learning from past successes and failures. They represent highly specific knowledge gained while completing a project or task. They lie toward the tacit end of the tacit-explicit continuum. Undocumented lessons are in the heads of people who learned them. To the extent lessons are documented, their transferability is improved (in a networked organization), but their applicability remains highly contextual. Recognizing the similarities between the characteristics of the current task with those of an earlier one from which the lesson was learned is an important step in their application. This type of knowledge is created when one recognizes that something substantial of recurring value has been learned. The shelf life of a lesson depends on its generalizability and the persistence of the context. The more generalized a lesson, the broader is its applicability and the longer its life. Organizations that exploit this type of knowledge have reported substantial cost savings (O’Dell & Grayson, 1998).

Knowledge Documents

Knowledge documents represent explicit knowledge such as project reports, technical reports, policies and procedures, research reports, publications, pictures, drawings, diagrams, audio and video clips, and so forth. Knowledge documents encompass internally generated as well as external information (Zack, 1999). Market research reports and operating manuals of complex machinery are good examples. Knowledge documents contain the background knowledge that can be referred to by a knowledge worker to educate themselves—to increase their awareness and understanding—about an area that they work in. Well understood taxonomies and archives, as well as the ease of access of relevant documents, is important to maximize the transferability and reuse of this knowledge. In contrast to lessons learned, the knowledge contained in knowledge documents is more permanent.

Data

The most explicit form of knowledge is contained in data used for strategic and tactical decision making (Fahey & Prusak, 1998). Here we do not refer to operational data generated by the day-to-day transactions of a business, but aggregated and historical data such as that stored in a data warehouse. Such data can be a constant source of useful knowledge when used for analytical processing, detecting patterns, modeling business situations, and so forth. The quality of metadata (design of the structure and descriptions of data) determines the availability and usability of this type of knowledge. The shelf life of data as a knowledge source can be very long; many retail corporations have spent millions of dollars on creating large data warehouses that store years of summary data for discovering trends and patterns (knowledge) that can have a direct impact on strategic decisions.

One may argue that there is a substantial overlap among the knowledge assets described above. While we recognize that the lines separating these knowledge assets are gray, the core characteristics of the knowledge areas differ substantially, and therefore the knowledge needs of an organization can be more clearly understood if they are broken up among the different types of knowledge assets. Hansen, Nohria, and Tierney (1999) describe the differing views of knowledge in different organizations and show how an organization's business strategy drives its knowledge needs. We found that, particularly in large organizations, the functional nature of a business unit emphasizes the unit's knowledge needs.

While each business unit within Intel utilized all types of knowledge, we found that the importance, and therefore the strategic focus of a business unit, varied based on its core functional responsibility. TMG, an organizational unit focused on the rapid ramp-up of production operations, required a high level of capability within the lessons-learned category. Identifying shortcomings within this unique capability area therefore became critical. In contrast, SSG, a unit responsible for the development of system software solutions, required emphasis on different capability areas, namely, in expertise and knowledge documents. Being able to assess the existing capability levels in these differing knowledge areas is not only essential for benchmarking, but also for directing efforts to improve them and to monitor progress over time. The importance of KM capability assessment is validated by the actions of the business units subsequent to the assessment; most of the business units have already started investing in planned KM initiatives in those knowledge areas that are deemed important but low in capability level.

WHAT DOES MANAGING KNOWLEDGE MEAN?

Like any other intangible asset, knowledge needs to be managed in order to maximize its value by fully exploiting its utility. Each type of knowledge asset has its own unique characteristics as described above, however, a common framework can be applied to understand how it can be managed. One such framework stems from the concept of the knowledge life cycle (Alavi & Leidner, 2001). The four distinct stages of the knowledge life cycle are creation and capture, storage and archival, retrieval and transfer, and application and reuse. We found that, although these stages seem to apply only to explicit knowledge, they do apply to tacit knowledge as well. For example, in the context of highly tacit knowledge such as expertise, the capture stage corresponds to the process of identifying domain experts and registering their expertise. This information about specific fields of expertise is then stored in an expertise database. The retrieval stage occurs when a potential user of knowledge searches for and locates the appropriate expert, and the application stage is the culmination of the life cycle resulting in a consultation with the expert. The knowledge life-cycle framework can thus be applied to manage both explicit and tacit knowledge.

In assessing KM capabilities of an organization, ascertaining how well each stage of the knowledge life cycle is managed becomes important. Stages of the life cycle may be assisted by the necessary technology support and the integration of KM-related activities into normal business processes. While technology automates parts of the knowledge life cycle, process integration ensures participation in KM-related activities. In addition, the cultural underpinnings of an organization determine the extent to which organizational knowledge may be shared.

Technology Support

Although technology is not the solution to managing knowledge, it provides the means to participate in certain stages of the knowledge life cycle. KM systems are a class of information systems built around this need. Examples of KM systems that offer support for sharing knowledge in various capability areas are a form-based registration system for capturing the areas of expertise of experts, a storage and retrieval system for categorizing and searching knowledge documents, a data warehouse with decision-support and modeling tools, and so forth.

Process Integration

If knowledge-sharing activities are made part of normal business processes, it is more likely to result in higher KM capabilities. Purely voluntary participation in KM-related activities is hard to come by because its direct and immediate benefits are difficult to measure. Nevertheless, large and small organizations have started embedding knowledge capture and access activities into work flows. Examples of such practices are routine engagement in reflective activities after reaching major milestones of projects to capture lessons learned, or looking for relevant knowledge documents at the beginning of a new task or project.

The Role of Culture

Organizational culture plays a significant role in defining the extent to which knowledge may be shared. The environments in which employees work can affect both the supply and demand aspects of every type of knowledge. On the supply side, it is the willingness to share expertise, taking the time to catalog important knowledge documents, and investing time in postmortems and debriefings to capture lessons learned from completed projects and tasks. On the demand side, culture can promote looking for and reusing available knowledge.

The existence of a positive knowledge-sharing culture is a precondition for an organization to have any capability in KM (Adams & Lamont, 2003). No amount of sophisticated KM systems and process changes can enhance KM capabilities if the culture discourages sharing and promotes hoarding. Organizations that have this problem and recognize it need to work on creating the appropriate environment for their knowledge workers. As a first step, immediate supervisors may encourage the regular sharing of work-related problem solutions and be role models by demonstrating knowledge-sharing behavior. The next higher level in this direction may be reached by recognizing and rewarding knowledge-sharing behavior, and instituting training and education on systems and processes used for knowledge sharing. At the highest level, the top management of the company may demonstrate its commitment by having a well articulated KM strategy and setting goals for KM-related undertakings.

HOW CAN ONE MEASURE KNOWLEDGE MANAGEMENT CAPABILITY?

Since KM assessment is an opportune topic, a few assessment tools and frameworks have been developed and presented at practitioner conferences and Web sites of such companies. Noteworthy among these are two methods, both based on the five level capability maturity model of the Software Engineering Institute (Humphrey, 1995). One is from Siemens that divides KM-related issues into eight key areas and a progressive maturity-level scale (Ehms & Langen, 2002; Langen, 2002), and another is from InfoSys Technologies focusing on three key result areas and a maturity model (Kochikar, 2002). However, apart from the terminology and some semantic transformations from software engineering to KM, there is no detailed description of the model, no operational classification of different types of knowledge, and no definitions of levels in terms of goals. For example, the general and specific goals of each level and the activities needed to attain the various levels of maturity are not available. Moreover, there is no scientific study reporting attempts made to test for content and construct validity of either the measurement instrument or the process adopted.

Our case-study team consisted of experts from Intel Corporation from process management, value measurement, change management, and information technology, in addition to the external academic researchers (authors). We undertook a structured conceptual development process to design a knowledge management capability assessment (KMCA) instrument. With the identification of knowledge-asset areas, a consistent nomological measure across all knowledge areas was needed to identify the capability level achieved within each area of knowledge.

Development of the KMCA Instrument

The KMCA model also adapts the framework of the five level capability maturity model to the KM context. The conceptual structure of the KMCA emphasizes the top-down design of the measurement instrument. The five capability levels of the KMCA are described in terms of their general goals in Table 1. The general goals indicate the milestones to be achieved in order for an organization (or an organizational unit) to reach the corresponding capability level. These goals are general enough to apply to each of the four knowledge capability areas. One can see that lower level goals are easier to achieve than higher level goals. This progression gives the questionnaire the ability to discern between capability levels accurately, an important design aspect of the KMCA.

The KMCA team mapped each general goal to one or more specific goals for each knowledge area: expertise, lessons learned, knowledge documents, and data. For example, consider one of the general goals of Capability Level 3 (see Table 1): “Systems/tools to enable KM activities exist.” Emanating from this general goal, one of the corresponding specific goals for the expertise area is “Experts are able to register their expertise in an expertise profiling system.” Such mapping was completed for each general goal of each capability level (for every capability area). Specific goals of each capability level of each knowledge area were then mapped to one or more specific practices, which are work practices that employees could identify with in their day-to-day work life. Specific practices were, in turn, converted into questions for the first version of the questionnaire. By strictly adhering to this procedure, the team was not only able to include questions represent-

Table 1. Capability levels

Capability Level	General Goals	Examples of Specific Goals
Level 1: Possible	Knowledge sharing is not discouraged. There is a general willingness to share. People who understand the value of sharing do it. The meaning of knowledge assets is understood.	Previous lessons learned can be found with perseverance.
		Some experts are willing to share expertise when consulted.
Level 2: Encouraged	The culture encourages the sharing of knowledge assets. The value of knowledge assets is recognized. Knowledge assets are stored/tracked in some fashion.	Supervisors encourage regular meetings to share knowledge/solutions.
		Experts and their expertise are identifiable.
		The importance of prior lessons learned is recognized.
Level 3: Enabled/ Practiced	The sharing of knowledge assets is practiced. Systems/tools to enable KM activities exist. Rewards/incentives promote knowledge sharing.	Organizational leadership understands how KM is applied to business.
		Lessons learned are captured.
		Taxonomies and centralized repositories for knowledge documents exist.
		Experts are able to register their expertise.
		Historical data is available for decision making.
Level 4: Managed	Employees expect to locate knowledge. Training is available. KM-related activities are part of work flow. Systems/tools for supporting KM activities are easy to use. KM capabilities and benefits are assessed. Leadership exhibits commitment to KM. Leadership provides a KM strategy.	Senior management sets policy, guidelines, and goals with respect to KM.
		Tools to locate experts are easy to use.
		Capturing, storing, and using lessons learned are part of normal work process.
		Knowledge-document retrieval is fast and easy.
		Historical data utilized for decision making is easy to access and manipulate.
Level 5: Continuous Improvement	KM processes are reviewed/improved. KM systems/tools are widely accepted, monitored, and updated. The KM assessment generates realistic improvement.	Senior management periodically reviews the effectiveness of KM investments to the whole organization.
		Recent improvements in document access have been implemented.
		Expert and expertise identification has expanded and been refined.
		New tools for data manipulation are tested and implemented.
		The impact of lessons learned on operations is communicated.

ing all levels (Level 1 through Level 5), but also able to maintain the relative progression of levels of questions within each area.

The prototype and subsequent versions of the instrument were developed and validated in four distinct phases over a 24 month period. These phased activities and accomplishments are described in Table 2, which details the deliberate, step-by-step process. The questionnaire consists of sections for each knowledge area and one for the cultural aspects of an organization. Within each section, questions are grouped by the components of that knowledge area. For example, the components under the knowledge documents section are taxonomy, the categorization process, the repository, the search and retrieval process, and the application and use process. Each question is mapped to a capability level according to the specific goals of that level. The final questionnaire consists of about 120 questions that can be completed in about 20 minutes.

Instrument Validation

Translation validity, which includes both the face and content validity of items included in the instrument, attempts to assess the degree to which the accurate translation of the constructs occurs while operationalizing the instrument (Trochim, 2001). This was a major focus in the early phases of the project, which provided substantial input as to the applicability of the concepts to Intel.

The criterion-related validity assesses the measurement accuracy of the instrument. It checks the predictive capability of the instrument based on the theory of the construct. In our case, this is the ability of our instrument to accurately measure the capability level of an organization in each knowledge area. Because of the strict design considerations, we expected to observe that for each capability area, all the requirements of a lower level of capability would be fully met before requirements of any of the higher levels are met. Results from the three business units at Intel confirmed this expectation, and we conclude that the capability levels are a progression. We also expected the KMCA to be able to compare relative capabilities across knowledge areas within a single organization and across multiple organizations for a given knowledge area. Our results also

Table 2. Instrument construction in validation

	Activities	Accomplishments
Phase 1 May 2002– Aug. 2002	Background research and identification of knowledge capability areas Conceptual design of the instrument, capability levels, and goals Initial survey construction Focus group of 12 knowledge workers	Confirmation of knowledge areas Initial questionnaire with about 145 questions and a 45-minute completion time Applicability of the survey to the work environment (face and content validity)
Phase 2 Aug. 2002– Nov. 2002	Survey administration to 38 volunteers from one business unit	Ability of the instrument to measure KM capabilities of the unit (criterion-related validity) Survey modification based on open-ended feedback (face and content validity)
Phase 3 Nov. 2002– Aug. 2003	Full-scale pilot study administration to a large business unit Elimination of redundant questions after data analysis, formatting, and readability improvements Interrater reliability test utilizing six domain experts on KM	Final questionnaire with about 120 questions and a 20-minute completion time Improvement in the instrument's ability to recommend specific KM practices Ability of the instrument to discern between capability levels
Phase 4 Aug. 2003– May 2004	Final version administered to three large business units (population 650 to 1,000 employees) Confirmatory factor analysis and other testing of capability areas, their components, and measurement accuracy	Ascertaining the ability of the instrument to measure capability levels in each knowledge area Response bias test indicated no bias Ability to make comparisons of KM capabilities within and between business units

confirmed this expectation. The overall results thus confirm that the mapping from general goals to specific goals and practices, and then to actual questions was accurately accomplished, and that KMCA is able to measure and compare the separate KM capabilities of organizations.

Up to this point, we have focused on item construction and its translation to knowledge areas and levels. The overall goal is one of establishing the four capability areas as measurable constructs. For this final step, we used confirmatory factor analysis and represented each capability area as a latent factor whose measurement consistency was established using two measurement model forms: (a) the general-specific model and (b) the second-order model (Chen, West, & Sousa, in press). The results of both structural equation models provided fit indices for all capability areas, indicating models of good fit. The significance of the general factor and the second-order factor representing the overall capability area provides strong evidence supporting these knowledge assets as measurable capabilities. Using both measurement models within each business unit provided experimental rigor and external validity.

Measurement Results

The results of the KMCA are in the form of capability-level scores in each knowledge area accompanied by a report describing the highlights and detailed information concerning the status

Figure 1. Sample KMCA results page

Unit Name:	________________
Capability Area:	***Lessons Learned***
Capability Level Achieved:	***3 (on a scale of 1 to 5, with 5 being the highest)***

<u>Highlights:</u>

Usage

- **Ninety percent of the respondents use lessons learned.**
- **Among the four knowledge areas, lessons learned were considered the least important to the job.**
- **Individuals use lessons learned three to four times a week and spend a total of 30 to 60 minutes a week looking for lessons learned.**

Observations

- **Looking for lessons learned is part of work practices; lessons learned do provide insights that promote successful practices and avoiding mistakes.**
- **Although the electronic storage system for lessons learned seems to be adequate, it is deficient in terms of ease of use, documentation, accessibility, and search categories.**

Recommendations

- ✓ **Electronic storage and search systems for lessons learned need improvement.**
- ✓ **A systematic process for the capture and periodic review of existing lessons learned needs to be instituted.**

<u>Detailed Information:</u>

Component Analysis: Detailed analysis of each component of the lessons-learned area: capture, taxonomy, repository, and application and use

Descriptive Statistics: Detailed statistics regarding the response rate, mean, variance, maximum, minimum, and so forth for every question

Summary of open-ended qualitative comments made by respondents

of KM capability in each area. Figure 1 shows a sample page from the results of the lessons-learned knowledge area pertaining to one of the business units at Intel. "Usage" summarizes the usage and importance of the knowledge area to the unit. The observations are factual statements that convey to the business unit the highlights of the unit's capability in a particular area. The recommendations are prescriptions for action. The specificity of the recommendations allows a unit to start planning for KM initiatives. Additionally, "Detailed Information" contains the capability analysis of each component of the knowledge area (which, in the case of lessons learned, are capture, taxonomy, repository, and application and use), descriptive statistics, and a summary of respondents' qualitative comments.

As a consequence of the KMCA, one of the business units, SSG, has already started major efforts in most of the suggested directions. SSG has constituted five overlapping teams of knowledge workers to plan and design KM initiatives: one in each of the knowledge areas and one specifically to address organizational culture in the context of knowledge sharing. The long-term effect of these efforts needs to be seen.

FUTURE TRENDS: IMPACT ON BUSINESS PERFORMANCE

Ultimately, the proof of the pudding is in eating. Assessing KM capabilities is an interim step toward the ultimate goal of making a positive impact on business performance. The direct impact of KM initiatives on bottom-line performance metrics, such as profit, revenue, and market share, is difficult to establish. Nonetheless, efforts need to be made in choosing the appropriate metrics. In the case of semiautonomous business units, bottom-line metrics are not pertinent. In such cases, indicators more relevant to the business of the unit, such as productivity, quality (of the product or service), and responsiveness, may be chosen. Complicating the relationship between KM initiatives and business performance is the fact that the gestation period for reaping benefits is longer, unlike installations of new equipment or implementations of business process changes. Thus, investments in KM initiatives must be viewed longitudinally.

Of the three large business units that have participated in the KM capability assessment at Intel, one is a manufacturing unit (TMG), another is responsible for providing systems software embedded in chips (SSG), and the third is the corporate quality-assurance unit (CQN). The population surveyed within the manufacturing unit was the engineers and technicians responsible for maximizing the yield and quality of semiconductor wafers using the most sophisticated and expensive equipment in its category. By far, the most important goal of this group is keeping the machines up and running at the optimum levels. Given the nature of their responsibility, as a relatively short-term measure of performance, we devised a metric to measure the delay experienced in getting the right knowledge (expertise, lessons learned, knowledge documents, and data) to the right person whenever needed. A longer term metric of performance is the average down times and ultimately the yield of the particular factory.

In the case of the other two units, although there are no direct measures of white-collar productivity, the effects of knowledge sharing and reuse can be observed by way of time saved in isolating a problem, finding solutions, and completing projects. The effects of knowledge sharing may also result in better decisions in choosing vendors, arriving at more accurate lab test results, and so forth. Hence, in addition to the quantitative measures of time spent to get the knowledge, we used qualitative measures such as the adequacy of various knowledge sources in satisfactorily fulfilling the requirements of individual managers.

As one moves away from the direct impact of KM initiatives to improvements over the long term, confounding factors obfuscate the relationship between KM and business performance. The benefits of KM become harder to assert, and investments in KM initiatives become harder to justify.

CONCLUSION

Knowledge management is increasingly viewed as a way to improve firm performance and potentially to provide a competitive advantage. Successes have been documented in corporate initiatives (sometimes referred to as KM initiatives) by utilizing knowledge in the form of best practices that resides within the firm. The descriptions of success have been predominantly anecdotal. To allay the complexity of the concept of knowledge assets, we identified four distinct types of knowledge assets, each with its own mix of tacit-explicit content, method of transfer, and life cycle. Through our case study, we demonstrated that it is not only possible to obtain a realistic assessment of KM capabilities of an organization in each knowledge area, but that the assessment offers specific directions for improving such capabilities. We found that the business units that we analyzed had differing knowledge-area emphases and capabilities based on the business unit's function and objectives. These results have several implications going forward for both business practice and research.

From a business perspective, our study demonstrates that the assessment of KM capabilities can be prescribed as a key component of an organization's KM program. Since organizations possess and require varied capabilities in different areas of knowledge, a capability assessment (such as the KMCA) should occur as one of the first steps toward improvement. Additionally, an organization should conduct a macrolevel review of its business goals and the knowledge needs of its processes to most effectively achieve those goals. Once a review of these goals and knowledge needs is completed, an assessment of the capability areas will provide an alignment analysis of the fit with the stated business objectives. Initiatives can then be designed to target those knowledge capabilities that are deemed important but deficient within the organization. Such goal-directed targeting of specific capabilities via well-designed initiatives, coupled with the tracking of business performance metrics, would greatly enhance the effectiveness of a KM program. The ability to correctly measure knowledge capabilities and prescribe improvements thus provides an initial step to capitalize fully on the management of knowledge.

For successfully contributing to research in the area of KM capability assessment, two items need to be kept in focus: the choice of success metrics and the longitudinal nature of this research. The business performance metrics chosen must be measurable and should be an acceptable measure of success of KM initiatives; they are critical in establishing relationships between KM capabilities and business performance. Since the return on investments in KM initiatives of any kind—systems, processes, or cultural aspects—usually occurs over an extended period, an organization participating in such a scientific study has to recognize the long-term nature of its commitment. A standardized instrument that can measure various KM capabilities consistently over long periods becomes an essential component of the undertaking.

INTRODUCTION

The goal of educational methods is to allow the pupil the acquisition of knowledge. Even so, the way in which this aim is pursued originates four different currents of methods sorted by two criteria: (1) who leads the educational process and (2) requirement of pupil physical attendance. Regarding the former criterion, the process may be conducted either by the teacher—Teaching-Oriented Process—or by the pupil—Learning-Oriented Process. Obviously, both processes have the same aim: the interiorization and comprehension of knowledge by the pupil. But the difference between them is based on the distinctive procedure followed in each case to achieve the common goal. Regarding the second criterion, the methods may or may not require pupil attendance.

Bearing in mind this classification, four different types of educational methods could be described:

1. Teaching Method: This includes the already known classic educational methods, the Conductivity Theory (Good & Brophy, 1990) being the foremost one. This method is characterized by the fact that the teacher has the heavier role during education—the transmission of knowledge.
2. E-Teaching Method: This second type comes from the expansion and popularity of communication networks, especially the Internet. This method brings the teacher to the physical location of the pupil; one of its most important representative elements is the videoconference.
3. Learning Method: This constitutes a new vision of the educational process, since the teacher acts as a guide and reinforcement for the pupil. The educational process has the heavier role in this method. In other words, the teacher creates a need for learning and afterwards provides the pupil with the necessary means in order to fill these created requests. Piaget Constructionist Theory is one of the most remarkable methods for this (Piaget, 1972, 1998).
4. E-Learning Method: This method is supported both by learning methods and by the expansion of communication networks in order to facilitate access to education with no physical or temporal dependence from pupil or teacher. As in learning methods, the pupil, not the teacher, is the one who sets the learning rhythm.

Each of these types of educational methods may be suitable for a given context, the e-learning systems being the preferred ones in the following circumstances:

1. When looking for a no-attendance-required educational method.
2. When the pupil, not the teacher, wants to set the educational rhythm. This choice might be based on several reasons, ranging from the need of adaptation to the availability of a pupil (i.e., to achieve temporal independence), to the consideration of learning as a more accurate approach than teaching, bearing in mind a particular application context (Pedreira, 2003).
3. When the knowledge to be transmitted is to be accessible to a high number of pupils. In teaching methods, the teacher is the one who transmits knowledge and supervises the pupils; therefore, the quality of the education is influenced by the number of pupils. Nevertheless, in e-learning the core of the educational process is the relationship between pupil and didactical material, with the teacher acting as a consultant. In this way, a teacher could pay attention to a higher number of pupils without causing any damage to the quality of the education.

This article is focused both on the study of e-learning systems and on the application procedure for this new discipline. The Background section is a brief discussion regarding currently used e-learning systems and their points of view. The Main Focus of the Article section suggests a new focus for this type of system in an attempt to solve some shortages detected in already existing systems. The Future Trends section introduces some guidelines that may conduct the evolution of this discipline in the future. Finally, the Conclusion section presents the conclusion obtained.

BACKGROUND

Nowadays, there are numerous applications that are self-named as e-learning tools or systems. Table 1 shows the results of the study regarding main identified applications such as Moodle (http://moodle.org), Ilias (http://www.ilias.uni-koeln.de/ios/index-e.html), ATutor (http://www.atutor.ca/atutor), WebCT (http://www.webct.com), BlackBoard (http://www. blackboard.net),

Table 1. Functional summary of main e-learning applications

	Moodle	Ilias	ATutor	WebCT	BlackBoard	QSTutor
Course Manager	√	√	√	√	√	√
Content Manager	√	√	√	√	√	√
Complementary readings	√			√	√	
FAQ's				√	√	√
Notebook	√	√	√		√	
Search		√	√			
Chat	√	√	√	√	√	√
Videoconference						√
Forum	√	√	√	√	√	√
E-mail		√	√			√

and QSTutor (http://www. qsmedia.es). Each of these applications has been analyzed from the point of view of the functionality to which it gives support. As can be noticed in the table, these applications are based mainly on document management and provide a wide range of communication possibilities (especially forum and chat) and agendas.

Nevertheless, and despite the increasing appearance of e-learning applications, the point of view of this discipline currently is being discussed. This is due to the fact that, despite the important conceptual differences that e-learning has with classical teaching methods, the developers of that type of application usually operate with the same frame of mind as with classical methods; that is, an editorial mindset. In other words, it is common to find the situation in which an e-learning application merely is reduced to a simple digitalization and distribution of the same contents used in classical teaching (Martínez, 2003). In this scenario, pupils read content pages that have been structured in an analogous way to student books or traditional class notes, using multimedia applications with self-evaluating exercises in order to verify the assimilation of what previously has been read.

The systems developed in this way, and which should not be considered as e-learning but as e-reading (Martínez, 2002), are inappropriate, since technology must not be seen as a purpose in itself but as a means that eases the access to education. Then again, the docent material that has been elaborated as described needs attendance to an explanative lesson; therefore, it is not enough for pupils to auto-regulate their apprenticeship. All that has been said should induce a change in the existing orientation of this discipline, paying more attention instead to the elaboration and structuration of docent material.

MAIN FOCUS OF THE ARTICLE

In this situation, the present work intends to palliate the shortages previously identified by means of the definition of the basic structure; that is, any docent material should have to accurately achieve the goal of any e-learning application—the appropriate transmission of knowledge. In order to obtain this structure, the selected route has been the knowledge management (KM) discipline; one of its main purposes is the determination of knowledge representation intended for easier assimilation.

The following subsections detail not only the proposed structure for development of an e-learning application but also the defined ontology that should be used to structure one of its key aspects: the knowledge base.

Proposed Structure for E-Learning Systems

Three key elements may be identified at any educational process: pupil, teacher, and contents/docent material. E-learning is not an exception to this, therefore, any system that may give support to this discipline should be structured with the same triangular basis (Friss, 2003) by means of the definition of modules regarding the three described factors. All these modules should be supported by a communication module.

Pupil Information Module

This module provides pupils and teacher with information regarding the former. More specifically, this information should include for every pupil not only his or her personal information (especially contact data) together with an academic and/or professional profile, but also more dynamic aspects such as current courses and levels achieved, along with the evolution related to what was expected and a reflection of problems that might have been aroused.

Teacher Information Module

This module makes teacher information available for pupils. In this way, a given pupil should know not only how to contact a specific teacher but also the topics in which this teacher could help him or her.

Contents Module

The different resources available for pupils in order to acquire, consolidate, or increase their knowledge are contained in this module. The organization proposed for this module is based on the three basic pillars of KM discipline for the structure setting of the knowledge to be transmitted: knowledge base, lessons learned, and yellow pages (Andrade et al., 2003). These pillars, after subtle adaptations, are perfectly valid for the organization of this module:

1. The submodule named as knowledge base constitutes the central nucleus, not only of this module but also of e-learning, since it is the container for each course-specific content. Given its importance, this aspect will be approached later on.
2. The lessons learned (Van Heijst, Van der Spek & Kruizinga, 1997) submodule contains the experiences of both pupils and teacher regarding knowledge base. It is important to point out not only the positive experiences, like hints for a better solution, but also the negative ones, such as frequent mistakes during the application of knowledge.
3. The yellow pages (Davenport & Prusak, 2000) help the pupil to identify the most suitable teacher in order to solve a particular question as well as to distinguish the appropriate resources (books, class notes, etc.) for digging out a specific topic.

Communication Module

This module, as shown in Figure 1, gives support to the previous ones. Its main task is giving users access to the e-learning system. By this means, teachers and pupils have access not only to the previous modules but also to communication and collaboration among the different system users. It

Figure 1. Structure of e-learning systems

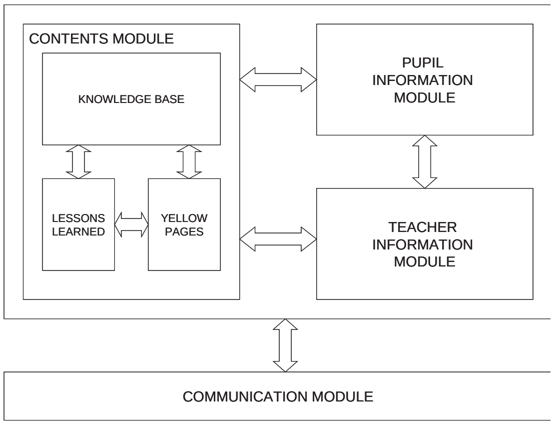

Figure 2. Ontology for the development and implementation of a knowledge base

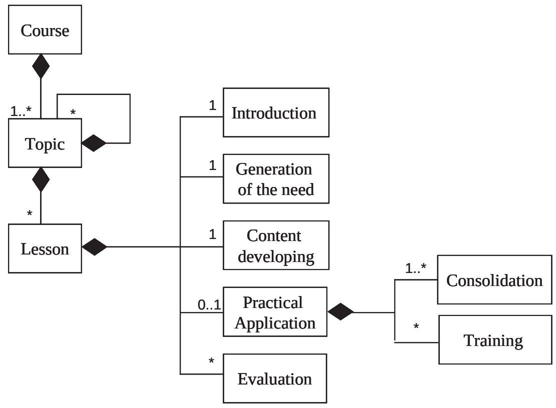

is important to point out that this communication should not be limited to that between a pupil and a teacher, but in some domains, it also could be interesting to allow pupils and even teachers to intercommunicate.

Ontology for the Definition of Knowledge Base

As previously mentioned, the knowledge base acts like a storage space and a source of specific contents for the pupils to obtain the desired knowledge. The type of organization of these contents should allow significant learning in which pupils should be able to assimilate, conceptualize, and apply the acquired knowledge to new environments (Ausubel, David, Novak, & Hanesian, 1978; Michael, 2001).

In order to achieve this type of structure, the first step is the partition of the course into topics and subtopics for the identification of the specific lessons. This division will generate a subject tree that represents a useful tool for the pupil, so that he or she may understand the global structure of the course.

The following step should be the description of those lessons that have been identified. To achieve this, it is proposed that every lesson should be preceded by a brief introduction. Having done this, it is suggested to generate a genuine need of learning into the pupil, aiming for an increased receptiveness of the contents. Once the lesson has been displayed, the pupil should be guided with regard to the practical application of previously acquired theoretical knowledge. As a final stage, a verification of the evolution might be performed by means of an evaluation of the acquired knowledge.

Figure 2 shows the proposed ontology for definition and implementation of the knowledge base, supported by these components. As can be noticed, on some occasions, one or more components might not be applicable for a specific lesson. The necessary distinction of the relevant aspects for each case should be performed by the teacher. These components are detailed next.

Introduction of the Lesson

The aim of this component is to show the pupil a global vision of the lesson that is going to start. To achieve this, not only the purposes of its performance should be outlined clearly, but also the contents have to be described briefly. In addition, it should be made noticeable that lessons are codependent regarding themselves and/or the rest of the basic knowledge. It is also important to specify clearly what the basic knowledge requirements are for a successful approach.

Generation of the Need

The motivation of the pupil constitutes a key aspect of learning. A good strategy for achieving this is to stimulate the pupil's understanding of the usefulness of the knowledge that he or she is going to acquire (Wilkerson & Gijselaers, 1996). This purpose might be accomplished by generating need exercises, which consisting of a problem proposal whose method of solving is not known by the learner.

Content Developing

This is the component where the knowledge included in the lesson is maintained and transmitted. That knowledge may be dynamic or static, both constituting the so-called functional taxonomy of knowledge, which more specifically makes a distinction between them (Andrade et al., 2004a):

1. Dynamic Knowledge: Knowledge related to the behavior that exists in the domain; that is, functionality, action, processes, and control.
   This level can be divided into two sublevels:
   a. Strategic: Specifies what to do and where as well as when, in what order, and why to do it. This knowledge handles the functional decomposition of each operation in its constituent steps as well as the order in which they have to be undertaken.
   b. Tactical: Specifies how to do the tasks and under what circumstances they have to be done. This type of knowledge is associated with the execution process for each strategic step of the latest level.
2. Static Knowledge: Conforms the structural or declarative domain knowledge and specifies the elements—concepts, relations, and properties—that are handled when carrying out the tasks (i.e., handled by tactical knowledge) and the elements that are the basis for the decisions (i.e., implied in the decisions of strategic knowledge).

Therefore, a lesson should give support to the types of knowledge that have been identified. With this intention and given the different characteristics of each of them, they should be described on the basis of different parameters. In this way, Table 2 shows in schematic fashion those aspects that should be kept in mind when describing a knowledge asset, depending on the type of considered knowledge.

This taxonomy has been used by the authors not only for conceptualization and modeling of problems (Andrade et al., 2004b) but also for KM systems definition and implementation (Andrade et al., 2003). As a result, it has been concluded that the organization of knowledge, based on this taxonomy, facilitates its transmission, understanding, and assimilation. This statement is supported by the fact that functional taxonomy is consonant with human mindset, and therefore, it is sensitive to people (Andrade et al., 2004a).

Practical Application

Once the pupil has acquired the required knowledge assets, he or she should put them into practice for proper interiorization and assimilation. This task will be performed in two phases: consolidation and training.

The consolidation phase intends to reinforce theory by means of practice. With this aim, a group of examples will be made available for the pupil, who will be guided through his or her

Table 2. Aspects to be considered when describing a type of knowledge

Level	Characteristics to consider	
Strategic	Functional decomposition of each operation in its constituent sub-steps. Execution order for the identified steps for operation fulfilling. Pre-conditions and post-conditions for the execution of every identified step. Entries and exits of each identified step. Responsible for each step.	
Tactical	Operation mode—algorithm, mathematical expression or inference—of each identified step. Limitative aspects in its application. Elements—concepts, relations and properties—which it handles and produces.	
Declarative	Concepts	Relevant properties. Relations in which it participates.
	Relations	Properties, concepts and, or, relations participating in the relation. Limitative aspects in its application.
	Properties	Type of value. Possible values which it can take. Source which provides its value/s. Limitative aspects in its application.

resolution by means of the rationalization of every decision made.

During the training phase, the aim is for the pupil to apply the resolution method straightforward by the use of a group of exercises increasingly complex.

It should be highlighted that when exercises are more similar to real circumstances, the results obtained will be enhanced; consequently, exercises and examples should be as realistic as possible.

Evaluation

The evaluation of the acquired knowledge will provide useful information for both pupils and teachers who would be able to verify a pupil's evolution regarding what was expected and whether pre-established levels have been accomplished or not. Likewise, the evolution would allow the detection of any learning problem in order to handle it appropriately.

FUTURE TRENDS

As previously mentioned in this article, e-learning discipline has been shown as an inappropriate approach; it is the mere digitalization and publication of the same docent material commonly used at attendance lessons, making technology not a tool but a goal in itself. The perception of this situation should induce a change when dealing with the development of e-learning systems in terms of fitting the definition and structuration of the docent material to the needs that human beings might present. In other words, as human computer interaction (HCI) emphasizes, human beings should not be servants of but served by technology.

Shown here is a first attempt toward the attainment of this objective. A lot of work remains to be done; therefore, it is predicted that future investigations will be focused on a more exhaustive definition regarding the way in which docent material should be elaborated in order to be more easily assimilated by pupils.

CONCLUSION

The present work has catalogued the different existing educational methods that attend both to who may lead the process and to whether physical attendance of the pupil is required or not. This classification has allowed, for every method and especially for e-learning, the identification of their inherent particulars.

Nonetheless, most of the so-called e-learning systems do not properly support the intrinsic characteristics of these types of systems, since they merely provide an electronic format for the docent material of classical teaching.

KM techniques have been used with the aim of providing an answer to this situation. This discipline tries to find the optimal strategies for the representation and transmission of knowledge so that its latter comprehension might be facilitated. Following this, a basic structure for e-learning systems was defined using modules and submodules. Similarly, after the identification of the knowledge base as one of the key aspects of the mentioned structure, a specific ontology was described for its definition and implementation.

Finally, it should be mentioned that the attainment of auto-content and auto-explanative docent material for an easier acquisition of knowledge could be achieved by the use of the defined ontology.

ACKNOWLEDGMENT

We would like to thank the Dirección Xeral de Investigación e Desenvolvemento da Xunta de Galicia (Autonomous Government of Galicia), for funding project PGIDIT03PXIA10501PR.

Knowledge Management as a Reference Theory for E-Learning:
A Conceptual and Technological Perspective

ABSTRACT

E-learning as a scientific field is in an era of transition. In the last decade, several scientific fields worked as reference disciplines for the promotion of the value delivery that new technologies offered to learning. In this paper, we will emphasize the role of knowledge management as a reference theory for e-learning.

INTRODUCTION

E-learning provides an extremely challenging research context. The facilitation of learning through technology requires a multifold consideration of issues that fall into the categories of cognition, behavior, beliefs, attitudes, and social constructions such as networks, communities, group formations, recommendations, and utilization of human capital.

Knowledge management, on the other hand, poses a critical question to researchers: How do we justify abstractions that provide a systematic way for the management of knowledge? Extremely interesting literature covers a wide range of issues that relate to knowledge management processes and knowledge category models, as well as to knowledge networks and communities. From another point of view, the discussion of knowledge management strategies is based on a five-layer approach: Artifact, Individual, Group, Organization, and Interorganizational Network are recognized as critical locations where knowledge can be identified and utilized.

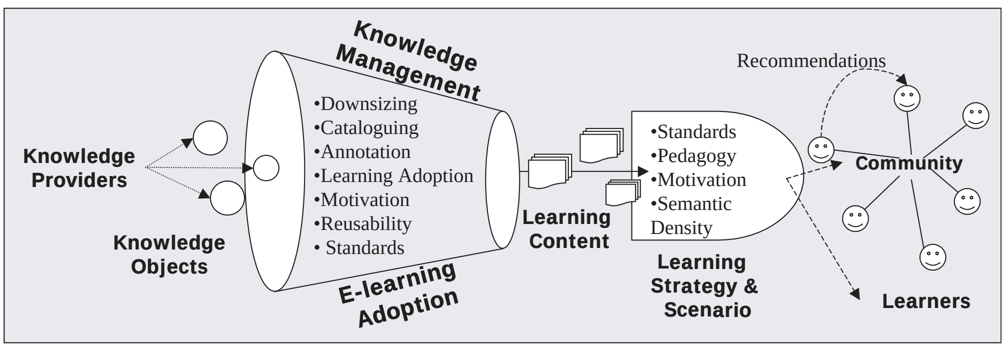
This paper summarizes the importance of knowledge management for e-learning. In the past, researchers have tried to investigate the role of knowledge management for e-learning. The convergence of these approaches is visualized in Figure 1.

In Figure 1, knowledge management is presented as a critical diode, where a plethora of knowledge objects have to be managed and adopted in order to fulfill the requirements for learning utilization. The issue of learning utilization is not a linear function nor even guided from a well-defined cause-and-effect formula, where learning outcome is directly related to independent variables. Knowledge management can be utilized in many different ways in the context of e-learning. A first point of argument is the direct linkage of knowledge to learning content and, thus, the need to justify the ways that diverse knowledge objects are used in an e-learning system in order to provide learning material. The downsizing of knowledge in reusable parts, the annotation of relevant knowledge objects, and the establishment of effective management mechanisms require the promotion of standards as well as the specification of a clear learning strategy. These issues are critical milestones for knowledge management and e-learning convergence.

In this article, two general pillars from the knowledge management literature are discussed further:

- The knowledge artifact approach, where knowledge management's main emphasis is on the epistemology of knowledge and the specification of relevant types of knowledge. As depicted in Figure 2, there is a direct linkage of knowledge types to learning content types. The debate on tacit and explicit knowledge provides an epistemological background for the analysis of their implications in an e-learning environment: In the past years, the e-learning community seems to have been dominated by the learning objects research stream, where the relevant research agenda includes semantic annotation, embodiment of instructional design, and guidance on the transformation of learning content to the learning object metaphor.
- The knowledge process approach, where several value-adding processes summarize significant transformation mechanisms and a life cycle that brings together providers and users of knowledge.

Figure 1. Investigating knowledge management role in e-learning

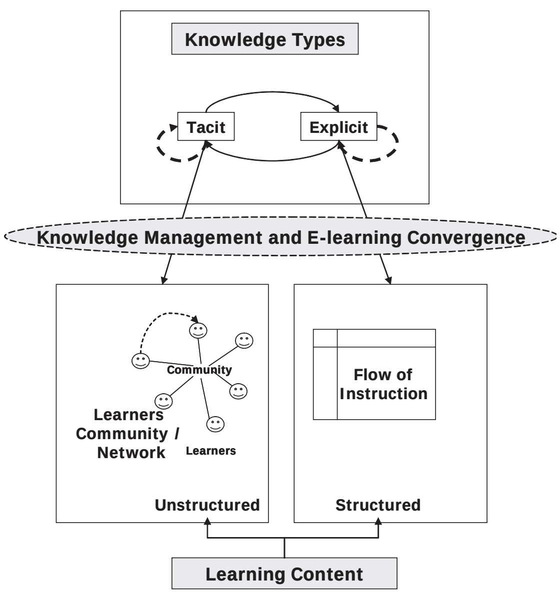


A number of complementary approaches to knowledge category models promote an interesting discussion for types of learning content that can be identified and managed in an e-learning setting. The evolution of databases, multimedia technologies, human computer interactivity, adaptive hypermedia, mobile and wireless technologies, and the advent of the Semantic Web have moved the emphasis from the traditional artifact approaches to a process approach to the utilization of unstructured content.

Figure 2 summarizes the underlying linkage between knowledge types and learning content. Knowledge management literature utilizes further the epistemology of knowledge and promotes a number of knowledge category models.

The knowledge management research community has promoted an interesting discussion on the role of ontological engineering toward the development of adaptive, flexible, and dynamic systems. Miguel-Ángel Sicilia and Elena García from the University of Alcala, Spain, provide an excellent discussion on the convergence of formal ontologies and standardized e-learning. Current efforts to standardize e-learning resources are centered on the notion of a learning object as a piece of content that can be reused in diverse educational contexts. The embodiment of instructional design to learning objects poses new challenges for the standardization process: In e-learning, the key issue is neither the interoperability nor the reusability of content, but rather the support of learning as a cognitive and constructive process. For the development of this critical milestone, knowledge management and ontologies provide several alternative options and new reference models for the representation and diffusion of content. Value delivery through annotation and semantics will be forthcoming as an excellent research context for e-learning.

Figure 2. A rich picture



The other critical point of view for the convergence of knowledge management and e-learning refers directly to the community of learners that promote the social character of e-learning. This community is anticipated to have a great potential of unutilized knowledge, which basically is considered to be unstructured. The next paper summarizes a quite promising work: Sheizaf Rafaeli and Yuval Dan-Gur from the University of Haifa, Mt. Carmel, Israel, and Miri Barak from the Massachusetts Institute of Technology, discuss the importance of the social recommendation systems on e-learning. In such systems, users can receive guidance in locating and ranking references, knowledge bits, test items, and so forth. In these systems, users' ratings can be applied to items, users, other users' ratings, and, if allowed, raters of raters of items recursively. This is an interesting issue concerning the flow of instruction. The traditional author-led design and implementation of online learning experiences require a greater openness and utilization of contributions directly derived from learners (with some prerequisites).

In the same context, agent-based e-learning systems will realize sophisticated and integrated approaches to dynamic learning content assembly.

H.K. Yau, E.W.T. Ngai, and T.C.E. Cheng from Hong Kong Polytechnic University, Hong Kong, PR China, provide an interesting conceptual model and an architecture for an agent-based and knowledge-management-enabled e-learning system.

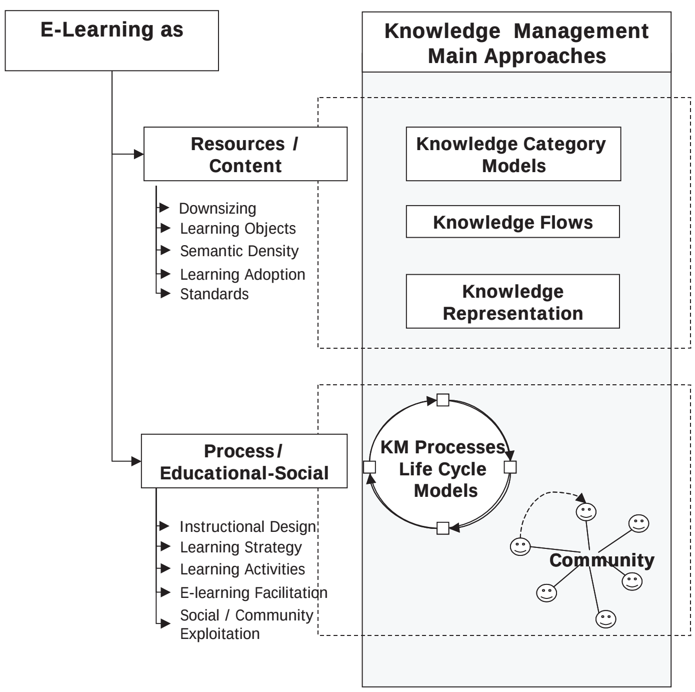
DISCUSSION OF KEY PROPOSITIONS AND THE CONTRIBUTION OF THIS PAPER

The initial idea for a special issue on the role of knowledge management for E-learning was derived from the extraordinary interest of many researchers all around the world to investigate conceptual frameworks and technologies from the knowledge management field toward the promotion of more effective, dynamic, and personalized e-learning.

The decision of JDET editors to approve our idea for this paper was a critical milestone, and several alternative strategies were considered in order to promote a high-quality issue with balanced contributions. With an acceptance rate of 15%, we decided finally to accept three areas that cover a wide range of knowledge management aspects and pose significant research questions for the future. Moreover, we decided to follow a strategy in which selected topics as a whole volume could promote a balanced theoretical and practical overview with a significant contribution for the emerging, knowledge-management-enabled research agenda in e-learning.

In this section, we will try to outline the contribution of this special issue. From the beginning, we have said that in each section of the issue, there are several significant "hidden" aspects that could initiate a PhD research.

Figure 3. Aspects of e-learning and knowledge management convergence



In Figure 3, the e-learning and knowledge management convergence is linked to five general pillars of literature:

- Knowledge Category Models
- Knowledge Flows
- Knowledge Representation
- Knowledge Management Processes and Life Cycle Models
- Communities and Social Capital

In this issue, Sicilia and Garcia discuss from an interesting point of view the convergence of formal ontologies and standardized e-learning. In fact, they extend the debate on learning objects' metadata and provide to the reader an excellent and intensive presentation of organizational and technical issues that have to be addressed. According to their concluding remark, "the use of modern Web-enabled ontology languages has been sketched, and an illustration of the benefits of the integration of learning object descriptions has been provided through OpenCyc examples. More comprehensive learning object specifications, including the description of learning process, should be addressed in the future."

From this point of view, the annotation of the learning objects has to promote further the dynamic features of modern e-learning systems as well as their value proposition. In fact, this criticism brings forward the need to define learning objects.

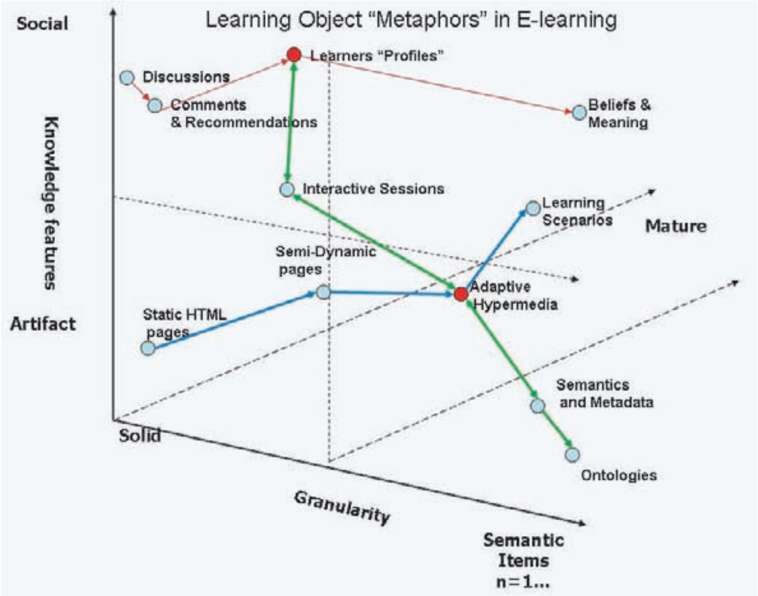
The literature on learning objects is extremely substantial (McGreal, 2004). The limited length of this paper does not allow us to present it in detail. Instead, we will summarize the basic properties of a learning object. In other words, we have selected some typical characteristics for learning objects found either in the literature or in practical implementations of e-learning systems. In Figure 4, a three-dimensional space provides the setting for our constructive point of view. Several items directly related to learning objects have been summarized, and three paths (from several others already mapped in our research) have been indicated.

The basic idea is that three critical perceptions provide significant considerations for value adding features of learning objects:

- Knowledge Features: Ranges from artifact to social (an analogy of explicit to tacit); the great challenge is to investigate new ways for utilizing meaning, belief, and community.
- Granularity: Refers to the modular nature of learning objects. This dimension ranges from solid, in which case only a component realizes the LO, to Semantic Items, where a significant number of semantic items provide new meaningful insights to learning objects (e.g., context, learning processes, target groups, etc.).
- Maturity: This dimension is a critical but rather blurred dimension. Maturity is perceived as a continuous process where the usage of innovative technologies provides new possibilities for adaptive and personalized e-learning environments. This aspect will not be discussed in detail in this paper but provides input for the process of designing new generations of learning objects.

In Figure 4 we have specified a number of heterogeneous metaphors for learning objects that depict the quite different approaches in LO design: static HTML pages, comments and recommendations, learners' profiles, interactive sessions, adaptive hypermedia, learning scenarios, ontologies, semantic, and metadata provide an overall idea. From this point of view, it is extremely interesting as outlined in the work of Rafaeli, Dan-Gur, and Barak, to investigate new methods for incorporating tacit knowledge elements in learning objects. The annotation of LOs should not be considered as a technical issue but purely as a cognitive process with direct linkage to the learning outcome. According to Rafaeli, Dan-Gur, and Barak, the convergence

Figure 4. Outlining learning object metaphors in e-learning



of recommenders in e-learning requires learners to employ critical judgment, first when they rank various knowledge items, and then when they choose the source of recommendation. The sharing of their judgments and information in a way that encourages collaboration and trust can increase the delivered value of an e-learning system and also has the potential to enhance critical thinking and promote the growth of tactic knowledge among its users. By implementing various recommendation approaches, learners engage in critical reading and learn to choose the most sought and required knowledge items. Moreover, participating in the community of learners might designate the intuitions that are gained through experience and enhance the sense of competency acquired by participating in communities of practice.

The work of Sicilia and Garcia as well as the interesting proposition of Rafaeli, Dan-Gur, and Barak justify the need to modify our mental model of learning objects in order to meet pedagogical as well as social and learning challenges. In this context, we will use the term Semantic Learning Cube in order to summarize this new paradigm for learning content.

Learning Cubes are an alternative proposition for learning objects representation and utilization. In fact, they can be defined in a simple way: Learning Objects (LOs) with well defined meaning and scalable embedded pedagogical value that can be adjusted to social characteristics of learners promoting a mature learning experience in highly adaptive e-learning environments.

From their definition, Learning Cubes require significant work in several issues and themes which can be undertaken in the near future from several researches whose origins are in various disciplines: Artificial Intelligence, Semantic Web, Knowledge Management, E-business, and so forth.

Concerning well-defined meaning, ontologies and the Semantic Web set specific challenges to the Semantic Learning Cube paradigm. In our perspective, ontology of Learning Cubes provides answers to three critical questions:

1. How do we codify scalable pedagogical value in LOs?
2. How do we incorporate social or tacit knowledge features with LOs?
3. How do we outline the paths for mature learning experiences through constructive learning tasks?

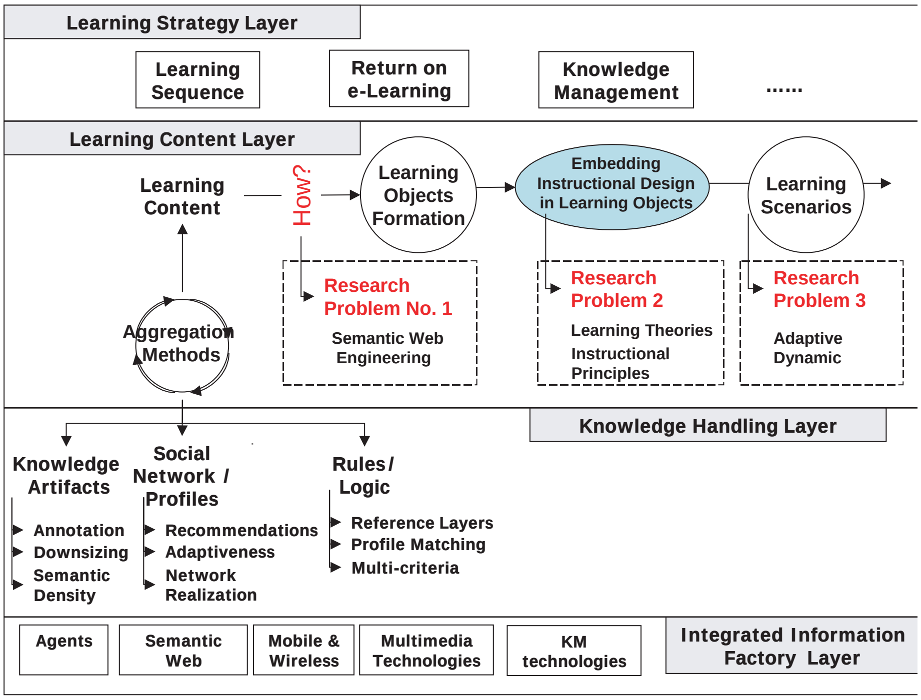
Scalable embedded pedagogical value relates to semantic annotation of content that promotes the learning context realization in terms of learning processes. The benefits from such a practice have been pointed out in extensive literature. Associating meaning to content through semantic markup will facilitate search, interoperability, and the composition of complex information through an interoperable meaning (Fiensel et al., 2000). According to Lytras et al. (2002a), e-learning cannot be evaluated as value-adding without promoting unique learning experiences. Semantic Learning Cubes go a step further in this approach by developing a Semantic-Web-enabled tool for the composition of Learning Cubes and relevant services (marketplaces of Learning Cubes, Dynamic Learning Cubes Composition).

Towards this direction, the work of Yau, Ngai and Cheng is extremely important. The design and implementation of intelligent agents is critical for the promotion of e-learning. In order to be successful, intelligent infrastructures supporting unique learning experiences and fulfilling a motivating learning context will have to be based on well chosen theoretical abstractions. Multiagent Societies will provide an extremely interesting research area within the near future. The mobility of agents is also an exciting area for further research. Mobile agents that travel from one machine to another (e.g., from a desktop to a palm pilot) will promote the vision of ubiquitous learning.

In order to summarize this paper, we have tried to develop a "rich misture" of research problems that are linked directly to the convergence of knowledge management and e-learning. In Figure 5, a four-level approach to e-learning strategy is provided. Four levels provide a concrete strategy targeting the utilization of different knowledge items for learning purposes:

- Integrated Information Factory Layer: Refers to a number of diverse technologies like Agents, Semantic Web, Mobile and Wireless Networks, Knowledge Management Technologies, and so forth, that have established a holistic approach for the management of information resources.
- Knowledge Handling Layer: This layer addresses the key demand for managing knowledge in codified formats and social flows. Thus, knowledge artifacts, Social Network, Profiles Management, Specifications of Rules, and logic are issues of critical significance for the performance of knowledge resident in an Information Factory.
- Learning Content Layer: In e-learning implementations, this layer is of critical importance. Several dynamic aggregation methods provide the convergence of knowledge handling and learning content layer. Diverse knowledge items are utilized in a learning content item, and for this reason, we have to decide on the structural unit. In our LO Cube approach the Learning Objects formation is facilitated by the advent of Semantic Web Engineering. This is depicted as the first critical aspect of the research problem: The specification of SW-enabled content formation according to clear descriptive logic. Ontologies and other approaches play a key role in this direction. In our approach, a new ontology titled Learning Process (Figure 5) is the key contribution toward this direction. The second critical aspect of the research problem is the Embedding of Instructional Design Principles in Learning Objects. This ultimate objective requires an extensive transformation of guiding learning theories to principles and guidance for

Figure 5. A learning process to LO formation



LO construction. In the next step, learning context (Figure 5) is anticipated as the third pillar of our research problem.

- Learning Strategy Layer: The fourth layer guides the whole process. Learning strategy has to be crafted, and several decisions have to be made. In Figure 2, we did not provide an exhaustive list of relevant themes, but in our whole approach, there is a concrete discussion of the whole strategy agenda.

Over the next years, we will face an extraordinary interest in research in e-learning and KM. According to Prof. Michael Spector:

Technology changes. Technology changes what people do and can do. Technology is changing how people learn and work. Embracing innovation and changes is characteristically human. Technology-based changes are pervasive, which means that researchers interested in the impact of technology on learning and working are living in the best of times. How fortunate. (Spector in Lytras, 2002, Knowledge and Learning Management, Papasotiriou Publications)

In this direction, we encourage researchers to continue and to strengthen their interest in the convergence of Knowledge Management and E-Learning. In a visioning section at the end of the paper titled, "A Knowledge Management Roadmap for E-Learning: The Way Ahead," we discuss in more detail the future of this convergence.

ACKNOWLEDGMENTS

For their various forms of support in our effforts of compiling this special issue, we would like to express our gratitude to our colleagues in our respective research units: Elpida Prasopoulou, Xenia Ziouvelou, Olga Chaidou, Korina Diamanti, Ilias Kastritis, Irini Kaliamvakou, Lina Ioannou,Ioannis Sideris, Maria Tsaousoglou, Nikos Tsipouras, Panagiotis Ziotopoulos, Achilleas Anagnostopoulos, Nikos Labropoulos and Sotiris Michalakos from the ELTRUN Research Unit (http://www.eltrun.gr) of the Athens University of Economics and Business in Greece, and Mikael Nilsson, Matthias Palmér, Fredrik Paulsson, Claus Knudsen, Henrik Eriksson, Pär Sjöberg, Richard Wessblad and Ioana Predonescu from the KMR group (http://kmr.nada.kth.se) at the Royal Institute of Technology (KTH) in Stockholm, Sweden.

We would also like to acknowledge a number of colleagues within our national and international networks of excellence for technology enhanced learning, people who share a common vision for the future role of advanced learning technologies and who have extraordinary abilities to collaborate:

Chapter 1.36
Beyond Knowledge Management:
Introducing Learning Management Systems

Audrey Grace
University College Cork, Ireland

Tom Butler
University College Cork, Ireland

EXECUTIVE SUMMARY

In the knowledge economy, a firm's intellectual capital represents the only sustainable source of competitive advantage; accordingly, the ability to learn, and to manage the learning process are key success factors for firms. The knowledge management approach to learning in organizations has achieved limited success, primarily because it has focused on knowledge as a resource rather than on learning as a people process. Many world-class organizations, such as Procter & Gamble, Cisco Systems and Deloitte Consulting, are now employing a new breed of systems known as Learning Management Systems (LMS) to foster and manage learning within their organizations1. This article reports on the deployment of an LMS by a major US multinational, CEM Corporation, and proposes a framework for understanding learning in organizations, which highlights the roles that LMS can play in today's knowledge-intensive organizations.

ORGANIZATIONAL BACKGROUND

CEM Corporation2 is a world leader in the design, development and manufacture of Internetworking storage IT infrastructures. The company's core competencies are in networked storage technologies, storage platforms, software, and, also, in services that enable organizations to better and more cost-effectively manage, protect and share information. CEM was founded in 1979 and launched its first product in 1981 — a 64-kilobyte integrated circuit memory board developed for the then popular Prime minicomputer platform. CEM's sales passed the $3 million mark in 1982 and reached $18.8 million two years later. In the mid-1980s, CEM launched a series of memory and storage products that improved performance and capacity for minicomputers made by IBM, Hewlett-Packard, Wang, and Digital Equipment Corporation. The company went public in April 1986; a year in which sales hit $66.6 million and a net income of $18.6 million was achieved.

In the late 1980s, CEM expanded strongly into the auxiliary storage arena, where it remarketed other suppliers' magnetic disk drive storage subsystems, often coupled with its own controller units. In 1987, the company introduced solid state disk (SSD) storage systems for the minicomputer market and its headquarters moved to Hopkinton, Massachusetts. In 1988, its stock was listed on the New York Stock Exchange and in 1989 CEM accelerated the transition from a supplier of memory enhancement products to a provider of mass storage solutions. In 1997, more than 70% of the company's engineers were dedicated to software development for mass storage technologies. Software sales rose from $20 million in 1995 to $445 million in 1998, making CEM the fastest growing major software company in the industry sector. In 2001, CEM was named as one of Fortune's 100 best companies to work for in America. In the same year, the company launched a major new global branding initiative. CEM Corporation's total consolidated revenue for 2002 was $5.44 billion.

SETTING THE STAGE

From its inception, CEM recognized the importance of learning within the organization: accordingly, it facilitated learning development and support for its employees, including: technical skills; business skills; IT skills; management skills; and individual personal development. Prior to 2000, learning development and support was facilitated through a number of training services, which included:

- A Corporate University, which provides training throughout CEM, including induction training for new staff, corporate guidelines, professional and project management guidelines, and computer skills.
- A Professional Global Services Training department, which supports field and sales staff at CEM.
- A Global Technical Training Department, whose main aim is to address the advancing technologies in the ever-evolving hardware, software products, and support applications and processes.
- Human Resources Training Centers, which support the soft skill training of managers, supervisors and individual employees.
- Technical Libraries and Personal Development Libraries.
- A Continuing Education Program, which provides financial support and study leave.

These diverse training services within CEM had, for some time, been successfully delivering training and learning support to a number of distinct areas within the corporation. However, by the year 2000, CEM recognized that it was facing a number of key challenges in relation to its organizational learning processes. These included the following:

- As a large multinational organization with a constantly growing global workforce of 20,000-plus employees, the overall management of the learning of all employees using multiple training organizations was becoming increasingly difficult. In particular, the management of course enrollments, training paths and individual competency levels posed a significant challenge.
- There was some duplication of effort across many of the training services and a distinct lack of consistency in how training was being developed and delivered. Specifically, there

was a lack of coherence in relation to how content was being created and administered. From the point of view of an employee, there was no overall catalogue of courses available that outlined the training or learning programs available from each of the training services.

- By 2000, the business environment in which CEM Corporation operated was rapidly evolving and becoming more intensely competitive: hence, learning and the management of learning began to play an increasingly critical role in the ongoing success of the organization. Within this context, CEM needed to replace the isolated and fragmented learning programs with a systematic means of assessing and raising competency and performance levels of all employees throughout the organization.
- In addition, CEM wished to establish itself as an employer of choice by offering its people extensive career planning and development opportunities.

In response to these challenges, CEM decided to implement an enterprise learning solution. The stated business drivers for deploying this enterprise learning solution were to:

- Decrease time-to-competency.
- Develop and manage skill sets for all employees.
- Leverage global, repeatable and predictable curriculum.
- Integrate competency assessments with development plans.
- Accelerate the transfer of knowledge to employees, partners, and customers.
- Provide a single learning interface for all internal and external users.

CEM went to the market looking for an off-the-shelf corporate-based learning management system (LMS) that could be used to formulate and manage learning across multiple functions within the organization, including: technical functions; business functions; IT professional functions; and management functions. The system would also need to facilitate the delivery and tracking of disparate training programs, including the tracking of individual personal development training. Having considered several LMS then available from different vendors, CEM Corporation chose Saba Learning Enterprise™ (see Appendix A for a brief overview of Saba Software Inc.). In February 2001, CEM deployed its enterprise learning solution, incorporating this new LMS to employees across the entire organization as well as to CEM customers and business partners.

Based on an exhaustive analysis of previous research in the area and an extensive case study of the deployment and use of Saba Learning Enterprise™ at CEM Corporation, this article proposes a framework that places LMS in context with other categories of IS said to underpin learning in organizations. The framework also highlights the roles that LMS can play in the support and management of learning within knowledge-intensive business enterprises. Thus, it is hoped that this framework will deepen the IS field's understanding of the contribution of LMS to learning within organizations.

Motivation for the Study

Significance of Learning in Organizations

The importance of facilitating and managing learning within organizations is well accepted. Zuboff (1988), for example, argues that learning, integration and communication are critical to leveraging employee knowledge; accordingly, she maintains that managers must switch from being drivers of people to being drivers of learning. Harvey and Denton (1999) identify several antecedents that help to explain the rise to prominence of organizational learning, viz.

- The shift in the relative importance of factors of production away from capital towards labor, particularly in the case of knowledge workers.
- The increasing pace of change in the business environment.
- Wide acceptance of knowledge as a prime source of competitive advantage.
- The greater demands being placed on all businesses by customers.
- Increasing dissatisfaction among managers and employees with the traditional "command control" management paradigm.
- The intensely competitive nature of global business.

Deficiencies in the Knowledge Management Approach

During the 1990s, there was a major shift in focus from organizational learning to knowledge management in both applied and theoretical contexts (Alvesson & Kärreman, 2001; Easterby-Smith, Crossan & Nicolini, 2000; Scarbrough & Swan, 2001). Knowledge management systems (KMS) sought to facilitate the sharing and integration of knowledge (Alavi & Leidner, 1999; Chait, 1999; Garavelli, Gorgoglione & Scozzi, 2002). However, these systems had limited success (Shultz & Boland, 2000), with reported failure rates of over 80% (Storey & Barnett, 2000). This was because many of them were, for the most part, used to support data and information processing, rather than knowledge management (Borghoff & Pareschi, 1999; Butler, 2003; Garavelli et al., 2002; Hendricks, 2001; Sutton, 2001) and also because many implementations neglected the social, cultural and motivational issues that were critical to their success (Huber, 2001; McDermott, 1999; Schultze & Boland, 2000). Indeed, some argue the knowledge management paradigm may be little more than the latest "fad" to be embraced by the IS field (Butler, 2000; Galliers & Newell, 2001; Swan, Scarborough & Preston, 1999), and its popularity may have been heightened by glossing over complex and intangible aspects of human behavior (Scarborough & Swan, 2001).

New Potential Offered by Learning Management Systems

It is perhaps time to admit that neither the learning organization concept, which is people oriented and focuses on learning as a process, nor the knowledge management concept, which focuses on knowledge as a resource, can stand alone. These concepts compliment each other, in that the learning process is of no value without an outcome, while knowledge is too intangible, dynamic and contextual to allow it to be managed as a tangible resource (Rowley, 2001). She emphasizes that successful knowledge management needs to couple a concern for systems with an awareness of how organizations learn. Researchers believe that what is needed is to better manage the flow of information through and around the "bottlenecks" of personal attention and learning capacity (Brennan, Funke & Andersen, 2001; Wagner, 2000) and to design systems where technology services and supports diverse learners and dissimilar learning contexts (McCombs, 2000). In response to these needs, learning management systems (LMS) evolved; accordingly, an increasing number of firms are using such technologies in order to adopt new approaches to learning within their organizations. This new learning management approach has been led primarily by practitioners and IT vendors; as it is a relatively new phenomenon, there is a dearth of empirical research in the area. Therefore, an important challenge for the IS field is to better understand LMS and to examine the role that these new systems play in organizations.

CASE DESCRIPTION

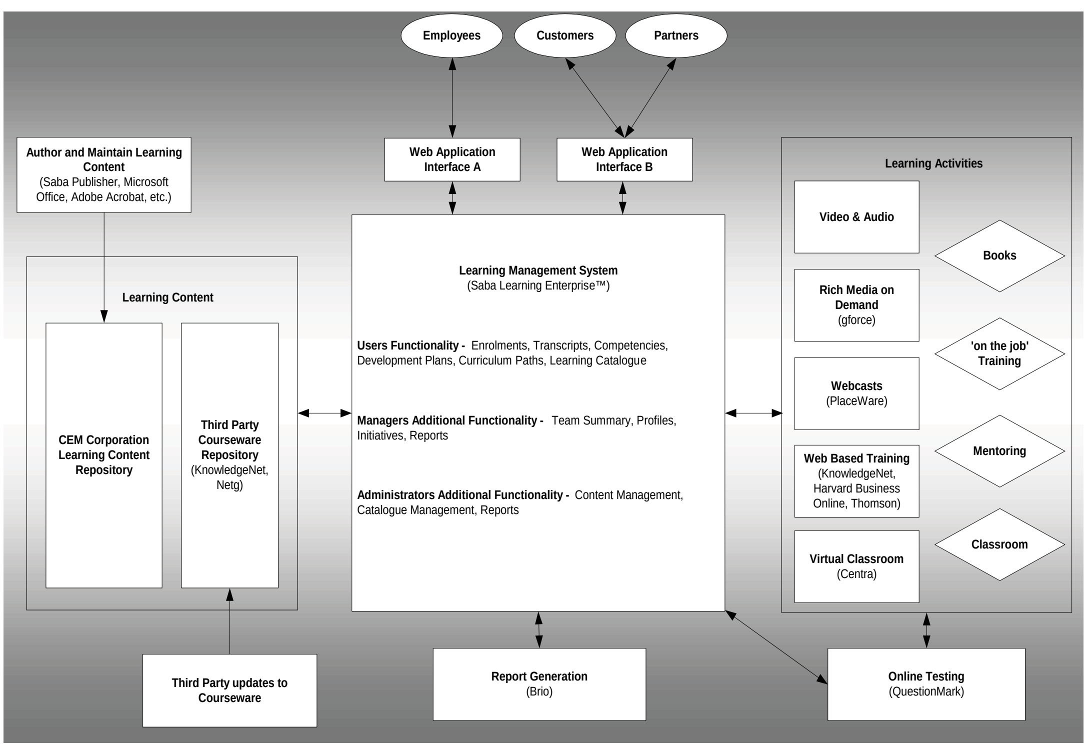
Conduct of the Study

This case study was conducted over a period of 11 months from October 2002 to August 2003. The LMS in use at CEM is a complex and multifaceted system; hence, it was necessary to first conduct several exploratory interviews with the subject matter expert. Five such site visits occurred over a six-month period and each meeting lasted between one and one and a half hours. This type of elite interviewing (Marshall & Rossman, 1989) is sometimes necessary to investigate little understood phenomena. In one of these sessions, a detailed demonstration of how the system operates was provided by this expert. A second demonstration of the system was subsequently obtained from a training manager within CEM Corporation. This provided the researchers with an understanding of the system's capabilities and an insight into how the system is used on a day-to-day basis. The human resources manager was also interviewed at this stage. Subsequently, the researcher carried out eight semi-structured interviews with key personnel, including an administrator of the system, a number of employees and managers who use the system, and several training specialists, one of whom had responsibility for knowledge management initiatives at CEM. Appendix B provides an outline of the interview guide used in the semi-structured interviews.

The Enterprise Learning Solution

The Enterprise Learning Solution implemented by CEM Corporation consists of several components, one of which is an LMS called Saba Learning Enterprise™ (Figure 1). Much of the learning material is created and maintained by CEM employees using a range of off-the-shelf products that includes Microsoft Office, Adobe

Figure 1. CEM Corporation – Enterprise learning solution components



Acrobat and Saba Publisher, while the systems learning content is stored in CEM's own on-site storage repository. In addition, courseware is created and maintained directly by third parties including KnowledgeNet and Netg, and is stored offsite in the storage repository of both third-party organizations.

Employees at CEM manage their own learning processes by accessing the LMS through the Internet. Using the Web, they can enrol in classroom courses; search for learning material; engage in online learning activities; and look at what development options are suitable for their role within the organization. Managers also use the system to administer the employee learning processes; for example, managers can examine the status of the learning activities of their employees; assign learning initiatives to their employees; and generate reports on learning activities. Administrators and training personnel use the system to supervise employee training; for example, they publish and manage learning content; manage a catalogue of courses; and create reports on learning activities. While much of the required reporting is provided by the LMS, administrators also use a third-party software application called Brio to generate more sophisticated reports.

The Saba Learning Enterprise™ LMS has the capability of managing and tracking offline activities (e.g., books, "on the job" training, mentoring, classroom training) and online activities (e.g., video and audio, Webcasts, Web-based training, virtual classroom training, and rich media). Learning content for online activities may be accessed and delivered through the Web application interface either from CEM's own learning content repository or from a third party's storage repository. Certain post-training testing is built into the learning content itself, but additional pre-training testing and post-training testing may be invoked, and this is provided by another third-party product called QuestionMark.

LMS: Toward a Better Understanding

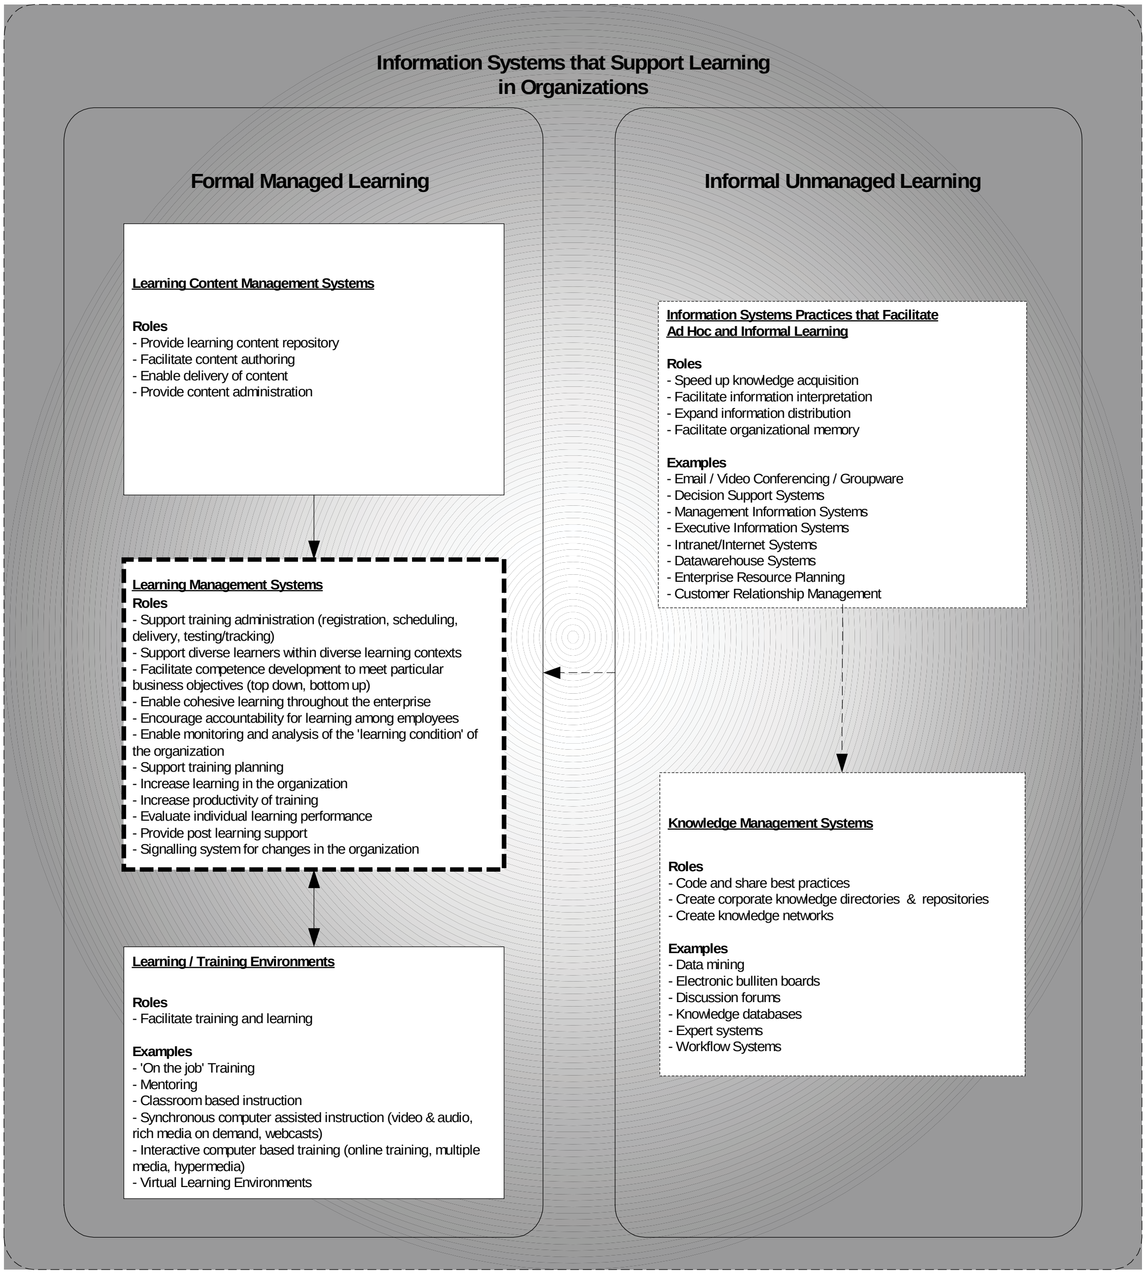
Figure 2 summarizes the case study findings. In this diagram, an empirically tested framework is presented that places LMS in context within a wider topology of the key categories of IS that underpin learning in organizations. Furthermore, the framework describes the principal attributes of each category of IS and highlights the roles that LMS can play in the support and management of learning within an organization. The categories of IS have been segregated into two groups: those that support formal managed learning within the organization, and those that support informal or unmanaged learning. The IS category of LMS is highlighted within the framework to emphasize that this new breed of system is central to the strategic "people oriented" approach to managing learning that is now emerging in many organizations.

LMS: In Context

On one hand, the findings illustrate that CEM found that their new LMS, learning content management systems (LCMS), and learning/training environments all contributed to the process of formal managed learning in the organization. On the other hand, it was clear that informal unmanaged learning within the organization was facilitated through IS that supported ad hoc learning in concert with the extant knowledge management system (KMS). The reason for this situation is that KMS, while supporting knowledge management in a formal way, only support informal learning, as learning is not facilitated in a structured way, nor is it measured or validated by the KMS.

In Figure 2, the arrows describe the links that exist from one IS category to another (i.e., LMS, LCMS, KMS, etc.), signifying the interrelationships between them. For example, the case study findings indicate that LMS are fed content directly by LCMS (as illustrated by the solid

Figure 2. Learning in organizations – Framework incorporating LMS



arrows lines). The LMS Manager elaborated on this: "a link is created in the LMS that contains the address where content is located, either on CEM's own storage repository or on the third party courseware repository." The findings also highlighted that LMS have a strong two-way relationship with learning/training environments, as training programs are often initiated from within the LMS and information on the outcome of this training is often captured directly by the

LMS. It was clear that LMS had only a tenuous link to other information systems that support ad hoc or informal learning (as illustrated by the broken arrowed lines). In describing this type of linkage, the LMS Manager pointed out that "the link from these systems consists primarily of a need which they generate for formal learning and training programs to be carried out." He added that "the content for this training will often stem from the IS itself and the type of environment used will, more than likely, be decided by the nature of the system in question." He indicated that KMS often store information on problems and solutions relating to other systems that support informal learning; hence, there is a tenuous link between these two categories of IS.

LMS: Key Roles

The framework shown in Figure 2 lists a number of key roles that LMS can play in supporting and managing learning. These roles indicate the dimensions, factors, or variables that future researchers should try to capture when evaluating the roles of LMS. One of the more significant roles listed is that LMS can support the administration of training3 across large organizations with a variety of training needs (Barron, 2000; Brennan et al., 2001; Zeiberg, 2001). A training manager within CEM Corporation commented that "the main role of the LMS is to automate training administration and then to add value." He also maintained that "with the LMS, the amount of work that you can get through is greater…it improves the efficiency of delivering and managing training." Thus, the LMS facilitates an increase in the productivity of training. From a learner's perspective, the principal role of the LMS is that it can provide a central repository for a range of learning material in a structured way that enables the system to support a diverse body of learners within diverse learning contexts (Brennan et al., 2001; McCombs, 2000; Wagner, 2000). As one user of the LMS within CEM Corporation put it, "employees who work in areas of the business can identify their role and cross reference the LMS for recommendations on what training is appropriate for that role…the system also provides guidance with recommended paths through several training courses." Another user of the LMS emphasized that "before, it was known that the Training Organization facilitated training, but you couldn't put your finger on something you wanted…now there is a central repository and you can see all the training that is being delivered." This leads to the most critical role of all, which is that it can increase the degree to which training is utilized and hence, increase learning in the organization. Also, from the perspective of the learner, the research findings identified two other significant and emerging roles of the LMS, which are listed within the framework. The first of these is the provision of post learning support, whereby, as the LMS manager explained, "the LMS enables employees to return to material from a course or download documents associated with a course that they have already completed." The second emerging role of the LMS is that it acts as a signaling system for changes in the organization. This was highlighted by one user of the system, who holds a software development role within the organization. He argued that "when new training becomes available on the LMS within our area, this normally signals that either new software product features have been released or that software product changes have taken place."

CEM's LMS also allows for competency mapping and facilitates career development paths. Using the LMS, an employee's competencies may be assessed using a predefined competency model for their particular job role. Subsequently, a number of development options or learning activities are suggested by the system, which may be carried out by the individual in order to fill any skill gap or competency deficiency for their role type. Thus, the LMS facilitates competence development to meet particular business objectives (see also: Brennan et al., 2001; Hall, 2001). The competency assessment process enables a dual approach to learning management (i.e., top-down and bottom-up). From a top-down perspective, training managers can use the LMS skill-assessment process to automate the training needs analysis process, which will assist them in the identification of training needs and will support training planning. Furthermore, from a management perspective, it is possible for a manager to get an overall picture of the competency levels within their department. One technical manager maintained that "although it started as just automation of training needs analysis, managers then saw that they can get a picture of training gaps and competency levels …they can also see overlaps in competencies." The LMS manager also commented on the bottom-up approach facilitated by the system viz. "self assessment and self directed learning is offered, which has passive approval." In this context, passive approval means that if an employee registers for a particular course or learning activity, they are automatically approved for that training unless the training is specifically disapproved by their manager within a certain limited time period. In this way, employees are encouraged to self-manage their own learning using the LMS: this has the added benefit of encouraging accountability for learning among employees (see also Hall, 2000).

The use of competency models for assessing and developing employee capabilities forms the basis of a number of other evolving roles of the LMS. Through standardizing role-based competency requirements and development options, the LMS can enable more consistent and cohesive learning throughout the enterprise (see also Greenberg, 2002). The LMS manager pointed out that "the status of competencies within the organization may be reported on at a number of different levels, using the LMS." This enables the monitoring and analysis of the "learning condition" of an organization (see also Nichani, 2001). Furthermore, a department manager described how "the LMS can support a manager in assessing an employee's role-based competencies and having agreed development plans with that employee, a subsequent competency assessment can help that manager to determine the employee's 'learning performance' in acquiring the new competencies, as per the development plan." Thus, by reviewing progress between one competency assessment and the next, the evaluation of individual learning performance for an employee is facilitated. This may then form part of the individual's overall performance evaluation.

CEM Corporation: Overall Benefits of the Enterprise Learning Solution

The deployment of the enterprise learning solution has enabled CEM Corporation to address many of the challenges that it faced in 2000, prior to the system's implementation. In particular, CEM has achieved the following:

- CEM now has a single enterprise system that supports the administration of all training across the entire organization. From the point of view of the employees, the system provides a centralized mechanism that enables them to search for and to enrol in selected courses or training programs; it also offers guidance on recommended training paths and curriculums. Furthermore, the competency assessment facility enables employees to determine and rectify competency gaps as well as providing management at CEM with a means of monitoring and managing overall employee competency levels within the organization.
- The enterprise learning solution supports all training content whatever its subject matter or form and enables the management and control of access to this content using one system. This has the added advantage of highlighting duplication of training material in different parts of the organization and paves the way for streamlining the efforts

of different training services within the company.

- The flexibility and dynamic nature of the system allows CEM Corporation to unilaterally introduce and to quickly implement new training requirements across the organization in response to changing business needs or new technical advances.
- The Saba Learning Enterprise™ LMS may help to attract or retain key personnel by offering them a unique opportunity to monitor and develop their competencies and to manage their careers within the organization.

CURRENT CHALLENGES/ PROBLEMS FACING THE ORGANIZATION

As outlined earlier, CEM Corporation is a hi-tech organization that operates in a very competitive and dynamic business environment. Managing learning and measuring learning outcomes are in themselves difficult tasks, but they are made even more problematic within complex learning domains, such as those that exist at CEM. It is unlikely that the LMS will enable the full management of all of the learning in the organization in a truly scientific way, though it will assist greatly in managing the diverse and extensive array of learning contexts and learning processes that must be supported. The system's strengths lie in the new approach and attitude that it will encourage and inspire in the hearts and minds of individuals within the organization, as it enables learning that is highly visible, structured, and more accessible within the organization. This stimulation of the hearts and minds is a major contributing factor to learning and is known as "emotional quotient" (Goleman, 1996). Having deployed the enterprise learning solution, CEM Corporation now faces a number of key challenges. These are outlined next:

Control vs. Creativity: Managing the Delicate Balance

The findings of this case study demonstrate that CEM's new LMS can play a vital role in increasing learning within across the organization. This will be achieved by improving the control and management of employee competency levels, and also by empowering employees to be creative in managing their own learning and competency development. Thus, the key challenge for management at CEM is to increase their influence and control over training and learning within the organization, while at the same time increasing employee commitment to managing their ongoing self-development by taking responsibility for improving their knowledge of the business and building related competencies. These objectives are delicately balanced and must therefore be handled carefully. Too much control may de-motivate employees and discourage them from engaging with the system, but at the same time, enough control must be exerted to ensure that employees are developing competencies that support the day-to-day operational requirements of the organization, as well as being in sync with the overall goals and objectives of the company.

Exploiting the Benefits of the LMS: Incorporating all Training & Learning

Another key challenge presently facing CEM Corporation is that they have a long way to go before all of the benefits offered by their new LMS can be fully exploited. Not all formal training is currently being tracked and managed through the LMS and some departments independently organize their own training outside of the system. One engineer argued that "there doesn't appear to be a large amount of suitable training available for our department." The benefits offered by this enterprise learning solution will not be fully realized until sufficient training or learning programs are offered to all employees in all departments within the organization. Furthermore, while it is possible to take certain online training directly through the Internet, it is not possible to track or manage associated learning outcomes, as this training is initiated and completed outside of the LMS, and is not currently recorded by it. It is understandable that it will take some time to incorporate every training program for all employees onto the system, but it is critical that this is achieved as quickly and efficiently as possible, to ensure support for the system and ongoing use of the system across the entire organization.

Drawing Up Competency Models for All Employees

Role-based competency models have not yet been drawn up for all roles within the organization. As the LMS Manager pointed out, "there is difficulty in having accurate competency models for all roles when there is such a vast array of diverse technical positions." He added that "as you drill down, you find that there are a lot of specialist functional competencies and you get into the ROI question…because there is such a large investment in time and effort involved in devising competency models for all technical roles, it has to be driven by the local business needs". Competency assessments are instrumental to determining if positive learning outcomes have been achieved and they will also demonstrate if the organization is obtaining a return on its investment in implementing and deploying the LMS. Furthermore, competency assessments offer management at CEM an opportunity to identify and rectify gaps or overlaps in competency levels as well as providing a means of assessing and managing overall competency levels within the organization. CEM Corporation is now faced with the daunting task of drawing up and maintaining competency models for the vast array of role types of its 20,000-plus employees, many of whom work in dynamic and highly technical areas.

Managing the Competency Assessment Process

Even where competency models are available, the study revealed that the process of self-management of career development has, for the most part, not yet been taken up within the organization. Moreover, many employees, and indeed managers, have not yet engaged with the competency assessment process. A structured plan or roadmap needs to be formulated in conjunction with local business needs for the formal migration of all employees onto the system for competency assessment and competency development planning to take place.

Fully Mobilizing the LMS within the Organization

One manager observed that "many employees still feel that the system is primarily designed for course registration and the other elements of the system may need to be emphasized more internally." Another user of the LMS argued that "although the initial rollout of the LMS seems to have been good and although there is a growing awareness of the system, people still have not got to grips with using it." The challenge facing CEM Corporation is to raise internal awareness of the functions and capabilities that are now provided by the LMS, and to educate the employees on how these functions and features operate. This education program needs to address cultural issues, as well as dealing with the fears and anxieties that employees may have in relation to the use of the system. This finding was supported by one manager who noted that "some employees may fear that if they use the system to log their competencies, their career may be negatively affected."

CEM Corporation needs to encourage the active participation of senior management in the mobilization of the LMS and perhaps consider the appointment of an overall champion for the initiative at senior management level. This chief learning officer4 could promote the utilization of the system at a senior level within the business units and ensure that any synergies that exist between them are exploited. Finally, a number of managers felt that CEM needs to publicize and promote the benefits of engaging with the LMS and find ways of formalizing and integrating this novel strategic learning management system with extant business processes and work practices.

APPENDIX A

Saba Software Inc. Overview

Founded in 1997, Saba Software Inc. (quoted on the NASDAQ stock exchange as SABAD) is a global company headquartered in Redwood Shores, California, and is a leading provider of Human Capital Development and Management (HCDM) solutions. The Saba vision is to make it possible for every enterprise to manage its human capital by bringing together learning, performance, content and resource management in a holistic, seamless way. To satisfy this vision, Saba offers two key products sets, namely, its "Enterprise Learning Suite" and "Saba Performance". "Saba Learning" is an Internet-based learning management system within the Enterprise Learning Suite that automates many of the learning processes for both learners and learning providers. Table A(1) lists some of Saba Software's major customers.

Table A(1). Saba Software Incorporated – Major customers

Business Area	**Customers**
High Tech	Cisco Systems, Cypress, EMC^2, Xilinx, i2 Technologies, VERITAS Software
Telecommunications	ALCTEL, Telecom Italia, CENTEC, Lucent Technologies
Professional Services	Kendle International, Deloitte & Touche, EDS, Bearing Point (Formerly KPMG)
Financial and Insurance Services	ABN Amro, Royal & Sun Alliance, Scotiabank, Principal Financial Group, BPM, Standard Chartered, Wells Fargo
Government	United States of America Department of the Army, Distributed Learning Services, LearnDirect Scotland
Life Science	Aventis, Novartis, Procter & Gamble, Medtronic
Automotive	Ford Motor Company, General Motors, Daimler Chrysler
Transportation	Continental Airlines, BAA
Energy	Duke Energy, Energy Australia
Manufacturing and Distribution	Caterpillar, Cemex, Grainger.
Consumer Goods and Retail Distribution	Best Buy, Kinkos

APPENDIX B

<u>What are the roles of the LMS in managing learning within the organization?</u>

1.1 Does LMS support training administration?
- registration
- scheduling
- delivery
- testing
- tracking/reporting of individual learning

1.2 Does LMS support diverse learners within diverse learning contexts?
- large number of learners
- diverse learning contexts
- online and offline learning

1.3 Does LMS facilitate competence development to meet particular business objectives?
- skills specification needed to fulfil particular objective
- skills assessment to establish gap in learning
- recommended learning to fill identified gap in learning

1.4 Does LMS enable cohesive learning throughout the enterprise?
- learning development plan for organization
- learning plan for individuals in sync with overall learning plan

1.5 Does LMS encourage accountability for learning among employees?
- self-service learning
- self-planning and self-assessment of career development

1.6 Does LMS enable monitoring and analysis of “learning condition” within the organization?
- overall picture of competencies within the organization
- overall picture of learning achieved in organization
- overall picture of learning required within the organization

1.7 What are the other key roles/attributes of the LMS?
- provision of any content authoring
- provision of any content management
- provision of any knowledge management
- synchronization with HR system
- provision of post-learning support
- adherence to learning content standards
- integration of incompatible systems for learning management
- support for large range of third-party courseware
- other

INTRODUCTION

Systematic development of new knowledge is as important in the developing field of knowledge management (KM) as in other social science and technological domains. Careful research is essential for the development of new knowledge in a systematic manner (e.g., avoiding the process of trial and error). The problem is, throughout the era of modern science, a chasm has persisted between laboratory and field research that impedes knowledge development about knowledge management.

This article combines and builds upon recent results to describe a research approach that bridges the chasm between laboratory and field methods in KM: computational experimentation. As implied by the name, computational experiments are conducted via computer simulation. But such experiments can go beyond most simulations (e.g., incorporating experimental controls, benefiting from external model validation). And they can offer simultaneously benefits of laboratory methods (e.g., internal validity, lack of confounding) and fieldwork (e.g., external validity, generalizability). Further, computational experiments can be conducted at a fraction of the cost and time associated with either laboratory experiments or field studies. And they provide a window to view the kinds of meta-knowledge that are important for understanding knowledge management. Thus, computational experimentation offers potential to mitigate many limitations of both laboratory and field methods and to enhance KM research. We discuss computational modeling and simulation as a complementary method to bridge the chasm between laboratory and field methods—not as a replacement for either of these methods.

BACKGROUND

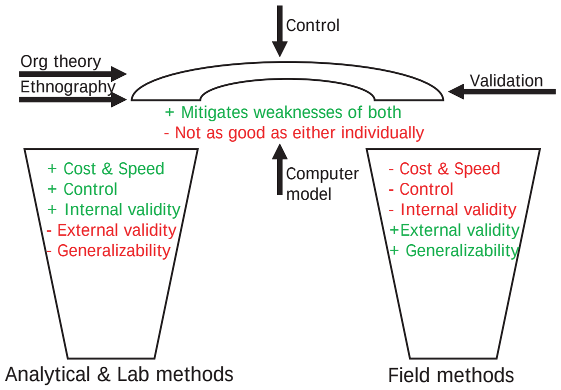
To appreciate the power of computational experimentation, we draw heavily from Nissen and Buettner (2004) in this section, and outline the key relative advantages and disadvantages of laboratory and field methods. To begin, the laboratory provides unparalleled opportunity for controlled experimentation. Through experimentation the researcher can manipulate only a few variables of interest at a time and can minimize the confounding associated with the myriad factors affecting complex systems and processes in the field (Box, Hunter, & Hunter, 1978; Johnson & Wichern, 1992). However, limitations of laboratory experimentation are known well (Campbell & Stanley, 1973) and are particularly severe in the KM domain. In KM experimentation such limitations center on problems with external validity. Laboratory conditions can seldom replicate the complexity, scope, and scale of the physical organizations and systems of interest for research. KM experiments also include problems with generalizability. Many experiments utilize samples of convenience (esp. university students) instead of working professionals. This practice calls into question how closely the associated experimental results are representative of KM behavior in operational organizations.

Alternatively, field research provides unparalleled opportunity for realism (Denzin & Lincoln, 1994). The researcher in the field can study full-scale artifacts in operational environments (Yin, 1994) and can minimize the abstraction away from working people, systems, and organizations (Glaser & Strauss, 1967). However, limitations of field research are known well also (Campbell & Stanley, 1973) and are particularly severe in the KM domain also. In KM field research such limitations center on problems with internal validity. Field research affords little opportunity for controlled experimentation (cf. Cook & Campbell, 1979). Also, confounding results often from the myriad influences on complex systems and organizations that cannot be isolated in the field. This practice makes it difficult to identify and trace the causes of differential behaviors—better as well as worse—in KM. In addition, field research can be very expensive, particularly to support researchers' efforts to enhance internal validity and ameliorate confounding. And many research designs for fieldwork (e.g., case study, ethnography, natural experiment) require considerable time for planning and analysis.

As implied by the name, computational experiments are conducted via computer simulation. As such, they offer all of the cost and time advantages of computational analysis (see Law & Kelton, 1991). But computational experiments go beyond most simulations. Rigorous experimental designs are employed to capture the benefits of laboratory experimentation. The variables affecting physical systems and organizations in the field can be isolated and examined under controlled conditions. This also addresses the internal validity and confounding limitations of field research. Yet computational experiments can be conducted at a fraction of the cost and time required to set up and run experiments with human subjects in the laboratory. Further, through external validation, computational models can emulate key qualitative and quantitative behaviors of the physical systems and organizations they represent with "good" fidelity (e.g., good enough to have confidence that results of computational experiments will track those of physical experiments in the laboratory or field). This mitigates the problems of external validity and generalizability noted above.

Figure 1 illustrates the essential elements of computational experimentation as a research method. The top of the figure includes a shape to depict the bridge metaphor associated with this method. It spans a wide gap between laboratory and field methods. From the left side of this "bridge," two arrows represent inputs to describe the behaviors of computational models. Organization theory, which is predicated upon many thousands of studies over the last half century, provides the basis for most such behaviors. Behaviors pertaining to organizational factors such as centralization, division of labor, task interdependence, function, coordination, formalization, technology, and information processing are captured from organization theory. Where extant theory does not address a behavior of interest (e.g., knowledge flows) well, ethnographic

Figure 1. Bridge method (Adapted from: Nissen and Buettner, 2004)



and similar immersive field studies (Bernard, 1998) are conducted to understand the associated organizational behaviors. Because organization theory attempts to be general, and is not based on any single organization, the associated behaviors have broad applicability across organizations in practice. This provides in part for the generalizability attainable through the method of computational experimentation.

From the bottom of the "bridge," an arrow represents the use of computer models to represent organizations and emulate their key behaviors. Some variety exists in terms of specific implementations. But most computer models adhere to standards, norms, and conventions associated with the field of Computational Organization Theory (COT; see Carley & Prietula, 1994). The central goal is to develop computer models that emulate the key behaviors of organizations and to use such models to examine alternate methods of organization and coordination. As such COT shares a focus on many factors of importance in knowledge management.

From the right side of the "bridge" in the figure, one arrow represents a requirement in our approach for model validation. Through validation, the organizational behaviors emulated by computer models are examined and compared with those of operational organizations in the field. We view this as an essential step. It provides confidence that the behaviors emulated by the computer model have sufficient fidelity to mirror faithfully the behaviors of the operational organizations they represent. This provides in part for the external validity attainable through the method of computational experimentation.

It is important to note, not all COT models are subjected to such validation. Many researchers use computational models to conduct theorem-proving studies. Such studies are valuable in their own right to demonstrate various aspects of organization theory (e.g., see Carley, 1999). But without thorough validation of representation and usefulness (Thomsen, Levitt, Kunz, Nass, & Fridsma, 1999), such researchers have difficulty making claims that the theoretical insights derived from their models mirror the behavior of organizations in the field. Hence comprehensive validation represents an important characteristic to distinguish computational experimentation as the research method described specifically in this article from COT in general.

Finally, from the top of the "bridge," an arrow represents the use of experimental controls in research. Following the same rich set of experimental designs available to laboratory researchers, computational experimentation as a research method can be used to control for myriad factors and manipulate just one or a few variables at a time to examine causality. Further, the same experimental design and setup can be replicated any number of times, for instance using Monte Carlo techniques or other computational approaches to introduce variation. This provides for the internal validity attainable through the method of computational experimentation. Combining these "bridge" inputs together—organization theory and ethnography, computer models, validation, and control—the method of computational experimentation can be understood in terms of, and indeed inherits, the various properties of its constituent elements.

COMPUTATIONAL EXPERIMENTATION IN KM

In this section, we draw heavily from Nissen and Levitt (2004) to summarize our approach to computational experimentation in KM. We begin by highlighting key aspects of our research on agent-based modeling and then illustrate its KM application through an example of technological development.

Virtual Design Team Research

The Virtual Design Team (VDT) Research Program (VDT, 2004) reflects the planned accumulation of collaborative research over two decades to develop rich, theory-based models of organizational processes. Using an agent-based representation (Cohen, 1992; Kunz, Levitt, & Jin, 1998), micro-level organizational behaviors have been researched and formalized to reflect well-accepted organization theory (Levitt et al., 1999). Extensive empirical validation projects (e.g., Christiansen, 1993; Thomsen, 1998) have demonstrated representational fidelity and have shown how the emulated behaviors of VDT computational models correspond closely with a diversity of enterprise processes in practice.

The development and evolution of VDT has been described in considerable detail elsewhere (e.g., Jin & Levitt, 1996; VDT, 2004), so we do not repeat such discussion here. The VDT modeling environment has been developed directly from Galbraith's (1977) information processing view of organizations. This information processing view has two key implications (Jin & Levitt, 1996). The first is ontological: we model knowledge work through interactions of tasks to be performed, actors communicating with one another and performing tasks, and an organization structure that defines actors' roles and that constrains their behaviors. In essence this amounts to overlaying the task structure on the organization structure and to developing computational agents with various capabilities to emulate the behaviors of organizational actors performing work.

The VDT modeling environment benefits from extensive fieldwork in many diverse enterprise domains (e.g., power plant construction and offshore drilling, see Christiansen, 1993; aerospace, see Thomsen, 1998; software development, see, Nogueira 2000; healthcare, see Cheng & Levitt, 2001). Through the process of "backcasting"—predicting known organizational outcomes using only information that was available at the beginning of a project—VDT models of operational enterprises in practice have demonstrated dozens of times that emulated organizational behaviors and results correspond qualitatively and quantitatively to their actual counterparts in the field (Kunz et al., 1998). Thus the VDT modeling environment has been validated repeatedly and longitudinally as representative of both organization theory and enterprises in practice. This gives us considerable confidence in its results.

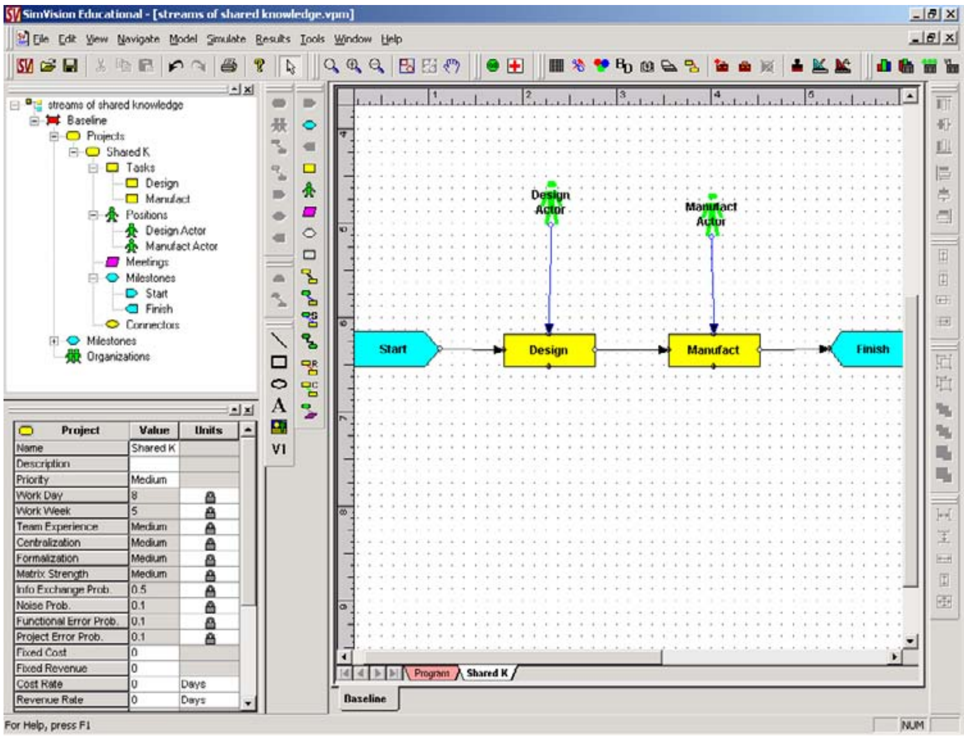
Moreover, VDT is designed specifically to model the kinds of knowledge work and information processing tasks that comprise the bulk of KM processes. In this sense, the computational model is imbued with meta-knowledge in terms of the constructs and relationships that are important to KM. In particular, building upon emerging knowledge-flow theory (e.g., see Nissen, 2002)—which describes the dynamics of how knowledge "moves" between various people, organizations, locations, and points in time—we are extending VDT methods and tools to reproduce increasingly fine-grained behaviors of knowledge in motion. This includes knowledge-flow processes and tools such as direct experience, formal training, transactive memory, mentoring, and simulation, in addition to commonplace KM approaches such as Web portals, knowledge maps, and communities of practice.

VDT Knowledge Management Model

Here we employ the VDT modeling environment to represent work processes associated with a high-level technology development project. The key KM question of interest here is: To what extent should the organization focus on developing specialist knowledge within its two functional areas of design and manufacturing vs. promoting generalist knowledge across functional areas? Figure 2 presents a screenshot delineating two primary tasks (i.e., design and manufacturing), each performed by a corresponding organizational unit (i.e., design actor and manufacturing actor). The two milestone markers ("Start" and "Finish") shown in the figure are used in VDT to denote progress, but such markers neither represent tasks nor entail effort. The tree structure shown in the top left of the figure displays several of the different ontological elements of the VDT model (e.g., tasks, positions, milestones). The table shown in the bottom left displays numerous program-level parameters (e.g., team experience, centralization, formalization), which are all set to empirically determined "normal" values for product development work. Values for such parameters are held constant (i.e., controlled) across simulations of alternate cases and scenarios.

To set up a computational experiment, this model is parameterized to reflect "medium" specialist knowledge and "medium" cross-functional knowledge. The null hypothesis is: varying the relative levels of specialist and cross-functional knowledge has negligible impact on project performance. To test this null, we conduct a full-factorial experiment, with knowledge levels at both "low" and "high" levels for all combinations of specialist and cross-functional settings. Examining each

Figure 2. VDT baseline product development model



case individually provides us with precise control over which factors can vary and hence excellent insight into causality. Examining exhaustively all combinations of specialist and cross-functional knowledge levels provides us with insight into the entire design space associated with these KM variables of interest. Using consistently the output measure project duration enables us to employ a common metric to assess relative performance. These benefits all accrue from our experimental methods and controls. Moreover, using empirically determined and validated "normal" settings to depict the behavior of a representative technology project provides us with confidence that results of our simulations bear resemblance to those of operational organizational projects in the field. This benefit accrues from employing the general and validated modeling environment VDT.

Computational results for the product development model are summarized in Table 1. The values listed in the table reflect simulated project duration and are expressed in workdays. For instance, notice the result in the table's center (highlighted in bold print for emphasis): a project staffed with actors possessing medium levels of manufacturing specialist knowledge (z) and medium levels of cross-functional knowledge (h) is projected by the model to require 216 workdays to complete. This reflects a nominal 200 days of work specified (i.e., work volume), along with 16 days of additional problem solving (e.g., internal communication, delay, and exception handling associated with noise, uncertainty, and errors). The additional 16 days' problem-solving time reflects empirically determined relationships between model parameters (e.g., levels of z and h) and organizational performance.

Table 1 reports full-factorial results of nine simulation runs, with both the z (i.e., specialist knowledge) and h (i.e., cross-functional) parameters varying across three levels: low, medium, and high. Notice the simulation results vary in understandable ways across the three levels of both specialist and cross-functional knowledge. For instance, holding the parameter h constant at the medium level of cross-functional knowledge, performance in terms of project duration ranges from 264 days when specialist knowledge is low, to 178 days when specialist knowledge is high. This indicates the marginal product of such knowledge is positive (i.e., consistent with classical microeconomic theory). This same monotonic relationship is evident at the other levels of cross-functional knowledge (i.e., low h, high h) as well. Likewise, holding the parameter z constant at the medium level of specialist knowledge, performance in terms of project duration ranges symmetrically from 264 days when cross-functional knowledge is low, to 178 days when cross-functional knowledge is high. This is also consistent with classical microeconomic theory and is evident too at the other levels of specialist knowledge (i.e., low z, high z).

The symmetry reflected in the results of Table 1 corresponds to the microeconomic case of perfect knowledge substitution: specialist and cross-functional knowledge can be substituted—unit for unit—to maintain performance at some arbitrary level (e.g., along an isoquant). For instance, from the table, where specialist knowledge (z) is low, but cross-functional knowledge (h) is medium, performance (264 workdays) is the same as where specialist knowledge (z) is medium (i.e., one unit higher), but cross-functional knowledge (h) is low (i.e., one unit lower). Other instances of such substitutability can be identified readily through different combinations of knowledge types z and h (e.g., low z, high h <—> high z, low h [226

Table 1. Computational model results

Parameter	Low z	Medium z	High z
High h	226	178	141
Medium h	264	**216**	178
Low h	310	264	226

Project Duration in Workdays

days]; high z, medium h <—> medium z, high h [178 days]). With this our computational model indicates that specialist and cross-functional knowledge represent substitutes for one another. It is important to note here, this result reflecting perfect substitution reflects an emergent property of the computational model, not an explicit behavior—that is, nowhere in the development of the VDT environment or this computational project model do we specify behaviors of perfect substitution. Rather, the nature of interactions between VDT actors, tasks, organizations, and environmental settings lead dynamically to this result. In a sense this provides some additional validation of VDT (i.e., from classical microeconomics) behaviors.

Clearly this relatively simple computational experiment excludes several factors and aspects of the world that would complicate the analysis and alter the symmetry of results. For instance, we model the design and manufacturing tasks as sequential, with little interaction and no rework. However, few contemporary technology development projects separate design and manufacturing so cleanly. Designers today are required to understand an organization's manufacturing capabilities, and manufacturers today need to understand the limitations of design. In the case, the coordination requirements associated with concurrency between design and manufacturing functional tasks would skew our results in terms of substitution between specialist and generalist knowledge. Similarly, few contemporary technology development projects are devoid of rework between design and manufacturing tasks. Indeed, a key aspect of concurrency in fast-track projects involves multiple prototypes that are developed, evaluated, and reworked through successive iterations and refinements.

In the case, the rework requirements associated with iterative prototyping would also skew our results in terms of substitution between specialist and generalist knowledge. Other complications (e.g., inclusion of marketing and service organizations, differential pay scales, different rates of change pertaining to specialist and generalist knowledge, different learning rates among actors in the various organizations, different KM technologies in place) can be modeled and simulated as well—one at a time—using experimental controls. Through such computational experimentation, researchers and managers alike can learn much about how knowledge flows in a modeled project organization. Such knowledge can be used to help researchers focus on the most sensitive variables to study in future laboratory and field experiments. It can also be instrumental directly in enhancing the organization's KM projects.

FUTURE TRENDS

The kind of computational experimentation illustrated in the simple example above represents only a modest beginning to what can be accomplished over time by exploiting these new tools and techniques. For instance, as the theoretical basis of KM continues to develop and accumulate, an increasing number of knowledge-specific micro-behaviors can be represented and incorporated into modeling environments such as VDT. This will enable increasingly fine-grained and complex analyses to be conducted, with computational experimentation used to differentiate between closely matched KM alternatives (e.g., competing organizational designs, process flows, personnel systems, technological architectures). In complementary fashion, as computational models become increasingly sophisticated and based on KM theory, using such models through experimentation will enable new KM knowledge to develop and accumulate at an ever faster rate. Hence in a mutually reinforcing manner, KM theory can inform and improve upon computational experimentation, while computational experiments can inform and accelerate the development of KM theory.

Moreover, as computer technology continues to advance, larger and more complex computational experiments can be conducted in less time. As the approach of computational experimentation diffuses through the research and management communities, it may become increasingly routine to employ this technique in everyday settings (Schrage, 1999). Today, the designs of airplanes, bridges, and computers are accomplished principally via computational modeling and analysis. Tomorrow, such modeling and analysis may become indispensable to designing organizations, work processes, personnel systems, and information technologies (Levitt, 2004). Before any KM project reaches a stage of prototyping, much less organizational implementation, it will have undergone extensive computational analysis. Thus, the approach of computational experimentation that we illustrate in this article offers potential to become a mainstay of KM research and practice.

CONCLUSION

Systematic development of new knowledge in the developing field of knowledge management (KM) is impeded by a chasm between laboratory and field research methods. This article describes computational experimentation as a research approach that bridges this chasm and hence offers potential for understanding KM better. Examining a high-level project model, we illustrate how the VDT modeling environment can be employed for computational experimentation through a full-factorial design. And we indicate how this approach can be extended to examine large, complex, and detailed organizations and projects, in addition to adding increasingly sophisticated and analytically demanding factors to the models.

More than simply simulating organizational behaviors, computational experimentation can facilitate the development of knowledge about knowledge management. In time we may find such experimentation used to design KM projects and associated organizations in a manner similar to the use of computational models for the design of complex physical artifacts such as airplanes, bridges, and computers. Should this vision obtain, the KM researcher, manager, and practitioner alike will all be well versed in—and indeed critically dependent upon—computational experimentation. The research described in this article represents a substantial step toward such vision.

Chapter 1.38
Object–Process Methodology

Dov Dori
Technion, Israel Institute of Technology, Israel, & Massachusetts Institute of Technology, USA

INTRODUCTION

Capturing the knowledge about existing systems and analysis and design of conceived systems requires an adequate methodology, which should be both formal and intuitive. Formality is required to maintain a coherent representation of the system under study, while the requirement that the methodology be intuitive stems from the fact that humans are the ultimate consumers of the knowledge. Object-Process Methodology (OPM) is a vehicle for knowledge representation and management that perfectly meets the formality and intuition requirements through a unique combination of graphics and natural language.

Function, structure, and behavior are the three main aspects that systems exhibit. Function is the top-level utility that the system provides its beneficiaries who use it or are affected by it, either directly or indirectly. The system's function is enabled by its architecture—the combination of structure and behavior. The system's architecture is what enables it to function so as to benefit its users.

Most interesting, useful, and challenging systems are those in which structure and behavior are highly intertwined and hard to separate. For example, in a manufacturing system, the manufacturing process cannot be contemplated in isolation from its inputs—raw materials, model, machines, and operators—and its outputs—the resulting product. The inputs and the output are objects, some of which are transformed by the manufacturing process, while others just enable it.

Modeling of complex systems should conveniently combine structure and behavior in a single model. Motivated by this observation, OPM (Dori, 1995, 2002) is a comprehensive, holistic approach to modeling, study, development, engineering, evolution, and lifecycle support of systems. Employing a combination of graphics and a subset of English, the OPM paradigm integrates the object-oriented, process-oriented, and state transition approaches into a single frame of reference. Structure and behavior coexist in the same OPM model without highlighting one at the expense of suppressing the other to enhance the comprehension of the system as a whole.

Rather than requiring that the modeler views each of the system's aspects in isolation and struggle to mentally integrate the various views, OPM offers an approach that is orthogonal to customary practices. According to this approach, various system aspects can be inspected in tandem for better comprehension. Complexity is managed via the ability to create and navigate across possibly multiple detail levels, which are generated and traversed through by several abstraction/refinement mechanisms.

Due to its structure-behavior integration, OPM provides a solid basis for representing and managing knowledge about complex systems, regardless of their domain. This chapter provides an overview of OPM, its ontology, semantics, and symbols. It then describes applications of OPM in various domains.

THE OPM ONTOLOGY

The elements of the OPM ontology, shown in Figure 1, are divided into three groups: entities, structural relations, and procedural links.

Entities

Entities, the basic building blocks of any system modeled in OPM, are of three types: stateful objects, namely objects with states, and processes. As defined below, processes transform objects by (1) creating them, (2) destroying them, or (3) changing their state. The symbols for these three entities are respectively shown as the first group of symbols at the left-hand side of Figure 1, which are the symbols in the toolset available as part of the GUI of OPCAT 2 (Dori, Reinhartz-Berger et al., 2003).

OPM Things: Objects and Processes

Objects are (physical or informatical) things that exist, while processes are things that transform (create, destroy, or change the state of) objects. Following is a set of basic definitions that build upon each other.

An object is a thing that exists.

Objects are the things that are being transformed in the system.

Transformation is generation (creation) or consumption (destruction) of an object, or a change of its state.

Processes are the things that transform objects in the system.

A process is a thing that represents a pattern of object transformation.

Table 1 shows the OPM things and their basic attributes. The third column on Table 1 contains a description of each thing or attribute and below it the syntax of the corresponding sentence in Object-Process Language (OPL)—a subset of English that

Figure 1. The three groups of OPM symbols in the toolset of OPCAT 2

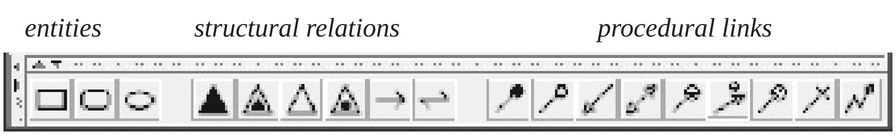

Table 1. Things of the OPM ontology and their basic attributes

Thing / Attribute	Symbol	Description / OPL sentence
Object	Object	A thing (entity) that has the potential of stable, unconditional physical or mental existence.
		Object Name is an object.
Process	Processing	A thing representing a pattern of transformation that objects undergo.
		Processing is a process.
Essence	Object Processing	An attribute that determines whether the thing (object or process) is physical (shaded) or informatical.
		Processing is physical.
Affiliation	Object Processing	An attribute that determines whether the thing is environmental (external to the system, dashed contour) or systemic.
		Processing is environmental.

Table 2. States and values

	Symbol	Description / OPL sentence
Stateful object with two states	Website reachable unreachable	A situation at which an object can exist.
		Web site can be reachable or unreachable.
Value	Temperature 15	A value that an object can assume.
		Temperature is 15.
Stateful object with three states: initial, default, and final	Car new used junk	A state can be initial, default, or final.
		Car can be new, which is initial, used, which is default, or junk, which is final.

reflects the graphical representation. In OPL, bold Arial font denotes non-reserved phrases, while non-bold Arial font denotes reserved phrases. In OPCAT, various OPM elements are colored with the same color as their graphic counterparts (by default, objects are green, processes are blue, and states are brown).

Objects and processes are collectively called things.

The first two lines of Table 1 show the symbol and a description of the two types of OPM things. The next two lines show two basic attributes that things can have: essence and affiliation.

Essence is an attribute that determines whether the thing is physical or informational.

The default essence is informatical. A thing whose essence is physical is symbolized by a shaded shape.

Affiliation is an attribute that determines whether the thing is environmental (external to the system) or systemic.

The default affiliation is systemic. A thing whose affiliation is environmental is symbolized by a dashed contour.

OPM States

Objects can be stateful, that is, they may have one or more states.

A state is a situation at which an object can exist at certain points during its lifetime or a value it can assume.

Stateful objects can be affected, that is, their states can change.

Effect is a change in the state of an object.

OPM STRUCTURE MODELING

Structural relations express static, time-independent relations between pairs of entities, most often between two objects. Structural relations, shown as the middle group of six symbols in Figure 1, are of two types: fundamental and tagged.

The Four Fundamental Structural Relations

Fundamental structural relations are a set of four structural relations that are used frequently to denote relations between things in the system. Due to their prevalence and usefulness, and in order to prevent too much text from cluttering the diagram, these relations are designated by the four distinct triangular symbols shown in Figure 1.

The four fundamental structural relations are:

1. Aggregation-participation: A solidtriangle, , which denotes the relation between a whole thing and its parts
2. Generalization-specialization: A blank tiangle, , which denotes the relation between a general thing and its specializations, giving rise to inheritance;
3. Exhibition-characterization: A solid inside blanktriangle, , which denotes the relation between an exhibitor—a thing exhibiting one or more features (attributes and/or operations)—and the things that characterize the exhibitor; and
4. Classification-instantiation: A solid circle inside a blanktriangle, , which denotes the relation between a class of things and an instance of that class.

Table 3 lists the four fundamental structural relations and their respective OPDs and OPL sentences. The name of each such relation consists of a pair of dash-separated words. The first word is the forward relation name, i.e., the name of the relation as seen from the viewpoint of the thing up in the hierarchy. The second word is the backward (or reverse) relation name, i.e., the name of the relation as seen from the viewpoint of the thing down in the hierarchy of that relation.

Each fundamental structural relation has a default, preferred direction, which was determined by how natural the sentence sounds. In Table 3, the preferred shorthand name for each relation is underlined. As Table 3 shows, each one of the four fundamental structural relations is characterized by the hierarchy it induces between the root—the

Table 3. The fundamental structural relation names, OPD symbols, and OPL sentences

Structural Relation Name		Root Refineables	OPD with 3 refineables	OPL Sentences with 1, 2, and 3 refineables
Forward	Backward			
Aggregation	Participation	Whole Part		A consists of B. A consists of B and C. A consists of B, C, and D.
Exhibition	Characterization	Exhibitor Features		A exhibits B. A exhibits B and C. A exhibits B, C, and D.
Generalization	Specialization	General Specializations		B is an A. B and C are As. B, C, and D are As.
Classification	Instantiation	Class Instances		B is an instance of A. B and C are instances of A. B, C, and D are instances of A.

thing attached to the tip of the triangle, and the leaves—the thing(s) attached to the base of the triangle, as follows.

1. In aggregation-participation, the tip of the solidtriangle, , is attached to the whole thing, while the base is attached to the parts.
2. In generalization-specialization, the tip of the blanktriangle, , is attached to the general thing, while the base is attached to the specializations.
3. In exhibition-characterization, the tip of the solid inside blanktriangle, , is attached to the exhibitor (the thing which exhibits the features), while the base is attached to the features (attributes and operations).
4. In classification-instantiation, the tip of the solid circle inside a blanktriangle, , is attached to the thing class, while the base is attached to the thing instances.

The things which are the leaves of the hierarchy tree, namely the parts, features, specializations, and instances, are collectively referred to as refineables, since they refine the ancestor, the root of the tree.

Refineable is a generalization of part, feature, specialization, and instance.

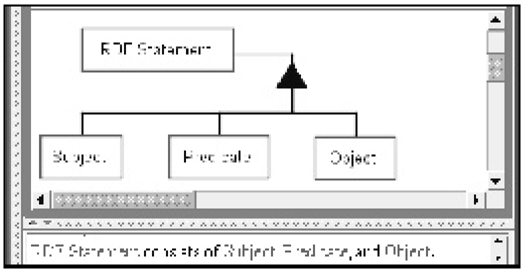
The third column in Table 3 lists for each fundamental structural relation the name of the root (whole, exhibitor, general, class) and the corresponding refineables (parts, features, specializations, and instances). The next column contains an OPD with three refineables, while the rightmost column lists the syntax of three OPL sentences for each fundamental structural relation, with one, two, and three refineables, respectively.

Having presented the common features of the four fundamental structural relations, in the next four subsections we provide a small example for each one of them separately.

Aggregation-Participation

Aggregation-participation denotes the relation between a whole and it comprising parts or components. Consider, for example, the excerpt taken from Section 2.2 of the RDF Primer (Manola & Miller, 2003):

Figure 2. OPD of the sentence "RDF statement consists of subject, predicate, and object"



…each statement consists of a subject, a predicate, and an object.

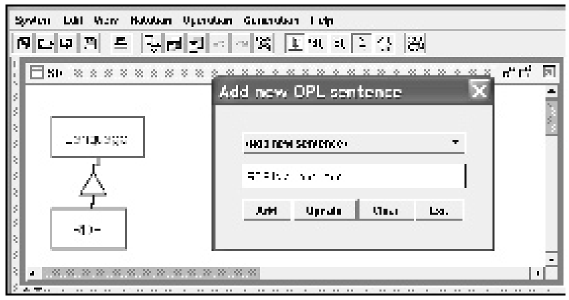
This is a clear case of whole-part, or aggregation-participation relation. The OPM model of this statement, which consists of both the OPD and the corresponding OPL, is shown in Figure 2. Note that the OPL sentence, "RDF Statement consists of Subject, Predicate, and Object," which was generated by OPCAT automatically from the graphic input, is almost identical to the one cited from the RDF Primer. The same OPD exactly (disregarding the graphical layout) can be produced by inputting the text of the OPL sentence above. This is a manifestation of the OPM graphics-text equivalence principle.

Generalization-Specialization

Generalization-specialization is a fundamental structural relationship between a general thing and one or more of its specializations. Continuing our example from the RDF Primer (Manola & Miller 2003), consider the very first sentence from the abstract:

The Resource Description Framework RDF is a Language for representing information about resources in the World Wide Web.

Figure 3. The OPD obtained by inputting into OPCAT the OPL sentence "RDF is a Language"



Let us take the main message of this sentence, which is that RDF is a language. This is exactly in line with the OPL syntax, so we can input the OPL sentence "RDF is a Language" into OPCAT and see what we get.

The result, without any diagram editing, is shown in Figure 3, along with the conversation window titled "Add new OPL sentence," in which this sentence was typed prior to the OPD creation.

Exhibition-Characterization

Continuing to scan the RDF Primer (Manola & Miller 2003), in Section 2.2.1 we find the sentence:

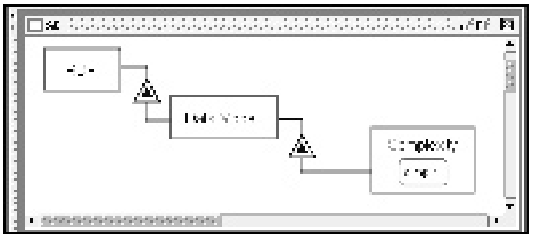
RDF has a simple data model.

To model this statement, we need to rephrase this sentence into the following three sentences:

1. RDF is characterized by a data model.
2. The data model of RDF is characterized by a complexity attribute.
3. The value of this complexity attribute is "simple."

These three sentences are further rephrased to conform to the OPL syntax as follows:

Figure 4. The OPD representing the sentence "RDF has a simple data model"



1. RDF exhibits Data Model.
2. Data Model exhibits Complexity.
3. Complexity is simple.

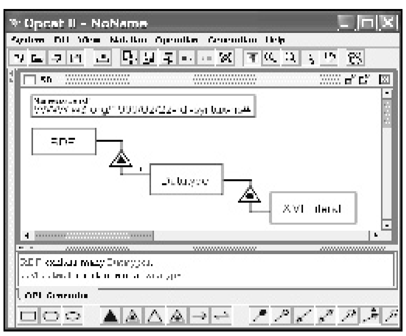
Classification-Instantiation

Reading through the RDF Primer, we find:

Datatypes are used by RDF in the representation of values, such as integers, floating point numbers, and dates.
…

RDF predefines just one datatype, rdf:XMLLiteral, used for embedding XML in RDF.

Figure 5. The OPM model of XMLLiteral, an instance of a Datatype of RDF



An OPL interpretation of these two sentences, respectively, is:

1. RDF exhibits many Datatypes.
2. XMLLiteral is an instance of Datatype.

Figure 5 is the OPM model of XMLLiteral, an instance of a Datatype of RDF.

OPM BEHAVIOR MODELING

Procedural links connect entities (objects, processes, and states) to express dynamic, time-dependent behavior of the system. Behavior, the dynamic aspect of a system, can be manifested in OPM in three ways:

1. A process can transform (generate, consume, or change the state of) objects
2. An object can enable a process without being transformed by it
3. An object or a process can trigger an event that might, in turn, invoke a process if some conditions are met

Accordingly, a procedural link can be a transformation link, an enabling link, or an event link.

In order to be able to talk about object transformation, we need to first define state and demonstrate how states are used.

Object States

In Figure 6 we added to the object Check two states: the initial state uncashed and the final state cashed. This causes the addition of the following OPL sentence to the OPL paragraph:

Check can be uncashed, which is initial, or cashed, which is final.

Figure 6. Adding states to Check

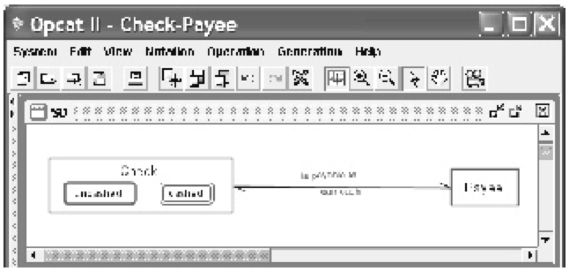


Table 4 shows the OPD and OPL syntax for objects with one, two, and three or more states, and optional time designator attributes: initial, final, and default.

Transformation Links

A transformation link expresses how a process transforms one or more objects. The transformation of an object can be its consumption, generation, or state change. The transforming process is the transformer, while the object being transformed is called transformee.

Input and Output Links

Having added the states to the object Check , we can now show how the process Cashing affects Check by changing its state. In Figure 7, Cashing was added and linked to the two states of Check: an input link leads from the initial uncashed state to Cashing, while an output link leads from Cashing to the final state cashed.

Figure 7. The Cashing process changes the state of Check from uncashed to cashed

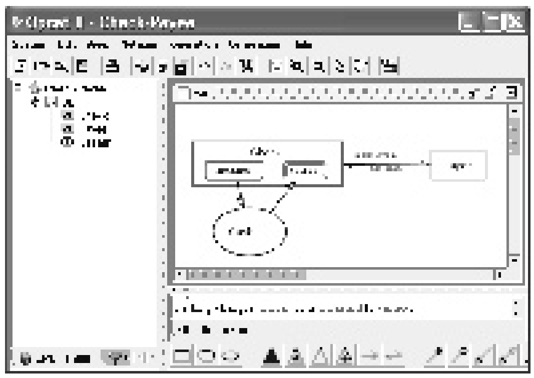

Table 4. OPD and OPL syntax for objects with one, two, and three or more states, and optional time designator attributes

Number of states or timeline	OPD	OPL
Single state	Stateful Object [singular]	Stateful Object is singular.
Two states	Stateful Object [singular] [plural]	Stateful Object can be singular or plural.
Three states or more	Stateful Object [first] [second] [third] [fourth]	Stateful Object can be first, second, third, or fourth.
Three states or more	Stateful Object [first] [second] [third] [fourth]	Stateful Object can be first, which is initial, second, third, which is default, or fourth, which is final.

The OPL sentence generated automatically by OPCAT as a result of adding these input and output links is:

Cashing changes Check from uncased to cashed.

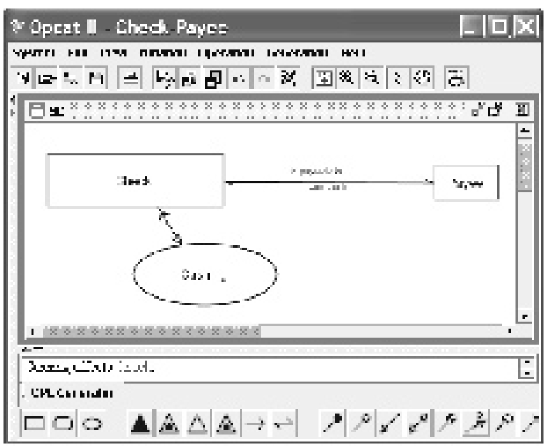
Effect Link

Sometimes we may not be interested in specifying the states of an object, but still show that a process does affect an object by changing its state from some unspecified input state to another unspecified output state. To express this, we suppress (hide) the input and output states of the object, so the edges of the input and output links "migrate" to the contour of the object and coincide, yielding the effect link shown in Figure 8.

The OPL sentence that represents this graphic construct is:

Cashing affects Check.

Figure 8. Suppressing the input and output states of Check causes the two link edges to migrate to the contour of Check and coincide, yielding the single bidirectional effect link between Check and Cashing



Result and Consumption Links

We have seen that one type of object transformation is effect, in which a process changes the state of an object from some input state to another output state. When these two states are expressed (i.e., explicitly shown), then we can use the pair of input and output links to specify the source and destination states of the transformation. When the states are suppressed, we express the state change by the effect link, a more general and less informative transformation link.

State change is the least drastic transformation that an object can undergo. Two more extreme transformations are generation and consumption, denoted respectively by the result and consumption links.

Generation is a transformation that causes an object, which had not existed prior to the process execution, to become existent. For example, Check is born as a result of a Check Making process.

As Figure 9 shows, the object Check is generated as a result of executing the process Check Making. The result link is the arrow originating from the generating process and leading to the generated object. The OPL sentence that

Figure 9. The object Check is generated as a result of executing the Check Making process.

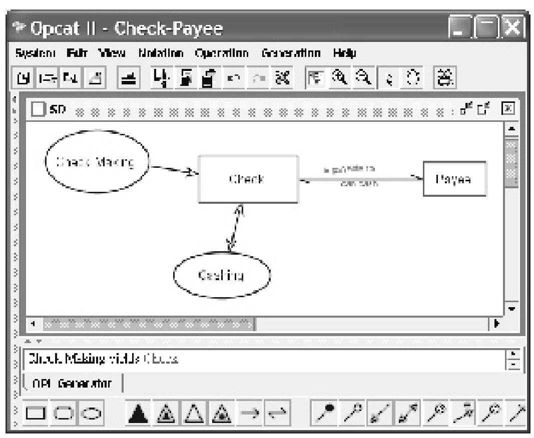


Figure 10. The object Check is consumed as a result of executing the Destroying process.

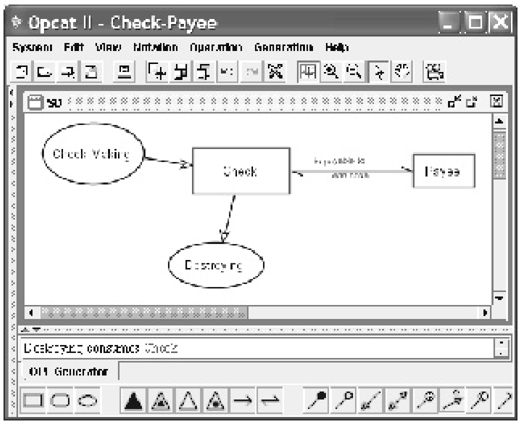


represents this graphic construct (shown also in Figure 9) is:

Check Making yields Check.

In contrast to generation, consumption is a transformation which causes an object, which had existed prior to the process execution, to become non-existent. For example, Check is consumed as a result of a Destroying process.

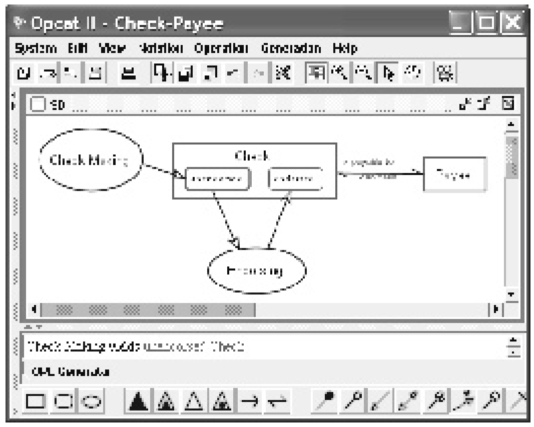
As Figure 10 shows, the object Check is consumed as a result of executing the process Destroying. The consumption link is the arrow originating from the consumed object and leading to the consuming process. The OPL sentence that represents this graphic construct (shown also in Figure 10) is:

Destroying consumes Check.

STATE-SPECIFIED RESULT AND CONSUMPTION LINKS

We sometimes wish to be specific and state not only that an object is generated by a process, but also at what state that object is generated. Some

Figure 11. The object Check is generated in its unendorsed state as a result of executing the Check Making process



other times, we might wish to be able to state not only that an object is consumed by a process, but also at what state that object has to be in order for it to be consumed by the process. As Figure 9 shows, the object Check is generated in its unendorsed state as a result of executing the process Check Making.

The OPL sentence that represents this state-specified result link graphic construct (shown also in Figure 11) is:

Check Making yields unendorsed Check.

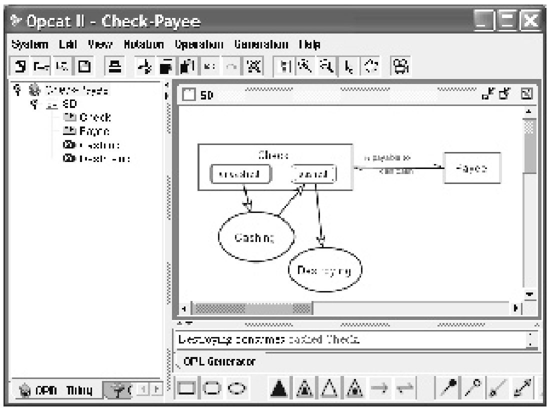
In comparison, the "regular," non-state-specified result link is the same, except that the (initial) state is not specified:

Check Making yields Check.

The difference is the addition of the state name (unendorsed in our case) before the name of the object (Check) that owns that state.

Analogously, a state-specified consumption link leads from a (final) state to the consuming process. For example, assuming a check can only be destroyed if it is cashed, Figure 12 shows the

Figure 12. The object Check is consumed in its cashed state as a result of executing the Destroying process



state-specified consumption link leading from the final state cashed of Check to the consuming process Destroying.

The OPL sentence that represents this state-specified consumption link graphic construct (shown also in Figure 12) is:

Destroying consumes cashed Check.

Summary of Procedural Links Between Processes and Objects

Table 5 provides a summary of the six procedural links between a process and a (possibly stateful) object. They are divided into three pairs: input and output links, which always come as a pair; consumption and result links; and state-specified consumption and result links.

Enablers and Enabling Links

An enabler is an object that is required for a process to happen, but is not transformed by the process.

Table 5. Summary of the procedural links between a process and an object or its state

Transformation Link Type	Source Entity	Destination Entity	OPD	OPL
Input link	Input state	Affecting process		Affecting Process changes Object from input state to output state.
Output link	Affecting process	Output state		
Consumption link	Consumed object	Consuming process		Consuming Process consumes Consumed Object
Result link	Generating process	Resulting object		Generating Process yields Generated Object
State-specified Consumption link	Final state of the consumed object	Consuming process		Consuming Process consumes terminal Consumed Object
State-specified Result link	Generating process	Initial state of the resulting object		Generating Process yields initial Generated Object

An enabling link expresses the need for a (possibly state-specified) object to be present in order for the enabled process to occur. The enabled process does not transform the enabling object. Enablers are divided into instruments and conditioners, each of which can be stateless or stateful.

APPLICATIONS OF OPM AND SUMMARY

OPM has been applied in many domains, including education (Dori & Dori, 1996), computer integrated manufacturing (Dori, 1996a; Dori, Gal, & Etzion, 1996), the R&D universe and its feedback cycles (Myersdorf & Dori, 1997), real-time systems (Peleg & Dori, 2000), banking (Dori, 2001), requirements engineering (Soffer, Golany, Dori, & Wand, 2001), Web applications development (Reinhartz-Berger, Dori, & Katz, 2002a), ERP modeling (Soffer, Golany, & Dori, 2003), axiomatic design (Soderborg, Crawley, & Dori, 2002), computational synthesis (Dori & Crawley, 2003), software reuse (Reinhartz-Berger, Dori, & Katz, 2002b), systems architecture (Soderborg, Crawley, & Dori, 2003), and Web Service Composition (Yin, Wenyin, & Chan. 2004).

This article has presented an overview of Object-Process Methodology and its applications in a variety of domains. There are a number of important OPM-related issues that could not be discussed in detail in this article due to space limitations. One such topic is complexity management. Complexity is managed in OPM via in-zooming, unfolding, and state-expression, which provide for looking at any complex system at any desired level of granularity without losing the context and the "big picture." Another issue is the systems development and evolution methodology with OPM, for which a comprehensive reflective metamodel (which uses OPM) has been developed. These issues and others are treated in detail in the book, Object-Process Methodology: A Holistic Systems Paradigm (Dori, 2002).

The domain-independent nature of OPM makes it suitable as a general, comprehensive, and multidisciplinary framework for knowledge representation and reasoning that emerge from conceptual modeling, analysis, design, implementation, and lifecycle management. The ability of OPM to provide comprehensive lifecycle support for systems of all kinds and complexity levels is due to its foundational ontology that builds on a most minimal set of stateful objects and processes that transform them. Another significant uniqueness of OPM is its unification of system knowledge from both the structural and behavioral aspects in a single diagram—OPD. It is hard to think of a significant domain of discourse and a system in it, in which structure and behavior are not interdependent and intertwined. A third unique feature of OPM is its dual knowledge representation in graphics and text, and the capability to automatically switch between these two modalities. Due to its single model, expressed in both graphics and text, OPM lends itself naturally for representing and managing knowledge, as it is uniquely poised to cater to the tight interconnections between structure and behavior that are so hard to separate.

OPM and its supporting tool OPCAT continue to evolve. The site www.ObjectProcess.org is a rich, continuously updated resource of OPM-related articles, free software downloads, and more.

Chapter 1.39
Uncertainty and Information in Construction: From the Socio-Technical Perspective 1962-1966 to Knowledge Management — What Have We Learned?

Alan Wild
Consultant, Birmingham, UK

ABSTRACT

This chapter questions the possibility of knowledge management in construction, other than among leading organisations handling a restricted population of projects. Socio-technical research in UK coal mining from the 1950s and construction from the 1960s and other relevant studies are compared. The extent to which the tacit order, instability, and diffuseness of construction may, practically, undermine knowledge management is explored. Knowledge management is compared to other methods in terms of the stability required for it to be effective. It is demonstrated that this stability is not usually available in construction, whose projects and processes are subject to an unusually wide range of disturbances.

INTRODUCTION

This book offers a socio-technical perspective on knowledge management in construction. This chapter discusses the original socio-technical research on construction, the Building Industry Communications Research Project (BICRP) by the Tavistock Institute of Human Relations (TIHR) from 1962-1966 (Boyd & Wild, 2003; Wild, 2004). Located between TIHR studies of UK coal mining and concepts of contextual turbulence in 1965, BICRP archives and publications demonstrate the state of construction, revealing the tacit order as deeper and wider than assumed. Problems of information, uncertainty, and indeterminacy pushed socio-technical ideas to their limit.

The knowledge management discourse assumes accessibility of the tacit order through structured inquiry. Are the categories of sense making; communications; information management; intellectual property and capital; innovation, communities of practice, and knowledge capture through IT latent within TIHR ideas? As a then leading analysis for re-framing managerial practice, these compare to knowledge management, which may also reach the limits of analytical penetration in the tacit order of construction. The chapter discusses TIHR work; 1960s studies of organisation; reflective practice and knowledge management, and uncertainty and information in the tacit order of construction and mining.

LEARNING OBJECTIVES

By the end of this chapter, readers will

1. appreciate the intrinsic instability of construction projects and
2. appreciate the effects of this instability on 'methods of management'.

TAVISTOCK (TIHR) STUDIES OF MINING: KNOWLEDGE AND LEARNING; RECURSIVENESS AND REFLEXIVITY IN A TRADITIONAL WORKING CLASS COMMUNITY OF PRACTICE

TIHR studies of mining are organisation theory classics. In the transition to the 'long-wall method', the responsible autonomy of the previous craft mining process was lost. This aligned methods, organisational and legal constraints within the face-to-face, self-managing workgroup; its context of time, space, and darkness; the absence of intermediate management and the moral intensity of the community, which buffered the operational core of collieries, and stabilised the 'organisational ground'. Long-wall technology never realised its production engineering potential. It required an organised, large working group to match the "…structure of the long face and the shift sequence…(creating) difficulties of communication and working relationships…the scale…of the task transcend(ed) the limits of simple spatio-temporal structure…" completion of a job in one place at one time. Engineering difficulties exacerbated the differentiation and interdependence of the workforce. Production required "…one hundred percent performance at each step…working to some extent against the threat of its own breakdown…," creating a tendency to crisis management. Stability implied "…a common skill of a higher order than that required…to carry out, as such, any of the operations belonging to the production cycle…" (Trist & Bamforth, 1951).

Adaptation of the craft system, assisted by the sociologically bounded community and stable political support, created the 'composite long-wall'. This early example of 'learning organisation' and 'community of practice' recorded improved efficiency, safety, and welfare (Trist, Higgin, Murray, & Pollock, 1963). The composite long-wall method was developed from the tacit and local knowledge of the pits without knowledge managers (Heller, 1993).

"At the time the long-wall method developed, there were no precedents for the adaptive underground application of a machine technology. In the absence of relevant experience in the mining tradition, it was…inevitable that…culture borrowing...should have taken place. There was also no psychological or sociological knowledge in existence at that time which might have assisted in lessening the difficulties." (Trist & Bamforth, 1951)

The 'composite long-wall system' resolved tensions between uncertainty and norms of rationality (Thompson, 1967). Consensus in the local industry permitted attainment of the design principle (Clark, 2000) for coordination by mutual feedback through multi-skilling, self-regulation, and redundancy in people (Emery & Trist, 1973), reducing coordination costs. Transferring the concept (Trist et al., 1990) required a learning process involving reflexivity and recursive-ness:

"…the capacity of actors to modify present action by imagining its consequences based on previous experiences…" and "…the socially accomplished reproduction of sequences of activity and action because the actors involved possess a negotiated sense that one template from their repertoire will address a new situation with improvisation through time as events inside processes." (Clark, 2000, p. 69)

Improvisation implies finite capacity for change (Clark, 2000), given the pluralism of social structure in organisations (Burns, 1966) and the re-construction of the role systems of mining.

THE EVOLUTION OF TAVISTOCK RESEARCH AND SOCIAL THOUGHT

TIHR studies in the 1950s confronted problems of communication, learning, information, and uncertainty. Later projects including the BICRP (Higgin & Jessop, 1963, 1965; Crichton, 1966) added wider multi-organisational and longer time horizons as uncertainty and complexity rose in contextual and task environments (Emery & Trist, 1973). BICRP archives clarify the socio-technical theory of construction evolved (Boyd & Wild, 2003) to cope with these problems. Construction exposed the limits of socio-technical ideas, which focus on the inter-penetration of the psychological, social, and technological in work roles and culture. Roles vary in their definition, integration with, and contradiction of other aspects of organisation. People carry the environment as culture to and from work roles, inducing instability and acting as change agents. This personal quality of culture imparts social vitality.

Interactions of individuals and groups involve potentially competing systems including technologies as cultural artefacts (Trist, 1990). Roles constrain through designated rights, obligations of status, mutual expectations, and the array of roles in the role-set. Misalignment generates role conflict, overload, and stress (Merton, 1958). Project teams change through time, implying cultural diversity, unstable roles, and tacit coordination (Stringer, 1967) within "…unpredictable (but inventable) configurations of people and technologies…" (Groak, 1994).

Mining and construction compare in their male workforce and spatio-temporal difficulties. Contextual instability makes the population of construction projects (Groak, 1994) a set of shifting figures on a shifting sociological ground (Trist, 1976). The organisational ground of projects is unstable. Production "…that is subcontracts, is a set of shifting figures in a world of stratified instabilities, sociologically derived at first and then self-induced" (Wild, 2003a).

THE BICRP 1962-1966: AN EMERGING THEORY OF CONSTRUCTION

Higgin and Jessop (1963) used communications and role diagnostically, revealing instability and variability across project role systems and teams. Unsettled definitions of jobs and responsibilities, threat of losses, and absence of agreed rules for relationships induced offensive and defensive behaviour by representative bodies:

"As the social aspects of…communications…embody the fabric of the building team structure, it would be necessary…to learn something of the

way in which the teams get built up from among interdependent, autonomous units…communications in the building team are up against built-in difficulties before they start." (Higgin & Jessop, 1963, p. 37)

External economic, social, and technical forces beyond the control of any party weakened internal coordination. OR analysis had linked communications and roles to the institutions, interests and value systems of construction, and their diverse configurations in projects (Higgin & Jessop, 1963). This diagnosis of a mismatch in "…the network of technical and social relationships forming the structure of the building team" (BICRP Archives, Research Committee, 18 November 1963) was confirmed at two conferences in spring 1963. The research proceeded from this, seeking consensual adaptation and improvement, through appropriate redefinition of roles and responsibilities derived from a formal view of the intrinsic technical relatedness of operations. Design was indeterminate. Construction operations could be foreseen reasonably accurately and had improved in efficiency through critical path and related methods. The phases required different approaches. Signing of contracts changed roles as team members became subject to constructor not architect coordination. The research focussed on acute problems of relationships and communications with complex clients and multiple participants in design and construction processes:

- Building the brief, including sketch plans
- The structure and relationships of the design team beyond this initial stage
- Contractor assumption of responsibility from the design team leading to a planning process
- The conduct and control of the building operations (BICRP Archives, Research Committee, 18 November 1963)

The sequence of briefing, exploration, decision, re-appraisal, and revision in the design team, along with the communications network and reasons for later client intervention were relevant. Operations involved people engaged at the professional and commercial interface where "…many of the tensions created by the instability of the environment were manifested" (BICRP Archives, 18 August 1964).

Scheduling had implications for relationships and communications and was affected by design decisions. Construction operations could be improved given unified control and communications processes. The research would develop critical path methods in design using OR concepts: computer logic; viewing design as a progression of decision 'states', analogous with certain types of statistical system; the 'theory of games' and 'information theory':

"…'sharper' techniques are necessary…which will more closely identify the complex of inter-related decisions necessary for developing a design…reached in various organisational frameworks by a design team of different groups communicating information in different ways at different stages of development…" to formally optimise "…an overall result from a set of value variables, which, at this stage, seems to be the essential operation in developing the brief and in the contractors' building himself into the process." (BICRP Archives, Research Committee, 18 November 1963)

Non-technical aspects of operations originated in institutional roles. This division of responsibility and the personal, group, social, and economic interests implied:

"…the strength of these attachments and…possibilities for change in them, which will allow development…Merging the two lines of inquiry should produce an integrated concept of role. The

connecting concept for this merging will probably be that of distinctive competence, which is at once both a technical and a social definition of a role, or perhaps a combination of roles." (BICRP Archives, Research Committee, 18 November 1963)

In August 1964 the researchers extended indeterminacy to construction planning and control. Construction planning was apparent. They were trying to understand briefing, design, and control to generate the information required for construction operations. A constrained prototype model had emerged from house design. The constraints were:

- Incomplete control over the operational environment translates into instability.
- There is uncertainty in the supply chain over quality, availability, and delivery.
- Formal techniques imply stability, hence their poor performance in practice.
- Attempts to use (and justify) them lead to inter-role tensions.
- Informal (un-verbalised) techniques allowing greater adaptability are applied—what are they and can they be formalised and improved?
- Single pieces of information are generated from many sources, often insufficiently related; confusion results and responsibility is unclear.
- The hidden agendas of site meetings and how these relate to instability in construction control processes.

They were asking about the purpose:

"… any form of communication serves as a contribution to the operations of the building process as a whole…Only when the operations involved and the responsibilities of those undertaking them have been understood, is it possible to know what form an appropriate network of communications…should take." (BICRP Archives, 18 August 1964)

On the 29th of January 1965, a more complex, abstract re-interpretation, essentially Crichton (1966), emerged. There were five interacting systems:

1. Operations: Action necessary to design and construct, divorced of people.
2. Resource Controllers: Architects, QSs, Contractors, and so forth
3. Directive Functions: Briefing, designing, design costing, constructional control
4. Adaptive Functions: Variations, extemporisation, buildability, design ahead of consents, cut and load, claim in anticipation, post-contract working drawings, exploitation of errors and crises, re-deployment, use of substitutes, re-design, and on-site design. There were immense differences between the directive functions and the adaptive functions, and these led to ill-will and confusion and the establishment of the fifth system.
5. A 'Psycho-Social System': Which reflected these differences

Rational accounting was unavailable (Higgin & Jessop, 1963; Crichton, 1966). The construction process was not self-contained as the client:

"…continued to influence action throughout and after the briefing stage and the variation order recognised this fact. The lack of formal links between the different directive functions was exemplified by three different costing systems: cost planning in terms of elements, by trades in the bill of quantities and by certificates etc. in final accounts. Effective comparison between these three was not possible. " (BICRP Archives, 29 January 1965)

But a wider problem existed. No one really knew what was going on. Detailed information on the processes and purposes of communications was lacking (BICRP Archives, 18 August 1964):

"Dr. Higgin elaborated on the normal method of Construction Control. The General Contractor set up agreed time targets (a Programme). This depended on variables not within the control of the Builder, the nature of the contract between the General Contractor and the supplier; the effect of previous negotiations between the Architect and Sub-contractor or supplier and the nature of the Nominated Sub-contractor. The myth of certainty was essential for work to start. The function of contingencies was to reconcile formal/informal systems, and the new contract tried to adapt to the variability of the system. In these conditions, a critical path network became a record, not a planning technique, and rigidity was a common defence against chaos." (BICRP Archives, 29 January 1965)

Andrew Darbyshire, Chairman, stated that his Steering Committee:

"…had always worried about the acceptability and the usefulness of the research from the point of view of the sponsors... They might thus have come to expect too much from the project; but they had come to realise very strongly what immense gaps there were in our knowledge and understanding of the building industry." (BICRP Archives, Research Committee, 15 June 1965)

THE TACIT ORDER OF CONSTRUCTION IN THE 1960S

Turbulent environments demonstrate an intricate enmeshing of diverging causal strands (Emery & Trist, 1965). In construction, contextual and task environments, communications, information, uncertainty, and institutionalised role conflicts inter-penetrated so far, only the most abstract theory was available. The innovative operational research offered required significant development (Friend, 1997) to penetrate the complexity and dynamism of decision processes, align values, and avoid conflicts. The depth, complexity, and impenetrability of the tacit order of this fragmented system characterised by self-interest is asserted. Assumption of the 'myth of certainty' for a project - the transition of so many with different variants of personal knowledge dependent upon verbal transmission through a range of diverse, transient project teams- required tacit coordination within an unstable order.

TIHR presented the problem of knowledge and information as culture. Tacit knowledge is carried by individuals and groups inducing change (Trist, 1990; Trist et al., 1963). In mining, the composite long-wall system was elicited from local and tacit knowledge by a community, bounded by isolation, moral intensity, and political and economic support. In construction diffuseness, diversity, indeterminacy, and fragmentation flow from shifting social priorities and impatience. (Higgin & Jessop, 1963) Dynamic processes confront the unique configuration of many social knowledges and their coordination in the unstable temporal structures (Wild, 2003a) of projects. Tacit knowledge is contextual, but contexts vary in continuity and the potential for knowledge capture.

UNCERTAINTY, INTERDEPENDENCE AND THE SOCIOLOGY OF VALUES

The BICRP is a critical milestone in the analysis of construction. Crichton (1966, p. 19) summarises problems of uncertainty and information played out in communications:

"It was found…in one particular case study that each time a design decision was taken, it set in train a chain of consequences which could and

did cause the initial decision to be changed, a clear example of how decisions and actions depend on one another. Since the full implications of any decision or action can seldom if ever be forecast with absolute accuracy, a communications system which assumes that they can will simply not work"

Projects may be driven towards their origins in the indeterminacy and diffuseness of design at the professional and commercial interface, especially susceptible to value conflicts and environmental instability. This is 'reverse time compression': contingencies stack up against schedules (Wild, 2003b). External, shifting social forces and conservative ideologies acting in fragmented project role systems transformed (Higgin & Jessop, 1963) serial into reciprocal interdependence. This reflects tensions between information, uncertainty, and norms of rationality. Pooled, serial, and reciprocal interdependence require standardisation, planning, and mutual adjustment. Each contains the others, implying increasing costs of coordination and time. The most formally efficient structure works back from reciprocal to pooled interdependence (Thompson, 1967). A valid operational decision sequence implied comprehensive attention and feedback (Crichton, 1966). Computer metaphors assumed serial interdependence, requiring disavowal in the face of tacit coordination (Stringer, 1967), that is 'adaptive functions'. Such organisational pluralism required attention to a:

"…sociology of values, or perhaps a calculus of values, which is more than just experiential…the connections between systems must be realised in terms which are categorically different from those applying within systems. They relate to the value systems of the individuals and of the culture…any preference ordering between systems (which must be a moral ordering) has to be in accordance with fundamentally different criteria from those which obtain within systems (which can be a technical ordering)." (Burns, 1966, p. 248)

Bresnen (1991) demonstrates project integration, attained through contingent alignment of a client interest, seeking allies in a context of shifting client roles with the strategy of a management contractor. At the temporal and organisational boundary of design and contracting to which TIHR researchers attached importance, an alignment of values occurred. It was sufficient to steer the project to completion, confirming the TIHR focus on optimisation through this route. Strategic intent was reflected in project staffing by the contractor and client attention at board level. Management contracting was innovative, requiring new roles and behaviour including re-negotiation of previously adversarial relationships. This led to knowledge exchange in a re-design imposed by a budget cut. Despite tensions, the contextual organisational features facilitated collaboration.

Management contracting emerged after the BICRP. Higgin and Jessop (1963) recognised, in relation to the 'package deal', that procurement method is contingent on a wider envelope of accountability. Techniques are insufficient onto themselves, requiring conditions of stability to work (Beardsworth, Keil, Bresnen, & Bryman, 1988; BICRP Archives, 18 August 1964). Strategic choice - evolved from the BICRP (Friend, 1997) - reflects structured exploration of uncertainties over environments, governing values, and information. Green (2001) argues for this, deconstructing value and risk management, which:

"…do not have any meaning in isolation of the way they are enacted and people enact value management in many different ways. There is no established causal link between the use of value management and a resulting better product…Furthermore there is no consensus on which techniques constitute value management."

Uncertainty and information underpin transaction cost economics (Winch, 1989, 2000, 2001). Rationality and efficiency lie in reduction through hierarchy or markets of information costs. Uncertainty lies in information processing capacity and bounded rationality. Parties to transactions experience different levels of information. Computational difficulties around configurations and interactions in complex problem areas generate uncertainty. The coordination costs of reciprocal interdependence are equivalent to information costs in transaction cost economics (Clark, 2000). Opportunism, driven by self-interest in a fragmented system (Higgin & Jessop, 1963) and the effects of impacted information, are experienced as different uncertainties and communication difficulties.

CONSTRUCTION, SITUATIONS AND REFLECTIVE PRACTICE

Construction is a world of potential situations (Wild, 2004) characterised by complexity, instability, uncertainty, uniqueness, and value conflict (Schon, 1983):

"...the presence of a great number of organisational interests creates a pull towards underboundedness within construction projects whose teams rarely attain stability and this must be recognised as their normal condition." (Boyd & Wild, 1999)

Bresnen (1991) exemplifies non-emergence of a situation as strategic intents fortuitously converged into collaboration. Different interorganisational and power dynamics, including the treatment of subcontractors, facilitated communications and knowledge exchange.

Sub-contracting and indirect management induce a game of wider discretion and instability due to unfamiliarity of people. Implicit strategies reduce uncertainty from project transience affecting power dynamics, surveillance, and performance expectations. Long-term networks with teams of transferable, subcontracted core workers buttress market relationships improving performance and quality. Market variations influence power and dependence. Problems of time and unpredictable activity inhibit management continuity. Spatial constraints clash with parallel events in critical paths inducing a conflicted, improvised production process. Time compression, which concentrates activities more densely into limited space, induces directive management. Roles, authority, and the expectations of site managers are clear in a fragile environment at the mercy of the weather, deliveries, labour and information problems, and accommodating multiple demands in temporally limited contexts of short-termism, a fragmented division of labour and subcontracting; pressures from the client, firm, and the value of the job are also considered (Beardsworth, Keil, Bresnen, & Bryman, 1988).

Construction as a system of Situations (Wild, 2004) requires the judgements of practitioners in constructing and setting problems as a condition for problem solving (Schon, 1983). This counters the recursive drift of managerial solutions into technical rationality, which:

"…responds to Situations through: selective inattention, simplification for situational control and…residual categories…the Reflective Practitioner proceeds through: Appreciative Systems; Over-arching Theories; Role Frames and Media, Languages and Repertoires." (Boyd & Wild, 1999)

Expert consultancy frequently replicates prepackaged (Mumford, 1980) techniques dependent on stability (BICRP Archives, 18 August 1964) and susceptible to institutionalised fragmentation (Wild, 2001). Appreciative Systems (Vickers, 1965) meld judgements of facts and values, returning to the sociology of values; assimilating socio-technical theory to Schon (1983), given technological change as a source of instability (Schon, 1971) and transaction cost economics given problems of uncertainty and information.

CONSTRUCTION, THE TACIT ORDER AND KNOWLEDGE MANAGEMENT

Construction is striking in its cohesive fragmentation (Wild, 2002a, 2002b, 2001) and recalcitrance (Reed, 1989) to official reform efforts. It is a precarious social field, "…constrained…to systemic reproduction…" (Archer, 1995) in which "...conflict may be both endemic and intense…without causing any basic structural change" (Lockwood, 1964, p. 249).

Tacit coordination (Stringer, 1967), a distinctive organising process, involves knowledge exchange, and a 'negotiated order' between roles with a limited time of service to a project.

TIHR metaphors of 'computer logic' (BICRP Archives, Research Committee, 18 November 1963) anticipate the use of IT in knowledge management. Techniques of exploration are emphasised to provide optimisation models. This 1960s discourse did not offer discursive penetration (Clark, 2000) of the shifting complexities of construction. Skills in improvising industry linkages and technology fusion generate opacity in the project. This:

"...defines ad hoc whatever supply of services, finance, information and products are possible and necessary…the project induces its own demand chain, its needs and resources, its own process and consequential processes and its own specific organisation…dominance of the project changes ideas about how we organise highly responsive networks of skills, where we locate research and development effort, on what we focus for productivity improvements...It all gives renewed significance to Hillebrandt's potent and fundamental research question: What do we mean by the capacity of construction?" (Groak, 1994)

There are no intrinsic reasons for supposing that appreciation of construction is more easily attained today. Knowledge management is sophisticated, but construction is more complex than in the 1960s, implying the importance of the tacit order as theories-in-use (Argyris & Schon, 1974). Client experience is critical (Atkins & Wild, 2000; Sabbagh 2000). Why should a client, who has never procured construction previously, see knowledge management as a strategy for reducing his uncertainty about the services offered? "How often does a client find that had he known as much at the beginning of a project as he knows at the end, he would have made quite different decisions?" (Higgin & Jessop, 1963 p. 75).

Post-war reports on British construction reflect a template (Wild, 2004) of problems and rational managerial solutions backed by uncritical research (Connaughton, 2000). Until 1963 they lacked an analytical framework for the wider context of construction operations "…and had not been able to do more than canvass best opinion and agree [to] general precepts on that basis" (Higgin & Jessop, 1963 p. 35).

Policy is always pursuing a shifting, complex, and opaque world. An impressive array of client and public resources backs present attempts at construction 'reform'. The slow response to current initiatives (Murray, 2003) echoes the BICRP. Aylwyn Lewis, BICRP Secretary, wrote to the Research Committee chairman (1 July 1965):

"…I do not think that I have really changed the two basic views with which I started the Project. These were:

1. *that a combination of sociology and operational research was necessary to tackle the problems of communication between the*

autonomous units that make up the building team;

2. *that change in these relationships would only come about in a controlled manner if the research was integrated with a representative but progressive cross-section of the industry who would sponsor and promote its findings." (BICRP Archives)*

Construction apparently replicated the finite capacity for change of organisations (Burns, 1966) exacerbated by production as projects. Crichton (1966) argued that this stability had advantages but changed too slowly for 'modern' needs. Post-war reports (Murray & Langford, 2003) reflect a treadmill of societal impatience (Higgin & Jessop, 1963) and political criticism, a reflexive, double-edged rhetoric of modernisation as its own theme (Beck, 1986) with proliferating change and research agendas. C.E.D. (known as Bertie - BICRP Archives) Wooster, Director of Building Management, Ministry of Public Building and Works, exemplifies this rhetoric:

"To the extent that society is not satisfied with the performance of the industry (already overloaded by about 10 per cent, and who is satisfied with our buildings and towns?), and to the extent that the industry does not match up to the task facing it, in the next ten years, it is failing to meet its objectives; and the failure can only be due to inadequate resources or mis-application of those we have." (Wooster, 1964)

Yet technology fusion (Groak, 1994) implies a capacity for innovation despite the apparent disorganisation of construction. Does this enable change by the tacit transmission of ideas and practices? Does knowledge require formalisation in a managerial system to be made effective? There had been the:

"…remarkable recovery of the building materials…and the construction industries from the war period …their flexibility in meeting new demands on their services in the past fifteen years; the introduction of new materials, increased mechanisation and new techniques; the steady rise in output, and the avoidance of major industrial disputes." (Emmerson, 1962, p. 4)

Does this imply interaction of organisational conservatism, misinterpreted as fragmentation, with technical innovation and tacit R&D inducing disjointed incrementalism (Hirschman & Lindblom, 1962) in projects? In this world taken for granted is innovation and learning denied by 'assumptions of ordinariness' (Trist et al., 1990)? Are paradoxes resolved as mutual adjustment, partly driven by power? Concurrently with BI-CRP there were strikes on the Horseferry Road and Barbican projects. Variations and instability in design provoked disputes over incentive pay, earnings, and related areas (Clegg, 1972). Is this also the metropolitan leading edge?

CONSTRUCTION IN SOCIETY AND SOCIETY IN CONSTRUCTION

"We have…been surprised at the long list of the sorts of people with whom communications, usually of a consulting nature, will be undertaken - chemists, physicists, engineers of all kinds, doctors, financiers, sociologists, other clients, meteorologists, and many others." (Higgin & Jessop, 1963, p.18)

Briefing reveals the socio-technical complexity of buildings. Design intensity (Clark, 2000) is a source of potential uncertainty, instability, and value conflicts in a process, which quickly attains the character of an extensive conference of both sides. A requirement for optimisation emerges here and later in construction from sources related to the client, whose complexity was poorly appreciated. Construction failed to account for and was impatient with such social forces. A general awareness and a capacity to engage with the client, developing appropriate techniques to deal with interdependent decisions, were required. Internal diversity implied an unusually wide range of interests, institutionally conditioned by uncertainty, including that from other projects, creating an ideal context for conflict and intrinsic difficulties for reforms. The system partly determined the behaviour of all the parties (Crichton, 1966).

Schon (1971) provides a comparison. In 1963 the U.S. Government focussed on 'backward' industries, whose R&D lagged behind their contribution to GNP and were composed of a few large firms and lots of small ones, low profit margins, and little investment in technology. American construction was considered fragmented. Only $1 million had been spent on product development in 1962. The report concluded that the government should stimulate building research. The dynamic conservatism of the industry, as an organised constituency, killed off a proposed public R&D programme. The proposals had clarified the networks of a complex coalition of shared interests, livelihoods, and a 'theory-in-use' (Argyris & Schon, 1974) relating prevailing technologies to individual and collective values. Without a clearly visualised future stable state, the existing system would have to be pulled apart. This is a view of construction as embedded (Clark, 2000) in society. London is a dynamic construction forcing-house (Ackroyd, 2001), explaining the metropolitan character of the 'progressive cross section'. Construction reform without public participation would lack viability:

"…no single characteristic…will be appropriate to measure the efficiency of a building process. We must measure the total performance by a yardstick of total performances…In the final analysis the community only gets the building industry it deserves. Therefore the client/user/community complex also needs to associate itself with the industry in…coordinating…further large-scale research." (Crichton, 1966, pp. 59 & 61)

In the context of a politically driven impatience (Higgin & Jessop, 1963) with a wider stagnation, could society attain a viable consensus over the opaque social field of construction disturbed by national planning and political change? (Wild, 2002a, 2002b). The Barbican and Horseferry Road disputes reflected, partly, the disruption of "what sometimes passes for consensus in Britain…the artefact of a tenuous balance of opposing forces" (Birnbaum, 1962, p. 283).

A similar sociological concern pervades Boyd and Wild (1999). They assert the equivalence of construction and organisation development. OD involves those who do the work in diagnosing the efficiency and effectiveness of their work organisation, rather than offering a recipe or formula (French & Bell, 1990). The organisational iceberg reflects a Pareto ratio of the 'formal' and 'informal'. Construction is multi-organisational (Stringer, 1967). The multiple interactions of multiple 'informal systems' imply construction as a 'sociological iceberg' explaining self-induced uncertainty (Stringer, 1967). Beyond this there are objections to the formal-informal systems dichotomy. TIHR researchers (BICRP Archives, 18 August 1964) suggested a synthesis of these, transcending their own assumptions. However:

"…the informal system has served as a receptacle for (matters) which were seen as irrelevant to the formal organisation or incompatible with its purpose…all that had defeated Taylorite attempts at human engineering…." (Burns, 1966, p. 235)

Managers and workers devise multiple interpretations of an organisation and institute mutually sustained working relationships. Multiple organisational goals emerge and a "…different conceptual framework, from that of the formal organisation of management…" (Burns 1966, p. 235).

Rational models imply instrumentalism towards goals and valued future states. This reflects misplaced concreteness and ignores the problem of reconciling the unity of aims in the model with the empirical fact of disunity of purpose within organisations (Burns, 1966). Does under-boundedness (Boyd & Wild, 1999) to society proliferate disunities of purpose in projects? Can demand side conditions of power and organisation insulate the project? Tate Modern (Sabbagh, 2000) was doubly insulated. Stewardship for a protected building avoided internal value conflicts over aesthetics, leaving the 'technical' problem of optimising display space. The clients' establishment constitution and experience rendered the project hegemonic (Lukes, 1974), structuring information to set aside bounded rationality, align values around project prestige, and suppress information uncertainty. Such concerns provoked Green (2001) to comment on one of the many proliferating boundaries (Wild, 2002c) between construction and society:

"The process of risk management…depends… upon…the need to maintain a viable political consistency within the client organisation. It is notable that there is as yet no framework that embraces both the notion of technical risk with the less tangible uncertainties that characterise the strategic interface between construction projects and client organisations…."

CONCLUSION (AND A PROVOCATION TO A DEBATE)

"…Is it somehow 'natural' that we appear to find the challenge of solving new problems (or of finding apparently fresh solutions) more seductive than plugging away at the old?" (Connaughton, 2000)

The BICRP anticipated the discourse of knowledge management. Will this permit us to learn more about construction? Is this relevant when the problem may be to learn to manage projects differently? Successes will be presented. Will they confirm that a new perspective induces these until it reaches its limits, as did socio-technical ideas when exposed to construction in the 1960s?

The diffuseness of construction requires a significant tacit order. Knowledge management assumes this is accessible to structured inquiry (Clark, 2000). Are there constraints such as spatio-temporal fragmentation (Wild, 2003a) appreciable from socio-technical research? Does integration require contextual conditions not readily present in the under-bounded (Boyd & Wild, 1999) world of construction? Is knowledge management a 'fresh solution', a renewed combination of sociology and operational research, an old wine poured in a new bottle by a new generation of 'experts'? As 'technique' is it as dependent on stability as other formal methods reported in the BICRP? Can it operate undisturbed by existing strategic recipes, networks, professional values, and personal constructs (Boyd & Wild, 1996)? The BICRP was assimilated to a construction project. Why should or how could knowledge management avoid being drawn into the turbulence and communication difficulties of construction like previous initiatives? Will it be routinised as a technique and fall away in effectiveness as construction is still improvised to completion in a project-based world of intrinsic unmanageability? (Wild, 2004, 2002c).

"If so many have preached the unification of the UK construction industry for so long with so little effect, how could we succeed? Is it indeed a lost cause? Have we been barking up the wrong tree all these years? Is it our destiny to build a fragmented future on a fragmented past and make the best of it?" (Andrews & Darbyshire, 1993, p. 37)

Andrews (1984) and Connaughton (2000) on the managerial - the socio - and Koskela (2003) on production - the technical side of the socio-technical equation - replicate Darbyshire's statement from June 1965 concerning the need for:

- "…a general theory of the organisation and management of construction." (Andrews, 1984)
- "…consistency and coherence in the development and accumulation of knowledge necessary for a useful, coherent theory of construction management…." (Connaughton, 2000)
- "…integrated prescription for construction renewal…Our present theoretical understanding is not necessarily solid enough. We need to develop fully the theoretical foundation or first principles of production in general and of construction especially." (Koskela, 2003)

In the problem of 'society in construction and construction in society', expectations outrun the capacity of construction to deliver, generating an eternal performance gap. Putative theories and methodologies of reform are drawn into the turbulence of construction as a cohesively fragmented social field. Knowledge management awaits its own partial demise. In contradistinction to 'integration', a theory of improvisation may explain the production of the built environment in under-bounded project worlds of non-recurrence and re-configuration.

Post-war reports (Murray & Langford, 2003) are symptoms of the instability and indeterminacy of construction. Hence the focus of management attention and research can be shifted from control to the steering of projects as negotiated orders (Reed, 1989). The difficulties of construction can be grounded on the qualities sought from the constructed world, which people inhabit, work in, and pass through. What is constructed and how is ideological. Powerful and cohesive clients get the buildings they want. Society, indifferent to other aspirations, gets the constructed order it deserves. This refracts what is there; what can be built; what we are prepared to pay for, and the resulting constraints upon us. In principle, construction is impossible, given the potential for value conflicts in and around the process. Dilemmas are resolved tacitly within the project. Within a mobile, masculine confraternity creativity is re/de-constructed as yarns. That projects are completed is a profound tribute to those who do the work, both because and in spite of the situations within which they labour. This, the real achievement of construction, truly constitutes the management of knowledge.

PRACTICAL TIPS AND LESSONS LEARNED

Construction projects are streams of disturbances punctuated by crises and occasional episodes of calm. The skills of project management (Boyd & Wild, 1999) include:

- Coping with discontinuity at start up
- Eliciting organising behaviour: consulting to the uncertainty in the client
- "Est": working in left- and right-brain modes
- Handling network centrality
- Holding and sharing power, laterally and vertically
- Negotiating and re-negotiating: contracts, roles, and expectations
- Skills of collaboration: managing the uncertainty in the project
- Spanning boundaries
- Steering through complexity
- Working with procedures as diagnostic devices

ACKNOWLEDGMENT

This chapter is dedicated to Professor John Andrews who, in the last two years of his life, took an active interest in my attempt to re-interpret construction. He died in November 2003.

Section 2
Knowledge Management:
Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures and knowledge management frameworks to provide the reader with a comprehensive understanding of the emerging technological developments within the field of knowledge management while offering research fundamentals imperative to the understanding of research processes within the knowledge management discipline. On a more global scale, many chapters explore cultural and infrastructural issues related to the management of knowledge in developing countries. From basic designs to abstract developments, this section serves to expand the reaches of development and design technologies within the knowledge management community. Included in this section are 45 contributions from researchers throughout the world on the topic of information development and knowledge sharing within the information science and technology field.

Chapter 2.1
IT in Knowledge Management

Petter Gottschalk
Norwegian School of Management BI, Norway

As we trace the evolution of computing technologies in business, we can observe their changing level of organizational impact. The first level of impact was at the point work got done, and transactions (e.g., orders, deposits, reservations) took place. The inflexible, centralized mainframe allowed for little more than massive number crunching, commonly known as electronic data processing. Organizations became data heavy at the bottom, and data management systems were used to keep the data in check. Later, the management information systems were used to aggregate data into useful information reports, often prescheduled, for the control level of the organization: people who were making sure that organizational resources like personnel, money, and physical goods were being deployed efficiently. As information technology (IT) and information systems (IS) started to facilitate data and information overflow, and corporate attention became a scarce resource, the concept of knowledge emerged as a particularly high-value form of information (Grover & Davenport, 2001).

Information technology can play an important role in successful knowledge management initiatives. However, the concept of coding and transmitting knowledge in organizations is not new: training and employee development programs, organizational policies, routines, procedures, reports, and manuals have served this function for many years. What is new and exciting in the knowledge management area is the potential for using modern information technology (e.g., the Internet, intranets, extranets, browsers, data warehouses, data filters, software agents, expert systems) to support knowledge creation, sharing, and exchange in an organization and between organizations. Modern information technology can collect, systematize, structure, store, combine, distribute, and present information of value to knowledge workers (Nahapiet & Ghoshal, 1998).

According to Davenport and Prusak (1998), more and more companies have instituted knowledge repositories that support such diverse types of knowledge as best practices, lessons learned, product development knowledge, customer knowledge, human resource management knowledge, and methods-based knowledge. Groupware and intranet-based technologies have become standard knowledge infrastructures. A new set of professional job titles—the knowledge manager, the chief knowledge officer (CKO), the knowledge coordinator, and the knowledge-network facilitator—affirms the widespread legitimacy that knowledge management has earned in the corporate world.

The low cost of computers and networks has created a potential infrastructure for knowledge sharing and opened up important knowledge management opportunities. The computational power, as such, has little relevance to knowledge work, but the communication and storage capabilities of networked computers make it an important enabler of effective knowledge work. Through e-mail, groupware, the Internet, and intranets, computers and networks can point to people with knowledge, and connect people who need to share knowledge independent of time and place.

For example, electronic networks of practice are computer-mediated discussion forums focused on problems of practice that enable individuals to exchange advice and ideas with others, based on common interests. Electronic networks make it possible to share information quickly, globally, and with large numbers of individuals. Electronic networks that focus on knowledge exchange frequently emerge in fields where the pace of technological change requires access to knowledge unavailable within any single organization (Wasko & Faraj, 2005).

In the knowledge-based view of the firm, knowledge is the foundation of a firm's competitive advantage and, ultimately, the primary driver of a firm's value. Inherently, however, knowledge resides within individuals and, more specifically, in the employees who create, recognize, archive, access, and apply knowledge in carrying out their tasks. Consequently, the movement of knowledge across individual and organizational boundaries, into and from repositories, and into organizational routines and practices is ultimately dependent on employees' knowledge sharing behaviors (Bock, Zmud, & Kim, 2005).

According to Grover and Davenport (2001), most knowledge management projects in organizations involve the use of information technology. Such projects fall into relatively few categories and types, each of which has a key objective. Although it is possible, and even desirable, to combine multiple objectives in a single project, this was not normally observed in a study of 31 knowledge management projects in 1997 (Davenport & Prusak, 1998). Since that time, it is possible that projects have matured and have taken on more ambitious collections of objectives.

Regardless of definition of knowledge as the highest value of content in a continuum starting at data, encompassing information, and ending at knowledge, knowledge managers often take a highly inclusive approach to the content with which they deal. In practice, what companies actually manage under the banner of knowledge management is a mix of knowledge, information, and unrefined data—in short, whatever anyone finds that is useful and easy to store in an electronic repository. In the case of data and information, however, there are often attempts to add more value and create knowledge. This transformation might involve the addition of insight, experience, context, interpretation, or the myriad of other activities in which human brains specialize (Grover & Davenport, 2001).

Identifying, nurturing, and harvesting knowledge is a principal concern in the information society and the knowledge age. Effective use of knowledge-facilitating tools and techniques is critical, and a number of computational tools have been developed. While numerous techniques are available, it remains difficult to analyze or compare the specific tools. In part, this is because knowledge management is a young discipline. The arena is evolving rapidly as more people enter the fray and encounter new problems (Housel & Bell, 2001).

In addition, new technologies support applications that were impossible before. Moreover, the multidisciplinary character of knowledge management combines several disciplines including business and management, computer science, cybernetics, and philosophy. Each of these fields may lay claim to the study of knowledge management, and the field is frequently defined so broadly that anything can be incorporated. Finally, it is difficult to make sense of the many tools available. It is not difficult to perform a search to produce a list of more than 100 software providers. Each of the software packages employ unique visions and aims to capture its share of the market (Housel & Bell, 2001).

Ward and Peppard (2002) find that there are two dominant and contrasting views of IS/IT in knowledge management: the engineering perspective, and the social process perspective. The engineering perspective views knowledge management as a technology process. Many organizations have taken this approach in managing knowledge, believing that it is concerned with managing pieces of intellectual capital. Driving this view is the view that knowledge can be codified and stored; in essence that knowledge is explicit knowledge and therefore, is little more than information.

The alternative view is that knowledge is a social process. As such, it asserts that knowledge resides in people's heads and that it is tacit. As such, it cannot be easily codified and only revealed through its application. As tacit knowledge cannot be directly transferred from person to person, its acquisition occurs only through practice. Consequently, its transfer between people is slow, costly, and uncertain. Technology, within this perspective, can only support the context of knowledge work. It has been argued that IT-based systems used to support knowledge management can only be of benefit if used to support the development and communication of human meaning. One reason for the failure of IT in some knowledge management initiatives is that the designers of the knowledge management systems fail to understand the situation and work practices of the users and the complex human processes involved in work.

While technology can be used with knowledge management initiatives, Ward and Peppard (2002) argue that it should never be the first step. Knowledge management is, to them, primarily a human and process issue. Once these two aspects have been addressed, then the created processes are usually very amenable to being supported and enhanced by the use of technology.

What, then, is knowledge management technology? According to Davenport and Prusak (1998), the concept of knowledge management technology is not only broad, but also a bit slippery to define. Some infrastructure technology that we do not ordinarily think of in this category can be useful in facilitating knowledge management. Examples are videoconferencing and the telephone. Both of these technologies do not capture or distribute structured knowledge, but they are quite effective at enabling people to transfer tacit knowledge.

Our focus here, however, is on technology that captures, stores, and distributes structured knowledge for use by people. The goal of these technologies is to take knowledge that exists in human heads and partly in paper documents, and make it widely available throughout an organization. Similarly, Alavi and Leidner (2001) argue that information systems designed to support knowledge in organizations may not appear radically different from other forms of IT support, but will be geared toward enabling users to assign meaning to information and to capture some of their knowledge in information. Therefore, the concept of knowledge management technology in this book is less concerned with any degree of technology sophistication, and more concerned with the usefulness in performing knowledge work in organizations and between organizations.

Moffett and McAdam (2003) illustrate the variety of knowledge management technology tools by distinguishing between collaborative tools, content management, and business intelligence. Collaborative tools include groupware technology, meeting support systems, knowledge directories, and intranets/extranets. Content management includes the Internet, agents and filters, electronic publishing systems, document management systems, and office automation systems. Business intelligence includes data warehousing, decision support systems, knowledge-based systems, and workflow systems.

In addition to technologies, we also present techniques in this book. The term technique is defined as a set of precisely described procedures for achieving a standard task (Kettinger, Teng, & Guha, 1997).

KNOWLEDGE MANAGEMENT PROCESSES

Alavi and Leidner (2001) have developed a systematic framework that will be used to analyze and discuss the potential role of information technology in knowledge management. According to this framework, organizations consist of four sets of socially enacted knowledge processes: (1) creation (also referred to as construction), (2) storage and retrieval, (3) transfer, and (4) application. The knowledge-based view of the firm represents, here, both the cognitive and social nature of organizational knowledge, and its embodiment in the individual's cognition and practices as well as the collective (i.e., organizational) practices and culture. These processes do not represent a monolithic set of activities, but an interconnected and intertwined set of activities.

Knowledge Creation

Organizational knowledge creation involves developing new content or replacing existing content within the organization's tacit and explicit knowledge. Through social and collaborative processes as well as individual's cognitive processes (e.g., reflection), knowledge is created. The model developed by Nonaka et al. (Nonaka, Toyama, & Konno, 2000) involving SECI, ba, and knowledge assets, views organizational knowledge creation as involving a continual interplay between the tacit and explicit dimensions of knowledge, and a growing spiral flow as knowledge moves through individual, group, and organizational levels. Four modes of knowledge creation have been identified: socialization, externalization, internalization, and combination (SECI), and these modes occur at "ba," which means place.

Nonaka et al. (2000) suggest that the essential question of knowledge creation is establishing an organization's ba, defined as a commonplace or space for creating knowledge. Four types of ba corresponding to the four modes of knowledge creation are identified:

1. Originating ba
2. Interacting ba,
3. Cyber ba
4. Exercising ba

Originating ba entails the socialization mode of knowledge creation, and is the ba from which the organizational knowledge creation process begins. Originating ba is a common place in which individuals share experiences primarily through face-to-face interactions, and by being at the same place at the same time. Interacting ba is associated with the externalization mode of knowledge creation, and refers to a space where tacit knowledge is converted to explicit knowledge and shared among individuals through the process of dialogue and collaboration. Cyber ba refers to a virtual space of interaction, and corresponds to the combination mode of knowledge creation. Finally, exercising ba involves the conversion of explicit to tacit knowledge through the internalization process. Thus, exercising ba involves the conversion of explicit to tacit knowledge through the internalization process.

Understanding the characteristics of various ba and the relationship with the modes of knowledge creation is important to enhancing organizational knowledge creation. For example, the use of IT capabilities in cyber ba is advocated to enhance the efficiency of the combination mode of knowledge creation. Data warehousing and data mining, document management systems, software agents, and intranets may be of great value in cyber ba. Considering the flexibility of modern IT, other forms of organizational ba and the corresponding modes of knowledge creation can be enhanced through the use of various forms of information systems. For example, information systems designed for support or collaboration, coordination, and communication processes, as a component of the interacting ba, can facilitate teamwork and thereby, increase an individual's contact with other individuals.

Electronic mail and group support systems have the potential of increasing the number of weak ties in organizations. This, in turn, can accelerate the growth of knowledge creation. Intranets enable exposure to greater amounts of online organizational information, both horizontally and vertically, than may previously have been the case. As the level of information exposure increases, the internalization mode of knowledge creation, wherein individuals make observations and interpretations of information that result in new individual tacit knowledge, may increase. In this role, an intranet can support individual learning (conversion of explicit knowledge to personal tacit knowledge) through provision of capabilities such as computer simulation (to support learning-by-doing) and smart software tutors.

Computer-mediated communication may increase the quality of knowledge creation by enabling a forum for constructing and sharing beliefs, for confirming consensual interpretation, and for allowing expression of new ideas. By providing an extended field of interaction among organizational members for sharing ideas and perspectives, and for establishing dialog, information systems may enable individuals to arrive at new insights and/or more accurate interpretations than if left to decipher information on their own.

Although most information repositories serve a single function, it is increasingly common for companies to construct an internal "portal" so that employees can access multiple different repositories and sources from one screen. It is also possible and increasingly popular for repositories to contain not only information, but also pointers to experts within the organization on key knowledge topics. It is also feasible to combine stored information with lists of the individuals who contributed the knowledge and could provide more detail or background on it (Grover & Davenport, 2001).

According to Grover and Davenport (2001), firms increasingly view attempts to transform raw data into usable knowledge as part of their knowledge management initiatives. These approaches typically involve isolating data in a separate "warehouse" for easier access, and the use of statistical analysis or data mining and visualization tools. Since their goal is to create data-derived knowledge, they are increasingly addressed as a part of knowledge management. Some vendors have already begun to introduce e-commerce tools. They serve to customize the menu of available knowledge to individual customers, allowing sampling of information before buying and carrying out sales transactions for knowledge purchases. Online legal services are typical examples where clients can sample legal information before buying lawyer's time.

For knowledge creation, there is currently idea-generation software emerging. Idea-generation software is designed to help stimulate a single user or a group to produce new ideas, options, and choices. The user does all the work, but the software encourages and pushes, something like a personal trainer. Although idea-generation software is relatively new, there are several packages on the market. IdeaFisher, for example, has an associative lexicon of the English language that cross-references words and phrases. These associative links, based on analogies and metaphors, make it easy for the user to be fed words related to a given theme. Some software packages use questions to prompt the user toward new, unexplored patterns of thought. This helps users to break out of cyclical thinking patterns and conquer mental blocks.

Knowledge Storage and Retrieval

According to Alavi and Leidner (2001), empirical studies have shown that while organizations create knowledge and learn, they also forget (i.e., do not remember or lose track of the acquired knowledge). Thus, the storage, organization, and retrieval of organizational knowledge, also referred to as organizational memory, constitute an important aspect of effective organizational knowledge management. Organizational memory includes knowledge residing in various component forms, including written documentation, structured information stored in electronic databases, codified human knowledge stored in expert systems, documented organizational procedures and processes, and tacit knowledge acquired by individuals and networks of individuals.

Advanced computer storage technology and sophisticated retrieval techniques, such as query languages, multimedia databases, and database management systems, can be effective tools in enhancing organizational memory. These tools increase the speed at which organizational memory can be accessed.

Groupware enables organizations to create intraorganizational memory in the form of both structured and unstructured information, and to share this memory across time and space. IT can play an important role in the enhancement and expansion of both semantic and episodic organizational memory. Semantic memory refers to general, explicit, and articulated knowledge, whereas episodic memory refers to context-specific and situated knowledge. Document management technology allows knowledge of an organization's past, often dispersed among a variety of retention facilities, to be effectively stored and made accessible. Drawing on these technologies, most consulting firms have created semantic memories by developing vast repositories of knowledge about customers, projects, competition, and the industries they serve.

Grover and Davenport (2001) found that in Western organizations, by far the most common objective of knowledge management projects involves some sort of knowledge repository. The objective of this type of project is to capture knowledge for later and broader access by others within the same organization. Common repository technologies include Lotus Notes, Web-based intranets, and Microsoft's Exchange, supplemented by search engines, document management tools, and other tools that allow editing and access. The repositories typically contain a specific type of information to represent knowledge for a particular business function or process, such as:

- "Best practices" information within a quality or business process management function
- Information for sales purposes involving products, markets, and customers
- Lessons learned in projects or product development efforts
- Information around implementation of information systems
- Competitive intelligence for strategy and planning functions
- "Learning histories" or records of experience with a new corporate direction or approach

The mechanical generation of databases, Web sites, and systems that process data are good, and have the potential to take us to a higher plane in the organization, help us understand workflows better, and help us deal with organizational pathologies and problems. The data-to-information transition often involves a low-level mechanical process that is well within the domain of contemporary information technologies, though humans are helpful in this transition as well. This information could exist in different forms throughout the organization and could even form the basis of competitive advantage or information products. For example, provision of information to customers about their order or shipment status is something that companies like Baxter and FedEx have been doing for years. But unlike knowledge, mechanically supplied information cannot be the source of sustained competitive advantage, particularly when the architectures on which it is based are becoming more open and omnipresent .

IT in knowledge management can be used to store various kinds of information. For example, information about processes, procedures, forecasts, cases, and patents in the form of working documents, descriptions, and reports can be stored in knowledge management systems. TietoEnator, a Scandinavian consulting firm, has a knowledge base where they store methods, techniques, notes, concepts, best practices, presentations, components, references, guidelines, quality instructions, process descriptions, routines, strategies, and CVs for all consultants in the firm (Halvorsen & Nguyen, 1999).

Knowledge retrieval can find support in content management and information extraction technology, which represents a group of techniques for managing and extracting knowledge from documents, ultimately delivering a semantic meaning for decision makers or learners alike. This type of computer applications is targeted at capturing and extracting the content of free-text documents. There are several tasks that fall within the scope of content management and information extraction (Wang, Hjelmervik, & Bremdal, 2001):

- Abstracting and summarizing. This task aims at delivering shorter, informative representations of larger (sets of) documents.
- Visualization. Documents can often be visualized according to the concepts and relationships that play a role. Visualization can be either in an introspective manner, or using some reference model/view of a specific topic.
- Comparison and search. This task finds semantically similar pieces of information.
- Indexing and classification. This considers (partial) texts, usually according to certain categories.
- Translation. Context-driven translation of texts from one language into another. Language translation has proven to be highly context specific, even among closely related languages. Some kind of semantic representation of meaning is needed in order to be able to make good translations.
- Question formulation and query answering. This is a task in human-computer interaction systems.
- Extraction of information. This refers to the generation of additional information that is not explicit in the original text. This information can be more or less elaborate.

A group of computational techniques are available to alleviate the burden of these tasks. They include fuzzy technology, neural networks, and expert systems. On a more application-oriented level, there are several approaches that apply one or more of the general techniques. The field is currently very dynamic, and new advances are made continuously. One novel approach is the CORPORUM system, to be presented in the section on expert systems.

Knowledge Transfer

Knowledge transfer can be defined as the communication of knowledge from a source so that it is learned and applied by a recipient (Ko, Kirsch, & King, 2005). Knowledge transfer occurs at various levels in an organization: transfer of knowledge between individuals, from individuals to explicit sources, from individuals to groups, between groups, across groups, and from the group to the organization. Considering the distributed nature of organizational cognition, an important process of knowledge management in organizational settings is the transfer of knowledge to locations where it is needed and can be used. However, this is not a simple process in that organizations often do not know what they know, and have weak systems for locating and retrieving knowledge that resides in them. Communication processes and information flows drive knowledge transfer in organizations.

Depending on the completeness or incompleteness of the sender's and the receiver's information sets, there are four representative types of information structure in knowledge transfer according to Lin, Geng, and Whinston (2005): symmetric complete information, sender-advantage asymmetric information, symmetric incomplete information, and receiver-advantage asymmetric information. Lin et al. (2005) found that because of asymmetry and incompleteness, parties seeking knowledge may not be able to identify qualified knowledge providers, and the appropriate experts may fail to be motivated to engage in knowledge transfer.

Knowledge transfer channels can be informal or formal; personal or impersonal. IT can support all four forms of knowledge transfer, but has mostly been applied to informal, impersonal means (such as discussion databases), and formal, impersonal means (such as corporate directories). An innovative use of technology for transfer is use of intelligent agent software to develop interest profiles of organizational members in order to determine which members might be interested recipients of point-to-point electronic messages exchanged among other members. Employing video technologies can also enhance transfer.

IT can increase knowledge transfer by extending the individual's reach beyond the formal communication lines. The search for knowledge sources is usually limited to immediate coworkers in regular and routine contact with the individual. However, individuals are unlikely to encounter new knowledge through their close-knit work networks because individuals in the same clique tend to possess similar information. Moreover, individuals are often unaware of what their cohorts are doing. Thus, expanding the individual's network to more extended, although perhaps weaker connections, is central to the knowledge diffusion process because such networks expose individuals to more new ideas.

Computer networks and electronic bulletin boards and discussion groups create a forum that facilitates contact between the person seeking knowledge and those who may have access to the knowledge. Corporate directories may enable individuals to rapidly locate the individual who has the knowledge that might help them solve a current problem. For example, the primary content of such a system can be a set of expert profiles containing information about the backgrounds, skills, and expertise of individuals who are knowledgeable on various topics. Often such metadata (knowledge about where knowledge resides) proves to be as important as the original knowledge itself. Providing taxonomies or organizational knowledge maps enables individuals to rapidly locate either the knowledge or the individual who has the needed knowledge, more rapidly than would be possible without such IT-based support.

Communication is important in knowledge management because technology provides support for both intraorganizational as well as interorganizational knowledge networks. Knowledge networks need technology in the form of technical infrastructure, communication networks, and a set of information services. Knowledge networks enable knowledge workers to share information from various sources.

Traditional information systems have been of importance to vertical integration for a long time. Both customers and suppliers have been linked to the company through information systems. Only recently has horizontal integration occurred. Knowledge workers in similar businesses cooperate to find optimal solutions for customers. IT has become an important vertical and horizontal interorganizational coordination mechanism. This is not only because of the availability of broadband and standardized protocols. It is also caused by falling prices for communication services, and by software programs' ability to coordinate functions between firms.

One way to reduce problems stemming from paper work flow is to employ document-imaging systems. Document imaging systems are systems that convert paper documents and images into digital form so they can be stored and accessed by a computer. Once the document has been stored electronically, it can be immediately retrieved and shared with others. An imaging system requires indexes that allow users to identify and retrieve a document when needed (Laudon & Laudon, 2005).

Knowledge Application

An important aspect of the knowledge-based view of the firm is that the source of competitive advantage resides in the application of the knowledge rather than in the knowledge itself. Information technology can support knowledge application by embedding knowledge into organizational routines. Procedures that are culture-bound can be embedded into IT so that the systems themselves become examples of organizational norms. An example according to Alavi and Leidner (2001) is Mrs. Field's use of systems designed to assist in every decision, from hiring personnel to when to put free samples of cookies out on the table. The system transmits the norms and beliefs held by the head of the company to organizational members.

Technology enforced knowledge application raises a concern that knowledge will continue to be applied after its real usefulness has declined. While the institutionalization of best practices by embedding them into IT might facilitate efficient handling of routine, linear, and predictable situations during stable or incrementally changing environments, when change is radical and discontinuous, there is a persistent need for continual renewal of the basic premises underlying the practices archived in the knowledge repositories. This underscores the need for organizational members to remain attuned to contextual factors and explicitly consider the specific circumstances of the current environment.

Although there are challenges with applying existing knowledge, IT can have a positive influence on knowledge application. IT can enhance knowledge integration and application by facilitating the capture, updating, and accessibility of organizational directives. For example, many organizations are enhancing the ease of access and maintenance of their directives (repair manuals, policies, and standards) by making them available on corporate intranets. This increases the speed at which changes can be applied. Also, organizational units can follow a faster learning curve by accessing the knowledge of other units having gone through similar experiences. Moreover, by increasing the size of individuals' internal social networks, and by increasing the amount of organizational memory available, information technologies allow for organizational knowledge to be applied across time and space.

IT can also enhance the speed of knowledge integration and application by codifying and automating organizational routines. Workflow automation systems are examples of IT applications that reduce the need for communication and coordination, and enable more efficient use of organizational routines through timely and automatic routing of work-related documents, information, rules, and activities. Rule-based expert systems are another means of capturing and enforcing well-specified organizational procedures.

To summarize, Alavi and Leidner (2001) have developed a framework to understand IS/IT in knowledge management processes through the knowledge-based view of the firm. One important implication of this framework is that each of the four knowledge processes of creation, storage and retrieval, transfer, and application can be facilitated by IT:

- Knowledge creation. Examples of supporting information technologies are data mining and learning tools that enable combining new sources of knowledge and just in time learning.
- Knowledge storage and retrieval. Examples of supporting information technologies are electronic bulletin boards, knowledge repositories, and databases that provide support of individual and organizational memory as well as intergroup knowledge access.
- Knowledge transfer. Examples of supporting information technologies are electronic bulletin boards, discussion forums, and knowledge directories that enable more extensive internal network, more available communication channels, and faster access to knowledge sources.
- Knowledge application. Examples of supporting information technologies are expert systems and workflow systems that enable knowledge application in many locations and more rapid application of new knowledge through workflow automation.

KNOWLEDGE MANAGEMENT SYSTEMS

There is no single information system that is able to cover all knowledge management needs in a firm. This is evident from the widespread potential of IT in knowledge management processes. Rather, knowledge management systems (KMS) refer to a class of information systems applied to managing organizational knowledge for use at the individual, group, and organizational level. These systems are IT applications to support and enhance the organizational processes of knowledge creation, storage and retrieval, transfer, and application.

Knowledge management systems can be classified as illustrated in Figure 1. Systems are exemplified along the axis of internal support vs.

Figure 1. Classification of knowledge management systems

Tools	Information	
Tools for external communications such as customer relationship management services	Information for external electronic cooperation such as web-based	**External**
Tools for internal work by knowledge workers	Information for internal work by knowledge workers	**Internal**

external support, and along the axis of technology support vs. content support for knowledge workers. As an example of a knowledge management system, we find customer relationship management (CRM) systems in the upper left quadrant. CRM systems support knowledge exchange between the firm and its customers.

Despite widespread belief that information technology enables knowledge management and knowledge management improves firm performance, researchers have only recently found empirical evidence of these relationships. For example, Tanriverdi (2005) used data from 250 Fortune 1000 firms to provide empirical support for these relationships.

Knowledge management systems are becoming ubiquitous in today's organizations. Knowledge management systems facilitate the efficient and effective sharing of an organization's intellectual resources. To ensure effective usage, a knowledge management system must be designed such that knowledge workers can readily find high-quality content without feeling overwhelmed (Poston & Speier, 2005).

Requirements from Knowledge Management

The critical role of information technology and information systems lies in the ability to support communication, collaboration, and those searching for knowledge, and the ability to enable collaborative learning (Ryu, Kim, Chaudhury, & Rao, 2005). We have already touched on important implications for information systems:

1. Interaction between information and knowledge. Information becomes knowledge when it is combined with experience, interpretation, and reflection. Knowledge becomes information when assigned an explicit representation. Sometimes information exists before knowledge; sometimes knowledge exists before information. One important implication of this two-way direction between knowledge and information is that information systems designed to support knowledge in organizations may not appear radically different from other forms of IT support, but will be geared toward enabling users to assign meaning to information, and to capture some of their knowledge in information (Alavi & Leidner, 2001).
2. Interaction between tacit and explicit knowledge. Tacit and explicit knowledge depend on each other, and they influence each other. The linkage of tacit and explicit knowledge suggests that only individuals with a requisite level of shared knowledge are able to exchange knowledge. They suggest the existence of a shared knowledge space that is required in order for individual A to understand individual B's knowledge. The knowledge space is the underlying overlap in knowledge base of A and B. This overlap is typically tacit knowledge. It may be argued that the greater the shared knowledge space, the less the context needed for individuals to share knowledge within the group and, hence, the higher the value of explicit knowledge. IT is both dependent on the shared knowledge space and an important part of the shared knowledge space. IT is dependent on the shared knowledge space because knowledge workers need to have a common understanding of available information in information systems in the organization. If common understanding is missing, then knowledge workers are unable to make use of information. IT is an important part of the shared knowledge space because information systems make common information available to all knowledge workers in the organization. One important implication of this two-way relationship between knowledge space and information systems is that a minimum knowledge space has to be present, while IT can contribute to growth

in the knowledge space (Alavi & Leidner, 2001).

3. Knowledge management strategy. Efficiency-driven businesses may apply the stock strategy where databases and information systems are important. Effectiveness-driven businesses may apply the flow strategy where information networks are important. Expert-driven businesses may apply the growth strategy where networks of experts, work processes, and learning environments are important (Hansen, Nohria, & Tierney, 1999).
4. Combination in SECI process. The SECI process consists of four knowledge conversion modes. These modes are not equally suited for IT support. Socialization is the process of converting new tacit knowledge to tacit knowledge. This takes place in the human brain. Externalization is the process of converting tacit knowledge to explicit knowledge. The successful conversion of tacit knowledge into explicit knowledge depends on the sequential use of metaphors, analogy, and model. Combination is the process of converting explicit knowledge into more complex and systematic sets of explicit knowledge. Explicit knowledge is collected from inside and outside the organization and then combined, edited, and processed to form new knowledge. The new explicit knowledge is then disseminated among the members of the organization. According to Nonaka et al. (2000), creative use of computerized communication networks and large-scale databases can facilitate this mode of knowledge conversion. When the financial controller collects information from all parts of the organization and puts it together to show the financial health of the organization, that report is new knowledge in the sense that it synthesizes explicit knowledge from many different sources in one context. Finally, internalization in the SECI process converts explicit knowledge into tacit knowledge. Through internalization, explicit knowledge created is shared throughout an organization and converted into tacit knowledge by individuals.
5. Explicit transfer of common knowledge. If management decides to focus on common knowledge as defined by Dixon (2000), knowledge management should focus on the sharing of common knowledge. Common knowledge is shared in the organization using five mechanisms: serial transfer, explicit transfer, tacit transfer, strategic transfer, and expert transfer. Management has to emphasize all five mechanisms for successful sharing and creation of common knowledge. For serial transfer, management has to stimulate meetings and contacts between group members. For explicit transfer, management has to stimulate documentation of work by the previous group. For tacit transfer, management has to stimulate contacts between the two groups. For strategic transfer, management has to identify strategic knowledge and knowledge gaps. For expert transfer, management has to create networks where experts can transfer their knowledge. These five mechanisms are not equally suited for IT support. Explicit transfer seems very well suited for IT support as the knowledge from the other group is transferred explicitly as explicit knowledge in words and numbers, and shared in the form of data, scientific formulae, specifications, manuals, and the like. Expert transfer also seems suited for IT support when generic knowledge is transferred from one individual to another person to enable the person to solve new problems with new methods.
6. Link knowledge to its uses. One of the mistakes in knowledge management presented by Fahey and Prusak (1998) was disentangling knowledge from its uses. A major manifestation of this error is that

knowledge management initiatives become ends in themselves. For example, data warehousing can easily degenerate into technological challenges. The relevance of a data warehouse for decisions and actions gets lost in the turmoil spawned by debates about appropriate data structures.

7. Treat knowledge as an intellectual asset in the economic school. If management decides to follow the economic school of knowledge management, then intellectual capital accounting should be part of the knowledge management system. The knowledge management system should support knowledge markets where knowledge buyers, knowledge sellers, and knowledge brokers can use the system.
8. Treat knowledge as a mutual resource in the organizational school. The potential contribution of IT is linked to the combination of intranets and groupware to connect members and pool their knowledge, both explicit and tacit.
9. Treat knowledge as a strategy in the strategy school. The potential contribution of IT is manifold once knowledge as a strategy is the impetus behind knowledge management initiatives. One can expect quite an eclectic mix of networks, systems, tools, and knowledge repositories.
10. Value configuration determines knowledge needs in primary activities. Knowledge needs can be structured according to primary and secondary activities in the value configuration. Depending on the firm being a value chain, a value shop, or a value network, the knowledge management system must support more efficient production in the value chain, adding value to the knowledge work in the value shop, and more value by use of IT infrastructure in the value network.
11. Incentive alignment. The first dimension of information systems design is concerned with software engineering (error-free software, documentation, portability, modularity & architecture, development cost, maintenance cost, speed, and robustness). The second dimension is concerned with technology acceptance (user friendliness, user acceptance, perceived ease-of-use, perceived usefulness, cognitive fit, and task-technology fit). The third dimension that is particularly important to knowledge management systems is concerned with incentive alignment. Incentive alignment includes incentives influencing user behavior and the user's interaction with the system, deterrence of use for personal gain, use consistent with organizational goals, and robustness against information misrepresentation (Ba, Stallaert, & Whinston, 2001).

EXPERT SYSTEMS

Expert systems can be seen as extreme knowledge management systems on a continuum representing the extent to which a system possesses reasoning capabilities. Expert systems are designed to be used by decision makers who do not possess expertise in the problem domain. The human expert's representation of the task domain provides the template for expert system design. The knowledge base and heuristic rules that are used to systematically search a problem space, reflect the decision processes of the expert. A viable expert system is expected to perform this search as effectively and efficiently as a human expert. An expert system incorporates the reasoning capabilities of a domain expert and applies them in arriving at a decision. The system user needs little domain specific knowledge in order for a decision or judgment to be made. The user's main decision is whether to accept the system's result (Dillard & Yuthas, 2001).

Decisions or judgments made by an expert system can be an intermediate component in a larger decision context. For example, an audit expert system may provide a judgment as to the adequacy of loan loss reserves that an auditor would use as input for making an audit opinion decision. The fact that the output supports or provides input for another decision does not make the system any less an expert system, according to Dillard and Yuthas (2001). The distinguishing feature of an expert system lies in its ability to arrive at a nonalgorithmic solution using processes consistent with those of a domain expert.

Curtis and Cobham (2002) define an expert system as a computerized system that performs the role of an expert or carries out a task that requires expertise. In order to understand what an expert system is, then, it is worth paying attention to the role of an expert and the nature of expertise. It is then important to ascertain what types of expert and expertise there are in business, and what benefits will accrue to an organization when it develops an expert system.

For example, a doctor having knowledge of diseases arrives at a diagnosis of an illness by reasoning from information given by the patient's symptoms, and then prescribes medication on the basis of known characteristics of available drugs, together with the patient's history. The lawyer advises the client on the likely outcome of litigation based on the facts of the particular case, an expert understanding of the law, and knowledge of the way the courts work ,and interpret this law in practice. The accountant looks at various characteristics of a company's performance and makes a judgment as to the likely state of health of that company.

All of these tasks involve some of the features for which computers traditionally have been noted—performing text and numeric processing quickly and efficiently—but they also involve one more ability: reasoning. Reasoning is the movement from details of a particular case and knowledge of the general subject area surrounding that case to the derivation of conclusions. Expert systems incorporate this reasoning by applying general rules in an information base to aspects of a particular case under consideration (Curtis & Cobham, 2002).

Expert systems are computer systems designed to make expert-level decisions within complex domains. The business applications of this advanced information technology has been varied and broad reaching, directed toward making operational, management, and strategic decisions.

Audit expert systems are such systems applied in the auditing environment within the public accounting domain. Major public accounting firms have been quite active in developing such systems, and some argue that these tools and technologies will be increasingly important for survival as the firms strive to enhance their competitive position and to reduce their legal and business risk.

Dillard and Yuthas (2001) find that the implementation and use of these powerful systems raise a variety of significant ethical questions. As public accounting firms continue to devote substantial resources to the development of audit expert systems, dealing with the ethical risks and potential consequences to stakeholders takes on increasing significance. For example, when responsible behavior of an auditor is transferred to an audit expert system, then the system is incapable of being held accountable for the consequences of decisions.

Expert systems can be used in all knowledge management processes described earlier. For knowledge retrieval, content management, and information extraction technology represent a useful group of techniques. An example of an expert system for knowledge retrieval is the CORPORUM system. There are three essential aspects of this system (Wang et al., 2001).

First, the CORPORUM system interprets text in the sense that it builds ontologies. Ontologies describe concepts and relationships between them. Ontologies can be seen as the building blocks of knowledge. The system captures ontologies that reflect world concepts as the user of the system sees and expresses them. The ontology produced constitutes a model of a person's interest or concern. Second, the interest model is applied as a knowledge base in order to determine contextual and thematic correspondence with documents available in the system. Finally, the interest model and the text interpretation process drive an information search and extraction process that characterizes hits in terms of both relevance and content. This new information can be stored in a database for future reference.

The CORPORUM software consists of a linguistic component, taking care of tasks such as lexical analysis and analysis at the syntactical level. At the semantic level, the software performs word sense disambiguation by describing the context in which a particular word is being used. This is naturally closely related to knowledge representation issues. The system is able to augment meaning structures with concepts that are invented from the text. The core of the system is also able to extract the information most pertinent to a specific text for summary creation, extract the so-called core concept area from a text, and represent results according to ranking that is based on specified interest for a specific contextual theme set by the user. In addition, the system generates explanations that will allow the user to make an informed guess about which documents to look at and which to ignore. The system can point to exactly those parts of targeted documents that are most pertinent to a specific user's interest (Wang et al., 2001).

Like all software, CORORUM is continuously improved and revised. The Content Management Suport (CMS) system was introduced in 2005 (http://www.cognit.no). It is based on technology that applies linguistics to characterize and index document content. The ontology-based approach focuses on semantics rather than shallow text patterns. The software can be applied for intelligent search and indexing, structure content in portals, annotate documents according to content, summarize and compress information, and extract names and relations from text.

Another software created in 2005, CORPORUM Best Practice, enables organizations to structure their business and work processes and improve value creation. It is a software tool and associated methodology to build organization-wide best practice. In operation, the Web part of the system is a work portal. It embraces an ontology-based set of templates that helps to publish work-related documentation. Company resources like check lists, control plans MS Word templates, images, and e-learning material that is relevant for any process or activity described can be linked in where it is useful and intuitive (http://www.cognit.no).

A final software to be mentioned is CORPORUM Intranet Search & Navigation (SLATEWeb), which is used for indexing and categorizing corporate information sources. Featuring language detection and find-related concept search, this tool lets companies find documents that would otherwise be hard to find. Categories are available to dynamically classify documents into a taxonomy or group structure (http://www.cognit.no).

Analysis and design necessary for building an expert system differ from a traditional data processing or information system. There are three major points of distinction that prevent expert systems development being subsumed under general frameworks of systems development (Curtis & Cobham, 2002):

1. The subject matter is knowledge and reasoning as contrasted with data and processing. Knowledge has both form and content that need investigation. Form is connected with the mode of representation chosen, for instance, rules, semantic networks, or logic. Content needs careful attention as once the form is selected, it is still a difficult task to translate the knowledge into the chosen representation form.
2. Expert systems are expert/expertise orientated, whereas information systems are

decision/function/organization directed. The expert system encapsulates the abilities of an expert or expertise, and the aim is to provide a computerized replica of these facilities.

3. Obtaining information for expert systems design presents different problems from those in traditional information systems design. Many expert systems rely, partly at least, on incorporating expertise obtained from an expert. Few rely solely on the representation of textbook or rulebook knowledge. It is difficult, generally, to elicit this knowledge from an expert. In contrast, in designing an information system, the analyst relies heavily on existing documentation as a guide to the amount, type, and content of formal information being passed around the system. In the development of an expert system, the experts are regarded as repositories of knowledge.

Expert systems and traditional information systems have many significant differences. While processing in a traditional information system is primarily algorithmic, processing in an expert system includes symbolic conceptualizations. Input must be complete in a traditional system, while input can be incomplete in an expert system. Search approach in a traditional system is frequently based on algorithms, while search approach in an expert system is frequently based on heuristics. Explanations are usually not provided in a traditional system. Data and information is the focus of a traditional system, while knowledge is the focus of an expert system.

Expert systems can deliver the right information to the right person at the right time if it is known in advance what the right information is, who the right person to use or apply that information would be, and, what would be the right time when that specific information would be needed. Detection of nonroutine and unstructured change in business environment will, however, depend upon sense-making capabilities of knowledge workers for correcting the computational logic of the business and the data it processes (Malhotra, Gosain, & El Sawy, 2005).

Chapter 2.2
Using Inquiring Practice and Uncovering Exformation for Information Systems Development

Martina Sophia Lundin
Copenhagen Business School, Denmark

Morten Thanning Vendelø
Copenhagen Business School, Denmark

ABSTRACT

One of the oldest themes in information systems (IS) research concerns the relationship between developers and users of information systems. Over the years, IS scholars and IS practitioners have addressed the problem in a variety of ways, often focusing on how the use of social techniques can improve understanding between the two parties. Users, however, still find themselves working with systems, which do not match their requirements, needs, and expectations. We suggest that the problematic developer-user dynamic can be addressed by introducing an inquiring practice approach to information systems development. Consequently, this chapter conceptualizes a new way of understanding information systems development through the lenses of inquiring practice, Socratic dialogue, and the uncovering of exformation. We show that by applying this approach, we can enhance the inquiring capabilities of organizations, and thereby facilitate design and development of better information systems.

INTRODUCTION

One of the oldest themes in information systems (IS) research concerns the relationship between developers and users of information systems. Over the years, the theme has been addressed in a variety of ways by IS scholars and IS practitioners, for example, as a systems development problem (Fitzgerald, Russo & Stolterman, 2002; Hirschheim, Klein & Lyytinen, 1995; Mumford, 1996; Wood-Harper, Antill & Avison, 1985), as a problem that can be solved through end-user computing (Jarke, 1986), or by engaging in participatory design (Ehn, 1988; Greenbaum & Kyng, 1991). No matter how the problem is addressed, the underlying theme always seems to be how understanding between the two parties can be improved, typically through the use of various social techniques. The results, however, are not convincing. Users still find themselves working with systems which match neither their requirements nor their expectations.

We believe that attempts to address the problematic developer-user dynamic can be aided by a return to fundamental systems theory and the key questions raised by this body of knowledge. Churchman (1968) provides an example of such a key question in his book Challenge to Reason. He says, "How can we design improvement in large systems without understanding the whole system, and if the answer is that we cannot, how is it possible to understand the whole system?" (p. 3).

We argue that in aiming to develop improved information systems, we need to strive for an understanding of the whole system, and thus we pose the question: How can we facilitate a progression towards this understanding? For our part, we have chosen to focus on an inquiring practice approach to information systems development. In this chapter, we conceptualize a new way of looking at the theme through the lenses of inquiring practice, Socratic dialogue, and the uncovering of exformation. We suggest that by applying this approach, we can enhance the inquiring capabilities of organizations, and thereby facilitate the design and development of better information systems. In order to fulfill this purpose, the chapter proceeds in the following manner. First, we elaborate on the problems related to communication and understanding between developers and users of information systems, describe how conventional approaches to information systems development have dealt with the developer-user communication problem, and explain why it is appropriate to regard developers and users of information systems as belonging to different communities of practice. Second, we present the Socratic dialogue method and demonstrate how this approach to communication between different communities of practice is likely to enhance their inquiring capabilities. Third, we develop a model for how to apply Socratic dialogue method in information systems development practice, and thereafter we apply the model to a case of information systems development in order to demonstrate how developers and users can benefit from the use of Socratic dialogue method. For this purpose, we use the FX-system case, which describes the developer-user communication difficulties encountered by the Danish software firm, Unique, while developing a Foreign Exchange System for West Bank. Finally, we conclude and identify the point of arrival for our inquiring endeavor.

INQUIRING PRACTICE AND INFORMATION SYSTEMS RESEARCH

The idea of inquiring organizations originates from the works on inquiring systems by Churchman (1971). The concept of inquiring organizations has predominantly attracted attention from scholars working in the fields of organization theory (Mirvis, 1996; Richardson, Courtney & Paradice, 2001), information systems research (Courtney, 2001; Klein & Hirschheim, 2001), and, more recently, knowledge management (Malhotra, 1997). While scholars of organization theory have focused on organizational learning, scholars of information systems research have addressed decision support systems and information systems development. The decision support systems approach focuses on building inquiring information systems for inquiring organizations, whereas the information systems development approach focuses on how organizations can take on an inquiring perspective when designing and developing information systems. Although differing in their focus, both approaches share the intention of creating viable alternatives to the rational choice approach to development and use of information systems in organizations. In their seminal article on management of information systems (MIS), Mason and Mitroff (1973) suggest "that the current philosophy underlying the design of MIS has presupposed a greatly restricted view of 'knowledge', 'effectiveness', 'action' and 'purpose'" and "that to date much of the research and development work on MIS has assumed only one underlying psychological type, one class of problems, one or two methods of generating evidence, and finally, one mode or method of presentation" (p. 475). Mason and Mitroff (1973) maintain that a one thinking-sensation approach tends to dominate the design of MIS in such a way that they only produce systems for one kind of people. Accordingly they suggest other methods to explore the variables in a systematic fashion. One variable offered by Mason and Mitroff (1973) is Singerian-Churchmanian IS, also defined as learning systems.

We find that the same type of philosophy prevails in the field of design and development of information systems and suggest that a new approach to this must take its point of departure in focusing on what we have labeled the developer-user communication problem. Belardo, Ballou, and Pazer (2004) recently articulated a similar point of view, noting that one of the most significant factors in the difficulty of producing information systems that satisfactorily meet user needs "is ineffective communication between the user group and the development group" (p. 43).

DEVELOPER-USER COMMUNICATION PROBLEM

Developers and users of information systems have different backgrounds. Typically developers are employed in IS departments where they work and socialize with other IS professionals with whom they share language, concepts, and so on. Users, on the other hand, work in a context where vocation-specific languages and practices dominate. Although they may use information systems to carry out large sections of their duties, they seldom find themselves occupying the same world as IS professionals. Hence, when developers and users meet with the purpose of designing information systems, they both find themselves introduced to worlds which they have little knowledge of. Just like sellers and buyers of high-tech products who, by Darr and Talmud (2003), are found not to have a common image of product use and thus, to reach that common image, they must communicate contextual knowledge rooted in engineering practice, implying that an intense dialogue must take place between seller and buyer.

Developer-User Communication Problem in Conventional Information Systems Development Methodologies

Information systems are designed and developed for different purposes, and a variety of methodologies have been conceptualized to assist developers in designing and developing them. The methodologies are "coherent and integrated sets of methods, techniques, and tools to assist the developer" (Hirschheim, 1985, p. 80), and typically they comprise the two major tasks of systems analysis and systems development. According to Hirschheim (1985) "systems analysis is the process of collecting, organizing, analyzing facts about a particular system and the environment in which it operates" (p. 80), whereas systems development includes "requirements analysis, requirements specification, system design and systems implementation" (p. 80). Typically, a methodology includes a predetermined set of tasks, grouped into stages according to a prespecified method by use of tools and techniques. We find that the methodologies are characterized by a preoccupation with technicalities rather than with deep involvement of humans in the process.

It is possible to observe this characteristic in the methodologies even when we take into account a sample including sociotechnical methodologies (Wood-Harper et al., 1985), participatory design methodologies (Greenbaum & Kyng, 1991), and structured methodologies (Yourdon, 1989). Even within the participatory design approach, humans and the interaction between them are described at a very abstract level, for example, when describing how user participation can take place in systems design and development processes. Mumford and Weir (1979) end up with a diagrammatical representation of the process, thereby not addressing the content of the process.

From our perspective, developers and users of information systems belong to different communities of practice (Brown & Duguid, 1991, 1998; Wenger, 1998) who are unlikely to have the same view on several factors. For example, the other party, its organization, and the information system to be developed, but they share an interest in getting the information system developed. Knowledge creation and knowledge sharing within and between communities of practice have been widely discussed for some years. Brown & Duguid (1991), for example, argue that working, learning, and innovating are interrelated, and to understand this, we must study formations and changes within the communities that actually do the work. Brown and Duguid (1998) stress the difficulties with the absence of interaction between different communities of practice, and they argue that innovations, including new information systems, emerge when different communities share and discuss experiences and best practices.

THE SOCRATIC DIALOGUE

Our point of departure is the speculation about how communication and understanding between developers and users coming from two different communities of practice can be improved. Maruyama (1974) states that the difficulty in cross-disciplinary communication lies not so much in the fact that communicating parties use different vocabularies or language to talk about the same thing but rather in the fact that they use different structuring of reasoning. If they use different structures of reasoning and different terminologies, which communication method could be applied? Furthermore, Maruyama argues that when communicating parties remain unaware that they use different structures of reasoning but are aware of their communication difficulties, each party will tend to perceive communication difficulties as resulting from the other parties being illogical, lacking intelligence, or even insincerity. Consequently, we wanted to advance a method that can facilitate the development of a better understanding of this communication problem, and we found the Socratic dialogue method (Apatow, 1999; Hansen, 2000).

Background

The Socratic dialogue is a group discussion method that aims to identify hidden and taken for granted assumptions, as participants learn to think together with others and to strive to reach understanding of the others at a fundamental level, including understanding of their values and beliefs.

The idea of Socratic dialogue originates from the German philosopher Leonard Nelson who developed and used it as a pedagogical tool for adult education in the early 1920s (Hansen, 2002), and as far as we know, it has never before been applied in an information systems context. As a group discussion method, Socratic dialogue aims at creating an elaborate and deep common understanding of information and ideas from a specific context. In the dialogue, the participants advance their own thoughts, expecting others reflection to improve them rather than threaten them. Ergo, the participants in the dialogue must have an interest in expressing their own basic values, as well as in understanding the basic values of others concerning specific issues. From an existential point of view, this means that everyone involved must go back to the very basics of the problem being addressed. If the values and beliefs do not concern the participants from an existential perspective, we cannot say that they are involved in a Socratic dialogue.

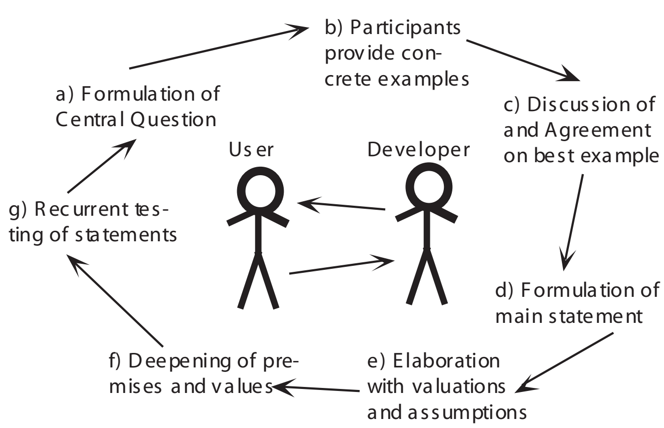
The Method of Socratic Dialogue

The Socratic dialogue begins with the formulation of a question, which all parties agree is relevant in the specific situation (Hansen, 2000). Thereafter, each participant provides a concrete example of what comes to mind when they consider the chosen question. Second, the group collectively selects the example, which it thinks provides the best outset for the dialogue. In the dialogue, the group now begins to form a main statement about the chosen question. In this process, it uses the chosen example as its point of departure. With the main statement as a background, the group then elaborates with values and assumptions underlying the statement. This inquiry into each participant's arguments and basic assumptions leads to further deepening of the premises and values that until now have been argued for. Hence, at this point in the process, the original statement has been revised several times, and more fundamental philosophical problems have been attached to the chosen question. Still, the focus of the group is on reaching the objective, namely, to find a common statement on the question. Finally, the group engages in testing the validity of the statement. This testing happens not only against the originally chosen example but also against the other examples mentioned by the participants. Thus, the testing enables the participants to reach a more general statement.

Modified Model of Socratic Dialogue Method

For several reasons, the original Socratic dialogue method needs to be modified in order to fit the information systems design and development context. First, the original method points out that the process must be given unlimited time for the parties to reach a statement that suits all. In a user-developer situation, one must face the fact that there is limited time for dialogue. Deadlines are reality, and both parties must be aware of this. Second, the original model argues that there is no need for reaching a common agreement. The

Figure 1. Socratic Dialogue Method for information systems development



objective here is the process. In our case, the objective must be more than this because users and developers need to reach a common understanding to afford product arrival. Third, in an information systems context, the starting question is unlikely to be philosophical in character. Hence, we arrived with the following picture of the Socratic dialogue method for information systems development.

Exformation: The Product of Socratic Dialogue

In relation to the Socratic dialogue, one must ask what output it produces, what is the role of this output in the information systems design and development process, and what makes the output of Socratic dialogue crucial? Using Nørretranders (1991),1 we suggest that the output take the form of exformation. "Exformation is the history of a statement, information is the product of history. Both are meaningless without each other—information without exformation is empty talk; exformation without information is not exformation, but only thrown away information" (p. 131).

The basic hypothesis is that information or knowledge exchanged between communities of practice is only a small and limited part of the knowledge creation process. The awareness of exformation as the context, the history, and the process behind the creation of information and knowledge needs as much attention as the information or knowledge itself. Exformation is an abbreviated form of explicitly discarded information. More specifically, Nørretranders (1991) states that "Exformation is everything we do not actually say but have in our heads when or before we say anything at all. Information is the measurable, demonstrable utterance we actually come out with" (p. 127).

Hence, from the information content of a message alone, there is no way of measuring how much information it contains. Nørretranders (1991) argues that exformation is produced in a process of chucking away information, and it is this process which is evident in automatic behavior of expertise (riding a bicycle, playing the piano) and which is therefore the most precious. Some might argue that exformation is similar to tacit knowledge (Nonaka, 1994). Yet, unlike tacit knowledge, exformation does not exist as something we know but cannot tell (Nonaka, 1994). Instead, exformation describes a person's nondisclosed thoughts, values, and assumptions concerning a given situation or task, and thus we maintain that talking about exformation rather than about tacit knowledge has relevance. We believe that the disclosure of exformation in the Socratic dialogue is highly beneficial for the conceptualization and design of information systems, as it enables developers and users of future information systems to produce intelligent understandings of the other party.

CASE: DESIGN AND DEVELOPMENT OF THE FX-SYSTEM

Unique is a rapidly growing Danish software firm occupied with design, development, and implementation of advanced turn-key software applications for industrial, scientific, and administrative purposes.2

In the spring in year X, salesmen in Unique discovered that West Bank wanted to purchase a Foreign Exchange System (FX-system). Yet, Unique did not have an FX-system, and West Bank wanted a ready to go FX-system. In order to address this demand, Unique decided to perceive West Bank as a potential sponsor for the development of an FX-system, which the firm subsequently could refine and sell as an off-the-shelf FX-system. Therefore, Unique initiated activities aimed at selling an FX-system to West Bank. These activities focused on explaining to West Bank that Unique knew what an FX-system was and that the firm had almost finished development of such a system. For this purpose, the manager of the Financial Services Division in Unique initiated development of a prototype of an FX-system. One of the systems developers in the division later explained how the prototype was developed:

First, we spend three days on development of a prototype generator for Presentation Manager. This generator could pick text-files and display them on a screen with fancy colors. Then, we ordered sales-material from other suppliers of FX-systems, and reproduced their user-interface. In total, we designed 20 screens with different colors and of different size. Also, they showed numbers in the different screen fields, but it was impossible to make changes in the numbers. Thereafter, we implemented the prototype as an extension to our system for online trade with stocks and bonds, because we had to have some screens with moving numbers to demonstrate a working system.

When presenting the prototype to West Bank, employees from Unique informed them that the FX-system was almost finished but that the user-interface had yet to be completed, and therefore it was impossible to demonstrate a working version of the FX-system. Also, Unique arranged that currency dealers from those customers who already used other financial systems sold by the firm answered questions from West Bank about the functionality of the FX-system. Using this approach, Unique succeeded in persuading West Bank to buy "their" FX-system, and in June, Unique and West Bank signed a contract stating that an FX-system was to be delivered to West Bank in December that very same year.

The contract signed with West Bank included some general provisions of the contract and three pages with one-liners describing the functions to be included in the FX-system. Mainly, these three pages had their outset in the sales material collected from other suppliers of FX-systems and then mixed to compose a presentation of Unique's FX-system. Hence, the contract only provided a few conceptual guidelines for design of the system.

Development and Delivery of the FX-System

Nobody in Unique knew much about foreign currency trading; also, they had no time to develop a requirement specification for the system, as the project team (six to seven systems developers) had to observe a tight deadline for delivery of the system to West Bank. Hence, the project team assumed that trade with foreign currencies was almost similar to trade with stocks and bonds, which they had some experience with. Therefore, the project team copied the source-code from Unique's systems for this activity, changed the headlines in the user-interface, and started editing the code to facilitate what they believed was FX-operations. By the end of July, the project team delivered the first modules of the FX-system to West Bank, but the delivery was not successful, as Unique did not deliver what West Bank expected. However, users in West Bank had difficulties in explaining exactly what they expected. Given the problems, the management of Unique assigned a new project manager. He discovered that no plans existed for the FX-project, that project management was almost absent, and that to some systems developers, OS/2 constituted new technology. Furthermore, representatives of West Bank explained to the new project manager that West Bank expected delivery of an FX-system similar to the one specified in the contract, which in their opinion, was not what Unique delivered. Yet, the contract did not specify the FX-system apart from stating the different subsystems to be included in the FX-system. This problem was compounded by the fact that West Bank had difficulties in specifying exactly what kind of system they wanted. Also, the new project manager realized that the schedule for the FX-project was not realistic when considering the large number of tasks to be accomplished.

A New Start on the FX-Project

With the above mentioned problems in mind, the new project manager developed a revised project plan, which divided the FX-system into subsystems and initiated development of the system from scratch. Furthermore, he explained to the top management that Unique had to perceive the project as a collaboration with West Bank. Thus, he initiated regular meetings between systems developers from Unique and users from West Bank, as he realized that Unique needed the currency dealers to tell the project team about their demands to the FX-system, since none of the system developers assigned to the project knew anything about foreign exchange. Six months later, the systems developers were in a position to produce parts of the FX-system, which were accepted by West Bank. However, at that point in time, the project was half a year behind schedule. Also, the new project manager conducted regular meetings with representatives of West Bank, as he wanted them to realize that the contract was unrealistic and to accept a revision of it. The strategy succeeded slowly as the representatives of West Bank learned that Unique did not know how to develop an FX-system. Yet, West Bank was not likely to accept a revision of the contract, as they felt that they would then have to accept a less advanced FX-system.

In the fall one year after initiation of the project, Unique faced new problems in the FX-project. The system often broke down due to problems with the software produced by Unique. The project team experienced that somehow these problems were related to the fact that West Bank did not know what they wanted and constantly changed their demands for the FX-system. In order to identify solutions to the problems, the project team intensified its meetings with users from West Bank, and thereby Unique managed to restore West Bank's confidence in the firm, as well as in persuading West Bank to stay in the project. In the end, Unique managed to develop and deliver the FX-system to West Bank, although it took more than one and a half years of extra work to finish the project, which in total meant a project which lasted for two years.

INTERPRETATION OF THE CASE

In the present paragraph, we interpret the FX-case through the Socratic dialogue model presented above. First, we identify communicative acts, which we find are representative for the case. Second, we interpret the acts with the use of the model, thereby we identify how the communicating parties acted and reacted in the process, and we seek to explain how their acting and reacting influenced the process over time. Third, we speculate how the process might have evolved if the Socratic dialogue had been applied.

Identifying Communicative Acts

For the purpose of interpretation of the case, we needed communicative acts representative for the case. Hence, we began our analysis by looking for such acts in the case. As communicative acts, we defined points in time where either of the involved parties "send messages" to the other party leading to some kind of response. As our first example, we identify the point in time where developers in Unique make contact with West Bank and suggest themselves as potential suppliers of an FX-system to West Bank. West Bank, which we now term the user, responds by agreeing to visit Unique on-site and see a presentation of the system. In total, we identified eight communicative acts. These, however, vary with regard to both content and form. Foremost, it is important to note that the form changes significantly after the first unsuccessful delivery of modules of the FX-system. We therefore talk about phase 1 initial communicative acts and phase 2 adapted communicative acts.

Initial Communicative Acts

As the first five communicative acts, we have identified the following:

Example A1:
- Developers make contact to users and suggest their firm as supplier of an FX-system
- Users accept invitation to visit developers' site and take a look at the system

Example A2:
- Developers present the proposed system to the users
- Users accept the proposed system as a suitable response to their needs

Example A3:
- Users pose questions regarding technical and functional aspects of the proposed system
- Developers answer the technical questions, and the currency dealers borrowed from existing customers answer questions about functional aspects of the system

Example A4:
- Developers write up contract about sale and delivery of the FX-system
- Users sign contract and buy the proposed FX-system

Example A5:
- Developers initiate development of the proposed FX-system
- Users passively await delivery of the FX-system

Looking at these communicative acts, it appears that they all have a similar form and content. Starting with the form, it can be observed that the communication is initiated by the developer-side as it approaches the user-side and suggests itself as an appropriate supplier of the FX-system that the user-side is looking for. From the developer-side, this gives the communicative acts a focus on convincing the user-side about the appropriateness in choosing it as the FX-system supplier. Also, it gives the communicative acts a flavor of being orchestrated by the developer-side constantly looking for the user's approval of its points of view.

As the dialogue evolves, the developer-side increasingly focuses on getting the user-side to confirm that it is on the right track regarding the proposed FX-system. This happens even though the developer-side must have some doubts about their actual capacity to deliver the proposed FX-system. In other words, no uncertainty is revealed and communicated by the developer-side. Viewing this from a Singerian perspective, it would be perceived as a highly unethical act. We do not claim that the developer-side knew that it would be difficult to deliver the system, but we assume that they must have had some doubt and that this doubt could have been articulated in an early stage of the dialogue. However, little dialogue about the users' requirements to the system took place in the initial stages of the process.

When interpreting the communicative acts in the light of the Socratic dialogue, we are afforded the following picture. The central question is formulated by the developer-side and is never tested in the dialogue with the user-side. The central question may be formulated as "We have an excellent FX-system here, don't you think?" If we then move on to Step 2 in the Socratic dialogue, the provision of concrete examples, it happens as the developer-side demonstrates the constructed FX-system to the user-side, and experiences that the user-side accepts the shown system as a suitable response to its needs, not even questioning the existence of the system. In neither of these two examples does the user-side inquire about the developer-side's understanding of its demands to such a system. Instead, "feedback" from users continuously confirmed the developers' formulation of the central question.

Adapted Communicative Acts

As the final three communicative acts, we have identified the following:

Step B1:

- Users respond to delivery by stating that this is not an FX-system
- Developers respond by assigning a new project manager who reorganizes the project team

Step B2:

- Developers begin to inquire into the users' demands to the system
- Users accept the developers' invitation to inquiring dialogue

Step B3:

- Developers suggest a step-by-step procedure for identification of the demands of the users, based on the one-liner contractual descriptions of the functionality of the FX-system
- Users engage in this activity by joining the dialogue with the developers

When looking at these three communicative acts, it appears that the initial failure by the developer-side to deliver what the user-side expected had an impact on how the dialogue evolved. In the adapted phase, far more open-ended communicative acts dominate. The weaknesses of the developer-side, which used to be hidden, are now obvious and need to be dealt with if the project is to continue. However, these inquiries from the user-side only emerged as the developer-side failed to fulfill the user-side's expectations to the delivery of the first modules of the system. The reorganization of the managerial setup following the failed delivery provided for initiation of an inquiring dialogue between the two parties.

Viewing the adapted communicative acts in the light of the Socratic dialogue, we can say that the new project manager initiates reformulation of the central question. Basically, the developer-side says: "What does an FX-system look like?" And essentially, the user-side replies: "That is actually a very good question." Here we witnesses a break point in the way the developer-side approaches the problem of developing the FX-system, and the user-side responds by accepting that this break with the prior pattern of communicative acts is highly needed. Hence, a new central question is being formulated through the involvement of both parties.

As the Socratic dialogue proceeds, the step-by-step procedure for identification of the user-side's needs implies inquiring into the meaning of the one-liner descriptions of the various functions in the proposed FX-system. If we perceive these one-liners as high-level abstractions containing a huge amount of exformation, it obviously becomes important that each party's interpretation of the one-liner is revealed, as most likely each interpretation is unknown to the other party. Hence, in this instance, the Socratic dialogue is about transforming abstractions to raw data. This happened as the involved parties provided concrete examples of how they interpret the one-liners. Examples may have been elaborated by provision of counter-examples or more detailed examples. Then, as the parties discuss and agree on best concrete examples, they obtain verification of their reciprocal understanding. Of course, the parties can never be sure of their full common understanding, and that is exactly why continuous dialogue is important.

Based on these discussions and agreements, formulation of main statements about the functionalities could take place. The main statements then serve as the basis for elaboration about the content of the functionalities to be included in the system. We cannot say much about E and F in the model, although we would expect that uncovering of crucial and case related exformation takes place here. We are however quite sure that in the FX-case testing of statements happened as modules were delivered and accepted or rejected by the users.

An important insight, which emerged in the adapted phase is that the user-side had a very vague picture of their demands to the FX-system. We see this in the fact that the user-side constantly changes its requirements to the system, and this uncertainty may have influenced them to not inquire about the presented FX-system in the initial phase.

Closure on Case Interpretation

Our interpretation of the FX-case has demonstrated that inquiring practice based on Socratic dialogue can make a difference in the quality of the output produced in IS development processes. The question that, of course, emerges is whether the developer-side had succeeded if the initial communicative acts with the user-side had started with an inquiring approach. Although we emphasize the importance of an inquiring approach in the user-developer communication, we cannot neglect that this kind of dialogue may foster uncertainty and anxiety in and among participants. However, all face-off actions demand boldness and courage, and we must take into account that our behavior may influence our counterparts to perceive us as less trustworthy. Another question is whether it was the developer-side that held the key to the initiative of inquiring practice.

Addressing the first question, we acknowledge that West Bank openly expressed that it was looking for a complete FX-system and that it would not buy a turn-key delivery. Yet, we maintain that the possibility for succeeding with an inquiring approach depends on the perspective taken by the counterpart, whether that be a developer or a user. Therefore, if West Bank had responded positively to an inquiring approach taken by Unique, we submit that the firm would have succeeded with this approach.

So, why did an inquiring approach not develop earlier on? Of course, the developers were quite street-wise in the initial phases, but on the other hand, the users did not act intelligently. They did not pose critical questions, and thereby they did not insist on engaging in an inquiring practice. In a Socratic dialogue perspective, neither the developers nor the users took responsibility for their own organization. We thus maintain that inquiring practice is always a two-way responsibility, which however might be provoked by one of the involved parties. Every stage must include inquiry, reflection, and active listening, with active listening including both listening to the counterpart and, perhaps even more important, listening to oneself.

Until now, we have argued for the Socratic dialogue method, but little has been said about how to initiate this method. From an information systems development point of view, we believe that the initiative must come from the developer-side, and in a sales context, it is probably the seller who has the greatest interest in implementing this kind of dialogue. We are aware of the problems arising when one party explicitly tries to introduce a philosophical tool in this situation, mainly, because tradition and norms tells us that this is not the way of conducting business. Therefore, we suggest that the developer-side initiates this in a manner that tells the user-side that it is important to open up ones basic thoughts and values without experiencing that these issues are too simple to highlight. Hence, the developer-side must state early on an example that is in line with the Socratic dialogue method.

CLOSURE: SOCRATIC DIALOGUE AND WISDOM

In this chapter, we have argued for a more intelligent way of organizing the cross-disciplinary dialogue between developers and users of information systems. For this purpose, we identified Socratic dialogue method and argued that it can be used in an information systems development context. The Socratic dialogue method enhances the inquiring capabilities of organizations, and thereby it allows for uncovering of exformation, which is crucial if developers and users of information systems are to obtain a more advanced understanding of one another's positions. We argue that instead of asking, "Did we get the information and knowledge we searched for?" one should ask, "Did we uncover exformation in this dialogue that can facilitate the development of this system?" Consequently, Socratic dialogue is a new way of approaching the process rather than a tool.

When organizations apply Socratic dialogue in the developer-user communication, there is a high possibility that both parties will display exformation of a far more substantial kind than the information usually being developed and exchanged. Also, viewing developers and users from the point of view of inquiring communities of practice could, in fact, produce more open flows of information in organizations and thereby provide for more innovation in organizations. Therefore, we suggest that Socratic dialogue is useful beyond the area of application dealt with in the present chapter. It could be applied both among sellers and buyers of high-tech products and in the process of creating new management practice in organizations. Because this philosophical approach opens for a new way of viewing cross-disciplinary communication, regardless of business field or vocation function, Socratic dialogue can bring about exformation being held inside people—exformation that is crucial in order to understand and share knowledge between communities. Hopefully, this dialogue can help us not only to facilitate understanding but also to develop a new type of language in management and organizations (Lundin & Rasmussen, 2002). As with information flows, flows of often used words and phrases in a community make us unaware of their meaning for other groups of people. We simply forget to reflect on it and then take it for granted. By learning and developing our choice of semantics together with others in a Socratic dialogue, we can become more aware of what we actually communicate in and between these inquiring communities.

We realize that our attempt to apply the Socratic dialogue in an information systems context is only the first move in a new endeavor aimed at formulating a new methodology for use in this context. Hopefully, further research will help refine and modify the methodology and also through experiments in real-life environments, as it is important to remember that the Socratic dialogue method was originally developed for a different context with the aim of creating a methodology that facilitates critical reflection about issues that, at the first glance, may seem obvious to us. Yet, it is by reflecting over precisely those kind of questions that we can discover exformation and thereby arrive at a better understanding of our counterparts.

APPENDIX A: CASE METHODOLOGY

The case—Design and Development of an FX-system—is borrowed from a longitudinal study of new business creation in the Danish software firm Unique. The case study took place over a period of two years and used an explorative approach to study three different cases of new business creation in the firm. One case was Financial Products, of which the present case constituted one central activity. The main source of empirical evidences in the study was qualitative data gathered on-site in the organization. Several data generation techniques of ethnographic nature (Van Maanen, 1988) were employed, such as semi-structured interviews, informal talks, direct observations, collection and review of documents, and social contact. Hence, multiple sources of evidence were used in order to collect evidences conveying the same facts. Yet, interviews with members of the organization lasting from one to two hours were the main source of empirical evidence. For the Financial Products case, a total of 12 interviews were conducted. Selection of interviewees for the case happened based on information obtained from either prior interviews or written material collected in the firm. Also, a knowledge-based sampling method was used by asking interviewees to suggest others who had knowledge of, or were involved in, certain aspects of the case. Especially, the selection focused on people believed to hold central positions in each case; that is, interviewees were selected based on their information value (Enderud, 1987). Occasionally, people, who for different reasons had left the organization, were interviewed in order to obtain information about issues which people inside the organization were reluctant to talk about. Most interviews were taped and transcribed, but occasionally tape recording did not take place. Instead, interviews were recorded in shorthand notes. After transcription interview texts were handed over to interviewees in order to ensure that they could review and correct or add information in the interviews.

Another important source of empirical evidences were written material collected in various ways. Some documents were easily accessible in the organization. Such documents included annual reports, organization charts, messages from management to the employees, memos, strategic plans, firm journals, and news clipping. Some interviewees allowed the researcher to go through their personal files and handed over to him documents related to the cases studied. Finally, a kind kitchen midden technique was used, as occasionally the researcher was moved to offices previously occupied by people who had left the organization without removing their files and collection of documents. A couple of times the researcher took the liberty to go through these files and record information of interest to the case study.

Based on the empirical evidences gathered using the different data generation techniques described above, write up of chronological case stories took place in order to reveal the progression in the processes. Before writing up the cases, the researcher went through the empirical evidences in order to get an initial impression of the data and write notes about the activities and people involved in each case. Thereafter, a write up of the first draft took place, followed by two to three revisions of each case, and a final write up occurred on completion of the collection of empirical evidences.

This work was previously published in *Inquiring Organizations: Moving from Knowledge Management to Wisdom* edited by J. Courtney, J. D. Haynes, and D. Paradice, pp. 154-172, copyright 2005 by Idea Group Publishing (an imprint of IGI Global).

Chapter 2.3
Engineering Design Knowledge Management

Z. M. Ma
Northeastern University, China

INTRODUCTION

In recent years, greater global competition is pressuring organizations to produce industrial products with the shortest possible lead times, high quality, and lowest costs. The lifecycle of a product includes many phases such as requirement definition, conceptual design, production, operation, maintenance, and so forth. Each phase in the lifecycle would involve the product information, for example, using some information that comes from other phase(s) and generating some new information during the phase. Engineering design knowledge (EDK) of a product consists of the product information related to the design process of the product.

It should be noticed that modern products are complex, and their developments have increasingly become collaborative tasks among teams that are physically, geographically, and temporally separated (Caldwell et al., 2000; Szykman, Sriram, Bochenek, Racz, & Senfaute, 2000). As design becomes increasingly knowledge intensive and collaborative, traditional design databases, which merely provide access to schematics, computer-aided design (CAD) models, and documentation, are inadequate for modern product design (Szykman et al., 2000), and the need for computational design frameworks to support the representation, integration, maintenance, and use of knowledge among distributed designers becomes more critical. The representation, integration, maintenance, and use of knowledge consist of the knowledge management of engineering knowledge.

BACKGROUND

Nowadays most engineering design is a knowledge-intensive process undertaken by teams dispersed across multiple disciplines. So it needs to be supported with relevant engineering design knowledge. We call engineering design knowledge all the standards, laws, and best practices that need to affect the design decision. Engineering design knowledge attempts to integrate three fundamental facts of artifact representation: the physical layout of the artifact (structure), an indication of the artifact's overall effect (function), and a causal account of the artifact's operation (behavior) (Szykman et al., 2000). The function-behavior-structure (FBS) engineering design model has been developed in Tomiyama, Umeda, and Yoshikawa (1993) and Tomiyama, Mantyla, and Finger (1995). Based on the model, four categories of design knowledge were basically classified (Li & Zhang, 1999): artifact functions, artifact behaviors, artifact structures, and the causalities among structures, behaviors, and functions. Function knowledge is about the purpose of an artifact; behavior knowledge is about the changes of states of an artifact; structure knowledge is about a set of components and their relationships; causality knowledge is about design constraints, wishes, physical principles, heuristic rules, and so on.

Corresponding to contemporary engineering design, engineering design knowledge is structured, distributed, and evolving. It is generally already formal or can be easily formalized. It essentially consists of sets of constraints with additional references, justifications, illustrations, examples, and other documentation. This knowledge lends itself to a formal, machine-readable representation. Engineering design knowledge is typically distributed because most engineering artifacts involve a variety of domains of expertise (e.g., electrical, mechanical, styling, and manufacturing) and a variety of stakeholders (e.g., manufacturers, suppliers, servicing agents, legislators). The knowledge is distributed in the sense that each area of expertise and each stakeholder authors, publishes, and maintains their own repository. The SAE (Society of Automotive Engineers) handbook and EPA (Environmental Protection Agency) publications, for example, are published and updated independently of each other. Finally, the knowledge is rapidly evolving because it is meant to be a live reflection of the state of the art and the state of the technology relevant to the engineering domain of interest. The knowledge gets updated asynchronously, and the updated information is made immediately available to the user.

Because engineering design knowledge has a large size, rapid pace of growth and evolution, and distributed ownership, it is better managed as an independent resource rather than hard-coded within the CAD systems or their satellite tools. The management of the engineering knowledge entails its modeling (representation), maintenance, integration, and use.

ENGINEERING DESIGN KNOWLEDGE MANAGEMENT

The management of engineering design knowledge entails its modeling (representation), maintenance, integration, and use. Knowledge modeling consists of representing the knowledge in some selected language or notation. Knowledge maintenance encompasses all activities related to the validation, growth, and evolution of the knowledge. Knowledge integration is the synthesis of knowledge from related sources. The use of the knowledge requires bridging the gap between the objectives expressed by the knowledge and the directives needed to support the designer in creating valid engineering artifacts. The management of engineering design knowledge requires an adequate modeling language and an associate inferencing mechanism. So in this short article, we only focus on the modeling of engineering design knowledge.

Knowledge Modeling

Knowledge modeling and the representation of structural information have been prominent issues in artificial intelligence, knowledge representation, and advanced applications of databases. Although the design knowledge representation itself is not a new subject, there is no commonly agreed approach to the problem, and it still represents an active area of research (Vranes & Stanojevic, 1999). A number of solutions have emerged from these domains, and various researchers have developed models that attempt to capture the facts of structure, function, and behavior (Gorti, Gupta, Kim, Sriram, & Wong, 1998; Vranes & Stanojevic, 1999).

An integrated artifact metamodel was developed in BEST's knowledge representation language, Prolog/Rex (Vranes & Stanojevic, 1999). The Prolog/Rex concepts were used to define generic classes and describe the workpiece, which are instances of generic classes; Prolog/Rex relations were used to describe the relationships between the concepts. Then the knowledge used in the design process was divided into declarative and procedural knowledge. Similarly, in Gorti et al. (1998), an object model was developed which formed the basis of the design knowledge representation. Their model consists of objects, relationships among objects, and classes (object class and relationship class). An object-oriented model has been developed and applied for design knowledge modeling (Mili et al., 2001; Ma & Mili, 2003).

Class with Constraints

Knowledge units were basically constraints (Mili et al., 2001). Constraints are always associated with engineering artifacts, modeled by classes. Instances of a given class are created and modified through the direct setting and update of their parameters. These parameters, because they are the subjects of direct decisions, are called decision parameters. Most constraints on a class do not constrain directly the decision parameters. They generally refer to more complex and more abstract parameters, called performance parameters. This leads to the modeling of a class using the UML notation in which we represent four compartments: The class name in the top compartment identifies the concept of interest. The bottom compartment contains (a reference to) the constraints that class instances are bound by. These constraints typically refer to parameters of the concept. Some of these parameters are attributes directly set by the designer. They are listed under the second compartment. Most of the parameters referred to in the constraints are measures of "performance" of the class. They are not direct decision parameters, but are functions of some decision parameters. The performance parameters are included in the third compartment along with their expression in terms of decision parameters. The decision parameters used are added to the second compartment.

For example, a door panel may be represented as follows:

Door Panel
Decision parameters
    length: Real
    width: Real
    contour: Curve
Performance parameters
    top to bottom curvature = curvature
    Function (length, contour),
    corner angles = corners
    Function (contour)
Design constraints
    constraint on top to bottom curvature
    constraint on corner angles

Constraints

The most interesting elements in this model are the constraints themselves. In fact, we refer to them as constraints even though they are generally complex documents encompassing source, motivation, rationale, consequences, and a log of the various changes and updates they have undergone. Because of this existing and potential complexity, the constraints are represented within their own class. A number of attributes are used to describe the constraints. These attributes can be very useful when it comes to assessing the authority and criticality of a given constraint. For example, a constraint of type standard authored by a trusted authority from the federal agency EPA is likely to have high criticality. On the other hand, a constraint classified as best practice, whose consequence is a slightly more costly assembly procedure, can conceivably be violated in order to ensure that some other constraint is met.

Constraint
Name:
Source: {EPA, SAE, SME, …}
Author: (authority)
Classification: {standard, best practice, …}
Last updated:
Replaces: Constraint
Overrides: (Class, Constraint, Class)
Formula:
Rationale:
Consequences:
Parameters directly referenced: set of parameters
Parameters indirectly referenced: set of Parameters
Replaces older—not less recent constraints
Overrides weaker—not stronger constraints

In a word, a class with constraints representing a piece of design knowledge is defined by the quintuplet <CN, DP, PP, MT, CT>. Here, CN is the name of the class, and DP, PP, MT, and CT are the sets of decision parameters, performance parameters, methods, and constraints, respectively.

Relationships Among Design Knowledge and Comparison

Since design knowledge is represented by classes with constraints, semantic relationships among design knowledge turn out to be the semantic relationships among classes with constraints. It should be pointed out that, however, the distributed design knowledge may result in syntactic and semantic conflicts among classes with constraints, which affect the identification and determination of the relationships among design knowledge. Here we assume that all possible conflicts are identified and solved.

The following semantic relationships among classes with constraints can be classified in the knowledge model above.

- Subclass relationship
- Part-feature relationship
- Equivalence relationship
- Inclusion relationship
- Approximate equivalence relationship
- Approximate inclusion relationship

Among these relationships, some, like subclass relationship, part-feature relationship, and aggregate relationship, are common in object-oriented model; some, like assembly-component relationship, are crucial for engineering design and manufacturing; and some, like (approximate) equivalence relationship and (approximate) inclusion relationship, are very useful for design knowledge fusion and design knowledge use.

The comparison of design knowledge is a very important topic in the context of design knowledge management. During design of a product, for example, designers would usually think if there has existed a similar product designed before, if there have been some standard parts in CAD systems that could be directly used to design the product, or if some components existed in CAD systems that can be used as references to the designed product. Designers therefore would try to answer these questions by findings from CAD systems or design repositories, when the designed product is very complex or the design repositories are very large and located in heterogeneous systems. In addition, managing design knowledge federations need to integrate knowledge from different sources. In order to cerate the integrated knowledge repositories, it is necessary to identify and capture the semantic relationships among different knowledge models. The purpose of comparing design knowledge is to identify the relationships among design knowledge given above. Since design knowledge is represented by classes with constraints, comparison of design knowledge turns out to be the comparison of classes with constraints. In Ma and Mili (2003), based on the object-oriented knowledge model above, the semantic relationships among design classes with constraints were identified and the methods to determining these relationships were hereby developed. In particular, the comparison of constraints and the semantic relationships on approximate basis were investigated.

Regarding comparison of design knowledge, Tischler, Samuel, and Hunt (1995) focused on the comparison of design knowledge at the artifact structure level, where only the kinematic motion is considered in the domain of machine conceptual design. A conceptual graph (Sowa, 1999) has been used to represent the domain level of an expertise model (Dieng, 1996), and knowledge-intensive design has been represented graphically (Balazs, Brown, Bastien, & Wills, 1997). Therefore, in Li and Zhang (1999), a hybrid graph approach was proposed to represent four kinds of design knowledge: artifact functions, artifact behaviors, artifact structures, and the causalities among structures, behaviors, and functions. Then the comparison of design knowledge turned out to be the comparison of hybrid graphs. Using the Hopfield-Tank neural network algorithm, an algorithm for the graph comparison purpose was developed. Moreover, some research work has also focused on comparison of conceptual graphs (Dieng, 1996; Montes-y-Gómez, Gelbukh, López-López, & Baeza-Yates, 2001).

CONCLUSION

Most of engineering design is a knowledge-intensive process undertaken by teams dispersed across multiple disciplines. So it is essential that engineering design needs to be supported with relevant engineering design knowledge, and engineering design knowledge is better managed as an independent resource rather than hard-coded within the CAD systems or their satellite tools. In this article, we review the issues related to the modeling of engineering design knowledge. In particular, an object-oriented knowledge model to represent design knowledge associated with their categories is presented. Based on the knowledge model, the semantic relationships among design knowledge can be identified and determined. Engineering design knowledge can hereby be compared for design knowledge integration and use.

Engineering design knowledge is represented with the object-oriented model. The management of engineering design knowledge such as maintenance, integration, and use can be achieved in the context of object-oriented database management.

Chapter 2.4
Supporting Research and Development Processes Using Knowledge Management Methods

EXECUTIVE SUMMARY

This chapter shows the integration of formal and informal knowledge and information exchange methodologies for an integrative product development process. It describes in detail how to transfer knowledge between organizational-related units to allow a smooth transition of development projects. Based on communities and information technology support, the concept offers a substantial way to bridge communication gaps to increase efficiency. Furthermore the authors hope that this chapter increases understanding of existing problems in manufacturing companies and enables practitioners to find a basic idea of how to solve their own challenges.

BACKGROUND

Trumpf Maschinen Austria (TAT) was founded 1990 near the city of Linz, Austria, as an independent subsidiary of the Trumpf group. TAT is a competence center for press brake and bending technology and produces TrumaBend® press brakes, the TRUMPF BendMaster®, and laser-hardened bending tools.

TAT had a turnover of 94.5 million euros and employs 168 people, and has a very low fluctuation rate. Two thirds of produced CNC machines are exported worldwide. The main focus of research and development (R&D) is on the process chain of "Blech" (sheet plates).

Currently three TrumaBend® press brakes are delivered every day and production capacities are in the process of being expanded to prepare to meet the constantly increasing demand for TRUMPF press brakes in future. Tool machines and production technology by TAT are in a leading position on the world market.

SETTING THE STAGE

The following case study is based on an information and communication problem between the R&D department and the construction department of a large machine manufacturing company with subsidiaries all over the world.

Problem Details

In the past the development of new machines was done in one big department (construction department) which also had to handle customer orders. Knowledge and experience transfer from R&D activities to order processing was an integrative part of daily business.

Later on, the fast growth of the company led to less R&D activities and required the split into an R&D department and a construction department. The R&D department was then responsible for the development of new machines, and the construction department was responsible for processing customer orders. In this department special needs of the customer concerning a machine had to be implemented within the general technical specifications. The specialization allows a more focused work and clear responsibilities for customer adoptions versus new product development.

Dividing the department caused cultural side effects. The staff of the construction team lost the status of being members of the "creative" R&D department and were very disappointed about this fact. This cultural problem resulted in a structural and emotional gap between these newly formed departments, which was reflected by less communication. Additionally, the formal information exchange has not been defined anew, so the handover happened only after the finalization of the R&D activities.

Now the big challenge is to handle the formal and informal transfer of knowledge and experience produced in the development projects within the R&D department to the construction department, which has to use the project results when processing customer orders. So the overall target of a new concept for exchanging and sharing knowledge and experience is to include know-how and experiences of all departments of the company within development projects and to bridge the emotional gap and friction between these two departments.

General Conditions

Development projects in this company are of highest complexity and last up to three years, and a normal lifetime of such a machine (including modifications) is about 10 years. A development project in this context is defined as a project that develops a machine type in several similar specifications. Additionally the machine manufacturing company required that a new concept for optimizing knowledge and information transfer among the different departments, should support

- integration of know-how of all company departments (e.g., sales, assembly, production);
- reduction of the cycle time for machine development projects;
- serial production has to start right after finishing the R&D project;
- providing up-to-date information about R&D projects for all employees;
- and should also be complementary to an overall "integrated product development process," which was worked out and applied in this company.

CASE DESCRIPTION

To solve the problems, a new concept concerning exchange and transfer of information, knowledge, experience, and know-how had to be developed. Current literature and cases only provide theoretical background and some examples for large firms, which made it necessary to adapt existing approaches and mix them with a new solution.

Current State Analysis

During the current state analysis the existing "integrated product development process" as well as the split of functions among the departments were analyzed. Additionally the employees' concerns have been integrated during an online survey about special topics, which was completed by 35 employees from several departments. This was a very good response rate (47 employees had received an invitation). Some completed questionnaires made no sense, so they had to be omitted.

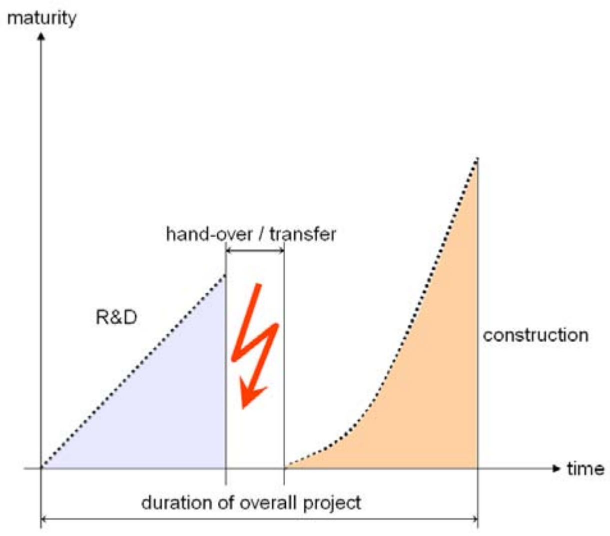
Results of the current state analysis were (including questionnaires and interviews) as follows:

- No clear work order between development and construction
- Demand for an increase of informal communication to foster the exchange (large projects involve up to 40 employees)
- Employees think that the workload of their own and their branch is very high
- A structured project result handover is needed (Figure 1)
- Reuse of essential documents is often not possible

The organizational analysis (structure, products) detected further problems caused by the strong increase of staff, no existing team or project coordination structures, and extreme pressure from market. New product development is often the starting point for a complete replacement of a whole product series. Based on the high complexity of the development process, changes during the prototype design and later on during the series production cause high efforts.

As a major point of the survey, the project handover between development and construction department had been analyzed in more details:

Figure 1. Current state of project handover



- Delivery of project results can be done by exchange of documents, but parts must be supported by communication or discussion processes.
- In principle, all results and interfaces of components or assembly groups are described as complex and time critical (for the delivery process).
- Results about new technologies are also time consuming at the delivery.
- The employees are positively motivated to use a project management tool as support for delivery.
- The construction department should be informed about the current status and content during the project to be able to bring in its know-how for optimal results.
- After delivery, there should be responsible persons at the development department for each technical aspect for assistance with various problems.

One important activity within this phase was to review existing knowledge management methods regarding their applicability within the context of this machine manufacturing company.

Theoretical Backgrounds

Before the concept is described in detail, it is important to emphasize that this solution is not an existing knowledge management approach but a combination of existing tools and instruments. In this section we explain the theory the authors used for designing the concept. Main sources are the approaches of community of practice, moderation and coaching aspects, project and team meetings, lessons learned, and aspects of organizational learning.

First of all, it is important to say that with the concept we intend to approach the existing structure of the organization to the structure of hypertext organization. This kind of organization is characterized on the one hand by a hierarchical structure, and on the other hand by the cooperation of the employees in projects in their department but also to projects with members of different departments. The advantage of this kind of organization is the contact between experts in different areas and, as a result, the exchange of their knowledge (Nonaka & Takeuchi, 1995).

We distinguish the concept of formal and informal dissemination of knowledge. For the formal spread of information, there is a start-up meeting to inform all employees about the new project. Moreover, the project manager immediately sends out important news so that all employees are "on the same page." Standardized templates support the optimal documentation during the whole development process. The existing project management tool stores these documents. One example of a template is the Project Transfer Matrix, a generated knowledge management tool for efficient planning, controlling, and managing the transfer of the project results. The matrix is described more in detail later on. Last but not least, the accomplishment of "lessons learned" in each project group is very important at the end of the project. The team members together document the positive and negative aspects of the whole project and describe how problems could have been avoided. As result, future project teams can learn from their experience (Probst, Raub, & Romhardt, 1999).

The theoretical background of the informal exchange of knowledge provides as basic principle Etienne Wenger's communities of practice concept. A community of practice is a group of people with the same interest in a certain topic, informally bound together with the aim of building and exchanging knowledge. Everyone with interest in the certain topic can participate in sharing knowledge on a Web site. The community runs as long as the members are interested (Wenger, McDermott, & Snyder, 2002). Furthermore, we distinguish between work groups and project teams. A work group has the aim of delivering a product or a service. The members are employees reporting to the same manager and work together until the next reorganization or reassignment. A project team has to accomplish a certain task, is assigned by management, and has a specific deadline. In our concept, thematic groups are built (see section on applied knowledge management methods), which are a combination of the three types.

Furthermore, regular meetings, discussions between the employees, and workshops are possibilities to generate and exchange knowledge. It is also possible to invite an external moderator to accomplish workshops with the advantage that he/she is not involved in the processes of the organization.

To encourage employees to discuss and talk about the new project, it is useful to place charts or whiteboards at meeting points in the company. Meeting points, such as a cafeteria, where members of different areas of the organization meet, facilitate contact between employees. One possibility is the creation of a "topic of the week" to enhance discussions. Possible results and new ideas can be noted on the charts.

There is one more approach of knowledge management in the concept: organizational learning. It describes how groups and so also organizations can learn from the knowledge of the individual and how the knowledge can be spread (Van Heijst et al., 1998). Learning through communication and feedback should be an additional point of this concept, which involves a combination and distribution of existing knowledge.

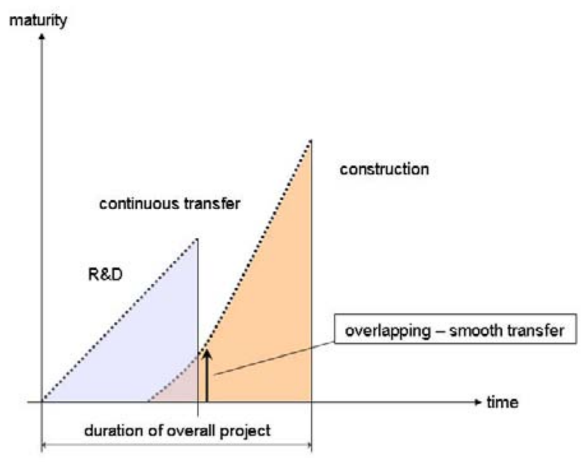
Having discussed the theoretical background in knowledge management, the concept and its development are described in detail below.

Action Plan

In a workshop with the management team and the project managers, the results of the analysis have been discussed and an optimized situation was drafted. This draft did not contain any idea about the new concept but it described the "to-be" situation within the company very clearly. Derived from this "to-be" description, a list of main goals was prepared, which is divided into three major parts: organization/structure, information/communication, and project management/documentation.

The optimization of the existing interface between development and construction cannot be taken under consideration separately from other departments of TAT. This means that there is a

Figure 2. Planned smooth project handover



higher demand for structural and organizational handling of development projects (Figure 2). The following steps have been planned:

- Definition of work distribution among involved departments in development projects
- Definition of specialized technical topic groups (a mixture of teams and communities of practice) for supporting information and communication in projects
- Standardization of documentation and storage of project documents
- Usage of a project management software

For better information and communication during the project delivery, the concept defined the following:

- Support of informal communication of employees of both departments (development and construction)
- Formal communication to grant feedback and commitment of employees to official project documentation
- Information of employees about ongoing development activities and current status of development projects

The last points of the concept handle project management and documentation. The main goal is the structured documentation of project results. To reach this, we planned the following:

- Common vision and mission in the project management
- Structured way of delivering project results

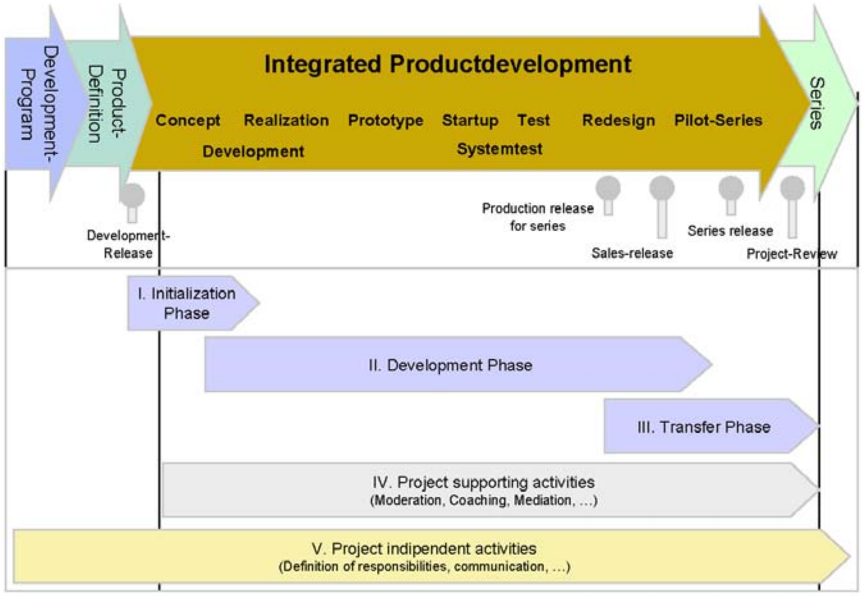
Concept Overview

To solve the existing problems, the concept is oriented along the integrated production development process of TAT (Figure 3). Project management is done very well and clearly defined by internal processes, but information and knowledge interchange must be increased and structured. As a conclusion from the analysis phase, the concept concentrates on communication via different stages, structured and informal information, know-how transfer, and documentation of relevant or critical information handover.

TAT's integrated development process follows the defined process for development of new products which is based on the strategic development program. The first two stages, "Development Program" and "Product Definition," are mainly influenced by the Trumpf Group, which defines every three years development visions for the subsidiary companies. The vague specifications of the development program define the direction of future R&D efforts. Derived from this input, the local subsidiary defines new products or product families in a more detailed way such as a functional specification and technological details, which are worked out in more details in the development department. This functional specification is a starting point for the integrated product development and provides the first input for the knowledge management concept phase — the Initialization Phase.

As shown in Figure 3, the concept consists of five main phases, of which some are partly overlapping. These overlapping parts are necessary to handle preparation activities (e.g., planning workshops), although the actual phase is not completed. Phases I (Initializing), II (Development), and III (Transfer) focus on the product development process and the ongoing interaction of all included departments (development, construction, production). Phase IV (production support) accompanies the whole development project and contains activities and measures to support tasks that are performed in phases I, II, and III. Caused by the identification of optimization potentials beside the interface of development and construction department, we developed Phase V (project-independent activi-

Figure 3. Concept overview



ties) which contains activities and measures to increase transparency and information transfer in the whole organization.

The following sections will describe the five phases of our approach and the included measures in more detail.

Procedure Model in Detail

Figure 4 shows a closer look on Phases I and II. The special task here is the target definition workshop, which is responsible for the definition of knowledge goals, responsibilities, exchange and feedback, information, and communication tasks, which are necessary for project execution (for details take a look at regarding chapter).

Initializing Phase (I)

Phase I (Initializing) handles all preparation activities for the execution of the development phase, which starts overlapping with it. Preparation means securing ongoing information exchange, communication, and exchange of experiences between all participating departments.

Subphase I.1 – Preparation

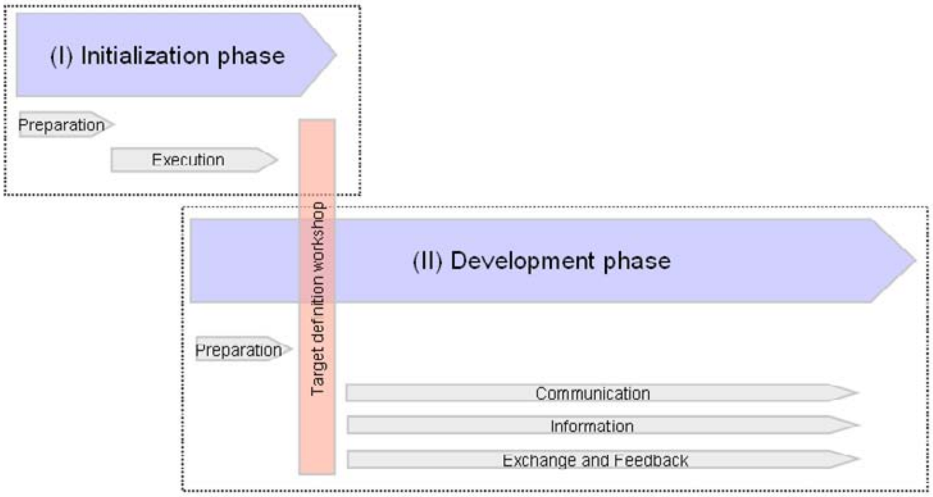
In this subphase, the project manager of the development project prepares a presentation of the idea behind a new product (e.g., machine or new series), which contains the news and makes the differences to actual products more transparent.

After this, the project manager holds a presentation in front of leaders and experienced employees of all departments of TAT to obtain initial feedback. This also fosters initial discussion processes among employees and guarantees the same amount of information to all personnel, which is highly important for motivating employees (Davenport, 1998).

Presentation of ideas:

- Participants: leaders and experienced employees of departments (selected by heads of departments)

Figure 4. Concept detail – part 1



- Responsibility: project manager and management
- Content: presentation of idea of new machine (or series), special differences to existing machines. Technological details are not presented in detail
- Goal: collecting initial feedback and initiating first discussion processes in the company

The second important activity of this subphase is the creation of a concept presentation, which can be done after finishing the concept subphase in the integrated development process (Figure 3). The presentation contains the most important facts such as technological requirements, innovations, or complex elements.

Concept presentation:

- Participants: if possible, all employees of TAT
- Responsibility: project manager
- Content: presentation of machine concept, including all defined technological details, requirements, and performance facts
- Goal: identification of all employees with new machine and motivation of employees by early involvation, intensivation of discussion processes eased by equal information level

Subphase I.2 – Execution

This subphase handles the execution of all presentations that are not part of the target definition workshop. The main idea besides the equal information level and discussion processes is the identification of employees with "their" machine.

Target Definition Workshop

The preparation of the target definition workshop is done in subphase 1 of Phase II — preparation (see section on subphase II.1). Content of this workshop is the definition of so-called "knowledge goals." These knowledge goals are relevant for co-operation of the different departments within the development project. The result of the workshop should be a way to secure the communication, information, and experience exchange and feedback between employees of these departments. It is NOT the goal of this workshop to work out technological requirements, because these are defaults already defined by product idea and concept of the new machine (series).

Participants are all heads of units and selected employees (if possible opinion leaders) of participating departments. The participants document their commitment by signing the protocol of the workshop.

As another result of this workshop, technical topic groups (see section on applied knowledge management methods) are defined to build project support structures and activities. Special technical topic groups could be electronics, mechanics, and so forth, which handle a smaller field in the development process.

Target Definition Workshop:

- Participants: leaders of participating departments and (if possible) opinion leaders
- Responsibility: project manager (for preparation and execution of workshop)
- Preparation: meeting schedule, invitations, preparation of agenda, preparation of short presentation about critical elements of the new machine. Critical means elements with "high effort for TAT," "completely new for TAT," or "success factor for TAT"
- Content: discussion of critical elements and the ongoing information and experience exchange in the development process across department borders. Definition of technical topic groups and their leaders/participants
- Goal: definition of cooperation in development process across departments. No technological goals for machine (which are already stored in the concept)

Possible goals out of such a workshop are as follows:

- Goal 1: securing feedback from all TAT departments
- Goal 2: monthly exchange of project status, experiences, and problems between development and construction staff
- Goal 3: quarterly information of all departments about project status and experiences

All defined goals are tracked with adequate measures in the development phase (see following section).

Development Phase (II)

The development phase is of great importance for the successful implementation of the procedure model, because in this phase the interaction of all participating departments occurs. Substantial for this phase is the definition of knowledge and communication goals in the target definition workshop.

The three subphases (1-3) execute and track the defined and committed goals out of the target definition workshop. This fosters efficient cooperation, successive construction of know-how in all departments, following the development department, usage of know-how of the following departments, and last but not least, securing the ongoing information about the project realization of all TAT employees.

Subphase II.1 – Preparation

As preparation work is already done before the target definition workshop, there is an overlapping part with subphase 2 of the initialization phase. A suggestion for the workshop is to take an external moderator for efficiency and meeting targets. During this preparation phase, the heads of units also select members of their departments for participation.

Subphase II.2 – Communication

Communication, meaning active and directed information transfer, is established in group meetings (see section on applied knowledge management methods) and an electronic project management tool. Van Heijst et al. (1998) described the act of organizational learning through communication. As one can see in Figure 5, the communication of experience brings an increase in organizational knowledge.

This constellation works both ways for learning out of communication (Van Heist et al., 1998): supply-driven and demand-driven learning. In supply-driven learning, the individual employee gains experience and deeper know-how and communicates this to his/her colleagues. Demand-driven learning describes the situation of an employee, who is searching for an answer for a specific problem or topic.

In TAT, the members of the service department obtained input from customers and thus learned about problems and failures. Structured meetings where this customer knowledge is spread among concerned employees led to constructive innovations and improvements during the series production.

Fostered by the heterogeneous participants of such group meetings, new and important information is spread very efficiently to all departments of TAT. The more formal communication is handled by a project management tool which is described in more detail later. This tool secures the documented information broadcast and supports feedback rules, which force people to react and provide input. As a result from former studies and projects, it is necessary to force people at a certain point to commit or to provide feedback.

Subphase II.3 – Information

Based on committed information goals, the project manager informs all participating employees by e-mail about the actual situation of the project or further news. In parallel, the same information will be published on posters or blackboards in all central areas (e.g., kitchen, coffee machine, smoking area, etc.) to keep all employees informed.

Different to the communication phase is the fact that in this phase (information), the communication runs one way. This is a push methodology, the goal of which is to spread information.

All group meetings are documented in a protocol which is published via the electronic project management tool to all relevant employees (mostly all participating employees), which grants that all involved people have the actual information about decisions, problems, or facts. The IT solution also enables employees who are not directly involved to keep in touch and stay informed, for example, marketing or purchasing department as members of the information group.

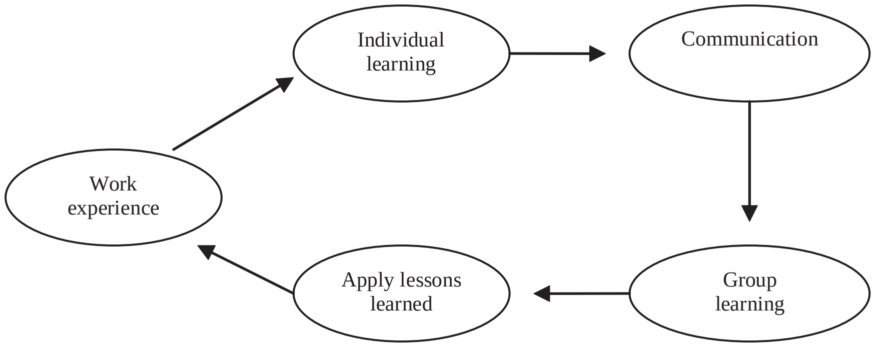
Information means, therefore, creating the possibility for facing future situations. In a special case, the purchasing department was so able to check possible suppliers in advance to obtain better conditions.

Subphase II.4 – Exchange and Feedback

The exchange process defines the interaction between all technical topic groups to prevent information gaps. In their group meetings, the technical topic groups work out important elements of their special areas of interest. Important elements include those that are of highly complex or are very time critical during the transfer between development and construction department. These elements are gathered in a structured collection which is periodically reviewed.

A possible way to increase the quality of work is to establish an internal (or if possible,

Figure 5. Organizational learning through communication (Van Heijst et al., 1998)



external) feedback group, consisting of experts or experienced people. The optional involvement of external specialists could be done by cooperations with universities or research institutes, which is an upcoming topic in Germany (Edler, 2003).

The results (relevant elements, part concepts, solution concepts, or important experiences) of a technical topic group are sent to a defined feedback group. This group reviews the results and brings in their own opinion and also experience. The main goal is here to use synergies between the knowledge of different groups and also to avoid technological or organizational blindness.

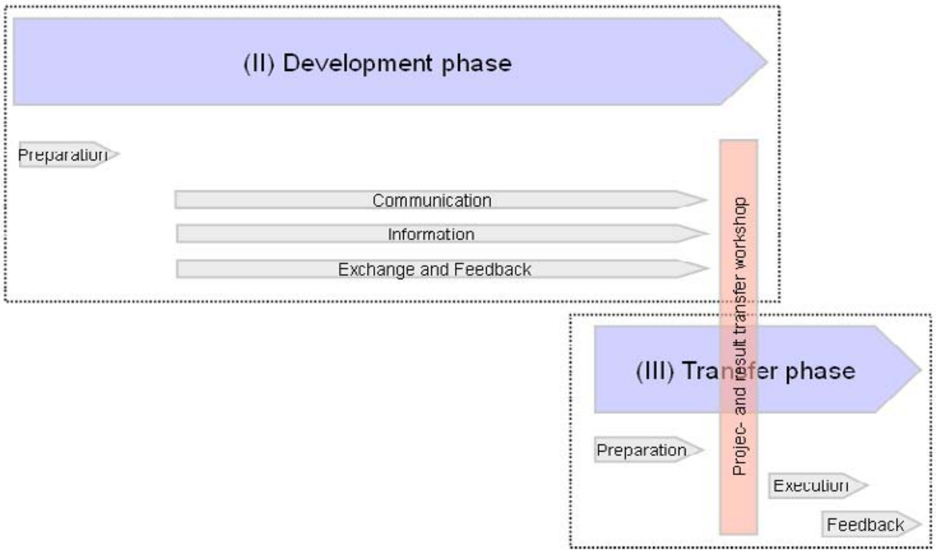
Communication, information, exchange, and feedback:

- Participants: all employees (partly), technical topic groups for communication, exchange and feedback are managed by members of the development or construction department
- Responsibility: project manager (for informing all employees) group responsible for the work in the group
- Preparation: information for all employees; in special cases (confidential information), it is useful to involve the top management, organization of technical topic groups and search for group manager (this task is performed during the target definition workshop)
- Content: information about project realization status; communication, exchange, and feedback about important (development or transfer) topics
- Goal: ongoing information of all employees during the project run time in all departments following the development department. Usage of existing know-how in following departments. Creating an increased "our product" feeling in all participating employees for securing efficient and target-oriented cooperation

Project and Result Transfer Workshop

As described in Figure 6, the concept includes also a workshop for defining how to transfer the project itself and special results between development department and construction department. This workshop initializes the transfer phase and must already be planned for in the overall project plan. The main subject of the transfer workshop is the formulation of a detailed transfer plan. Participants are largely the same as in the target definition workshop.

Figure 6. Concept detail – part 2



A moderator (external) prepares afterward a protocol and a transfer plan in digital media. The protocol and transfer plan must be committed by each participant of the workshop, which is done by using the project management software and its feedback functionality. The project transfer plan provides a summary of what, who, with whom, when, and in which way it has to be delivered. As an instrument for planning, execution, and control, a transfer matrix has been developed, which is described in more detail in another section.

A precondition of a successful application is the ongoing documentation of activities and results done by technical topic groups during the development process.

Project and result transfer workshop:

- Participants: leaders of participating departments and (if possible) opinion leaders
- Responsibility: project manager (for preparation and execution of workshop)
- Preconditions: activities and outputs are already in required form included in the project transfer matrix
- Content: specification of single elements of project transfer matrix, such as priority, start-end dates, responsible persons, and participants of transfer
- Goal: detailed planning of transfer, which is done during the execution of the transfer phase (III)

Transfer Phase (III)

The execution of this phase grants the efficient transfer of project results to following departments, for example, the construction department.

Subphase III.1 – Preparation

Like the preparation of the target definition workshop, the preparation of the transfer workshop overlaps the preliminary phase. The project manager plans with the (external) moderator the workshop to fix the essential points. The target is to grant after the workshop a detailed transfer plan (consisting of what, who, with whom, when, in which kind) is available.

Subphase III.2 – Execution

The execution this subphase handles mainly the implementation of the transfer plan and the documentation of occurring problems and responding solutions. To document these steps, a transfer protocol is used.

Subphase III.3 – Feedback

The subphase feedback is the final step of the cooperating project handling. Of importance for future projects is the documentation of gained experiences from the current development project. To grant the best possible reuse of experience, it is necessary to collect "lessons learned" of the technical topic groups, from the project manager and subproject managers. This can be done by collecting special topics, such as problem-solution combinations, or by using a storytelling, "light" approach (or something like action reviews). Resulting documents will be collected and provided in the project management software.

It is crucial to encourage or to "force" project managers to take a look at the "experience database" before they start a new project. This is a point to change organizational culture. Accepting know-how out of the experiences of others. "Moreover, they must clearly explain the rationale for their final decision, including why they chose to accept some input and advice while rejecting other suggestions. By doing so, leaders can encourage divergent thinking while building decision acceptance" (Roberto, 2002, p. X).

Project Supporting Activities (IV)

Project supporting activities are not directed to a certain stage of the project but chronological delimited by the project duration. So measures lasting the whole period such as established technical topic groups are started at the project start and finished by a structured closing. Structured closing means the collection of gained know-how, findings of lessons learned, and review of managed processes (including communication processes) as described in subphase III.3 – Feedback.

The following measures could be defined as project supporting activities:

- Establishing of technical topic groups
- Organization of group meetings
- Providing IT support
- Creation of a standardized documentation and folder structure
- Moderation, coaching, mediation (providing staff or competence)
- Information activities (e.g., topic of the week)

Information Activities

As part of the information strategy, the publication of special topics for a short period (a week) is done by publishing posters on blackboards or similar information points in central communication areas such as coffee corners, buffet area, or smoking areas. A future idea could also be the establishing of "infopoints" with specially configured PCs accessing the intranet. Such information and knowledge markets (Davenport, 1998) foster communication, information transfer, and knowledge exchange concerning this special topic. The topic responsible person is the project manager.

Project-Independent Activities (V)

Project-independent activities are institutionalized in the organization. These activities affect the organizational structure more than the virtual organization of a project management structure.

The following activities are defined as independent from a running project and can be initiated every time:

- Definition of a responsible contact person for each department

- Supply of communication means
- Clearly defined work distribution

The first two activities increase internal (and external) communication by providing methods and structures and another topic, clearly pointed out in the online survey, is the clearness of work distribution. A solution for the last point is a team around the head of unit, which describes the work of the department.

Definition of Contact Person for Each Department

To increase the efficiency of communication, especially after delivery of machines that reached the maturity phase, it is necessary to define a responsible contact person per department. Additionally, the technical topic group agents could be defined as contact persons for the individual development topics.

Communication Means

To support informal discussions (which lead to the most creative solutions), it is possible to provide whiteboards or flip charts in communication areas. Ideas could so be described more easily and worked out in more detail than only telling it. Additionally more people could take part in the discussion because it is documented.

Applied Knowledge Management Methods

To achieve the final result of a knowledge-oriented R&D process, the following knowledge management methods have been used and implemented: teams and communities of practice (CoPs) (Wenger, McDermott, & Snyder, 2002); interface handling methods such as workshops; early information system to create awareness; IT system support for decisions; information transfer; and process documentation (Maier, 2004). As a final step, a reflection step has also been integrated to obtain lessons learned and further improvements along the process.

Technical Topic Groups

These groups are a mixture of CoPs and teams, a semi-open community with a more-or-less defined goal — development of special topics of a new machine (e.g., electronics, mechanics). Like other constructs (CoPs) (Lave & Wenger, 1991), Ba (Nonaka & Konno, 1998), communities of creation (Sawhney & Prandelli, 2000), or networks of collaborating organizations (Powell, Koput, & Smith-Doerr, 1992), such technical topic groups are an extremely important issue for knowledge creation within a company.

Technical topic groups are not organizational units. They consist of participants from different departments (not only development or construction department) who are also involved in the topic of the group (e.g., technical topic group for hydraulic systems). Technical topic groups should not exceed seven members for efficiency (Fay, Garrod, & Carletta, 2000).

Each technical topic group nominates an agent who acts as feedback responder. This means the agent answers and comments all feedback inquiries from other groups. All other participants of the technical topic group will only be informed and deliver their comments to their agent.

Results and developments (including relevance) of technical topic groups are documented later on in the transfer matrix.

Organization of Group Meetings

To optimize the cross-department information and communication, it is necessary to institutionalize group meetings of technical topic groups. Each meeting should have a certain topic: development problem, development status, new technology, and so forth. These topics should be primarily suggested by development staff, and the other participants provide input and participate in discussions (bringing in their experience). Group meetings should be arranged periodically (e.g., starting with one meeting per month at the beginning up to weekly). To keep the organizational effort per meeting as small as possible, the meeting organization could be done in a rotating system. The organization could be kept simple: agenda, reservation of meeting room, sending out invitations, and documentation of meeting in meeting protocol.

Like CoPs, technical topic groups share knowledge among different departments and increase the amount of knowledge carriers (not only one person, who could get lost) and also organizational knowledge (institutionalization of know-how and best practices) (Van Heijst et al., 1998).

Project Management Tool/Software

IT support of development is split into two major parts: first is the project documentation (structured documents and folders) and second is the project management software itself. All documents and templates for protocols are provided by the project management software; that is the reason for combining these points into one topic.

Creation of Standardized Documents

The creation of a standardized documentation and folder structure should increase the efficiency in project management. The structure provides information about the point of time when documents have to be created and how they must be structured. To ease the access to these documents, it is useful to create a project-independent folder structure or to implement a document management system.

Implemented standard documents are as follows:

- Feedback document: for feedback groups to obtain feedback in structured and similar form
- Status document: designed for ongoing overview about project status and relevant results. This document is also used for the project information group. The project plan must contain points of time when such documents have to be created
- Agenda and protocol templates for technical topic groups: for a consistent documentation
- Transfer protocol template: for consistent documentation of project-result transfer among involved employees

Project Management Software

During the conceptual planning, it was necessary to plan the application of the existing project management software. As described above, the project management tool supports, additional to the provision of documents, information and feedback processes. To reach this, it was necessary to implement the following roles and dedicated functionalities:

- Project manager: person responsible for project, who accepts document release
- Project member: according to the field of activity in the development project, these persons are responsible for providing and creating documents
- Technical topic group leaders: can create documents to inform their group and project members
- Project feedback group: consists of one agent per technical topic group. The members of this group must give their feedback to documents from project management, project members, and other technical topic groups.
- Project information group: this group contains all other technical topic group members

and employees who must be kept informed about the ongoing development activities. This is necessary to prepare early upcoming activities. This information process enables employees to keep a complete overview and it also initiates an informal communication about new developments.

Project Transfer Matrix

During the transfer workshop, the team fills the project transfer matrix, which is used for planning and controlling the transfer of the development project results. The matrix contains all necessary information for the transfer of elements, responsibilities, and status (Table 1).

In detail, the complete TAT matrix consists of the following columns:

- Project steps: contains all process steps that have been executed during the product development. This column is filled out by the project members in the technical topic group meetings.
- Executing department: the current step is managed and executed by department (XY), or in combination with department (AB).
- Output: describes the output of the current project step.
- Status: current status of execution in percent.
- Transfer relevance: (priority) the definition of A (high), B (medium), or C (low) describes the importance of the transfer of these elements (and defines the order of the transferred elements).
- Transfer complexity: the definition of A (high), B (medium), or C (low) describes how difficult it is to transfer this element.
- Transfer responsibility: name of employee who is responsible for transfer of this element.
- Transfer start: date of when transfer should start.
- Transfer end: date of when transfer should be finished.
- Status of transfer (%): the transfer responsible person documents in this weekly up-

Table 1. Project transfer matrix (excerpt)

Project steps	Executing division	Output	Status (in per cent)	Transfer relevance	Transfer complexy	Transfer responsibility
List of Requirements; Functional Specification and Specification Sheet for the whole project and for the teams	D		100	C	C	
List of suppliers and possible suppliers	D		95	A	B	
List of specific assembly instructions	D		0	A	B	
Project documentation of the R&D	D		running	C	C	
Update list of risks	D		running	B	C	
Test planning and supervision	D		running	C	C	
Training Service	D/C		0	A	A	
Creation of acceptance report	C/D		10	A	A	
Creation of maintenance timetable	C/D		0	A	A	
Training Production	C/D		20	A	A	
Training Assembling	C/D		20	A	A	
Training Sales and Marketing	C/D		10	A	B	

dated column the transfer status. If a delay arises, the project manager can intervene.

- Transfer protocol (yes/no): during the transfer workshop, it is defined if it is necessary to create a protocol for this transfer element, because if the element is not important and there is only low complexity, it is not always necessary to prepare a protocol. To prepare useless protocols would lead to less motivation.
- Target department: department that gets output of current project step.
- Target responsible: employee of target department who is responsible for transfer.
- Notes: additional information for documentation, for example, reasons for delay.

The project transfer matrix is a vital document that describes not only the transfer process but also documents it.

CURRENT CHALLENGES FACING THE ORGANIZATION

Challenges During the Project and Current Status

Based on the fact that the project has been initiated under the pressure of an existing development project, at the beginning the concept could only support this project in the last phases — transfer of experiences and information. The departments used the transfer matrix and managed a structured handover. In parallel, the organization established two technical topic groups (hydraulic systems and electronic systems) and built up the reporting, information, and feedback groups within the project management software.

Current status is now a broad acceptance of the concept. The employees of the R&D and construction departments are now aware that they need each other and work more cooperatively. Company representatives lead this back to team meetings and technical topic groups, where they sit together and discuss constructively — "work is easier if we approach a challenge together." As a tool for measuring this fact, one employee told us that employees now go for coffee break together. Another result is the involvement of the service and after-sales department in the development process. Due to the good experiences with the supporting project management tool, there will be further activities to improve its functionalities. Information providers, for example, like the possibility of the tool to check who read the information and who gave feedback. Project-independent activities (e.g., posters, etc.) have also been implemented and the top-down information flows.

General Challenges

Companies have to concentrate on their own core competencies to compensate the pressure arising from the market and the increasing complexity of processes, products, or surrounding environment. Modern companies are specialized on similar fields and form work groups, work lines, or even companies for this ones. Specialization in this context means, on the one hand, highly qualified employees and very special know-how, but on the other hand, a large amount of communication work. A holistic view and a long-term plan are necessary to achieve such ambitious goals as knowledge management in a diversified or spread company.

Today, employees need not only physical material for their daily work, but also an increasing amount of information and knowledge. Codification of knowledge and dedicated sharing of this information is used for keeping knowledge within the company and to support all working steps where this information is needed. This requires also knowing more than one simple task for a further understanding of the whole process. Employees must be able to get more than a local view to notice barriers or critical interfaces to neighbor tasks. This consciousness enables innovation and further improvements on the process. The same is valid for departments and their organizational borders.

The more specialized a department, the higher the need for a common understanding of company goals and project goals. Employees from different departments work together on different projects and interact in teams. These teams form a special kind of dynamic information network cross to typical information channels of a company. Nonaka called this a "hypertext organization" (Nonaka & Takeuchi, 1995) and later an organization as organic configuration of ba (Nonaka & Konno, 2003), because the structure is dynamically formed on demand and changes over time.

Chapter 2.5
E-mail and Knowledge Creation:
Supporting Inquiring Systems and Enhancing Wisdom

Sharman Lichtenstein

Margaret Cybulski
Deakin University, Australia

ABSTRACT

The real promise of organizational communication technologies may lie in their potential to facilitate participative discourse between knowledge workers at all levels in distributed locations and time zones. Such discourse enables the exchange of sometimes conflicting viewpoints through which resolution and symbiosis, organizational knowledge can be built. This chapter presents a case study of a Singerian inquiring organization which illustrates how a fluid dynamic community of employees can use email to build knowledge, learn, make decisions, and enhance wisdom through a cycle of knowledge combination (divergence) and knowledge qualification (convergence). The chapter offers new theoretical perspectives on the enhancement of wisdom in inquiring organizations and provides practical insights into the use of email for supporting effective knowledge creation in inquiring organizations.

INTRODUCTION

In today's globalized business environment, many companies recognize the strategic role of the generation, capture, and dissemination of knowledge in developing inimitable competencies, innovations, and competitive advantages. In particular, the constant creation of new knowledge has been identified as a key business objective. While some experts see the value of ongoing knowledge creation in terms of accelerating innovation (Sharkie, 2003), others focus on its value for enhancing a firm's ability to act—the hallmark of a learning organization (Loermans, 2002; Senge, 1990). When such an approach uses a systematic method for justifying knowledge claims about complex social alternatives, the company evolves into an inquiring organization, employing inquiring systems.

Inquiring systems were originally conceptualized by the pragmatist philosopher Churchman (1971), who strongly believed that knowledge should be created for practical problem-solving purposes and that its creation should be ethically grounded. He specified five archetypal inquiring systems to assist with complex problem solving, each corresponding to a particular philosophy for discovering knowledge truth. A comprehensive view of inquiring systems proposes that they systematically generate knowledge, resolve complex problems, and enhance organizational learning capability, leading to continuous learning and improvement (Courtney, Chae & Hall, 2000).

In the past decade, a diverse body of knowledge has accumulated around identifying, understanding, and linking the key concepts of inquiring systems and organizations. Some of this work has focused on the development of design frameworks for inquiring systems. In a recent development, Hall, Paradice, and Courtney (2003) described a conceptual model for a Learning Organization Knowledge Management System (LOKMS) that portrays a design for an environmentally aware extended inquiring system. Their model shows how key information and knowledge can be continuously and systematically captured and employed to hypothesize and select new states or goals. To achieve these goals, alternative solutions are generated, each based on a recognized mode of inquiry. From among the alternatives, the best option is selected in a decision-making process. A key feature of LOKMS is its reliance on an organizational memory comprising a constantly verified and updated knowledge base and a store of extraneous accumulated knowledge which, while not immediately useful, may acquire validity at some future time. Monitoring of the external environment introduces new and updated knowledge into the organization.

While such designs appear promising, we still lack ways to support such organizations and systems and also need a greater understanding of the underlying concepts. One way to explore and understand the constructs and their support is to study environments where the systems are in evidence. We noticed in the discourse of the ubiquitous organizational tool electronic mail (email), the enactment of some of the key processes appearing in LOKMS—in particular, information and knowledge discovery, the creation of organizational knowledge from the resolution of multiple perspectives, decision support, and the building of organizational memory.

These knowledge processes were discovered in email conversations between people collaborating in distributed networks to solve practical problems. The linchpin knowledge process identified in the conversations was knowledge creation, suggesting to us that in the group appropriation of email for collaboratively solving problems, characteristics of inquiring systems might emerge through the patterns of discourse. We wondered whether discourse found in the simple tool, email, could support some of the components of inquiring systems and organizations. Reaching for wisdom, it was also worth considering whether email could support the enhancement of wisdom.

In this chapter, we explore the potential of email for supporting inquiring organizations and enhancing wisdom. We begin the chapter by looking at an information hierarchy that shows how data can be transformed into knowledge and wisdom. Knowledge creation and other key concepts of inquiring organizations and systems are then reviewed, guided by a simplified conceptual model of inquiring systems in inquiring organizations that incorporates wisdom development structures.

We then analyze how knowledge creation takes place in a collection of email conversations and how inquiring system characteristics emerge. A cycle of collaborative knowledge creation found in email conversations is described, highlighting a pattern of discourse interaction that may enhance wisdom. The chapter provides insights into how inquiring systems and wisdom can be enabled in organizations through specific discourse structures supported by email. This understanding highlights a previously overlooked value in email and also suggests potentially valuable design elements and interventions for inquiring organizations.

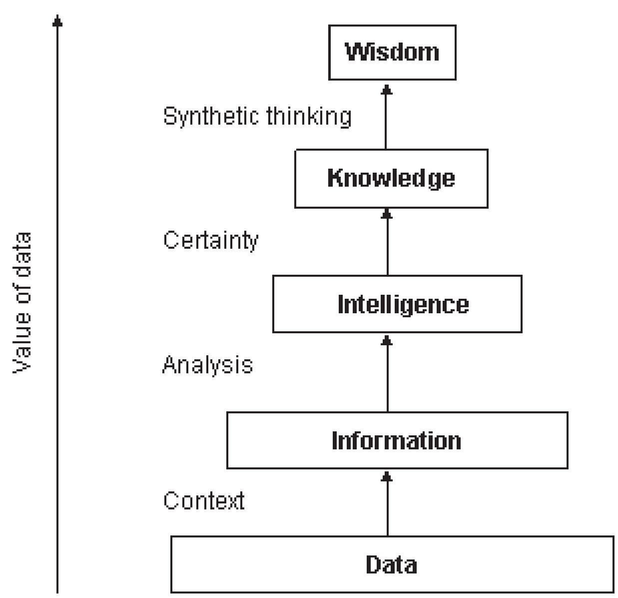
KNOWLEDGE CREATION IN ORGANIZATIONS

The Information Hierarchy

To understand how knowledge is created in organizations, we must first settle the meaning of knowledge in terms of its position within an information hierarchy. In Figure 1, we illustrate an information hierarchy developed by Barabba and Zaltman (1991) and Haeckel and Nolan (1993). According to Barabba and Zaltman, many codified observations or data are obtained from a marketplace of data which, when placed in a decision context, become information. By analyzing information, intelligence is developed. In developing high levels of certainty in intelligence (not necessarily 100%), we create knowledge. Through synthetic thinking about knowledge, a wise outcome is reached—that is, wisdom is achieved. Synthetic thinking involves synthesis, or the combining of ideas in such a way as to create a whole that is greater than the aggregation of its parts.

The value of data increases along the transformation path from data to wisdom, while the volume decreases. There are two distinct stages described: In the creation of collections of data, information is provided. When people use this information for a purpose, intelligence, knowl-

Figure 1. Information hierarchy (based on Barabba & Zaltman, 1991; Haeckel & Nolan, 1993)



edge, and wise decisions may be developed. What is emphasized in this model is Churchman's key observation that how users react to a collection of information alters outcomes and their meanings. Later in the chapter, we show how different modes of inquiry can systematically guide users in the way they create knowledge and even enhance wisdom.

We now proceed to explore how knowledge is created in organizations, how this is often linked with decision-making, and how, simultaneously, learning occurs.

How Knowledge is Created in Organizations

According to Nonaka (1994), knowledge is created from the interplay and transformations between the various knowledge types—individual or collective; tacit or explicit. The four basic transformations are socialization (the conversion of tacit knowledge to tacit knowledge); combination (the conversion of explicit knowledge to explicit knowledge); externalization (the conversion of tacit to explicit knowledge); and internalization (the conversion of explicit to tacit knowledge). This remains the most well known model of knowledge creation, although many others exist.

Various scenarios stimulate knowledge creation. First, within and across the boundaries of organizations, knowledge can be created when insights and intuitions are shared, combined, or gleaned during social processes that typically involve discourse. Second, through regular sampling of external environmental data (for example, scanning the World Wide Web), new knowledge can be brought into the firm and existing organizational knowledge thus validated, updated, and extended. Third, new knowledge may be discovered through a knowledge discovery process from databases. As we have highlighted in the information hierarchy, knowledge originates with people who use information. Thus, most knowledge creation models show the expansion of a knowledge base through collective human activity and are fundamentally social models.

Clearly, participatory organizational groups and networks are particularly useful for this purpose. Such structures are increasingly prevalent in organizations, given the need to coordinate and/or integrate temporally and geographically distributed specialist knowledge for wider purposes, such as projects, and the trend toward participatory work practices. Increasingly, emerging network structures support self-organizing groups whose members cluster around programs, practices, projects, and tasks.

Social Knowledge Creation and Decision Making

The creation of organizational knowledge through collective human activity is closely related to decision making. Knowledge from different people must be assembled to solve problems and make decisions because the likelihood that one person will contain all the relevant knowledge is miniscule—given the current paradigm of specialized knowledge and the limitations (bounded rationality) of the human mind (Jensen & Meckling, 1992).

As today's organizations are plagued by complex changing circumstances and destabilized authority, there are often many considerations and alternatives when resolving associated wicked decision problems (Rittel & Webber, 1973; Weick, 2001). According to Courtney's (2001) new paradigm for decision making in such settings, the interplay of diverse perspectives may assist in resolving wicked decision problems by producing new insights and updating the mental models of stakeholders with one another's perspectives and unspoken assumptions. Dialogue is an important medium that enables diverse views to be heard and resolved.

Social Knowledge Creation and Learning

The link between social knowledge creation and learning is also important to note. Dialogue plays a critical role, in that valuable learning occurs as a result of the interactions occurring in group discourse and collaboration (Bakhtin, 1986; Roschelle, 1992; Stahl, 2002). According to Bakhtin, learning is closely linked to the process of multiple voices coming into contact with one another via verbalized utterances. He suggests that in an utterance, both speaker and listener learn. Stahl describes how social and individual learning are enhanced through discursive debate and a negotiated outcome. Highlighting the nature of interactions needed, Roschelle suggests that effective learning occurs through patterns of divergence and convergence in discourse during collaborative problem solving. Convergence is associated with processes of analysis—for example, testing concepts and solving problems; while divergence is associated with processes of synthesis—for example, generating alternatives and recognizing problems.

Various well known learning models incorporate the ideas of analysis/convergence and synthesis/divergence--for example, Carlsson, Keane, and Martin (1976) and Kolb (1985). Roschelle and other researchers report how the presence of authority in a problem-solving/decision-making conversation can force early convergence and stifle learning (Hubscher-Younger & Narayanan, 2003; Roschelle, 1992), suggesting more generally that conversations require cooperative conditions for optimal learning to take place. Learning is also enhanced in situ (e.g., Lave & Wenger, 1991). Amalgamating these findings:

"Collaborative conversations based around pragmatic problem solving and decision making can be highly valuable for learning purposes, if skills of synthesis and analysis are employed, and if authority does not intervene."

As organizations aim not only for new knowledge and learning but also wisdom in decisions and people, we now discuss the role that knowledge creation can play in leading to wise decisions and, more generally, wisdom.

From Knowledge Creation to Wisdom Enhancement

We review two perspectives of wisdom enhancement: making wise decisions and enhancing wisdom through an attitude of fallible knowing.

In order to make wise decisions, the information hierarchy suggests that analysis (convergence) and synthesis (divergence) are needed (Barabba & Zaltman, 1991; Haeckel & Nolan, 1993). Considering also the value to learning of collaborative problem-solving/decision-making conversations involving cycles of convergence and divergence as discussed previously, we propose a cycle of wisdom enhancing problem solving and decision making in discourse, as shown in Figure 2. The knowledge processes involved are knowledge sharing, creation, convergence and divergence. Wisdom is not indefinitely increased through this cycle, however, because, for example, too many cycles will lessen commitment to continue or follow through with a decision at the end.

Weick (2001) views wisdom as a balanced attitude of fallible knowing, a conceptualization originally espoused by Meacham (1990). Weick suggests that the influx of knowledge in dialogue adds to overly cautious participants' knowledge while removing some of the existing doubt, thereby increasing wisdom. Conversely, doubt raised by the input of new knowledge provided to overly confident participant attitudes increases wisdom. This effect is illustrated in Figure 3. Remaining mindful of ongoing fallibility in knowing during knowledge creation through a combination of acts of doubt and acts of confidence will ultimately lead, according to Weick, to wisdom.

We argue that in today's organizations, where specialization is the norm for distribut-

Figure 2. Enhancing wisdom in decision making in discourse

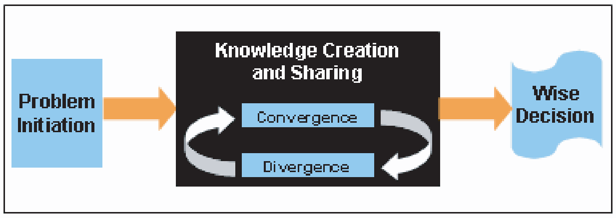


Figure 3. Wisdom as fallible knowing

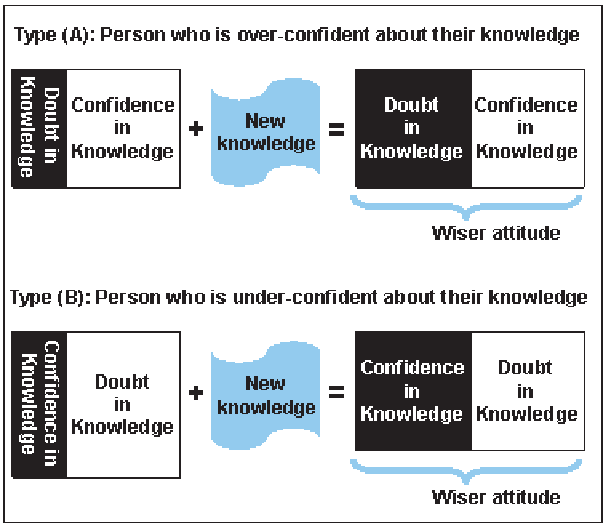


ing knowledge among workers, there tends to be greater doubt than confidence in domains that lie outside one's area of specialization. In such settings, gathering knowledge from others offsets excessive doubt by imbuing the recipient with new confidence once such knowledge is internalized. Confidence is also increased when knowledge creation is situated in practice, and the new knowledge created is highly relevant, accordingly. Furthermore, if this knowledge is collaboratively created, it can later be defended by those who constructed it, providing greater confidence in the validity of the knowledge within the organizational context.

KNOWLEDGE CREATION IN INQUIRING ORGANIZATIONS

In this chapter, we are particularly concerned with social knowledge creation, decision making, and wisdom enhancement in inquiring systems. As we wish to review the concepts of inquiring systems and organizations, we begin by summarizing a complex design model of an inquiring system, LOKMS, introduced earlier and fully described in Hall, Paradice, and Courtney (2003). LOKMS comprises a staged view of how an inquiring system can reach a decision while simultaneously building and refreshing an organizational memory. The system aims to have verified knowledge in its memory, thus storing only concrete types of knowledge. Softer knowledge including semi-abstract types of knowledge, such as stories and artifacts, and abstract knowledge, such as organizational structure, roles, and culture, is not stored.

Simon's (2003) Intelligence-Design-Choice model underpins the three basic stages of LOKMS, comprising Intelligence—information discovery, hypothesis generation, and goal selection; Design--generation and analysis of alternatives developed from different modes of inquiry; and Choice—selection of the best option by a decision maker. In the Intelligence phase, key information and knowledge are continuously and systematically captured from knowledge sources and employed to hypothesize and select new states or goals. In the Design phase, alternative solutions and analyses are generated, each based on a different inquiry paradigm. In the Choice phase, one of the candidate solutions is selected. Feedback loops—and environmental and time-space checks for currency—are built in throughout. The model is fully explained in Hall, Paradice, and Courtney (2003).

LOKMS is a specific and complex design for an inquiring system. Our objective in this chapter is to show how discourse in email can support the basic elements of inquiring systems and enhance wisdom. For this purpose, in Figure 4 we provide a simplified conceptual model of how inquiring systems operate inside inquiring organizations, incorporating the wisdom enhancement principle of convergence-divergence in discourse, introduced in the previous section. This model encompasses the external environment and internal environment, which is comprised of the organizational memory, inquiring system knowledge flow domain, and philosophies guiding knowledge claim justification (knowledge creation) in the domain. We review each of these elements in more detail.

Organizational Memory

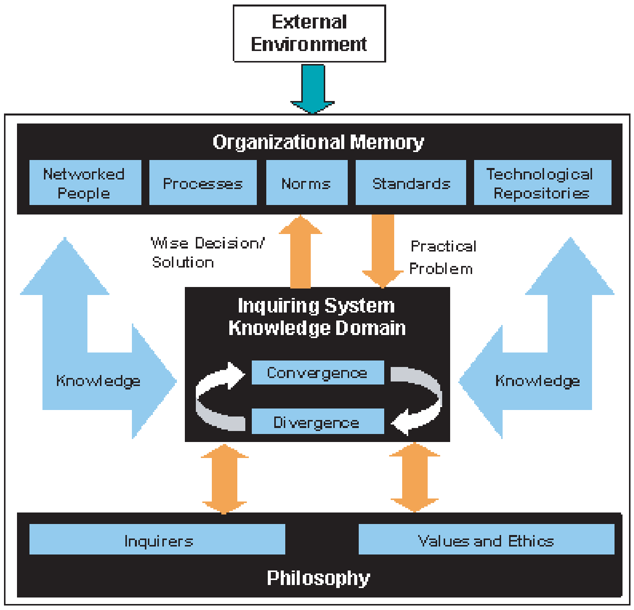
An organizational memory (OM) is a place to retain, integrate, and provide access to organizational knowledge. Most modern definitions for OM include people, processes, norms, standards, and technological repositories. Wickramasinghe (2003) found that although ideally OM should be composed of objective components (explicit knowledge), such as recorded knowledge in repositories, and subjective components (tacit knowledge), such as personal knowledge, the subjective component is typically missing in practice. In inquiring organizations, as shown in Figure 4, subjective knowledge is made available through interpersonal interaction in the group and participation in norms, processes, and standards. Knowledge that has been created in the inquiring system knowledge domain is returned to the OM, while knowledge in the OM is continually validated against scanned external knowledge.

The codified component of OM faces significant problems, such as its potential for sustaining indefinite growth. Another problem is that nowadays codified OM is often fractured into localized repositories (e.g., intranets) that grow in isolation and, to be useful at a broader level at a future time, need reintegration or coordination. In inquiring systems, knowledge held in the OM is coordinated and/or integrated through pragmatic knowledge creation.

Inquiring System Knowledge Domain and Inquirers

A practical problem requiring a solution will lead problem solvers to tap into knowledge from OM and/or the external environment in order to develop a solution/decision. This knowledge creation activity occurs inside a knowledge work domain. Inquiring systems that support inquiring organizations in order to arrive at solutions or decisions are composed of inputs, operators,

Figure 4. Supporting inquiring organizations and wisdom enhancement



outputs, and inquirers that define particular modes of inquiry for ascertaining the truth of knowledge claims. Each inquirer represents a specific philosophy for determining knowledge—inductive and consensual (Locke); deductive and analytic (Leibniz); multiple realities (Kant); conflicting and dialectic (Hegel); and multiple perspectives (Singer).

Courtney, Chae, and Hall (2000) describe five types of inquiring organizations. Liebnizian and Lockean organizations are basically scientific with the first determining truth through theory and the second determining truth through empirics. A Liebnizian organization argues with formal logic, assumes cause and effect, and uses predetermined axioms. In contrast, a Lockean organization is empirically focused, valuing group observation, discourse, and validation in a social context in which group consensus is sought in order to meet group needs. Majority support provides validation of any given observation, input or other information, with an efficient solution sought to meet a group's current needs.

In the Kantian organization, the elements of Liebnizian (truth by theory) and Lockean (truth by empirics) are combined and enhanced through an analytical approach where various alternative models of meaning, explaining the data through a particular theory, are constructed and evaluated. A best fit is obtained through judgment in the particular context. The Hegelian organization takes a dialectic approach that assumes that through conflict of opposing views—thesis and antithesis—a solution better than either view can be synthesized.

Finally, the Singerian organization encompasses all the other types of inquiring organizations by enabling and resolving multiple competing viewpoints, aiming for the common good. Existing knowledge is challenged, and new information representing technical, organizational/social, personal, ethical, and aesthetic perspectives is swept in whenever current models fail to explain a particular situation. Discrepancies are analyzed using methods from the four previous inquirer styles with an emphasis on an ethical and practical approach.

The model depicted in Figure 4 also illustrates knowledge creation and learning as well as the wisdom enhancement cycle of convergence and divergence processes introduced earlier, which, we have argued, can enhance wisdom.

Level of Complexity of Knowledge Work Domain

The level of complexity of a knowledge work domain (Snowden, 2002) shapes and is shaped by the inquirer employed in that domain. In complicated domains, the relationships between cause of knowledge outcome and the outcome itself (that is, cause and effect) are already known, or knowable given sufficient resources. There is high predictive ability for knowledge outcomes in such domains, suggesting that the Liebnizian or Lockean inquiry approaches may be successful.

In complex domains, there are many interacting human agents, each with multiple identities. The interactions form patterns whose outcomes are unpredictable. However, the patterns can be recognized, disrupted, and reoriented, suggesting the potential for Kantian, Hegelian, or Singerian inquirers. In chaotic domains, while patterns of interaction are not emergent, they can be imposed as interventions. According to Snowden, people can mold complex or chaotic domains into known or knowable domains through applying regulation and order. The problem does not determine the inquiry style but rather, people do. Thus, there is always some opportunity to organize all these types of knowledge domains through appropriate management. Snowden further suggested that different managerial and leadership approaches are needed for each domain type.

Values and Ethics

Recent sociopolitical pressures have highlighted the role of ethical values in global healing (Simon, 2003), and ethical values are considered important to inquiring organizations. The values of an organization are embedded in knowledge work through the participants, whose individual values are recreated or reinforced as a result. Internally, a morally sound framework will contribute to increased intraorganizational trust with positive ramifications for open and cooperative team functioning, as required for collective inquiry. Network structures that enable equitable participation and addressing of diverse concerns are suggested.

Ethical organizations exhibit and reinforce values in all activities, including knowledge work. As there is often more than one set of personal values at play in collaborative problem solving, people with values lying outside the boundary of common or majority may be excluded and marginalized. However, with reflection upon this situation by a decision maker, group, or other agent, their views can be accommodated. This reflective process is termed system intervention by Midgley (2000), who suggests that the particular "boundary critique" policy adopted will affect the ethical nature of the organization.

We now proceed to explore these concepts empirically through a study of knowledge creation in discourse in email.

SUPPORT OF KNOWLEDGE CREATION AND INQUIRING SYSTEMS IN E-MAIL DISCOURSE

We conducted a case study involving the knowledge creation activities of a community of practice in a large Australian university, as found in email discourse. The results of this qualitative research are primarily based on a qualitative content analysis of the patterns of discourse involved in knowledge creation in 300 complete email conversations collected from a Eudora email archive in the community under study. Each conversation analyzed contained more than 10 messages and featured the creation of new organizational knowledge. Two of the authors were participants in the academic community while one was the archive owner. Thus, an ethnographic understanding of the context of the conversations was present during analysis, helping us to develop greater insights.

Knowledge Creation Cycle in E-mail Discourse

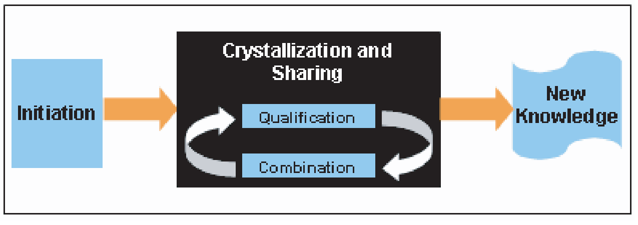
In LOKMS, the three basic stages are intelligence, design, and choice. In the email discourse studied, knowledge was created incrementally through discourse interactions that interwove the elements of intelligence, design, and choice. We identified a pattern of collaborative knowledge development and creation in the conversations studied, described in depth in Lichtenstein (2004) and shown in Figure 5. There are five underlying processes—initiation, crystallization, sharing, qualification, and combination--leading to the creation of new organizational knowledge. The life cycle is illustrated by the email conversation shown in Figure 6.

To summarize, transient virtual teams, operating more like microcommunities, are summoned through an initial message inspired by a need perceived to be of mutual interest to others in the group. This message becomes part of a knowledge trail consisting of successive related emails in one or more threads emanating from the first knowledge seed email. In the conversations, selected because knowledge development took place, knowledge is crystallized along the knowledge trail through processes of knowledge qualification and combination with reference to knowledge resources, including authorities, documents, contributions of insights, ideas, suggestions, and context by participants.

New participants are co-opted as needed for their decision-making power, interest, or additional knowledge. From time to time, participants are omitted from the circulation list. By the end of the knowledge trails, the tacit knowledge of participants has been shared and combined in useful ways, and new organizational knowledge has been created in the form of organized plans and innovation, decisions, and actions. As a result of the continuous learning occurring concurrently, new social and intellectual capital has also been created at individual and collective levels. Thus, there has been knowledge integration in which the specific knowledge held by individual participants has been combined, imbued with collective meaning, and integrated into the group members' tacit knowledge in a potentially valuable way.

In the conversations studied, we observed that the impetus for the cycle of inquiry and knowledge creation arose from an individual (alone, or on behalf of a collective) raising issues for discussion, such as new directions, problems, challenges, or opportunities. These issues had diverse origins including the environment external

Figure 5. Collaborative knowledge creation life cycle in e-mail (Lichtenstein, 2004)



to the organizational unit (for example, competitive threats and mandates from elsewhere in the organization, or outside the organization), the individual's own needs, or a perceived need of the organizational unit.

From Knowledge to Wisdom in E-mail Discourse

It is important to assess the value of the knowledge created in this way. A key advantage of email in this respect is its ability to access a wide variety of people's knowledge through its great reach. Thus, knowledgeable people were co-opted into discussions through the copy or forward facilities, when access was sought to newly needed knowledge. People were included in the initiating message or called upon during email discussions only when needed, including peers, decision makers, knowledge experts, administrators, and knowledge archivists. This may have enabled key people with little time and attention to con-

Figure 6. Sample of knowledge creation in e-mail discourse

Ray (initiation): "I am planning to teach Subject A next year on week nights, instead of weekends. In order to do that, I need a free week night when there are no other classes for students. Bob, can you swap times with me for Subject B, and teach on weekends?"

Bob (crystallization, sharing, combination): "I wish I could help, Ray, but I can't do weekends, either. I've been thinking though of changing the teaching for Subject B. I've noticed students don't get much out of Tutorials in Subject B, so I might omit those and have a two hour seminar which I can put on at 4pm. You can then teach three hours of Subject A afterward at 6pm, Ray. What do you all think?"

Sue (crystallization, sharing, qualification): "As I recall, Marcia says all postgraduate subjects need three hours of class contact."

Marcia (crystallization, sharing, qualification): "Colleagues, yes, the students like three hours of class contact a week, to provide the understanding they need in the subject."

Ray (crystallization, sharing): "Maybe it is time to look at alternative ways that provide even better value?"

Marcia (crystallization, sharing, qualification): "Well, perhaps Bob can find an innovative way of doing that? Bob, I will leave it to you to come up with something."

Bob (crystallization, sharing, combination): "After some discussions with others about this, I suggest we have a two hour workshop each week at 4pm, and a two day workshop during the mid-semester break."

Marcia (crystallization, sharing, qualification): "Sounds good to me. What do you think, Sue and Ray?"

Sue (crystallization, sharing, qualification): "Good idea!"

Ray (crystallization, sharing, qualification): "Yup. Thanks, Bob."

tribute in a timely and economical fashion. The participation of decision makers also meant there was an extremely high likelihood that the created knowledge would have a practical immediate outcome—thereby motivating participants to develop a good solution, quickly.

The raising of a variety of viewpoints allowed assumptions and other issues to surface in the form of disagreement, for resolution. The time available for reflection between attendances on email enabled an important issue to be identified off-line, then raised in email discussion on the next attendance. Finally, issues could be relatively easily brought to the attention of key decision makers without the need for scheduled appointments, providing motivation for raising a concern in email that might otherwise remain unvoiced.

Over and above the advantages discussed above, we suggest that the main value of the knowledge generated is to be found in the method of resolution of multiple perspectives. This resolution was driven by the emerging inquiry mode (as discussed later) as well as the cycles of qualification and combination.

Comparing the cycle in Figure 6 with the cycle of wise decision making in Figure 2 (and shown again in Figure 4), we observe a correspondence between the qualification and convergence processes in that current alternatives are being considered and judged, hastening decision closure. Similarly, there is a correspondence between the combination and the divergence processes in that new alternatives are offered for consideration, showing expansion. We suggest that in general, the greater the number of cycles of qualification and combination, the wiser the resulting solution. A caveat to this is that there will be a point of diminishing returns in repeating the cycle in that, eventually, cooperation in problem solving will diminish under perceived group dissonance.

According to the second perspective of wisdom as fallible knowing, expressed in Figure 3, it is through such combinations in email that an attitude of wisdom can be nurtured, in adding knowledge that balances doubt or confidence in knowing. An attitude of fallible knowing through email discourse is also encouraged at a collective level.

Mode of Inquiry and Decision Making

The mode of inquiry drove the resolution of diverse perspectives. We observed an eclectic array of inquirers: Hegelian (for example, new academic programs in development were considered both with and without particular content); Kantian (for example, reasoning about possible causes for enrolment trends); Singerian (for example, the synthesis of academic content for new units being developed from multiple contributions); Lockean (for example, analyzing enrollment information to make key enrollment decisions); and Leibnizian (for example, an analysis of the number of cars needed to transport employees to an event). We found the Singerian cycle to be the dominant inquirer for knowledge truth in the email conversations studied, with other inquirers utilized as needed. Importantly, the multiple discordant voices appearing in discourse acted as stimuli for the cycle of knowledge creation described.

However, we observed examples where more was needed to achieve closure in the email conversations. There were challenges to the knowledge base—or assumptions or problems—that were difficult to resolve. An impasse, in which no decision was possible as a consensual outcome was required, necessitated moving a discussion off-line. At times, a decision-making authority was brought into a conversation to guarantee resolution in an act of power (Lichtenstein, 2004), or this person simply observed the conversation until the “dust had settled” and then pronounced the outcome, providing a rationale based on assessment of the conversation.

Domain Complexity

We noticed significant disorder in the patterns of knowledge processes occurring, with chaotically (rather than linearly) ordered employee contributions to knowledge development. It is impossible in email, as it presently exists, to ensure linear development of a threaded discussion. After an initiator sent an initial message, a number of people responded at different times, possibly without reading the most current response. This resulted in quite fragmented discussions, which may have reduced the effectiveness of email-based decision making and knowledge creation. On the other hand, this may have encouraged the submission of diverse views, as the protocol of turn taking was simply not possible.

Yet, despite this obstacle, most conversations still resulted in successful outcomes. We recognized that the knowledge work in our email sample resembled the domain of complexity reviewed earlier. This pattern was observed in many of the conversations studied and ties into our finding that the dominant mode of inquiry was Singerian. As mentioned previously, Snowden (2002) suggests that complex domains are managed and led by the early identification of pattern formation, followed by disruption of any undesirable patterns, and stabilization of those desired. We observed signs of this type of management and leadership in the discourse interactions, although this did not appear to be planned. The leadership which emerged seemed to be based mainly on natural authority of a patriarchal or matriarchal nature and was obtained through the process of knowledge qualification, although at times an act of power was clearly linked to an actor with designated authority, as we discuss in the next section.

Organizational Memory and External Knowledge Resources

In our study, the important role that was played by an organization's memory and the external environment was observed because email participants often included knowledge resources of high quality to inform the decision-making process. For example, documents and hyperlinks from sources in organizational memory or outside the organization were included in emails and, in some cases, participants prepared documents over the course of the email conversation if needed. The knowledge of the participants themselves was available through email discourse—as far as participants were prepared to share and able to articulate such knowledge. The tacit knowledge of experts and decision makers who were not initially included in the conversation was accessed when needed. Similarly, affected knowledge stakeholders could be accessed when needed for their opinions or authorization by adding them to the list of email recipients.

The email discourse itself resulted in new codified knowledge being added to organizational memory because participants used the quote function to generate a knowledge trail. This trail provided a record of the way in which the issues and knowledge had developed over a conversation and acted as a reminder of the state of play, considering the lack of continuity inherent in communicating with an asynchronous medium. Possibly, it was an attempt to mimic threaded conversations on a message board in which entire discussions are always viewable. However, there was some confusion experienced whenever participants chose to respond without including the previously maintained knowledge trail.

A major concern with organizational memory repositories is the issue of ensuring that the knowledge retained is accurate. In the organizational unit studied, we found that key people "in the know"—as well as recent credible external information—were accessed for the most recent knowledge and information, while some current participants brought this knowledge with them as they were also participants in other groups (as mentioned earlier, such people can be termed knowledge integrators). Indeed, the degree of accuracy within the email conversations was largely dependent on participants' awareness of who was "in the know" in order to co-opt those experts or peers into the discussion (for example, via the copy feature of email).

A danger thus exists in that if current participants lack accurate knowledge as well as the knowledge of who has the accurate knowledge and is accessible to share it, inaccurate knowledge could be accepted and employed as fact. This is a likely advantage of the LOKMS model, which attempts to link explicit knowledge to individuals who possess the requisite tacit knowledge. However, it was certainly true that in the email conversations in our empirical study there was usually an attempt to co-opt the needed people and thus correct possible errors in the knowledge being shared (and hence ensure that the resulting knowledge created had a greater chance of accuracy).

In some respects, we saw accuracy as enhanced through email via the rationales and results of the additional "information gathering" (the first phase of the LOKMS model) provided by participants. Even stored presumably static knowledge was not always taken as commonly agreed but rather consulted, queried, debated, and sometimes revised when arising in discussion—suggesting that such static knowledge is merely a starting point for developing a situated form of the knowledge. Because participants could view the rationale provided, for instance, they could assess more openly the accuracy of the facts or explicit knowledge on which a decision was being made. Further, we found that accuracy problems in email discourse were reduced to some extent because errors could be detected quite late in the cycle and be relatively easily corrected.

Values and Ethics in Knowledge Creation in E-mail

Importantly, in email, compared with face-to-face meetings and various synchronous collaborative tools, we discovered a strong sense of participatory and democratic involvement in decision making, with all participants given plenty of opportunity to reflect, formulate, and contribute individual opinions, as well as consider at leisure the other perspectives offered and formulate and contribute responses. Furthermore, the fact that key decision makers were accessible and accountable loaned credibility and weight to the decision-making processes involved—in particular, the qualification processes—as well as to the final knowledge outcome.

Participants clearly cooperated and collaborated in their efforts to build knowledge for a team-driven common purpose. There was generalized team spirit and determination to find a solution, however.

A further finding was that email encouraged only participants who felt they had "something genuine to say," or those who read their email in a timely manner, to contribute. Other participants effectively excluded themselves from the process by choosing to remain passive. This questions the true extent of participation provided by email.

CONCLUSION

This chapter aimed to explore the potential of email for supporting inquiring organizations and enhancing wisdom. We first reviewed how knowledge can be created when solving problems and making decisions in organizations during social processes involving discourse and circumstances in which this may lead to the enhancement of wisdom. In particular, the chapter highlights the value of a cycle of convergence and divergence in discourse for the promotion of learning and wisdom and the wisdom of maintaining an attitude of fallible knowing throughout knowledge creation and decision making. We also reviewed key concepts of inquiring organizations, highlighting the influences of different inquiry modes for guiding knowledge creation and decision making and introducing a conceptual model for supporting inquiring organizations (Figure 4) that incorporates the wisdom enhancement principle of cycles of convergence-divergence.

We reported an empirical study of knowledge creation in email from which emerged some of the key characteristics of inquiring systems. More specifically, we observed a cyclic knowledge creation life cycle (Figure 5) that highlights cycles of qualification (convergence) and combination (divergence), suggesting that wisdom may be enhanced through this email-enabled knowledge creation cycle.

The potential of email for supporting pragmatic collaborative knowledge creation, learning, and wisdom enhancement has been highlighted in this chapter. In looking for ways to promote the valuable patterns found, the structuring of collaborative spaces with negotiation discourse templates is one avenue to explore (Ing & Simmonds, 2000; Turoff et. al, 1999). A simpler idea is to train employees in the types of conversations that best promote learning, wise decisions, and wisdom in general. Leadership provides yet another path for influencing domains by modifying the complexity of knowledge work, thus encouraging different patterns of discourse.

We saw that the interplay of perspectives enabled the coordination and integration of tacit knowledge between organizational participants who, possessing only specialized knowledge, otherwise tended to remain isolated and unable to contribute to the larger goals of the organization. Participants also integrated their tacit knowledge with codified knowledge in knowledge trails and internal repositories. These findings are important because, as noted earlier, OM is piecemeal, and its fragments require integration or coordination, while it is generally difficult to access the subjective component of OM. An emerging key role for people possessing integrated knowledge was highlighted by the study. Such people can be termed knowledge integrators, and their increasing importance for collaborative learning and decision making suggests a shift away from valuing specialist knowledge toward valuing people with interdisciplinary and "big picture" understanding.

In closing, we remark an increasing need, in our times, for wisdom. The way forward may lie in giving people voices that are genuinely heard, as people strive to achieve their individual goals, together. This chapter has suggested that it is in the resulting symbiosis of individual ideas and judgments that wisdom, so greatly needed, may well be found.

Chapter 2.6
Stages of Knowledge Management Systems

Petter Gottschalk
Norwegian School of Management BI, Norway

Knowledge management systems refer to a class of information systems applied to manage organizational knowledge. These systems are IT applications to support and enhance the organizational processes of knowledge creation, storage and retrieval, transfer, and application (Alavi & Leidner, 2001).

The knowledge management technology stage model presented in this chapter is a multistage model proposed for organizational evolution over time. Stages of knowledge management technology are a relative concept concerned with IT's ability to process information for knowledge work. The knowledge management technology stage model consists of four stages (Gottschalk, 2005). When applied to law enforcement in the following chapters, the stages are labeled officer-to-technology, officer-to-officer, officer-to-information, and officer-to-application.

KNOWLEDGE TECHNOLOGY STAGES

Stages-of-growth models have been used widely in both organizational research and information technology management research. According to King and Teo (1997), these models describe a wide variety of phenomena: the organizational life cycle, product life cycle, biological growth, and so forth. These models assume that predictable patterns (conceptualized in terms of stages) exist in the growth of organizations, the sales levels of products, and the growth of living organisms. These stages are (1) sequential in nature, (2) occur as a hierarchical progression that is not easily reversed, and (3) involve a broad range of organizational activities and structures.

Benchmark variables are often used to indicate characteristics in each stage of growth. A one-dimensional continuum is established for each benchmark variable. The measurement of benchmark variables can be carried out using Guttman scales (Frankfort-Nachmias & Nachmias, 2002). Guttman scaling is a cumulative scaling technique based on ordering theory that suggests a linear relationship between the elements of a domain and the items on a test.

In the following main part of this chapter, a four-stage model for the evolution of information technology support for knowledge management is proposed and empirically tested. The purpose of the model is both to understand the current situation in an organization in terms of a specific stage, and to develop strategies for moving to a higher stage in the future. We are concerned with the following question: Do organizations move through various stages of growth in their application of knowledge management technology over time, and is each theoretical stage regarded as an actual stage in an organization?

STAGES-OF-GROWTH MODELS

Various multistage models have been proposed for organizational evolution over time. These models differ in the number of stages. For example, Nolan (1979) introduced a model with six stages for IT maturity in organizations that later was expanded to nine stages. Earl (2000) suggested a stages-of-growth model for evolving the e-business consisting of the following six stages: external communication, internal communication, e-commerce, e-business, e-enterprise, and transformation. Each of these models identifies certain characteristics that typify firms in different stages of growth. Among these multistage models, models with four stages seem to have been proposed and tested most frequently (King & Teo, 1997).

In the area of knowledge management, Housel and Bell (2001) described a knowledge management maturity model. The knowledge management maturity (KMM) model is used to assess the relative maturity of a company's knowledge management efforts. The KMM model defines the following five levels (Housel & Bell 2001, p. 136):

1. Level one is the default stage in which there is low commitment to managing anything other than essential, necessary survival-level tasks. At level one, formal training is the main mechanism for learning, and all learning is taken to be reactive. Moreover, level-one organizations fragment knowledge into isolated pockets that are not explicitly documented.
2. Level two organizations share only routine and procedural knowledge. Need-to-know is characteristic, and knowledge awareness rises with the realization that knowledge is an important organizational resource that must be managed explicitly. Databases and routine tasks exist, but are not centrally compiled or managed.
3. Level three organizations are aware of the need for managing knowledge. Content fit for use in all functions begins to be organized into a knowledge life cycle, and enterprise knowledge-propagation systems are in place. However, general awareness and maintenance are limited.
4. Level four is characterized by enterprise knowledge sharing systems. These systems respond proactively to the environment, and the quality, currency, utility, and usage of these systems are improved. Knowledge processes are scaled up across the organization, and organization knowledge boundaries become blurred. Benefits of knowledge sharing and reuse can be explicitly quantified, and training moves into an ad hoc basis as the technology infrastructure for knowledge sharing is increasingly integrated and seamless.
5. Level five is where knowledge sharing is institutionalized and organizational boundaries are minimized. Human know-how and content expertise are integrated into

a seamless package, and knowledge can be most effectively leveraged. Level-five organizations have the ability to accelerate the knowledge life cycle to achieve business advantage.

According to Kazanjian and Drazin (1989), the concept of stages of growth is widely employed. A number of multistage models have been proposed that assume that predictable patterns exist in the growth of organizations, and that these patterns unfold as discrete time periods best thought of as stages. These models have different distinguishing characteristics. Stages can be driven by the search for new growth opportunities, or as a response to internal crises. Some models suggest that firms progress through stages, while others argue that there may be multiple paths through the stages.

Kazanjian (1988) applied dominant problems to stages of growth. Dominant problems imply that there is a pattern of primary concerns that firms face for each theorized stage. In the area of IT maturity, dominant problems can shift from lack of skills to lack of resources to lack of strategy associated with different stages of growth.

Kazanjian and Drazin (1989) argue that either implicitly or explicitly, stage-of-growth models share a common underlying logic. Organizations undergo transformations in their design characteristics that enable them to face the new tasks or problems that growth elicits. The problems, tasks, or environments may differ from model to model, but almost all suggest that stages emerge in a well-defined sequence, so that the solution of one set of problems or tasks leads to the emergence of a new set of problems or tasks that the organization must address. Growth in areas such as IT maturity can be viewed as a series of evolutions and revolutions precipitated by internal crises related to leadership, control, and coordination. The striking characteristic of this view is that the resolution of each crisis sows the seeds for the next crisis. Another view is to consider stages of growth as responses to the firm's search for new growth opportunities once prior strategies have been exhausted.

Stages-of-growth models may be studied through organizational innovation processes. Technological innovation is considered the primary driver of improvements in many businesses today. Information technology represents a complex organizational technology, that is, technology that, when first introduced, imposes a substantial burden on would-be adopters in terms of the competence needed to use it effectively (Levina & Vaast, 2005). According to Fichman and Kemerer (1997), such technology typically has an abstract and demanding scientific base, it tends to be fragile in the sense that it does not always operate as expected, it is difficult to test in a meaningful way, and it is unpackaged in the sense that adopters cannot treat the technology as a black box.

Embodying such characteristics, organizational learning and innovation diffusion theory can be applied to explain stages-of-growth models. Organizational learning is sometimes placed at the center of innovation diffusion theory through a focus on institutional mechanisms that lower the burden of organizational learning related to IT adoption. Organizations may be viewed, at any given moment, as possessing some bundle of competence related to their current operational and managerial processes. In order to successfully assimilate a new process technology, an organization must somehow reach a state where its bundle of competence encompasses those needed to use the new technology (Fichman & Kemerer, 1997).

Innovations through stages of growth can be understood in terms of technology acceptance over time. Technology acceptance has been studied for several decades in information systems research. Technology acceptance models explain perceived usefulness and usage intentions in terms of social influence and cognitive instrumental processes. For example, Venkatesh and Davis (2000) found that social influence processes (subjective norm, voluntariness, and image) and cognitive instrumental processes (job relevance, output quality, result demonstrability, and perceived ease of use) significantly influenced user acceptance. Similarly, Venkatesh (2000) identified determinants of perceived ease of use, a key driver of technology acceptance, adoption, and usage behavior.

Stages-of-growth models have been criticized for a lack of empirical validity. Benbasat et al. (Benbasat, Dexter, Drury, & Goldstein, 1984) found that most of the benchmark variables for stages used by Nolan (1979) were not confirmed in empirical studies. Based on empirical evidence, Benbasat et al. (1984) wrote the following critique of Nolan's stage hypothesis:

The stage hypothesis on the assimilation of computing technology provides one of the most popular models for describing and managing the growth of administrative information systems. Despite little formal evidence of its reliability or robustness, it has achieved a high level of acceptance among practitioners. We describe and summarize the findings of seven empirical studies conducted during the past six years that tested various hypotheses derived from this model. The accumulation of evidence from these studies casts considerable doubt on the validity of the stage hypothesis as an explanatory structure for the growth of computing in organizations.

For example, Nolan (1979) proposed that steering committees should be constituted in later stages of maturity. However, an empirical study showed that of 114 firms, 64 of which had steering committees, the correlation between IT maturity and steering committees was not significant. In practice, organizations adopt steering committees throughout the development cycle rather than in the later stages.

Another example is charge-back methods. In a survey, approximately half of the firms used charge-back systems and the other half did not. In the Nolan (1979) structure, as firms mature through later stages, they should have adopted charge-back systems. Yet, in the empirical analysis, there were no significant correlations between maturity indicators and charge-back system usage, according to Benbasat et al. (1984). Benchmark variables such as steering committees and charge-back systems have to be carefully selected and tested before they are applied in survey research.

The concept of stages of growth has created a number of skeptics. Some argue that the concept of an organization progressing unidirectionally through a series of predictable stages is overly simplistic. For example, organizations may evolve through periods of convergence and divergence related more to shifts in information technology than to issues of growth for specific IT. According to Kazanjian and Drazin (1989), it can be argued that firms do not necessarily demonstrate any inexorable momentum to progress through a linear sequence of stages, but rather that observed configurations of problems, strategies, structures, and processes will determine a firm's progress.

Kazanjian and Drazin (1989) addressed the need for further data-based research to empirically examine whether organizations in a growth environment shift according to a hypothesized stage of growth model, or whether they follow a more random pattern of change associated with shifts in configurations that do not follow such a progression. Based on a sample of 71 firms, they found support for the stage hypothesis.

To meet the criticism of lacking empirical validity, this research presentation describes the careful development, selection, and testing of a variety of instrument parts to empirically validate a knowledge management technology stage model.

Guttman Scaling for Cumulative Growth

Benchmark variables in stages-of-growth models indicate the theoretical characteristics in each stage of growth. The problem with this approach is that not all indicators of a stage may be present in an organization, making it difficult to place the organization in any specific stage.

Guttman scaling is also known as cumulative scaling or scalogram analysis. Guttman scaling is based on ordering theory, which suggests a linear relationship between the elements of a domain and the items on a test. The purpose of Guttman scaling is to establish a one-dimensional continuum for a concept to measure. We would like a set of items or statements so that a respondent who agrees with any specific question in the list will also agree with all previous questions. This is the ideal for a stage model, or for any progression. By this we mean that it is useful when one progresses from one state to another, so that upon reaching the higher stage, one has retained all the features of the earlier stage (Trochim, 2002).

For example, a cumulative model for knowledge transfer could consist of six stages: awareness, familiarity, attempt to use, utilization, results, and impact. Byers and Byers (1998) developed a Guttman scale for knowledge levels consisting of stages by order of learning difficulty. Trochim (2002) developed the following cumulative six-stage scale for attitudes towards immigration:

1. I believe that this country should allow more immigrants in.
2. I would be comfortable with new immigrants moving into my community.
3. It would be fine with me if new immigrants moved onto my block.
4. I would be comfortable if a new immigrant moved next door to me.
5. I would be comfortable if my child dated a new immigrant.
6. I would permit a child of mine to marry an immigrant.

Guttman (1950) used scalogram analysis successfully during the war in investigating morale and other problems in the United States Army. In scalogram analysis, items are ordered such that, ideally, organizations that answer a given question favorably all have higher ranks than organizations that answer the same question unfavorably. According to Guttman (1950, p. 62), the ranking of organizations provides a general approach to the problem of scaling:

We shall call a set of items of common content a scale if an organization with a higher rank than another organization is just as high or higher on every item than the other organization.

Kline (1998, p. 75) discusses three problems with Guttman scales that may, he claims, render them of little scientific value:

1. The underlying measurement model. The first concerns the fact that items correlate perfectly with the total scale score or the attribute being measured. This is unlikely of any variable in the real world. In general terms, it means the measurement model does not fit what is being measured. This is not dissimilar to the difficulty that in psychological measurement, it is simply assumed that the attribute is quantitative.
2. Unidimensionality of the scale. It has been argued that all valid measuring instruments must be unidimensional. Now the construction of a Guttman scale does not ensure unidimensionality. It would be perfectly possible to take items from different scales, each item of a considerably different level of difficulty, and these would form a Guttman scale. This is because the scaling characteristics of Guttman scales are dependent only on difficulty levels. Thus, Guttman scales may not be unidimensional. The only practical way round the problem is to factor the items first, but then it may prove difficult to make a Guttman scale with so restricted an item pool.

3. Ordinal measurement. The construction of Guttman scales may only permit ordinal measurement. This severely restricts the kinds of statistical analyses that can be used with Guttman scales.

These problems also occurred in the conducted empirical tests of the knowledge management technology stage model in Norway and Australia, as is evident in the book by Gottschalk (2005).

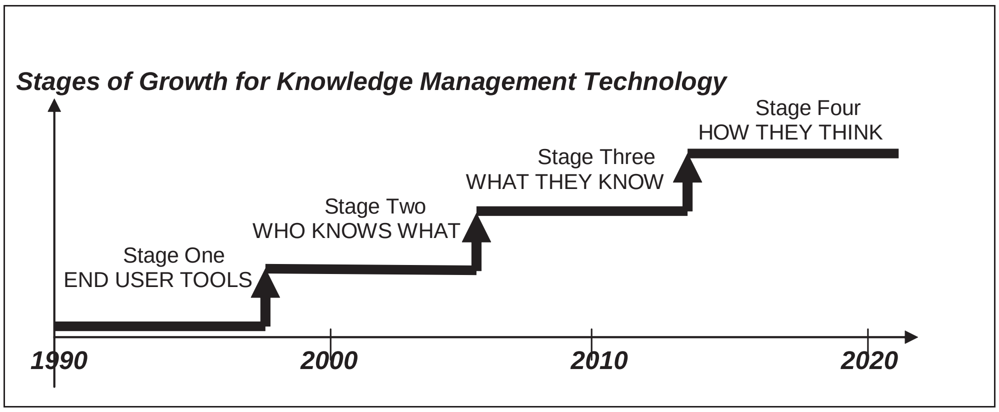
THE KMT STAGE MODEL

Stages of knowledge management technology are a relative concept concerned with IT's ability to process information for knowledge work. IT at later stages is more useful to knowledge work than IT at earlier stages. The relative concept implies that IT is more directly involved in knowledge work at higher stages, and that IT is able to support more advanced knowledge work at higher stages. The knowledge management technology (KMT) stage model consists of four stages. The first stage is general IT support for knowledge workers. This includes word processing, spreadsheets, and e-mail. The second stage is information about knowledge sources. An information system stores information about who knows what within the firm and outside the firm. The system does not store what they actually know. A typical example is the company intranet. The third stage is information representing knowledge. The system stores what knowledge workers know in terms of information. A typical example is a database. The fourth and final stage is information processing. An information system uses information to evaluate situations. A typical example here is an expert system.

The contingent approach to firm performance implies that Stage 1 may be right for one firm, while Stage 4 may be right for another firm. Some firms will evolve over time from Stage 1 to higher stages, as indicated in Figure 1. The time axis, ranging from 1990 to 2020 in Figure 1, suggests that it takes time for an individual firm and a whole industry to move through all stages. As an example applied later in this chapter, the law-firm industry is moving slowly in its use of information technology.

Stages of IT support in knowledge management are useful for identifying the current situation, as well as planning for future applications in the firm. Each stage is described in the following:

Figure 1. The knowledge management technology stage model



1. Tools for end users are made available to knowledge workers. In the simplest stage, this means a capable networked PC on every desk or in every briefcase with standardized personal productivity tools (word processing, presentation software) so that documents can be exchanged easily throughout a company. More complex and functional desktop infrastructures can also be the basis for the same types of knowledge support. Stage 1 is recognized by widespread dissemination and use of end-user tools among knowledge workers in the company. For example, lawyers in a law firm will, in this stage, use word processing, spreadsheets, legal databases, presentation software, and scheduling programs.

   Stage 1 can be labeled end-user-tools or people-to-technology, as information technology provides knowledge workers with tools that improve personal efficiency.
2. Information about who knows what is made available to all people in the firm and to selected outside partners. Search engines should enable work with a thesaurus, since the terminology in which expertise is sought may not always match the terms the expert uses to classify that expertise.

   According to Alavi and Leidner (2001), the creation of corporate directories, also referred to as the mapping of internal expertise, is a common application of knowledge management technology. Because much knowledge in an organization remains uncodified, mapping the internal expertise is a potentially useful application of technology to enable easy identification of knowledgeable persons.

   Here we find the cartographic school of knowledge management (Earl, 2001), which is concerned with mapping organizational knowledge. It aims to record and disclose who in the organization knows what by building knowledge directories. Often called Yellow Pages, the principal idea is to make sure knowledgeable people in the organization are accessible to others for advice, consultation, or knowledge exchange. Knowledge-oriented directories are not so much repositories of knowledge-based information as gateways to knowledge, and the knowledge is as likely to be tacit as explicit.

   Information about "who knows what" is sometimes called metadata, representing knowledge about where the knowledge resides. Providing taxonomies or organizational knowledge maps enables individuals to rapidly locate the individual who has the needed knowledge, more rapidly than would be possible without such IT-based support.

   One starting approach in Stage 2 is to store curriculum vitae (CV) for each knowledge worker in the firm. Areas of expertise, projects completed, and clients helped may, over time, expand the CV. For example, a lawyer in a law firm works on cases for clients using different information sources that can be registered on yellow pages in terms of an intranet.

   At Stage 2, firms apply the personalization strategy in knowledge management. According to Hansen et al. (Hansen, Nohria, & Tierney, 1999), the personalization strategy implies that knowledge is tied to the person who developed it, and is shared mainly through direct person-to-person contact. This strategy focuses on dialogue between individuals; knowledge is transferred mainly in personal e-mail, meetings, and one-on-one conversations.

   The creation of a knowledge network is an important part of Stage 2. Unless specialists can communicate easily with each other across platform types, expertise will deteriorate. People have to be brought together both virtually and face-to-face to exchange and build their collective knowledge in each of the specialty areas. The knowledge management effort is focused on bringing the experts together so that important knowledge can be shared and amplified, rather than on mapping expertise or benchmarking, which occurs in Stage 3.

Electronic networks of practice are computer-mediated discussion forums focused on problems of practice that enable individuals to exchange advice and ideas with others based on common interests. Electronic networks have been found to support organizational knowledge flows between geographically dispersed coworkers and distributed research and development efforts. These networks also assist cooperative open-source software development and open congregation on the Internet for individuals interested in a specific practice. Electronic networks make it possible to share information quickly, globally, and with large numbers of individuals (Wasko & Faraj, 2005).

The knowledge network is built on modern communication technology. Advance in portable computers such as palmtops and laptops, in conjunction with wireless network technologies, has engendered mobile computing. In a mobile computing environment, users carrying portable computers are permitted to access the shared computing resources on the network through wireless channels, regardless of their physical locations.

According to Earl (2001), knowledge directories represent more of a belief in personalized knowledge of individuals than the codified knowledge of knowledge bases, and may demonstrate organizational preferences for human, not technology-mediated, communication and exchange. The knowledge philosophy of firms that settle in Stage 2 can be seen as one of people connectivity. Consequently, the principal contribution from IT is to connect people via intranets, and to help them locate knowledge sources and providers using directories accessed by the intranet. Extranets and the Internet may connect knowledge workers to external knowledge sources and providers.

Communication competence is important at Stage 2. Communication competence is the ability to demonstrate skills in the appropriate communication behavior to effectively achieve one's goals. Communication between individuals requires both the decoding and encoding of messages (Ko, Kirsch, & King, 2005). Lin et al. (Lin, Geng, & Whinston, 2005) found that knowledge transfer depends on the completeness or incompleteness of the sender's and the receiver's information sets.

The dramatic reduction in electronic communication costs and ease of computer-to-computer linkages has resulted in opportunities to create new channel structures, fueling interest in interorganizational systems. Interorganizational systems are planned and managed ventures to develop and use IT-based information exchange systems to support collaboration and strategic alliances between otherwise independent actors. These systems allow for the exchange of information between partners for the purpose of coordination, communication, and cooperation (Malhotra, Gosain, & El Sawy, 2005).

Stage 2 can be labeled who-knows-what or people-to-people, as knowledge workers use information technology to find other knowledge workers.

3. Information from knowledge workers is stored and made available to everyone in the firm, and to designated external partners. Data-mining techniques can be applied here to find relevant information and combine information in data warehouses. On a broader

basis, search engines are Web browsers and server software that operate with a thesaurus, since the terminology in which expertise is sought may not always match the terms used by the expert to classify that expertise.

One starting approach in Stage 3 is to store project reports, notes, recommendations, and letters from each knowledge worker in the firm. Over time, this material will grow fast, making it necessary for a librarian or a chief knowledge officer (CKO) to organize it. In a law firm, all client cases will be classified and stored in databases using software such as Lotus Notes.

An essential contribution that IT can make is the provision of shared databases across tasks, levels, entities, and geographies to all knowledge workers throughout a process (Earl, 2001). For example, Infosys Technologies—a U.S. $1 billion company with over 23,000 employees and globally distributed operations—created a central knowledge portal called KShop. The content of KShop was organized into different content types, for instance, case studies, reusable artifacts, and downloadable software. Every knowledge asset under a content type was associated with one or more nodes (representing areas of discourse) in a knowledge hierarchy or taxonomy (Garud & Kumaraswamy, 2005).

According to Alavi and Leidner (2001), one survey found that 74% of respondents believed that their organization's best knowledge was inaccessible, and 68% thought that mistakes were reproduced several times. Such a perception of failure to apply existing knowledge is an incentive for mapping, codifying, and storing information derived from internal expertise.

However, sifting though the myriad of content available through knowledge management systems can be challenging, and knowledge workers may be overwhelmed when trying to find the content most relevant for completing a new task. To address this problem, system designers often include rating schemes and credibility indicators to improve users' search and evaluation of knowledge management system content (Poston & Speier, 2005).

According to Alavi and Leidner (2001), one of the most common applications is internal benchmarking, with the aim of transferring internal best practices. To be successful, best practices have to be coded, stored, and shared among knowledge workers.

In addition to (1) best practices knowledge within a quality or business process management function, other common applications include (2) knowledge for sales purposes involving products, markets, and customers, (3) lessons learned in projects or product development efforts, (4) knowledge around implementation of information systems, (5) competitive intelligence for strategy and planning functions, and (6) learning histories or records of experience with a new corporate direction or approach (Grover & Davenport, 2001).

In Stage 3, access both to knowledge (expertise, experience, and learning) and to information (intelligence, feedback, and data analyses) is provided by systems and intranets to operatives, staff, and executives. The supply and distribution of knowledge and information are not restricted. Whereas we might say in Stage 1, "give knowledge workers the tools to do the job," we now add, "give knowledge workers the knowledge and information to do the job." According to Earl (2001), this is another way of saying that the philosophy is enhancing the firm's capabilities with knowledge flows.

Although most knowledge repositories serve a single function, Grover and Davenport (2001) found that it is increasingly common for companies to construct an internal portal so that employees can access multiple, different repositories and sources from one screen. It is also possible and increasingly popular for repositories to contain information as well as pointers to experts within the organization on key knowledge topics. Often called Knowledge Yellow Pages, these systems facilitate contact and knowledge transfer between knowledgeable people and those who seek their knowledge. Stored, codified knowledge is combined with lists of individuals who contributed the knowledge and could provide more detail or background on it.

An enterprise information portal is viewed as a knowledge community. Enterprise information portals are of multiple forms, ranging from Internet-based data management tools that bring visibility to previously dormant data so that their users can compare, analyze, and share enterprise information to a knowledge portal that enables its users to obtain specialized knowledge that is related to their specific tasks (Ryu, Kim, Chaudhury, & Rao, 2005).

Individuals' knowledge does not transform easily into organizational knowledge even with the implementation of knowledge repositories. According to Bock et al. (Bock, Zmud, & Kim, 2005), individuals tend to hoard knowledge for various reasons. Empirical studies have shown that the greater the anticipated reciprocal relationships are, the more favorable the attitude toward knowledge sharing will be.

Electronic knowledge repositories are electronic stores of content acquired about all subjects for which the organization has decided to maintain knowledge. Such repositories can comprise multiple knowledge bases, as well as the mechanisms for acquisition, control, and publication of the knowledge. The process of knowledge sharing through electronic knowledge repositories involves people contributing knowledge to populate repositories (e.g., customer and supplier knowledge, industry best practices, and product expertise) and people seeking knowledge from repositories for use (Kankanhalli, Tan, & Wei, 2005).

In Stage 3, firms apply the codification strategy in knowledge management. According to Hansen et al. (1999), the codification strategy centers on information technology: knowledge is carefully codified and stored in knowledge databases, and can be accessed and used by anyone. With a codification strategy, knowledge is extracted from the person who developed it, is made independent from the person, and stored in form of interview guides, work schedules, benchmark data, and so forth, and then searched and retrieved and used by many employees.

According to Grover and Davenport (2001), firms increasingly view attempts to transform raw data into usable knowledge as part of their knowledge management initiatives. These approaches typically involve isolating data in a separate warehouse for easier access, and the use of statistical analysis or data mining and visualization tools. Since their goal is to create data-derived knowledge, they are increasingly addressed as part of knowledge management in Stage 3.

Stage 3 can be labeled what-they-know or people-to-docs, as information technology provides knowledge workers with access to information that is typically stored in documents. Examples of documents are contracts and agreements, reports, manuals and handbooks, business forms, letters, memos, articles, drawings, blueprints, photographs, e-mail and voice mail messages, video clips, script and visuals from presentations, policy statements, computer printouts, and transcripts from meetings.

Sprague (1995) argues that concepts and ideas contained in documents are far more valuable and important to organizations than facts traditionally organized into data records. A document can be described as a unit of recorded information structured for human consumption. It is recorded and stored, so a speech or conversation for which no transcript is prepared is not a document. A document is a snapshot of some set of information that can incorporate many complex information types, exist in multiple places across a network, depend on other documents for information, change as subordinate documents are updated, and be accessed and modified by many people simultaneously.

4. Information systems solving knowledge problems are made available to knowledge workers and solution seekers. Artificial intelligence is applied in these systems. For example, neural networks are statistically oriented tools that excel at using data to classify cases into one category or another. Another example is expert systems that can enable the knowledge of one or a few experts to be used by a much broader group of workers requiring the knowledge.

   According to Alavi and Leidner (2001), an insurance company was faced with the commoditization of its market, and declining profits. The company found that applying the best decision-making expertise via a new underwriting process, supported by a knowledge management system based on best practices, enabled it to move into profitable niche markets and, hence, to increase income.

   According to Grover and Davenport (2001), artificial intelligence is applied in rule-based systems, and more commonly, case-based systems are used to capture and provide access to resolutions of customer service problems, legal knowledge, new product development knowledge, and many other types of knowledge.

   Biodiversity is a data-intense science, drawing as it does on data from a large number of disciplines in order to build up a coherent picture of the extent and trajectory of life on earth. Bowker (2000) argues that as sets of heterogeneous databases are made to converge, there is a layering of values into the emergent infrastructure. This layering process is relatively irreversible, and it operates simultaneously at a very concrete level (fields in a database) and at a very abstract one (the coding of the relationship between the disciplines and the production of a general ontology).

   Knowledge is explicated and formalized during the knowledge codification phase that took place in Stage 3. Codification of tacit knowledge is facilitated by mechanisms that formalize and embed it in documents, software, and systems. However, the higher the tacit elements of the knowledge, the more difficult it is to codify. Codification of complex knowledge frequently relies on information technology. Expert systems, decision support systems, document management systems, search engines, and relational database tools represent some of the technological solutions developed to support this phase of knowledge management. Consequently, advanced codification of knowledge emerges in Stage 4, rather than in Stage 3, because expert systems and other artificial intelligence systems have to be applied to be successful.

   Stage 4 can be labeled how-they-think or people-to-systems, where the system is intended to help solve a knowledge problem. The label how-they-think does not mean that the systems, as such, think. Rather, it means that the thinking of people has been implemented in the systems.

Stage 1 is a technology-centric stage, while Stage 2 is a people-oriented stage, Stage 3 is a technology-driven stage, while Stage 4 is a process-centric stage. A people- oriented perspective draws from the work of Nonaka et al. (Nonaka, Toyama, & Konno, 2000). Essential to this perspective of knowledge sharing and knowledge creation is that people create knowledge, and that new knowledge, or the increasing of the extant knowledge base, occurs as a result of human cognitive activities and the effecting of specific knowledge transformations (Wasko & Faraj, 2005). A technology-driven perspective to knowledge management at Stage 3 is often centered on the computerized technique of data mining, and the many mathematical and statistical methods available to transform data into information and then meaningful knowledge (e.g., Poston & Speier, 2005). A process-centric approach tries to combine the essentials of both the people-centric and the technology-centric and technology-driven perspectives in the earlier stages. It emphasizes the dynamic and ongoing nature of the process, where artificial intelligence might help people understand how to proceed in their tasks. Process-centered knowledge generation is concerned with extraction of critical and germane knowledge in a decision-making perspective (Bendoly, 2003).

The stages-of-growth model for knowledge management technology is mainly a sequential and accumulative model. However, in practice, the model can also be applied in a cyclical mode. For example, when a firm reaches 2020 in Figure 1, the firm might return to Stage 3 from Stage 4 to improve information sources and information access at Stage 3 that will improve the performance of systems applied at Stage 4. Therefore, in a short-term perspective, the stages model is sequential, while in a long-term perspective it consists of several cycles.

When companies want to use knowledge in real-time, mission-critical applications, they have to structure the information base for rapid, precise access. A Web search yielding hundreds of documents will not suffice when a customer is waiting on the phone for an answer. Representing and structuring knowledge is a requirement that has long been addressed by artificial intelligence researchers in the form of expert systems and other applications. Now their technologies are being applied within the context of knowledge management. Rule-based systems and case-based systems are used to capture and provide access to customer service problem resolution, legal knowledge, new product development knowledge, and many other types of knowledge. Although it can be difficult and labor-intensive to author a structured knowledge base, the effort can pay off in terms of faster responses to customers, lower cost per knowledge transaction, and lessened requirements for experienced, expert personnel (Grover & Davenport, 2001).

Expert systems are in Stage 4 in the proposed model. Stewart (1997) argues for Stage 2, stating that knowledge grows so fast that any attempt to codify all is ridiculous; but the identities of in-house experts change slowly. Corporate yellow pages should be easy to construct, but it's remarkable how few companies have actually done this. A simple system that connects inquirers to experts saves time, reduces error and guesswork, and prevents the reinvention of countless wheels.

What may be stored in Stage 3, according to Stewart (1997), are lessons learned and competitor intelligence. A key way to improve knowledge management is to bank lessons learned, in effect, prepare checklists of what went right and wrong, together with guidelines for others undertaking similar projects. In the area of competitor intelligence, companies need to organize knowledge about their suppliers, customers, and competitors.

Information technology can be applied at four different levels to support knowledge management in an organization, according to the proposed stages of growth. At the first level, end-user tools are made available to knowledge workers. At the second level, information on who knows what is made available electronically. At the third level, some information representing knowledge is stored and made available electronically. At the fourth level, information systems capable of simulating human thinking are applied in the organization. These four levels are illustrated in Figure 2, where they are combined with knowledge management tasks. The entries in the figure only serve as examples of current systems.

One reason for Stage 3 emerging after Stage 2 is the personalization strategy vs. the codification strategy. The individual barriers are significantly lower with the personalization strategy, because the individual professional maintains the control through the whole knowledge management cycle. According to Disterer (2001), the individual is recognized as an expert and is cared for.

Knowledge management strategies focusing on personalization could be called communication strategies, because the main objective is to foster personal communication between people. Core IT systems with this strategy are yellow pages (directories of experts, who-knows-what systems, people finder database) that show inquirers who they should talk to regarding a given topic or problem. The main disadvantages of personalization strategies are a lack of standards, the high dependence on communication skills, and the will of the professionals. Such disadvantages make firms want to advance to Stage 3. In Stage 3, independence, in time, among knowledge suppliers and knowledge users is achieved (Disterer, 2002).

When we look for available computer software for the different stages, we find a variety of offers from software vendors. At Stage 1, we find Microsoft software such as Word, Outlook, Excel, and Powerpoint. At Stage 2, we find knowledge software such as Knowledger from Knowledge Associates (http://www.knowledgeassociates.com). The Knowledger 4.0 helps companies collect and categorize internal and external information. It allows individuals to capture information, together with its context, into a knowledge repository.

At Stage 3, we find Novo Knowledge Base Enterprise (http://www.novosolutions.com), Confluence the Enterprise Wiki (http://www.atlassian.com), and Enterprise Edition X1 Technologies (http://www.x1.com). While Novo's KnowledgeBase provides Web support and documentation solutions, Atlassian's JIRA is tracking and managing the issues and bugs that emerge during a project.

Figure 2. Examples of IS/IT in different knowledge management stages

STAGES TASKS	**I END USER TOOLS people-to-technology**	**II WHO KNOWS WHAT people-to-people**	**III WHAT THEY KNOW people-to-docs**	**IV WHAT THEY THINK people-to-systems**
Distribute knowledge	Word Processing Desktop Publishing Web Publishing Electronic Calendars Presentations	Word Processing Desktop Publishing Web Publishing Electronic Calendars Presentations	Word Processing Desktop Publishing Web Publishing Electronic Calendars Presentations	Word Processing Desktop Publishing Web Publishing Electronic Calendars Presentations
Share knowledge		Groupware Intranets Networks E-mail	Groupware Intranets Networks E-mail	Groupware Intranets Networks E-mail
Capture knowledge			Databases Data Warehouses	Databases Data Warehouses
Apply knowledge				Expert systems Neural networks Intelligent agents

Finally, at Stage 4, we find DecisionScript by Vanguard Software Corporation (http://www.vanguardsw.com) and CORVID Knowledge Automation Expert System Software by Xsys (http://www.exsys.com). Vanguard provides decision-support system software ranging from desktop tools for managing decision-making to server-based systems that help the entire organization work smarter. Vanguard's desktop software, DecisionPro, is designed for managers, consultants, and analysts who make business decisions based on uncertain estimates and imperfect information. Exsys argues that their software and services enable businesses, government, and organizations to distribute a company's most valuable asset-expert knowledge-to the people who need it, through powerful interactive Web-enabled systems.

Benchmark variables have been developed by Gottschalk (2005) for the stages-of-growth model. Benchmark variables indicate the theoretical characteristics in each stage of growth. Examples of benchmark variables include trigger of IT, management participation, critical success factor, and performance indicator.

Chapter 2.7
Knowledge Management Systems

Ronald Maier
Martin-Luther-University Halle-Wittenberg, Germany

Thomas Hädrich
Martin-Luther-University Halle-Wittenberg, Germany

INTRODUCTION

Knowledge management systems (KMSs) are seen as enabling technologies for an effective and efficient knowledge management (KM). However, up to date the term knowledge management system has often been used ambiguously. Examples are its use for specific KM tools, for KM platforms, or for (a combination of) tools that are applied with KM in mind. So far, investigations about the notion of KMS remain on the abstract level of what a KMS is used for, for example, "a class of information systems applied to managing organizational knowledge" (Alavi & Leidner, 2001, p. 114). The following two sections define the term KMS and obtain a set of characteristics that differentiates KMS from traditional information systems, such as intranet infrastructures, document- and content-management systems, groupware, or e-learning systems. Then, two ideal architectures for KMS are contrasted. It is discussed which KMS architecture fits what type of KM initiatives, and some empirical findings on the state of practice of KMS are summarized. The last sections give an outlook on future trends and conclude the article.

BACKGROUND

A review of the literature on information and communication technologies to support KM reveals a number of different terms in use, such as knowledge warehouse, KM software, KM suite, KM (support) system, and KM technology as well as learning-management platform, learning-management portal, learning-management suite, learning-management system, or organizational-memory (information) system (e.g., Alavi & Leidner, 2001; Maier, 2004; McDermott, 1999; Mentzas, Apostolou, Young, & Abecker, 2001; Nedeß & Jacob, 2000; Schwartz, Divitini, & Brasethvik, 2000; Seifried & Eppler, 2000; Stein & Zwass, 1995). In addition to these terms meaning a comprehensive platform in support of KM, many authors provide more or less extensive lists of individual tools or technologies that can be used to support KM initiatives as a whole or for certain processes, life-cycle phases, or tasks thereof (e.g., Allee, 1997; Binney, 2001; Borghoff & Pareschi, 1998; Hoffmann, 2001; Jackson, 2003; Meso & Smith, 2000; Ruggles, 1998).

TOWARD A DEFINITION OF KNOWLEDGE MANAGEMENT SYSTEMS

Recently, the terms KM tools and KMS have gained wide acceptance both in the literature and on the market. Consequently, we use the term KMS being well aware that there are a number of similar conceptualizations that complement the functionality and architectures of KMS. In the following, we will summarize the most important characteristics of KMS as found in the literature.

Goals

The primary goal of KMS is to bring knowledge from the past to bear on present activities, thus resulting in increased levels of organizational effectiveness (Lewin & Minton, 1998; Stein & Zwass, 1995). Thus, a KMS is the technological part of a KM initiative that also comprises person-oriented and organizational instruments targeted at improving the productivity of knowledge work (Maier, 2004). KM initiatives can be classified according to the strategy in human-oriented personalization initiatives and technology-oriented codification initiatives (Hansen, Nohria, & Tierney, 1999). They can further be distinguished according to the scope into enterprise-specific initiatives and initiatives that cross organizational boundaries. According to organizational design, initiatives can establish a central organizational unit responsible for KM, or they can be run by a number of projects and/or communities. The initiatives can focus on a certain type of content along the knowledge life cycle, for example, ideas, experiences, lessons learned, approved knowledge products, procedures, best practices, or patents. Finally, the organizational culture can be characterized as open, trustful, or collective where willingness to share knowledge is high; or as confidential, distrustful, or individual where there are high barriers to knowledge sharing (see Maier, 2004, for a definition of and empirical results about this typology of KM initiatives). The type of initiative determines the type of KMS for its support.

Processes

KMSs are developed to support and enhance knowledge-intensive tasks, processes, or projects (Detlor, 2002; Jennex & Olfmann, 2003) of, for example, knowledge creation, organization, storage, retrieval, transfer, refinement and packaging, (re)use, revision, and feedback, also called the knowledge life cycle, ultimately to support knowledge work (Davenport, Jarvenpaa, & Beers, 1996). In this view, a KMS provides a seamless pipeline for the flow of explicit knowledge through a refinement process (Zack, 1999).

Comprehensive Platform

Whereas the focus on processes can be seen as a user-centric approach, an IT-centric approach provides a base system to capture and distribute knowledge (Jennex & Olfmann, 2003). This platform is then used throughout the organization. In this case, a KMS is not an application system targeted at a single KM initiative, but a platform that can be used either as is to support knowledge processes or as the integrating base system and repository on which KM application systems are built. Comprehensive in this case means that the platform offers functionality for user administration, messaging, conferencing, and the sharing of (documented) knowledge, that is, publishing, searching, retrieving, and presenting.

Advanced Knowledge Services

KMSs are ICT platforms on which a number of integrated services are built. The processes that have to be supported give a first indication of the types of services that are needed. Examples are rather basic services, for example, collaboration, work-flow management, document and content management, visualization, search, and retrieval (e.g., Seifried & Eppler, 2000); or more advanced services, for example, personalization, text analysis, clustering and categorization to increase the relevance of retrieved and pushed information, advanced graphical techniques for navigation, awareness services, shared work spaces, and (distributed) learning services as well as the integration of and reasoning about various (document) sources on the basis of a shared ontology (e.g., Bair, 1998; Borghoff & Pareschi, 1998; Maier, 2004).

KM Instruments

KMSs are applied in a large number of application areas (Tsui, 2003) and specifically support KM instruments, such as (a) the capture, creation, and sharing of good or best practices, (b) the implementation of experience-management systems, (c) the creation of corporate knowledge directories, taxonomies, or ontologies, (d) competency management, (e) collaborative filtering and handling of interests used to connect people, (f) the creation and fostering of communities or knowledge networks, or (g) the facilitation of intelligent problem solving (e.g., Alavi & Leidner, 2001; McDermott, 1999; Tsui, 2003). Thus, KMSs offer a targeted combination and integration of knowledge services that together foster one or more KM instruments.

Specifics of Knowledge

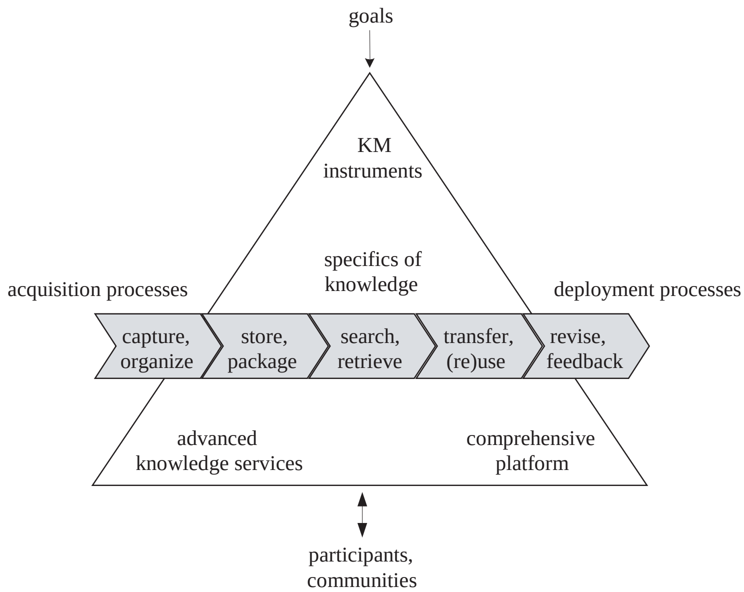
KMSs are applied to managing knowledge that is described as "personalized information…related to facts, procedures, concepts, interpretations, ideas, observations, and judgements" (Alavi & Leidner, 2001). From the perspective of KMS, knowledge is information that is meaningfully organized, accumulated, and embedded in a context of creation and application. KMSs primarily leverage codified knowledge, but also aid communication or inference used to interpret situations and to generate activities, behaviour, and solutions. KMSs help to assimilate contextualized information, provide access to sources of knowledge, and, with the help of shared context, increase the breadth of knowledge sharing between persons rather than storing knowledge itself (Alavi & Leidner, 2001).

Participants

The internal context of knowledge describes the circumstances of its creation. The external context relates to the retrieval and application of knowledge (Barry & Schamber, 1998; Eppler, 2003). Contextualization is one of the key characteristics of KMS (Apitz, Lattner, & Schäffer, 2002) that provides a semantic link between explicit, codified knowledge and the persons that hold or seek knowledge in certain subject areas. Thus, it creates a network of artifacts and people, of memory and of processing (Ackerman & Halverson, 1998). Decontextualization and recontextualization turn static knowledge objects into knowledge processes (Ackerman & Halverson, 1998). Metaknowledge in a KMS is sometimes as important as the original knowledge itself (Alavi & Leidner, 2001). Therefore, users play the roles of active, involved participants in the knowledge network fostered by KMS.

In addition to the previous characteristics, a KMS has to be aligned with the specifics of its

Figure 1. Characteristics of KMS



application environment, the goals, and the types of KM initiatives as well as the acquisition and deployment processes required for managing knowledge (see Figure 1).

Consequently, a KMS is defined as a comprehensive ICT platform for collaboration and knowledge sharing with advanced knowledge services built on top that are contextualized and integrated on the basis of a shared ontology, and personalized for participants networked in communities. KMSs foster the implementation of KM instruments in support of knowledge processes targeted at increasing organizational effectiveness.

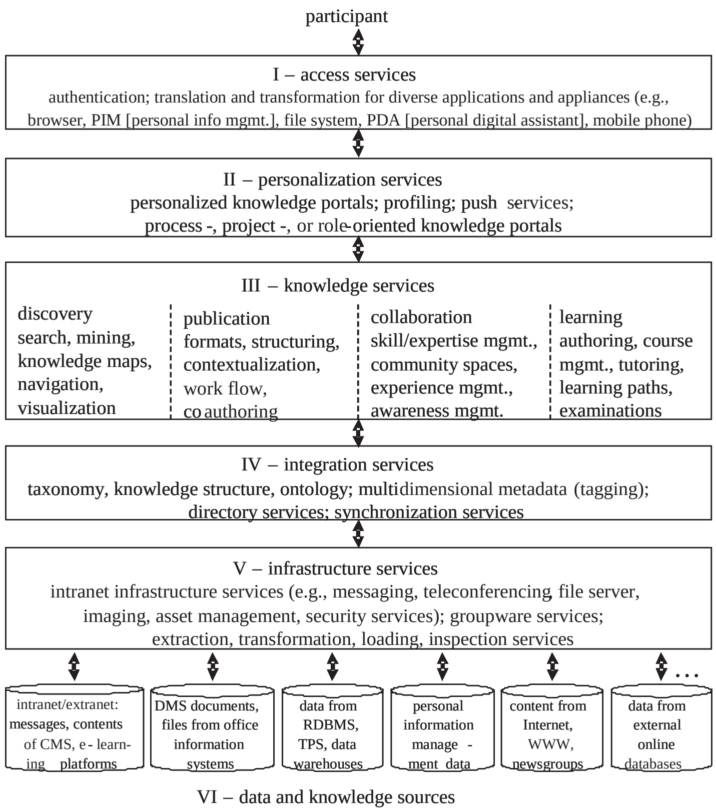
Actual implementations of ICT systems certainly fulfill the characteristics of an ideal KMS only to a certain degree. Thus, a continuum between traditional IS and advanced KMS might be imagined with minimal requirements providing some orientation (see Maier & Hädrich, 2004).

ARCHITECTURES FOR KNOWLEDGE MANAGEMENT SYSTEMS

There are basically two ideal types of architectures of KMS: centralistic KMS and peer-to-peer (p2p) KMS.

Many KMS solutions implemented in organizations and offered on the market are centralistic client-server solutions (Maier, 2004). Figure 2 shows an ideal layered architecture for KMS that represents an amalgamation of theory-driven (e.g., Apitz et al., 2002; Zack, 1999), market-oriented (e.g., Applehans, Globe, & Laugero, 1999; Bach, Vogler, & Österle, 1999), and vendor-specific architectures (e.g., Hyperwave, Open Text Livelink). A thorough analysis of these architectures and the process of amalgamation can be found in Maier, 2004. The ideal architecture is oriented toward the metaphor of a central KM server that integrates

Figure 2. Architecture of a centralized KMS



all knowledge shared in an organization and offers a variety of services to the participant or to upward layers (see Figure 2).

Data and knowledge sources include organization-internal as well as organization-external sources, and sources of structured as well as semi-structured information and knowledge.

Infrastructure services provide basic functionality for synchronous and asynchronous communication, sharing of data and documents as well as the management of electronic assets. Extraction, transformation, and loading tools provide access to data and knowledge sources. Inspection services (viewers) are required for heterogeneous data and document formats.

Integration services help to meaningfully organize and link knowledge elements from a variety of sources by means of an ontology. They are used to analyze the semantics of the organizational knowledge base and to manage metadata about knowledge elements and users. Synchronization services export and (re)integrate a portion of the knowledge work space for work off-line.

Knowledge services provide intelligent functions for discovery, that is, the search, retrieval, and presentation of knowledge elements and experts; publication, that is, the structuring, contextualization, and release of knowledge elements; collaboration, the joint creation, sharing, and application of knowledge; and learning, the authoring that is supported by tools and tools for managing courses, tutoring, learning paths, and examinations as well as the reflection on learning and knowledge processes established in the organization (commonly referred to as double-loop learning; see Argyris & Schön, 1978).

Personalization services provide more effective access to the large amounts of knowledge elements. Subject-matter specialists or managers of knowledge processes can organize a portion of the KMS contents and services for specific roles or develop role-oriented push services. The services can be personalized with the help of, for example, (automated) interest profiles, personal category nets, and personalized portals.

Access services transform contents and communication to and from the KMS to fit heterogeneous applications and appliances. The KMS has to be protected against eavesdropping and unauthorized use by tools for authentication and authorization.

Recently, the peer-to-peer (p2p) metaphor has gained increasing attention from both academics and practitioners (e.g., Barkai, 1998; Schoder, Fischbach, & Teichmann, 2002). There have been several attempts to design information-sharing systems or even KMSs to profit from the benefits of this metaphor (Benger, 2003; Maier & Sametinger, 2004; Parameswaran, Susarla, & Whinston, 2001; Susarla, Liu, & Whinston, 2003). This promises to resolve some of the shortcomings of centralized KMS, for example:

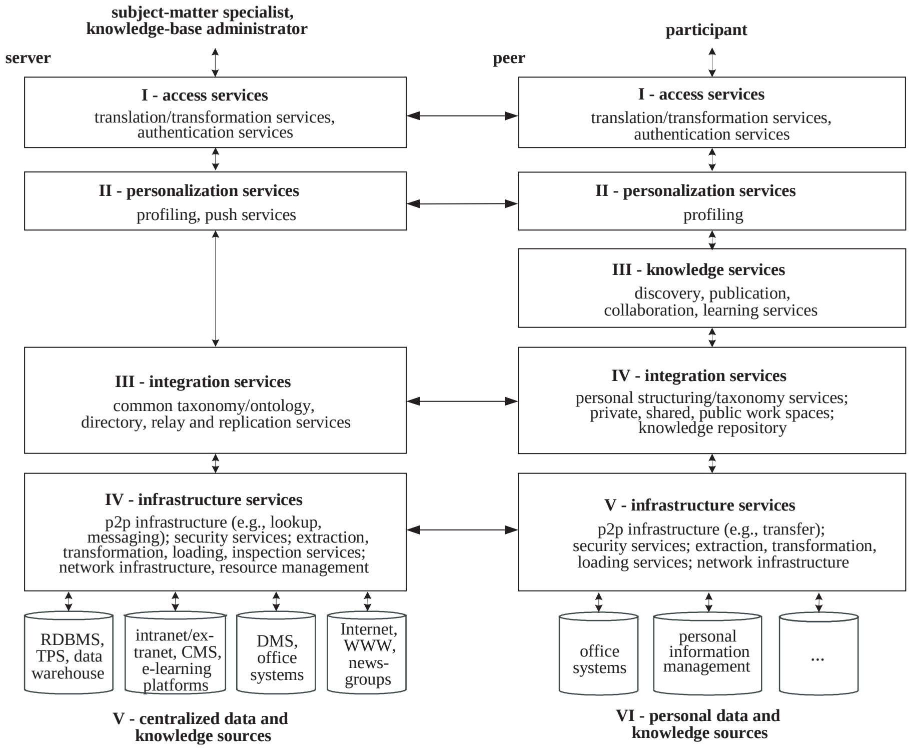
- to reduce the costs of the design, implementation, and maintenance of a centralized knowledge server,
- to overcome the limitations of a KMS that focuses on organization-internal knowledge whereas many knowledge processes cross organizational boundaries,
- to reduce the barriers to actively participate and share in the benefits of a KMS, and
- to seamlessly integrate the shared knowledge work space with personal knowledge work spaces and messaging objects.

However, there is no common architecture or an agreed list of functions yet for this type of KMS. Generally, the p2p label is used for different architectures, for example, pure p2p architectures or hybrid architectures such as assisted and super p2p architectures (e.g., Dustdar, Gall, & Hauswirth, 2003). The more functionality for central coordination that is required in a p2p system, as is the case in a KMS, the more likely it is that some kind of assistance by a server is needed to coordinate the system (hybrid architecture). Still, the difference to the centralized architecture is that p2p systems allow users to develop personal knowledge bases locally and to directly share knowledge with other peers without the need to design a shared space on a server. Figure 3 depicts the architecture of a peer and a server to assist the network. Both architectures basically consist of the same layers as the architecture of the centralized KMS.

The differences between a single peer's architecture and the centralistic architecture are the following:

- Infrastructure services handle personal data and knowledge sources and provide the p2p infrastructure for locating peers, exchanging data with other peers, and assuring the security of the personal knowledge base.
- Integration services handle the meta-data of the knowledge objects in the personal knowledge base and establish a personal ontology. Private work spaces contain information that is only accessible by its owner. Public work spaces hold knowledge objects that are published via the Internet. Protected work spaces contain knowledge objects that are accessible by a single peer or a group of peers that the owner explicitly grants access to.
- Knowledge services build upon the knowledge base, just as in the centralized case.

Figure 3. Architecture of server and peer



The knowledge repository is now spread across a number of collaborating peers.

- Personalization services build on individual user profiles and on centralized personalization services provided by the server.
- Access services are similar to those in the centralized KMS architecture.

The differences between a server's architecture and the centralistic architecture are the following:

- Infrastructure services enable a server to access a number of additional shared data and knowledge sources. He provides services for lookup and message handling that improve the efficiency of the p2p infrastructure.
- Integration services offer a shared ontology for the domain handled by, for example, a network of subject-matter specialists. This addresses the challenge in a distributed KMS that the personal knowledge bases cannot be integrated without a mapping of ontologies. The server might offer replication services to peers that sometimes work off line.
- There are no central knowledge services in addition to the peers' services.
- Personalization services include profiles and push services that ease in accessing the organized collection of (quality-approved or even-improved) knowledge that the subject-matter specialists administer.
- Access services are restricted to the administration of the server, the central knowledge

structure, and the profiles for personalization.

DISCUSSION

Centralized KMSs offered on the market differ with respect to the extent and intensity with which they cover the services included in the centralized architecture. Some focus on learning management (e.g., Hyperwave), integration (e.g., Lotus Notes/Workspace), discovery (e.g., Verity K2 Enterprise), publication (e.g., Open Text Livelink), collaboration (e.g., Quovix CommunityBuilder), or on access and personalization (portal solutions, e.g., Plumtree Corporate Portal, SAP Enterprise Portal). In addition to several research prototypes (e.g., Benger, 2003; Maier & Sametinger, 2004), Groove Networks Groove is an example for a p2p collaboration tool that is readily available on the market and at least offers some of the functions that are needed in KM (Maier & Hädrich, 2004).

Table 1 shows for what type of KM initiative centralized and p2p KMSs are suited. Consequently, a centralized KMS seems to be more adequate for a KM initiative that can be described as a codification initiative restricted to the organization's boundaries and managed by a central organizational unit that fosters the handling of all types of knowledge. A p2p information-sharing system targets a KM initiative that can be described as a personalization initiative involving members from a number of institutions. Thus, the initiative is managed decentrally, requiring an open, trustful, collective organizational culture and a focus on the exchange of individual knowledge, ideas, and experiences.

However, there are still serious technical challenges that have to be overcome in p2p computing in general. These challenges concern connectivity, security, and privacy, especially the risk of spreading viruses, unauthorized access to confidential and private information, the installation of unwanted applications, fault tolerance, availability, and scalability (Barkai, 1998). There are also organizational issues that have to be resolved before a p2p KMS can be fully deployed in an organization, for example, the coordination issue, meaning that structuring and quality management of the knowledge contained in a p2p network have to be supported.

In the following, the state of practice of KMS is summarized in the form of theses that describe activities concerning KMS in German-speaking countries as investigated in an empirical study conducted by one of the authors (Maier, 2004).

1. Almost all large organizations have an intranet and/or groupware platform in place that offers a solid foundation for KMS. These platforms, together with a multitude

Table 1. Type of KMS and type of KM initiative

characteristics	centralized KMS	p2p KMS
strategy	codification	personalization
organizational design	central	decentralized
content	primarily lessons learned, (approved) knowledge products, and secured knowledge, but also ideas, experiences, and individual contents	individual contents, ideas, and results of group sessions and experiences
organizational culture	both types of culture (restrictive or loose user privileges)	open, trustful culture

of extensions and add-on tools, provide good basic KM functionality, for example, the easy sharing of documents and access to company information.

2. Large organizations have also already implemented KM-specific functions. Most rely on the centralized KMS architecture, but many experiment with p2p solutions. Many of the implemented functions are not used intensively, in some cases due to technical problems, but mostly because they require substantial organizational changes and significant administrative effort.
3. The majority of organizations relies on organization-specific developments and combinations of tools and systems rather than on standard KMS solutions. The market for KMS solutions is a confusing and dynamic one, and integration with existing systems is often difficult. Organizations might also fear the loss of strategic advantages if they exchange their homegrown KMS solutions for standard software.
4. There has been a strong emphasis on explicit, documented knowledge. This is not surprising as in many cases large amounts of documents have already existed in electronic form, and improved handling of documents and the redesign of corresponding business processes can quickly improve organizational effectiveness. Recently, there has been a trend toward collaboration and learning functions because technical requirements for media-rich electronic communication can now be met at reasonable costs.
5. Comprehensive KMSs are highly complex ICT systems because of (a) the technical complexity of advanced knowledge services and of large volumes of data, documents, messages, and links as well as contextualization and personalization data, (b) the organizational complexity of a solution that affects business and knowledge processes throughout the organization, and (c) human complexity due to the substantial change in habits, roles, and responsibilities that is required as KMSs have to be integrated into daily practices of knowledge work.
6. In many organizations, a multitude of partial systems is developed without a common framework that could integrate them. Some organizations also build enterprise knowledge portals that at least integrate access to ICT systems relevant for the KM initiative. Only recently have comprehensive and integrated KMSs offered functionality integrated within one system and realized the vision of an enterprise knowledge infrastructure (Maier, Hädrich & Peinl, 2005).

FUTURE TRENDS

Generally, there has been a shift in the perspective of KMS vendors as well as organizations applying those systems from a focus on documents containing knowledge, and thus from a pure codification strategy, to a combination and integration of functions for handling internal and external contexts, locating experts, managing competency, and so forth that bridges the gap to a personalization strategy (Maier, 2004). Advanced functions supporting collaboration in teams and communities, tools linking knowledge providers and seekers, and e-learning functionality have been integrated into many centralized KMSs. This trend will continue as many organizations strive to profit from the promised benefits of comprehensive ICT platforms for the increase of productivity of knowledge work and, consequently, of organizational effectiveness.

CONCLUSION

This article has studied the notion of the term KMS. Ideal architectures for centralized and peer-to-peer KMSs were contrasted. Each of these architectures targets a different type of KM initiative. Summing up, it seems that centralized KMSs offered on the market more and more live up to the expectations of organizations ready to apply ICT to support a KM initiative. Peer-to-peer KMSs promise to resolve some of the shortcomings of centralized KMS, especially concerning the time-consuming effort to build and maintain a central knowledge repository. However, major challenges still lie ahead until peer-to-peer systems can truly be called KMSs and can be used to support the still-growing share of users involved in knowledge work.

There seem to be four main approaches to deploying KMSs in organizations: (a) A KMS can be seen as a general infrastructure that supports knowledge work throughout the organization, (b) business processes, projects, and/or theme-oriented activities are the nexus of knowledge and thus are specifically targeted by KMSs, (c) communities and knowledge networks can be fostered by ICT, which aids knowledge sharing throughout the life cycle of these organizational entities, and (d) certain types of knowledge, for example, lessons learned and best practices, can be at the core of the design of a KMS.

Chapter 2.8
Conceptual Confusions in Knowledge Management and Knowledge Management Systems:
Clarifications for Better KMS Development

Michael Boahene
Holism Information Systems Management, Australia

George Ditsa
University of Wollongong, Australia

ABSTRACT

Knowledge Management and Knowledge Management Systems are slowly but surely capturing the attention of many organisations in a quest for competitive advantage. Like many other computing fads before them, there is no shortage of recipes by its proponents. This chapter discusses the emerging discipline of Knowledge Management in computing and explains the concepts underlying Knowledge Management Systems that will lead to a better development and implementation of these systems. In particular, it tackles the conceptual confusion about data, information, and knowledge, which appears to be finding its way into the Knowledge Management literature. The terms, 'capta' (Checkland, Howell, 1998) and 'constructed data' (Flood, 1999), are used in analysing these concepts to clear some of the confusion surrounding them. The use of these terms also highlights our (the IT community) taking for granted assumptions about the hierarchical relationship and the more insightful emergent relationships.

INTRODUCTION

Every few years, the IT community comes up with a promised panacea to cure all ills. There was once the push for office automation, artificial intelligence, decision support, groupware, reverse engineering, MIS, B2B, B2C and now, it is KM - Knowledge Management. These are often brilliant concepts and while they all find their level of utility, usually more modest than their proponents' claims, they have by and large been misunderstood and misapplied, to the disadvantage of some stakeholders and, ultimately, investors. This misunderstanding is often characterised by a lack of foundational concepts about the development and management of information systems, of which knowledge management systems are now a particular type.

Knowledge Management Systems (KMS) are now being touted as yet another silver bullet. How can a would-be investor in a KMS realise its anticipated benefits and how would an implementor know they are on the right path, thereby avoiding this characteristic confusion that may inevitably snuff out the promise shown by this idea? The urgency for such a conceptual cleansing is echoed by White and Sutton (2001, p. 180) who note that, "the kinds of rationalist assumptions about knowledge creation and use, which characterise Knowledge Management, are inadequate." They suggest the need for a broader approach to, and definition of, knowledge as an essential pre-requisite to attempts to harness and exploit it: otherwise, the emerging discipline may also be consigned to the ranks of yet another 'management fad'.

This chapter looks at some concepts underlying Knowledge Management and suggests some ways of bringing the concepts to bear on Knowledge Management Systems. Following this introduction, the chapter first highlights the current state of affairs and then some of the conceptual confusion in the area of Knowledge Management. This is followed by a brief overview of a target environment, which Knowledge Management Systems are supposed to serve (i.e., help organise and manage). The chapter then continues by presenting a critical analysis of some terms which KMS thrives on. The chapter then presents a conceptual cleansing that will lead to the realisation of a better KMS.

Our analysis follows a systemic account that draws heavily on concepts and insights originating from the works of Hirschheim et al. (1995) concerning information systems development methodologies, Checkland's (1998) work concerning the nature of information systems and Flood (1999) and Senge's (1995) work concerning the organisation and management of complex systems.

Current State of Affairs

The implementation of Knowledge Management Systems has generally focused on the technological capabilities of data representation and access, to the detriment of foundational concepts about the generation of data itself. As noted by Yen (2001), of the many vital issues in knowledge management, knowledge representation has been studied more thoroughly than others. However, without a foundationally coherent and consistent understanding of data, information, knowledge and the organisation and the management of complexity within the target environment (Boahene, Ditsa, 2001), all the technological sophistication is unlikely to guarantee the realisation of any anticipated benefits.

By far, the literature on KMS has focused on the categorisation, classification and processing of invariances, assuming some relationship between data, information and knowledge. Hence, we have categorisations such as tacit and explicit knowledge, objective and subjective knowledge, certain and uncertain knowledge and so on. These categorisations—while interesting—are, however, of little value in providing insights into the conception and development of Knowledge Management Systems. The problem is that such categorisations do not distinguish between data originating from observations in the target environment, on one hand, and the 'knowledge-base' needed to make sense of the observations, on the other. As such, any given set of data may have characteristics of both.

White and Sutton (2001), in their inquiry into knowledge management in clinical practice within the NHS in Britain, make a similar observation when they note that no work was found which analysed types of clinical knowledge in such a way as to define which phenomena fell into which category and what the relative percentages were.

The Conceptual Confusion

A relationship between data, information and knowledge is widely recognised in the literature. This relationship is popularly recognised as a hierarchy where data, being plentiful, sits at the base, followed by information and then knowledge. However, the distinction often seems arbitrary. These terms are often used inter-changeably, making it difficult to make sense of the emergent relationships that exist between them. This confusion has found its way into the knowledge management literature, where a diverse range of application systems lay claim to being Knowledge Management Systems.

Further, organisation and management are underpinned by thinking, which can be categorised in philosophical and sociological terms. From a philosophical perspective, there is positivism and phenomenology at opposite ends of a continuum. The positivist stance refers to a philosophical position characterised by a readiness to concede primacy to the given world as known through experimental evidence. The phenomenological stance, on the other hand, refers to the position characterised by a readiness to concede primacy to the mental processes of observers rather than to the external world (Checkland, 1981).

From a sociological perspective, there are functionalist and interpretivist views at polar ends of a continuum, yielding 'hard' and 'soft' systems thinking approaches to the organisation and management of phenomena (e.g., problem of choice in a dynamic environment). The functionalist view adopts a realist ontology and assumes that facts about the world exist and are waiting to be discovered; hence, knowledge is perceived as an immutable object that exists in a variety of forms (e.g., tacit, explicit) and reside in a variety of locations (e.g., individuals, culture, work routines). The interpretivist perspective maintains that reality is socially constructed; hence, knowledge is perceived as a process of knowing that is continually emerging, indeterminate and closely linked with practice (Detlor, 2001).

These philosophical and sociological viewpoints form the basis of all thinking and practice in the inquiry into a target environment, the selection of relevant data and the development of information systems that serve systems of purposeful action (e.g., managing complexity).

Can both viewpoints be right or is one right and the other wrong? Or, more importantly, how can each be leveraged off the other to deepen our understanding and reduce uncertainty in inquiries concerning the development of Knowledge Management Systems? To answer these questions we first need to understand the nature of the phenomena (i.e., data, information and knowledge) that fuels the creation, access, use and sustenance of Knowledge Management Systems.

Target Environment

Little attention has been paid to the nature of a target environment, which invariably gives rise to the management and organisational functions, which a Knowledge Management system is supposed to serve. To understand the emergent relationships between data, information and knowledge, we need to take a closer look at organisation and management, the reason for the generation of data in any target environment. A target environment being any bounded area in which we set out to intervene in a problem situation. In this environment, problem situations that arise do not come neatly packaged to fit into any predetermined classifications. These are messy, real world problems, as Checkland (1981) puts it. A target environment is characterised by complexity with elements exhibiting dynamic behaviour. According to Flood (1999, p. 86), "dynamic behaviour is capable of producing unexpected variety and novelty through spontaneous self-organisation. … a complex of variables interrelates with multiple feedback, which spontaneously creates a new order."

Senge (1990), however, makes an important contribution to understanding complexity in a target environment by distinguishing between two kinds of complexity in management situations, reflecting the nature of the target phenomena that Knowledge Management Systems aim to support. These he classifies as detail complexity and dynamic complexity. Detail complexity refers to situations where there are many variables; however, outcomes are predictable. Dynamic complexity refers to situations where cause and effect are subtle and where the outcomes of interventions over time are not obvious. As he points out, mixing many ingredients into a stew involves detail complexity, as does taking inventory in a retail store. But balancing market growth and capacity expansion or improving quality while reducing total costs and satisfying customers in a sustainable manner are examples of dynamic complexity problems.

In problems involving detail complexity, cause and effect are closely linked; therefore, it is possible to predict outcomes based on a given set of variables relevant to the problem situation. For instance, it is relatively easy to predict the composition and even taste of a hamburger given the proportionate mix and the order of introducing the ingredients (a problem of detail complexity). Using the taste of the hamburger, it is a lot more uncertain, if at all reliable, to predict if it would attract customers and, therefore, increase sales or the market share for the hamburger (a problem of dynamic complexity), because other factors such as market conditions and consumer behaviour may be at play in influencing the outcome.

Detail and dynamic complexity are the challenges that Knowledge Management Systems and, for that matter, all other information systems aim to help users organise and manage in problem situations.

The following section presents an analysis of the terms (data, capta, information, knowledge and organisation and management) on which Knowledge Management Systems thrive.

ANALYSIS OF TERMS IN KNOWLEDGE MANAGEMENT SYSTEMS

Data

Hirschheim et al. (1995, p. 14) defines data as "invariances with potential meaning to someone who can interpret them." According to Hirschheim et al., the basis of all communication technically, biologically or socially are invariances encoded in some medium and transmitted in many forms (e.g., waves, electrical currents).

The encoded invariances are received through our senses (e.g., vision, hearing, smell, touch, taste). It is important to note that following the receipt of invariances, via a communication medium through our senses, what is expressed as data may be represented as a word, sentence, number, sign, symbol or some other form of representation.

Hirschheim et al. distinguish between invariances that occur naturally, such as bird markings, and invariances created by humans for some purpose, such as letters and graphics. In this chapter, we shall concentrate on the invariances created by humans through observations (with our senses) or cognitive capabilities.

Also, through his analysis of Systems Thinking, Checkland (1981) makes an important contribution to the understanding of the nature of data. He distinguishes between two types of data. One that is independently verifiable (that which positivists and functionalists propose as a reality outside ourselves which actually exists) and one that is perceptive and, therefore, within oneself (that which phenomenologists and interpretivists propose as the continually negotiated truth).

Consider the following examples of data. If I observe an object (e.g., a dog), which other observers that I am not in collusion with can confirm, or a camera can record the same object as a dog, then I am prepared to say there is an immutable invariance that may be expressed as data (e.g., "This is a dog" or dog) which exist outside of ourselves and is real. This type of invariance seems to be what the functionalists refer to as data.

However, if I observe a dog and describe it as cute or beautiful or ugly, then while the fact remains that it is a dog (which agrees with the functionalists view of data), it can hardly be argued that 'a beautiful dog' is an immutable invariance, since it is my perception of the dog which may or may not be confirmed by any other observer. This type of invariance seems to be what the interpretivists refer to as data.

Capta

As Checkland and Howell (1998) point out, there could be a multitude of data (or invariances) pertaining to any particular object or phenomenon, but we choose, for one reason or another, to focus on a subset which is of interest to us at any time. They make a defining distinction between the multitude of data attributable to an object or phenomenon and the subset we choose to pay attention to. This, they refer to as 'capta'.

Flood (1999) complements this line of reasoning. He uses the term 'data construction' instead of 'data collection' to distinguish between the mass of data that could be attributed to a phenomenon or item of interest and the portion that is considered and chosen to be of interest. He points out rather understatedly that, "data is not waiting out there in volumes to be reaped like corn in an autumn harvest, but it is rather the product of a process of investigation" (p. 145).

For instance, of all the invariances that may be observed about dogs and represented as data, a breeder may choose to pay attention to (i.e., 'capta') colour, breed and origin rather than size, age or sex, as a result of some interests (e.g., breeding exotic dogs) that the breeder may have and the environment (e.g., locality, regulations, etc.) within which the inquiry is conducted. It is, however, possible that at some future time the breeder may choose to pay attention to a different subset of data if the environment or his/her interests change.

This distinction is important as it draws attention to the fact that the selection of a subset of all possible data about an object or phenomenon should not be taken for granted, since it defines boundaries of the target environment. More importantly, it also limits the subsequent insights that may be generated about the object or phenomenon. Therefore, the current assumption that 'data-warehouses' could be the repository of all data about an object or phenomenon in advance and 'mined' for insights is not very well grounded, because the bounded environment keeps changing.

In summary, data are the starting point in our mental processing. That is, invariances about an object or a phenomenon that could be paid attention to. 'Capta', on the other hand, are the result of selecting some for attention. The emergent property in the relation between data and capta being the decision to pay attention to the data that is selected because of a perceived interest.

Information

Having constructed data (through the process of investigation) or chosen to pay attention to a subset of the mass of possible data (capta) about an object or a phenomenon, we put it into context or attribute meaning to it. Hirschheim et al. (1995) contends that by themselves these invariances have no intrinsic meaning. The invariances acquire meaning through social conventions of individuals and communities. The invariances received are transformed through a process of meaning attribution (or interpretation) into information, which then triggers a behaviour. Attribution of meaning to 'capta' is a creative act and it may be argued that no two interpretations are ever quite the same. In other words, there is no guarantee that the same meaning will be attributed to the same observation by two individuals or even the same individual on different occasions.

For instance, at a dog show the dog breeder may observe, for argument sake, a red, white and blue striped chihuahua from France and attribute meaning such as, 'cute but not exotic', which triggers a 'don't buy' behaviour. Another may make the same observation, but attribute meaning such as, 'interesting, worth trying' and trigger a 'buy' behaviour.

This complements the observations of Sutton and White (2001) when they point out that, technically, clinical observations can be readily translated into data and that data can be shared. However, accurate technical performance does not necessarily equate to transfer of knowledge. It rather gives a partly illusory and misleading representation.

In summary, information is created through the attribution of meaning (by individuals) to 'capta'. Information, therefore, is a far more personal, variable, esoteric and ephemeral concept, dependent on the receiver's point of interest and 'knowledge-base', which is private and only available to the individual. Information, however, should not be confused with knowledge.

Knowledge

'Capta' that has been generated as a result of a process of inquiry or observation, the meaning attributed to it and the behaviour that follows can all be transformed into a new 'form' exhibiting different emergent properties. This new 'form', also 'capta', is stored as part of a 'knowledge-base'. It enriches the 'knowledge-base' and may be used for further meaning attribution to new 'capta' on another occasion.

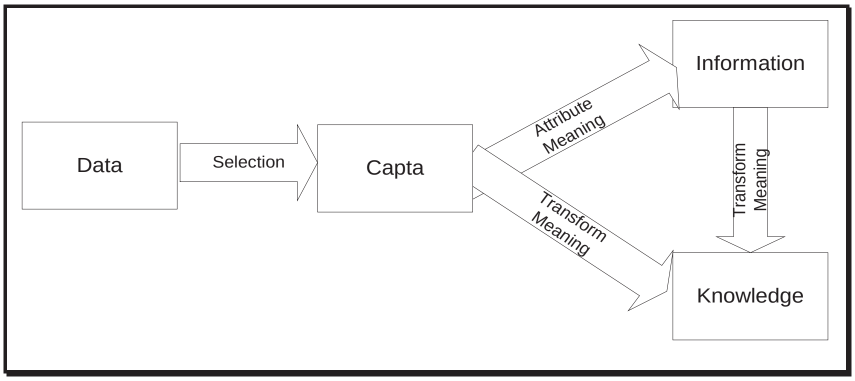
From the previous statements, we assert that there are two types of 'capta': one that is about observations, ephemeral meaning and behaviour pertaining to a target environment and one that enriches the 'knowledge-base'. The first type of 'capta' referred to as 'observation induced capta' is transformed into the second type of capta referred to as 'transformed capta'. The 'transformed capta' is represented as concepts, methods, beliefs, values and normative principles, forming a filter through which we perceive events and observations, thereby enabling us to attribute particular meanings to new 'observation induced capta'. This, however, does not preclude the 'garbage-in garbage-out' principle. If the 'knowledge-base' is unreliable, it is unlikely to support the effective attribution of meaning to new 'observation induced capta'.

This concept complements what White and Sutton (2001) noted as a process of knowledge generation and decision making by one of the participants in their study. The participant explains that, "following the initial discussion with the patient, I take the data collected [i.e., 'observation induced capta'] and put it in my knowledge base [i.e., transformed 'capta'] and conclude a number of things [i.e., further meaning attribution to 'observation induced capta'] about the present state of the individual" (p. 179).

With respect to 'capta', Hirschheim et al. (1995, p. 14) cite four types of speech acts (cf. Deitz, Widdershoven, 1992, cited in Hirschheim et al., 1995) following from Habermas' Theory of Communicative Action:

- To express how one feels or thinks (expressiva), e.g., I love pink dogs;

Figure 1. "Capta" relationships



- To get someone to do something (orders, imperativa), e.g., When you see a pink dog, buy one;
- To appeal to others to obey accepted social norms (regulativa), e.g., Dogs should be well cared for; and
- To get someone to accept something as true (assertions about the external world, also called constantiva), e.g., Pink dogs are a money spinner.

'Observation induced capta', which may be captured in a raw form or deduced, manifest as expressiva or imperativa speech acts, while 'transformed capta', stored as part of a 'knowledge-base', manifest as regulativa or constantiva speech acts – accepted social norms and assertions of truth about the external world.

As a further example, let's go back to the information created by the breeder's observation. In speech acts, the information created is expressiva (i.e., 'cute' and 'not exotic') and the behaviour triggered, i.e., 'don't buy', is imperativa. But why does the breeder come to this conclusion? Perhaps the breeder, knowing that his/her clients are only attracted to mono colour, pure-bred dogs originating from hard-to-reach countries or higher profit margins for such dogs. Whatever the reasons (i.e., the 'Whys'), this knowledge expresses the breeder's assertions of truth about a perceived external world (i.e., constantiva).

In summary, knowledge is a reserve of 'transformed capta', expressed as constativa or regulativa that can be applied to new 'observation induced capta'. Knowledge may be personal or collective, but definitely more stable than information.

From the discussion so far, we recognise an emergent relationship between data, capta, information and knowledge as shown in the following diagram. The question then is, can computers automatically undertake the transformation of 'capta' into knowledge?

In the next section we present a conceptual cleansing which we hope will lead to a better understanding of the conception, development and implementation of Knowledge Management Systems.

Conceptual Cleansing

We have so far been laying the foundation from which to clarify the competing claims about knowledge management and the confusing manifestations of Knowledge Management Systems.

Knowledge Management Systems have been popularly defined by different writers from either a structural or functional perspective. From a structural point of view, Morse (2001) defines Knowledge Management Systems as follows: "Knowledge [management] systems take a large, diverse collection of document-based knowledge, provide a physical infrastructure for storing those documents and provide a logical structure for retrieving information" (p. 230). He also provides a functional definition as follows. "Knowledge [management] systems are centralised computer systems that store, structure and provide access to the corporation's document-based knowledge" (p. 230).

We find the structural perspective somewhat deficient, because of the variety of possible compliant components which do not particularly contribute to either a necessary or sufficient condition for the attainment of an effective knowledge management system. The functional perspective, although it gets us closer to a unifying definition, does not surface fundamental assumptions (e.g., beliefs and values) made about content which is necessary for the KMS to function adequately.

Knowledge management in any target environment may be viewed as an ongoing 'journey' rather than an end or a destination in itself. Knowledge changes over time since it is a synthesis of the perceptions of a target environment, which is in a constant state of flux. Further, in knowledge-intensive working environments where people deal with dynamic complexity, consensus building as an approach to decision-making is rarely the norm. However, most conventional KMS implementations assume and model interventions around consensus (as the dominant cultural approach to decision-making) and determinism – a characteristic of detail complexity.

Following from our earlier discussion about the philosophical and sociological perspectives of organisation and management of phenomena (and objects) and its relationship to data, it is apparent that the ontology and epistemology of systems developed to support problem situations will contain an indeterminate mixture of positivist (functionalist) and phenomenologist (interpretivist) stances. The ontology is concerned with the fundamental units (or elements) which are assumed to exist in a target environment. The units may be composed of hard tangible structures (e.g., dog, building, car) with a concrete material base (realism), or composed of malleable, vague phenomena (e.g., sale, agreement, service), which are socially constructed through an intellectual or cultural base of values and concepts (nominalism or idealism). The epistemology is concerned with how an investigator inquires into a target environment and sees phenomena (observation 'capta') in them (Hirschheim et al., 1995).

These will reflect the relative mix of detail and dynamic complexity requiring management in the problem situation. In practice, each polar end of the continuum is unlikely to capture the relevant nature of the target environment or managing complexity (detailed and dynamic) of problem situations arising within them.

To support the organisation and management of the requisite mix of detail and dynamic complexity in a target environment, we distinguish between four categories of information systems:

- Transaction Processing Systems – Capturing observation, observation induced and transformed capta.
- Information Management Systems – Consisting of observations and observation induced 'capta'. A base of expressiva speech acts, mainly supporting the recall of meaning-attribution.
- Knowledge-based Systems – Consisting of 'observation induced capta'. A base of codified meaning representing imperativa speech acts. Mainly to support the organisation and management of detail complexity.
- Knowledge Management Systems – Consisting of 'transformed capta'. A base of concepts representing regulativa and con-

stantiva speech acts. Mainly to support the organisation and management of dynamic complexity.

As a consequence of this distinction, we assert that there is only one type of Knowledge Management system. Defined from a content perspective, a Knowledge Management system is an organised collection of concepts, methods, beliefs, values and normative principles (i.e., 'knowledge-base') supported by material resources (e.g., technology). Our definition is similar to Hirschheim et al's (1995) definition of an information systems development methodology. A 'knowledge-base' is used to make sense of invariances (i.e., 'observation capta'), not to provide codified meaning about an object or phenomenon that has been chosen for attention. A 'knowledge-base' is the source of our 'know-why' (Boahene, 1999), used to organise and manage uncertainty in complex problem situations, which is an essential property of knowledge.

As a rule of thumb, Information Management Systems have the capability to provide answers to questions of 'Where', 'Who', 'When' and What', while Knowledge-based Systems go a step further, providing answers to questions of 'How', but Knowledge Management Systems will have the capability to provide answers to questions of 'Why' and, in some cases, 'How'.

Notwithstanding the dizzying array of application systems that claim to support knowledge management, if the system does not articulate a 'knowledge-base' that supports dynamic complexity, then it is not a KMS.

Since dynamic behaviour is characterised by unexpected variety and novelty through spontaneous self-organisation, solutions to issues and problems cannot be known a priori. We learn our way into the unknown. The 'knowledge-base' in a knowledge management system ought to provide the frame of reference that will be consistently used to provide insights that support the organisation and management of dynamic complexity in a target environment, that is, new and deeper understandings of problem situations and how to intervene in them.

Concepts in a 'knowledge-base' are structures used to classify, explain and give order to phenomena or an object in a target environment. As an example, Flood (1999) provides an insightful conceptual structure for deepening systemic appreciation of a problem situation. According to Flood, any investigation into a problem situation will use ideas from systems of processes, structure, meaning and knowledge-power. These different views may be combined to provide a panoramic view, which he terms prismatic thought.

Beliefs are inferences of 'truth' that we hold in esteem and values help us to justify and uphold those beliefs. These beliefs affect our attitude toward, and our perception of, phenomena and the environment in which it occurs. Truth, however, should not be viewed as unchanging. As Flood's concept of prismatic thought suggests, a target environment is determined by boundary judgment. Boundaries are mental constructs, which determine what is in view (and might be taken into account at the moment) and what is out of view (and thus excluded from consideration). As

Table 1. Rule of thumb

System Type	Problem Situation	Typical Capability	Speech Act
Information Management	Detail complexity	Where,Who, When, What,	Expresiva
Knowledge-based	Detail complexity	How	Impreratíva
Knowledge Management	Dynamic complexity	How, Why	Constantiva Regulativa

such, the determination of a target environment (i.e., bounded action area) and what is taken to be relevant and worthy of having knowledge about is influenced by beliefs and values, both of which may change (in space and time) as different complex mixes of variables come into view and others drop out of view. It, therefore, follows that knowledge also changes as truth is continually renegotiated.

Concepts, beliefs and values can be organised into coherent sets of technical and behavioural rules which guide an approach to investigating problem situations in a target environment. These rules may be expressed as methods and normative principles. These elements of a 'knowledge-base' are what transformed 'capta' is about.

The 'knowledge-base' so constructed with the support of material resources can then be used to make sense of the nature of what is known about a target phenomenon (e.g., problem situation and possible insights that can be acquired through different types of inquiry) and alternative methods of investigation (i.e., observation capta) and thereby intervene more effectively.

While computers may be used to deduce expresiva and imperativa speech acts, it is unlikely that they can be used to deduce regulativa or constantiva speech acts. However, a computer will be perfectly capable of capturing and storing all speech acts.

CONCLUSION

This chapter has discussed the emerging discipline of Knowledge Management in computing and explained the concepts underlying Knowledge Management Systems which we believe will lead to a better understanding for the development and implementation of these systems. An attempt has been made to clear some of the conceptual confusion surrounding data, information, and knowledge which appears to be finding its way into the Knowledge Management literature.

Chapter 2.9
Internet Support for Knowledge Management Systems

Murray E. Jennex
San Diego State University, USA

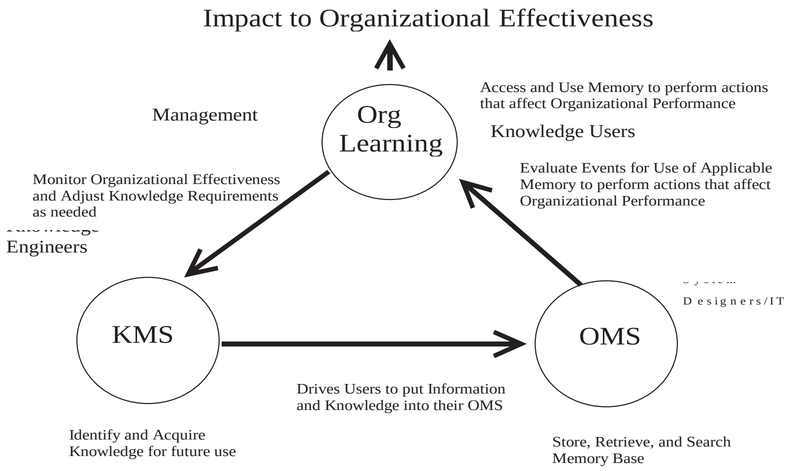
INTRODUCTION

Organizations are building and maintaining systems for managing organizational knowledge and memory. Users of these systems may not be at the same location; in many cases they are distributed across large geographical distances and multiple offices. Key to this task is developing an infrastructure that facilitates distributed access and utilization of the retained knowledge and memory. Connectivity and easy to use interfaces are main concerns. Jennex (2000) found that using the Internet as a common communications platform (either as an Intranet or an Extranet) and Web browsers as an interface is a viable, low cost solution. Newell, et al. (1999) found that Intranets not only supported distributed knowledge processes but also enhanced users' abilities to capture and control knowledge. Stenmark (2002) proposes that using a multiple perspective of the Internet— information, awareness, and communication—allows developers to build successful Internet-based knowledge management systems, KMS. This article discusses how the Internet can be effectively used as an infrastructure for knowledge management/organizational memory systems, KMS/OMS.

BACKGROUND

The OMS consists of the processes and information system components used to capture, store, search, retrieve, display, and manipulate knowledge. The KMS consists of the tools and processes used by knowledge workers to interface with the knowledge contained in the OMS. Knowledge is managed and used through a combination of the KMS and OMS. Jennex and Olfman (2002) identified the KMS-OMS model in Figure 1 as a representation of the relationships between the OMS, KMS, and organizational learning. Organizational learning, OL, is identified as a quantifiable improvement in activities, increased available knowledge for decision-making, or sustainable competitive advantage (Cavaleri, 1994; Dodgson, 1993; Easterby-Smith, 1997; Miller, 1996).

Figure 1. The Jennex-Olfman KMS-OMS model



There are two approaches to building a KMS as discussed by Hansen et al. (1999), Morrison and Weiser (1996), and Stenmark (2002). These can be described as a process/task approach and the infrastructure/generic approach. The process/task approach focuses on the use of knowledge/OM by participants in a process, task or project in order to improve the effectiveness of that process, task or project. This approach identifies the information and knowledge needs of the process, where they are located, and who needs them. This approach requires the KMS to capture less context, as users are assumed to understand the knowledge that is captured and used.

The infrastructure/generic approach focuses on building a system to capture and distribute knowledge/OM for use throughout the organization. Concern is with the capturing of context to explain the captured knowledge and the technical details needed to provide good mnemonic functions associated with the identification, retrieval, and use of knowledge/OM. The approach focuses on network capacity, database structure and organization, and knowledge/information classification.

Both approaches may be used to create a complete KMS. The process/task approach supports specific work activities, while the infrastructure/generic approach integrates organizational knowledge into a single system that can be leveraged over the total organization instead of just a process or project.

Jennex and Olfman (2001) developed a set of design recommendations for enabling KM/OM in systems. The recommendations, Table 1, are based on studies of KMS/OMS success factors. One recommendation calls for use of a common infrastructure. The Internet is suggested for this due to its widespread availability, open architecture, and developed interfaces. This also assists in standardizing software across the organization through the use of browsers and Web applications.

The Internet meets several of these recommendations. It provides a common network that is global. Use of common browsers aids in

Table 1. KMS design recommendations

- Use a common network structure, such as the Internet.
- Add KM/OM skills to the tech support skill set.
- Use high-end PCs and/or clients.
- Standardize hardware and software across the organization.
- Incorporate the KMS into everyday processes and IS.
- Use an enterprise-wide data dictionary to design knowledge base.
- Allocate maintenance resources for KMS.
- Train users on use and content of the KMS.
- Create and implement a KM strategy/process for identifying/maintaining the knowledge base.
- Expand system models/life cycles to include the knowledge process.
- Assess system/process changes for impact to the KMS.
- Automate data capture.
- Design security into the knowledge base.
- Incorporate KM into personnel evaluation processes.
- Implement KMS use/satisfaction metrics.
- Identify organizational culture concerns that could inhibit KMS usage.

Table 2. Internet features/technologies that support KMS

- Common Architecture and Interfaces
- Easy to Use Front-end Systems (Browser User Interface)
- Trends Towards Internet-Based Processes
- Back-end Systems that Provide Database Access to Users
- XML wrapping of documents and other data
- Powerful Search Engines
- Virtual Private Networks
- Internet Opportunities Include:
  - Ability to push time-sensitive data quickly to a wide audience
  - To answer frequently asked questions
  - To create 24-hour service
  - To make knowledge additions/updates available quickly
  - To allow feedback from users
  - To service both specialized teams/users and generic users

standardizing software. Ease of use of browsers and in building and maintaining Internet-based systems empowers users (Newell et al., 1999) and simplifies incorporating the KMS into everyday processes. Ease in handling unstructured data as well as databases simplifies knowledge representation, capture, and dissemination. Table 2 lists Internet tools and features that expand the ability of the Internet to serve as the infrastructure for a KMS. Some of these features are expanded in the following.

Gandon et al. (2000) propose using XML to encode memory and knowledge, and suggest using a multi-agent system that can exploit this technology. The proposed system would have improved search capabilities and would improve the disorganization and poor search capability normally associated with Web pages. Chamberlin et al. (2001) and Robie et al. (1998) discuss using XML query language to search and retrieve XML encoded documents.

Dunlop (2000) proposes using clustering techniques to group people around critical knowledge links. As individual links go dead due to people leaving the organization, the clustered links will provide a linkage to people who are familiar with the knowledge of the departed employee. Lindgren (2002) proposes the use of Competence Visualizer to track skills and competencies of teams and organizations.

Te'eni and Feldman (2001) propose using task-adapted Web sites to facilitate searches. This approach requires the site be used specifically for a KMS. Research has shown that some tailored sites, such as those dedicated to products or communities, have been highly effective.

Eppler (2001), Smolnik and Nastansky (2002), and Abramowicz et al. (2002) use knowledge maps to graphically display knowledge architecture. This technique uses an intranet hypertext clickable map to visually display the architecture of a knowledge domain. Knowledge maps are also known as topic maps and skill maps. Knowledge maps are useful, as they create an easy to use standard graphical interface for the Intranet users and an easily understandable directory to the knowledge.

The use of ontologies and taxonomies to classify and organize knowledge domains is growing. Zhou et al. (2002) propose the use of

Table 3. A summary of issues for future trends of Internet-based KMS

Bandwidth Restrictions and Latency Improving transmission and methods to enable large numbers of users to receive knowledge from the KMS
Organizing Knowledge Creating standard ontologies and taxonomies to enable standard knowledge structures
Flooding of the Web with content Improving knowledge acquisition so that content not helpful to the users is captured
Maintenance and integrity of data Keeping Web maintenance up-to-date and accurate knowledge on the site for users
Exposure Points/Security Creating secure systems that allow remote access yet keep unauthorized user access out
System incompatibilities Improving cross-platform compatibility to improve system integrations and access

ROD, rapid ontology development, as a means of developing an ontology for an undeveloped knowledge domain.

FUTURE TRENDS

Although there is strong support for using the Internet as a knowledge infrastructure, there are areas that current research is improving. Chief among these is the difficulty in organizing and searching large quantities of knowledge in varying knowledge formats and structures. Knowledge can be stored as documents, audio, images, databases, and spreadsheets. Lack of standard structure can make organizing knowledge difficult, while the lack of standard terms and naming conventions makes searching difficult. An example is Ernst & Young UK, who in early 2000 had in excess of one million documents in its KMS (Ezingeard et al., 2000). Another concern is the tendency to not to use the system. Jennex and Olfman (2002) fount that voluntary use is enhanced if the system provides near and long-term job benefits, is not too complex, and the organization's culture supports sharing and using knowledge and the system. Other significant issues requiring resolution are summarized in Table 3 and include security, having adequate bandwidth for the expected use, maintaining content in large sites, and system incompatibilities between distributed offices/users.

CONCLUSION

The conclusion is that the Internet is an effective infrastructure for a KMS. However, there are issues associated with using the Internet that KMS designers need to be aware of. Chief among these are knowledge representation and search. Several tools such as knowledge maps, XML, adaptive Web sites, clustering, and examples of effective Internet-based KMSs were discussed that addressed these issues. However, as knowledge bases grow, designers need to be aware of increasing search times as well as a variety of knowledge artifacts. This is perhaps the most important area for future research. Developing ontologies and taxonomies to aid in classifying and structuring knowledge domains is critical.

Maintaining a site is critical. User, organizational, and/or project needs for knowledge change over time, requiring the KMS to change its knowledge content. Also, knowledge has a life cycle and eventually reaches a point where it is no longer useful. Organizations must allocate resources to update and maintain every KMS.

Securing the KMS is also critical, as knowledge is valuable. KMS/OMS designers need to ensure the security of captured knowledge and use of secure connections is a viable alternative. This may be the greatest impediment to the development of Internet-based KMSs.

The final issue is the tendency of people not to use the computer portion of a KMS. Jennex and Olfman (2002) found that this is a tendency of new members and suggest that this is a matter of context. New members do not understand the context under which the knowledge was created and stored so do not know how to retrieve and use the knowledge. As these members gain experience they gain context and rely more upon the computer and less upon their peers.

Chapter 2.10
Developing and Maintaining Knowledge Management Systems for Dynamic, Complex Domains

Lisa J. Burnell
Texas Christian University, USA

John W. Priest
University of Texas, USA

John R. Durrett
Texas Tech University, USA

ABSTRACT

An effective knowledge-based organization is one that correctly captures, shares, applies and maintains its knowledge resources to achieve its goals. Knowledge Management Systems (KMS) enable such resources and business processes to be automated and are especially important for environments with dynamic and complex domains. This chapter discusses the appropriate tools, methods, architectural issues and development processes for KMS, including the application of Organizational Theory, knowledge-representation methods and agent architectures. Details for systems development of KMS are provided and illustrated with a case study from the domain of university advising.

INTRODUCTION

An effective knowledge-based organization is one that correctly captures, shares, applies, and maintains its knowledge resources to achieve its goals. Knowledge Management Systems (KMS) enable such resources and business processes to be automated. Possibly the greatest benefits, but with the biggest challenges, emerge from creating KMS for environments with dynamic and complex domains (DCD). If knowledge is viewed as information applied in a particular context, then a dynamic domain is one in which information such as policies and procedures are subject to frequent change. A complex domain is one in which many interrelated policies exist with informally defined and tacit exceptions.

Typical parameters used to describe or classify organizational structures in any environment are centralization, hierarchy, and standardization. Dynamic and complex environments tend to coerce organizations into highly centralized, hierarchical structures with many strictly enforced standards-based rules of operation. This environment results in organizations wherein only a few experienced individuals have the knowledge and experience to cope with frequent change, exceptions, and their complex interrelationships. The rest of the organization is thus poorly informed and subject to making errors when employees must make decisions. Obviously, this highly centralized, hierarchical structure is the wrong approach for a knowledge-based organization. The organizational goal is to get the right knowledge to the right person at the right time so better decisions and fewer mistakes will be made. The knowledge management challenge is to support this goal through the development of KMS that can readily adapt to change while dealing with complexity. The emerging science of knowledge management should preserve and build upon literature that exists in other fields (Alavi & Leidner, 2001). We believe, and research on knowledge as a contingency variable (Birkinshaw, Nobel et al., 2002) indicates, that any KMS will benefit from the application of Contingency Theory (CT) and Information Processing Theory (IPT), both well established in the field of Organizational Theory (OT).

The chapter begins with the role of CT and IPT in examining the organizational aspects of dynamic, complex environments, followed by an overview of classic knowledge management and tools for KMS development. Next, the organizational, domain, development, maintenance, and KMS issues for dynamic, complex domain environments are presented. The recommended strategies and tools are illustrated through a case study of a recently developed university advising system, a classic case in which a few knowledgeable individuals (departmental advisors) attempt to serve a large population (students) in a dynamic, complex domain. Additional recommendations and future trends conclude the chapter.

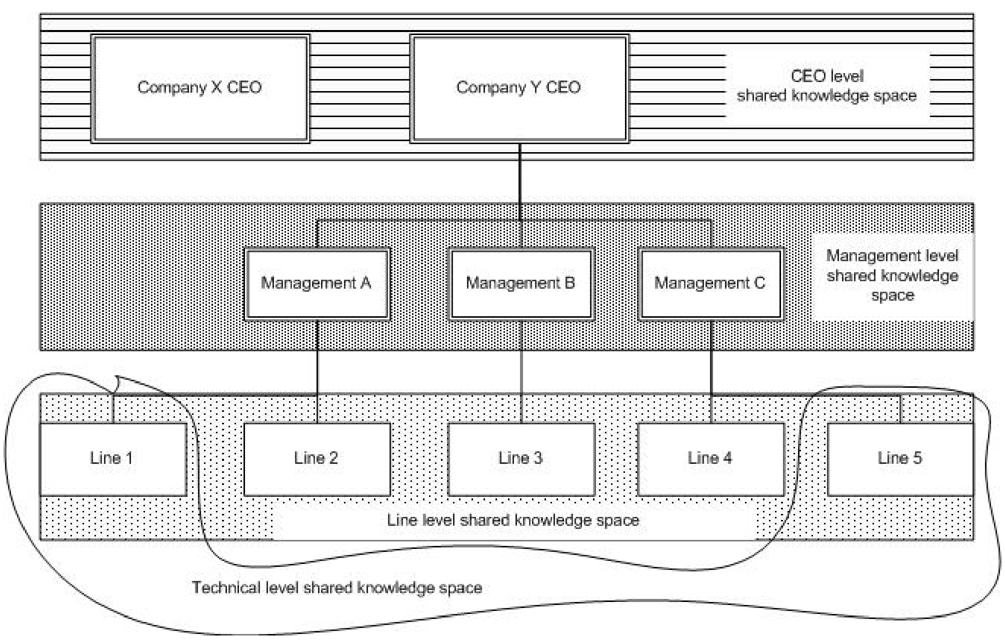
CONTINGENCY THEORY

A basic tenet of CT is that organizations are structured according to their situational environment. OT is a field of study that examines an organization's structure, constituencies, processes, and operational results in an effort to understand the relationships involved in creating effective and efficient organizations. Countering the "one best" organizational structure approach of classical organization theory, the subfield known as CT (Galbraith, 1973; Pfeffer & Salanick, 1978; Dess & Beard, 1984; Thompson, 1967) recognizes that environment influences appropriate structure. CT has been applied to a wide variety of fields including software design (Lai, 1999). In CT an organization's environmental context may be described by two characteristics: (1) the complexity and heterogeneity of the entities in the environment and (2) their rate and predictability of change (dynamicism). Successful organizations survive by adapting to the demands of their task environments (March & Simon, 1958). There may be more than one equally effective organizational design, as each varies by degree of centralization, hierarchy, and standardization. Fortunately, due to interdependencies between components, organizational configurations tend to fall into a limited number of coherent patterns, and thus the set of possibilities is limited. In proposing IPT-aiding application of this theory, Galbraith proposed that complexity, predictability, and interdependence actually measure one underlying concept, that of task information processing requirements (Galbraith, 1973; Galbraith, Downey et al., 2001). Thus, the basic concept to be analyzed is the task and its information processing requirements. A task may be defined as a relatively independent sequence of activities that serves a purpose for some user.

The more heterogeneous, unpredictable, and dependent upon other environmental resources a task is, the greater the information processing that the organization must be able to do in order to successfully accomplish it. IPT shows that as diversity and unpredictability increase, uncertainty increases due to incomplete information. As diversity of resources, processes, or outputs increase, inter-process coordination requirements and system complexity increase. As uncertainty increases, information-processing requirements increase because of management's inability to predict every situation. Thus, the basic premise of IPT is that the greater the uncertainty in the overall tasks in an organizational system, the greater the amount of information that the system must process. When a task environment is stable with few or no exceptions, then standard operating procedures, hierarchical control, and specific goal-setting can be used to coordinate activities. When a task environment is less stable or more diverse, alternative organizational structures must be used either to reduce information processing requirements or raise information processing capability. Organizational structures are therefore a result of attempts to deal with uncertainty, the result of which is complexity and dynamicism.

As an example of how organizational structures can limit the effectiveness of KMS, consider the situation in Figure 1 in which the worker at Line 1 needs knowledge held by the employee at Line 5. In this simplified example using a traditionally structured, hierarchical organization, the knowledge request would have to be propagated up the organizational hierarchy until a common departmental shared knowledge space was reached (in this example, the CEO) then

Figure 1. Knowledge vocabularies based on shared knowledge spaces



down to the employee, and then back up through the hierarchy. This communication sequence is lengthy primarily because it relies only on tacit knowledge and hierarchical control. However, following IPT guidelines allows the use of this "exception" to create a much more direct path using a technical-level knowledge space. Once this vocabulary is encoded into the KMS by either a human or by the KMS's learning module, future communication is greatly facilitated.

As shown in the above example, a conceptual transformation must take place in order to apply CT and IPT to the design of KMS in a dynamic, complex environment. The technological complexity-information processing relationship from the viewpoint of the IS and KMS as a whole must be examined. Among the factors a designer should consider are: (1) how this interaction affects organizational control structure, (2) how this interaction is affected by organizational control structure, (3) the importance of the development groups, (4) the time constraints on the results, and (5) management's viewpoint. This complex analysis is aided by first developing the basic relationship, then examining limitations and effects by the listed factors one at a time.

A series of questions must be considered related to the individual concepts and their interactions. What exactly does technological complexity mean when it is considered as part of a KMS rather than as a separate construct? How does the nature of information processing in a KMS change when it is part of a single team, which is part of other organizational systems? How long has this level of technological complexity been used in this industry, and how well standardized is its infrastructure? All of these questions relate to the constraints that are placed on this one system by other systems within the organization.

The primary determinants in this relationship are the environmental variables of heterogeneity and stability. In distributed IS design for KMS the concept of heterogeneity can be measured in terms of output requirements, IS familiarity and ability, physical location, connectivity method and type of device; data — in terms of location, source, rate of change; and processes — in terms of both business and software; and system hardware. These indicators, along with the stability or predictability of each constituency, provide a means for concept categorization.

In the following sections the knowledge management and KBS tools overviews provide the necessary background and then the case study demonstrates how these concepts are applied to a real project. Additional details on the application of CT and IPT to KMS design, along with examples, may be found in Durrett, Burnell and Priest (2003, 2002a, 2002b, 2001).

KNOWLEDGE MANAGEMENT OVERVIEW AND CHALLENGES

Knowledge management focuses on knowledge creation, storage, sharing, and application. Knowledge management systems are then developed to support these tasks. The specific types of knowledge needed will determine the organizational structure. A full review of knowledge management and KMS are beyond the scope of this chapter. The focus is on how KM and KMS can improve knowledge in a dynamic, complex environment. Properly implemented KMS can provide the following benefits to an organization: (1) fewer mistakes, (2) less redundancy, (3) quicker problem-solving, (4) better decision-making, (5) increased worker independence, (6) enhanced customer relations, and (7) improved products and services.

KMS are a class of information systems used to manage organizational knowledge (Alavi & Leidner, 2001). While information systems are not absolutely required in KM, they can be an important enabler for finding, storing, and distributing information quickly and efficiently throughout the organization. KMS can extend an individual's knowledge beyond formal communication lines (Alavi & Leidner, 2001).

Knowledge management classifies knowledge into two types:

- Tacit Knowledge (informal) — knowledge held by an individual or organization, but which has not been documented and is not widely known.
- Explicit Knowledge (formal) — information that has been documented and shared for others to use. This type includes procedures, manuals, policies, guides, and customer databases.

The goals of transfer, creation, and expansion of knowledge require that knowledge be transformed from tacit to explicit and back to tacit again as it is utilized. Unfortunately in a DCD environment the amount of tacit information is widespread, large, complex, and constantly changing. In this environment, a KMS needs to (Tiwana, 2000):

- Have a shared knowledge space which provides a consistent, well-understood vocabulary;
- Be able to identify, model, and explicitly represent their knowledge;
- Share knowledge among employees and re-use knowledge between differing applications; and
- Create a culture that encourages knowledge sharing.

Databases (DB) and other technologies such as data mining, bulletin boards, best practices, expert directories, expert systems, and case-based reasoning are just some of the methods used. However, knowledge does not thrive by IT alone. The challenges of a dynamic, complex environment require the organization to recognize change and complexity as normal and use these technologies accordingly. A review of the knowledge literature shows several mentions of flexibility and scalability as development objectives but almost no mention of "designing for change and complexity."

TOOLS FOR KMS DEVELOPMENT

In order to develop software that manages change and complexity, sophisticated methods and data representations need to be applied appropriately. A number of these tools are summarized in this section. The three basic categories described are Data Base Management Systems (DBMS), Artificial Intelligence (AI), and distributed communication. For each, recommendations and limitations are given.

DBMS

Much of the basic data needed for creating a knowledge-based organization will reside in databases. A DBMS takes care of concurrent access, security, and data integrity, and can handle large data items, such as audio or video. Processing can be performed by small programs (triggers) to respond to events like deleting a row in a table. Database design and performance-tuning methods are well developed, and personnel with such skills are readily available. Most companies will already have, and should use, a relational DBMS. Pure object-oriented DBMS have essentially found use in a small number of niche markets. Furthermore, major relational DBMS vendors are continuing to expand the capabilities of their products to include object-oriented support.

Not all data is best suited for storage in a DBMS. While a particular DB design can accommodate moderate amounts of change over time, such as adding new tables or attributes, large changes to the schema or processing requirements are difficult to accommodate. While standard relational databases should be employed for some domain knowledge and facts, declarative representations such as rules are the better choice for dynamic or complex policies and procedures. When trying to represent complex policies, a database solution (commonly attempted) becomes too complex or incomprehensible for system designers to understand or for anyone to try to modify. The same is true for hard-coding business logic into programs, which not only creates a confusing system, but also possesses great inflexibility to change. A combination of rules and relational database management systems, sometimes called an active DBMS, allows both declarative and relational representations to be defined using a single product. While this model can be useful, it is not required to integrate both paradigms into one solution. Later, in the case study, we show how separate DBMS and knowledge-based tools are integrated to provide a solution. But first we discuss powerful tools and methods from Artificial Intelligence (AI) that are used to capture an organization's knowledge.

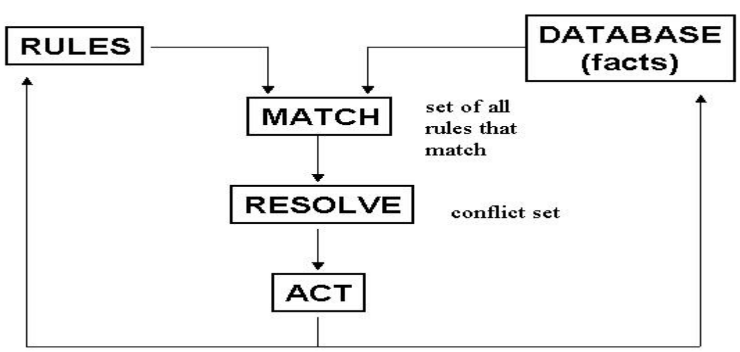
Knowledge-Based and Expert Systems

Systems that represent and reason with knowledge are generally referred to as knowledge-based systems (KBS). While the term KBS can be used to describe any system that uses or delivers knowledge in some way, a KBS is traditionally defined to be a program or collection of programs that represents and reasons with declaratively specified knowledge. Current KBS often integrate the knowledge component with other processing so that the knowledge-based part of the system is hidden from the user and may be a small, though critical, part of overall system functionality. Within this section, the term KBS will refer to the specific knowledge component or components within a larger system. A KBS is sometimes referred to as an Expert System if the performance matches or exceeds that normally found in experts within a discipline.

A number of methods for constructing KBS are available. We will discuss a few of these. Developing KBS typically requires advanced training and experience, but some vendor tools provide specific support for staff without such training. A given problem may require combining multiple KBS methods to obtain a satisfactory solution. Some important methods are rules, cases, belief networks, fuzzy systems and business-rule systems.

Rule-based systems represent knowledge in an IF-THEN format. The inputs for solving a problem are the rules plus facts that represent a current situation. An inference engine executes

Figure 2. Execution cycle in a rule-based system



by finding patterns in the rules that match the facts, "firing" (executing) the rule, and repeating these two steps until no more patterns match facts (Figure 2). Each cycle through the rules may result in changes to current facts, so dynamic behavior can be achieved. As an example, with facts that state that a student has a GPA of 3.7 and has taken a DB course, the following rule will fire.

IF the student has a GPA>3.5 AND has taken the DB course
THEN approve student for the AI course

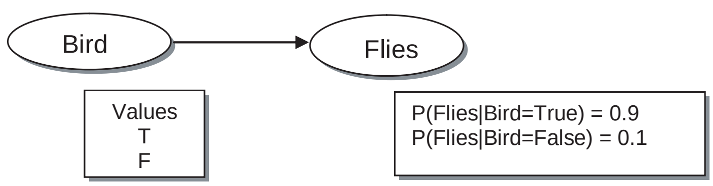
A number of commercial and free shells exist that provide the inference engine, supporting functions for string and numeric processing, and required format for creating rules. Examples include JESS (JESS, 2002) and CLIPS (CLIPS, 2002).

Case-based reasoning (CBR) attempts to solve problems by comparing them to those that have previously been solved. The reasoner searches a case-base of problems and their solutions to find those that best match the description of a current problem, then attempts to adapt the stored solution to the new problem. The new problem and its solution may be stored into the case-base for future reference. A common application of CBR is to support help-desks.

Belief nets, also known as Bayesian belief networks, are used to represent uncertainty, specifically the probabilistic causal relationship between objects or attributes. For example, the relationship between a person's age, weight, blood pressure, and other factors influences the belief that the person is at risk for heart disease in the future. An extension to belief nets, called influence diagrams, adds decision nodes to the representation to recommend a choice among actions that maximizes value to the decision-maker. Using the same example above, a decision node could be added to recommend if the person should undergo the expense of a stress test. Rather than trying to represent a complete model of some phenomena, probabilities are used to summarize knowledge. The result is that computationally tractable large models can be constructed. Taking another example, consider the need to represent that most birds fly. Using a logic-based representation, we would need to describe all the exceptions to the most likely case that if something is a bird, then it flies. Exceptions include the species, if the bird is dead, or has its wings clipped. We can group these exceptions into one or more belief net nodes, depending on how the knowledge is to be used in the overall system. A belief net for the simplest case is shown in Figure 3.

Fuzzy systems, which can extend the representational power of rule-based systems, commonly are used to represent vagueness, not uncertainty, such as is found in the statement "Elton is tall." Here, the statement is certain, but the term "tall" is vague. A fuzzy calculus is used to map natural language terms to numbers, and to combine those numbers in a meaningful way to determine if a rule should fire.

Figure 3. A belief net for the simplest case



Business-rules systems (BRS) are a subcategory of KBS that encode particular kinds of knowledge. BRS capture, disseminate, and enforce the current explicit and tacit policies, procedures, and guidelines of an organization. Because such knowledge must be adaptable to changing market and economic demands, business rules must be easily identifiable and maintainable. While the term "rules" is part of the BRS acronym, and standard expert system style "If-Then" rules are often used, this encoding is not a requirement. Other declarative knowledge-representation systems, such as cases (as in case-based reasoning systems), are appropriate. The rationale for choosing a declarative representation is to give end-users (knowledge-workers) the ability to comprehend and modify the business logic.

Other Techniques from AI

Two important techniques that can be used with the methods of the previous section are neural networks and machine-learning methods. By adding the capability to learn autonomously from past data, these methods can be used to create knowledge components or to adapt the behavior of a system to changes over time. This capability allows tacit knowledge to be more easily encoded into explicit knowledge.

Complex problems with multiple input and output values can also be modeled using neural networks. Patterned conceptually after the human brain, this technique allows weighted linkages between value nodes to transform input data to output knowledge. Neural nets (networks) learn a mathematical function that describes the relationship between variables by using example data. Common uses include classification, speech, and vision tasks. Complex functions can be learned that, unlike statistical models, do not require the user to specify the expected type of function. Unlike the other representations discussed here, neural nets are a "black box"—it is not possible to uncover the model learned. In a rule-based system, for example, a user can view the chain of reasoning (rule firings) used to solve a problem. Despite this disadvantage, neural nets are powerful problem solvers that can tackle problems the other reasoning methods have difficulty solving.

Machine learning methods can be employed with many representations, including databases, precise and fuzzy rule-based systems, belief nets, and case-based reasoning. The learning can be used to enhance system capabilities (be able to create new explicit knowledge) or performance (solve problems faster). In data mining, machine learning and statistical methods can be used to discover new knowledge. For example, a grocery store could discover that customers who buy lots of fresh fruit also tend to buy soy milk. Using knowledge of buyer patterns of behavior, product selection and display can then be adjusted to maximize profits. Rules can be learned by supplying past data, for example, to classify the creditworthiness of persons seeking loans. Belief net learning algorithms either learn the basic structure of the belief net or improve the accuracy of the results. CBR learning algorithms, often integrated within the CBR tool, learn new cases or combine several specific cases into general ones that can solve a wider range of problems.

Web Services and Distributed Communication

More systems development is becoming distributed across computers. Part of the reason for this shift is a desire to take advantage of the trend in using many computers instead of one big mainframe. Systems have become developed by individual departments or divisions that need to work together. This trend toward distributed computing is necessary because the systems being developed are much too complex to consider as one monolithic system, and must be decomposed into subsystems so developers can understand them. Further, the trend is towards piecing together components, some custom developed, some purchased, where each component performs some specific tasks, such as credit card processing. Finally, intercompany processing means that disparate computing systems need to communicate. A Web service is a software entity that is capable of inter-application communication over any local or wide area network. Web services enable the creation of dynamic intra- and intercompany systems.

Standards exist, and are continuing to be developed. There is a confusing and overwhelming array of communications protocols. The old EDI (Electronic Data Interchange) for intercompany communication is giving way to many other standards, including but not limited to XML. WSL, CORBA, KQML, FIPA, SOAP, UPNP are a few of the standards. Some of the newest standards target security (XML Signature), requirements (Web Services Description Usage Scenarios), and design (Web Services Architecture and Descriptions Requirements). These and other standards documents are published by the World Wide Web Consortium (W3C).

Currently, XML and some of the protocols built on top of it are reasonably safe choices. XML can be used to share data between databases and programs running across the Internet. Unlike HTML, which simply describes the formatting of data within a web browser, XML describes what data items are. Like a database scheme, an XML tag describes what a piece of data is, for example <price>$19.99</price> uses the <price> tag to identify the data $19.99 as the price of some item. In order to use XML for communication, the programs sharing the XML data must agree on what the tags mean. Some communities, like medicine, have created XML vocabularies, with the expectation that any program wishing to communicate about medical data will use this standard vocabulary. Creating these standards, and then using with existing programs and databases, is a major challenge.

Having reviewed CT/IPT and key software technologies, the following section shows how these concepts and methods can be used in the development of a KMS in a DCD. Software development phases, each with specific issues when applied to dynamic and complex domains, are presented, then demonstrated by the example KMS currently being developed.

DEVELOPING KMS FOR DCD

There are a number of fundamental work phases, each with issues and choices, in the development of a complete KMS solution. The domain analysis phase involves acquiring an accurate model of business processes including data elements, policies, and their stability over time. The requirements phase entails eliciting, analyzing, and specifying the system behavior, including interaction with users and other systems. In architectural design, the blueprint for the system is constructed to define major components and their interactions. In detailed design, the components are fully specified, including data representation and algorithm selection. Implementation translates the design into executable code. Testing is an integral part of each phase and continues throughout the lifecycle of the product. Once the system is in place, maintenance is necessary to correct errors and to respond to changes in the domain and operational environment. This process is especially important for a DCD where needed changes are frequent. The goal of designing for systems in DCD is to reduce the maintenance burden, which accounts for up to 80% of system lifecycle costs in many instances.

The work phases are performed within a software engineering methodology and generally require a number of iterations through each phase. For DCD systems, an agile methodology, such as FDD (Palmer & Felsing, 2000) or XP (Beck, 2000), should be considered because it provides better support for change throughout development. The standard notation for describing artifacts of software development is the Unified Modeling Language (UML). An easy-to-use guide to the UML is Fowler and Scott (2000). Computer Aided Software Engineering (CASE) tools are available to support collaborative development of one or more phases. Commercial and free tools include products from Rational, TogetherSoft, and Gentleware.

Domain Analysis

Knowing your domain is vital to successful knowledge management. For DCD, it is not enough to only look at your current operation. The best thing to do is to collect three types of data from (1) your current domain, (2) your domain history, and (3) other organizations. The data you should collect includes the language (terms used and their precise definitions), business policies and processes, and specific overrides to those policies and processes. A primary benefit of CT/IPT-based KMS is the utilization of situations not covered by existing policy. In traditional systems, such exceptions are propagated up a control hierarchy to eventually land in a log file and thus on a human's desk. In a KMS utilizing IPT's organizational model, common exceptions are sent to a learning module and are used to create new knowledge. This structure allows tacit knowledge to be more easily encoded into explicit knowledge. For example, the policy for offering a book discount may be that the discount is only given if a person presents a discount card, with a learned exception to offer a discount if the person spends more than $100 on their first purchase and turns in an application for a new discount card at the cash register.

Following this advice obviously will take more time, but the result in a DCD will be much easier maintenance. Designers must understand which items are likely to change and which can be abstracted. For example, terms may change over time. What is called a "general education requirement" may later be called an "undergraduate core requirement." Abstract the term in the ontology to use internally, and add specific terms as synonyms for display to users (each synonym can be augmented with an audience and date range to determine when appropriate to use). Users need to see the terms they know, but finding and changing them throughout a database and programs is time consuming and error prone. Policies and processes also change over time, often with more frequency than language.

Policies are the guiding principles by which the organization operates. These principles can be stated succinctly in a single statement or a series of if-then-else clauses. An example policy is, "Senior level electives require completion of the software engineering course and a GPA greater than 3.2." A more complex policy is, "If the student has the course prerequisites, then they may take the course; else if they get departmental approval, then they may take the course; else they may not take the course." Notice the many terms used within these two simple examples — course, prerequisite, departmental approval, GPA, elective, (course) completion.

Processes describe steps that need to be performed. These steps may involve many data changes or the execution of multiple policies and can be quite complex. Example processes are purchasing books online or getting approval for a college degree plan.

Within all these three areas — language, policies, processes — the domain can change. In a DCD, the goal is to develop systems that can be easily modified when needed.

Requirements

There are three major tasks in the requirements phase. These are elicitation, in which you get the requirements from the users; specification, in which you record these requirements; and analysis, in which you organize and correct the specification. Each is discussed in this section, including how to deal with change during and after initial requirements are gathered.

Eliciting requirements is a similar process to domain modeling, but the focus is different. In

Figure 4. Example use case with multiple scenarios for buying groceries

Buy Groceries using self check-out
1. Customer goes to check out with items to purchase
2. Customer scans each item and places it in a bag
3. Customer indicates last item has been scanned
4. System displays total
5. System requests payment information (credit, debit)
6. Customer inputs payment information
7. System confirms purchase

Alternative: Card authorization failure
At step 7, system requests customer to reenter information up to two more times, then notifies store employee for assistance.
Other Possible Alternatives: dealing with coupons, discount cards and scan failures are described in alternative scenarios.

domain modeling, designers are trying to understand the domain — what the users do and how they do it. This process facilitates communication with the users, in their language, to determine what they need the system to do. There are many structured and unstructured methods for requirements elicitation, including interviews, process tracing, and user interface prototyping (McGraw & Harbison, 1989). Prototyping is a particularly powerful method for eliciting requirements that have significant user interaction, since it is generally easier for a user to critique a simulation than to construct a comprehensive list of their needs. The process almost always starts with interviewing and some initial specification before the prototype is developed. Further elicitation and specification then proceed iteratively.

A powerful technique for capturing functional requirements is the use-case model. A use case describes the interaction of a user with the system to perform a task of value to that user. For example, entering a PIN number into an ATM is not of value to the user; getting cash from a bank account is. Use cases specify the external systems and types of users, collectively called actors; preconditions that stipulate the required system state for the use case to be valid; and possibly post-conditions, or changes to system state after the steps of the use case have been completed. Use case scenarios describe particular sequences of steps involving interaction with the system. A use case with multiple scenarios for buying groceries is shown in Figure 4. Nonfunctional requirements that do not fit into a single use case, such as specification of platform or performance needs, are recorded in a supplementary document. The use-case model and supplementary documentation together form the requirements specification.

An important facet of using use cases for requirements determination in DCDs is that they allow an analysis of the potential exceptions that will be generated out of a particular process. In use cases where there are a great many alternative scenarios, the IPT guidelines tell us that support objects and rules created should be very flexible, containing more functionality and thus minimizing the inter-object communication requirements. In some cases, these guidelines can dictate violations to traditional software development models.

In requirements analysis, the specification is examined to identify missing, conflicting, or incorrect requirements and to organize the specifications to aid understanding and communication with potential users (Priest & Sanchez, 2001). Use cases that perform similar tasks may be combined, or complex use cases may be decomposed into multiple user cases. Another analysis task is to find steps that occur in multiple use cases and extract them into a single use case. This process often results in the specification of basic system utilities like retrieving student transcript data. The collection of use cases, actors, and their relationships may be represented in a graphical format to communicate a high-level view of the total system capabilities. While early analysis aims to capture all the requirements, this goal is not usually possible, especially in DCD environments. As in all the phases of development, dealing with change must be built into the process.

To account for later change, the analysis model must be readily maintainable. Extremely detailed and large numbers of use cases are too hard to keep current. Instead, limit use-case specification to major functions. Alternative scenarios can be summarized as brief text statements instead of a detailed sequence of steps. Identify each use case using a project standard identification scheme. As development progresses, each developer should know which use case she is designing, implementing, or testing. Each artifact produced and each milestone scheduled should be tied to specific use cases. Each use case should also reference any related artifacts produced in domain analysis. This traceability is key to maintaining a live requirements specification — one that accurately reflects the current purpose of the system.

Design and Architectural issues for DCD

With maintainability as a major design goal for DCD, general software design principles are just the first consideration in selecting an appropriate architecture. Two important general principles are high cohesion, where each component is responsible for a related set of tasks, and low coupling, where the communication between components is small. Using these principles provides a starting point from which CT and IPT principles are applied to examine the concepts, and their interactions, stability and heterogeneity. In the resulting architecture, the number of required specialized components (agents) increases with the number of dynamic and/or unique processes. While this negatively effects coupling, the advantage is that policy and language changes are simpler to implement.

Two design issues of particular relevance to design for DCD are ontology creation and agent-based architectures. Ontology creation, begun in domain and requirements analysis, is fully developed during design to create a central repository for the domain language. Agent-based architectures are a means for structuring a software system that adhere to Contingency Theoretic principles. Contingency-theoretic system development (CTSD) adapts contingency theory to development and maintenance of software systems (Burnell, Durrett, & Priest, 2002; Durrett, Burnell, & Priest, 2001). A summary of CTSD is given in Table 1.

Ontologies are specifications of conceptualizations, used to help programs and humans share knowledge. They are sets of concepts — such as things, events, and relations — that are in some way congruous (such as specific natural language) and thereby create an agreed-upon vocabulary for exchanging information. They allow one group's knowledge to be understood by and shared with other groups. The DCD environment requires the ontology to be a continuously evolving effort.

Table 1. CTSD design principles

Design Principle	Rational
Isolate dynamic concept names in ontology	As terms change over time or across organizations, updating only needs to be performed in the ontology.
Isolate external systems connections	Subsystems that interface with external databases and systems tend to be highly dynamic, both in connection method and format of returned data.
Create agents for specialized complex processing; each agent performs a tightly related set of tasks	Changes to processes are localized into specialist agents, thereby aiding reuse of components.
Software Teams	IPT suggests to minimize communication requirements by combining agents into "teams"
Exception Management	To follow CT guidelines and quickly identify exceptions to existing policy, overrides are propagated to human and AI-based knowledge creation modules.
Do not use DBMS for dynamic policies or processes	Makes DBMS structure overly complex and difficult to modify, especially after system has gone into production
Incrementally design and deliver fully tested functionality	Waiting for a complete system can result in delivery of an obsolete system.

Keeping a well maintained ontology facilitates the continued use of and even allows the expansion of existing knowledge spaces

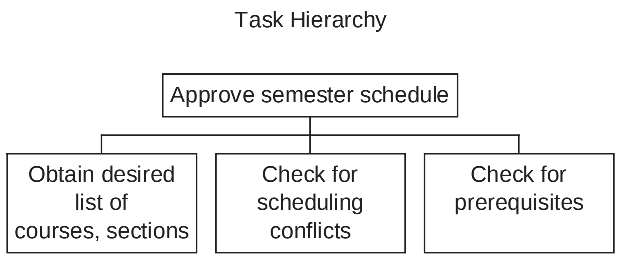
There are many definitions of and arguments over agents. Agents can be autonomous, mobile and/or intelligent. A generally agreed upon viewpoint is that an agent is a program or collection of programs that lives (continuously runs) for some purpose (is goal-based) in a dynamic environment (changing access to resources) and can make decisions to perform actions to achieve its goals. Agents have been created to schedule meetings, to find and filter news items, and to perform military reconnaissance. To illustrate how an agent operates, consider meeting scheduling. I simply notify my agent that I need to meet with my staff this week about a new project. My agent then automatically contacts the agents of each of my staff members, coordinates a suitable time, arranges the meeting room, places the meeting on my calendar, and notifies me at the appropriate time. Like the best administrative assistants, agents both know and adapt to their boss.

Multi-agent systems are those in which multiple agents (usually) cooperate to perform some task. In the meeting example above, the agents for each employee communicate directly to negotiate a time to meet. The agents may or may not be developed together. A vision for the future is that agents will seek out other agents anywhere on the Internet to find the information or resources they need to achieve a goal. This interaction will all be transparent to the user and completely secure. A less ambitious goal for multi-agent systems is to decompose a complex task into a collection of interacting agents that together solve some problem. In a military reconnaissance application, separate agents may be responsible for collecting images, navigation, and detecting threats.

The design of an individual agent is flexible. It may be object-oriented, a rule-based expert system, a neural net, or any other design. Legacy software may be "wrapped" with an agent interface. The key point is to design the agent using good design principles. This requirement means that the interfaces to the agent are clearly defined and the internal operation is hidden from all external software.

A thorough analysis of tasks and the environment are used to guide architectural design

Figure 5. Example task hierarchy for approving a semester schedule



issues. Tasks capture the actions that need to be performed by the system. Often, it is necessary to create a task hierarchy (Figure 5) so that the appropriate level of task is assigned to a computational component (or software team of multiple components), which is performed later. For each task, a predictability metric is assigned to indicate the expected stability of the task over time. This predictability metric allows us to follow IPT guidelines and create components for high predictability tasks and software teams for low predictability tasks. From domain analysis in our case study, approving a semester schedule is dynamic — the process changes over time and across universities. Conversely, checking for scheduling conflicts is static — the task of checking if there are time conflicts between two courses must always be done. Maintenance is driven by measuring the frequency with which manager (exception-handling) modules are employed to complete processing tasks.

Testing

The test effort should demonstrate that the product satisfies the customer, meets the design requirements, performs properly under all conditions, and satisfies the interface requirements of the hardware and other software components. The product is incrementally validated using the use-case scenarios. Since each scenario provides a complete description and can be immediately prototyped, this testing allows user validation to begin very early in the development process. The validation process also uses scenarios for documentation, training, and user manual purposes. Feedback is gathered from users as they learn to use the system. Issues are efficiently defined within the scenario task context and task ontology and problems can be automatically traced back to the appropriate design area. Analysis of the system by users may result in new scenarios. The best approach is to use several test methods continuously throughout design and coding. Testing rules adapted from Myers (1976) are shown below:

- A good test is one that discovers an undiscovered error.
- The biggest problem in testing is knowing when enough testing has been done.
- A programmer cannot adequately test his or her own program.
- Every test plan must describe the expected results.
- Avoid unpredictable testing.
- Develop tests for unexpected conditions as well as expected conditions.
- Thoroughly inspect all test results.
- As the number of detected errors increases, the probability that more errors exist also increases.

- Assign the most creative programmers to the test group.
- Testability must be designed into a program. Do not alter the program to make tests.

Well designed code and a development process that recognizes the importance of near-continuous testing will result in fewer schedule delays and software that performs to its specifications. One of the tenets of extreme programming is to write the test cases before writing code and to perform regression testing as part of frequent code integration.

CASE STUDY: A VIRTUAL ADVISOR

A recently designed expert advising system will be used to illustrate the process for developing a KMS for a DCD application. The student advising process found at most universities is an example of a knowledge-intensive process within a dynamic, complex environment. The process can prove to be tedious, time-consuming, inconsistent, and error-prone. From a student's perspective, the task of deciding what courses to take and when to take them can leave many students frustrated and confused. Students only need advising a limited number of times throughout their college experience, so their level of knowledge varies and is often incomplete. Designing a degree plan for a given time period and creating a schedule for each semester requires an understanding of all the policies and regulations within a university, college, and department. Student objectives and preferences mean that some semester schedules or degree plans are preferred over others, i.e., optimization. These users want a quick, effective process with limited training required.

From a faculty member's perspective, the advising process includes not only an understanding of the documented policies and rules of the university, i.e., explicit knowledge, but also an understanding of the rules and exceptions or choices that may not be explicitly stated within her own department. Many of the interrelationships between the rules are confusing, and many exceptions are often not documented. Because of this dynamic complexity, most departments identify a few individuals as departmental advisors. The departmental advisors become the knowledge center for the advising process. This organizational structure results in tacit knowledge only being known by a few individuals. The overall goal is to ensure that a student takes the appropriate courses mandated for his graduation and appropriate for his capabilities, interests, and scheduling constraints. However the level of knowledge both tacit and explicit between different faculty and faculty advisors can vary greatly. Faculty objectives focus on time management, consistency, and minimizing mistakes. Students depend on faculty advisors to know all of the rules and exceptions, as well as the students' preferences, in order to guide them appropriately.

Administrators have to manage data for each student, each semester, and each degree plan. With numerous rules and the exceptions and interrelationships between rules that are constantly changing, complexity increases exponentially. Administrators need up-to-date information about each student's course schedule and transcript, departmental schedules, lists of classes that are full, and degree, course, or section changes. Their objectives are time management, responsiveness, and maintenance.

The purpose of the Virtual Advisor (VA) system is to quickly and accurately aid students and faculty advisors in selecting courses for a semester and planning courses needed for graduation. Furthermore, the system is end-user customizable across departments and universities. Because the data, policies and procedures change frequently, are heavily interrelated, and vary widely across universities and departments, the environment is dynamic and complex. Any system built with hard-coding constraints will become obsolete within a matter of months after implementation.

A university or department cannot rely upon inflexible and non-customizable systems in adapting to the dynamic nature of curriculum changes and university rules. In the following, the major KMS development tasks are described. These tasks are performed in an iterative, not purely sequential fashion, for reasons discussed in the prior section.

Domain Analysis

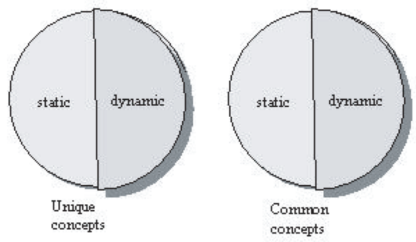
In domain analysis, we first analyzed several existing departmental advising systems, including those we had used ourselves as advisors. This analysis yielded a number of important insights. First, the existing systems were either tightly integrated with external systems, in which calls to external databases were embedded within processing code, making maintenance difficult, or they were not integrated at all, requiring downloading and manual reformatting of data before use in the system. Second, maintenance, if it occurred at all, was passed around to novice personnel with heavy workloads resulting in shoddy patches just to keep the code running. One system analyzed was so brittle that only a few of the many functions worked at all, and these required much manual effort to input and maintain accurate data. Finally, none of the systems had the capability that students want, including the ability to specify preferences for course times, or spreading difficult courses evenly over multiple semesters.

According to CTSD principles, a domain with frequent changes like this one requires a measure of the type and frequency of changes. We examined two departments at two universities, then looked at the changes that had occurred at each over the past five years. We found that an initial decomposition of terms and policies was useful (Table 2). Static concepts are those that are not subject to change. These concepts describe the fundamental terms and processes within a domain, e.g., students, instructors, and courses. This data is generally already represented in a database system. Dynamic concepts are those that have shown to change over time or are new concepts. The stability of such concepts is uncertain, and therefore the representation needs to be amenable to change. In education, policies for curriculum and admissions requirements change over time. New programs for distance education, which may have little or no history, might be categorized as dynamic, since changes are likely after the organization gains experience with the new model for education delivery. Static and dynamic concepts may be either common or unique. Common concepts are those found widely across organizations, whereas unique concepts are specific to a small percentage of organizations. Looking at these two dimensions by which a concept can be categorized, a student is a static, common concept. A requirement for an undergraduate thesis may be a static, unique concept. How the four decompositions are related is shown in Figure 6.

Table 2. Categories of domain concepts

Decomposition of Domain Concepts	Example
Static	A student ID; classification (e.g., freshman)
Dynamic	General curriculum requirements and exceptions
Common	Courses have prerequisites
Unique	Requirements for admittance into upper division technical program

Figure 6. Relationship of domain concept categories



An important task for ontology development was the creation of abstract names for common concepts. The prior concept analysis activity showed that some concepts change slightly over time within departments, and others are static, but are named differently by different organizations. In order to support maintainability, we needed to represent these differences in the ontology. For a simple example that illustrates both these characteristics, consider the static concept of a set of courses that are required for all students graduating from a particular university. In one university, the name for this concept changed from UCR to CUE. The same concept was called GEC or had no specific name at two other universities. Previous systems hard coded these names into databases, variable names, and user interfaces. The better approach is to use the abstracted name wherever invisible to the user and translate to the appropriate specific term for display. Changes are thus isolated to changing the ontology, a key tenet for supporting maintainability.

Based on the understanding gained from the domain analysis and additional interviews with domain experts, the use-case model was then prepared. Here the focus is on clearly demarcating the desired functions of the system. Since

Figure 7. Use case for checking student degree plan

USE CASE: USER DEFINED DEGREE PLAN CHECKER

Use Case ID: A13

Priority: 1   Implementation difficulty: 3

Description: The student can chose to create their degree plan for a selected number of semesters. The student is given a list of courses offered within the university. The student can then assign courses to specific semesters. The student then submits the degree plan created for system verification.

Precondition: Student logged in; in academic good-standing

Actors: Student, Online Enrollment System

Primary Scenario:

1. Student selects Degree Planner option
2. Student selects what type of degree plan he/she wants to perform
3. Student enters desired number of semesters to plan for and college/major info
4. System retrieves information on student courses and displays them
5. Student assigns desired courses into appropriate semesters
6. Student repeats step 5 as often as desired
7. Student submits created degree plan for verification
8. System checks rules and prerequisites
9. System returns with approval or an error message for any conflicts

each use case describes an interaction with the system to perform a task of value, a use case can be assigned measures to rank its priority and implementation difficulty. Analyzing the preconditions and post-conditions, a graph showing the dependencies between use cases is also developed to show, for example, that checking a degree plan is dependent upon being able to select courses for a single semester. The dependency graph and ranking measures are then used to prepare an implementation schedule, in which major milestones result in the delivery of a core set of functionality to the user. A sample use case for the virtual advisor is shown in Figure 7.

Design

To transition to design, two major activities occur that shift the focus from the external, or behavioral, view of the system, to the internal system construction. One activity is the construction of an initial class model containing only the objects and attributes that describe the major entities and their relationships. The other activity is the extraction of tasks, which will become the object methods. A useful technique for extracting these items from the use cases is to use Class-Responsibility-Collaboration (CRC) cards. A card is filled out that contains a class name, the major tasks this class is responsible for, and the other classes with which this class interacts. The strength of CRC cards is that, when utilized by a team, the interaction between the members (in simulating the execution of the system) can highlight missing or incorrect fields in a class, whether attributes or methods (Schach, 2002).

Following CTSD for the design of VA, the design grouped related classes from the CRC cards according to the considerations given below. The related classes are implemented as major modules in the systems and, if processing or communications requirements are complex, are designated to be implemented as "employee" or "manager" agents. Factors to consider when selecting the grouping of tasks, classes, and modules are:

1. the predictability/stability of the task environment and business processes involved;
2. the diversity of the task environment in terms of each relevant constituency;
3. scope or granularity of "line-level" software teams;
4. inter-team coordination techniques used and business knowledge involved; and
5. "management-level" control teams.

In the system architecture design phase CT design guidelines tell us that domain policies must be specified declaratively and grouped according to predictability to minimize the impact of change. We used relational database tables to store raw data, downloaded from external systems. This design choice isolates legacy system interface tasks. Domain policies are categorized and stored as rules. These rules are implemented in JESS. JESS rules represent and check prerequisites, degree requirements and other university rules. The Java degree planner manager interfaces with the rules and internal database to provide a degree of isolation of policy and implementation. The degree-planner manager controls the mechanics of supplying data to and storing data supplied by the degree planner rules. Thus, individual rule bases that behave as employee specialists are strictly focused on solving specific domain problems, such as creation of a degree plan based on student and university constraints. Managers handle the mundane tasks of acquiring and distributing resources (data) from the appropriate sources. A separate user interface again isolates domain policies and procedures from mechanics of implementation. Graphical rule editors, templates and parameter-setting forms allow an administrator, typically a department chair or lead advisor, to maintain the system to meet their needs and to provide portability across departments and

Figure 8. Virtual advisor architecture

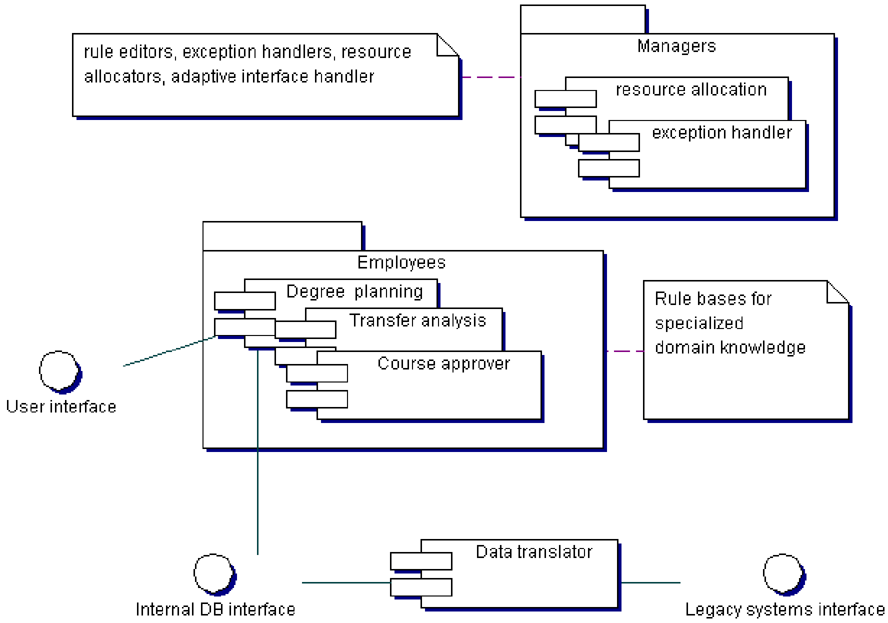


Figure 9. Semester scheduler with student preferences

universities. The resulting architecture for the system is shown in Figure 8.

Figure 9 shows one option for the semester scheduler that allows the student to select courses that match a set of preferences, and for which the student has prerequisites. As courses in the desired subject areas are selected, they are checked for time conflicts with those already selected. In the display, generic terms used internally within the system have been mapped to the specific terms used at this student's university, as specified in the ontology.

FURTHER RECOMMENDATIONS AND CONCLUSION

The development of an effective knowledge management system in any organization is a complex process. This fact is especially true in an environment subject to rapid and unpredictable changes and with many differing and interrelated resource, processing, and output requirements. However, in this type of dynamic complex environment, KMS can be extremely beneficial and can be used to create a true knowledge-based organization.

The initial design steps in any project are especially important. In developing tools to support an organization's evolution toward a flexible, knowledge-based organization the first and most important step is the creation of a vision. The vision statement for our example advising system is:

To provide accurate, timely, specific guidance to students, faculty, support staff, and others about the services provided by and the rules, requirements, and procedures of the university while remaining flexible to changing requirements and as easy to learn and use as possible.

As with all such statements, one stating the motivation for a KMS should be in terms of benefits to company, customers, and other stakeholders, not in terms of technology. It should motivate designers and users of the system toward cooperation in the realization of a greater goal. This motivation is potentially the most important part of the design of a KMS.

Equipped with the right processes, methods, and tools, it is the people that create a knowledge-based organization. It takes an upper-management champion for the system vision, the right team of developers, a good team leader, and enthusiastic users, all within an environment that encourages and rewards knowledge sharing. Developers, chosen for their creativity and flexibility as well as their technical talent, should be given the resources to learn and experiment. A team leader acts primarily in the role of coach, i.e., providing guidance, motivation, resources, and a common vision. An upper-management champion works to keep the projects funded and to garner support for larger scale efforts. Enthusiastic users are critical as well, for without their knowledge and feedback, developed products will not solve the correct problems, nor will they be used.

Chapter 2.11
Interesting Knowledge Patterns in Databases

Indian Institute of Management Bangalore (IIMB), India

INTRODUCTION

Knowledge management (KM) transforms a firm's knowledge-based resources into a source of competitive advantage. Knowledge creation, a KM process, deals with the conversion of tacit knowledge to explicit knowledge and moving knowledge from the individual level to the group, organizational, and interorganizational levels (Alavi & Leidner, 2001). Four modes—namely, socialization, externalization, combination, and internalization—create knowledge through the interaction and interplay between tacit and explicit knowledge. The "combination" mode consists of combining or reconfiguring disparate bodies of existing explicit knowledge (like documents) that lead to the production of new explicit knowledge (Choo, 1998). Transactional databases are a source of rich information about a firm's processes and its business environment. Knowledge Discovery in Databases (KDD), or data mining, aims at uncovering trends and patterns that would otherwise remain buried in a firm's operational databases. KDD is "the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data." (Fayyad, Piatetsky-Shapiro, & Smyth, 1996). KDD is a typical example of IT-enabled combination mode of knowledge creation (Alavi & Leidner, 2001).

An important issue in KDD concerns the glut of patterns generated by any knowledge discovery system. The sheer number of these patterns makes manual inspection infeasible. In addition, one cannot obtain a good overview of the domain. Most of the discovered patterns are uninteresting since they represent well-known domain facts. The two problems—namely, rule quality and rule quantity—are interdependent. Knowledge of a rule's quality can help in reducing the number of rules. End-users of data mining outputs are typically managers, hard pressed for time. Hence, the need for automated methods to identify interesting, relevant, and significant patterns. This article discusses the interestingness of KDD patterns. We use the association rule (AR) (Agrawal, Imielinski, & Swami, 1993) in a market-basket context as an example of a typical KDD pattern. However, the discussions are also applicable to patterns like classification rules.

BACKGROUND

The Rule Quantity Problem: Solution Perspectives

The rule quantity problem may be a result of the automated nature of many KDD methods, such as AR mining methods. In one study, Brin, Motwani, Ullman, and Tsur (1997) discovered 23,712 rules on mining a census database. Approaches to alleviate this problem aim at reducing the number of rules required for examination while preserving relevant information present in the original set. Redundancy reduction, rule templates, incorporation of additional constraints, ranking, grouping, and visualization are some of the techniques that address the rule quantity problem.

In AR mining, additional constraints in conjunction with support and confidence thresholds can reveal specific relationships between items. These constraints reduce the search space and bring out fewer, relevant, and focused rules. Rule templates (Klemettinen, Mannila, Ronkainen, Toivonen, & Verkamo, 1994) help in selecting interesting rules by allowing a user to pre-specify the structure of interesting and uninteresting class of rules in inclusive and restrictive templates, respectively. Rules matching an inclusive template are interesting. Such templates are typical post-processing filters. Constraint-based mining (Bayardo, Agrawal, & Gunopulos, 2000) embeds user-specified rule constraints in the mining process. These constraints eliminate any rule that can be simplified to yield a rule of equal or higher predictive ability. Association patterns like negative ARs (Savasere, Omiecinski, & Navathe, 1998; Subramanian, Ananthanarayana, & Narasimha Murty, 2003), cyclic ARs (Ozden, Sridhar, & Silberschatz, 1998), inter-transactional ARs (Lu, Feng, & Han, 2000), ratio rules (Korn, Labrinidis, Kotidis, & Faloutos, 1998), and substitution rules (Teng, Hsieh, & Chen, 2002) bring out particular relationships between items. In the market-basket context, negative ARs reveal the set of items a customer is unlikely to purchase with another set. Cyclic association rules reveal purchases that display periodicity over time. Thus, imposition of additional constraints offers insight into the domain by discovering focused and tighter relationships. However, each method discovers a specific kind of behaviour. A large number of mined patterns might necessitate the use of other pruning methods. Except for rule templates, methods that enforce constraints are characterized by low user-involvement.

Redundancy reduction methods remove rules that do not convey new information. If many rules refer to the same feature of the data, then the most general rule may be retained. "Rule covers" (Toivonen, Klemettinen, Ronkainen, Hatonen, & Mannila, 1995) is a method that retains a subset of the original set of rules. This subset refers to all rows (in a relational database) that the original ruleset covered. Another strategy in AR mining (Zaki, 2000) is to determine a subset of frequently occurring closed item sets from their supersets. The magnitude of cardinality of the subset is several orders less than that of the superset. This implies fewer rules. This is done without any loss of information. Sometimes, one rule can be generated from another using a certain inference system. Retaining the basic rules may reduce the cardinality of the original rule set (Cristofor & Simovici, 2002). This process being reversible can generate the original ruleset if required. Care is taken to retain the information content of the basic unpruned set. Redundancy reduction methods may not provide a holistic picture if the size of the pruned ruleset is large. Further, the important issue of identification of interesting patterns is left unaddressed. For example, a method preserving generalizations might remove interesting exceptions.

Visualization techniques take advantage of the intuitive appeal of visual depiction that aids in easy understanding (Hilderman, Li, & Hamilton, 2002). Various features like use of graphs, colour, and charts help in improved visualization. Rules depicted in a visual form can be easily navigated to various levels of detail by iteratively and interactively changing the thresholds of rule parameters. The main drawback in visualization approaches is the difficulty of depicting a large rule/attribute space. In addition, understandability of visual depiction decreases drastically with increase in dimensions. Hence, a user might fail to detect an interesting phenomenon if it is inlaid in a crowd of mundane facts. However, for browsing a limited rule space, visualization techniques provide an intuitive overview of the domain.

A user might be able to get a good overview of the domain with a few general rules that describe its essentials. Mining generalized association rules using product/attribute taxonomies is one such approach (Srikant & Agrawal, 1995). If all items at lower levels of a product taxonomy exhibit the same relationship, then rules describing them may be replaced by a general rule that directly relates product categories. General Rules, Summaries, and Exceptions (GSE) patterns introduced by Liu, Hu, and Hsu (2000) is an approach to summarization. The general rules, along with summaries, convey an overview while exceptions point to cases differing from the general case. Another approach is to group rules on the basis of exogenous criteria such as economic assessment, profit margin, period of purchase, and so forth (Baesens, Viaene, & Vanthienen, 2000). Clustering techniques group "similar" rules (Gupta, Strehl, & Ghosh, 1999) by imposing a structure on them. Rules within each group can then be studied and evaluated based on this structure. Most of the techniques stated help in consolidating existing knowledge rather than identifying new/latent knowledge.

The Rule Quality Problem: Solution Perspectives

The "rule-quality" problem is a consequence of most of the discovered patterns referring to obvious and commonplace domain features. For example, Major and Mangano (1995) mined 529 rules from a hurricane database of which only 19 were found to be actually novel, useful, and relevant. The most common and obvious domain facts are easily discovered since they have strong presence in databases. In addition, such facts form a core component of the user's domain knowledge due to repeated observation and application. Examination of these patterns is a waste of time since they do not further a user's knowledge. Ranking rules based on their interestingness is one approach that may address the rule-quality problem.

INTERESTINGNESS MEASURES

Interestingness measures try to capture and quantify the amount of "interest" that any pattern is expected to evoke in a user. Interesting patterns are expected to arouse strong attention from users. "Interestingness," an elusive concept, has many facets that may be difficult to capture and operationalize. Some of them may be domain and user-dependent. In other cases, depending on the context, the same features may be domain and user-independent. Capturing all features of interestingness in one single measure simultaneously is an arduous task. Therefore, researchers typically concentrate on those features that are important and relevant for a particular application. Thus, operationalization of interestingness may be context-dependent. Information retrieval and KM literature allude to "relevance ranking" schemes that bring out the relevance of a particular piece of knowledge such as document and Web site. Interestingness in KDD is a much more complex concept with many facets in addition to relevance. Although relevance contributes to interestingness, a relevant pattern may not be interesting if it is commonplace knowledge. Thus, the interplay of various facets like relevance, novelty, unexpectedness, surprisingness, user knowledge, and others together determine the interestingness of a KDD pattern. A broad classification of interestingness measures may be based on user-involvement.

Objective Measures of Interestingness

Objective measures quantify a pattern's interestingness in terms of its structure and the underlying data used in the discovery process. Researchers have used measures developed in diverse fields such as statistics, social sciences, machine learning, information theory, and others to measure specific data characteristics. These include statistical measures like confidence, support (Agrawal, Imielinski, & Swami, 1993), lift (Piatetsky-Shapiro & Steingold, 2000), conviction (Brin, Motwani, Ullman, & Tsur, 1997), rule interest (Brin et al., 1997), and others. Information theoretic measures such as entropy, information content, the Kullback and the Hellinger measures have also been used in other data mining studies (Hilderman & Hamilton, 1999). Occurrence of odd events/phenomena such as Simpson's paradox is also deemed interesting (Freitas, 1998). Freitas (1999) has adopted a multi-criteria approach for evaluation of objective interestingness. Incorporation of rule-quality factors such as disjunct size, imbalance of class distributions, misclassification costs, and asymmetry help in the objective evaluation of a rule's "surprisingness." With A→B denoting an AR, P(A) and P(B) denoting the probabilities of occurrence of sets A and B, respectively, we have the following key properties (Piatetsky-Shapiro & Steingold, 2000) that should satisfy a good objective measure of interestingness (RI)

1. RI=0, if A and B are statistically independent, that is, P(A,B)=P(A).P(B)
2. RI monotonically increases with P(A,B), other parameters such as P(A) and P(B) being fixed.
3. RI monotonically decreases with P(A) (or P(B)), other parameters (i.e., P(A,B) and P(B) or P(A)) being constant.

It may be observed that these properties are tied to the co-occurrence of A and B. The interestingness of A→B increases with increase in the co-occurrence of A and B relative to individual occurrences of A or B.

Objective measures are strongly domain- and user-independent. They reveal data characteristics that are not tied to domain/user-related definitions. However, this property may limit their power of discrimination. Since any objective measure has to hold across domains, it takes care of a limited aspect of data that is common across domains. Hence, objective measures cannot capture all complexities of the discovery process (Silberschatz & Tuzhilin, 1996). Many objective measures are based on strength of the dependence relationship between items (Shekar & Natarajan, 2004b). Conventionally, interestingness is regarded as being directly proportional to strength of the dependence relationship. However, this view may lead to erroneous results (Brin et al., 1997). For example, while "Support" is useful in measuring the statistical significance of a rule, rules that are most obvious to the user have high support values. Similarly, other objective measures have their own limitations and biases.

It is also common for different objective measures to convey contradictory evaluation or conceal certain facts about a domain. Therefore, it is not only important to select the appropriate measure(s) for each domain, but also specify the correct order of application (Tan, Kumar, & Srivastava, 2004). Only then, the truly interesting rules would get revealed. An important application of objective measures is their use as initial filters to remove definitely uninteresting or unprofitable rules. Rules that reflect insignificant presence of transactions do not warrant further attention and hence may be removed by objective measures.

Subjective Measures of Interestingness

Users play an important role in the interpretation and application of KDD results. Therefore, interestingness measures need to incorporate user-views in addition to data-related aspects. Users differ in their beliefs and interests since they may have varied experience, knowledge, and psychological makeup. In addition, they also may have varying goals and difference of opinions about the applicability and usefulness of KDD results. This variation in interest enhances the importance of injecting subjectivity into interestingness evaluation (Silberschatz & Tuzhilin, 1996). "Actionability" and "Unexpectedness" are two facets that determine subjective interestingness (Silberschatz & Tuzhilin, 1996). Interesting rules may be unexpected (i.e., surprising to the user) or actionable (translating results into actions).

Actionability is an important criterion in KM because organizational performance often depends more on the ability to turn knowledge into effective action, rather than on knowledge itself (Alavi & Leidner, 2001). Actionable patterns are interesting since they offer opportunity for direct action. However, operationalization of "actionability" has proved to be an extremely difficult task due to the inherent difficulty in associating patterns with actions. Also, it may not be possible to pre-specify all possible actions. Studies centered on actionability tend to be domain-specific (Silberschatz & Tuzhilin, 1996). The demand that patterns be related to actions is one difficult task in all but the narrowest of domains where actions are clearly defined. The KEFIR system (Matheus, Piatetsky-Shapiro, & McNeill, 1996) is a typical example. Adomavicius and Tuzhilin (1997) propose an approach to defining actionability, using "action hierarchy." An action hierarchy is a tree (Deo, 1989) of actions with patterns and pattern templates (KDD queries) assigned to its nodes. This approach provides a framework for operationalizing actionability with some domain independence.

Roddick and Rice (2001) bring out the temporal and dynamic nature of interestingness. Using events in the sporting arena as a running example, they show how "anticipation" has a critical effect on both: selection of interesting events and variation of interestingness threshold as events unfold. However, the concept of anticipation needs to be further explored. Information about a subject is interesting if the user has some prior knowledge about it and also if this knowledge is relevant to user-goals (Ram, 1990). Accordingly, interestingness may be defined as a heuristic that measures relevance of the input to a person's knowledge goals. "Knowledge goals" (Ram, 1990) is related to acquiring some piece of information required for a reasoning task. If a piece of information is relevant to "knowledge goals," interest toward it increases.

Silberschatz and Tuzhilin (1996, p. 971) argue that "the majority of actionable patterns are unexpected and that the majority of unexpected patterns are actionable." Hence, they hypothesize that unexpectedness is a good approximation for actionability and vice-versa. Since unexpectedness is easier to operationalize than actionability, most studies concerning subjective interestingness employ "unexpectedness" as the main subjective criterion. Approaches to determination of subjective interestingness using "unexpectedness" tend to follow the general approach given below:

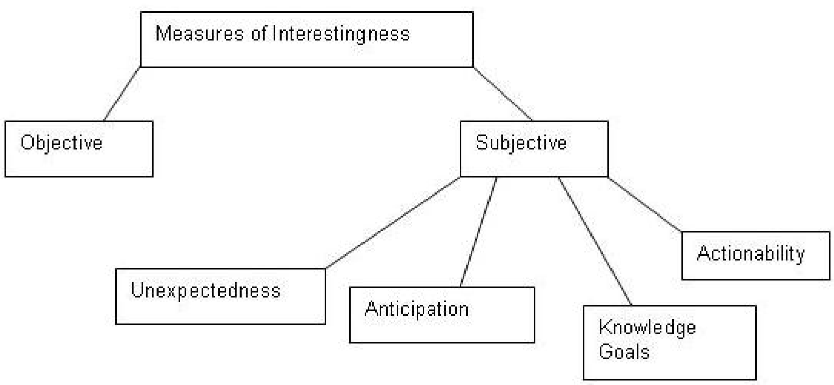
- Eliciting user-views
- Representing user-views in a form suitable for computation
- Mining the database to extract rules about the domain
- Comparing mined rules with user-views to determine the degree of conflict
- Presenting and labeling, rules that conflict user-views (on attributes such as relationship, strength, and direction), as interesting

However, methods using unexpectedness may differ in implementation details such as representation schema, method of comparison, and interestingness measures (Padmanabhan & Tuzhilin, 1999; Liu, Hsu, Mun, & Lee, 1999, Shekar & Natarajan, 2004a). One limitation of this methodology is the knowledge acquisition issue. Eliciting views from users is difficult, and acquired knowledge could be incomplete. Users may not be able to completely specify all their views about a domain. This may result in a large number of rules having high interestingness scores. Many of these rules might concern attributes, relationships, and beliefs, the user has failed to specify. Other limitations are more approach-specific, such as specifying a priori probabilities in the Bayesian approach (Silberschatz & Tuzhilin, 1996) and fuzzy membership functions (Liu et al., 1999). Figure 1 displays a partial classification of the approaches toward interestingness in KDD. Pruning and ranking of patterns on the basis of interestingness measures is an intuitive approach to rule quality and rule quantity problems.

FUTURE TRENDS

Interestingness, an elusive concept, may have many facets intrinsic to a particular domain. A combination of objective and subjective measures may be necessary to reveal interesting patterns. Some issues concerning application of interestingness measures may be generic while others may be domain-specific. One important issue is the genesis of interestingness and its constituent features. Unexpectedness and actionability do not characterize interestingness in its totality. There might be other domain-dependent features worthy of consideration and incorporation. A detailed study of interestingness in specific domains and across domains can help in capturing and operationalizing subtle features. These features could then form the basis for more comprehensive interestingness evaluation.

Figure 1. Partial classification of interestingness measures (based on Silberschatz and Tuzhilin, 1996)



Another issue concerns the joint application of objective and subjective measures. Objective measures could be used as a first filter to remove rules that are definitely uninteresting. This should be based on certain requirements, such as significance and predictive ability. Subjective measures can then bring in user-biases and beliefs into interestingness evaluations. Interaction between objective and subjective measures has not been sufficiently explored. In addition, few studies have considered the appropriateness of applying a specific interestingness measure across domains. The effect of changing the order of application of interestingness measures and the interaction between them are issues worthy of future study. Some relationships are a logical consequence of a firm's operational business rules. Such knowledge, being intuitive and tacit due to daily application, may not be specified during the knowledge elicitation phase. Incorporating such logical inferences in subjective measures is another issue for future research.

An important consideration with storing knowledge in KM systems is context inclusion (Alavi & Leidner, 2001). Without contextual information, knowledge may not be efficiently and effectively operationalized. Interestingness may be strongly domain and user-dependent and hence highly subjective. On the other hand, if objective measures can be made context-dependent by infusing them with domain-related data definitions, then the user-dependence may be reduced. This might allow sharing of KDD results across an organization.

Application of interestingness measures during the various phases of knowledge discovery has its own advantages and disadvantages. If the dataset is large, then it may be advantageous to mine rules and then apply interestingness measures. On the other hand, for a small one, application of interestingness measures during the mining phase may be preferable. Ideally, a data mining system should contain a repository of interestingness measures, both objective and subjective. Choice of measures could be based on the patterns mined, application, and purpose of the user. Here, the importance of integrating mining methods with interestingness evaluation cannot be over-emphasized.

Another problem with rule ranking concerns the possible lack of relationship among interesting rules. Thus, two consecutive interesting rules could pertain to different domains/sub-domains. Hence, it may be difficult for a user to connect them and obtain an overview of the domain. Combining methods that address the rule quantity problem with interestingness might partially address this problem. Clustering of similar rules could possibly be studied as a pre-processing step followed by a ranking scheme based on interestingness. Thus, a user might be able to obtain an overview of the domain and also discover implicit hidden knowledge brought out by interesting rules. Visualization techniques that display interestingness evaluations in an intuitive and understandable manner may be helpful.

CONCLUSION

Initial focus in the KDD community was with respect to algorithm development—toward newer and faster methods operating on large datasets. This resulted in a large number of patterns—sheer numbers of which contributed to incomprehensibility. The importance of understandability of discovered patterns, especially with respect to practical applications has been acknowledged. Recent literature in KDD has focused on various approaches to alleviate the rule quality and rule quantity problem. Ranking patterns according to interestingness is an important approach to addressing the rule quality problem. Interestingness is both data-driven and user-view driven. Correspondingly, patterns may be evaluated on the basis of objective and subjective measures. However, interestingness is an elusive concept, whose many facets are both difficult to capture and difficult to operationalize. Many of these facets are yet to be identified. Future research pertaining to interestingness is expected to yield results with respect to more complete characterizations. KM deals with the creation, storage/retrieval, transfer, and application of relevant knowledge in any organization. Interestingness measures and other methods, which address the problem of immensity of mined patterns are vital contributors to knowledge creation processes in KM. It is not uncommon to find organizations struggle to make sense of data captured through automated processes. Frameworks and methodologies for selecting relevant and significant patterns that add to organizational knowledge are expected to feature as important issues in KM.

Chapter 2.12
User Modelling and Personalisation of Knowledge Management Systems

Liana Razmerita
INRIA (The National Institute for Research in Computer Science and Control), France

ABSTRACT

This chapter focuses on the role of user models and user modelling for enhanced, personalised user support within knowledge management systems (KMSs). Personalisation can bring a utility function as well as a conviviality function with "high touch" impact for the users. From this utility and conviviality perspective, various personalised services enable KMSs to adapt their functionality, structure, and content to match the needs and preferences of users based on a user model that is stored and updated dynamically. The chapter presents a set of examples, different types of adaptations and personalised services specific to KMSs.

INTRODUCTION

User modelling is a multidisciplinary and broad area of research. Amongst many objectives related to user modelling research, in the last few years, personalisation emerges as an important strand. In general, the goal of personalisation is to improve the efficiency of interaction with the users, to simplify the interaction, and to make complex systems more usable. Important application areas of personalisation include: customer relationship management (Kobsa, Koenemann, & Pohl, 2001; Fink & Kobsa, 2001; Schafer, Konstan, & Riedl, 2001; Ardissono, Goy, Petrone, & Segnan, 2003), educational software (Brusilovsky, 1998, 2001), and Web search and retrieval (Tanudjaja & Mui, 2002; Ardissono et al., 2003; Kurki, Jokela, Sulonen, & Turpeinen, 1999). Personalisation has already proved its utility in e-commerce and e-learning. For example Clark and Mayer (2002) emphasise the role of personalisation in e-learning. In this sense, they are quoting studies conducted by Moreno et al. (2001) and Atkinson (2002) which prove the role of the coaching agents for learning. In the domain of customer relationship management, Kobsa et al. (2001) provide data from communication reports showing that personalisation based on purchased data and personal data has a considerable payoff.

This chapter focuses on the role of user models and user modelling for enhanced, personalised user support within KMSs. Building and maintaining users' models enable one to capture their competencies, their expertise, their interests, and implicitly to better manage the tacit knowledge and the human capital. User models and user modelling are the key elements in the management of tacit knowledge, but they have a much broader scope that is not limited to human resource management and expertise finding. The user model is extended with certain characteristics of the users (level of activity, type of activity, level of knowledge sharing, etc.), and the rationale for extending the user model is explained.

The main contribution of this work is to emphasise the role of user modelling in KMSs. The chapter presents the different ways in which user modelling can be applied to KMSs. User model and user modelling are identified as key components for supporting: expertise finding, personalisation, collaboration and networking, learning, and change (Razmerita, Angehrn, & Nabeth, 2003a). Examples of specific types of adaptations and personalised services for KMSs are given.

The chapter is structured as follows. The second section introduces briefly the context of the research. It presents some issues, problems, and challenges associated with the design of actual KMSs. KMSs are high functionality systems with limited personalisation features. Personalisation has two main roles. It has utility and conviviality functionality. The main thrust of the chapter is constituted of the third, fourth, and fifth section. The third section introduces the structure of the user ontology and describes specific user modelling processes. The fourth section elaborates on the role of user models and user modelling for enhanced user support and personalisation in KMSs. Personalisation mechanisms specific to KMSs are described and some specific examples are provided. The fifth section overviews various personalised services. Finally, the sixth section includes conclusions and future research work.

TRENDS AND CHALLENGES FOR KMSS

KMSs can be defined as a "class of information systems applied to managing organisational knowledge" (Leidner & Alavi, 2001). KMSs are designed to allow their users to access and utilise the rich sources of data, information, and knowledge stored in different forms, but also to support knowledge creation, knowledge transfer, and continuous learning for the knowledge workers. Knowledge in the context of KMSs consists of experience, know-how, and expertise of the people (tacit knowledge), and different information artefacts and data stored in documents and reports available within and outside the organisation (explicit knowledge).

Even if traditional KMSs tend to provide more functionality, they are still mainly centred on content manipulation (storing, searching, and retrieving). In the last few years, various researchers have pointed out that information technology dimension is a crucial success factor, but not the most important one. Organisational culture aspects and a human-centred perspective need also to be addressed (O'Leary & Studer, 2001; Nabeth Angehrn, & Roda, 2002). Following this stream of thinking, we also believe that designing effective KMSs requires not only a view that is achieved by considering organisational imperatives and technological solutions, but it also requires taking into account a more user-centred perspective, by considering the real individual needs of the users (work tasks, responsibilities), usability and ergonomics issues, and so forth. In that sense, we agree with Prusak (2001), who emphasises that the user satisfaction is more important than the performance of technology: "Knowledge management shares information management's user perspective; a focus on value as a function of user satisfaction rather than the efficiency of the technology that houses and delivers the information." To a certain extent, user satisfaction depends on how useful and how usable the system is perceived to be. More high-touch features — such as personalisation, providing users with experience fitting their background knowledge, and task to handle — could be a plus in the acceptance and impact of KMSs.

Recently KMSs are challenged to address ambitious goals. They aim to go beyond the mere administration of electronic information; they aim to support complex business processes. These complex business processes include: learning processes, knowledge sharing, and collaboration between knowledge workers irrespective of their location, with the ultimate goal of increasing the productivity of its knowledge workers.

The complexity of business processes implies capturing, storing, and deploying a lot of knowledge. The amount of knowledge available requires an enhanced support of business processes and better mechanisms of structuring knowledge.

Actual KMSs featuring intelligence are implemented as Web-enabled environments. Ontologies, software agents, and user modelling are emerging technologies to be integrated in KMSs to help in handling this complexity. Ontologies are knowledge representation mechanisms for better structuring the domain model. Existing knowledge sources (documents, reports, images, videos, etc.) are mapped into the domain ontology and semantically enriched. This semantically enriched information enables better knowledge indexing and searching processes, and implicitly a better management of knowledge. The distributive nature of tasks to be handled in a KMS determines a natural choice for the use of multi-agent systems. Societies of agents can act with the purpose of helping the user or solving problems on behalf of the users. Specialised agents are cooperating, negotiating, and communicating in order to achieve various functions such as: discovery and classification of new knowledge, search and retrieval of information, the automatic evolution of the domain ontology, and so forth.

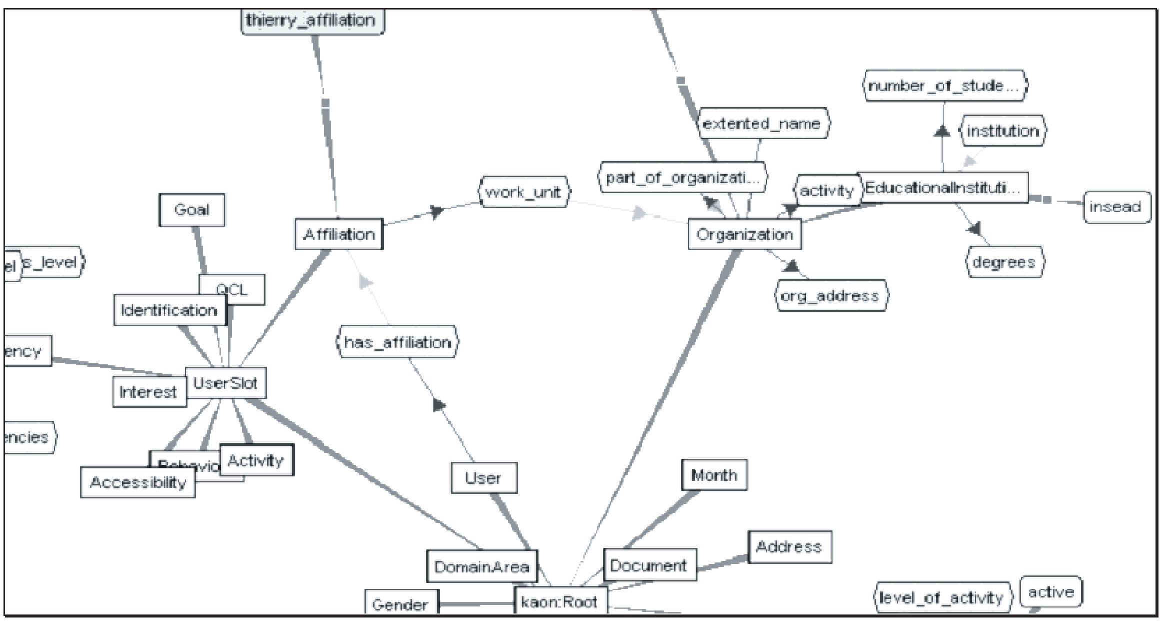
In Web-based applications personalisation is usually obtained by dynamically tailoring the content of the Web pages according to the user's model characteristics. "Adaptation decisions in adaptive systems are based taking into account various characteristics of the users represented in the user model" (Brusilovsky, 2001). Many of the Web personalisation techniques and especially adaptive hypermedia techniques methods can be successfully applied to the context of KMSs. An important strand of research in user modelling aims to enhance the interaction between the users and the systems. Numerous researchers have reported on: human-agent interaction, how to construct adaptive systems, how to tailor and filter information, how to personalise help and dialogue systems, and how to personalise interaction in e-commerce and e-learning. All these traditional application areas of user modelling brought us insights on how user modelling can contribute to enhanced features of KMSs. There clearly exist adaptation methods and personalisation techniques that are specific to KMSs. These adaptation methods and personalisation techniques relate to specific objectives of KMSs. Amongst these objectives are: how to motivate people to create knowledge and to submit new knowledge assets in the system, how to stimulate collaboration and knowledge sharing between knowledge workers irrespective of their location, how to alleviate information overload, how to simplify business processes and work tasks, and so forth. Personalisation techniques rely on the user's characteristics captured and named user models or user profiles. Building a user model, or knowing more about a user, is a first step for achieving personalised interaction. The following section presents the user ontology, including the different characteristics. These characteristics relate to personalised user support in a KMS.

BUILDING A USER ONTOLOGY FOR KMSS

The user model is defined as a user ontology describing the different characteristics of a user and the relationships between the different concepts. The first ideas of using ontologies for learner modelling have been reported by Chen and Mizoguchi (1999). Kay (1999) also argues for the use of ontologies for reusable and "scrutable" student models. More recently, the idea of using sharable data structures containing the user's features and preferences are proposed in order to enable personalised interactions with different devices for the benefit of the users. For this purpose, a user modelling mark-up language for ubiquitous computing built on XML technology has been proposed as a platform for communication by Heckmann and Krueger (2003).

The definition of the user ontology captures rich metadata about the employee's profiles comprising different characteristics such as: name, e-mail, address, competencies, cognitive style, preferences, and so forth, but also a behavioural profile specific to the user interaction with a KMS. The proposed user model is extending the Information Management System Learner Information Package specification (IMS LIP, 2001). IMS LIP is structured into 11 groupings, including: Identification, Goal, QCL (Qualifications, Certifications, and Licenses), Accessibility, Activity, Competence, Interest, Affiliation, Security Key, and Relationship. These groupings are implemented as abstract concepts in the user ontology. The concept Identification contains attributes and other sub-concepts that help to identify an individual (name, address, e-mail, etc.) within the system. Affiliation includes information on the descriptions of the organisations associated with the user/learner. QCL contains concepts related to the different qualifications, certifications, and licenses the user has. Competence contains skills associated with formal or informal training or work history. Activity includes activities related

Figure 1. A partial graph-based view of the user ontology



to the education/training work of the user. Accessibility contains concepts related to: user preferences, language information, disabilities, and so forth. The concept Interest contains information on hobbies and other recreational activities. The concept Goal contains a learner's/user's goals. The user ontology contains a set of concepts, a set of taxonomic relations (User, Learner), and a set of non-taxonomic relations ('User works_on Project', 'User has_affiliation Affiliation').

The user ontology has been implemented using KAON. A partial view of the user ontology using

Table 1. User model components and enhanced features of KMSs

User model	Functions of the KMSs
Identification first_name, email, address, etc.	Achieve access on the platform Achieve access to the user's data through the user profile editor Search for people/experts Contact people/experts
Affiliation title work_unit	Search for experts-contact units of expertise Personalize the layout Customize the user interface
Competency/QCL knowledge interests level of expertise	Filter content Use agent/event-based notification Customize an ontology/taxonomy Personalize the content
Activity working papers projects white papers documentations prototypes	Share a document Manage contributions Provide incentives for contributors Manage the "usability" of the different documents Infer the activity of the users in KMSs ProvideResources - publish ProvideMetadata -comments documents, etc.
Behavior level_of_activity type_of_activity level_of_knowledge_ sharing	Infer the user's behavior Provide incentives for change management Acknowledge the active users/provide rewards Provide incentives for knowledge sharing
Accessibility languages small/ large fonts likes/ dislikes interface agents learning style	Customize the user interface Personalize the layout Select documents based on the language criteria
Interest hobbies classical /modern music	Organize social activities Provide social networking facilities
Goal search for docs/case studies learn search for people contact people	Search/Query Retrieve documents ProvideResources - Publish ProvideMetadata Manage Documents and Folders Manage Links Manage Index/Taxonomies/Ontologies Contact people/experts Communicate and collaborate

a graph-based representation using OI-Modeler is represented in Figure 1. KAON is a tool suite for ontology management and for the development of ontology-based applications (Maedche, Motik, Stojanovic, Studer, & Volz, 2002).

KMSs aim to support people to codify their experience, to share their knowledge, and to be active in the system. For this purpose the IMS LIP groupings are extended with the Behaviour concept (see the fifth row of Table 1).

The Behaviour concept describes some characteristics of a user interacting with a KMS such as: type_of_activity, level_of_activity, level_of_knowledge_sharing. The Behaviour concept and its sub-concepts were introduced to "measure" two processes that are important for the effectiveness of a KMS, namely knowledge sharing and knowledge creation. The user modelling systems classify the users into three categories: readers, writers, or lurkers. The description of the ontology-based user-modelling system and its integration into the KMS is presented in Razmerita et al. (2003b). These categories are properties of the type_of_activity concept. The level_of_activity comprises four attributes that can be associated with the users: very active, active, passive, or inactive. The classification of users according to the type_of_activity or level_of_activity is based on heuristics. The user ontology also includes a representation of the user's level of knowledge sharing. Through the level_of_knowledge_sharing feature (Table 1), the level of adoption of knowledge sharing practices is captured. The level of adoption of knowledge sharing is defined using Near's terminology and mapping it into Roger's theory (see Angehrn & Nabeth, 1997). The user states in relation to the level of knowledge sharing are: unaware, aware, interested, trial, and adopter.

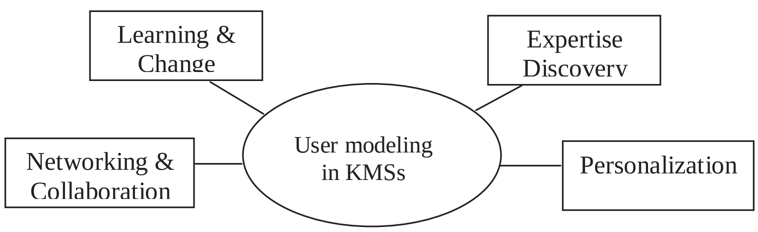
An analysis of the user's characteristics reveals the different functions that need/could be integrated in the KMS (Table 1). The components of the user model can be correlated either with the different functions required by a KMS, with enhanced user support or other personalised services.

ROLES OF USER MODELLING IN KMSS

The integration of user modelling processes in a KMS can enhance their functionality in several ways: expertise discovery, networking and collaboration, learning and change, and personalisation as represented in Figure 2.

Expertise discovery, expert finding, skill mining, or intellectual capital management are widely discussed topics in knowledge management. Making the competencies, the qualifications, and the domains of interests of the users explicit enables location of domain experts, knowledgeable

Figure 2. User modelling in KMSs facilitates enhanced functionality in four domains



persons, and how to contact them. This is also a valuable option not only for the knowledge workers who need to complete different job-related tasks, but also for human resource management units, especially for big, distributed organisations.

The use of ontologies for the user model's representation seems to be a more powerful approach for expertise discovery. Let's have a look at a more specific example of applying ontologies for user modelling and expertise finding in the context of KMSs. The user ontology describes various properties and concepts relevant for the user model. The concepts of the user ontology are bridged with the concepts of the domain ontology through properties. Figure 3 depicts in a graph-based representation a part of the concepts and properties of the user ontology. Concepts are represented with green ovals, while properties of the concepts are represented with orange ovals. The application scenario includes the followings relationships between the concepts: User, Project, and Topic described as RDFS tuples:

(User, works_on, Project)
(Project, related_to, Topic)

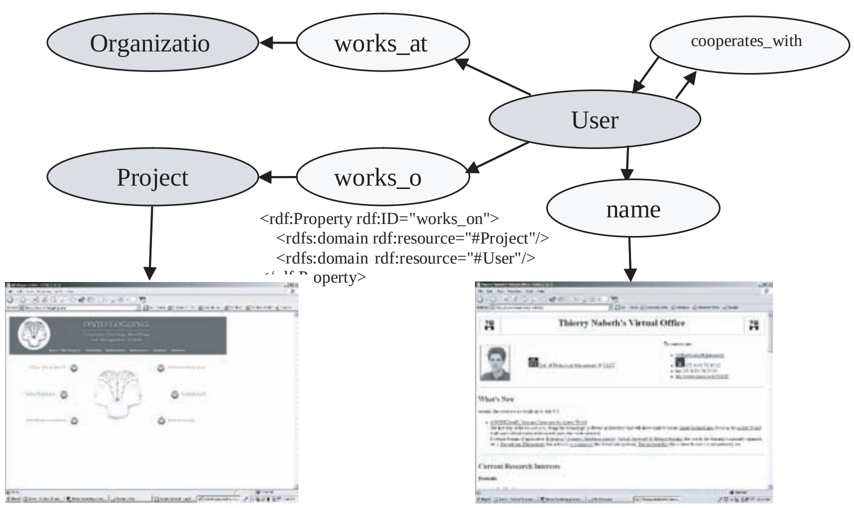
In our examples the previous RDFS tuples are instantiated as the following:

(Thierry, works_on, Ontologging)
(Ontologging, related_to, Knowledge Management)
(Ontologging, related_to, Ontology)
(Ontologging, related_to, User modelling)

The properties and the relationships between the different concepts such as: 'works_at', 'works_on', 'cooperates_with' enable us to make further inferences. Consider, for instance, the fact that: 'Thierry works_on Ontologging project'. Ontologging is described as a project about: knowledge management, user modelling, and ontologies. The range of the property 'works_on' is restricted to the concept Project. Based on these facts the system automatically infers that Thierry might have expertise in: ontology, knowledge management, and user modelling.

An Ontobroker-specific syntax (Decker, Erdmann, Fensel, & Studer, 1999) written in F-logic (Kifer, 1995) enables one to query all the people

Figure 3. Application scenario of the user ontology



working in knowledge management. This query looks like:

FORALL Y, Z <- Y: User [works_on ->>Z] and Z: Project [related_to->>KnowledgeManagement]

Thus without requiring people to keep their profiles updated, in our example the expertise, an ontology-based KMS can facilitate making the domain experts visible.

Networking and Collaboration

The dynamic exchange of tacit knowledge can be facilitated through networking and collaborative tools. In the last few years, computer-mediated collaboration or computer-supported collaborative work has developed a lot. Different types of communication systems, from e-mail to more advanced groupware systems (shared workspaces, discussion forums, chat systems, instant messaging systems, etc.), enable virtual interactions, knowledge exchanges, collaboration, and learning in distributed working environments. Social processes can facilitate networking and collaboration, and can be organised to take into account the user's characteristics (hobbies, interests). In certain systems, communities are built based on the user's domain of interests (Snowdon & Grasso, 2002).

Learning and Change

Learning is not only a process of acquiring new pieces of knowledge, but it often involves a behavioural change for the user at the individual level. From this perspective a system can also provide feedback and stimulus for behavioural change at the individual level. A KMS facilitates storing, searching, and retrieving of knowledge assets, but it also needs to promote users' participation in knowledge sharing and knowledge creation. Therefore the system tracks a series of "behavioural" characteristics of the user interaction with the system (such as level of activity, level of adoption of knowledge sharing, type of activity, etc.). These elements make the user aware of his behaviour in the system and are intended to motivate the user to be active in the system. Moreover, based on the identified stages of the users, different types of agents can intervene to stimulate and coach a user towards the adoption of a set of desired behaviours (adopters of knowledge sharing behaviour) (Angehrn, Nabeth, Razmerita, & Roda, 2001; Roda, Angehrn, Nabeth, & Razmerita, 2003).

Personalisation is an opportunity to provide more 'high-touch' features for users. It has a utility function and a conviviality function. Issues related to personalisation of KMSs will be elaborated in the following section.

PERSONALISATION OF KMSS

In the last few years, personalisation has started to become an important issue in Web-based applications. Hypermedia systems are Web-based applications consisting of various hypermedia objects (text, images, video/audio, etc.). A personalised hypermedia application is defined as a hypermedia system that adapts the content, structure, or/and presentation of networked hypermedia to each individual user's characteristics, usage behaviour, and/or usage environment (Kobsa et al., 2001).

Personalisation is obtained by dynamically tailoring the content of the Web pages according to the user's characteristics. Personalisation of hypermedia presentations has already been proved to be beneficial in learning environments, customer relationship management, or e-commerce. Nevertheless aspects of personalisation are important in most Web-based applications. The widespread integration of personalisation techniques in Web-based applications could be hindered by two main issues: (1) the complexity and implicitly of the increased cost of developing such a system, and (2) the specificity of personalisation of the different applications.

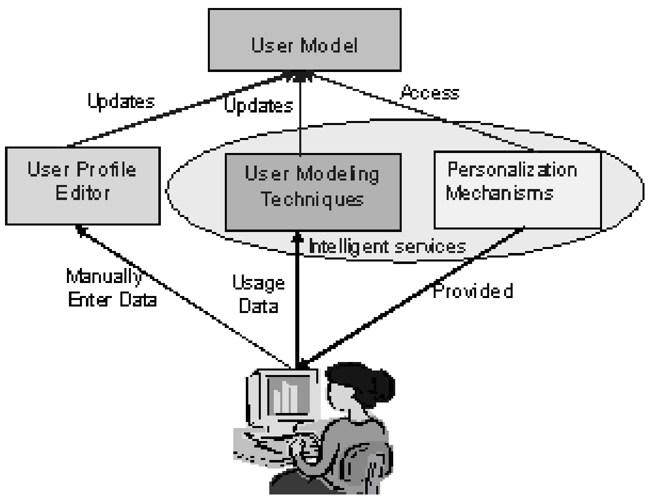
The following definition is proposed for personalisation of a KMS:

"Personalisation of a KMS as the process that enables interface customisation, adaptations of the functionality, structure, content and modality in order to increase its relevance for its individual users."

Blom (2000) distinguishes between two main roles of personalisation: (1) to facilitate the work, and (2) to accommodate social requirements. In the first category he includes enabling access to information content, accommodating work goals, and accommodating individual differences, while the second category contains eliciting an emotional response and expressing identity. These two main roles of personalisation apply to the context of KMSs, and both of them are important. A utility function that personalisation could bring to the users of a system, as well as a conviviality function with high-touch impact for the users can be differentiated. Moreover, significant differences between the role and the associated work tasks of the different knowledge workers in an organisation can be distinguished. Most of the actual KMSs include certain customisation features based on the user's preferences. Personalisation is similar to interface customisation and is usually initiated by the user. Some systems give the possibility of filtering the knowledge assets corresponding to the domain of interest of the user. Adaptive KMSs can automatically adapt to the inferred user's preferences, needs, and goals. User modelling processes enable KMSs to change their structure and content to match the needs and preferences of users based on a user model that is stored and updated dynamically.

A simplified form of a user modelling system including personalisation mechanisms is represented in Figure 4. The user modelling server acquires and maintains the user's data through a user profile editor (explicitly) and through different user modelling techniques (implicitly). The user modelling techniques and the personalisation mechanisms are named intelligent services. Under the term of personalisation mechanisms are grouped various adaptive techniques or agent-based interactions, as will be presented in subsequent sections.

Figure 4. User modelling and personalisation mechanisms



Such personalisation mechanisms are based on the user's characteristics and could include:

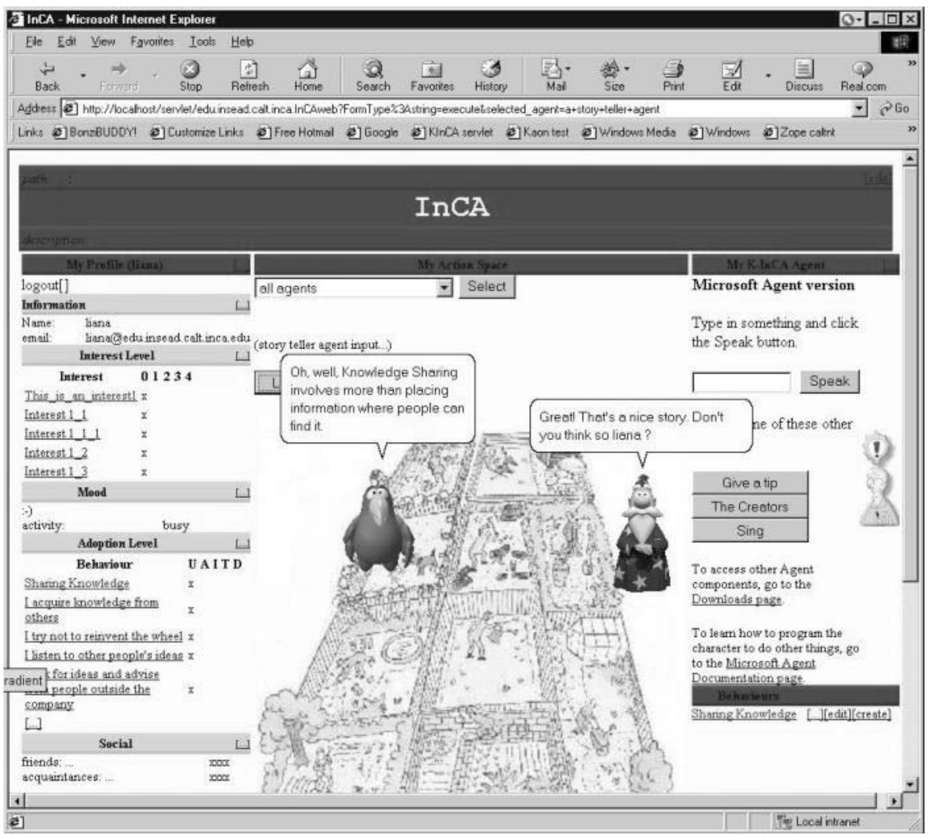
- direct access to customised relevant knowledge assets;
- provide unobtrusive assistance;
- help to find/recall information needed for a task; and
- offer to automate certain tasks through implicit or explicit interventions.

Even certain agent-based interactions can be fit into the process of adaptation; personalised interaction based on agents' intervention is presented as a distinctive type of personalisation. From this perspective personalisation can be achieved in two different ways:

- based on the agent's intervention; and
- based on various types of intelligent services that are transparent for the users also addressed as adaptive features in the user modelling literature.

Software agents possess attractive features including autonomy, proactiveness, intelligence (reasoning capability), social ability (interaction with the environment, user, and other agents), and mentalist characterisation (beliefs, desires, motivations, etc.) that can be used to build advanced adaptive, distributed systems. Agent-based systems have been used with a wide range of purposes. The agent-based approach offers a much greater opportunity for tailoring to the individual user. For this purpose the agent needs to

Figure 5. Story telling agents in KInCA



have access to information about the user (goals, objectives, preferences, interests, etc.). Agents can intervene beyond adaptation: they can support users to perform different tasks or they can be delegated to perform tasks by the users. They can reduce work and information overload (intelligent information agents, personal assistants), they can search and guide users to find different knowledge assets (filtering agents), or they can enhance learning processes (pedagogical agents, story-telling agents) (Maes,1994; Thomas & Fischer, 1996; Decker & Sycara, 1997; Klusch, 2001; Lieberman, 1996; Greer et al., 1998, Brna, Cooper, & Razmerita, 2001).

Some prototypes of the agents mentioned above have been implemented in the KInCA (Knowledge Intelligent Conversational Agents) system described in Angehrn et al. (2001) and Roda et al. (2001). KInCA is an agent-based system designed to support the adoption of knowledge sharing practices within organisations. The system observes the user's actions and, whenever appropriate, it makes suggestions, introduces concepts, proposes activities, and, in general, encourages the user in the adoption of the desired knowledge sharing behaviours.

Conversational agents aim at providing personalised guidance through the whole adoption process, from the introduction of the behaviours to the user (explaining what the desired behaviours are and why they should be adopted) to their practice within the community. Story telling has recently emerged as a practical, efficient technique for knowledge disclosure and communication in knowledge management. For instance, the story telling agents, represented in Figure 5, address the novices in the domain of knowledge sharing, namely unaware users, who get some basic ideas about the importance of sharing knowledge through entertaining conversation which takes place between two synthetic characters Peeddy and Merlin. In the following section a set of adaptive features specific to KMSs are presented.

ADAPTIVE FEATURES FOR KMSS

A flexible, adaptive system would enable the adaptation of its functionality and its hypermedia content to the basic needs of the different users. The functionality of the system is presented through the user interface. Well-designed interfaces present orderly and attractive views to the users. Bannon (1986) points out that more usable human computer interfaces can be built based on a thorough understanding of the users and of their task domain.

The main objective of the integration of adaptive features in KMSs is the dynamic generation of hypermedia spaces tailored to the characteristics and preferences of the different users. In a comprehensive overview of adaptive hypermedia systems, Brusilovky (2001) classifies the adaptive hypermedia technologies into two main groups, based on the type of adaptation provided: adaptive presentation or content-level adaptation, and link-level adaptation or adaptive navigation support.

In the following, a set of adaptive features that can be integrated in KMSs are identified and classified using Kobsa's (2001) taxonomy of adaptation. From this perspective, the adaptation techniques, at the level of the user interface, can be classified into three categories: adaptation of structure, adaptation of content, adaptation of modality and presentation.

Adaptation of Structure

Adaptation of structure refers to the way in which the hypermedia space is structured and presented to the different groups of users. Fischer (2001) provides some insights in the design of human-centred systems supported by user modelling techniques. He emphasises that high functionality applications must address three problems: (1) the unused functionality must not get in the way; (2) unknown existing functionality must be accessible or delivered at times when it is needed; and (3) commonly used functionality should be not too difficult to be learned, used, and remembered.

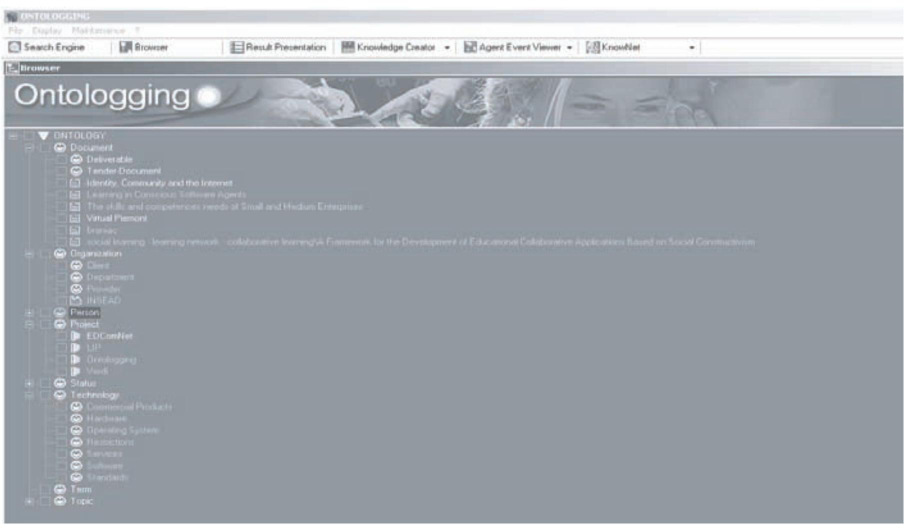
Taking into account these principles and applying them in the context of KMSs as part of a global, default view, several types of personalised views of KMSs can be designed and integrated into the system.

"Personalised views are a way to organise an electronic workplace for the users who need an access to a reasonably small part of a hyperspace for their everyday work." (Brusilovsky, 1998)

For a KMS two main types of personalised views are proposed. These personalised views can be designed as domain-oriented subsystems of the KMS. Fischer (2001) argues that high functionality applications have often migrated to a collection of domain-oriented subsystems containing their own forms, templates. For instance the system can offer a personalised view of the corporate knowledge based on the interest areas and the knowledge of the users or based on the role and competencies of the users.

- Personalised views based on the job title: Based on the role of the users and the associated work tasks, different views on the systems can be designed. Taking into account the job titles and the most important associated work tasks, several stereotyped views can be designed. A set of richer features and complex functionality can be associated with certain jobs. Similar to a system administrator, a knowledge manager or a knowledge engineer has access to a richer functionality than a normal end user. Simplified views with limited functionality can be offered to other categories of users.
- Personalised views based on the interest areas and the knowledge of the users: Implies the possibility of selecting different views or subdomains of the domain ontology/taxonomies. In an ontology-based KMS, the domain ontology or the corporate memory can be made up of different sub-ontologies. For example, financial experts could have the possibility of selecting the finance ontology, ignoring other parts of the domain ontology.

Figure 6. Ontologging system: A view of the tendering process ontology



> The DUI (Distributed User Interface) of an Ontologging system is designed using XML-driven components. The interface includes a 'template mechanism' to customise a personalised view. The DUI includes two main layers: the user interface layer and the component layer. The user interface layer consists of: search interface, browse interface, property edition and upload, result presentation interface, document download' and agent management interface. Thus through this template mechanism the different work units can personalise their view of the organisational memory, or select parts of it that are related to their expertise, interests, and so forth.
